TABLE 16.2 Base-Catalyzed Condensations Showing the Active-Hydrogen Components and the Carbonyl Compounds

Reaction Number	Reaction	Active Hydrogen Component	Carbonyl Component	Subsequent Reaction
16-34	<i>Aldol</i>	 	Aldehyde, ketone	Dehydration may follow
16-36			Aldehyde, ketone (usually without α -hydrogens)	Dehydration may follow
16-38	<i>Knoevenagel</i>	 ,  and similar molecules	Aldehyde, ketone (usually without α -hydrogens)	Dehydration usually follows
16-41	<i>Peterson</i>		Aldehyde, ketone	Dehydration may follow
16-42		 $Z = \text{COR}, \text{COOR}, \text{NO}_2$	CO_2, CS_2	
16-39	<i>Perkin</i>		Aromatic aldehyde	Dehydration usually follows
16-40	<i>Darzen's</i>		Aldehyde, ketone	Epoxidation
16-43	<i>Tollen's</i>	 	Formaldehyde	Crossed-Cannizzaro reaction follows
16-44	<i>Wittig</i>		Aldehyde, ketone	Dehydration always follows
16-50	<i>Thorpe</i>		Nitrile	

ketone.¹⁰¹⁹ Although hydroxide was commonly used in early versions of this reaction, stronger bases [e.g., alkoxides (RO^-) or amides (R_2N^-)] are also common. Amine bases have been used to catalyze the aldol condensation.¹⁰²⁰ Hydroxide ion is not a strong

enough base to convert substantially all of an aldehyde or ketone molecule to the corresponding enolate ion; that is, the equilibrium lies well to the left, for both aldehydes

and ketones. Nevertheless, enough enolate ion is present for the reaction to proceed:

This equilibrium lies further to the right with alkoxide relative to hydroxide, but the equilibrium still lies predominantly to the left. With amide bases, and particularly with aprotic solvents, the equilibrium usually lies much more to the right when compared with alkoxides or hydroxide. Protic solvents, (e.g., water or alcohol) are acidic enough to react with the enolate anion and shift the equilibrium to the left. As noted, in an aprotic solvent (e.g., ether or THF), with a strong amide base (e.g., LDA, sec. Sec. 8.F, category 7), the equilibrium lies more to the right.¹⁰²¹ A variety of amide bases can be used to deprotonate the ketone or aldehyde, and in the case of an unsymmetrical ketone removal of the more acidic proton leads to the kinetic enolate anion.¹⁰²² Note that a polymer-bound amide base has been used¹⁰²³ and solid-phase chiral lithium amides are known.¹⁰²⁴ A polymer-supported phosphoramidate has been used as a catalyst for the aldol condensation.¹⁰²⁵

The product of an aldol condensation is a β -hydroxy aldehyde (called an *aldol*) or a β -hydroxy ketone, which in some cases is dehydrated during the course of the reaction. An aldol is readily isolated unless the substrate is an aromatic aldehyde or ketone when the reaction is done in aprotic solvents with a mild workup procedure. The aldol reaction has been done in ionic liquids.¹⁰²⁶ Even if the dehydration is not spontaneous, it can usually be done easily, since the new double bond is in conjugation with the $\text{C}=\text{O}$ bond; so that this is a method of preparing α,β -unsaturated aldehydes and ketones, as well as β -hydroxy aldehydes and ketones. One-pot procedures have been reported to give the conjugated product.¹⁰²⁷ The entire reaction is an equilibrium (including the dehydration step), and α,β -unsaturated and β -hydroxy aldehydes and ketones can be cleaved by treatment with ^-OH (the *retrograde aldol reaction*). The retro-aldol condensation has been exploited for crossed-aldol reactions.¹⁰²⁸ A vinylogous (Sec. 6.B) aldol reaction is known¹⁰²⁹ as is a

‘double’ aldol.¹⁰³⁰ Enzyme-mediated aldol reactions have been reported using two aldehydes, including formaldehyde.¹⁰³¹

Under the principle of vinylogy (Sec. 6.B), the active hydrogen can be one in the γ position of an α,β -unsaturated carbonyl compound:

The scope of the aldol reaction may be discussed under five headings:

1. *Reaction between Two Molecules of the Same Aldehyde.* Homo-coupling. Hydroxide or alkoxide bases are used in protic solvents,¹⁰³² and the reaction is quite feasible. Nowadays, the use of dialkylamide bases in aprotic solvents (e.g., ether or THF) is more common. Many aldehydes have been converted to aldols and/or their dehydration products in this manner. The most effective catalysts are basic ion-exchange resins. Of course, the aldehyde must possess an α hydrogen.
2. *Reaction between Two Molecules of the Same Ketone.* Homo-coupling. With hydroxide or alkoxide bases in protic solvents the equilibrium lies well to the left,¹⁰³³ and the reaction is feasible only if the equilibrium can be shifted. This can often be done by allowing the reaction to proceed in a Soxhlet extractor (e.g., See OS I, 199). As with aldehydes, the use of dialkylamide bases (e.g., LDA or lithium hexamethyldisilazide, Sec. 8.F., category 7) in aprotic solvents (e.g., ether or THF) are more common. Unsymmetrical ketones condense on the side that has the most hydrogens with dialkylamide bases in aprotic solvents, but on the side with the fewest hydrogens with alkoxide bases in alcohol solvents.
3. *Reaction between Two Different Aldehydes.* Cross-coupling. In protic solvents with an alkoxide base, this will produce a mixture of four products (eight, if the alkenes are counted). However, if one aldehyde does not have an α hydrogen, only two aldols are possible, and in many cases the crossed product is the main one. The crossed-aldol reaction is often called the *Claisen–Schmidt reaction*.¹⁰³⁴ The crossed-aldol reaction is readily accomplished using amide bases in aprotic solvent. The first aldehyde is treated with LDA in THF at -78°C , for example, to form the enolate anion. Subsequent treatment with a second aldehyde leads to the mixed-aldol product. The crossed-aldol of two aldehydes has been done using potassium *tert*-butoxide and $\text{Ti}(\text{OBu})_4$.¹⁰³⁵
4. *Reaction between Two Different Ketones.* Cross-coupling. This is seldom attempted with hydroxide or alkoxide bases in protic solvents since similar considerations apply to those discussed for aldehydes. This reaction is commonly done with amide bases in aprotic solvents, but with somewhat more difficulty than with aldehydes.

¹⁰³³ The equilibrium concentration of the product from acetone in pure acetone was determined to be 0.01%: Maple, S.R.; Allerhand, A. *J. Am. Chem. Soc.* **1987**, *109*, 6609.

¹⁰³⁴ For an aqueous version, see Buonora, P.T.; Rosauer, K.G.; Dai, L. *Tetrahedron Lett.* **1995**, *36*, 4009.

¹⁰³⁵ Han, Z.; Yorimitsu, H.; Shinokubo, H.; Oshima, K. *Tetrahedron Lett.* **2000**, *41*, 4415.

5. *Reaction between an Aldehyde and a Ketone.* This is usually feasible with hydroxide or alkoxides bases in protic solvents when the aldehyde has no α hydrogen, since there is no competition from ketone condensing with itself.¹⁰³⁶ This is also called the *Claisen–Schmidt reaction*. Even when the aldehyde has an α hydrogen, it is generally the α carbon of the ketone that adds to the carbonyl of the aldehyde, not the other way around. Mixtures are usually produced, however. If the ketone or the aldehyde is treated with an amide base in aprotic solvents, a second aldehyde or ketone can be added to give the aldolate with high regioselectivity. The reaction can be also made regioselective by preparing an enol derivative of the ketone separately¹⁰³⁷ and then adding this to the aldehyde (or ketone). Other types of preformed derivatives that react with aldehydes and ketones are enamines (with a Lewis acid catalyst),¹⁰³⁸ and enol borinates ($R'CH=CR^2-OBR_2$),¹⁰³⁹ which can be synthesized by Reaction **15-27** or directly from an aldehyde or ketone¹⁰⁴⁰. Preformed metallic enolates are also used. For example, lithium enolates¹⁰⁴¹ (prepared by Reaction **12-23**) react with the substrate in the presence of $ZnCl_2$.¹⁰⁴² In this case, the aldol product is stabilized by chelation of its two oxygen atoms with the zinc ion.¹⁰⁴³ Other metallic enolates can be used for aldol reactions, either preformed or generated *in situ* with a catalytic amount of a metal compound. Compounds used for this purpose include metal complexes of Mg,¹⁰⁴⁴ Ti,¹⁰⁴⁵ Zr,¹⁰⁴⁶ Pd,¹⁰⁴⁷ In,¹⁰⁴⁸ Sn,¹⁰⁴⁹ La,¹⁰⁵⁰ and Sm,¹⁰⁵¹ all of which give products with moderate-to-excellent diastereoselectivity¹⁰⁵² and regioselectivity. α -Alkoxy ketones react with lithium enolates particularly fast.¹⁰⁵³ A bis(aldol) condensation has been reported with epoxy ketones and aldehydes using SmI_2 .¹⁰⁵⁴

There are discussions that relate to the transition state of the aldol condensation. There is experimental evidence for chair-like transition states in the aldol reactions of methyl

ketone lithium enolate anions.¹⁰⁵⁵ A computational study gave the gas-phase activation energies for lithium enolate anions in an aldol-type reaction.¹⁰⁵⁶ There is a computational study of the mechanism for an aldol reaction in pure water.¹⁰⁵⁷

The reactions with pre-formed enol derivatives provide a way to control the stereoselectivity of the aldol reaction.¹⁰⁵⁸ As with the *Michael reaction* (15-24), the aldol reaction creates two new stereogenic centers. In the most general case, there are four stereoisomers of the aldol product (two racemic diastereomers), which can be represented as the syn and anti diastereomers shown. The reaction may be diastereoselective, however, if one is preferred over the other.

Among the preformed enol, derivatives used for diastereoselective aldol condensations have been enolates of Li,¹⁰⁵⁹ Mg, Ti,¹⁰⁶⁰ and Sn,¹⁰⁶¹ silyl enol ethers,¹⁰⁶² enol borinates,¹⁰⁶³ and enol borates [R'CH=CR²OB(OR)₂].¹⁰⁶⁴ The nucleophilicity of silyl enol ethers has been examined¹⁰⁶⁵ and reactions of these compounds are discussed in Reaction 16-35.

Base-induced formation of the enolate anion generally leads to a mixture of (*E*)- and (*Z*)-isomers, and dialkyl amide bases are used in most cases. The (*E/Z*) stereoselectivity depends on the structure of the lithium dialkylamide base, with the highest (*E/Z*) ratios obtained with LiTMP–butyllithium mixed aggregates in THF.¹⁰⁶⁶ The use of LiHMDS resulted in a reversal of the (*E/Z*) selectivity. In general, metallic (*Z*)-enolates give the syn (or erythro) pair, and this reaction is highly useful for the diastereoselective synthesis of these products.¹⁰⁶⁷ The (*E*) isomers generally react nonstereoselectively. However, anti-stereoselectivity has been achieved in a number of cases, with Ti enolates,¹⁰⁶⁸ with Mg

media.¹⁰⁸⁵ Chiral auxiliaries¹⁰⁸⁶ have been developed that can be used in conjunction with the aldol condensation, as well as chiral transition metal complexes¹⁰⁸⁷ and chiral ligands¹⁰⁸⁸ in catalytic reactions. The enantioselective condensation of methyl vinyl ketone and an aldehyde used a chiral Zn catalyst.¹⁰⁸⁹ Structural variations in the aldehyde or ketone are compatible with many enantioselective condensation reactions. An α -hydroxy ketone was condensed with an aldehyde using a chiral Zn catalyst to give the aldol (an α,β -dihydroxy ketone) with good syn selectivity and good enantioselectivity.¹⁰⁹⁰ Chiral vinylogous aldol reactions (Sec. 6.B) have been reported.¹⁰⁹¹ Formation of the magnesium enolate anion of a chiral amide, adds to aldehydes to give the alcohol enantioselectively.¹⁰⁹² Diamine protonic acids have been used for catalytic asymmetric aldol reactions.¹⁰⁹³

Silyl enol ethers react with aldehydes in the presence of chiral boranes¹⁰⁹⁴ or other additives¹⁰⁹⁵ to give aldols with good asymmetric induction (see the *Mukaiyama aldol Reaction* in **16-35**). Chiral boron enolates have been used.¹⁰⁹⁶ Since both new stereogenic centers are formed enantioselectively, this kind of process is called *double asymmetric synthesis*.¹⁰⁹⁷ Where both the enolate derivative and substrate were achiral, carrying out the reaction in the presence of an optically active boron compound¹⁰⁹⁸ or a diamine coordinated with a Sn compound¹⁰⁹⁹ gave the aldol product with excellent enantioselectivity for one stereoisomer. Boron triflate (R_2BOTf) derivatives have been used for the condensation of ketals and ketone to give β -alkoxy ketones.¹¹⁰⁰

It is possible to make the α carbon of the aldehyde add to the carbonyl carbon of the ketone, by using an imine instead of an aldehyde, and $\text{LiN}(\text{iPr})_2$ as the base to form the α -lithio imine (**40**).¹¹⁰¹ This is known as a *directed aldol reaction*. Similar reactions have been performed with α -lithiated dimethylhydrazones of aldehydes or ketones¹¹⁰² and with α -lithiated aldoximes.¹¹⁰³

The aldol reaction can also be performed with acid catalysts, as mentioned above, in which case dehydration usually follows. Here there is initial protonation of the carbonyl group, which attacks the α carbon of the *enol* form of the other molecule¹¹⁰⁴:

With respect to the enol, this mechanism is similar to that of halogenation (Reaction 12-4). A side reaction that is sometimes troublesome is further condensation, since the product of an aldol reaction is still an aldehyde or ketone. The aldol condensation of aldehydes has also been done using a mixture of pyrrolidine and benzoic acid.¹¹⁰⁵

The intramolecular aldol condensation is well known, and aldol reactions are often used to close five- and six-membered rings. Because of the favorable entropy (Sec. 6.D), such ring closures generally take place with ease¹¹⁰⁶ when using hydroxide or alkoxide bases in protic solvents. In aprotic solvents with amide bases, formation of the enolate anion occurs by deprotonation of the more acidic site, followed by cyclization to the second carbonyl. The acid-catalyzed intramolecular aldol condensation is known, and the mechanism has been studied.¹¹⁰⁷ Stereoselective proline-catalyzed intramolecular aldol reactions give the cyclized product with good enantioselectivity.¹¹⁰⁸ Chiral ligands, in conjugation with transition metal compounds of Cu¹¹⁰⁹, lead to asymmetric intramolecular aldol condensation reactions. An asymmetric intramolecular aldol reaction was catalyzed by a chiral

amine.¹¹¹⁰ The regioselectivity of an intramolecular aldol condensation of unsaturated 1,5-diketones is strongly influenced by the presence or absence of a trialkylphosphine.¹¹¹¹

An important extension of the intramolecular aldol condensation is the *Robinson annulation* reaction,¹¹¹² which has often been used in the synthesis of steroids and terpenes. In original versions of this reaction, a cyclic ketone is converted to another cyclic ketone under equilibrium conditions using hydroxide or alkoxide bases in a protic solvent, forming one additional six-membered ring containing a double bond. The reaction can be done in a stepwise manner using amide bases in aprotic solvents. In the reaction with hydroxide or alkoxide bases in alcohol or water solvents, the substrate is treated with methyl vinyl ketone (or a simple derivative of methyl vinyl ketone) and a base.¹¹¹³ The enolate ion of the substrate adds to the methyl vinyl ketone in a *Michael reaction* (**15-24**) to give a diketone that undergoes or is made to undergo an internal aldol reaction and subsequent dehydration to give the product.¹¹¹⁴ The *Robinson annulation* can be combined with alkylation.¹¹¹⁵ Enantioselective *Robinson annulation* techniques have been developed, including a proline-catalyzed reaction.¹¹¹⁶ The *Robinson annulation* has been done in ionic liquids¹¹¹⁷ and a solvent-free version of the reaction is known.¹¹¹⁸

Because methyl vinyl ketone has a tendency to polymerize, surrogates are often used instead (i.e., compounds that will give methyl vinyl ketone when treated with a base). One common example, $\text{MeCOCH}_2\text{CH}_2\text{NEt}_2\text{Me}^+ \text{I}^-$ (see Reaction **17-9**), is easily prepared by quaternization of $\text{MeCOCH}_2\text{CH}_2\text{NEt}_2$, which itself is prepared by a *Mannich Reaction* (**16-19**) involving acetone, formaldehyde, and diethylamine. α -Silylated vinyl ketones $[\text{RCOC}(\text{SiMe}_3)=\text{CH}_2]$ have also been used successfully in annulation reactions¹¹¹⁹ because the SiMe_3 group is easily removed. When the ring closure of a 1,5-diketone is catalyzed by the amino acid (*S*)-proline, the product is optically active with high ee.¹¹²⁰ *Stryker's reagent*,¹¹²¹ $[(\text{Ph}_3\text{P})\text{CuH}]_6$, has been used for an intramolecular addition where a ketone enolate anion adds to a conjugated ketone, giving cyclic alcohol with a pendant ketone unit.¹¹²²

16-35 Mukaiyama Aldol and Related Reactions¹¹²³

O-Hydro-C-(α -acylalkyl)-addition

An important variation of the aldol condensation involves treatment of an aldehyde or ketone with a silyl ketene acetal [$R_2C=C(OSiMe_3)OR'$]¹¹²⁴ or a silyl enol ether, in the presence of $TiCl_4$ ¹¹²⁵, to give **41**. This variation is known as the *Mukaiyama aldol reaction*, or simply the *Mukaiyama reaction*. The silyl ketene acetal can be considered a pre-formed enolate that gives aldol product with $TiCl_4$ in aqueous solution, or with no

catalyst at all.¹¹²⁶ A combination of $TiCl_4$ and *N*-tosyl imine has also been used to facilitate the Mukaiyama aldol reaction.¹¹²⁷ Reaction at the carbonyl of saturated carbonyl compounds is significantly faster than 1,2-addition to unsaturated carbonyl compounds.¹¹²⁸ The mechanism of this reaction has been explored.¹¹²⁹ Other catalysts have been used for this reaction, including $InCl_3$,¹¹³⁰ SmI_2 ,¹¹³¹ HgI_2 ,¹¹³² $Yb(OTf)_3$,¹¹³³ $Cu(OTf)_2$,¹¹³⁴ $LiClO_4$,¹¹³⁵ $VOCl_3$,¹¹³⁶ an Fe catalyst,¹¹³⁷ and $Bi(OTf)_3$.¹¹³⁸ Lithium perchlorate in acetonitrile (5 M) can be used for the reaction of an aldehyde and a silyl enol ether.¹¹³⁹

The reaction can be done in water using a Sc catalyst¹¹⁴⁰ or on a Montmorillonite K-10 clay.¹¹⁴¹ Silyl enol ethers react with aq formaldehyde in the presence of TBAF to give the aldol product.¹¹⁴² A catalytic amount of Me₃SiCl facilitates the Ti mediated reaction.¹¹⁴³ Sulfonamides (e.g., HNTf₂) have been used as a catalyst¹¹⁴⁴ as has pyridine *N*-oxide¹¹⁴⁵ and *N*-methylimidazole.¹¹⁴⁶ An *ab initio* study of the uncatalyzed Mukaiyama aldol reaction showed that the nucleophilicity of silyl enol ether and the electrophilicity of the aldehyde are important in promoting the reactivity.¹¹⁴⁷ This reaction can also be run with the aldehyde or ketone in the form of its acetal [R³R⁴C(OR')₂], in which case the product is the ether R¹COCHR₂CR³R⁴OR' instead of **41**.¹¹⁴⁸ Vinylogous (Sec. 6.B) silyl ketene acetals with Ti,¹¹⁴⁹ Cu,¹¹⁵⁰ In,¹¹⁵¹ Fe,¹¹⁵² or Zn¹¹⁵³ catalysts or an organocatalyst,¹¹⁵⁴ give the product with good enantioselectivity.

Silyl enol ethers¹¹⁵⁵ derived from esters (silyl ketene acetals) react with aldehydes in the presence of various catalysts to give β-hydroxy esters. Water accelerates the reaction of an aldehyde and a ketene silyl acetal with no other additives.¹¹⁵⁶ The reaction is catalyzed by triphenylphosphine¹¹⁵⁷ and also by SiCl₄ with a chiral bis(phosphoramidate) catalyst.¹¹⁵⁸ The reaction was done without a catalyst in an ionic liquid.¹¹⁵⁹ A vinylogous reaction (Sec. 6.B) is known that gives δ-hydroxy-α,β-unsaturated esters.¹¹⁶⁰ An interesting variation in this reaction combined an intermolecular *Mukaiyama aldol* followed by an intramolecular reaction (a “domino” *Mukaiyama aldol*) that gave cyclic conjugated ketone products.¹¹⁶¹ Under different conditions, silyl ketene acetals of conjugated esters react with aldehydes to give conjugated lactones.¹¹⁶² Imines react with silyl ketene acetals in the presence of SmI₃

to give β -amino esters.¹¹⁶³ Imines react with silyl enol ethers in the presence of $\text{BF}_3 \cdot \text{OEt}_2$ to give β -amino ketones.¹¹⁶⁴ Silyl ketene acetals also undergo conjugate addition in reactions with conjugated ketones.¹¹⁶⁵ Propargylic acetals react with silyl enol ethers and a Sc catalyst to give β -alkoxy ketones.¹¹⁶⁶ α -Silyl silyl enol ethers $[\text{RCH}=\text{CH}(\text{OTMS})\text{SiMe}_3]$ react with acetals in the presence of SnCl_4 to give β -alkoxy silyl ketones.¹¹⁶⁷ Borane derivatives [e.g., $\text{C}=\text{C}-\text{OB}(\text{NMe}_2)_2$] react with aldehydes to give β -amino ketones.¹¹⁶⁸

Asymmetric *Mukaiyama aldol reactions* and reactions of silyl ketene acetals have been reported,¹¹⁶⁹ usually using chiral additives¹¹⁷⁰ although chiral auxiliaries have also been used.¹¹⁷¹ Chiral catalysts, usually transition metal complexes using chiral ligands, are quite effective¹¹⁷² but chiral organocatalysts¹¹⁷³ are increasingly important.

Enol acetates and enol ethers also give this product when treated with acetals and TiCl_4 or a similar catalyst.¹¹⁷⁴ A variation of this condensation uses an enol acetate with an aldehyde in the presence of Et_2AlOEt to give the aldol product.¹¹⁷⁵

16-36 Aldol-Type Reactions between Carboxylic Acid Derivatives and Aldehydes or Ketones

O-Hydro-C-(α -alkoxycarbonylalkyl)-addition; α -Alkoxycarbonylalkylidene-de-oxo-bisubstitution

In the presence of a strong base, removal of a proton from the α carbon of a carboxylic ester or other acid derivative generates an enolate anion that can condense with the carbonyl carbon of an aldehyde or ketone to give a β -hydroxy ester,¹¹⁷⁶ amide, and so on. These products may or may not be dehydrated to the α,β -unsaturated derivative. This

reaction is sometimes called the *Claisen reaction*,¹¹⁷⁷ an unfortunate usage since that name is more firmly connected to Reaction **16-85**. *Claisen condensation* is a better descriptor. Early reactions used hydroxide or an alkoxide base in water or alcohol solvents, where self-condensation was the major process. Under such conditions, the aldehyde or ketone was usually chosen for its lack of an α -proton. Much better control of the reaction was achieved when dialkylamide bases in aprotic solvents (e.g., ether or THF) were used. The reaction of *tert*-butyl acetate and LDA¹¹⁷⁸ in hexane or more commonly THF at $-78\text{ }^{\circ}\text{C}$ gives the enolate anion of *tert*-butyl acetate,¹¹⁷⁹ (Reaction **12-23**, e.g., although self-condensation is occasionally a problem even here). Additives play an important role in the LDA mediated enolization of esters¹¹⁸⁰. Subsequent reaction of a ketone provides a simple rapid alternative to the *Reformatsky Reaction* (**16-28**) as a means of preparing β -hydroxy *tert*-butyl esters. It is also possible for the α carbon of an aldehyde or ketone to add to the carbonyl carbon of a carboxylic ester, but this is a different reaction (**16-86**) involving nucleophilic substitution and not addition to a $\text{C}=\text{O}$ bond. It can, however, be a side reaction if the aldehyde or ketone has an α hydrogen.

Transition metal mediated condensation of esters with aldehydes is known. The reaction of a thioester and an aryl aldehyde with $\text{TiCl}_4\text{--NBU}_3$, for example, gave a β -hydroxy thioester with good syn selectivity.¹¹⁸¹ Selenoamides $[\text{RCH}_2\text{C}(=\text{Se})\text{NR}'_2]$ react with LDA and then an aldehyde to give β -hydroxy selenoamides.¹¹⁸² The reaction of an α,β -unsaturated ester and benzaldehyde with a chiral Rh catalyst gave a β -hydroxy ester with good diastereoselectivity and good enantioselectivity.¹¹⁸³

Besides ordinary esters (containing an α hydrogen), the reaction can also be carried out with lactones and, as in Reaction **16-34**, with the γ position of α,β -unsaturated esters (vinyloly; Sec. 6.B). The enolate anion of an amide can be condensed with an aldehyde.¹¹⁸⁴ Thioesters undergo aldol-type condensations.¹¹⁸⁵

For most esters, a much stronger base is needed than for aldol reactions; $(i\text{Pr})_2\text{NLi}$ (LDA, Sec. 8.F, category 7), Ph_3CNa and LiNH_2 are among those employed. However, esters of malonic and succinic acid react more easily, and such strong bases are not needed. For example, diethyl succinate and its derivatives condense with aldehydes and ketones in the presence of bases (e.g., NaOEt , NaH , or KOCMe_3). This reaction is called the *Stobbe condensation*.¹¹⁸⁶ One of the ester groups (sometimes both) is hydrolyzed in the course of the reaction. The following mechanism accounts for (1) the fact the succinic esters react so much better than others; (2) one ester group is always cleaved; and (3) the alcohol is not the product but the alkene. In addition, intermediate lactones (**42**) have been isolated from the mixture.¹¹⁸⁷ The *Stobbe condensation* has been extended to di-*tert*-butyl esters of glutaric acid.¹¹⁸⁸ The boron-mediated reaction is known.¹¹⁸⁹

The intramolecular reaction of an aldehyde–carboxylic acid in the presence of triethylamine and a pyridinium salt led to the ring-forming condensation reaction, followed by formation of a β -lactone.¹¹⁹⁰

Amides participate in this condensation reaction, reacting with aldehydes in the presence of a Ba catalyst to give a β -hydroxy amide derivative.¹¹⁹¹ The reaction of an amide with LDA in the presence of an acyl silane, followed by reaction with an alkyl halide, leads to the β -hydroxy amide with the additional alkyl group at the β -carbon.¹¹⁹²

Chiral additives (e.g., diazaborolidines) can be added to an ester, and subsequent treatment with a base, and then an aldehyde leads to a chiral β -hydroxy ester.¹¹⁹³ A variety of chiral amide or oxazolidinone derivatives have been used to form amide linkages to carboxylic acid derivatives. These chiral auxiliaries lead to chirality transfer from the enolate anion of such derivatives, in both alkylation reactions and acyl substitution reactions with aldehydes and ketones. The so-called *Evans auxiliaries* (**43–45**) are commonly used and give good enantioselectivity.¹¹⁹⁴ A variation is the magnesium halide-catalyzed anti-aldol reaction of chiral *N*-acylthiazolidinethiones (see **46**).¹¹⁹⁵ The use of chiral *N*-acyloxazolidinethiones with TiCl_4 and sparteine also gave good selectivity in the acyl addition.¹¹⁹⁶ Chiral diazaboron derivatives have also been used to facilitate the condensation of a α -phenylthio ester with an aldehyde.¹¹⁹⁷

The condensation of an ester enolate and a ketone¹¹⁹⁸ can be used as part of a *Robinson annulation*-like sequence (see Reaction **16-34**).

16-37 The Henry Reaction¹¹⁹⁹

The classical condensation of an aliphatic nitro compound with an aldehyde or ketone is usually called the *Henry reaction*¹²⁰⁰ or the *Kamlet reaction*, and is essentially a nitro aldol reaction. A variety of conditions have been reported, including the use of a recoverable polymer catalyst,¹²⁰¹ a silica catalyst,¹²⁰² a tetraalkylammonium hydroxide,¹²⁰³ proazaphosphatranes,¹²⁰⁴ and it has been done in an aqueous media¹²⁰⁵ or an ionic liquid.¹²⁰⁶ A solvent-free *Henry reaction* was reported in which a nitroalkane and an aldehyde were reacted on KOH powder.¹²⁰⁷ A solvent-free microwave assisted reaction was reported.¹²⁰⁸ Potassium phosphate has been used with nitromethane and aryl aldehydes.¹²⁰⁹ The *Henry reaction* has been done using ZnEt₂ and 20% ethanolamine.¹²¹⁰ A gel-entrapped base has been used to catalyze this reaction.¹²¹¹ Biocatalysts have been used.¹²¹²

Catalytic enantioselective *Henry reactions* are known,¹²¹³ including the use of a chiral Cu,¹²¹⁴ Zn,¹²¹⁵ Nd,¹²¹⁶ or Ti catalyst.¹²¹⁷ The *Henry reaction* of nitromethane and a chiral aldehyde under high pressure gives the β-nitro alcohol with excellent

enantioselectivity.¹²¹⁸ Enantioselective nitro–aldol reactions are catalyzed by organo-catalysts (e.g., Cinchona alkaloids¹²¹⁹ or other organocatalysts).¹²²⁰

A variation of this reaction converts nitro compounds to nitronates [$\text{RCH}=\text{N}^+(\text{OTMS})-\text{O}^-$], which subsequently react with aldehydes in the presence of a Cu catalyst to give the β -nitro alcohol.¹²²¹ *Aza-Henry reactions* condense nitroalkanes with imine derivatives, and the resulting amino nitro compounds are formed with good enantioselectivity in the presence of organocatalysts¹²²² or Brønsted acid catalysts.¹²²³ *Aza-Henry products* are also formed by the reaction of amines with activated unsaturated compounds.¹²²⁴

16-38 The Knoevenagel Reaction

Bis(ethoxycarbonyl)methylene-de-oxo-bisubstitution, and so on

The condensation of aldehydes or ketones, usually not containing an α hydrogen, with compounds of the form $\text{Z}-\text{CH}_2-\text{Z}'$ or $\text{Z}-\text{CHR}-\text{Z}'$ is called the *Knoevenagel reaction*.¹²²⁵ Both Z and Z' may be CHO, COR, CO₂H, CO₂R, CN, NO₂, SOR, SO₂R, SO₂OR, or similar groups. The presence of two electron-withdrawing groups makes the α -proton much more acidic (Table 8.1 in Sec. 8.A.i), and such compounds have a significantly higher enol content.¹²²⁶ When Z = CO₂H, decarboxylation of the product often takes place *in situ*.¹²²⁷ As shown in the example, the reaction of β -keto esters and aldehydes to give **47** is promoted by diethylamine at 0 °C. Nitroalkanes,¹¹⁹⁹ as well as β -keto sulfoxides,¹²²⁸ undergo the reaction.

As with Reaction **16-34**, these reactions have sometimes been mediated by an acid catalyst.¹²²⁹ Ionic liquid solvents have been used,¹²³⁰ and heating on quaternary

ammonium salts without solvent leads to a *Knoevenagel reaction*.¹²³¹ Other solvent-free reactions are known.¹²³² Ultrasound has been used to promote the reaction,¹²³³ and it has also been done using microwave irradiation¹²³⁴ or on silica,¹²³⁵ with microwave irradiation. Another solid-state variation is done on moist LiBr,¹²³⁶ heating with sodium carbonate and molecular sieves 4 Å promotes the reaction,¹²³⁷ as do zeolites.¹²³⁸ High-pressure conditions have been used.¹²³⁹ Transition metal compounds of Pd,¹²⁴⁰ Sm¹²⁴¹ Ce,¹²⁴² Ti,¹²⁴³ or Bi¹²⁴⁴ have been used to promote the *Knoevenagel reaction*.

With most of these reagents the alcohol is not isolated (only the alkene) if the alcohol has a hydrogen in the proper position,¹²⁴⁵ but with a careful workup the alcohol may be the major product. With suitable reactants, the *Knoevenagel reaction*, like the aldol condensation (**16-34**), has been carried out diastereoselectively¹²⁴⁶ and enantioselectively.¹²⁴⁷ When the reactant is of the form ZCH₂Z', aldehydes react much better than ketones and few successful reactions with ketones have been reported. However, it is possible to get good yields of the alkene from the condensation of diethyl malonate [CH₂(CO₂Et)₂] with ketones, as well as with aldehydes, if the reaction is run with TiCl₄ and pyridine in THF.¹²⁴⁸ In reactions with ZCH₂Z', the catalyst is most often a secondary amine (piperidine is the most common, but see formation of **47**), but many other catalysts have been used. Alkoxides are also common catalysts. When the catalyst is pyridine (to which piperidine may or may not be added) the reaction is known as the *Doebner modification* of the *Knoevenagel reaction* and the product is usually the conjugated acid (**48**). Microwave-induced *Doebner condensation* reactions are known.¹²⁴⁹

A number of special applications of the *Knoevenagel reaction* follow:

1. The dilithio derivative of *N*-methanesulfinyl-*p*-toluidine¹²⁵⁰ (**49**) adds to aldehydes and ketones to give, after hydrolysis, the hydroxysulfinamides (**50**). Subsequent heating leads to a stereospecific syn eliminations to give an alkene.¹²⁵¹ The reaction is thus a method for achieving the conversion $RR'CO \rightarrow RR'C=CH_2$ and represents an alternative to the *Wittig reaction*.¹²⁵² Note that sulfones with an amide group at the α -position, $[ArSO_2CH(R)N(R)C=O]$ react with ketones via acyl addition in the presence of SmI_2 .¹²⁵³

2. The reaction of ketones with tosylmethylisocyanide (**51**) gives different products,¹²⁵⁴ depending on the reaction conditions. When the reaction is run with potassium *tert*-butoxide in THF at -5°C , one obtains (after hydrolysis) the normal *Knoevenagel* product (**52**), except that the isocyano group has been hydrated (Reaction 16-97).¹²⁵⁵ With the same base but with 1,2-dimethoxyethane (DME) as solvent the product is the nitrile (**53**).¹²⁵⁶ When the ketone is treated with **51** and thallium(I) ethoxide in a 4: 1 mixture of absolute ethanol and DME at room temperature, the product is a 4-ethoxy-2-oxazoline (**54**).¹²⁵⁷ Since **53** can be hydrolyzed to a carboxylic acid¹¹⁹⁸ and **54** to an α -hydroxy aldehyde,¹²⁵⁷ this versatile reaction provides a means for achieving the conversion of $RCOR'$ to $RCHR'CO_2H$, $RCHR'CN$, or $RCR'(OH)CHO$. The conversions to $RCHR'COOH$ and to $RCHR'CN$ ¹²⁵⁸ have also been carried out with certain aldehydes ($R' = H$).

3. Aldehydes and ketones (RCOR') react with α -methoxyvinyl lithium $[\text{CH}_2=\text{C}(\text{Li})\text{OMe}]$ to give hydroxy enol ethers $[\text{RR}'\text{C}(\text{OH})\text{C}(\text{OMe})=\text{CH}_2]$, which are easily hydrolyzed to acyloins $[\text{RR}'\text{C}(\text{OH})\text{COMe}]$.¹²⁵⁹ In this reaction, the $\text{CH}_2=\text{C}(\text{Li})\text{OMe}$ is a synthon for the unavailable $\text{H}_3\text{C}-\text{C}=\text{O}$,¹²⁶⁰ and is termed an *acyl anion equivalent*. The reagent also reacts with esters (RCOOR') to give $\text{RC}(\text{OH})(\text{COMe}=\text{CH}_2)_2$. A synthon for the $\text{Ph}-\text{C}=\text{O}$ ion is $\text{PhC}(\text{CN})\text{OSiMe}_3$, which adds to aldehydes and ketones (RCOR') to give, after hydrolysis, the α -hydroxy ketones $[\text{RR}'\text{C}(\text{OH})\text{COPh}]$.¹²⁶¹
4. Lithiated allylic carbamates (**55**) (prepared as shown) react with aldehydes or ketones (R^6COR^7), in a reaction accompanied by an allylic rearrangement, to give (after hydrolysis) γ -hydroxy aldehydes or ketones.¹²⁶² The reaction is called *the homoaldol reaction*, since the product is a homologue of the product of Reaction 16-34. The reaction has been performed enantioselectively.¹²⁶³

5. The lithium salt of an active hydrogen compound adds to the lithium salt of the tosylhydrazone of an aldehyde to give product **56**. If $\text{X} = \text{CN}$, SPh , or SO_2R , **56** spontaneously loses N_2 and LiX to give the alkene **57**. The entire process is done in one reaction vessel: The active hydrogen compound is mixed with the tosylhydrazone and the mixture is treated with $(i\text{Pr})_2\text{NLi}$ to form both salts at once.¹²⁶⁴ This process is another alternative to the *Wittig reaction* for forming double bonds.

16-39 The Perkin Reaction

 α -Carboxyalkylidene-de-oxo-bisubstitution

The condensation of aromatic aldehydes with anhydrides is called the *Perkin reaction*.¹²⁶⁵ When the anhydride has two α hydrogen atoms (as shown), dehydration almost always occurs; the β -hydroxy acid salt is rarely isolated. In some cases, anhydrides of the form $(\text{R}_2\text{CHCO})_2\text{O}$ have been used, and then the hydroxy compound is the product since dehydration cannot take place. The base in the *Perkin reaction* is nearly always the salt of the acid corresponding to the anhydride. Although the Na and K salts have been most frequently used, higher yields and shorter reaction times have been reported for the Cs salt.¹²⁶⁶ Besides aromatic aldehydes, their vinylogs ($\text{ArCH}=\text{CHCHO}$) also give the reaction (see Sec. 6.B). Otherwise, the reaction is not suitable for aliphatic aldehydes.¹²⁶⁷

OS I, 398; II, 61, 229; III, 426.

16-40 Darzens Glycidic Ester Condensation

(2+1) OC,CC-cyclo- α -Alkoxycarbonylmethylene-addition

Aldehydes and ketones condense with α -halo esters in the presence of bases to give α,β -epoxy esters, called *glycidic esters*. This is called the *Darzens condensation*.¹²⁶⁸ The reaction consists of an initial *Knoevenagel-type* Reaction (16-38), followed by an internal S_N^2 Reaction (10-9)¹²⁶⁹:

Although the intermediate halo alkoxide is generally not isolated,¹²⁷⁰ it has been done, not only with α -fluoro esters (since fluorine is such a poor leaving group in nucleophilic substitutions), but also with α -chloro esters.¹²⁷¹ This is only one of several types of evidence that rule out a carbene intermediate.¹²⁷² Sodium ethoxide is often used as the base, but other bases, including sodium amide, are sometimes used. Aromatic aldehydes and ketones give good yields. The reaction can be made to give good yields ($\sim 80\%$) with simple aliphatic aldehydes, as well as with aromatic aldehydes and ketones, by treatment of the α -halo ester with the base lithium bis(trimethylsilyl)amide $[\text{LiN}(\text{SiMe}_3)_2]$ in THF at

–78 °C (to form the conjugate base of the ester) and addition of the aldehyde or ketone to this solution.¹²⁷³ If a preformed dianion of an α -halo carboxylic acid ($\text{Cl}^-\text{CRCO}_2^-$) is used instead, α,β -epoxy acids are produced directly.¹²⁷⁴ The *Darzens reaction* has also been carried out on α -halo ketones, α -halo nitriles,¹²⁷⁵ α -halo sulfoxides¹²⁷⁶ and sulfones,¹²⁷⁷ α -halo N,N-disubstituted amides,¹²⁷⁸ α -halo ketimines,¹²⁷⁹ and even on allylic¹²⁸⁰ and benzylic halides. Phase-transfer catalysis has been used.¹²⁸¹ Note that the reaction of a β -bromo- α -oxo ester and a *Grignard reagent* leads to the glycidic ester.¹²⁸² Acid-catalyzed *Darzens reactions* have also been reported.¹²⁸³ (see also, Reaction 16-46).

Diastereoselective *Darzens condensations* are possible.¹²⁸⁴ The *Darzens reaction* has been performed with good enantioselectivity,¹²⁸⁵ and chiral additives have proven to be effective.¹²⁸⁶ Chiral phase-transfer agents have been used to give epoxy ketones with modest enantioselectivity.¹²⁸⁷

Glycidic esters can easily be converted to aldehydes (Reaction 12-40). The reaction has been extended to the formation of analogous aziridines by treatment of an imine with an α -halo ester or an α -halo N,N-disubstituted amide and *t*-BuOK in the solvent 1,2-dimethoxyethane.¹²⁸⁸ However, yields were not high.

OS III, 727; IV, 459, 649.

16-41 The Peterson Alkenylation Reaction

Alkylidene-de-oxo-bisubstitution

In the *Peterson alkenylation reaction*¹²⁸⁹, the lithio (or sometimes magnesio) derivative of a trialkylsilane adds to an aldehyde or ketone to give a β -hydroxysilane, which spontaneously eliminates water, or can be made to do so by treatment with acid or base, to produce an alkene. This reaction is still another alternative to the *Wittig reaction* (16-44), and is sometimes

called the *silyl-Wittig reaction*.¹²⁹⁰ The R group can also be a COOR group, in which case the product is an α,β -unsaturated ester,¹²⁹¹ or an SO₂Ph group, in which case the product is a vinylic sulfone.¹²⁹² The stereochemistry of the product can often be controlled by whether an acid or a base is used to achieve elimination. The role of Si—O interactions has also been examined.¹²⁹³ Use of a base generally gives syn elimination (Ei mechanism, see Sec. 17.C.i), while an acid usually results in anti elimination (E2 mechanism, see Sec. 17.A.i).¹²⁹⁴ Samarium(II) iodide in HMPA has also been used for elimination of the hydroxy sulfone.¹²⁹⁵

When aldehydes or ketones are treated with reagents of the form **58**, the product is an epoxy silane (Reaction **16-46**), which can be hydrolyzed to a methyl ketone.¹²⁹⁶ For aldehydes, this is a method for converting RCHO to a methyl ketone (RCH₂COMe).

The reagents Me₃SiCHRM (M = Li or Mg) are often prepared from Me₃SiCHRCI¹²⁹⁷ (by Reaction **12-38** or **12-39**), but they have also been made by Reaction **12-22** and other procedures.¹²⁹⁸ Lithio alkenylsilanes have been used for this reaction.¹²⁹⁹

A new version of the reaction has been developed, reacting Me₃SiCH₂CO₂Et with an aldehyde and a catalytic amount of CsF in DMSO.¹³⁰⁰ A seleno-amide derivative has been used in a similar manner.¹³⁰¹

There are no references in *Organic Syntheses*, but see OS **VIII**, 602, for a related reaction.

Ketones of the form RCOCH_3 and $\text{RCOCH}_2\text{R}'$ can be carboxylated indirectly by treatment with magnesium methyl carbonate (**59**).¹³⁰² Because formation of the chelate (**60**) provides the driving force of the reaction, carboxylation cannot be achieved at a disubstituted α position. The reaction has also been performed on CH_3NO_2 , on compounds of the form RCH_2NO_2 ¹³⁰³ and on certain lactones.¹³⁰⁴ Direct carboxylation has been reported in a number of instances. Ketones have been carboxylated in the α position to give β -keto acids.¹³⁰⁵ The base here was lithium 4-methyl-2,6-di-*tert*-butylphenoxide.

Ketones ($\text{RCOCH}_2\text{R}'$), as well as other active hydrogen compounds, undergo base-catalyzed addition to CS_2 ¹³⁰⁶ to give a dianion intermediate ($\text{RCOC}^-\text{R}'\text{CSS}^{2-}$), which can be dialkylated with a halide (R^2X) to produce α -dithiomethylene ketones $[\text{RCOCR}'=\text{C}(\text{SR}^2)_2]$.¹³⁰⁷ Compounds of the form $\text{ZCH}_2\text{Z}'$ also react with bases and CS_2 to give analogous dianions.¹³⁰⁸

Although reactions with $\text{N}=\text{O}$ derivatives do not formally fall into this category of reactions, it is somewhat related. Nitroso compounds react with activated nitriles in the presence of LiBr and microwave irradiation to give a cyano imine $[\text{ArN}=\text{C}(\text{CN})\text{Ar}]$.¹³⁰⁹ This transformation has been called the *Ehrlich–Sachs reaction*.¹³¹⁰

16-43 Tollens' Reaction

O-Hydro-C (β -hydroxyalkyl)-addition

In the *Tollens' reaction*, an aldehyde or ketone containing an α hydrogen is treated with formaldehyde in the presence of Ca(OH)_2 or a similar base. The first step is a mixed-aldol reaction (**16-34**).

The reaction can be stopped at this point, but more often a second equivalent of formaldehyde is permitted to reduce the newly formed aldol to a 1,3-diol, in a *crossed-Cannizzaro Reaction* (**19-81**). If the aldehyde or ketone has several α hydrogen atoms, they can all be replaced. An

important use of the reaction is to prepare pentaerythritol from acetaldehyde:

OS I, 425; IV, 907; V, 833.

16-44 The Wittig Reaction

Alkylidene-de-oxo-bisubstitution

In the *Wittig reaction*, an aldehyde or ketone is treated with a *phosphorus ylid* (a *phosphorane*; also spelled *ylide*) to give an alkene.¹³¹¹ The conversion of a carbonyl compound to an alkene with a phosphorus ylid is called the *Wittig reaction*. Phosphorus ylids are usually prepared by treatment of a phosphonium salt with a base,¹³¹² and phosphonium salts (**61**) are usually prepared from a triaryl phosphine and an alkyl halide (Reaction **10-31**):

The reaction of triphenylphosphine and an alkyl halides is facilitated by the use of microwave irradiation.¹³¹³ Indeed, the *Wittig reaction* itself is assisted by microwave irradiation.¹³¹⁴ Phosphonium salts are also prepared by addition of phosphines to *Michael alkenes* (like Reaction **15-8**) and in other ways.

The phosphonium salts are most often converted to the ylids by treatment with a strong base (e.g., butyllithium, sodium amide,¹³¹⁵ sodium hydride, or a sodium alkoxide, though weaker bases can be used if the salt is acidic enough. In some cases, and excess of fluoride ion is sufficient.¹³¹⁶ For $(\text{Ph}_3\text{P}^+)_2\text{CH}_2$, sodium carbonate is a strong enough base.¹³¹⁷ When the base used does not contain lithium, the ylid is said to be prepared under “salt-free” conditions¹³¹⁸ because the lithium halide (where the halide counterion comes from

the phosphonium salt) is absent. *Wittig reactions* can be done in aqueous media in the presence of surfactants.¹³¹⁹

When the phosphorus ylid reacts with the aldehyde or ketone to form an alkene, a phosphine oxide is also formed. When triphenylphosphine is used to give $\text{Ph}_3\text{P}=\text{CRR}'$, for example, the byproduct is triphenylphosphine oxide (Ph_3PO), which is sometimes difficult to separate from the other reaction products. Other triarylphosphines¹³²⁰ and trialkylphosphines¹³²¹ have been used. Phosphines that have an α -hydrogen should be avoided, so that reaction with the chosen alkyl halide will lead to a phosphonium salt (**61**) with the α -proton at the desired position. This limitation is essential if a specific ylid is to be formed from the alkyl halide precursor. The *Wittig reaction* has been carried out with polymer-supported ylids.¹³²² It has also been done on silica gel.¹³²³ Polymer-bound aryldiphenylphosphino compounds¹³²⁴ have been used in reactions with alkyl halides to complete a *Wittig reaction*.

If an alkyl halide is viewed as the starting material (alkyl halide phosphonium salt \rightarrow phosphorus ylid \rightarrow alkene), the halogen-bearing carbon of an alkyl halide must contain at least one hydrogen, as in **62** (for deprotonation at the phosphonium salt stage).

The reaction is very general.¹³²⁵ The aldehyde or ketone may be aliphatic, alicyclic, or aromatic (including diaryl ketones). *Wittig reactions* are known in which the ylid and/or the carbonyl substrate contain double or triple bonds; various functional groups may be present (e.g., OH, OR, NR_2 , aromatic nitro or halo, acetal, amide,¹³²⁶ or even ester groups).¹³²⁷ Note, however, that a *Wittig reaction* has been reported in which the carbonyl group of an ester was converted to a vinyl ether.¹³²⁸ An important advantage of the *Wittig reaction* is that the *position* of the new double bond is always certain, in contrast to the result in most of the base-catalyzed condensations (Reactions **16-34–16-43**). Ylids have been shown to react with lactones, however, to form ω -alkenyl alcohols.¹³²⁹ β -Lactams have also been converted to alkenyl-azetidine derivatives using phosphorus ylids.¹³³⁰ Double or triple bonds *conjugated* with the carbonyl also do not interfere, the attack being at the $\text{C}=\text{O}$ carbon. The carbonyl partner can be generated *in situ*, in the presence of an ylid; the reaction of an alcohol with a mixture of an oxidizing agent and an ylid generates an alkene. Oxidizing agents used in this manner include BaMnO_4 ,¹³³¹ MnO_2 ,¹³³² and $\text{PhI}(\text{OAc})_2$.¹³³³

Weinreb amides (Reaction 16-82) can be converted to the corresponding aldehyde via the *Wittig reaction*.¹³³⁴

As noted above, the phosphorus ylid may also contain double or triple bonds and certain functional groups. Simple ylids ($R, R' = \text{hydrogen or alkyl}$) are highly reactive, reacting with oxygen, water, hydrohalic acids, and alcohols, as well as carbonyl compounds and carboxylic esters, so the reaction must be run under conditions where these materials are absent. When an electron-withdrawing group (e.g., COR, CN, CO₂R, CHO) is present in the α position, the ylids are much more stable, because the charge on the carbon is delocalized by

resonance as in **63**. Such ylids react readily with aldehydes, but slowly or not at all with ketones.¹³³⁵ In extreme cases (e.g., **64** where the carbanion unit is part of the aromatic cyclopentadienyl anion), the ylid does not react with ketones *or* aldehydes. Besides these groups, the ylid may contain one or two α halogens¹³³⁶ or

an α OR or OAr group. In the latter case, the product is an enol ether, which can be hydrolyzed (Reaction 10-6) to an aldehyde,¹³³⁷ so that this reaction is a means of achieving the conversion $\text{RCOR}' \rightarrow \text{RR}'\text{CHCHO}$.¹³³⁸ However, the ylid may not contain an α nitro group. If the phosphonium salt contains a potential leaving group (e.g., Br or OMe) in the β position, treatment with a base gives elimination, instead of the ylid:

However, a β COO⁻ group may be present, and the product is a β,γ -unsaturated acid:¹³³⁹ This is the only convenient way to make these compounds, since elimination by any other route gives the thermodynamically more stable α,β -unsaturated isomers. This is an illustration of the utility of the *Wittig* method for the specific location of a double bond. Another illustration is the conversion of cyclohexanones to alkenes containing exocyclic double bonds, for example:¹³⁴⁰

Still another example is the formation of *anti-Bredt* bicycloalkenones¹³⁴¹ (see Sec. 4.Q.iii). As indicated above, α,α' -dihalophosphoranes can be used to prepare 1,1-dihaloalkenes. Another way to prepare haloalkenes¹³⁴² is to treat the carbonyl compound with a mixture of CX_4 ($X = Cl, Br, \text{ or } I$) and triphenylphosphine, either with or without the addition of zinc dust, which allows less Ph_3P to be used.¹³⁴³ Aryl aldehydes react with these dihalophosphoranes to give aryl alkynes after treatment of the initially formed vinyl halide with potassium *tert*-butoxide.¹³⁴⁴

The mechanism¹³⁴⁵ of the key step of the *Wittig reaction* is as follows:¹³⁴⁶

The energetics of ylid formation and their reaction in solution has been studied.¹³⁴⁷ For many years it was assumed that a diionic compound, called a *betaine*, is an intermediate on the pathway from the starting compounds to the oxaphosphetane, but it has been argued that there is little evidence for it.¹³⁴⁸ However, “betaine” precipitates have been isolated in certain *Wittig reactions*,¹³⁴⁹ although these are betaine–lithium halide adducts, and might just as well have been formed from the oxaphosphetane as from a true betaine.¹³⁵⁰ There is one report of an observed betaine lithium salt during the course of a *Wittig reaction*.¹³⁵¹ An X-ray structure was determined for a *gauche* betaine from a thio-*Wittig reaction*.¹³⁵² In contrast, there is much evidence for the presence of the oxaphosphetane intermediates, at least with unstable ylids. For example, ^{31}P NMR spectra taken of the reaction mixtures at low temperatures¹³⁵³ are compatible with an oxaphosphetane structure that persists for some time but not with a tetra-coordinated phosphorus species. Since a betaine, an ylid, and a phosphine oxide all have tetracoordinated phosphorus, these species could not be causing the spectra, leading to the conclusion that an oxaphosphetane intermediate is present in the solution. In certain cases, oxaphosphetanes have been isolated.¹³⁵⁴ It has even been

¹³⁴¹ Bestmann, H.J.; Schade, G. *Tetrahedron Lett.* **1982**, 23, 3543.

¹³⁴⁶ It has been contended that another mechanism, involving single electron transfer, may be taking place in some cases: Olah, G.A.; Krishnamurthy, V.V. *J. Am. Chem. Soc.* **1982**, 104, 3987; Yamataka, H.; Nagareda, K.; Hanafusa, T.; Nagase, S. *Tetrahedron Lett.* **1989**, 30, 7187. possible to detect *cis* and *trans* isomers of the intermediate oxaphosphetanes by NMR spectroscopy.¹³⁵⁵ According to this mechanism, an optically active phosphonium salt ($\text{RR}^1\text{R}^2\text{P}^+\text{CHR}^2$) should retain its configuration all the way through the reaction, and it should be preserved in the phosphine oxide ($\text{RR}^1\text{R}^2\text{PO}$). This has been shown to be the case.¹³⁵⁶

Note that the proposed betaine intermediates can be formed, in a completely different manner, by nucleophilic substitution by a phosphine on an epoxide (**10-35**):

Betaines formed in this way can then be converted to the alkene. This is one reason why betaine intermediates were long accepted in the *Wittig reaction*. It is also noteworthy that stable phosphonium enolate zwitterions have been formed by the reaction of an aryl aldehyde, a phosphine, and a propargylic ester.¹³⁵⁷

Phosphorus is not the only key element used to produce useful ylids. Triphenylarsine¹³⁵⁸ has been used. Tellurium ylids have been prepared *in situ* from α -halo esters and $\text{BrTeBu}_2\text{OTeBu}_2\text{Br}$ and react with aldehydes to give conjugated esters.¹³⁵⁹

The *Wittig reaction* has been carried out with phosphorus ylids other than phosphoranes, the most important being prepared from phosphonate esters (e.g., **65**).¹³⁶⁰

This method, sometimes called the *Horner-Emmons*, *Wadsworth-Emmons*, *Wittig-Horner*, or *Horner-Wadsworth-Emmons reaction*,¹³⁶¹ has several advantages over the use of phosphoranes, including selectivity.¹³⁶² These ylids are more reactive than the corresponding phosphoranes, and when R^1 or R^2 is an electron-withdrawing group, these compounds often react with ketones that are inert to phosphoranes. High pressure has been used to facilitate this reaction.¹³⁶³ In addition, the phosphorus product is a phosphate ester, and hence soluble in water, unlike Ph_3PO , which makes it easy to separate it from the

alkene product. Phosphonates are also cheaper than phosphonium salts and can easily be prepared by the *Arbuzov reaction*.¹³⁶⁴

Phosphonates have also been prepared from alcohols and $(\text{ArO})_2\text{P}(=\text{O})\text{Cl}$, NEt_3 , and a TiCl_4 catalyst.¹³⁶⁵ The reaction of $(\text{RO})_2\text{P}(=\text{O})\text{H}$ and aryl iodides with a CuI catalyst leads to aryl phosphonates.¹³⁶⁶ Polymer-bound phosphonate esters have been used for olefination.¹³⁶⁷ Dienes are produced when allylic phosphonate esters react with aldehydes.¹³⁶⁸ Nucleophilicity parameters have been determined for phosphoryl-stabilized carbanions.¹³⁶⁹ A Zn promoted reaction is known using diprotic phosphonates.¹³⁷⁰ *Wittig reactions* of stabilized phosphorus ylids have also been done in water.¹³⁷¹

Stereoselective alkenylation reactions have been achieved using chiral additives¹³⁷² or auxiliaries.¹³⁷³ Ylids formed from phosphine oxides $[\text{Ar}_2\text{P}(=\text{O})\text{CHRR}']$, phosphonic acid bis(amides), $(\text{R}_2^2\text{N})_2\text{POCHRR}^1]$,¹³⁷⁴ and alkyl phosphonothionates $[(\text{MeO})_2\text{PSCHRR}^1]$,¹³⁷⁵ share some of these advantages. Reagents (e.g., $\text{Ph}_2\text{POCH}_2\text{NR}_2'$) react with aldehydes or ketones (R^2COR^3) to give good yields of enamines ($\text{R}^2\text{R}^3\text{C}=\text{CHNR}$).¹³⁷⁶ (*Z*)-Selective reagents are also known,¹³⁷⁷ including the use of a di(2,2,2-trifluoroethoxy)phosphonate with KHMDs and 18-crown-6.¹³⁷⁸ An interesting intramolecular version of the *Horner–Emmons reaction* leads to alkynes.¹³⁷⁹ The reaction of a functionalized aldehyde ($\text{R}-\text{CHO}$) with $(\text{MeO})_2\text{POCHN}_2$, leads to an alkyne ($\text{R}-\text{C}\equiv\text{CH}$).¹³⁸⁰

Some *Wittig reactions* give the (*Z*)-alkene; some the (*E*), and others give mixtures. The question of which factors determine the stereoselectivity has been much studied.¹³⁸¹ It is generally found that ylids containing stabilizing groups or formed from trialkylphosphines give (*E*)-alkenes. The origin of the (*E*) selectivity in salt-free stabilized ylids may be related to dipole–dipole interactions.¹³⁸² The energy of the elimination transition state must also be taken into account.¹³⁸³ It has been shown that ylids formed from triarylphosphines and not containing stabilizing groups often give (*Z*) or a mixture of (*Z*)- and (*E*)-alkenes.¹³⁸⁴ One explanation for this¹³⁵⁶ is that the reaction of the ylid with the carbonyl compound is a [2+2]-cycloaddition, which in order to be concerted must adopt the $[\pi 2_s + \pi 2_a]$ -pathway. As discussed in Reaction **15-63**, this pathway leads to the formation of the more sterically crowded product, in this case the (*Z*)-alkene. If this explanation is correct, it is not easy to explain the predominant formation of (*E*) products from stable ylids, but (*E*) compounds are of course generally thermodynamically more stable than the (*Z*) isomers, and the stereochemistry seems to depend on many factors.

The (*E/Z*) ratio of the product can often be changed by a change in solvent or by the addition of salts.¹³⁸⁵ Another way of controlling the stereochemistry of the product is by use of the aforementioned phosphonic acid bis(amides). In this case, the betaine (**66**) does form and when treated with water gives the β -hydroxyphosphonic acid bis(amides) (**67**), which can be crystallized and then cleaved to $\text{R}^1\text{R}^2\text{C}=\text{CR}^3\text{R}^4$ by refluxing in benzene or toluene in the presence of silica gel.¹³⁷⁴ β -Hydroxy products (**67**) are generally formed as mixtures of diastereomers, and these mixtures can be separated by recrystallization. Each diastereomer will give one of the two isomeric alkenes. Optically active phosphonic acid bis(amides) have been used to give optically active alkenes.¹³⁸⁶ Another method of controlling the stereochemistry of the alkene [to obtain either the (*Z*)- or (*E*)-isomer] starting with a phosphine oxide ($\text{Ph}_2\text{POCH}_2\text{R}$) has been reported.¹³⁸⁷

In reactions where the betaine–lithium halide intermediate is present, it is possible to extend the chain further if a hydrogen is present α to the phosphorus. For example, reaction of ethylenetriphenylphosphorane with heptanal at $-78\text{ }^{\circ}\text{C}$ gave **68**, and subsequent treatment with butyllithium gave the ylid, (**69**). Treatment of **69** with an aldehyde ($\text{R}'\text{CHO}$) gave the intermediate (**70**) that gave, after workup, **71**¹³⁸⁸ stereoselectively. Alkoxide **69** also reacts with other electrophiles. For example, treatment of **69** with NCS or PhICl_2 gave the vinylic chloride ($\text{RCH}=\text{CMeCl}$) stereoselectively: NCS gave the cis and PhICl_2 the trans-isomer.¹³⁸⁹ The use of Br_2 and FCIO_3 (several explosions¹³⁹⁰ have been observed with this reagent) gives the corresponding bromide or fluoride, respectively.¹³⁹¹ Reactions of **69** with electrophiles have been called *scoopy reactions* (α substitution plus carbonyl alkenylation via β -oxido phosphorus ylids).¹³⁹²

The reaction of a phosphonate ester, DBU, NaI, and HMPA with an aldehyde leads to a conjugated ester with excellent (*Z*)-selectivity.¹³⁹³ A (*Z*)-selective reaction was reported using a trifluoroethyl phosphonate in a reaction with an aldehyde and potassium *tert*-butoxide.¹³⁹⁴

The Wittig reaction has been carried out intramolecularly, to prepare rings containing from 5 to 16 carbons,¹³⁹⁵ both by single-ring closure to give alkenes (e.g., **70**), or by double-ring closure, as in the conversion of **71** to **72**).¹³⁹⁶

The Wittig reaction has proved very useful in the synthesis of natural products, some of which are quite difficult to prepare in other ways.¹³⁹⁷

Phosphorus ylids also react in a similar manner with the C=O bonds of ketenes,¹³⁹⁸ isocyanates,¹³⁹⁹ certain anhydrides¹⁴⁰⁰ lactones,¹⁴⁰¹ and imides,¹⁴⁰² the N=O of nitroso groups, and the C=N of imines,¹⁴⁰³ as shown in the composite reaction. Phosphorus ylids react with carbon dioxide to give the isolable salts (**74**),¹⁴⁰⁴ which can be hydrolyzed to the carboxylic acids (**75**) (thus achieving the conversion $RR'CHX \rightarrow RR'CHCOOH$) or (if neither R nor R' is hydrogen) dimerized to allenes (**76**).

Although phosphorus ylids are most commonly used for alkenylation reactions, nitrogen ylids can occasionally be used. However, nitrogen ylids are often difficult to form, are unstable and highly reactive. The reaction of *N*-benzyl-*N*-phenylpiperidinium bromide with base to give an N-ylid is one example, and it reacted with benzaldehyde to form styrene.¹⁴⁰⁵ The structure has been determined for an intermediate in an *aza*-Wittig reaction.¹⁴⁰⁶ An *aza*-Wittig reaction¹⁴⁰⁷ has been used to prepare pyrrolines and tetrahydropyridines.¹⁴⁰⁸

pyridine¹⁴¹⁰ leads to the alkene. Dimethyltitanocene (Me_2TiCp_2), called the *Petasis reagent*, is a convenient and highly useful alternative to **77**.¹⁴¹¹ The mechanism of *Petasis olefination* has been examined.¹⁴¹² Both the *Tebbe* and the *Petasis reagent* give good results with ketones.¹⁴¹³ An important feature of these new reagents is that carboxylic esters and lactones¹⁴¹⁴ can be converted to the corresponding enol ethers in good yields. The enol ether can be hydrolyzed to a ketone (Reaction **10-6**), so this is also an indirect method for making the conversion $\text{RCO}_2\text{R}' \rightarrow \text{RCOCH}_3$ (see also, Reaction **16-82**). Conjugated esters are converted to alkoxy-dienes with this reagent.¹⁴¹⁵ Lactams, including β -lactams, are converted with alkylidene cycloamines (alkylidene azetidines from β -lactams, which are easily hydrolyzed to β -amino ketones).¹⁴¹⁶

Besides stability and ease of preparation, another advantage of the *Petasis reagent* is that structural analogues can be prepared, including $\text{Cp}_2\text{Ti}(\text{C}_3\text{H}_5)_2$ ¹⁴¹⁷ (C_3H_5 = cyclopropyl), $\text{CpTi}(\text{CH}_2\text{SiMe}_3)_3$,¹⁴¹⁸ and $\text{Cp}_2\text{TiMe}(\text{CH}=\text{CH}_2)$.¹⁴¹⁹ In another variation, 2 molar equivalents of $\text{Cp}_2\text{Ti}[\text{P}(\text{OEt})_3]_2$ reacted with a ketone in the presence of 1,1-diphenylthiocyclobutane to give the alkenylcyclobutane derivative.¹⁴²⁰ An alternative Ti reagent was prepared using TiCl_4 , Mg metal and dichloromethane, reacting with both ketones¹⁴²¹ and esters¹⁴²² to give alkenes or vinyl ethers, respectively. Alkenes are generated from ketones and alkyl iodides in the presence of a catalytic amount of $\text{Cp}_2\text{Ti}[\text{POEt}]_3$.¹⁴²³

Carboxylic esters undergo the conversion $\text{C}=\text{O} \rightarrow \text{C}=\text{CHR}$ (R = primary or secondary alkyl) when treated with RCHBr_2 , Zn ,¹⁴²⁴ and TiCl_4 in the presence of N,N,N',N' -tetramethylethylenediamine.¹⁴²⁵ Metal carbene complexes¹⁴²⁶ $\text{R}_2\text{C}=\text{ML}_n$ (L = ligand), where M is a transition metal (e.g., Zr , W , or Ta) have also been used to convert the $\text{C}=\text{O}$ of carboxylic esters and lactones to CR_2 .¹⁴²⁷ It is likely that the complex $\text{Cp}_2\text{Ti}=\text{CH}_2$ is an

and ordinarily must be used as soon as it is formed, while **78** can be stored several days at room temperature. When diastereomeric epoxides can be formed, **79** usually attacks from the more hindered and **78** from the less-hindered side. Thus, 4-*tert*-butylcyclohexanone, treated with **78** gave exclusively **80** while **79** gave mostly **81**.¹⁴⁴² Another difference in behavior between the two reagents is that with α,β -unsaturated ketones, **78** gives

only cyclopropanes (Reaction **15-64**), while **79** gives oxirane formation. Other sulfur ylids have been used in an analogous manner, to transfer CHR or CR₂.¹⁴⁴³ Other sulfur ylids convert aldehydes to epoxides.¹⁴⁴⁴ High yields have been achieved by the use of sulfonium ylids anchored to insoluble polymers under phase-transfer conditions.¹⁴⁴⁵ A solvent-free version of this reaction has been developed using powdered K *tert*-butoxide and Me₃S⁺T⁻.¹⁴⁴⁶ Note that treatment of epoxides with 2 equiv of Me₂S=CH₂ leads to allylic alcohols.¹⁴⁴⁷

Chiral sulfur ylids¹⁴⁴⁸ have been prepared, giving the epoxide with good asymmetric induction,¹⁴⁴⁹ and chiral additives have also been used.¹⁴⁵⁰ Chiral Se ylids have been used in a similar manner.¹⁴⁵¹

The generally accepted mechanism for the reaction between sulfur ylids and aldehydes or ketone is formation of **82**, with displacement of the Me₂S leaving group by the alkoxide.¹⁴⁵² This mechanism is similar to that of the reaction of sulfur ylids with C=C double bonds (Reaction **15-64**).¹⁴⁵³ The stereochemical difference in the behavior of **78** and **79** has been attributed to formation of the betaine (**82**) being reversible for **78**, but not for the less stable **79**, so that the more-hindered product is the result of kinetic control and the less hindered of thermodynamic control.¹⁴⁵⁴

Phosphorus ylids do not give this reaction, but give **16-44** instead.

Aldehydes and ketones can also be converted to epoxides by treatment with a diazoalkane.¹⁴⁵⁵ Most commonly it is diazomethane, but an important side reaction is the formation of an aldehyde or ketone with one more carbon than the starting compound (Reaction **18-9**). The reaction can be carried out with many aldehydes, ketones, and quinones, usually with a Rh catalyst.¹⁴⁵⁶ A mechanism that accounts for both products follows:

Compound **83** or nitrogen-containing derivatives of it have sometimes been isolated.

An alternative route to epoxides from ketones uses α -chloro sulfones and potassium *tert*-butoxide to give α,β -epoxy sulfones.¹⁴⁵⁷ A similar reaction was reported using KOH and 10% of a chiral phase-transfer agent, giving moderate enantioselectivity in the epoxy sulfone product.¹⁴⁵⁸

Dihalocarbenes and carbenoids, which readily add to C=C bonds (Reaction **15-64**), do not generally add to the C=O bonds of ordinary aldehydes and ketones.¹⁴⁵⁹ See also, Reaction **16-91**.

There is a report of a strained azetidinium ylid that has been used for epoxidation.¹⁴⁶⁰ OS V, 358, 755.

16-47 The Formation of Aziridines from Imines

(1+2)NC,CC-cyclo-Methylene-addition

Just as sulfur ylids (e.g., **78**) react with the carbonyl of an aldehyde or ketone to give an epoxide, Te ylids react with imines to give an aziridine. The reaction of an allylic Te salt ($\text{RCH=CHCH}_2\text{Te}^+\text{Bu}_2\text{Br}^-$), with lithium hexamethyldisilazide in HMPA/toluene leads to the tellurium ylid via deprotonation. In the presence of an imine, the ylid add to the imine and subsequent displacement of Bu_2Te generates an aziridine with a pendant vinyl group.¹⁴⁶¹ Catalytic aziridination of tosylimines was reported and mediated by arsonium ylids.¹⁴⁶²

16-48 The Formation of Episulfides and Episulfones¹⁴⁶³

Epoxides can be converted directly to episulfides by treatment with NH_4SCN and ceric ammonium nitrate.¹⁴⁶⁴ Diazoalkanes, treated with sulfur, give episulfides.¹⁴⁶⁵ It is likely that $\text{R}_2\text{C}=\text{S}$ is an intermediate, which is attacked by another molecule of diazoalkane, in a process similar to that shown in Reaction 16-46. Thioketones *do* react with diazoalkanes to give episulfides,¹⁴⁶⁶ and have also been converted to episulfides with sulfur ylids.¹⁴⁴² Carbenes (e.g., the dichlorocarbene from CHCl_3) and base react with thioketones to give an α,α -dichloro episulfide.¹⁴⁶⁷

Alkanesulfonyl chlorides, when treated with diazomethane in the presence of a base (usually a tertiary amine), give episulfones (85).¹⁴⁶⁸ The base removes HCl from the sulfonyl halide to produce the highly reactive sulfene (84) (see Reaction 17-14), which then adds CH_2 . The episulfone can then be heated to give off SO_2 (see Reaction 17-20), making the entire process a method for achieving the conversion $\text{RCH}_2\text{SO}_2\text{Cl} \rightarrow \text{RCH}=\text{CH}_2$.¹⁴⁶⁹ OS V, 231, 877.

16-49 Cyclopropanation of Conjugated Carbonyl Compounds

Double-bond compounds that undergo the *Michael reaction* (15-24) can be converted to cyclopropane derivatives with sulfur ylids.¹⁴⁷⁰ Among the most common of these is dimethyloxosulfonium methylid (78),¹⁴⁷¹

which is widely used to transfer CH_2 to activated double bonds, but other sulfur ylids have also been used. A combination of DMSO and KOH in an ionic liquid converts conjugated

ketones to α,β -cyclopropyl ketones.¹⁴⁷² Both CHR and CR₂ can be added in a similar manner with certain nitrogen-containing compounds. For example, ylids¹⁴⁷³ (e.g., **86**), add various groups to activated double bonds.¹⁴⁷⁴ Sulfur ylids react with allylic alcohols in the presence of MnO₂ and molecular sieve 4 Å to give the cyclopropyl aldehyde.¹⁴⁷⁵ Similar reactions have been performed with phosphorus ylids,¹⁴⁷⁶ with pyridinium ylids,¹⁴⁷⁷ and with the compounds (PhS)₃CLi and Me₃Si(PhS)₂CLi.¹⁴⁷⁸ The reactions with ylids such as these of course involve nucleophilic acyl addition. Enantioselective cyclopropanation occurs in the presence of certain organocatalysts¹⁴⁷⁹ or chiral metal catalysts.¹⁴⁸⁰

Other reagents can be used to convert an aldehyde or ketone to a cyclopropane derivative. Tellurium ylids react with conjugated imines to the cyclopropyl aldehyde after hydrolysis of the imine.¹⁴⁸¹ Conjugated ketones react with Cp₂Zr(CH₂=CH₂) and PMe₃ to give a vinyl cyclopropane derivative after treatment with aq H₂SO₄.¹⁴⁸²

16-50 The Thorpe Reaction

N-Hydro-C-(α -cyanoalkyl)-addition

In the *Thorpe reaction*, the α carbon of one nitrile molecule is added to the CN carbon of another, so this reaction has analogies with the aldol reaction (**16-34**). The C=NH bond is, of course, hydrolyzable (Reaction **16-2**), so β -keto nitriles can be prepared in this manner. The *Thorpe reaction* can be done intramolecularly, in which case it

is called the *Thorpe–Ziegler reaction*.¹⁴⁸³ As with other cyclization methods, yields are high for 5–8-membered rings, fall off to about zero for rings of 9–13 members, but are high

again for 14-membered and larger rings, if high-dilution techniques are employed. The product in the *Thorpe–Ziegler reaction* is not the imine, but the tautomeric enamine (e.g., **87**); if desired this can be hydrolyzed to an α -cyano ketone (Reaction **16-2**), which can in turn be hydrolyzed and decarboxylated (Reactions **16-4** and **12-40**). Other active-hydrogen compounds can also be added to nitriles.¹⁴⁸⁴

OS VI, 932.

H. Other Carbon or Silicon Nucleophiles

16-51 Addition of Silanes

O-Hydro-*C*-alkyl-addition

Allylic silanes react with aldehydes, in the presence of Lewis acids, to give a homoallylic alcohol.¹⁴⁸⁵ In the case of benzylic silanes, this addition reaction has been induced with Mg (ClO₄)₂ under photochemical conditions.¹⁴⁸⁶ Cyclopropylcarbinyl silanes add to acetals in the presence of TMSOTf to give a homoallylic alcohol.¹⁴⁸⁷ Allyltrichlorosilane adds an allyl group to an aldehyde in the presence of a cyclic urea and AgOTf.¹⁴⁸⁸ In a related reaction, allylic silanes react with acyl halides to produce the corresponding carbonyl derivative. The reaction of phenyl chloroformate, allyltrimethylsilane, and AlCl₃, for example, gave phenyl but-3-enoate.¹⁴⁸⁹ The use of chiral additives leads to the alcohol with good asymmetric induction.¹⁴⁹⁰

Allylic silanes also add to imines, in the presence of TiCl₄, to give amines.¹⁴⁹¹ Silanes also add to iminium salts, mediated by alkyltin compounds.¹⁴⁹²

16-52 The Formation of Cyanohydrins

O-Hydro-*C*-cyano-addition

The addition of HCN to aldehydes or ketones produces cyanohydrins.¹⁴⁹³ This is an equilibrium reaction, and for aldehydes and aliphatic ketones the equilibrium lies to the right; therefore the reaction is quite feasible, except with sterically hindered ketones (e.g., diisopropyl ketone). However, ketones (ArCOR) give poor yields, and the reaction cannot be carried out with ArCOAr since the equilibrium lies too far to the left. With aromatic

aldehydes the *benzoin condensation* (Reaction **16-55**) competes. With α,β -unsaturated aldehydes and ketones, 1,4-addition competes (Reaction **15-38**).

Ketones of low reactivity (e.g., ArCOR) can be converted to cyanohydrins by treatment with diethylaluminum cyanide (Et_2AlCN) (see OS **VI**, 307) or, indirectly, with cyano-trimethylsilane (Me_3SiCN)¹⁴⁹⁴ in the presence of a Lewis acid or base,¹⁴⁹⁵ followed by hydrolysis of the resulting *O*-trimethylsilyl cyanohydrin (**88**). Both direct formation of the cyanohydrin (hydrocyanation) and formation of the cyano-*O*-silyl ether have been carried out enantioselectively using chiral catalysts,¹⁴⁹⁶ including chiral organocatalysts,¹⁴⁹⁷ or chiral additives.¹⁴⁹⁸ Biocatalysts have been used.¹⁴⁹⁹ Hydrogen cyanide adds to aldehydes in the presence of a lyase to give the cyanohydrin with good enantioselectivity.¹⁵⁰⁰ Cyanohydrins have been formed using a lyase in an ionic liquid.¹⁵⁰¹

Solvent-free conditions have been reported using TMSCN , an aldehyde, and potassium carbonate.¹⁵⁰² Amine *N*-oxides catalyze the reaction,¹⁵⁰³ as does tetrabutylammonium cyanide.¹⁵⁰⁴ Lithium perchlorate in ether facilitates this reaction,¹⁵⁰⁵ and LiCl catalyzes the reaction with Me_3SiCN .¹⁵⁰⁶ *N*-Heterocyclic carbenes catalyze the reaction,¹⁵⁰⁷ as do certain ionic liquids.¹⁵⁰⁸ With MgBr_2 as a catalyst, the reaction proceeds with good syn selectivity.¹⁵⁰⁹ Other useful catalysts include Pt ,¹⁵¹⁰ Au ,¹⁵¹¹ or Ti ¹⁵¹² compounds, and InBr_3 .¹⁵¹³ The use of chiral additives leads to cyanohydrins with good asymmetric

induction.¹⁵¹⁴ Chiral transition metal catalysts have been used to give *O*-trialkylsilyl cyanohydrins with good enantioselectivity.¹⁵¹⁵ A vanadium catalyst has been used in an ionic liquid.¹⁵¹⁶ Note that the reaction of an aldehyde and TMSCN in the presence of aniline and a BiCl₃ catalyst leads to an α -cyano amine.¹⁵¹⁷ Potassium cyanide and acetic anhydride react with an aldehyde in the presence of a chiral Ti catalyst to give an α -acetoxy nitrile.¹⁵¹⁸

Rather than direct reaction with an aldehyde or ketone, the bisulfite addition product is often treated with cyanide. The addition is nucleophilic and the actual nucleophile is ⁻CN, so the reaction rate is increased by the addition of base.¹⁵¹⁹ This was demonstrated by Lapworth in 1903, and consequently this was one of the first organic mechanisms to be known.¹⁵²⁰ This method is especially useful for aromatic aldehydes, since it avoids competition from the benzoin condensation. If desired, it is possible to hydrolyze the cyanohydrin *in situ* to the corresponding α -hydroxy acid. This reaction is important in the *Kiliani–Fischer* method of extending the carbon chain of a sugar.

A particularly useful variation of this reaction uses cyanide rather than HCN. α -Amino nitriles¹⁵²¹ can be prepared in one step by the treatment of an aldehyde or ketone with NaCN and NH₄Cl. This is called the *Strecker synthesis*;¹⁵²² and it is a special case of the *Mannich reaction* (16-19). Since the CN group is easily hydrolyzed to the acid, this is a convenient method for the preparation of α -amino acids. The reaction has also been carried out with NH₃ + HCN and with NH₄CN. Salts of primary and secondary amines can be used instead of NH₄⁺ to obtain *N*-substituted and *N,N*-disubstituted α -amino nitriles. Brønsted acids can also be used.¹⁵²³ Unlike Reaction 16-52, the *Strecker synthesis* is useful for aromatic as well as aliphatic ketones. As in Reaction 16-52, the Me₃SiCN method has been used; **76** is converted to the product with ammonia or an amine.¹⁵²⁴ The effect of pressure on the *Strecker synthesis* has been studied.¹⁵²⁵ A catalyst-free multi-component *Strecker reaction* is known.¹⁵²⁶ There is also an In mediated *Strecker reaction* in aq media.¹⁵²⁷ Enantioselective *Strecker syntheses* are possible using chiral ammonium salts¹⁵²⁸ and

16-53 The Addition of HCN to C=N and C≡N Bonds

N-Hydro-C-cyano-addition

Hydrogen cyanide adds to imines, *Schiff bases*, hydrazones, oximes, and similar compounds. Cyanide can be added to iminium ions to give α -cyano amines (**89**). As in Reaction 16-50, the addition to imines has been carried out enantioselectively.¹⁵³³ Chiral ammonium salts have been used with HCN.¹⁵³⁴ Trimethylsilyl cyanide (TMSCN) reacts with *N*-tosyl

imines in the presence of $\text{BF}_3 \cdot \text{OEt}_2$ to give the α -cyano *N*-tosyl amine.¹⁵³⁵ In the presence of a chiral Zr^{1536} or Al^{1537} catalyst, Bu_3SnCN reacts with imines to give α -cyanoamines enantioselectively. The imine can be formed *in situ* by reaction of an aldehyde or ketone with an amine, in the presence of TMSCN and a suitable promoter.¹⁵³⁸ The reaction of an imine and TMSCN gives the cyano amine with good enantioselectivity using a chiral Sc catalyst.¹⁵³⁹ Titanium catalysts have been used in the presence of a chiral *Schiff base*.¹⁵⁴⁰

The addition of KCN to triisopropylbenzenesulfonyl hydrazones (**90**) provides an indirect method for achieving the conversion $\text{RR}'\text{CO} \rightarrow \text{RR}'\text{CHCN}$.¹⁵⁴¹ The reaction is successful for hydrazones of aliphatic aldehydes and ketones.

Hydrogen cyanide can also be added to the $C\equiv N$ bond to give iminonitriles or α -amino-malononitriles.¹⁵⁴²

The acylcyanation of imines is known, and enantioselectivity is achieved with a suitable catalyst.¹⁵⁴³

16-54 The Prins Reaction

The addition of an alkene to formaldehyde in the presence of an acid¹⁵⁴⁴ catalyst is called the *Prins reaction*.¹⁵⁴⁵ Three main products are possible; which one predominates depends on the alkene and the conditions. When the product is the 1,3-diol or the dioxane,¹⁵⁴⁶ the reaction involves addition to the $C=C$ as well as to the $C=O$. The mechanism is one of electrophilic attack on both double bonds. The acid first protonates the $C=O$, and the resulting carbocation is attacked by the $C=C$ to give **91**. The cation product **91** can

undergo loss of H^+ to give the alkene or add water to give the diol.¹⁵⁴⁷ It has been proposed that **91** is stabilized by neighboring-group attraction, with either the oxygen¹⁵⁴⁸ or a carbon¹⁵⁴⁹ stabilizing the charge (**92** and **94**, respectively). This stabilization is postulated to explain the fact that with 2-butenes¹⁵⁵⁰ and with cyclohexenes the addition is anti. A backside attack of H_2O on the three- or four-membered ring would account for it. Other products are obtained too, which can be explained on the basis of **92** or **93**.^{1548,1549}

Additional evidence for the intermediacy of **92** is the finding that oxetanes (**94**) subjected to the reaction conditions, which would protonate **94** to give **92**, give essentially the same product ratios as the corresponding alkenes.¹⁵⁵¹ An argument against the intermediacy of **92** and **93** is that not all alkenes show the anti-stereoselectivity mentioned above. Indeed, the stereochemical results are often quite complex, with syn, anti, and nonstereoselective addition reported, depending on the nature of the reactants and the reaction conditions.¹⁵⁵² Since addition to the C=C bond is electrophilic, the reactivity of the alkene increases with alkyl substitution and *Markovnikov's rule* is followed. The dioxane product may arise from a reaction between the 1,3-diol and formaldehyde¹⁵⁵³ (**16-5**) or between **92** and formaldehyde. Racemization may occur in the *Prins cyclization* reaction by 2-oxonia-Cope rearrangements (see **18-32**) by way of a (Z)-oxocarbenium ion intermediate.¹⁵⁵⁴

Iodine can promote the *Prins reaction*.¹⁵⁵⁵ Lewis acids (e.g., SnCl₄) also catalyze the reaction, in which case the species that adds to the alkenes is H₂C⁺-O-SnCl₄.¹⁵⁵⁶ The reaction can also be catalyzed by peroxides, in which case the mechanism is probably a free radical one. Other transition metal complexes can be used to form homoallylic alcohols. A typical example is the reaction of methylenecyclohexane with an aryl aldehyde to give **95**.¹⁵⁵⁷

Samarium iodide promotes this addition reaction.¹⁵⁵⁸ In a related reaction, simple alkene units add to esters in the presence of sodium and liquid ammonia to give an alcohol.¹⁵⁵⁹ Dienes react with alcohols in the presence of a transition metal compound, to give alkenyl alcohols.¹⁵⁶⁰ Allenes also add to aldehydes.¹⁵⁶¹ Enynes undergo *Prins cyclization* with Au catalysts.¹⁵⁶²

Structural variations in the alkene lead to different products. Homoallylic alcohols react with aldehydes in the presence of Montmorillonite-KSF clay to give 4-hydroxytetrahydropyrans.¹⁵⁶³ A variation of this reaction converts an aryl aldehyde and a homoallylic alcohol to a 4-chlorotetrahydropyran in the presence of InCl_3 .¹⁵⁶⁴ Homoallylic alcohols, protected as $-\text{O}(\text{CHMeOAc})$ react with $\text{BF}_3 \cdot \text{OEt}_2$ and acetic acid to give 4-acetoxytetrahydropyrans or with SnBr_4 to give 4-bromotetrahydropyrans.¹⁵⁶⁵ Homoallylic alcohols with a vinyl silane moiety react with InCl_3 and an aldehyde to give a dihydropyran.¹⁵⁶⁶

A closely related reaction has been performed with activated aldehydes or ketones; without a catalyst (e.g., chloral and acetoacetic ester), but with heat.¹⁵⁶⁷ The product in these cases is a β -hydroxy alkene, and the mechanism is pericyclic:¹⁵⁶⁸

This reaction is reversible and suitable β -hydroxy alkenes can be cleaved by heat (**17-32**). There is evidence that the cleavage reaction occurs by a cyclic mechanism (see **17-32**), and, by the principle of microscopic reversibility, the addition mechanism should be cyclic too.¹⁵⁶⁹ Note that this reaction is an oxygen analogue of the ene synthesis (**15-23**). This reaction can also be done with unactivated aldehydes¹⁵⁷⁰ and ketones¹⁵⁷¹ if Lewis acid catalysts [e.g., dimethylaluminum chloride (Me_2AlCl) or ethylaluminum dichloride (EtAlCl_2)] are used.¹⁵⁷² Lewis acid catalysts also increase rates with activated aldehydes.¹⁵⁷³ The use of optically active catalysts has given optically active products with a high % ee.¹⁵⁷⁴

In a related reaction, alkenes can be added to aldehydes and ketones to give reduced alcohols (**96**). This has been accomplished by several methods,¹⁵⁷⁵ including treatment

with SmI_2 ¹⁵⁷⁶ or Zn and Me_3SiCl ,¹⁵⁷⁷ and by electrochemical¹⁵⁷⁸ and photochemical¹⁵⁷⁹ methods. Most of these methods have been used for intramolecular addition and most or all involve free radical intermediates.

There is an *aza-Prins reaction*, promoted by TiI_4 and I_2 .¹⁵⁸⁰

OS IV, 786. See also, OS VII, 102.

16-55 The Benzoin Condensation

Benzoin aldehyde condensation

When certain aldehydes are treated with cyanide ion, *benzoins* (**97**) are produced in a reaction called the *benzoin condensation*. The condensation can be regarded as involving the addition of one molecule of aldehyde to the $\text{C}=\text{O}$ group of another. The reaction only occurs with aromatic aldehydes, but not all of them,¹⁵⁸¹ and for glyoxals (RCOCHO). The two molecules of aldehyde obviously perform different functions. The one that no longer has a $\text{C}-\text{H}$ bond in the product is called the *donor*, because it has “donated” its hydrogen to the oxygen of the other molecule, the *acceptor*. Some aldehydes can perform only one of these functions, and hence cannot be self-condensed, though they can often be condensed with a different aldehyde. For example, *p*-dimethylaminobenzaldehyde is not an acceptor, but only a donor. Thus it cannot condense with itself. It can condense with benzaldehyde, which can perform both functions, but is a better acceptor than it is a donor. *N*-alkyl-3-methylimidazolium salts catalyze the reaction,¹⁵⁸² as does an imidazole-based solid supported catalyst.¹⁵⁸³

The following is the accepted mechanism¹⁵⁸⁴ for this reversible reaction, which was originally proposed by Lapworth in 1903.¹⁵⁸⁵

¹⁵⁸⁴ See Kuebrich, J.P.; Schowen, R.L.; Wang, M.; Lupes, M.E. *J. Am. Chem. Soc.* **1971**, 93, 1214.

¹⁵⁸⁵ Lapworth, A. *J. Chem. Soc.* **1903**, 83, 995; **1904**, 85, 1206.

The key step, the loss of the aldehyde proton, can take place because the acidity of this C—H bond is increased by the electron-withdrawing power of the CN group. Thus, cyanide is a highly specific catalyst for this reaction, because, almost uniquely, it can perform three functions: (1) It acts as a nucleophile; (2) its electron-withdrawing ability permits loss of the aldehyde proton; and (3) having done this, it then acts as a leaving group. Certain thiazolium salts can also catalyze the reaction.¹⁵⁸⁶ In this case, aliphatic aldehydes can also be used¹⁵⁸⁷ (the products are called *acyloins*), and mixtures of aliphatic and aromatic aldehydes give mixed α -hydroxy ketones.¹⁵⁸⁸ The reaction has also been carried out without cyanide, by using the benzoylated cyanohydrin as one of the components in a phase-transfer catalyzed process. By this means, products can be obtained from aldehydes that normally fail to self-condense.¹⁵⁸⁹ The condensation has also been done with excellent enantioselectivity using benzoyl formate decarboxylase.¹⁵⁹⁰ Enantiopure triazolium salts have been evaluated as catalysts in the enantioselective benzoin condensation.¹⁵⁹¹ *N*-Heterocyclic carbene catalysts have been used for asymmetric induction.¹⁵⁹²

A “mixed”-benzoin condensation has been accomplished by using aryl silyl ketones [ArC(=O)SiMe₂Ph] and aldehydes with a La catalyst.¹⁵⁹³ The reaction of acylsilanes and aldehydes, catalyzed by metal cyanides, is known as the silyl-benzoin reaction.¹⁵⁹⁴

OS I, 94; VII, 95.

16-56 Addition of Radicals to C=O, C=S, C=N Compounds

Radical cyclization is not limited to reaction with a C=C unit (see **15-29** and **15-30**), and reactions with both C=N and C=O moieties are known. Reaction of MeON=CH(CH₂)₃CHO with Bu₃SnH and AIBN, for example, led to *trans*-2-(methoxyamino)cyclopentanol in good yield.¹⁵⁹⁵ Conjugated ketones add to aldehyde via the β carbon under radical conditions (2 molar equivalents of Bu₃SnH and 0.1 equiv of CuCl) to give a β -hydroxy ketone.¹⁵⁹⁶

In a related reaction, diazo compounds add to ketenes to give allenes.¹⁵⁹⁷

Addition of radical to the C=N unit of R—C=N—SPh¹⁵⁹⁸ or R—C=N—OBz¹⁵⁹⁹ led to cyclic imines. Radical addition to simple imines leads to aminocycloalkenes.¹⁶⁰⁰ Radicals

also add to the carbonyl unit of phenylthio esters to give cyclic ketones.¹⁶⁰¹ Carbon-centered radicals add to imines.¹⁶⁰² The reaction of an alkyl halide with BEt_3 in aq methanol, for example, gives the imine addition product, an alkylated amine.¹⁶⁰³

Secondary alkyl iodides add to *O*-alkyl oximes in the presence of BEt_3 and AIBN. This methodology was used to convert $\text{MeO}_2\text{C}-\text{CH}=\text{NOBn}$ to $\text{MeO}_2\text{C}-\text{CH}(\text{R})\text{NOBn}$.¹⁶⁰⁴ Benzylic halides add to imines under photochemical conditions, and in the presence of 1-benzyl-1,4-dihydronicotinamide¹⁶⁰⁵ or with BEt_3 in aq methanol.¹⁶⁰⁶ Tertiary alkyl iodides add to oxime ethers using $\text{BF}_3 \cdot \text{OEt}_2$ in the presence of BEt_3/O_2 .¹⁶⁰⁷ *O*-Trityl oximes of 5- and 6-iodoaldehydes undergo radical cyclization to give oximes¹⁶⁰⁸ (also see Reaction 15-30). Enantioselective radical addition reactions to *N*-benzoyl hydrazones used chiral ammonium salts.¹⁶⁰⁹ The Mn mediated reaction of allyl iodides with chiral *N*-acylhydrazones leads to chiral hydrazine derivatives.¹⁶¹⁰

N,N-Dimethylaniline reacts with aldehydes under photochemical conditions to give acyl addition via the carbon atom of one of the methyl groups.¹⁶¹¹ The reaction of PhNMe_2 and benzaldehyde, for example, gave $\text{PhN}(\text{Me})\text{CH}_2\text{CH}(\text{OH})\text{Ph}$ upon photolysis.

16.B.ii. Acyl Substitution Reactions

A. O,N, and S Nucleophiles

16-57 Hydrolysis of Acyl Halides

Hydroxy-de-halogenation

Acyl halides are so reactive that hydrolysis is easily carried out.¹⁶¹² In fact, most simple acyl halides must be stored under anhydrous conditions or they may react with water in the air. Consequently, water is usually a strong enough nucleophile for the reaction, but in unreactive systems hydroxide ion may be required. The reaction is seldom synthetically useful, because acyl halides are normally prepared from acids. The reactivity order is $\text{F} < \text{Cl} < \text{Br} < \text{I}$.¹⁶¹³ If a carboxylic acid is used as the nucleophile, an exchange may take place (see Reaction 16-79). The mechanism¹⁶¹³ of hydrolysis can be either $\text{S}_{\text{N}}1$ or tetrahedral, the former occurring in highly polar solvents and in the absence of strong nucleophiles.¹⁶¹⁴ There is also evidence for the $\text{S}_{\text{N}}2$ mechanism in some cases.¹⁶¹⁵

Hydrolysis of acyl halides is not usually catalyzed by acids, except for acyl fluorides, where hydrogen bonding can assist in the removal of F.¹⁶¹⁶ There are several methods available for the hydrolysis of acyl fluorides.¹⁶¹⁷

OS II, 74.

16-58 Hydrolysis of Anhydrides

Hydroxy-de-acyloxy-substitution

Anhydrides are somewhat more difficult to hydrolyze than acyl halides, but here too water is usually a strong enough nucleophile. The mechanism is usually tetrahedral.¹⁶¹⁸ The S_N1 mechanism only occurs with acid catalysis and seldom even then.¹⁶¹⁹ Anhydride hydrolysis can also be catalyzed by bases. Of course, hydroxide ion attacks more readily than water, but other bases can also catalyze the reaction. This phenomenon, called *nucleophilic catalysis* (Sec. 16.A.i, category 4), is actually the result of two successive tetrahedral mechanisms. For example, pyridine catalyzes the hydrolysis of acetic anhydride in this manner.¹⁶²⁰

Many other nucleophiles similarly catalyze the reaction.

OS I, 408; II, 140, 368, 382; IV, 766; V, 8, 813.

16-59 Hydrolysis of Carboxylic Esters

Hydroxy-de-alkoxylation

Ester hydrolysis is usually catalyzed by acids or bases. Since OR is a much poorer leaving group than halide or OCOR, water alone does not hydrolyze most esters. When bases catalyze the reaction, the attacking species is the more powerful nucleophile [−]OH. This reaction is called *saponification* and gives the salt of the acid. Acids catalyze the reaction by making the carbonyl carbon more positive, and therefore more susceptible to attack by the nucleophile. Both reactions are equilibrium reactions, so there must be a way to shift the equilibrium to the right for this to be useful. Since formation of the salt does just this, ester hydrolysis is almost always done for preparative purposes in basic solution,

unless the compound is base sensitive. Even in the case of **98**, however, selective base hydrolysis of the ethyl ester gave an 80% yield of the acid–dimethyl ester (**99**).¹⁶²¹

Ester hydrolysis can also be catalyzed¹⁶²² by metal ions, by cyclodextrins,¹⁶²³ by enzymes,¹⁶²⁴ and by nucleophiles.¹⁶²¹ Other reagents used to cleave carboxylic esters include Dowex-50,¹⁶²⁵ Me_3SiI ,¹⁶²⁶ and InCl_3 on moist silica gel using microwave irradiation.¹⁶²⁷ Cleavage of phenolic esters is usually faster than carboxylic esters derived from aliphatic acids. The reagent Sm/I_2 at -78°C has been used,¹⁶²⁸ ammonium acetate in aq methanol,¹⁶²⁹ Amberlyst 15 in methanol,¹⁶³⁰ and phenolic esters have been selectively hydrolyzed in the presence of alkyl esters on alumina with microwave irradiation.¹⁶³¹ Allylic esters were cleaved with $\text{DMSO}-\text{I}_2$.¹⁶³² Thiophenol with K_2CO_3 in NMP quantitatively converted methyl benzoate to benzoic acid.¹⁶³³ Allylic esters were cleaved with 2% Me_3SiOTf in dichloromethane,¹⁶³⁴ with $\text{CeCl}_3 \cdot 7\text{H}_2\text{O}-\text{NaI}$,¹⁶³⁵ and with NaHSO_4 –silica gel.¹⁶³⁶ Lactones also undergo the reaction¹⁶³⁷ (but if the lactone is five- or six-membered, the hydroxy acid often spontaneously re-forms the lactone) and thiol esters (RCOSR') give thiols $\text{R}'\text{SH}$. Typical reagents for this latter transformation include NaSMe in methanol,¹⁶³⁸ borohydride exchange resin– $\text{Pd}(\text{OAc})_2$ for reductive cleavage of thiol esters to thiols,¹⁶³⁹ and TiCl_4/Zn for the conversion of phenylthioacetates to thiophenols.¹⁶⁴⁰ Sterically hindered esters are hydrolyzed with difficulty (Sec. 10.G.i), but reaction of 2 equiv of $t\text{-BuOK}$ with 1 equiv of water is effective.¹⁶⁴¹ Hindered esters can also be cleaved by sequential treatment with zinc bromide and then water,¹⁶⁴² with

silica gel in refluxing toluene,¹⁶⁴³ and on alumina when irradiated with microwaves.¹⁶⁴⁴ For esters insoluble in water the rate of two-phase ester saponification can be greatly increased by the application of ultrasound,¹⁶⁴⁵ and phase-transfer techniques have been applied.¹⁶⁴⁶

Enzymatic hydrolysis of diesters with esterase has been shown to give the hydroxy-ester,¹⁶⁴⁷ and selective hydrolysis of dimethyl succinate to monomethyl succinic acid was accomplished with aq NaOH in THF.¹⁶⁴⁸ Hydrolysis of vinyl esters leads to ketones, and the reaction of *C*-substituted vinyl acetates with an esterase derived from *Marchantia polymorpha* gave substituted ketones with high enantioselectivity.¹⁶⁴⁹ Scandium triflate was shown to hydrolyze α -acetoxy ketones to α -hydroxy ketones.¹⁶⁵⁰

Ingold¹⁶⁵¹ has classified the acid- and base-catalyzed hydrolyses of esters (and the formation of esters, since these are reversible reactions and thus have the same mechanisms) into eight possible mechanisms (Table 16.3),^{1651,1652} depending on the following criteria: (1) acid- or base catalyzed, (2) unimolecular or bimolecular, and (3) acyl cleavage or alkyl cleavage.¹⁶⁵³ All eight of these are S_N1 , S_N2 , or tetrahedral mechanisms. The acid-catalyzed mechanisms are shown with reversible arrows. They are not only reversible, but also symmetrical; that is, the mechanisms for ester formation are exactly the same as for hydrolysis, except that H replaces R. Internal proton transfers, such as shown for **B** and **C**, may not actually be direct but may take place through the solvent. There is much physical evidence to show that esters are initially protonated on the carbonyl and not on the alkyl oxygen (Chap 8, Ref. 17). Nevertheless the $A_{AC}1$ mechanism is shown as proceeding through the ether-protonated intermediate **A**, since it is difficult to envision OR' as a leaving group here. It is of course possible for a reaction to proceed through an intermediate even if only a tiny concentration is present. The designations $A_{AC}1$, and so on, are those of Ingold. The $A_{AC}2$ and $A_{AC}1$ mechanisms are also called $A2$ and $A1$, respectively. Note that the $A_{AC}1$ mechanism is actually the same as the S_N1cA mechanism for this type of substrate and that $A_{AL}2$ is analogous to S_N2cA . Some authors use $A1$ and $A2$ to refer to all types of nucleophilic substitution in which the leaving group first acquires a proton. The base-catalyzed reactions are not shown with reversible arrows, since they are reversible only in theory and not in practice. Hydrolyses taking place under neutral conditions are classified as B mechanisms. Molecular dynamics has shown that “the rate of hydrolysis of methyl formate in pure water is consistent with mechanisms involving cooperative catalysis by autoionization-generated hydroxide and hydronium, a process known to have an activation free energy of $23.8 \text{ kcal mol}^{-1}$ (99.6 kJ mol^{-1}).”¹⁶⁵⁴

^aSee Ref. 1652

Of the eight mechanisms, seven have actually been observed in the hydrolysis of carboxylic esters. The one that has not been observed is the $B_{AC}1$ mechanism.¹⁶⁵⁵ The most common mechanisms are the $B_{AC}2$ for basic catalysis and the $A_{AC}2$ ¹⁶⁵⁶ for acid catalysis, that is, the two tetrahedral mechanisms. Both involve acyl–oxygen cleavage. The evidence is (1) hydrolysis with $H_2^{18}O$ results in the ^{18}O appearing in the acid and not in the alcohol;¹⁶⁵⁷ (2) esters with chiral R' groups give alcohols with *retention* of configuration;¹⁶⁵⁸ (3) allylic R' gives no allylic rearrangement;¹⁶⁵⁹ (4) neopentyl R' gives no rearrangement¹⁶⁶⁰; all these facts indicate that the $O-R'$ bond is not broken. It has been concluded that two molecules of water are required in the $A_{AC}2$ mechanism, as shown:

If this were so, the protonated derivatives **B** and **C** would not appear at all. This conclusion stems from a value of w (see Sec. 8.C) of ~ 5 , indicating that water acts as a proton donor here as well as a nucleophile.¹⁶⁶¹ Termolecular processes are rare, but in this case the two water molecules are already connected by a hydrogen bond. (A similar mechanism, called $B_{AC}3$, also involving two molecules of water, has been found for esters that hydrolyze without a catalyst.¹⁶⁶² Such esters are mostly those containing halogen atoms in the R group.)

The other mechanism involving acyl cleavage is the $A_{AC}1$ mechanism. This is rare, being found only where R is very bulky, so that bimolecular attack is sterically hindered, and only in ionizing solvents. The mechanism has been demonstrated for esters of 2,4,6-trimethylbenzoic acid (mesitoic acid). This acid depresses the freezing point of sulfuric acid four times as much as would be predicted from its molecular weight, which is evidence for the equilibrium

In a comparable solution of benzoic acid, the freezing point is depressed only twice the predicted amount, indicating only a normal acid–base reaction. Further, a sulfuric acid solution of methyl mesitoate when poured into water gave mesitoic acid, while a similar solution of methyl benzoate similarly treated did not.¹⁶⁶³ The $A_{AC}1$ mechanism is also found when acetates of phenols or of primary alcohols are hydrolyzed in concentrated ($>90\%$) H_2SO_4 (the mechanism under the more usual dilute acid conditions is the normal $A_{AC}2$).¹⁶⁶⁴

The mechanisms involving alkyl–oxygen cleavage are ordinary S_N1 and S_N2 mechanisms in which $OCOR$ (an acyloxy group) or its conjugate acid is the leaving group. Two of the three mechanisms, the $B_{AL}1$ and $A_{AL}1$ mechanisms, occur most readily when R' comes off as a stable carbocation (i.e., when R' is tertiary alkyl, allylic, benzylic, etc.). For acid

¹⁶⁵⁵ This is an S_N1 mechanism with OR' as leaving group, which does not happen.

catalysis, most esters with this type of alkyl group (especially tertiary alkyl) cleave by this mechanism, but even for these substrates, the B_{AL}1 mechanism occurs only in neutral or weakly basic solution, where the rate of attack by hydroxide is so slowed that the normally slow (by comparison) unimolecular cleavage takes over. These two mechanisms have been established by kinetic studies, ¹⁸O labeling, and isomerization of R'.¹⁶⁶⁵ Secondary and benzylic acetates hydrolyze by the A_{AC}2 mechanism in dilute H₂SO₄, but in concentrated acid the mechanism changes to A_{AL}1.¹⁶⁶⁵ Despite its designation, the B_{AL}1 mechanism is actually uncatalyzed (as is the unknown B_{AC}1 mechanism).

The two remaining mechanisms, B_{AL}2 and A_{AL}2, are very rare. The B_{AL}2 mechanism because it requires hydroxide ion to attack an alkyl carbon when an acyl carbon is also available,¹⁶⁶⁶ and the A_{AL}2 because it requires water to be a nucleophile in an S_N2 process. Both have been observed, however. The B_{AL}2 has been seen in the hydrolysis of β-lactones under neutral conditions¹⁶⁶⁷ (because cleavage of the C—O bond in the transition state opens the four-membered ring and relieves strain), the alkaline hydrolysis of methyl 2,4,6-tri-*tert*-butyl benzoate,¹⁶⁶⁸ and in the unusual reaction:¹⁶⁶⁹

When it does occur, the B_{AL}2 mechanism is easy to detect, since it is the only one of the base-catalyzed mechanisms that requires inversion at R'. However, in the last example given, the mechanism is evident from the nature of the product, since the ether could have been formed in no other way. The A_{AL}2 mechanism has been reported in the acid cleavage of γ-lactones.¹⁶⁷⁰

To sum up the acid-catalysis mechanisms, A_{AC}2 and A_{AL}1 are the common mechanisms, the latter for R' that give stable carbocations, the former for practically all the rest. The A_{AC}1 mechanism is rare, being found mostly with strong acids and sterically hindered R. The A_{AL}2 mechanism is even rarer. For basic catalysis, B_{AC}2 is almost universal; B_{AL}1 occurs only with R' that give stable carbocations and then only in weakly basic or neutral solutions; B_{AL}2 is very rare; and B_{AC}1 has never been observed.

The above results pertain to reactions in solution. In the gas phase,¹⁶⁷¹ reactions can take a different course, as illustrated by the reaction of carboxylic esters with MeO[−], which in the gas phase was shown to take place only by the B_{AL}2 mechanism,¹⁶⁷² even with aryl esters,¹⁶⁷³ where this means that an S_N2 mechanism takes place at an aryl substrate. However, when the gas-phase reaction of aryl esters was carried out with MeO[−] ions, each of which was solvated with a single molecule of MeOH or H₂O, the B_{AC}2 mechanism was observed.¹⁶⁷²

In the special case of alkaline hydrolysis of *N*-substituted aryl carbamates, there is another mechanism¹⁶⁷⁴ involving elimination–addition:¹⁶⁷⁵

This mechanism does not apply to unsubstituted or *N,N*-disubstituted aryl carbamates, which hydrolyze by the normal mechanisms. Carboxylic esters substituted in the α position by an electron-withdrawing group (e.g., CN or CO₂Et) can also hydrolyze by a similar mechanism involving a ketene intermediate.¹⁶⁷⁶ These elimination–addition mechanisms usually are referred to as E1cB mechanisms, because that is the name given to the elimination portion of the mechanism (Sec. 17.A.iii).

The acid-catalyzed hydrolysis of enol esters (RCOOCR' = CR) can take place either by the normal A_{AC}2 mechanism or by a mechanism involving initial protonation on the double-bond carbon, similar to the mechanism for the hydrolysis of enol ethers given in Reaction 10-6,¹⁶⁷⁷ depending on reaction conditions.¹⁶⁷⁸ In either case, the products are the carboxylic acid (RCO₂H) and the aldehyde or ketone (R—CHCOR').

Ester hydrolyses with concomitant decarboxylation are listed at Reaction 12-40.

16-60 Hydrolysis of Amides

Hydroxy-de-amination

Unsubstituted amides (RCONH₂) can be hydrolyzed with either acidic or basic catalysis, and the products are, respectively, the free acid and the ammonium ion or the salt of the acid and ammonia. *N*-Substituted (RCONHR') and *N,N*-disubstituted (RCONR'₂) amides can be hydrolyzed analogously, and the product is the primary or secondary amine, respectively (or their salts), rather than ammonia. Twisting of the amide bond leads to an acceleration of water-promoted hydrolysis reactions.¹⁶⁷⁹ Lactams, imides, cyclic imides, hydrazides, and so on, also undergo the reaction.

Water alone is not sufficient to hydrolyze most amides,¹⁶⁸⁰ since NH₂ is even a poorer leaving group than OR.¹⁶⁸¹ Prolonged heating is often required, even with acidic or basic catalysts.¹⁶⁸² Treatment of primary amides with phthalic anhydride at 250 °C and 4 atm

gives the carboxylic acid and phthalimide.¹⁶⁸³ Hydrolysis of carbamates (RNHCO₂R) to the corresponding amine can be categorized in this section. Although the product is an amine and the carboxyl unit fragments, this reaction is simply a variation of amide hydrolysis. Strong acids [e.g., trifluoroacetic acid (in dichloromethane)] are usually employed.¹⁶⁸⁴ Treatment of *N*-Boc derivatives (RNHCO₂*t*-Bu) with AlCl₃¹⁶⁸⁵ or with aq sodium *tert*-butoxide¹⁶⁸⁶ gave the amine. The byproducts of this reaction are typically carbon dioxide and isobutylene.

In difficult cases, nitrous acid, NOCl, N₂O₄,¹⁶⁸⁷ or a similar compound can be used (unsubstituted amides only¹⁶⁸⁸). These reactions involve a diazonium ion (see Reaction **13-19**) and are much faster than ordinary hydrolysis. The benzamide–nitrous acid reaction took place 2.5×10^7 times faster than ordinary hydrolysis, for example.¹⁶⁸⁹ Another procedure for difficult cases involves treatment with aq sodium peroxide.¹⁶⁹⁰ In still another method, the amide is treated with water and *t*-BuOK at room temperature.¹⁶⁹¹ A kinetic study has been done on the alkaline hydrolyses of *N*-trifluoroacetyl aniline derivatives.¹⁶⁹² Amide hydrolysis can also be catalyzed by nucleophiles (see Sec. 16.A.i, category 4).

The same framework of eight possible mechanisms discussed for ester hydrolysis in Reaction **16-59** can also be applied to amide hydrolysis.¹⁶⁹³ Both the acid- and base-catalyzed hydrolyses are essentially irreversible, since salts are formed in both cases. For basic catalysis¹⁶⁹⁴ the mechanism is B_{AC}2. There is much evidence for this mechanism, similar to that discussed for ester hydrolysis. Molecular orbital studies on the mechanism of amide hydrolysis suggest a highly tetrahedral transition state.¹⁶⁹⁵ In certain cases, kinetic studies have shown that the reaction is second order in OH[−] indicating that **100** can lose a proton to give **101**.¹⁶⁹⁶ Depending on the nature of R', **101** can cleave directly to give the two negative ions (path *a*) or become N-protonated prior to or during the act of cleavage

The four mechanisms involving alkyl–N cleavage (the AL mechanisms) do not apply to this reaction. They are not possible for unsubstituted amides, since the only N–C bond is the acyl bond. They are possible for *N*-substituted and *N,N*-disubstituted amides, but in these cases they give entirely different products and are not amide hydrolyses at all.

The reaction shown involves attack by the base on an *N*-alkyl group to give an alcohol. While rare, it has been observed for various *N-tert*-butylamides in 98% sulfuric acid, where the mechanism was A_{AL}1,¹⁷⁰³ and for certain amides containing an azo group, where a B_{AL}1 mechanism was postulated.¹⁷⁰⁴ Of the two first-order acyl cleavage mechanisms, only the A_{AC}1 has been observed, in concentrated sulfuric acid solutions.¹⁷⁰⁵ Of course, the diazotization of unsubstituted amides might be expected to follow this mechanism, and there is evidence that this is true.¹⁶⁸⁹

OS **I**, 14, 111, 194, 201, 286; **II**, 19, 25, 28, 49, 76, 208, 330, 374, 384, 457, 462, 491, 503, 519, 612; **III**, 66, 88, 154, 256, 410, 456, 586, 591, 661, 735, 768, 813; **IV**, 39, 42, 55, 58, 420, 441, 496, 664; **V**, 27, 96, 341, 471, 612, 627; **VI**, 56, 252, 507, 951, 967; **VII**, 4, 287; **VIII**, 26, 204, 241, 339, 451.

The oxidation of aldehydes to carboxylic acids can proceed by a nucleophilic mechanism, but more often it does not. The reaction is considered in Reaction **19-23**. Basic cleavage of β-keto esters and the haloform reaction could be considered at this point, but they are also electrophilic substitutions and are treated in Reactions **12-43** and **12-44**.

B. Attack by OR at an Acyl Carbon

16-61 Alcoholysis of Acyl Halides

Alkoxy-de-halogenation

The reaction between acyl halides and alcohols or phenols is the best general method for the preparation of carboxylic esters. It is believed to proceed by a S_N2 mechanism.¹⁷⁰⁶ As with Reaction **16-57**, however, the mechanism can be S_N1 or tetrahedral.¹⁶¹³ Lewis acids (e.g., lithium perchlorate) can be used.¹⁷⁰⁷ The reaction is of wide scope, and many functional groups do not interfere. A base is frequently added to combine with the HX formed. When aq alkali is used, this is called the *Schotten–Baumann procedure*, but pyridine is also frequently used. Indeed, pyridine catalyzes the reaction by the nucleophilic catalysis route (see Reaction **16-58**). Both R and R' may be primary, secondary, or tertiary alkyl or aryl. Enol esters can also be prepared by this method, though C-acylation competes in these cases. In difficult cases, especially with hindered acids or tertiary R', the alkoxide can be used instead of the alcohol.¹⁷⁰⁸ Activated alumina has also been used as a catalyst,

for tertiary R'.¹⁷⁰⁹ Thallium salts of phenols give very high yields of phenolic esters,¹⁷¹⁰ and BiOCl is very effective for the preparation of phenolic acetates.¹⁷¹¹ Phase-transfer catalysis has been used for hindered phenols.¹⁷¹² Zinc has been used to couple alcohols and acyl chlorides,¹⁷¹³ Zr compounds were used,¹⁷¹⁴ and catalytic Cu(acac)₂ and benzoyl chloride was used to prepare the monobenzoate of ethylene glycol.¹⁷¹⁵ Selective acylation is possible in some cases.¹⁷¹⁶

Acyl halides react with thiols, in the presence of Zn, to give the corresponding thio-ester.¹⁷¹⁷ The reaction of acid chlorides or anhydrides (see **16-62**) with diphenyldiselenide, in the presence of Sm/CoCl₂¹⁷¹⁸ or Sm/CrCl₃¹⁷¹⁹ gave the corresponding seleno ester (PhSeCOMe).

Acyl halides can also be converted to carboxylic acids by using ethers instead of alcohols, as shown, in MeCN in the presence of certain catalysts [e.g., cobalt(II) chloride].¹⁷²⁰ A variation of this reaction has been reported that uses acetic anhydride (also see **16-62**).¹⁷²¹

This is a method for the cleavage of ethers (see also, Reaction **10-49**).

16-63 Esterification of Carboxylic Acids

Alkoxy-de-hydroxylation

The acid-catalyzed esterification of carboxylic acids with alcohols¹⁷³⁶ is the reverse of Reaction **16-60** and can be accomplished only if a means is available to drive the equilibrium to the right.¹⁷³⁷ There are many ways of doing this, among which are (1) addition of an excess of one of the reactants, usually the alcohol; (2) removal of the ester or the water by distillation; (3) removal of water by azeotropic distillation; and (4) removal of water by use of a dehydrating agent, silica gel,¹⁷³⁸ or a molecular sieve. When R' is methyl, the most common way of driving the equilibrium is by adding excess MeOH ; when R' is

ethyl or larger, it is preferable to remove water by azeotropic distillation.¹⁷³⁹ The most common catalysts are H_2SO_4 and TsOH , but some reactive carboxylic acids (e.g., formic,¹⁷⁴⁰ trifluoroacetic¹⁷⁴¹) do not require a catalyst. Ammonium salts have been used to initiate esterification,¹⁷⁴² and boric acid has been used to esterify α -hydroxy acids.¹⁷⁴³ The R' group may be primary or secondary alkyl groups other than methyl or ethyl, but tertiary alcohols usually give carbocations and elimination. Phenols can sometimes be used to prepare phenolic esters, but yields are generally very low. Selective esterification of an aliphatic carboxylic acid in the presence of an aromatic acid was accomplished with $\text{NaHSO}_4 \cdot \text{SiO}_2$ and methanol.¹⁷⁴⁴ Diphenylammonium triflate was useful for direct esterification of carboxylic acids with longer chain aliphatic alcohols.¹⁷⁴⁵ Photoirradiation of carboxylic acid with CBr_4 ¹⁷⁴⁶ or CCl_4 ¹⁷⁴⁷ in methanol was shown to give the methyl ester, with high selectivity for nonconjugated acids in the case of CBr_4 . Esterification has been accomplished in ionic liquids.¹⁷⁴⁸ A solid-state esterification was reported on $\text{P}_2\text{O}_5/\text{SiO}_2$.¹⁷⁴⁹ Diols are converted to the monoacetate by heating with acetic acid on a zeolite.¹⁷⁵⁰ Vinyl acetate and iodine has been used for the acetylation of alcohols.¹⁷⁵¹

O-Alkylisoureas react with conjugated carboxylic acids to give the corresponding ester with microwave irradiation,¹⁷⁵² and a polymer-bound *O*-alkylurea has been used as well.¹⁷⁵³ Transition metal compounds of Ti,¹⁷⁵⁴ or Co¹⁷⁵⁵ catalyze esterification. Allylic sulfonium salts react with carboxylic acids to give allylic esters in the presence of CuBr .¹⁷⁵⁶ Triphenylphosphine dibromide is a useful esterification reagent.¹⁷⁵⁷ Phenols can be esterified using amide acetals.¹⁷⁵⁸

The reaction of a carboxylic acid with an alcohol, in the presence of triphenylphosphine and DEAD gives the corresponding ester. This reaction is known as the *Mitsunobu reaction* (see 10-17). A variation of this esterification reaction used azopyridines to mediate formation of the ester.¹⁷⁵⁹

Both γ - and δ -hydroxy acids (e.g., **103**) are easily converted to a lactone by treatment with acids, or often simply on standing, but larger and smaller lactone rings cannot be made in this manner, because polyester formation occurs more readily.¹⁷⁶⁰ Often the conversion of one group to a hydroxyl group, gives the lactone directly, since the hydroxy acid cyclizes too rapidly for isolation. Such groups include keto or halogen that are γ or δ to a carbonyl group. β -Substituted β -hydroxy acids can be converted to β -lactones by treatment with benzenesulfonyl chloride in pyridine at 0–5 °C.¹⁷⁶¹ ϵ -Lactones (seven-membered rings) have been made by cyclization of ϵ -hydroxy acids at high dilution.¹⁷⁶² Macrocyclic lactones¹⁷⁶³ can be prepared indirectly in very good yields by conversion of the hydroxy acids to 2-pyridinethiol esters and adding these to refluxing xylene.¹⁷⁶⁴

A closely related method, which often gives higher yields of a macrocyclic lactone, involves treatment of the hydroxy acids with 1-methyl- or 1-phenyl-2-halopyridinium salts, especially 1-methyl-2-chloropyridinium iodide (*Mukaiyama's reagent*).¹⁷⁶⁵ A macrocyclization technique has been developed based on formation of a mixed anhydride. The *Yamaguchi protocol*¹⁷⁶⁶ reacts a seco acid (the hydroxy acid precursor of a macrocyclic lactone) with 2,4,6-trichlorobenzoyl chloride. The resulting mixed anhydride is heated with DMAP in toluene.

Esterification is catalyzed by acids (not bases) in ways that were presented in Table 16.3 in Reaction **16-59**.¹⁶⁵³ The mechanisms are usually $A_{AC}2$, but $A_{AC}1$ and $A_{AL}1$ have also been observed.¹⁷⁶⁷ Certain acids (e.g., 2,6-di-ortho-substituted benzoic acids), cannot be esterified by the $A_{AC}2$ mechanism because of steric hindrance (Sec. 10.G.i, category 1). In such cases, esterification can be accomplished by dissolving the acid in 100% H_2SO_4 (forming the ion RCO^+) and pouring the solution into the alcohol ($A_{AC}1$ mechanism). The

reluctance of hindered acids to undergo the normal $A_{AC}2$ mechanism can sometimes be put to advantage when, in a molecule containing two CO_2H groups, only the less hindered one is esterified. The $A_{AC}1$ pathway cannot be applied to unhindered carboxylic acids.

Another way to esterify a carboxylic acid is to treat it with an alcohol in the presence of a dehydrating agent.¹⁷³⁸ One of these is dicyclohexylcarbodiimide (DCC), which is converted in the process to dicyclohexylurea (DHU). The mechanism¹⁷⁶⁸ has much in common with the nucleophilic catalysis mechanism; the acid is converted to a compound with a better leaving group, but the conversion is not by a tetrahedral mechanism (as it is in nucleophilic catalysis), since the C—O bond remains intact during this step:

Evidence for this mechanism was the preparation of *O*-acylureas similar to **104** and the finding that when catalyzed by acids they react with alcohols to give esters.¹⁷⁶⁹ Hindered tertiary alcohols can be coupled via DCC to give the hindered ester.¹⁷⁷⁰ A polymer-bound carbodiimide has been used to prepare macrocyclic lactones.¹⁷⁷¹ In at least one case, the reaction of $HOOCCH_2CN$ with DCC and *tert*-butanol gave the *tert*-butyl ester via a ketene intermediate.¹⁷⁷²

There are limitations to the use of DCC; yields are variable and *N*-acylureas are side products. Many other dehydrating agents¹⁷⁷³ have been used, including DCC and an aminopyridine,¹⁷⁷⁴ chlorosilanes,¹⁷⁷⁵ and *N,N'*-carbonyldiimidazole (**105**).¹⁷⁷⁶ In the latter case, imidazolides (**106**) are intermediates that react with alcohols.

It is known that the Lewis acid BF_3 promotes the esterification by converting the acid to $\text{RCO}^+\text{BF}_3^-\text{OH}$, so the reaction proceeds by an $\text{A}_{\text{AC}}1$ type of mechanism. The use of BF_3 -etherate is simple and gives high yields.¹⁷⁷⁷ Other Lewis acids can be used.¹⁷⁷⁸

Carboxylic esters can also be prepared by treating carboxylic acids with *tert*-butyl ethers and acid catalysts:¹⁷⁷⁹

Carboxylic esters can be formed from the carboxylate anion and a suitable alkylating agent (Reaction **10-26**).

Thioesters of the type $\text{RSC}(=\text{S})\text{R}'$ (a dithiocarboxylic ester) and $\text{RSC}(\text{C}=\text{O})\text{R}'$ (a thio-carboxylic ester) can be generated by reaction of carboxylic acids with thiols. In one example, phosphorous pentasulfide was used in conjunction with a thiol to make dithiocarboxylic esters¹⁷⁸⁰ or thiocarboxylic esters.¹⁷⁸¹ Thiocarboxylic esters were prepared from thiols and triflic acid.¹⁷⁸²

16-64 Transesterification

Alkoxy-de-alkoxylation

Transesterification¹⁷⁸³ is catalyzed¹⁷⁸⁴ by acids¹⁷⁸⁵ or bases,¹⁷⁸⁶ or done under neutral conditions.¹⁷⁸⁷ It is an equilibrium reaction that must be shifted in the desired direction.¹⁷⁸⁸

In many cases, low-boiling esters can be converted to higher-boiling ones by the distillation of the lower-boiling alcohol as fast as it is formed. Reagents used to catalyze¹⁷⁸⁹

transesterification include various Lewis acids.¹⁷⁹⁰ Zwitterionic salts have been used as organocatalysts for this reaction.¹⁷⁹¹ A polymer-bound siloxane has been used to induce transesterification.¹⁷⁹² Vinyl acetate has been used for transesterification, usually with a coreagent or metal mediator.¹⁷⁹³ This reaction has been used as a method for the acylation of a primary OH in the presence of a secondary OH.¹⁷⁹⁴ Regioselectivity has also been accomplished by using enzymes (lipases) as catalysts.¹⁷⁹⁵ Lactones, (e.g., **107**) are easily opened by treatment with alcohols¹⁷⁹⁶ to give open-chain hydroxy esters.

Transesterification has been carried out with phase-transfer catalysts, without an added solvent.¹⁷⁹⁷ Nonionic superbases (see Sec. 8.A.i) of the type $\text{P}(\text{RNCH}_2\text{CH}_2)_3\text{N}$ catalyze the transesterification of carboxylic acid esters at 25 °C.¹⁷⁹⁸ Silyl esters ($\text{R}'\text{CO}_2\text{SiR}_3$) have been converted to alkyl esters ($\text{R}'\text{CO}_2\text{R}$) via reaction with alkyl halides and tetrabutylammonium fluoride.¹⁷⁹⁹ Thioesters are converted to phenolic esters by treatment with triphosgene–pyridine and then phenol.¹⁸⁰⁰

Transesterification occurs by mechanisms¹⁸⁰¹ that are identical with those of ester hydrolysis, except that ROH replaces HOH (by the acyl–oxygen fission mechanisms). When alkyl fission takes place, the products are the *acid* and the *ether*:

Therefore, transesterification reactions frequently fail when R' is tertiary, since this type of substrate most often reacts by alkyl–oxygen cleavage. In such cases, the reaction is of the Williamson type with OCOR as the leaving group (see Reaction 10-10).

With enol esters (e.g., **108**), reaction with an alcohol gives an ester and the enol of a ketone, which readily tautomerizes to the ketone as shown. Hence, enol esters are good acylating agents for alcohols.¹⁸⁰² This transformation has been accomplished in ionic liquid media,¹⁸⁰³ and there is a PdCl₂/CuCl₂ mediated version.¹⁸⁰⁴ Isopropenyl acetate can also be used to convert other ketones to the corresponding enol acetates in an exchange reaction:¹⁸⁰⁵

Enol esters can also be prepared in the opposite type of exchange reaction, catalyzed by mercuric acetate¹⁸⁰⁶ or Pd(II) chloride,¹⁸⁰⁷ for example,

A closely related reaction is equilibration of a dicarboxylic acid and its diester to produce monoesters: The reaction of a carboxylic acid with ethyl acetate, in the presence of NaHSO₄·SiO₂, was shown to give the corresponding ethyl ester.¹⁸⁰⁸ Iodine catalyzes the transesterification of β-keto esters.¹⁸⁰⁹

16-65 Alcoholysis of Amides

Alkoxy-deamidation

Alcoholysis of amides is possible,¹⁸¹⁰ although it is usually difficult. It has been most common with the imidazolidine type of amides (e.g., **100**). For other amides, an activating agent is usually necessary before the alcohol will replace the NR₂ unit. *N,N*-Dimethylformamide, however, reacted with primary alcohols in the presence of 2,4,6-trichloro-1,3,5-pyrazine (cyanuric acid) to give the corresponding formate ester.¹⁸¹¹ Treatment of an amide with triflic anhydride (CF₃SO₂OSO₂CF₃) in the presence of pyridine, and then with an excess of alcohol, leads to the ester,¹⁸¹² as does treatment with Me₂NCH(OMe)₂ followed by

the alcohol.¹⁸¹³ Trimethyloxonium tetrafluoroborate converted primary amides to methyl esters.¹⁸¹⁴ The reaction of acetanilide derivatives with sodium nitrite in the presence of acetic anhydride–acetic acid leads to phenolic acetates.¹⁸¹⁵ Acyl hydrazides (RCONHNH₂) were converted to esters by reaction with alcohols and various reagents,¹⁸¹⁶ and methoxyamides (RCONHOMe) were converted to esters with TiCl₄/ROH.¹⁸¹⁷ The reaction of an oxazolidinone amide (**109**) with methanol and 10% MgBr₂ gave the corresponding methyl ester.¹⁸¹⁸

C. Attack by OCOR at an Acyl Carbon

16-66 Acylation of Carboxylic Acids with Acyl Halides

Acyloxy-de-halogenation

Unsymmetrical, as well as symmetrical, anhydrides are often prepared by the treatment of an acyl halide with a carboxylic acid salt. If a metallic salt is used, Na⁺, K⁺, or Ag⁺ are the most common cations, but more often pyridine or another tertiary amine is added to the free acid. The resulting salt is subsequently treated with the acyl halide. Zinc–DMF has been used to mediate the synthesis of symmetrical anhydrides from acid chlorides.¹⁸¹⁹ Cobalt(II) chloride (CoCl₂) has been used as a catalyst.¹⁸²⁰ Mixed formic anhydrides are prepared from sodium formate and an aryl halide, by use of a solid-phase copolymer of pyridine-1-oxide.¹⁸²¹ Symmetrical anhydrides can be prepared by reaction of the acyl halide with aq NaOH or NaHCO₃ under phase-transfer conditions,¹⁸²² or with sodium bicarbonate with ultrasound.¹⁸²³

Anhydrides can be formed from two molecules of an ordinary carboxylic acid only if a dehydrating agent is present so that the equilibrium can be driven to the right. Common dehydrating agents¹⁸²⁴ are acetic anhydride, trifluoroacetic anhydride, dicyclohexylcarbodiimide,¹⁸²⁵ and P_2O_5 . Triphenylphosphine/ CCl_3CN with triethylamine has also been used with benzoic acid derivatives.¹⁸²⁶ The method is very poor for the formation of mixed anhydrides, which in any case generally undergo disproportionation to the two simple anhydrides when they are heated. However, simple heating of dicarboxylic acids does give cyclic anhydrides, provided that the ring formed contains five, six, or seven members, for example:

Malonic acid and its derivatives, which would give four-membered cyclic anhydrides, do not give this reaction when heated, but undergo decarboxylation (**12-40**) instead.

Carboxylic acids exchange with amides and esters; these methods are sometimes used to prepare anhydrides if the equilibrium can be shifted. Enolic esters are especially good for this purpose, because the equilibrium is shifted by formation of the ketone.

The combination of KF with 2-acetoxypropene under microwave conditions was effective.¹⁸²⁷ Carboxylic acids also exchange with anhydrides; indeed, this is how acetic anhydride acts as a dehydrating agent in this reaction.

Anhydrides can be formed from certain carboxylic acid salts (e.g., by treatment of trimethylammonium carboxylates with phosgene):¹⁸²⁸

or of thallium(I) carboxylates with thionyl chloride,¹⁷¹⁰ or of sodium carboxylates with CCl_4 and a catalyst (e.g., CuCl or FeCl_2).¹⁸²⁹

16-68 Preparation of Mixed Organic–Inorganic Anhydrides

Nitrooxy-de-acyloxy-substitution

Mixed organic–inorganic anhydrides are seldom isolated, although they are often intermediates when acylation is carried out with acid derivatives catalyzed by inorganic acids. Sulfuric, perchloric, phosphoric, and other acids form similar anhydrides, most of which are unstable or not easily obtained because the equilibrium lies in the wrong direction. These intermediates are formed from amides, carboxylic acids, and esters, as well as anhydrides. Organic anhydrides of phosphoric acid are more stable than most others and, for example, $\text{RCOOPO}(\text{OH})_2$ can be prepared in the form of its salts.¹⁸³⁰ Mixed anhydrides of carboxylic and sulfonic acids ($\text{RCOOSO}_2\text{R}'$) are obtained in high yields by treatment of sulfonic acids with acyl halides or (less preferred) anhydrides.¹⁸³¹

OS I, 495; VI, 207; VII, 81.

16-69 Attack by SH or SR at an Acyl Carbon¹⁸³²

Mercapto-de-halogenation

Alkylthio-de-halogenation

Thiol acids and thiol esters¹⁸³³ can be prepared in this manner, which is analogous to Reaction 16-57 and 16-64. Anhydrides¹⁸³⁴ and aryl esters (RCOOAr)¹⁸³⁵ are also used as substrates, but the reagents in these cases are usually HS^- and RS^- . Thiol esters can also be prepared by treatment of carboxylic acids with P_4S_{10} – Ph_3SbO ,¹⁸³⁶ or with a thiol (RSH) and either polyphosphate ester or phenyl dichlorophosphate (PhOPOCl_2).¹⁸³⁷ Carboxylic acids are converted to thioacids with *Lawesson's reagent* (structure 18 in Reaction 16-11).¹⁸³⁸ Esters RCOOR' can be converted to thiol esters (RCOSR') by treatment with trimethylsilyl sulfides ($\text{Me}_3\text{SiSR}'$) and AlCl_3 .¹⁸³⁹

Alcohols, when treated with a thiol acid and zinc iodide, give thiol esters ($\text{R}'\text{COSR}$)¹⁸⁴⁰

16-70 Transamidation

Alkylamino-de-amidation

It is sometimes necessary to replace one amide group with another, particularly when the group attached to nitrogen functions as a protecting group.¹⁸⁴¹ *N*-Benzyl amides can be converted to the corresponding *N*-allyl amide with allylamine and Ti catalysts.¹⁸⁴² Reaction of *N*-Boc 2-phenylethylamine with Ti(OiPr)₄ and benzyl alcohol, for example, gives the *N*-Cbz derivative.¹⁸⁴³ *N*-Carbamoyl amines were converted to *N*-acetyl amines with acetic anhydride, Bu₃SnH, and a Pd catalyst.¹⁸⁴⁴ Triethylaluminum converts methyl carbamates (ArNHCO₂Me) to the corresponding propanamide.¹⁸⁴⁵

A related process reacts acetamide with amines and aluminum chloride to give the *N*-acetyl amine.¹⁸⁴⁶ Another related process converted imides to *O*-benzyloxy amides by the Sm catalyzed reaction with *O*-benzylhydroxylamine.¹⁸⁴⁷

Thioamides can be prepared from amide by reaction with an appropriate sulfur reagent. The reaction of *N,N*-dimethylacetamide under microwave irradiation, with the polymer-bound reagent **110** (where  = polymeric backbone) gave **111**.¹⁸⁴⁸ Reaction of the thioamide with Bi(NO₃)₃·5 H₂O regenerates the amide.¹⁸⁴⁹ Other methods are known to convert a thioamide to an amide.¹⁸⁵⁰ Selenoamides [RC(=Se)NR'₂] have also been prepared from amides.¹⁸⁵¹

D. Attack by Halogen

16-71 The Conversion of Carboxylic Acids to Halides

Halo-de-oxido,oxo-tersubstitution

In certain cases, carboxyl groups can be replaced by halide. Acrylic acid derivatives (ArCH=CHCOOH), for example, react with 3 molar equivalents of Oxone in the presence of NaBr to give a vinyl bromide (ArCH=CHBr).¹⁸⁵² Diphosphorus tetraiodide/tetraethylammonium bromide (TEAB) readily converts conjugated acids to vinyl

bromides.¹⁸⁵³ In other cases, conjugated acids, (e.g., **112**), have been converted to the bromide by reaction with (NBS, Reaction **14-3**) and LiOAc.¹⁸⁵⁴

E. Attack by Nitrogen at an Acyl Carbon¹⁸⁵⁵

16-72 Acylation of Amines by Acyl Halides

Amino-de-halogenation

The treatment of acyl halides with ammonia or amines is a very general reaction for the preparation of amides.¹⁸⁵⁶ The reaction is exothermic and must be carefully controlled, usually by cooling or dilution. Ammonia gives unsubstituted amides, primary amines give *N*-substituted amides,¹⁸⁵⁷ and secondary amines give *N,N*-disubstituted amides. Arylamines can be similarly acylated. Hydroxamic acids have been prepared by this route.¹⁸⁵⁸ In some cases, aq alkali is added to combine with the liberated HCl. This is called the *Schotten–Baumann procedure*, as in Reaction **16-61**. Activated Zn can be used to increase the rate of amide formation when hindered amines and/or acid chlorides are used.¹⁸⁵⁹ A solvent-free reaction was reported using DABCO and methanol.¹⁸⁶⁰ Metal-mediated reactions using In,¹⁸⁶¹ Sm,¹⁸⁶² or a BiOCl mediated reaction¹⁸⁶³ have been reported. A variation of this basic reaction uses DMF with acyl halides to give *N,N*-dimethylamides.¹⁸⁶⁴ Formic acid and iodine react with amines to give the formamide.¹⁸⁶⁵

Hydrazine and hydroxylamine also react with acyl halides to give, respectively, hydrazides (RCONHNH_2)¹⁸⁶⁶ and hydroxamic acids (RCONHOH).¹⁸⁶⁷ When phosgene is the acyl halide, both aliphatic and aromatic primary amines give chloroformamides

(ClCONHR) that lose HCl to give isocyanates (RNCO).¹⁸⁶⁸ This is one of the most common methods for the preparation of isocyanates.¹⁸⁶⁹ Similar

treatment with thiophosgene¹⁸⁷⁰ gives isothiocyanates. A safer substitute for phosgene in this reaction is trichloromethyl chloroformate (CCl₃OCOC(=O)Cl).¹⁸⁷¹ When chloroformates (ROCOCl) are treated with primary amines, carbamates (ROCONHR') are obtained.¹⁸⁷² An example of this reaction is the use of benzyl chloroformate to protect the amino group of amino acids and peptides.

The PhCH₂OCO group in **113** has been called the carbobenzoxy group,¹⁸⁷³ and is often abbreviated Cbz or Z, but it is really a benzyl carbamate. Another important group similarly used is Boc, which is a *tert*-butyl carbamate. In this case, the chloride (Me₃COC(=O)Cl) is unstable, so the anhydride [(Me₃COC(=O))₂O] is used instead, in an example of Reaction **16-73**. Amino groups in general are often protected by conversion to amides.¹⁸⁷⁴ The reactions proceed by the tetrahedral mechanism.¹⁸⁷⁵

An interesting variation of this transformation reacts carbamoyl chlorides with organocuprates to give the corresponding amide.¹⁸⁷⁶

¹⁸⁷⁶ Lemoucheux, L.; Seitz, T.; Rouden, J.; Lasne, M.-C. *Org. Lett.* **2004**, 6, 3703.

This reaction, similar in scope and mechanism¹⁸⁷⁷ to Reaction **16-72**, can be carried out with ammonia or primary or secondary amines.¹⁸⁷⁸ Note that there is a report where a tertiary amine (an *N*-alkylpyrrolidine) reacted with acetic anhydride at 120 °C, in the presence of a BF₃·etherate catalyst, to give *N*-acetylpyrrolidine (an acylative dealkylation).¹⁸⁷⁹ Amino acids can be *N*-acylated using acetic anhydride and ultrasound.¹⁸⁸⁰ However, ammonia and primary amines can also give imides, in which two acyl groups are attached to the nitrogen. The conversion of cyclic anhydrides to cyclic imides is generally facile,¹⁸⁸¹ although elevated temperatures are occasionally required to generate the imide.¹⁸⁸² Microwave irradiation of formamide and a cyclic anhydride generates the cyclic imide.¹⁸⁸³ Cyclic imides have also been formed in ionic liquids.¹⁸⁸⁴ Cyclic imides were also formed by microwave irradiation of a polymer-bound phthalate after initial reaction with an amine.¹⁸⁸⁵

The second step for imide formation, which is much slower than the first, is the attack of the amide nitrogen on the carboxylic carbon. Unsubstituted and *N*-substituted amides have been used instead of ammonia. Since the other product of this reaction is RCOOH, this is a way of “hydrolyzing” such amides in the absence of water.¹⁸⁸⁶

Even though formic anhydride is not a stable compound (see Reaction **11-17**), amines can be formylated with the mixed anhydride of acetic and formic acids (HCOOCOME)¹⁸⁸⁷ or with a mixture of formic acid and acetic anhydride. Acetamides are not formed with these reagents. Secondary amines can be acylated in the presence of a primary amine by conversion to their salts and addition of 18-crown-6.¹⁸⁸⁸ The crown ether complexes the primary ammonium salt, preventing its acylation, while the secondary ammonium salts, which do not fit easily into the cavity, are free to be acylated. Dimethyl carbonate can be used to prepare methyl carbamates in a related procedure.¹⁸⁸⁹ *N*-Acetylsulfonamides were prepared from acetic anhydride and a primary sulfonamide, catalyzed by Montmorillonite K10-FeO¹⁸⁹⁰ or sulfuric acid.¹⁸⁹¹

There are acylating reagents other than anhydrides of course. The reaction with acyl halides is discussed in Reaction **16-72**. There are a few specialized reagents. Kinetic resolution of racemic amines was accomplished using (1*S*,2*S*)-*N*-acetyl-1,2- bis(trifluoromethanesulfonamido)cyclohexane.¹⁸⁹²

16-74 Acylation of Amines by Carboxylic Acids

Amino-de-hydroxylation

When carboxylic acids are treated with ammonia or amines, salts are obtained. The salts of ammonia or primary or secondary amines can be pyrolyzed to give amides,¹⁸⁹³ but the method is less convenient than Reaction **16-72**, **16-73**, and **16-75** and is seldom of preparative value.¹⁸⁹⁴ Heating in the presence of a base (e.g., hexamethyldisilazide) makes the amide-forming process more efficient.¹⁸⁹⁵ Boronic acids catalyze the direct conversion of carboxylic acid and amine to amides.¹⁸⁹⁶ Polymer-bound reagents have also been used.¹⁸⁹⁷ Triphenylphosphine/-trichloroisocyanuric acid converts acids and amides to the amide.¹⁸⁹⁸ The *Burgess reagent* ($\text{Et}_3\text{N}^+\text{SO}_2\text{N}^-\text{CO}_2\text{Me}$; see Reaction **17-29**) activates carboxylic acids for amide formation.¹⁸⁹⁹ The reaction of a carboxylic acid and imidazole under microwave irradiation gives the amide.¹⁹⁰⁰ Microwave irradiation of a secondary amine, formic acid, 2-chloro-4,6-dimethoxy [1,3,5]triazine, and a catalytic amount of DMAP leads to the formamide.¹⁹⁰¹ Ammonium bicarbonate and formamide converts acids to amides with microwave irradiation.¹⁹⁰² Formamides are produced from formic acid and anion nitriles in the presence of ZnO .¹⁹⁰³

Lactams are readily produced from γ - or δ -amino acids,¹⁹⁰⁴ for example,

This lactonization process can be promoted by enzymes (e.g., pancreatic porcine lipase).¹⁹⁰⁵ Reduction of ω -azide carboxylic acids leads to macrocyclic lactams.¹⁹⁰⁶

Although treatment of carboxylic acids with amines does not directly give amides, the reaction can be made to proceed in good yield at room temperature or slightly above by the use of coupling agents,¹⁹⁰⁷ the most important of which is dicyclohexylcarbodiimide. This reagent is very convenient and is used¹⁹⁰⁸ a great deal in peptide synthesis.¹⁹⁰⁹ A polymer-supported carbodiimide has been used.¹⁹¹⁰ The mechanism is probably the same as in Reaction 16-63 up to the formation of **114**. This intermediate is then attacked by another molecule of RCOO^- to give the anhydride $(\text{RCO})_2\text{O}$, which is the actual species that reacts with the amine:

The anhydride has been isolated from the reaction mixture and then used to acylate an amine.¹⁹¹¹

The synthetically important *Weinreb amides* $[\text{RCON}(\text{Me})\text{OMe}]$, see Reaction 16-82] can be prepared from the carboxylic acid and $\text{MeO}(\text{Me})\text{NH}\cdot\text{HCl}$ in the presence of tributylphosphine and 2-pyridine-*N*-oxide disulfide.¹⁹¹² Di(2-pyridyl)carbonate has been used in a related reaction that generates amides directly.¹⁹¹³ Other promoting agents¹⁹¹⁴ are $\text{ArB}(\text{OH})_2$ reagents,¹⁹¹⁵ N,N' -carbonyldiimidazole (**115**, in Reaction 16-63),¹⁹¹⁶ POCl_3 ,¹⁹¹⁷ TiCl_4 ,¹⁹¹⁸ molecular sieves,¹⁹¹⁹ *Lawesson's reagent* (Reaction 16-11),¹⁹²⁰ and $(\text{MeO})_2\text{POCl}$.¹⁹²¹ Certain dicarboxylic acids form amides simply on treatment with primary aromatic amines. In these cases, the cyclic anhydride is an intermediate and is the species actually attacked by the amine.¹⁹²² Carboxylic acids can also be

converted to amides by heating with amides of carboxylic acids (exchange),¹⁹²³ sulfonic acids, or phosphoric acids, for example,¹⁹²⁴

or by treatment with trisalkylaminoboranes $[\text{B}(\text{NHR}')_3]$, with trisdialkylaminoboranes $[\text{B}(\text{NR}_2')_3]$,¹⁹²⁵

or with bis(diorganoamino)magnesium reagents $[(\text{R}_2\text{N})_2\text{Mg}]$.¹⁹²⁶ The reaction of thio-carboxylic acids and azides, in the presence of triphenylphosphine, gives the corresponding amide.¹⁹²⁷

An important technique, discovered by R.B. Merrifield¹⁹²⁸ and since used for the synthesis of many peptides,¹⁹²⁹ is called *solid-phase synthesis* or *polymer-supported synthesis*.¹⁹³⁰ The reactions used are the same as in ordinary synthesis, but one of the reactants is anchored onto a solid polymer. For example, if it is desired to couple two amino acids (to form a dipeptide), the polymer selected might be polystyrene with CH_2Cl side chains. One of the amino acids, protected by (Boc), would then be coupled to the side chains. It is not necessary that all the side chains be converted, but a random selection will be converted. The Boc group is then removed by hydrolysis with trifluoroacetic acid in CH_2Cl_2 and the second amino acid is coupled to the first, using DCC or some other coupling agent. The second Boc group is removed, resulting in a dipeptide that is still anchored to the polymer. If this dipeptide is the desired product, it can be cleaved from the

polymer by various methods,¹⁹³¹ one of which is treatment with HF. If a longer peptide is wanted, additional amino acids can be added by repeating the requisite steps.

The basic advantage of the polymer support techniques is that the polymer (including all chains attached to it) is easily separated from all other reagents, because it is insoluble in the solvents used. Excess reagents, other reaction products (e.g., dicyclohexylurea), side products, and the solvents themselves are quickly washed away. Purification of the polymeric species is rapid and complete. The process can even be automated,¹⁹³² to the extent that six or more amino acids can be added to a peptide chain in one day. Commercial automated peptide synthesizers are now available.¹⁹³³

Although the solid-phase technique was first developed for the synthesis of peptide chains and has seen considerable use for this purpose, it has also been used to synthesize chains of polysaccharides and polynucleotides; in the latter case, solid-phase synthesis has almost completely replaced synthesis in solution.¹⁹³⁴ The technique has been applied less often to reactions in which only two molecules are brought together (nonrepetitive syntheses), but many examples have been reported.¹⁹³⁵ Combinatorial chemistry in some ways can be viewed as an extension of the *Merrifield synthesis*, particularly when applied to peptide synthesis, and continues as an important part of modern organic chemistry.¹⁹³⁶

16-75 Acylation of Amines by Carboxylic Esters

Amino-de-alkoxylation

The conversion of carboxylic esters to amides is a useful reaction, and unsubstituted, *N*-substituted, and *N,N*-disubstituted amides can be prepared this way from the appropriate amine¹⁹³⁷ or ammonia.¹⁹³⁸ Both R and R' can be alkyl or aryl, but *an especially good leaving group is p-nitrophenyl*. Ethyl trifluoroacetate was found to react selectively with primary amines to form the corresponding trifluoroacetyl amide.¹⁹³⁹ Many simple esters

(R = Me, Et, etc.) are not very reactive, and strongly basic catalysis has been used in such cases,¹⁹⁴⁰ but catalysis by cyanide ion¹⁹⁴¹ MgBr₂,¹⁹⁴² InI₃,¹⁹⁴³ and acceleration by high pressure¹⁹⁴⁴ have been reported. Methyl esters¹⁹⁴⁵ and ethyl esters¹⁹⁴⁶ have been converted to the corresponding amide under microwave irradiation. Lithium amides have been used to convert esters to amides as well.¹⁹⁴⁷ β-Keto esters undergo the reaction especially easily.¹⁹⁴⁸ Aniline was treated with *n*-butyllithium to form the lithium amide, which reacted with an ester to give the amide.¹⁹⁴⁹ An enzyme-mediated amidation is known using amino cyclase I.¹⁹⁵⁰ The reaction of dimethyl carbonate and an amine is an effective way to prepare methyl carbamates.¹⁹⁵¹

Lactones give lactams when treated with ammonia or primary amines. Lactams are also produced from γ- and δ-amino esters in an internal example of this reaction. Lactonization has been accomplished in ionic liquids.¹⁹⁵²

As in Reaction 16-72, hydrazides and hydroxamic acids can be prepared from carboxylic esters, with hydrazine and hydroxylamine,¹⁹⁵³ respectively. Both hydrazine and hydroxylamine react more rapidly than ammonia or primary amines (the alpha effect, Sec. 10.G.ii). Imidates [RC(=NH)OR'] give amidines [RC(=NH)NH₂]. Isopropenyl formate is a useful compound for the formylation of primary and secondary amines.¹⁹⁵⁴

Although more studies have been devoted to the mechanism of the acylation of amines with carboxylic esters than with other reagents, the mechanistic details are not yet entirely clear.¹⁹⁵⁵ In its broad outlines, the mechanism appears to be essentially B_{AC}2.¹⁹⁵⁶ Under normal basic conditions, the reaction is general base catalyzed,¹⁹⁵⁷ indicating that a proton is being transferred in the rate-determining step and that two molecules

of amine are involved.¹⁹⁵⁸ Alternatively, another base (e.g., H₂O or OH[−]) can substitute for the second molecule of amine. With some substrates and under some conditions, especially at low pH, the breakdown of **116** can become rate determining.¹⁹⁵⁹ The reaction also takes place under acidic conditions and is general acid catalyzed, so that breakdown of **116** is rate determining and proceeds as follows:¹⁹⁶⁰

Here HA may be R²NH₃⁺ or another acid. Intermediate **116** may or may not be further protonated on the nitrogen. Even under basic conditions, a proton donor may be necessary to assist leaving-group removal. Evidence for this is that the rate is lower with NR₂[−] in liquid ammonia than with NHR₂ in water, apparently owing to the lack of acids to protonate the leaving oxygen.¹⁹⁶¹

In the special case of β-lactones, where small-angle strain is an important factor, alkyl-oxygen cleavage is observed (B_{AL}2 mechanism, as in the similar case of hydrolysis of β-lactones, Reaction **16-59**), and the product is not an amide but a β-amino acid (β-alanine).

A similar result has been found for certain sterically hindered esters.¹⁹⁶² This reaction is similar to **10-31**, with OCOR as the leaving group. Other lactones have been opened to ω-hydroxy amides with Dibal-H:BnNH₂.¹⁹⁶³

This is an exchange reaction and is usually carried out with the salt of the amine.¹⁹⁶⁴ The leaving group is usually NH_2 rather than NHR or NR_2 and primary amines (in the form of their salts) are the most common reagents. Boron trifluoride can be added to complex with the leaving ammonia. Neutral amines also react in some cases to give the new amide.¹⁹⁶⁵ The reaction is catalyzed by Al(III) .¹⁹⁶⁶ The reaction is often used to convert urea to substituted ureas: $\text{NH}_2\text{CONH}_2 + \text{RNH}_3^+ \rightarrow \text{NH}_2\text{CONHR} + \text{NH}_4^+$.¹⁹⁶⁷ An *N*-aryl group of a urea can be converted to a *N,N*-dialkyl group by heating the urea with the amine in an autoclave.¹⁹⁶⁸ *N*-alkyl substituted amides (alkyl = R) are converted to *N*-R'-substituted amides, where alkyl = R', by treatment with N_2O_4 to give an *N*-nitroso compound, followed by treatment of this with a primary amine ($\text{R}'\text{NH}_2$).¹⁹⁶⁹ Lactams can be converted to ring-expanded lactams (e.g., **117**) if a side chain containing an amino group is present on the nitrogen. A strong base is used to convert the NH_2 to NH^- , which then acts as a nucleophile, expanding the ring by means of a transamidation.¹⁹⁷⁰ The discoverers call it the *Zip reaction*, by analogy with the action of zippers.¹⁹⁷¹

Lactams can be opened to ω -amino amides by reaction with amines at 10 kbar.¹⁹⁷²

prepare amides and related compounds. The reaction of a primary amine, an alkyl halide with CO_2 , in the presence of $\text{Cs}_2\text{CO}_3/\text{Bu}_4\text{NI}$, gave the corresponding carbamate.¹⁹⁷⁶

OS **III**, 394; **IV**, 6, 569; **V**, 160, 166; **VI**, 1004.

Imides can be prepared by the attack of amides or their salts on acyl halides, anhydrides, and carboxylic acids or esters.¹⁹⁷⁷ A good synthetic method for the preparation of acyclic imides is the reaction between an amide and an anhydride at 100°C catalyzed by H_2SO_4 .¹⁹⁷⁸

When acyl chlorides are treated with amides in a 2: 1 molar ratio at low temperatures in the presence of pyridine, the products are *N,N*-diacylamides $[(\text{RCO})_3\text{N}]$.¹⁹⁷⁹

This reaction is often used to prepare urea derivatives, an important example being the preparation of barbituric acid (**118**).¹⁹⁸⁰

When the substrate is oxalyl chloride (ClCOCOCl) and the reagent an unsubstituted amide, an acyl isocyanate (RCONCO) is formed. The “normal” product (RCONHCOCOCl) does not form, or if it does, it rapidly loses CO and HCl .¹⁹⁸¹

The same inorganic acid halides that convert alcohols to alkyl halides (Reaction **10-48**) also convert carboxylic acids to acyl halides.¹⁹⁸⁴ The reaction is the best and the most common method for the preparation of acyl chlorides. Bromides and iodides¹⁹⁸⁵ are also made in this manner, but much less often. Acyl bromides can be prepared with BBr₃ on alumina,¹⁹⁸⁶ or with ethyl tribromoacetate/PPh₃.¹⁹⁸⁷ Thionyl chloride¹⁹⁸⁸ is a good reagent, since the byproducts are gases and the acyl halide is easily isolated, but PX₃ and PX₅ (X = Cl or Br) are also commonly used.¹⁹⁸⁹ Hydrogen halides do not give the reaction. A particularly mild procedure, similar to one mentioned in Reaction **10-48**, involves reaction of the acid with Ph₃P in CCl₄, whereupon acyl chlorides are produced without obtaining any acidic compound as a byproduct.¹⁹⁹⁰

Oxalyl chloride (**113**) and oxalyl bromide are mild and often superior reagents, since the oxalic acid byproduct decomposes to CO and CO₂, and the equilibrium is thus driven to the side of the other acyl halide.¹⁹⁹¹ These reagents are commonly the reagent of choice, particularly when sensitive functionality is present elsewhere in the molecule.

Acyl fluorides can be prepared by treatment of carboxylic acids with cyanuric fluoride.¹⁹⁹² *N*-Chelated di-*n*-butyltin(IV) fluoride has been used to prepare acyl fluorides.¹⁹⁹³ Acid salts are also sometimes used as substrates and acyl halides are used as reagents in an exchange reaction:

which probably involves an anhydride intermediate. This is an equilibrium reaction that must be driven to the desired side.

These reactions are most important for the preparation of acyl fluorides.¹⁹⁹⁴ Acyl chlorides and anhydrides can be converted to acyl fluorides by treatment with polyhydrogen fluoride–pyridine solution¹⁹⁹⁵ or with liquid HF at $-10\text{ }^{\circ}\text{C}$.¹⁹⁹⁶ Formyl fluoride, which is a stable compound, was prepared by the latter procedure from the mixed anhydride of formic and acetic acids.¹⁹⁹⁷ Acyl fluorides can also be obtained by reaction of acyl chlorides with KF in acetic acid¹⁹⁹⁸ or with diethylaminosulfur trifluoride (DAST).¹⁹⁹⁹ Carboxylic esters and anhydrides can be converted to acyl halides other than fluorides by the inorganic acid halides mentioned in Reaction 16-79, as well as with Ph_3PX_2 ($\text{X} = \text{Cl}$ or Br),²⁰⁰⁰ but this is seldom done. Halide exchange can be carried out in a similar manner. When halide exchange is done, it is always acyl bromides and iodides that are made from chlorides, since chlorides are by far the most readily available.²⁰⁰¹

reagents $[\text{RCu}(\text{CN})\text{ZnI}]$.²⁰⁰⁹ The R group may be alkynyl if a cuprous acetylide ($\text{R}^2\text{C}\equiv\text{CCu}$) is the reagent.²⁰¹⁰ Organocopper reagents generated *in situ* from highly reactive copper, and containing such functional groups as cyano, chloro, and ester, react with acyl halides to give ketones.²⁰¹¹

When the organometallic compound is a *Grignard reagent*,²⁰¹² ketones are generally not obtained because the initially formed ketone reacts with a second molecule of RMgX to give the salt of a tertiary alcohol (Reaction **16-82**). Ketones *have* been prepared in this manner by the use of low temperatures, inverse addition (i.e., addition of the *Grignard reagent* to the acyl halide rather than the other way), excess acyl halide, and so on, but the yields are usually low, although high yields have been reported in THF at -78°C .²⁰¹³ Pretreatment with a trialkylphosphine followed by the *Grignard reagent* gave the ketone.²⁰¹⁴ Using CuBr ²⁰¹⁵ or a Ni catalyst²⁰¹⁶ with the *Grignard reagent* can lead to the ketone. Some ketones are unreactive toward *Grignard reagents* for steric or other reasons; these can be prepared in this way.²⁰¹⁷ Other methods involve running the reaction in the presence of Me_3SiCl ²⁰¹⁸, which reacts with the initial adduct in the tetrahedral mechanism (Sec. 16.A.i), and the use of a combined *Grignard*– LiNEt_2 reagent.²⁰¹⁹ Certain metallic halides, notably ferric and cuprous halides, are catalysts that improve the yields of ketone at the expense of tertiary alcohol.²⁰²⁰ For this catalysis, both free radical and ionic mechanisms have been proposed.²⁰²¹

Grignard reagents react with ethyl chloroformate to give carboxylic esters $[\text{EtOCOC}l + \text{RMgX} \rightarrow \text{EtOCOR}]$.

The Pd catalyzed reaction of an acyl chloride and an arylboronic acid²⁰²² or an alkenylboronic acid²⁰²³ gives a ketone. Surfactants are known to promote arylboronic acid coupling reactions.²⁰²⁴ Arylboronic esters add to carbamoyl halides, in the presence of a Pd catalyst, to give the corresponding benzamide.²⁰²⁵ Arylboronic acids also react with

anhydrides to give a ketone in the presence of a Pd catalyst.²⁰²⁶ Similar reaction of acid chlorides, NaBPh₄, KF, and a Pd catalyst gave the aryl ketone.²⁰²⁷

Other organometallic reagents²⁰²⁸ give good yields of ketones when treated with acyl halides because, as with R₂CuLi or R₂Cd, these compounds do not generally react with the ketone product. A particularly useful class of organometallic reagent are the organo-cadmium reagents (R₂Cd), prepared from *Grignard reagents* (Reaction 12-22). In this case, R may be an aryl or primary alkyl. In general, secondary and tertiary alkylcadmium reagents are not stable enough to be useful in this reaction.²⁰²⁹ An ester group may be present in either R'COX or R₂Cd. Direct treatment of the acid chloride with an alkyl halide and Cd metal leads to the ketone in some cases.²⁰³⁰ Organozinc compounds behave similarly to dialkylcadmium reagents, but are used less often.²⁰³¹ Organotin reagents (R₄Sn) react with acyl halides to give high yields of ketones, if a Pd complex is present.²⁰³² Organolead reagents (R₄Pb) behave similarly.²⁰³³ Allylic halides and In metal react with acyl chlorides to give the ketone.²⁰³⁴ Various other groups (e.g., nitrile, ester, and aldehyde) can be present in the acyl halide without interference. Other reagents include organomanganese compounds²⁰³⁵ (R can be primary, secondary, or tertiary alkyl, vinylic, alkynyl, or aryl), organozinc,²⁰³⁶ organobismuth,²⁰³⁷ and organothallium compounds (R can be primary alkyl or aryl).²⁰³⁸ The reaction of an α -halo-ketone and an acyl chloride with SmI₂ leads to a β -diketone.²⁰³⁹

Antimony alkynes (e.g., Ph₂Sb—C \equiv C—Ph) react with acid chloride in the presence of a Pd catalyst to give the conjugated alkynyl ketone.²⁰⁴⁰ Such conjugated ketones can also be prepared from an acyl halide, a terminal alkyne, and a CuI,²⁰⁴¹ Pd,²⁰⁴² or Fe catalyst,²⁰⁴³

or with In metal.²⁰⁴⁴ Terminal alkynes react with chloroformates and a Pd catalyst to give the corresponding propargyl ester.²⁰⁴⁵ Similar reaction of an alkyne with an acid chloride and a Pd—Cu²⁰⁴⁶ or CuI catalyst,²⁰⁴⁷ both with microwave irradiation, gave alkynyl ketones.

Acyl halides can also be converted to ketones by treatment with Na₂Fe(CO)₄ followed by R'X (Reaction 10-76).

16-82 The Conversion of Anhydrides, Carboxylic Esters, or Amides to Ketones with Organometallic Compounds²⁰⁴⁸

Dialkyl,hydroxy-de-alkoxy,oxo-tersubstitution; Alkyl-de-acyloxy- or de-amido substitution

When carboxylic esters are treated with *Grignard reagents*, addition to the carbonyl (Reaction 16-24) generates a ketone. Under the reaction conditions, the initially formed ketone usually undergoes acyl substitution of R² for OR' (Reaction 16-81), so that tertiary alcohols are formed in which two R groups are the same. Isolation of the ketone as the major product is possible in some cases, particularly when the reaction is done at low temperature²⁰⁴⁹ and when there is steric hindrance to the carbonyl in the first-formed ketone. Esters (RCO₂Me) react with Zn(BH₄)₂/EtMgBr to give an alcohol [RCH(OH)Et].²⁰⁵⁰ Formates give secondary alcohols and carbonates give tertiary alcohols in which all three R groups are the same: (EtO)₂C=O + RMgX → R₃COMgX. Acyl halides and anhydrides behave similarly, though these substrates are employed less often.²⁰⁵¹ Many side reactions are possible, especially when the acid derivative or the *Grignard reagent* is branched: enolizations, reductions (not for esters, but for halides), condensations, and cleavages, but the most important is simple substitution (16-81), which in some cases can be made to predominate. When 1,4-dimagnesium compounds are used, carboxylic esters are converted to cyclopentanols.²⁰⁵² 1,5-Dimagnesium compounds give cyclohexanols, but in lower yields.²⁰⁵³

As is the case with acyl halides (Reaction 16-81), anhydrides and carboxylic esters give tertiary alcohols (Reaction 16-82) when treated with *Grignard reagents*. Low temperatures,²⁰⁵⁴ the solvent HMPA,²⁰⁵⁵ and inverse addition have been used to increase the yields of ketone.²⁰⁵⁶ Amides give better yields of ketone at room temperature, but still not very high.²⁰⁵⁷ Anhydrides can react with arylmagnesium halides at low temperature, and in the presence of (–)-sparteine, to give a keto acid with good enantioselectivity.²⁰⁵⁸ Organo-cadmium reagents are less successful with these substrates than with acyl halides (Reaction 16-81). Esters of formic acid, dialkylformamides, and lithium or sodium formate²⁰⁵⁹ give good yields of aldehydes, when treated with *Grignard reagents*.

Organolithium compounds have been used to give ketones from carboxylic esters. The reaction must be carried out in a high-boiling solvent (e.g., toluene), since reaction at lower temperatures gives tertiary alcohols.²⁰⁶⁰ Organolithium reagents also give good yields of carbonyl compounds with *N,N*-disubstituted amides.²⁰⁶¹ Dialkylformamides react to give aldehydes, other disubstituted amides give ketones and other acid derivatives have been used.²⁰⁶²

Ketones can also be obtained by treatment of the lithium salt of a carboxylic acid with an organolithium reagent (Reaction 16-28). For an indirect way to convert carboxylic esters to ketones, see Reaction 16-82. A similar reaction with hindered aryl carboxylic acids has been reported.²⁰⁶³ Carboxylic acids can be treated with 2-chloro-4,6-dimethoxy[1,3,5] triazine and the RMgX/CuI to give ketones.²⁰⁶⁴

Disubstituted formamides can give addition of 2 molar equivalents of *Grignard reagent*. The products of this reaction (called *Bouveault reaction*) are an aldehyde and a tertiary amine.²⁰⁶⁵ The use of an amide other than a formamide can give a ketone instead of an aldehyde, but yields are generally low. The addition of 2 molar equivalents of

phenyllithium to a carbamate gave good yields of the ketone, however.²⁰⁶⁶ The reaction of *N*-(3-bromopropyl) lactams with *tert*-butyllithium gave cyclization to the bicyclic amino alcohol, and subsequent reduction with LiAlH₄ (Reaction **19-64**) gave the bicyclic amine.²⁰⁶⁷ Ketones can also be prepared by treatment of thioamides with organolithium compounds (alkyl or aryl).²⁰⁶⁸ Cerium reagents (e.g., MeCeCl₂) also add two R groups to an amide.²⁰⁶⁹ More commonly, an organolithium reagent is treated with CeCl₃ to generate the organocerium reagent *in situ*.²⁰⁷⁰ It has proven possible to add two different R groups by sequential addition of two *Grignard reagents*.²⁰⁷¹ Diketones have also been produced by using the bis(imidazole) derivative of oxalic acid.²⁰⁷² When an amide having a *gem*-dibromocyclopropyl unit elsewhere in the molecule was treated with methyllithium, Li—Br exchange was accompanied by intramolecular acyl addition to the amide carbonyl, giving a bicyclic amino alcohol.²⁰⁷³

N-Methoxy-*N*-methyl amides, (e.g., **120**) are referred to as a *Weinreb amide*.²⁰⁷⁴ When a *Weinreb amide* reacts with a *Grignard reagent* or an organolithium reagent,²⁰⁷⁵ the product is the ketone. The reaction of **121** (TBDPSO = tertiarybutyldiphenylsilyl) with 3-butenylmagnesium bromide to give ketone **122** is a typical example.²⁰⁷⁶ Aryloxy carbamates with a *Weinreb amide* unit [ArO₂C-NMe(OMe)] react with RMgBr and then R'Li to give an unsymmetrical ketone [RC(=O)R'].²⁰⁷⁷ Intramolecular displacement of a *Weinreb amide* by an organolithium reagent generated *in situ* from an iodide precursor leads to cyclic ketones.²⁰⁷⁸ Reaction with vinylmagnesium bromide led to a β-*N*-methoxy-*N*-methylamino ketone, presumably by initial formation of the conjugated ketone followed by *Michael addition* (Reaction **15-24**) of the liberated amine.²⁰⁷⁹ By the use of the compound *N*-methoxy-*N,N',N'*-trimethylurea, it is possible to add two R groups as RLi, the same or different, to a CO group.²⁰⁸⁰ Another variant used organocerium reagents with (*Z*)-α,β-unsaturated *Weinreb amides* to give (*Z*)-α,β-unsaturated ketones.²⁰⁸¹

N,N-Disubstituted amides can be converted to alkynyl ketones by treatment with alkynylboranes: $\text{RCONR}_2 + (\text{R}'\text{C}\equiv\text{C})_3\text{B} \rightarrow \text{RCOC}\equiv\text{CR}'$.²⁰⁸² Lactams react with triallylborane to give cyclic 2,2-diallyl amines after treatment with methanol and then aq hydroxide.²⁰⁸³ Triallylborane reacts with the carbonyl group of lactams, and after treatment with methanol and then aq NaOH gives the *gem*-diallyl amine: 2-pyrrolidinone \rightarrow 2,2-diallylpyrrolidine.²⁰⁸⁴ *N,N*-Disubstituted carbamates ($\text{X}=\text{OR}^2$) and carbamoyl chlorides ($\text{X}=\text{Cl}$) react with 2 molar equivalents of an alkyl- or aryllithium or *Grignard reagent* to give symmetrical ketones, in which both R groups are derived from the organometallic compound: $\text{R}_2'\text{NCOX} + 2 \text{RMgX} \rightarrow \text{R}_2\text{CO}$.²⁰⁸⁵ *N,N*-Disubstituted amides give ketones in high yields when treated with alkylaluminum triflates $[\text{RLa}(\text{OTf})_2]$.²⁰⁸⁶

Other organometallic reagents give acyl substitution. Sodium naphthalenide reacts with esters to give naphthyl ketones.²⁰⁸⁷ Trimethylaluminum, which exhaustively methylates ketones (Reaction 16-24), also exhaustively methylates carboxylic acids to give *tert*-butyl compounds²⁰⁸⁸ (see also, Reaction 10-63). Trimethylaluminum reacts with esters to form ketones, in the presence of *N,N*-dimethylethylenediamine.²⁰⁸⁹ Trialkylboranes have been used to convert thioesters to ketones.²⁰⁹⁰ Thioesters (RCOSR') react with arylboronic acids, in the presence of a Pd catalyst, to give the corresponding ketone,²⁰⁹¹ and esters react similarly with arylboronic acids (a Pd catalyst)²⁰⁹² or arylboronates (a Ru catalyst).²⁰⁹³ Arylboronic acids also react with dialkyl anhydrides, with a Rh²⁰⁹⁴ or a Pd catalyst,²⁰⁹⁵ to give the ketone. Thioesters are converted to ketones with organoindium compounds.²⁰⁹⁶ Thioesters give good yields of ketones when treated with lithium dialkylcopper reagents ($\text{R}_2'\text{CuLi}$, R'' = primary or secondary alkyl or aryl).²⁰⁹⁷ Organozinc reagents convert thioesters to ketones.²⁰⁹⁸ Diaryl- or dialkylzinc reagents react with anhydrides and a Pd²⁰⁹⁹ or a Ni catalyst²¹⁰⁰ to give the ketone. The reaction of alkylzinc halides and thioesters leads to ketones in the presence of 1.5% Pd/C,²¹⁰¹ in what has been called *Fukuyama coupling*.²¹⁰² Note that in the presence of a SmI_2 catalyst and 2 molar equivalents of

16-83 The Coupling of Acyl Halides

De-halogen-coupling

Acyl halides can be coupled with pyrophoric lead to give symmetrical α -diketones in a *Wurtz-type reaction*.²¹¹² The reaction has been performed with $\text{R} = \text{Me}$ and Ph . Samarium iodide²¹¹³ gives the same reaction. The photochemical coupling of acyl iodides gives α -diketones.²¹¹⁴ Benzoyl chloride was coupled to give benzil by subjecting it to ultrasound in the presence of Li wire: $2 \text{PhCOCl} + \text{Li} \rightarrow \text{PhCOCOPh}$.²¹¹⁵

Unsymmetrical α -diketones (RCOCOR') have been prepared by treatment of an acyl halide (RCOCl) with an acyltin reagent $\text{R}'\text{COSnBu}_3$, with a Pd complex catalyst.²¹¹⁶

16-84 Acylation at a Carbon Bearing an Active Hydrogen

Bis(ethoxycarbonyl)methyl-de-halogenation, and so on

This reaction is similar to **10-67**, but there are fewer examples.²¹¹⁷ Either Z or Z' may be any of the electron-withdrawing groups listed in Reaction **10-67** (CO₂R, COR, CN, etc.)²¹¹⁸ Anhydrides react similarly but are used less often. The product contains three Z groups, since RCO is a Z group. One or two of these can be cleaved (Reactions **12-40** and **12-43**). In this way, a compound ZCH₂Z' can be converted to ZCH₂Z² or an acyl halide (RCOCl) to a methyl ketone (RCOCH₃). O-Acylation is sometimes a side reaction.²¹¹⁹ When thallium(I) salts of ZCH₂Z' are used, it is possible to achieve regioselective acylation at either the C or the O position. For example, treatment of the thallium(I) salt of MeCOCH₂COMe with acetyl chloride at -78 °C gave >90% O-acylation, while acetyl fluoride at room temperature gave >95% C-acylation.²¹²⁰ The use of an alkyl chloroformate gives triesters.²¹²¹

The application of this reaction to simple ketones²¹²² (in parallel with Reaction **10-68**) requires a strong base (e.g., NaNH₂ or Ph₃CNa) and is often complicated by O-acylation, which in many cases becomes the principal pathway because acylation at the oxygen is usually much faster. It is possible to increase the proportion of C-acylated product by employing an excess (2–3 molar equivalents) of enolate anion (and adding the substrate to this, rather than vice versa), by the use of a relatively nonpolar solvent and a metal ion (e.g., Mg²⁺), which is tightly associated with the enolate oxygen atom, by the use of an acyl halide rather than an anhydride,²¹²³ and by working at low temperatures.²¹²⁴ In cases where the use of an excess of enolate anion results in C-acylation, it is because O-acylation takes place first, and the O-acylated product (an enol ester) is then C-acylated. Simple ketones can also be acylated by treatment of their silyl enol ethers with an acyl chloride in the presence of ZnCl₂ or SbCl₃.²¹²⁵ Ketones can be acylated by anhydrides to give β-diketones, with BF₃ as catalyst.²¹²⁶ Simple esters (RCH₂CO₂Et) can be acylated at the α carbon (at -78 °C) if a strong base (e.g., lithium *N*-isopropylcyclohexylamide) is used to remove the proton.²¹²⁷

16-85 Acylation of Carboxylic Esters by Carboxylic Esters: The Claisen and Dieckmann Condensations

Alkoxy-carbonyl-alkyl-de-alkoxy-substitution

When carboxylic esters containing an α hydrogen are treated with a strong base (e.g., sodium ethoxide), a condensation occurs to give a β -keto ester via an ester enolate anion.²¹²⁹ This reaction is called the *Claisen condensation*. When it is carried out with a mixture of two different esters, each of which possesses an α hydrogen (this reaction is called a *mixed-Claisen* or a *crossed-Claisen condensation*), a mixture of all four products is generally obtained and the reaction is seldom useful synthetically.²¹³⁰ However, if only one of the esters has an α hydrogen, the mixed reaction is frequently satisfactory. Among esters lacking α hydrogen atoms (hence acting as the substrate ester) that are commonly used in this way are esters of aromatic acids, and ethyl carbonate and ethyl oxalate. When the ester enolate reacts with ethyl carbonate, the product is a malonic ester, and reaction with ethyl formate introduces a formyl group. *Claisen condensation* of phenyl esters with ZrCl_4 and diisopropylethylamine (*Hünigs base*) give the corresponding keto ester.²¹³¹ Titanium compounds catalyze a *crossed-Claisen condensation*.²¹³² Boron(III) compounds also catalyzed ester condensation reactions.²¹³³

As with ketone enolate anions (see Reaction 16-34), the use of amide bases under kinetic control conditions (strong base with a weak conjugate acid, aprotic solvents, low temperatures), allows the *mixed-Claisen condensation* to proceed. Self-condensation of the lithium enolate with the parent ester is a problem when LDA is used as a base,²¹³⁴ but this is minimized with LICA.²¹³⁵ Note that solvent-free *Claisen condensation* reactions have been reported.²¹³⁶ There is a *retro-Claisen condensation*, catalyzed by indium.²¹³⁷

When the two ester groups involved in the condensation are in the same molecule, the product is a cyclic β -keto ester (**122**) and the reaction is called the *Dieckmann*

²¹³⁷ Kawata, A.; Takata, K.; Kuninobu, Y.; Takai, K. *Angew. Chem. Int. Ed.* **2007**, 46, 7793.

condensation.²¹³⁸ The *Dieckmann condensation* is most successful for the formation of 5-, 6-, and 7-membered rings, but yields for rings of 9–12 members are very low or nonexistent. Reactions that form large rings are generally assisted by high dilution. A solvent-free *Dieckmann condensation* has been reported on solid potassium *tert*-butoxide.²¹³⁹ *Dieckmann condensation* of unsymmetrical substrates can be made regioselective by the use of solid-phase supports.²¹⁴⁰ The *Dieckmann condensation* has also been done using $\text{TiCl}_3/\text{NBu}_3$ with a TMSOTf catalyst.²¹⁴¹ A *Dieckmann-like condensation* was reported where an α,ω -dicarboxylic acid was heated to 450 °C on graphite, with microwave irradiation, to give the cyclic ketone.²¹⁴²

The mechanism of the *Claisen* and *Dieckmann condensations* (steps 1–3) is the ordinary *tetrahedral mechanism*,²¹⁴³ with one molecule of ester being converted to a nucleophile by the base and the other serving as the substrate. This reaction illustrates the striking difference in behavior between carboxylic esters on the one hand and aldehydes and ketones on the other. When a carbanion (e.g., an enolate anion) is added to the carbonyl group of an aldehyde or ketone (Reaction 16-38), the H or R is not lost, since these groups are much poorer leaving groups than OR. Instead, the intermediate similar to **123** adds a proton at the oxygen to give a hydroxy compound.

In contrast to Reaction 10-67, ordinary esters react quite well; that is, two Z groups are not needed. A lower degree of acidity is satisfactory because it is not necessary to convert the attacking ester entirely to its ion. Step 1 is an equilibrium that lies well to the left, but the small amount of enolate anion formed is sufficient to attack the readily approachable ester substrate. All the steps are in equilibria. The reaction proceeds because the product is converted to its conjugate base by the base present (i.e., a β -keto ester is a stronger acid than an alcohol):

The use of a stronger base (e.g., NaNH_2 , NaH , or KH),²¹⁴⁴ often increases the yield. For some esters, stronger bases *must* be used, since sodium ethoxide is ineffective. Among these are

16-86 Acylation of Ketones and Nitriles by Carboxylic Esters

α -Acylalkyl-de-alkoxy-substitution

Carboxylic esters can be treated with ketones to give β -diketones. The reaction is so similar that it is sometimes also called the *Claisen reaction*, but this usage may be confusing. A strong base (e.g., sodium amide or sodium hydride) is required. Yields can be increased by the catalytic addition of crown ethers.²¹⁴⁶ Esters of formic acid ($R = H$) give β -keto aldehydes and ethyl carbonate gives β -keto esters. β -Keto esters can also be obtained by treating the lithium enolates of ketones with methyl cyanofornate (MeOCOCN ,²¹⁴⁷ in this case CN is the leaving group) and by treating ketones with KH and diethyl dicarbonate $[(\text{EtOCO})_2\text{O}]$.²¹⁴⁸ This reaction has been used to effect cyclization, especially to prepare five- and six-membered rings. Nitriles are frequently used instead of ketones, the products being β -keto nitriles, as shown.

Other nucleophilic carbon reagents (e.g., acetylide ions) and ions derived from α -methylpyridines have also been used. A particularly useful nucleophile is the methylsulfinyl carbanion ($\text{CH}_3\text{SOCH}_2^-$),²¹⁴⁹ the conjugate base of DMSO, since the β -keto sulfoxide produced can easily be reduced to a methyl ketone (see Reaction 10-67). The methylsulfonyl carbanion ($\text{CH}_2\text{SO}_2\text{CH}_2^-$), the conjugate base of dimethyl sulfone, behaves similarly,²¹⁵⁰ and the product can be similarly reduced. Certain carboxylic esters, acyl halides, and DMF will acylate 1,3-dithianes²¹⁵¹ (see Reaction 10-71) to give, after oxidative hydrolysis with NBS or NCS, α -keto aldehydes or α -diketones.²¹⁵²

As in Reaction 10-67, a ketone is deprotonated at the most acidic proton first and the second most acidic position after that if 2 equivs of base are used, to give dianion 124.

²¹⁴⁵ See Garst, J.F. *J. Chem. Educ.* **1979**, 56, 721.

Thus, β -diketones have been converted to 1,3,5-triketones.²¹⁵³

Side reactions are condensation of the ketone with itself (**16-34**), of the ester with itself, and of the ketone with the ester but with the ester supplying the α -position (**16-36**). The mechanism is the same as in Reaction **16-85**.²¹⁵⁴

OS **I**, 238; **II**, 126, 200, 287, 487, 531; **III**, 17, 251, 291, 387, 829; **IV**, 174, 210, 461, 536; **V**, 187, 198, 439, 567, 718, 747; **VI**, 774; **VII**, 351.

16-87 Acylation of Carboxylic Acid Salts

α -Carboxyalkyl-de-alkoxy-substitution

As seen previously (Reaction **10-70**), dianions of carboxylic acids can be alkylated in the α position. These ions can also be acylated on treatment with a carboxylic ester²¹⁵⁵ to give salts of β -keto acids. As in Reaction **10-70**, the carboxylic acid can be of the form $\text{RCH}_2\text{CO}_2\text{H}$ or $\text{RR}^2\text{CHCO}_2\text{H}$. Since β -keto acids are so easily converted to ketones (Reaction **12-40**), this is also a method for the preparation of ketones ($\text{R}'\text{COCH}_2\text{R}$ and $\text{R}'\text{COCHRR}^2$), where R' can be primary, secondary, or tertiary alkyl, or aryl. If the ester is ethyl formate, an α -formyl carboxylate salt ($\text{R}' = \text{H}$) is formed, which on acidification spontaneously decarboxylates into an aldehyde.²¹⁵⁶ This method accomplishes the conversion $\text{RCH}_2\text{CO}_2\text{H} \rightarrow \text{RCH}_2\text{CHO}$, and is an alternative to the reduction methods discussed in Reaction **19-39**. When the carboxylic acid is of the form $\text{RR}^2\text{CHCO}_2\text{H}$, better yields are obtained by acylating with acyl halides rather than esters.²¹⁵⁷

16-88 Preparation of Acyl Cyanides

Cyano-de-halogenation

Acyl cyanides²¹⁵⁸ can be prepared by treatment of acyl halides with copper cyanide. The mechanism could be free radical or nucleophilic substitution. The reaction has also been accomplished with thallium(I) cyanide,²¹⁵⁹ with Me_3SiCN and an SnCl_4 catalyst,²¹⁶⁰ and with Bu_3SnCN ,²¹⁶¹ but these reagents are successful only when $\text{R} = \text{aryl}$ or tertiary alkyl.

Potassium cyanide has also been used, along with ultrasound,²¹⁶² as has NaCN with phase-transfer catalysts.²¹⁶³

OS III, 119.

16-89 Preparation of Diazo Ketones

Diazomethyl-de-halogenation

The reaction between acyl halides and diazomethane is of wide scope and is the best way to prepare diazo ketones.²¹⁶⁴ Diazomethane must be present in excess or the HX produced will react with the diazo ketone (Reaction 10-52). This reaction is the first step of the *Arndt–Eistert synthesis* (18-8). Diazo ketones can also be prepared directly from a carboxylic acid and diazomethane or diazoethane in the presence of DCC.²¹⁶⁵

OS III, 119; VI, 386, 613; VIII, 196.

16-90 Ketonic Decarboxylation²¹⁶⁶

Alkyl-de-hydroxylation

Carboxylic acids can be converted to symmetrical ketones by pyrolysis in the presence of thorium oxide. In a mixed reaction, formic acid and another acid heated over thorium oxide give aldehydes. Mixed alkyl aryl ketones have been prepared by heating mixtures of ferrous salts.²¹⁶⁷ When the R group is large, the methyl ester rather than the acid can be decarbomethoxylated over thorium oxide to give the symmetrical ketone.

The reaction has been performed on dicarboxylic acids, whereupon cyclic ketones are obtained:

This process, called *Ruzicka cyclization*, is good for the preparation of rings of six and seven members and, with lower yields, of C₈–C₁₀ to C₃₀ cyclic ketones.²¹⁶⁸

Not much work has been done on the mechanism of this reaction. However, a free radical mechanism has been suggested on the basis of a thorough study of all the side products.²¹⁶⁹

16.B.iii. Reactions in which Carbon Adds to the Heteroatom

A. Oxygen Adding to the Carbon

16-91 The Ritter Reaction

N-Hydro,*N*-alkyl-*C*-oxo-biaddition

Alcohols can be added to nitriles in an entirely different manner from that seen in Reaction 16-9. In this reaction, the alcohol is converted by a strong acid to a carbocation, which is attacked by the nucleophilic nitrogen atom to give **125**. Subsequent addition of water to the electrophilic carbon atom leads to the enol form of the amide (see Reaction 126), which tautomerizes (Sec. 2.N.i) to the *N*-alkyl amide.

Only alcohols that give rise to fairly stable carbocations react (secondary, tertiary, benzylic, etc.); non-benzylic primary alcohols do not give the reaction. The carbocation need not be generated from an alcohol, but may come from protonation of an alkene or from other sources. In any case, the reaction is called the *Ritter reaction*.²¹⁷⁰ Lewis acids [e.g., $\text{Mg}(\text{HSO}_4)_2$] have been used to promote the reaction.²¹⁷¹ Highly sterically hindered nitriles have been converted to *N*-methyl amides by heating with methanol and sulfuric acid.²¹⁷² Hydrogen cyanide also gives the reaction, the product being a formamide. Trimethylsilyl cyanide has also been used.²¹⁷³

Since the amides (especially the formamides) are easily cleaved to amines under hydrolysis conditions, the *Ritter reaction* provides a method for achieving the conversions $\text{R}'\text{OH} \rightarrow \text{R}'\text{NH}_2$ (see 10-32) and $\text{alkene} \rightarrow \text{R}'\text{NH}_2$ (see 15-8) in those cases, where R' can form a relatively stable carbocation. The reaction is especially useful for the preparation of tertiary alkyl amines because there are few alternate ways of preparing these compounds. The reaction can be extended to primary alcohols by treatment with triflic anhydride²¹⁷⁴ or $\text{Ph}_2\text{CCl}^+ \text{SbCl}_6^-$ or a similar salt²¹⁷⁵ in the presence of the nitrile. A mixture of P_2O_5 and silica gel has been used to mediate the *Ritter reaction*.²¹⁷⁶ There is a Nafion-catalyzed,

microwave assisted variation,²¹⁷⁷ as well as FeCl₃ catalyzed²¹⁷⁸ and iodine-catalyzed²¹⁷⁹ reactions.

Alkenes of the form RCH=CHR' and RR'C=CH₂ add to nitriles in the presence of mercuric nitrate to give, after treatment with NaBH₄, the same amides that would be obtained by the *Ritter reaction*.²¹⁸⁰ This method has the advantage of avoiding strong acids.

Benzylic compounds (e.g., ethylbenzene) react with alkyl nitriles, ceric ammonium nitrate, and a catalytic amount of *N*-hydroxysuccinimide to give the *Ritter* product, the amide.²¹⁸¹

The *Ritter reaction* can be applied to cyanamides RNHCN to give ureas (RNHCONHR').²¹⁸²

OS V, 73, 471.

16-92 The Addition of Aldehydes to Aldehydes

When catalyzed by acids, low-molecular-weight aldehydes add to each other to give cyclic acetals, the most common product being the trimer.²¹⁸³ The cyclic trimer of formaldehyde is called *trioxane*,²¹⁸⁴ and that of acetaldehyde is known as *paraldehyde*. Under certain conditions, it is possible to get tetramers²¹⁸⁵ or dimers. Aldehydes can also polymerize to linear polymers, but a small amount of water is required to form hemiacetal groups at the ends of the chains. The linear polymer formed from formaldehyde is called *paraformaldehyde*. Since trimers and polymers of aldehydes are acetals, they are stable to bases, but can be hydrolyzed by acids. Because formaldehyde and acetaldehyde have low boiling points, it is often convenient to use them in the form of their trimers or polymers.

A slightly related reaction involves nitriles, which can be trimerized with various acids, bases, or other catalysts to give triazines (see OS III, 71).²¹⁸⁶ Here HCl is most often used. Most nitriles with an α hydrogen do not give the reaction.

B. Nitrogen Adding to the Carbon

16-93 The Addition of Isocyanates to Isocyanates (Formation of Carbodiimides)

Alkylimino-de-oxo-bisubstitution

The treatment of isocyanates with 3-methyl-1-ethyl-3-phospholene-1-oxide (**127**) is a useful method for the synthesis of carbodiimides²¹⁸⁷ in good yields.²¹⁸⁸ The mechanism does not simply involve the addition of one molecule of isocyanate to another, since the kinetics are first order in isocyanate and first order in catalyst. The following mechanism has been proposed (the catalyst is here represented as $\text{R}_3\text{P}^+ - \text{O}^-$):²¹⁸⁹

According to this mechanism, one molecule of isocyanate undergoes addition to $\text{C}=\text{O}$, and the other addition to $\text{C}=\text{N}$. Evidence is that ^{18}O labeling experiments have shown that each molecule of CO_2 produced contains one oxygen atom derived from the isocyanate and one from **127**,²¹⁹⁰ precisely what is predicted by this mechanism. Certain other catalysts are also effective.²¹⁹¹ High load, soluble oligomeric carbodiimides have been prepared.²¹⁹²

OS V, 501.

16-94 The Conversion of Carboxylic Acid Salts to Nitriles

Nitrilo-de-oxido,oxo-tersubstitution

Salts of aliphatic or aromatic carboxylic acids can be converted to the corresponding nitriles by heating with BrCN or ClCN . Heating with acetonitrile in sulfuric acid also gave the nitrile.²¹⁹³ Despite appearances, this is not a substitution reaction. When $\text{R}^{14}\text{COO}^-$ was used, the label appeared in the nitrile, not in the CO_2 ,²¹⁹⁴ and optical activity in R was retained.²¹⁹⁵ The acyl isocyanate ($\text{RCON}=\text{C}=\text{O}$) could be isolated from the reaction

mixture; hence the following mechanism was proposed:²¹⁹⁴

C. Carbon Adding to the Carbon

The reactions in this group are cycloadditions.

16-95 The Formation of β -Lactones and Oxetanes

(2+2)OC,CC-cyclo-[oxoethylene]-1/2/addition

Aldehydes, ketones, and quinones react with ketenes to give β -lactones,²¹⁹⁶ diphenylketene being used most often.²¹⁹⁷ The reaction is catalyzed by Lewis acids, and without them most ketenes do not give adducts because the adducts decompose at the high temperatures necessary when no catalyst is used. When ketene was added to chloral (Cl_3CCHO) in the presence of the chiral catalyst (+)-quinidine, one enantiomer of the β -lactone was produced with excellent enantioselectivity.²¹⁹⁸ Enantioselective β -lactone formation was accomplished using chiral oxazaborolidines.²¹⁹⁹ The use of a chiral Al catalyst also led to β -lactones with good syn selectivity and good enantioselectivity.²²⁰⁰ Other di- and trihalo aldehydes and ketones also give the reaction enantioselectively, with somewhat lower enantioselectivity.²²⁰¹ Ketene adds to another molecule of itself:

This dimerization is so rapid that ketene does not form β -lactones with aldehydes or ketones, except at low temperatures. Other ketenes dimerize more slowly. In these cases, the major dimerization product is not the β -lactone, but a cyclobutanedione (see Reaction 15-63). However, the proportion of ketene that dimerizes to β -lactone can be increased by the addition of catalysts (e.g., triethylamine or triethyl phosphite).²²⁰² Ketene acetals [$\text{R}_2\text{C}=\text{C}(\text{OR}')_2$] add to aldehydes and ketones in the presence of ZnCl_2 to give the

corresponding oxetanes.²²⁰³

Ordinary aldehydes and ketones can add to alkenes, under the influence of UV light, to give oxetanes. Quinones also react to give spirocyclic oxetanes.²²⁰⁴ This reaction, called the *Paterno-Büchi reaction*,²²⁰⁵ is similar to the photochemical dimerization of alkenes discussed at Reaction 15-63. In general, the mechanism consists of the addition of an excited state of the carbonyl compound to the ground state of the alkene. Both singlet (S_1)²²⁰⁶ and n,π^* triplet²²⁰⁷ states have been shown to add to alkenes to give oxetanes. A diradical intermediate $\cdot\text{O}-\text{C}-\text{C}-\text{C}\cdot$ ²²⁰⁸ has been detected by spectroscopic methods.²²⁰⁹ Yields in the *Paterno-Büchi reaction* are variable, ranging from very low to fairly high (90%). The reaction can be highly diastereoselective,²²¹⁰ and allylic alcohols were shown to react with aldehydes to give an oxetane with syn selectivity.²²¹¹ There are several side reactions. When the reaction proceeds through a triplet state, it can in general be successful only when the alkene possesses a triplet energy comparable to, or higher than, the carbonyl compound; otherwise energy transfer from the excited carbonyl group to the ground-state alkene can take place (triplet-triplet photosensitization, see Sec. 7.A.vi).²²¹² In most cases, quinones react normally with alkenes, giving oxetane products, but other α,β -unsaturated ketones usually give preferential cyclobutane formation (Reaction 15-63). Aldehydes and ketones also add photochemically to allenes to give the corresponding alkylideneoxetanes and dioxaspiro compounds.²²¹³ Aldehydes add to silyl enol ethers.²²¹⁴ An intramolecular reaction of ketones was reported to give a bicyclic oxetane via

16-96 The Formation of β -Lactams

(2+2)NC,CC-cyclo-[oxoethylene]-1/2/addition

Ketenes add to imines to give β -lactams.²²¹⁶ The reaction is generally carried out with ketenes of the form $\text{R}_2\text{C}=\text{C}=\text{O}$. It has not been successfully applied to $\text{RCH}=\text{C}=\text{O}$, except when these are generated *in situ* by decomposition of a diazo ketone (the *Wolff rearrangement*, Reaction 18-8) in the presence of the imine. It has been done with ketene, but the more usual course with this reagent is an addition to the enamine tautomer of the substrate. Thioketenes²²¹⁷ ($\text{R}_2\text{C}=\text{C}=\text{S}$) give β -thiolactams.²²¹⁸ Imines also form β -lactams when treated with (1) zinc (or another metal²²¹⁹) and an α -bromo ester (*Reformatsky* conditions, 16-28),²²²⁰ or (2) the chromium carbene complexes $[(\text{CO})_5\text{Cr}=\text{C}(\text{Me})\text{OMe}]$.²²²¹ The latter method has been used to prepare optically active β -lactams.²²²² Ketenes have also been added to certain hydrazones (e.g., $\text{PhCH}=\text{NNMe}_2$) to give N-amino β -lactams.²²²³ A polymer-bound pyridinium salt facilitates β -lactam formation from carboxylic acids and imines.²²²⁴ α -Chloroimines have been used as chiral inductors in this reaction.²²²⁵

N-Tosyl imines react with ketenes, Proton Sponge (Sec. 8.A.i) and a chiral amine to give the N-tosyl β -lactam with good enantioselectivity.²²²⁶ A chiral ferrocenyl catalyst also

gives good enantioselectivity,²²²⁷ and chiral ammonium salts²²²⁸ or chiral cinchona alkaloids²²²⁹ have been used as catalysts. A catalytic amount of benzoyl quinine gives β -lactams with good enantioselectivity.²²³⁰

An intramolecular version of this ketene–imine reaction is known.²²³¹

Like the similar cycloaddition of ketenes to alkenes (Reaction **15-63**), most of these reactions probably take place by the diionic mechanism *c* (See **15-63**).²²³² β -Lactams have also been prepared in the opposite manner by the addition of enamines to isocyanates:²²³³

The reactive compound chlorosulfonyl isocyanate²²³⁴ (ClSO_2NCO) forms β -lactams even with unactivated alkenes,²²³⁵ as well as with imines,²²³⁶ allenes,²²³⁷ conjugated dienes,²²³⁸ and cyclopropenes.²²³⁹ With microwave irradiation, alkyl isocyanates also react.²²⁴⁰

α -Diazo ketones react with imines and microwave irradiation to give β -lactams.²²⁴¹ Allylic phosphonate esters react with imines, in the presence of a Pd catalyst, to give β -lactams.²²⁴² Alkynyl reagents (e.g., $\text{BuC}\equiv\text{CO}^-\text{Li}^+$) react with imines to form β -lactams.²²⁴³ Imines and benzylic halides react to give β -lactams in the presence of CO and a Pd catalyst.²²⁴⁴ Conjugated amides react with NBS and 20% sodium acetate to give an α -bromo β -lactam.²²⁴⁵ A different approach to β -lactams heated aziridines with CO and a Co catalyst.²²⁴⁶ Aziridines also react with CO and a dendrimer catalyst to such a β -lactam.²²⁴⁷

β -Thiolactams are prepared from aryl isothiocyanates.²²⁴⁸

16.B.iv. Addition to Isocyanides²²⁴⁹

Addition to $\text{R}-\text{N}^+\equiv\text{C}^-$ is not a matter of a species with an electron pair adding to one atom and a species without a pair adding to the other, as is addition to the other types of double and triple bonds in this chapter and Chapter 15. In these additions, the electrophile and the nucleophile *both add to the carbon*. No species add to the nitrogen, which, however, loses its positive charge by obtaining as an unshared pair one of the triple-bond pairs of electrons to give **128**. In most of the reactions considered below, **128** undergoes a further reaction, so the product is of the form $\text{R}-\bar{\text{N}}\text{H}-\text{CR}_3$.

**16-97 The Addition of Water to Isocyanides****1/ N,2/C-Dihydro-2/C-oxo-biaddition**

Formamides can be prepared by the acid-catalyzed addition of water to isocyanides. The mechanism is probably²²⁵⁰

The reaction has also been carried out under alkaline conditions, with hydroxide in aq dioxane.²²⁵¹ The mechanism here involves nucleophilic attack by hydroxide at the carbon atom. An intramolecular addition of an alkyne (in an ortho alkynyl phenyl isonitrile) to the carbon of an isonitrile occurred with heating in methanol to give quinoline derivatives.²²⁵²

²²⁵³ Ugi, I. *Angew. Chem. Int. Ed.* **1982**, *21*, 810; Marquarding, D.; Gokel, G.W.; Hoffmann, P.; Ugi, I. in Ugi, I. *Isonitrile Chemistry*, Academic Press, NY, **1971**, pp. 133–143; Gokel, G.W.; Lüdke, G.; Ugi, I. in Ugi, I. Ref. 936, pp. 145–199, 252–254.

When an isocyanide is treated with a carboxylic acid and an aldehyde or ketone, an α -acyloxy amide is the product in what is called the *Passerini reaction*. A SiCl_4 mediated reaction in the presence of a chiral bis(phosphoramidate) gives an α -hydroxy amide with good enantioselectivity.²²⁵⁴ There is a solvent-free *Passerini reaction*²²⁵⁵ and ionic liquids²²⁵⁶ can be used. The following mechanism has been postulated for the basic reaction:²²⁵⁷

If ammonia or an amine is also added to the mixture (in which case the reaction is known as the *Ugi reaction*, or the *Ugi four-component condensation*), the product is $\text{R}'(\text{C}=\text{C})\text{NH}-\text{C}-(\text{C}=\text{O})\text{NHR}$ [the corresponding bis(amide) from NH_3] or $\text{R}'(\text{C}=\text{C})\text{NR}'-\text{C}-(\text{C}=\text{O})\text{NHR}$ (from a primary amine R^2NH_2). There is a catalytic *three-component Ugi reaction*.²²⁵⁸ Repetitive *Ugi reactions* are known.²²⁵⁹ This product probably arises from a reaction between the carboxylic acid, the isocyanide, and the *imine* formed from the aldehyde or ketone and ammonia or the primary amine. “Isocyanide-free” *Ugi reactions* use alkyl halides/silver cyanide and KCN to generate the isocyanide *in situ*.²²⁶⁰ The use of an *N*-protected amino acid²²⁶¹ or peptide as the carboxylic acid component and/or the use of an isocyanide containing a C-protected carboxyl group allows the reaction to be used for peptide synthesis.²²⁶² Rare earth metal triflates catalyze this reaction.²²⁶³

16-99 The Formation of Metalated Aldimines

1/1/Lithio-alkyl-addition

Isocyanides that do not contain an α hydrogen react with alkyllithium compounds,²²⁶⁴ as well as with *Grignard reagents*, to give lithium (or magnesium) aldimines.²²⁶⁵ These

metalated aldimines are versatile nucleophiles and react with various substrates as follows:

The reaction therefore constitutes a method for converting an organometallic compound ($R'M$) to an aldehyde ($R'CHO$, see also, Reaction **12-33**), an α -keto acid,²²⁶⁶ a ketone $R'COR$ (see also, Reaction **12-33**), an α -hydroxy ketone, or a β -hydroxy ketone. In each case, the $C=N$ bond is hydrolyzed to a $C=O$ bond (Reaction **16-2**).

In a related reaction, isocyanides can be converted to aromatic aldimines by treatment with an iron complex followed by irradiation in benzene solution: $RNC + C_6H_6 \rightarrow PhCH=NR$.²²⁶⁷

OS VI, 751.

16.B.v. Nucleophilic Substitution at a Sulfonyl Sulfur Atom²²⁶⁸

Nucleophilic substitution at RSO_2X is similar to attack at $RCOX$. Many of the reactions are essentially the same, though sulfonyl halides are less reactive than halides of carboxylic acids.²²⁶⁹ The mechanisms²²⁷⁰ are not identical, because a “tetrahedral” intermediate in this case (**129**) would have five groups on the central atom. This is possible since sulfur can accommodate up to 12 electrons in its valence shell, but it seems more likely that these mechanisms more closely resemble the S_N2 mechanism, with a trigonal-bipyramidal transition state (**130**). There are two major experimental results leading to this conclusion.

1. The stereospecificity of this reaction is more difficult to determine than that of nucleophilic substitution at a saturated carbon, where chiral compounds are relatively easy to prepare. Recall (Sec. 4.C, category 2) that optical activity is possible in a compound of the form RSO_2X if one oxygen is ^{16}O and the other is ^{18}O . When a sulfonate ester possessing this type of chirality was converted to a sulfone by reaction with a *Grignard reagent* (**16-105**), inversion of configuration was found.²²⁷¹ This is not incompatible with an intermediate (e.g., **129**), but it is in good accord with an S_N2 -like mechanism with backside attack.

²²⁷⁰ See Gordon, I.M.; Maskill, H.; Ruasse, M. *Chem. Soc. Rev.* **1989**, 18, 123.

²²⁷¹ Sabol, M.A.; Andersen, K.K. *J. Am. Chem. Soc.* **1969**, 91, 3603. See also, Jones, M.R.; Cram, D.J. *J. Am. Chem. Soc.* **1974**, 96, 2183.

2. More direct evidence against **129** (though still not conclusive) was found in an experiment involving acidic and basic hydrolysis of aryl arenesulfonates, where it has been shown by the use of ^{18}O that an intermediate like **129** is not reversibly formed, since ester recovered when the reaction was stopped before completion contained no ^{18}O when the hydrolysis was carried out in the presence of labeled water.²²⁷²

Other evidence favoring the $\text{S}_{\text{N}}2$ -like mechanism comes from kinetics and substituent effects.²²⁷³ However, evidence for the mechanism involving **129** is that the rates did not change much with changes in the leaving group²²⁷⁴ and the ρ values were large, indicating that a negative charge builds up in the transition state.²²⁷⁵

In certain cases in which the substrate carries an α hydrogen, there is strong evidence²²⁷⁶ that at least some of the reaction takes place by an elimination–addition mechanism (E1cB , similar to the one shown in Reaction **16-69**), going through a *sulfene* intermediate,²²⁷⁷ as in the reaction between methanesulfonyl chloride and aniline.

In the special case of nucleophilic substitution at a sulfonic ester ($\text{RSO}_2\text{OR}'$), where R' is alkyl, $\text{R}'\text{—O}$ cleavage is much more likely than S—O cleavage because the OSO_2R group is such a good leaving group (Sec. 10.G.iii).²²⁷⁸ Many of these reactions have been considered previously (e.g., Reactions **10-4** and **10-10**) as nucleophilic substitutions at an alkyl carbon atom and not at a sulfur atom. However, when R' is aryl, then the S—O bond is much more likely to cleave because of the low tendency of aryl substrates for nucleophilic substitution.²²⁷⁹

The order of nucleophilicity toward a sulfonyl sulfur has been reported as $\text{OH}^- > \text{RNH}_2 > \text{N}_3 > \text{F}^- > \text{AcO}^- > \text{Cl}^- > \text{H}_2\text{O} > \text{I}^-$.²²⁸⁰ This order is similar to that at a carbonyl carbon (Sec. 10.G.ii). Both of these substrates can be regarded as relatively hard acids, compared to a saturated carbon that is considerably softer and has a different order of nucleophilicity (Sec. 10.G.ii).

Sulfonyl chlorides as well as esters and amides of sulfonic acids can be hydrolyzed to the corresponding acids. Sulfonyl chlorides can be hydrolyzed with water or with an alcohol in the absence of acid or base. Basic catalysis is also used, though of course the salt is the product obtained. Esters are readily hydrolyzed, many with water or dilute alkali. This is the same reaction as **10-4**, and usually involves R'—O cleavage, except when R' is aryl. In some cases, retention of configuration has been shown at alkyl R', indicating S—O cleavage.²²⁸¹ Sulfonamides are generally *not* hydrolyzed by alkaline treatment, not even with hot concentrated alkali. Acids, however, do hydrolyze sulfonamides, but less readily than they do sulfonyl halides or sulfonic esters. Of course, ammonia or the amine appears as the salt. However, sulfonamides can be hydrolyzed with base if the solvent is HMPA.²²⁸²

Magnesium in methanol has been used to convert sulfonate esters to the parent alcohol.²²⁸³ Likewise, $\text{CeCl}_3 \cdot 7 \text{H}_2\text{O} - \text{NaI}$ in acetonitrile converted aryl tosylates to the parent phenol derivative.²²⁸⁴

16-101 Attack by OR: Formation of Sulfonic Esters

S-Alkoxy-de-chlorination, and so on

Sulfonic esters are most frequently prepared by treatment of the corresponding sulfonyl halides with alcohols in the presence of a base.²²⁸⁵ This procedure is the most common method for the conversion of alcohols to tosylates, brosylates, and similar sulfonic esters. Both R and R' may be alkyl or aryl. The base is often pyridine or another amine, which functions as a nucleophilic catalyst,²²⁸⁶ as in the similar alcoholysis of carboxylic acyl halides (Reaction **16-61**). Primary alcohols react most rapidly, and it is often possible to sulfonate a primary OH group selectively in a molecule that also contains secondary or tertiary OH groups. The reaction with sulfonamides has been much less frequently used and is limited to *N,N*-disubstituted sulfonamides; that is, R may not be hydrogen. However, within these limits it is a useful reaction. The nucleophile in this case is actually RO^- . The R' may be hydrogen (as well as alkyl) if the nucleophile is a phenol, so that the product is RSO_2OAr . Acidic catalysts are used in this case.²²⁸⁷ Sulfonic acids have been converted directly to sulfonates by treatment with triethyl or trimethyl orthoformate $[\text{HC}(\text{OR})_3]$, without catalyst or solvent,²²⁸⁸ and with a trialkyl phosphite $[\text{P}(\text{OR})_3]$.²²⁸⁹

Mono-tosylation of a 1,2-diol was achieved using tosyl chloride and triethylamine, with a tin oxide catalyst.²²⁹⁰

16-102 Attack by Nitrogen; Formation of Sulfonamides

S-Amino-de-chlorination

Microwave assisted conversion of sulfonic acids to a 2,4,6-trichloro[1,3,5]triazine derivative is followed by formation of the sulfonamide.²²⁹¹ The treatment of sulfonyl chlorides with ammonia or amines is the usual way of preparing sulfonamides.²²⁹² Primary amines give *N*-alkyl sulfonamides, and secondary amines give *N,N*-dialkyl sulfonamides. The reaction is the basis of the *Hinsberg test* for distinguishing between primary, secondary, and tertiary amines. *N*-Alkyl sulfonamides, having an acidic hydrogen, are soluble in alkali, while *N,N*-dialkyl sulfonamides are not. Since tertiary amines are usually recovered unchanged, primary, secondary, and tertiary amines can be told apart. However, the test is limited for at least two reasons.²²⁹³ (1) Many *N*-alkyl sulfonamides in which the alkyl group has six or more carbons are insoluble in alkali, despite their acidic hydrogen,²²⁹⁴ so that a primary amine may appear to be a secondary amine. (2) If the reaction conditions are not carefully controlled, tertiary amines may not be recovered unchanged.²²⁸⁹

A primary or a secondary amine can be protected by reaction with phenacysulfonyl chloride ($\text{PhCOCH}_2\text{SO}_2\text{Cl}$) to give a sulfonamide ($\text{RNHSO}_2\text{CH}_2\text{COPh}$ or $\text{R}_2\text{NSO}_2\text{CH}_2\text{COPh}$).²²⁹⁵ The protecting group can be removed when desired with zinc and acetic acid. Sulfonyl chlorides react with azide ion to give sulfonyl azides (RSO_2N_3).²²⁹⁶ Chlorothioformates, $[\text{ROC}(=\text{S})\text{Cl}]$ react with triethylamine to give the *N,N*-diethylthioamide.²²⁹⁷

A quite different synthesis of sulfonamides treated allyltributyltin with $\text{PhI}=\text{NTs}$, in the presence of copper(II) triflate.²²⁹⁸ Another alternative method treats silyl enol ethers with sulfur dioxide, and subsequent reaction with a secondary amine gave the β -sulfonamido ester.²²⁹⁹

substrates. Cyanuric acid (2,4,6-trichloro[1,3,5]triazene) serves as a chlorinating agent.²³⁰⁰ Sulfonyl bromides and iodides have been prepared from sulfonyl hydrazides ($\text{ArSO}_2\text{NHNH}_2$), themselves prepared by Reaction **16-102** by treatment with bromine or iodine.²³⁰¹ Sulfonyl fluorides are generally prepared from the chlorides, by halogen exchange.²³⁰²

OS **I**, 84; **IV**, 571, 693, 846, 937; **V**, 196. See also, OS **VII**, 495.

16-104 Attack by Hydrogen: Reduction of Sulfonyl Chlorides

S-Hydro-de-chlorination or S -Dechlorination

Sulfinic acids can be prepared by reduction of sulfonyl chlorides. Though mostly done on aromatic sulfonyl chlorides, the reaction has also been applied to alkyl compounds. Zinc, sodium sulfite, hydrazine, sodium sulfide, and other reducing agents have been used. For reduction of sulfonyl chlorides to thiols, see Reaction **19-78**.

OS **I**, 7, 492; **IV**, 674.

16-105 Attack by Carbon: Preparation of Sulfones

S-Aryl-de-chlorination

Grignard reagents convert aromatic sulfonyl chlorides or aromatic sulfonates to sulfones. Organolithium reagents react with sulfonyl fluorides at -78°C to give the corresponding sulfone.²³⁰³ Aromatic sulfonates have been converted to sulfones with organolithium compounds,²³⁰⁴ with aryltin compounds,²³⁰⁵ with an Fe catalyst,²³⁰⁶ and with alkyl halides and Zn metal.²³⁰⁷ Vinylic and allylic sulfones have been prepared by treatment of sulfonyl chlorides with a vinylic or allylic stannane and a Pd complex catalyst.²³⁰⁸ Alkynyl sulfones can be prepared by treatment of sulfonyl chlorides with trimethylsilylalkynes, with an AlCl_3 catalyst.²³⁰⁹ Note that trifluoromethylsulfones were converted to methyl sulfones by reaction with methylmagnesium bromide.²³¹⁰

Arylboronic acids (Reaction **12-28**) react with sulfonyl chlorides in the presence of PdCl_2 to give the corresponding sulfone.²³¹¹ Arylboronic acids also react with sulfinate anions (RSO_2Na) in the presence of $\text{Cu}(\text{OAc})_2$ to give the sulfone.²³¹²

Eliminations

A so-called β -*elimination* reaction occurs when two groups are lost from adjacent atoms so that a new double¹ (or triple) bond is formed. In general, the atom bearing a leaving group is the α , and the other the β atom. In an α -elimination, both groups are lost from the same atom to give a carbene (or a nitrene):

In a γ -elimination, a three-membered ring is formed:

Some of these processes were discussed in Chapter 10. Another type of elimination involves the expulsion of a fragment from within a chain or ring ($\text{X---Y---Z} \rightarrow \text{X---Z} + \text{Y}$). Such reactions are called *extrusion reactions*. This chapter discusses β -elimination and extrusion reactions (see Sec. 2.F.vi); however, β -elimination in which both X and W are hydrogen atoms are oxidation reactions. They are treated in Chapter 19.

17.A. MECHANISMS AND ORIENTATION

β -Elimination reactions may be divided into two types: one type taking place largely in solution, the other (pyrolytic eliminations) mostly in the gas phase. In the reactions, one group leaves with its electrons and the other without (i.e., it is pulled off), the latter most

¹ See Williams, J.M.J. *Preparation of Alkenes, A Practical Approach*, Oxford Univ. Press, Oxford, **1996**.

often being hydrogen. In these cases, the former leaves as the *leaving group or nucleofuge*. For pyrolytic eliminations, there are two principal mechanisms, one pericyclic and the other a free radical pathway. A few photochemical eliminations are also known (the most important is *Norrish-type II* cleavage of ketones, Sec. 7.A.vii), but these are not generally of synthetic importance² and will not be discussed further. In most β -eliminations, the new bonds are $C=C$ or $C\equiv C$. The discussion of mechanisms is largely confined to these cases.³ Mechanisms in solution ($E2$, $E1$)⁴ and $E1cB$ are discussed first. While standard methods are used to examine elimination reactions, new techniques (e.g., the velocity map ion imaging technique) have been used to study ultrafast elimination reactions.⁵

17.A.i. The $E2$ Mechanism

In the $E2$ mechanism (elimination, bimolecular), the proton on the β carbon is pulled off by a base, leading to near-simultaneous expulsion of the leaving group (nucleofuge):

The mechanism takes place in one step and is kinetically second order: first order in substrate and first order in base. An *ab initio* study has produced a model for the $E2$ transition state geometry.⁶ The IUPAC designation is $A_{xH}D_HD_N$, or more generally (to include cases where the electrofuge is not hydrogen), $A_nD_ED_N$. It often competes with the S_N2 mechanism (Sec. 10.A.i). With respect to the substrate, the difference between the two pathways is whether the species with the unshared pair attacks the carbon (and thus acts as a nucleophile) or the hydrogen (and thus acts as a base). As in the case of the S_N2 mechanism, the leaving group may be positive or neutral and the base may be negatively charged or neutral.

Evidence for the existence of the $E2$ mechanism includes (1) the reaction displays the proper second-order kinetics; (2) when the hydrogen is replaced by deuterium in second-order eliminations, there is an isotope effect of from 3 to 8, consistent with breaking of this

bond in the rate-determining step.⁷ However, neither of these results alone could prove an E2 mechanism, since both are compatible with other mechanisms also (e.g., see E1cB, Sec. 17.A.iii). The most compelling evidence for the E2 mechanism is found in stereochemical studies.⁸

As will be illustrated in the examples below, the E2 mechanism is stereospecific: The five atoms involved (including the base) in the transition state must be in one plane. There are two ways for this to happen. The H and X may be trans to one another (**A**) with a dihedral angle of 180° , or they may be cis (**B**) with a dihedral angle of 0° .⁹ Conformation **A** is called *antiperiplanar*, and this type of elimination, in which H and X depart in opposite directions, is called *anti elimination*. Conformation **B** is *syn periplanar*, and this type of elimination, with H and X leaving in the same direction, is called *syn elimination*. Many examples of both kinds have been discovered. In the absence of special effects (discussed below), anti elimination is usually greatly favored over syn elimination, probably because **A** is a staggered conformation (Sec. 4.O.i) and the molecule requires less energy to reach this transition state than it does to reach the eclipsed transition state **B**. Solvent effects play an important role in the conformational preference. A few of the many known examples of predominant or exclusive anti elimination follow:

1. Elimination of HBr from *meso*-1,2-dibromo-1,2-diphenylethane gave *cis*-2-bromostilbene, while the (+) or (–) isomer gave the *trans*-alkene. This stereospecific result, which was obtained in 1904,¹⁰ demonstrates that in this case elimination is anti. Many similar examples have been discovered since. Obviously, this type of experiment need not be restricted to compounds that have a *meso* form. Anti elimination requires that an erythro *dl* pair (or either isomer) give the *cis* alkene, and the threo *dl* pair (or either isomer) give the *trans* isomer. This result has been found many times. Anti elimination has also been demonstrated in cases where the electrofuge is not hydrogen. In the reaction of 2,3-dibromobutane with iodide

¹⁰ Pfeiffer, P. *Z. Phys. Chem.* **1904**, *48*, 40.

ion, the two bromines are removed (**17-22**). Using iodide as a base in this manner is unusual nowadays, and common bases are discussed in several sections below, including Reaction **17-13**. In this case, the meso compound gave the trans alkene while the *dl* pair gave the cis:¹¹

- In open-chain compounds, rotation about C—C bonds usually lead to conformation in which H and X are antiperiplanar. However, in cyclic systems this is not always the case. There are nine stereoisomers of 1,2,3,4,5,6-hexachlorocyclohexane: seven meso forms and a *dl* pair (see Sec. 4.G). Four of the meso compounds and the *dl* pair) were treated with base to initiate elimination. Only one of these (**1**) has no Cl that is trans to an H. Of the other isomers, the fastest elimination rate was about three times as fast as the slowest, but the rate for **1** was 7000 times slower than that of the slowest of the other isomers.¹² This result demonstrates that anti elimination is greatly favored over syn elimination, although the latter must be taking place on **1**, but very slowly, to be sure.

- The preceding result shows that elimination of HCl in a six-membered ring proceeds best when the H and X are trans to each other. Adjacent trans groups on a six-membered ring can be diaxial or diequatorial (Sec. 4.O.ii) and the molecule is generally free to adopt either conformation, although one may have a higher energy than the other. Antiperiplanarity of the leaving group and the proton on the adjacent carbon requires that they be diaxial, even if this is the conformation of higher energy. The results with menthyl and neomenthyl chlorides are easily interpretable on this basis. Menthyl chloride has two chair conformations, **2** and **3**. Compound **3**, in which the three substituents are all equatorial, is the more stable and less reactive. The more stable chair conformation of neomenthyl chloride is **4**, in which the chlorine is axial; there are axial hydrogen atoms on both C-2 and C-4. The results are the following: neomenthyl chloride gives rapid E2 elimination and the alkene produced is predominantly **6** (**6/5** ratio is ~ 3:1) in accord with *Zaitsev's rule* (see Reaction **12-2**, Sec. 17.B). Since an axial hydrogen is available on both sides, this factor does not control the direction of elimination and *Zaitsev's rule* is free to operate. However, for menthyl chloride, elimination is much slower and the product is entirely the *anti-Zaitsev* alkene **5**. It is slow because the unfavorable

¹¹ Winstein, S.; Pressman, D.; Young, W.G. *J. Am. Chem. Soc.* **1939**, 61, 1645.

¹² Cristol, S.J.; Hause, N.L.; Meek, J.S. *J. Am. Chem. Soc.* **1951**, 73, 674.

conformation (**2**) must be achieved before elimination can take place. There is an axial hydrogen only on this side as the product must be **5**.¹³

4. Anti elimination also occurs in the formation of triple bonds, as shown by elimination from *cis*- and *trans*-HO₂C-CH=C(Cl)CO₂H. In this case, the product in both cases is HO₂CC≡CCO₂H, but the *trans* isomer reacts ~ 50 times faster than the *cis* compound.¹⁴

Some examples of syn elimination have been found in molecules where H and X could not achieve an antiperiplanar conformation.

1. The deuterated norbornyl bromide (**7**, X = Br) gave 94% of the product containing no deuterium.¹⁵ Similar results were obtained with other leaving groups and with bicyclo [2.2.2] compounds.¹⁶ In these cases the *exo* X group cannot achieve a dihedral angle of 180° with the *endo* β hydrogen because of the rigid structure of the molecule. The dihedral angle here is ~ 120°. Syn elimination with a dihedral angle of ~ 0° is clearly preferred to anti elimination where the angle is restricted to ~ 120°.

2. Molecule **8** is a particularly graphic example of the need for a planar transition state. In **8**, each Cl has an adjacent hydrogen *trans* to it, and if planarity of leaving groups were not required, anti elimination could easily take place. However, the crowding of the rest of the molecule forces the dihedral angle to be ~ 120°, and elimination of HCl from **8** is much slower than from corresponding nonbridged compounds.¹⁷ Note that syn elimination from **8** is even less likely than anti elimination. Syn elimination can take place from the *trans* isomer of **8** (dihedral angle ~ 0°); this isomer reacted about eight times faster than **8**.¹⁷

¹⁵ Kwart, H.; Takeshita, T.; Nyce, J.L. *J. Am. Chem. Soc.* **1964**, 86, 2606.

¹⁶ See Sicher, J.; Pánková, M.; Závada, J.; Kněžo, L.; Oráhovats, A. *Collect. Czech. Chem. Commun.* **1971**, 36, 3128; Bartsch, R.A.; Lee, J.G. *J. Org. Chem.* **1991**, 56, 212, 2579.

¹⁷ Cristol, S.J.; Hause, N.L. *J. Am. Chem. Soc.* **1952**, 74, 2193.

The examples given so far illustrate two points. (1) Anti elimination *requires* a dihedral angle of 180° . When this angle cannot be achieved, anti elimination is greatly slowed or prevented entirely. (2) For the simple systems so far discussed, syn elimination is not found to any significant extent unless anti elimination is greatly diminished by failure to achieve the 180° angle.

The concept of vinylogy was introduced in Section 6.B and in Reaction 10-68, category 4. Using this concept, a 1,2-elimination can be extended to give a 1,x-elimination when π bonds are incorporated between the carbon bearing the acidic proton and the leaving group (e.g., $\text{X}-\text{C}-\text{C}=\text{C}-\text{C}$, $\text{X}-\text{C}-\text{C}=\text{C}-\text{C}=\text{C}-\text{C}$ or $\text{X}-\text{C}-\text{C}\equiv\text{C}-\text{C}$).¹⁸

As noted in Section 4.Q.ii, six-membered rings are the only ones among rings of 4–13 members in which strain-free antiperiplanar conformations can be achieved. It is not surprising, therefore, that syn elimination is least common in six-membered rings. Cycloalkyltrimethylammonium hydroxides were subjected to elimination (Reaction 17-7) and the following percentages of syn elimination were found with each ring size: four-membered, 90%; five-membered, 46%; six-membered, 4% seven-membered, 31–37%.¹⁹ Note that the NMe_3^+ group has a greater tendency to syn elimination than do other common leaving groups (e.g., OTs, Cl, and Br).

Other examples of syn elimination have been found in medium-ring compounds, where both cis and trans alkenes are possible (Sec. 4.K.i). As an illustration, elimination of 1,1,4,4-tetramethyl-7-cyclodecyltrimethylammonium chloride (**9**)²⁰ gave mostly *trans*-but also some *cis*-tetramethylcyclodecenes as products. Note that *trans*-cyclodecenes, although stable, are less stable than the *cis* isomers. In order to determine the stereochemistry of the reaction, the elimination was repeated, this time using deuterated substrates. When **9** was deuterated in the *trans* position ($\text{H}_t = \text{D}$), there was a substantial isotope effect in the formation of *both* *cis* and *trans* alkenes, but when **9** was deuterated in the *cis* position ($\text{H}_c = \text{D}$), there was *no* isotope effect in the formation of either alkene. Since an isotope effect is expected for an E2 mechanism,²¹ these results indicated that *only* the *trans* hydrogen (H_t) was lost, whether the product was the *cis* or the *trans* isomer.²² This in turn means that *the cis isomer must have been formed by anti elimination and the trans isomer by syn elimination*. Anti elimination could take place from approximately the conformation shown, but for syn elimination the molecule must twist into a conformation in which the $\text{C}-\text{H}_t$ and $\text{C}-\text{NMe}_3^+$ bonds are syn periplanar. Other types of evidence have also demonstrated this remarkable result, called the syn–anti dichotomy.²³ The fact that syn

¹⁸ See Werner, C.; Hopf, H.; Dix, I.; Bubenitschek, P.; Jone, P.G. *Chemistry: European J.* **2007**, *13*, 9462.

²¹ Other possible mechanisms [e.g., E1cB, Sec. 17.A.iii or α' , β -elimination (Reaction 17-8)], were ruled out in all these cases by other evidence.

²² This conclusion has been challenged by Coke, J.L. *Sel. Org. Transform* **1972**, *2*, 269.

²³ Sicher, J.; Závada, J. *Collect. Czech. Chem. Commun.* **1967**, *32*, 2122; Závada, J.; Sicher, J. *Collect. Czech. Chem. Commun.* **1967**, *32*, 3701. For a review, see Bartsch, R.A.; Závada, J. *Chem. Rev.* **1980**, *80*, 453.

elimination in this case predominates over anti (as indicated by the formation of trans-isomer in greater amounts than cis) has been explained by conformational factors.²⁴ The syn-anti dichotomy has also been found in other medium-ring systems (8–12 membered),²⁵ although the effect is greatest for 10-membered rings. With leaving groups,²⁶ the extent of this behavior decreases in the order $^+\text{NMe}_3 > \text{OTs} > \text{Br} > \text{Cl}$, which parallels steric requirements. When the leaving group is uncharged, syn elimination is favored by strong bases and by weakly ionizing solvents.²⁷

Syn elimination and the syn-anti dichotomy have also been found in open-chain systems, although to a lesser extent than in medium-ring compounds. For example, in the conversion of 3-hexyl-4-*d*-trimethylammonium ion to 3-hexene with potassium *sec*-butoxide, $\sim 67\%$ of the reaction followed the syn-anti dichotomy.²⁸ In general, syn elimination in open-chain systems is only important in cases where certain types of steric effect are present. One such type is compounds in which substituents are found on both the β' and the γ carbons (the unprimed letter refers to the branch in which the elimination takes place). The factors that cause these results are not completely understood, but the following conformational effects have been proposed as a partial explanation.²⁹ The two anti- and two syn-periplanar conformations are, for a quaternary ammonium salt:

In order for an E2 mechanism to take place, a base must approach the proton marked *. In **C**, this proton is shielded on both sides by R and R'. In **D**, the shielding is on only one side. Therefore, when anti elimination does take place in such systems, it should give more cis product than trans. Also, when the normal anti elimination pathway is hindered sufficiently to allow the syn pathway to compete, the anti \longrightarrow trans route should be diminished more than the anti \longrightarrow cis route. When syn elimination begins to appear, it seems clear that **E**, which is less eclipsed than **F**, should be the favored pathway and syn elimination should generally give the trans-isomer. In general, deviations from the synanti dichotomy are greater on the trans side than on the cis. Thus, trans-alkenes are formed partly or mainly by syn elimination, but *cis*-alkenes are formed entirely by anti elimination.

²⁹ Chiao, W.; Saunders, Jr., W.H. *J. Am. Chem. Soc.* **1977**, 99, 6699.

Predominant syn elimination has also been found in compounds of the form $R^1R^2CHCHDNMe_3^+$, where R^1 and R^2 are both bulky.³⁰ In this case, the conformation leading to syn elimination (**H**) is also less strained than **G**, which gives anti elimination. The **G** compound has three bulky groups (including NMe_3^+) in the *gauche* position to each other.

It was mentioned above that weakly ionizing solvents promote syn elimination when the leaving group is uncharged. This is probably caused by ion pairing, which is greatest in nonpolar solvents.³¹ Ion pairing can cause syn elimination with an uncharged leaving group by means of the transition state shown in **10**. This effect was graphically illustrated by elimination from 1,1,4,4-tetramethyl-7-cyclodecyl bromide.³² The ratio of syn to anti elimination when this compound was treated with *t*-BuOK in the nonpolar benzene was 55.0. When the crown ether dicyclohexano-18-crown-6 was added (this compound selectively removes K^+ from the $t-BuO^- K^+$ ion pair and thus leaves $t-BuO^-$ as a free ion), the syn/anti ratio decreased to 0.12. Large decreases in the syn/anti ratio on addition of the crown ether were also found with the corresponding tosylate and with other nonpolar solvents.³³ However, with positively charged leaving groups the effect is reversed. Here, ion pairing *increases* the amount of anti elimination.³⁴ In this case, a relatively free base (e.g., PhO^-) can be attracted to the leaving group (see **11**), putting it in a favorable position for attack on the syn β hydrogen, while ion pairing would reduce this attraction.

It can be concluded that anti elimination is generally favored in the E2 mechanism, but that steric (inability to form the antiperiplanar transition state), conformational, ion pairing, and other factors cause syn elimination to intervene (and even predominate) in some cases.

17.A.ii. The E1 Mechanism

The E1 mechanism is a two-step process in which the rate-determining step is ionization of the substrate to give a carbocation that rapidly loses a β proton to a base, usually the solvent:

The IUPAC designation is $\text{D}_\text{N} + \text{D}_\text{E}$ (or $\text{D}_\text{N} + \text{D}_\text{H}$). This mechanism normally operates without an *added* base. Just as the E2 mechanism competes with the $\text{S}_\text{N}2$,³⁵ so the E1 mechanism competes with the $\text{S}_\text{N}1$. In fact, the first step of the E1 is exactly the same as that of the $\text{S}_\text{N}1$ mechanism. The second step differs in that the solvent pulls a proton from the β carbon of the carbocation rather than attacking it at the positively charged carbon, as in the $\text{S}_\text{N}1$ process. In a pure E1 reaction (without ion pairs, etc.), the product should be completely nonstereospecific, since bond rotation is possible in the carbocation before deprotonation.

Some of the evidence for the E1 mechanism is as follows:

1. The reaction exhibits first-order kinetics (in substrate) as expected. Of course, the solvent is not expected to appear in the rate equation, even if it were involved in the rate-determining step (Sec. 6.J.vi), but this point can be checked easily by adding a small amount of the conjugate base of the solvent. It is generally found that such an addition does not increase the rate of the reaction. If this more powerful base does not enter into the rate-determining step, it is unlikely that the solvent does. An example of an E1 mechanism with a rate-determining second step (proton transfer) has been reported.³⁶
2. If the reaction is performed on two molecules that differ only in the leaving group (e.g., $t\text{-BuCl}$ and $t\text{-BuSM}_2^+$), the rates should obviously be different, since they depend on the ionizing ability of the molecule. However, once the carbocation is formed, if the solvent and the temperature are the same, it should suffer the same fate in both cases. This means that the nature of the leaving group does not affect the second step, and *the ratio of elimination to substitution should be the same*. The compounds mentioned in the example were solvolyzed at 65.3°C in 80% aq ethanol with the following results:³⁷

³⁵ See Villano, S.M.; Eyet, N.; Lineberger, W.C.; Bierbaum, V.M. *J. Am. Chem. Soc.* **2009**, *131*, 8227.

³⁶ Baciocchi, E.; Clementi, S.; Sebastiani, G.V.; Ruzziconi, R. *J. Org. Chem.* **1979**, *44*, 32.

³⁷ Cooper, K.A.; Hughes, E.D.; Ingold, C.K.; MacNulty, B.J. *J. Chem. Soc.* **1948**, 2038.

Although the rates were greatly different (as expected with such different leaving groups), the product ratios were the same, within 1%. If this had taken place by a second-order mechanism, the nucleophile would not be expected to have the same ratio of preference for attack at the β hydrogen compared to attack at a *neutral* chloride as for attack at the β hydrogen compared to attack at a *positive* SMe_2 group.

- Many reactions carried out under first-order conditions on systems where E2 elimination is anti proceed quite readily to give alkenes where a *cis* hydrogen must be removed, often in preference to the removal of a *trans* hydrogen. For example, menthyl chloride (**2**), which by the E2 mechanism gave only **5**, under E1 conditions gave 68% **6** and 32% **5**, since the steric nature of the hydrogen is no longer a factor here, and the more stable alkene (*Zaitsev's rule*, Reaction **12-2**) is predominantly formed.
- If carbocations are intermediates, rearrangements should occur with suitable substrates. These have often been found in elimination reactions performed under E1 conditions.

E1 reactions can involve ion pairs, just as is true for $\text{S}_{\text{N}}1$ reactions (Sec. 10A.iii).³⁸ This effect is naturally greatest for nondissociating solvents: It is least in water, greater in ethanol, and greater still in acetic acid. It has been proposed that the ion-pair mechanism (Sec. 10A.iii, category 1) extends to elimination reactions too, and that the $\text{S}_{\text{N}}1$, $\text{S}_{\text{N}}2$, E1, and E2 mechanisms possess in common an ion-pair intermediate, at least occasionally.³⁹

17.A.iii. The E1cB Mechanism⁴⁰

In the E1 mechanism, X leaves first and then H is removed. In the E2 mechanism, H is removed, which triggers the expulsion of X. There is a third possibility: The H is removed first to form **12**, and then X leaves. This reaction is a two-step process, called the E1cB mechanism,⁴¹ or the *carbanion mechanism*, since the intermediate is a carbanion, (**12**). The

name E1cB comes from the fact that it is the conjugate base of the substrate that is giving up the leaving group (see the $\text{S}_{\text{N}}1\text{cB}$ mechanism, Sec. 10.G.iii, category 1). The IUPAC designation is $\text{A}_{\text{n}}\text{D}_{\text{E}} + \text{D}_{\text{N}}$ or $\text{A}_{\text{xh}}\text{D}_{\text{H}} + \text{D}_{\text{N}}$ (see Sec. 9.F). Three limiting cases can be distinguished: (1) The carbanion returns to starting material faster than it forms product: step 1 is reversible; step 2 is slow. (2) Step 1 is the slow step, and formation of product is faster than return of the carbanion to starting material. In this case, step 1 is essentially

³⁸ See Thibblin, A. *J. Am. Chem. Soc.* **1987**, 109, 2071; *J. Phys. Org. Chem.* **1989**, 2, 15.

irreversible. (3) Step 1 is rapid, and the carbanion goes slowly to product. This case occurs only with the most stable carbanions. Here, too, step 1 is essentially irreversible. These cases have been given the designations: (1) (E1cB)_R, (2) (E1cB)_I (or E1cB_{irr}), and (3) (E1)_{anion}. Their characteristics are listed in Table 17.1.⁴² Investigations of the reaction order are generally not very useful (except for case 3, which is first order), because cases 1 and 2 are second order and thus difficult or impossible to distinguish from the E2 mechanism by this procedure.⁴³ The greatest likelihood of finding the E1cB mechanism is expected in substrates that have (a) a poor nucleofuge and (b) an acidic hydrogen. In addition, most investigations have concerned such substrates. The following is some of the evidence in support of the E1cB mechanism:

1. The first step of the (E1cB)_R mechanism involves a reversible exchange of protons between the substrate and the base. In that case, if deuterium is present in the base, recovered starting material should contain deuterium. This was found to be the case in the treatment of Cl₂C=CHCl with NaOD to give ClC≡CCl. When the reaction was stopped before completion, there *was* deuterium in the recovered alkene.⁴⁴ A similar result was found for pentahaloethanes.⁴⁵ These substrates are relatively acidic. In both cases, the electron-withdrawing halogens increase the acidity of the hydrogen, and in the case of trichloroethylene there is the additional factor that a hydrogen on an *sp*² carbon is more acidic than one on an *sp*³ carbon (Sec. 8.F, category 7). Thus, the E1cB mechanism is more likely to be found in eliminations yielding triple bonds than in those giving double bonds. Another likely place for the E1cB mechanism should be in reaction of a substrate like PhCH₂CH₂Br, since the carbanion is stabilized by resonance with the phenyl group. Nevertheless, no deuterium exchange was found here.⁴⁶ If this type of evidence is a guide, then it may be inferred that the (E1cB)_R mechanism is quite rare, at least for eliminations with common leaving groups (e.g., Br, Cl, or OTs), which yield C=C double bonds.
2. When the reaction shown was carried out in water containing acetohydroxamate buffers, a plot of the rate against the buffer concentration was curved and the rate leveled off at high buffer concentrations, indicating a change in rate-determining step.⁴⁷ This rules out an E2 mechanism, which has only one step.⁴⁸ When D₂O was used instead of H₂O as solvent, there was an initial inverse solvent isotope effect of 7.7 (the highest inverse solvent isotope effect yet reported).

⁴² This table, which appears in Cockerill, A.F.; Harrison, R.G. in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 9, Elsevier, NY, **1973**, p. 161, was adapted from a longer one in Bordwell, F.G. *Acc. Chem. Res.* **1972**, 5, 374, see p. 375.

⁴³ The (E1cB)_I mechanism cannot be distinguished from E2 by this means, because it has the identical rate law: Rate = *k*[substrate][B[−]]. The rate law for (E1cB)_R is different: Rate = *k*[substrate][B[−]]/[BH], but this is often not useful because the only difference is that the rate is also dependent (inversely) on the concentration of the conjugate acid of the base, and this is usually the solvent, so that changes in its concentration cannot be measured.

That is, the reaction took place faster in D_2O than in H_2O . This is compatible only with an $E1cB$ mechanism in which the proton-transfer step is not entirely rate determining. The isotope effect arises from a partitioning of the carbanion intermediate (**12**). This intermediate either can go to product or it can revert to starting compound, which requires taking a proton from the solvent. In D_2O , the latter process is slower (because the $O-D$ bond of D_2O , cleaves less easily than the $O-H$ bond of H_2O), reducing the rate at which **12** returns to starting compound. With the return reaction competing less effectively, the rate of conversion of **12** to product is increased.

3. Substrates containing acidic hydrogen atoms and poor leaving groups are most likely to proceed by the $E1cB$ mechanism. Compounds of the type ZCH_2CH_2OPh , where Z is an electron-withdrawing group (e.g., NO_2 , SMe_2^+ , $ArSO_2$, CN , CO_2R), belong to this category, because OPh is a very poor leaving group (Sec. 10.A.iii, category 1). There is much evidence to show that the mechanism here is indeed $E1cB$.⁴⁹ Isotope effects, measured for $MeSOCD_2CH_2OPh$ and $Me_2S^+CD_2CH_2OPh$ with $NaOD$ in D_2O , are ~ 0.7 . This is compatible with an $(E1cB)_R$ mechanism, but not with an $E2$ mechanism for which an isotope effect of perhaps 5 might be expected (of course, an $E1$ mechanism is precluded by the extremely poor nucleofugal ability of OPh). The fact that k_H/k_D is less than the expected value of 1 is attributable to solvent and secondary isotope effects. Among other evidence for an $E1cB$ mechanism in these systems is that changes in the identity of Z had a dramatic effect on the relative rates: a span of 10^{11} between NO_2 and COO^- . Note that elimination from substrates of the type $RCOCH_2CH_2Y$ is the reverse of *Michael-type addition* to $C=C$ bonds. Such addition involves initial attack by a nucleophile Y and subsequent protonation (see Sec. 15.A.ii). Thus the initial loss of a proton from substrates of this type (i.e., an $E1cB$ mechanism) is in accord with the principle of microscopic reversibility.⁵⁰ It may also be recalled that benzyne formation (Sec. 13.A.iii) can occur by such a process. It has been suggested that all base-initiated eliminations wherein the proton is activated by a strong electron-withdrawing group are $E1cB$ reactions,⁵¹ but there is evidence that this is not the case when there is a good nucleofuge, the mechanism is $E2$ even when strong electron-withdrawing groups are present.⁵² On the other hand, Cl^- has been found to be a leaving group in an $E1cB$ reaction.⁵³

Of the three cases of the $E1cB$ mechanism, the one most difficult to distinguish from $E2$ is $(E1cB)_I$. One way to make this distinction is to study the effect of a change in leaving group. This was done in the case of the three acenaphthylenes (**13**), where it was found that (1) the three rates were fairly similar, the largest being

⁴⁹ Cann, P.F.; Stirling, C.J.M. *J. Chem. Soc. Perkin Trans. 2* **1974**, 820. For other examples; see Kurazawa, J.; Leffek, K.T. *Can. J. Chem.* **1977**, *55*, 1696.

only about four times that of the smallest, and (2) in compound **c** ($X = \text{Cl}$, $Y = \text{F}$), the only product contained Cl and no F (i.e., only the poorer nucleofuge F departed

while Cl remained).⁵⁴ Result (1) rules out all the E1cB mechanisms except (E1cB)₁, because the others should all have considerable leaving group effects (Table 17.1). An ordinary E2 mechanism should also have a large leaving-group effect, but an E2 mechanism with substantial carbanionic character (see Section 17.A.iv) might not. However, no E2 mechanism can explain result (2), which can be explained by the fact that an α Cl is more effective than an α F in stabilizing the planar carbanion that remains when the proton is lost. Thus (as in the somewhat similar case of aromatic nucleophilic substitution, see Sec. 13.B.ii), when X^- leaves in the second step, the one that leaves is not determined by which is the better nucleofuge, but by which has had its β hydrogen removed.⁵⁵ Additional evidence for the existence of the (E1cB)₁ mechanism was the observation of a change in the rate-determining step in the elimination reaction of *N*-(2-cyanoethyl)pyridinium ions (**14**), treated with base, when X was changed.⁵⁶ Once again, the demonstration that two steps are involved precludes the one-step E2 mechanism. Note that pyridyl systems appear to be a borderline case, and it is not obvious if the reaction involves a carbanion intermediate (E1cb, $A_{\text{XH}}D_{\text{H}} + D_{\text{N}}$) or if the reaction proceeds by concerted loss of a proton and the halide (E2, $A_{\text{N}}D_{\text{E}}D_{\text{N}}$) with attack by the base.⁵⁷

4. An example of an (E1)_{anion} mechanism has been found with the substrate **15**, which when treated with methoxide ion undergoes elimination to **17**, which is unstable under the reaction conditions and rearranges as shown.⁵⁸ Among the evidence for the proposed mechanism in this case were kinetic and isotope-effect results, as well as the spectral detection of **16**.⁵⁹

5. In many eliminations to form C=O and C≡N bonds, the initial step is loss of a positive group (normally a proton) from the oxygen or nitrogen. These may also be regarded as E1cB processes.

There is evidence that some E1cB mechanisms can involve carbanion ion pairs, for example,⁶⁰

This case is designated (E1cB)_{ip}; its characteristics are shown in Table 17.1.

17.A.iv. The E1–E2–E1cB Spectrum

In the three mechanisms so far considered, the similarities are greater than the differences. In each case, there is a leaving group that comes off with its pair of electrons and another group (usually hydrogen) that comes off without them. The only difference is in the order of the steps. It is now generally accepted that there is a spectrum of mechanisms ranging from one extreme, in which the leaving group departs well before the proton (pure E1), to the other extreme, in which the proton is removed first and then, after some time, the leaving group follows (pure E1cB). The *pure* E2 case would be somewhere in the middle, with both groups leaving simultaneously. However, most E2 reactions are not exactly in the middle, but somewhere to one side or the other. For example, the nucleofuge might depart just before the proton. This case may be described as an E2 reaction with a small amount of E1 character. The concept can be expressed by the question: In the transition state, which bond (C–H or C–X) has undergone more cleavage?⁶¹

Note that in both E1 and E2 reactions, removal of the hydrogen atom is an acid–base reaction, requiring a base. A stronger base is required for the E2, and a weaker base for E1. Further, the E1 reaction requires a solvent that facilitates ionization to a carbocation (e.g., aqueous media), whereas the E2 reaction is usually done in a protic solvent (e.g., an alcohol).

One way to determine just where a given reaction stands on the E1–E2–E1cB spectrum is to study isotope effects, which ought to tell something about the behavior of bonds in the transition state.⁶² For example, CH₃CH₂NMe₃⁺ showed a nitrogen isotope effect (k^{14}/k^{15}) of 1.017, while PhCH₂CH₂NMe₃⁺ gave a corresponding value of 1.009.⁶³ It would be expected that the phenyl group would move the reaction toward the E1cB side of the line, which means that for this compound the C–N bond is not as greatly broken in the

transition state as it is for the unsubstituted one. The isotope effect bears this out, for it shows that in the phenyl compound, the mass of the nitrogen has less effect on the reaction rate than it does in the unsubstituted compound. Similar results have been obtained with SR_2^+ leaving groups by the use of $^{32}\text{S}/^{34}\text{S}$ isotope effects⁶⁴ and with Cl ($^{35}\text{Cl}/^{37}\text{Cl}$).⁶⁵ The position of reactions along the spectrum has also been studied from the other side of the newly forming double bond by the use of H/D and H/T isotope effects,⁶⁶ although interpretation of these results is clouded by the fact that β hydrogen isotope effects are expected to change smoothly from small to large to small again as the degree of transfer of the β hydrogen from the β carbon to the base increases⁶⁷ (in Sec. 6.B, it was noted that isotope effects are greatest when the proton is half-transferred in the transition state), by the possibility of secondary isotope effects (e.g., the presence of a β deuterium or tritium may cause the leaving group to depart more slowly), and by the possibility of tunneling.⁶⁸ Other isotope-effect studies have involved labeled α or β carbon, labeled α hydrogen, or labeled base.⁵⁸

Another way to study the position of a given reaction on the spectrum involves the use of β aryl substitution. Since a positive *Hammett* ρ value is an indication of a negatively charged transition state, the ρ value for substituted β aryl groups should increase as a reaction moves from E1-to-E1cB-like along the spectrum. This has been shown to be the case in a number of studies;⁶⁹ for example, ρ values of $\text{ArCH}_2\text{CH}_2\text{X}$ increase as the leaving-group ability of X decreases. A typical set of ρ values was X = I, 2.07; Br, 2.14; Cl, 2.61; SMe_2^+ , 2.75; F, 3.12.⁷⁰ As seen previously, decreasing leaving-group ability correlates with increasing E1cB character.

Still another method measures volumes of activation.⁷¹ These are negative for E2 and positive for E1cB mechanisms. Measurement of the activation volume therefore provides a continuous scale for deciding just where a reaction lies on the spectrum.

17.A.v. The E2C Mechanism⁷²

Certain alkyl halides and tosylates undergo E2 eliminations faster when treated with such weak bases as Cl^- in polar aprotic solvents or PhS^- than with the usual E2 strong bases (e.g., RO^- in ROH).⁷³ In order to explain these results, it was proposed⁷⁴ that there is a spectrum⁷⁵ of E2 transition states in which the base can interact in the transition state with the α carbon, as well as with the β hydrogen. At one end of this spectrum is a mechanism (called E2C) in which, in the transition state, the base interacts mainly with the carbon. The

⁷⁵ This is apart from the E1-E2-E1cB spectrum.

E2C mechanism is characterized by strong nucleophiles that are weak bases. At the other extreme is the normal E2 mechanism, here called E2H to distinguish it from E2C, characterized by strong bases. Transition state **18** represents a transition state between these extremes. Additional evidence⁷⁶ for the E2C mechanism is derived from *Brønsted equation* considerations (Sec. 8.D), from substrate effects, from isotope effects, and from the effects of solvents on rates.

However, the E2C mechanism has been criticized, and it has been contended that all the experimental results can be explained by the normal E2 mechanism.⁷⁷ McLennan and Lim⁷⁸ suggested that the transition state is that shown as **19**. An ion-pair mechanism has also been proposed.⁷⁹ Although the actual mechanisms involved may be a matter of controversy, there is no doubt that a class of elimination reactions exists that is characterized by second-order attack by weak bases.⁸⁰ These reactions also have the following general characteristics:⁸¹ (1) they are favored by good leaving groups; (2) they are favored by polar aprotic solvents; (3) the reactivity order is tertiary > secondary > primary, the opposite of the normal E2 order (Sec. 17.D.i); (4) the elimination is always anti (syn elimination is not found), but in cyclohexyl systems, a diequatorial anti elimination is about as favorable as a diaxial anti elimination (unlike the normal E2 reaction, Sec. 17.A.i, categories 2,3); (5) they follow *Zaitsev's rule* (see below), where this does not conflict with the requirement for anti elimination.

17.B. REGIOCHEMISTRY OF THE DOUBLE BOND

With some substrates, a β hydrogen is present on only one carbon and (barring rearrangements) there is no doubt as to the identity of the product. For example, PhCH₂CH₂Br can give only PhCH=CH₂. However, in many other cases two or three alkenyl products are possible. In the simplest such case, a *sec*-butyl compound can give either 1- or 2-butene. There are a number of rules that enable a prediction, in many instances, of which product will predominantly form.⁸²

1. No matter the mechanism, a double bond does not go to a bridgehead carbon unless the ring sizes are large enough (*Bredt's rule*, see Sec. 4.P.iii). This means, for

⁸⁰ For convenience, these are called E2C reactions, although the actual mechanism is in dispute.

example, not only that **20** gives only **21** and not **22** (indeed **22** is not a known compound), but also that **23** does *not* undergo elimination.

- No matter the mechanism, if there is a double bond (C=C or C=O) or an aromatic ring already in the molecule that can be in conjugation with the new double bond, the conjugated product usually predominates, sometimes even when the stereochemistry is unfavorable (for an exception, see Sec. 17.C).
- In the E1 mechanism, the leaving group is gone before the choice is made as to which direction the new double bond takes. Therefore the direction is determined almost entirely by the relative stabilities of the two (or three) possible alkenes. In such cases, *Zaitsev's rule*⁸³ operates. This rule states that *the double bond goes mainly toward the most highly substituted carbon*. That is, 3-bromo-2,3-dimethylpentane gives more 2,3-dimethyl-2-pentene than either 3,4-dimethyl-2-pentene or 2-ethyl-3-methyl-1-butene. Thus *Zaitsev's rule* predicts that the alkene predominantly formed will be the one with the largest possible number of alkyl groups on the C=C carbons, and in most cases this is what is found. From heat of combustion data (see Sec. 1.L), it is known that alkene stability increases with alkyl substitution, although just why this should be is a matter of conjecture. The most common explanation is hyperconjugation. For E1 eliminations, *Zaitsev's rule* governs the orientation whether the leaving group is neutral or positive, since, as already mentioned, the leaving group is not present when the choice of direction is made. This statement does not hold for E2 eliminations, and it may be mentioned here, for contrast with later results, that E1 elimination of $\text{Me}_2\text{CHCHMeSMe}_2^+$ gave 91% of the *Zaitsev* product and 9% of the other.⁸⁴ However, there *are* cases in which the leaving group affects the direction of the double bond in E1 eliminations.⁸⁵ This may be attributed to ion pairs; that is, the leaving group is not completely gone when the hydrogen departs. *Zaitsev's rule* breaks down in cases where the non-*Zaitsev* product is more stable for steric reasons. For example, E1 or E1-like eliminations of 1,2-diphenyl-2-X-propanes ($\text{PhMeCXCH}_2\text{Ph}$) were reported to give $\sim 50\%$ $\text{CH}_2=\text{CPhCH}_2\text{Ph}$, despite the fact that the double bond of the *Zaitsev* product ($\text{PhMeC}=\text{CHPh}$) is conjugated with two benzene rings.⁸⁶
- For the anti E2 mechanism, a trans β proton is necessary; if this is available in only one direction, that is the way the double bond will form. Because of the free rotation in acyclic systems (except where steric hindrance is great), this is a factor only in cyclic systems. Where trans β hydrogen atoms are available on two or three carbons, two types of behavior are found, depending on substrate structure and the nature of the leaving group. Some compounds follow *Zaitsev's rule* and give predominant formation of the most highly substituted alkene, but others follow *Hofmann's rule*: *The double bond goes mainly toward the least highly substituted carbon*. Although many exceptions are known, the following general statements can be made: In most

⁸³ Often given the German spelling: Saytzeff, or Saytseff, or Saytzev.

cases, compounds containing uncharged nucleofuges (those that come off as negative ions) follow *Zaitsev's rule*, just as they do in E1 elimination, no matter what the structure of the substrate. However, elimination from compounds with charged nucleofuges (e.g., NR_3^+ , SR_2^+ , those that come off as neutral molecules), follow *Hofmann's rule* if the substrate is acyclic,⁸⁷ but *Zaitsev's rule* if the leaving group is attached to a six-membered ring.⁸⁸

Much work has been devoted to searching for reasons for the differences in orientation. Since *Zaitsev* orientation almost always gives the thermodynamically more stable isomer, we must explain why in some cases the less stable *Hofmann* product predominates. Three explanations have been offered for the change in orientation in acyclic systems with a change from uncharged to charged nucleofuges. The first of these⁸⁹ is that *Hofmann orientation* is caused by the fact that the acidity of the β hydrogen is decreased by the presence of the electron-donating alkyl groups. For example, under E2 conditions $\text{Me}_2\text{CHCHMeSMe}_2^+$ gives more of the

Hofmann product; it is the more acidic hydrogen that is removed by the base. Of course, the CH_3 hydrogen atoms would still be more acidic than the Me_2CH hydrogen even if a neutral leaving group were present, but the explanation presented was that acidity matters with charged and not with neutral leaving groups, because the charged groups exert a strong electron-withdrawing effect, making differences in acidity greater than they are with the less electron-withdrawing neutral groups.^{85,90} According to this, the change to a positive leaving group causes the mechanism to shift toward the E1cB end of the spectrum, where there is more $\text{C}-\text{H}$ bond breaking in the rate-determining step and where, consequently, acidity is more important. In this view, when there is a neutral leaving group, the mechanism is more E1 -like, $\text{C}-\text{X}$ bond breaking is more important, and alkene stability determines the direction of the new double bond.

The third explanation is completely different: Field effects are unimportant, and the difference in orientation is largely a steric effect caused by the fact that charged groups are usually larger than neutral ones. A CH_3 group is more open to attack than a CH_2R group and a CHR_2 group is still less easily attacked. Of course, these considerations also apply when the leaving group is neutral, but they are proposed to be much less important here because the neutral groups are smaller and do not block access to the hydrogen atoms as much. Experiments showed that *Hofmann elimination* increases with the size of the leaving group. Thus the percentage of 1-ene obtained from $\text{CH}_3\text{CH}_2\text{CH}_2\text{CHXCH}_3$ was as follows (X listed in order of

increasing size): Br, 31%; I, 30%; OTs, 48%; SMe_2^+ , 87%; SO_2Me , 89%; NMe_3^+ , 98%.⁹¹ *Hofmann elimination* was also shown to increase with increase in bulk of the substrate.⁹² With large enough compounds, *Hofmann orientation* can be obtained even with halides. *tert*-Amyl bromide gave 89% of the *Hofmann* product, for example. Even those who believe in the acidity explanations concede that these steric factors operate in extreme cases.⁹³

There is one series of results incompatible with the steric explanation that E2 elimination from the four 2-halopentanes gave the following percentages of 1-pentene: F, 83%; Cl, 37%; Br, 25%; I, 20%.⁹⁴ The same order was found for the four 2-halohexanes.⁹⁵ Although there is some doubt about the relative steric requirements of Br, Cl, and I, there is no doubt that F is the smallest of the halogens, and if the steric explanation were the only valid one, the fluoroalkanes could not give predominant *Hofmann orientation*. Another result that argues against the steric explanation is the effect of changing the nature of the base. An experiment in which the effective size of the base was kept constant while its basicity was increased (by using as bases a series of $\text{XC}_6\text{H}_4\text{O}^-$ ions) showed that the percentage of *Hofmann elimination* increased with increasing base strength, although the size of the base did not change.⁹⁶ These results are in accord with the previous explanation, since an increase in base strength moves an E2 reaction closer to the E1cB end of the spectrum. In further experiments, a large series of bases of different kinds was shown to obey linear free energy relationships between basicity and percentage of *Hofmann elimination*.⁹⁷ Certain very large bases (e.g., 2,6-di-*tert*-butyl-phenoxide) did not obey the relationships and steric effects are important in these cases. How large the base must be before steric effects are observed depends on the pattern of alkyl substitution in the substrate, but not on the nucleofuge.⁹⁸ One further result may be noted. In the gas phase, elimination of H and BrH^+ or H and ClH^+ using Me_3N as the base predominantly followed *Hofmann's rule*,⁹⁹ although BrH^+ and ClH^+ are not very large.

5. Only a few investigations on the orientation of syn E2 eliminations have been carried out, but these show that *Hofmann orientation* is greatly favored over *Zaitsev*.¹⁰⁰
6. In the E1cB mechanism, the question of orientation seldom arises because the mechanism is generally found only where there is an electron-withdrawing group in the β position, and that is where the double bond goes.

7. As already mentioned, E2C reactions show a strong preference for Zaitsev orientation.¹⁰¹ In some cases, this can be put to preparative use. For example, the compound $\text{PhCH}_2\text{CHOTsCHMe}_2$ gave $\sim 98\%$ $\text{PhCH}=\text{CHCHMe}_2$ under the usual E2 reaction conditions ($t\text{-BuOK}$ in $t\text{-BuOH}$). In this case, the double bond goes to the side with more hydrogen atoms because on that side it will be able to conjugate with the benzene ring. However, with the weak base $\text{Bu}_4\text{N}^+ \text{Br}^-$ in acetone the *Zaitsev* product ($\text{PhCH}_2\text{CH}=\text{CMe}_2$) was formed in 90% yield.¹⁰²

17.C. STEREOCHEMISTRY OF THE DOUBLE BOND

When elimination takes place on a compound of the form $\text{CH}_3\text{—CABX}$ or CHAB—CGGX , the new alkene does not have cis–trans isomerism, but for compounds of the form CHEG—CABX (E and G *not* H) (**24**) and $\text{CH}_2\text{E—CABX}$ (**25**), cis and trans isomers are possible. When the anti E2 mechanism is in operation, **24** gives the isomer

arising from trans orientation of X and H. As seen previously (Sec. 17.A.i), an erythro compound gives the cis alkene and a threo compound gives the trans. For **25**, two conformations are possible for the transition state; these lead to different isomers and often both are obtained. However, the one that predominates is often determined by an eclipsing effect.¹⁰³ For example, *Zaitsev elimination* from 2-bromopentane can occur as follows: In conformation **I**, the ethyl group is between Br and Me, while in **J** it is between Br and H. This means that **J** is more stable, and most of the elimination should occur from this conformation. This is indeed what happens, and 51% of the trans isomer is formed (with KOEt) compared to 18% of the cis (the rest is the *Hofmann* product).¹⁰⁴ These effects become larger with increasing size of groups A, B, and E.

However, eclipsing effects are not the only factors that affect the cis/trans ratio in anti E2 eliminations. Other factors are the nature of the leaving group, the base, the solvent, and the substrate. Not all of these effects are completely understood.¹⁰⁵

For E1 eliminations, if there is a free carbocation (**26**), it is free to rotate, and no matter the geometry of the original compound, the more stable situation is the one where the larger of the D—E pair is opposite the smaller of the A—B pair and the corresponding alkene should form. If the carbocation is not completely free, then to that extent, E2-type products are formed. Similar considerations apply in E1cB eliminations.¹⁰⁶

17.D. REACTIVITY

In this section, we examine the effects of changes in the substrate, base, leaving group, and medium on (1) overall reactivity, (2) E1 versus E2 versus E1cB,¹⁰⁷ and (3) elimination versus substitution.

17.D.i. Effect of Substrate Structure

1. *Effect on Reactivity.* The carbon containing the nucleofuge (X) is referred to as the α carbon and the carbon that loses the positive species (usually a proton) as the β carbon. Groups attached to the α or β carbons can exert at least four kinds of influence:
 - a. They can stabilize or destabilize the incipient double bond (both α and β groups).
 - b. They can stabilize or destabilize an incipient negative charge, affecting the acidity of the proton (β groups only).
 - c. They can stabilize or destabilize an incipient positive charge (α groups only).
 - d. They can exert steric effects (e.g., eclipsing effects) (both α and β groups).

Effects *a* and *d* can apply in all three mechanisms, although steric effects are greatest for the E2 mechanism. Effect *b* does not apply in the E1 mechanism, and effect *c* does not apply in the E1cB mechanism. Groups such as Ar and C=C increase the rate by any mechanism, except perhaps when formation of the C=C bond is not the rate-determining step, whether they are α or β (effect *a*). Electron-withdrawing groups increase the acidity when in the β position, but have little effect in the α position unless they also conjugate with the double bond. Thus Br, Cl, CN, Ts, NO₂, CN, and SR in the β position all increase the rate of E2 eliminations.

2. *Effect on E1 versus E2 versus E1cB.* The α alkyl and α aryl groups stabilize the carbocation character of the transition state, shifting the spectrum toward the E1 end. β Alkyl groups also shift the mechanism toward E1, since they *decrease* the acidity of the hydrogen. However, β aryl groups shift the mechanism the other way (toward E1cB) by stabilizing the carbanion. Indeed, as seen in Section 17.A.iii, all electron-withdrawing groups in the β position shift the mechanism toward E1cB.¹⁰⁸ α alkyl groups also increase the extent of elimination with weak bases (E2C reactions).

TABLE 17.2 The Effect of α and β Branching on the Rate of E2 Elimination and the Amount of Alkene Formed^a

Substrate	Temperature (°C)	Alkene (%)	Rate $\times 10^5$ of E2 reaction	Reference
CH ₃ CH ₂ Br	55	0.9	1.6	109
(CH ₃) ₂ CHBr	24	80.3	0.237	110
(CH ₃) ₃ Br	25	97	4.17	111
CH ₃ CH ₂ CH ₂ Br	55	8.9	5.3	109
(CH ₃) ₂ CHCH ₂ Br	55	59.5	8.5	109

^aThe reactions were between the alkyl bromide and ⁻OEt. The rate for isopropyl bromide was actually greater than that for ethyl bromide, if the temperature difference is considered. Neopentyl bromide, the next compound in the β -branching series, cannot be compared because it has no β hydrogen and cannot give an elimination product without rearrangement.

3. *Effect on Elimination versus Substitution.* Under second-order conditions, increased branching increases elimination, to the point where tertiary substrates undergo few S_N2 reactions, as seen in Chapter 10. For example, Table 17.2 shows results on some simple alkyl bromides. Similar results were obtained with SMe₂⁺ as the leaving group.¹¹¹ Two reasons can be presented for this trend. One is statistical: As α branching increases, there are usually more hydrogen atoms for the base to attack. The other is that α branching presents steric hindrance to attack of the base at the carbon. Under first-order conditions, increased α branching also increases the amount of elimination (E1 vs S_N1), although not so much, and usually the substitution product predominates. For example, solvolysis of *tert*-butyl bromide gave only 19% elimination¹¹² (cf. with Table 17.2). β Branching also increases the amount of E2 elimination with respect to S_N2 substitution (Table 17.2), not because elimination is faster, but because the S_N2 mechanism is so greatly slowed (Sec. 10.G. i). Under first-order conditions too, β branching favors elimination over substitution, probably for steric reasons.¹¹³ However, E2 eliminations from compounds with charged leaving groups are slowed by β branching. This is related to *Hofmann's rule* (Sec. 17.B, category 4). Electron-withdrawing groups in the β position not only increase the rate of E2 eliminations and shift the mechanisms toward the E1cB end of the spectrum, but also increase the extent of elimination as opposed to substitution.

Another method that compares E2 and S_N2 reactions is called the *activation-strain model*. In this model, the activation energy = activation strain + transition state interaction, and corresponds directly to the strength of the Lewis acid or base. A more basic nucleophile or base, with a higher energy HOMO, and a more acidic substrate, with a lower energy LUMO, interact more strongly.¹¹⁴ Activation strain is connected with the strength of the bonds broken: A strong C-leaving group bond has a higher activation strain and a higher barrier. Using this model, the E2 reaction has

a higher activation strain than S_N2 because two bonds are broken, and with weak bases, S_N2 dominates E2 because S_N2 has less activation strain.¹¹⁵ With strong bases, a favorable interaction of the more acidic transition state for the E2 reaction leads to a preference for E2.

17.D.ii. Effect of the Attacking Base

1. *Effect on E1 versus E2 versus E1cB.* In the E1 mechanism, an external base is generally not required: The solvent acts as the base. Hence, when external bases are added, the mechanism is shifted toward E2. Stronger bases and higher base concentrations cause the mechanism to move toward the E1cB end of the E1–E2–E1cB spectrum.¹¹⁶ However, weak bases in polar aprotic solvents can also be effective in elimination reactions with certain substrates (the E2C reaction). Normal E2 elimination has been accomplished with the following bases:¹¹⁷ H_2O , NR_3 , ^-OH , ^-OAc , ^-OR , ^-OAr , $^-NH_2$, CO_3^{2-} , $LiAlH_4$, I^- , ^-CN , and organic bases. However, the only bases of preparative importance in the normal E2 reaction are ^-OH , ^-OR , and $^-NH_2$, usually in the conjugate acid as solvent, and certain amines. Weak bases effective in the E2C reaction are Cl^- , Br^- , F^- , ^-OAc , and RS^- . These bases are often used in the form of their R_4N^+ salts.
2. *Effect on Elimination versus Substitution.* Strong bases not only benefit E2 as against E1, but also benefit elimination as against substitution. With a high concentration of strong base in a nonionizing solvent, bimolecular mechanisms are favored and E2 predominates over S_N2 . At low-base concentrations, or in the absence of base altogether, in ionizing solvents, unimolecular mechanisms are favored, and the S_N1 mechanism predominates over the E1. Chapter 10 pointed out that some species are strong nucleophiles but weak bases (Sec. 10.G.ii). The use of these obviously favors substitution, except that, as seen, elimination can predominate if polar aprotic solvents are used. It has been shown for the base cyanide that in polar aprotic solvents, the less the base is encumbered by its counterion in an ion pair (i.e., the freer the base), the more substitution is favored at the expense of elimination.¹¹⁸

17.D.iii. Effect of the Leaving Group

1. *Effect on Reactivity.* The leaving groups in elimination reactions are similar to those in nucleophilic substitution. The E2 eliminations have been performed with the following groups: $^+NR_3$, $^+PR_3$, $^+SR_2$, ^+OHR , SO_2R , OSO_2R , $OCOR$, OOH , OOR , NO_2 ,¹¹⁹ F , Cl , Br , I , and CN (*not* $^+OH_2$). The E1 eliminations have been

¹¹⁹ See Ono, N. in Feuer, H.; Nielsen, A.T. *Nitro Compounds; Recent Advances in Synthesis and Chemistry*, VCH, NY, **1990**, pp. 1–135, pp. 86–126.

carried out with: $^+\text{NR}_3$, $^+\text{SR}_2$, $^+\text{OH}_2$, ^+OHR , OSO_2R , OCOR , Cl , Br , I , and $^+\text{N}_2$.¹²⁰ However, the major leaving groups for preparative purposes are $^+\text{OH}_2$ (always by E1) and Cl , Br , I , and $^+\text{NR}_3$ (usually by E2).

2. *Effect on E1 versus E2 versus E1cB.* Better leaving groups shift the mechanism toward the E1 end of the spectrum, *since they make ionization easier*. This effect has been studied in various ways. One way already mentioned was a study of ρ values (Sec. 17.A.iv). Poor leaving groups and positively charged leaving groups shift the mechanism toward the E1cB end of the spectrum because the strong electron-withdrawing field effects increase the acidity of the β hydrogen.¹²¹ The E2C reaction is favored by good leaving groups.
3. *Effect on Elimination versus Substitution.* As seen previously (Sec. 17.A.ii), for first-order reactions the leaving group has nothing to do with the competition between elimination and substitution, since it is gone before the decision is made as to which path to take. However, where ion pairs are involved, this is not true, and results have been found where the nature of the leaving group does affect the product.¹²² In second-order reactions, the elimination/substitution ratio is not greatly dependent on a halide leaving group, although there is a slight increase in elimination in the order $\text{I} > \text{Br} > \text{Cl}$. When OTs is the leaving group, there is usually much more substitution. For example, $n\text{-C}_{18}\text{H}_{37}\text{Br}$ treated with $t\text{-BuOK}$ gave 85% elimination, while $n\text{-C}_{18}\text{H}_{37}\text{OTs}$ gave, under the same conditions, 99% substitution.¹²³ On the other hand, positively charged leaving groups increase the amount of elimination.

17.D.iv. Effect of the Medium

1. *Effect of Solvent on E1 versus E2 versus E1cB.* With any reaction a more polar environment enhances the rate of mechanisms that involve ionic intermediates. For neutral leaving groups, it is expected that E1 and E1cB mechanisms will be aided by increasing the polarity of the solvent and by increasing the ionic strength. With certain substrates, polar aprotic solvents promote elimination with weak bases (the E2C reaction).
2. *Effect of Solvent on Elimination versus Substitution.* Increasing polarity of solvent favors $\text{S}_{\text{N}}2$ reactions at the expense of E2. In the classical example, alcoholic KOH is used to effect elimination, while the more polar aq KOH is used for substitution. Charge-dispersal discussions, similar to those in Section 10.G.iv,¹²⁴ only partially explain this. In most solvents, $\text{S}_{\text{N}}1$ reactions are favored over E1. The E1 reactions compete best in polar solvents that are poor nucleophiles, especially dipolar aprotic solvents.¹²⁵ A study made in the gas phase, where there is no solvent, has shown that

when 1-bromopropane reacts with MeO^- only elimination takes place (no substitution) even with this primary substrate.¹²⁶

3. *Effect of Temperature.* Elimination is favored over substitution by increasing temperature, whether the mechanism is first or second order.¹²⁷ The reason is that the activation energies of eliminations are higher than those of substitutions (because eliminations have greater changes in bonding).

17.E. MECHANISMS AND ORIENTATION IN PYROLYTIC ELIMINATIONS

17.E.i. Mechanisms¹²⁸

Several types of compound undergo elimination on heating, with no other reagent present. Reactions of this type are often run in the gas phase. The mechanisms are obviously different from those already discussed, since all those require an external base, which may be the solvent, in one of the steps, and there is no external base or solvent present in pyrolytic elimination. Two mechanisms have been found to operate. One involves a cyclic transition state, which may be four, five, or six membered. Examples of each size are

In this mechanism, the two groups leave at about the same time and bond to each other as they are doing so. The designation is E^i in the Ingold terminology and *cyclo*- $\text{D}_\text{E}\text{D}_\text{N}\text{A}_\text{n}$ in the IUPAC system. The elimination must be syn and, for the four- and five-membered transition states, the four or five atoms making up the ring must be coplanar. Coplanarity is not required for the six-membered transition state, since there is room for the outside atoms when the leaving atoms are staggered.

As in the E_2 mechanism, it is not necessary that the $\text{C}-\text{H}$ and $\text{C}-\text{X}$ bond be broken simultaneously in the transition state. In fact, there is also a spectrum of mechanisms here, ranging from a mechanism in which $\text{C}-\text{X}$ bond breaking is a good deal more advanced

than C—H bond breaking to one in which the extent of bond breaking is virtually identical for the two bonds. Evidence for the existence of the E^i mechanism includes:

1. The kinetics are first order, so only one molecule of the substrate is involved in the reaction (i.e., if one molecule attacked another, the kinetics would be second order in substrate).¹²⁹
2. Free radical inhibitors do not slow the reactions, so no free radical mechanism is involved.¹³⁰
3. The mechanism predicts exclusive syn elimination, and this behavior has been found in many cases.¹³¹ The evidence is inverse to that for the anti E2 mechanism and generally involves the following facts: (1) an erythro isomer gives a *trans*-alkene and a threo isomer gives a *cis*-alkene; (2) the reaction takes place only when a *cis* β hydrogen is available; (3) if, in a cyclic compound, a *cis* hydrogen is available on only one side, the elimination goes in that direction. Another piece of evidence involves a pair of steroid molecules. In 3 β -acetoxy-(*R*)-5 α -methylsulfinylcholestane (**27** shows rings A and B of this compound) and in 3 β -acetoxy-(*S*)-5 α -methylsulfinylcholestane (**28**: rings A and B), the *only* difference is the configuration of oxygen and methyl about the sulfur. Yet pyrolysis of **27** gave only elimination to the 4-side (86% 4-ene), while **28** gave predominant elimination to the 6-side (65% 5-ene and 20% 4-ene).¹³² Models show that interference from the 1- and 9-hydrogen atoms causes the two groups on the sulfur to lie *in front of it* with respect to the rings, rather than behind it. Since the sulfur is a stereogenic center, this means that in **27** the oxygen is near the 4-hydrogen, while in **28** it is near the 6-hydrogen. This experiment is compatible only with syn elimination.¹³³

4. The ^{14}C isotope effects for the *Cope elimination* (17-9) show that both the C—H and C—N bonds have been extensively broken in the transition state.¹³⁴
5. Some of these reactions have been shown to exhibit negative entropies of activation, indicating that the molecules are more restricted in geometry in the transition state than they are in the starting compound.

Where a pyrolytic elimination lies on the mechanistic spectrum seems to depend mostly on the leaving group. When this is halogen, all available evidence suggests that in the transition state the C—X bond is cleaved to a much greater extent than the C—H bond; that is, there is a considerable amount of carbocation character in the transition state. This

observation is in accord with the fact that a completely nonpolar four-membered cyclic transition state violates the *Woodward–Hoffmann rules* (see the similar case of Reaction **15-63**). Evidence for the carbocation-like character of the transition state when halide is the leaving group is that relative rates are in the order $I > Br > Cl$ ¹³⁵ (see Sec. 10.G.iii), and that the effects of substituents on reaction rates are in accord with such a transition state.¹³⁶ Rate ratios for pyrolysis of some alkyl bromides at 320 °C were ethyl bromide, 1; isopropyl bromide, 280; *tert*-butyl bromide, 78,000. Also, α -phenylethyl bromide had about the same rate as *tert*-butyl bromide. On the other hand, β -phenylethyl bromide was only slightly faster than ethyl bromide.¹³⁷ This result indicates that C—Br cleavage was much more important in the transition state than C—H cleavage, since the incipient carbocation was stabilized by a alkyl and α -aryl substitution, while there was no incipient carbanion to be stabilized by β aryl substitution. These substituent effects, as well as those for other groups, are very similar to the effects found for the S_N1 mechanism and thus in very good accord with a carbocation-like transition state.

For carboxylic esters, the rate ratios were much smaller,¹³⁸ although still in the same order, so that this reaction is closer to a pure E^i mechanism, although the transition state still has some carbocationic character. Other evidence for a greater initial C—O cleavage with carboxylic esters is that a series of 1-arylethyl acetates followed σ^+ rather than σ , showing carbocationic character at the 1 position.¹³⁹ The extent of $E1$ character in the transition state increases in the following order of ester types: acetate < phenylacetate < benzoate < carbamate < carbonate.¹⁴⁰ Cleavage of xanthates (Reaction **17-5**), cleavage of sulfoxides (Reaction **17-12**), the *Cope Reaction* (**17-9**), and Reaction **17-8** are probably very close to straight E^i mechanisms.¹⁴¹

The second type of pyrolysis mechanism is completely different and involves free radicals. Initiation occurs by pyrolytic homolytic cleavage. The remaining steps may vary, and a few are shown below. Free radical mechanisms are mostly found in pyrolyses of polyhalides and of primary monohalides,¹⁴² although they also have been postulated in pyrolysis of certain carboxylic esters.¹⁴³ β -Elimination of tosyl radicals is known.¹⁴⁴ Much less is known about these mechanisms and we will not consider them further. Free radical eliminations in solution are also known, but are rare.¹⁴⁵

17.E.ii. Orientation in Pyrolytic Eliminations

As in the E1–E2–E1cB mechanistic spectrum, *Bredt's rule* applies; and if a double bond is present, a conjugated system will be preferred, if sterically possible. Apart from these considerations, the following statements can be made for Eⁱ eliminations:

1. In the absence of considerations mentioned below, orientation is statistical and is determined by the number of β -hydrogen atoms available (therefore *Hofmann's rule* is followed). For example, *sec*-butyl acetate gives 55–62% 1-butene and 38–45% 2-butene,¹⁴⁶ which is close to the 3:2 distribution predicted by the number of hydrogen atoms available.¹⁴⁷
2. A cis β hydrogen is required. Therefore in cyclic systems, if there is a cis hydrogen on only one side, the double bond will go that way. However, when there is a six-membered transition state, this does not necessarily mean that the leaving groups must be cis to each other, since such transition states need not be completely coplanar. If the leaving group is axial, then the hydrogen obviously must be equatorial (and consequently cis to the leaving group), since the transition state cannot be realized when the groups are both axial. But if the leaving group is equatorial, it can form a transition state with a β hydrogen that is either axial (hence, cis) or equatorial (hence, trans). Thus **29**, in which the leaving group is most likely axial, does not form a double bond in the direction of the carboxyl group, even though that would be conjugated, because there is no equatorial hydrogen on that side. Instead, it gives 100% **30**.¹⁴⁸ On the other hand, **31**, with an equatorial leaving group, gives $\sim 50\%$ of each alkene, even though, for elimination to the 1-ene, the leaving group must depart with a trans hydrogen.¹⁴⁹

3. In some cases, especially with cyclic compounds, the more stable alkene forms and *Zaitsev's rule* applies. For example, menthyl acetate gives 35% of the *Hofmann* product and 65% of the *Zaitsev*, even though a cis β hydrogen is present on both sides and the statistical distribution is the other way. A similar result was found for the pyrolysis of menthyl chloride.¹⁵⁰

¹⁵⁰ See Bamkole, T.; Maccoll, A. *J. Chem. Soc. B* **1970**, 1159.

4. There are also steric effects. In some cases the direction of elimination is determined by the need to minimize steric interactions in the transition state or to relieve steric interactions in the ground state.

17.E.iii. 1,4-Conjugate Eliminations¹⁵¹

1,4-eliminations of the type $\text{H}-\text{C}-\text{C}=\text{CC}-\text{X} \rightarrow \text{C}=\text{C}-\text{C}=\text{C}$ are much rarer than conjugate additions (Chapter 15), but some examples are known.¹⁵² One such is the conversion of **32** to **33**.¹⁵³

17.F. REACTIONS

Reactions in which a $\text{C}=\text{C}$ or a $\text{C}\equiv\text{C}$ bond is formed will be considered first. From a synthetic point of view, the most important reactions for the formation of double bonds are **17-1** (usually by an E1 mechanism), **17-7**, **17-13**, and **17-22** (usually by an E2 mechanism), and **17-4**, **17-5**, and **17-9** (usually by an E^{i} mechanism). The only synthetically important method for the formation of triple bonds is **17-13**.¹⁵⁴ In the second section, reactions in which $\text{C}\equiv\text{N}$ bonds and $\text{C}=\text{N}$ bonds are formed will be considered, and then eliminations that give $\text{C}=\text{O}$ bonds and diazoalkanes. Finally, extrusion reactions will be discussed.

17.F.i. Reactions in which $\text{C}=\text{C}$ and $\text{C}\equiv\text{C}$ Bonds Are Formed

A. Reactions in which Hydrogen Is Removed from One Side

In Reactions **17-1**–**17-6**, the other leaving atom is oxygen. In Reactions **17-7**–**17-11**, it is nitrogen. For reactions in which hydrogen is removed from both sides, see **19-1**–**19-6**.

17-1 Dehydration of Alcohols

Hydro-hydroxy-elimination

For a comparative study of various methods, see Mesnard, D.; Bernadou, F.; Miginiac, L. *J. Chem. Res. (S)* **1981**, 270, and references cited therein.

Dehydration of alcohols can be accomplished in several ways. Both H_2SO_4 and H_3PO_4 are common reagents, but formation of an intermediate carbocation can lead to rearrangement products and to ether formation (Reaction 10-12). If the alcohol is volatile, vapor-phase elimination over Al_2O_3 is an excellent method since side reactions are greatly reduced. This method has even been applied to such high-molecular-weight alcohols as 1-dodecanol.¹⁵⁵ Other metallic oxides (e.g., Cr_2O_3 , TiO_2 , WO_3) have been used, as have been sulfides, other metallic salts, and zeolites. The presence of an electron-withdrawing group usually facilitates elimination of water, as in the *aldol condensation* (Reaction 16-34). Similarly, 2-nitroalcohols (products of the *Henry reaction*, 16-37) give conjugated nitro compounds when heated with zeolite $\text{Y}-\text{Y}$.¹⁵⁶ Treating a 4-hydroxy lactam with DMAP and Boc anhydride leads to the conjugated lactam.¹⁵⁷ Elimination of serine derivatives to α -alkylidene amino acid derivatives was accomplished with $(\text{EtO})_2\text{POCl}$.¹⁵⁸ Another method of avoiding side reactions is the conversion of alcohols to esters, followed by pyrolysis (17-4–17-6). The ease of dehydration increases with α branching, and tertiary alcohols are dehydrated so easily with only a trace of acid that it sometimes happens even when the investigator desires otherwise. Indeed, the initial alcohol products of many base-catalyzed condensations dehydrate spontaneously after an acid workup (Chapter 16) because the new double bond can be in conjugation with one already there.

Many other dehydrating agents¹⁵⁹ have been used on occasion: P_2O_5 , I_2 , and PPh_3-I_2 ,¹⁶⁰ BF_3 -etherate, DMSO, $\text{SiO}_2-\text{Cl}/\text{Me}_3\text{SiCl}$,¹⁶¹ KHSO_4 anhydrous CuSO_4 , and phthalic anhydride, among others. Secondary and tertiary alcohols can also be dehydrated, without rearrangements, simply on refluxing in HMPA.¹⁶² With nearly all reagents, dehydration follows *Zaitsev's rule*. An exception involves the passage of hot alcohol vapors over thorium oxide at 350–450 °C, under which conditions *Hofmann's rule* is followed.¹⁶³

Transition metals can induce the dehydration of certain alcohols. β -Hydroxy ketones are converted to conjugated ketones by treatment with CeCl_3 and NaI .¹⁶⁴ In the presence of a Pd complex, alkyl cyclopropanols undergo a dehydration reaction to give a conjugated ketone.¹⁶⁵ A δ -hydroxy- α,β -unsaturated aldehyde was converted to a dienyl aldehyde with a Hf catalyst.¹⁶⁶ β -Hydroxy esters are converted to conjugated esters when treated with 2 molar equivalents of SmI_2 .¹⁶⁷ The reaction of a β -hydroxy nitrile

with MeMgCl ¹⁶⁸ or with MgO ¹⁶⁹ leads to a conjugated nitrile. In another variation of the dehydration reaction, vicinal bromohydrins are converted to alkenes upon treatment with In , InCl_3 , and a Pd catalyst.¹⁷⁰ Chlorohydrins react similarly when treated with Sm , and then diiodomethane.¹⁷¹

Carboxylic acids can be dehydrated by pyrolysis to give a ketene: $\text{RCH}_2\text{CO}_2\text{H} \rightarrow \text{RCH}=\text{C}=\text{O}$. Ketene itself is commercially prepared in this manner. Carboxylic acids have been converted to ketenes by treatment with certain reagents, including TsCl ,¹⁷² dicyclohexylcarbodiimide,¹⁷³ and 1-methyl-2-chloropyridinium iodide (*Mukaiyama's reagent*).¹⁷⁴ Analogously, amides can be dehydrated with P_2O_5 , pyridine, and Al_2O_3 to give ketenimines:¹⁷⁵

There is no way in which dehydration of alcohols can be used to prepare triple bonds: *gem*-diols and vinylic alcohols are not normally stable compounds and *vic*-diols¹⁷⁶ give either conjugated dienes or lose only 1 equiv of water to give an aldehyde or ketone. Dienes can be prepared, however, by heating alkynyl alcohols with triphenylphosphine.¹⁷⁷

When proton acids catalyze alcohol dehydration, the mechanism is E1 .¹⁷⁸ The principal process involves conversion of ROH to ROH_2^+ and cleavage of the latter to R^+ and H_2O , although with some acids a secondary process probably involves conversion of the alcohol to an inorganic ester and ionization of that ester (illustrated for H_2SO_4):

Note that these mechanisms are the reverse of those involved in the acid-catalyzed hydration of double bonds (Reaction 15-3), in accord with the principle of microscopic reversibility. With anhydrides (e.g., P_2O_5 , phthalic anhydride), as well as with some other reagents (e.g., HMPA),¹⁷⁹ it is likely that an ester is formed, and the leaving group is the conjugate base of the corresponding acid. In these cases, the mechanism can be E1 or E2 . The mechanism with Al_2O_3 and other solid catalysts has been studied extensively, but is poorly understood.¹⁸⁰

Magnesium alkoxides (formed by $\text{ROH} + \text{Me}_2\text{Mg} \rightarrow \text{ROMgMe}$) have been decomposed thermally, by heating at 195–340 °C to give the alkene, CH_4 , and MgO .¹⁸¹ Syn elimination is found and an E^i mechanism is likely. Similar decomposition of aluminum and zinc alkoxides has also been accomplished.¹⁸²

17-2 Cleavage of Ethers to Alkenes

Hydro-alkoxy-elimination

Alkenes can be formed by the treatment of ethers with very strong bases (e.g., alkylsodium or alkyllithium¹⁸³ compounds, sodium amide,¹⁸⁴ or LDA),¹⁸⁵ although there are side reactions with many of these reagents. The reaction is aided by electron-withdrawing groups in the β position, and, for example, $\text{EtOCH}_2\text{CH}(\text{COOEt})_2$ can be converted to $\text{CH}_2=\text{C}(\text{COOEt})_2$ without any base at all, but simply by heating.¹⁸⁶ *tert*-Butyl ethers are cleaved more easily than others. Several mechanisms are possible. In many cases, the mechanism is probably E1cB or on the E1cB side of the mechanistic spectrum,¹⁸⁷ since the base required is so strong, but it has been shown (by the use of PhCD_2OEt) that PhCH_2OEt reacts by the five-membered E^i mechanism.¹⁸⁸ Propargylic benzyl ethers are converted to conjugated dienes by heating with a Ru catalyst.¹⁸⁹ Ethers also have been converted to alkenes and alcohols by passing vapors over hot P_2O_5 or Al_2O_3 (this method is similar to Reaction 17-1), but this is not a general reaction.

Cyclic ethers (e.g., THF) react slowly with organolithium reagents with cleavage that produces a $\text{C}=\text{C}$ unit.¹⁹⁰ Fragmentation of 2,5-dihydrofuran with ethylmagnesium chloride and a chiral Zr catalyst leads to a chiral, homoallylic alcohol.¹⁹¹ Acetals can be converted to enol ethers (**34**) in this manner. When ketals react with 2 molar equivalents of tri-isobutylaluminum, the product is a vinyl ether.¹⁹² This can also be done at room temperature by treatment with trimethylsilyl triflate and a tertiary amine¹⁹³ or with Me_3SiI in the presence of hexamethyldisilazane.¹⁹⁴

Conversion of a carbonyl compound to an enol phosphate¹⁹⁵ or triflate¹⁹⁶ allows a subsequent elimination reaction to give an alkyne. Conversion of an aldehyde to the vinyl nonaflate (nonafluorobutane-1-sulfonyl) was followed by reaction with a phosphazene base to give the alkyne.¹⁹⁷

Enol ethers can be pyrolyzed to alkenes and aldehydes in a manner similar to that of Reaction 17-4

The rate of this reaction for $R-O-CH=CH_2$ increased in the order $Et < iPr < t-Bu$.¹⁹⁸ The mechanism is similar to that of Reaction 17-4.

17-3 The Conversion of Epoxides and Episulfides to Alkenes

epi-Oxy-elimination

Epoxides can be converted to alkenes¹⁹⁹ by treatment with triphenylphosphine²⁰⁰ or triethylphosphite $P(OEt)_3$.²⁰¹ The first step of the mechanism is nucleophilic substitution (Reaction 10-35), followed by a four-center elimination. Since inversion accompanies the substitution, the overall elimination is anti; that is, if two groups A and C are cis in the epoxide, they will be trans in the alkene:

Alternatively, the epoxide can be treated with lithium diphenylphosphide (Ph_2PLi), and the product quaternized with methyl iodide.²⁰² Alkenes have also been obtained from epoxides

by reaction with a large number of reagents,²⁰³ among them Li in THF,²⁰⁴ trimethylsilyl iodide,²⁰⁵ $\text{F}_3\text{COOH}-\text{NaI}$,²⁰⁶ and compounds of Sm,²⁰⁷ Mo, In,²⁰⁸ and the W reagents mentioned in Reaction 17-18. Some of these methods give syn elimination. Treatment of cyclooctane oxide with $\text{Ph}_3\text{P}-\text{OPPh}_3$ and NEt_3 gave cyclooctadiene.²⁰⁹ Sodium amalgam with a Co-salen complex converted epoxides to alkenes.²¹⁰

Epoxides can be converted to allylic alcohols²¹¹ by treatment with several reagents, including *sec*-butyllithium,²¹² and $i\text{Pr}_2\text{NLi}-t\text{-BuOK}$ (the *LIDAKOR reagent*).²¹³ These bases remove the proton from the adjacent carbon, leading to formation of a $\text{C}=\text{C}$ unit and opening of the epoxide to give an alkoxide. Phenyllithium reacts with epoxides in the presence of LTMP to give a *trans*-alkene.²¹⁴ Sulfur ylids (e.g., $\text{Me}_2\text{S}=\text{CH}_2$) also convert epoxides to allylic alcohols.²¹⁵ Bromomethyl epoxides react with $\text{InCl}_3/\text{NaBH}_4$ to give an allylic alcohol²¹⁶ or with $\text{Me}_3\text{S}^+\text{Br}^-$ and butyllithium to give a dienyl alcohol.²¹⁷ α,β -Epoxy ketones are converted to conjugated ketones by treatment with NaI in acetone in the presence of Amberlyst 15,²¹⁸ or with 2.5 molar equivalents of SmI_2 .²¹⁹

When an optically active reagent is used, optically active allylic alcohols can be produced from achiral epoxides.²²⁰ Sparteine and *sec*-butyllithium generate a chiral base that leads to formation of chiral allylic alcohols.²²¹ Chiral diamines react with organolithium reagents to produce chiral bases that convert epoxides to allylic alcohols with good enantioselectivity.²²² Chiral diamines with a mixture of LDA and DBU (Reactions 15-32 and 17-13) give similar results.²²³

Episulfides²²⁴ can be converted to alkenes.²²⁵ However, in this case the elimination is syn, so the mechanism cannot be the same as that for conversion of epoxides. The phosphite attacks sulfur rather than carbon. Among other reagents that convert episulfides to alkenes are certain Rh complexes,²²⁶ LiAlH_4 ²²⁷ (this compound behaves quite differently with epoxides, see Reaction 19-35), and MeI .²²⁸ Episulfoxides can be converted to alkenes and sulfur monoxide simply by heating.²²⁹

17-4 Pyrolysis of Carboxylic Acids and Esters of Carboxylic Acids

Hydro-acyloxy-elimination

Direct elimination of a carboxylic acid (decarboxylation) to an alkene has been accomplished by heating in the presence of Pd catalysts.²³⁰ Carboxylic esters that bear an alkyl group with a β hydrogen can be pyrolyzed, most often in the gas phase, to give the corresponding acid and an alkene.²³¹ No solvent is required. Since rearrangement and other side reactions are few, the reaction is synthetically very useful and is often carried out as an indirect method of accomplishing 17-1. The yields are excellent and the workup is easy. Many alkenes have been prepared in this manner. For higher alkenes (above $\sim \text{C}_{10}$) a better method is to pyrolyze the alcohol in the presence of acetic anhydride.²³²

The mechanism is E^i (see Sec. 17.E.i). Lactones can be pyrolyzed to give unsaturated acids, provided that the six-membered transition state required for E^i reactions is available (it is not for five- and six-membered lactones, but it is for larger rings²³³). Amides give a similar reaction, but require higher temperatures.

Allylic acetates give dienes when heated with certain Pd²³⁴ or Mo²³⁵ compounds.

Methyl xanthates are prepared by treatment of alcohols with NaOH and CS₂ to give RO—C(=S)—SNa, followed by treatment of this with iodomethane.²³⁶ Pyrolysis of the xanthate to give the alkene, COS, and the thiol is called the *Chugaev reaction*.²³⁷ The reaction is like **17-4**; an indirect method of accomplishing **17-2**. The temperatures required with xanthates are lower than with ordinary esters, which is advantageous because possible isomerization of the resulting alkene is minimized. The mechanism is Eⁱ, similar to that of Reaction **17-4**. For a time, there was doubt as to which sulfur atom closed the ring, but now there is much evidence, including the study of ³⁴S and ¹³C isotope effects, to show that it is the C=S sulfur (see **35**).²³⁸ In a structural variation of this reaction, heating a propargylic xanthate with 2,4,6-trimethylpyridinium trifluoromethyl sulfonate leads to formation of an alkene.²³⁹

The mechanism is thus exactly analogous to that of Reaction **17-5**.

OS **VII**, 139.

17-6 Decomposition of Other Esters

Hydro-tosyloxy-elimination

Several types of inorganic ester can be cleaved to alkenes by treatment with bases. Esters of sulfuric, sulfurous, and other acids undergo elimination in solution by E1 or E2 mechanisms, as do tosylates and other esters of sulfonic acids.²⁴⁰ It has been shown that bis(tetra-*n*-butylammonium) oxalate, (Bu₄N⁺)₂ (COO[−])₂, is an excellent reagent for inducing tosylates to undergo elimination rather than substitution.²⁴¹ Aryl sulfonates have also been cleaved without a base. Esters of 2-pyridinesulfonic acid and 8-quinolinesulfonic acid gave alkenes in high yields simply on heating, without a solvent.²⁴² Phosphonate esters have been cleaved to alkenes by treatment with *Lawesson's reagent*²⁴³ (see Reaction **16-11**).

17-7 Cleavage of Quaternary Ammonium Hydroxides

Hydro-trialkylammonio-elimination

Cleavage of quaternary ammonium hydroxides is the final step of the process known as *Hofmann exhaustive methylation* or *Hofmann degradation* or just *Hofmann elimination*.²⁴⁴ In the first step, a primary, secondary, or tertiary amine is treated with enough iodomethane to convert it to the quaternary ammonium iodide (Reaction **10-31**). In the second step, the iodide counterion is converted to the hydroxide counterion by treatment with silver oxide. In the cleavage step, an aqueous or alcoholic solution of the ammonium hydroxide is distilled, often under reduced pressure. The decomposition generally takes place between 100 and 200 °C. Alternatively, the solution can be concentrated to a syrup by distillation or freeze-drying.²⁴⁵ When the syrup is heated at low pressures, the cleavage reaction takes place at lower temperatures than are required for the reaction in the ordinary solution, probably because the base (HO^- or RO^-) is less solvated.²⁴⁶ The reaction has never been an important synthetic tool, but has been used in the determination of the structure of unknown amines, especially alkaloids. In many of these compounds, the nitrogen is in a ring, or even at a ring junction, and in such cases formation of the alkene is incomplete. Repetitions of the process are required to remove the nitrogen completely, as in the conversion of 2-methylpiperidine to 1,5-hexadiene by two rounds of exhaustive methylation followed by pyrolysis.

A side reaction involving nucleophilic substitution to give an alcohol ($\text{R}_4\text{N}^+ \text{OH}^- \rightarrow \text{ROH} + \text{R}_3\text{N}$) generally accompanies the normal elimination reaction,²⁴⁷ but seldom causes trouble. However, when none of the four groups on the nitrogen has a β hydrogen, substitution is the only reaction possible. On heating $\text{Me}_4\text{N}^+ \text{OH}^-$ in water, methanol is obtained, although without a solvent the product is not methanol, but dimethyl ether.²⁴⁸

The mechanism of elimination is usually E2 in protic solvents. *Hofmann's rule* is generally obeyed by acyclic and *Zaitsev's rule* by cyclohexyl substrates (Sec. 17.B, category 4). In certain cases, where the molecule is highly hindered or if the ammonium hydroxide is heated without solvent (neat), a five-membered E^i mechanism, similar to that in Reaction **17-8**, has been shown to operate. That is, the hydroxide in these cases does not attract the β hydrogen, but instead removes one of the methyl hydrogen atoms (see **36**), which removes a proton from the less substituted β -carbon atom to give the less substituted alkene with loss of the amine. It is also possible that the hydroxide (rather than the *N*-ylid) removes the β -hydrogen atom via an eclipsed rotamer in which the hydroxide is tethered to the ammonium unit and a syn-transition state is lower in energy.

The obvious way to distinguish between this mechanism and the ordinary E2 mechanism is by the use of deuterium labeling. For example, if the reaction is carried out on a quaternary hydroxide deuterated on the β carbon ($\text{R}_2\text{CDCH}_2\text{NMe}_3^+ \text{OH}^-$), the fate of the deuterium indicates the mechanism. If the E2 mechanism were in operation, the trimethylamine produced would contain no deuterium, which would be found only in the water. But if the mechanism is E^1 , the amine would contain deuterium. In the case of the highly hindered compound $(\text{Me}_3\text{C})_2\text{CDCH}_2\text{NMe}_3^+ \text{OH}^-$, the deuterium did appear in the amine, demonstrating an E^1 mechanism for this case.²⁴⁹ With simpler compounds, the mechanism is E2, since here the amine was deuterium-free.²⁵⁰

When the nitrogen bears more than one group possessing a β hydrogen, which group cleaves? The *Hofmann rule* says that *within* a group the hydrogen on the least alkylated carbon cleaves. This tendency is also carried over to the choice of which group cleaves: thus ethyl with three β -hydrogen atoms cleaves more readily than any longer n -alkyl group, all of which have two β -hydrogen atoms. "The β hydrogen is removed most readily if it is located on a methyl group, next from RCH_2 , and least readily from R_2CH ."²⁵¹ In fact, the *Hofmann rule* as first stated²⁵² in 1851 applied only to which group cleaved, not to the orientation within a group. The latter could not have been specified in 1851, since the structural theory of organic compounds was not formulated until 1857–1860. Of course, the *Hofmann rule* (applied to which group cleaves *or* to orientation within a group) is superseded by conjugation possibilities. Thus $\text{PhCH}_2\text{CH}_2\text{N}^+\text{Me}_2\text{Et}^- \text{OH}^-$ gives mostly styrene instead of ethylene.

Triple bonds have been prepared by pyrolysis of 1,2-bis(ammonium) salts.²⁵³

When quaternary ammonium halides are treated with strong bases (e.g., PhLi, KNH₂ in liquid NH₃²⁵⁴), an elimination can occur that is similar in products, although not in mechanism, to Reaction 17-7. This is an alternative to Reaction 17-7 and is done on the quaternary ammonium halide, so that it is not necessary to convert this to the hydroxide. The mechanism is E¹:

An α' hydrogen is obviously necessary in order for the ylid to be formed. This type of mechanism is called α',β elimination, since a β hydrogen is removed by the α' carbon. The mechanism has been confirmed by labeling experiments similar to those described at Reaction 17-7,²⁵⁵ and by isolation of the intermediate ylids.²⁵⁶ An important synthetic difference between this and most instances of Reaction 17-7 is that syn elimination is observed here and anti elimination in Reaction 17-7, so products of opposite configuration are formed when the alkene exhibits cis-trans isomerism.

An alternative procedure that avoids the use of a very strong base is heating the salt with KOH in polyethylene glycol monomethyl ether.²⁵⁷

Benzotriazole has been shown to be a good leaving group for elimination reactions. The reaction of an allylic benzotriazole (3-benzotriazolyl-4-trimethylsilyl-1-butene) with *n*-butyllithium, and then an alkyl halide leads to an alkylated 1,3-diene upon heating.²⁵⁸

17-9 Cleavage of Amine Oxides

Hydro-(Dialkyloxidoammonio)-elimination

Cleavage of amine oxides to produce an alkene and a hydroxylamine is called the *Cope reaction* or *Cope elimination* (not to be confused with the *Cope rearrangement*, 18-32). It is an alternative to Reactions 17-7 and 17-8.²⁵⁹ The reaction is usually performed with a mixture of amine and oxidizing agent (see 19-29) without isolation of the amine oxide. Because of the mild conditions, side reactions are few, and the alkenes do not usually rearrange. The reaction is thus very useful for the preparation of many alkenes. A limitation is that it does not open six-membered rings containing nitrogen, although it does open rings of 5 and 7–10 members.²⁶⁰ Rates of the reaction increase with increasing size of α - and

β -substituents.²⁶¹ The reaction can be carried out at room temperature in dry Me_2SO or THF.²⁶² The influence of solvent effects has been examined.²⁶³ The elimination is a stereoselective syn process,²⁶⁴ and the five-membered E^i mechanism operates:

Almost all evidence indicates that the transition state must be planar. Deviations from planarity as in Reaction 17-4 (see Sec. 17.E.i) are not found here, and indeed this is why six-membered heterocyclic nitrogen compounds do not react. Because of the stereoselectivity of this reaction and the lack of rearrangement of the products, it is useful for the formation of *trans*-cycloalkenes (eight-membered and higher). A polymer-bound *Cope elimination* reaction has been reported.²⁶⁵

OS IV, 612.

17-10 Pyrolysis of Keto-ylids

Hydro-(oxophosphoryl)-elimination

Phosphorus ylids are quite common (see Reaction 16-44) and keto-phosphorus ylids ($\text{RCOCH}=\text{PPh}_3$) are also known. When these compounds are heating (flash vacuum pyrolysis, FVP) to $> 500^\circ\text{C}$, alkynes are formed. Simple alkynes²⁶⁶ can be formed as well as keto-alkynes²⁶⁷ and en-yne.²⁶⁸ Rearrangement from ylids derived from tertiary amines and α -diazo ketones is also known.²⁶⁹

17-11 Decomposition of Toluene-p-sulfonylhydrazones

Treatment of the tosylhydrazone of an aldehyde or a ketone with a strong base leads to the formation of an alkene, the reaction being formally an elimination accompanied by a hydrogen shift.²⁷⁰ The reaction (called the *Shapiro reaction*) has been applied to

tosylhydrazones²⁷¹ of many aldehydes and ketones. The most useful synthetic method involves treatment of the substrate with at least 2 molar equivalents of an organolithium compound²⁷² (usually MeLi) in ether, hexane, or tetramethylenediamine.²⁷³ This procedure gives good yields of alkenes without side reactions and, where a choice is possible, predominantly gives the less highly substituted alkene. Tosylhydrazones of α,β -unsaturated ketones give conjugated dienes.²⁷⁴ The mechanism²⁷⁵ has been formulated as that shown.

Evidence for this mechanism is (1) two molar equivalents of RLi are required; (2) the hydrogen in the product comes from the water and not from the adjacent carbon, as shown by deuterium labeling;²⁷⁶ and (3) the intermediates **37**–**39** have been trapped.²⁷⁷ This reaction, when performed in tetramethylenediamine, can be a synthetically useful method²⁷⁸ of generating vinylic lithium compounds (**39**), which can be trapped by various electrophiles²⁷⁹ (e.g., D₂O, to give deuterated alkenes), CO₂ (to give α,β -unsaturated carboxylic acids, Reaction **16-30**), or DMF (to give α,β -unsaturated aldehydes, Reaction **16-82**). Treatment of *N*-aziridino hydrazones with LDA leads to alkenes with high *cis* selectivity.²⁸⁰

The reaction also takes place with other bases (e.g., NaH, LiH,²⁸¹ Na in ethylene glycol, NaNH₂) or with smaller amounts of RLi, but in these cases side reactions are common and the orientation of the double bond is in the other direction (to give the more highly substituted alkene). The reaction with Na in ethylene glycol is called the *Bamford–Stevens reaction*.²⁸² For these reactions, two mechanisms are possible: a carbenoid and a carbocation mechanism.²⁸³ The side reactions found are those expected of carbenes and carbocations. In general, the carbocation mechanism is chiefly found in protic solvents and the carbenoid mechanism in aprotic solvents. Both routes involve formation of a diazo compound (**40**), which in some cases can be isolated. In fact, this reaction has been used as a synthetic method for the preparation of diazo compounds.²⁸⁴ In the absence of protic solvents, **36** loses N₂, and hydrogen migrates, to give the alkene product. The migration of hydrogen may immediately follow, or be simultaneous with, the loss of N₂. In a protic

17-12 Cleavage of Sulfoxides, Selenoxides, and Sulfones

Hydro-alkylsulfinyl-elimination

Hydro-alkylsulfonyl-elimination

Sulfonium compounds ($-C-SR_2^+$) undergo elimination similar to that of their ammonium counterparts (Reactions 17-7 and 17-8) in scope and mechanism, but this reaction is not of great synthetic importance. These syn-elimination reactions are related to the *Cope elimination* (Reaction 17-9) and *Hofmann elimination* (Reaction 17-7).²⁸⁶

²⁸⁶ See Smith, M.B. *Organic Synthesis*, 3rd ed., Wavefunction Inc./Elsevier, Irvine, CA/London, England, **2010**, pp. 161–171.

Sulfones and sulfoxides²⁸⁷ with a β hydrogen, on the other hand, undergo elimination on treatment with an alkoxide or, for sulfones,²⁸⁸ even with hydroxide.²⁸⁹ Sulfones also eliminate in the presence of an organolithium reagent and a Pd catalyst.²⁹⁰ Mechanistically, these reactions belong on the E1–E2–E1cB spectrum.²⁹¹ Although the leaving groups are uncharged, the orientation follows *Hofmann's rule*, not *Zaitsev's*. Sulfoxides (but not sulfones) also undergo elimination upon pyrolysis at $\sim 80^\circ\text{C}$ in a manner analogous to Reaction 17-9. The mechanism is also analogous, being the five-membered Eⁱ mechanism with syn elimination.²⁹²

Selenoxides²⁹³ and sulfinate esters ($\text{R}_2\text{CH}-\text{CHR}-\text{SO}-\text{OMe}$)²⁹⁴ also undergo elimination by the Eⁱ mechanism, and the selenoxide reaction takes place at room temperature. The reaction with selenoxides has been extended to the formation of triple bonds.²⁹⁵

Both α -keto selenoxides²⁹⁶ and sulfoxides²⁹⁷ have been used in a method for the conversion of ketones, aldehydes, and carboxylic esters to their α,β -unsaturated derivatives. Allylic sulfoxides undergo 1,4-elimination to give dienes.²⁹⁸

A radical elimination reaction generates alkenes from sulfoxides. The reaction of a 2-bromophenyl alkylsulfoxide with Bu_3SnH and AIBN (see Sec. 14.A.i for a discussion of these standard radical conditions) leads to an alkene.²⁹⁹

OS VI, 23, 737; VIII, 543; IX, 63.

17-13 Dehydrohalogenation of Alkyl Halides

Hydro-halo-elimination

The elimination of HX from an alkyl halide is a very general reaction and can be accomplished with chlorides, fluorides, bromides, and iodides.³⁰⁰ Hot alcoholic KOH is the

most frequently used base, although stronger bases³⁰¹ (^-OR , $^-\text{NH}_2$, etc.) or weaker ones (e.g., amines) are used where warranted.³⁰² The bicyclic amidines 1,5-diazabicyclo[3.4.0]non-5-ene (DBN)³⁰³ and DBU³⁰⁴ are good reagents for difficult cases.³⁰⁵ Solvation by HMPA promotes LDA mediated dehydrobromination.³⁰⁶

Dehydrohalogenation with the non-ionic base $(\text{Me}_2\text{N})_3\text{P}=\text{N}-\text{P}(\text{NMe}_3)_2=\text{NMe}$ is even faster.³⁰⁷ A Co catalyst with dimethylphenylsilylmethylmagnesium chloride leads to formation of terminal alkenes from 2° alkyl bromides.³⁰⁸ Phase-transfer catalysis has been used with hydroxide as base.³⁰⁹ As previously mentioned (Sec. 17.A.v), certain weak bases in dipolar aprotic solvents are effective reagents for dehydrohalogenation. Among those most often used for synthetic purposes are LiCl or LiBr-LiCO₃ in DMF.³¹⁰ Dehydrohalogenation occurs by simply heating the alkyl halide in HMPA with no other reagent present.³¹¹ As in nucleophilic substitution (Sec. 10.G.iii), the order of leaving group reactivity is $\text{I} > \text{Br} > \text{Cl} > \text{F}$.³¹² Tertiary halides undergo elimination most easily. Eliminations of chlorides, bromides, and iodides follow *Zaitsev's rule*, except for a few cases where steric effects are important (e.g., see Sec. 17.B, category 4). Eliminations of fluorides follow *Hofmann's rule* (Sec. 17.B, category 4).

This reaction is by far the most important way of introducing a triple bond into a molecule.³¹³ Alkyne formation can be accomplished with substrates of the types:³¹⁴

When the base is NaNH_2 , 1-alkynes predominate (where possible), because this base is strong enough to form the salt of the alkyne, shifting any equilibrium between 1- and

2-alkynes. When the base is ^-OH or ^-OR , the equilibrium tends to be shifted to the internal alkyne, which is thermodynamically more stable. If another hydrogen is suitably located (e.g., $-\text{CRH}-\text{CX}_2-\text{CH}_2-$), allene formation can compete, although alkynes are usually more stable. Tetrabutylammonium fluoride mediates the dehydrobromination of vinyl bromide to terminal alkynes.³¹⁵ Treatment of 1,1-dibromo-1-alkenes with a Pd-catalyst, followed by reaction with tetrabutylammonium hydroxide gives an internal alkyne.³¹⁶

1,1-Dibromoalkenes are converted to alkynes when treated with *n*-butyllithium.³¹⁷ This transformation is a modification of the *Fritsch–Buttenberg–Wiechell rearrangement* in which a 1,1-diaryl vinyl bromide (**42**) gives a diaryl alkyne upon treatment with base.³¹⁸ Vinyl sulfoxides that contain a leaving group (e.g., chloride) on the double bond react with *tert*-butyllithium to give a lithio alkyne, and hydrolysis leads to the final product, an alkyne.

Dehydrohalogenation is generally carried out in solution, with a base, and the mechanism is usually E2, although the E1 mechanism has been demonstrated in some cases. However, elimination of HX can be accomplished by pyrolysis of the halide, in which case the mechanism is Eⁱ (Sec. 17.E.i) or, in some instances, the free radical mechanism (Sec. 17.E.i). Pyrolysis is normally performed without a catalyst at $\sim 400^\circ\text{C}$. The pyrolysis reaction is not generally useful synthetically, because of its reversibility. Less work has been done on pyrolysis with a catalyst³¹⁹ (usually a metallic oxide or salt), but the mechanisms here are probably E1 or E2.

In the special case of the prochiral carboxylic acids (**43**), dehydrohalogenation with an optically active lithium amide gave an optically active product with %ee as high as 82%.³²⁰

17-14 Dehydrohalogenation of Acyl Halides and Sulfonyl Halides

Hydro-halo-elimination

Ketenes can be prepared by treatment of acyl halides with tertiary amines³²¹ or with NaH and a crown ether.³²² The scope is broad, and most acyl halides possessing an α hydrogen give the reaction, but if at least one R is hydrogen, only the ketene dimer, not the ketene, is isolated. However, if a reactive ketene must be used in a reaction with a given compound, the ketene can be generated *in situ* in the presence of the given compound.³²³

Closely related is the reaction of tertiary amines with sulfonyl halides that contain an α hydrogen. In this case, the initial product is the highly reactive sulfene, which cannot be isolated but reacts further to give products, one of which may be the alkene that is the dimer of RCH.³²⁴ Reactions of sulfenes *in situ* are also common (e.g., see 16-48).

OS IV, 560; V, 294, 877; VI, 549, 1037; VII, 232; VIII, 82.

17-15 Elimination of Boranes

Hydro-boranetriyl-elimination

Trialkylboranes are formed from an alkene and BH_3 (Reaction 15-16). When the resulting borane is treated with another alkene, an exchange reaction occurs.³²⁵ This is an equilibrium process that can be shifted by using a large excess of alkene, by using an unusually reactive alkene, or by using an alkene with a higher boiling point than the displaced alkene and removing the latter by distillation. The reaction is useful for shifting a double bond in the direction opposite to that resulting from normal isomerization methods (12-2). This cannot be accomplished simply by treatment of a borane with an alkene, because elimination in this reaction follows *Zaitsev's rule*: It is in the direction of the most stable alkene. However, heating borane (44) leads to 45 (Reaction 18-11) and when 45 is heated with a higher-boiling alkene (e.g., 1-decene), the exchange reaction gives 46. These isomerizations proceed essentially without rearrangement. The mechanism is probably the reverse of borane addition (Reaction 15-16).

A similar reaction, but irreversible, has been demonstrated for alkynes.³²⁶

17-16 Conversion of Alkenes to Alkynes

Hydro-methyl-elimination

Alkenes of the form shown lose the elements of methane when treated with sodium nitrite in acetic acid and water, to form alkynes in moderate-to-high yields.³²⁷ The R may contain additional unsaturation, as well as OH, OR, OAc, C=O, and other groups, but the $\text{Me}_2\text{C}=\text{CHCH}_2-$ portion of the substrate is necessary for the reaction to take place. The mechanism is complex, beginning with a nitration that takes place with allylic rearrangement [$\text{Me}_2\text{C}=\text{CHCH}_2\text{R} \rightarrow \text{H}_2\text{C}=\text{CMeCH}(\text{NO}_2)\text{CH}_2\text{R}$], and involving several additional intermediates.³²⁸ The CH_3 lost from the substrate appears as CO_2 , as demonstrated by the trapping of this gas.³²⁸

17-17 Decarbonylation of Acyl Halides or Aldehydes

Hydro-chloroformyl-elimination

Acyl chlorides containing an α hydrogen are smoothly converted to alkenes, with loss of HCl and CO, upon heating with chlorotris(triphenylphosphine)rhodium, with metallic Pt, or with certain other catalysts.³²⁹ The mechanism probably involves conversion of $\text{RCH}_2\text{CH}_2\text{COCl}$ to $\text{RCH}_2\text{CH}_2-\text{RhCO}(\text{Ph}_3\text{P})_2\text{Cl}_2$ followed by a concerted syn elimination of Rh and H^{330} (see also, Reactions **14-32** and **19-12**).

Aldehydes are decarbonylated to give the corresponding hydrocarbon in the presence of an Ir catalyst and triphenylphosphine.

B. Reactions in which Neither Leaving Atom Is Hydrogen

17-18 Deoxygenation of Vicinal Diols

Dihydroxy-elimination

vic-Diols can be deoxygenated by treatment of the dilithium dialkoxide with the tungsten halide (K₂WCl₆), or with certain other tungsten reagents, in refluxing THF.³³¹ Tetrasubstituted diols react most rapidly. The elimination is largely, but not entirely, syn. Several other methods have been reported,³³² in which the diol is deoxygenated directly, without conversion to the dialkoxide. These include treatment with Ti metal,³³³ with TsOH—NaI,³³⁴ and by heating with CpReO₃,³³⁵ where Cp is cyclopentadienyl.

vic-Diols can also be deoxygenated indirectly, through sulfonate ester derivatives. For example, *vic*-dimesylates and *vic*-ditosylates have been converted to alkenes by treatment, respectively, with naphthalene—sodium³³⁶ and with NaI in DMF.³³⁷ In another procedure, the diols are converted to bis(dithiocarbonates) [bis(xanthates)], which undergo elimination (probably by a free radical mechanism) when treated with tri-*n*-butylstannane in toluene or benzene.³³⁸ *vic*-Diols can also be deoxygenated through cyclic derivatives (Reaction 17-19).

17-19 Cleavage of Cyclic Thionocarbonates

Cyclic thionocarbonates (**47**) can be cleaved to alkenes (the *Corey–Winter reaction*)³³⁹ by heating with trimethyl phosphite³⁴⁰ or other trivalent phosphorus compounds³⁴¹ or by treatment with bis(1,5-cyclooctadiene)nickel.³⁴² The thionocarbonates (e.g., **47**) can be

prepared by treatment of 1,2-diols with thiophosgene and DMAP.³⁴³ The elimination is of course syn, so the product is sterically controlled. Alkenes that are not sterically favored can be made this way in high yield (e.g., *cis*-PhCH₂CH=CHCH₂Ph).³⁴⁴ Certain other five-membered cyclic derivatives of 1,2-diols can also be converted to alkenes.³⁴⁵

17-20 The Ramberg–Bäcklund Reaction

Ramberg–Bäcklund halosulfone transformation

The reaction of an α -halo sulfone with a base to give an alkene is called the *Ramberg–Bäcklund reaction*.³⁴⁶ The reaction is quite general for α -halo sulfones with an α' hydrogen, despite the unreactive nature of α -halo sulfones in normal S_N2 reactions (Sec. 10.G.i, category 6). Halogen reactivity is in the order I > Br \gg Cl. Phase-transfer catalysis has been used.³⁴⁷ In general, mixtures of *cis* and *trans* isomers are obtained, but usually the less stable *cis* isomer predominates. The mechanism involves formation of an episulfone, and then elimination of SO₂. There is much evidence for this mechanism,³⁴⁸

including the isolation of the episulfone intermediate,³⁴⁹ and also the preparation of episulfones in other ways and the demonstration that they give alkenes under the reaction conditions faster than the corresponding α -halo sulfones.³⁵⁰ Episulfones synthesized in other ways (e.g., Reaction 16-48) are reasonably stable compounds, but eliminate SO₂ to give alkenes when heated or treated with base.

If the reaction is run on the unsaturated bromosulfones (RCH₂CH=CHSO₂CH₂Br, prepared by reaction of BrCH₂SO₂Br with RCH₂CH=CH₂ followed by treatment with Et₃N), RCH=CHCH=CH₂ is produced in moderate-to-good yields.³⁵¹ The compound mesyltriflone (CF₃SO₂CH₂SO₂CH₃) can be used as a synthon for the tetraion ²⁻C=C²⁻. Successive alkylation (Reaction 10-67) converts it to CF₃SO₂CR¹R²SO₂CHR³R⁴

(anywhere from one to four alkyl groups can be put in), which, when treated with base, gives $R^1R^2C=CR^3R^4$.³⁵² The nucleofuge here is the $CF_3SO_2^-$ ion. There is an example of a *Ramberg–Bäcklund reaction* that is induced by a *Michael addition*.³⁵³

2,5-Dihydrothiophene-1,1-dioxides (**48**) and 2,17-dihydrothiepin-1,1-dioxides (**49**) undergo analogous 1,4- and 1,6-eliminations, respectively (see also, Reaction **17-36**). These are concerted reactions and, as predicted by the orbital-symmetry rules (Reaction **15-50**, A, and immediately preceding pages), the former³⁵⁴ is a suprafacial process and the latter³⁵⁵ an antarafacial process. The rules also predict that elimination of SO_2 from episulfones cannot take place by a concerted mechanism (except antarafacially, which is unlikely for such a small ring), and evidence shows that this reaction occurs by a nonconcerted pathway.³⁵⁶ The eliminations of SO_2 from **48** and **49** are examples of *cheletropic reactions*,³⁵⁷ which are defined as reactions in which two σ bonds that terminate at a single atom (in this case the sulfur atom) are made or broken in concert.³⁵⁸

α,α -Dichlorobenzyl sulfones (**50**) react with an excess of the base triethylenediamine (TED) in DMSO at room temperature to give 2,3-diarylthiiren-1,1-dioxides (**51**), which can be isolated.³⁵⁹ Thermal decomposition of **51** gives the alkynes **52**.³⁶⁰

A *Ramberg–Bäcklund-type reaction* has been carried out on the α -halo sulfides ($ArCHClSCH_2Ar$), which react with *t*-BuOK and PPh_3 in refluxing THF to give the alkenes ($ArCH=CHAr$).³⁶¹ Cyclic sulfides lead to ring-contracted cyclic alkenes upon treatment with NCS in CCl_4 followed by oxidation with *m*-chloroperoxybenzoic acid.³⁶²

17-21 The Conversion of Aziridines to Alkenes

epi-Imino-elimination

Aziridines not substituted on the nitrogen atom react with nitrous acid to produce alkenes.³⁶³ An *N*-nitroso compound is an intermediate (Reaction 12-50); other reagents that produce such intermediates also give alkenes. The reaction is stereospecific: *cis*-aziridines give *cis*-alkenes and *trans*-aziridines give *trans*-alkenes.³⁶⁴ Aziridines carrying *N*-alkyl substituents can be converted to alkenes by treatment with ferrous iodide³⁶⁵ or with *m*-chloroperoxybenzoic acid.³⁶⁶ An *N*-oxide intermediate (Reaction 19-29) is presumably involved in the latter case. *N*-Tosylaziridines give allylic sulfonamides when treated with butyllithium.³⁶⁷ *N*-Tosyl aziridines are converted to *N*-tosyl imines when treated with boron trifluoride.³⁶⁸ 2-Tosylmethyl *N*-tosylaziridines react with Te^{2-} in the presence of Adogen 464 to give allylic *N*-tosyl amines.³⁶⁹ 2-Halomethyl *N*-tosyl aziridines also react with In metal in methanol to give *N*-tosyl allylic amines.³⁷⁰

17-22 Elimination of Vicinal Dihalides

Dihalo-elimination

Dehalogenation has been accomplished with many reagents, the most common being Zn, Mg, and iodide ion.³⁷¹ Heating in HMPA is often enough to convert a *vic*-dibromide to an alkene.³⁷² Among reagents used less frequently have been phenyllithium, phenylhydrazine, CrCl_2 , Na_2S in DMF,³⁷³ and LiAlH_4 .³⁷⁴ Electrochemical reduction has also

³⁷⁴ For a lists of reagents, with references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley–VCH, NY, **1999**, pp. 259–263.

been used.³⁷⁵ Treatment with In³⁷⁶ or Sm³⁷⁷ metal in methanol, InCl₃/NaBH₄,³⁷⁸ heating with Zn in acetic acid,³⁷⁹ or reaction of a *Grignard reagent* and Ni(dppe)Cl₂ (dppe = 1,2-diphenylphosphinoethane).³⁸⁰ When the reagent is Zn, antistereospecificity has been observed in some cases,³⁸¹ but not in others.³⁸² Microwave irradiation of a *vic*-dibromide in an ionic liquid leads to the alkene.³⁸³ The reaction of a vicinal dibromide with triethylamine and DMF with microwave irradiation leads to vinyl bromide.³⁸⁴ α,β -Dibromo amides are converted to conjugated amides upon photolysis in methanol.³⁸⁵

One useful feature of this reaction is that there is no doubt about the *position* of the new double bond, so that it can be used to give double bonds exactly where they are wanted. For example, allenes, which are not easily prepared by other methods, can be prepared from X—C—CX₂—C—X or X—C—CX=C— systems.³⁸⁶ Cumulenes have been obtained from 1,4-elimination:

Cumulenes have also been prepared by treating alkynyl epoxides with boron trifluoride.³⁸⁷ 1,4-Elimination of BrC—C=C—CBr has been used to prepare conjugated dienes C=C—C=C.³⁸⁸ Allenes are formed by heating propargylic alcohols with arylboronic acids (Reaction 12-28) and a Pd catalyst.³⁸⁹ Allenes are also formed from propargylic amines using a CuI and a Pd catalyst.³⁹⁰ In addition, allenenes are formed from lithium bromocyclopropylidenoids.³⁹¹

The reaction can be carried out for any combination of halogens, except where one is fluorine. Mechanisms are often complex and depend on the reagent and reaction conditions.³⁹² For different reagents, mechanisms involving carbocations, carbanions, and free radical intermediates, as well as concerted mechanisms, have been proposed.

17-23 Dehalogenation of α -Halo Acyl Halides

Dihalo-elimination

Ketenes can be prepared by dehalogenation of α -halo acyl halides with zinc or with triphenylphosphine.³⁹³ The reaction generally gives good results when the two R groups are aryl or alkyl, but not when either one is hydrogen.³⁹⁴

OS IV, 348; VIII, 377.

17-24 Elimination of a Halogen and a Hetero Group

Alkoxy-halo-elimination

The elimination of OR and halogen from β -halo ethers is called the *Boord reaction*. It can be carried out with Zn, Mg, Na, or certain other reagents.³⁹⁵ The yields are high and the reaction is of broad scope. β -Halo acetals readily yield vinylic ethers, $\text{X}-\text{C}-\text{C}(\text{OR})_2 \rightarrow \text{C}=\text{C}-\text{OR}$ and 2 molar equivalents of SmI_2 in HMPA is effective.³⁹⁶ Besides β -halo ethers, the reaction can also be carried out on compounds of the formula $\text{Z}-\text{C}-\text{C}-\text{Z}$ where X is halogen and Z is OCOR, OTs,³⁹⁷ NR_2 ,³⁹⁸ or SR.³⁹⁹ When $\text{X} = \text{Cl}$ and $\text{Z} = \text{OAc}$, heating in THF with an excess of SmI_2 followed by treatment with dilute aq HCl gives an alkene.⁴⁰⁰ When $\text{Z} = \text{I}$ and the other Z is an oxygen of an oxazolone (a carbamate unit), heating with In metal in methanol leads to an allylic amine.⁴⁰¹ The Z group may also be OH, but then X is limited to Br and I.⁴⁰² Like Reaction 17-22, this method ensures that the new double bond will be in a specific position. The fact that Mg causes elimination in these cases limits the preparation of *Grignard reagents* from these compounds. It has been shown that treatment of β -halo ethers and esters with Zn gives nonstereospecific elimination,⁴⁰³ so the mechanism was not E2. An E1cB mechanism was postulated because of the poor leaving-group ability of OR and OCOR. Bromohydrins can be converted to alkenes (elimination of Br, OH) in high yields by treatment with $\text{LiAlH}_4\text{-TiCl}_3$.⁴⁰⁴

17.F.ii. Fragmentations

When carbon is the positive leaving group (the electrofuge) in an elimination, the reaction is called *fragmentation*.⁴⁰⁵ These processes occur on substrates of the form $W-C-C-X$, where X is a normal nucleofuge (e.g., halogen, OH_2^+ , OTs, NR_3^+) and W is a positive-carbon electrofuge. In most of the cases, W is $HO-C-$ or R_2N-C- , so that the positive charge on the carbon atom is stabilized by the unshared pair of the oxygen or nitrogen, for example,

The mechanisms are mostly E1 or E2. We will discuss only a few fragmentations, since many are possible and not much work has been done on most of them. Reactions **17-25–17-28** and **17-30** may be considered fragmentations (see also, Reactions **19-12** and **19-13**).

17-25 1,3-Fragmentation of γ -Amino, γ -Hydroxy Halides and 1,3-Diols

Dialkylaminoalkyl-halo-elimination, and so on

Hydroxyalkyl-hydroxy-elimination

γ -Dialkylamino halides undergo fragmentation when heated with water to give an alkene and an iminium salt, which under the reaction conditions is hydrolyzed to an aldehyde or ketone (**16-2**).⁴⁰⁶ γ -Hydroxy halides and tosylates are fragmented with base. In this instance, the base does not play its usual role in elimination reactions, but instead serves to remove a proton from the OH group, which enables the carbon leaving group to come off more easily:

Prelog and Zalán⁴⁰⁷ first observed this type of fragmentation in work that solved the structure of quinine and other Cinchona alkaloids in a 1,3-elimination ring-opening reaction. Subsequent work by Grob⁴⁰⁸ elucidated the mechanism of the reaction, and this 1,3-elimination is often referred to as *Grob fragmentation*.⁴⁰⁹ The mechanism of these

⁴⁰⁶ Grob, C.A.; Ostermayer, F.; Raudenbusch, W. *Helv. Chim. Acta* **1962**, 45, 1672.

⁴⁰⁷ Prelog, V.; Zalán, E. *Helv. Chim. Acta* **1944**, 27, 535; Prelog, V.; Häfliger, O. *Helv. Chim. Acta* **1950**, 33, 2021.

⁴⁰⁸ Grob, C.A. *Angew. Chem. Int. Ed.* **1969**, 8, 535 and references cited therein; Grob, C.A.; Kiefer, H.R.; Lutz, H. J.; Wilkens, H.J. *Helv. Chim. Acta* **1967**, 50, 416.

⁴⁰⁹ See Prantz, K.; Mulzer, J. *Chem. Rev.* **2010**, 110, 3741.

reactions is often E1, but an E2 mechanism also operates.⁴¹⁰ It has been shown that stereoisomers of cyclic γ -amino halides and tosylates in which the two leaving groups can assume an antiperiplanar conformation react by the E2 mechanism, while those isomers in which the groups cannot assume such a conformation either fragment by the E1 mechanism or do not undergo fragmentation at all, but in either case give rise to side products characteristic of carbocations.⁴¹¹ An example of a *Grob fragmentation* is the conversion of **53** to **54**.⁴¹²

γ -Dialkylamino alcohols do not give fragmentation, since for ionization the OH group must be converted to $^+\text{OH}_2$ and this would convert NR_2 to $^+\text{NR}_2\text{H}$, which does not have the unshared pair necessary to form the double bond with the carbon.⁴¹³

1,3-Diols in which at least one OH group is tertiary or is located on a carbon with aryl substituents can be cleaved by acid treatment.⁴¹⁴ The reaction is most useful synthetically when at least one of the OH groups is on a ring.⁴¹⁵

17-26 Decarboxylation of β -Hydroxy Carboxylic Acids and of β -Lactones

Carboxy-hydroxy-elimination

An OH and a CO_2H group can be eliminated from β -hydroxy carboxylic acids by refluxing with excess DMF dimethyl acetal.⁴¹⁶ Mono-, di-, tri-, and tetrasubstituted alkenes have been prepared by this method in good yields.⁴¹⁷ There is evidence that the mechanism involves E1 or E2 elimination from the zwitterionic intermediate $^-\text{O}_2\text{C}-\text{C}-\text{O}-\text{C}=\text{N}^+\text{Me}_2$.⁴¹⁸ The reaction has also been accomplished⁴¹⁹ under extremely mild conditions (a few seconds at 0°C) with PPh_3 and $\text{EtO}_2\text{C}-\text{N}=\text{N}-\text{CO}_2\text{Et}$,

diethyl azodicarboxylate.⁴²⁰ In a related procedure, β -lactones undergo thermal decarboxylation to give alkenes in high yields. The reaction has been shown to be stereospecific syn elimination.⁴²¹ There is evidence that this reaction also involves a zwitterionic intermediate.⁴²²

There are no OS references, but see OS VII, 172, for a related reaction.

17-27 Fragmentation of α,β -Epoxy Hydrazones

Eschenmoser–Tanabe ring cleavage

Cyclic α,β -unsaturated ketones⁴²³ can be cleaved by treatment with base of their epoxy tosylhydrazone derivatives to give acetylenic ketones,⁴²⁴ in what is known as the *Eschenmoser–Tanabe ring cleavage*. The reaction can be applied to the formation of acetylenic aldehydes ($\text{R}=\text{H}$) by using the corresponding, 2,4-dinitro-tosylhydrazone derivatives.⁴²⁵ Hydrazones (e.g., **55**) prepared from epoxy ketones and ring-substituted *N*-aminoaziridines undergo similar fragmentation when heated.⁴²⁶

On heating, bicyclo[2.2.1]hept-2,3-en-17-ones (**56**) usually lose CO to give cyclohexadienes,⁴²⁷ in a type of *reverse Diels–Alder reaction*. Bicyclo[2.2.1]heptadienones (**57**) undergo the reaction so readily (because of the stability of the benzene ring produced) that

they cannot generally be isolated. The parent (**57**) has been obtained at 10–15 K in an Ar matrix, where its spectrum could be studied.⁴²⁸ Both **56** and **57** can be prepared by a *Diels–Alder reactions* between a cyclopentadienone and an alkyne or alkene, so that this reaction is a useful method for the preparation of specifically substituted benzene rings and cyclohexadienes.⁴²⁹ Unsaturated bicyclic lactones of the type **58** can also undergo the reaction, losing CO₂ (see also, **17-35**).

OS **III**, 807; **V**, 604, 1037.

Reversal of the *Diels–Alder reaction* may be considered a fragmentation (see **15-50**).

17.F.iii. Reactions in which C≡N or C=N Bonds Are Formed

17-29 Dehydration of Oximes and Similar Compounds

C- Hydro- N- hydroxy-elimination; C- Acyl- N- hydroxy-elimination

Aldoximes can be dehydrated to nitriles⁴³⁰ by many dehydrating agents, of which acetic anhydride is the most common. Among reagents that are effective under mild conditions⁴³¹

(room temperature) are $\text{Ph}_3\text{P}-\text{CCl}_4$,⁴³² PPh_3-I_2 ,⁴³³ $\text{Pd}(\text{OAc})_2/\text{PPh}_3$ in refluxing CH_3CN ,⁴³⁴ ferric sulfate,⁴³⁵ $\text{Cu}(\text{II})$ with ultrasound,⁴³⁶ and $\text{ZnO}/\text{CH}_3\text{COCl}$ under solvent-free conditions.⁴³⁷ N,N -Dimethylformamide catalyzes the thermal dehydration of aldoximes.⁴³⁸ Heating an oxime with a Ru catalyst gives the nitrile.⁴³⁹ Heating with the *Burgess reagent* $[\text{Et}_3\text{N}^+-\text{SO}_2\text{N}-\text{CO}_2\text{Me}]$ in PEG is effective for this transformation.⁴⁴⁰ Sulfuric acid impregnated silica gel⁴⁴¹ gives the nitrile, as does microwave irradiation of an oxime with tetrachloropyridine on alumina.⁴⁴² Aldehydes can be converted to oximes *in situ* and microwave irradiation on alumina⁴⁴³ or with ammonium acetate⁴⁴⁴ gives the nitrile. Solvent-free reactions are known.⁴⁴⁵ The reaction is most successful when the H and OH are anti. Various alkyl and acyl derivatives of aldoximes ($\text{RCH}=\text{NOR}$,⁴⁴⁶ $\text{RCH}=\text{NO}-\text{COR}$, $\text{RCH}=\text{NOSO}_2\text{Ar}$, etc.), also give nitriles, as do chlorimines ($\text{RCH}=\text{NCl}$; the latter with base treatment).⁴⁴⁷ N,N -Dichloro derivatives of primary amines give nitriles upon pyrolysis: $\text{RCH}_2\text{NCl}_2 \rightarrow \text{RCN}$.⁴⁴⁸

Quaternary hydrazonium salts (derived from aldehydes) give nitriles when treated with $-\text{OEt}$ ⁴⁴⁹ or DBU (see Reaction 17-13):⁴⁵⁰ as do dimethylhydrazones ($\text{RCH}=\text{NNMe}_2$), when treated with Et_2NLi and HMPA.⁴⁵¹ All these are methods of converting aldehyde derivatives to nitriles. For the conversion of aldehydes directly to nitriles, without isolation of intermediates (see Reaction 16-16).

Hydroxylamines that have an α -proton are converted to nitrones when treated with a Mn-salen complex.⁴⁵²

Certain ketoximes can be converted to nitriles by the action of proton or Lewis acids.⁴⁵³ Among these are oximes of α -diketones (illustrated above), α -keto acids, α -dialkylamino ketones, α -hydroxy ketones, β -keto ethers, and similar compounds.⁴⁵⁴ These are fragmentation reactions, analogous to **17-25**. For example, α -dialkylamino ketoximes also give amines and aldehydes or ketones besides nitriles:⁴⁵⁵

The reaction that normally occurs on treatment of a ketoxime with a Lewis or proton acid is the *Beckmann rearrangement* (**18-17**); fragmentations are considered side reactions, often called “abnormal” or “second-order” *Beckmann rearrangements*.⁴⁵⁶ Obviously, the substrates mentioned are much more susceptible to fragmentation than are ordinary ketoximes, since in each case an unshared pair is available to assist in removal of the group cleaving from the carbon. However, fragmentation is a side reaction even with ordinary ketoximes⁴⁵⁷ and, in cases where a particularly stable carbocation can be cleaved, may be the main reaction:⁴⁵⁸

There are indications that the mechanism at least in some cases first involves a rearrangement and then cleavage. The ratio of fragmentation to *Beckmann rearrangement* of a series of oxime tosylates [$\text{RC}(=\text{NOTs})\text{Me}$] was not related to the solvolysis rate but *was* related to the stability of R^+ (as determined by the solvolysis rate of the corresponding RCl), which showed that fragmentation did not take place in the rate-determining step.⁴⁵⁹ It may be postulated then that the first step in the fragmentation and in the rearrangement is the same and that this is the rate-determining step. The product is determined in the second step:

17-30 Dehydration of Unsubstituted Amides

N,N-Dihydro- *C*-oxo-bielimination

Unsubstituted amides can be dehydrated to nitriles.⁴⁶¹ Phosphorous pentoxide is the most common dehydrating agent for this reaction, but many others, including POCl₃, PCl₅, CCl₄—Ph₃P,⁴⁶² HMPA,⁴⁶³ LiCl with a Zr catalyst,⁴⁶⁴ MeOOCNSO₂NEt₃ (the *Burgess reagent*),⁴⁶⁵ Me₂N=CHCl⁺ Cl[−],⁴⁶⁶ AlCl₃/KI/H₂O,⁴⁶⁷ PPh₃/NCS,⁴⁶⁸ oxalyl chloride/DMSO/−78 °C⁴⁶⁹ (*Swern* conditions, see Reaction 19-3), *o*-iodoxybenzoic acid/Et₄NBr,⁴⁷⁰ PdCl₂ in aq media,⁴⁷¹ TBAF and hydrosilanes,⁴⁷² Fe complexes,⁴⁷³ and SOCl₂ have also been used.⁴⁷⁴ Heating an amide with paraformaldehyde and formic acid gives the nitrile.⁴⁷⁵ It is possible to convert an acid to the nitrile, without isolation of the amide, by heating its ammonium salt with the dehydrating agent,⁴⁷⁶ or by other methods.⁴⁷⁷ *N,N*-Disubstituted ureas give cyanamides (R₂N—CO—NH₂ → R₂N—CN) when dehydrated with CHCl₃—NaOH under phase-transfer conditions.⁴⁷⁸ Treatment of an amide with aq NaOH and ultrasound leads to the nitrile.⁴⁷⁹

N-Alkyl-substituted amides can be converted to nitriles and alkyl chlorides by treatment with PCl₅. This is called the *von Braun reaction* (not to be confused with the other von Braun reaction, 10-54).

17-31 Conversion of N-Alkylformamides to Isonitriles (Isocyanides)**CN-Dihydro-C-oxo-bielimination**

Isonitriles (isonitriles) can be prepared by elimination of water from *N*-alkylformamides⁴⁸⁰ with phosgene and a tertiary amine.⁴⁸¹ Other reagents, among them TsCl in quinoline, POCl₃ and a tertiary amine,⁴⁸² triflic anhydride/*i*Pr₂NEt,⁴⁸³ 2,4,6-Trichloro [1,3,5]triazine (cyanuric chloride, TCT), with microwave irradiation,⁴⁸⁴ and Ph₃P—CCl₄—Et₃N⁴⁸⁵ have also been employed. Formamides react with thionyl chloride (two sequential treatments) to give an intermediate that gives an isonitrile upon electrolysis in DMF with LiClO₄.⁴⁸⁶

A variation of this process uses carbodiimides,⁴⁸⁷ which can be prepared by the dehydration of *N,N'*-disubstituted ureas with various dehydrating agents,⁴⁸⁸ among which are TsCl in pyridine, POCl₃, PCl₅, P₂O₅–pyridine, and TsCl (with phase-transfer catalysis).⁴⁸⁹ Hydrogen sulfide can be removed from the corresponding thioureas by treatment with HgO, NaOCl, or diethyl azodicarboxylate–triphenylphosphine.⁴⁹⁰

When pyrolyzed, β -hydroxy alkenes cleave to give alkenes and aldehydes or ketones.⁴⁹¹ Alkenes produced this way are quite pure, since there are no side reactions. The mechanism has been shown to be pericyclic, primarily by observations that the kinetics are first order⁴⁹² and that, for ROD, the deuterium appeared in the allylic position of the new alkene.⁴⁹³ This mechanism is the reverse of that for the oxygen analogue of the ene synthesis (Reaction 16-54). β -Hydroxyacetylenes react similarly to give the corresponding allenes and carbonyl compounds.⁴⁹⁴ The mechanism is the same despite the linear geometry of the triple bonds.

In a related reaction, pyrolysis of allylic ethers that contain at least one α hydrogen gives alkenes and aldehydes or ketones. The mechanism is also pericyclic⁴⁹⁵

17.F.v. Reactions in which N=N Bonds Are Formed

17-33 Eliminations to Give Diazoalkanes

N-Nitrosoamine-diazoalkane transformation

Various *N*-nitroso-*N*-alkyl compounds undergo elimination to give diazoalkanes.⁴⁹⁶ One of the most convenient methods for the preparation of diazomethane involves base treatment of *N*-nitroso-*N*-methyl-*p*-toluenesulfonamide (illustrated above, with R = H).⁴⁹⁷ However, other compounds commonly used are (base treatment is required in all cases):

Soc.* **1970**, *24*, 119, pp. 126–131; Smith, P.A.S. *Open-chain Nitrogen Compounds*, W. A. Benjamin, NY, **1966**, pp. 257–258, 474–475, in Vol. 2.

⁴⁹⁷ de Boer, T.J.; Backer, H.J. *Org. Synth.* **IV**, 225, 250; Hudlicky, M. *J. Org. Chem.* **1980**, *45*, 5377.

All of these compounds can be used to prepare diazomethane, although the sulfonamide, which is commercially available, is most satisfactory. *N*-Nitroso-*N*-methylcarbamate and *N*-nitroso-*N*-methylurea give good yields, but are highly irritating and carcinogenic.⁴⁹⁸ For higher diazoalkanes, the preferred substrates are nitrosoalkylcarbamates.

Most of these reactions probably begin with a 1,3 nitrogen-to-oxygen rearrangement, followed by the actual elimination (illustrated for the carbamate):

OS II, 165; III, 119, 244; IV, 225, 250; V, 351; VI, 981.

17.F.vi. Extrusion Reactions

We consider an *extrusion reaction*⁴⁹⁹ to be one in which an atom or group Y connected to two other atoms X and Z is lost from a molecule, leading to a product in which X is bonded directly to Z.

Reactions **14-32** and **17-20** also fit this definition. Reaction **17-28** does not fit the definition, but is often also classified as an extrusion reaction. A scale of extrusion facility has been developed, showing that the ease of extrusion of the common Y groups is in the order: $-\text{N}=\text{N}- > -\text{COO}- > -\text{SO}_2- > -\text{CO}-$.⁵⁰⁰

17-34 Extrusion of N₂ from Pyrazolines, Pyrazoles, and Triazolines

Azo-extrusion

⁴⁹⁹ Stark, B.P.; Duke, A.J. *Extrusion Reactions*, Pergamon, Elmsford, NY, **1967**. For a review of extrusions that are photochemically induced, see Givens, R.S. *Org. Photochem.* **1981**, 5, 227.

⁵⁰⁰ Paine, A.J.; Warkentin, J. *Can. J. Chem.* **1981**, 59, 491.

1-Pyrazolines (**59**) can be converted to cyclopropane and N_2 on photolysis⁵⁰¹ or pyrolysis.⁵⁰² The tautomeric 2-pyrazolines (**60**), which are more stable than **59**, also give the reaction, but in this case an acidic or basic catalyst is required, the function of which is to convert **60** to **59**.⁵⁰³ In the absence of such catalysts, **60** does not react.⁵⁰⁴ In a similar manner, triazolines (**61**) are converted to aziridines.⁵⁰⁵ Side reactions are frequent with both **59** and **61**, and some substrates do not give the reaction at all. However, the reaction has proved synthetically useful in many cases. In general, photolysis gives better yields and fewer side reactions than pyrolysis with both **59** and **61**. 3*H*-Pyrazoles⁵⁰⁶ (**62**) are stable to heat, but in some cases can be converted to cyclopropenes on photolysis,⁵⁰⁷ although in other cases other types of products are obtained.

There is much evidence that the mechanism⁵⁰⁸ of the 1-pyrazoline reactions generally involves diradicals, although the mode of formation and detailed structure (e.g., singlet vs triplet) of these radicals may vary with the substrate and reaction conditions. The reactions of the 3*H*-pyrazoles (**62**) have been postulated to proceed through a diazo compound that loses N_2 to give a vinylic carbene.⁵⁰⁹

OS V, 96, 929. See also, OS VIII, 597.

17-35 Extrusion of CO or CO₂

Carbonyl-extrusion

Although the reaction is not general, certain cyclic ketones can be photolyzed to give ring-contracted products.⁵¹⁰ In the example above, the cyclobutanone (**63**) was

photolyzed to give **64**.⁵¹¹ This reaction was used to synthesize tetra-*tert*-butyltetrahydronaphthalene, (**65**).⁵¹²

The mechanism probably involves a *Norrish-type I cleavage* (Sec. 7.A.vii), loss of CO from the resulting radical, and recombination of the radical fragments.

Certain lactones extrude CO₂ on heating or on irradiation (e.g., the pyrolysis of **66**).⁵¹³

Decarboxylation of β -lactones (see **17-26**) may be regarded as a degenerate example of this reaction. Unsymmetrical diacyl peroxides (RCO—OO—COR') lose two molecules of CO₂ when photolyzed in the solid state to give the product RR'.⁵¹⁴ Electrolysis was also used, but yields were lower. This is an alternative to the *Kolbe reaction* (**11-34**) (see also, **17-28** and **17-38**).

There are no OS references, but see OS VI, 418, for a related reaction.

17-36 Extrusion of SO₂

Sulfonyl-extrusion

In a reaction similar to **17-35**, certain sulfones, both cyclic and acyclic,⁵¹⁵ extrude SO₂ on heating or photolysis to give ring-contracted products.⁵¹⁶ An example is the preparation of naphtho(*b*)cyclobutene shown above.⁵¹⁷ In a different kind of reaction, five-membered

cyclic sulfones can be converted to cyclobutenes by treatment with butyllithium followed by LiAlH_4 ,⁵¹⁸ for example,

This method is most successful when both the α and α' position of the sulfone bear alkyl substituents (see also, Reaction 17-20). Treating four-membered ring sultams with SnCl_2 led to aziridine products via loss of SO_2 .⁵¹⁹

OS VI, 482.

17-37 The Story Synthesis

When cycloalkylidene peroxides (e.g., **60**) are heated in an inert solvent (e.g., decane), extrusion of CO_2 takes place; the products are the cycloalkane containing three carbon atoms less than the starting peroxide and the lactone containing two carbon atoms less⁵²⁰ (the *Story synthesis*).⁵²¹ The two products are formed in comparable yields, usually ~ 15 –25% each. Although the yields are low, the reaction is useful because there are not many other ways to prepare large rings. The reaction is versatile, having been used to prepare rings of every size from 8 to 33 members.

Both dimeric and trimeric cycloalkylidene peroxides can be synthesized⁵²² by treatment of the corresponding cyclic ketones with H_2O_2 in acid solution.⁵²³ The trimeric peroxide is formed first and is subsequently converted to the dimeric compound.⁵²⁴

Rearrangements

In a rearrangement reaction, a group moves from one atom to another in the same molecule.¹ Most are migrations from an atom to an adjacent one (called 1,2-shifts), but some are over longer distances. The group

that migrates (W) may move with its electron pair (these can be called *nucleophilic* or *anionotropic* rearrangements; the migrating group can be regarded as a nucleophile), without its electron pair (*electrophilic* or *cationotropic* rearrangements; in the case of migrating hydrogen, *prototropic* rearrangements), or with just one electron (radical rearrangements). The atom A is called the *migration origin* and B is the *migration terminus*. However, there are some rearrangements that do not lend themselves to neat categorization in this manner. Among these are those with cyclic transition states (Reactions **18-27–18-36**).

As will be seen, nucleophilic 1,2-shifts are much more common than electrophilic or free radical 1,2-shifts. The reason for this can be seen by a consideration of the transition states (or in some cases intermediates) involved. The transition state or intermediate for all three cases can be represented by **1**, in which the two-electron A—W bond overlaps with the orbital on atom B, which contains zero, one, and two electrons, in the case of nucleophilic, free radical, and electrophilic migration, respectively. The overlap of these orbitals gives rise to three new orbitals, which have an energy relationship similar to those in Section 2.K.i (one bonding and two degenerate antibonding orbitals). In a nucleophilic migration, where only two electrons are involved, both can go into the bonding orbital and **1** is a low-energy transition state. In a free radical or electrophilic migration, there are, respectively, three or four electrons that must be accommodated, and antibonding orbitals

¹ de Mayo, P. *Rearrangements in Ground and Excited States*, 3 Vols., Academic Press, NY, **1980**; Stevens, T.S.; Watts, W.E. *Selected Molecular Rearrangements*, Van Nostrand-Reinhold, Princeton, **1973**; Collins, C.J.; Eastham, J.F. in Patai, S. *The Chemistry of the Carbonyl Group*, Vol. 1, Wiley, NY, **1966**, pp. 761–821. See also, the series *Mechanisms of Molecular Migrations*.

must be occupied. It is not surprising therefore that, when 1,2-electrophilic or free radical shifts are found, the migrating group W is usually aryl or some other group that can accommodate the extra one or two electrons and thus effectively remove them from the three-membered transition state or intermediate (see 41).

In any rearrangement two possible modes of reaction can, in principle, be distinguished. In one of these, the group W becomes completely detached from A and may end up on the B atom of a different molecule (*intermolecular* rearrangement). In the other, W goes from A to B in the *same* molecule (*intramolecular* rearrangement), in which case there must be some continuing tie holding W to the A—B system, preventing it from coming completely free. Strictly speaking, only the intramolecular type fits our definition of a rearrangement, but the general practice, which is followed here, is to include under the title “rearrangement” all net rearrangements whether they are inter- or intramolecular. It is usually not difficult to tell whether a given rearrangement is inter- or intramolecular. The most common method involves the use of *cross over* experiments. In this type of experiment, rearrangement is carried out on a mixture of W—A—B and V—A—C, where V is closely related to W (say, methyl vs ethyl) and B to C. In an intramolecular process, only A—B—W and A—C—V are recovered, but if the reaction is intermolecular, then not only will these two be found, but also A—B—V and A—C—W.

18.A. MECHANISMS

18.A.i. Nucleophilic Rearrangements²

Broadly speaking, such rearrangements consist of three steps, of which the actual migration is the second:

This process has been called the *Whitmore 1,2-shift*.³ Since the migrating group carries the electron pair with it, the migration terminus B must be an atom with only six electrons in its outer shell (an open sextet). The first step therefore is creation of a system with an open sextet. Such a system can arise in various ways, but two of these are the most important:

1. *Formation of a Carbocation:* These can be formed in a number of ways (see Sec. 5. A.iii), but one of the most common methods is the acid treatment of an alcohol to give **2** from an intermediate oxonium ion. Such carbocations are subject to rearrangement to a more stable carbocation. These two steps are of course the same as the first two steps of the S_N1cA or the E1 reactions of alcohols.

² Vogel, P. *Carbocation Chemistry*; Elsevier, NY, **1985**, pp. 323–372; Shubin, V.G. *Top. Curr. Chem.* **1984**, 116/117, 267; Saunders, M.; Chandrasekhar, J.; Schleyer, P.v.R. in de Mayo, P. *Rearrangements in Ground and Excited States*, Vol. 1, Academic Press, NY, **1980**, pp. 1–53; Kirmse, W. *Top. Curr. Chem.* **1979**, 80, 89. For reviews of rearrangements in vinylic cations, see Schegolev, A.A.; Kanishchev, M.I. *Russ. Chem. Rev.* **1981**, 50, 553; Lee, C.C. *Isot. Org. Chem.* **1980**, 5, 1.

³ It was first postulated by Whitmore, F.C. *J. Am. Chem. Soc.* **1932**, 54, 3274.

2. *Formation of a Nitrene:* The decomposition of acyl azides is one of several ways in which acyl nitrenes (**3**) are formed (see Sec. 5.E). After the migration has taken place, the atom at the migration origin (A) must necessarily have an open sextet. In the third step, this atom acquires an octet. In the case of carbocations, combinations with a nucleophile (rearrangement with substitution) and loss of H^+ (rearrangement with elimination). Constitute the most common third step.

Although this mechanism is presented as taking place in three steps, and some reactions do take place in this way, in others the transformation is simultaneous. For example, in the nitrene example above, as the R migrates, an electron pair from the nitrogen moves into the C—N bond to give a stable isocyanate, (**4**). In this example, what are shown as the second and third steps are simultaneous. It is also possible for the second and third steps to be simultaneous even when the “third” step involves more than just a simple motion of a pair of electrons. Similarly, there are many reactions in which the first two steps are simultaneous; that is, there is no actual formation of a species (e.g., **2** or **3**). In these instances, it may be said that R assists in the removal of the leaving group, with migration of R and the removal of the leaving group taking place simultaneously. Many investigations have been carried out in attempts to determine, in various reactions, whether such intermediates as (**2**) or (**3**) actually form, or whether the steps are simultaneous (see, e.g., the discussions in Reaction **16-45** and Sec. 18.A.ii), but the difference between the two possibilities is often subtle, and the question is not always easily answered.⁴

Evidence for this mechanism is that rearrangements of this sort occur under conditions where previously carbocations have been encountered: $\text{S}_{\text{N}}1$ conditions, *Friedel–Crafts alkylation*, and so on. Solvolysis of neopentyl bromide leads to rearrangement products, and the rate increases with increasing ionizing power of the solvent, but is unaffected by concentration of base,⁵ so that the first step is carbocation formation. The same compound under $\text{S}_{\text{N}}2$ conditions gave no rearrangement, but slowly gave only ordinary substitution. Thus with neopentyl bromide, formation of a carbocation leads only to rearrangement. Carbocations usually rearrange to more stable carbocations. Thus the direction of rearrangement is usually primary \rightarrow secondary \rightarrow tertiary. Neopentyl (Me_3CCH_2), neophyl ($\text{PhCMe}_2\text{CH}_2$), and norbornyl (e.g., **5**) type systems are especially prone to carbocation rearrangement

⁴ The IUPAC designations depend on the nature of the steps. For the rules, see Guthrie, R.D. *Pure Appl. Chem.* **1989**, 61, 23, pp. 44–45.

⁵ Dostrovsky, I.; Hughes, E.D. *J. Chem. Soc.* **1946**, 166.

reactions. It has been shown that the rate of migration increases with the degree of electron deficiency at the migration terminus.⁶

It was previously mentioned (Sec. 5.A.ii) that stable tertiary carbocations could be obtained, in solution, at very low temperatures. The NMR studies have shown that when these solutions are warmed, rapid migrations of hydride and of alkyl groups take place, resulting in an equilibrium mixture of structures.⁷ For example, the *tert*-pentyl cation (**5**)⁸ equilibrates as follows:

Carbocations that rearrange to give products of identical structure ($\mathbf{6} \rightleftharpoons \mathbf{6'}$, $\mathbf{7} \rightleftharpoons \mathbf{7'}$) are called *degenerate carbocations*. Such rearrangements are *degenerate rearrangements* and many examples are known.⁹

18.A.ii. The Actual Nature of the Migration

Most nucleophilic 1,2-shifts are intramolecular. The W group does not become free, but always remains connected in some way to the substrate. Apart from the evidence from cross-over experiments, the strongest evidence is that when the W group is chiral, the configuration is *retained* in the product. For example, (+)-PhCHMeCO₂H was converted to (–)-PhCHMeNH₂ by the *Curtius* (**18-14**), *Hofmann* (**18-13**), *Lossen* (**18-15**), and *Schmidt* (**18-16**) reactions.¹⁰ In these reactions, the extent of retention varied from 95.8 to 99.6%. Retention of configuration in the migrating group has been shown many times since.¹¹ Another experiment demonstrating retention was the easy conversion of **8** to **9**.¹¹ Neither inversion nor racemization could take place at a bridgehead.

Using the simple example W-A-B, there is much evidence that retention of configuration usually occurs in W, and inversion never occurs.¹² However, this is not the state of affairs at A and B. In many reactions, of course, the structure of W—A—B is such that the product has only one steric possibility at A or B or both, and in most of these cases nothing can be learned. But in cases where the steric nature of A or B can be investigated, the results are mixed. It has been shown that either inversion or racemization can occur at A or B. One example is **10**, where the conversion proceeded with inversion (equivalent to inversion at B).¹³ Inversion at A has been

shown in other cases.¹⁴ However, in many other cases, racemization occurs at A or B or both.¹⁵ It is not always necessary for the product to have two steric possibilities in order to investigate the stereochemistry at A or B. Thus, in most *Beckmann rearrangements* (18-17), only the group trans (usually called *anti*) to the hydroxyl group migrates, as illustrated by formation of **11**, which shows inversion at B.

This information tells us about the degree of concertedness of the three steps of the rearrangement. First, consider the migration terminus B in R—A—B—X. If racemization is found at B, it is probable that the first step takes place before the second and that a positively charged carbon (or other sextet atom) is present at B:

With respect to B this is an S_N1 type process. If inversion occurs at B, it is likely that the first two steps are concerted, that a carbocation is *not* an intermediate, and that the process is S_N2 like:

In this case, participation by R assists in removal of X in the same way that neighboring groups do (Sec. 10.C). Indeed, R *is* a neighboring group here. The only difference is that, in the case of the neighboring-group mechanism of nucleophilic substitution, R never becomes detached from A, while in a rearrangement the bond between R and A is broken.

In either case, the anchimeric assistance results in an increased rate of reaction. Of course, for such a process to take place, R must be in a favorable geometrical position (R and X antiperiplanar). Intermediate **12** may be a true intermediate, or there may only be a transition state, depending on what migrates. In certain cases of the S_N1 type process, it is possible for migration to take place with net retention of configuration at the migrating terminus because of conformational effects in the carbocation.¹⁶

A few conclusions may be summarized:

1. The S_N1 type process occurs mostly when B is a tertiary atom or has one aryl group and at least one other alkyl or aryl group. In other cases, the S_N2 type process is more likely. Inversion of configuration (indicating an S_N2 type process) has been shown for a neopentyl substrate by the use of the chiral neopentyl-1-*d* alcohol.¹⁷ There is other evidence that neopentyl systems undergo rearrangement by a carbocation (S_N1 type) mechanism.¹⁸
2. The question as to whether **12** is an intermediate or a transition state has been much debated. When R is aryl or vinyl, then **12** is probably an intermediate and the migrating group lends anchimeric assistance¹⁹ (see Sec. 10.C.i, category 3-preceding category 4 for resonance stabilization of this intermediate, when R is aryl). When R is alkyl, **12** is a protonated cyclopropane (edge- or corner protonated; see Sec. 15.B.iv). There is much evidence that in simple migrations of a methyl group, the bulk of the products formed do not arise from protonated cyclopropane *intermediates*. Evidence for this statement has already been given (Sec. 10.C.i, category 4c). Further evidence was obtained from experiments involving labeling.

Rearrangement of the neopentyl cation labeled with deuterium in the 1 position (**13**) gave only *tert*-pentyl products with the label in the 3 position (derived from **15**), though if **14** were an intermediate, the cyclopropane ring could just as well cleave the other way to give *tert*-pentyl derivatives labeled in the 4 position (derived from **16**).²⁰ Another experiment that led to the same conclusion was the generation, in several ways, of $\text{Me}_3\text{C}^{13}\text{CH}_2^+$. The only *tert*-pentyl products isolated were labeled in C-3, that is, $\text{Me}_2\text{C}^+-^{13}\text{CH}_2\text{CH}_3$ derivatives; no derivatives of $\text{Me}_2\text{C}^+-\text{CH}_2^{13}\text{CH}_3$ were found.²¹

Although the bulk of the products are not formed from protonated cyclopropane intermediates, there is considerable evidence that at least in 1-propyl systems, a small part of the product can in fact arise from such intermediates.²² Among this evidence is the isolation of 10–15% cyclopropanes (mentioned in Sec. 10.C.i, category 4c). Additional evidence comes from propyl cations generated by diazotization of labeled amines ($\text{CH}_3\text{CH}_2\text{CD}_2^+$, $\text{CH}_3\text{CD}_2\text{CH}_2^+$, $\text{CH}_3\text{CH}_2^{14}\text{CH}_2^+$), where isotopic distribution in the products indicated that a small amount ($\sim 5\%$) of the product had to be formed from protonated cyclopropane intermediates, for example,²³

Even more scrambling was found in trifluoroacetolysis of 1-propyl-1- ^{14}C -mercuric perchlorate.²⁴ However, protonated cyclopropane intermediates accounted for $< 1\%$ of the products from diazotization of labeled isobutylamine²⁵ and from formolysis of labeled 1-propyl tosylate.²⁶

It is likely that protonated cyclopropane transition states or intermediates are also responsible for certain non-1,2 rearrangements. For example, in superacid solution, the ions **17** and **19** are in equilibrium. It is not possible for these to interconvert solely by 1,2-alkyl or hydride shifts unless primary carbocations, which are highly unlikely, are intermediates. However, the reaction can be explained²⁷ by postulating that (in the forward reaction) it is the 1,2-bond of the intermediate or transition state **18** that opens up rather than the 2,3-bond, which is the one that would open if the reaction were a normal 1,2-shift of a methyl group. In this case, opening of the 1,2-bond produces a tertiary cation, while opening of the 2,3-bond would give a secondary cation. (In the reaction **19** \rightarrow **17**, it is of course the 1,3-bond that opens).

3. There has been much discussion of H as the migrating group. There is no conclusive evidence that **10** in this case is or is not a true intermediate, although both positions have been argued (see Sec. 10.C.i, category 4c).

The stereochemistry at the migration origin A is less often involved, since in most cases it does not end up as a tetrahedral atom; but when there is inversion here, there is an S_N2 type process at the beginning of the migration. This may or may not be accompanied by an S_N2 process at the migration terminus B:

In some cases, it has been found that, when H is the migrating species, the configuration at A may be *retained*.²⁸

There is evidence that the configuration of the molecule may be important even where the leaving group is gone long before migration takes place. For example, the 1-adamantyl cation (**20**) does not equilibrate intramolecularly, even at temperatures up to 130 °C,²⁹ though open-chain (e.g., **6-6'**) and cyclic tertiary carbocations undergo such equilibration at 0 °C or below. On the basis of this and other evidence, it has been concluded that for a 1,2-shift of hydrogen or methyl to proceed as smoothly as possible, the vacant *p* orbital of the carbon bearing the positive charge and the *sp*³ orbital carrying the migrating group must be coplanar,²⁹ which is not possible for **20**.

18.A.iii. Migratory Aptitudes³⁰

In many reactions, there is no question about which group migrates. For example, in the *Hofmann*, *Curtius*, and similar reactions there is only one possible migrating group in each molecule, and one can measure migratory aptitudes only by comparing the relative rearrangement rates of different compounds. In other instances, there are two or more potential migrating groups, but which migrates is settled by the geometry of the molecule. The *Beckmann rearrangement* (Reaction **18-17**) provides an example. As seen in the formation of **11**, only the group trans to the OH migrates. In compounds whose geometry is not restricted in this manner, there still may be eclipsing effects (see Sec. 17.C), so that the choice of migrating group is largely determined by which group is in the right place in the most stable conformation of the molecule.³¹ However, in some reactions, especially the *Wagner–Meerwein* (**18-1**) and the *pinacol* (**18-2**) rearrangements, the molecule may contain several groups that, geometrically at least, have approximately equal chances

³¹ See Cram, D.J. in Newman, M.S. *Steric Effects in Organic Chemistry*, Wiley, NY, **1956**, pp. 270–276. For an interesting example, see Nickon, A.; Weglein, R.C. *J. Am. Chem. Soc.* **1975**, *97*, 1271.

of migrating, and these reactions have often been used for the direct study of relative migratory aptitudes. In the *pinacol rearrangement*, there is the additional question of which OH group leaves and which does not, since a group can migrate only if the OH group on the *other* carbon is lost.

We deal with the second question first. To study this question, the best type of substrate to use is one of the form $R_2C(OH)-C(OH)R'_2$, since the only thing that determines migratory aptitude is which OH group comes off. Once the OH group is gone, the migrating group is determined. As might be expected, the OH that leaves is the one whose loss gives rise to the more stable carbocation. Thus 1,1-diphenylethanediol (**21**) gives diphenylacetaldehyde (**22**), not phenylacetophenone (**23**). Obviously, it does not matter in this case whether phenyl has a greater inherent migratory aptitude than hydrogen or not. Only the hydrogen can migrate because **24** is not formed. Remember that carbocation stability is enhanced by groups in the order aryl > alkyl > hydrogen, and this normally determines which side loses the OH group. However, exceptions are known, and which group is lost may depend on the reaction conditions (e.g., see the reaction of **59**).

In order to answer the question about inherent migratory aptitudes, the obvious type of substrate to use (in the pinacol rearrangement) is $R'RC(OH)-COH)RR'$, since the same carbocation is formed no matter which OH leaves, and it would seem that a direct comparison of the migratory tendencies of R and R' is possible. On closer inspection, however, it is clear that several factors are operating. Apart from the question of possible conformational effects, already mentioned, there is also the fact that whether the group R or R' migrates is determined not only by the relative inherent migrating abilities of R and R', but also by whether the group that does *not* migrate is better at stabilizing the positive charge that will now be found at the migration origin.³² Thus, migration of R gives rise to the cation $R'C^+(OH)CR_2R'_2$, while migration of R' gives the cation $R^+C(OH)CRR'_2$ and these cations have different stabilities. It is possible that in a given case R might be found to migrate less than R', not because it actually has a lower inherent migrating tendency, but because it is much

better at stabilizing the positive charge. In addition to this factor, the migrating ability of a group is also related to its capacity to render anchimeric assistance to the departure of the

³² See McCall, M.J.; Townsend, J.M.; Bonner, W.A. *J. Am. Chem. Soc.* **1975**, *97*, 2743; Brownbridge, P.; Hodgson, P.K.G.; Shepherd, R.; Warren, S. *J. Chem. Soc. Perkin Trans. 1* **1976**, 2024.

nucleofuge. An example of this effect is the decomposition of tosylate (**25**) where only the phenyl group migrates, while in acid treatment of the corresponding alkene (**26**), there is competitive migration of both methyl and phenyl (in these reactions ^{14}C labeling is necessary to determine which group has migrated).³³ Both **25** and **26** give the same carbocation; the differing results must be caused by the fact that in **25** the phenyl group can assist the leaving group, while no such process is possible for **26**. This example clearly illustrates the difference between migration to a relatively free terminus and one that proceeds with the migrating group lending anchimeric assistance.³⁴

Therefore, it is not surprising that clear-cut answers as to relative migrating tendencies are not available. More often than not migratory aptitudes are in the order aryl > alkyl, but exceptions are known, and the position of hydrogen in this series is often unpredictable. In some cases, migration of hydrogen is preferred to aryl migration; in other cases, migration of alkyl is preferred to that of hydrogen. Mixtures are often found, and the isomer that predominates often depends on conditions. For example, the comparison between methyl and ethyl has been made many times in various systems, and in some cases methyl migration and in others ethyl migration has been found to predominate.³⁵ However, it can be said that among aryl migrating groups, electron-donating substituents in the para and meta positions increase the migratory aptitudes, while the same substituents in the ortho positions decrease them. Electron-withdrawing groups decrease migrating ability in all positions. The following are a few of the relative migratory aptitudes determined for aryl groups:³⁶ *p*-anisyl, 500; *p*-tolyl, 15.7; *m*-tolyl, 1.95; phenyl, 1.00; *p*-chlorophenyl, 0.7; *o*-anisyl, 0.3. For the *o*-anisyl group, the poor migrating ability probably has a steric cause, while for the others there is a fair correlation with activation or deactivation of electrophilic aromatic substitution, which is what the process is with respect to the benzene ring. It has been reported that at least in certain systems acyl groups have a greater migratory aptitude than alkyl groups.³⁷

18.A.iv. Memory Effects³⁸

Solvolysis of the endo bicyclic compound (**27**, X = ONs, see Sec. 10.G.iii, or Br) gave mostly the bicyclic allylic alcohol (**30**), along with a smaller amount of the tricyclic alcohol (**34**), while solvolysis of the exo isomers, (**31**), gave mostly **34**, with smaller amounts of **30**.³⁹ Note that endo and exo here refers to the position of the XCH_2 group over the $\text{C}=\text{C}$ unit or opposite the $\text{C}=\text{C}$ unit, respectively. The two isomers gave entirely different ratios of products, although the carbocation initially formed seems to be the same for each (marked **28** and **32** for convenience). With **28**, a second rearrangement (a shift of the 1,7 bond) follows to give **29**, while with **32**

³⁹ Berson, J.A.; Poonian, M.S.; Libbey, W.J. *J. Am. Chem. Soc.* **1969**, 91, 5567; Berson, J.A.; Donald, D.S.; Libbey, W.J. *J. Am. Chem. Soc.* **1969**, 91, 5580; Berson, J.A.; Wege, D.; Clarke, G.M.; Bergman, R.G. *J. Am. Chem. Soc.* **1969**, 91, 5594, 5601.

an intramolecular addition of the positive carbon to the double bond gives **33**. It seems as if **28** and **32** “remember” how they were formed before they go on to give the second step. Such effects are called *memory effects* and other such cases are known.⁴⁰ The causes of these effects are not well understood, although there has been much discussion. One possible cause is differential solvation of the apparently identical ions **28** and **32**. Other possibilities are (1) that the ions have geometrical structures that are twisted in opposite senses (e.g., a twisted **32** might have its positive

carbon closer to the double bond than a twisted **28**); (2) that ion pairing is responsible⁴¹; and (3) that nonclassical carbocations are involved.⁴² One possibility that has been ruled out is that steps **27** → **28** → **29** and **31** → **32** → **33** are concerted, so that **28/32** never exist at all. This possibility has been excluded by several kinds of evidence, including the fact that **27** gives not only **30**, but also some **34**; and **31** gives some **30** along with **34**. This means that some of the **28** and **32** ions interconvert, a phenomenon known as *leakage*.

18.B. LONGER NUCLEOPHILIC REARRANGEMENTS

The question as to whether a group can migrate with its electron pair from A to C in W—A—B—C or over longer distances has been much debated. Although claims have been made that alkyl groups can migrate in this way, the evidence is that such migration is extremely rare, if it occurs at all. One experiment that demonstrated this was the generation of the 3,3-dimethyl-1-butyl cation ($\text{Me}_3\text{CCH}_2\text{CH}_2^+$). If 1,3-methyl migrations are possible, this cation would appear to be a favorable substrate, since such a migration would convert a primary cation into the tertiary 2-methyl-2-pentyl cation ($\text{Me}_2\text{C}^+\text{CH}_2\text{CH}_2\text{CH}_3$), while the only possible 1,2 migration (of hydride) would give only a secondary cation. However, no products arising from the 2-methyl-2-pentyl cation were found, the only rearranged products being those formed by the 1,2-hydride migration.⁴³ 1,3-Migration of bromine has been reported.⁴⁴

Most of the debate over the possibility of 1,3-migrations has concerned not methyl or bromine but 1,3-hydride shifts.⁴⁵ Many instances have been found of *apparent* 1,3-hydride shifts, but the question is whether they are truly direct hydride shifts or whether they occur by another mechanism. There are at least two ways in

which indirect 1,3-hydride shifts can take place: (1) by successive 1,2-shifts or (2) through the intervention of protonated cyclopropanes (see Sec. 18.A.ii, category 2). A direct 1,3-shift would have transition state **A**, while the transition state for a 1,3-shift involving a protonated cyclopropane intermediate would resemble **B**. The evidence is that most reported 1,3-hydride shifts are actually the result of successive 1,2-migrations,⁴⁶ but in some cases small amounts of products cannot be accounted for in this way. The reaction of 2-methyl-1-butanol with KOH and bromoform gave a mixture of alkenes, nearly all of which could have arisen from simple elimination or 1,2-shifts of hydride or alkyl. However, 1.2% of the product was **35**.⁴⁷ Hypothetically, **35** could have arisen from a 1,3 shift (direct or through a protonated cyclopropane) or from two successive 1,2-shifts:

However, the same reaction applied to 2-methyl-2-butanol gave no **35**, which demonstrated that **38** was not formed from **37**. The conclusion made was that **38** was formed directly from **36**. This experiment does not answer the question as to whether **38** was formed by a direct shift or through a protonated cyclopropane, but from other evidence⁴⁸ it appears that 1,3-hydride shifts that do not result from successive 1,2-migrations usually take place through protonated cyclopropane intermediates, which (as seen in Sec. 18.A.ii, category 2) account for only a small percentage of the product in any case. However, there is evidence that direct 1,3-hydride shifts by way of **A** (see above) may take place in superacid solutions.⁴⁹ Although direct nucleophilic rearrangements over distances $>1,2$ are rare (or perhaps nonexistent) when the migrating atom or group must move along a chain, this is not so for a shift across a ring of 8–11 members. Many such transannular rearrangements are known⁵⁰ (see Sec. 4.Q.ii): the mechanism for the

conversion of **39** to **40** is shown.⁵¹

Note that the *methyl* group does not migrate in this system. *It is generally true that alkyl groups do not undergo transannular migration.*⁵² In most cases, it is the hydride that undergoes this type of migration, though a small amount of phenyl migration has also been shown.⁵³

18.C. FREE RADICAL REARRANGEMENTS⁵⁴

1,2-Free radical rearrangements are much less common than the nucleophilic type previously considered, for the reasons mentioned in the introductory Section 18.A. Where they do occur, the general pattern is similar. There must first be generation of a free radical, and then the actual migration in which the migrating group moves with one electron:

Finally, the new free radical will undergo a further reaction to generate a neutral molecule. The order of radical stability leads to a prediction that here too, as with carbocation rearrangements, migrations should be in the order primary \rightarrow secondary \rightarrow tertiary, and that the logical place to look for them should be in neopentyl and neophyl systems. The most common way of generating free radicals for the purpose of detection of rearrangements is by decarbonylation of aldehydes (Reaction **14-32**). In this manner, it was found that neophyl radicals *do* undergo rearrangement.⁵⁵ Thus, $\text{PhCMe}_2\text{CH}_2\text{CHO}$ treated with di-*tert*-butyl peroxide gave about equal amounts of the normal product $\text{PhCMe}_2\text{CH}_3$ and the product arising from migration of phenyl⁵⁶:

Many other cases of free radical migration of aryl groups have been found.⁵⁷ Intramolecular radical rearrangements are known.⁵⁸ The C-4 radicals of α - and β -thujone undergo two distinct rearrangement reactions, and it has been proposed that these could serve as simultaneous but independent radical clocks.⁵⁹

A 1,2-shift has been observed in radicals bearing an OCOR group at the β -carbon where the oxygen group migrates as shown in the interconversion of **41** and **42**. This has been proven by ^{18}O isotopic labeling experiments⁶⁰ and other mechanistic explorations.⁶¹ A similar rearrangement was observed with phosphatoxy alkyl radicals (e.g., as **43**).⁶² A 1,2-shift of hydrogen atoms has been observed in aryl radicals.⁶³

Note that the extent of migration is much less than with corresponding carbocations: Thus in the example given, there was only $\sim 50\%$ migration, whereas the carbocation would have given much more. Also noteworthy is that there was no migration of the methyl group. In general, it may be said that free radical migration of alkyl groups does not occur at ordinary temperatures. *Many attempts have been made to detect such migration on the traditional neopentyl and bornyl types of substrates. However, alkyl migration is not observed, even in substrates where the corresponding carbocations undergo facile rearrangement.*⁶⁴ Another type of migration that is very common for carbocations, but not observed for free radicals, is 1,2-migration of hydrogen. We confine ourselves to a few examples of the lack of migration of alkyl groups and hydrogen:

1. 3,3-Dimethylpentanal ($\text{EtCMe}_2\text{CH}_2\text{CHO}$) gave no rearranged products on decarbonylation.⁶⁵
2. Addition of RSH to norbornene gave only *exo*-norbornyl sulfides, though **44** is an intermediate, and the corresponding carbocation cannot be formed without rearrangement.⁶⁶

3. The cubylcarbonyl radical did not rearrange to the 1-homocubyl radical, though doing so would result in a considerable decrease in strain.⁶⁷
4. It was shown⁶⁸ that no rearrangement of isobutyl radical to *tert*-butyl radical, which would involve the formation of a more stable radical by a hydrogen shift, took place during the chlorination of isobutane.

However, 1,2-migration of alkyl groups has been shown to occur in certain *diradicals*.⁶⁹ For example, the following rearrangement has been established by tritium labeling.⁷⁰

In this case, the fact that migration of the methyl group leads directly to a compound in which all electrons are paired undoubtedly contributes to the driving force of the reaction.

The fact that aryl groups migrate, but alkyl groups and hydrogen generally do not, leads to the proposition that **45**, in which the odd electron is not found in the three-membered ring, may be an intermediate. There has been much controversy on this point, but the bulk of the evidence indicates that **45** is a transition state, not an intermediate.⁷¹ Among the evidence is the failure to observe **45** either by ESR⁷² or CIDNP.⁷³ Both of these techniques can detect free radicals with extremely short lifetimes (Sec. 5.C.i).⁷⁴

In addition, aryl, vinylic⁷⁵ and acetoxy groups⁷⁶ also migrate. Vinylic groups migrate via a cyclopropylcarbinyl radical intermediate (**46**),⁷⁷ while the migration of acetoxy groups may involve the charge-separated structure shown.⁷⁸ Thermal isomerization of 1-(3-butenyl)cyclopropane at 415 °C leads to bicyclo[2.2.1]heptane.⁷⁹ Migration has been

observed for chloro (and to a much lesser extent bromo) groups.

For example, in the reaction of Cl₃CCH=CH₂ with bromine under the influence of peroxides, the products were 47% Cl₃CCHBrCH₂Br (the normal addition product) and 53% BrCCl₂CHClCH₂Br, which arose by rearrangement:

In this particular case, the driving force for the rearrangement is the particular stability of dichloroalkyl free radicals.⁸⁰ It has been shown that the 1,2-migration of Cl readily occurs if the migration origin is tertiary and the migration terminus is primary.⁸¹ Migration of Cl and Br could take place by a transition state in which the odd electron is accommodated in a vacant *d* orbital of the halogen.

Migratory aptitudes have been measured for the phenyl and vinyl groups, and for three other groups, using the system RMe₂CH₂• → Me₂OC•CH₂R. These were found to be in the order R = H₂C=CH₂ > Me₃CC=O > Ph > Me₃CC≡C > CN.⁸²

In summary, 1,2 free radical migrations are much less prevalent than the analogous carbocation processes, and are important only for aryl, vinylic, acetoxy, and halogen migrating groups. The direction of migration is normally toward the more stable radical, but “wrong-way” rearrangements are also known.⁸³

Despite the fact that hydrogen atoms do not migrate 1,2, longer free radical migrations of hydrogen are known.⁸⁴ The most common are 1,5-shifts, but 1,6 and longer shifts have also been found (see Reaction 18-29). The possibility of 1,3-hydrogen shifts has been much investigated, but it is not certain if any actually occur. If they do they are rare, presumably because the most favorable geometry for C••H••C in the transition state is linear and this geometry cannot be achieved in a 1,3-shift. 1,4-Shifts are definitely known, but are still not very common. These long shifts are best regarded as internal abstractions of hydrogen (for Reactions, see 14-6 and 18-40):

Transannular shifts of hydrogen atoms have also been observed.⁸⁵

18.D. CARBENE REARRANGEMENTS⁸⁶

Carbenes can rearrange to alkenes in many cases.⁸⁷ A 1,2-hydrogen shift leads to an alkene, and this is often competitive with insertion reactions.⁸⁸ Benzylchlorocarbene (**47**) rearranges via a 1,2-hydrogen shift to give the alkene.⁸⁹ Similarly, carbene **48** rearranges to alkene **49**, and replacement of H on the α -carbon with D showed a deuterium isotope effect of ~ 5 .⁹⁰ Vinylidene carbene ($\text{H}_2\text{C}=\text{C}:$) rearranges to acetylene.⁹¹ Rearrangement of alkylidene carbene (**50**) has been calculated to give the highly unstable cyclopentyne (**51**), which cannot be isolated, but can give a [2 + 2] cycloaddition product (Reaction 15-63) when generated in the presence of a simple alkene.⁹² The spiro carbenes undergo rearrangement reactions.⁹³

18.E. ELECTROPHILIC REARRANGEMENTS⁹⁴

Rearrangements in which a group migrates without its electrons are rarer than the two kinds previously considered, but the general principles are the same. A carbanion (or other negative ion) is created first, and the actual rearrangement step involves migration of a group without its electrons:

The product of the rearrangement may be stable or may react further, depending on its nature (see also, Reaction 18-2). An *ab initio* study predicts that a [1,2]-alkyl shift in alkyne anions should be facile.⁹⁵

18.F. REACTIONS

The reactions in this chapter are classified into three main groups and 1,2-shifts are considered first. Within this group, reactions are classified according to (1) the identity of the substrate atoms A and B and (2) the nature of the migrating group W. The cyclic

rearrangements are in the second group. The third group consists of rearrangements that cannot be fitted into either of the first two categories.

Reactions in which the migration terminus is on an aromatic ring have been treated under aromatic substitution. These are Reactions **11-27–11-32**, **11-36**, **13-30–13-32**, and, partially, **11-33**, **11-38**, and **11-39**. Double-bond shifts have also been treated in other chapters, although they may be considered rearrangements (Sec. 8.A and Reactions **12-4**, and **12-2**). Other reactions that may be regarded as rearrangements are the *Pummerer* (**19-83**) and *Willgerodt* (**19-84**) reactions.

18.F.i. 1,2-Rearrangements

A. Carbon-to-Carbon Migrations of R, H, and Ar

18-1 Wagner–Meerwein and Related Reactions

1/Hydro,1/hydroxy-(2/→1/alkyl)- migro- elimination, and so on

Wagner–Meerwein rearrangements were first discovered in reactions of bicyclic terpenes, and most of the early development of this reaction was with these compounds.⁹⁶ An example is the conversion of isoborneol to camphene. It fundamentally involves a 1,2-alkyl shift of an intermediate carbocation, (e.g., **52** \rightarrow **53**). When alcohols are treated with acids, simple substitution (e.g., Reaction **10-48**) or elimination (Reaction **17-1**) usually accounts for most or all of the products. But in many cases, especially where two or three alkyl or aryl groups are on the β carbon, some or all of the product is rearranged. These rearrangements have been called *Wagner–Meerwein rearrangements*, although this term is nowadays reserved for relatively specific transformations (e.g., isoborneol to camphene and related reactions). As pointed out previously, the carbocation that is a direct product of the rearrangement must stabilize itself, and most often it does this by the loss of a hydrogen β to it, so the rearrangement product is usually an alkene.⁹⁷ If there is a choice of protons, *Zaitsev's rule* (Sec. 17.A.i, category 3) governs the direction, as expected. Sometimes a different positive group is lost instead of a proton. Less often, the new carbocation reacts with a nucleophile instead of losing a proton. The nucleophile may be the water that is the original leaving group, in which case the product is a rearranged alcohol; or it may be some other species present (solvent, added nucleophile, etc.).

Rearrangement is usually predominant in neopentyl and neophyl types of substrates, and with these types normal nucleophilic substitution is difficult (normal elimination is of course impossible). Under S_N2 conditions, substitution is extremely slow⁹⁸; and under S_N1 conditions, carbocations are formed that rapidly rearrange. However, free radical

⁹⁶ See Hogeveen, H.; van Kruchten, E.M.G.A. *Top. Curr. Chem.* **1979**, 80, 89; Arbuzov, B.A.; Isaeva, Z.G. *Russ. Chem. Rev.* **1976**, 45, 673; Banthorpe, D.V.; Whittaker, D. *Q. Rev. Chem. Soc.* **1966**, 20, 373.

⁹⁷ See Kaupp, G. *Top. Curr. Chem.* **1988**, 146, 57.

⁹⁸ See, however, Lewis, R.G.; Gustafson, D.H.; Erman, W.F. *Tetrahedron Lett.* **1967**, 401; Paquette, L.A.; Philips, J.C. *Tetrahedron Lett.* **1967**, 4645; Anderson, P.H.; Stephenson, B.; Mosher, H.S. *J. Am. Chem. Soc.* **1974**, 96, 3171.

substitution, unaccompanied by rearrangement, can be carried out on neopentyl systems, although, as seen previously (Sec. 18.C), neophyl systems undergo rearrangement as well as substitution.

Examples of carbocation rearrangements are found in simpler systems (e.g., neopentyl chloride, example *a*) and even 1-bromopropane (example *b*). These examples illustrate the following points:

1. Hydride ion can migrate. In example *b*, it was hydride that shifted, not bromine:

2. The leaving group does not have to be H₂O, but can be any departing species whose loss creates a carbocation, including N₂ from aliphatic diazonium ions⁹⁹ (see the section on leaving groups in nucleophilic substitution in Sec. 10.A.ii, category 1). Rearrangement may follow when the carbocation is created by addition of a proton or other positive species to a double bond.
3. Example *b* illustrates that the last step can be substitution instead of elimination.
4. Example *a* illustrates that the new double bond is formed in accord with *Zaitsev's rule*.

2-Norbornyl cations (see **52**), besides displaying the 1,2-shifts of a CH₂ group previously illustrated for the isoborneol → camphene conversion, are also prone to rapid hydride shifts from the 3 to the 2 position (known as 3,2-shifts). These 3,2-shifts usually take place from the *exo* side¹⁰⁰; that is, the 3-*exo* hydrogen migrates to the 2-*exo* position.¹⁰¹ This stereoselectivity is analogous to the behavior previously seen for norbornyl systems, namely, that nucleophiles attack norbornyl cations from the *exo* side (Sec. 10.C.i, category 4) and that addition to norbornenes is also usually from the *exo* direction (Sec. 15.B.iii).

For rearrangements of alkyl carbocations, the direction of rearrangement is usually toward the most stable carbocation (or radical), which is tertiary > secondary > primary, but rearrangements in the other direction have also been found,¹⁰² and the product is

⁹⁹ See, in Patai, S. *The Chemistry of the Amino Group*, Wiley, NY, **1968**, the articles by White, E.H.; Woodcock, D.J. pp. 407–497 (473–483) and by Banthorpe, D.V. pp. 585–667 (pp. 586–612).

¹⁰⁰ See Berson, J.A.; Hammons, J.H.; McRowe, A.W.; Bergman, R.G.; Remanick, A.; Houston, D. *J. Am. Chem. Soc.* **1967**, 89, 2590.

¹⁰¹ For an example of a 3,2-endo shift, see Wilder, Jr., P.; Hsieh, W. *J. Org. Chem.* **1971**, 36, 2552.

¹⁰² See Cooper, C.N.; Jenner, P.J.; Perry, N.B.; Russell-King, J.; Storesund, H.J.; Whiting, M.C. *J. Chem. Soc. Perkin Trans. 2* **1982**, 605.

sometimes a mixture corresponding to an equilibrium mixture of the possible carbocations. The *Wagner–Meerwein rearrangement* has been observed for a secondary to a secondary carbocation rearrangement, leading to some controversy. Winstein¹⁰³ described norbornyl cations in terms of the resonance structures represented by the nonclassical ion **54**.¹⁰⁴ This view was questioned, primarily by Brown,¹⁰⁵ who suggested that the facile rearrangements could be explained by a series of fast *1,3-Wagner–Meerwein shifts*.¹⁰⁶ There is considerable evidence, however, that *the norbornyl cation rearranges with σ participation*,¹⁰⁷ and there is strong NMR evidence for the nonclassical ion in superacids at low temperatures.¹⁰⁸

As alluded to above, the term “*Wagner–Meerwein rearrangement*” is not precise. Some use it to refer to all the rearrangements in this section and in Reaction **18-2**. Others use it only when an alcohol is converted to a rearranged alkene. Many use the term only for rearrangements that involve a nonclassical carbocation intermediate. Terpene chemists call the migration of a methyl group the *Nametkin rearrangement*. The term *retropinacol rearrangement* is often applied to some or all of these. Fortunately, this disparity in nomenclature does not seem to cause much confusion. Catalytic asymmetric *Wagner–Meerwein shifts* have been observed.¹⁰⁹ An asymmetric, Pd catalyzed *Wagner–Meerwein shift* has been reported with allenic alcohols.¹¹⁰

Several of these rearrangements sometimes occur in one molecule, either simultaneously or in rapid succession. A spectacular example is found in the triterpene series. Friedelin is a triterpenoid ketone found in cork. Reduction gives 3 β -friedelanol (**55**). When this compound is treated with acid, 13(18)-oleanene (**56**) is formed.¹¹¹ In this case, *seven* 1,2-shifts take place. Loss of H₂O from position 3 leaves a positive charge, and

the following shifts occur: hydride from 4 to 3; methyl from 5 to 4; hydride from 10 to 5; methyl from 9 to 10; hydride from 8 to 9; methyl from 14 to 8; and methyl from 13 to 14. This leaves a positive charge at position 13, which is stabilized by loss of the proton at the 18 position to give **56**. All these shifts are stereospecific, the group always migrating on the side of the ring system on which it is located; that is, a group above the “plane” of the ring system (indicated by a solid line in **55**) moves above the plane, and a group below the plane (dashed line) moves below it. It is probable that the seven shifts are not all concerted, although some of them may be, for intermediate products can be isolated.¹¹² As an illustration of point 2 (see above), it may be mentioned that friedelene, derived from dehydration of **55**, also gives **56** on treatment with acid.¹¹³

Some alkanes undergo *Wagner–Meerwein rearrangements* if treated with Lewis acids and a small amount of initiator. An interesting application of this reaction is the conversion of tricyclic molecules to adamantane and its derivatives.¹¹⁴ It has been found that *all* tricyclic alkanes containing 10 carbons are converted to adamantane by treatment with a Lewis acid, (e.g., AlCl_3). If the substrate contains > 10 carbons, alkyl-substituted adamantanes are produced. The IUPAC name for these reactions is *Schleyer adamantization*. Two examples are the AlCl_3 -mediated reactions of **57** and **58**.

If 14 or more carbons are present, the product may be diamantane or a substituted diamantane.¹¹⁵ These reactions are successful because of the high thermodynamic stability of adamantane, diamantane, and similar diamond-like molecules. The most stable of a set of C_nH_m isomers (called the *stabilomer*) will be the end product if the reaction reaches equilibrium.¹¹⁶ Best yields are obtained by the use of “sludge” catalysts¹¹⁷ (i.e., a mixture of AlX_3 and *tert*-butyl bromide or *sec*-butyl bromide).¹¹⁸ Though it is certain that these adamantane-forming reactions take place by nucleophilic 1,2 shifts, the exact pathways are not easy to unravel because of their complexity.¹¹⁹ Treatment of adamantane-2- ^{14}C with AlCl_3 results in total carbon scrambling on a statistical basis.¹²⁰

As already indicated, the mechanism of the *Wagner–Meerwein rearrangement* is usually nucleophilic. Free radical rearrangements are also known (see Section 18.A), though virtually only with aryl migration. However, carbanion mechanisms (electrophilic)

have also been found.⁹⁴ Thus $\text{Ph}_3\text{CCH}_2\text{Cl}$ treated with sodium gave $\text{Ph}_2\text{CHCH}_2\text{Ph}$ along with unrearranged products.¹²¹ This is called the *Grovenstein-Zimmerman rearrangement*. The intermediate is $\text{Ph}_3\text{CCH}_2^-$, and the phenyl moves without its electron pair. Only aryl and vinylic,¹²² and not alkyl, groups migrate by the electrophilic mechanism (see the introductory section preceding Sec. 18.A) and transition states or intermediates analogous to **41** and **42** are likely.¹²³

18-2 The Pinacol Rearrangement

1/O-Hydro,3/hydroxy-(2/→3/alkyl)-migr-o-elimination

When 1,2-diols (*vic*-diols; glycols) are treated with acids,¹²⁴ they rearrange to give aldehydes or ketones, although elimination without rearrangement can also be accomplished. This reaction is called the *pinacol rearrangement*; the reaction gets its name from a prototype compound pinacol ($\text{Me}_2\text{COHCOHMe}_2$), which is rearranged to pinacolone ($\text{Me}_3\text{C-COCH}_3$).¹²⁵ In this type of reaction, reduction can compete with rearrangement.¹²⁶ The reaction has been accomplished many times, with alkyl, aryl, hydrogen, and even ethoxycarbonyl (CO_2Et)¹²⁷ as migrating groups. In most cases, each carbon has at least one alkyl or aryl group, and the reaction is most often carried out with tri- and tetrasubstituted glycols. As mentioned earlier, glycols in which the four R groups are not identical can give rise to more than one product, depending on which group migrates (see Sec. 18.A.iii for a discussion of migratory aptitudes). A noncatalytic reaction is possible in supercritical water.¹²⁸

Stereodifferentiation is possible in this reaction.¹²⁹ When TMSOTf was used to initiate the reaction, it was shown to be highly regioselective.¹³⁰ Mixtures are often produced, and which group preferentially migrates may depend on the reaction conditions as well as on the nature

of the substrate. Thus the action of cold, concentrated sulfuric acid on **59** produces mainly the ketone **60** (methyl migration), while treatment of **59** with acetic acid containing a trace of sulfuric acid gives mostly **61** (phenyl migration).¹³¹ If at least one R is hydrogen, aldehydes can be produced as well as ketones. Generally, aldehyde formation is favored by the use of mild conditions (lower temperatures, weaker acids), because under more drastic conditions the aldehydes may be converted to ketones (Reaction **18-4**). The reaction has been carried out in the solid state, by treating solid substrates with HCl gas or with a solid organic acid.¹³²

The mechanism involves a simple 1,2-shift. The ion **62** (where all four R groups are Me) has been trapped by the addition of tetrahydrothiophene.¹³³ A migration takes place from the tertiary position because carbocations stabilized by an oxygen atom are even more stable than tertiary alkyl cations (Sec. 5.A.ii). In addition, the new carbocation can immediately stabilize itself by losing a proton.

It is obvious that other compounds in which a positive charge can be placed on a carbon α to one bearing an OH group can also give this rearrangement. This is true for β -amino alcohols, which rearrange on treatment with nitrous acid (this is called the *semipinacol rearrangement*), for iodohydrins, for which the reagent is mercuric oxide or silver nitrate, for β -hydroxyalkyl selenides $[\text{R}^1\text{R}^2\text{C}(\text{OH})\text{C}(\text{SeR}^5)\text{R}^3\text{R}^4]$,¹³⁴ and for allylic alcohols,¹³⁵ which can rearrange on treatment with a strong acid that protonates the double bond. A related rearrangement is the Et_2Zn mediated rearrangement of bromohydrins to give ketones.¹³⁶

A similar rearrangement is given by epoxides, when treated with acidic reagents (e.g., BF_3 -etherate or MgBr_2 -etherate), 5M LiClO_4 in ether,¹³⁷ InCl_3 ,¹³⁸ $\text{Bi}(\text{OTf})_3$,¹³⁹ or sometimes by heat alone.¹⁴⁰ Epoxides are converted to aldehydes or ketones on treatment with certain metallic catalysts¹⁴¹ including treatment with iron complexes,¹⁴² IrCl_3 ,¹⁴³ or

with BiOClO_4 .¹⁴⁴ Base-induced rearrangement is also known, but the products are usually different.¹⁴⁵

The *Meinwald rearrangement* converts epoxides to carbonyl compounds.¹⁴⁶ Several reagents mediate this transformation, including Cu compounds.¹⁴⁷ A closely related reaction of vinyl epoxides gives alkenyl ketones upon treatment with Ga compounds.¹⁴⁸ It has been shown that epoxides are intermediates in the pinacol rearrangements of certain glycols.¹⁴⁹ Among the evidence for the mechanism given is that $\text{Me}_2\text{COHCOHMe}_2$, $\text{Me}_2\text{COHC}(\text{NH}_2)\text{Me}_2$, and $\text{Me}_2\text{COHCClMe}_2$ gave the reaction at different rates (as expected), but yielded the *same mixture* of two products, pinacol and pinacolone, indicating a common intermediate.¹⁵⁰

A good way to prepare β -diketones consists of heating α,β -epoxy ketones at 80–140 °C in toluene with small amounts of $(\text{Ph}_3\text{P})_4\text{Pd}$ and dppe.¹⁵¹ Epoxides are converted to 1,2-diketones with Bi, DMSO, O_2 and a catalytic amounts of $\text{Cu}(\text{OTf})_2$ at 100 °C.¹⁵² α,β -Epoxy ketones are also converted to 1,2-diketones with a Ru catalyst¹⁵³ or an Fe catalyst.¹⁵⁴ Epoxides with an α -hydroxyalkyl substituent give a pinacol rearrangement product in the presence of a ZnBr_2 ¹⁵⁵ or $\text{Tb}(\text{OTf})_3$ ¹⁵⁶ catalyst to give a γ -hydroxy ketone.

Oxaziridines are converted to ring-expanded lactams under photochemical conditions.¹⁵⁷ *N*-Tosyl aziridines with an α -hydroxyalkyl substituent give a pinacol rearrangement product in the presence of Lewis acids (e.g., SmI_2), in this case a keto-*N*-tosyl amide.¹⁵⁸

β -Hydroxy ketones can be prepared by treating the silyl ethers (**63**) of α,β -epoxy alcohols with TiCl_4 .¹⁵⁹

18-3 Expansion and Contraction of Rings

Demyanov ring contraction; Demyanov ring expansion

When a positive charge is formed on an alicyclic carbon, migration of an alkyl group can take place to give ring contraction, producing a ring that is one carbon smaller than the original, as in the interconversion of the cyclobutyl cation and the cyclopropylcarbinyl cation (**64**). Note that this change involves conversion of a

secondary to a primary carbocation. In a similar manner, when a positive charge is placed on a carbon α to an alicyclic ring, ring expansion can take place.¹⁶⁰ The new carbocation, and the old one, can then give products by combination with a nucleophile (e.g., the alcohols shown above), or by elimination, so that this reaction is a special case of **18-1**. Often, both rearranged and unrearranged products are formed, so that, for example, cyclobutylamine and cyclopropylmethanamine give similar mixtures of the two alcohols shown above on treatment with nitrous acid (a small amount of 3-buten-1-ol is also produced). When the carbocation is formed by diazotization of an amine, the reaction is called the *Demyanov rearrangement*,¹⁶¹ but of course similar products are formed when the carbocation is generated in other ways. The expansion reaction has been performed on rings of C_3 – C_8 ,¹⁶² but yields are best with the smaller rings, where relief of small-angle strain provides a driving force for the reaction. Strain is apparently much less of a factor in the cyclobutyl–cyclopropylmethyl interconversion (for a discussion of this interconversion, see Sec. 10.C.i). The influence of substituents on this rearrangement has been examined.¹⁶³ Note that a hybrid of a [1,2]-sigmatropic hydrogen shift (also See **18-29**) and a two-electron-electrocyclic ring opening has been discovered for cyclopropylcarbinyl cations that was labeled as a “hiscotropic” rearrangement.”¹⁶⁴ The contraction reaction has been applied to four-membered rings and to rings of C_6 – C_8 , but contraction of a cyclopentyl cation to a cyclobutylmethyl system is generally not feasible because of the additional strain involved.

A related rearrangement involves cyclopropyl propargylic alcohols, which gives an alkylidene cyclobutanone in the presence of Ag and Au catalysts,¹⁶⁵ or Ru and In catalysts.¹⁶⁶ Cyclopropylcarbinyl rearrangements are catalyzed by ionic liquids under

solvent-free conditions.¹⁶⁷ Methylene cyclopropanes rearrange to cyclobutenes in the presence of 1 atm of CO and Pt catalyst¹⁶⁸ or a Pd catalyst, mediated by a Cu catalyst.¹⁶⁹ Arylvinylenecyclopropanes rearrange to bicyclic systems in the presence of a Lewis acid.¹⁷⁰

Ring expansions of certain hydroxyamines (e.g., **65**) are analogous to the semipinacol rearrangement (Reaction **18-2**). This reaction is called the *Tiffeneau–Demyanov ring expansion*. These have been performed on rings of C_4 – C_8 and the yields are better than for the simple *Demyanov ring expansion*. A similar reaction has been used to expand rings of from five to eight members.¹⁷¹ In this case, a cyclic bromohydrin of the form **66** is treated with a *Grignard reagent*, which, acting as a base, removes the OH proton to give the alkoxide **67**. When **67** is heated to reflux, ring enlargement occurs. The reaction has been done with **66** in which at least one R group is phenyl or methyl,¹⁷² but fails when both R groups are hydrogen.¹⁷³

A positive charge generated on a three-membered ring gives “contraction” to an allylic cation, as shown.¹⁷⁴

As seen in Section 10.G.i, category 7, this is the reason nucleophilic substitutions are not feasible at a cyclopropyl substrate. The reaction is often used to convert cyclopropyl halides and tosylates to allylic products, especially for the purpose of ring expansion, an example being the conversion of **68** to **69**.¹⁷⁵ The stereochemistry of these cyclopropyl cleavages is governed by the principle of orbital symmetry conservation (for a discussion, see Reaction **18-27**, the *Möbius–Hückel method*).

Three-membered rings can also be cleaved to unsaturated products in at least two other ways. (1) Upon pyrolysis, cyclopropanes can undergo “contraction” to propenes.¹⁷⁶ In the simplest case, cyclopropane gives propene when heated to 400–500 °C. The mechanism is generally regarded¹⁷⁷ as involving a diradical

intermediate¹⁷⁸ (recall that free radical 1,2-migration is possible for diradicals, Sec. 18.C). (2) The generation of a carbene or carbenoid carbon in a three-membered ring can lead to allenes, and allenes are often prepared in

this way.¹⁷⁹ Flash vacuum pyrolysis of 1-chlorocyclopropane thermally rearranges to chloroallene.¹⁸⁰ One way to generate such a species is treatment of a 1,1-dihalocyclopropane with an alkyl lithium compound (Reaction 12-39).¹⁸¹ In contrast, the generation of a carbene or carbenoid at a cyclopropylmethyl carbon gives ring expansion.¹⁸²

Some free radical ring enlargements are also known, an example being¹⁸³:

This reaction has been used to make rings of 6, 7, 8, and 13 members. A possible mechanism is

This reaction has been extended to the expansion of rings by three or four carbons, by the use of a substrate containing $(\text{CH}_2)_n\text{X}$ ($n = 3$ or 4) instead of CH_2Br .¹⁸⁴ By this means, 5-, 6-, and 7-membered rings were enlarged to 18–11-membered rings. A β -keto ester (e.g., 2-carboxyethyl cyclohexanone) is converted to 3-carboxyethyl cycloheptanone when treated with $\text{CF}_3\text{CO}_2\text{ZnCH}_2\text{I}$.¹⁸⁵

18-4 Acid-Catalyzed Rearrangements of Aldehydes and Ketones

1/Alkyl,2/alkyl-interchange, and so on

Rearrangements of this type, where a group α to a carbonyl “changes places” with a group attached to the carbonyl carbon, occur when migratory aptitudes are favorable.¹⁸⁶ The R^2 , R^3 , and R^4 groups may be alkyl or hydrogen. Certain aldehydes have been converted to ketones, and ketones to other ketones (though more drastic conditions are required for the latter), but no rearrangement of a ketone to an aldehyde ($\text{R}^1 = \text{H}$) has so far been reported. There are two mechanisms,¹⁸⁷ each beginning with protonation of the oxygen and each involving two migrations. In one pathway, the migrations are in opposite directions¹⁸⁸:

In the other pathway, the migrations are in the same direction. The actual mechanism of this pathway is not certain, but an epoxide (protonated) intermediate¹⁸⁹ is one possibility¹⁹⁰:

If the reaction is carried out with ketone labeled in the $\text{C}=\text{O}$ group with ^{14}C , the first pathway predicts that the product will contain all the ^{14}C in the $\text{C}=\text{O}$ carbon, while in the second pathway the label will be in the α carbon (demonstrating migration of oxygen). The results of such experiments¹⁹¹ have shown that in some cases only the $\text{C}=\text{O}$ carbon was

¹⁸⁹ Zook, H.D.; Smith, W.E.; Greene, J.L. *J. Am. Chem. Soc.* **1957**, 79, 4436.

¹⁹⁰ Some such pathway is necessary to account for the migration of oxygen that is found. It may involve a protonated epoxide, a 1,2-diol, or simply a 1,2-shift of an OH group.

¹⁹¹ See Fry, A.; Oka, M. *J. Am. Chem. Soc.* **1979**, 101, 6353.

labeled, in other cases only the α carbon, while in still others both carbons bore the label, indicating that in these cases both pathways were in operation. With α -hydroxy aldehydes and ketones, the process may stop after only one migration (this is called the α -ketol rearrangement).

The α -ketol rearrangement can also be brought about by base catalysis, but only if the alcohol is tertiary, since if R^1 or $R^2 = \text{hydrogen}$, enolization of the substrate is more favored than rearrangement.

18-5 The Dienone–Phenol Rearrangement

2/C→5/O-Hydro,1/C→2/C-alkyl-bis-migration

Cyclohexadienone derivatives that have two alkyl groups in the 4 position undergo, on acid treatment,¹⁹² 1,2-migration of one of these groups from **70** to give the phenol. Note that a photochemical version of this reaction has been observed.¹⁹³ The driving force in the overall reaction (the *dienone–phenol rearrangement*) is of course creation of an aromatic system.¹⁹⁴ Note that **70** and **71** are arenium ions (Sec. 5.A.ii), the same as those generated by attack of a phenol on an electrophile.¹⁹⁵ Sometimes, in the reaction of a phenol with an electrophile, a kind of reverse rearrangement (called the *phenol–dienone rearrangement*) takes place, though without an actual migration.¹⁹⁶ An example is

18-6 The Benzil–Benzilic Acid Rearrangement

1/*O*-Hydro,3/oxido-(1/→2/aryl)-*migro*-addition

When treated with base, α -diketones rearrange to give the salts of α -hydroxy acids, a reaction known as the *benzil–benzilic acid rearrangement* (benzil is PhCOCOPh ; benzilic acid is $\text{Ph}_2\text{COHCO}_2\text{H}$).¹⁹⁷ A Rh catalyzed version of this reaction has also been reported.¹⁹⁸ Though the reaction is usually illustrated with aryl groups, it can also be applied to aliphatic diketones¹⁹⁹ and to α -keto aldehydes. The use of an alkoxide instead of hydroxide gives the corresponding ester directly,²⁰⁰ although alkoxide ions that are readily oxidized (e.g., OEt^- or OCHMe_2^-) are not useful here, since they reduce the benzil to a benzoin. The mechanism is similar to the rearrangements in Reaction 18-1–18-4, but there is a difference: The migrating group does not move to a carbocation. The first step is attack of the base at the carbonyl group, the same as the first step of the tetrahedral mechanism of nucleophilic substitution (Sec. 16.A.i) and of many additions to the $\text{C}=\text{O}$ bond (Chapter 16):

The mechanism has been intensely studied,¹⁸⁸ and there is much evidence for it.²⁰¹ The reaction is irreversible.

OS I, 89.

18-7 The Favorskii Rearrangement

2/Alkoxy-de-chloro(2/→1/alkyl)-*migro*-substitution

The reaction of α -halo ketones (chloro, bromo, or iodo) with alkoxide ions²⁰² to give rearranged esters is called the *Favorskii rearrangement*.²⁰³ The use of hydroxide ions or amines as bases leads to the free carboxylic acid (salt) or amide, respectively,

instead of the ester. Cyclic α -halo ketones give ring contraction, as in the conversion of **72** to **73**.

The reaction has also been carried out on α -hydroxy ketones²⁰⁴ and on α,β -epoxy ketones, which give β -hydroxy acids.²⁰⁵ The fact that an epoxide gives a reaction analogous to a halide indicates that the oxygen and halogen are leaving groups in a nucleophilic substitution step.

Investigation of the mechanism²⁰⁶ of the *Favorskii rearrangement* has led to proposals for at least five different mechanisms. However, the finding²⁰⁷ that **74** and **75** both give **76** (this behavior is typical) shows that any mechanism where the halogen leaves and R^1 takes its place is invalid, since in such a case **74** would be expected to give **76** (with PhCH_2 migrating), but **75** should give PhCHMeCOOH (with CH_3 migrating). That is, in the case of **75**, it was PhCH that migrated and not methyl. Another important result was determined by radioactive labeling. Chloroketone (**72**), in which C-1 and C-2 were equally labeled with ^{14}C , was converted to **73**. The product was found to contain 50% of the label on the carbonyl carbon, 25% on C-1, and 25% on C-2.²⁰⁸ Now the carbonyl carbon, which originally carried half of the radioactivity, still had this much, so the rearrangement did not directly affect it. However, if the C-6 carbon had migrated to C-2, the other half of the radioactivity would be only on C-1 of the product:

On the other hand, if the migration had gone the other way (if the C-2 carbon had migrated to C-6), then this half of the radioactivity would be found solely on C-2 of the product. The fact that C-1 and C-2 were equally labeled showed that *both migrations occurred*, with equal probability. Since C-2 and C-6 of **72** are not equivalent, this means that there must be a symmetrical intermediate.²⁰⁹ The type of intermediate that best fits the circumstances is a cyclopropanone,²¹⁰ and the mechanism (for the general case) is formulated (replacing R^1

²⁰⁸ Loftfield, R.B. *J. Am. Chem. Soc.* **1951**, 73, 4707.

²⁰⁹ A preliminary migration of the chlorine from C-2 to C-6 was ruled out by the fact that recovered **72** had the same isotopic distribution as the starting **72**.

²¹⁰ See Wasserman, H.H.; Clark, G.M.; Turley, P.C. *Top. Curr. Chem.* **1974**, 47, 73; Turro, N.J. *Acc. Chem. Res.* **1969**, 2, 25.

of our former symbolism with CHR^5R^6 , since it is obvious that for this mechanism an α hydrogen is required on the non-halogenated side of the carbonyl):

The intermediate corresponding to **78**, in the case of **72**, is a symmetrical compound, and the three-membered ring can be opened with equal probability on either side of the carbonyl, accounting for the results with ^{14}C . In the general case, **78** is not symmetrical and should open on the side that gives the more stable carbanion.²¹¹ This accounts for the fact that **74** and **75** give the same product. The intermediate in both cases is **77**, which always opens to give the carbanion stabilized by resonance. The cyclopropanone intermediate (**78**) has been isolated in the case where $\text{R}^2 = \text{R}^5 = t\text{-Bu}$ and $\text{R}^3 = \text{R}^6 = \text{H}$,²¹² and it has also been trapped.²¹³ Also, cyclopropanones synthesized by other methods have been shown to give Favorskii products on treatment with NaOMe or other bases.²¹⁴

The mechanism discussed is in accord with all the facts when the halo ketone contains an α hydrogen on the other side of the carbonyl group. However, ketones that do not have an α hydrogen also rearrange to give the same type of product in what is usually called the *quasi-Favorskii rearrangement*. The *quasi-Favorskii rearrangement* cannot take place by the cyclopropanone mechanism. The mechanism that is generally accepted (called the *semibenzilic mechanism*²¹⁵) is a base-catalyzed pinacol rearrangement-type mechanism similar to that of **18-6**. This mechanism requires inversion at the migration terminus and this has been found.²¹⁶ It has been shown that even where there is an appropriately situated α hydrogen, the semibenzilic mechanism may still operate.²¹⁷

An interesting analogue of the *Favorskii rearrangement* treats a ketone, (e.g., 4-*tert*-butylcyclohexanone), without an α -halogen with $\text{Ti}(\text{NO}_3)_3$ to give 3-*tert*-butylcyclopentane-1-carboxylic acid.²¹⁸

In the *Arndt–Eistert synthesis*, an acyl halide is converted to a carboxylic acid with one additional carbon.²¹⁹ The first step of this process is Reaction **16-89**. The actual rearrangement occurs in the second step after treatment of the diazo ketone with water and silver oxide or with silver benzoate and triethylamine. This rearrangement is called the *Wolff rearrangement*.²²⁰ It is the best method of increasing a carbon chain by one from a *carboxylic acid* (see Reaction **10-75** and **16-30**). If an alcohol ($R'OH$) is used instead of water, the ester (RCH_2CO_2R') is isolated.²²¹ Similarly, treatment with ammonia gives the amide. Other catalysts are sometimes used (colloidal Pt, Cu, etc.), but occasionally the diazo ketone is simply heated or photolyzed in the presence of water, an alcohol, or ammonia, with no catalyst at all using ultrasound.²²² The photolysis method²²³ often gives better results than the Ag catalysis method. Of course, diazo ketones prepared in any other way also give the rearrangement.²²⁴ The reaction is of wide scope. The R group may be alkyl or aryl and may contain many functional groups including unsaturation, but not including groups acidic enough to react with CH_2N_2 or diazo ketones (e.g., Reaction **10-5** and **10-19**). Sometimes the reaction is performed with other diazoalkanes (i.e., $R'CHN_2$) to give $RCHR'COOH$. The reaction has been used for ring contraction of cyclic diazo ketones²²⁵ (e.g., **79**).²²⁶

An asymmetric variation converted ketones to esters using an azaferrocene catalyst.²²⁷

The mechanism is generally regarded as involving formation of a carbene.²²⁸ It is the divalent carbon that has the open sextet and to which the migrating group brings its electron pair:

The actual product of the reaction is thus the ketene, which then reacts with water (**15-3**), an alcohol (**15-5**), or ammonia or an amine (**15-8**). Particularly stable ketenes²²⁹

(e.g., $\text{Ph}_2\text{C}=\text{C}=\text{O}$) have been isolated and others have been trapped in other ways (e.g., as β -lactams,²³⁰ reaction **16-96**). The purpose of the catalyst is not well understood, though many suggestions have been made. This mechanism is strictly analogous to that of the *Curtius rearrangement* (Reaction **18-14**). Although the mechanism as shown above involves a free carbene and there is much evidence to support this,²³¹ it is also possible that at least in some cases the two steps are concerted and a free carbene is absent.

When the *Wolff rearrangement* is carried out photochemically, the mechanism is basically the same,²²³ but another pathway can intervene. Some of the ketocarbene originally formed can undergo a carbene-carbene rearrangement, through an oxirene intermediate.²³² This was shown by ^{14}C labeling experiments, where

diazoketones labeled in the carbonyl group gave rise to ketenes that bore the label at both $\text{C}=\text{C}$ carbons.²³³ In general, the smallest degree of scrambling (and thus of the oxirene pathway) was found when $\text{R}'=\text{H}$. An intermediate believed to be an oxirene has been detected by laser spectroscopy.²³⁴ The oxirene pathway is not found in the thermal *Wolff rearrangement*. It is likely that an excited singlet state of the carbene is necessary for the oxirene pathway to intervene.²³⁵ In the photochemical process, ketocarbene intermediates, in the triplet state, have been isolated in an Ar matrix at 10–15 K, where they have been identified by UV-visible, IR, and ESR spectra.²³⁶ These intermediates went on to give the rearrangement via the normal pathway, with no evidence for oxirene intermediates.

The diazo ketone can exist in two conformations, called *s*-(*E*) and *s*-(*Z*). Studies have shown that *Wolff rearrangement* takes place preferentially from the *s*-(*Z*) conformation.²³⁷ OS **III**, 356; **VI**, 613, 840.

18-9 Homologation of Aldehydes and Ketones

Methylene-insertion

Aldehydes and ketones²³⁸ can be converted to their homologues with diazomethane.²³⁹ Several other reagents²⁴⁰ are also effective, including Me_3SiI , and then silica gel.²⁴¹ With the diazomethane reaction, formation of an epoxide (**16-46**) is a side reaction. Superficially, this reaction appears to be similar to the insertion of carbenes into C—H bonds, (Reaction **12-21**, and IUPAC names it as an insertion), but the mechanism is quite different. However, it is a true rearrangement and no free carbene is involved. The first step is an addition to the C=O bond:

The betaine (**80**) can sometimes be isolated. As shown in Reaction **16-46**, intermediate **80** can also go to the epoxide. The evidence for this mechanism has been summarized in the review by Gutsche.²³⁹ Note that this mechanism is essentially the same as in the apparent “insertions” of oxygen (Reaction **18-19**) and nitrogen (Reaction **18-16**) into ketones.

1,3-Diketones are converted to 1,4-diketones upon treatment with $\text{CF}_3\text{CO}_2\text{ZnCH}_2\text{I}$.²⁴² In a related reaction, alkenes insert into aldehydes in the presence of a Rh catalyst to give the corresponding ketone.²⁴³

Aldehydes give fairly good yields of methyl ketones; that is, hydrogen migrates in preference to alkyl. The most abundant side product is not the homologous aldehyde, but the epoxide. However, the yield of aldehyde at the expense of methyl ketone can be increased by the addition of methanol. If the aldehyde contains electron-withdrawing groups, the yield of epoxides is increased and the ketone is formed in smaller amounts, if at all. Ketones give poorer yields of homologous ketones. Epoxides are usually the predominant product here, especially when one or both R groups contain an electron-withdrawing group. The yield of ketones also decreases with increasing length of the chain. The use of a Lewis acid increases the yield of ketone.²⁴⁴ Cyclic ketones,²⁴⁵ three membered²⁴⁶ and larger, behave particularly well and give good yields of ketones with the ring expanded by one.²⁴⁷ Aliphatic diazo compounds (RCHN_2 and R_2CN_2) are sometimes used instead of

diazomethane, with the expected results.²⁴⁸ Ethyl diazoacetate can be used analogously, in the presence of a Lewis acid or of triethyloxonium fluoroborate,²⁴⁹ to give a β -keto ester, (e.g., **81**).

When unsymmetrical ketones were used in this reaction (with BF_3 as catalyst), the less highly substituted carbon preferentially migrated.²⁵⁰ The reaction can be made regioselective by applying this method to the α -halo ketone, in which case only the other carbon migrates.²⁵¹ The ethyl diazoacetate procedure has also been applied to the acetals or ketals of α,β -unsaturated aldehydes and ketones.²⁵²

Bicyclic ketones can be expanded to form monocyclic ketones in the presence of certain reagents. Treatment of a bicyclo[4.1.0]hexan-4-one derivative with SmI_2 led to a cyclohexanone.²⁵³ The SmI_2 also converts α -halomethyl cyclic ketones to the next larger ring ketone²⁵⁴ and cyclic ketones to the next larger ring ketone in the presence of CH_2I_2 .²⁵⁵

Another homologation reaction converts an aldehyde to its tosyl hydrazone, and subsequent reaction with an aldehyde and NaOEt/EtOH give a ketone.²⁵⁶ The reaction of an aldehyde with vinyl acetate and Ba(OH)_2 gives the homologated conjugated aldehyde.²⁵⁷

B. Carbon-to-Carbon Migrations of Other Groups

18-10 Migrations of Halogen, Hydroxyl, Amino, and so on

Hydroxy-de-bromo-*cine*-substitution, and so on

When a nucleophilic substitution is carried out on a substrate that has a neighboring group (Sec. 10.C) on the adjacent carbon, a cyclic intermediate can be generated that is opened on the opposite side, resulting in migration of the neighboring group. In the example shown above (NR_2 = morpholino),²⁵⁸ the reaction took place via an aziridinium salt (**82**) to give an α -amino- β -hydroxy ketone. Sulfonate esters and halides can also

migrate in this reaction.²⁵⁹

α-Halo and α-acyloxy epoxides undergo ready rearrangement to α-halo and α-acyloxy ketones, respectively.²⁶⁰ These substrates are prone to rearrange, and often do so upon standing without a catalyst, although an acid catalyst is necessary in some cases. The reaction is essentially the same as the rearrangement of epoxides shown in **18-2**, except that halogen or acyloxy is the migrating group (as shown above; however, it is also possible for one of the R groups (alkyl, aryl, or hydrogen) to migrate instead, and mixtures are sometimes obtained). In a related reaction, α-bromoaziridines undergo rearrangement to the isomerized α-bromoaziridine in the presence of MgBr₂.²⁶¹

In the presence of a Cu catalyst, alkenyl epoxides (vinyl oxiranes) rearrange to a 2,5-dihydrofuran.²⁶² Alkenyl thiiranes are similarly converted to 2,5-dihydrothiophenes with a Cu catalyst.²⁶³

Allylic alcohols migrate to give a new allylic alcohol in the presence of a Re catalyst. An example is the conversion of **83** to **84**.²⁶⁴ Variations using Rh²⁶⁵ or Ir²⁶⁶ catalysts are known, and methanesulfonic acid catalyzes the isomerization.²⁶⁷ In the presence of a Ru catalyst, an allylic alcohol was isomerized to an aliphatic ketone.²⁶⁸ There is a similar Au catalyzed isomerization of allylic acetates.²⁶⁹

The *Meyer-Schuster Rearrangement* is an acid-catalyzed rearrangement of a propargyl alcohol to a conjugated carbonyl compound.²⁷⁰ Rearrangement was also catalyzed by a cationic Rh-bisphosphane complex.²⁷¹ An Au catalyzed rearrangement of ethoxyalkynyl carbinols gave α,β-unsaturated esters.²⁷² The base-induced isomerization of a propargylic

alcohol gave a conjugated ketone,²⁷³ and a combination of Mo—Au led to rapid 1,3-rearrangement of propargyl alcohols.²⁷⁴ An Au—Ag catalyzed reaction with propargyl esters gave a 2-O-pivaloyl conjugated aldehyde.²⁷⁵ A similar reaction with a Pt catalyst converted a 1-ethoxy propargylic ester to a 2-carboethoxy conjugated ketone.²⁷⁶ An Au catalyzed isomerization of allenyl carbinol esters is also known.²⁷⁷

18-11 Migration of Boron

Hydro,dialkylboro-interchange, and so on

Boranes are prepared by the reaction of BH_3 (B_2H_6) or an alkylborane with an alkene (**15-16**). When a nonterminal borane is heated at temperatures ranging from 100 to 200 °C, the boron moves toward the end of the chain.²⁷⁸ The reaction is catalyzed by small amounts of borane or other species containing B—H bonds. The boron can move past a branch, for example,

but not past a double branch, for example,

The reaction is an equilibrium: **85**, **86**, and **87** each gave a mixture containing ~40% **85**, 1% **86**, and 59% **87**. The migration can go quite a long distance, including a migration of 11 positions.²⁷⁹ If the boron is on a cycloalkyl ring, it can move around the ring; if any alkyl chain is also on the ring, the boron may move from the ring to the chain, ending up at the end of the chain.²⁸⁰ The reaction is useful for the migration of double bonds in a controlled way (see **12-2**). The mechanism may involve a π complex, at least partially.²⁸¹

18-12 The Neber Rearrangement

Neber oxime tosylate-amino ketone rearrangement

α -Amino ketones can be prepared by treatment of ketoxime tosylates with a base (e.g., ethoxide or pyridine).²⁸² This reaction is called the *Neber rearrangement*. The R group is usually aryl, although the reaction has been carried out with R = alkyl or hydrogen. The R' group may be alkyl or aryl, but not hydrogen. The *Beckmann rearrangement* (Reaction 18-17) and the abnormal *Beckmann reaction* (elimination to the nitrile, Reaction 17-30) may be side reactions, although these generally occur in acid media. A similar rearrangement is given by *N,N*-dichloroamines of the type $\text{RCH}_2\text{CH}(\text{NCl}_2)\text{R}'$, where the product is also $\text{RCH}(\text{NH}_2)\text{COR}'$.²⁸³ The mechanism of the Neber rearrangement involves an azirine intermediate (**88**).²⁸⁴ The best evidence for this mechanism is that the azirine intermediate has been isolated.²⁸⁵ In contrast to the *Beckmann rearrangement*, this one is sterically indiscriminate.²⁸⁶ Both a syn and an anti ketoxime give the same product. The mechanism, as shown above, consists of three steps. However, it is possible that the first two steps are concerted, and it is also possible that what is shown as the second step is actually two steps: loss of OTs to give a nitrene, and formation of the azirine. In the case of the dichloroamines, HCl is first lost to give $\text{RCH}_2\text{C}(=\text{NCl})\text{R}'$, which then behaves analogously.²⁸⁷ *N*-Chloroimines prepared in other ways also give the reaction.²⁸⁸ Indoles have been prepared via a *Neber rearrangement*.²⁸⁹

OS V, 909; VII, 149.

C. Carbon-to-Nitrogen Migrations of R and Ar

The reactions in this group are nucleophilic migrations from a carbon to a nitrogen atom. In each case, the nitrogen atom either has six electrons in its outer shell (and thus invites the migration of a group carrying an electron pair) or else loses a nucleofuge concurrently with the migration (Sec. 18.A.i). Reactions 18-13–18-16 are used to prepare amines from acid derivatives. Reactions 18-16 and 18-17 are used to prepare amines from ketones. The mechanisms of Reaction 18-13–18-16 (with carboxylic acids) are very similar and follow

one of two patterns:

Some of the evidence²⁹⁰ is (1) configuration is retained in R (Sec. 18.A.ii); (2) the kinetics are first order; (3) intramolecular rearrangement is shown by labeling; and (4) no rearrangement occurs *within* the migrating group, for example, a neopentyl group on the carbon of the starting material is still a neopentyl group on the nitrogen of the product.

In many cases, it is not certain whether the nucleofuge X is lost first, creating an intermediate nitrene²⁹¹ or nitrenium ion, or whether migration and loss of the nucleofuge are simultaneous, as shown above.²⁹² It is likely that both possibilities can exist, depending on the substrate and reaction conditions.

18-13 The Hofmann Rearrangement

Bishydrogen-(2/→1/N-alkyl)-migro-detachment (formation of isocyanate)

In the *Hofmann rearrangement*, an unsubstituted amide is treated with sodium hypobromite (or sodium hydroxide and bromine, which is essentially the same thing) to give an isocyanate, but this compound is seldom isolated²⁹³ since it is usually hydrolyzed under the reaction conditions. The final isolated product is a primary amine that has one carbon fewer than the starting amide.²⁹⁴ The R group may be alkyl or aryl, but if it is an alkyl group of more than about six or seven carbons, low yields are obtained unless Br₂ and NaOMe are used instead of Br₂ and NaOH.²⁹⁵ Another modification uses NBS/NaOMe.²⁹⁶ Under these conditions, the product of addition to the isocyanate is the carbamate (RNHCOOMe, Reaction 16-8), which is easily isolated or can be hydrolyzed to the amine.²⁹⁷ A mixture of NBS and DBU (see Reaction 17-13) in methanol gives the carbamate,²⁹⁸ as does electrolysis in methanol.²⁹⁹

Side reactions when NaOH is the base are formation of ureas (RNHCONHR) and acylureas (RCONHCONHR) by addition, respectively, of RNH₂ and RCONH₂ to RNCO (16-20). If acylureas are desired, they can be made the main products by using only one-half of the usual quantities of Br₂ and NaOH. Another side product, but only from primary R, is the nitrile derived from oxidation of RNH₂ (Reaction 19-5).

Imides react to give amino acids, (e.g., phthalimide gives *o*-aminobenzoic acid). α-Hydroxy and α-halo amides give aldehydes and ketones by way of the unstable

α -hydroxy- or α -haloamines. However, a side product with an α -halo amide is a *gem*-dihalide. Ureas analogously give hydrazines.

The mechanism follows the pattern outlined in the discussion preceding Reaction 18-13.

The first step is an example of Reaction 12-52 and intermediate *N*-halo amides (**89**) have been isolated. Compound **89** is acidic because of the presence of two electron-withdrawing groups (acyl and halo) on the nitrogen, and in the second step, **89** loses a proton to the base. It is possible that the third step is actually two steps: loss of bromide to form a nitrene, followed by the actual migration, but most of the available evidence favors the concerted reaction.³⁰⁰ A similar reaction can be effected by the treatment of amides with lead tetraacetate.³⁰¹ Among other reagents that convert RCONH_2 to RNH_2 (R = alkyl, but not aryl) are phenyliodosyl bis(trifluoroacetate) $[\text{PhI}(\text{OCOCF}_3)_2]$ ³⁰² and hydroxy(tosyloxy) iodobenzene $[\text{PhI}(\text{OH})\text{OTs}]$.³⁰³

A variation of the *Hofmann rearrangement* treated a β -hydroxy primary amide with $\text{PhI}(\text{O}_2\text{CCF}_3)_3$ in aq acetonitrile, giving an isocyanate via $-\text{CON}-\text{I}$, which reacts with the hydroxyl group intramolecularly to give a cyclic carbamate.³⁰⁴ Note that carbamates are converted to isocyanates by heating with Montmorillonite K-10.³⁰⁵

OS II, 19, 44, 462; IV, 45; VIII, 26, 132.

18-14 The Curtius Rearrangement

Dinitrogen-(2/→1/*N*-alkyl)-migratio-detachment

The *Curtius rearrangement* involves heating acyl azides to yield isocyanates.³⁰⁶ The reaction gives good yields of isocyanates, since no water is present to hydrolyze them to the amine. Of course, they can be subsequently hydrolyzed, and indeed the reaction *can* be carried out in water or alcohol, in which case the products are amines, carbamates, or acylureas, as in 18-13.³⁰⁷ This is a very general reaction and can be applied to almost any carboxylic acid: aliphatic, aromatic, alicyclic, heterocyclic, unsaturated, and containing many functional groups. Acyl azides can be prepared as in Reaction 10-43 or by treatment

of acylhydrazines (hydrazides) with nitrous acid (analogous to Reaction 12-49). The Curtius rearrangement is catalyzed by Lewis acids or protic acids, but these are usually not necessary for good results.

The mechanism is similar to that in Reaction 18-13 to give an isocyanate. Also note the exact analogy between this Reaction and 18-8. However, in this case, there is no evidence for a free nitrene and it is probable that the conversion is concerted.³⁰⁸

Alkyl azides can be similarly pyrolyzed to give imines, in an analogous reaction³⁰⁹:

The R groups may be alkyl, aryl, or hydrogen, although if hydrogen migrates, the product is the unstable $\text{R}_2\text{C}=\text{NH}$. The mechanism is essentially the same as that of the *Curtius rearrangement*. However, in pyrolysis of tertiary alkyl azides, there is evidence that free alkyl nitrenes are intermediates.³¹⁰ The reaction can also be carried out with acid catalysis, in which case lower temperatures can be used, although the acid may hydrolyze the imine (16-2). Cycloalkyl azides give ring expansion as shown.³¹¹

Aryl azides also give ring expansion on heating, for example,³¹²

OS III, 846; IV, 819; V, 273; VI, 95, 910. Also see, OS VI, 210.

18-15 The Lossen Rearrangement

Hydro,acetoxy-(2/→1*N*-alkyl)-migr-o-detachment

³⁰⁸ See, Smalley, R.K.; Bingham, T.E. *J. Chem. Soc. C* **1969**, 2481.

The *O*-acyl derivatives of hydroxamic acids³¹³ give isocyanates when treated with bases or sometimes even just on heating, in a reaction known as the *Lossen rearrangement*.³¹⁴ The mechanism is similar to that of Reaction 18-13 and 18-14:

In a similar reaction, aromatic acyl halides are converted to amines in one laboratory step by treatment with hydroxylamine-*O*-sulfonic acid.³¹⁵

A chiral *Lossen rearrangement* is known.³¹⁶

18-16 The Schmidt Reaction

There are actually three reactions called by the name *Schmidt reaction*, involving the addition of hydrazoic acid to carboxylic acids, aldehydes and ketones, and alcohols and alkenes.³¹⁷ The most common is the reaction with carboxylic acids, illustrated above.³¹⁸ Sulfuric acid is a common catalyst, but Lewis acids have also been used. Good results are obtained for aliphatic R, especially for long chains. When R is aryl, the yields are variable, being best for sterically hindered compounds like mesitoic acid. This method has the advantage over Reaction 18-13 and 18-14 in that there is just one laboratory step from the acid to the amine, but conditions are more drastic.³¹⁹ Under the acid conditions employed, the isocyanate is virtually never isolated.

The reaction between a ketone and hydrazoic acid is a method for “insertion” of NH between the carbonyl group and one R group, converting a ketone into an amide.³²⁰

Either or both of the R groups may be aryl. In general, dialkyl ketones and cyclic ketones react more rapidly than alkyl aryl ketones, and these more rapidly than diaryl ketones. The latter require sulfuric acid and do not react in concentrated HCl, which is strong enough for

dialkyl ketones. Dialkyl and cyclic ketones react sufficiently faster than diaryl or aryl alkyl ketones or carboxylic acids or alcohols so that these functions may be present in the same molecule without interference. Cyclic ketones give lactams³²¹. With alkyl aryl ketones, it is the aryl group that generally migrates to the nitrogen, except when the alkyl group is bulky.³²²

The reaction has been applied to a few aldehydes, but rarely. With aldehydes the product is usually the nitrile (Reaction **16-16**). Even with ketones, conversion to the nitrile is often a side reaction, especially with the type of ketone that gives **17-30**. A useful variation of the Schmidt reaction treats a cyclic ketone with an alkyl azide (RN₃)³²³ in the presence of TiCl₄, generating a lactam.³²⁴ An intramolecular *Schmidt reaction* gives bicyclic amines.³²⁵ Another variation treats a silyl enol ether of a cyclic ketone with TMSN₃ and photolyzes the product with UV light to give a lactam.³²⁶ An α-azido cyclic ketone rearrangement to lactams under radical conditions (Bu₃SnH/AIBN).³²⁷

Alcohols and alkenes react with HN₃ to give alkyl azides,³²⁸ which in the course of reaction rearrange in the same way as discussed in Reaction **18-14**.³⁰⁹ The *Mitsunobu Reaction* (**10-17**) can be used to convert alcohols to alkyl azides, and an alternative reagent for azides [(PhO)₂PON₃], for use in the *Mitsunobu* is now available.³²⁹ In the presence of an Au catalyst, an acetylenic azide was converted to a pyrrole derivative.³³⁰ An intramolecular *Schmidt reaction* gives bicyclic lactams in the presence of MeAlCl₂.³³¹

There is evidence that the mechanism with carboxylic acids³²⁰ is similar to that of Reaction **18-14**, except that it is the protonated azide that undergoes the rearrangement³³²:

The first step is the same as that of the A_{AC}1 mechanism (Reaction **16-59**, which explains why good results are obtained with hindered substrates. The mechanism with ketones

18-17 The Beckmann Rearrangement

Beckmann oxime–amide rearrangement

When oximes are treated with PCl₅ or a number of other reagents, they rearrange to substituted amides in a reaction called the *Beckmann rearrangement*.³³⁵ Reagents used include concentrated H₂SO₄ acid, formic acid, liquid SO₂, silica gel,³³⁶ RuCl₃,³³⁷ Y(OTf)₃,³³⁸ I₂,³³⁹ HgCl₂,³⁴⁰ triphosphazene,³⁴¹ bromodimethylsulfonium bromide–ZnCl₂,³⁴² neat with FeCl₃,³⁴³ cyanuric acid,³⁴⁴ and polyphosphoric acid.³⁴⁵ Simply heating the oxime of benzophenone neat leads to *N*-phenyl benzamide.³⁴⁶ The reaction has been

done in supercritical water³⁴⁷ and in ionic liquids.³⁴⁸ A polymer-bound Beckman rearrangement has been reported.³⁴⁹ Microwave assisted *Beckmann rearrangements* are known.³⁵⁰ Note that the reaction of an imine with $\text{BF}_3 \cdot \text{OEt}_2$ and *m*-chloroperoxybenzoic acid leads to a formamide.³⁵¹

The oximes of cyclic ketones give ring enlargement and form the lactam,³⁵² as in the formation of caprolactam (see Reaction **18-16**) from the oxime of cyclohexanone. Solvent-free reactions are known.³⁵³ Cyclic ketones can be converted directly to lactams in one laboratory step by treatment with $\text{NH}_2\text{OSO}_2\text{OH}$ and formic acid (Reaction **16-14** takes place first, then the *Beckmann rearrangement*).³⁵⁴

Of the groups attached to the carbon of the $\text{C}=\text{N}$ unit, the one that migrates in the *Beckman rearrangement* is generally the one anti to the hydroxyl, and this is often used as a method of determining the configuration of the oxime. However, it is not unequivocal. It is known that with some oximes the syn group migrates and that with others, especially where R and R' are both alkyl, mixtures of the two possible amides are obtained. However, this behavior does not necessarily mean that the syn group actually undergoes migration. In most cases, the oxime undergoes isomerization under the reaction conditions *before* migration takes place.³⁵⁵ The scope of the reaction is quite broad and R and R' may be alkyl, aryl, or hydrogen. However, hydrogen very seldom migrates, so the reaction is not generally a means of converting aldoximes to unsubstituted amides (RCONH_2). This latter conversion can be accomplished, however, by treatment of the aldoxime with nickel acetate under neutral conditions³⁵⁶ or by heating the aldoxime for 60 h at 100 °C after it has been adsorbed onto silica gel.³⁵⁷ As in the case of the *Schmidt rearrangement* (Reaction **18-16**), when the oxime is derived from an alkyl aryl ketone, it is generally the aryl group that preferentially migrates.³⁵⁸

Not only do oximes undergo the *Beckmann rearrangement*, but so also do esters of oximes with many acids, organic and inorganic. A side reaction with many substrates is the formation of nitriles (the "abnormal" *Beckmann rearrangement*, Reaction **17-30**). The *O*-carbonates of imines (e.g., $\text{Ph}_2\text{C}=\text{N}-\text{OCO}_2\text{Et}$) react with $\text{BF}_3 \cdot \text{OEt}_2$ to give the corresponding amide in this case *N*-phenyl benzamide.³⁵⁹

In the first step of the mechanism, the OH group is converted by the reagent to a better leaving group, for example, proton acids convert it to OH_2^+ . After that, the mechanism³⁶⁰ follows a course analogous to that for the *Schmidt reaction* of ketones (**18-16**) from the

formation of nitrilium ion (**92**) on³⁶¹: Alternative modes of reaction are possible. For example, when PCl_5 is used to induce the reaction, a N-O-PCl_4 species is formed, which generates **92**. Intermediates of the form **92** have been detected by NMR and UV spectroscopy.³⁶² The rearrangement has also been found to take place by a different mechanism, involving formation of a nitrile by fragmentation, and then addition by a *Ritter Reaction* (**16-91**).³⁶³ *Beckmann rearrangements* have also been carried out photochemically.³⁶⁴ A computational study compared concerted versus stepwise mechanisms for the *Beckmann rearrangement*, and found that proton relay between the substrate and the solvent molecules controls the reaction, and migration and N-O bond scission occur simultaneously.³⁶⁵

If the rearrangement of oxime sulfonates is induced by organoaluminum reagents,³⁶⁶ the nitrilium ion intermediate (**92**) is captured by the nucleophile originally attached to the Al. By this means an oxime can be converted to an imine, an imino thioether (R-N=C-SR), or an imino nitrile (R-N=C-CN).³⁶⁷ In the last case, the nucleophile comes from added trimethylsilyl cyanide. In the presence of LiI , 2-benzoyloxypyridine is converted to *N*-benzyl-2-pyridone.³⁶⁸

In a related reaction, treatment of spirocyclic oxaziridines with $\text{MnCl}(\text{tpp})$ (tpp = triphenylphosphine, ligand)³⁶⁹ or photolysis³⁷⁰ leads to a lactam.

OS II, 76, 371; VIII, 568.

18-18 Stieglitz and Related Rearrangements

Methoxy-de-*N*-chloro-(2/→1/*N*-alkyl)-migno-substitution, and so on

In addition to the reactions discussed at **18-13–18-17**, other rearrangements are known in which an alkyl group migrates from C to N. Certain bicyclic *N*-haloamines (e.g.,

N-chloro-2-azabicyclo[2.2.2]octane, above), undergo rearrangement when solvolyzed in the presence of silver nitrate.³⁷¹ This reaction is similar to the *Wagner–Meerwein rearrangement* (**18-1**) and is initiated by the silver-catalyzed departure of the chloride ion.³⁷² Similar reactions have been used for ring expansions and contractions, analogous to those discussed for Reaction **18-3**.³⁷³ An example is the conversion of 1-(*N*-chloroamino)cyclopropanols to β -lactams.³⁷⁴ Methyl prolinate was converted to the 2-piperidone upon treatment with SmI_2 and pivalic acid–THF.³⁷⁵

The name *Stieglitz rearrangement* is generally applied to the rearrangements of trityl *N*-haloamines and

hydroxylamines. These reactions are similar to the rearrangements of alkyl azides (**18-14**), and the name *Stieglitz rearrangement* is also given to the rearrangement of trityl azides. Another similar reaction is the rearrangement undergone by tritylamines when treated with lead tetraacetate ($\text{Ar}_3\text{CNH}_2 \rightarrow \text{Ar}_2\text{C}=\text{NAr}$).³⁷⁶

D. Carbon-to-Oxygen Migrations of R and Ar

18-19 The Baeyer–Villiger Rearrangement³⁷⁷

Oxy-insertion

The treatment of ketones with peroxyacids (e.g., peroxybenzoic or peroxyacetic acid or with other peroxy compounds in the presence of acid catalysts, gives carboxylic esters by migration of an alkyl group oxygen³⁷⁸ and the carboxylic acid parent of the peroxyacid as a byproduct. In other words, there is a $\text{C} \rightarrow \text{O}$ rearrangement, and the reaction is called the *Baeyer–Villiger rearrangement*.³⁷⁹ A particularly good reagent is peroxytrifluoroacetic

Benjamin, NY, **1972**, pp. 321–329; Lewis, S.N. in Augustine, R.L. *Oxidation*, Vol. 1, Marcel Dekker, NY, **1969**, pp. 237–244. Also see, Carlqvist, P.; Eklund, R.; Brinck, T. *J. Org. Chem.* **2001**, 66, 1193.

acid. Reactions with this reagent are rapid and clean, giving high yields of product, although it is often necessary to add a buffer (e.g., Na_2HPO_4), to prevent transesterification of the product with trifluoroacetic acid that is also formed during the reaction. The reaction is often applied to cyclic ketones to give lactones.³⁸⁰ Hydrogen peroxide has been used to convert cyclic ketones to lactones using a catalytic amount of MeReO_3 ³⁸¹ or a diselenide catalyst.³⁸² Heterogeneous catalysts are used for the *Baeyer–Villiger reaction*.³⁸³ Transition metal catalysts have been used with peroxyacids to facilitate the oxidation.³⁸⁴ Polymer-supported peroxy acids have been used,³⁸⁵ and solvent-free *Bayer–Villiger reactions* are known.³⁸⁶ Potassium peroxomonosulfate supported on acidic silica gel has been used.³⁸⁷

Enantioselective synthesis³⁸⁸ of chiral lactones from achiral ketones has been achieved by the use of enzymes³⁸⁹ and other asymmetric reactions are known.³⁹⁰ Chiral Pd complexes give chiral lactones from cyclic ketones with high enantioselectivity.³⁹¹ Other chiral catalysts include those based on Al.³⁹² *Baeyer–Villiger oxidation* of chiral substrates with *m*-chloroperoxybenzoic acid (mcpba) also leads to chiral lactones.³⁹³

For acyclic compounds, R' must usually be secondary, tertiary, or vinylic, although primary R' has been rearranged with peroxytrifluoroacetic acid,³⁹⁴ with $\text{I}_2\text{—H}_2\text{O}_2$,³⁹⁵ $\text{BF}_3\text{—H}_2\text{O}_2$,³⁹⁶ and with $\text{K}_2\text{S}_2\text{O}_8\text{—H}_2\text{SO}_4$.³⁹⁷ For unsymmetrical ketones, the approximate order of migration is tertiary alkyl > secondary alkyl, aryl > primary alkyl > methyl. Since the methyl group has a low migrating ability, the reaction provides a means of cleaving a methyl ketone ($\text{R}'\text{COMe}$) to produce an alcohol or phenol ($\text{R}'\text{OH}$, by hydrolysis of the ester $\text{R}'\text{OCOMe}$). The migrating ability of aryl groups is increased by electron-donating and decreased by electron-withdrawing substituents.³⁹⁸ There is a preference of *anti*- over *gauche* migration.³⁹⁹

Enolizable β -diketones do not react. α -Diketones can be converted to anhydrides.⁴⁰⁰ With aldehydes, migration of hydrogen gives the carboxylic acid, and this is a way of accomplishing Reaction **19-23**. Migration of the other group would give formates, but this seldom happens, though aryl aldehydes have been converted to formates with H_2O_2 and a selenium compound⁴⁰¹ (see also, the *Dakin Reaction* in **19-11**).

The mechanism⁴⁰² is similar to those of the analogous reactions with hydrazoic acid (**18-16** with ketones) and diazomethane (**18-8**):

One important piece of evidence for this mechanism was that benzophenone- ^{18}O gave ester entirely labeled in the carbonyl oxygen, with none in the alkoxy oxygen.⁴⁰³ Carbon-14 isotope-effect studies on acetophenones have shown that migration of aryl groups takes place in the rate-determining step,⁴⁰⁴ demonstrating that migration of Ar is concerted with departure of OCOR^2 .⁴⁰⁵ It is hardly likely that migration would be the slow step if the leaving group departed first to give an ion with a positive charge on an oxygen atom, which would be a highly unstable species.

18-20 Rearrangement of Hydroperoxides

C-Alkyl-O-hydroxy-elimination

Hydroperoxides (R = alkyl, aryl, or hydrogen) can be cleaved by proton or Lewis acids in a reaction whose principal step is a rearrangement.⁴⁰⁶ The reaction has also been applied to peroxy esters ($\text{R}_3\text{COOCOR}'$), but less often. When aryl and alkyl groups are both present, migration of aryl dominates. It is not necessary actually to prepare and isolate hydroperoxides. The reaction takes place when the alcohols are treated with H_2O_2 and acids. Migration of an alkyl group of a primary hydroperoxide provides a means for converting an alcohol to its next lower homolo ($\text{RCH}_2\text{OOH} \rightarrow \text{CH}_2=\text{O} + \text{ROH}$).

The mechanism is as follows⁴⁰⁷:

The last step is hydrolysis of the unstable hemiacetal. Alkoxy carbocation intermediates (**93**, R = alkyl) have been isolated in superacid solution⁴⁰⁸ at low temperatures, and their structures proved by NMR.⁴⁰⁹ The protonated hydroperoxides could not be observed in these solutions, evidently reacting immediately on formation.

E. Nitrogen-to-Carbon, Oxygen-to-Carbon, and Sulfur-to-Carbon Migration

18-21 The Stevens Rearrangement

Hydron-(2/N→1/alkyl)-migrato-detachment

In the *Stevens rearrangement*,⁴¹⁰ a quaternary ammonium salt containing an electron-withdrawing group Z on one of the carbons attached to the nitrogen is treated with a strong base (e.g., NaOR or NaNH₂) to give a rearranged tertiary amine. The Z group may be RCO, ROOC, or phenyl.⁴¹¹ The most common migrating groups are allylic, benzylic, benzhydryl, 3-phenylpropargyl, and phenacyl, though even methyl migrates to a sufficiently negative center. Migration of aryl is rare, but has been reported.⁴¹² When an allylic group migrates, it may or may not involve an allylic rearrangement within the migrating group (see Reaction **18-35**), depending on the substrate and reaction conditions. The reaction has been used for ring enlargement,⁴¹³ illustrated by the rearrangement of **94**.

⁴¹³ Elmasmodi, A.; Cotellet, P.; Barbry, D.; Hasiak, B.; Couturier, D. *Synthesis* **1989**, 327.

The mechanism has been the subject of much study.⁴¹⁴ The rearrangement is intramolecular, as shown by cross-over experiments, by ¹⁴C labeling,⁴¹⁵ and by the fact that retention of configuration is found at R¹.⁴¹⁶ The first step is loss of the acidic proton to give the ylid (**95**), which has been isolated.⁴¹⁷ The finding⁴¹⁸ that CIDNP is observed⁴¹⁹ in many instances shows that in these cases the product is formed directly from a free-radical precursor. The following radical pair mechanism was proposed⁴²⁰:

The radicals do not drift apart because the solvent cage holds them together. According to this mechanism, the radicals must recombine rapidly in order to account for the fact that R¹ does not racemize. Other evidence in favor of mechanism *a* is that in some cases small amounts of coupling products (R¹–R¹) have been isolated,⁴²¹ which would be expected if some •R¹ leaked from the solvent cage. However, not all the evidence is easily compatible with mechanism *a*.⁴²² It is possible that another mechanism (*b*), similar to mechanism *a*, but

involving ion pairs in a solvent cage instead of radical pairs, operates in some cases. A third possible mechanism would be a concerted 1,2-shift,⁴²³ but the orbital symmetry principle requires that this take place with inversion at R¹.⁴²⁴ (see Reaction **18-30** and [1,5]-migration). *Since the actual migration takes place with retention, it cannot, according to this argument, proceed by a concerted mechanism.* However, in the case where the migrating group is allylic, a concerted mechanism can also operate (Reaction **18-35**). An interesting finding compatible with all three mechanisms is that optically active allylbenzylmethylphenylammonium iodide (asymmetric nitrogen, see Sec. 4.C, category 3) gave an optically active product⁴²⁵:

The *Sommelet–Hauser rearrangement* competes when Z is an aryl group (see Reaction 13-31). *Hofmann elimination* competes when one of the R groups contains a β hydrogen atom (Reaction 17-7 and 17-8).

Sulfur ylids containing a Z group give an analogous rearrangement (see the reaction), sometimes referred to as a *Stevens rearrangement*.⁴²⁶ In this case too, there is much evidence (including CIDNP) that a radical-pair cage mechanism is operating,⁴²⁷ except that when the migrating group is allylic, the mechanism may be different (see Reaction 18-35).

Another reaction with a similar mechanism⁴²⁸ is the *Meisenheimer rearrangement*,⁴²⁹ in which certain tertiary amine oxides rearrange on heating to give substituted hydroxylamines (see reaction).⁴³⁰ The migrating group R¹ is almost always allylic or benzylic.⁴³¹ Both R² and R³ may be alkyl or aryl, but if one of the R groups contains a β hydrogen, *Cope elimination* (Reaction 17-9) often competes. In a related reaction, when 2-methylpyridine N-oxides are treated with trifluoroacetic anhydride, the *Boekelheide reaction* occurs to give 2-hydroxymethylpyridines.⁴³²

Certain tertiary benzylic amines, when treated with BuLi, undergo a rearrangement analogous to the *Wittig rearrangement* (Reaction 18-22, e.g., PhCH₂NPh₂ → Ph₂CHNPh).⁴³³ Only aryl groups migrate in this reaction.

Isocyanides, when heated in the gas phase or in nonpolar solvents, undergo a 1,2-intramolecular rearrangement to nitriles (RNC → RCN).⁴³⁴ In polar solvents, the mechanism is different.⁴³⁵

The rearrangement of ethers upon treatment with alkyllithium reagents is called the *Wittig rearrangement* (not to be confused with the *Wittig Reaction*, **16-44**) and is similar to **18-21**.⁴⁴¹ However, a stronger base is required (e.g., phenyllithium or sodium amide). The R and R' groups may be alkyl,⁴³⁷ aryl, or vinylic.⁴³⁸ Also, one of the hydrogen atoms may be replaced by an alkyl or aryl group, in which case the product is the salt of a tertiary alcohol. Migratory aptitudes here are allylic, benzylic > ethyl > methyl > phenyl.⁴³⁹ The stereospecificity of the *1,2-Wittig rearrangement* has been discussed.⁴⁴⁰ The following radical-pair mechanism⁴⁴¹ (similar to mechanism *a* of Reaction **18-21**) is likely, after removal of the proton by the base. One of the

the radical pair is a ketyl. Evidence for this mechanism includes (1) the rearrangement is largely intramolecular; (2) migratory aptitudes are in the order of free-radical stabilities, not of carbanion stabilities⁴⁴² (which rules out an ion-pair mechanism similar to mechanism *b* of Reaction **18-21**); (3) aldehydes are obtained as side products⁴⁴³; (4) partial racemization of R' has been observed⁴⁴⁴ (the remainder of the product retained its configuration); (5) cross-over products have been detected⁴⁴⁵; and (6) when ketyl radicals and R• radicals from different precursors were brought together, similar products resulted.⁴⁴⁶ However, there is evidence that at least in some cases the radical-pair mechanism accounts for only a portion of the product, and some kind of concerted mechanism can also take place.⁴⁴⁷ Most of the above investigations were carried out with systems where R' is alkyl, but a radical-pair mechanism has also been suggested for the case where R' is aryl.⁴⁴⁸ When R' is allylic a concerted mechanism can operate (Reaction **18-35**).

When R is vinylic it is possible, by using a combination of an alkyllithium and *t*-BuOK, to get migration to the γ carbon (as well as to the α carbon), producing an enolate that, on hydrolysis, gives an aldehyde⁴⁴⁹:

An *aza-Wittig rearrangement* is also known.⁴⁵⁰ Other [2,3]-rearrangements are discussed in Reaction 18-35.

There are no OS references, but see OS VIII, 501, for a related reaction.

F. Boron-to-Carbon Migrations⁴⁵¹

For another reaction involving boron-to-carbon migration, see 10-73.

18-23 Conversion of Boranes to Alcohols

Oxidation of trialkylboranes (see Reaction 15-16) uses NaOH and H₂O₂, which react to give the hydroperoxide anion, (HOO[−]). Reaction of the organoborane with basic H₂O₂ (via HOO[−]) leads to an ate-complex, and subsequent B → O rearrangement of an alkyl group on boron to a peroxy oxygen, with expulsion of hydroxide, leads to a borate, and then an alcohol after hydrolysis. The proposed mechanism⁴⁵² is shown in which a trialkylborane is converted to 3 molar equivalents of the alcohol, along with boric acid.

Using the hydroboration reaction in 15-16, this procedure converts alkenes to an *anti-Markovnikov* borane, and oxidation leads to the *anti-Markovnikov alcohol*. An example is the conversion of methylcyclopentene to *trans*-2-methylcyclopentanol.⁴⁵³ Formation of the organoborane proceeds via a cis-addition of B—H, placing the boron trans to the methyl group, and stereoselective oxidation and B → O rearrangement leads to retention of configuration in the alcohol, as shown.

⁴⁵³ Zweifel, G.; Brown, H.C. *Org. React.* **1964**, 13, 1.

Trialkylboranes can be prepared from alkenes by Reaction **15-16**, and they react with carbon monoxide⁴⁵⁴ at 100–125 °C in the presence of ethylene glycol to give the 2-bora-1,3-dioxolanes (**96**), which are easily oxidized (Reaction **12-27**) to tertiary alcohols.⁴⁵⁵ The R groups may be primary, secondary, or tertiary, and may be the same or different.⁴⁵⁶ Yields are high and the reaction is quite useful, especially for the preparation of sterically hindered alcohols (e.g., tricyclohexylcarbinol, **97** and tri-2-norbornylcarbinol, **98**), which are difficult to prepare by Reaction **16-24**. Heterocycles in which boron is a ring atom react similarly (except that high CO pressures are required), and cyclic alcohols can be obtained from these substrates.⁴⁵⁷ The preparation of such heterocyclic boranes was discussed at Reaction **15-16**. The overall conversion of a diene or triene to a cyclic alcohol has been described by H.C. Brown as “stitching” with boron and “riveting” with carbon.

The mechanism has been shown to be intramolecular by the failure to find cross-over products when mixtures of boranes are used.⁴⁵⁸ The following scheme, involving three boron-to-carbon migrations, to **99** and then to **100** has been suggested.

The purpose of the ethylene glycol is to intercept the boronic anhydride (**100**), which otherwise forms polymers that are difficult to oxidize. As will be seen in Reaction **18-23** and **18-24**, it is possible to stop the reaction after only one or two migrations have taken place.

There are two other methods for achieving the conversion $\text{R}_3\text{B} \rightarrow \text{R}_3\text{COH}$, which often give better results: (1) treatment with α,α -dichloromethyl methyl ether and the base lithium triethylcarboxide⁴⁵⁹ (2) treatment with a suspension of sodium cyanide in THF

followed by reaction of the resulting trialkylcyanoborate (**101**) with an excess (>2 equiv) of trifluoroacetic anhydride.⁴⁶⁰ All the above migrations take place with retention of configuration at the migrating carbon.⁴⁶¹

Several other methods for the conversion of boranes to tertiary alcohols are also known.⁴⁶²

If the reaction between trialkylboranes and carbon monoxide (**18-23**) is carried out in the presence of water followed by addition of NaOH, the product is a secondary alcohol. If H₂O₂ is added along with the NaOH, the corresponding ketone is obtained instead.⁴⁶³ Various functional groups (e.g., OAc, COOR, CN) may be present in R without being affected,⁴⁶⁴ although if they are in the α or β position relative to the boron atom, difficulties

may be encountered. The use of an equimolar amount of trifluoroacetic anhydride leads to the ketone rather than the tertiary alcohol.⁴⁶⁵ By this procedure the xylboranes (RR'R²B, where R² = hexyl) can be converted to unsymmetrical ketones (RCOR').⁴⁶⁶ Variations of this methodology have been used to prepare optically active alcohols.⁴⁶⁷ For another conversion of trialkylboranes to ketones see Reaction **18-26**.⁴⁶⁸

OS VII, 427. Also see, OS VI, 137.

18-24 Conversion of Boranes to Primary Alcohols, Aldehydes, or Carboxylic Acids

When the reaction between a trialkylborane and carbon monoxide (**18-23**) is carried out in the presence of a reducing agent (e.g., lithium borohydride or potassium triisopropoxyborohydride), the reduction agent intercepts the intermediate (**99**), so that only one boron→carbon migration takes place, and the product is hydrolyzed to a primary alcohol or oxidized to an aldehyde.⁴⁶⁹ This procedure wastes two of the three R groups, but this problem can be avoided by the use of B-alkyl-9-BBN derivatives (see Reaction **15-16**).

Since only the 9-alkyl group migrates, this method permits the conversion in high yield of an alkene to a primary alcohol or aldehyde containing one more carbon.⁴⁷⁰ When B-alkyl-9-BBN derivatives are treated with CO and lithium tri-*tert*-butoxyaluminum hydride,⁴⁷¹ other functional groups (e.g., CN and ester) can be present in the alkyl group without being reduced.⁴⁷² Boranes can be directly converted to carboxylic acids by reaction with the dianion of phenoxyacetic acid.⁴⁷³

Boronic esters $[\text{RB}(\text{OR}')_2]$ react with methoxy(phenylthio)methyl lithium $[\text{LiCH}(\text{OMe})\text{SPh}]$ to give salts, which, after treatment with HgCl_2 , and then H_2O_2 , yield aldehydes.⁴⁷⁴ This synthesis has been made enantioselective, with high ee values ($>99\%$), by the use of an optically pure boronic ester,⁴⁷⁵ for example:

18-25 Conversion of Vinylic Boranes to Alkenes

The reaction between trialkylboranes and iodine to give alkyl iodides was mentioned at **12-31**. When the substrate contains a vinylic group, the reaction takes a different course,⁴⁷⁶ with one of the R' groups migrating to the carbon, to give alkenes.⁴⁷⁷ The reaction is stereospecific in two senses: (1) if the groups R and R'' are cis in the starting compound, they will be trans in the product; (2) there is retention of configuration within the migrating group R' .⁴⁷⁸ Since vinylic boranes can be prepared from alkynes (Reaction **15-16**), this is a method for the addition of R' and H to a triple bond. If $\text{R}^2 = \text{H}$, the product is a (*Z*)-alkene. The mechanism is believed to involve an iodonium intermediate, (e.g., **102**) and attack by iodide on boron. When R' is vinylic, the product is a conjugated diene.⁴⁷⁹

In another procedure, the addition of a dialkylborane to a 1-haloalkyne produces an α -halo vinylic borane (**103**).⁴⁸⁰ Treatment of **103** with NaOMe gives the rearrangement shown, and protonolysis of the product produces the (*E*)-alkene.⁴⁷⁸ If R is a vinylic group, the product is a 1,3-diene.⁴⁸¹ If one of the groups is thexyl, the other migrates.⁴⁸² A combination of both of the procedures described above results in the preparation of trisubstituted alkenes.⁴⁸³

18-26 Formation of Alkynes, Alkenes, and Ketones from Boranes and Acetylides

A hydrogen directly attached to a triple-bond carbon can be replaced in high yield by an alkyl or an aryl group, by treatment of the lithium acetylide with a trialkyl- or triarylborane, followed by reaction of the lithium alkynyltrialkylborate (**104**) with iodine.⁴⁸⁴ The R' group may be primary or secondary alkyl as well as aryl, so the reaction has a broader scope than the older Reaction 10-74.⁴⁸⁵ The R group may be alkyl, aryl, or hydrogen, although in the last-mentioned case satisfactory yields are obtained only if lithium acetylide-ethylenediamine is used as the starting compound.⁴⁸⁶ Optically active alkynes can be prepared by using optically active thexylborinates ($\text{RR}^2\text{BOR}'$, $\text{R}^2 = \text{thexyl}$, where R is chiral) and $\text{LiC}\equiv\text{CSiMe}_3$.⁴⁸⁷ The reaction can be adapted to the preparation of alkenes⁴⁸⁸ by treatment of **104** with an electrophile (e.g., propanoic acid⁴⁸⁹ or tributyltin chloride).⁴⁹⁰ The reaction with Bu_3SnCl produces the (*Z*)-alkene stereoselectively.

Treatment of **104** with electrophiles (e.g., methyl sulfate, allyl bromide, or triethyloxonium borofluoride), followed by oxidation of the resulting vinylic borane, gives a ketone (illustrated for methyl sulfate)⁴⁹¹:

Note that there are reactions that involve $N \rightarrow O$ rearrangements, including those mediated by silicon.⁴⁹²

18.F.ii. Non-1,2 Rearrangements

A. Electrocyclic Rearrangements

18-27 Electrocyclic Rearrangements of Cyclobutenes and 1,3-Cyclohexadienes

(4) *seco*-1/4/Detachment; (4) *cyclo*-1/4/Attachment

(6) *seco*-1,6/Detachment; (6) *cyclo*-1/6/Attachment

Cyclobutenes and 1,3-dienes can be interconverted by treatment with UV light or with heat.⁴⁹³ These are 4π -electrocyclizations. The thermal reaction is generally not reversible (although exceptions⁴⁹⁴ are known), and many cyclobutenes have been converted to 1,3-dienes by heating at temperatures between 100 and 200 °C.⁴⁹⁵ Benzocyclobutenes also undergo electrocyclic ring opening,⁴⁹⁶ as do benzocyclobutanones.⁴⁹⁷ The photochemical conversion can in principle be carried out in either direction, but most often 1,3-dienes are converted to cyclobutenes rather than the reverse, because the dienes are stronger absorbers of light at the wavelengths used.⁴⁹⁸ In a similar reaction, 1,3-cyclohexadienes interconvert with 1,3,5-trienes, but in this case the ring-closing process is generally favored thermally and the ring-opening process photochemically, but exceptions are known in both

directions.⁴⁹⁹ Substituent effects can lead to acceleration of the electrocyclization process.⁵⁰⁰ *Torquoselectivity* in cyclobutene ring-opening reaction has been examined.⁵⁰¹

Examples of these types of reactions include:

Ref. 502

An interesting example of 1,3-cyclohexadiene→1,3,5-triene interconversion is the reaction of norcaradienes to give cycloheptatrienes.⁵⁰³ This is a 6 π -electrocyclization, and it has been catalyzed by Lewis acids.⁵⁰⁴ Norcaradienes give this reaction so readily (because they are *cis*-1,2-divinylcyclopropanes, see Reaction 18-32) that they cannot generally be isolated, though some exceptions are known⁵⁰⁵ (see also, 15-64).

These reactions, called *electrocyclic rearrangements*,⁵⁰⁶ take place by pericyclic mechanisms. The evidence comes from stereochemical studies, which show a remarkable stereospecificity whose direction depends on whether the reaction is induced by heat or light. For example, it was found for the thermal reaction that *cis*-3,4-dimethylcyclobutene gave only *cis,trans*-2,4-hexadiene, while the *trans* isomer gave only the *trans-trans*-diene⁵⁰⁷:

This is evidence for a four-membered cyclic transition state and arises from conrotatory motion about the C-3–C-4 bond.⁵⁰⁸ It is called conrotatory because both movements are clockwise (or both counterclockwise). Because both rotate in the same direction, the *cis* isomer gives the *cis*–*trans*-diene.⁵⁰⁹ The other possibility (*disrotatory* motion) would have one moving clockwise while the other moves counterclockwise; the *cis* isomer would have given the *cis*–*cis*-diene (shown) or the *trans*–*trans*-diene. If the motion had been disrotatory, this would still have been evidence for a cyclic mechanism. If the mechanism were a diradical or some other kind of noncyclic process, it is likely that no stereospecificity of either kind would have been observed. The reverse

reaction is also conrotatory. In contrast, the photochemical cyclobutene: 1,3-diene interconversion is *disrotatory* in either direction.⁵¹⁰ On the other hand, the cyclohexadiene: 1,3,5-triene interconversion shows precisely the opposite behavior. The thermal process is *disrotatory*, while the photochemical process is *conrotatory* (in either direction). These startling results are a consequence of the symmetry rules mentioned in Section 15-60, the FOM.⁵¹¹ As in the case of cycloaddition reactions, we will use the FOM and *Möbius–Hückel* approaches.⁵¹²

The Frontier Orbital Method (FOM)⁵¹³

As applied to these reactions, the FOM may be expressed: *A σ bond will open in such a way that the resulting p orbitals will have the symmetry of the highest occupied π orbital of the product.* In the case of cyclobutenes, the HOMO of the product in the thermal reaction is the χ_2 orbital (Fig. 18.1). Therefore, in a thermal process, the cyclobutene must open so that on one side the positive lobe lies above the plane, and on the other side below it. Thus the substituents are forced into conrotatory motion (Fig. 18.2). On the other hand, in the photochemical process, the HOMO of the product is now the χ_3 orbital (Fig. 18.1), and in order for the p orbitals to achieve this symmetry (the two plus lobes on the same side of the plane), the substituents are forced into disrotatory motion.

This reaction may be considered from the opposite direction (ring closing). For this direction, the rule is that *those lobes of orbitals that overlap (in the HOMO) must be of the same sign.* For thermal cyclization of butadienes, this requires conrotatory motion

FIG. 18.1. Symmetries of the X_2 and X_3^* orbitals of a conjugated diene

FIG. 18.2. Thermal opening of 1,2-diethylcyclobutene. The two hydrogens and two methyls are forced into conrotatory motion so that the resulting p -orbitals have the symmetry of the HOMO of the diene.

(Fig. 18.3). In the photochemical process, the HOMO is the χ_3 orbital, so that disrotatory motion is required for lobes of the same sign to overlap.

The Möbius–Hückel Method

As seen in Reaction 15-60, the *Möbius–Hückel Method*, a basis set of p orbitals is chosen and inspected for sign inversions in the transition state. Figure 18.4 shows a basis set for a 1,3-diene. It is seen that disrotatory ring closing (Fig. 18.4a) results in overlap of plus lobes only, while in conrotatory closing (Fig. 18.4b) there is one overlap of a plus with a minus lobe. In the first case, there are zero sign inversions, while in the second there is one sign inversion. With zero (or an even number of) sign inversions, the disrotatory transition state is a *Hückel system*, and so is allowed thermally only if the total number of electrons is $4n + 2$ (Sec. 15-60, the *Möbius–Hückel Method*). Since the total here is 4, the disrotatory process is not allowed. On the other hand, the conrotatory process, with one sign inversion, is a *Möbius*

FIG. 18.3. Thermal ring closing of a 1,3-diene. Conrotatory motion is required for two + lobes to overlap.

FIG. 18.4. The 1,3-diene–cyclobutene interconversion. The orbitals shown are *not* molecular orbitals, but a basis set of *p* atomic orbitals. (a) Disrotatory ring closure gives zero sign inversion. (b) Conrotatory ring closure gives one sign inversion. We could have chosen to show any other basis set (another basis set would have two plus lobes above the plane and two below, etc.). This would change the number of sign inversion, but the disrotatory mode would still have an even number of sign inversions, and the conrotatory mode an odd number, whichever basis set was chosen.

system, which is thermally allowed if the total number is $4n$. The conrotatory process is therefore allowed thermally. For the photochemical reactions, the rules are reversed: A reaction with $4n$ electrons requires a *Hückel* system, so only the disrotatory process is allowed.

Both the FOM and the *Möbius–Hückel* methods can also be applied to the cyclohexadiene: 1,3,5-triene reaction⁵¹⁴; in either case the predicted result is that for the thermal process, only the disrotatory pathway is allowed, and for the photochemical process, only the conrotatory. For example, for 1,3,5-hexatriene, the symmetry of the HOMO is

⁵¹⁴ For a discussion of the transition structures and energy, see Zora, M. *J. Org. Chem.* **2004**, 69, 1940.

In the thermal cleavage of cyclohexadienes, then, the positive lobes must lie on the same side of the plane, requiring disrotatory motion:

Disrotatory motion is also necessary for the reverse reaction, in order that the orbitals that overlap may be of the same sign:

All these directions are reversed for photochemical processes, because in each case a higher orbital, with inverted symmetry, is occupied.

In the *Möbius–Hückel* approach, diagrams similar to Fig. 18.4 can be drawn for this case. Here too, the disrotatory pathway is a *Hückel* system and the conrotatory pathway a *Möbius* system, but since six electrons are now involved, the thermal reaction follows the *Hückel* pathway and the photochemical reaction the *Möbius* pathway.

In the most general case, four possible products can arise from a given cyclobutene or cyclohexadiene: two from the conrotatory and two from the disrotatory pathway. For example, conrotatory ring opening of **105** gives either **106** or **107**, while disrotatory opening gives either **108** or **109**. The orbital-symmetry rules indicate when a given reaction will operate by the conrotatory and when by the disrotatory mode, but not which of the two possible conrotatory or disrotatory pathways will be followed. Often, however, it is possible to make such

predictions on steric grounds. For example, in the opening of **105** by the disrotatory pathway, **108** arises when groups A and C swing in toward each other (clockwise motion around C-4,

counterclockwise around C-3), while **109** is formed when groups B and D swing in and A and C swing out (clockwise motion around C-3, counterclockwise around C-4). This observation leads to a prediction that when A and C are larger than B and D, the predominant or exclusive product will be **109** rather than **108**. Predictions of this kind have largely been borne out.⁵¹⁵ There is evidence, however, that steric effects⁵¹⁶ are not the only factor, and that electronic effects also play a role, and their role may be even greater.⁵¹⁷ An electron-donating group stabilizes the transition state when it rotates *outward*, because it mixes with the LUMO; if it rotates *inward*, it mixes with the HOMO, destabilizing the transition state.⁵¹⁸ The compound 3-formylcyclobutene provided a test. Steric factors would cause the CHO (an electron-withdrawing group) to rotate outward; electronic effects would cause it to rotate inward. The experiment showed inward rotation.⁵¹⁹

Cyclohexadienes are of course 1,3-dienes, and in certain cases it is possible to convert them to cyclobutenes instead of to 1,3,5-trienes.⁵²⁰ An interesting example is found in the pyrocalciferols. Photolysis of the syn isomer (**110**) (or of the other syn isomer, not shown) leads to the corresponding cyclobutene,⁵²¹ while photolysis of the anti isomers (one of them is **111**) gives the ring-opened 1,3,5-triene (**112**). This difference in behavior is at first sight remarkable, but is easily explained by the orbital-symmetry rules. Photochemical ring opening to a 1,3,5-triene must be conrotatory. If **110** were to react by this pathway, the product would be the triene **112**, but this compound would have to contain a *trans*-cyclohexene ring (either the methyl group or the hydrogen would have to be directed inside the ring). On the other hand, photochemical conversion to a cyclobutene must be disrotatory, but if **111** were to give this reaction, the product would have to have a *trans*-fused ring junction. Compounds with such ring junctions are known (Sec. 4.K.iii), but are very strained. Stable *trans*-cyclohexenes are unknown (Sec. 4.Q.iii). Thus, **110** and **111** give the products they do owing to a combination of orbital-symmetry rules and steric influences.

A related process is the *Bergmann cyclization*,⁵²² where an ene-diyne cyclizes to a biradical (**103**) and then aromatizes as shown. Simply heating the en-diyne will usually lead to aromatization via this pathway.⁵²³ Quinones can be formed via *Bergman*

cyclization⁵²⁴ and there are other synthetic applications.⁵²⁵ The role of vinyl substitution has been examined.⁵²⁶ An *aza-Bergman cyclization* is known.⁵²⁷

The 1,3-diene-cyclobutene interconversion can even be applied to benzene rings. For example,⁵²⁸ photolysis of 1,2,4-tri-*tert*-butylbenzene (**114**) gives 1,2,5-tri-*tert*-butyl [2.2.0]hexadiene (**115**, a *Dewar benzene*).⁵²⁹ The reaction owes its success to the fact that once **115** is formed, it cannot, under the conditions used, revert to **114** by either a thermal or a photochemical route. The orbital-symmetry rules prohibit thermal conversion of **115** to **114** by a pericyclic mechanism, because thermal conversion of a cyclobutene to a 1,3-diene must be conrotatory, and conrotatory reaction of **115** would result in a 1,3,5-cyclohexatriene containing one trans double bond (**116**), which is of course too strained to exist. Compound **115** cannot revert to **114** by a photochemical pathway either, because light of the frequency used to excite **114** would not be absorbed by **115**. This is another example of a molecule that owes its stability to the orbital-symmetry rules (see Reaction 15-63). Pyrolysis of **115** does give **114**, probably by a diradical mechanism.⁵³⁰ In the case of **117** and **118**, the *Dewar benzene* is actually more stable than the benzene. Compound **117** rearranges to **118** in 90% yield at 120 °C.⁵³¹ In this case, thermolysis of the benzene gives the *Dewar benzene* (rather than the reverse), because of the strain of four adjacent *tert*-butyl groups on the ring.

A number of electrocyclic reactions have been carried out with systems of other sizes, [(e.g., conversion of the 1,3,5,7-octatetraene (**119**) to the cyclooctatriene (**120**)].⁵³² The

stereochemistry of these reactions can be predicted in a similar manner. The results of such predictions can be summarized according to whether the number of electrons involved in the cyclic process is of the form $4n$ or $4n + 2$ (where n is any integer including zero).

	Thermal Reaction	Photochemical Reaction
$4n$	Conrotatory	Disrotatory
$4n + 2$	Disrotatory	Conrotatory

Although the orbital-symmetry rules predict the stereochemical results in almost all cases, it is necessary to recall (Reaction **15-60**, the *Möbius–Hückel* Method) that they only say what is allowed and what is forbidden, but *the fact that a reaction is allowed does not necessarily mean that the reaction takes place*, and if an allowed reaction does take place, it does not *necessarily* follow that a concerted pathway is involved, since other pathways of lower energy may be available.⁵³³ Furthermore, a “forbidden” reaction might still be made to go, if a method of achieving its high activation energy can be found. This was, in fact, done for the cyclobutene–butadiene interconversion (*cis*-3,4-dichlorocyclobutene gave the forbidden *cis,cis*- and *trans,trans*-1,4-dichloro-1,3-butadienes, as well as the allowed *cis*, *trans* isomer) by the use of IR laser light.⁵³⁴ This is a thermal reaction. The laser light excites the molecule to a higher vibrational level (Sec. 7.A.i), but not to a higher electronic state.

As is the case for $[2 + 2]$ -cycloaddition reactions (**15-63**), certain forbidden electrocyclic reactions can be made to take place by the use of metallic catalysts.⁵³⁵ An example is the silver ion-catalyzed conversion of tricyclo[4.2.0.0^{2,5}]octa-3,7-diene to cyclooctatetraene⁵³⁶:

rule is invoked that the σ bond opens in such a way that the resulting p orbitals have the symmetry of the highest occupied orbital of the product, in this case,

an allylic cation. Recall that an allylic system has three molecular orbitals (Sec. 2.C, category 3). For the cation, with only two electrons, the highest occupied orbital is the one of lowest energy (**HOMO**). Thus, the cyclopropyl cation must undergo a disrotatory ring opening in order to maintain the symmetry. Note that, in contrast, ring opening of the cyclopropyl *anion* must be conrotatory,⁵⁴⁰ since in this case it is the next orbital of the allylic system that is the highest occupied, and this has the opposite symmetry.⁵⁴¹ However, it is difficult to generate a free cyclopropyl cation (Sec. 10.G.i, category 7), and it is likely that in most cases, cleavage of the σ bond is concerted with departure of the leaving group in the original cyclopropyl substrate. This, of course, means that the σ bond provides anchimeric assistance to the removal of the leaving group (an S_N2 type process), and we would expect that such assistance should come from the back side. This has an important effect on the direction of ring opening. The orbital-symmetry rules require that the ring opening is disrotatory, but as seen above, there are two disrotatory pathways and the rules do not indicate which is preferred. But the fact that the σ orbital provides assistance from the backside means that the two substituents that are trans to the leaving group must move *outward*, not inward.⁵⁴² Thus, the disrotatory pathway that is followed is the one shown in **B**, not the one shown in **B'**, because the former puts the electrons of the σ bond on the side opposite

that of the leaving group.⁵⁴³ Strong confirmation of this picture⁵⁴⁴ comes from acetolysis of *endo*- (**121**) and *exo*-bicyclo[3,1,0]hexyl-6-tosylate (**112**). The groups trans to the tosylate must move outward. For **121**, this means that the two hydrogen atoms can go outside the

⁵⁴² DePuy, C.H.; Schnack, L.G.; Hausser, J.W.; Wiedemann, W. *J. Am. Chem. Soc.* **1965**, 87, 4006.

⁵⁴³ It has been suggested that the pathway shown in **C** is possible in certain cases: Hausser, J.W.; Grubber, M.J. *J. Org. Chem.* **1972**, 37, 2648; Hausser, J.W.; Uchic, J.T. *J. Org. Chem.* **1972**, 37, 4087.

⁵⁴⁴ Also see Reese, C.B.; Shaw, A. *J. Am. Chem. Soc.* **1970**, 92, 2566; Dolbier, Jr., W.R.; Phanstiel, O. *Tetrahedron Lett.* **1988**, 29, 53, and references cited therein.

framework of the six-membered ring, but for **122** they

are forced to go inside. Consequently, it is not surprising that the rate ratio for solvolysis of **121/122** was found to be $>2.5 \times 10^6$ and that at 150°C , **122** did not solvolyze at all.⁵⁴⁵ This evidence is kinetic. Unlike the cases of the cyclobutene (1,3-diene and cyclohexadiene) 1,3,5-triene interconversions, the direct product here is a cation, which is not stable but reacts with a nucleophile and loses some of its steric integrity in the process, so that much of the evidence has been of the kinetic type rather than from studies of product stereochemistry. However, it has been shown by investigations in superacids (Sec. 5.A.ii), where it is possible to keep the cations intact and to study their structures by NMR, that in all cases studied the cation that is predicted by these rules is in fact formed.⁵⁴⁶

18-28 Conversion of One Aromatic Compound to Another

(6) *cyclo-de-hydrogen-coupling* (Overall transformation)

Stilbenes can be converted to phenanthrenes by irradiation with UV light⁵⁴⁷ in the presence of an oxidizing agent, (e.g., dissolved molecular oxygen, FeCl_3 , or iodine).⁵⁴⁸ The reaction is a photochemically allowed conrotatory⁵⁴⁹ conversion of a 1,3,5-hexatriene to a cyclohexadiene, followed by removal of two hydrogen atoms by the oxidizing agent. The intermediate dihydrophenanthrene has been isolated.⁵⁵⁰ The actual reacting species must be the *cis*-stilbene, but *trans*-stilbenes can often be used, because they are isomerized to the *cis* isomers under the reaction conditions. The reaction can be extended to the preparation of many fused aromatic systems, for example⁵⁵¹:

though not all such systems give a reaction.⁵⁵² The use of substrates containing heteroatoms (e.g., PhN=NPh) allows the formation of heterocyclic ring systems.

Isomerization of biphenylene to benzo[*a*]pentalene⁵⁵³ is a well-known benzene ring contraction rearrangement,⁵⁵⁴ driven by relief of strain in the four-membered ring. Related to this process is the flash vacuum pyrolysis (FVP) of the alternant polycyclic aromatic hydrocarbon benzo[*b*]biphenylene at 1100 °C, which gives fluoranthene, a nonalternant polycyclic aromatic hydrocarbon, as the major product at 1100 °C in the gas phase.⁵⁵⁵ The mechanism used explain that this isomerization involves equilibrating diradicals of 2-phenyl-naphthalene, which rearrange by the net migration of a phenyl group to give equilibrating diradicals of 1-phenylnaphthalene, one isomer of which then cyclizes to fluoranthene.

Another transformation of one aromatic compound to another is the *Stone–Wales rearrangement* of pyracyclene (**123**),⁵⁵⁶ which is a bond-switching reaction. The rearrangement of bifluorenylidene (**124**) to dibenzo[*g,p*]chrysene (**125**) occurs at temperatures as low as 400 °C and is accelerated in the presence of decomposing iodomethane, a convenient source of methyl radicals.⁵⁵⁷ This result suggested a radical rearrangement. This rearrangement is believed to occur by a radical-promoted mechanism consisting of a sequence of homoallyl-cyclopropylcarbinyl rearrangement steps.⁵⁵⁸

B. Sigmatropic Rearrangements

A sigmatropic rearrangement is defined⁵⁵⁹ as migration, in an uncatalyzed intramolecular process, of a σ bond, adjacent to one or more π systems, to a new position in a molecule, with the π systems becoming reorganized in the process. Examples are

The *order* of a sigmatropic rearrangement is expressed by two numbers set in brackets: [*i,j*]. These numbers can be determined by counting the atoms over which each end of the

σ bond has moved. Each of the original termini is given the number 1. Thus in the first example above, each terminus of the σ bond has migrated from C-1 to C-3, so the order is [3,3]. In the second example, the carbon terminus has moved from C-1 to C-5, but the hydrogen terminus has not moved at all, so the order is [1,5].

18-29 [1,j]-Sigmatropic Migrations of Hydrogen

1/ \rightarrow 3/Hydrogen-migration; 1/ \rightarrow 5/Hydrogen-migration

Many examples of thermal or photochemical rearrangements in which a hydrogen atom migrates from one end of a system of π bonds to the other have been reported,⁵⁶⁰ although the reaction is subject to geometrical constraints. Isotope effects play a role in sigmatropic rearrangements, and there is evidence for a kinetic silicon isotope effect.⁵⁶¹ Pericyclic mechanisms are involved,⁵⁶² and the hydrogen must, in the transition state, be in contact with both ends of the chain at the same time. This means that for [1,5] and longer rearrangements, the molecule must be able to adopt the cisoid conformation. Furthermore, there are two geometrical pathways by which any sigmatropic rearrangement can take place, illustrated for the case of a [1,5]-sigmatropic rearrangement,⁵⁶³ starting with a substrate of the form **126**, where the migration origin is an asymmetric carbon atom and $U \neq V$. In one of the two pathways, the hydrogen moves along the top or bottom face of the π system. This is called *suprafacial migration*. In the other pathway, the hydrogen moves *across* the π system, from top to bottom, or vice versa. This is *antarafacial migration*. Altogether, a single isomer like **126** (different rotamers) can give four products. In a suprafacial migration, H can move across the top of the π system (as drawn above) to give the (*R,Z*)-isomer, or it can rotate 180° and move across the bottom of the π system to give the (*S,E*)-isomer.⁵⁶⁴ The antarafacial migration can similarly lead to two diastereomers, in this case the (*S,Z*)- and (*R,E*)-isomers.

⁵⁶⁰ Gajewski, J.J. *Hydrocarbon Thermal Isomerizations*, Academic Press, NY, **1981**; Mironov, V.A.; Fedorovich, A.D.; Akhrem, A.A. *Russ. Chem. Rev.* **1981**, 50, 666; Spangler, C.W. *Chem. Rev.* **1976**, 76, 187.

⁵⁶¹ Lin, Y.-L.; Turos, E. *J. Am. Chem. Soc.* **1999**, 121, 856.

⁵⁶² Moss, S.; King, B.T.; de Meijere, A.; Kozhushkov, S.I.; Eaton, P.E.; Michl, J. *Org. Lett.* **2001**, 3, 2375.

⁵⁶³ Note that a [1,5]-sigmatropic rearrangement of hydrogen is also an internal ene synthesis (Reaction **15-20**).

⁵⁶⁴ The designations U, V, Y, and Z are arbitrary, so which isomer is (*R,Z*) and which is (*S,E*) is arbitrary.

In any given sigmatropic rearrangement, only one of the two pathways is allowed by the orbital-symmetry rules; the other is forbidden. To analyze this situation, first use a modified frontier orbital approach.⁵⁶⁵ Imagine that in the transition state **C**, the migrating H atom breaks away from the rest of the system, which is treated as if it were a free radical.

Note that this is not what actually takes place; it is *imagined* in order to analyze the process. In a [1,3]-sigmatropic rearrangement, the imaginary transition state consists of a hydrogen atom and an allyl radical. The latter species (Sec. 2.C, category 3) has three π orbitals, but the only one that is of concern, the HOMO, which, in a thermal rearrangement is **D**. The electron of the hydrogen atom is of course in a $1s$ orbital, which has only one lobe. The rule governing sigmatropic migration of hydrogen is *the H must move from a plus to a plus or from a minus to a minus lobe, of the HOMO*; it cannot move to a lobe of opposite sign.⁵⁶⁶ The only way this can happen in a thermal [1,3]-sigmatropic rearrangement is by an antarafacial migration. Consequently, the rule predicts that antarafacial thermal [1,3]-sigmatropic rearrangements are allowed, but the suprafacial pathway is forbidden. However, in a photochemical reaction, promotion of an electron means that **E** is now the HOMO; the suprafacial pathway is now allowed and the antarafacial pathway is forbidden.

A similar analysis of [1,5]-sigmatropic rearrangements shows that in this case the thermal reaction must be suprafacial and the photochemical process antarafacial. For the general case, with odd-numbered j , [1, j]-suprafacial migrations are allowed thermally when j is of the form $4n + 1$, and photochemically when j has the form $4n - 1$; the opposite is true for antarafacial migrations.

⁵⁶⁵ See Woodward, R.B.; Hoffmann, R. *The Conservation of Orbital Symmetry*, Academic Press, NY, **1970**, pp. 114–140.

⁵⁶⁶ This follows from the principle that bonds are formed only by overlap of orbitals of the same sign. Since this is a concerted reaction, the hydrogen orbital in the transition state must overlap simultaneously with one lobe from the migration origin and one from the terminus. It is obvious that both of these lobes must have the same sign.

As expected, the *Möbius–Hückel* method leads to the same predictions. Here, examine the basis set of orbitals shown in **F** and **G** for [1,3]- and [1,5]-rearrangements, respectively. A [1,3]-shift involves four electrons, so an allowed thermal pericyclic reaction must be a *Möbius* system (**15-60**, the *Möbius–Hückel* Method) with one or an odd number of sign inversions. As can be seen in **F**, only an antarafacial migration can achieve this. A [1,5]-shift, with six electrons, is allowed thermally only when it is a *Hückel* system with zero or an even number of sign inversions; hence it requires a suprafacial migration.⁵⁶⁷

The actual reported results bear out this analysis. Thus a thermal [1,3]-migration is allowed to take place only antarafacially, but such a transition state would be extremely strained, and thermal [1,3]-sigmatropic migrations of hydrogen are unknown.⁵⁶⁸ On the other hand, the photochemical pathway allows suprafacial [1,3]-shifts, and a few such reactions are known, an example being the photochemical rearrangement of **127** to **128**.⁵⁶⁹ Substituents influence the efficacy of the [1,3]-hydrogen shift.⁵⁷⁰

The situation is reversed for [1,5]-hydrogen shifts. In this case, the thermal rearrangements, being suprafacial, are quite common, while photochemical rearrangements are rare.⁵⁷¹ Two examples of the thermal reaction are

Note that the first example bears out the stereochemical prediction made earlier. Only the two isomers shown were formed. In the second example, migration can continue around the ring. Migrations of this kind are called *circumambulatory rearrangements*,⁵⁷⁴ and such migrations

are known for cyclopentadiene,⁵⁷⁵ pyrrole, and phosphole derivatives.⁵⁷⁶ Geminal bond participation has been observed in pentadienes,⁵⁷⁷ the effects of phenyl substituents have been studied,⁵⁷⁸ and the kinetics and activation parameters of [1,5]-hydrogen shifts have been examined.⁵⁷⁹ The [1,5]-hydrogen shifts are also known with vinyl aziridines.⁵⁸⁰ A Ru catalyzed cycloisomerization of en-1-yne leads to cyclic dienes.⁵⁸¹

The rare [1,4]-hydrogen transfer has been observed in radical cyclizations.⁵⁸² With respect to [1,7]-hydrogen shifts, the rules predict the thermal reaction to be antarafacial.⁵⁸³ Unlike the case of [1,3]-shifts, the transition state is not too greatly strained, and an example of such rearrangements is the formation of **129** and **130**.⁵⁸⁴ Photochemical [1,7]-shifts are suprafacial and, not surprisingly, many of these have been observed.⁵⁸⁵

The orbital symmetry rules also help to explain the unexpected stability of certain compounds (see Reaction **15-63**, preceding Reaction **15-64** and **18-27**, the *Möbius-Hückel* Method). Thus, **130** could, by a thermal [1,3]-sigmatropic rearrangement, easily convert to toluene, which of course is far more stable because it has an aromatic sextet. Yet **130** has been prepared and is stable at dry ice temperature and in dilute solutions.⁵⁸⁶

Analogues of sigmatropic rearrangements in which a cyclopropane ring replaces one of the double bonds are also known, for example,⁵⁸⁷

The reverse reaction has also been reported.⁵⁸⁸ 2-Vinylcycloalkanols⁵⁸⁹ undergo an analogous reaction, as do cyclopropyl ketones (see **18-33**, preceding **18-34** for this reaction).

18-30 [1,j]-Sigmatropic Migrations of Carbon

[1,3] migration of alkyl

Ref. 590

[1,5] migration of phenyl

Ref. 591

Sigmatropic migrations of alkyl or aryl groups⁵⁹² are less common than the corresponding hydrogen migrations.⁵⁹³ When they do take place, there is an important difference. Unlike a hydrogen atom, whose electron is in a $1s$ orbital with only one lobe, a carbon free radical has its odd electron in a p orbital that has *two lobes of opposite sign*. Therefore, if the imaginary transition states for this case are drawn (see above), a thermal suprafacial [1,5]-process (Fig. 18.5) is observed, and symmetry can be conserved only if the migrating carbon moves in such a way that the lobe that was originally attached to the π system remains attached to the π system.

This can happen only if configuration is *retained within the migrating group*. On the other hand, thermal suprafacial [1,3]-migration (Fig. 18.6) *can* take place if the migrating carbon switches lobes. If the migrating carbon was originally bonded by its minus lobe, it must now use its plus lobe to form the new C—C bond. Thus, configuration in the migrating group will be *inverted*. From these considerations, suprafacial [1, j]-sigmatropic rearrangements in which carbon is the migrating group should always be allowed, both thermally and photochemically, but thermal [1,3]-migrations⁵⁹⁴ will proceed with inversion and thermal [1,5]-migrations with retention of configuration within the migrating group. More generally, suprafacial [1, j]-migrations of carbon in systems where $j = 4n - 1$ proceed with inversion thermally and retention photochemically, while systems where $j = 4n + 1$ show the opposite behavior. Where antarafacial migrations take place, all these predictions are of course reversed.

FIG. 18.5. Hypothetical orbital movement for a thermal [1,5]-sigmatropic migration of carbon. To move from one negative lobe, the migrating carbon uses only its own negative lobe, retaining its configuration.

FIG. 18.6. Hypothetical orbital movement for a thermal [1,3]-sigmatropic migration of carbon. The migrating carbon moves a negative to a positive lobe, requiring it to switch its own bonding lobe from negative to positive, inverting its configuration.

The first laboratory test of these predictions was the pyrolysis of deuterated *endo*-bicyclo[3.2.0]hept-2-en-6-yl acetate (**131**), which gave the *exo*-deuterio-*exo*-norbornyl acetate (**132**).⁵⁹⁵ Thus, as predicted by the orbital symmetry rules, this thermal suprafacial [1,3]-sigmatropic reaction took place with complete inversion at C-7. Similar results have been obtained in a number of other cases.⁵⁹⁶ However, similar studies of the pyrolysis of the parent hydrocarbon of **131**, labeled with D at C-6 and C-7, showed that while most of the product was formed with inversion at C-7, a significant fraction (11–29%) was formed with retention.⁵⁹⁷ Other cases of lack of complete inversion are also known.⁵⁹⁸ A diradical mechanism has been invoked to explain such cases.⁵⁹⁹ There is strong evidence for a radical mechanism for some [1,3]-sigmatropic rearrangements.⁶⁰⁰

Photochemical suprafacial [1,3]-migrations of carbon have been shown to proceed with retention, as predicted.⁶⁰¹

Although allylic vinylic ethers generally undergo [3,3]-sigmatropic rearrangements (Reaction 18-33), they can be made to give the [1,3] kind, to give aldehydes, for example,

by treatment with LiClO_4 in diethyl ether.⁶⁰² In this case, the C—O bond undergoes a 1,3-migration from the O to the end vinylic carbon. When the vinylic ether is of the type $\text{ROCR}'=\text{CH}_2$, ketones ($\text{RCH}_2\text{COR}'$) are formed. There is evidence that this [1,3]-sigmatropic rearrangement is not concerted, but involves dissociation of the substrate into ions.⁶⁰²

Thermal suprafacial [1,5]-migrations of carbon have been found to take place with retention,⁶⁰³ but also with inversion.⁶⁰⁴ A diradical mechanism has been suggested for the latter case.⁶⁰⁴

Simple nucleophilic, electrophilic, and free radical 1,2-shifts can also be regarded as sigmatropic rearrangements (in this case, [1,2]-rearrangements). As previously discussed (see discussion in introductory section preceding 18.A) similar principles applied to such rearrangements show that nucleophilic 1,2-shifts are allowed, but the other two types are forbidden unless the migrating group has some means of delocalizing the extra electron or electron pair. The mechanism of the forbidden [3s,5s]-sigmatropic shift has been examined.⁶⁰⁵

18-31 Conversion of Vinylcyclopropanes to Cyclopentenenes

The thermal expansion of a vinylcyclopropane to a cyclopentene ring⁶⁰⁶ is a special case of a [1,3]-sigmatropic migration of carbon, although it can also be considered an internal

[$\pi 2 + \sigma 2$]-cycloaddition reaction (see **15-63**). It is known as a *vinylcyclopropane rearrangement*.⁶⁰⁷ The reaction has been carried out on many vinylcyclopropanes bearing various substituents in the ring⁶⁰⁸ or on the vinyl group and has been extended to 1,1-dicyclopropylethene⁶⁰⁹ and (both thermally⁶¹⁰ and photochemically⁶¹¹) to vinylcyclopropenes. This

rearrangement can be catalyzed by Rh and Ag compounds, and has been used to form rings.⁶¹² Two competing reactions are the homodienyl [1,5]-shift (if a suitable H is available, see **18-29**), and simple cleavage of the cyclopropane ring, leading in this case to a diene (see **18-3**).

Flash vacuum pyrolysis of the trimethylsilyl ether of cyclopropylcarbinyl alcohols gives ring expanded ketones.⁶¹³ Various heterocyclic analogues⁶¹⁴ are also known, as in the rearrangement of aziridinyl amides (**133**).⁶¹⁵ Cyclopropyl ketones can be treated with tosylamine and a Zr catalyst, which converts the imine formed *in situ* to a pyrroline.⁶¹⁶ *N*-Cyclopropylimines undergo rearrangement to cyclic imines (pyrrolines) under photochemical conditions.⁶¹⁷ *P*-Vinyl phosphiranes (the P analogue of cyclopropanes with P in the ring) under a similar rearrangement, and the mechanism has been studied.⁶¹⁸

Vinylcyclobutanes can be converted to cyclohexenes,⁶¹⁹ but larger ring compounds do not generally give the reaction.⁶²⁰ Tricyclo[4.1.0.0^{2,5}]heptanes rearrange to give nonconjugated cycloheptadienes.⁶²¹ The bicyclo[2.1.0]pentane derivatives undergo this reaction.

The reaction rate has also been greatly increased by the addition of a one-electron oxidant tris-(4-bromophenyl)aminium hexafluoroantimonate ($\text{Ar}_3\text{N}^+\text{SbF}_6^-$, $\text{Ar} = p\text{-bromophenyl}$).⁶²² This reagent converts the substrate to a cation radical, which undergoes ring expansion much faster.⁶²³

The mechanisms of these ring expansions are not certain. Both concerted⁶²⁴ and diradical⁶²⁵ pathways have been proposed,⁶²⁶ and it is possible that both pathways operate, in different systems.

For the conversion of a vinylcyclopropane to a cyclopentene in a different way, see OS 68, 220.

18-32 The Cope Rearrangement

(3/4)→(1/6)-sigma-Migration

When 1,5-dienes are heated, a [3,3]-sigmatropic rearrangement known as the *Cope rearrangement* (not to be confused with the *Cope elimination* Reaction, 17-9) occurs to generate an isomeric 1,5-diene.⁶²⁷ When the diene is symmetrical about the 3,4-bond, the reaction gives a product identical with the starting material⁶²⁸:

Therefore, a *Cope rearrangement* can be detected only when the diene is not symmetrical about this bond. Any 1,5-diene gives the rearrangement; for example, 3-methyl-1,5-hexadiene heated to 300 °C gives 1,5-heptadiene.⁶²⁹ However, the reaction takes place more easily (lower temperature required) when there is a group on the C-3 or C-4 which leads to the new double bond being substituted. The reaction is reversible⁶³⁰ and produces an equilibrium mixture of the two 1,5-dienes, which is *richer in the thermodynamically*

more stable isomer. However, the equilibrium can be shifted to the right for 3-hydroxy-1,5-dienes,⁶³¹ because the product tautomerizes to the ketone or aldehyde:

This reaction of 3-hydroxy-1,5-dienes is called the *oxy-Cope rearrangement*,⁶³² and has proved highly useful in synthesis.⁶³³ The *oxy-Cope rearrangement* is greatly accelerated (by factors of 10^{10} – 10^{17}) if the alkoxide is used rather than the alcohol (the *anionic oxy-Cope rearrangement*),⁶³⁴ where the direct product is the enolate ion, which is hydrolyzed to the ketone. A metal-free reaction using a phosphazene base has been reported.⁶³⁵ The silyloxy-*Cope rearrangement* has proven to be quite useful.⁶³⁶ An antibody-catalyzed *oxy-Cope reaction* is known,⁶³⁷ and the mechanism and origins of catalysis for this reaction have been studied.⁶³⁸ Sulfur substituents also lead to rate enhancement of the *oxy-Cope rearrangement*.⁶³⁹ Note that 2-*oxonia Cope rearrangements* have been implicated in *Prins cyclization* reactions (16-54).⁶⁴⁰ A highly diastereoselective *oxonia-Cope rearrangement* proceeded using a chiral aldehyde with a chiral conjugated ester.⁶⁴¹

aza-Cope rearrangements are also known.⁶⁴² There is an enantioselective *aza-Cope rearrangement*.⁶⁴³ There is also a 1,2-*oxaza-Cope rearrangement*. Involving esters and alkyl nitrites.⁶⁴⁴ In *amino-Cope rearrangements*, the solvent plays a role in the regioselectivity of the reaction.⁶⁴⁵ It has been suggested that this latter reaction does not proceed solely by a concerted [3.3]-sigmatropic rearrangement.⁶⁴⁶

The 1,5-diene system may be inside a ring or part of an allenic system⁶⁴⁷ (the example shown illustrates both of these situations).⁶⁴⁸ However, the reaction does not take place when one of the double bonds is part of

an aromatic system (e.g., 4-phenyl-1-butene).⁶⁴⁹ When the two double bonds are in vinylic groups attached to adjacent ring positions, the product is a ring four carbons larger. This has been applied to divinylcyclopropanes and divinylcyclobutanes, as shown.⁶⁵⁰ Indeed, *cis*-1,2-divinylcyclopropanes give this rearrangement so rapidly

that they generally cannot be isolated at room temperature,⁶⁵¹ but exceptions are known.⁶⁵² Note that divinylloxiranes, divinylphosphiranes, and divinylthiiranes undergo similar rearrangements.⁶⁵³ When heated, 1,5-diynes are converted to 3,4-dimethylenecyclobutenes (**134**).⁶⁵⁴ A rate-determining *Cope rearrangement* is followed by a very rapid electrocyclic (**18-27**) reaction.

The interconversion of 1,3,5-trienes and cyclohexadienes (in Reaction **18-27**) is very similar to the *Cope rearrangement*, but in **18-27**, the 3,4-bond goes from a double to a single bond rather than from a single bond to no bond. Like [2 + 2]-cycloadditions (Reaction **15-63**), *Cope rearrangements* of simple 1,5-dienes can be catalyzed by certain transition metal compounds. For example, the addition of a Pd catalyst causes the reaction to take place at room temperature.⁶⁵⁵

As indicated with the arrows, the mechanism of the uncatalyzed *Cope rearrangement* is a simple six-centered pericyclic process.⁶⁵⁶ Since the mechanism is so simple, it has been possible to study some rather subtle points, among them the question of whether the six-membered transition state is in the boat or the chair form.⁶⁵⁷ For the case of 3,4-dimethyl-1,5-hexadiene, it was demonstrated conclusively that the transition state is in the chair form. This was shown by the stereospecific nature of the reaction: The meso isomer gave the *cis*–*trans* product, while the (\pm) diastereomer gave the *trans*–*trans*-diene.⁶⁵⁸ If the transition state is in the chair form (taking the meso isomer, e.g.), one methyl must be “axial” and the other “equatorial” and the product must be the

cis–*trans*-alkene. There are two possible boat forms for the transition state of the meso isomer. One leads to a *trans*–*trans* product; the other to a *cis*–*cis*-alkene. For the (\pm) pair, the predictions are just the opposite: There is just one boat form, and it leads to the *cis*–*trans*-alkene, while one chair form (“diaxial” methyls) leads to the *cis*–*cis* product and the other (“diequatorial” methyls) predicts the *trans*–*trans* product. Thus the nature of the products obtained demonstrates that the transition state is a chair and not a boat.⁶⁵⁹ While 3,4-dimethyl-1,5-hexadiene is free to assume either the chair or boat (it prefers the chair), other compounds are not so free. Thus 1,2-divinylcyclopropane (see above) can react *only* in the boat form, demonstrating that such reactions are possible.⁶⁶⁰

Because of the nature of the transition state⁶⁶¹ in the pericyclic mechanism, optically active substrates with a stereogenic carbon at C-3 or C-4 transfer the chirality to the product (see Reaction 18-33 for an example in the mechanistically similar *Claisen rearrangement*).⁶⁶² There are many examples of asymmetric [3,3]-sigmatropic rearrangements.⁶⁶³

Not all *Cope rearrangements* proceed by the cyclic six-centered mechanism.⁶⁶⁴ Thus *cis*-1,2-divinylcyclobutane (see above) rearranges smoothly to 1,5-cyclooctadiene, since the geometry is favorable. The *trans* isomer also gives this product, but the main product is 4-vinylcyclohexene (resulting from Reaction **18-31**). This reaction can be rationalized as proceeding by a diradical mechanism (see **135**),⁶⁶⁵ although it is possible that at least part of the cyclooctadiene produced comes from a prior epimerization of the *trans*- to the *cis*-divinylcyclobutane followed by *Cope rearrangement* of the latter.⁶⁶⁶

It has been suggested that another type of diradical two-step mechanism may be preferred by some substrates.⁶⁶⁷ Indeed, a nonconcerted *Cope rearrangement* has been reported.⁶⁶⁸ In this pathway,⁶⁶⁹ the 1,6-bond is formed before the 3,4-bond breaks:

This is related to the *Bergman cyclization* that was introduced in Reaction **18-27**.

It was pointed out earlier that a *Cope rearrangement* of the symmetrical 1,5-hexadiene gives 1,5-hexadiene. This is a *degenerate Cope rearrangement* (Sec. 18.A.ii). Bicyclo[5.1.0]octadiene (**136**) undergoes a similar rearrangement.⁶⁷⁰ At room temperature, the NMR spectrum of this compound is in accord with the structure shown on the left. At 180 °C, it is converted by a *Cope reaction* to a compound equivalent to itself. The interesting thing is that at 180 °C the NMR spectrum shows that what exists is an equilibrium mixture of the two

structures. That is, at this temperature the molecule rapidly (faster than 10^3 times per second) changes back and forth between the two structures. This is called *valence tautomerism* and is quite distinct from resonance, even though only electrons shift⁶⁷¹ (see Sec. 2.N for other types of tautomerism). The positions of the nuclei are not the same in the two structures. Molecules like **136** that exhibit valence tautomerism (in this case, at

180 °C) are said to have *fluxional* structures. It may be recalled that *cis*-1,2-divinylcyclopropane does not exist at room temperature because it rapidly rearranges to 1,4-cycloheptadiene (see above), but in **136** the *cis*-divinylcyclopropane structure is frozen into the molecule in both structures. Several other compounds with this structural feature are also known. Of these, *bullvalene* (**137**) is especially interesting. The *Cope rearrangement* shown for **137** changes the position of the cyclopropane ring from 4,5,10 to 1,7,8. But the molecule could also have undergone rearrangements to put this ring at 1,2,8 or 1,2,7. Any of these could then undergo several *Cope*

rearrangements. In all, there are $\frac{10!}{3}$ or >1.2 million tautomeric forms, and the cyclopropane ring can be at any three carbons that are adjacent. Since each of these tautomers is equivalent to all the others, this has been called an infinitely degenerate *Cope rearrangement*. Bullvalene has been synthesized and its ^1H NMR spectrum was determined.⁶⁷² At –25 °C, there are two peaks with an area ratio of 6 : 4. This is in accord with a single nontautomeric structure. The six protons are the vinylic protons and the four protons are the allylic ones. But at 100 °C, the compound shows only one NMR peak, indicating that the compound rapidly interchanges its structure among 1.2 million equivalent forms.⁶⁷³ The ^{13}C NMR spectrum of bullvalene also shows only one peak at 100 °C.⁶⁷⁴

Another compound for which degenerate *Cope rearrangements* result in equivalence for all the carbons is *hypostrophene* (**138**).⁶⁷⁵ In the case of the compound *barbaralane* (**139**)⁶⁷⁶ (bullvalene in which one $\text{CH}=\text{CH}$ has been replaced by a CH_2), there are only 2 equiv tautomers.⁶⁷⁷ However, NMR spectra indicate that even at room temperature a rapid interchange of both tautomers is present, although by about –100 °C this has slowed

Ed.* **1967**, 6, 176; Doering, W. von E.; Ferrier, B.M.; Fossel, E.T.; Hartenstein, J.H.; Jones, Jr., M.; Klumpp, G.W.; Rubin, R.M.; Saunders, M. *Tetrahedron* **1967**, 23, 3943; Henkel, J.G.; Hane, J.T. *J. Org. Chem.* **1983**, 48, 3858.

to the point where the spectrum is in accord with a single structure. In the case of *semibullvalene* (**140**) (barbaralane in which the CH₂ has been removed), not only is there a rapid interchange at room temperature, but even at -110°C .⁶⁷⁸ Compound **140** has the lowest energy barrier of any known compound capable of undergoing the *Cope rearrangement*.⁶⁷⁹

The molecules taking part in a valence tautomerization need not be equivalent. Thus, NMR spectra indicate that a true valence tautomerization exists at room temperature between the cycloheptatriene (**141**) and the norcaradiene (**142**).⁶⁸⁰ In this case, one isomer (**142**) has the *cis*-1,2-divinylcyclopropane structure, while the other does not. In an analogous interconversion, benzene oxide⁶⁸¹ and oxepin exist in a tautomeric equilibrium at room temperature.⁶⁸²

Bullvalene and hypostrophene are members of a group of compounds all of whose formulas can be expressed by the symbol $(\text{CH})_{10}$.⁶⁸³ Many other members of this group are known. Similar groups of $(\text{CH})_n$ compounds exist for other even-numbered values of "*n*".⁶⁸⁵ For example, there are 20 possible $(\text{CH})_8$ ⁶⁸⁴ compounds,⁶⁸⁵ and five possible $(\text{CH})_6$ compounds,⁶⁸⁶ all of which are known: benzene, prismane (Sec. 4.Q.i), Dewar benzene (see Reaction 18-27, the *Möbius–Hückel Method*), bicyclopentenyl,⁶⁸⁷ and benzvalene.⁶⁸⁸

An interesting example of valence tautomerism is the case of 1,2,3-*tert*-butylcyclobutadiene (Sec. 2.K.ii). There are two isomers, both rectangular, and ¹³C NMR spectra show that they exist in a dynamic equilibrium, even at -185°C .⁶⁸⁹

18-33 The Claisen Rearrangement⁶⁹⁰

Allylic aryl ethers, when heated, rearrange to *o*-allylphenols in a reaction called the *Claisen rearrangement*.⁶⁹¹ If both ortho positions are filled, the allylic group migrates to the para position (this is often called the *para*-Claisen rearrangement).⁶⁹² There is no reaction when the para and both ortho positions are filled. Migration to the meta position has not been observed. In the ortho migration, the allylic group always undergoes an allylic shift. That is, as shown above, a substituent α to the oxygen is now γ to the ring (and vice versa). On the other hand, in the para migration there is never an allylic shift: The allylic group is found exactly as it was in the original ether. Compounds with propargylic groups (i.e., groups with a triple bond in the appropriate position) do not generally give the corresponding products.

The mechanism is a concerted pericyclic [3,3]-sigmatropic rearrangement⁶⁹³ and accounts for all these facts. For the ortho rearrangement,

Evidence is the lack of a catalyst, the fact that the reaction is first order in the ether, the absence of cross-over products when mixtures are heated, and the presence of the allylic shift, which is required by this mechanism. The allylic shift for the ortho rearrangement (and the absence of one for the para) has been demonstrated by ¹⁴C labeling, even when no substituents are present. Studies of the transition state geometry have shown that, like the *Cope rearrangement*, the *Claisen rearrangement* usually prefers a chair-like transition state.⁶⁹⁴ A *retro*-Claisen rearrangement is known and its mechanism has been examined.⁶⁹⁵

When the ortho positions have no hydrogen, a second [3,3]-sigmatropic migration (a *Cope reaction*) follows:

and the migrating group is restored to its original structure. Intermediates of structure **143** have been trapped by means of a *Diels–Alder reaction* (**15–60**).⁶⁹⁶ The rearrangement of aryl allyl ethers is facilitated by Ag–KI in hot acetic acid,⁶⁹⁷ and by AlMe₃ in water.⁶⁹⁸ A solid-phase reaction of polymer-bound substrate undergoes the *Claisen rearrangement* with microwave irradiation.⁶⁹⁹

Allylic ethers of enols (allylic vinylic ethers, **144**) also undergo the *Claisen rearrangement*⁷⁰⁰; in fact, it was discovered with these compounds first.⁷⁰¹ In these cases of course, the final tautomerization does not take place even when R' = H, since there is no aromaticity to restore, and ketones are more stable than enols.⁷⁰² Catalytic *Claisen rearrangements* of allyl vinyl ethers are well known.⁷⁰³ The use of water as solvent accelerates the reaction.⁷⁰⁴ Microwave induced reactions on silica gel⁷⁰⁵ and in ionic liquids⁷⁰⁶ are known. The mechanism is similar to that with allylic aryl ethers.⁷⁰⁷ In the presence of a chiral Cu complex, *Claisen rearrangements* proceed with good enantioselectivity.⁷⁰⁸ *N*-Heterocyclic carbenes catalyzed an enantioselective *Claisen rearrangement*.⁷⁰⁹ A chiral hydrogen-bond donor has been used for enantioselective *Claisen rearrangements*.⁷¹⁰ A chiral allylic ether gave an enantioselective *Claisen rearrangement* with an Ir catalyst.⁷¹¹

Since the *Claisen rearrangement* mechanism does not involve ions, it should not be greatly dependent on the presence or absence of substituent groups on the ring.⁷¹² This is the case. Electron-donating groups increase the rate and electron-withdrawing groups decrease it, but the effect is small, with the *p*-amino compound reacting only ~10–20 times faster than the *p*-nitro compound.⁷¹³ However, solvent effects⁷¹⁴ are greater: Rates varied over a 300-fold range when the reaction was run in 17 different solvents.⁷¹⁵ An especially good solvent is trifluoroacetic acid, in which the reaction can be carried out at room temperature.⁷¹⁶ Most *Claisen rearrangements* are performed without a catalyst, but AlCl₃ or BF₃ are sometimes used.⁷¹⁷ In this case, it may become a *Friedel–Crafts reaction*, with the mechanism no longer cyclic,⁷¹⁸ and ortho, meta, and para products may be obtained.

Allyl allene ethers undergo a *Claisen rearrangement* when heated in DMF to give the expected diene with a conjugated aldehyde unit.⁷¹⁹ Butenolides with a β-allylic ether unit undergo *Claisen rearrangement–Conia reaction*⁷²⁰ cascade to give an oxaspiroheptane with β-keto lactone comprising the five-membered ring.⁷²¹ Allylic esters of β-keto acids undergo a *Claisen rearrangement* in what is known as the *Carroll rearrangement*⁷²² (also called the *Kimel–Cope rearrangement*⁷²³), and the reaction can be catalyzed by a Ru complex.⁷²⁴ An asymmetric *Carroll rearrangement* was catalyzed by a chiral Pd complex.⁷²⁵

Heating an allylic alcohol with *N,N*-dimethylacetamide dimethyl acetal yields a transient intermediate, and subsequent *Claisen rearrangement* gives an amide in a sequence that is known as the *Eschenmoser variant* or the *Eschenmoser–Claisen rearrangement*.⁷²⁶ This reaction has also been called the *Meerwein–Eschenmoser Claisen rearrangement*.⁷²⁷ An enantioselective version has been reported using a chiral Pd complex.⁷²⁸

The enolate anions (**145**) of allylic esters (formed by treatment of the esters with LICA) rearrange to γ,δ-unsaturated acids.⁷²⁹ Alternatively, the silylketene acetal [R³R²C=C(OSiR₃)OCH₂CH=CHR¹] may be used instead of **145**.⁷³⁰ This rearrangement also proceeds at room temperature. By either procedure, the reaction is called the *Ireland–*

Claisen rearrangement.⁷³¹ Note the presence of the negative charge in **145**. As with the *oxy-Cope rearrangement* (in Reaction **18-34**), negative charges generally accelerate the *Claisen reaction*,⁷³² although the extent of the acceleration can depend on the identity of the positive counterion.⁷³³ The reaction proceeds with good syn selectivity in many cases.⁷³⁴ The *Ireland-Claisen rearrangement* has been made enantioselective by converting **145** to an enol borinate in which the boron is attached to a chiral group.⁷³⁵ The *Ireland-Claisen rearrangement* can be done with amide derivatives also.⁷³⁶

As just mentioned, asymmetric *Claisen rearrangement* reactions are well known.⁷³⁷ Chiral Lewis acids have been designed for this purpose.⁷³⁸ In general, asymmetric [3,3]-sigmatropic rearrangements are well known.⁷³⁹

A number of analogues of the *Claisen rearrangement* are known, for example, rearrangement of $\text{ArNHCH}_2\text{CH}=\text{CH}_2$,⁷⁴⁰ of *N*-allylic enamines ($\text{R}_2\text{C}=\text{CRNRCR}_2\text{CR}=\text{CR}_2$)⁷⁴¹ of allylic imino esters $[\text{RC}(\text{OCH}_2\text{CH}=\text{CH}_2)=\text{NR}]$ ⁷⁴² (these have often been rearranged with transition metal catalysts⁷⁴³), and of $\text{RCH}=\text{NRCHRCH}_2\text{CH}=\text{CH}_2$. These rearrangements of nitrogen-containing compounds can be called *aza-Claisen rearrangements*,⁷⁴⁴ but are sometimes called *aza-Cope rearrangements*,⁷⁴⁵ as described in Reaction **18-32**. A Pd catalyzed *aza-Claisen* has been reported.⁷⁴⁶ An important contribution to this variation is the rearrangement of

trichloroacetimidate derivatives of prochiral (Z)-2-alken-1-ols, usually with a Pd catalyst, to give chiral allylic esters.⁷⁴⁷ There is a catalytic enantioselective *aza-Cope rearrangement*.⁷⁴⁸ A so-called *amine-Claisen rearrangement* was reported for *N*-allyl indoles, when heated in the presence of $\text{BF}_3 \cdot \text{OEt}_2$.⁷⁴⁹ An *azo-Cope* rearrangement, $\text{CH}_2=\text{CHCR}_2'\text{CR}_2'\text{N}=\text{NAr} \rightarrow \text{R}_2'\text{C}=\text{CHCH}_2\text{NArN}=\text{CR}_2'^2$, has been reported.⁷⁵⁰ In a related reaction, allylic phosphorimidates undergo [3,3]-sigmatropic rearrangement.⁷⁵¹

The conversion of allylic aryl thioethers, ($\text{ArSCH}_2\text{CH}=\text{CH}_2$) to *o*-allylic thiophenols is not feasible, because the latter are not stable,⁷⁵² but react to give bicyclic compounds.⁷⁵³ However, many allylic vinylic sulfides do give the rearrangement (the *thio-Claisen rearrangement*).⁷⁵⁴ Allylic vinylic sulfones (e.g., $\text{H}_2\text{C}=\text{CRCH}_2-\text{SO}_2-\text{CH}=\text{CH}_2$) rearrange, when heated in the presence of ethanol and pyridine, to unsaturated sulfonate salts ($\text{CH}_2=\text{CRCH}_2\text{CH}_2\text{CH}_2\text{SO}_3^-$), produced by reaction of the reagents with the unstable sulfene intermediates $\text{CH}_2=\text{CRCH}_2\text{CH}_2\text{CH}=\text{SO}_2$.⁷⁵⁵ Allylic vinylic sulfoxides rapidly rearrange at room temperature or below.⁷⁵⁶ Chiral vinyl sulfoxides undergo *Claisen rearrangement* with good enantioselectivity.⁷⁵⁷

Ethers with an alkyl group in the γ position ($\text{ArO}-\text{C}-\text{C}=\text{C}-\text{R}$ systems) sometimes give abnormal products, with the β carbon becoming attached to the ring⁷⁵⁸:

It has been established that these abnormal products do not arise directly from the starting ether, but are formed by a further rearrangement of the normal product⁷⁵⁹:

This rearrangement, which has been called an *enolene rearrangement*, a *homodienyl* [1,5]-*sigmatropic hydrogen shift* (see Reaction **18-29**), and a [1,5]-*homosigmatropic rearrangement*, involves a shift of three electron pairs over seven atoms. It has been found that this “abnormal” *Claisen rearrangement* is general and can interconvert the enol forms of systems of the types **146** and **147** through the cyclopropane intermediate (**148**).⁷⁶⁰

18-34 The Fischer Indole Synthesis

When arylhydrazones of aldehydes or ketones are treated with a catalyst, elimination of ammonia takes place and an indole is formed, in the *Fischer indole synthesis*.⁷⁶¹ Zinc chloride is a commonly used catalyst, but dozens of others, including other metal halides, proton and Lewis acids, and certain transition metals have also been used. Microwave irradiation has been used to facilitate this reaction.⁷⁶² The reaction has been done using an AlCl_3 complex as an ionic liquid,⁷⁶³ and solid-phase *Fischer indole syntheses* are known.⁷⁶⁴ Aniline derivatives react with α -diazoketones, in the presence of a Rh catalyst, to give indoles as well.⁷⁶⁵ Arylhya zones are easily prepared by the treatment of aldehydes or ketones with phenylhydrazine (Reaction **16-2**) or by aliphatic diazonium coupling (Reaction **12-7**). However, it is not necessary to isolate the arylhydrazone. The aldehyde or ketone can be treated with a mixture of phenylhydrazine and the catalyst; this is now common practice. In order to obtain an indole, the aldehyde or ketone must be of the form $\text{RCOCH}_2\text{R}'$ (R = alkyl, aryl, or hydrogen). Vinyl ethers (e.g., dihydrofuran) serve as an aldehyde surrogate when treated with phenylhydrazine and a catalytic amount of aq H_2SO_4 to give an 3-substituted indole.⁷⁶⁶

At first glance, the reaction does not seem to be a rearrangement. However, the key step of the mechanism⁷⁶⁷ is a [3,3]-sigmatropic rearrangement⁷⁶⁸:

There is much evidence for this mechanism, for example, (1) the isolation of **153**,⁷⁶⁹ (2) the detection of **152** by ^{13}C and ^{15}N NMR,⁷⁷⁰ (3) the isolation of side products that could only have come from **151**,⁷⁷¹ and (4) ^{15}N -labeling experiments showing that it was the nitrogen farther from the ring that is eliminated as ammonia.⁷⁷² The main function of the catalyst seems to be to speed the conversion of **149** to **150**. The reaction can be performed without a catalyst.

18-35 [2,3]-Sigmatropic Rearrangements

(2/*S*-3/) \rightarrow (1/*5*/)-*sigma*-Migration

Sulfur ylids bearing an allylic group are converted to unsaturated sulfides on heating.⁷⁷³ This is a concerted [2,3]-sigmatropic rearrangement⁷⁷⁴ and has also been demonstrated for the analogous cases of nitrogen ylids⁷⁷⁵ and the conjugate bases of allylic ethers (in the last case it is called a [2,3]-Wittig rearrangement).⁷⁷⁶ It has been argued that the [2,3]-Wittig rearrangement demands severe deformation of the molecule in order to proceed.⁷⁷⁷ It has been shown that SmI_2 induces a [2,3]-Wittig rearrangement.⁷⁷⁸ The reaction has been

extended to certain other systems,⁷⁷⁹ even to an all-carbon system.⁷⁸⁰

Treatment of an α -(*N*-allylic amino) ketone with NaH led to 2-allylic α -amino ketones via a [2,3]-rearrangement.⁷⁸¹ In the presence of a chiral ligand on nitrogen,⁷⁸¹ or with a chiral additive,⁷⁸² good asymmetric induction is possible. Vinylaziridines undergo [2,3]-sigmatropic rearrangement.⁷⁸³

Since the reactions involve migration of an allylic group from a sulfur, nitrogen, or oxygen atom to an adjacent negatively charged carbon atom, they are special cases of the *Stevens or Wittig rearrangements* (**18-21** and **18-22**). However, in this case the migrating group *must* be allylic (in **18-21** and **18-22** other groups can also migrate). Thus, when the migrating group is allylic, there are two possible pathways: (1) the radical-ion or ion-pair mechanisms (**18-21** and **18-22**) and (2) the concerted pericyclic [2,3]-sigmatropic rearrangement. These are easily distinguished since the latter always involves an allylic shift (as in the *Claisen rearrangement*), while the former pathway does not.

Of these reactions, the [2,3]-*Wittig rearrangement* in particular has often been used as a means of transferring chirality. The product of this reaction has potential stereogenic centers at C-3 and C-4 (if $R^5 \neq R^6$), and if the starting ether is optically active because of a stereogenic center at C-1, the product may be optically active as well. Many examples are known in which optically active ethers were converted to a product that was optically active because of chirality at C-3, C-4, or both.⁷⁸⁴ If a suitable stereogenic center is present in R^1 (or if a functional group in R^1 can be so converted), then stereocontrol over three contiguous stereogenic centers can be achieved. Stereocontrol of the new double bond (*E* or *Z*) has also been accomplished.

If an OR or SR group is attached to the negative carbon, the reaction becomes a method for the preparation of β,γ -unsaturated aldehydes, because the product is easily hydrolyzed.⁷⁸⁵

Another [2,3]-sigmatropic rearrangement converts allylic sulfoxides to rearranged allylic alcohols by treatment with a thiophilic reagent (e.g., trimethyl phosphite).⁷⁸⁶ This is the *Mislow–Evans rearrangement*. In this case, the migration is from sulfur to oxygen. [2,3]-Oxygen-to-sulfur migrations are also known.⁷⁸⁷ The *Sommelet–Hauser rearrangement* discussed in Reaction 13-31 is also a [2,3]-sigmatropic rearrangement.

OS VIII, 427.

18-36 The Benzidine Rearrangement

When hydrazobenzene is treated with acids, it rearranges to give ~70% 4,4'-diaminobiphenyl (**154**, benzidine) and ~30% 2,4'-diaminobiphenyl. This reaction is called the *benzidine rearrangement* and is general for *N,N'*-diarylhydrazines.⁷⁸⁸ Usually, the major product is the 4,4'-diaminobiaryl, but four other products may also be produced: the 2,4'-diaminobiaryl, already referred to, the 2,2'-diaminobiaryl, and the *o*- and *p*-arylaminoanilines (called *semidines*). The 2,2'- and *p*-arylaminoaniline compounds are formed less often and in smaller amounts than the other two side products. Usually, the 4,4'-diaminobiaryl predominates, except when one or both para positions of the diarylhydrazine are occupied. However, the 4,4'-diamine may still be produced even if the para positions are occupied. If SO_3H , CO_2H , or Cl (but not R , Ar , or NR_2) is present in the para position, it may be ejected. With dinaphthylhydrazines, the major products are not the 4,4'-diaminobinaphthyls, but the 2,2' isomers. Another side reaction is disproportionation to ArNH_2 and $\text{ArN}=\text{NAr}$. For example, *p,p'*- $\text{PhC}_6\text{H}_4\text{NHNHC}_6\text{H}_4\text{Ph}$ gives 88% disproportionation products at 25 °C.⁷⁸⁹

The mechanism has been exhaustively studied and several mechanisms have been proposed.⁷⁹⁰ At one time, it was believed that NHAr broke away from ArNHNHAr and became attached to the para position to give the semidine, which then went on to product. The fact that semidines could be isolated lent this argument support, as did the fact that this would be analogous to the rearrangements considered in Chapter 11 (Reaction 11-28–11-32). However, this theory was proved incorrect when it was discovered that semidines could not be converted to benzidines under the reaction conditions. Cleavage into two

independent pieces (either ions or radicals) has been ruled out by many types of cross-over experiments, which always showed that the two rings of the starting material are in the product; that is, $\text{ArNHNHAr}'$ gives no molecules (of any of the five products) containing two Ar groups or two Ar' groups, and mixtures of ArNHNHAr and $\text{Ar}'\text{NHNHAr}'$ give no molecules containing both Ar and Ar' . An important discovery was the fact that, although the reaction is always first order in substrate, it can be either first⁷⁹¹ or second⁷⁹² order in $[\text{H}^+]$. With some substrates the reaction is entirely first order in $[\text{H}^+]$, while with others it is entirely second order in $[\text{H}^+]$, regardless of the acidity. With still other substrates, the reaction is first order in $[\text{H}^+]$ at low acidities and second order at higher acidities. With the latter substrates fractional orders can often be observed,⁷⁹³ because at intermediate acidities, both processes take place simultaneously. These kinetic results seem to indicate that the actual reacting species can be either the monoprotonated substrate ArNHNH_2Ar or the diprotonated $\text{ArNH}_2\text{NH}_2\text{Ar}$.

Most of the proposed mechanisms⁷⁹⁴ attempted to show how all five products could be produced by variations of a single process. An important breakthrough was the discovery that the two main products are formed in entirely different ways, as shown by isotope-effect studies.⁷⁹⁵ When the reaction was run with hydrazobenzene labeled with ^{15}N at both nitrogen atoms, the isotope effect was 1.022 for formation of **154**, but 1.063 for formation of 2,4'-diaminobiphenyl. This showed that the N—N bond is broken in the rate-determining step in both cases, but the steps themselves are obviously different. When the reaction was run with hydrazobenzene labeled with ^{14}C at a para position, there was an isotope effect of 1.028 for formation of **154**, but essentially no isotope effect (1.001) for formation of 2,4'-diaminobiphenyl. This can only mean that for **154** formation of the new C—C bond *and* breaking of the N—N bond both take place in the rate-determining step; in other words, the mechanism is concerted. The following [5,5]-sigmatropic rearrangement accounts for this⁷⁹⁶:

The diion **155** was obtained as a stable species in superacid solution at -78°C by treatment of hydrazobenzene with $\text{FSO}_3\text{H}\text{---}\text{SO}_2$ (SO_2ClF).⁷⁹⁷ Although the results just given were obtained with hydrazobenzene, which reacts by the diprotonated pathway, monoprotonated substrates have been found to react by the same [5,5]-sigmatropic mechanism.⁷⁹⁸

Some of the other rearrangements in this section are also sigmatropic. Thus, formation of the *p*-semidine takes place by a [1,5]-sigmatropic rearrangement,⁷⁹⁹ and the conversion of 2,2'-hydrazonaphthalene to 2,2'-diamino-1,1'-binaphthyl by a [3,3] sigmatropic rearrangement.⁸⁰⁰

2,4'-Diaminobiphenyl is formed by a completely different mechanism, though the details are not known. There is rate-determining breaking of the N—N bond, but the C—C bond is not formed during this step.⁸⁰¹ The formation of the *o*-semidine also takes place by a nonconcerted pathway.⁸⁰² Under certain conditions, benzidine rearrangements have been found to go through radical cations.⁸⁰³

C. Other Cyclic Rearrangements

18-37 Metathesis of Alkenes (Alkene or Olefin Metathesis)⁸⁰⁴

Alkene metathesis

When alkenes are treated with certain catalysts they are converted to other alkenes in a reaction in which one set of alkylidene groups ($\text{R}^1\text{R}^2\text{C}=\text{}$) have become interchanged with other alkylidene groups ($\text{R}^3\text{R}^4\text{C}=\text{}$) by a process schematically illustrated by the equilibrium reaction shown below. In an early example shown above, 2-pentene (either *cis*, *trans*, or a *cis*–*trans* mixture) is converted to a mixture of ~50% 2-pentene, 25% 2-butene, and 25% 3-hexene. Nowadays, superior catalysts and experimental procedures have made this reaction synthetically useful (see below). The reaction is reversible⁸⁰⁵ and the alkene starting material and products exist in equilibrium, so the same mixture can be obtained by starting with equimolar quantities of 2-butene and 3-hexene.⁸⁰⁶ The reaction is called *metathesis* of alkenes or *alkene metathesis* (*olefin metathesis*).⁸⁰⁷ In general, the reaction can be applied to a single unsymmetrical alkene, giving a mixture of itself and two other

alkenes, or to a mixture of two alkenes, in which case the number of different molecules in the product depends on the symmetry of the reactants. In the example, a mixture of $R^1R^2C=CR^1R^2$ and $R^3R^4C=CR^3R^4$ gives rise to only one new alkene ($R^1R^2C=CR^3R^4$), while in the most general case, the reaction of two alkenes ($R^1R^2C=CR^3R^4$ and $R^5R^6C=CR^7R^8$) can give a mixture of 10 alkenes: the original 2 + 8 new ones. In early work, W, Mo,⁸⁰⁸ or Re complexes were used, and with simple alkenes the proportions of products are generally statistical,⁸⁰⁹ which limited the synthetic utility of the reaction since the yield of any one product is low. In some cases, one alkene may be more or less thermodynamically stable than the rest, so that the proportions are not statistical in all cases.

It is possible to shift the equilibrium to favor certain products. For example, 2-methyl-1-butene gives rise to ethylene and 3,4-dimethyl-3-hexene. By allowing the gaseous ethylene to escape, the yield of 3,4-dimethyl-3-hexene can be raised to 95%.⁸¹⁰ This example shows that it is possible to tailor the substrate to include two terminal alkenes that lead to ethylene as a product, whose escape from the reaction drives the equilibrium to product.

The development of better catalysts has revolutionized this reaction,⁸¹¹ making it one of the most important methods available for modern synthesis. Both homogeneous⁸¹² and heterogeneous⁸¹³ catalysts have been used for this reaction. Of the many homogeneous catalysts, Ru complexes are the most important,⁸¹⁴ and important heterogeneous catalysts include oxides of Mo, W, and Re deposited on alumina or silica gel.⁸¹⁵ The major breakthrough in these catalysts was the development of catalysts that are relatively air stable. Three important catalysts are metal carbene complexes **156**⁸¹⁶ and **157**⁸¹⁷ (*Grubbs catalyst I and II*; Mes = mesityl, respectively), and **158** (the *Shrock catalyst*).⁸¹⁸

Catalyst **157** can be generated *in situ* from air stable precursors.⁸¹⁹

The synthetic importance⁸²⁰ of ring-closing and ring-opening metathesis reactions has, in part, led to the ongoing development of new catalysts.⁸²¹ Catalysts have been developed that are compatible with both water and methanol.⁸²² The reaction is compatible with the presence of other functional groups⁸²³ (e.g., other alkene units,⁸²⁴ carbonyl units,⁸²⁵ the alkene unit of conjugated esters,⁸²⁶ butenolides⁸²⁷ and other lactones,⁸²⁸ amines,⁸²⁹ amides,⁸³⁰ sulfones,⁸³¹ phosphine oxides,⁸³² sulfonate esters,⁸³³ and sulfonamides,⁸³⁴ see **149**).⁸³⁵ Ether groups,⁸³⁶ including vinyl ethers,⁸³⁷ vinyl halides,⁸³⁸ vinyl silanes,⁸³⁹ vinyl sulfones,⁸⁴⁰ allylic ethers,⁸⁴¹ and thioethers⁸⁴² are also compatible.

Asymmetric ring-closing metathesis reactions have been reported,⁸⁴³ and chiral metathesis catalysts are continually being developed.⁸⁴⁴ The enantioselective synthesis of bicyclic lactams from dienyl lactams used a chiral Mo catalyst.⁸⁴⁵ Asymmetric ring-opening metathesis has also been reported.⁸⁴⁶

Recyclable catalysts have been developed,⁸⁴⁷ and the reaction has been done in ionic liquids,⁸⁴⁸ supercritical CO₂⁸⁴⁹ (Sec. 9.D.ii), and in aqueous media.⁸⁵⁰ Microwave-induced ring-closing metathesis⁸⁵¹ and also cross-metathesis reactions⁸⁵² are known. Polymer-bound Ru⁸⁵³ and Mo catalysts⁸⁵⁴ have been used, and catalyst **157** has been immobilized on PEG.⁸⁵⁵ Efficient methods have been developed for the removal of Ru byproducts from metathesis reactions that include the use of a scavenger resin,⁸⁵⁶ and removal by aqueous extraction.⁸⁵⁷

By choice of the proper catalyst, the reaction has been applied to terminal and internal alkenes, straight chain or branched. The effect of substitution on the ease of reaction is $\text{CH}_2 = >\text{RCH}_2\text{CH} = >\text{R}_2\text{CHCH} = >\text{R}_2\text{C} =$.⁸⁵⁸ Note that isomerization of the C=C unit can occur after metathesis,⁸⁵⁹ but methods have been developed to prevent this, including addition of 2,6-dichlorobenzoquinone.⁸⁶⁰ Cross-metathesis⁸⁶¹ (or symmetrical homo-metathesis⁸⁶²) of alkenes to give new alkenes can be accomplished. Monosubstituted alkenes react faster than disubstituted alkenes.⁸⁶³ A double metathesis reaction of a diene (also called *domino*⁸⁶⁴ or *tandem metathesis*⁸⁶⁵) with conjugated aldehydes has been

reported,⁸⁶⁶ and a triple metathesis was reported to for a dihydropyran with two dihydropyran substituents.⁸⁶⁷ Cross-metathesis of vinylcyclopropanes leads to an alkene with two cyclopropyl substituents.⁸⁶⁸ Vinylcyclopropane-alkyne metathesis reactions have been reported.⁸⁶⁹ Cyclic alkenes can be opened, usually with polymerization using metathesis catalysts. Ring-opening metathesis generates dienes from cyclic alkenes.⁸⁷⁰ Allenes undergo a metathesis reaction to give symmetrical allenenes.⁸⁷¹ An interesting variation reacts an α,ω -diene with a cyclic alkene. The combination of ring-opening metathesis and ring-closing cross-metathesis leads to ring expansion to give a macrocyclic nonconjugated diene.⁸⁷² Note that an alkane metathesis reaction is known.⁸⁷³

Dienes can react intermolecularly or intramolecularly.⁸⁷⁴ Intramolecular reactions generate rings, including small rings,⁸⁷⁵ usually alkenes or dienes. Alkene metathesis can be used to form very large rings, including 21-membered lactone rings.⁸⁷⁶ Diynes undergo both cross-metathesis and ring-closing metathesis.⁸⁷⁷ Diynes can also react intramolecularly to give large-ring alkynes.⁸⁷⁸ Metathesis with vinyl-cyclopropyl-alkynes is also known, producing a ring-expanded product (see **159**).⁸⁷⁹ Vinyl halides undergo metathesis reactions.⁸⁸⁰

Two cyclic alkenes react to give dimeric dienes,⁸⁸¹ for example,

With many catalysts, the products can then react with additional monomers and with each other, so that polymers are produced, and the cyclic dienes are obtained only in low yield.

The reaction between a cyclic and a linear alkene can give a ring-opened diene⁸⁸²:

The reaction has also been applied to internal alkynes⁸⁸³:

and some success has been reported for terminal triple bonds.⁸⁸⁴ As noted above, molecules with a terminal alkene and a terminal alkyne react quite well (ene-yne metathesis).⁸⁸⁵ Intramolecular reactions of a double bond with a triple bond are known⁸⁸⁶ and a tetracyclic tetraene has been prepared from a poly-yne-diene.⁸⁸⁷ Cross-metathesis of terminal alkynes and terminal alkenes (en-yne)⁸⁸⁸ to give a diene has also been reported.⁸⁸⁹ Enyne metathesis generates 1,3-dienes.⁸⁹⁰

The generally accepted mechanism is a chain mechanism,⁸⁹¹ involving the intervention of a metal–carbene complex (**160** and **161**)⁸⁹² and a four-membered ring containing a metal⁸⁹³ (**162–165**).⁸⁹⁴ In the cross-metathesis reaction shown as an example, $R_2C=CR_2$ reacts with $R^1_2C=CR^1_2$ in the presence of a metal catalyst (M). Initial reaction with the catalyst leads to the two expected metal carbenes, (**160** and **161**). Metal carbene (**161**) can react with both alkenes to form metallocyclobutanes **162** and **163**. Each of these intermediates loses the metal to form the alkenes, the product of metathesis ($R_2C=CR^1_2$) and one of the original alkenes. In a likewise manner, **160** reacts with each alkene to form metallocyclobutanes **164** and **165**, which decomposes to $R_2C=CR_2$ and the metathesis product. It has been shown that the phosphine-containing methyldiene complexes decompose to methylphosphonium salts,⁸⁹⁵

OS 80, 85; **81**, 1.

18-38 Metal-Ion-Catalyzed σ -Bond Rearrangements

Many highly strained cage molecules undergo rearrangement when treated with metallic ions [e.g., Ag^+ , Rh(I), or Pd(II)].⁸⁹⁶ The bond rearrangements observed can be formally classified into two main types: (Type 1)

[2 + 2]-ring openings of cyclobutanes and (Type 2) conversion of a bicyclo[2.2.0] system to a bicyclic system. The molecule cubane supplies an example of each type

(see above). Treatment with Rh(I) complexes converts cubane to tricyclo[4.2.0.0^{2,5}]octa-3,7-diene (**166**),⁸⁹⁷ an example of type 1, while Ag⁺ or Pd(II) causes the second type of reaction, producing cuneane.⁸⁹⁸ Other examples are the conversion of **167** to **168**, and formation of **159**, the 9,10-dicarbomethoxy derivative of *snoutane* (pentacyclo[3.3.2.0^{2,4}.0^{3,7}.0^{6,8}]decane).

Type 1

Ref. 899

Type 2⁹⁰⁰

Ref. 901

The mechanisms of these reactions are not completely understood, although relief of strain undoubtedly supplies the driving force. The reactions are thermally forbidden by the orbital-symmetry rules, and the role of the catalyst is to provide low-energy pathways so that the reactions can take place. Type 1 reactions are the reverse of the catalyzed [2 + 2] ring closures discussed at Reaction **15-63**. The following mechanism, in which Ag⁺ attacks one of the edge bonds, has been suggested for the conversion of **167** to **168**.⁹⁰²

Simpler bicyclobutanes can also be converted to dienes, but in this case the products usually result from cleavage of the central bond and one of the edge bonds.⁹⁰³ For example, treatment of **170** with AgBF₄,⁹⁰⁴

or [(π -allyl)PdCl]₂⁹⁰⁵ gives a mixture of the two dienes shown, resulting from a formal cleavage of the C-1—C-3 and C-1—C-2 bonds (note that a hydride shift has taken place). Dienes can also be converted to bicyclobutanes under photochemical conditions.⁹⁰⁶

18-39 The Di- π -methane and Related RearrangementsDi- π -methane rearrangement

1,4-Dienes carrying alkyl or aryl substituents on C-3⁹⁰⁷ can be photochemically rearranged to vinylcyclopropanes in a reaction called the *di- π -methane rearrangement*.⁹⁰⁸ An example is conversion of **171** to **172**.⁹⁰⁹ For most 1,4-dienes, it is only the singlet excited state that gives the reaction; triplet states generally take other pathways.⁹¹⁰ For unsymmetrical dienes, the reaction is regioselective. For example, **173** gave **174**, not **175**.⁹¹¹

The mechanism can be described by the diradical pathway given⁹¹² (the C-3 substituents act to stabilize the radical), although the species shown are not necessarily intermediates, but may represent transition states. It has been shown, for the case of certain substituted substrates, that configuration is retained at C-1 and C-5 and inverted at C-3.⁹¹³

The reaction has been extended to allylic benzenes⁹¹⁴ (in this case C-3 substituents are not required), to β,γ -unsaturated ketones⁹¹⁵ (the latter reaction, which is called the *oxa-di-*

π -methane rearrangement,⁹¹⁶ generally occurs only from the triplet state), to β,γ -unsaturated imines,⁹¹⁷ and to triple-bond systems.⁹¹⁸

When photolyzed, 2,5-cyclohexadienones can undergo a number of different reactions, one of which is formally the same as the di- π -methane rearrangement.⁹¹⁹ In this reaction, photolysis of the substrate **176** gives the bicyclo[3.1.0]hexenone (**181**). Although the reaction is formally the same (note the conversion of **171** to **172**),

the mechanism is different from that of the di- π -methane rearrangement, because irradiation of a ketone can cause an $n \rightarrow \pi^*$ transition, which is of course not possible for a diene lacking a carbonyl group. The mechanism⁹²⁰ in this case has been formulated as proceeding through the excited triplet states **178** and **179**. In step 1, the molecule undergoes an $n \rightarrow \pi^*$ excitation to the singlet species **177**, which cross to the triplet **178**. Step 3 is a rearrangement from one excited state to another. Step 4 is a $\pi^* \rightarrow n$ electron demotion (an intersystem crossing from $T_1 \rightarrow S_0$, see Sec. 7.A.vi, category 4). The conversion of **180** to **181** consists of two 1,2-alkyl migrations (a one-step process would be a 1,3-migration of alkyl to a carbocation center): The old C-6—C-5 bond becomes the new C-6—C-4 bond and the old C-6—C-1 bond becomes the new C-6—C-5 bond.⁹²¹

2,4-Cyclohexadienones also undergo photochemical rearrangements, but the products are different, generally involving ring opening.⁹²²

A common feature of the reactions in this section⁹²³ is that they serve to introduce functionality at a position remote from functional groups already present. As such, they have proved very useful in synthesizing many compounds, especially in the steroid field (see also, Reactions **19-2** and **19-17**). When *N*-haloamines in which one alkyl group has a hydrogen in the 4 or 5 position are heated with sulfuric acid, pyrrolidines, or piperidines are formed, in a reaction known as the *Hofmann-Löffler reaction* (also called the *Hofmann-Löffler-Freytag reaction*).⁹²⁴ The R' group is normally alkyl, but the reaction has been extended to R' = H by the use of concentrated sulfuric

acid solution and ferrous salts.⁹²⁵ The first step of the reaction is a rearrangement, with the halogen migrating from the nitrogen to the 4 or 5 position of the alkyl group. It is possible to isolate the resulting haloamine salt, but usually this is not done, and the second step, the ring closure (Reaction **10-31**), takes place. The reaction is most often induced by heat, but this is not necessary, and irradiation and chemical initiators (e.g., peroxides) have been used instead. The mechanism is of a free radical type, with the main step involving an internal hydrogen abstraction.⁹²⁶

A similar reaction has been carried out on *N*-halo amides, which give γ -lactones⁹²⁷:

Another related reaction is the *Barton reaction*,⁹²⁸ by which a methyl group in a unique position relative to an OH group can be oxidized to a CHO group. The alcohol is first converted to the nitrite ester. Photolysis of the nitrite results in conversion of the nitrite group to the OH group and nitrosation of the methyl group. Formation of a radical and with the methyl group in the appropriate position, hydrogen-atom transfer via a six-center transition state leads to a nitrite. Hydrolysis of the oxime tautomer gives the aldehyde, for example⁹²⁹

This reaction takes place only when the methyl group is in a favorable steric position.⁹³⁰ The mechanism is similar to that of the *Hofmann-Löffler reaction*.⁹³¹

This is one of the few known methods for effecting substitution at an angular methyl group. Not only CH_3 groups but also alkyl groups of the form RCH_2 and R_2CH can give the Barton reaction if the geometry of the system is favorable. An RCH_2 group is converted to the oxime $\text{R}(\text{C}=\text{NOH})$, which is hydrolyzable to a ketone, or to a nitroso dimer, while an R_2CH group gives a nitroso compound $[\text{R}_2\text{C}(\text{NO})]$. With very few exceptions, the only carbons that become nitrosated are those in the position δ to the original OH group, indicating that a six-membered transition state is necessary for the hydrogen abstraction.⁹³²

In the *Chapman rearrangement*, *N,N*-diaryl amides are formed when aryl imino esters are heated.⁹³⁴ Best yields are obtained in refluxing tetraethylene glycol dimethyl ether (tetraglyme),⁹³⁵ although the reaction can also be carried out without any solvent at all. Many groups may be present in the rings (e.g., alkyl, halo, OR, CN, and CO₂R). Aryl migrates best when it contains electron-withdrawing groups. On the other hand, electron-withdrawing groups in Ar² or Ar³ decrease the reactivity. The products can be hydrolyzed to

diarylamines, and this is a method for preparing these compounds. The mechanism probably involves an intramolecular⁹³⁶ aromatic nucleophilic substitution, resulting in a 1,3 oxygen-to-nitrogen shift via a species (e.g., **182**). Aryl imino esters can be prepared from *N*-aryl amides by reaction with PCl₅, followed by treatment

of the resulting imino chloride (**183**) with an aroxide ion.⁹³⁷ Imino esters with any or all of the three groups being alkyl also rearrange, but they require catalysis by H₂SO₄ or a trace of methyl iodide or methyl sulfate.⁹³⁸ The mechanism is different, involving an intermolecular process.⁹³⁹ This is also true for derivatives for formamide (Ar² = H).

18-43 The Wallach Rearrangement

The conversion of azoxy compounds (e.g., **184**), upon acid treatment, to *p*-hydroxy azo compounds (e.g., **185**, or sometimes the *o*-hydroxy isomers⁹⁴⁰) is called the *Wallach rearrangement*.⁹⁴¹ When both para positions are occupied, the *o*-hydroxy product may be

obtained, but ipso substitution at one of the para positions is also possible.⁹⁴² The following facts are known for the proposed mechanism⁹⁴³: (1) The para rearrangement is intermolecular.⁹⁴⁴ (2) When the reaction was carried out with an azoxy compound in which the N—O nitrogen was labeled with ¹⁵N, *both* nitrogens of the product carried the label equally,⁹⁴⁵ demonstrating that the oxygen did not have a preference for migration to either the near or the far ring. This shows that there is a symmetrical intermediate. (3) Kinetic studies show that two protons are normally required for the reaction.⁹⁴⁶ The following mechanism,⁹⁴⁷ involving the symmetrical intermediate (**187**), has been proposed to explain the facts.⁹⁴⁸ It has proved possible to obtain **186** and **187** as stable species in superacid solutions.⁹⁴⁹ Another mechanism, involving an intermediate with only one positive charge, has been proposed for certain substrates at low acidities.⁹⁴⁹

A photochemical *Wallach rearrangement*⁹⁵⁰ is also known: The product is the *o*-hydroxy azo compound, the OH group is found in the farther ring, and the rearrangement is intramolecular.⁹⁵¹

18-44 Dyotropic Rearrangements

1/*C*-Trialkylsilyl,2/*O*-trialkylsilyl-interchange

A *dyotropic rearrangement*⁹⁵² is an uncatalyzed process in which two σ bonds simultaneously migrate intramolecularly.⁹⁵³ There are two types. The above is an example of type 1, which consists of reactions in which the two σ bonds interchange positions.

The *Brook rearrangement* has been used in two important synthetic applications, a multicomponent coupling protocol initiated by a *Brook rearrangement* involving silyl dithianes as mentioned, and anion relay chemistry (ARC) involving a *Brook rearrangement*. An example of the former is the conversion of the 2-silyl dithiane (**190**) to the anion with *tert*-butyllithium followed by ring opening of an epoxide to give **191**.⁹⁶⁵ Treatment with HMPA triggers a solvent-controlled *Brook rearrangement* that gives a new dithiane anion (**192**), which then reacts with a different epoxide to give the final product **193**. An example of the anion relay chemistry treats dithiane (**194**) with *n*-butyllithium, and then **195** to give **196**.⁹⁶⁶ Subsequent treatment with a variety of electrophiles (e.g., allyl bromide, in HMPA), leads to **197** via a *Brook rearrangement*, and then alkylation of the resultant dithiane anion. This reaction can be initiated by nucleophiles other than dithiane anion.

Oxidations and Reductions

First, the terms oxidation and reduction must be clarified. Inorganic chemists define oxidation in two ways: loss of electrons and an increase in oxidation number. In organic chemistry, these definitions, while still technically correct, are not easy to apply. While electrons are directly transferred in some organic oxidations and reductions, and electrons are certainly transferred by making and breaking bonds, the mechanisms of most of these reactions do not involve a direct electron transfer. As for oxidation number, while this is easy to apply in some cases (e.g., the oxidation number of carbon in CH_4 is -4), in most cases attempts to apply the concept lead to fractional values or to apparent absurdities. Thus carbon in propane has an oxidation number of -2.67 and in butane of -2.5 , although organic chemists seldom think of these two compounds as being in different oxidation states. An improvement could be made by assigning different oxidation states to different carbon atoms in a molecule, depending on what is bonded to them (e.g., the two carbons in acetic acid are obviously in different oxidation states), but for this a whole set of arbitrary assumptions would be required, since the oxidation number of an atom in a molecule is assigned on the basis of the oxidation numbers of the atoms attached to it. There would seem little to be gained by such a procedure. The practice in organic chemistry has been to set up a series of functional groups, in a qualitative way, arranged in order of increasing oxidation state, and then to define oxidation as *the conversion of a functional group in a molecule from one category to a higher one*. Reduction is the opposite. For the simple functional groups, this series is shown in Table 19.1.¹ Note that this classification applies only to a single carbon atom or to two adjacent carbon atoms. Thus 1,3-dichloropropane is in the same oxidation state as chloromethane, but 1,2-dichloropropane is in a higher one. Obviously, such distinctions are somewhat arbitrary, and if we attempt to carry them too far, we will find ourselves painted into a corner. Nevertheless, the basic idea has served organic chemistry well. Note that conversion of any compound to another in the same category is not an oxidation or a reduction. Most oxidations in organic chemistry involve a gain of oxygen and/or a loss of hydrogen (Lavoisier's original definition of oxidation). The reverse is true for reductions.

Of course, there is no oxidation without a concurrent reduction. However, reactions are classified as oxidations or reductions depending on whether the *organic compound* is oxidized or reduced. In some cases, both the oxidant and reductant are organic; those reactions are treated separately at the end of the chapter.

¹ For more extensive tables, see Soloveichik, S.; Krakauer, H. *J. Chem. Educ.* **1966**, *43*, 532.

TABLE 19.1 Categories of Simple Functional Groups Arranged According to Oxidation State^a

RH		$\text{—C}\equiv\text{C—}$		CO ₂
	ROH			CO ₄
	RCl			
	RNH ₂			
	... and so on			
			... and so on	
				
		... and so on		
Approximate Oxidation Number				
−4	−2	0	+2	+4

^aOxidation is the conversion of a functional group in a molecule to a higher category; reduction is conversion to a lower one. Conversions within a category are neither oxidations nor reductions. The numbers given at the bottom are only approximations.

19.A. MECHANISMS

Note that our definition of oxidation has nothing to do with mechanism. Thus the conversion of bromomethane to methanol with KOH (Reaction 10-1) and to methane with LiAlH₄ (Reaction 19-53) have the same S_N2 mechanisms, but one is a reduction (according to our definition) and the other is not. It is impractical to consider the mechanisms of oxidation and reduction reactions in broad categories in this chapter as done for the reactions considered in Chapters 10–18.² The main reason is that the mechanisms are too diverse, and this in turn is because the bond changes are too different. For example, in Chapter 15, most reactions involved the bond change C=C → W—C—C—Y yet a relatively few mechanisms covered those reactions. But for oxidations and reductions the bond changes are far more diverse. Another reason is that the mechanism of a given oxidation or reduction reaction can vary greatly with the oxidizing or reducing agent employed. Very often the mechanism has been studied intensively for only one or a few of many possible agents.

² See Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 16, Elsevier, NY, 1980; *Oxidation in Organic Chemistry*, Academic Press, NY, pt. A [Wiberg, K.B.], 1965, pts. B, C, and D [Trahanovsky, W.S.], 1973, 1978, 1982; Waters, W.A. *Mechanisms of Oxidation of Organic Compounds*, Wiley, NY, 1964; Stewart, R. *Oxidation Mechanisms*; W. A. Benjamin, NY, 1964. For a review, see Stewart, R. *Isot. Org. Chem.* 1976, 2, 271.

Although oxidation and reduction mechanisms are not covered in the same way as other mechanisms, it is still possible to list a few broad mechanistic categories. The scheme of Wiberg is followed.³

1. *Direct Electron Transfer*.⁴ Several reactions have been encountered in which the reduction is a direct gain of electrons or the oxidation is a direct loss of them. An example is the *Birch reduction* (Reaction **15-13**), where sodium directly transfers an electron to an aromatic ring. An example from this chapter is found in the bimolecular reduction of ketones with a metal (**19-76**), where again it is a metal that supplies the electrons. This kind of mechanism is found largely in three types of reaction:⁵ (a) the oxidation or reduction of a free radical (oxidation to a positive or reduction to a negative ion), (b) the oxidation of a negative ion or the reduction of a positive ion to a comparatively stable free radical, and (c) electrolytic oxidations or reductions (an example is the *Kolbe reaction*, **14-29**). An important example of (b) is oxidation of phenolate ions:

These reactions occur easily because of the relative stability of the radicals involved.⁶ The (SET) mechanism, which has been seen several times (see Sec. 10.B) is an important case.

2. *Hydride Transfer*.⁷ In some reactions, a hydride ion is transferred to or from the substrate. The reduction of epoxides with LiAlH_4 is an example (**19-35**). Another is the *Cannizzaro reaction* (**19-81**). Reactions in which a hydride ion is transferred to a carbocation belong in this category:⁸

3. *Hydrogen-Atom Transfer*. Many oxidation and reduction reactions are free radical substitutions and involve the transfer of a hydrogen atom. For example, one of the two main propagation steps of Reaction **14-1** involves abstraction of hydrogen:

This is the case for many of the reactions of Chapter 14.

4. *Formation of Ester Intermediates*. A number of oxidations involve the formation of an ester intermediate (usually of an inorganic acid), and then the cleavage of this intermediate:

⁸ See Nenitzescu, C.D. in Olah, G.A.; Schleyer, P.v.R. *Carbonium Ions*, Vol. 2, Wiley, NY, **1970**, pp. 463–520.

Z is usually CrO_3H , MnO_3 , or a similar inorganic acid moiety. One example of this mechanism will be seen in Reaction **19-23**, where A was an alkyl or aryl group, B was OH, and Z was CrO_3H . Another is the oxidation of a secondary alcohol to a ketone (Reaction **19-3**), where A and B are alkyl or aryl groups and Z is also CrO_3H . In the lead tetraacetate oxidation of glycols (Reaction **19-7**), the mechanism also follows this pattern, but the positive leaving group is carbon instead of hydrogen. Note that the cleavage shown is an example of an E2 elimination.

5. *Displacement Mechanisms.* In these reactions, the organic substrate uses its electrons to cause displacement on an electrophilic oxidizing agent. One example is the addition of bromine to an alkene (Reaction **15-39**).

An example from this chapter is found in Reaction **19-29**:

6. *Addition-Elimination Mechanisms.* In the reaction between α,β -unsaturated ketones and alkaline peroxide (**15-50**), the oxidizing agent adds to the substrate and then part of it is lost:

In this case, the oxygen of the oxidizing agent is in oxidation state -1 and the hydroxide ion departs with its oxygen in the -2 state, so it is reduced and the substrate is oxidized. There are several reactions that follow this pattern of addition of an oxidizing agent and the loss of part of the agent, usually in a different oxidation state. Another example is the oxidation of ketones with SeO_2 (Reaction **19-17**). This reaction is also an example of category 4, since it involves formation and E2 cleavage of an ester. This example shows that these six categories are not mutually exclusive.

19.B. REACTIONS

In this chapter, the reactions are classified by the type of bond change occurring to the organic substrate, in conformity with other chapters.⁹ This means that there is no discussion in any one place of the use of a particular oxidizing or reducing agent (e.g., acid dichromate or LiAlH_4 ; except for a discussion of selectivity of reducing agents Sec. 19.B.ii, A). Some oxidizing or reducing agents are fairly specific in their action,

⁹ See Hudlicky, M. J. *Chem. Educ.* **1977**, *54*, 100.

attacking only one or a few types of substrate. Others, like acid dichromate, permanganate, LiAlH_4 , and catalytic hydrogenation, are much more versatile.^{10,11}

19.B.i. Oxidations¹¹

In some cases, oxidations have been placed in another chapter. The oxidations of an alkene to a diol (Reaction 15-48), and an aromatic compound to a diol (Reaction 15-49), or oxidations to an epoxide (Reaction 15-50) are placed in Chapter 15, for consistency with the concept of addition to a π bond. Diamination of an alkene (Reaction 15-53) and formation of aziridines (Reaction 15-54) are in Chapter 15 for the same reason. Most other oxidations have been placed here. The reactions in this section are classified into groups depending on the type of bond change involved. These groups are Section (A) eliminations of hydrogen, Section (B) oxidations involving cleavage of carbon-carbon bonds, Section (C) reactions involving replacement of hydrogen by oxygen, Section (D) reactions in which oxygen is added to the substrate, and Section (E) oxidative coupling.

A. Eliminations of Hydrogen

19-1 Aromatization of Six-Membered Rings

Hexahydro-terelimination

Six-membered alicyclic rings can be aromatized in a number of ways.¹² Aromatization is accomplished most easily if there are already one or two double bonds in the ring or if the ring is fused to an aromatic ring. The reaction can also be applied to heterocyclic five- and six-membered rings. Many groups may be present on the ring without interference, and even *gem*-dialkyl substitution does not always prevent the reaction: In such cases, one alkyl group often migrates or is eliminated, but more drastic conditions are usually required for this. In some cases, OH and COOH groups are lost from the ring. Cyclic ketones are converted to phenols. Seven-membered and larger rings are often isomerized to six-membered aromatic rings, although this is not the case for partially hydrogenated azulene systems, which are frequently found in nature; these are converted to azulenes.

There are three types of reagents most frequently used to effect aromatization.

1. Hydrogenation catalysts¹³ (e.g., Pt, Pd,¹⁴ and Ni). Palladium trifluoroacetate also facilitates oxidative aromatization of cyclohexene.¹⁵ In this case, the reaction is the reverse of double-bond hydrogenation (**15-11** and **15-15**), and presumably the mechanism is also the reverse, although not much is known.¹⁶ Cyclohexene has been detected as an intermediate in the conversion of cyclohexane to benzene, using Pt.¹⁷ The substrate is heated with the catalyst at ~300–350 °C. The reactions can often be carried out under milder conditions if a hydrogen acceptor (e.g., maleic acid, cyclohexene, or benzene) is present to remove hydrogen as it is formed. The acceptor is reduced to the saturated compound. Other transition metals can be used.¹⁸ It has been reported that dehydrogenation of 1-methylcyclohexene-1-¹³C over an alumina catalyst gave toluene with the label partially scrambled throughout the aromatic ring.¹⁹ For polycyclic systems, heating with oxygen on activated carbon generates the aromatic compound, as in the conversion of dihydroanthracene to anthracene.²⁰
2. The elements sulfur and selenium, which combine with the hydrogen evolved to give, respectively, H₂S and H₂Se. Little is known about this mechanism either.²¹

3. Quinones²² become reduced to the corresponding hydroquinones. Two important quinones often used for aromatizations are chloranil (2,3,5,6-tetrachloro-1,4-benzoquinone) and DDQ (2,3-dichloro-5,6-dicyano-1,4-benzoquinone).²³ The latter is more reactive and can be used in cases where the substrate is difficult to dehydrogenate. It is likely that the mechanism involves a transfer of hydride to the quinone oxygen, followed by the transfer of a proton to the phenolate ion.²⁴

Other reagents²⁵ have been used for aromatization of six-membered rings, including atmospheric oxygen, MnO_2 ,²⁶ SeO_2 , H_2SO_4 , and a Ru catalyst.²⁷ The last-mentioned reagent also dehydrogenates cyclopentanes to cyclopentadienes. In some instances, the hydrogen is not released as H_2 or transferred to an external oxidizing agent, but instead serves to reduce another molecule of substrate. This is a disproportionation reaction and can be illustrated by the conversion of cyclohexene to cyclohexane and benzene.

Heteroatom rings, as found in quinoline derivatives, for example, can be generated from amino-ketones with [hydroxy(tosyloxy)iodo]benzene and perchloric acid²⁸ or with $\text{NaHSO}_4\text{--Na}_2\text{Cr}_2\text{O}_7$ on wet silica.²⁹ Dihydropyridines are converted to pyridines with $\text{NaNO}_2\text{--oxalic acid}$ and wet silica,³⁰ BaMnO_4 ,³¹ $\text{FeCl}_3\text{--acetic acid}$,³² or SeO_2 .³³ *Hantzsch 1,4-dihydropyridines* (see Reactions **15-14** and **16-17**) are aromatized by treatment with ferric perchlorate in acetic acid.³⁴ Cyclic imines are converted to pyridine derivatives with NCS and then excess sodium methoxide.³⁵ Enamines are aromatized with Sn or Sb compounds.³⁶

19-2 Dehydrogenations Yielding Carbon–Carbon Double Bonds

Dihydro-elimination

Dehydrogenation of an aliphatic compound to give a double bond in a specific location is not usually a feasible process, although industrially mixtures of alkenes are obtained in this way from mixtures of alkanes (generally by heating with chromia–alumina catalysts). There are, however, some notable exceptions. Heating cyclooctane with an Ir catalyst leads to cyclooctene.³⁸ Treating alkenes that have an allylic hydrogen with CrCl_2 converts them to allenes.³⁹ It is not surprising, however, that most of the exceptions generally involve cases where the new double bond can be in conjugation with a double bond or with an unshared pair of electrons already present.⁴⁰ One example is the synthesis developed by Leonard and Musker,⁴¹ in which tertiary amines give enamines (Reaction **10-69**) when treated with mercuric acetate⁴² (see the example above). In this case, the initial product is the iminium ion (**1**) that loses a proton to give the enamine. Other transition metal catalysts convert amines to enamines, including Co compounds.⁴³ *Hünig's base* (diisopropylethylamine) was converted to the enamine *N,N*-diisopropyl-*N*-vinylamine by heating with an Ir catalyst.⁴⁴

The oxidizing agent SeO_2 can in certain cases convert a carbonyl compound to an α,β -unsaturated carbonyl compound by removing H_2 ⁴⁵ (note that this reagent more often gives Reaction 19-17). This reaction has been most often applied in the steroid series, an example being formation of **2** from **3**.⁴⁶ Similarly, SeO_2 has been used to dehydrogenate 1,4-diketones⁴⁷ and 1,2-diaryllkanes. These conversions can also be carried out by certain quinones, most notably DDQ (see Reaction 19-1).²⁴ Molecular oxygen has been used to convert cyclic ketones to the conjugated ketone in the presence of a Pd catalyst.⁴⁸

Simple aldehydes and ketones have been dehydrogenated (e.g., cyclopentanone \rightarrow cyclopentenone) by PdCl_2 ,⁴⁹ by FeCl_3 ,⁵⁰ and by benzeneseleninic anhydride⁵¹ (this reagent also dehydrogenates lactones in a similar manner), among other reagents. In an indirect method of achieving this conversion, the silyl enol ether of a simple ketone is treated with DDQ⁵² or with triphenylmethyl cation⁵³ (for another indirect method, see Reaction 17-12). Silyl enol ethers give the conjugated ketone upon treatment with ceric ammonium nitrate in DMF⁵⁴ or with $\text{Pd}(\text{OAc})_2/\text{NaOAc}/\text{O}_2$.⁵⁵

Simple linear alkanes have been converted to alkenes by treatment with certain transition metal compounds.⁵⁶

An entirely different approach (remote functionalization) allows specific dehydrogenation, as reported by R. Breslow⁵⁷ and by J.E. Baldwin et al.⁵⁸ 3 α -Cholesterol (**4**) was converted to 5 α -cholest-14-en-3 α -ol (**5**), for example, thus introducing a double bond at a specific site remote from any functional group.⁵⁹

Certain 1,2-diarylalkenes ($\text{ArCH}=\text{CHAR}'$) have been converted to the corresponding alkynes ($\text{ArC}\equiv\text{CAR}'$) by treatment with *t*-BuOK in DMF.⁶⁰ Dihydroindoles are converted to indoles with *N,N',N''*-trichloro-1,3,5-triazin-2,4,6-trione and DBU.⁶¹

A different kind of dehydrogenation was used in the final step of Paquette's synthesis of dodecahedrane⁶²:

OS V, 428, VII, 4, 473.

19-3 Oxidation or Dehydrogenation of Alcohols to Aldehydes and Ketones

C,O-Dihydro-elimination

Primary alcohols can be converted to aldehydes and secondary alcohols to ketones in seven main ways:⁶³

1. *With Chromium Reagents.*⁶⁴ Secondary alcohols are easily oxidized to ketones by dichromate in acidic media⁶⁵ at room temperature or slightly above. A solution of chromic and sulfuric acid in water is known as the *Jones reagent*.⁶⁶ Secondary alcohols are oxidized to ketones rapidly and in high yield without disturbing any double or triple bonds that may be present (see Reaction **19-10**) and without epimerizing an adjacent stereogenic center.⁶⁷ Mixing sodium dichromate with an alcohol, without solvent, provides a method for oxidation when the mixture is shaken.⁶⁸ Chromium trioxide (CrO_3)⁶⁹ has been used to oxidize primary and alcohols under solvent-free conditions. Chromium trioxide on silica gel, in supercritical CO_2 ,

oxidizes alcohols to the corresponding carbonyl.⁷⁰ For acid-sensitive compounds, trimethylsilyl chromates⁷¹ can be used. Chromium trioxide with aq *tert*-butylhydroperoxide oxidizes benzylic alcohols with microwave irradiation.⁷² Phase-transfer catalysis is particularly useful,⁷³ especially when the substrates are generally insoluble in water (see Sec. 10.G.v). A catalytic amount of Cr(acac)₃ in conjunction with H₃IO₅ oxidizes benzylic alcohols to aldehydes.⁷⁴

The Jones reagent can also oxidize primary allylic alcohols to the corresponding aldehydes,⁷⁵ although overoxidation to the carboxylic acid is a problem.⁷⁶ Oxidative cleavage of primary alcohols has been observed in the presence of molecular sieves 3 Å.⁷⁷ One way to mitigate overoxidation is to distil the aldehyde as it is formed, but this is not always possible. Due to these problems, other oxidizing conditions have been used to convert at least some primary alcohols to aldehydes.⁷⁸ Perhaps the three most commonly used Cr(VI) reagents used for the oxidation of allylic alcohols include⁷⁹ dipyridine Cr(VI) oxide (*Collins' reagent*),⁸⁰ pyridinium chlorochromate (PCC),⁸¹ and pyridinium dichromate (PDC).⁸² The PCC is somewhat acidic, and acid-catalyzed rearrangements have been observed.⁸³

Analogous to the use of pyridine for PCC and PDC, a variety of amines and diamines have been converted to tetraalkylammonium halochromates or dichromates, including *N*-benzyl 1,4-diazabicyclo[2.2.2]octane ammonium dichromate with microwave irradiation,⁸⁴ γ -picolinium chlorochromate,⁸⁵ and quinolinium fluorochromate.⁸⁶ Benzyltriphenylphosphonium chlorochromate has been used in a similar manner.⁸⁷ Oxidizing agents have been supported on a polymer,⁸⁸

including chromic acid,⁸⁹ as well as poly[vinyl(pyridinium fluorochromate)].⁹⁰ Triphenylmethylphosphonium dichromate is effective for selective oxidation of benzylic alcohols.⁹¹

Studies on the mechanism of oxidation with acid dichromate⁹² led to the currently accepted mechanism as proposed by Westheimer⁹³ (cf. the first two steps with Sec. 19.A, category 4).

The base in the second step may be water, although it is also possible⁹⁴ that in some cases no external base is involved and that the proton is transferred directly to one of the CrO₃H oxygen atoms in which case the Cr(IV) species produced would be H₂CrO₃. Part of the evidence for this mechanism was the isotope effect of ~6 found on use of MeCDOHMe, showing that the α hydrogen is removed in the rate-determining step.⁹⁵ Note that, as in Reaction 19-23 the substrate is oxidized by three different oxidation states of chromium.⁹⁶

With other oxidizing agents discussed below, mechanisms are less clear.⁹⁷ It seems certain that some oxidizing agents operate by a hydride-shift mechanism,⁹⁸ for example, dehydrogenation with triphenylmethyl cation⁹⁹ and the *Oppenauer oxidation*, and some by a free radical mechanism (e.g., oxidation with $\text{S}_3\text{O}_8^{2-}$ ¹⁰⁰ and with VO_2^{+} ¹⁰¹). A summary of many proposed mechanisms is given by Littler.¹⁰²

2. *With Manganese and Other Metal Oxidizing Agents.* Potassium permanganate (KMnO_4) has been used for the oxidation of alcohols.¹⁰³ Benzylic and allylic alcohols have been selectively oxidized to the aldehydes in the presence of saturated alcohols by the use of potassium permanganate (KMnO_4) under phase-transfer conditions.¹⁰⁴ Phase-transfer catalysis has also been used with chromic acid,¹⁰⁵ and ruthenium tetroxide.¹⁰⁶ Ultrasound has been used for KMnO_4 oxidations.¹⁰⁷ Permanganate supported on a polymer has been used.¹⁰⁸

Permanganate¹⁰⁹ is an important reagent for the selective oxidation of benzylic alcohols primary and benzylic alcohols, in preference to aliphatic substrates.¹¹⁰ A variation oxidizes alcohols with $\text{MnO}_2/\text{AlCl}_3$.¹¹¹

An alternative to MnO_2 is the oxidation of allylic and benzylic alcohols with Me_3NO in the presence of $\text{CHDFe}(\text{CO})_3$.¹¹² Similar oxidation occurs with NaBrO_3 in aq MeCN ¹¹³ or K_2FeO_4 on clay.¹¹⁴ The reaction of AuCl with an anionic ligand leads to oxidation of primary alcohols to aldehydes.¹¹⁵ The *Grubbs' catalyst*, $\text{PhCH}=\text{Ru}(\text{PCy}_3)_2\text{Cl}_2$, where Cy = cyclohexyl, (see **156** in Reaction **18-37**), in the presence of KOH , oxidized alcohols.¹¹⁶

$\text{Br}_2\text{—Ni}(\text{OBz})_2$ ¹³⁶ all oxidize primary OH groups in the presence of a secondary OH group.¹³⁷ Certain zirconocene complexes can selectively oxidize only one OH group of a diol, even if both are primary.¹³⁸ α -Hydroxy ketones are oxidized to 1,2-diketones with $\text{Bi}(\text{NO}_3)_3$ and a $\text{Cu}(\text{OAc})_2$ catalyst,¹³⁹ ferric chloride (solid state),¹⁴⁰ or O_2 and a V catalyst.¹⁴¹ 1,2-Diols are oxidized to chiral α -hydroxy-ketones using NBS with a chiral Cu catalyst.¹⁴²

3. *The Oppenauer Oxidation.* When a ketone in the presence of an aluminum alkoxide is used as the oxidizing agent (it is reduced to a secondary alcohol), the reaction is known as the *Oppenauer oxidation*.¹⁴³ This is the reverse of the *Meerwein–Ponndorf–Verley reaction* (19-36) and the mechanism is also the reverse. The ketones most commonly used are acetone, butanone, and cyclohexanone. A common base is aluminum *tert*-butoxide. The chief advantage of the method is its high selectivity. Although the method is most often used for the preparation of ketones, it has also been used for aldehydes. An Ir catalyst¹⁴⁴ has been developed for the *Oppenauer oxidation*, and also a water-soluble Ir catalyst.¹⁴⁵ Homogeneous water-soluble complexes catalyze the reaction.¹⁴⁶ An uncatalyzed reaction under supercritical conditions was reported.¹⁴⁷
4. *DMSO Based Reagents.* The use of oxalyl chloride and DMSO at low temperature is called the *Swern oxidation*¹⁴⁸ and is widely used. A sulfonium salt is produced *in situ*, which reacts with the alcohol to generate the key intermediate required for oxidation.¹⁴⁹ Maintaining the low-reaction temperature is essential in this reaction, however, since the reagent generated *in situ* decomposes at temperatures significantly below ambient. Note that *Swern oxidation* of molecules having alcohol moieties, as well as a disulfide, leads to the ketone without oxidation of the sulfur.¹⁵⁰ Sulfoxides other than DMSO can be used in conjunction with oxalyl chloride for the oxidation of alcohols,¹⁵¹ including fluorinated sulfoxides¹⁵² and a polymer-bound sulfoxide.¹⁵³

Similar oxidation of alcohols has been carried out with DMSO and other reagents¹⁵⁴ in place of DCC: acetic anhydride,¹⁵⁵ SO₃–pyridine–triethylamine,¹⁵⁶ trifluoroacetic anhydride,¹⁵⁷ pivaloyl chloride,¹⁵⁸ tosyl chloride,¹⁵⁹ Ph₃P⁺Br[−],¹⁶⁰ trimethylamine *N*-oxide,¹⁶¹ a Mo catalyst and O₂,¹⁶² and methanesulfonic anhydride.⁵¹⁷ Dimethyl sulfoxide in 48% HBr oxidizes benzylic alcohols to aryl aldehydes.¹⁶³ An alcohol is treated with DMSO, DCC,¹⁶⁴ and anhydrous phosphoric acid¹⁶⁵ in what is called *Moffatt oxidation*. In this way, a primary alcohol can be converted to the aldehyde with no carboxylic acid being produced. The strong acid conditions are sometimes a problem, and complete removal of the dicyclohexylurea byproduct can be difficult.

5. *TEMPO and Related Reagents*. The nitroxyl radical TEMPO (**6**) has been used in conjunction with coreagents, including mcpba,¹⁶⁶ O₂ with transition metal catalysts,¹⁶⁷ O₂ with HBr and *tert*-butylnitrite,¹⁶⁸ CuBr₂(bpy)–air (bpy = 2,2′-bipyridyl),¹⁶⁹ CuBr•SMe₂ in perfluorous solvents,¹⁷⁰ bromohydantoins,¹⁷¹ enzymes,¹⁷² carbenes,¹⁷³ NaNO₂–HCl,¹⁷⁴ NaIO₄,¹⁷⁵ and H₅IO₆.¹⁷⁶ Silica-supported TEMPO,¹⁷⁷ polymer-bound TEMPO,¹⁷⁸ and PEG–TEMPO¹⁷⁹ have been used. The TEMPO derived ionic liquids,¹⁸⁰ or ionic liquid-supported TEMPO¹⁸¹ have

been used for the oxidation of alcohols. The TEMPO compound has also been used with a polymer-bound hypervalent iodine reagent.¹⁸² A catalytic reaction using 5% TEMPO and 5% CuCl with O₂ in an ionic liquid oxidizes benzylic alcohols to the corresponding aldehyde.¹⁸³ Ion-supported TEMPO oxidation in water is possible.¹⁸⁴

Other nitroxyl radical oxidizing agents are known.¹⁸⁵ A related oxidizing agent is oxoammonium salt **7** (*Bobbitt's reagent*), a stable and nonhygroscopic salt that oxidizes primary and secondary alcohols in dichloromethane.¹⁸⁶ The mechanism of oxidation for **7** has been examined.¹⁸⁷

6. *With Hypervalent Iodine Reagents.*¹⁸⁸ Treatment of 2-iodobenzoic acid with KBrO₃ in H₂SO₄ and heating the resulting product to 100 °C with acetic anhydride and acetic acid¹⁸⁹ gives hypervalent iodine reagent (**8**), the so-called *Dess–Martin Periodinane*.¹⁹⁰ This reagent reacts with alcohols at ambient temperature to give the corresponding aldehyde or ketone.¹⁹¹ The reaction is accelerated by water¹⁹² and a water-soluble periodinane [*o*-iodoxybenzoic acid (**9**), IBX]¹⁹³ has been prepared that oxidized allylic alcohols to conjugated aldehydes.¹⁹⁴ 2-Methyl-2-propanol has been used as a solvent.¹⁹⁵ The reagent has an indefinite shelf-life in a sealed container, but hydrolysis occurs upon long-term exposure to atmospheric moisture. A note of CAUTION! The *Dess–Martin reagent* can be shock sensitive under some conditions and explode ~200 °C.¹⁹⁶

Iodine has been used as a cocatalyst.¹⁹⁷ Other hypervalent iodine oxidizing reagents are known,¹⁹⁸ including $\text{PhI}(\text{OAc})_2/\text{TEMPO}$,¹⁹⁹ $\text{PhI}(\text{OAc})_2$ -chromium salen,²⁰⁰ $\text{PhI}(\text{OAc})_2$ supported on alumina with microwave irradiation,²⁰¹ and an ion-supported hypervalent iodine(III) reagent.²⁰² Microwave irradiation of benzylic alcohols with $\text{PhI}(\text{OH})\text{OTs}$ gave the corresponding aldehyde.²⁰³ Hypervalent iodine compounds have been used in ionic liquids.²⁰⁴ Heating benzylic alcohols with *o*-iodoxybenzoic acid under solvent-free conditions gave the aldehyde.²⁰⁵ 2-Iodobenzenesulfonic acid is a very active catalyst for oxidation of alcohols using Oxone.²⁰⁶

7. *By Catalytic Dehydrogenation.* For the conversion of primary alcohols to aldehydes, dehydrogenation catalysts have the advantage over strong oxidizing agents that further oxidation to the carboxylic acid is prevented. Copper chromite is often used, but other catalysts (e.g., Ag and Cu), have also been employed. Many ketones were prepared in this manner. Catalytic dehydrogenation is more often used industrially than as a laboratory method. However, procedures using $\text{Cu}(\text{II})$ complexes,²⁰⁷ Rh complexes,²⁰⁸ Ru complexes,²⁰⁹ Raney nickel,²¹⁰ and Pd complexes²¹¹ (under phase transfer conditions)²¹² have been reported. Allylic alcohols²¹³ are oxidized to the corresponding saturated aldehyde or ketone by heating with a Rh catalyst, and benzylic alcohols are converted to the aldehyde with a Rh

irradiation has been used to oxidize benzylic alcohols.²³⁶ Hydrogen bromide in aq H_2O_2 oxidizes secondary alcohols to ketones.²³⁷ With ultrasound, DDQ selectively oxidizes a benzylic or allylic hydroxyl group of 1,2-diols with those substituents.²³⁸ Photooxidation of alcohols is possible in the presence of a catalytic amount of NBS.²³⁹ A mixture of $\text{I}_2\text{—KI—K}_2\text{CO}_3\text{—H}_2\text{O}$ oxidizes alcohols to aldehydes or ketones under anaerobic conditions.²⁴⁰ Similarly $\text{KBrO}_3/\text{ZrClO}_2\cdot 8\text{H}_2\text{O}$ can be used to oxidize alcohols.²⁴¹ Oxone oxidizes alcohols, catalyzed by AlCl_3 .²⁴²

Tetrabutylammonium periodate²⁴³ and benzyltriphenylphosphonium periodate.²⁴⁴ oxidizes primary alcohols to aldehydes. On the other hand, *Fremy's salt* (see Reaction 19-4) selectively oxidizes benzylic alcohols and not allylic or saturated ones.²⁴⁵

In a related reaction to the oxidation of alcohols, it is possible to oxidize ethers to aldehydes. Oxidation of trimethylsilyl ethers with O_2 , a catalytic amount of *N*-hydroxyphthalimide and a Co catalyst, give an aldehyde.²⁴⁶ Microwave irradiation with BiCl_2 oxidizes benzylic TMS ethers to the aldehyde.²⁴⁷ Microwave irradiation on zeolite supported ferric nitrate has been used.²⁴⁸ *O*-Tetrahydropyranyl ethers (*O*-THP) have been oxidized to the aldehyde with ferric nitrate on zeolites,²⁴⁹ and the Pd catalyzed oxidation of allylic esters to conjugated ketones is known.²⁵⁰ *N*-Bromosuccinimide with β -cyclodextrin oxidizes tetrahydropyranyl ethers in water.²⁵¹

Ortho and para diols are easily oxidized to o- and p-quinones, respectively.²⁵² Either or both OH groups can be replaced by NH₂ groups to give the same products, although for the preparation of o-quinones only OH groups are normally satisfactory. The reaction has been successfully carried out with other groups para to OH or NH₂; halogen, OR, Me, *t*-Bu, and even H, although yields are poor with the latter. Many oxidizing agents have been used: acid dichromate,²⁵³ silver oxide, silver carbonate, lead tetraacetate, HIO₄, NBS—H₂O—H₂SO₄,²⁵⁴ dimethyl dioxirane,²⁵⁵ and atmospheric oxygen.²⁵⁶ Oxidation has been done photochemically with O₂ and tetraphenylporphine.²⁵⁷ A particularly effective reagent for rings with only one OH or NH₂ group is (KSO₃)₂N—O• (dipotassium nitrosodisulfonate; *Fremy's salt*), which is a stable free radical.²⁵⁸ A mixture of 4-iodophenoxyacetic acid and Oxone is an effective catalyst for the oxidation of *p*-alkoxyphenols to *p*-quinones.²⁵⁹ A supported iron phthalocyanine facilitates the aromatic oxidation of phenols.²⁶⁰

Less is known about the mechanism than is the case for oxidizing simple alcohols in Reaction 19-3, and it seems to vary with the oxidizing agent. For oxidation of catechol with NaIO₄, it was found that the reaction conducted in H₂¹⁸O gave unlabeled quinone.²⁶¹ Therefore the following mechanism²⁶² was proposed:

When catechol was oxidized with MnO₄[−] under aprotic conditions, a semiquinone radical ion intermediate was involved.²⁶³ For autoxidations²⁶⁴ (i.e., with atmospheric O₂) a free radical mechanism is known to operate.²⁶⁵

Primary amines at a primary carbon can be dehydrogenated to nitriles. The reaction has been carried out with a variety of reagents, among others, I_2 in aq NH_3 ,²⁶⁶ IBX see **19-3**, category 6),²⁶⁷ $NaOCl$,²⁶⁸ Me_3N-O/OsO_4 ,²⁶⁹ $Ru/Al_2O_3/O_2$,²⁷⁰ and $CuCl/O_2/pyridine$.²⁷¹ Iodine and 1,3-diiodo-5,5-dimethylhydantoin in aq ammonia converted both amines and alcohols to nitriles.²⁷² Dehydrogenation of amines has been done in aq micelles.²⁷³

Several methods have been reported for the dehydrogenation of secondary amines to imines.²⁷⁴ Among them²⁷⁵ are treatment with (1) iodosylbenzene (PhIO) alone or in the presence of a Ru complex,²⁷⁶ (2) DMSO and oxalyl chloride,²⁷⁷ and (3) *t*-BuOOH and a Rh catalyst.²⁷⁸ *N*-Tosyl aziridines are converted to *N*-tosyl imines when heated with a Pd catalyst.²⁷⁹ An interesting variation treats pyrrolidine with iodobenzene and a Rh catalyst to give 2-phenylpyrroline.²⁸⁰

A reaction that involves dehydrogenation to an imine that then reacts further is the reaction of primary or secondary amines²⁸¹ with Pd black.²⁸² The imine initially formed by the dehydrogenation reacts with another molecule of the same or a different amine to give an aminal, which loses NH_3 or RNH_2 to give a secondary or tertiary amine. An example is the reaction between *N*-methylbenzylamine and butylmethylamine, which produces 95% *N*-methyl-*N*-butylbenzylamine.

In a related reaction, alkyl azides react with BrF_3 to give the corresponding nitrile.²⁸³

N,N'-Diarylhydrazines (hydrazo compounds) are oxidized to azo compounds by several oxidizing agents, including NaOBr, $\text{K}_3\text{Fe}(\text{CN})_6$ under phase-transfer conditions²⁸⁴ FeCl_3 ,²⁸⁵ MnO_2 (this reagent yields *cis* azobenzenes),²⁸⁶ CuCl_2 , and air and NaOH.²⁸⁷ The reaction is also applicable to *N,N'*-dialkyl- and *N,N'*-diacylhydrazines. Hydrazines (both alkyl and aryl) substituted on only one side also give azo compounds,²⁸⁸ but these are unstable and decompose to nitrogen and the hydrocarbon:

Aniline derivatives are converted to azo compounds by heating with cetyltrimethylammonium dichromate in chloroform.²⁸⁹ When hydrazones are oxidized with HgO , Ag_2O , MnO_2 , PbO_4 , or certain other oxidizing agents, diazo compounds ($\text{R}_2\text{C}=\text{N}-\text{NH}_2 \rightarrow \text{R}_2\text{C}=\text{N}^+=\text{N}^-$) are obtained²⁹⁰:

Hydrazones of the form $\text{ArCH}=\text{NNH}_2$ react with HgO in solvents, (e.g., diglyme or ethanol) to give nitriles (ArCN).²⁹¹ It is possible to oxidize dimethylhydrazones ($\text{R}-\text{C}=\text{N}-\text{NMe}_2$) to the corresponding nitrile ($\text{R}-\text{C}\equiv\text{N}$) with magnesium monoperoxyphthalate (MMP),²⁹² or with dimethyl dioxirane.²⁹³ Oxone on wet alumina also converts hydrazones to nitriles with microwave irradiation.²⁹⁴ Oximes of aromatic aldehydes are converted to aryl nitriles with InCl_3 ²⁹⁵ (ketoximes give a *Beckmann rearrangement*, Reaction 18-17).

In a related reaction, primary aromatic amines have been oxidized to azo compounds by a variety of oxidizing agents, among them MnO_2 , lead tetraacetate, O_2 and a base, BaMnO_4 ,²⁹⁶ and sodium perborate in acetic acid. *tert*-Butyl hydroperoxide has been used to oxidize certain primary amines to azoxy compounds.²⁹⁷

Nitrones [$\text{C}=\text{N}^+(\text{R})-\text{O}^-$] are generated by the oxidation of *N*-hydroxyl secondary amines with 5% aq NaOCl.²⁹⁸ Secondary amines (e.g., dibenzylamine) can be converted to the corresponding nitrone by heating with cumyl hydroperoxide in the presence of a titanium catalyst.²⁹⁹

B. Oxidations Involving Cleavage of Carbon–Carbon Bonds³⁰⁰

19-7 Oxidative Cleavage of Glycols and Related Compounds

2/O-De-hydrogen-uncoupling

1,2-Diols (glycols) are easily cleaved under mild conditions and in good yield with periodic acid or lead tetraacetate.³⁰¹ The reaction generates 2 molar equivalents of aldehyde, or 2 molar equivalents of ketone, or 1 molar equivalent of each, depending on the groups attached to the two carbons. The yields are so good that alkenes are often converted to diols (Reaction 15-48), and then cleaved with HIO_4 or $\text{Pb}(\text{OAc})_4$ rather than being cleaved directly with ozone (Reaction 19-9) or dichromate or permanganate (Reaction 19-10). The diol can be generated and cleaved *in situ* from an alkene to give the carbonyl compounds.³⁰² A number of other oxidizing agents also give the same products, among them³⁰³ aq sodium hypochlorite (NaOCl),³⁰⁴ activated MnO_2 ,³⁰⁵ O_2 and a Ru catalyst,³⁰⁶ or PCC.³⁰⁷ Permanganate, dichromate, and several other oxidizing agents³⁰⁸ also cleave glycols, giving carboxylic acids rather than aldehydes, but these reagents are seldom used synthetically.

The two reagents (periodic acid and lead tetraacetate) are complementary, since periodic acid is best used in water and lead tetraacetate in organic solvents. Chiral lead carboxylates have been prepared for the oxidative cleavage of 1,2-diols.³⁰⁹ When three or more OH groups are located on adjacent carbons, the middle one (or ones) is converted to formic acid.

Other compounds that contain oxygen atoms or nitrogen atoms on adjacent carbons undergo similar cleavage:

Cyclic 1,2-diamines are cleaved to diketones with dimethyl dioxirane.³¹⁰ α -Diketones and α -hydroxy ketones are also cleaved by alkaline H_2O_2 .³¹¹ Periodic acid (HIO_4) has been used to cleave epoxides to aldehydes,³¹² for example,

α -Hydroxy and α -keto acids are not cleaved by HIO_4 but are cleaved by NaIO_4 in methanol in the presence of a crown ether $\text{Pb}(\text{OAc})_4$,³¹³ alkaline H_2O_2 , and other reagents. These are oxidative decarboxylations. α -Hydroxy acids give aldehydes or ketones, and α -keto acids give carboxylic acids. Also see, Reaction **19-12** and **19-13**.

The mechanism of glycol oxidation with $\text{Pb}(\text{OAc})_4$ was proposed by Criegee et al.:³¹⁴

This mechanism is supported by (1) the kinetics are second order (first order in each reactant); (2) added acetic acid retards the reaction (drives the equilibrium to the left); and (3) *cis*-glycols react much more rapidly than *trans* glycols.³¹⁵ For periodic acid, the mechanism is similar, with the intermediate (**10**)³¹⁶

However, the cyclic-intermediate mechanism cannot account for all glycol oxidations, since some glycols that cannot form such an ester (e.g., **11**) are nevertheless cleaved by lead tetraacetate (although other glycols that cannot form cyclic esters are *not* cleaved, by either reagent³¹⁷). To account for cases like **11**, a cyclic transition state has been proposed:³¹⁵

19-8 Oxidative Cleavage of Ketones, Aldehydes, and Alcohols

Cycloalkanone oxidative ring opening

Oxidative cleavage of open-chain ketones or alcohols³¹⁸ is a preparative procedure that is seldom useful, not because these compounds do not undergo oxidation (they do, except for diaryl ketones), but because the result is generally a hopeless mixture. Aryl methyl ketones (e.g., acetophenone), however, are readily oxidized to aryl carboxylic acids with Re_2O_7 and 70% aq *tert*-butyl hydroperoxide.³¹⁹ Oxygen with a mixture of Mn and Co catalysts give similar oxidative cleavage,³²⁰ as do hypervalent iodine compounds.³²¹ Aldehydes, (e.g., PhCH_2CHO) are cleaved to benzaldehyde with phosphonium dichromate in refluxing acetonitrile.³²² 1,3-Diketones (e.g., 1,3-diphenyl-1,3-propanedione) are oxidatively cleaved with aq Oxone to give benzoic acid.³²³ Cyclic α -chloro ketones are cleaved to give an α,ω -functionalized compound (acetal-ester) when treated with cerium (IV) sulfate tetrahydrate and O_2 .³²⁴

Despite problems with acyclic ketones, the reaction is useful for the conversion of cyclic ketones and the corresponding secondary alcohols to the dicarboxylic acid in good yield. The formation of adipic acid from cyclohexanone (shown above) is an important industrial procedure. Dichromate in acidic media and permanganate are the most common oxidizing agents, although autoxidation (oxidation with atmospheric oxygen) in alkaline solution³²⁵ and potassium superoxide under phase-transfer conditions³²⁶ have also been used. *O*-Silyl-ketones have been cleaved to esters using electrolysis in alcohol solvents.³²⁷

Cyclic 1,3-diketones, which exist mainly in the mono-enolic form, can be cleaved with sodium periodate with loss of one carbon, for example,³²⁸

The species actually undergoing the cleavage is the triketone, so this is an example of Reaction 19-7. Cyclic 1,3-diketones are converted to α,ω -diesters with an excess of KHSO_5 in methanol.³²⁹

19-9 Ozonolysis

Oxo-uncoupling

When compounds containing double bonds are treated with ozone, usually at low temperatures, initial formation of a 1,2,3-trioxolane is followed by formation of compounds called 1,2,4-trioxolanes (*ozonides*, **12**). These compounds can be isolated but, because some of them are explosive, they are decomposed with Zn and acetic acid or catalytic hydrogenation. More commonly they are decomposed with DMS³³⁰ to give 2 molar equivalents of aldehyde, or 2 molar equivalents of ketone, or 1 molar equivalent of each, depending on the groups attached to the alkene.³³¹ The decomposition of **12** has also been carried out with triethylamine³³² and with reducing agents (e.g., trimethyl phosphite³³³ or thiourea).³³⁴ However, ozonides can also be *oxidized* with oxygen, peroxyacids, or H₂O₂ to give ketones and/or carboxylic acids. Note that the presence of a hydrogen atom on the C=C unit (C=C—H) leads to differences in oxidation or reduction of **12**. In such a system, oxidation leads to the acid, whereas reduction leads to the aldehyde. Note that the presence of a hydrogen atom on the C=C unit (C=C—H) leads to differences in oxidation or reduction of **12**. In such a system, oxidation leads to the acid, whereas reduction leads to the aldehyde. It is also possible to reduce **12** with LiAlH₄, NaBH₄, BH₃, or catalytic hydrogenation with excess H₂ to give 2 molar equivalents of alcohol.³³⁵ Ozonides can be treated with ammonia, hydrogen, and a catalyst to give the corresponding amines,³³⁶ or with an alcohol and anhydrous HCl to give the corresponding carboxylic esters.³³⁷ Ozonolysis is therefore an important synthetic reaction.³³⁸ Ozonolysis can be done in solvent–water mixtures.³³⁹

Many alkenes undergo ozonolysis, including cyclic alkenes, where cleavage gives rise to one bifunctional product (an α,ω -difunctional molecule). Alkenes in which the double bond is connected to electron-donating groups react many times faster than those in which it is connected to electron-withdrawing groups.³⁴⁰ Ozonolysis of compounds containing more than one double bond generally leads to cleavage of all the bonds. In some cases,

especially when bulky groups are present, conversion of the substrate to an epoxide (**15-50**) becomes an important side reaction and can be the main reaction.³⁴¹ Rearrangement is possible in some cases.³⁴² Ozonolysis of triple bonds³⁴³ is less common and the reaction proceeds less easily, since ozone is an electrophilic agent³⁴⁴ and prefers double to triple bonds (Sec. 15.B.i). Compounds that contain triple bonds generally give carboxylic acids, although sometimes ozone oxidizes them to α -diketones (Reaction **19-26**).

Aromatic compounds are attacked less readily than alkenes, but cleavage is known. Aromatic compounds behave as if the double bonds in the Kekulé structures were really there. Thus benzene gives 3 molar equivalents of glyoxal (HCOCHO), and *o*-xylene gives a glyoxal/MeCOCHO/MeCOCOMe ratio of 3 : 2 : 1, which shows that in this case cleavage is statistical. With polycyclic aromatic compounds the site of attack depends on the structure of the molecule and on the solvent.³⁴⁵

Although a large amount of work has been done on the mechanism of ozonization (formation of **12**), not all the details are known. Note that a primary ozonide has been trapped.³⁴⁶ Criegee³⁴⁷ formulated the basic mechanism. The first step of the *Criegee mechanism*³⁴⁸ is a 1,3-dipolar addition (Reaction **15-58**) of ozone to the substrate to give the “initial” or “primary” ozonide, the structure of which has been shown to be the 1,2,3-trioxolane (**13**) by microwave and other spectral methods.³⁴⁹ However, **13** is highly unstable and cleaves to an aldehyde or ketone (**14**) and an intermediate³⁵⁰ that Criegee showed as a zwitterion (**15**), but which may be a diradical (**16**). This intermediate is usually referred to as a carbonyl oxide.³⁵¹ The carbonyl oxide, which will be represented as **15**, can then undergo various reactions, three of which lead to normal products. One is a recombination with **14**, which leads to ozonide **12**. The second is a dimerization to the bis(peroxide) **17**, and the third a kind of dimerization to **18**.³⁵² If the first path is taken (this

(photooxidation of diazo compounds), reacted with aldehydes to give ozonides³⁶⁰; and (3) *cis*- and *trans*-alkenes generally give the same ozonide, which would be expected if they cleave first.³⁶¹ However, this was not true for $\text{Me}_3\text{CCH}=\text{CHCMe}_3$, where the *cis*-alkene gave the *cis*-ozonide (chiefly), and the *trans* gave the *trans*.³⁶²

The latter result is not compatible with the Criegee mechanism. Also incompatible with the Criegee mechanism was the finding that the *cis*/*trans* ratios of symmetrical (cross) ozonides obtained from *cis*- and *trans*-4-methyl-2-pentene were not the same.³⁶³ If the Criegee mechanism operated as shown above, the *cis*/*trans* ratio for each of the two cross ozonides would have to be identical for the *cis*- and *trans*-alkenes, since in this mechanism they are completely cleaved.

The above stereochemical results have been explained³⁶⁴ on the basis of the Criegee mechanism with the following refinements: (1) The formation of **13** is stereospecific, as expected from a 1,3-dipolar cycloaddition. (2) Once formed, **15** and **14** remain attracted to each other, much like an ion pair. (3) Intermediate **15** exists in *syn* and *anti* forms, which are produced in different amounts and can hold their shapes, at least for a time. This is plausible if we remember that a $\text{C}=\text{O}$ canonical form contributes to the structure of **19**. (4) The combination of **15** and **14** is also a 1,3-dipolar cycloaddition, so configuration is retained in this step too.³⁶⁵

Evidence that the basic Criegee mechanism operates even in these cases comes from ¹⁸O labeling experiments, making use of the fact, mentioned above, that mixed ozonides (e.g., **15**) can be isolated when an external aldehyde is added. Both the normal and modified Criegee mechanisms predict that if ¹⁸O-labeled aldehyde is added to the ozonolysis mixture, the label will appear in the ether oxygen (see the reaction between **15** and **14**), and this is what is found.³⁶⁶ There is evidence that the *anti*-**15** couples much more readily than the *syn*-**15**.³⁶⁷

The ozonolysis of ethylene³⁶⁸ in the liquid phase (without a solvent) was shown to take place by the Criegee mechanism.³⁶⁹ This reaction has been used to study the structure of the intermediate **15** or **16**. The compound dioxirane (**20**) was identified in the reaction mixture³⁷⁰ at low temperatures and is probably in equilibrium with the biradical **16** (R = H). Dioxirane has been produced in solution, but it oxidatively cleaves dialkyl ethers (e.g., Et—O—Et) via a chain-radical process,³⁷¹ so the choice of solvent is important.

Ozonolysis in the gas phase is not generally carried out in the laboratory. However, the reaction is important because it takes place in the atmosphere and contributes to air pollution.³⁷² There is much evidence that the Criegee mechanism operates in the gas phase too, although the products are more complex because of other reactions that also take place.³⁷³

19-10 Oxidative Cleavage of Double Bonds and Aromatic Rings

Oxo-de-alkylidene-bisubstitution, and so on

Carbon–carbon double bonds can be cleaved by many oxidizing agents,³⁷⁴ the most common of which are permanganate in neutral or acid media and dichromate in acid media. The products are generally 2 molar equivalents of ketone, 2 molar equivalents of carboxylic acid, or 1 molar equivalent of each, depending on what groups are attached to the alkene. With ordinary solutions of permanganate or dichromate, yields are generally low and the reaction is seldom a useful synthetic method; but high yields can be obtained by oxidizing with KMnO_4 dissolved in benzene containing the crown ether dicyclohexano-18-crown-6 (see Sec. 3.C.ii).³⁷⁵ The crown ether coordinates with K^+ , permitting the KMnO_4 to dissolve in benzene. Another reagent frequently used for synthetic purposes is the *Lemieux-von Rudloff reagent*: HIO_4 containing a trace of MnO_4^- .³⁷⁶ The MnO_4^- is the actual oxidizing agent, being reduced to the manganate stage, and the

purpose of the HIO_4 is to reoxidize the manganate back to MnO_4^- . Another reagent that behaves similarly is NaIO_4 –ruthenium tetroxide.³⁷⁷ Oxidative cleavage of alkenes is catalyzed by Ru with $\text{IO}(\text{OH})_5$.³⁷⁸ Cyclic alkenes are cleaved to α,ω -diketones, keto-acids, or dicarboxylic acids. Cyclic alkenes are cleaved to dialdehydes with $\text{KMnO}_4\cdot\text{CuSO}_4$ in dichloromethane.³⁷⁹ A combination of $\text{RuCl}_3/\text{HIO}_5$ oxidatively cleaves cyclic alkenes to dicarboxylic acids.³⁸⁰

The *Barbier–Wieland procedure* for decreasing the length of a chain by one carbon involves oxidative cleavage by acid dichromate (NaIO_4 – RuO_4 has also been used), but this is cleavage of a 1,1-diphenyl alkene (**21**), which generally gives good yields. Addition of a catalytic amount of OsO_4 to *Jones reagent* (Reaction **19-3**) leads to good yields of the carboxylic acid from simple alkenes.³⁸¹ A combination of Oxone and OsO_4 in DMF cleaves alkenes to carboxylic acids.³⁸² Cleavage of alkynes is generally rather difficult, but treatment of internal alkynes with an excess of Oxone with a Ru catalyst leads to aliphatic carboxylic acids.³⁸³

With certain reagents, the oxidation of double bonds can be stopped at the aldehyde stage, and in these cases the products are the same as in the ozonolysis procedure. Among these reagents are *tert*-butyl iodoxybenzene,³⁸⁴ KMnO_4 in $\text{THF}-\text{H}_2\text{O}$,³⁸⁵ and NaIO_4 – OsO_4 .³⁸⁶ Enol ethers, $[\text{RC}(\text{OR}')=\text{CH}_2]$ have been cleaved to carboxylic esters $[\text{RC}(\text{OR}')=\text{O}]$ by atmospheric oxygen.³⁸⁷ Oxidative cleavage of alkenes is catalyzed by a Mn–porphyrin complex.³⁸⁸

The mechanism of oxidation probably involves in most cases the initial formation of a glycol (Reaction **15-29**) or cyclic ester,³⁸⁹ and then further oxidation as in Reaction **19-7**.³⁹⁰ In line with the electrophilic attack on the alkene, triple bonds are more resistant to oxidation than double bonds. Terminal triple-bond compounds can be cleaved to

carboxylic acids with Ti(III)NO_3 ³⁹¹ or with [bis(trifluoroacetoxy)iodo]pentafluorobenzene [i.e., $\text{C}_6\text{F}_5\text{I(OCOCF}_3)_2$].³⁹²

Aromatic rings can be cleaved with strong enough oxidizing agents. An important laboratory reagent for this purpose is RuO_4 along with a cooxidant (e.g., NaIO_4 or NaOCl and household bleach can be used). Ruthenium tetroxide is an expensive reagent, but the cost can be greatly reduced by the use of an inexpensive cooxidant (e.g., NaOCl), the function of which is to oxidize RuO_2 back to ruthenium tetroxide. Examples³⁹³ are the oxidation of naphthalene to phthalic acid³⁹⁴ and, even more remarkably, of cyclohexylbenzene to cyclohexanecarboxylic acid³⁹⁵ (note the contrast with Reaction 19-11). The latter conversion was also accomplished with ozone.³⁹⁶ Another reagent that oxidizes aromatic rings is air catalyzed by V_2O_5 . The oxidations of naphthalene to phthalic anhydride and of benzene to maleic anhydride by this reagent are important industrial procedures.³⁹⁷ *o*-Diamines have been oxidized with nickel peroxide, with lead tetraacetate,³⁹⁸ and with O_2 catalyzed by CuCl .³⁹⁹

The last-named reagent also cleaves *o*-dihydroxybenzenes (catechols) to give, in the presence of MeOH , the monomethylated dicarboxylic acids ($\text{HO}_2\text{C}-\text{C}=\text{C}-\text{C}=\text{C}-\text{CO}_2\text{Me}$).⁴⁰⁰

19-11 Oxidation of Aromatic Side Chains

Oxo,hydroxy-de-dihydro,methyl-tersubstitution

Alkyl chains on aromatic rings can be oxidized to CO_2H groups by many oxidizing agents, including permanganate, nitric acid, and acid dichromate.⁴⁰¹ The method is most often applied to the methyl group ($\text{CH}_3 \rightarrow \text{CO}_2\text{H}$), although longer side chains can also be cleaved. Tertiary alkyl groups are resistant to oxidation, and when they *are* oxidized, ring cleavage usually occurs too.⁴⁰² It is usually difficult to oxidize an R group on a fused

aromatic system without cleaving the ring or oxidizing it to a quinone (Reaction **19-19**). However, this has been done (e.g., 2-methylnaphthalene was converted to 2-naphthoic acid) with aq $\text{Na}_2\text{Cr}_2\text{O}_7$.⁴⁰³ Aryl methyl groups are oxidized to aryl CO_2H with NaOCl in acetonitrile,⁴⁰⁴ or with NBS in aqueous NaOH under photochemical conditions.⁴⁰⁵ Functional groups can be present anywhere on the side chain and, if in the α position, greatly increase the ease of oxidation. An exception is an α phenyl group. In such cases, the reaction stops at the diaryl ketone stage. Molecules containing aryl groups on different carbons cleave so that each ring gets one carbon atom, as in the cleavage of the 9,10-bond of dihydrophenanthrenes (**21** to **22**).

It is possible to oxidize only one alkyl group of a ring that contains more than one. The order of reactivity⁴⁰⁶ toward most reagents is $\text{CH}_2\text{Ar} > \text{CHR}_2 > \text{CH}_2\text{R} > \text{CH}_3$.⁴⁰⁷ Groups on the ring susceptible to oxidation (OH , NHR , NH_2 , etc.) must be protected. The oxidation can be performed with oxygen, in which case it is autoxidation, and the mechanism is like that in Reaction **14-7**, with a hydroperoxide intermediate.⁴⁰⁸ With this procedure it is possible to isolate ketones from ArCH_2R , and this is often done.⁴⁰⁹

The mechanism has been studied for the following closely related reaction: $\text{Ar}_2\text{CH}_2 + \text{CrO}_3 \rightarrow \text{Ar}_2\text{C}=\text{O}$.⁴¹⁰ A deuterium isotope effect of 6.4 was found, indicating that the rate-determining step is either $\text{Ar}_2\text{CH}_2 \rightarrow \text{Ar}_2\text{CH}\cdot$ or $\text{Ar}_2\text{CH}_2 \rightarrow \text{Ar}_2\text{CH}^+$. Either way this explains why tertiary groups are not converted to CO_2H and why the reactivity order is $\text{CHR}_2 > \text{CH}_2\text{R} > \text{CH}_3$, as mentioned above. Both free radicals and carbocations exhibit this order of stability (Chapter 5). The two possibilities are examples of categories 2 and 3 in Section 19.A. Just how the radical or the cation goes on to the product is not known.

When the alkyl group is one oxidizable to CO_2H (Reaction **19-11**), cupric salts are oxidizing agents, and the OH group is found in a position ortho to that occupied by the alkyl group.⁴¹¹ This reaction is used industrially to convert toluene to phenol.

In another kind of reaction, an aromatic aldehyde (ArCHO) or ketone (ArCOR') is converted to a phenol (ArOH) on treatment with alkaline H_2O_2 ,⁴¹² but there must be an OH or NH_2 group in the ortho or para position. This is called the *Dakin reaction*.⁴¹³ The

19-12 Oxidative Decarboxylation

Acetoxy-de-carboxy-substitution

Hydro-carboxyl-elimination

Carboxylic acids can be decarboxylated⁴¹⁸ with lead tetraacetate to give a variety of products: an ester (ROAc), the alkane (RH) (see Reaction 12-40), an alkene if α,β hydrogen is present, as well as numerous other products arising from rearrangements, internal cyclizations,⁴¹⁹ and reactions with solvent molecules. When R is tertiary, the chief product is usually the alkene. High yields of alkenes can also be obtained when R is primary or secondary using Cu(OAc)₂ along with the Pb(OAc)₄.⁴²⁰ In the absence of Cu(OAc)₂, primary acids give mostly alkanes (though yields are generally low) and secondary acids may give carboxylic esters or alkenes. Other oxidizing agents,⁴²¹ including Co(III), Ag(II), Mn(III), and Ce(IV), have also been used to effect oxidative decarboxylation.⁴²²

The mechanism with lead tetraacetate is generally accepted to be of the free radical type.⁴²³ First, there is an interchange of ester groups:

A free radical chain mechanism follows (shown for **24** although **25** and other lead esters can behave similarly)

Products can then be formed either from $\text{R}\bullet$ or R^+ . Primary $\text{R}\bullet$ abstract H from solvent molecules to give RH. The R^+ ion can lose H^+ to give an alkene, react with HOAc to give the carboxylic ester, react with solvent molecules or with another functional group in the same molecule, or rearrange, thus accounting for the large number of possible products. The radical $\text{R}\bullet$ can also dimerize to give RR. The effect of Cu^{2+} ions⁴²⁴ is to oxidize the radicals to alkenes, thus producing good yields of alkenes from primary and secondary substrates. The Cu^{2+} ion has no effect on tertiary radicals, because these are efficiently oxidized to alkenes by lead tetraacetate.

In another type of oxidative decarboxylation, arylacetic acids can be oxidized to aldehydes with one less carbon ($\text{ArCH}_2\text{COOH} \rightarrow \text{ArCHO}$) by tetrabutylammonium periodate.⁴²⁵ Simple aliphatic carboxylic acids were converted to nitriles with one less carbon ($\text{RCH}_2\text{COOH} \rightarrow \text{RC}\equiv\text{N}$) by treatment with trifluoroacetic anhydride and NaNO_2 in $\text{F}_3\text{CCO}_2\text{H}$.⁴²⁶

See also, Reaction **14-37**.

19-13 Bis(decarboxylation)

Dicarboxy-elimination

Compounds containing carboxyl groups on adjacent carbons (succinic acid derivatives) can be bis(decarboxylated) with lead tetraacetate in the presence of O_2 .⁴¹⁷ The reaction is of wide scope. The elimination is stereoselective, but not stereospecific (both *meso*- and

dl-2,3-diphenylsuccinic acid gave *trans*-stilbene)⁴²⁷; a concerted mechanism is thus unlikely. The following mechanism is compatible with the data:

though a free radical mechanism seems to hold in some cases. Bis(decarboxylation) of succinic acid derivatives to give alkenes⁴²⁸ has also been carried out by other methods.⁴²⁹ Compounds containing geminal carboxyl groups (disubstituted malonic acid derivatives) can be bis(decarboxylated) with lead tetraacetate,⁴³⁰ *gem*-diacetates (acylals) being produced, which are easily hydrolyzable to ketones:⁴³¹

A related reaction involves α -substituted aryl nitriles having a sufficiently acidic α hydrogen, which can be converted to ketones by oxidation with air under phase-transfer conditions.⁴³² The nitrile is added to NaOH in benzene or DMSO, containing a catalytic amount of triethylbenzylammonium chloride (TEBA).⁴³³ This reaction could not be applied to aliphatic nitriles, but an indirect method for achieving this conversion is given in Reaction 19-60.

C. Reactions Involving Replacement of Hydrogen by Heteroatoms

19-14 Hydroxylation at an Aliphatic Carbon

Hydroxylation or Hydroxy-de-hydrogenation

Compounds containing susceptible C—H bonds can be oxidized to alcohols.⁴³⁴ Nearly always, the C—H bond involved is tertiary, so the product is a tertiary alcohol. This is partly because tertiary C—H bonds are more susceptible to free radical attack than primary and secondary bonds and partly because the reagents involved would oxidize primary and

secondary alcohols further. In the best method, the reagent is ozone and the substrate is absorbed on silica gel.⁴³⁵ Yields as high as 99% have been obtained by this method. Other reagents are chromic acid,⁴³⁶ ruthenium tetroxide (RuO_4),⁴³⁷ thallium acetate,⁴³⁸ sodium chlorite (NaClO_2) with a metalloporphyrin catalyst,⁴³⁹ OsO_4 ,⁴⁴⁰ and certain peroxybenzoic acids.⁴⁴¹ Alkanes and cycloalkanes have been oxidized at secondary positions, to a mixture of alcohols and trifluoroacetates, by 30% aq H_2O_2 in trifluoroacetic acid.⁴⁴² This reagent does not oxidize the alcohols further and ketones are not found. As in the case of chlorination with *N*-haloamines and sulfuric acid (see Reaction 14-1), the $\omega - 1$ position is the most favored. Another reagent⁴⁴³ that oxidizes secondary positions is iodosylbenzene, catalyzed by Fe(III)–porphyrin catalysts.⁴⁴⁴ Use of an optically active Fe(III)–porphyrin gave modest enantioselective hydroxylation.⁴⁴⁵

When chromic acid is the reagent, the mechanism is probably as follows: a Cr^{6+} species abstracts a hydrogen to give $\text{R}_3\text{C}^\bullet$, which is held in a solvent cage near the resulting Cr^{5+} species. The two species then combine to give $\text{R}_3\text{COCr}^{4+}$, which is hydrolyzed to the alcohol. This mechanism predicts retention of configuration; this is largely observed.⁴⁴⁶ The oxidation by permanganate also involves predominant retention of configuration, and a similar mechanism has been proposed.⁴⁴⁷

Treatment of double-bond compounds with selenium dioxide introduces an OH group into the allylic position (see also, Reaction 19-17).⁴⁴⁸ This reaction also produces conjugated aldehydes in some cases.⁴⁴⁹ Allylic rearrangements are common. There is evidence that the mechanism does not involve free radicals, but includes two pericyclic steps (A and B):⁴⁵⁰

The step marked **A** is similar to the ene reaction (Reaction 15-23). The step marked **B** is a [2,3]-sigmatropic rearrangement (see Reaction 18-35). The reaction can also be

accomplished with *tert*-butyl hydroperoxide, if SeO_2 is present in catalytic amounts (the *Sharpless method*).⁴⁵¹ The SeO_2 is the actual reagent; the peroxide reoxidizes the $\text{Se}(\text{OH})_2$.⁴⁵² This method makes work up easier, but gives significant amounts of side products when the double bond is in a ring.⁴⁵³ Alkynes generally give α, α' dihydroxylation.⁴⁵⁴ Allylic hydroxylation⁴⁵⁵ with selenium dioxide often gives aldehydes, but in the presence of acetic anhydride and oxygen, SeO_2 converts alkenes to homoallylic acetates as the major product, $\text{C}=\text{C}-\text{C}-\text{C} \rightarrow \text{C}=\text{C}-\text{C}-\text{C}-\text{OAc}$.⁴⁵⁶

Hydroxylation of unactivated sp^3 hybridized bonds is possible using an oxaziridine-mediated, organocatalyzed reaction.⁴⁵⁷ Ruthenium tetroxide oxidizes alkanes.⁴⁵⁸ Nanocrystalline cobalt oxide is another catalyst for alkane oxidation.⁴⁵⁹ The $\text{H}_2\text{O}_2-\text{NaVO}_3-\text{H}_2\text{SO}_4$ system facilitates alkane oxidation in aqueous acetonitrile.⁴⁶⁰

Benzylic methylene groups are more readily oxidized to benzylic alcohols when compared to simple alkanes. Typical reagents include manganese salen and PhIO^{461} or peroxides.⁴⁶² Oxidation to an acetoxy benzyl derivative was accomplished with $\text{PhI}(\text{OAc})_2$ in acetic acid with a Pd catalyst,⁴⁶³ and with $\text{PhI}(\text{OH})\text{OTs}$ in aq DMSO.⁴⁶⁴ With minimal water, cerium (IV) triflate converts benzylic arenes to benzylic alcohols, although the major product is the ketone when >15% of water is present.⁴⁶⁵

Allylic benzyloxylation occurs when an alkene is treated with *t*-BuOOCOPh and a Cu—Na zeolite,⁴⁶⁶ a Cu catalyst,⁴⁶⁷ or with a chiral Cu catalyst to give modest enantioselectivity.⁴⁶⁸ Allylic methylene groups can be converted to ester ($-\text{CH}-\text{OCOR}$) derivatives in a similar manner using copper triflate.⁴⁶⁹ Cupric acetate has been used,⁴⁷⁰ as well as Cu_2O .⁴⁷¹ A chiral Lewis acid has been used for an enantioselective allylic CH oxidation to an allylic acyl derivative.⁴⁷² α -Acetoxylation of allylic alkenes can proceed with allylic rearrangement.⁴⁷³

Hydroxylation can be accomplished using enzymatic systems. In the presence of *Bacillus megaterium* and oxygen, cyclohexane is converted to cyclohexanol.⁴⁷⁴ Allylic oxidation to an allylic alcohol was accomplished with cultured cells of *Gossypium hirsutum*.⁴⁷⁵ Benzylic arenes are converted to the corresponding α -hydroxy compound by treatment with the enzymes of *B. megaterium*, with modest enantioselectivity.⁴⁷⁶ The reaction of tetradecanoic acid with the α -oxidase from *Pisum sativum*, in the presence of molecular oxygen, gives 2(*R*)-hydroxytetradecanoic acid with high asymmetric induction.⁴⁷⁷

Simple alkanes can be converted to esters with dialkyloxiranes. Cyclic alkanes are oxidized to alcohols with dimethyl dioxirane.⁴⁷⁸ Cyclohexane was converted to cyclohexyl trifluoroacetate with di(trifluoromethyl) dioxirane and trifluoroacetic anhydride⁴⁷⁹ and also with $\text{RuCl}_3/\text{MeCO}_3\text{H}/\text{CF}_3\text{CO}_2\text{H}$.⁴⁸⁰ Dimethyl dioxirane converts alkanes to alcohols in some cases.⁴⁸¹ Adamantane is converted to adamantyl alcohol with DDQ (see Reaction 19-1, category 3) and triflic acid.⁴⁸² The mechanism of oxygen insertion into alkanes has been examined.⁴⁸³

It is possible to perform the conversion $\text{CH}_2 \rightarrow \text{C}=\text{O}$ on an alkane, with no functional groups at all, although the most success has been achieved with substrates in which all CH_2 groups are equivalent (e.g., unsubstituted cycloalkanes). Hydrogen peroxide and trifluoroacetic acid has also been used for oxidation of alkanes.⁴⁸⁴ With this method, cyclohexane was converted with 72% efficiency to give 95% cyclohexanone and 5% cyclohexanol.⁴⁸⁵ The same type of conversion, with lower yields (20–30%), has been achieved with the *Gif* system.⁴⁸⁶ There are several variations. One consists of pyridine–acetic acid, with H_2O_2 as oxidizing agent and tris(picolinato)iron(III) as catalyst.⁴⁸⁷ Other *Gif* systems use O_2 as oxidizing agent and Zn as a reductant.⁴⁸⁸ The selectivity of the *Gif* systems toward alkyl carbons is $\text{CH}_2 > \text{CH} \geq \text{CH}_3$, which is unusual, and shows that a simple free radical mechanism (see Sec. 14.A.iv) is not involved.⁴⁸⁹ Another reagent that can oxidize the CH_2 of an alkane is methyl(trifluoromethyl)dioxirane, but this produces $\text{CH}-\text{OH}$ more often

19-15 Oxidation of Methylene to OH, O_2CR , or OR

Hydroxy (or alkoxy) - α -dihydro-bisubstitution

Methyl or methylene groups α to a carbonyl can be oxidized to give α -hydroxy ketones, aldehydes, or carboxylic acid derivatives. Ketones can be α hydroxylated in good yields, without conversion to the enolates, by treatment with the hypervalent iodine reagents⁴⁹³ *o*-iodosobenzoic acid.⁴⁹⁴ Dioxygen (O_2) and a chiral phase-transfer catalyst gave enantioselective α hydroxylation of ketones, if the α position was tertiary.⁴⁹⁵ Dimethyl dioxirane is quite effective for hydroxylation of 1,3-dicarbonyl compounds,⁴⁹⁶ and O_2 with a Mn catalyst also gives hydroxylation.⁴⁹⁷ Oxygen with a Ce catalyst α -hydroxylates β -keto esters.⁴⁹⁸ The Pd—C catalyzed α -oxygenation of 1,3-dicarbonyl compounds can be accomplished using O_2 .⁴⁹⁹ An engineered Cytochrome P450 BM-3 is effective for the enantioselective α -hydroxylation of esters of benzylic acids.⁵⁰⁰ The reaction of ketones with $\text{Ti}(\text{O}i\text{Pr})_4$, diethyl tartrate and *tert*-butylhydroperoxide gave the α -hydroxy ketone with good enantioselectivity, albeit in low yield.⁵⁰¹ α -Hydroxylation of ketones was reported using H_2O_2 and 12-tungstophosphoric acid—cetylpyridinium chloride as a catalyst.⁵⁰² Hypervalent iodine(III) sulfonate has been used for the α -hydroxylation of aryl ketones.⁵⁰³

Ketones and carboxylic esters can be α hydroxylated by treatment of their enolate anions (prepared by adding the ketone or ester to LDA) with a Mo peroxide reagent (MoO_5 —pyridine—HMPA; called MoOPH) in THF—hexane at -70°C .⁵⁰⁴ The enolate forms of amides and esters⁵⁰⁵ and the enamine derivatives of ketones⁵⁰⁶ can similarly be

converted to their α -hydroxy derivatives by reaction with molecular oxygen. The MoO_5 method can also be applied to certain nitriles.⁵⁰⁷

Ketones are converted to α -hydroxy ketones by reaction of the enolate anion with a 2-sulfonyloxaziridine (e.g., **25**).⁵⁰⁸ This is not a free radical process; the mechanism shown is likely. The method is also successful for carboxylic esters⁵⁰⁹ and *N,N*-disubstituted amides,⁵¹⁰ and can be made enantioselective by the use of a chiral oxaziridine.⁵¹¹ Dimethyldioxirane also oxidizes the enolate anions of ketones to α -hydroxy ketones.⁵¹² Titanium enolates are oxidized with *tert*-butyl hydroperoxide⁵¹³ or with dimethyldioxirane⁵¹⁴ and hydrolyzed with aq ammonium fluoride to give the α -hydroxy ketone. Ketones are converted to the α -oxamino derivative ($\text{O}=\text{C}-\text{CH}_2-\rightarrow \text{O}=\text{C}-\text{CHONHPh}$) with excellent enantioselectivity using $\text{PhN}=\text{O}$ and L-proline⁵¹⁵ or (S)-proline.⁵¹⁶ Aldehydes undergo a similar oxidation.⁵¹⁷ α -Lithio sulfones have been hydroxylated with $\text{Me}_3\text{SiOO}t\text{-Bu}$.⁵¹⁸

Dimethyldioxirane

Ketones have been α hydroxylated by conversion to the silyl enol ether, followed by treatment with *m*-chloroperoxybenzoic acid,¹⁶⁶ or with certain other oxidizing agents.⁵¹⁹ α -Hydroxyketones can be accomplished from silyl enol ethers with a catalytic amount of MeReO_3 and H_2O_2 .⁵²⁰ When the silyl enol ethers are treated with iodobenzene in the presence of trimethylsilyl trifluoromethyl sulfonate, the product is the α -keto triflate.⁵²¹

Silyl ketene ethers are converted to α -hydroxy esters with H_2O_2 and methyl trioxorhenium.⁵²² The α' -position of α,β -unsaturated ketones can be selectively oxidized.⁵²³ *N*-Acyl amines are converted to the α -hydroxy derivative with PhIO and a Mn salen catalyst.⁵²⁴ Note that homoallylic-type oxidation occurs when an α,α -dimethyl oxime ether is treated with $\text{PhI}(\text{OAc})_2$ and a Pd catalyst in acetic acid/acetic anhydride, converting one of the methyl groups to an acetoxymethyl.⁵²⁵

α -Acetoxylation of ketones with concurrent α -arylation occurs when ketones react with $\text{Mn}(\text{OAc})_3$ in benzene.⁵²⁶ α -Acetoxylation of ketones can occur under similar conditions without arylation.⁵²⁷ α -Methyl ketones are converted to the α -acetoxy derivative under the same conditions.⁵²⁸ Iodobenzene with 30% aq H_2O_2 and acetic anhydride generates α -acetoxy ketones.⁵²⁹ Thallium(III) triflate converts acetophenone to α -formyloxy acetophenone.⁵³⁰ Methanesulfonic acid and CuO converts ketones to α -mesyloxy ($-\text{OMs}$) ketones⁵³¹ and $\text{PhI}(\text{OH})\text{OTs}$ converts ketones to α -tosyloxy ($-\text{OTs}$) ketones.⁵³² *N*-Methyl-*O*-tosylhydroxylamine is another reagent that effects direct α -oxytosylation of ketones and aldehydes.⁵³³ α -Acetoxylation of ketones results from *in situ* generation of hypervalent iodine species in the presence of acetic acid.⁵³⁴

N-tosylamine.⁵³⁷ When an α -keto ester reacts with DEAD and a chiral Cu complex, an α -carbamate is formed, $\text{RCH}(\text{NHCO}_2\text{Et})\text{C}(=\text{O})\text{CO}_2\text{Et}$, with modest enantioselectivity.⁵³⁸

Cyclic amines react with *Pseudomonas oleovorans* GPOL to give hydroxy amines; *N*-benzylpyrrolidine is converted to 3-hydroxy *N*-benzylpyrrolidine.⁵³⁹ *Sphingomonas* sp. HXN-200 gives similar results,⁵⁴⁰ and lactams are converted to the corresponding 3-hydroxy lactam with *sphingomonas* sp. HXN-200.⁵⁴¹ *N*-Benzyl piperidine is converted to the 4-hydroxy derivative under the same conditions.⁵⁴² *N*-Benzyl phthalimide reacts with NBS, NaOAc, and acetic acid to give *N*-(α -acetoxybenzyl)phthalimide.⁵⁴³

Tetrahydrofuran was converted to the hemiacetal 2-hydroxytetrahydrofuran, which was relatively stable under the conditions used, by electrolysis in water.⁵⁴⁴ α -Hydroxy ethers are generated by reaction of SO_2/O_2 and a V catalyst with ethers.⁵⁴⁵

Similar reactions are possible, in some cases, to produce sulfur containing compounds.

Sulfo-de-dihydro-bisubstitution

Cyclic alkanes are converted to the corresponding alkylsulfonic acid with SO_2/O_2 and a V catalyst.⁵⁴⁶

19-17 Oxidation of Methylene to Carbonyl

Oxo-de-dihydro-bisubstitution

Methyl or methylene groups α to a carbonyl can be oxidized with selenium dioxide to give, respectively, α -keto aldehydes (see Reaction 19-18) and α -diketones.⁵⁴⁷ The reaction can also be carried out α to an aromatic ring or to a double bond, although in the latter case, hydroxylation (see 19-14) is the more common result. Selenium dioxide, (SeO_2) is often used, but the reaction has also been carried out with other oxidizing agents,⁵⁴⁸ including hypervalent iodine compounds.⁵⁴⁹ Sodium nitrite/HCl oxidizes cyclic ketones to the diketone.⁵⁵⁰ Substrates most easily oxidized contain two aryl groups on CH_2 , and these substrates can be oxidized with many oxidizing agents (see Reaction 19-11). The benzylic

a Hg(II)—EDTA (EDTA = ethylenediaminetetraacetic acid) complex in basic solution.⁵⁷⁶ Lactams, which need not be *N*-substituted, can be converted to cyclic imides by oxidation with a hydroperoxide or peroxyacid and an Mn(II) or Mn(III) salt.⁵⁷⁷ Lactams are oxidized to cyclic imides with oxygen and Co(OAc)₂ in the presence *N*-hydroxysuccinimide.⁵⁷⁸

Ethers in which at least one group is a primary alkyl can be oxidized to the corresponding carboxylic esters in high yields with ruthenium tetroxide.⁵⁷⁹ Molecular oxygen with a binuclear Cu(II) complex⁵⁸⁰ or PdCl₂/CuCl₂/CO⁵⁸¹ also converts ethers to esters. Cyclic ethers are oxidized to lactones.⁵⁸² Cyclic ethers are oxidized to lactones with CrO₃/Me₃SiONO₂.⁵⁸³ Lactones are also formed from cyclic ethers with NaBrO₃—KHSO₄ in water.⁵⁸⁴ The reaction has also been accomplished with CrO₃ in H₂SO₄,⁵⁸⁵ and with benzyltriethylammonium permanganate.⁵⁸⁶

Two mechanisms have been suggested for the reaction with SeO₂. One of these involves a selenate ester of the enol:⁵⁸⁷

In the other proposed mechanism,⁵⁸⁸ the principal intermediate is α,β -ketoseleninic acid ($\text{O}=\text{C}-\text{CH}=\text{SeO}_2\text{H}$) and a selenate ester is not involved.

Oxidation of CH_2 to $\text{C}=\text{O}$ groups is possible even if they are not near any functional groups, indirectly, by the remote oxidation method of Breslow⁵⁷ (see Reaction 19-2). One of the CH_2 groups of *n*-hexadecanol monosuccinate [$\text{CH}_3(\text{CH}_2)_{14}\text{CH}_2\text{OCOCH}_2\text{CH}_2\text{CO}_2\text{H}$] was oxidized to a $\text{C}=\text{O}$ group to give a mixture of it and benzophenone-4-carboxylic acid [*p*-PhCOC₆H₄CO₂H] in CCl₄.⁵⁸⁹ Other remote oxidations⁵⁹⁰ also have been reported. Among these are conversion of aryl ketones [$\text{ArCO}(\text{CH}_2)_3\text{R}$] to 1,4-diketones [$\text{ArCO}(\text{CH}_2)_4\text{COR}$] by photoirradiation in the presence of such oxidizing agents as K₂Cr₂O₇ or KMnO₄,⁵⁹¹ and conversion of alkyl ketones [$\text{RCO}(\text{CH}_2)_3\text{R}'$] to 1,3- and 1,4-diketones with

19-18 Oxidation of Arylmethanes to Aldehydes

Oxo-de-dihydro-bisubstitution

Methyl groups on an aromatic ring can be oxidized to an aldehyde by several oxidizing agents. The reaction is a special case of **19-17**. When the reagent is chromyl chloride (CrO_2Cl_2), the reaction is called the *Étard reaction*⁵⁹⁴ and the yields are high.⁵⁹⁵ Another oxidizing agent is a mixture of CrO_3 and Ac_2O , where the reaction stops at the aldehyde stage because the initial product is $\text{ArCH}(\text{OAc})_2$ (an acylal), which is resistant to further oxidation. Hydrolysis of the acylal gives the aldehyde.

Among other oxidizing agents⁵⁹⁶ that have been used to accomplish the conversion of ArCH_3 to ArCHO are ceric ammonium nitrate,⁵⁹⁷ PCC,⁵⁹⁸ hypervalent iodoso compounds (see Reaction **19-3**),⁵⁹⁹ Bi-*t*-BuOOH,⁶⁰⁰ and urea- H_2O_2 with microwave irradiation.⁶⁰¹ Oxidative of benzylic positions to the corresponding carbonyl has been reported using two heterogeneous catalysts.⁶⁰² Oxidation of ArCH_3 to carboxylic acids is considered at Reaction **19-11**.

Conversion of ArCH_3 to ArCHO can also be achieved indirectly by bromination to give ArCHBr_2 (**14-1**), followed by hydrolysis (Reaction **10-2**).

The mechanism of the *Étard reaction* is not completely known.⁶⁰³ An insoluble complex is formed on addition of the reagents, which is hydrolyzed to the aldehyde. The complex is probably a kind of acylal, but the identity of the structure is not fully settled, although many proposals have been made as to its structure and as to how it is hydrolyzed. It is known that ArCH_2Cl is not an intermediate (see Reaction **19-20**), since it reacts only very slowly with chromyl chloride. Magnetic susceptibility measurements⁶⁰⁴ indicate that the complex from toluene is **26**, a structure first proposed by Étard. According to this proposal, the reaction

stops after only two hydrogen atoms have been replaced because of the insolubility of **26**. There is a disagreement on how **26** is formed, assuming that the complex has this structure. Both an ionic⁶⁰⁵ and a free radical⁶⁰⁶ process have been proposed. An entirely different structure for the complex was proposed by Nenitzescu et al.⁶⁰⁷ On the basis of ESR studies, they proposed that the complex is $\text{PhCH}_2\text{OCrCl}_2\text{OCrCl}_2\text{OH}$, which is isomeric with **26**. However, this view has been challenged by Wiberg and Eisenthal,⁶⁰⁶ who interpret the ESR result as being in accord with **26**. Still another proposal is that the complex is composed of benzaldehyde coordinated with reduced chromyl chloride.⁶⁰⁸

OS II, 441; III, 641; IV, 31, 713.

19-19 Oxidation of Aromatic Hydrocarbons to Quinones

Arene-quinone transformation

Condensed aromatic systems (including naphthalenes) can be directly oxidized to quinones by various oxidizing agents.⁶⁰⁹ Yields are generally not high, although good yields have been reported with ceric ammonium sulfate.⁶¹⁰ Benzene cannot be so oxidized by strong oxidizing agents, but can be electrolytically oxidized to benzoquinone.⁶¹¹ Naphthalene derivatives, however, are oxidized to naphthoquinones with H_5IO_6 and CrO_3 .⁶¹² 1,4-Dimethoxy aromatic compounds are oxidized to *p*-quinones with an excess of CoF_3 in water–dioxane.⁶¹³

19-20 Oxidation of Primary Halides and Esters of Primary Alcohols to Aldehydes⁶¹⁴

Oxo-de-hydro,halo-bisubstitution

Primary alkyl halides (chlorides, bromides, and iodides) can be oxidized to aldehydes easily and in good yields with DMSO,⁶¹⁵ in what has been called the *Kornblum reaction*. In Kornblum's original work, the reaction of α -halo ketones with DMSO at elevated temperatures gave good yields of the corresponding glyoxal (an α -keto-aldehyde).⁶¹⁶ If the glyoxal could be removed from the reaction medium by distillation as it was formed, the reaction was very efficient. In many cases, it was difficult to isolate high-boiling glyoxals from DMSO. Primary and secondary⁶¹⁷ alkyl iodides or tosylates⁶¹⁸ can be converted to aldehydes or ketones, although they are much less reactive than α -halo ketones. Primary chlorides with DMSO, NaBr, and ZnO give the corresponding aldehyde when heated to 140 °C.⁶¹⁹ Benzylic halides are oxidized to aryl aldehydes with MnO_2 ⁶²⁰ or with $\text{NaIO}_4\text{—LiBr}$.⁶²¹ Hydrogen peroxide in ethanol oxidizes organic halides to carbonyl compounds.⁶²² Pyridine *N*-oxide in the presence of silver oxide oxidizes benzylic and allylic halides.⁶²³

The mechanism of these DMSO oxidations is probably that shown with **27** and **28**,⁶²⁴ although in some cases the base abstracts a proton directly from the carbon being oxidized, in which case the ylide (**28**) is not an intermediate. Alkoxysulfonium salts (**27**) have been isolated.⁶²⁵ This mechanism predicts that secondary compounds should be oxidizable to ketones, and this is the case. In a related procedure for the oxidation of alcohols, the

intermediate **27**⁶²⁶ is formed without the use of DMSO by treating the substrate with a complex generated from chlorine or NCS and DMS.⁶²⁷ Also see the *Swern oxidation* in Reaction **19-3**.

Another way to oxidize primary alkyl halides to aldehydes is by the use of hexamethylenetetramine followed by water. However, this reaction, called the *Sommelet reaction*,⁶²⁸ is limited to benzylic halides. The reaction is seldom useful when the R in RCH₂Cl is alkyl. The first part of the reaction is conversion to the amine (ArCH₂NH₂), which can be isolated. Reaction of the amine with excess hexamethylenetetramine gives the aldehyde. It is this last step that is the actual *Sommelet reaction*, although the entire process can be conducted without isolation of intermediates. Once the amine is formed, it is converted to an imine (ArCH₂N=CH₂) with formaldehyde liberated from the reagent. The key step then follows: transfer of hydrogen from another mole of the arylamine to the imine. This last imine is then hydrolyzed by water to the aldehyde. Alternatively, the benzylamine may transfer hydrogen directly to hexamethylenetetramine.

Pyridine followed by *p*-nitrosodimethylaniline and then water converts benzylic halides to aldehydes, and is called the *Kröhnke reaction*. Primary halides and tosylates have been oxidized to aldehydes by trimethylamine *N*-oxide,⁶²⁹ and by pyridine *N*-oxide with microwave irradiation.⁶³⁰

Epoxides⁶³¹ have been used to give α-hydroxy ketones or aldehydes.⁶³²

19-21 Oxidation of Amines or Nitro Compounds to Aldehydes, Ketones, or Dihalides

Oxo-de-hydro-amino-bisubstitution (overall transformation)

Primary aliphatic amines can be oxidized to aldehydes or ketones, using silver compounds as shown.⁶³³ Other reagents have been used,⁶³⁴ including *N*-bromoacetamide⁶³⁵ (for benzylic amines), or aq NaOCl with phase-transfer catalysts.⁶³⁶ Several indirect methods for achieving the conversion RR'CHNH₂ → RR'C=O (R' = alkyl, aryl, or H) have been reported.⁶³⁷

Primary, secondary, and tertiary aliphatic amines have been cleaved to give aldehydes, ketones, or carboxylic acids with aq bromine⁶³⁸ and with neutral permanganate.⁶³⁹ The other product of this reaction is the amine with one less alkyl group. Reaction of a primary amine with benzoyl peroxide/CsCO₃ and subsequent heating of the hydroxylamine product gives the ketone.⁶⁴⁰ In a different type of procedure, primary alkyl primary amines can be converted to *gem*-dihalides [RCH₂NH₂ → RCHX₂ (X = Br or Cl)] by treatment with an alkyl nitrite and the anhydrous copper(I) halide.⁶⁴¹

Primary and secondary aliphatic nitro compounds have been oxidized to aldehydes and ketones, respectively (RR'CHNO₂ → RR'C=O), with sodium chlorite under phase-transfer conditions,⁶⁴² tetrapropylammonium perruthenate (TPAP),⁶⁴³ as well as with other reagents.⁶⁴⁴

19-22 Oxidation of Primary Alcohols to Carboxylic Acids or Carboxylic Esters

Oxo-de-dihydro-bisubstitution

Primary alcohols can be oxidized to carboxylic acids by many strong oxidizing agents including chromic acid, permanganate,⁶⁴⁵ nitric acid,⁶⁴⁶ or H₅IO₆/CrO₃.⁶⁴⁷ The reaction can be looked on as a combination of **19-3** and **19-23**. Aliphatic primary alcohols are converted to the carboxylic acid with 30% aq H₂O₂, tetrabutylammonium hydrogen sulfate and a W catalyst with microwave irradiation.⁶⁴⁸ Benzylic alcohols are oxidized to benzoic acid derivatives by treatment first with TEMPO⁶⁴⁹ (Sec. 5.C.i), and then NaClO₂.⁶⁵⁰ Oxidation with 5% aq NaOCl and a Ni catalyst oxidizes primary alcohols to the corresponding acid.⁶⁵¹ Similar oxidation to the acid occurred with NaIO₄/RuCl₃ in aq acetonitrile,⁶⁵² or 30% aq H₂O₂ and a Co salen catalyst.⁶⁵³ Oxammonium salts and NaClO₂ oxidize alcohols to carboxylic acids.⁶⁵⁴

When acidic conditions are used, a considerable amount of carboxylic ester (RCOOCH_2R) is often isolated, although this is probably not formed by a combination of the acid with unreacted alcohol, but by a combination of intermediate aldehyde with unreacted alcohol to give an acetal or hemiacetal, which is oxidized to the ester.⁶⁵⁵ A mixture of Oxone and NaCl converts alcohols to symmetrical esters.⁶⁵⁶ Aliphatic alcohols are converted to a symmetrical ester ($\text{RCH}_2\text{OH} \rightarrow \text{RCOOCH}_2\text{R}$) by oxidation with PCC on aluminum without solvent.⁶⁵⁷ Hydrogen with a Ru—CO complex converts primary alcohols (ROH) to an ester (RCO_2R).⁶⁵⁸ Iodine has been used to convert alcohols to esters.⁶⁵⁹ Hydrogen transfer with a Ru catalyst has been used to convert primary alcohols to methyl esters.⁶⁶⁰ Oxone in aq methanol also converts aryl aldehydes to the corresponding ester.⁶⁶¹ Allylic alcohols are converted to conjugated esters with MnO_2 and NaCN in methanol–acetic acid.⁶⁶² Primary alcohols are oxidized to the methyl ester with trichloroisocyanuric acid in methanol.⁶⁶³ This reagent also converts diols to lactones. Lactones can be prepared by oxidizing diols in which at least one OH is primary,⁶⁶⁴ and addition of a chiral additive (e.g., sparteine) leads to lactones with high asymmetric induction.⁶⁶⁵

Primary alcohols (RCH_2OH) can be directly oxidized to acyl fluorides (RCOF) with cesium fluoroxysulfate.⁶⁶⁶ 2-(3-Hydroxypropyl)aniline was oxidized to an acyl derivative that cyclized to give a lactam when heated with a Rh catalyst.⁶⁶⁷

chromic acid,⁶⁷⁰ bromine, and Oxone.⁶⁷¹ Silver oxide is a fairly specific oxidizing agent for aldehydes and does not readily attack other groups. *Benedict's* and *Fehling's solutions* oxidize aldehydes,⁶⁷² and there is a test for aldehydes that depends on this reaction, but the method is seldom used for preparative purposes and gives very poor results with aromatic aldehydes. α,β -Unsaturated aldehydes can be oxidized by sodium chlorite without disturbing the double bond.⁶⁷³ Aldehydes are also oxidized to carboxylic acids by atmospheric oxygen, but the actual direct oxidation product in this case is the peroxy acid (RCO_3H),⁶⁷⁴ which with another molecule of aldehyde disproportionates to give two molecules of acid (see Reaction 14-7).⁶⁷⁵ The air oxidation of aldehydes to carboxylic acids is mediated by a mixture of Pd/C — NaBH_4 and KOH .⁶⁷⁶ An aldehyde can be converted to the carboxylic acid by treatment with 30% H_2O_2 and methyl(trioctyl) ammonium hydrogen sulfate at 90 °C.⁶⁷⁷ Aryl aldehydes are similarly oxidized by a mixture of H_2O_2 and selenium dioxide (SeO_2).⁶⁷⁸ Polymer-bound hypervalent iodine + TEMPO oxidizes aldehydes to acids.⁶⁷⁹ Hydrogen peroxide oxidizes aldehydes to carboxylic acids in the presence of a AgNO_3 catalyst⁶⁸⁰ or a Pd catalyst.⁶⁸¹

Aryl aldehydes are converted to the corresponding aryl carboxylic ester with H_2O_2 and a V_2O_5 catalyst⁶⁸² or a titanosilicate⁶⁸³ in an alcohol solvent. Esterification of aldehydes with alcohols uses an Ir catalyst.⁶⁸⁴ The reaction of aldehydes with aq alcohols, in the presence of iodine and NaNO_2 , gives an ester.⁶⁸⁵ Organoboronic acids and molecular oxygen convert aldehydes to an ester using a Pd catalyst.⁶⁸⁶ *N*-heterocyclic carbenes catalyze oxidation of aldehydes to the corresponding ester.⁶⁸⁷ Aldehydes (RCHO) can be directly converted to carboxylic esters (RCOOR') by treatment with Br_2 in the presence of an alcohol.⁶⁸⁸

Aldehydes react with amines, mediated by La catalysts, to give amides.⁶⁸⁹

Mechanisms of aldehyde oxidation⁶⁹⁰ are not firmly established, but there are at least two main types: a free radical mechanism and an ionic one. In the free radical process, the aldehyde hydrogen is abstracted to leave an acyl radical, which obtains OH from the oxidizing agent. In the ionic process, the first step is addition of a species ^-OZ to the carbonyl bond to give **29** in alkaline solution and **30** in acid or neutral solution. The aldehyde hydrogen of **29** or **30** is then lost as a proton to a base, while Z leaves with its electron pair.

For oxidation with acid dichromate the picture seems to be quite complex, with several processes of both types going on:⁶⁹¹

Steps 1 and 2 constitute an oxidation by the ionic pathway by Cr(VI), and steps 6 and 7 a similar oxidation by Cr(V), which is produced by an electron-transfer process. Either Cr(VI) (step 3) or Cr(IV) (step 4) [Cr(IV) is produced in step 2] may abstract a hydrogen and the resulting acyl radical is converted to carboxylic acid in step 5. Thus, Cr in three oxidation states is instrumental in oxidizing aldehydes. Still another possible process has been proposed in which the chromic acid ester decomposes as follows:⁶⁹²

⁶⁹² See Rocek, J.; Ng, C. *J. Org. Chem.* **1973**, *38*, 3348.

The mechanism with permanganate is less well known, but an ionic mechanism has been proposed⁶⁹³ for neutral and acid permanganate, similar to steps 1 and 2 for dichromate:

For alkaline permanganate, the following mechanism has been proposed:⁶⁹⁴

OS I, 166; II, 302, 315, 538; III, 745; IV, 302, 493, 499, 919, 972, 974.

The conversion of thioketones to sulfoxes ($\text{R}_2\text{C}=\text{S}=\text{O}$) is difficult to categorize into the sections available, and it placed after oxidation of ketones and aldehydes. The reaction of a thioketone with H_2O_2 and a catalytic amount of MTO (methyl trioxorhenium) gives the sulfoxine.⁶⁹⁵

19-24 Oxidation of Carboxylic Acids to Peroxy Acids

Peroxy-de-hydroxy-substitution

The oxidation of carboxylic acids with H_2O_2 and an acid catalyst is the best general method for the preparation of peroxy acids.⁶⁹⁶ A mixture of $\text{Me}_2\text{C}(\text{OMe})\text{OOH}$ and DCC has also been used.⁶⁹⁷ Concentrated H_2SO_4 is a common catalyst for aliphatic R. The reaction is in equilibrium and is driven to the right by removal of water or by the use of excess reagents. For aromatic R, the best catalyst is methanesulfonic acid, which is also used as the solvent.

Monosubstituted and 1,2-disubstituted alkenes can be oxidized to aldehydes and ketones by PdCl_2 , where the PdCl_2 is reduced to Pd.⁶⁹⁸ Similar salts of noble metals also work, but 1,1-disubstituted alkenes generally give poor results. The reaction is used industrially to prepare acetaldehyde from ethylene (the *Wacker process*),⁶⁹⁹ but it is also suitable for laboratory preparations. The reagent is expensive, so the reaction is usually carried out with a cooxidant, often CuCl_2 , whose function is to reoxidize the Pd to Pd(II) . The CuCl_2 is reduced to Cu(I) , which itself is reoxidized to Cu(II) by air, so that atmospheric oxygen is the only oxidizing agent actually used up. Many other cooxidants have been tried, among them O_3 , Fe^{3+} , and PbO_2 . Terminal alkenes are oxidized to methyl ketones with O_2 and a Pd catalyst.⁷⁰⁰ The principal product is an aldehyde only from ethylene: With other alkenes *Markovnikov's rule* is followed, and ketones are formed predominantly.

The generally accepted mechanism shown below involves π complexes of Pd.⁷⁰¹ This mechanism accounts for the fact, established by deuterium labeling, that the four hydrogen atoms of the acetaldehyde all come from the original ethylene and none from the solvent.

Similar reactions have been carried out with other oxidizing agents. An example involving migration of an alkyl group instead of hydrogen is oxidation of $\text{Me}_2\text{C}=\text{CMe}_2$ with peroxytrifluoroacetic acid–boron trifluoride to give Me_3COMe (pinacolone).⁷⁰² This reaction consists of epoxidation (**15-50**) followed by pinacol rearrangement of the epoxide (**18-2**). A migration is also involved in the conversion of $\text{ArCH}=\text{CHCH}_3$ to $\text{ArCH}(\text{CH}_3)\text{CHO}$ by treatment with $\text{I}_2\text{—Ag}_2\text{O}$ in aq dioxane.⁷⁰³

⁷⁰³ Kikuchi, H.; Kogure, K.; Toyoda, M. *Chem. Lett.* **1984**, 341.

Other reagents used have been $\text{Pb}(\text{OAc})_4\text{—F}_3\text{CCO}_2\text{H}$ ⁷⁰⁴ (e.g., $\text{PhCH=CH}_2 \rightarrow \text{PhCH}_2\text{CHO}$), H_2O_2 and a Pd catalyst,⁷⁰⁵ $\text{H}_2\text{O—PdCl}_2\text{—polyethylene glycol}$.⁷⁰⁶ Terminal alkenes react with ceric ammonium nitrate in methanol to give α -methoxy ketones.⁷⁰⁷

Alkenes have also been converted to more highly oxidized products. Examples are (1) Treatment with KMnO_4 in aq acetone containing acetic acid gives α -hydroxy ketones.⁷⁰⁸ (2) 1,2-Disubstituted and trisubstituted alkenes give α -chloro ketones when oxidized with chromyl chloride in acetone: $\text{RCH=CR}^1\text{R}^2 \rightarrow \text{RCOCClR}^1\text{R}^2$.⁷⁰⁹ (3) α -Iodo ketones can be prepared by treating alkenes with bis(*sym*-collidine)iodine(I) tetrafluoroborate.⁷¹⁰ (4) Potassium permanganate in acetic anhydride oxidizes large-ring cycloalkenes to 1,2-diketones.⁷¹¹

Enol ethers are oxidized to carboxylic esters ($\text{RCH=CHOR}' \rightarrow \text{RCH}_2\text{COOR}'$) with PCC ⁷¹² and enamines to α -amino ketones with *N*-sulfonyloxaziridines.⁷¹³ Enamines ($\text{R}^1\text{R}^4\text{C=CR}^2\text{NR}_2^3$, $\text{R}^4 \neq \text{H}$) do not give these products, but lose the amino group to give α -hydroxy ketones [$\text{R}^1\text{R}^4\text{C}(\text{OH})\text{COR}^2$].⁷¹³ Carboxylic acids can be prepared from terminal alkynes by conversion of the alkyne to its phenylthio ether ($\text{RC}\equiv\text{CPh}$) and treatment of this with HgSO_4 in $\text{HOAc—H}_2\text{SO}_4$.⁷¹⁴ *Aza-Wacker reactions* are known.⁷¹⁵

$\text{MeReO}_3/\text{H}_2\text{O}_2$,⁷²¹ or oxygen and a mixture of Pd and Cu catalysts.⁷²² A Ru complex with a small amount of trifluoroacetic acid converts internal alkynes to the α -diketone.⁷²³ Ozone generally oxidizes triple-bond compounds to carboxylic acids (Reaction 19-9), but α -diketones are sometimes obtained.⁷²⁴ Selenium dioxide (SeO_2) with a small amount of H_2SO_4 oxidizes alkynes to α -diketones, as well as arylacetylenes to α -keto acids ($\text{ArC}\equiv\text{CH} \rightarrow \text{ArCOCO}_2\text{H}$).⁷²⁵ A mixture of formic acid, methanesulfonic acid and DMSO with an HBr catalyst converts alkynes to α -diketones.⁷²⁶

19-27 Oxidation of Amines to Nitroso Compounds and Hydroxylamines and Related *N*-Oxo-de-dihydro-bisubstitution

Primary aromatic amines can be oxidized⁷²⁷ to nitroso compounds. Most often the conversion is accomplished by *Caro's acid* (H_2SO_5) or with H_2O_2 in HOAc.⁷²⁸ Other reagents used for this oxidation are sodium perborate⁷²⁹ H_2O_2 with a Ti complex,⁷³⁰ HOF generated *in situ*,⁷³¹ and $\text{Na}_2\text{WO}_4/\text{H}_2\text{O}_2$.⁷³² Hydroxylamines, which are probably intermediates in most cases, can sometimes be isolated, but under the reaction conditions they are generally oxidized to the nitroso compounds. Primary aliphatic amines can be oxidized in this manner, but the nitroso compound is stable only if there is no α hydrogen. If there is an α hydrogen, the compound tautomerizes to the oxime.⁷³³

The mechanism with H_2SO_5 has been postulated to be an example of category 5 (Sec. 19.A).⁷³⁴

Secondary amines (R_2NH) are oxidized to hydroxylamines (R_2NHOH), which are resistant to further oxidation, by dimethyldioxirane⁷³⁵ and by benzoyl peroxide and

Na_2HPO_4 .⁷³⁶ Oxone on silica also oxidizes secondary alcohols to the hydroxylamine.⁷³⁷ Hydroxylamines are formed when secondary amines react with the enzyme cyclohexanone monooxygenase.⁷³⁸ Carbamates (e.g., *N*-Boc amines) are converted to the *N*-hydroxy compound with bis(trifluoromethyl)dioxirane.⁷³⁹ Dialkylamines are oxidized to the *N*-nitroso compound with N_2O_2 on poly(vinylpyrrolidinone).⁷⁴⁰

OS III, 334; VIII, 93; 80, 207.

19-28 Oxidation of Primary Amines, Oximes, Azides, Isocyanates, or Nitroso Compounds to Nitro Compounds

Tertiary alkyl primary amines can be oxidized to nitro compounds in excellent yields with KMnO_4 .⁷⁴¹ This type of nitro compound is not easily prepared in other ways. All classes of primary amine (including primary, secondary, and tertiary alkyl, as well as aryl) are oxidized to nitro compounds in high yields with dimethyldioxirane.⁷⁴² Other reagents that oxidize various types of primary amines to nitro compounds are dry ozone,⁷⁴³ various peroxyacids,⁷⁴⁴ $\text{MeReO}_3/\text{H}_2\text{O}_2$,⁷⁴⁵ Oxone,⁷⁴⁶ *tert*-butyl hydroperoxide in the presence of certain Mo and V compounds,⁷⁴⁷ and sodium perborate.⁷⁴⁸ An aqueous solution of fluorine oxidizes amino esters to α -nitro esters.⁷⁴⁹

Dimethyldioxirane in wet acetone oxidizes isocyanates to nitro compounds ($\text{RNCO} \rightarrow \text{RNO}_2$).⁷⁵⁰ Oximes can be oxidized to nitro compounds with peroxytrifluoroacetic acid, or sodium perborate,⁷⁵¹ among other ways.⁷⁴¹ Secondary hydroxylamines are also oxidized to nitrones with MnO_2 in dichloromethane.⁷⁵² Primary and secondary alkyl azides have been converted to nitro compounds by treatment with Ph_3P followed by ozone.⁷⁵³ An aqueous solution of fluorine also oxidizes azides to the corresponding nitro

19-29 Oxidation of Tertiary Amines to Amine Oxides

N-Oxygen-attachment

Tertiary amines can be converted to amine oxides by oxidation. Hydrogen peroxide is often used, but peroxyacids are also important reagents for this purpose. Pyridine and its derivatives are oxidized by peroxyacids⁷⁵⁶ rather than hydrogen peroxide. Note, however, that urea–H₂O₂ in formic acid does indeed oxidize pyridine.⁷⁵⁷ Oxidation with *Caro's acid* has been shown to proceed in this manner.⁷⁵⁸

This mechanism is the same as that of Reaction **19-27**; the products differ only because tertiary amine oxides cannot be further oxidized. The mechanism with other peroxyacids is probably the same. A green procedure for oxidation of tertiary amines has been developed, using a Mg–Al complex with aq H₂O₂.⁷⁵⁹ Nitrones can be prepared using a ball-mill.⁷⁶⁰

An alternative oxidation using O₂ and a RuCl₃ catalyst converted pyridine to pyridine *N*-oxide.⁷⁶¹ Bromamine-T and RuCl₃ in aq acetonitrile also oxidizes pyridine to the *N*-oxide.⁷⁶² Tertiary amines are oxidized to the *N*-oxide with O₂ and Fe₂O₃ in the presence of an aliphatic aldehyde.⁷⁶³ Oxygen and a Co–Schiff base complex also oxidizes tertiary amines, including pyridine.⁷⁶⁴

Analogous to the oxidation of tertiary amines, tertiary phosphines are oxidized to phosphine oxides (R₃P=O). Triphenylphosphine is converted to triphenylphosphine oxide with N₂O at 100 °C, for example. Triphenylphosphine is also oxidized with PhIO on Montmorillonite K-10.⁷⁶⁵ *tert*-Butylhydroperoxide oxides Ph₃P → BH₃ to Ph₃P=O.⁷⁶⁶ *P*-Stereogenic phosphine oxides have been prepared.⁷⁶⁷

19-30 Oxidation of Thiols and Other Sulfur Compounds to Sulfonic Acids

Thiol-sulfonic acid oxidation

Thiols, sulfoxides, sulfones, disulfides,⁷⁶⁸ and other sulfur compounds can be oxidized to sulfonic acids with various oxidizing agents, but for synthetic purposes the reaction is most important for thiols.⁷⁶⁹ Among oxidizing agents used are boiling nitric acid, barium permanganate, and dimethyl dioxirane.⁷⁷⁰ Autoxidation (oxidation by atmospheric oxygen) can be accomplished in basic solution.⁷⁷¹ Oxidation of thiols with chlorine and water gives sulfonyl chlorides directly.⁷⁷² Thiols can also be oxidized to disulfides (Reaction 19-34).

OS II, 471; III, 226. Also see, OS V, 1070.

19-31 Oxidation of Thioethers to Sulfoxides and Sulfones

S-Oxygen-attachment

Thioethers can be oxidized to sulfoxides by 1 equiv of 30% H₂O₂ or by many other oxidizing agents,⁷⁷³ including NaIO₄,⁷⁷⁴ H₂O₂, and a Sc(OTf)₃ catalyst,⁷⁷⁵ HIO₃/wet SiO₂,⁷⁷⁶ dioxiranes,⁷⁷⁷ MeReO₃/H₂O₂,⁷⁷⁸ O₂ and a ceric ammonium nitrate catalyst,⁷⁷⁹ KO₂/Me₃SiCl,⁷⁸⁰ hexamethylene triamine-Br₂ with CHCl₃-H₂O,⁷⁸¹ H₅IO₆/FeCl₃,⁷⁸²

hypervalent iodine compounds,⁷⁸³ and peroxyacids.⁷⁸⁴ Sulfoxides can be further oxidized to sulfones by another equivalent of H₂O₂, KMnO₄, sodium perborate, or a number of other agents. If enough oxidizing agent is present, thioethers can be directly converted to sulfones without isolation of the sulfoxides.⁷⁸⁵ Thioethers can be oxidized directly to the sulfone by treatment with TPAP,⁷⁸⁶ H₂O₂,⁷⁸⁷ and an Fe catalyst,⁷⁸⁸ a Zr catalyst,⁷⁸⁹ a Ta catalyst,⁷⁹⁰ a V catalyst,⁷⁹¹ an Au catalyst,⁷⁹² a Mo catalyst,⁷⁹³ a flavin-ionic liquid catalyst,⁷⁹⁴ urea-H₂O₂,⁷⁹⁵ peroxy monosulfate and a Mn catalyst,⁷⁹⁶ or nitric acid with P₂O₅ on silica gel.⁷⁹⁷ These reactions give high yields, and many functional groups do not interfere.⁷⁹⁸

As with tertiary amines (Reaction 19-29), racemic thioethers can be kinetically resolved by oxidation to sulfoxides with an optically active reagent, and this has often been done.⁷⁹⁹ In addition, the use of chiral additives in conjunction with various oxidizing agents leads to chiral nonracemic sulfoxide with good-to-excellent enantioselectivity.⁸⁰⁰ Asymmetric oxidation using bacterial monooxygenases is known,⁸⁰¹ and horseradish peroxidase gives modest enantioselectivity.⁸⁰² Chiral sulfur reagents are also known.⁸⁰³ It is possible to oxidize a thioether to a sulfoxide in the presence of an alcohol moiety using MnO₂/HCl.⁸⁰⁴ *N*-Sulfonyloxaziridines can be used to oxidize sulfides to sulfoxides.⁸⁰⁵ Selenides (R₂Se) can be oxidized to selenoxides and selenones.⁸⁰⁶ Alkyl disulfides give oxidation of one

sulfur to give a $\text{RS}-\text{S}(=\text{O})\text{R}$ compound with good enantioselectivity when using aq H_2O_2 , a catalytic amount of a V catalyst, and a chiral Schiff base ligand.⁸⁰⁷

When the oxidizing agent is a peroxide, the mechanism⁸⁰⁸ of oxidation to the sulfoxide is similar to that of Reaction 19-29.⁸⁰⁹

The second oxidation, which is normally slower than the first, which is why sulfoxides are so easily isolable, has the same mechanism in neutral or acid solution, but in basic solution it has been shown that the conjugate base of the peroxy compound ($\text{R}'\text{OO}^-$) also attacks the SO group as a nucleophile:⁸¹⁰

There are some reagents that oxidize sulfoxides in preference to sulfides (e.g., NaMnO_4).⁸¹¹

(Ar₂CX₂) have been dimerized to tetraaryl alkenes (Ar₂C=CAr₂) with Cu,⁸¹⁵ and with iron(II) oxalate dihydrate.⁸¹⁶

A somewhat different type of coupling is observed when salts of β-keto esters, arylacetoneitriles (ArCH₂CN), and other compounds of the form ZCH₂Z' are treated with an oxidizing agent (e.g., iodine,⁸¹⁷ or Cu(II) salts.)⁸¹⁸ Arylmethanesulfonyl chlorides (ArCH₂SO₂Cl) couple to give ArCH=CHAr when treated with Et₃N.⁸¹⁹

19-33 Dimerization of Silyl Enol Ethers or of Lithium Enolates

3/O-De-trimethylsilyl-1/C-coupling

Silyl enol ethers can be dimerized to symmetrical 1,4-diketones by treatment with Ag₂O in DMSO or certain other polar aprotic solvents.⁸²⁰ The reaction has been performed with R², R³ = hydrogen or alkyl, although best yields are obtained when R² = R³ = H. In certain cases, unsymmetrical 1,4-diketones have been prepared by using a mixture of two silyl enol ethers. Other reagents that have been used to achieve either symmetrical or cross-coupled products are iodosobenzene–BF₃–OEt₂,⁸²¹ ceric ammonium nitrate,⁸²² and lead tetraacetate.⁸²³ If R¹ = OR (in which case the substrate is a ketene silyl acetal), dimerization with TiCl₄ leads to a dialkyl succinate (**31**, R¹ = OR).⁸²⁴

In a similar reaction, lithium enolates [RC(OLi)=CH₂] were dimerized to 1,4-diketones (RCOCH₂CH₂COR) with CuCl₂, FeCl₃, or copper(II) triflate, in a nonprotic solvent.⁸²⁵

OS VIII, 467.

19-34 Oxidation of Thiols to Disulfides

S-De-hydrogen-coupling

Thiols are easily oxidized to disulfides.⁸²⁶ Hydrogen peroxide is the most common reagent,⁸²⁷ but many oxidizing agents give the reaction, among them Br₂ on hydrated

silica,⁸²⁸ sodium perborate,⁸²⁹ SmI_2 ,⁸³⁰ PPh_3 with a Rh catalyst,⁸³¹ cetyltrimethylammonium dichromate,⁸³² and NO. Hydrogen peroxide (30%) in hexafluoro-2-propanol converts thiols to disulfides,⁸³³ and solventless reactions on MnO_2 ,⁸³⁴ PCC (Reaction **19-3**, category 1)⁸³⁵ or SO_2Cl_2 ⁸³⁶ are also effective. A potassium phosphate catalyst has been used for the oxidative coupling of thiols to disulfides.⁸³⁷ Strong oxidizing agents may give Reaction **19-26**. Even oxygen in the air oxidizes thiols on standing, if a small amount of base is present. The reaction is reversible (see Reaction **19-75**), and the interconversion between cysteine and cystine is an important one in biochemistry.

The mechanism has been studied for several oxidizing agents and varies with the agent.⁸³⁸ For oxygen it is⁸³⁹

With respect to the sulfur, this mechanism is similar to that of Reaction **14-16**, involving as it does loss of a proton, oxidation to a free radical, and radical coupling.

Unsymmetrical disulfides can be prepared⁸⁴⁰ by treatment of a thiol RSH with diethyl azodicarboxylate ($\text{EtOOCN}=\text{NCOOEt}$) to give an adduct, to which another thiol ($\text{R}'\text{SH}$) is then added, producing the disulfide (RSSR').⁸⁴¹

OS **III**, 86, 116.

19.B.ii. Reductions

For the most part, reductions have been grouped into this chapter, with a few notable exceptions. Catalytic hydrogenation of alkenes and alkynes in Reactions **15-11** and **15-12**, hydrogenation of aromatic rings in Reaction **15-13**, and reductive cleavage of cyclopropanes in Reaction **15-15** were placed in Chapter 15 to coincide with addition reactions, and protonolysis of alkyl boranes in Reaction **15-16** was placed there also for continuity. In general, reductions of functional groups encompass a variety of reaction types. The reactions in this section are classified into groups depending on the type of bond change

involved. These groups are (1) attack at carbon (C—O and C=O), (2) attack at non-carbonyl multiple bonds to heteroatoms, (3) reactions in which a heteroatom is removed from the substrate, (4) reduction with cleavage, (5) reductive coupling, and (6) reactions in which an organic substrate is both oxidized and reduced. Most of the reagents in this section are metal hydrides, metals with an acid or a protic solvent, hydrogen gas with a catalyst, and so on. Other reducing agents are available, and will be introduced in the appropriate section. Note that plants can be used as reducing agents.⁸⁴²

A. Selectivity⁸⁴³

It is often necessary to reduce one group in a molecule without affecting another reducible group (this is called chemoselectivity), and reducing agents are available that will do this. The most common broad-spectrum reducing agents are the metal hydrides⁸⁴⁴ or hydrogen (with a catalyst).⁸⁴⁵ Many different metal hydride systems and hydrogenation catalysts have been investigated in order to find conditions under which a given group will be reduced chemoselectively. The ease of reduction for various functional groups toward catalytic hydrogenation is acyl halides > alkyl nitro compounds > alkynes > aldehydes > alkenes > ketones > benzylic ethers > nitriles > esters > amides.⁸⁴⁶ Futher, Table 19.2 and 19.4 list the reactivity of various functional groups with LiAlH_4 , and BH_3 , respectively.⁸⁴⁶ Table 19.5 shows which groups can be reduced by catalytic hydrogenation and various metal hydrides.⁸⁴⁷ Of course, the tables cannot be exact, because the nature of R and the reaction conditions obviously affect reactivity. Nevertheless, the tables do give a fairly good indication of which reagents reduce which groups.⁸⁴⁸ Lithium aluminum hydride is very powerful and unselective reagent.⁸⁴⁹ Other metal hydrides are generally used when chemoselectivity is required. As will be seen in Reaction 19-36, less reactive (and more selective) reagents have been prepared by replacing some of the hydrogen atoms of LiAlH_4 with alkoxy groups.⁸⁵⁰ Most of the metal hydrides are nucleophilic reagents and attack the

⁸⁵⁸ Reacts with solvent, reduced in aprotic solvents.

⁸⁵⁹ Reduced to an aldehyde (Reaction 19-44).

B. Attack at Carbon (C—O And C=O)**19-35 Reduction of Epoxides****(3) *OC-seco*-Hydro-de-alkoxylation**

Reduction of epoxides is a special case of Reaction **19-56** and is easily carried out.⁸⁶⁰ A common reagent is LiAlH_4 ,⁸⁶¹ which reacts by the $\text{S}_{\text{N}}2$ -type mechanism, giving inversion of configuration. An epoxide on a substituted cyclohexane ring cleaves in such a direction as to give an axial alcohol. As expected for an $\text{S}_{\text{N}}2$ mechanism, the hydrogen atom is usually delivered to the less substituted carbon. The reaction has also been carried out with other reagents (e.g., sodium amalgam in EtOH, Li in ethylenediamine,⁸⁶² and by catalytic hydrogenolysis).⁸⁶³ Chemoselective and regioselective ring opening of allylic epoxides and of epoxy ketones and esters has been achieved with SmI_2 ,⁸⁶⁴ $\text{HCOOH}-\text{NEt}_3$ and a Pd catalyst,⁸⁶⁵ and sodium bis(2-methoxyethoxy)aluminum hydride (Red-Al; also known as Vitride).⁸⁶⁶ Highly hindered epoxides can be conveniently reduced, without rearrangement, with lithium triethylborohydride (called Super Hydride).⁸⁶⁷ For certain substrates, the epoxide ring can be opened the other way by reduction with $\text{NaBH}_4-\text{ZrCl}_4$,⁸⁶⁸ Pd/C and HCOONH_4 ,⁸⁶⁹ or with BH_3 in THF.⁸⁷⁰

Epoxy ketones are selectively reduced with lithium naphthalenide⁸⁷¹ or Cp_2TiCl in THF/MeOH⁸⁷² to the β -hydroxyketone. Other reduction methods can lead to the epoxy alcohol. Reduction of epoxy amides with SmI_2 in methanol gave the α -hydroxyamide.⁸⁷³

Epi-sulfides can be reduced to give the alkene using Bu_3SnH in the presence of BEt_3 .⁸⁷⁴

The usual product of epoxide reductions is the alcohol, but epoxides are reduced all the way to the alkane by titanocene dichloride⁸⁷⁵ and by $\text{Et}_3\text{SiH}-\text{BH}_3$.⁸⁷⁶

19-36 Reduction of Aldehydes and Ketones to Alcohols⁸⁷⁷

C,O-Dihydro-addition

Aldehydes can be reduced to primary alcohols, and ketones to secondary alcohols, by a number of reducing agents.⁸⁷⁸ Among the most common are the metal hydrides (e.g., LiAlH_4 , NaBH_4 , and related compounds).⁸⁷⁹ These reagents have two main advantages over many other reducing agents: They do not reduce carbon-carbon double or triple bonds (with the exception of propargylic alcohols),⁸⁸⁰ and with LiAlH_4 all four hydrogen atoms are theoretically usable for reduction. Methods are available for titrating hydride reagents.⁸⁸¹ The scope of these reagents with ketones is similar to that with aldehydes. Lithium aluminum hydride reduces even sterically hindered ketones.

The reaction is broad and general. Lithium aluminum hydride easily reduces aliphatic, aromatic, alicyclic, and heterocyclic aldehydes or ketones, containing double or triple bonds and/or nonreducible groups (e.g., NR_3 , OH, OR, and F). If the molecule contains a group reducible by LiAlH_4 (e.g., NO_2 , CN, COOR), then that group is usually reduced. Since LiAlH_4 reacts readily with water and alcohols, protic solvents must be excluded. Despite limited solubility, common solvents are ether and THF.

The compound NaBH_4 (sodium borohydride) has a similar scope, but is less reactive, so it is more selective and so may be used with NO_2 , Cl, COOR, CN, and so on in the molecule. Another advantage of NaBH_4 is that it can be used in water or alcoholic solvents, and so reduces compounds, (e.g., sugars) that are not soluble in ethers.⁸⁸² Other solvents can be used with some modification of the borohydride. For example, butyltriphenylphosphonium borohydride reduces aldehydes to alcohols in dichloromethane.⁸⁸³ Reduction with solid acid activated NaBH_4 has been reported.⁸⁸⁴ A polymer-bound phase-transfer material with NaBH_4 in wet THF has also been used.⁸⁸⁵ Sodium borohydride on

alumina, under microwave irradiation, is an effective reagent.⁸⁸⁶ Sodium borohydride has been used on silica gel.⁸⁸⁷

Red-Al was prepared by Vit in 1967,⁸⁸⁸ and its reducing power is close to that of LiAlH_4 . In addition, it is stable to dry air (it does not ignite in even moist air or oxygen), and is thermally stable up to 200 °C. The greatest practical utility of Red-Al is its solubility in aromatic hydrocarbon and ether solvents, which allows it to be conveniently used for applications that require inverse addition of hydrides. Red-Al essentially reacts the same as LiAlH_4 , reducing aldehydes, ketones⁸⁸⁹ and acid derivatives to alcohols.⁸⁹⁰ Reduction of conjugated carbonyls gives primarily 1,2-reduction to an allylic alcohol.⁸⁹¹ Other functional groups can be reduced.⁸⁹²

The $\text{C}=\text{C}$ units in compounds that contain double bonds are generally not affected by metallic hydrides, and the $\text{C}=\text{C}$ unit may be isolated or conjugated, but double bonds that are conjugated with the $\text{C}=\text{O}$ group may or may not be reduced, depending on the substrate, reagent, and reaction conditions.⁸⁹³ Some reagents that reduce only the $\text{C}=\text{O}$ bonds of α,β -unsaturated aldehydes and ketones are AlH_3 ,⁸⁹⁴ NaBH_4 , or LiAlH_4 in the presence of lanthanide salts,⁸⁹⁵ Co complexes,⁸⁹⁶ $\text{NaBH}_4\text{—LiClO}_4$,⁸⁹⁷ Ni compounds,⁸⁹⁸ $\text{NaBH}_3(\text{OAc})$,⁸⁹⁹ $\text{Zn}(\text{BH}_4)_2$ ⁹⁰⁰ on Y-zeolite,⁹⁰¹ and Et_3SiH .⁹⁰² Also, both LiAlH_4 ⁹⁰³ and NaBH_4 ⁹⁰⁴ predominantly reduce only the $\text{C}=\text{O}$ bonds of $\text{C}=\text{C—C}=\text{O}$ systems in most cases, although substantial amounts of fully saturated alcohols have been found in some cases⁹⁰³ (Reaction 15-14). For some reagents that reduce only the $\text{C}=\text{C}$ bonds of conjugated aldehydes and ketones, see Reaction 15-11. A mixture of InCl_3 and NaBH_4 reduced both the $\text{C}=\text{C}$ and $\text{C}=\text{O}$ units of conjugated ketones.⁹⁰⁵

When a functional group is selectively attacked in the presence of a different functional group, the reaction is said to be *chemoselective*.⁹⁰⁶ A number of reagents have been found to reduce aldehydes much faster than ketones. Among these⁹⁰⁷ are sodium triacetoxyborohydride⁹⁰⁸ ($\text{NaBH}_4\text{—HCO}_2\text{H}$),⁹⁰⁹ zinc borohydride in THF,⁹¹⁰ a complex of LiAlH_4 and *N*-methyl-2-pyrrolidinone (of particular interest since it is stable in air and to heating),⁹¹¹ and Raney nickel.⁹¹²

Ketones can be chemoselectively reduced in the presence of aldehydes with NaBH_4 in aq EtOH at -15°C in the presence of cerium trichloride (CeCl_3).⁹¹³ The reagent lithium *n*-dihydropyridylaluminum hydride reduces diaryl ketones much better than dialkyl or alkyl aryl ketones.⁹¹⁴ Most other hydrides reduce diaryl ketones more slowly than other types of ketones. Saturated ketones can be reduced in the presence of α,β -unsaturated ketones with $\text{NaBH}_4\text{—}50\% \text{ MeOH—CH}_2\text{Cl}_2$ at -78°C ,⁹¹⁵ and with zinc borohydride.⁹¹⁶

In general, NaBH_4 reduces carbonyl compounds in the order aldehydes $> \alpha,\beta$ -unsaturated aldehydes $>$ ketones $> \alpha,\beta$ -unsaturated ketones, and a carbonyl group of one type can be selectively reduced in the presence of a carbonyl group of a less reactive type.⁹¹⁷ A number of reagents will preferentially reduce the less sterically hindered of two carbonyl compounds, but by the use of Dibal-H in the presence of the Lewis acid methylaluminum bis(2,16-di-*tert*-butyl-4-methylphenoxide), it was possible selectively to reduce the *more hindered* of a mixture of two ketones.⁹¹⁸ It is obvious that reagents can often be found to reduce one kind of carbonyl function in the presence of another.⁹¹⁹ For a discussion of selectivity in reduction reactions (see Sec. 19.B.ii-A). A syn-selective reduction of β -hydroxy ketones was achieved using $(i\text{PrO})_2\text{TiBH}_4$.⁹²⁰ Quinones are reduced to hydroquinones by LiAlH_4 , $\text{SnCl}_2\text{—HCl}$, or sodium hydrosulfite ($\text{Na}_2\text{S}_2\text{O}_4$), as well as by other reducing agents.

The reagent lithium tri-*sec*-butylborohydride [$\text{LiBH}(\text{sec-Bu})_3$, L-Selectride] reduces cyclic and bicyclic ketones in a highly stereoselective manner.⁹²¹ For example, 2-methylcyclohexanone gave *cis*-2-methylcyclohexanol with an isomeric purity $> 99\%$. Both L-Selectride and the potassium salt (K-Selectride) reduce carbonyls in cyclic and acyclic molecules with high diastereoselectivity.⁹²² The more usual reagents (e.g., LiAlH_4 and NaBH_4) reduce relatively

unhindered cyclic ketones either with little or no stereoselectivity⁹²³ or give predominant formation of the more stable isomer (axial attack).⁹²⁴ Reduction of cyclohexanone derivatives with the very hindered $\text{LiAlH}(\text{Cet}_2\text{CMe}_3)_3$ gave primarily the cis-alcohol.⁹²⁵ Cyclohexanones that have a large degree of steric hindrance near the carbonyl group usually give predominant formation of the less stable alcohol, even with LiAlH_4 and NaBH_4 .

Other reagents reduce aldehydes and ketones to alcohols,⁹²⁶ including the following:

1. *Hydrogen and a Catalyst.*⁹²⁷ Common heterogeneous catalysts for carbonyls are Pt and Ru,⁹²⁸ and homogeneous catalysts are commonly used,⁹²⁹ especially for asymmetric hydrogenation (see **A** below). Before the discovery of the metal hydrides, this was one of the most common ways of effecting this reduction, but it suffers from the fact that $\text{C}=\text{C}$, $\text{C}\equiv\text{C}$, $\text{C}=\text{N}$ and $\text{C}\equiv\text{N}$ bonds are often more susceptible to attack than $\text{C}=\text{O}$ bonds.⁹³⁰ For aromatic aldehydes and ketones, reduction to the hydrocarbon (Reaction **19-61**) is a side reaction via hydrogenolysis of the initially produced alcohol (Reaction **19-54**). The mechanism of catalytic hydrogenation of aldehydes and ketones is probably similar to that of reaction **15-11**.⁹³¹
2. *Sodium in Ethanol.*⁹³² This is called the *Bouveault-Blanc procedure* and was more popular for the reduction of carboxylic esters (Reaction **19-38**) than of aldehydes or ketones before the discovery of LiAlH_4 .

For the reaction with sodium in ethanol the following mechanism⁹³³ has been suggested:⁹³⁴

The ketyl intermediate can be isolated.⁹³⁵ Lithium is often a superior metal for alkali metal reductions.⁹³⁶

3. *Other Metal Reductions.* A single carbonyl group of an α -diketone can be reduced to give an α -hydroxy ketone, by heating with Zn powder in aq DMF⁹³⁷ or Zn in methanol in the presence of benzyltriethylammonium chloride.⁹³⁸ Aluminum and NaOH in aq methanol reduces ketones.⁹³⁹ β -Hydroxy ketones are reduced with good antiselectivity using an excess of SmI_2 in water,⁹⁴⁰ and other ketones or aldehydes are reduced with SmI_2 ⁹⁴¹ in aq THF,⁹⁴² or in alcohols.⁹⁴³ Other metals can be used, including FeCl_3/Zn in aq DMF⁹⁴⁴ or Mg in alcohols.⁹⁴⁵ 1,2-Diketones were reduced to the α -hydroxy ketone with TiI_4 in acetonitrile, followed by hydrolysis.⁹⁴⁶ Ammonia and aq TiCl_3 in methanol reduces ketones.⁹⁴⁷
4. *Isopropyl Alcohol and Aluminum Isopropoxide.* This is called the *Meerwein-Ponndorf-Verley reduction*.⁹⁴⁸ It is reversible, and the reverse reaction is known as the *Oppenauer oxidation* (see **19-3**):

The equilibrium is shifted by removal of the acetone by distillation. There is a report of the reduction of benzaldehyde to benzyl alcohol by heating with 2-propanol at 225 °C for 1 day.⁹⁴⁹ The reaction usually takes place under very mild conditions and is highly specific for aldehydes and ketones, so that C=C bonds (including those conjugated with the C=O bonds) and many other functional groups can be present without themselves being reduced.⁹⁵⁰ This includes acetals, so that one of two carbonyl groups in a molecule can be specifically reduced if the other is first converted to an acetal. β -Keto esters, β -diketones, and other ketones and aldehydes with a relatively high enol content do not give this reaction. Zeolites have been used as a medium for this reduction.⁹⁵¹ This reduction can be done catalytically⁹⁵² and an

aluminum-free, Zr-zeolite catalyst has been developed.⁹⁵³ Microwave irradiation of a ketone with 2-propanol, KOH, and activated alumina gives good yields of the alcohol.⁹⁵⁴ When the carbonyl substrate has a stereogenic center, the reaction proceeds with good diastereoselectivity.⁹⁵⁵ The use of chiral metal complexes leads to chiral hydrogen transfer.⁹⁵⁶ A combination of 2-propanol with BINOL and AlMe₃ leads to reduction of α -chloroketones to the chlorohydrin with good enantioselectivity.⁹⁵⁷

The *Meerwein-Ponndorf-Verley reaction* usually⁹⁵⁸ involves a cyclic transition state:⁹⁵⁹

but in some cases 2 molar equivalents of aluminum alkoxide are involved: one attacking the carbon and the other the oxygen, a conclusion that stems from the finding that in these cases the reaction was 1.5 order in alkoxide.⁹⁶⁰ The alcohol solvent acts as a hydrogen donor in this reaction.⁹⁶¹ Although, for simplicity, the alkoxide is shown as a monomer, it actually exists as trimers and tetramers, which are the actual reactive species.⁹⁶² Note that supercritical 2-propanol has been used for reduction of ketones, without the need for a catalyst.⁹⁶³

5. *Boranes*. Borane (BH₃) and substituted boranes reduce aldehydes and ketones in a manner similar to their addition to C=C bonds (Reaction **15-16**).⁹⁶⁴ That is, the boron adds to the oxygen and the hydrogen to the carbon:⁹⁶⁵

The resulting borate is then hydrolyzed to the alcohol. A variety of alkylboranes can be used for reduction.⁹⁶⁶ Both 9-BBN⁹⁶⁷ (Reaction **15-16**) and $\text{BH}_3\text{—Me}_2\text{S}$ ⁹⁶⁸ reduce only the C=O group of conjugated aldehydes and ketones.⁹⁶⁹ Tributylborane in ionic solvents reduces aldehydes to alcohols.⁹⁷⁰ Enantioselective borane reductions lead to chiral alcohols.⁹⁷¹ Spiroborate esters have been used for enantioselective reduction,⁹⁷² and chiral boronic esters have also been used.⁹⁷³

Alane (AlH_3) derivatives can also be used, including diisobutylaluminum hydride.⁹⁷⁴

6. *Tin Hydrides*. Tributyltin hydride reduces aldehydes to primary alcohols by simply heating in methanol.⁹⁷⁵ A mixture of Bu_3SnH and phenylboronic acid (Reaction **12-28**) reduces aldehydes in dichloromethane.⁹⁷⁶ Reduction of ketones was achieved with Bu_2SnH_2 and a Pd catalyst.⁹⁷⁷ Using triaryl tin hydrides with $\text{BF}_3\cdot\text{OEt}_2$, where aryl is 2,6-diphenylbenzyl, selective reduction of aliphatic aldehydes in the presence of a conjugated aldehyde was achieved.⁹⁷⁸ Tris(trimethylsilyl)methane has been used as a tin-free radical reducing agent.⁹⁷⁹
7. *Cannizzaro Reaction*. In the Cannizzaro reaction (see **19-81**), aldehydes without an α hydrogen are reduced to alcohols.
8. *Silanes*. In the presence of bases, certain silanes can selectively reduce carbonyls.⁹⁸⁰ Transition metal complexes also catalyze hydrosilylation of ketones.⁹⁸¹ Controlling temperature and solvent leads to different ratios of *syn* and *anti* products.⁹⁸² Silanes reduce ketones in the presence of $\text{BF}_3\cdot\text{OEt}_2$.⁹⁸³ Ketones are reduced with Cl_3SiH in the presence of pyrrolidine carbaldehyde⁹⁸⁴ or under

photochemical conditions.⁹⁸⁵ Polymethylhydrosiloxane with tetrabutylammonium fluoride reduces α -amino ketones to give the syn amino alcohol.⁹⁸⁶

9. *Ammonium Formates.* Sodium formate and trialkylammonium formates can be used to reduce aldehydes and ketones to the corresponding alcohol. Decanal was reduced to decanol, for example, using sodium formate in *N*-methyl-2-pyrrolidinone as a solvent.⁹⁸⁷ A mixture of formic acid and ethyl magnesium bromide was used to reduce decanal to decanol in 70% yield.⁹⁸⁸ Transfer hydrogenation also occurs with formic acid–triethylamine and a Ru catalyst⁹⁸⁹ in water.⁹⁹⁰
10. *Enzymatic Reductions.* Successful asymmetric reductions (see Section A) have been achieved with biologically derived reducing agents⁹⁹¹ (e.g., baker's yeast),⁹⁹² enzymes from other organisms,⁹⁹³ or with other biocatalysts.⁹⁹⁴ Ionic liquids have been used in conjugation with enzymatic reduction,⁹⁹⁵ and enzymatic reduction has been done in supercritical CO₂.⁹⁹⁶

With most reagents there is an initial attack on the carbon of the carbonyl group by a hydride equivalent (H^-) although with BH_3 ,⁹⁹⁷ the initial attack is on the oxygen. Detailed mechanisms are not known in most cases.⁹⁹⁸ With $LiAlH_4$ or $NaBH_4$, the attacking species is the AlH_4^- (or BH_4^-) ion, which, in effect, transfers H^- to the carbon. The following mechanism has been proposed for $LiAlH_4$.⁹⁹⁹

Evidence that the cation plays an essential role, at least in some cases, is that when the Li^+ was effectively removed from LiAlH_4 (by the addition of a crown ether), the reaction did not take place.¹⁰⁰⁰ Complex **32** must be hydrolyzed to the alcohol. For NaBH_4 , the Na^+ does not seem to participate in the transition state, but kinetic evidence shows that an OR group from the solvent does participate and remains attached to B.¹⁰⁰¹

Free H^- cannot be the attacking entity in most reductions with boron or aluminum hydrides because the reactions are frequently sensitive to the size of the MH_4^- [or MR_mH_n^- or $\text{M}(\text{OR})_m\text{H}_n^-$ etc.].

The question of whether the initial complex in the LiAlH_4 reduction (**32**, or $\text{H}-\text{C}-\text{OAl}^-\text{H}_3 = \text{33}$) can reduce another carbonyl to give $(\text{H}-\text{C}-\text{O})_2\text{Al}^-\text{H}_2$, and so on has been controversial. It has been shown¹⁰⁰² that this is probably not the case but that, more likely, **33** disproportionates to $(\text{H}-\text{C}-\text{O})_4\text{Al}^-$ and AlH_4^- , which is the only attacking species. Disproportionation has also been reported in the NaBH_4 reaction.¹⁰⁰³

Aluminate (**33**) is essentially LiAlH_4 with one of the hydrogen atoms replaced by an alkoxy group (i.e., LiAlH_3OR). The fact that **33** and other alkoxy derivatives of LiAlH_4 are less reactive than LiAlH_4 itself has led to the use of such compounds as reducing agents that are less reactive and more selective than LiAlH_4 .¹⁰⁰⁴ An example is $\text{LiAlH}(\text{O}-t\text{-Bu})_3$ (Reactions **19-39–19-41**; see also, Table 19.5). As an example of chemoselectivity in this reaction it may be mentioned that $\text{LiAlH}(\text{O}-t\text{-Bu})_3$ has been used to reduce only the keto group in a molecule containing both keto and carboxylic ester groups.¹⁰⁰⁵ However, the use of such reagents is sometimes complicated by the disproportionation mentioned above, which may cause LiAlH_4 to be the active species, even if the reagent is an alkoxy derivative. Another highly selective reagent (reducing aldehydes and ketones, but not other functional groups), which does not disproportionate, is potassium triisopropoxyborohydride.¹⁰⁰⁶

For other reduction reactions of aldehydes and ketones, see **19-61**, **19-76**, and **19-81**.

A. Asymmetric Reduction

Unsymmetrical ketones are prochiral (Sec. 4.M); that is, reduction creates a new stereogenic center:

¹⁰⁰⁶ Brown, C.A.; Krishnamurthy, S.; Kim, S.C. *J. Chem. Soc. Chem. Commun.* **1973**, 391.

The relative effectiveness of various reagents for reduction of eight other types of ketone was determined, using several different reducing agents.¹⁰⁰⁷ The ketones examined included heterocyclic, aralkyl, β -keto esters, β -keto acids,¹⁰⁰⁸ and so on.⁹⁹¹ Much effort has been put into finding optically active reducing agents that will produce one enantiomer of the alcohol enantioselectively.¹⁰⁰⁹ Each reagent tends to show a specificity for certain types of ketones.¹⁰¹⁰ Good enantioselectivity is usually obtained with the proper reagent.¹⁰¹¹ Substituents that are remote to the carbonyl group can play a role in facial selectivity of the reduction.¹⁰¹² Asymmetric reduction has been accomplished using bio-reagents (e.g., enzymes, see item 10 above).

Asymmetric reduction with very high enantioselectivity has also been achieved with achiral reducing agents and optically active catalysts.¹⁰¹³ Homogeneous catalytic asymmetric hydrogenation leads to reduction of substrates with high enantioselectivity.¹⁰¹⁴ A typical chiral ligand is 2,2'-bis(diphenylphosphino)-1,1'-binaphthyl-ruthenium acetate (BINAP, **34**), used with a metal catalysts [e.g., Ru(OAc)₂],¹⁰¹⁵ β -Keto esters are reduced enantioselectively, for example.¹⁰¹⁶ A variety of chiral additives and/or ligands have been used with catalytic hydrogenation reactions. Many functional groups can be tolerated.¹⁰¹⁷ Asymmetric catalytic hydrogenation has been done in ionic liquids.¹⁰¹⁸

A second approach is reduction with BH_3 —THF or catecholborane,¹⁰¹⁹ using an oxazaborolidine (**35**, $\text{R} = \text{H}$, Me , or $n\text{-Bu}$; $\text{Ar} = \text{Ph}$ or $\beta\text{-naphthyl}$)¹⁰²⁰ or other chiral compounds¹⁰²¹ as a catalyst. Both a polymer-bound oxazaborolidine¹⁰²² and a dendritic chiral catalyst have been used in conjunction with borane,¹⁰²³ as well as other chiral additives can be used.¹⁰²⁴ Chiral sulfonamides have been used as additives.¹⁰²⁵

Lithium aluminum hydride in combination with a chiral diol¹⁰²⁶ or other chiral ligands¹⁰²⁷ leads to enantioselective reduction, often in the presence of a transition metal complex.¹⁰²⁸ Chiral additives have also been used with NaBH_4 .¹⁰²⁹ Examples include $\text{LiBH}_4/\text{NiCl}_2$ and a chiral amino alcohol,¹⁰³⁰ NaBH_4 with chiral Lewis acid complexes,¹⁰³¹ or $\text{NaBH}_4/\text{Me}_3\text{SiCl}$ and a chiral ligand.¹⁰³² A mixture of NaBH_4 and Me_3SiCl with a catalytic amount of a chiral, polymer-bound sulfonamide leads to asymmetric reduction.¹⁰³³

Enantioselective reduction is possible with the other methods mentioned above. Transition metal catalyzed asymmetric transfer hydrogenation is effective for the

preparation of chiral alcohols.¹⁰³⁴ Reduction with silanes and transition metal catalysts (e.g., Ru compounds) is also very effective.¹⁰³⁵ Chiral Ru catalysts have been used with triethylammonium formate for the enantioselective reduction.¹⁰³⁶ The transition metal catalyzed hydrosilylation of ketones gives chiral alcohols in the presence of suitable chiral ligands.¹⁰³⁷ Enantioselective reduction was observed with PhSiH₃ and Cu compounds with a chiral ligand,¹⁰³⁸ with a mixture of Ru and Ag catalysts,¹⁰³⁹ or with Mn(dpm)₃ and oxygen (dpm = diphenylmethylene).¹⁰⁴⁰ Enantioselective hydrosilylation is possible using chiral organocatalysts.¹⁰⁴¹ A chiral Sm complex has been used in conjunction with 2-propanol.¹⁰⁴² Chiral mercapto alcohols have also been used for asymmetric reduction.¹⁰⁴³

Enantioselective reduction is usually not possible for aldehydes,¹⁰⁴⁴ since the products are primary alcohols in which the reduced carbon is not chiral. Instead deuterated aldehydes (RCDO) give a chiral product, and these have been reduced enantioselectively with B-(3-pinanyl)-9-borabicyclo[3.3.1]nonane (Alpine-Borane) with almost complete optical purity.¹⁰⁴⁵ Other chiral boranes can be used to reduce aldehydes or ketones.¹⁰⁴⁶

In the above cases, an optically active reducing agent or catalyst interacts with a prochiral substrate. Asymmetric reduction of ketones has also been achieved with an achiral reducing agent, if the ketone is complexed to an optically active transition metal Lewis acid.¹⁰⁴⁷

There are other stereochemical aspects to the reduction of aldehydes and ketones. If there is a stereogenic center α to the carbonyl group,¹⁰⁴⁸ even an achiral reducing agent can give more of one diastereomer than of the other (a diastereoselective reduction). Such reductions have been carried out with considerable success.¹⁰⁴⁹ In most such cases, *Cram's rule* (Sec. 4.H., category 1) is followed, but exceptions are known.¹⁰⁵⁰

19-37 Reduction of Carboxylic Acids to Alcohols

Dihydro-de-oxo-bisubstitution

Carboxylic acids are easily reduced to primary alcohols by LiAlH_4 .¹⁰⁵¹ The conditions are particularly mild, the reduction proceeding quite well at room temperature. Other hydrides have also been used,¹⁰⁵² but not NaBH_4 (see Table 19.5).¹⁰⁵³ A combination of NaBH_4 and an arylboronic acid (Reaction 12-28) is also effective.¹⁰⁵⁴ A mixture of NaBH_4 , Me_2SO_4 , and $\text{B}(\text{OMe})_3$ is effective for the reduction of hydroxyl-substituted aromatic carboxylic acids.¹⁰⁵⁵ Benzyltriethylammonium borohydride in dichloromethane reduces carboxylic acids to the alcohol.¹⁰⁵⁶ Catalytic hydrogenation is generally ineffective.¹⁰⁵⁷

Borane (BH_3) is particularly good for carboxyl groups (Table 19.4) and permits selective reduction of them in the presence of many other groups (although the reaction with double bonds takes place at about the same rate in ether solvents).¹⁰⁵⁸ For many years, borane was the reagent of choice for this reduction. Borane also reduces carboxylic acid salts.¹⁰⁵⁹ Aluminum hydride reduces COOH groups without affecting carbon-halogen bonds in the same molecule. The reduction has also been carried out with SmI_2 in basic media¹⁰⁶⁰ or aq H_3PO_4 ,¹⁰⁶¹ or simply with SmI_2 in water.¹⁰⁶² A mixture of NaBH_4 and I_2 has been used to reduce amino acids to amino alcohols.¹⁰⁶³

19-38 Reduction of Carboxylic Esters to Alcohols

Dihydro,hydroxy-de-oxo,alkoxy-tersubstitution

Lithium aluminum hydride reduces carboxylic esters to give two different alcohols, as shown.¹⁰⁶⁴ The reaction is of wide scope and has been used to reduce many esters. Where the interest is in obtaining R'OH, this is a method that is often a working equivalent of "hydrolyzing" esters. Reduction of lactones yields diols.¹⁰⁶⁵ Among the reagents used for this reduction¹⁰⁶⁶ are Dibal-H, lithium triethylborohydride, LiAlH(Ot-Bu)₃,¹⁰⁶⁷ and BH₃—SMe₂ in refluxing THF.¹⁰⁶⁸ Although NaBH₄ reduces phenolic esters, especially those containing electron-withdrawing groups,¹⁰⁶⁹ its reaction with other esters is usually so slow that it is not the reagent of choice, but there are many exceptions.¹⁰⁷⁰ However, it is generally possible to reduce an aldehyde or ketone without reducing an ester function in the same molecule. Note that NaBH₄ reduces esters in the presence of certain compounds (see Table 19.5).¹⁰⁷¹ Note that NaBH₄ in DMF—MeOH reduces aryl carboxylic esters to benzylic alcohols,¹⁰⁷² and NaBH₄—LiCl with microwave irradiation also reduces esters to primary alcohols.¹⁰⁷³

Carboxylic esters can also be reduced to alcohols by hydrogenation over copper chromite catalysts,¹⁰⁷⁴ although high pressures and temperatures are required. Ester functions generally survive low-pressure catalytic hydrogenations, but homogeneous catalytic hydrogenation procedures have been developed.¹⁰⁷⁵ Before the discovery of LiAlH₄, the most common way of carrying out the reaction was with sodium in ethanol, a method known as the *Bouveault–Blanc procedure*.¹⁰⁷⁶ This procedure is still sometimes used where selectivity is necessary (see also, Reactions **19-62**, **19-65**, and **19-59**).

19-39 Reduction of Acyl Halides

Hydro-de-halogenation or Dehalogenation

Acyl halides can be reduced to aldehydes¹⁰⁷⁹ by treatment with lithium tri-*tert*-butoxyaluminum hydride in diglyme at -78°C .¹⁰⁸⁰ The R group may be alkyl or aryl and may contain many types of substituents, including NO_2 , CN, and EtOOC groups. The reaction stops at the aldehyde stage because steric hindrance prevents further reduction with this reagent. Acyl halides can also be reduced to aldehydes by hydrogenolysis with Pd on barium sulfate as catalyst in what is called the *Rosenmund reduction*.¹⁰⁸¹ A convenient hydrogenolysis procedure involves Pd on charcoal as the catalyst, with ethyldiisopropylamine as acceptor of the liberated HCl and acetone as the solvent.¹⁰⁸² The reduction of acyl halides to aldehydes has also been carried out¹⁰⁸³ with Bu_3SnH ,¹⁰⁸⁴ an InCl_3 catalyzed reaction using Bu_3SnH ,¹⁰⁸⁵ NaBH_4 in a mixture of DMF and THF,¹⁰⁸⁶ with $\text{Sm}-\text{PBU}_3$,¹⁰⁸⁷ and with formic acid/ NH_4OH .¹⁰⁸⁸ Polymethylhydrosiloxane (PMHS) reduces acid chlorides to aldehydes in the presence of a Pd catalyst.¹⁰⁸⁹ In some of these cases, the mechanisms are free radical.

There are several indirect methods for the conversion of acyl halides to aldehydes, most of them involving prior conversion of the halides to certain types of amides (see Reaction **19-41**). There is also a method in which the COOH group is replaced by a completely different CHO group (Reaction **16-87**).

19-40 Reduction of Carboxylic Acids, Esters, and Anhydrides to Aldehydes¹⁰⁹⁰**Hydro-de-hydroxylation or Dehydroxylation** (overall transformation)

With most reducing agents, reduction of carboxylic acids generally gives the primary alcohol (Reaction **19-37**) and the isolation of aldehydes is not feasible. However, simple straight-chain carboxylic acids have been reduced to aldehydes¹⁰⁹¹ by treatment with Li in MeNH₂ or NH₃ followed by hydrolysis of the resulting imine,¹⁰⁹² with

with thexylchloro(or bromo)borane-SMe₂¹⁰⁹³ (see Reaction **15-16** for the thexyl group), Me₂N=CHCl⁺ Cl⁻ in pyridine,¹⁰⁹⁴ and with diaminoaluminum hydrides.¹⁰⁹⁵ Benzoic acid derivatives were reduced to benzaldehyde derivatives with NaH₂PO₂ and a diacylperoxide and Pd catalyst.¹⁰⁹⁶ Caproic and isovaleric acids have been reduced to aldehydes in 50% yields or better with Dibal-H (*i*-Bu₂AlH) at -75 to -70 °C.¹⁰⁹⁷

Carboxylic esters have been reduced to aldehydes with Dibal-H at -70 °C, with diaminoaluminum hydrides,¹⁰⁹⁸ and for phenolic esters with LiAlH(*Ot*-Bu)₃ at 0 °C.¹⁰⁹⁹ Pretreatment of the acid with Me₃SiCl followed by reduction with Dibal-H also gives the aldehyde.¹¹⁰⁰ Aldehydes have also been prepared by reducing ethyl thiol esters (RCOSEt) with Et₃SiH and a Pd-C catalyst.¹¹⁰¹ Thioesters have been reduced to the aldehyde with Li metal in THF at -78 °C, followed by quenching with methanol.¹¹⁰²

Anhydrides, both aliphatic and aromatic, as well as mixed anhydrides of carboxylic and carbonic acids, have been reduced to aldehydes in moderate yields with disodium tetracarbonylferrate [Na₂Fe(CO)₄].¹¹⁰³ Heating a carboxylic acid, presumably to form the anhydride, and then reaction with Na/EtOH leads to the aldehyde.¹¹⁰⁴

Acid chlorides are reduced to aldehydes with Bu₃SnH and a Ni catalyst.¹¹⁰⁵

19-41 Reduction of Amides to Aldehydes

Hydro-de-dialkylamino-substitution

N,N-Disubstituted amides can be reduced to amines with LiAlH_4 (see Reaction **19-64**), but reduction to an aldehyde is possible.¹¹⁰⁶ Keeping the amide in excess gives the aldehyde rather than the amine. Sometimes it is not possible to prevent further reduction and primary alcohols are obtained instead. Other reagents¹¹⁰⁷ that give good yields of aldehydes are Dibal-H,¹¹⁰⁸ $\text{LiAlH}(\text{O}i\text{-Bu})_3$, diaminoaluminum hydrides,¹¹⁰⁹ disiamylborane (see Reaction **15-16** for the disiamyl group),¹¹¹⁰ and $\text{Cp}_2\text{Zr}(\text{H})\text{Cl}$.¹¹¹¹

Aldehydes have been prepared from carboxylic acids or acyl halides by first converting them to certain types of amides that are easily reducible. There are several examples:¹¹¹²

1. *Reissert Compounds*.¹¹¹³ Compounds, such as **36**, are prepared from the acyl halide by treatment with quinoline and cyanide ion. Treatment of **36** with sulfuric acid gives the corresponding aldehyde.

2. *Acyl Sulfonylhydrazides*. Compounds, such as **37**, are cleaved with base to give aldehydes. This reaction is known as the *McFadyen-Stevens reduction* and is applicable *only* to aromatic aldehydes or aliphatic aldehydes with no α hydrogen.¹¹¹⁴ Acyl imide ($\text{RCON}=\text{NH}$, see reaction **19-67**) has been proposed as an intermediate in this reaction.¹¹¹⁵
3. *Acyl Imidazoles*. Compounds **38**¹¹¹⁶ can be reduced to aldehydes with LiAlH_4 .

C. Attack at Non-Carbonyl Multiple Bonded Heteroatoms

19-42 Reduction of the Carbon–Nitrogen Double Bond (C=N)

C,N-Dihydro-addition

Imines and *Schiff bases*,¹¹¹⁹ hydrazones,¹¹²⁰ and other C=N compounds can be reduced with LiAlH_4 , NaBH_4 ,¹¹²¹ $\text{Na}-\text{EtOH}$, hydrogen and a catalyst, as well as with other reducing agents.¹¹²² Metal-free catalytic hydrogenation is known.¹¹²³ Transfer hydrogenation of imines leads to amines.¹¹²⁴ A mixture of Sm/I_2 ¹¹²⁵ or $\text{In}/\text{NH}_4\text{Cl}$ ¹¹²⁶ also reduces imines. Reduction with Bu_2SnClH in HMPA has been shown to be chemoselective for imines.¹¹²⁷ Iminium salts are reduced by LiAlH_4 to the corresponding amine, although here there is no “addition” to the nitrogen.¹¹²⁸ Silanes¹¹²⁹ with a triarylborane catalyst reduces *N*-sulfonyl imines¹¹³⁰ as does TiI_4 .¹¹³¹ Imines are reduced with samarium bromide in HMPA,¹¹³² 2-propanol with a Ru catalyst,¹¹³³ and with triethylammonium formate with microwave irradiation.¹¹³⁴ Oximes are reduced with hydrogen gas and a catalytic amount of 48% HBr .¹¹³⁵

Oximes are generally reduced to amines (Reaction 19-48),¹¹³⁶ but simple reduction to give hydroxylamines can be accomplished with borane¹¹³⁷ or sodium cyanoborohydride.¹¹³⁸ Oxime *O*-ethers are reduced with Bu₃SnH and BF₃·OEt₂.¹¹³⁹ Diazo compounds (ArN=NAr) are reductively cleaved to aniline derivatives with Zn and ammonium formate in methanol.¹¹⁴⁰

Reduction of imines has been carried out enantioselectively.¹¹⁴¹ Catalytic hydrogenation¹¹⁴² with a chiral Ir¹¹⁴³, Re,¹¹⁴⁴ Rh,¹¹⁴⁵ or Pd¹¹⁴⁶ catalyst is effective. Catalytic hydrogenation of iminium salts with a chiral Ru catalyst gives the amine.¹¹⁴⁷ Enantioselective reduction of imines is possible using a mixture of *Escherichia coli* whole cells and H₃N·BH₃.¹¹⁴⁸ *Hantzsch ester* (see Reactions 15-14 and 16-17) reduction of imine-esters, in the presence of a chiral phosphoric acid derivative, leads to chiral amino esters.¹¹⁴⁹ In a related reaction, enamines were reduced by hydrogenation over a chiral Rh catalyst.¹¹⁵⁰

Hydrogenation of oximes with Pd/C and a Ni complex gives the imine, and in the presence of a lipase and ethyl acetate the final product was an acetamide, formed with high enantioselectivity.¹¹⁵¹ Catalytic-transfer hydrogenation of imines leads with a chiral catalyst to chiral amines.¹¹⁵² Conjugated *N*-sulfonyl imines are reduced to the conjugated sulfonamide with good enantioselectivity using a chiral rhodium catalyst in the presence of LiF and PhSnMe₃.¹¹⁵³ Phosphinyl imines, R₂C=N—P(=O)Ar₂, are reduced with high enantioselectivity using a chiral Cu catalyst.¹¹⁵⁴ Silanes (e.g., PhSiH₃) can be used for the reduction of imines, and in the presence of a chiral Ti catalyst the resulting amine was formed with excellent enantioselectivity.¹¹⁵⁵ The enantioselective reduction of aromatic imines is possible using trichlorosilane.¹¹⁵⁶ Enzymatic reduction of imines leads to chiral amines.¹¹⁵⁷

19-43 The Reduction of Nitriles to Amines

CC,NN-Tetrahydro-biaddition

Nitriles can be reduced to primary amines with many reducing agents,¹¹⁶¹ including LiAlH_4 , and $\text{BH}_3\cdot\text{SMe}_2$.¹¹⁶² The reagent NaBH_4 does not generally reduce nitriles except in alcoholic solvents with a catalyst (e.g., CoCl_2 ,¹¹⁶³ NiCl_2 ,¹¹⁶⁴ or Raney nickel).¹¹⁶⁵ Lithium dimethylaminoborohydride ($\text{LiBH}_3\text{NMe}_2$) reduces aryl nitriles to the corresponding benzylamines.¹¹⁶⁶

The reduction of nitriles is of wide scope and has been applied to many nitriles. Catalytic hydrogenation converts nitriles to primary amines,¹¹⁶⁷ but secondary amines $[(\text{RCH}_2)_2\text{NH}]$ are often side products.¹¹⁶⁸ These can be avoided by adding a compound (e.g., acetic anhydride), which removes the primary amine as soon as it is formed,¹¹⁶⁹ or by the use of excess ammonia to drive the equilibria backward.¹¹⁷⁰ Sponge nickel¹¹⁷¹ or nickel on silica gel¹¹⁷² have been used for the catalytic hydrogenation of aryl nitriles to amines.

Attempts to stop with the addition with only 1 equiv of hydrogen, have failed; that is, to convert the nitrile to an imine, except where the imine is subsequently hydrolyzed (Reaction **19-44**).

N-Alkyltrinitilium ions are reduced to secondary amines by NaBH₄.¹¹⁷³

Since nitrilium salts can be prepared by treatment of nitriles with trialkyloxonium salts (see Reaction 16-8), this is a method for the conversion of nitriles to secondary amines.

Note that the related compounds, the isocyanides (R—N⁺≡CO[−], also called isocyanides) have been reduced to *N*-methyamines with LiAlH₄, as well as with other reducing agents.

OS III, 229, 358, 720; VI, 223.

19-44 The Reduction of Nitriles to Aldehydes

Hydro,oxy-de-nitrilo-tersubstitution

There are two principal methods for the reduction of nitriles to aldehydes.¹¹⁷⁴ In one of these, known as the *Stephen reduction*, the nitrile is treated with HCl to form an iminium salt (40). Subsequent reduction of (40) with anhydrous SnCl₂ gives RCH=NH, which precipitates as a complex with SnCl₄ and is then hydrolyzed (Reaction 16-2) to the aldehyde. The *Stephen reduction* is most successful when R is aromatic, but it can be done for aliphatic R up to about six carbons.¹¹⁷⁵ It is also possible to prepare 40 in a different way, by treating ArCONHPh with PCl₅, which can then be converted to the aldehyde. This is known as the *Sonn-Müller method*. Aqueous formic acid in the presence of PtO₂, followed by treatment with aqueous acid converts aryl nitriles to aryl aldehydes.¹¹⁷⁶

The other way of reducing nitriles to aldehydes involves using a metal hydride reducing agent to add 1 molar equivalent of hydrogen and subsequent hydrolysis, *in situ*, of the resulting imine (which is undoubtedly coordinated to the metal). This reaction has been carried out with LiAlH₄, LiAlH(OEt)₃,¹¹⁷⁷ LiAlH(NR₂)₃,¹¹⁷⁸ and Dibal-H.¹¹⁷⁹ The metal hydride method is useful for aliphatic and aromatic nitriles.

19-45 Reduction of Nitro Compounds to Amines

Both aliphatic¹¹⁸⁰ and aromatic nitro compounds can be reduced to amines, although the reaction has been applied much more often to aromatic nitro compounds, owing to their greater availability. Many reducing agents have been used to reduce aromatic nitro compounds, the most common being Zn, Sn, or Fe (or sometimes other metals) and acid, and catalytic hydrogenation.¹¹⁸¹ Chemoselective catalytic hydrogenation of nitro compounds is possible.¹¹⁸² Transfer hydrogenation is used to reduce nitro compounds.¹¹⁸³ Indium metal in aq ethanol with ammonium chloride¹¹⁸⁴ or with water in aq THF¹¹⁸⁵ also reduces aromatic nitro compounds to the corresponding aniline derivative. Indium metal in methanol, with acetic anhydride and acetic acid, converts aromatic nitro compounds to the acetanilide.¹¹⁸⁶ Both samarium metal in methanol with ultrasound,¹¹⁸⁷ and a mixture of SmI₂–water and an amine reduce nitro compounds.¹¹⁸⁸ Alternative reduction methods use ultrasound with Al(Hg) in aq THF¹¹⁸⁹ or with stannous chloride in an ionic liquid.¹¹⁹⁰ Some other reagents used¹¹⁹¹ were Et₃SiH/RhCl(PPh)₃,¹¹⁹² AlH₃–AlCl₃, formic acid and Pd–C,¹¹⁹³ or formic acid with Raney nickel in methanol.¹¹⁹⁴ The reaction with sulfides or polysulfides is called the *Zinin reduction*.¹¹⁹⁵ Amines are also the products when nitro compounds, both alkyl and aryl, are reduced with HCOONH₄–Pd–C.¹¹⁹⁶ Many other functional groups (e.g., COOH, COOR, CN, amide) are not affected by this reagent (although ketones are reduced, see Reaction 19-33). With optically active alkyl substrates this method gives retention of configuration.¹¹⁹⁷

Lithium aluminum hydride reduces aliphatic nitro compounds to amines, but with aromatic nitro compounds the products with this reagent are azo compounds (Reaction **19-80**). Most metal hydrides, including NaBH_4 and BH_3 , do not reduce nitro groups at all, although both aliphatic and aromatic nitro compounds have been reduced to amines with NaBH_4 and various catalysts (e.g., NiCl_2 or CoCl_2 ¹¹⁹⁸ and ZrCl_4).¹¹⁹⁹ Borohydride exchange resin (BER) in the presence of $\text{Ni}(\text{OAc})_2$, however, gives the amine.¹²⁰⁰ Treatment of aromatic nitro compounds with NaBH_4 alone has resulted in reduction of the *ring* to a cyclohexane ring with the nitro group still intact¹²⁰¹ or in cleavage of the nitro group from the ring.¹²⁰² With $(\text{NH}_4)_2\text{S}$ or other sulfides or polysulfides it is often possible to reduce just one of two or three nitro groups on an aromatic ring or on two different rings in one molecule.¹²⁰³ Bakers yeast reduces aromatic nitro compounds to aniline derivatives.¹²⁰⁴ A combination of $\text{NaH}_2\text{PO}_2/\text{FeSO}_4$ with microwave irradiation reduces aromatic nitro compounds to aniline derivatives.¹²⁰⁵ Hydrazine on alumina, with FeCl_3 and microwave irradiation, accomplishes this reduction.¹²⁰⁶ Hydrazine–formic acid with Raney nickel in methanol reduces aromatic nitro compounds.¹²⁰⁷ Heating aromatic nitro compounds with 57% HI reduces the nitro group to the amino group.¹²⁰⁸

With some reducing agents, especially with aromatic nitro compounds, the reduction can be stopped at an intermediate stage, and hydroxylamines (Reaction **19-46**), hydrazobenzenes, azobenzenes (Reaction **19-80**), and azoxybenzenes (Reaction **19-79**) can be obtained in this manner. However, nitroso compounds, which are often postulated as intermediates, are too reactive to be isolated, if indeed they are intermediates. Reduction by metals in mineral acids cannot be stopped, but always produces the amine.

The mechanisms of these reductions have not been much studied, although it is usually presumed that, at least with some reducing agents, nitroso compounds and hydroxylamines are intermediates. Both of these types of compounds give amines when exposed to most of these reducing agents (Reaction **19-47**), and hydroxylamines can be isolated (Reaction **19-46**). With metals and acid the following path has been suggested¹²⁰⁹:

Certain aromatic nitroso compounds (Ar—NO) can be obtained in good yields by irradiation of the corresponding nitro compounds in 0.1 M aq KCN with UV light.¹²¹⁰ The reaction has also been performed electrochemically.¹²¹¹ When nitro compounds are treated with most reducing agents, nitroso compounds are either not formed or react further under the reaction conditions and cannot be isolated.

Reductive alkylation of aromatic nitro compounds is possible. The reaction of nitrobenzene with allylic or benzyl halides in the presence of an excess of tin metal in methanol, leads to the *N,N*-diallyl or dibenzyl aniline.¹²¹² A similar reaction occurs with nitrobenzene, allyl bromide, and In metal in aq acetonitrile.¹²¹³

19-46 Reduction of Nitro Compounds to Hydroxylamines

When aromatic nitro compounds are reduced with zinc and water under neutral conditions,¹²¹⁴ hydroxylamines are formed. Among other reagents used for this purpose have been SmI₂,¹²¹⁵ N₂H₄—Rh—C,¹²¹⁶ and KBH₄/BiCl₃.¹²¹⁷ Borane in THF reduces aliphatic nitro enolate anions to hydroxylamines¹²¹⁸:

Nitro compounds have been reduced electrochemically, to hydroxylamines, as well as to other products.¹²¹⁹

N-Hydro-de-hydroxylation or N-Dehydroxylation

Nitroso compounds and hydroxylamines can be reduced to amines by the same reagents that reduce nitro compounds (Reaction 19-45). Reaction with CuCl, and then phenylboronic acid (Reaction 12-28), also reduces nitroso compounds to the amine.¹²²⁰ A hydroxylamine can be reduced to the amine with CS₂ in acetonitrile.¹²²¹ Indium metal in EtOH/aq NH₄Cl reduces hydroxylamines to the amine.¹²²² *N*-Nitroso compounds are similarly reduced to hydrazines (R₂N—NO → R₂N—NH₂).¹²²³

19-48 Reduction of Oximes to Primary Amines or Aziridines

Both aldoximes and ketoximes can be reduced to primary amines with LiAlH₄. The reaction is slower than similar reduction of ketones, so that, for example, PhCOCH=NOH gave 34% PhCHOHCH=NOH.¹²²⁴ Among other reducing agents that give this reduction¹²²⁵ are zinc and acetic acid, BH₃,¹²²⁶ NaBH₃CN—TiCl₃,¹²²⁷ PMHS with Pd-C,¹²²⁸ and sodium and an alcohol.¹²²⁹ Catalytic hydrogenation is also effective.¹²³⁰ Reduction of oximes with In metal in acetic anhydride/acetic acid–THF leads to the acetamide.¹²³¹

The reduction has been performed enantioselectively with Baker's yeast¹²³² and with Ph₂SiH₂ and an optically active Rh complex catalyst.¹²³³ Oxime *O*-ethers are reduced to the amine with modest enantioselectivity using a chiral boron compound.¹²³⁴

When the reducing agent is Dibal-H, the product is a secondary amine, arising from a rearrangement¹²³⁵:

With certain oximes (e.g., those of the type $\text{ArCH}_2\text{CR}=\text{NOH}$), treatment with LiAlH_4 gives aziridines,¹²³⁶ for example,

Hydrazones, arylhydrazones, and semicarbazones can also be reduced to amines with various reducing agents, including $\text{Zn}-\text{HCl}$ and H_2 and Raney nickel.

Oximes have been reduced in a different way, to give imines ($\text{RR}'\text{C}=\text{NOH} \rightarrow \text{RR}'\text{C}=\text{NH}$), which are generally unstable, but which can be trapped to give useful products. Among reagents used for this purpose have been $\text{Bu}_3\text{P}-\text{SPh}_2$ ¹²³⁷ and $\text{Ru}_3(\text{CO})_{12}$.¹²³⁸ Oximes can also be reduced to hydroxylamines (Reaction 19-42). Nitrones have been reduced to imines using $\text{AlCl}_3 \cdot 6 \text{H}_2\text{O}/\text{KI}$ followed by $\text{Na}_2\text{S}_2\text{O}_3-\text{H}_2\text{O}$.¹²³⁹

OS II, 318; III, 513; V, 32, 83, 373, 376.

19-49 Reduction of Aliphatic Nitro Compounds to Oximes or Nitriles

Nitro compounds that contain an α hydrogen can be reduced to oximes with zinc dust in acetic acid¹²⁴⁰ or with other reagents, among them CS_2-NEt_3 ,¹²⁴¹ CrCl_2 ,¹²⁴² and (for α -nitro sulfones) NaNO_2 .¹²⁴³ α -Nitro alkenes have been converted to oximes ($-\text{C}=\text{C}-\text{NO}_2 \rightarrow -\text{CH}-\text{C}=\text{NOH}$) with sodium hypophosphite, In with aq. $\text{NH}_4\text{Cl}/\text{MeOH}$,¹²⁴⁴ and with $\text{Pb}-\text{HOAc}-\text{DMF}$, as well as with certain other reagents.¹²⁴⁵

Primary aliphatic nitro compounds can be reduced to aliphatic nitriles with $t\text{-BuN}\equiv\text{C}/\text{BuN}=\text{C}=\text{O}$.¹²⁴⁶ Secondary compounds give mostly ketones (e.g., nitrocyclohexane gave 45% cyclohexanone, 30% cyclohexanone oxime, and 19% *N*-cyclohexylhydroxylamine). Tertiary aliphatic nitro compounds do not react with this reagent (see also, Reaction 19-45).

OS IV, 932.

19-50 Reduction of Azides to Primary Amines

N-Dihydro-de-diazo-bisubstitution

Azides are easily reduced to primary amines by LiAlH_4 , as well as by a number of other reducing agents,¹²⁴⁷ including NaBH_4 , $\text{NaBH}_4/\text{LiCl}$,¹²⁴⁸ $\text{NaBH}_4/\text{CoCl}_2/\text{H}_2\text{O}$,¹²⁴⁹ $\text{NaBH}_4/\text{ZrCl}_4$,¹²⁵⁰ H_2 and a catalyst, Mg or Ca in MeOH,¹²⁵¹ Sm/NiCl_2 ,¹²⁵² Sm/I_2 ,¹²⁵³ CeCl_3 ,¹²⁵⁴ $\text{Zn}/\text{NH}_4\text{Cl}/\text{aq EtOH}$,¹²⁵⁵ baker's yeast,¹²⁵⁶ and In metal in EtOH.¹²⁵⁷ Triethylsilane has been used for the radical reduction of azides to amines.¹²⁵⁸

Reaction with PPh_3 leads to a phosphazide ($\text{Ph}_3\text{P}=\text{N}-\text{N}=\text{N}-\text{R}$), which loses nitrogen in what is called the *Staudinger reaction*¹²⁵⁹: a method to prepare phosphazo compounds, but in this case leads to reduction. Alkylation is possible, and the reaction of an alkyl azide with PMe_3 , and then an excess of iodomethane, leads to the *N*-methylated amine.¹²⁶⁰ The reaction is diastereoselective.¹²⁶¹ Chiral *N*-heterocyclic carbenes catalyze the *Staudinger reaction* of ketenes with imines to form β -lactam derivatives.¹²⁶² This reaction, combined with $\text{RX} \rightarrow \text{RN}_3$ (10-43), is an important way of converting alkyl halides (RX) to primary amines (RNH_2); in some cases the two procedures have been

combined into one laboratory step.¹²⁶³ Sulfonyl azides (RSO_2N_3) have been reduced to sulfonamides (RSO_2NH_2) by irradiation in isopropyl alcohol¹²⁶⁴ and with NaH .¹²⁶⁵
OS V, 586; VII, 433.

19-51 Reduction of Miscellaneous Nitrogen Compounds

Isocyanate-methylamine transformation

Isothiocyanate-methylamine transformation

N,N-Dihydro-addition

Diazonium-arylhydrazone reduction

N-Hydro-de-nitroso-substitution

Isocyanates and isothiocyanates are reduced to methylamines on treatment with LiAlH_4 . Azo compounds are not usually reduced by LiAlH_4 ,¹²⁶⁶ (indeed these are the products from LiAlH_4 reduction of nitro compounds, Reaction 19-80), but they can be reduced to hydrazo compounds by catalytic hydrogenation or with diimide¹²⁶⁷ (see Reaction 15-11). Diazonium salts are reduced to hydrazines by sodium sulfite. This reaction probably has a nucleophilic mechanism.¹²⁶⁸ The initial product is a salt of hydrazinesulfonic acid, which is converted to the hydrazine by acid treatment. Diazonium salts can also be reduced to arenes (Reaction 19-69). *N*-Nitrosoamines can be denitrosated to secondary amines by a number of reducing agents, including H_2 and a catalyst,¹²⁶⁹ $\text{BF}_3\text{--THF--NaHCO}_3$,¹²⁷⁰ and $\text{NaBH}_4\text{--TiCl}_4$,¹²⁷¹ as well as by hydrolysis.¹²⁷²

¹²⁶³ See Koziara, A.; Osowska-Pacewicz, K.; Zawadzki, S.; Zwierzak, A. **1987**, 487. The Reactions **10-48**, **10-43**, and **19-50** have also been accomplished in one laboratory step: Koziara, A. *J. Chem. Res. (S)* **1989**, 296.

A cyano group can be reduced to a methyl group by treatment with a terpene (e.g., limonene), which acts as reducing agent in the presence of Pd-charcoal.¹²⁷³ Hydrogen gas (H_2) is also effective,¹²⁷⁴ although higher temperatures are required. The R group may be alkyl or aryl.

Aryl nitro compounds are reduced to diaryl hydrazines with Al-KOH in methanol.¹²⁷⁵ OS I, 442; III, 475. Also see, OS V, 43.

D. Reactions in which a Heteroatom Is Removed from the Substrate

19-52 Reduction of Silanes to Methylene Compounds

Si-Hydrogen-uncoupling

In certain cases, the C-Si bond of silanes can be converted to C-H. α -Silyl esters are reduced to esters with mercuric acetate and tetrabutylammonium fluoride, for example.¹²⁷⁶

19-53 Reduction of Alkyl Halides

Hydro-de-halogenation or Dehalogenation

This type of reduction can be accomplished with many reducing agents.¹²⁷⁷ A powerful but highly useful reagent (LiAlH_4)¹²⁷⁸ reduces almost all types of alkyl halide, including vinylic, bridgehead, and cyclopropyl halides.¹²⁷⁹ Reduction with lithium aluminum deuteride serves to introduce deuterium into organic compounds. An even more powerful reducing agent, lithium triethylborohydride (LiEt_3BH ; Super hydride), rapidly reduces primary, secondary, allylic, benzylic, and neopentyl halides, but not tertiary (these give elimination) or aryl halides.¹²⁸⁰ A complex formed from lithium trimethoxyaluminum hydride [$\text{LiAlH}(\text{OMe})_3$] and CuI is another powerful reagent, which reduces primary, secondary, tertiary, allylic, vinylic, aryl, and neopentyl halides.¹²⁸¹ Sodium borohydride (NaBH_4) is a milder reducing agent that reduces primary, secondary, and some tertiary¹²⁸²

halides in good yield, in a dipolar aprotic solvent (e.g., Me₂SO, DMF, or sulfolane)¹²⁸³ at room temperature or above without affecting other functional groups that would be reduced by LiAlH₄ (e.g., CO₂H, CO₂R, CN).¹²⁸⁴ A mixture of NaBH₄ and InCl₃ efficiently reduces secondary bromides.¹²⁸⁵ Borohydride exchange resin is also an effective reducing agent in the presence of metal catalysts [e.g., Ni(OAc)₂].¹²⁸⁶

Other reducing agents¹²⁸⁷ include Zn (with acid or base), SnCl₂, and Et₃SiH in the presence of an AlCl₃,¹²⁸⁸ and also an Ir¹²⁸⁹ or In¹²⁹⁰ catalyst. Diethyl phosphonate–Et₃N,¹²⁹¹ phosphorus tris(dimethylamide) [(Me₂N)₃P],¹²⁹² and organotin hydrides (R_nSnH_{4-n})¹²⁹³ (chiefly Bu₃SnH) usually used in conjunction with a radical-initiator (e.g., AIBN),¹²⁹⁴ or with transition metal salts (e.g., InCl₃).¹²⁹⁵ A water-soluble organotin hydride has been developed [(MeOCH₂CH₂OCH₂CH₂CH₂)₃SnH], which reduces alkyl halides.¹²⁹⁶ Raney nickel in 2-propanol reduces primary iodides in the presence of a lactone moiety.¹²⁹⁷ Aluminum amalgam efficiently reduced an iodohydrin to the alcohol.¹²⁹⁸

Reduction, especially of bromides and iodides, can also be effected by catalytic hydrogenation.¹²⁹⁹ Raney nickel by itself can reduce alkyl halides.¹³⁰⁰ Homogeneous, chiral transition metal complexes can be used for the asymmetric hydrogenation of halides.¹³⁰¹

Alkali metals (e.g., Li¹³⁰² or Na¹³⁰³ in *t*-BuOH or THF) are good reducing agents for the removal of all halogen atoms in a polyhalo compound (including vinylic, allylic, geminal, and even bridgehead halogens). Zinc and ammonium chloride in alcohol facilitates

dehalogenation with microwave irradiation.¹³⁰⁴ Nickel boride facilitates debromination.¹³⁰⁵ Propargylic halides can often be reduced with allylic rearrangement to give allenes.¹³⁰⁶

The choice of a reducing agent usually depends on what other functional groups are present since each reducing agent reduces certain groups and not others. This type of selectivity is called *chemoselectivity*. A chemoselective reagent is one that reacts with one functional group (e.g., halide), but not another (e.g., C=O). For example, there are several reagents that reduce only the halogen of α -halo ketones, leaving the carbonyl group intact.¹³⁰⁷ Among them are decaborane with 10% Pd/C,¹³⁰⁸ Bi in aq THF¹³⁰⁹ or In metal in water,¹³¹⁰ and *i*-Bu₂AlH–SnCl₂.¹³¹¹ Ionic liquids promote the selective debromination of α -bromo ketones.¹³¹² Debromination is also induced by indium metal in a carboxylic acid.¹³¹³ In a similar chemoselective reaction, the halogen in α -haloimines has been reduced with SnCl₂/MeOH without reducing the C=N bond.¹³¹⁴

Tertiary alkyl, benzylic, and allylic halides are reduced by NaBH₃CN–SnCl₂¹³¹⁵, but do not react with primary or secondary alkyl or aryl halides. Sodium cyanoborohydride (NaBH₃CN) in HMPA is another highly selective reagent, in this case for primary and secondary iodo and bromo groups.¹³¹⁶ Most of the reducing agents mentioned reduce chlorides, bromides, and iodides, but organotin hydrides also reduce fluorides.¹³¹⁷ See Section 19.B.ii-A for a discussion of selectivity in reduction reactions.

Alkyl halides, including fluorides and polyhalides, can be reduced with Mg and a secondary or tertiary alcohol (most often 2-propanol).¹³¹⁸ This is actually an example of the occurrence in one step of the sequence:

More often the process is carried out in two separate steps (Reactions 12-36 and 12-22).

Vinyl halides can be reduced to the corresponding alkene in some cases.¹³¹⁹ When vinyl dibromides (e.g., $\text{RCH}=\text{CBr}_2$) are treated with $(\text{MeO})_2\text{P}(=\text{O})\text{H}$ and triethylamine, for example, the product is the vinyl bromide ($\text{RCH}=\text{HBr}$).¹³²⁰ Indium metal in ethanol accomplishes the same transformation.¹³²¹ Similar reduction occurs when vinyl diiodides are treated with $\text{Zn}-\text{Cu}$ in acetic acid.¹³²²

With LiAlH_4 and most other metallic hydrides, the mechanism usually consists of simple nucleophilic substitution with attack by hydride ion equivalents. The mechanism is $\text{S}_{\text{N}}2$ rather than $\text{S}_{\text{N}}1$, since primary halides react better than secondary or tertiary (tertiary generally give alkenes or do not react at all) and since *Walden inversion* has been demonstrated. However, rearrangements found in the reduction of bicyclic tosylates with LiAlH_4 indicate that the $\text{S}_{\text{N}}1$ mechanism can take place.¹³²³ There is evidence that LiAlH_4 and other metal hydrides can also reduce halides by an SET mechanism,¹³²⁴ especially those (e.g., vinylic,¹³²⁵ cyclopropyl,¹³²⁶ or bridgehead halides) that are resistant to nucleophilic substitution. Reduction of halides by NaBH_4 in 80% aq diglyme¹³²⁷ and by BH_3 in nitromethane¹³²⁸ takes place by an $\text{S}_{\text{N}}1$ mechanism. It is known that NaBH_4 in sulfolane reduces tertiary halides possessing a β hydrogen by an elimination–addition mechanism.¹³²⁹

The mechanism for reduction of alkyl halides is not always nucleophilic substitution. For example, reductions with organotin hydrides generally¹³³⁰ take place by free radical mechanisms,¹³³¹ as do those with $\text{Fe}(\text{CO})_5$.

19-54 Reduction of Alcohols¹³³²

Hydro-de-hydroxylation or Dehydroxylation

The hydroxyl groups of most alcohols can seldom be cleaved by catalytic hydrogenation and alcohols are often used as solvents for hydrogenation of other compounds. However, benzyl-type alcohols undergo the reaction readily and have often been reduced.¹³³³ Diaryl

and triarylcarbinols are similarly easy to reduce with $\text{LiAlH}_4\text{--AlCl}_3$,¹³³⁴ with NaBH_4 in F_3CCOOH ,¹³³⁵ and with iodine, water, and red phosphorus (OS I, 224). Other reagents have been used,¹³³⁶ including $\text{Me}_3\text{SiCl--NaI}$,¹³³⁷ $\text{Et}_3\text{SiH--BF}_3$,¹³³⁸ $\text{SmI}_2\text{--THF--HMPA}$,¹³³⁹ and Sn/HCl . The reduction of secondary alcohols was accomplished using Ph_2SiClH and InCl_3 .¹³⁴⁰ 1,3-Diols are especially susceptible to hydrogenolysis. Tertiary alcohols can be reduced by catalytic hydrogenolysis when the catalyst is Raney nickel.¹³⁴¹ Allylic alcohols (and ethers and acetates) can be reduced (often with accompanying allylic rearrangement) with Zn amalgam and HCl, as well as with certain other reagents.¹³⁴² Reagents that reduce the OH group of α -hydroxy ketones without affecting the C=O group include red phosphorus-iodine,¹³⁴³ and Me_3SiI .¹³⁴⁴

Alcohols can also be reduced indirectly by conversion to a sulfonate and reduction of that compound (Reaction 19-57). The two reactions can be carried out without isolation of the sulfonate if the alcohol is treated with pyridine- SO_3 in THF, followed by LiAlH_4 .¹³⁴⁵ Another indirect reduction that can be done in one step involves treatment of the alcohol (primary, secondary, or benzylic) with NaI, Zn, and Me_3SiCl .¹³⁴⁶ In this case, the alcohol is first converted to the iodide, which is reduced. For other indirect reductions of OH, see Reaction 19-59.

The mechanisms of most alcohol reductions are obscure.¹³⁴⁷ Hydrogenolysis of benzyl alcohols can give inversion or retention of configuration, depending on the catalyst.¹³⁴⁸ The mechanism of electroreduction of allylic alcohols in acidic aqueous media has been examined.¹³⁴⁹

Oxygenated compounds (e.g., phenols, phenolic esters, and ethers) can be reduced.¹³⁵⁰ Phenols can be reduced by distillation over zinc dust or with HI and red phosphorus, but these methods are quite poor and are seldom feasible. Catalytic hydrogenation has also been used, but the corresponding cyclohexanol (see Reaction **15-13**) is a side product.¹³⁵¹

Much better results have been obtained by conversion of phenols to certain esters or ethers and reduction of the latter:

With a Pd–C catalyst, phenol derivatives are deoxygenated using Mg and MeO in the presence of ammonium acetate.¹³⁵⁵ Palladium-on-carbon also mediated hydrodeoxygenation of phenol derivatives in the presence of diethylamine.¹³⁵⁶

OS VI, 150. See also, OS VII, 476.

19-56 Replacement of Alkoxy by Hydrogen

Hydro-de-alkoxylation or Dealkoxylation

Simple ethers are not normally cleaved by reducing agents, although such cleavage has sometimes been reported¹³⁵⁷ [e.g., THF treated with $\text{LiAlH}_4\text{--AlCl}_3$ ¹³⁵⁸ or with a mixture of $\text{LiAlH}(\text{O}t\text{-Bu})_3$ and Et_3B ¹³⁵⁹ gave 1-butanol; the latter reagent also cleaves methyl alkyl ethers].¹³⁶⁰ Certain types of ethers can be cleaved quite well by reducing agents.¹³⁶¹

Among these are allyl aryl,¹³⁶² vinyl aryl,¹³⁶³ benzylic ethers,^{1333,1364} and anisole¹³⁶⁵ (for epoxides, see Reaction 19-35). 7-Oxobicyclo[2.2.1]heptanes can be reductively cleaved with Dibal-H and nickel catalysts.¹³⁶⁶ α -Methoxy ketones are demethoxylated ($\text{O}=\text{C}-\text{COMe} \rightarrow \text{O}=\text{C}-\text{CH}$) with SmI_2 .¹³⁶⁷

Acetals and ketals are resistant to LiAlH_4 and similar hydrides, and carbonyl groups are often converted to acetals or ketals for protection (Reaction 16-5). However, a combination of LiAlH_4 and AlCl_3 ¹³⁶⁸ does reduce acetals and ketals, removing one group, as shown above.¹³⁶⁹ The actual reducing agents in this case are primarily chloroaluminum hydride (AlH_2Cl) and dichloroaluminum hydride (AlHCl_2), which are formed from the reagents.¹³⁷⁰ This conversion can also be accomplished with Dibal-H,¹³⁷¹ as well as with other reagents.¹³⁷² Ortho esters are easily reduced to acetals by LiAlH_4 alone, offering a route to aldehydes, which are easily prepared by hydrolysis of the acetals (Reaction 10-6). Mixed ketals $[\text{R}(\text{OMe})\text{OR}']$ can be demethoxylated (to give RHOR') with $\text{Bn}_3\text{SnCl}/\text{NaCH}_2\text{BH}_3$ in the presence of AIBN.¹³⁷³

of borane hydrides.¹³⁷⁹ The scope of the reaction seems to be similar to that of **19-53**. When the reagent is LiAlH_4 , alkyl tosylates are reduced more rapidly than iodides or bromides if the solvent is Et_2O , but the order is reversed in diglyme.¹³⁸⁰ The reactivity difference is great enough so that a tosylate function can be reduced in the presence of a halide and vice versa.

19-58 Hydrogenolysis of esters (Barton–McCombie Reaction)

Hydro-de-thioacetoxylation

Alcohols can readily be converted to carbonate and thiocarbonate derivatives. Under radical conditions,¹³⁸¹ using AIBN (Sec. 14.A.i) and Bu_3SnH , the carbonate or thiocarbonate unit is reduced and replaced with hydrogen. The overall process is reduction of the ROH unit to RH and is called the *Barton–McCombie reaction*.¹³⁸² Both $\text{PhSiH}_3/\text{AIBN}$ ¹³⁸³ and $\text{PhSiH}_2-\text{BET}_3\cdot\text{O}_2$ can be used.¹³⁸⁴ This reaction can be catalytic in Bu_3SnH .¹³⁸⁵ Variations include reduction of ROCSNHPH derivatives using $\text{Ph}_3\text{SiH}/\text{BET}_3$.¹³⁸⁶ Another variation used water as the hydrogen atom source when BMe_3 was used.¹³⁸⁷ Tetrabutylammonium peroxydisulfate and formate ion has been used.¹³⁸⁸

19-59 Reductive Cleavage of Carboxylic Esters

Hydro-de-acyloxylation or Deacyloxylation

The alkyl group (R) of certain carboxylic esters can be reduced to RH ¹³⁸⁹ by treatment with lithium in ethylamine.¹³⁹⁰ The reaction is successful when R is a tertiary or a sterically

hindered secondary alkyl group. A free radical mechanism is likely.¹³⁹¹ Similar reduction, also by a free radical mechanism, has been reported with sodium in HMPA-*t*-BuOH.¹³⁹² In the latter case, tertiary R groups give high yields of RH, but primary and secondary R are converted to a mixture of RH and ROH. Both of these methods provide an indirect method of accomplishing Reaction 19-54 for tertiary R.¹³⁹³ The same thing can be done for primary and secondary R by treating alkyl chloroformates (ROCOCl) with tri-*n*-propylsilane in the presence of *tert*-butylperoxide¹³⁹⁴ and by treating thiono ethers [ROC(=S)W, where W can be OAr or other groups] with Ph₂SiH₂¹³⁹⁵ or Ph₃SiH¹³⁹⁶ and a free radical initiator. Allylic acetates can be reduced with NaBH₄ and a Pd complex,¹³⁹⁷ and with SmI₂-Pd(0).¹³⁹⁸ For other carboxylic ester reductions, see Reactions 19-62, 19-38, and 19-65.

Note that acid chlorides can be reduced (R-COCl → R-H) using (Me₃Si)₃SiH/AIBN.¹³⁹⁹

OS VII, 139.

19-60 Reduction of Hydroperoxides and Peroxides

Hydroperoxides can be reduced to alcohols with LiAlH₄ or Ph₃P¹⁴⁰⁰ or by catalytic hydrogenation. This functional group is very susceptible to catalytic hydrogenation, as shown by the fact that a double bond may be present in the same molecule without being reduced.¹⁴⁰¹

The reaction is an important step in a method for the oxidative decyanation of nitriles containing an α hydrogen.¹⁴⁰² The nitrile is first converted to the α-hydroperoxy nitrile by treatment with base at -78 °C followed by O₂. The hydroperoxy nitrile is then reduced to the cyanohydrin, which is cleaved (the reverse of Reaction 16-52) to the corresponding ketone. The method is not successful for the preparation of aldehydes (R' = H).

Peroxides are cleaved to 2 molar equivalents of alcohols by LiAlH_4 , Mg/MeOH ,¹⁴⁰³ or by catalytic hydrogenation. Peroxides can be reduced to ethers with P(OEt)_3 .¹⁴⁰⁴ In a similar reaction, disulfides (RSSR') can be converted to sulfides RSR' by treatment with tris(diethylamino)phosphine $[(\text{Et}_2\text{N})_3\text{P}]$.¹⁴⁰⁵

OS VI, 130.

19-61 Reduction of Carbonyl to Methylene in Aldehydes and Ketones

Dihydro-de-oxo-bisubstitution

There are various ways of reducing the C=O group of aldehydes and ketones to CH_2 .¹⁴⁰⁶ Two old but still popular methods are the *Clemmensen reduction*¹⁴⁰⁷ and the *Wolff-Kishner reduction*. The *Clemmensen reduction* consists of heating the aldehyde or ketone with zinc amalgam and aq HCl .¹⁴⁰⁸ Ketones are reduced more often than aldehydes. In the *Wolff-Kishner reduction*,¹⁴⁰⁹ the aldehyde or ketone is heated with hydrazine hydrate and a base (usually NaOH or KOH). The *Huang-Minlon modification*¹⁴¹⁰ of the *Wolff-Kishner reduction*, in which the reaction is carried out in refluxing diethylene glycol, has completely replaced the original procedure. A microwave-assisted *Huang-Minlon* procedure has been reported.¹⁴¹¹ The reaction can be carried out under more moderate conditions (room temperature) in DMSO with potassium *tert*-butoxide as base.¹⁴¹² A new modification of the reduction treats a ketone with hydrazine in toluene with microwave irradiation, and subsequent reaction with KOH with microwave irradiation completes the *Wolff-Kishner reduction*.¹⁴¹³ The *Wolff-Kishner reduction* can also be applied to the semicarbazones of aldehydes or ketones.

The *Clemmensen reduction* is usually easier to perform, but it fails for acid-sensitive and high-molecular-weight substrates. For these cases, the *Wolff-Kishner reduction* is quite useful. For high-molecular-weight substrates, a modified *Clemmensen reduction*, using activated zinc and gaseous HCl in an organic solvent (e.g., as ether or acetic anhydride) has proved successful.¹⁴¹⁴ The *Clemmensen* and *Wolff-Kishner reductions* are complementary, since the former uses acidic and the latter basic conditions.

¹⁴¹⁴ Toda, M.; Hayashi, M.; Hirata, Y.; Yamamura, S. *Bull. Chem. Soc. Jpn.* **1972**, 45, 264.

Both methods are fairly specific for aldehydes and ketones and can be carried out with many other functional groups present. However, certain types of aldehydes and ketones do not give normal reduction products. Under *Clemmensen* conditions,¹⁴¹⁵ α -hydroxy ketones give either ketones (hydrogenolysis of the OH, Reaction **19-54**) or alkenes, and 1,3-diones usually undergo rearrangement (e.g., $\text{MeCOCH}_2\text{COMe} \rightarrow \text{MeCOCHMe}_2$).¹⁴¹⁶ Neither method is suitable for α,β -unsaturated ketones, which give pyrazolines¹⁴¹⁷ under *Wolff-Kishner* conditions. Under *Clemmensen* conditions, both groups of these molecules may be reduced or if only one group is reduced, it is the C=C bond.¹⁴¹⁸ Sterically hindered ketones are resistant to both the *Clemmensen* and *Huang-Minlon* procedures, but can be reduced by vigorous treatment with anhydrous hydrazine.¹⁴¹⁹ In the *Clemmensen reduction*, pinacols (Reaction **19-76**) are often side products.

Other reagents have also been used to reduce the C=O of aldehydes and ketones to CH_2 .¹⁴²⁰ Among these are Me_3SiCl followed by $\text{Et}_3\text{SiH/TiCl}_4$,¹⁴²¹ Ni(OAc)_2 on borohydride exchange resin,¹⁴²² Et_3SiH on pyridinium poly(hydrogen fluoride) (PPHF),¹⁴²³ and, for aryl ketones (ArCOR and ArCOAr), NaBH_3CN in THF-aq HCl,¹⁴²⁴ Ni-Al in H_2O ,¹⁴²⁵ $\text{HCOONH}_4\text{-Pd-C}$,¹⁴²⁶ or trialkylsilanes in F_3CCOOH .¹⁴²⁷ Hydrogenation with a heterogeneous Cu-silica catalyst has been used.¹⁴²⁸ Silanes (e.g., Et_3SiH) and a triarylborane catalyst reduce aliphatic aldehydes to methyl, $-\text{CHO} \rightarrow -\text{CH}_3$.¹⁴²⁹ Zinc oxide/triethylsilane has been used,¹⁴³⁰ and also titanocene dichloride [$(\text{C}_5\text{H}_5)_2\text{TiCl}_2$].¹⁴³¹ Most of these reagents also reduce aryl aldehydes (ArCHO) to methylbenzenes (ArCH_3).¹⁴³² One carbonyl group of 1,2-diketones can be selectively reduced by H_2S with an amine catalyst¹⁴³³ or by HI in refluxing acetic acid.¹⁴³⁴ One carbonyl group of quinones (e.g., **41**), can be reduced with Cu and H_2SO_4 or with Sn and HCl.¹⁴³⁵ One carbonyl group of 1,3-diketones was selectively reduced by catalytic hydrogenolysis.¹⁴³⁶

Simply heating a ketone in supercritical 2-propanol reduces the ketone to the methylene compound.¹⁴³⁷

An indirect method of accomplishing the reaction is reduction of tosylhydrazones ($R_2C=N-NHTs$) to R_2CH_2 with $NaBH_4$, BH_3 , catecholborane, bis(benzyloxy)borane, or $NaBH_3CN$. The reduction of α,β -unsaturated tosylhydrazones with $NaBH_3CN$, with $NaBH_4-HOAc$, or with catecholborane proceeds with migration of the double bond to the position formerly occupied by the carbonyl carbon, even if this removes the double bond from conjugation with an aromatic ring,¹⁴³⁸ for example,

A cyclic mechanism is apparently involved:

Another indirect method is conversion of the aldehyde or ketone to a dithioacetal or ketal, and desulfurization using Raney nickel or another reagent (Reaction 14-27).

The first step in the mechanism¹⁴³⁹ of the *Wolff-Kishner reduction* consists of formation of the hydrazone (**16-14**). It is this species that undergoes reduction in the presence of base, most likely in the following manner:

Not much is known about the mechanism of the *Clemmensen reduction*. Several mechanisms have been proposed,¹⁴⁴⁰ including one going through a zinc–carbene intermediate.¹⁴⁴¹ One thing reasonably certain is that the corresponding alcohol is not an intermediate, since alcohols prepared in other ways fail to give the reaction. Note that the alcohol is not an intermediate in the *Wolff–Kishner reduction* either.

It is interesting to see that amines can be deaminated to give the corresponding methylene compounds with low-valent titanium (TiCl₃/Li/THF).¹⁴⁴²

19-62 Reduction of Carboxylic Esters to Ethers

Dihydro-de-oxo-bisubstitution

Carboxylic esters and lactones have been reduced to ethers, although 2 molar equivalents of alcohol are more commonly obtained (Reaction 19-38). Reduction to ethers has been accomplished with a reagent prepared from BF₃–etherate and either LiAlH₄, LiBH₄, or NaBH₄,¹⁴⁴³ with trichlorosilane and UV light,¹⁴⁴⁴ and with catalytic hydrogenation. The reaction with the BF₃ reagent apparently succeeds with secondary R', but not with primary R', which give 19-38. Acyloxy groups are reduced by cleavage of the C–C=O bond, R(Ar)COO–C → C–H) with an excess of Ph₂SiH₂ and di-*tert*-butyl peroxide.¹⁴⁴⁵ Esters are reduced to ethers using Et₃SiH and TiCl₄,¹⁴⁴⁶ BF₃,¹⁴⁴⁷ In(III) compounds,¹⁴⁴⁸ or FeCl₃.¹⁴⁴⁹ Lactones are converted to cyclic ethers¹⁴⁵⁰ by treatment with Cp₂TiCl₂ followed by Et₃SiH on Amberlyst 15.¹⁴⁵¹

Thiono esters (RCSOR') can be reduced to ethers (RCH₂OR') with Raney nickel (Reaction 14-27).¹⁴⁵² Reaction of thio esters (e.g., C–OC(=O)Ph) with Ph₂SiH₂ and Ph₃SnH with BEt₃, followed by AIBN (Sec. 14.A.i) leads to reduction of the C=S unit to give an ether.¹⁴⁵³ Since the thiono esters can be prepared from carboxylic esters (Reaction 16-11), this provides an indirect method for the conversion of carboxylic esters to ethers. Thiol esters (RCOSR') have been reduced to thioethers (RCH₂SR').¹⁴⁵⁴

19-63 Reduction of Cyclic Anhydrides to Lactones and Acid Derivatives to Alcohols**Dihydro-de-oxo-bisubstitution**

Cyclic anhydrides are reduced with Zn–HOAc to give lactones, and also with hydrogen and Pt or $\text{RuCl}_2(\text{Ph}_3\text{P})_3$,¹⁴⁵⁵ with NaBH_4 .¹⁴⁵⁶ With cyclic anhydrides the reaction with LiAlH_4 can be controlled to give either diols or lactones,¹⁴⁵⁷ although diols are the more usual product. A BINOL– LiAlH_4 –EtOH complex, however, gives smooth reduction to the lactone.¹⁴⁵⁸ With some reagents the reaction can be accomplished regioselectively; that is, only a specific one of the two C=O groups of an unsymmetrical anhydride is reduced.¹⁴⁵⁹ Open-chain anhydrides either are not reduced at all (e.g., with LiAlH_4 or NaBH_4) or give 2 molar equivalents of alcohol. The NaBH_4 in THF, with dropwise addition of methanol, reduces open-chain anhydrides to 1 equiv of primary alcohol and 1 equiv of carboxylic acid.¹⁴⁶⁰

Acyl halides are reduced¹⁴⁶¹ to alcohols by LiAlH_4 or NaBH_4 , as well as by other metal hydrides (Table 19.4), but not by borane.

In general, reduction of amides to alcohols is difficult. More commonly the amide is reduced to an amine. An exception uses LiH_2NBH_3 to give the alcohol.¹⁴⁶² Reduction with sodium metal in propanol also gives the alcohol.¹⁴⁶³ Acyl imidazoles are also reduced to the corresponding alcohol with NaBH_4 in aq HCl.¹⁴⁶⁴

There are no *Organic Syntheses* references, but see OS II, 526, for a related reaction. See OS VI, 482 for reduction to alcohols and OS IV, 271 for reduction of acyl halides.

19-64 Reduction of Amides to Amines**Dihydro-deoxo-bisubstitution**

A useful reagent is LiAlH_4 , although the reaction is more difficult than the reduction of most other functional groups. Other groups are often reduced without disturbing an amide function. Although NaBH_4 by itself does not reduce amides, it does so in the presence

of certain other reagents¹⁴⁶⁵ including iodine.¹⁴⁶⁶ Lithium borohydride reduces acetamides.¹⁴⁶⁷ Substituted amides can be reduced with these powerful reagents, and secondary amides are reduced to secondary amine and tertiary amides to tertiary amines. Borane¹⁴⁶⁸ and sodium in 1-propanol¹⁴⁶⁹ are good reducing agents for all three types of amides. Lithium triethylborohydride produces the alcohol with most *N,N*-disubstituted amides, but not with unsubstituted or *N*-substituted amides.¹⁴⁷⁰ Sodium (dimethylamino)borohydride reduces unsubstituted and disubstituted, but not monosubstituted amides.¹⁴⁷¹

Amides can be reduced¹⁴⁷² to amines by catalytic hydrogenation,¹⁴⁷³ but high temperatures and pressures are usually required. Another reagent that reduces disubstituted amides to amines is trichlorosilane.¹⁴⁷⁴ Other silanes (e.g., Et₃SiH) in the presence of a Re¹⁴⁷⁵ Pt,¹⁴⁷⁶ In,¹⁴⁷⁷ Zn,¹⁴⁷⁸ or Ru,¹⁴⁷⁹ catalyst, reduce amides to amines. Electrolytic reduction of carbamates to give an amine are possible.¹⁴⁸⁰

Hantzsch esters (see Reactions **15-14** and **16-17**) have been used for metal-free reduction of amides to amines.¹⁴⁸¹

With some RCONR₂, LiAlH₄ causes cleavage, and the aldehyde (Reaction **10-41**) or alcohol is obtained. Lactams are reduced to cyclic amines in high yields with LiAlH₄, although cleavage sometimes occurs here too. A mixture of LiBHet₃/Et₃SiH is also effective.¹⁴⁸² Lactams are also reduced to cyclic amines with 9-BBN¹⁴⁸³ (Reaction **15-16**) or LiBH₃NMe₂.¹⁴⁸⁴

Imides are generally reduced on both sides,¹⁴⁸⁵ although it is sometimes possible to stop with just one. Both cyclic and acyclic imides have been reduced in this manner, although with acyclic imides cleavage is often obtained.¹⁴⁸⁶

Note that imides can be reduced to hydroxy lactams using different reagents, including NaBH_4 .¹⁴⁸⁷

OS IV, 339, 354, 564; VI, 382; VII, 41.

19-65 Reduction of Carboxylic Acids and Esters to Alkanes

Trihydro-de-alkoxy,oxo-tersubstitution, and so on

The reagent titanocene dichloride reduces carboxylic esters in a different manner from that of Reactions **19-59**, **19-62**, or **19-38**. The products are the alkane RCH_3 and the alcohol $\text{R}'\text{OH}$. The mechanism probably involves an alkene intermediate. Aromatic acids can be reduced to methylbenzenes by a procedure involving refluxing first with trichlorosilane in MeCN, then with tripropylamine added, and finally with KOH and MeOH (after removal of the MeCN).¹⁴⁸⁸ The following sequence has been suggested¹⁴⁸⁸:

Esters of aromatic acids are not reduced by this procedure, so an aromatic COOH group can be reduced in the presence of a COOR' group.¹⁴⁸⁹ However, it is also possible to reduce aromatic ester groups, by a variation of the trichlorosilane procedure.¹⁴⁹⁰ Both *o*- and *p*-hydroxybenzoic acids and their esters have been reduced to cresols ($\text{HOC}_6\text{H}_4\text{CH}_3$) with sodium bis(2-methoxyethoxy)aluminum hydride $[\text{NaAlH}_2(\text{OC}_2\text{H}_4\text{OMe})_2, \text{Red-Al}]$.¹⁴⁹¹ Heating a 2-pyridylbenzyl ester with ammonium formate and a Ru catalyst leads to reduction of the CH_3COO unit to the alkane.¹⁴⁹²

Carboxylic acids can also be converted to alkanes, indirectly,¹⁴⁹³ by reduction of the corresponding tosylhydrazides (RCONHNH_2) with LiAlH_4 or borane.¹⁴⁹⁴

OS VI, 747.

19-66 Hydrogenolysis of Nitriles

Hydro-de-cyanation

This transformation is not common, but given the proliferation of nitriles in organic chemistry, it is potentially quite useful. In the presence of mercuric compounds, tertiary nitriles can be reduced to the hydrocarbon with sodium cyanoborohydride.¹⁴⁹⁵

gem-Dinitriles can be reduced to the corresponding mono-nitrile with SmI_2 .¹⁴⁹⁶ Hydro-silanes facilitate reductive cleavage of nitriles in the presence of a Rh catalyst.¹⁴⁹⁷

19-67 Reduction of the C–N Bond

Hydro-de-amination or Deamination

Benzylic amines are particularly susceptible to hydrogenolysis by catalytic hydrogenation¹⁴⁹⁸ or dissolving metal reduction.¹⁴⁹⁹ Note that the *Wolff–Kishner reduction* in Reaction 19-61 involved formation of a hydrazone and deprotonation by base that led to loss of nitrogen and reduction. Ceric ammonium nitrate in aq acetonitrile has also been shown to reductively cleave the *N*-benzyl group.¹⁵⁰⁰ Primary amines have been reduced to RH with hydroxylamine-*O*-sulfonic acid and aq NaOH to give the hydrocarbon, nitrogen gas, and the sulfate anion.¹⁵⁰¹ It is postulated that $\text{R}-\text{N}=\text{N}-\text{H}$ is an intermediate that decomposes to the carbocation. An indirect means of achieving the same result is the conversion of the primary amine to the sulfonamide ($\text{RNHSO}_2\text{R}'$) (Reaction 16-102) and subsequent treatment with $\text{NH}_2\text{OSO}_2\text{OH}$ ¹⁵⁰² or NaOH, and then NH_2Cl .¹⁵⁰³ Tosylaziridines derived from terminal alkenes are reduced to the corresponding primary tosylamine with polymethylhydrosiloxane/Pd-C.¹⁵⁰⁴ Aziridines can be reduced in the same way as epoxides (Reaction 19-35).

Other indirect methods involve reduction of *N,N*-ditosylates (Sec. 10.G.iii) with NaBH_4 in HMPA¹⁵⁰⁵ and modifications of the *Katritzky pyrylium–pyridinium method*.¹⁵⁰⁶ Allylic and benzylic amines¹³³³ can be reduced by catalytic hydrogenolysis. Aziridines can be reductively opened with SmI_2 ¹⁵⁰⁷ or with Bu_3SnH and AIBN.¹⁵⁰⁸ The C–N bond of enamines is reductively cleaved to give an alkene with alane (AlH_3)¹⁵⁰⁹:

and with 9-BBN (Reaction 15-16) or borane methyl sulfide (BMS).¹⁵¹⁰ Since enamines can be prepared from ketones (Reaction 16-13), this is a way of converting ketones to alkenes.

In the latter case, BMS gives retention of configuration [an (*E*)-isomer gives the (*E*)-product], while 9-BBN gives the other isomer.¹⁵¹⁰ Diazo ketones are reduced to methyl ketones by HI: $\text{RCOCHN}_2 + \text{HI} \rightarrow \text{RCOCH}_3$.¹⁵¹¹

Quaternary ammonium salts can be cleaved with LiAlH_4 , $\text{R}_4\text{N}^+ + \text{LiAlH}_4 \rightarrow \text{R}_3\text{N} + \text{R}^-$, as can quaternary phosphonium salts (R_4P^+). Other reducing agents have also been used (e.g., lithium triethylborohydride, which preferentially cleaves methyl groups,¹⁵¹² and Na in liquid ammonia). When quaternary salts are reduced with $\text{Na}(\text{Hg})$ in water, the reaction is known as the *Emde reduction*. However, this reagent is not applicable to the cleavage of ammonium salts with four *saturated* alkyl groups.

Nitro compounds (RNO_2) can be reduced to RH ¹⁵¹³ by sodium methylmercaptide (CH_3SNa) in an aprotic solvent¹⁵¹⁴ or by Bu_3SnH .¹⁵¹⁵ Both reactions have free radical mechanisms.¹⁵¹⁶ Tertiary nitro compounds can be reduced to RH by NaHTe .¹⁵¹⁷ The nitro group of aromatic nitro compounds has been removed with sodium borohydride.¹⁵¹⁸ Reduction of the C–N bond on aromatic amines with Li metal in THF generates the aryl compounds.¹⁵¹⁹ Sodium nitrite, sodium bisulfite in EtOH/water/acetic acid does a similar reduction.¹⁵²⁰ Conversion of the aniline derivative to the methanesulfonamide and subsequent treatment with NaH and NH_2Cl gives the same result.¹⁵²¹ The Bu_3SnH reagent also reduces isocyanides (RNC , prepared from RNH_2 by formylation followed by Reaction 17-31) to RH ,¹⁵²² a reaction that can also be accomplished with Li or Na in liquid NH_3 ,¹⁵²³ or with K and a crown ether in toluene.¹⁵²⁴ α -Nitro ketones can be reduced to ketones with $\text{Na}_2\text{S}_2\text{O}_4\text{--Et}_3\text{SiH}$ in $\text{HMPA--H}_2\text{O}$.¹⁵²⁵

Amine oxides¹⁵²⁶ and azoxy compounds (both alkyl and aryl)¹⁵²⁷ can be reduced practically quantitatively with triphenylphosphine.¹⁵²⁸ Other reducing agents have also been used, including LiAlH_4 , $\text{NaBH}_4/\text{LiCl}$,¹⁵²⁹ $\text{H}_2\text{-Ni}$, PCl_3 , $\text{Ga/H}_2\text{O}$,¹⁵³⁰ or In/TiCl_4 .¹⁵³¹ Indium metal with aq ammonium chloride in methanol gives good yields of pyridine from pyridine *N*-oxide.¹⁵³² Similar results are obtained using ammonium formate and Raney nickel¹⁵³³ or zinc.¹⁵³⁴ Sodium in ethanol, in a sealed tube, reduces pyridine *N*-oxide to pyridine.¹⁵³⁵ Similar reduction was accomplished with Mo(CO)_6 in ethanol.¹⁵³⁶ Indium (III) chloride has been used for the reduction of quinoline *N*-oxide to quinoline.¹⁵³⁷ Nitrile oxides¹⁵³⁸ ($\text{R-C}\equiv\text{N}^+-\text{O}^-$) can be reduced to nitriles with trialkylphosphines,¹⁵³⁹ and isocyanates (RNCO) to isocyanides (RNC) with $\text{Cl}_3\text{SiH-Et}_3\text{N}$.¹⁵⁴⁰

Analogous to amino *N*-oxides, phosphine oxides ($\text{R}_3\text{P=O}$) are reduced to phosphines (R_3P). Treatment of a phosphine oxide with MeOTf followed by reduced with LiAlH_4 ¹⁵⁴¹ or Dibal-H¹⁵⁴² gives the phosphine. Chiral phosphine oxides are reduced to the phosphine with excellent enantioselectivity using PPh_3 and Cl_3SiH .¹⁵⁴³

19-69 Replacement of the Diazonium Group by Hydrogen

Dediazoniation or Hydro-de-diazoniation

Reduction of a diazonium group (*dediazoniation*) provides an indirect method for the removal of an amino group from an aromatic ring.¹⁵⁴⁴ A common method uses hypophosphorous acid (H_3PO_2), although many other reducing agents¹⁵⁴⁵ have been used,

including HMPA,¹⁵⁴⁶ thiophenol,¹⁵⁴⁷ and sodium stannite (Na_2SnO_2). Ethanol was the earliest reagent used, and it frequently gives good yields, but ethers (ArOEt) are often side products. When H_3PO_2 is used, 5–15 molar equivalents of this reagent are required per molar equivalent of substrate. Diazonium salts can be reduced in nonaqueous media by several methods, including treatment with Bu_3SnH or Et_3SiH in ethers or MeCN ¹⁵⁴⁸ and by isolation as the BF_4^- salt and reduction of this with NaBH_4 in DMF.¹⁵⁴⁹ Aromatic amines can be deaminated ($\text{ArNH}_2 \rightarrow \text{ArH}$) in one laboratory step by treatment with an alkyl nitrite in DMF¹⁵⁵⁰ or boiling THF.¹⁵⁵¹ The corresponding diazonium salt is an intermediate.

Not many investigations of the mechanism have been carried out. It is generally assumed that the reaction of diazonium salts with ethanol to produce ethers takes place by an ionic ($\text{S}_{\text{N}}1$) mechanism while the reduction to ArH proceeds by a free radical process.¹⁵⁵² The reduction with H_3PO_2 is also believed to have a free radical mechanism.¹⁵⁵³ In the reduction with NaBH_4 , an aryldiazene intermediate ($\text{ArN}=\text{NH}$) has been demonstrated,¹⁵⁵⁴ arising from nucleophilic attack by BH_4^- on the β nitrogen. Such diazenes can be obtained as moderately stable (half-life of several hours) species in solution.¹⁵⁵⁵ It is not entirely clear how the aryldiazene decomposes, but there are indications that either the aryl radical (AR^\bullet) or the corresponding anion (Ar^-) may be involved.¹⁵⁵⁶

The dediazonation reaction is used for functionalization of aromatic rings, to remove an amino group after it has been used to direct one or more other groups to ortho and para positions. For example, the compound 1,3,5-tribromobenzene cannot be prepared by direct bromination of benzene because the bromo group is ortho–para directing; however, this compound is easily prepared by the following sequence:

Many other compounds that would otherwise be difficult to prepare are easily synthesized with the aid of the dediazonation reaction.

Unwanted dediazonation can be suppressed by using hexasulfonated calix[6]arenes (see Sec. 3.C.ii).¹⁵⁵⁷

19-70 Desulfurization

Hydro-de-thio-substitution, and so on

Thiols and thioethers,¹⁵⁵⁸ both alkyl and aryl, can be desulfurized by hydrogenolysis with Raney nickel.¹⁵⁵⁹ The hydrogen is usually not applied externally, since Raney nickel typically contains enough hydrogen for the reaction. Other sulfur compounds can be similarly desulfurized, including disulfides, thiono esters,¹⁵⁶⁰ thioamides, sulfoxides, and thioacetals.¹⁵⁶¹ Reduction of thioacetals is an indirect way of accomplishing reduction of a carbonyl to a methylene group (see Reaction 19-61), and it can also give the alkene if a hydrogen atom is present.¹⁵⁶² In most of the examples given, R can also be aryl. Other reagents¹⁵⁶³ have also been used.¹⁵⁶⁴ Reductive cleavage of sulfones and sulfonamides occurs with organobases [e.g., bis(imidazolylidenes)].¹⁵⁶⁵

Lithium aluminum hydride reduces most sulfur compounds with cleavage of the C–S bond, including thiols.¹⁵⁶⁶ Thioesters can be reduced with Ni_2B (from $\text{NiBr}_2/\text{NaBH}_4$).¹⁵⁶⁷ β -Ketosulfones are reduced with $\text{TiCl}_4\text{--Zn}$ ¹⁵⁶⁸ or $\text{TiCl}_4\text{--Sm}$.¹⁵⁶⁹

An important special case of RSR reduction is desulfurization of thiophene derivatives. This proceeds with concomitant reduction of the double bonds. Many compounds have been made by alkylation of thiophene to **42**, followed by reduction to give the alkane.

Thiophenes can also be desulfurized to alkenes ($\text{RCH}_2\text{CH=CHCH}_2\text{R}'$ from **42**) with a nickel boride catalyst prepared from NiCl_2 and NaBH_4 in CH_3OH .¹⁵⁷⁰ Only one SR group of a dithioacetal is reduced by treatment with borane–pyridine in trifluoroacetic acid or in CH_2Cl_2 in the presence of AlCl_3 .¹⁵⁷¹ Phenyl selenides (RSePh) can be reduced to RH with

Ph_3SnH ¹⁵⁷² and with nickel boride.¹⁵⁷³ Cleavage of the C–Se bond can also be achieved with SmI_2 .¹⁵⁷⁴

The exact mechanism of the Raney nickel reactions is still in doubt, although they are probably of the free radical type.¹⁵⁷⁵ It has been shown that reduction of thiophene proceeds through butadiene and butene, not through 1-butanethiol or other sulfur compounds; that is the sulfur is removed before the double bonds are reduced. This was demonstrated by isolation of the alkenes and the failure to isolate any potential sulfur-containing intermediates.¹⁵⁷⁶

OS IV, 638; V, 419; VI, 109, 581, 601. See also, OS VII, 124, 476.

19-71 Reduction of Sulfonyl Halides and Sulfonic Acids to Thiols or Disulfides

Thiols can be prepared by the reduction of sulfonyl halides¹⁵⁷⁷ with LiAlH_4 . Usually, the reaction is carried out on aromatic sulfonyl chlorides. Zinc and acetic acid, and HI, also give the reduction. Sulfonic acids have been reduced to thiols with a mixture of triphenylphosphine and either I_2 or a diaryl disulfide.¹⁵⁷⁸ For the reduction of sulfonyl chlorides to sulfinic acids, see Reaction 16-104.

Disulfides (RSSR) can also be produced.¹⁵⁷⁹ Other sulfonic acid derivatives can be converted to disulfides. Esters (e.g., PhSAc) are converted to disulfides (PhS-SPh) with Clayan and microwave irradiation.¹⁵⁸⁰ Thiobenzoate derivatives (PhSBz) are similarly converted to PhS-SPh with SmI_2 .¹⁵⁸¹ In a similar manner, $\text{RS-SO}_3\text{Na}$ is converted to RS-SR when heated with Sm metal in water.¹⁵⁸²

Sulfoxides can be reduced to sulfides by many reagents,¹⁵⁸³ including LiAlH_4 , HI , Bu_3SnH ,¹⁵⁸⁴ $\text{H}_2\text{—Pd—C}$,¹⁵⁸⁵ $\text{NaBH}_4\text{—NiCl}_2$,¹⁵⁸⁶ NaBH_4/I_2 ,¹⁵⁸⁷ catecholborane,¹⁵⁸⁸ BH_3 with a Mo catalyst,¹⁵⁸⁹ a Mo/In system,¹⁵⁹⁰ Ti compounds,¹⁵⁹¹ and Sm/methanolic NH_4Cl with ultrasound.¹⁵⁹² Sulfoxides are deoxygenated by treatment with 2,4-diphenyl-1,3-diselenadiphosphetane-2,4-diselenide.¹⁵⁹³ Sulfones, however, are usually more difficult to reduce, but they have been reduced to sulfides with Dibal-H.¹⁵⁹⁴ A less general reagent is LiAlH_4 , which reduces some sulfones to sulfides, but not others.¹⁵⁹⁵ Both sulfoxides and sulfones can be reduced by heating with sulfur, which is oxidized to SO_2 , although the reaction with sulfoxides proceeds at a lower temperature. It has been shown by using substrate labeled with ^{35}S that sulfoxides simply give up the oxygen to the sulfur, but that the reaction with sulfones is more complex, since $\sim 75\%$ of the original radioactivity of the sulfone is lost.¹⁵⁹⁶ This indicates that most of the sulfur in the sulfide product comes in this case from the *reagent*. There is no direct general method for the reduction of sulfones to sulfoxides, but an indirect method has been reported.¹⁵⁹⁷ Selenoxides can be reduced to selenides with a number of reagents.¹⁵⁹⁸

OS IX, 446

E. Reduction with Cleavage

19-73 de-Alkylation of Amines and Amides

Certain amines can be dealkylated, usually under reductive conditions. Both *N*-allyl amines and *N,N*-dialkyl allyl amines, are converted to the corresponding amine, $\text{R}_2\text{N—H}$, with Dibal-H/ NiCl_2dppp [$\text{dppp} = 1, 3\text{-bis(diphenylphosphino)propane}$],¹⁵⁹⁹ and with $\text{Pd}(\text{dba})_2\text{dppb}$ [$\text{dppb} = 1, 4\text{-bis(diphenylphosphino)butane}$].¹⁶⁰⁰ A mixture of TiCl_3 and

19-75 Reduction of Disulfides to Thiols

S-Hydrogen-uncoupling

Disulfides can be reduced to thiols by mild reducing agents¹⁶¹⁸ (e.g., Zn and dilute acid, In and $\text{NH}_4\text{Cl}/\text{EtOH}$,¹⁶¹⁹ or Ph_3P and H_2O).¹⁶²⁰ The reaction can also be accomplished simply by heating with alkali.¹⁶²¹ Among other reagents used have been LiAlH_4 , $\text{NaBH}_4/\text{ZrCl}_4$,¹⁶²² Mg/MeOH ,¹⁶²³ and hydrazine or substituted hydrazines.¹⁶²⁴

Aryl diselenides are similarly cleaved to selenols (ArSeH) with Cp_2TiH followed by $\text{Ph}_2\text{I}^+\text{X}^-$.¹⁶²⁵

OS II, 580. Also see, OS IV, 295.

F. Reductive Coupling

19-76 Bimolecular Reduction of Aldehydes and Ketones to 1,2-Diols and Imines to 1,2-Diamines

2/O-Hydrogen-coupling and 2/N-Hydrogen-coupling

1,2-Diols (pinacols) can be synthesized by reduction of aldehydes and ketones with active metals (e.g., Na, Mg, or Al).¹⁶²⁶ Aromatic ketones give better yields than aliphatic ones. The use of a Mg-MgI_2 mixture has been called the *Gomberg-Bachmann pinacol synthesis*.¹⁶²⁷ As with a number of other reactions involving Na, there is a direct electron transfer that converts the ketone or aldehyde to a ketyl, which dimerizes.

Other reagents have been used,¹⁶²⁸ including Sm,¹⁶²⁹ SmI₂,¹⁶³⁰ Pr,¹⁶³¹ Yb,¹⁶³² In with ultrasound,¹⁶³³ InCl₃ catalyst with Mg,¹⁶³⁴ InCl₃/Al in H₂O,¹⁶³⁵ Al/TiCl₃,¹⁶³⁶ VCl₃/Zn in H₂O,¹⁶³⁷ activated Mn,¹⁶³⁸ Zn,¹⁶³⁹ and a low-valent Ti reagent¹⁶⁴⁰ (see Reaction 19-76). Unsymmetrical coupling between two different ketones has been accomplished using TiCl₃ in aqueous solution,¹⁶⁴¹ and coupling of two different aldehydes has been achieved by the use of a V complex.¹⁶⁴² Two aldehydes have also been coupled using Mg in water.¹⁶⁴³ Coupling leads to a mixture of *syn*- and *anti*-diols. "Syn-selective" reagents are Cp₂TiCl₂/Mn,¹⁶⁴⁴ TiCl₄/Bu₄I,¹⁶⁴⁵ TiI₄,¹⁶⁴⁶ and NbCl₅.¹⁶⁴⁷ "Anti-selective" coupling reactions are also known: Ti-salen,¹⁶⁴⁸ Mg with a NiCl₂ catalyst,¹⁶⁴⁹ and Sm/SmCl₃.¹⁶⁵⁰ Aryl aldehydes are coupled to give the bis(trimethylsilyl) ether using Mn, Me₃SiCl and Cp₂TiCl₂.¹⁶⁵¹

Stereoselective pinacol coupling reactions are well known.¹⁶⁵² Chiral additives with pinacol couplings lead to formation of a diol with moderate to good enantioselectivity.¹⁶⁵³ A crossed-pinacol coupling was reported using Et₂Zn and with a BINOL catalyst gave good enantioselectivity.¹⁶⁵⁴ Enantioselective coupling was reported using a chiral salen-Mo

complex.¹⁶⁵⁵ A combination of Mg and Me₃SiCl was also used to effect a crossed-pinacol.¹⁶⁵⁶ Chiral metal complexes in conjunction with a metal leads to diol formation with good enantioselectivity.¹⁶⁵⁷

Intramolecular pinacol coupling reactions are known, giving cyclic 1,2-diols.¹⁶⁵⁸ Dialdehydes have been cyclized by reaction with TiCl₃ to give cyclic 1,2-diols in good yield.¹⁶⁵⁹

A variation of the pinacol coupling treats acyl nitriles with In metal and ultrasound to give a 1,2-diketone.¹⁶⁶⁰ Another variation couples acetals to give 1,2-diols.¹⁶⁶¹

The photochemical dimerization of ketones to 1,2-diols is one of the most common photochemical reactions.¹⁶⁶² The substrate, which is usually a diaryl or aryl alkyl ketone, is irradiated with UV light in the presence of a hydrogen donor (e.g., isopropyl alcohol, toluene, or an amine).¹⁶⁶³ In the case of benzophenone, irradiated in the presence of 2-propanol, the ketone molecule initially undergoes $n \rightarrow \pi^*$ excitation, and the singlet species thus formed crosses to the T_1 state with a very high efficiency.

The T_1 species abstracts hydrogen from the alcohol (Sec. 7.A.vii, category 4) and then dimerizes. The $i\text{PrO}^\bullet$ radical, which is formed by this process, reacts by atom transfer of H^\bullet to another molecule of ground-state benzophenone, producing acetone and another molecule of **51**. This mechanism¹⁶⁶⁴ predicts that the quantum yield for the disappearance of benzophenone should be 2, since each quantum of light results in the conversion of 2 equiv of benzophenone to **42**. Under favorable experimental conditions, the observed quantum yield does approach 2. Benzophenone abstracts hydrogen with very high efficiency. Other aromatic ketones are dimerized with lower quantum yields, and some (e.g., *p*-aminobenzophenone, *o*-methylacetophenone) cannot be dimerized at all in 2-propanol (although *p*-aminobenzophenone, e.g., can be dimerized in cyclohexane¹⁶⁶⁵). The reaction has also been carried out electrochemically.¹⁶⁶⁶

A coupling reaction similar to pinacol coupling has been used with imines, which dimerize to give 1,2-diamines. A number of reagents have been used, including treatment with $\text{TiCl}_4\text{-Mg}$,¹⁶⁶⁷ In/aq EtOH ,¹⁶⁶⁸ Zn/aq NaOH ,¹⁶⁶⁹ or SmI_2 .¹⁶⁷⁰

When electroreduction was used, it was possible to obtain cross-products by coupling a ketone to an *O*-methyl oxime¹⁶⁷¹: *O*-Methyl oxime ethers are coupled to give 1,2-diamines using Zn and TiCl_4 .¹⁶⁷² Aldehydes are converted to 1,2-diamines by treatment with TMS_2NH , NaH , and Li metal in 5 M LiClO_4 in ether, with sonication.¹⁶⁷³ Aldehydes are coupled with *N*-sulfinyl imines to give *N*-sulfinyl amino alcohols in the presence of SmI_2 .¹⁶⁷⁴ Hemiaminals are coupled to give 1,2-diamines with TiI_4/Zn .¹⁶⁷⁵ Amides are converted to 1,2-diamines with Cp_2TiF_2 and PhMeSiH_2 .¹⁶⁷⁶ Samarium(II) iodide was used to couple iminium salts, giving the 1,2-diamine.¹⁶⁷⁷ Ketones can be treated with Yb , and then an imine to give amino alcohols.¹⁶⁷⁸

The *N*-methoxyamino alcohol could then be reduced to the amino alcohol.¹⁶⁷¹ A photochemical coupling has also been reported.¹⁶⁷⁹ A variation of this reaction treats an imine with Yb in THF/HMPA , and then an aldehyde to give a 1,2-bis(imine).¹⁶⁸⁰

species to give a 1,2-dioxygen compound (a titanium pinacolate), which is then deoxygenated.¹⁶⁹⁹

OS VII, 1.

19-78 Acyloin Ester Condensation

When carboxylic esters are heated with sodium in refluxing ether or benzene, a bimolecular reduction takes place, and the product is an α -hydroxy ketone (called an acyloin).¹⁷⁰⁰ The reaction, called the *acyloin ester condensation* (or just *acyloin condensation*),¹⁷⁰¹ is quite successful when R is alkyl. Acyloins with long chains have been prepared in this way (e.g., R = C₁₇H₃₅), but for high-molecular-weight esters, toluene or xylene is used as the solvent. Modifications to this procedure have been reported, including an ultrasound-promoted acyloin condensation in ether,¹⁷⁰² which improved the yields of four-, five-, and six-membered rings, and Olah's procedure, which was also done in ether.¹⁷⁰³

The acyloin condensation has been used with great success, in boiling xylene, to prepare cyclic acyloins from diesters.¹⁷⁰⁴ The yields are 50–60% for the preparation of 6- and 7-membered rings, 30–40% for 8- and 19-membered, and 60–95% for rings of 10–20 members. Even larger rings have been closed in this manner. Indeed, this is one of the best ways of closing rings of 10 members or more. The reaction has been used to close 4-membered rings,¹⁷⁰⁵ although this is generally unsuccessful. For larger rings, the presence of double or triple bonds does not interfere.¹⁷⁰⁶ Even a benzene ring can be present, and many paracyclopentane derivatives (**44**) with $n=9$ or more have been synthesized in this manner.¹⁷⁰⁷

Yields in the acyloin condensation can be improved by running the reaction in the presence of chlorotrimethylsilane (Me₃SiCl), in which case the dianion (**43**) is converted to the bis (silyl) enol ether (**45**), which can be isolated and subsequently hydrolyzed to the acyloin with aq acid.¹⁷⁰⁸ This is now the standard way to conduct the acyloin condensation. Among other things, this method inhibits the *Dieckmann condensation*¹⁷⁰⁹ (Reaction **16-85**), which otherwise competes with the acyloin condensation when a five-, six-, or seven-membered ring can be closed (note that the ring formed by a *Dieckmann condensation* is

always one carbon atom smaller than that formed by an acyloin condensation of the same substrate). The Me_3SiCl method is especially good for the closing of four-membered rings.¹⁷¹⁰

The mechanism is usually presumed to have a diketone (RCOCOR) as an intermediate,¹⁷¹¹ since small amounts of it are usually isolated as side products, and when it is resistant to reduction (e.g., $t\text{-Bu-COCO-}t\text{-Bu}$), it is the major product. A possible sequence (analogous to that of Reaction 19-76) is

A large surface area for the Na is usually required for good results in this coupling, consistent with a surface reaction. In order to account for the ready formation of large rings, which means that the two ends of the chain must approach each other even though this is conformationally unfavorable for long chains, it may be postulated that the two ends become attached to nearby sites on the surface¹⁷¹² of the Na. Although high dilution techniques are not always necessary, effective stirring (high-speed stirrer at 2000–2500 rpm) is usually required to generate “sodium sand”. Highly pure Na gives poorer results because the presence of a small percentage of K is important. Up to 50% potassium (1 : 1 Na/K)¹⁷¹³ has been used in acyloin condensations.

In a related reaction, aromatic carboxylic acids were condensed to α -diketones ($2\text{ArCOOH} \rightarrow \text{ArCOCOAr}$) on treatment with excess Li in dry THF in the presence of ultrasound.¹⁷¹⁴

The acyloin condensation was used in an ingenious manner to prepare the first reported catenane (see Sec. 3.D).¹⁷¹⁵ This synthesis of a catenane produced only a small yield and relied on chance for threading the molecules before ring closure.

Azoxy compounds can be obtained from nitro compounds with certain reducing agents, notably sodium arsenite, sodium ethoxide, NaTeH,¹⁷¹⁶ and glucose. The most probable mechanism with most reagents is that one molecule of nitro compound is reduced to a nitroso compound and another to a hydroxylamine (Reaction 19-46), and these combine (Reaction 12-51). The combination step is rapid compared to the reduction process.¹⁷¹⁷ Nitroso compounds can be reduced to azoxy compounds with triethylphosphite or triphenylphosphine¹⁷¹⁸ or with an alkaline aqueous solution of an alcohol.¹⁷¹⁹

OS II, 57.

19-80 Reduction of Nitro to Azo Compounds

N-De-bisoxxygen-coupling

Nitro compounds can be reduced to azo compounds with various reducing agents, of which LiAlH₄ and Zn and alkali are the most common. A combination of triethylammonium formate and lead in methanol is also effective.¹⁷²⁰ With many of these reagents, slight differences in conditions can lead either to the azo or azoxy (Reaction 19-79) compound. By analogy to Reaction 19-79, this reaction may be looked on as a combination of ArN=O and ArNH₂ (13-24). However, when the reducing agent was NaBH₄,¹⁷²¹ it was shown that azoxy compounds were intermediates. Nitroso compounds can be reduced to azo compounds with LiAlH₄. Dicarborane, with a catalytic amount of acetic acid, reduces aromatic nitro compounds to the amine.¹⁷²²

Nitro compounds can be further reduced to hydrazo compounds with Zn and sodium hydroxide, with hydrazine hydrate and Raney nickel,¹⁷²³ or with LiAlH₄ mixed with a metal chloride (e.g., TiCl₄ or VCl₃).¹⁷²⁴ The reduction has also been accomplished electrochemically.

OS III, 103.

G. Reactions in which an Organic Substrate Is Both Oxidized and Reduced

Some reactions that belong in this category have been considered in earlier chapters. Among these are the *Tollens' condensation* (Reaction 16-43), the *benzil-benzilic acid rearrangement* (Reaction 18-6), and the *Wallach rearrangement* (Reaction 18-43).

19-81 The Cannizzaro Reaction

Aromatic aldehydes, and aliphatic ones with no α hydrogen, give the *Cannizzaro reaction* when treated with NaOH or other strong bases.¹⁷²⁵ Reaction with triethylamine and MgBr₂ gave a room temperature *Cannizzaro reaction*.¹⁷²⁶ The reaction is mediated by organobases.¹⁷²⁷ In this reaction, one molecule of aldehyde oxidizes another to the acid and is itself reduced to the primary alcohol. Aldehydes with an α hydrogen do not give the reaction, because when these compounds are treated with base, the aldol reaction (**16-34**) is much faster.¹⁷²⁸ Normally, the best yield of acid or alcohol is 50% each, but this can be altered in certain cases. Solvent-free reactions are known.¹⁷²⁹ On the other hand, high yields of alcohol can be obtained from almost any aldehyde by running the reaction in the presence of formaldehyde.¹⁷³⁰ In this case, the formaldehyde reduces the aldehyde to alcohol and is itself oxidized to formic acid. In such a case, where the oxidant aldehyde differs from the reductant aldehyde, the reaction is called the *crossed-Cannizzaro reaction*.¹⁷³¹ The *Tollens' condensation* (Reaction **16-43**) includes a *crossed-Cannizzaro reaction* as its last step. A *Cannizzaro reaction* with 1,4-dialdehydes (note that α -hydrogen atoms are present here) and a Rh catalyst gives ring closure, for example,¹⁷³²

The product is the lactone derived from the hydroxy acid that would result from a normal *Cannizzaro reaction*. Chiral additives have been used, but with bis(oxazolidine) derivatives, the reaction proceeded with poor enantioselectivity.¹⁷³³

α -Keto aldehydes give internal *Cannizzaro reactions*.¹⁷³⁴:

This product is also obtained on alkaline hydrolysis of compounds of the formula RCOCHX₂. Similar reactions have been performed on α -keto acetals¹⁷³⁵ and γ -keto aldehydes.

The mechanism¹⁷³⁶ of the *Cannizzaro reaction*¹⁷³⁷ involves a hydride shift (an example of mechanism type 2, Sec. 19.A). First OH^- adds to the C=O to give **46**, which may lose a proton in the basic solution to give the diion (**47**).

aldehydes, by disodium tetracarbonylferrate $[\text{Na}_2\text{Fe}(\text{CO})_4]$.¹⁷⁴⁸ Both CaO (noted above) and SrO have been used as catalysts.¹⁷⁴⁹ A bis(phenylenedioxy) bis(aluminum) catalyst has been used to convert aliphatic aldehydes to the corresponding ester.¹⁷⁵⁰ The bis $\text{Al}(\text{O}-i\text{Pr})_2$ derivative of catechol has also been used as a catalyst.¹⁷⁵¹

A *Tishchenko–aldol transfer reaction* was reported using β -hydroxy ketones and an aldehydes with an AlMe_3 catalyst, giving a monoacyl diol.¹⁷⁵²

OS I, 104.

19-83 The Pummerer Rearrangement¹⁷⁵³

Pummerer methyl sulfoxide rearrangement

When sulfoxides bearing an α hydrogen are treated with acetic anhydride, the product is an α -acetoxy sulfide. This is one example of the *Pummerer rearrangement*,¹⁷⁵⁴ in which the sulfur is reduced while an adjacent carbon is oxidized.¹⁷⁵⁵ The product is readily hydrolyzed (Reaction 10-6) to the aldehyde (R_2CHO).¹⁷⁵⁶ Besides acetic anhydride, other anhydrides and acyl halides give similar products. Inorganic acids (e.g., HCl), also give the reaction, and $\text{RSOCH}_2\text{R}'$ can be converted to $\text{RSCHCIR}'$ in this way. Sulfoxides can also be converted to α -halo sulfides¹⁷⁵⁷ by other reagents, including sulfonyl chloride, NBS, and NCS. Enantioselective *Pummerer rearrangements* are known.¹⁷⁵⁸ Uncatalyzed thermal rearrangements are also known.¹⁷⁵⁹

The following 4-step mechanism has been proposed for the reaction between acetic anhydride and DMSO¹⁷⁶⁰:

For DMSO and acetic anhydride, step 4 is intermolecular, as shown by ^{18}O isotopic labeling studies.¹⁷⁶¹ With other substrates, however, step 4 can be inter- or intramolecular, depending on the structure of the sulfoxide.¹⁷⁶² Depending on the substrate and reagent, any of the first three steps can be rate determining. In the case of Me_2SO treated with $(\text{F}_3\text{CCO})_2\text{O}$, the intermediate corresponding to **50**¹⁷⁶³ could be isolated at low temperature, and on warming gave the expected product.¹⁷⁶⁴ There is also an abundance of other evidence for this mechanism.¹⁷⁶⁵

A *sila-Pummerer rearrangement* has been reported.¹⁷⁶⁶

19-84 The Willgerodt Reaction

Willgerodt carbonyl transformation

In the *Willgerodt reaction*, a straight- or branched-chain aryl alkyl ketone is converted to the amide and/or the ammonium salt of the acid by heating with ammonium polysulfide.¹⁷⁶⁷ The carbonyl group of the product is always at the end of the chain. Thus $\text{ArCOCH}_2\text{CH}_3$ gives the amide and the salt of $\text{ArCH}_2\text{CH}_2\text{CO}_2\text{H}$ and $\text{ArCOCH}_2\text{CH}_2\text{CH}_3$ gives derivatives of $\text{ArCH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$. However, yields sharply decrease with increasing length of chain. The reaction has also been carried out on vinylic and ethynyl aromatic compounds and on aliphatic ketones, but yields are usually lower in these cases. Unlike the *Pummerer rearrangement* (Reaction 19-83), which involves transposition of an oxygen from S to C, the *Willgerodt reaction* involves oxygen migration and oxidation of the organic species. The use of sulfur and a dry primary or secondary amine (or ammonia), as the reagent is called the *Kindler modification* of the *Willgerodt reaction*.¹⁷⁶⁸ The product in this case is $\text{Ar}(\text{CH}_2)_n\text{CSNR}_2$,¹⁷⁶⁹ which can be hydrolyzed to the acid. Particularly good results are obtained with morpholine as the amine. For volatile amines, the HCl salts can be used instead, with NaOAc in DMF at 100°C .¹⁷⁷⁰ Dimethylamine has also been used in the form of dimethylammonium dimethylcarbamate ($\text{Me}_2\text{NCOO}^-\text{Me}_2\text{NH}_2^+$).¹⁷⁷¹ The *Kindler modification* has also been applied to aliphatic ketones.¹⁷⁷² Thioamides have been prepared from ketones in a base-catalyzed reaction.¹⁷⁷³

Alkyl aryl ketones can be converted to arylacetic acid derivatives in an entirely different manner. The reaction consists of treatment of the substrate with silver nitrate and I_2 or Br_2 .¹⁷⁷⁴

The mechanism of the *Willgerodt reaction* is not completely known, but some conceivable mechanisms can be excluded. Thus, one might suppose that the alkyl group becomes completely detached from the ring, and then attacks it with its other end. However, this possibility is ruled out by experiments, such as the following: When isobutyl phenyl ketone (**51**) is subjected to the *Willgerodt reaction*, the product is **52**, not **53**, which would arise if the end carbon of the ketone became bonded to the ring in the product¹⁷⁷⁵:

This also excludes a cyclic-intermediate mechanism similar to that of the *Claisen rearrangement* (Reaction 18-33). Another important fact is that the reaction is successful for singly branched side chains (e.g., **52**), but not for doubly branched side chains, as in PhCOCMe_3 .¹⁷⁷⁵ Still another piece of evidence is that compounds oxygenated along the chain give the same products; thus $\text{PhCOCH}_2\text{CH}_3$, PhCH_2COMe , and $\text{PhCH}_2\text{CH}_2\text{CHO}$ all give $\text{PhCH}_2\text{CH}_2\text{CONH}_2$.¹⁷⁷⁶ All these facts point to a mechanism consisting of consecutive oxidations and reductions along the chain, although just what form these take is not certain. Initial reduction to the hydrocarbon can be ruled out, since alkylbenzenes do not give the reaction. In certain cases, imines¹⁷⁷⁷ or enamines¹⁷⁷⁸ have been isolated from primary and secondary amines, respectively, and these have been shown to give the normal products, leading to the suggestion that they may be reaction intermediates.

The Literature of Organic Chemistry

All discoveries in the laboratory must be published somewhere if the information is to be made available to the scientific community. A new experimental result that is not published is useless, insofar as it benefits the entire chemical world. Traditionally, the total body of chemical knowledge (called *the literature*) is located on the combined shelves of all the chemical libraries in the world. Nowadays, books remain on library shelves, but many, if not most, chemical journals are available online. As e-books become increasingly available, however, books will be available online or for personal electronic reading devices. Anyone who wishes to learn the answer to a chemical question will access the chemical literature, both books and original articles in journals. The expressions “is known”, “has been done”, and so on, usually means “has been published”. The contents of the scientific literature may appear formidably large, but the process of extracting information from the literature of organic chemistry is usually manageable. Appendix A examines both the print literature of organic chemistry¹ and, within reasonable limits, electronic forms of the literature.

It is quite clear that the literature can be divided into two broad categories: primary sources and secondary sources. A *primary source* publishes the original results of laboratory investigations, usually in scientific journals. Indeed, the two chief kinds of primary source are journals and patents. Books, indexes, and other publications that cover material that has previously been published in primary sources are called *secondary sources*. Electronic search engines that use primary sources as a database are also considered to be secondary sources. It is because of the excellence of the secondary sources in organic chemistry (especially *Chemical Abstracts*, *SciFinder*) that literature searching is comparatively straightforward.

A. PRIMARY SOURCES

A.i. Journals

For well over 100 years, nearly all new work in organic chemistry (except for that disclosed in patents) has been published in journals. There are many journals that publish chemical papers, in many countries and in many languages. Nowadays, a high percentage of the journals are published in English, but not all. Some print papers cover all fields of science; some are restricted to chemistry; some to organic chemistry; and some are still more specialized. As noted above, many journals are now available in electronic form.² The actual article is usually offered as an html file, or a PDF file, often with links to the cited references. The vast majority of important papers in “pure” organic chemistry (as opposed to “applied”) are published in relatively few journals, perhaps 50 or fewer. The concept of “pure” organic chemistry is not as useful nowadays because organic chemistry is important in many areas, and multidisciplinary research often includes organic chemistry. Literature that is important to an organic chemist is found in journals and patents that focus on bioorganic, organometallic, materials science, polymer science, separation science, medicinal chemistry, pharmaceutical sciences, and medicine to name a few. The reader is therefore cautioned that the journals listed in this section have organic chemistry as their primary focus, but are by no means the only sources of information concerning organic chemistry. The literature is vast and many journals are published weekly and some semimonthly.

Ordinary papers, usually referred to as full papers, usually include full experimental details, either as part of the paper itself or as accompanying supplemental information. Such details are the mainstay of modern research, providing a guide to what has been done, and the experimental details allow one to repeat that work. With the increase in the volume of chemical literature, and especially with the proliferation of electronic journals, and as noted above, many journals now place full experimental details into “Supplemental Information”. For journals published by the American Chemical Society, a URL link is provided for each article that contains the supplemental information: experiential details, spectral data, visual reproductions of spectral data, X-ray crystallographic data, and so on. Other publishers offer similar links. Once a paper is accepted, the online version (e.g., American Chemical Society ASAP papers) can be found before the print version or the full electronic version that contains the page numbers appear.

In addition to full papers, there are two other types of publications in which original work is reported: *notes* and *communications*. A note is a brief paper, often without a summary (nearly all papers are published with summaries or abstracts prepared by the author). Otherwise, a note is similar to a paper.³ Some journals specialize in publishing only notes. Communications (also called *letters*) are also brief and are usually without summaries (some journals now publish summaries along with their communications), and there are journals that publish only communications or letters.

Communications differ from notes and papers in three respects:

1. They are brief, not because the work is of small scope, but because they are condensed. Usually they include only the most important experimental details or none at all.

² For examples of the contents of an academic electronic library see <http://lib.uconn.edu/> or <http://www.chem.ox.ac.uk/cheminfo/ejournals.html>. Also see eJournal Locator.

³ In some journals, notes are called “short communications”, an unfortunate practice, because they are not communications as that term is defined in this text.

2. They are often of immediate significance. Journals that publish communications make every effort to have them appear as soon as possible after they are received. With modern computer technology, communications can often be published in a matter of weeks.
3. Communications are preliminary reports, and the material in them may be republished as papers at a later date, in contrast to the material in papers and notes, which cannot be republished.

Although chemical publications are published in many languages, the vast majority of important papers in organic chemistry are published in English. For example, six prominent European journals (*Chemische Berichte*, *Liebigs Annalen der Chemie*, *Bulletin de la Société Chimique de France*, *Bulletin des Sociétés Chimique Belges*, *Recueil des Travaux Chimiques des Pays-Bas*, and *Gazzetta Chimica Italiana*) were discontinued. In their place is the *European Journal of Organic Chemistry*, published in English. Most of the articles published in other languages have summaries printed in English also. Important papers were published in German and French for >200 years, and these are generally not available in translation, so that the organic chemist was required to have at least a reading knowledge of these languages. Before ~1920, more than one-half of the important chemical papers were in these languages. In recent years, however, fewer papers in French or German have appeared without an English translation. Of course, a reading knowledge of French and German (especially German) is critical for the older literature. It must be realized that the original literature is never obsolete. With the rise of China in the scientific community, journals are published in Chinese, and there are journals and important chemical discoveries published in Japanese. Work by Chinese and Japanese scientists regularly appears in English-language journals. Secondary sources become superseded or outdated, but nineteenth century journals with primary literature are found in most chemical libraries and are still consulted. Table A.1 presents a list of important current journals that publish original papers⁴ and communications in organic chemistry. Some of them also publish review articles, book reviews, and other material. In 1999, the *Journal of Organic Chemistry* stopped publishing communications, and these are now published in *Organic Letters*.

For some years, the American Chemical Society journals, including *J. Am. Chem. Soc.* and *J. Org. Chem.*, provided supplementary material for some of their papers on microfilm or microfiche. As noted above, this material is now available online, and for older literature from the Microforms and Back Issues Office at the ACS Washington office, either on microfiche, or as a photocopy. These practices have not yet succeeded in substantially reducing the total volume of the world's primary chemical literature since many new journals have appeared, and the yearly page count for most journals has doubled or tripled.

A.ii. Patents

In many countries, including the United States, it is possible to patent a new compound or a new method for making a known compound (either laboratory or industrial procedures). It comes as a surprise to many to learn that a substantial proportion of the patents granted (perhaps 20–30%) have been chemical patents. Chemical patents are part of the chemical literature, and both U.S. and foreign patents were regularly abstracted by *Chemical Abstracts* and now *SciFinder*. In addition to learning about the contents of patents

⁴ In Table A.1, notes are counted as papers.

TABLE A.1 A List of the More Important *Current Journals*^a

No.	Name	Papers or Communications	Issues per Year
1	Angewandte Chemie (1887) ^b	C ^c	12
2	Angewandte Chemie International Edition (1962) ^b	C ^c	48
3	Australian Journal of Chemistry (1948)	P	12
4	Bioorganic Chemistry (1971)	P ^b	4
5	Bioorganic & Medicinal Chemistry Letters (1991)	C	12
6	Bulletin of the Chemical Society of Japan (1926)	P	12
7	Canadian Journal of Chemistry (1929)	P,C	12
8	Carbohydrate Research (1965)	P,C	22
9	Chemistry, a European Journal (1995)	P	24
10	Chemistry, an Asian Journal (2006)	P	24
11	Chemistry and Industry (London) (1923)	C	24
12	Chemistry Letters (1972)	C	12
13	Chimia (1947)	C ^b	12
14	ChemPlusChem	New	
15	Doklady Chemistry (1922) ^b	C	12
17.	European Journal of Organic Chemistry (1998)	P	12
18	Helvetica Chimica Acta (1918)	P	8
19	Heteroatom Chemistry (1990)	P	6
20	Heterocycles (1973)	C ^b	12
21	Indian Journal of Chemistry (Section B)	P	12
22	International Journal of chemical Kinetics (1969)	P	12
23	Israel Journal of Chemistry (1963)	P ^d	4
23	Journal of the American Chemical Society (1879)	P,C	52
25	Journal of Carbohydrate Chemistry (1981)	P,C	6
26	Journal of Chemical Research, Synopses (1977)	P	12
27	Chemical Communications (1965)	C	24
28	Journal of Combinatorial Chemistry (2000)	P,C	6
29.	Journal of Computational Chemistry (1979)	P	16
30	Journal of Fluorine Chemistry (1971)	P,C	12
31	Journal of Heterocyclic Chemistry (1964)	P,C	12
32	Journal of the Indian Chemical Society (1924)	P	12
33	Journal of Lipid Research (1959)	P	12
34	Journal of Medicinal Chemistry (1958)	P,C	12
35	Journal of Molecular Structure (1967)	P,C	16
36	Journal of Organometallic Chemistry (1963)	P,C	48
37	Journal of Organic Chemistry (1936)	P,C	26
38	Journal of Photochemistry and Photobiology, A: Chemistry (1972)	P	12
39	Journal of Physical Organic Chemistry (1988)	P	12
40	Journal of Polymer Science Part A (1962)	P	24
41	Journal für Praktische Chemie (1834)	P	6
42	Macromolecules (1968)	P,C	26
43	Liebigs Annalen der Chemie (1832)	P	12
44	Mendeleev Communications (1991)	C	8
45	Monatshefte für Chemie (1870)	P	12
46	New Journal of Chemistry (1977) ^d	P	11
47	Organometallics (1982)	P,C	12
48	Organic and Biomolecular Chemistry (2003)	P	24

49	Organic Letters (1999)	C	12
50	Organic Mass Spectrometry (1968)	PC	12
51	Organic Preparations and Procedures International (1969)	P ^b	6
52	Organic Process Research & Development (1997)	P	6
53	Photochemistry and Photobiology (1962)	P ^b	12
54	Polish Journal of Chemistry (1921) ^c	PC	12
55	Pure and Applied Chemistry (1960)	f	12
56	Research on Chemical Intermediates (1973) ^g	P ^b	6
57	Russian Journal of Organic Chemistry (1984)	P,C	12
58	Sulfur Letters (1982)	C	6
59	Synlett (1989)	C ^b	12
60	Synthetic Communications (1971)	C	22
61	Synthesis (1969)	P ^b	12
62	Tetrahedron (1958)	P ^b	52
63	Tetrahedron: Asymmetry (1990)	PC	12
64	Tetrahedron Letters (1959)	C	52

^aThese journals currently publish original papers in organic chemistry, listed in alphabetical order of *Chemical Abstracts* abbreviations, which are indicated in boldface. Also given are the year of founding, number of issues per year as of 2012, and whether the journal primarily publishes papers (P), communications (C), or both.

^gSee Ref. 10.

from this source, chemists may consult the *Official Gazette* of the U.S. Patent Office, which, published weekly and available in many libraries, lists titles of all patents issued that week. Bound volumes of all U.S. patents are kept in a number of large libraries, including the New York Public Library, which also has an extensive collection of foreign patents. Photocopies of any U.S. patent and most foreign patents were obtained at low cost from the U.S. Patent and Trademark Office, Washington, DC, 20231. Many patents can now be obtained online as well or are available as PDF files. Patents are also available via SciFinder (formerly, CAS online).

Although patents are often very useful to the laboratory chemist, and no literature search is complete that neglects relevant patents, as a rule they are not as reliable as papers. There are two reasons for this finding:

1. It is in the interest of the inventor to claim as much as possible. The patent may show, for example, that a reaction was actually carried with ethanol and with 1-propanol, but will claim all primary alcohols, and perhaps even secondary and tertiary alcohols, glycols, and phenols. An investigator repeating the reaction on an alcohol that the inventor did not use may find that the reaction gives no yield at all.

⁵ These journals are available in English translation.

⁶ These journals also publish review articles regularly.

⁷ Each issue of this journal is devoted to a specific topic.

⁸ Before 1978 this journal was called *Roczniki Chemii*.

⁹ *Pure Appl. Chem.* publishes IUPAC reports and lectures given at IUPAC meetings.

¹⁰ Before 1989 this journal was called *Reviews of Chemical Intermediates*.

In general, it is safest to duplicate the actual examples given, of which most chemical patents contain one or more.

2. Although legally a patent gives an inventor a monopoly, any alleged infringements must be protected in court, and this may cost a good deal of money. Therefore some patents are written so that certain essential details are concealed or entirely omitted. A patent is supposed to be a full disclosure, but patent attorneys are generally skilled in the art of writing patents, and procedures given are not always sufficient to duplicate the results.

Fortunately, the above statements do not apply to all chemical patents: many make full disclosures and claim only what was actually done. It must also be pointed out that it is not always possible to duplicate the work reported in every paper in a journal due to the use of proprietary catalysts or equipment not available to the public. It is not uncommon to literally purchase the world's supply of a key ingredient. Note, however, that some work is not published or patented but rather maintained within the company as a trade secret. Such work is not, of course, available to the public.

B. SECONDARY SOURCES

Journal articles and patents contain virtually all of the original work in organic chemistry. However, if this were all, if there were no indexes, abstracts, review articles, and other secondary sources, the literature would be unusable, because it is so vast that no one could hope to find anything in particular. Fortunately, the secondary sources are excellent. There are various kinds and the classification shown here is somewhat arbitrary.

B.i. Listings of Titles

The profusion of original papers is so great that publications that list the titles of current papers find much use. Such lists are primarily methods of alerting the chemist to useful papers published in journals that are not normally read. This approach using print versions containing lists or journals and articles is used sparingly nowadays. Most journals are available online with useful search engines, and most have the original papers, with supplemental material, as html and PDF¹¹ documents. The PDF document can be downloaded to the searcher's desktop, sometimes for a fee, shipped to other scientists electronically, and is most convenient. *Chemical Abstracts* was available online as *CAS OnLine*, but this service has been supplanted by *SciFinder* (see Appendix A.D.iii). University libraries and companies pay the appropriate fees, so access to the journals is usually quite easy if one is affiliated with these organizations. Search engines allow one to quickly scan an enormous amount of literature from office or home. In addition, most browsers have online searching capabilities via various search engines, and simply typing in an author, a topic, a chemical, or a few keywords can lead to important articles or information. "Google[®] searching"¹² is commonly employed for a "quick and dirty" search, but one is strongly urged to use one of the established scientific search engines for a proper search.

¹¹ Adobe Acrobat files.

¹² Available at www.google.com/

The more important online technology will be discussed below. However, some other resources¹³ include Specialty Citation Indexes Science Citation Index ExpandedTM, Web of Science[®], Science Citation Index[®], ISI ProceedingsSM, Reaction Citation IndexTM, and the Derwent Innovations IndexSM. The discussion will begin with the older print versions for chemical searches.

A print-version “title” publication covering the whole of chemistry is *Current Contents Physical, Chemical & Earth Sciences*,¹⁴ which began in 1967 and appears weekly, contains the contents pages of all issues of about 800 journals in chemistry, physics, earth sciences, mathematics, and allied sciences. Each issue contains an index of important words taken from the titles of the papers listed in that issue, and an author index, which, however, lists only the first-named author of each paper. The author’s address is also given, so that one may write for reprints. An online service is available called *Current Contents Connect*[®] is a multidisciplinary Web resource providing access to complete bibliographic information from >8000 of the world’s leading scholarly journals and >2000 books.¹⁵

Chemical titles is a similar publication produced by the Chemical Abstracts Service (CAS). SciFinder described below allows one to search a variety of databases, including journal titles.

B.ii. Abstracts

Listings of titles are valuable, as far as they go, but they do not tell what is in the paper, beyond the implications carried by the titles. Most current journals contain a graphic abstract, as well as a title and a brief print description of the research. The graphical abstract is extremely useful for scanning the literature presented in a journal, and both the print and graphical abstracts are available online for most journals.

From the earliest days of organic chemistry, abstracts of papers have been widely available, often as sections of journals whose principal interests lay elsewhere.¹⁶ At the present time there are only two publications entirely devoted to abstracts covering the whole field of chemistry. One of these, *Referativnyi Zhurnal, Khimiya*, which began in 1953, is published in Russian and is chiefly of interest to Russian-speaking chemists. The other is *Chemical Abstracts*, which was published until 2010. Abstracts are now available online via *SciFinder*. Although out of print, knowledge of Chemical Abstracts is important to properly do a literature search that includes older literature. *Chemical Abstracts* appeared weekly and printed abstracts in English of virtually every paper containing original work in pure or applied chemistry published anywhere in the world.¹⁷ More than 18,000 journals were covered, in many languages. In addition, *CA* published abstracts of every patent of chemical interest from 18 countries, as well as many patents from additional countries. The abstracts currently appeared in 80 sections, with sections 21–34 devoted to organic chemistry, under such headings as Alicyclic Compounds, Alkaloids, Physical Organic Chemistry, Heterocyclic Compounds (One Heteroatom),

¹³ See <http://scientific.thomson.com/products/categories/citation/>

¹⁴ Title pages of organic chemistry journals are also carried by *Current Contents Life Sciences*, which is a similar publication covering biochemistry and medicine.

¹⁵ Available at <http://scientific.thomson.com/products/ccc/>

¹⁶ For example, *Chem. Ind. (London)* publishes abstracts of papers that appear in other journals. In the past, journals, such as *J. Am. Chem. Soc.*, *J. Chem. Soc.*, and *Ber.* also did so.

¹⁷ For a guide to the use of *CA*, see Schulz, H. *From CA to CAS ONLINE*; VCH: NY, 1988.

and so on. Each abstract of a paper had a heading that gave (1) the abstract number;¹⁸ (2) the title of the paper; (3) the authors' names as given in the paper; (4) the authors' address; (5) the abbreviated name of the journal (see Table A.1);¹⁹ (6) the year, volume, issue, and page numbers; and (7) the language of the paper. In earlier years *CA* gave the language only if it differed from the language of the journal title. Abstracts of patents showed the abstract number, title, inventor and company (if any), patent number, patent class number, date patent issued, country of priority, patent application number, date patent applied for, and number of pages in the patent. The body of the abstract contained a concise summary of the information in the paper. For many common journals, the author's summary (if there is one) was used in *CA* as it appeared in the original paper, with perhaps some editing and additional information. Each issue of *CA* contained an author index, a patent index, and an index of keywords taken from the titles and the texts or contexts of the abstracts. The patent index listed all patents in order of number. The same compound or method is often patented in several countries. *Chemical Abstracts* abstracted only the first patent, but listed the patent numbers of the duplicated patents in the patent index along with all previous patent numbers that correspond to it. Before 1981 there were separate Patent Number Indexes and Patent Concordances (the latter began in 1963).

At the end of each section of *CA* a list of cross-references to related papers in other sections is given.

Chemical Abstracts is useful as a repository of chemical information, a place for finding out what was done in the past. This value stems from the excellent indexes, which enable the chemist in most cases to ascertain quickly where information is located. From the time of its founding in 1907 until 1961, *CA* published annual indexes. After 1962 there were two volumes published each year, and a separate index is issued for each volume. Each volume contained an index of subjects, authors, formulas, and patent numbers. Beginning in 1972, the subject index was issued in two parts, a chemical substance index and a general subject index, which included all entries that are not the names of single chemical substances. However, the indexes to each volume were essentially superseded by each collective index. The first collective indexes were 10-year (decennial) indexes, but the volume of information made 5-year indexes necessary since 1956. Collective indexes so far published are shown in Table A.2.

As noted above, the print form of Chemical Abstracts has been superseded by SciFinder (see Appendix A.D.iii)

Beginning with the Eighth collective index period, *CA* has published an *Index Guide*. This publication gave structural formulas and/or alternate names for thousands of compounds, as well as many other cross-references. It was designed to help the user efficiently and rapidly to find *CA* references to subjects of interest in the general subject, formula, and chemical substance indexes. Each collective index contained its own *Index Guide*. The *Index Guide* was necessary because the *CA* general subject index was a "controlled index", meaning it restricted its entries only to certain terms.

For example, anyone looking for the term "refraction" in the printed general subject index will not find it. The *Index Guide* included this term, and directed the reader to "Electromagnetic wave, refraction of", "Sound and ultrasound, refraction of", and other terms, all of which were found in the general subject index. Similarly, the chemical substance index usually listed a compound only under one name - the approved *CA* name.

¹⁸ Began in 1967. See Appendix A.B.ii.

¹⁹ These abbreviations are changed from time to time. Therefore the reader may notice inconsistencies.

TABLE A.2 CA Collective Indexes So Far Published

Collective Index	Subject General Subject	Chemical Substance	Author	Formula	Patents
1	1907–1916		1907–1916		
2	1917–1926		1917–1926		1907–1936
3	1927–1936		1927–1936	1920–1946	
4	1937–1946		1937–1946		1937–1946
5	1947–1956		1947–1956	1947–1956	1947–1956
6	1957–1961		1957–1961	1957–1961	1957–1961
7	1962–1966		1962–1966	1962–1966	1962–1966
8	1967–1971		1967–1971	1967–1971	1967–1971
9	1972–1976	1972–1976	1972–1976	1972–1976	1972–1976
10	1977–1981	1977–1981	1977–1981	1977–1981	1977–1981
11	1982–1986	1982–1986	1982–1986	1982–1986	1982–1986
12	1987–1991	1987–1991	1987–1991	1987–1991	1987–1991
13	1992–1996	1992–1996	1992–1996	1992–1996	1992–1996
14	1997–2001	1997–2001	1997–2001	1997–2001	1997–2001
15	2002–2006	2002–2006	2002–2006	2002–2006	2002–2006

Trivial and other names were found in the *Index Guide*. For example, the term “methyl carbonate” is not in the chemical substance index, but the *Index Guide* does have this term, and directs the reader to the chemical substance index under the headings “carbonic acid, esters, dimethyl ester” (for Me_2CO_3) and “carbonic acid, esters, monomethyl ester” (for MeHCO_3). Furthermore, the *Index Guide* gives terms related to the chosen term, helping users to broaden a search. For example, one who looks for “Atomic orbital” in the *Index Guide* will find the terms “Energy Level”, “Molecular orbital”, “Atomic integral”, and “Exchange, quantum mechanical, integrals for”, all of which are controlled index terms.

Each index (annual, semiannual, or collective) also provided an index of ring systems. This valuable index enables the user to ascertain immediately if any ring system appears in the corresponding subject or chemical substance index and under what names. For example, someone wishing to determine whether any compounds

Benz(h)isoquinoline

containing the benz(h)isoquinoline ring system are reported in the 1982–1986 collective index would locate, under the heading “3-ring systems”, the listing **6, 6, 6** (since the compound has three rings of six-members each), and would find the sublisting $\text{C}_5\text{N}-\text{C}_6-\text{C}_6$ (since one ring contains five carbons and a nitrogen while the others are all-carbon), under which is listed the name benz(h)isoquinoline, as well as the names of 30 other systems $\text{C}_5\text{N}-\text{C}_6-\text{C}_6$. A search of the chemical substance index under these names will give all references to these ring systems that appeared in *CA* from 1982 to 1986.

Nowadays, the drawing tools of *SciFinder* (sec. Appendix A.D.iii) are used to draw this structure, and then perform the search.

Before 1967, *CA* used a two-column page, with each column separately numbered. A row of letters from *a* to *h* appeared down the center of the page for the guidance of the user. Thus an entry 7337*b* refers to the *b* section of column 7337. In early years, superscript numbers (e.g., 4327⁵) were used in a similar manner. In very early years, these numbers were not printed on the page at all, though they are given in the decennial indexes, so that the user must mentally divide the page into nine parts. Beginning with 1967, abstracts are individually numbered and column numbers are discarded. Therefore, beginning with 1967, index entries give abstract number rather than column number. The abstract numbers are followed by a letter that serves as a check character to prevent miscopying errors in computer handling. To use the *CA* general subject, chemical substance, and formula indexes intelligently requires practice, and the student should become familiar with representative volumes of these indexes and with the introductory sections to them, as well as with the *Index Guides*.

In the *CA* formula indexes, formulas were listed in order of (1) number of carbon atoms; (2) number of hydrogen atoms; (3) other elements in alphabetic order. Thus, all C₃ compounds are listed before any C₄ compound; all C₅H₇ compounds before any C₅H₈ compound; C₇H₁₁Br before C₇H₁₁N; C₉H₆N₄S before C₉H₆O, and so on. Deuterium and tritium are represented by D and T and treated alphabetically (e.g., C₂H₅DO after C₂H₅Cl and before C₂H₅F or C₂H₆).

Since 1965, *CA* has assigned a Registry Number²⁰ to each unique chemical substance. This is a number of the form [766-51-8] that remains invariant, no matter what names are used in the literature. More than 64 million numbers have already been assigned and thousands are added each week. Registry Numbers are primarily for computer use, but chemical suppliers use CAS registry numbers to identify chemicals that are available for sale.

There were a number of earlier abstracting publications now defunct. The most important are *Chemisches Zentralblatt* and *British Abstracts*. These publications are still valuable because they began before *CA* and can therefore supply abstracts for papers that appeared before 1907. Furthermore, even for papers published after 1907, *Zentralblatt* and *British Abstracts* are often more detailed. *Zentralblatt* was published, under various names, from 1830 to 1969.²¹ *British Abstracts* was a separate publication from 1926 to 1953, but earlier abstracts from this source are available in the *Journal of the Chemical Society* from 1871 to 1925.

B.iii. Beilstein

This publication has been so important to organic chemistry that it deserves a section by itself. Beilstein's *Handbuch der Organischen Chemie*, usually referred to as *Beilstein*, lists all the known organic compounds reported in the literature during its period of coverage. The print version will be described first, as it is particularly important for older literature.

For each compound in *Beilstein*, the following data are given: all names; the molecular formula; the structural formula; all methods of preparation (briefly, e.g., "by refluxing 1-butanol with NaBr and sulfuric acid"); physical constants (melting point, refractive index, etc.); other physical properties; chemical properties including reactions; occurrence in nature (i.e., which species it was isolated from); biological properties, if any; derivatives

²⁰ See <http://www.cas.org/expertise/cascontent/registry/regsyst.html>

²¹ An "obituary" of *Zentralblatt* by Weiske, C., gives its history and statistical data about its abstracts and indexes, and was published in the April 1973 issue of *Chem. Ber.* (pp. I–XVI).

with melting points; analytical data, and any other information that has been reported in the literature.²² Equally important, for every piece of information, a reference is given to the original literature. Furthermore, the data in Beilstein have been critically evaluated. That is, all information is carefully researched and documented, and duplicate and erroneous results are eliminated. Some compounds are discussed in two or three lines and others require several pages.

The print editions are invaluable for searching older literature, but even today provide valuable data for many compounds used every day. A discussion of using *Beilstein* is therefore essential.

The first three editions of Beilstein are obsolete. The fourth edition (*vierte Auflage*) covers the literature from its beginnings through 1909. This edition, called *das Hauptwerk*, consists of 27 volumes. The compounds are arranged in order of a system too elaborate to discuss fully here.²³ The compounds are divided into three divisions that are further subdivided into “systems”:

Division	Volumes	System Numbers
I. Acyclic Compounds	1–4	1–499
II Carbocyclic Compounds	5–16	450–2359
III. Heterocyclic Compounds	17–27	2360–4720

Das Hauptwerk is still the basis of Beilstein and has not been superseded. The later literature is covered by supplements that have been arranged to parallel *das Hauptwerk*. The same system is used, so that the compounds are treated in the same order. The first supplement (*erstes Ergänzungswerk*) covers 1910–1919; the second supplement (*zweites Ergänzungswerk*) covers 1920–1929; the third supplement (*drittes Ergänzungswerk*) covers 1930–1949; the fourth supplement (*viertes Ergänzungswerk*) covers 1950–1959, and the fifth supplement covers 1960–1979. Like *das Hauptwerk*, each supplement contains 27 volumes,²⁴ except that supplements 3 and 4 are combined for Vols. 17–27, so that for these volumes the combined third and fourth supplement covers the years 1930–1959. Each supplement has been divided into volumes in the same way as *das Hauptwerk*, and, for example, compounds found in Vol. 3, system number 199 of *das Hauptwerk* will also be found in Vol. 3, system number 199 of each supplement. To make cross-referencing even easier, each supplement gives, for each compound, the page numbers at which the same compound can be found in the earlier books. Thus, on page 554 of Vol. 6 of the fourth supplement, under the listing phenetole are found the symbols (H 140; E I 80; E II 142; E III 545) indicating that earlier information on phenetole is given on page 140 of Vol. 6 of *das Hauptwerk*, on page 80 of the first, page 142 of the second, and

²² For a discussion of how data are processed for inclusion in Beilstein, see Luckenbach, R.; Ecker, R.; Sunkel, J. *Angew. Chem. Int. Ed. Engl.* **1981**, 20, 841 [*Angew. Chem.* 93, 876].

²³ For descriptions of the Beilstein system and directions for using it, see Sunkel, J.; Hoffmann, E.; Luckenbach, R. *J. Chem. Educ.* **1981**, 58, 982; Luckenbach, R. *CHEMTECH* **1979**, 612. The Beilstein Institute has also published two English language guides to the system. One, available free, is *How to Use Beilstein*, Beilstein Institute, Frankfurt/Main, **1979**. The other is by Weissbach, O. *A Manual for the Use of Beilstein's Handbuch der Organischen Chemie*, Springer, NY, **1976**. An older work, which many students will find easier to follow, is by Huntress, E.H. *A Brief Introduction to the Use of Beilstein's Handbuch der Organischen Chemie*, 2nd ed., Wiley, NY, **1938**.

²⁴ In some cases, to keep the system parallel and to avoid books that are too big or too small, volumes are issued in two or more parts, and, in other cases, two volumes are bound as one.

page 545 of the third supplement. Furthermore, each page of the supplements contains, at the top center, the corresponding page numbers of *das Hauptwerk*. Since the same systematic order is followed in all six series, location of a compound in any one series gives its location in the other five. If a compound is found, for example, in Vol. 5 of *das Hauptwerk*, one has but to note the page number and scan Vol. 5 of each supplement until that number appears in the top center of the page (the same number often covers several pages). Of course, many compounds are found in only one, two, three, four, or five of the series, since no work may have been published on that compound during a particular period covered.

From *das Hauptwerk* to the fourth supplement, Beilstein is in German, but it is not difficult to read since most of the words are the names of compounds (a Beilstein German–English Dictionary, available free from the publisher, is in many libraries). For the fifth supplement (covering 1960–1979), which is in English, publication of Division III began before the earlier divisions. Volumes 17–22 (totaling 70 separate parts exclusive of index volumes) of this supplement have been published, as well as a combined index for volumes 17–19. This index covers only the fifth supplement. The subject portion of this index, which lists compound names only, gives these names in English.

Volumes 28 and 29 of Beilstein are subject and formula indexes, respectively. The most recent complete edition of these volumes is part of the second supplement and covers only *das Hauptwerk* and the first two supplements (though complete indexes covering *das Hauptwerk* and the first four supplements have been announced to appear in the next few years). For Vol. 1, there is a cumulative subject and a cumulative formula index, which combine *das Hauptwerk* and the first four supplements.²⁵ Similar index volumes, covering all four supplements, have been issued for the other volumes, 2–27. Some of these are combined (e.g., 2–3, 12–14, and 23–25). For English-speaking chemists (and probably for many German-speaking chemists) the formula indexes are more convenient. Of course (except for the fifth supplement indexes), one must still know some German, because most formula listings contain the names of many isomers. If a compound is found only in *das Hauptwerk*, the index listing is merely the volume and page numbers (e.g., **1**, 501). Roman numbers are used to indicate the supplements (e.g., **26**, 15, **I** 5, **II** 7). Thus the subject and formula indexes lead at once to locations in *das Hauptwerk* and the first four supplements. The Beilstein formula indexes are constructed the same way as the *CA* indexes (Appendix A.B.ii).

There is also a fourth division of Beilstein (systems 4721–4877) that covers natural products of uncertain structure: rubbers, sugars, and so on. These are treated in Vols. 30 and 31, which do not go beyond 1935 and that are covered in the collective indexes. These volumes will not be updated. All such compounds are now included in the regular Beilstein volumes.

In recent years, Beilstein was available online, with the useful search engine *CrossFire*. However, this database is now incorporated into *Reaxys* (see Appendix A.D.vi).

B.iv. Tables of Information

In addition to Beilstein, there are many other print reference works in organic chemistry that are essentially compilations of data. These books are very useful and often save the

²⁵ Most page number entries in the combined indexes contain a letter (e.g., CHBr₂Cl 67f, **II** 33a, **III** 87d, **IV**, 81). These letters tell where on the page to find the compound and are useful because the names given in the index are not necessarily those used in the earlier series. The letter “a” means the compound is the first on its page, “b” is the second, and so on. No letters are given for the fourth supplement.

research worker a great deal of time. In this section, we discuss some of the more important of such works.

1. The sixth edition of *Heilbron's Dictionary of Organic Compounds*, J. Buckingham, Ed., 9 vols., Chapman and Hall, London, **1996**, contains brief listings of >150,000 organic compounds, giving names, structural formulas, physical properties, and derivatives, with references. For many entries, additional data concerning occurrence, biological activity, and toxicity hazard information are also given. The arrangement is alphabetical. The dictionary contains indexes of names, formulas, heteroatoms, and CA Registry Numbers. Annual supplements, with cumulative indexes, have appeared since 1983. A similar work, devoted to organometallic compounds, is the 2nd edition of the *Dictionary of Organometallic Compounds*, 6 vols. in its 5th supplement, published by Chapman and Hall in **1989**. Another, *Dictionary of Steroids*, 2 vols., 1991, is also published by Chapman and Hall.
2. A multivolume compendium of physical data is *Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, Geophysik, und Technik*, 6th ed., by H. Landolt and R. Börnstein, Springer, Berlin, 1950. There is also a "New Series", for which the volumes are given the English title *Numerical Data and Functional Relationships in Science and Technology*, as well as the German title. This compendium, which is not yet complete, lists a great deal of data, some of which are of interest to organic chemists (e.g., indexes of refraction, heats of combustion, optical rotations, and spectral data). Literature references are given for all data.
3. *The Handbook of Chemistry and Physics*, CRC Press, Boca Raton, FL (called the "rubber handbook"), which is revised annually (92nd ed., 2011–2012), is a valuable repository of data quickly found. For organic chemists an important table is *Physical Constants of Organic Compounds*, which lists names, formulas, color, solubility, and physical properties of thousands of compounds. However, there are many other useful tables. A similar work is *Lange's Handbook of Chemistry*, 16th ed., McGraw-Hill, New York, 2004. Another such handbook, but restricted to data of interest to organic chemists, is *Dean's Handbook of Organic Chemistry*, 2nd ed., McGraw-Hill, New York, 2003. This book also contains a long table of *Physical Constants of Organic Compounds*, and has much other information including tables of thermodynamic properties, spectral peaks, pK_a values, bond distances, and dipole moments.
4. A list of most of the known natural compounds (e.g., terpenes, alkaloids, carbohydrates) to which structures have been assigned, along with structural formulas, melting points, optical rotations, and references, is provided in T.K. Devon and A.J. Scott, *Handbook of Naturally Occurring Compounds*, 3 vols., Academic Press, New York, **1972**.
5. R.R. Dreisbach, *Physical Properties of Chemical Compounds*, Advances in Chemistry Series Nos. 15, 22, 29, American Chemical Society, Washington, 1955–1961 lists many physical properties of >1000 organic compounds.
6. Physical properties of thousands of organometallic compounds, with references, are collected in five large compendia: the *Dictionary of Organometallic Compounds*, mentioned under item 1, above; M. Dub, *Organometallic Compounds*, 2nd ed., 3 vols. with supplements and index, Springer, New York, 1966–1975; N. Hagihara, M. Kumada, and R. Okawara, *Handbook of Organometallic Compounds*,

- W.A. Benjamin, New York, **1968**; and H.C. Kaufman, *Handbook of Organometallic Compounds*, Van Nostrand, Princeton, NJ, **1961**; *Comprehensive Organometallic Chemistry II*, 14 vols, Pergamon, 1995.
7. The *Merck Index*, 14th ed., Merck and Company, Rahway, NJ, **2006** is a good source of information about chemicals of medicinal importance. Many drugs are given three types of name: chemical *name* (which is the name an organic chemist would give it; of course, there may well be more than one); *generic name*, which must be placed on all containers of the drug; and *trade names*, which are different for each company that markets the drug. For example, the generic name for 1-(4-chlorobenzhydryl)-4-methylpiperazine is chlorcyclazine. Among the trade names for this drug, which is an antihistamine, are Trihistan, Perazyl, and Alergicide. The *Merck Index* is especially valuable because it gives all known names of all three types for each compound and the names are cross-indexed. Also given, for each compound, are the structural formula, *CA* preferred name and Registry Number, physical properties, medicinal and other uses, toxicity indications, and references to methods of synthesis. There are indexes of formulas and Registry Numbers, and miscellaneous tables. The “*Merck Index*” also includes a lengthy list of organic name reactions, with references.
 8. There are two publications that list properties of azeotropic mixtures. J. Timmermans, *The Physico-chemical Constants of Binary Systems in Concentrated Solutions*, 4 vols., Interscience, New York, **1959–1960**, is by far the more comprehensive. The other is *Azeotropic Data*, 2 vols., Advances in Chemistry Series No. 6 and No. 35, American chemical Society, Washington, **1952, 1962**.
 9. Thousands of dipole moments, with references, are collected in V.A.L. McClellan, *Tables of Experimental Dipole Moments*, Vol. 1, W.H. Freeman, San Francisco, CA, **1963**; Vol. 2, Rahara Enterprises, El Cerrita, CA, **1974**.
 10. *Tables of Interatomic Distances and Configurations in Molecules and Ions*, London Chemical Society Special publication no. 11, **1958**, and its supplement, Special publication no. 18, **1965**, include bond distances and angles for hundreds of compounds, along with references.
 11. The *Ring Systems Handbook*, published in 1988 by the chemical Abstracts Service, provides the names and formulas of ring and cage systems that have been published in *CA*. The ring systems are listed under a system essentially the same as that used for the *CA* index of ring systems (sec. Appendix A.B.i, A.B.ii). Each entry gives the *CA* index name and Registry Number for that ring system. In many cases a *CA* reference is also given. There is a separate Formula Index (for the parent ring systems) and a *Ring Name Index*. Cumulative supplements are issued twice a year. The *Ring Systems Handbook* supersedes earlier publications called *The Parent Compound Handbook* and *The Ring Index*.
 12. The Sadtler Research Laboratories published large collections of IR, UV, NMR, and other spectra, in loose-leaf form. Indexes are available.
 13. Infrared, UV, NMR, Raman, and mass spectral data, as well as melting-point, boiling-point, solubility, density, and other data for >30,000 organic compounds are collected in the *CRC Handbook of Data on Organic Compounds*, 2nd ed., 9 vols., CRC Press, Boca Raton, FL, 1988, edited by R.C. Weast and J.G. Grasselli. It differs from the Sadtler collection in that the data are given in tabular form (lists of peaks)

rather than reproduction of the actual spectra, but this book has the advantage that all the spectral and physical data for a given compound appear at one place. References are given to the Sadtler and other collections of spectra. Volumes 7–9 contain indexes of spectral peaks for IR, UV, NMR, ^{13}C NMR, mass, and Raman spectra, as well as indexes of other names, molecular formulas, molecular weights, and physical constants. Annual updates began appearing in 1990 (the first one is called volume 10).

14. The *Aldrich Library of Infrared Spectra*, 3rd ed., Aldrich Chemical Company, Milwaukee, WI, **1981**, by Pouchert contains >12,000 IR spectra so arranged that the user could readily see the change that takes place in a given spectrum when a slight change is made in the structure of a molecule. The same company also publishes the *Aldrich Library of FT-IR Spectra* and the *Aldrich Library of NMR Spectra*, both also by C. Pouchert. A similar volume, which has IR and Raman spectra of ~1000 compounds, is *Raman/Infrared Atlas of Organic Compounds*, 2nd ed., VCH, New York, **1989**, by B. Schrader.
15. An extensive list of visible and uv peaks is given in *Organic Electronic Spectral Data*, Wiley, New York. Twenty-six volumes have appeared so far, covering the literature through 1984.
16. A collection of 500 ^{13}C NMR spectra is found in L.F. Johnson and W.C. Jankowski, *Carbon-13 NMR Spectra*, Wiley, New York, **1972**.

C. REVIEWS

A review article is an intensive survey of a rather narrow field. For example, the titles of some recent reviews are “Metathesis of Alkanes and Related Reactions”²⁶, “Potassium Organo-trifluoroborates: New Perspectives in Organic Synthesis”²⁷, and “Asymmetric Addition of Allylic Nucleophiles to Imino Compounds”.²⁸ A good review article is of enormous value, because it is a thorough survey of all the work done in the field under discussion. Review articles are printed in review journals and in certain books. The most important review journals in organic chemistry (though most are not exclusively devoted to organic chemistry) are shown in Table A.3. Some of the journals listed in Table A.1, for example, *Chemical Reviews*, *Accounts of Chemical Research*, and *Synlett*, *Tetrahedron*, *Synthesis*, *Organic Preparations and Procedures International*, and *J. Organomet. Chem.* also publish occasional review articles. As with other journals, journals that contain reviews are available online.

There are several open-ended serial publications that are similar in content to the review journals but are published irregularly (seldom more often than once a year) and are hardbound. Some of these publish reviews in all fields of chemistry; some cover only organic chemistry; some specialize further. The coverage is indicated by the titles. Table A.4 shows some of the more important such publications, with CA abbreviations.

Another publication is the *Index of Reviews in Organic Chemistry*, compiled by Lewis, Chemical Society, London, a classified listing of review articles. The first volume, published in 1971, lists reviews from ~1960 (in some cases much earlier) to ~1970 in alphabetical

²⁹ Successor to *Quarterly Reviews* (abbreviated as *Q. Rev., Chem. Soc.*).³⁰ Formerly called *Fortschritte der Chemischen Forschung*.

Progress in Heterocyclic Chemistry
Progress in Macrocyclic Chemistry
Progress in Physical Organic Chemistry
Reactive Intermediates (Plenum)
Reactive Intermediates (Wiley)
Survey of Progress in Chemistry
Topics in Physical Organometallic Chemistry
Topics in Stereochemistry

order of topic. Thus four reviews are listed under “Knoevenagel condensation”, five under “Inclusion compounds”, and one under “Vinyl ketones”. There is no index. A second volume (1977) covers the literature to 1976. Annual or biannual supplements appeared from 1979 until the publication was terminated in 1985. Classified lists of review articles on organometallic chemistry are found in articles by Smith and Walton³¹ and by Bruce.³² A similar list for heterocyclic chemistry is found in articles by A. Katritzky and others.³³ See also the discussion of the *Index of Scientific Reviews* in Appendix A.D.iv.

C.i. Annual Reviews

The review articles discussed in Table A.3 are each devoted to a narrow topic covering the work done in that area over a period of years. An annual review is a publication that covers a broad area but limits the period covered, usually to 1 or 2 years.

1. The oldest annual review publication still publishing is *Annual Reports on the Progress of Chemistry*, published by the Royal Society of Chemistry (formerly the chemical Society), which began in 1905 and which covers the whole field of chemistry. Since 1967 it has been divided into sections. Organic chemistry is found in Section B.
2. Because the number of papers in chemistry has become so large, the Royal Society of Chemistry publishes annual-review-type volumes of smaller scope, called *Specialist Periodical Reports*. Among those of interest to organic chemists are *Carbohydrate Chemistry* (Vol. 22 covers 1988); *Photochemistry* (Vol. 21 covers 1988–1989); and *General and Synthetic Methods* (Vol. 12 covers 1987).
3. *Organic Reaction Mechanisms*, published by Wiley, New York, is an annual survey that covers the latest developments in the field of mechanisms. The first volume, covering 1965, appeared in 1966.
4. There are two annual reviews devoted to progress in organic synthesis. Theilheimer, *Synthetic Methods of Organic Chemistry*, S. Karger, Verlag, Basel, is an annual compilation, beginning in 1946, of new methods for the synthesis of organic compounds, arranged according to a system based on bond closing and bond breaking reactions. Equations, brief procedures, yields, and literature references are given. Volume 44 was issued in 1990. Volumes 3 and 4 are available only in

³¹ Smith, J.D.; Walton, D.R.M. *Adv. Organomet. Chem.* **1975**, *13*, 453.

³² Bruce, M.I. *Adv. Organomet. Chem.* **1972**, *10*, 273, **1973**, *11*, 447, **1974**, *12*, 380.

³³ Belen'kii, L.I. *Adv. Heterocycl. Chem.* **1988**, *44*, 269; Katritzky, A.R.; Jones, P.M. *Adv. Heterocycl. Chem.* **1979**, *25*, 303; Katritzky, A.R.; Weeds, S.M. *Adv. Heterocycl. Chem.* **1966**, *7*, 225.

German, but all the rest are in English. There is an index to each volume. Cumulative indexes appear in every fifth volume. Beginning with vol. 8, each volume includes a short summary of trends in synthetic organic chemistry. A more recent series is *Annual Reports in Organic Synthesis*, Academic Press, New York, which has covered the literature of each year since 1970. Equations are listed with yields and references according to a fairly simple system.

C.ii. Awareness Services

Besides the annual reviews and the title and abstract services previously mentioned, there exist a number of publications designed to keep readers aware of new developments in organic chemistry or in specific areas of it.

1. *Chemtracts: Organic Chemistry* is a bimonthly Periodical, begun in 1988, that prints abstracts of certain recently published papers (those that the editors consider most important), with commentaries on these papers by distinguished organic chemists. Important current research in bioorganic, organometallic, synthesis, physical-organic and theoretical chemistry, and pharmaceutical/medicinal chemistry is covered in each issue, giving readers updates on the newest trends and developments in organic chemistry by summarizing and commenting on current and past research.
2. The Institute for Scientific Information (ISI), besides publishing *Current Contents* (sec. Appendix A.B.i) and the *Science Citation Index* (sec. Appendix A.B.i), also publishes *Index Chemicus* (formerly called *Current Abstracts of Chemistry and Index Chemicus*). This publication, begun in 1960 and appearing weekly, is devoted to printing structural formulas of all new compounds appearing in >100 journals, along with equations to show how they were synthesized and an author's summary of the work. Each issue contains five indexes: author, journal, biological activity, labeled compounds, and intermediates that were not isolated. These indexes are cumulated annually.
3. Theilheimer and the *Annual Reports on Organic Synthesis*, mentioned in the previous section, list new synthetic methods once a year. There are several publications that do this monthly. Among these are *Current Chemical Reactions* (begun in 1979 and published by ISI), *Journal of Synthetic Methods* (begun in 1975 and published by Derwent publications), and *Methods in Organic Synthesis*, begun in 1984 and published by the Royal Society of Chemistry. *Methods in Organic Synthesis* also lists books and review articles pertaining to organic synthesis.
4. *Natural Product Updates*, a monthly publication begun in 1987 and published by the Royal Society of Chemistry, lists recent results in the chemistry of natural products, along with structural formulas. It covers new compounds, structure determinations, new properties and total syntheses, among other topics.

C.iii. General Treatises

There are a number of large-scale multivolume treatises that cover the whole field of organic chemistry or large areas of it.

1. *Rodd's Chemistry of Carbon Compounds*, edited by S. Coffey, Elsevier, Amsterdam, is a treatise consisting of five main volumes, each of which contains several

parts. Publication began in 1964 and is not yet complete. The organization is not greatly different from most textbooks, but the coverage is much broader and deeper. Supplements to many of the volumes have appeared. An earlier edition, called *Chemistry of Carbon Compounds*, edited by E.H. Rodd, was published in 10 parts from 1951 to 1962.

2. Houben–Weyl's *Methoden der Organischen Chemie*, Georg Thieme Verlag, Stuttgart, is a major treatise in German devoted to laboratory methods. The fourth edition, which was begun in 1952 and consists of 20 volumes, most of them in several parts, is edited by E. Muller. The series includes supplementary volumes. The first four volumes contain general laboratory methods, analytical methods, physical methods, and general chemical methods. The later volumes are devoted to the synthesis of specific types of compounds (hydrocarbons, oxygen compounds, nitrogen compounds, etc.). Beginning in 1990 parts of the series have appeared in English.
3. *Comprehensive Organic Chemistry*, Pergamon, Elmsford, NY, **1979**, is a six-volume treatise on the synthesis and reactions of organic compounds. The first three volumes cover the various functional groups, Vol. 4, heterocyclic compounds, and Vol. 5, biological compounds (e.g., proteins, carbohydrates, and lipids). Probably the most useful volume is Vol. 6, which contains formula, subject, and author indexes, as well as indexes of reactions and reagents. The last two of these not only refer to pages within the treatise, but directly give references to review articles and original papers. Several similar treatises, including the nine-volume *Comprehensive Organometallic Chemistry* (1982), the eight-volume *Comprehensive Heterocyclic Chemistry* (1984), and the six-volume *Comprehensive Medicinal Chemistry* (1989) are also published by Pergamon. The indexes to these works also include references.
4. A major treatise devoted to experimental methods of chemistry is *Techniques of Chemistry*, edited first by A. Weissberger and then by J.K.M. Saunders, Wiley, New York. This publication, which began in 1970, so far consists of 21 volumes, most of them in several parts, covering such topics as electrochemical and spectral methods, kinetic methods, photochromism, and organic solvents. *Techniques of Chemistry* is a successor to an earlier series, called *Techniques of Organic Chemistry*, which appeared in 14 volumes, some of them in more than one edition, from 1945 to 1969.
5. *Comprehensive Chemical Kinetics*, edited by C.H. Bamford and C.F.H. Tipper, **1969**, Elsevier, Amsterdam, is a multivolume treatise covering the area of reaction kinetics. Six of these volumes (not all published at the time of writing) deal with the kinetics and mechanisms of organic reactions in a thorough and comprehensive manner.
6. Three multivolume treatises that cover specific areas are R.C. Elderfield, *Heterocyclic Compounds*, Wiley, New York, **1950**; R.H.F. Manske and H.L. Holmes, *The Alkaloids*, Academic Press, New York, **1950**; and J.L. Simonson, L.N. Owen, D.H. R. Barton, and W.C.J. Ross, *The Terpenes*, Cambridge University Press, London, 1947–1957.
7. *Encyclopedia of Reagents for Organic Synthesis*, edited by L. Paquette, Wiley, New York, was published in 1995. It is an 8 volume, alphabetic listing of reagents used in organic chemistry with descriptions of the preparation, use and chemistry, with references. Each reagent was researched by organic chemists active in research, who contributed to the total publication.

This latter work is available online as **eEROS**. The *Encyclopedia of Reagents for Organic Synthesis*, e-EROS, provides updated information on ~3800 reagents with a database of close to 50,000 reactions. Each reagent entry includes properties (e.g., physical data, solubility, form supplied in, purification, and preparative methods); examples of use in reactions; and literature references. Search options include: name, CAS number, structure and reaction.

8. *Comprehensive Organic Synthesis*, edited by B.M. Trost and I. Fleming, Pergamon, was published in 1991. It is a 9 volume compilation.
9. *Comprehensive Organic Functional Group Transformations*, edited by A.R. Katritzky, O. Meth-Cohn, and C.W. Rees, Pergamon, was published in 1995. It is a 7 volume compilation.

C.iv. Monographs and Treatises on Specific Areas

There are many books devoted to organic chemistry that provide a thorough coverage of a specific area. Many of these are essentially very long review articles, differing from ordinary review articles only in size and scope. Some are comprised of a series of articles, edited by an organic chemist for a specific area of research. Some of the books are by a single author, and others have chapters by different authors. All, however, are carefully planned to cover a specific area. Many of these books have been referred to in footnotes in appropriate places in this book. There have been several series of monographs, one of which is worth special mention: *The Chemistry of Functional Groups*, under the general editorship of Z. Rappoport (S. Patai was the original editor), published by Wiley, New York. Each volume deals with the preparation, reactions, and physical and chemical properties of compounds containing a given functional group. There are >130 volumes in the series, covering functional groups have appeared so far, including books on alkenes, cyano compounds, amines, carboxylic acids and esters, quinones, and so far. Since 2003, the series has appeared both in print and online.

C.v. Textbooks

There are many excellent textbooks in the field of organic chemistry. We restrict ourselves to listing only a few of those published, mostly since 1985. Some of these are first-year texts and some are advanced (advanced texts generally give references; first-year texts do not, though they may give general bibliographies, suggestions for further reading, etc.); some cover the whole field, and others cover reactions, structure, and/or mechanism only. All the books listed here are not only good textbooks and the advanced books are valuable reference books for graduate students and practicing chemists.

C.vi. Other Books

In this section, we mention several books that do not fit conveniently into the previous categories. All but the last have to do with laboratory synthesis.

1. *Organic Syntheses*, published by Wiley, New York is a collection of procedures for the preparation of specific compounds. *Organic Syntheses* is currently available online.³⁴ The thin annual volumes have appeared each year since 1921. For the first

³⁴ Available at <http://www.orgsyn.org/>

59 volumes, the procedures for each 10- (or 9-) year period are collected in cumulative volumes. Beginning with Vol. 60, the cumulative volumes cover 5-year periods. The cumulative volumes published so far are

Annual Volumes	Collective Volumes
1–9	I
10–19	II
20–29	III
30–39	IV
40–49	V
50–59	VI
60–64	VII
65–69	VIII
70–74	IX
75–80	X
81–84	XI

The advantage of the procedures in *Organic Syntheses*, compared with those found in original journals, is that these procedures are *tested*. Each preparation is carried out first by its author and then by a member of the *Organic Syntheses* editorial board, and only if the yield is essentially duplicated is the procedure published. While it is possible to repeat most procedures given in journals, this is not always the case. All *Organic Syntheses* preparations are noted in Beilstein and in *CA*. In order to locate a given reaction in *Organic Syntheses*, the reader may use the OS references given in the present volume (through OS 69); the indexes in *Organic Syntheses* itself; R. Shriner and R. Shriner, “*Organic Syntheses* Collective Volumes **I, II, III, IV, V** Cumulative Indices”, Wiley, New York, **1976**, or S. Sugawara and S. Nakai, “Reaction Index of *Organic Syntheses*”, Wiley, New York, **1967** (through OS 45). Another book classifies virtually all the reactions in *Organic Syntheses* (collective vols. **I–VII** and annual vols. 65–68) into 11 categories: annulation, rearrangement, oxidation, reduction, addition, elimination, substitution, C—C bond formation, cleavage, protection/deprotection, and miscellaneous. This is *Organic Syntheses: Reaction Guide*, by D. Liotta and M. Volmer, published by Wiley, New York, in **1991**. Some of the categories are subdivided further, and some reactions are listed in more than one category. What is given under each entry are the equation, the volume, and page reference to *Organic Syntheses*.

2. Volume 1 of *Reagents for Organic Synthesis*, by L. Fieser and M. Fieser, Wiley, New York, **1967**, is a 1457–page volume that discusses, in separate sections, some 1120 reagents and catalysts. It tells how each reagent is used in organic synthesis (with references) and, for each, tells which companies sell it, or how to prepare it, or both. The listing is alphabetical. There are now a total of 25 volumes published as of 2009, which continue the format of Vol. 1 and add more recent material. A cumulative index for Vols. 1–12, by J. Smith and M. Fieser, was published in **1990**. A cumulative index for volumes 1–22 was published in **2005**, by M.B. Smith. The series included volumes 1–18 with Mary Fieser.

After the death of Mary Fieser, the series was resumed by T.-L. Ho and now includes volumes 19–25.

3. *Comprehensive Organic Transformations*, 2nd ed. by R.C. Larock, Wiley-VCH, New York, **1999**, has been frequently referred to in footnotes in Part 2 of this book. This compendium is devoted to listings of methods for the conversion of one functional group into another, and covers the literature through 1987. It is divided into nine sections covering the preparation of alkanes and arenes, alkenes, alkynes, halides, amines, ethers, alcohols and phenols, aldehydes and ketones, and nitriles, carboxylic acids and derivatives. Within each section are given many methods for synthesizing the given type of compound, arranged in a logical system. A schematic equation is given for each method, and then a list of references (without author names, to save space) for locating examples of the use of that method. When different reagents are used for the same functional group transformation, the particular reagent is shown for each reference. There is a 164 page index of group transformations. The 2nd edition has only recently been published and is *not* referenced in this edition, and a CD-ROM version is now available.
4. *Survey of Organic Synthesis*, by C.A. Buehler and D.E. Pearson, Wiley, New York, 2 vols., **1970**, **1977**, discusses hundreds of reactions used to prepare the principal types of organic compounds. The arrangement is by chapters, each covering a functional group (ketones, acyl halides, amines, etc.). Each reaction is thoroughly discussed and brief synthetic procedures are given. There are many references.
5. A similar publication is S. Sandler and W. Karo, *Organic Functional Group Preparations*, 2nd ed., 3 vols., Academic Press, New York, 1983–1989. This publication covers more functional groups than Buehler and Pearson.
6. *Compendium of Organic Synthetic Methods*, Wiley, New York, contains equations describing the preparation of thousands of monofunctional and difunctional compounds with references. Twelve volumes have been published so far (Vols. 1–2, edited by I.T. Harrison and S. Harrison; Vol. 3, edited by L. Hegedus and L.G. Wade, Jr.; Vol. 4–5, edited by L.G. Wade, Jr.; Vols. 6–12, edited by M.B. Smith). Volume 13 will appear in 2014.
7. *The Vocabulary of Organic Chemistry*, by M. Orchin, F. Kaplan, R.S. Macomber, R. M. Wilson, and H. Zimmer, Wiley, New York, **1980**, presents definitions of >1000 terms used in many branches of organic chemistry, including stereochemistry, thermodynamics, wave mechanics, natural products, and fossil fuels. There are also lists of classes of organic compounds, types of mechanism, and name reactions (with mechanisms). The arrangement is topical rather than alphabetical, but there is a good index. *Compendium of Chemical Terminology*, by V. Gold, K.L. Loening, A. D. McNaught, and P. Sehmi (the “Gold book”), published by Blackwell Scientific Publications, Oxford, in **1987**, is an official IUPAC list of definitions of terms in several areas of chemistry, including organic.

D. LITERATURE SEARCHING

Until recently, searching the chemical literature meant looking only at printed materials (some of which might be on microfilm or microfiche). Now, however, virtually all of the literature can be searched online. Whether the search is online or uses only the printed material, there are two basic types of search, (1) searches for information about one or more specific compounds or classes of compounds, and (2)

other types of searches. First, we will discuss searches using only printed materials, and then online searching.³⁵

D.i. Literature Searching Using Printed Materials

Searching for Specific Compounds. Organic chemists often need to know if a compound has ever been prepared and if so, how, and/or they may be seeking a melting point, an ir spectrum, or some other property. Someone who wants all the information that has ever been published on any compound begins by consulting the formula indexes in Beilstein (sec. Appendix A.B.iii). At this time there are two ways to do this. (1) The formula index to the second supplement (Vol. 29, see Appendix A.B.iii) will quickly show whether the compound is mentioned in the literature through 1929. If it is there, the searcher turns to the pages indicated, where all methods used to prepare the compound are given, as well as all physical properties, with references. Use of the page heading method described in Appendix A.B.iii will then show the locations, if any, in the third and later supplements. (2) If one has an idea what volume of Beilstein the compound is in (and the tables of contents at the front of the volumes may help), one may search the cumulative index for that volume. If not sure, one may consult several indexes. One of these two procedures will locate all compounds mentioned in the literature through 1959. If the compound is heterocyclic, it may be in the fifth supplement. If it is in Vols. 17–19 (or in a later volume whose index has been published), the corresponding indexes may be consulted. If not, the page heading method will find it, if it was reported before 1960.³⁶ There is a way by which all of the above can be avoided. At this point, the investigator will know (1) all information published through 1959 or 1979,³⁵ or (2) that the compound is not mentioned in the literature through 1959 or 1979.³⁷ In some cases, scrutiny of Beilstein will be sufficient, perhaps if only a boiling point or a refractive index is required. In other cases, especially where specific laboratory directions are needed, the investigator will have to turn to the original papers.

To carry the search to more recent articles, the chemist turned to the collective formula indexes of *Chemical Abstracts* and such later collective indexes as have appeared; and the semiannual indexes thereafter. *However, such searches now would use SciFinder.*

If the compound has not been reported, the investigator will know that. Indeed, this is perhaps the most important consideration when considering a new area of research. It should be pointed out that for common compounds (benzene, ether, acetone, etc.), trivial mentions in the literature are not indexed (so they will not be found by this procedure), only significant ones. Thus, if acetone is converted to another compound, an index entry will be found, but not if it is used as a solvent or an eluant in a common procedure.

³⁵ For a monograph that covers both online searching and searching using printed materials, see Wiggins, G. *Chemical Information Sources*, McGraw-Hill, NY, **1991**.

³⁶ Compounds newly reported in the fifth supplement that are in a volume whose index has not yet been published will not be found by this procedure. To find them in Beilstein, it is necessary to know something about the system, but they may also be found by consulting *SciFinder*.

³⁷ For those heterocyclic compounds that would naturally belong to a volume for which the fifth supplement has been published.

While online searching is extraordinarily powerful, it should be pointed out that there are two problems with computer searches. First of all, far too many “hits” may be returned. For example, a 2011 research topic search (see Appendix A.D.iii) of the topic “macrolactones from hydroxy acids” gave the results:

Research Topic Candidates	References
159 references were found containing the two concepts “macrolactones” and “hydroxy acids” closely associated with one another	159
474 references were found where the two concepts “macrolactones” and “hydroxy acids” were present anywhere in the reference	474
35157 references were found containing the concept “macrolactones”	35157
193323 references were found containing the concept “hydroxy acids”	193323

Clearly, only examining the first few hundred references is practical. The search can, and must be refined. Depending on the scope of the search, this fact can be a limitation. The second problem relates to the search words used (the keywords). If they are too broad, little useful information is returned. If the keywords are too narrow in scope, many useful references may be missed. The point of these two cautions is to take care in choosing keywords. On the other hand, using many related keywords and doing multiple searches is very easy using SciFinder, and is probably a good strategy.

Often, all the information one needs about a compound will be found in one of the handbooks (Appendix A.C.i), in the *Dictionary of Organic Compounds* (Appendix A.C.i), or in one of the other compendia listed in this chapter, most of which give references to the original literature.

Other Searches. There is no definite procedure for making other literature searches using only printed materials. Any chemist who wishes to learn all that is known about the mechanism of the reaction between aldehydes and HCN, or which compounds of the general formula Ar_3CR have been prepared, or which are the best catalysts for *Friedel–Crafts acylation* of naphthalene derivatives with anhydrides, or where the group $-\text{C}(\text{NH}_2)=\text{N}-$ absorbs in the IR, is dependent on ingenuity and knowledge of the literature. If a specific piece of information is needed, it may be possible to find it in one of the compendia mentioned previously. If the topic is more general, the best procedure is often to begin by consulting one or more monographs, treatises, or textbooks that will give general background information and often provide references to review articles and original papers. In many cases this is sufficient, but when a complete search is required, it is necessary to consult the *CA* subject and/or chemical substance indexes, and also *SciFinder*, where the ingenuity of the investigator is most required, for now it must be decided which words to look under. This statement relates to the keyword used for a computer search, as indicated above. If one is interested in the mechanism of the reaction between aldehydes and HCN, one might look under “aldehydes”, or “hydrogen cyanide”, or even under “acetaldehyde” or “benzaldehyde”, and so on, but then the search is likely to prove long. A better choice in this case would be “cyanohydrin”, since these are the normal products and references there would be fewer. It would be a waste of time to look under “mechanism”. In any case, many of the abstracts would not prove helpful. If it is necessary to search before 1907

(and even before 1920, since *CA* was not very complete from 1907 to ~1920), recourse may be made to *Chemisches Zentralblatt* and the abstracts in the *Journal of the Chemical Society*.

D.ii. Literature Searching Online²⁰

Most of the *Chemical Abstracts* literature can be accessed online via *CAS*, using *SciFinder* in Appendix A.D.iii, the largest and most current database of chemical substance information in the world. *CAS* is located in Columbus, Ohio and is a division of the American Chemical Society. *CAS* can be contacted at Chemical Abstracts Service, 2540 Olentangy River Road, P.O. Box 3012, Columbus, Ohio 43210 (e-mail: help@cas.org). *CAS* is a team of scientists who provide digital information environment for scientific research and discovery. *CAS* provides pathways to published research in the world's journal and patent literature back to the beginning of the 20th century. Since 1907, *CAS* has indexed and summarized chemistry-related articles from >40,000 scientific journals, in addition to patents, conference proceedings and other documents pertinent to chemistry, life sciences, and many other fields. Through the printed *CA* (*Chemical Abstracts*), *CA* on CD, *STN*, the *CAS* files distributed through licensed vendors, the *SciFinder* and *SciFinder Scholar* desktop research tools, and the *STN Easy* or *STN* on the Web services, data produced by *CAS* is accessible to virtually any scientific researcher worldwide in industry, governmental research institutions, and academia.

Substance identification is a special strength of *CAS*. It is widely known as the *CAS Registry*, the largest substance identification system in existence. When a chemical substance, newly encountered in the literature, is processed by *CAS*, its molecular structure diagram, systematic chemical name, molecular formula, and other identifying information are added to the Registry and it is assigned a unique *CAS Registry* Number.

The *CAS REGISTRY* mostly covers substances identified from the scientific literature from 1957 to the present with some classes (fluorine- and silicon-containing compounds) going back to the early 1900s. An important piece of information that assists in such a search is the *CAS* registry number. Each substance in *REGISTRY* is identified by a unique numeric identifier called a *CAS Registry Number*.³⁸ "The *CAS Registry* number is a unique number assigned to a chemical by the Chemical Abstracts Service."³⁹ A fairly large collection of *CAS* numbers, with links to safety data for many chemicals, can be found at the listing of chemicals by *CAS* number at the Safety Home Page of the Physical and Theoretical Chemistry Laboratory at Oxford University".⁴⁰ The *CAS Registry Number* is a unique numeric identifier that designates only one substance, has no chemical significance, and is a link to finding information about a specific chemical substance. A *CAS Registry Number* includes up to 9 digits that are separated into 3 groups by hyphens. The first part of the number, starting from the left, has up to 6 digits; the second part has 2 digits. The final part consists of a single check digit.⁴¹

Online searching means using a computer terminal to search a *database*. Although databases in chemistry are available from several organizations, *STN International* (The

³⁸ Available at <http://www.cas.org/EO/regsys.html>

³⁹ Available at <http://www.cas.org/>

⁴⁰ Available at <http://ptcl.chem.ox.ac.uk/MSDS/glossary/casnumber.html>

⁴¹ Available at <http://www.cas.org/EO/checkdig.html>

Scientific & Technical Information Network) is important because it is comprehensive and available in many countries. STN has dozens of databases, including many that cover chemistry and chemical engineering. To access these databases a chemistry department, a library, or an individual subscribes to STN (for a nominal fee), and receives code numbers that will permit access to the system, usually via a desktop computer.

D.iii. SciFinder—the CAS database⁴²

Tutorials are available to help use Sci-Finder.⁴³ SciFinder can search a research topic⁴⁴ or a compound can be searched by structure⁴⁵ The search engine is known as STN Express with Discover!⁴⁶ and can easily and efficiently search >200 scientific and technical databases online through STN[®].⁴⁷ The Analysis Edition of STN Express with Discover! allows one to search, analyze, visualize, and discover sci-tech information by the ability to create a table for substance analysis that identifies the common substructure for an answer set of structurally related substances: Group related author/inventor names and company names for better analysis and visualization results; Analyze and tabulate data from single- or multi-file search results, and create a data table and 3D chart; Save an answer set from databases (e.g., CAPLUS, PCTFULL, and USPATFULL) with the Save for STN AnaVist Wizard, and then import and open it in STN[®] AnaVistTM; Create an interactive spreadsheet from all or only hit CAS Registry Numbers and their corresponding CAS Roles through the CAS Registry Number[®]; Upload lengthy genetic sequences automatically for searching in DGENE and PCTGEN via the Upload Query Wizard. STN Express was developed in collaboration with Hampden Data Services.

To illustrate how STN is used, an online tutorial is available.⁴⁸ A few online windows from a *SciFinder* search are provided to illustrate how searches can be done. This presentation is by no means complete or intended as an alternative to the actual tutorial. Indeed, one could *not* use *SciFinder* properly after simply reading this discussion. The intent is to illustrate some features that are available and to present an overview of the use of this important tool.

Using *SciFinder*[®], a search can be done in one of several different ways. Searches can be done by research topic, by substances, or by reactions. The latter two searches use drawing tools that are part of *SciFinder*. An example is shown of a search done by research topic:⁴⁹ The example shown in Fig. A.3. shows a search for intramolecular hydroamination of aminoalkenes. To begin, click Explore by research topic and enter the appropriate information.

It is possible to use filters (see Fig. A.1) in order to refine the search by year, document type (journal, patent, review, etc.), author or company. A window is returned that contain references categorized by their relationship to the search phrase, as shown in Fig. A.2. One simply checks those reference lists that appear closest to those of interest.

⁴⁹ Available at <http://www.cas.org/SCIFINDER/topic.html>

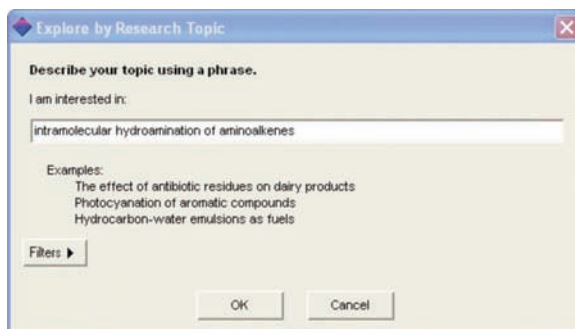

FIG. A.1. Explore by research topic.

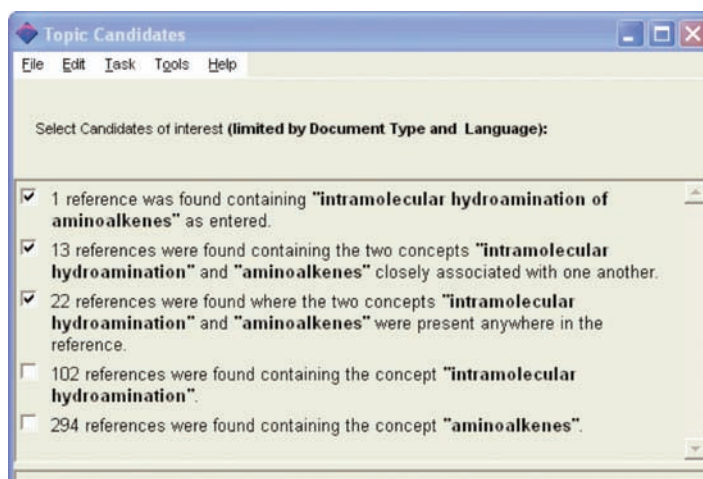

FIG. A.2. Selection of candidates of interest for search by research topic.

After clicking on “get references,” a screen is returned (Fig. A.3) that has the original references, as shown in the window. One is given the option of refining this list further, and for each reference, most browsers allow viewing the abstract or the full references as an HTML or a PDF file. However, your library must have paid the appropriate fees so the journal and volumes of interest are available online. Otherwise, interlibrary loan or direct ordering of the article may be necessary.

Other examples of typical searches allowed by SciFinder include search by author's name,⁵⁰ as with the example of Professor K. Barry Sharpless shown in Fig. A.4. Search by structure is also possible,⁵¹ such as the example shown in Fig. A.5, using SciFinder drawing tools. Once a structure is drawn, SciFinder searches to find matches based on that structure. The drawing tools can be used to show a reaction, and reaction information is returned, as shown in Fig. A.6. Ultimately, journal article and/or patents are returned that provide direct access to the literature of interest.

⁵⁰ Available at <http://www.cas.org/SCIFINDER/author.html>

⁵¹ Available at <http://www.cas.org/SCIFINDER/structure.html>

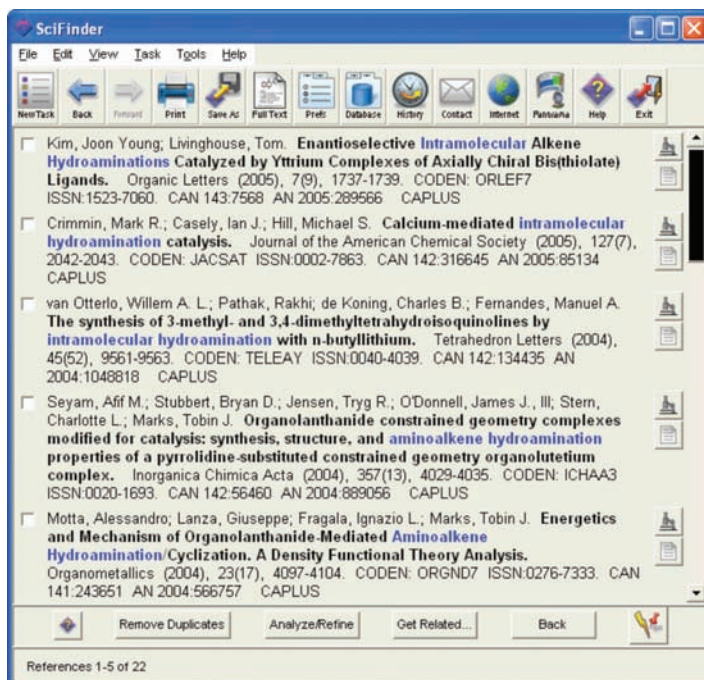

FIG. A.3. Original literature references returned for search by research topic.

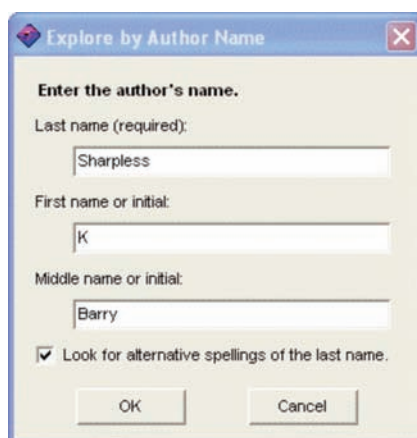

FIG. A.4. Screen shot for beginning a search by author.

D.iv. Science Citation Index

As seen in the SciFinder search tutorials, it is possible to track papers that have cited a particular article or author. A publication that can greatly facilitate literature searching is *Science Citation Index*(SCI), begun in 1961. This publication, which is quite different from any other mentioned in this chapter, gives a list of all papers in a given year that have cited a

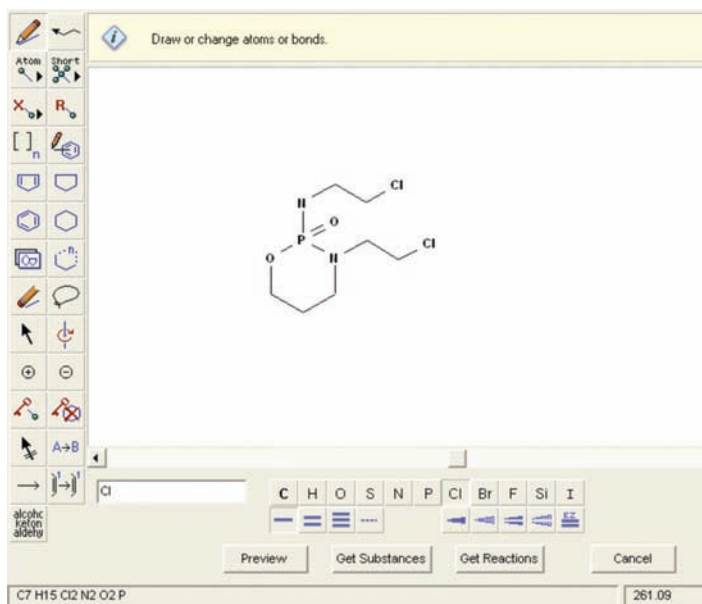

FIG. A.5. Screen shot for beginning a search by structure, using the drawing tools.

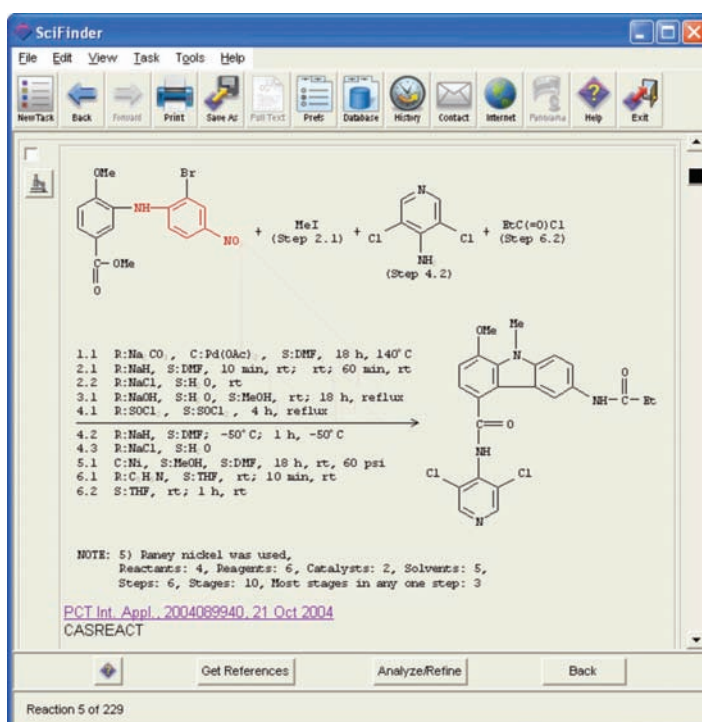

FIG. A.6. Screen shot of results for a search by reaction, using the drawing tools.

given paper, patent, or book. Its utility lies in the fact that it enables the user to search *forward* from a given paper or patent, rather than backward, as is usually the case. For example, suppose a chemist is familiar with a paper by W.P. Jencks and M. Gilchrist (*J. Am. Chem. Soc.*, **1968**, 90, 2622) entitled "Nonlinear Structure–Reactivity Correlations. The Reactivity of Nucleophilic Reagents toward Esters". The chemist is easily able to begin a search for earlier papers by using references supplied in this paper and can then go further backward with the aid of references in those papers, and so on. But for obvious reasons the paper itself supplies no way to locate *later* papers. *Science Citation Index* is designed to make up for this gap. The citation index of *SCI* lists all papers, patents, or books cited in a given year or 2-month period (by first author only) and then gives a list of papers that have done the citing. The index is published bimonthly and cumulated annually. For example, column 43901 of the 1989 citation index shows that the Jencks paper mentioned above was cited as a footnote in 16 papers published in 1989. It is reasonable to assume that most of the papers that cited the Jencks paper were on closely related subjects. For each of the 16 papers are listed the first author, journal abbreviation, volume and page numbers, and year. In a similar manner, if one consulted *SCI* for all the years from 1968 to date, one would have a complete list of papers that cited that paper. One could obviously broaden the search by then consulting *SCI* (from 1989 on) for papers that cited these 16 papers, and so on. Papers, patents, or books listed (e.g., in the 1989 *SCI*) may go back many years (e.g., papers published by A. Einstein in 1905 and 1906 are included). The only requirement is that a paper published in 1989 (or late 1988) has mentioned the earlier paper in a footnote. The arrangement of cited papers or books is alphabetical by cited first author and then by cited year. Cited patents are listed in a separate table, in order of patent number, though the inventor and country are also given.

SCI covers ~3200 journals in the physical and biological sciences, as well as in medicine, agriculture, and technology. In addition to the citation index, each bimonthly and annual *SCI* also includes three other indexes. One of these, called *Source Index*, is similar to the *CA* author index. It lists the titles, journal abbreviations, volume, issue, page numbers, and year of all papers published by a given author during that 2-month period or year. All authors are listed; not just first authors. The second, called the *Corporate Index*, lists all publications that have been published from a given institution during that period, by first author. Thus, the corporate index for 1989 lists 63 papers by 45 different first authors emanating from the Department of Chemistry of Rutgers University, New Brunswick, NJ. The main section of the corporate index (the Geographic Section) lists institutions by country or (for the US) by state. There is also an Organization Section, which lists the names of institutions alphabetically, and for each gives the location, so it can be found in the geographic section. The third index included in *SCI* is the *Permuterm*⁵²*Subject Index*. This index alphabetically lists every significant word in the titles of all papers published in that year or bimonthly period, paired with all other significant words in the same title. Thus, for example, a title with seven significant words appears at 42 separate places in the index. Each of the seven words appears six times as the main word, each time paired with a different word as the cword. The user is then led to the *Source Index*, where the full reference is given. *Science Citation Index* is also available online (though not through STN) and on CD-ROM discs. A version of *SCI* that is restricted to chemistry but also includes searchable abstracts, is available only in the CD-ROM format.

⁵² Registered trade name.

The publishers of *SCI* also produce another publication, called *Index to Scientific Reviews* that appears semiannually. This publication, which began in 1974, is very similar to *SCI*, but confines itself to listing citations to review articles. The citations come from ~2500 journals in the same general areas as are covered by *SCI*. The review articles cited appeared in ~215 review journals and books, as well as in those journals that publish occasional review articles. Like *SCI*, the *Index to Scientific Reviews* contains citation, source, corporate, and Permuterm indexes. It also contains a “Research Front Specialty Index”, which classifies reviews by subject.

D.v. How to Locate Journal Articles

Having obtained a reference from various sources or searches, one often needs to consult the original journal (patents are discussed in Appendix A.A.ii). The first step is to ascertain the full name of the journal, since it is the abbreviation that is generally given. Of course, everyone should be familiar with the abbreviations of the very important journals (*J. Org. Chem.*, *Chem. Ber.*, etc.), but references are often found to journals whose titles are not at all familiar (e.g., *K. Skogs Lantbruksakad. Tidskr.* or *Nauchn. Tr. Mosk. Lesotekh. Inst.*). In such cases, one consults the *Chemical Abstracts Service Source Index* (CASSI), 1989 edition, which contains the names of all the journals covered by *CA* from 1907 to 1989 (even those no longer published), with the most recent abbreviations in bold print. *Chemical Abstracts Service Source Index* also lists journals covered by *Chemisches Zentralblatt* and its predecessors from 1830 to 1969, and journals cited in Beilstein before 1907. The journals are listed in alphabetical order of the *abbreviations*, not of the titles. Journal title changes have not been infrequent, and *CASSI* also contains all former names, with cross-references to the current names. Quarterly supplements, cumulated annually, to *CASSI* have appeared since 1990 listing new journals and recent changes in journal titles. Note that while many publications use the *CA* abbreviations, not all do. Usage will vary from country to country, and even from journal to journal within a country. Furthermore, the *CA* abbreviations have changed from time to time. This latter point is particularly important when doing keywords searches. Using a structure search in SciFinder may get around this problem.

Once the complete title is known, the journal can easily be obtained if it is in the library customarily used by the chemist, or if that journal is available in electronic form. If not, one must use another library. The next step is to find out which libraries carry the journal and *CASSI* answers this question too, since it carries a list of some 360 libraries in the United States and other countries. *For each journal it tells which of these libraries carries it*, and furthermore, if the holdings are incomplete, which volumes of that journal are carried by each library. However, most libraries have an inter-library loan service that will provide access to such journal articles. It may be possible to visit the closest library personally and *CASSI* also includes lists of journal publishers, sales agents, and document depositories. Photocopies of most documents cited in *CA* can be obtained from chemical Abstracts Document Delivery Service, Customer Services, 2540 Olentangy River Road, Columbus OH, 43210, USA. Orders for documents can be placed by mail, telephone, Telex, fax, or online through STN or other services.

These latter comments are largely out of date given the online status of most journals. As mentioned above, PDF files of an article can be downloaded, or they can be read directly via the HTML file using any current browser. The reader is encouraged to contact the library person in your establishment that is responsible for chemical literature and to learn which online services are available through your local library.

D.vi. REAXYS®⁵³

Launched in 2009, “Reaxys was created through the merger of the existing *CrossFire* databases (Appendix A.B.iii.) into a single database with a new and intuitive user interface. Reaxys is a fully integrated content source providing in-depth coverage of inorganic, organic, and organometallic small molecule chemistries excerpted from appropriate journal and patent literature”.⁵⁴ Reaxys is available online with drawing tools that allows entry of a structure, or multiple structures as part of a reaction. Once the structure is drawn, Reaxys offers several options for the search:

Reaxys is a unique workflow solution for research chemists providing in depth coverage of inorganic, organic, and organometallic small molecule chemistries. The database consists of chemical compounds and related factual properties; chemical reaction and synthesis information; related bibliographic data, all of which have been excerpted from a carefully selected list of journals and patents: The latter is sourced from carefully selected patent classes and patent offices. This content is delivered through a web-based interface, designed for chemists, with powerful functionality that delivers the content in a flexible and intuitive way and helps a chemist with his/her major information tasks.

At the heart of Reaxys is the concept of “Chemistry as the organizing principle”. This means that the chemical compound or reaction is central to the way in which the data is organized in the database. This is fundamentally different from bibliographic databases in which a journal or patent record is at the center. This chemically focused approach allows all data from multiple sources to be combined together in one de duplicated record for a given compound or reaction (i.e., a single compound or reaction can have multiple source citations, whereas a bibliographic database will have one record per published item, so the same compound or reaction may be found in multiple records).

The value of Reaxys to organic chemists may be understood best in relation to the synthesis of compounds, which is at the core of organic chemistry. Devising new routes to unique and artificial scaffolds requires the skills of planning and executing multistep syntheses and having a toolbox of methodologies at one’s disposal. However, even the best conceived synthesis plans may require modifications, fine-tuning or entire rerouting, and chemists are faced with the daily challenge of choosing the right combination of reagents and building blocks for a whole set of problems: Which building blocks are optimal? In which sequence should they be assembled? Which reactions accomplish the task best? The Reaxys synthesis planning tool has been designed to make these choices as painless as possible using information and data from the journal and patent literature to investigate a number of possible alternative synthetic routes.

As an example, searching for papers that have reported direct arylation of indoles at the C-3 position. Construct a graphical search query (using one of the common graphical chemical structure editors, e.g., ChemDraw), with GH on indole nitrogen and also at the 5- and 6-positions of indole. The screen in Fig. A.7. shows the entry information required for the search. This query, retrieved 164 reactions from 45 citations (search results obtained in February 2012):

⁵³ Available at <https://www.reaxys.com/info/>

⁵⁴ Available at [Reaxys_whitepaper_2011_whatsinReaxys.pdf](#)

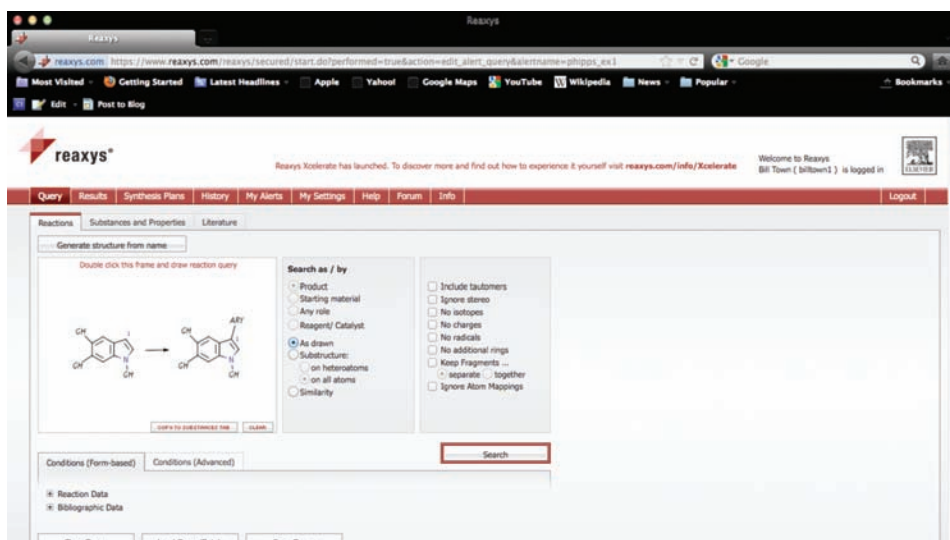

FIG. A.7. Search for direct arylation of indoles at C-3.

The Reaxys Version used in the above example is Application version: 1.0.9619; Content last updated: February 2012; Reactions: 31.681.788; Substances: 20.286.045; Citations: 4.504.504. Figure A.8 shows details for one of the reactions returned for this search. Also shown on this screen are various parameters that are available to search for this example. The original publication from which the reaction was taken is readily available.

It is also possible to expand the literature review by viewing the details of any recent articles that cite articles of interest. This is easily achieved by clicking on the 'view citing

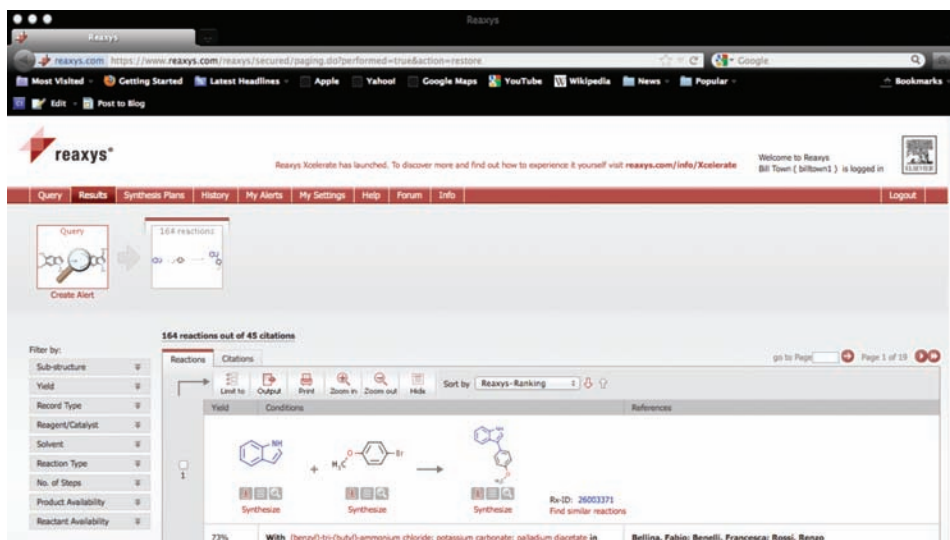

FIG. A.8. One reaction returned for this search.

1,3,6-SUBSTITUTED INDOLE DERIVATIVES HAVING INHIBITORY ACTIVITY FOR PROTEIN KINASE	Korea Institute of Science and Technology	2011	Patent: US2011/46370 A1, 2011 ; Patent Family: US2011/46370 A1; Full Text	

a. Title/Abstract
1,3,6-SUBSTITUTED INDOLE DERIVATIVES HAVING INHIBITORY ACTIVITY FOR PROTEIN KINASE
 Disclosed are a 1,3,6-substituted indole compound having inhibitory activity for protein kinase, a pharmaceutically acceptable thereof, and a pharmaceutical composition for prevention and treatment of diseases caused by abnormal cell growth including the compound as an active ingredient. Since the novel indole compound exhibits superior inhibitory activity for various protein kinases involved in growth factor signal transduction, it is useful as a novel for prevention or treatment of diseases caused by abnormal cell growth.

FIG. A.9. Papers that cited the work in Fig. A.8.

articles' hyperlink. The reaction shown in Fig. A.8 was cited in the patent literature and also in the *Journal of Organic Chemistry*, as shown in Fig. A.9. In this manner, relevant, more recent articles may be identified and explored using citation data from Scopus. A few of such citations are shown in Fig. A.10.

The synthesis planning tool allows a more in depth investigation. The Reaxys synthesis tool makes it easy to add more steps to the synthesis plan by searching the journal and patent literature for reactions designed to prepare the precursor molecules in any reaction step. Figure A.11 illustrates how a synthesis of a target that is consistent with the original

Classification of Reactions by Type of Compounds Synthesized

ACETALS

acetals + RM	10-64	carboxylic esters + organometallics	16-82
aldehydes + alcohols	16-05	cleavage of ethers	10-49
by transesterification	10-13	condensation of aldehydes	19-81
from dihalides	10-08	conjugate reduction	15-14
from hydroxy-ethers	14-06	epoxides + organometallics	10-65
ortho esters + RM	10-64	epoxides + silanes	10-55
reductive cleavage of ortho esters	19-56	from alcohols	10-17

ACYLALS (DIESTERS)

aldehydes + anhydrides	16-06	from amines	10-23
		from boranes	10-01
		from boranes	12-27
		from boranes	18-23
		from boronates	18-23
		from epoxides	10-65
		from ethers	10-13
		from silanes	10-16

ACYLOINS: See hydroxy-ketones

ALCOHOLS

addition of other organometallics to carbonyls	16-25	Grignard addition to aldehydes or ketones	16-24
aldehydes + allylic silanes	16-51	hydration of alkenes	15-03
alkenes + alcohols	15-33	hydrolysis of acetals and ketals	10-06
alkenes + aldehydes or ketones	16-54	hydrolysis of alkyl halides	10-01
alkenes-oxymmercuration	15-03	hydrolysis of inorganic esters	10-04
amides + organometallic compounds	16-82	hydrolysis of sulfonate esters	10-04
amines + KOH	10-23	hydrolysis of vinyl ethers	10-06
anhydrides + organometallic compounds	16-82	hydroxylation at aliphatic carbon	19-14
aromatics + carbonyls	11-12	hydroxymethylation of arenes	11-12
arylation of ketones	11-12	organolithium addition to aldehydes or ketones	16-24
boranes + CO; oxidation	18-23	organometallics + oxygen	12-25
boranes + CO; reduction	18-24	oxidation of boranes	12-27
by the Cannizzaro reaction	19-81	oxidation of boranes	15-16
by Wittig rearrangement	18-22	oxidation of boranes	18-23

aromatic compounds + haloamines	11-06	hydrolysis of isocyanates	18-16
aromatic compounds + hydrazoic acid	11-06	hydroxylamines + alkyl organometallics	12-32
aryl halides + amines	13-05	imines + allylic silanes	16-51
aryl halides + hydroxylamine- <i>O</i> -sulfonic acid	18-15	insertion of nitrenes	12-13
azides + haloboranes	12-32	Lossen rearrangement	18-15
aziridines + RM	10-66	Michael addition with N nucleophiles	15-31
boranes + ammonia + NaOCl	12-32	phenols + amines or ammonia	13-06
boranes + chloramine	12-32	Pictet–Spengler reaction	10-13
by amidomethylation	11-22	radical addition to C=N compounds	16-56
by reaction with nitrenes	12-13	rearrangement of ammonium salts	13-31
by the Stevens rearrangement	18-21	rearrangement of ammonium salts	18-21
by transamination	10-33	rearrangement of aryl hydroxylamines	13-32
Curtius rearrangement	18-14	reduction nitroso compounds	19-47
cyclization of haloamines	18-40	reduction of amides	19-64
dealkylation of amines	19-73	reduction of amine oxides	19-68
dehydrogenation	19-02	reduction of amines	19-64
displacement of cyano	10-62	reduction of azides	19-50
diynes + amines	15-08	reduction of azo compounds	19-74
enamines + boranes	15-16	reduction of azoxy compounds	19-74
from alcohols	10-31	reduction of C=N compounds	19-42
from alcohols	10-32	reduction of hydrazines	19-74
from alkanes	10-39	reduction of hydroxylamines	19-47
from amides	18-13	reduction of isocyanates	19-51
from amines	10-31	reduction of isothiocyanates	19-51
from amines	10-33	reduction of lactams	19-64
from amines	10-34	reduction of nitriles	19-43
from amines	10-71	reduction of nitro compounds	19-45
from amino-ethers	10-64	reduction of nitrosoamines	19-51
from amino-nitriles	10-62	reduction oximes	19-48
from ammonium salts	11-32	reductive alkylation of aldehydes or ketones	16-17
from boranes	10-31	Schmidt reaction	18-16
from cyanohydrins	10-32	Sommelet–Hauser rearrangement	13-31
from ethers	10-32	Stevens rearrangement	13-31
from haloamines	10-31	transamination	10-33
from hydrazones	10-71		
from hydroxylamines	13-32		
from nitroamines	11-28		
from nitrosamines	11-29		
from organometallics	12-32		
from phenols	11-22		
from phenols	13-06		
Hofmann rearrangement	18-13		
		AMINO ACIDS	
		lactones + ammonia or amines	16-75

AMINO ALCOHOLS

alkenes + amines	15-52
epoxides + amines or ammonia	10-35
from amino epoxides	10-36
from isonitriles	10-40
from nitroalcohols	10-35
oxetanes + amines or ammonia	10-37
rearrangement of haloamines	18-10
reductive coupling of C=N with C=O	19-76

AMINO ALDEHYDES

aldehydes + C=N compounds	16-31
---------------------------	-------

AMINO ESTERS

diazoesters + amines	15-64
----------------------	-------

AMINO ETHERS

aziridines + alcohols	10-14
-----------------------	-------

AMINO KETONES

base-induced rearrangement of sulfonyl oximes	18-12
ketones + HCHO + amines	16-19
Mannich reaction	16-19

AMINO NITRILES

from amines	12-19
from cyanohydrins	10-32
HCN or cyanide + C=N compounds	16-53

AMINO THIOETHERS

alkenes + sulfonamides	15-55
alkenes + sulfonium salts + amines	15-55

AMINO THIOLS

episulfides + amines or ammonia	10-35
---------------------------------	-------

AMMONIUM SALTS

alkyl halides + amines	10-31
------------------------	-------

ANHYDRIDES

acyl halides + carboxylic acids	16-66
aldehydes + acyl peroxides	14-09
carboxylic acids + vinyl esters	16-67
dehydration of carboxylic acids	16-67
dehydration of dicarboxylic acids	16-67

ANHYDRIDES,**ORGANIC-INORGANIC**

anhydrides + mineral acids	16-68
----------------------------	-------

ARENES

alkyl halides + ArM (Li, Na, K)	10-57
alkyl halides + aryl organometallics	10-57
alkyl halides + arylboronic acids	13-09
alkyl halides + organocuprates	10-58
alkyl halides + organometallics	13-17
aromatic compounds + active H compounds	13-17
aromatic compounds + acylperoxides	14-17
aromatic compounds + alcohols	11-11
aromatic compounds + alkenes	11-11
aromatic compounds + alkyl halides	11-11
aromatic compounds + carboxylic acids	14-19
aromatic compounds + ketones	11-12
aromatic compounds + peroxides	14-17
aryl halides + active methylene compounds	13-14
aryl halides + alkenes	13-10
aryl halides + alkenes	15-21
aryl halides + alkynes	15-21
aryl halides + organocuprates	10-58
aryl halides + RM (other metals)	10-59
aryl halides + trifluoroborates	13-09
aryl halides + vinylboronic acids	13-09
aryldiazonium salts + alkenes	13-26
aryldiazonium salts + alkyl organometallics	13-25
aryldiazonium salts + organometallics	13-25
by decarboxylation	12-40
by radical cyclization	15-30
coupling of aromatic compounds	11-15
cyclodehydration of carbonyl compounds	11-13
Friedel-Crafts alkylation	11-11
from alkylborates	10-59
from boranes	10-59
from ketones	11-13
hydrogen exchange	11-01
rearrangement of <i>N</i> -alkyl aryl amines	11-32

replacement of aryl nitro	13-29	AZIDO AMIDES	
α -halo ketones + organocuprates	10-58	from amides	12-11
AROMATIC COMPOUNDS		AZIDO AMINES	
alkylation of heteroaryls	14-19	from aziridines	10-38
aromatic compounds + carbenes	15-64		
aromatization of six-membered rings	19-01	AZIRIDINES	
cleavage of arenes	11-33	alkenes + alkyl azides	15-54
cleavage of aryl alkyl ethers	11-37	alkenes + halogen + haloamines	15-54
cyclization of ene-dienes	18-27	C=N compounds + sulfur ylids	16-47
cyclotrimerization of alkynes	15-65	extrusion of nitrogen from triazolines	17-34
deamination of aromatic compounds	19-69	form haloamines	10-31
decarbonylation of aryl aldehydes	11-34	from allene amides	15-09
decarboxylation of aryl carboxylic acids	11-35	from azido alcohols	10-43
dehalogenation of aryl halides	11-39	from epoxides	10-36
dehydrogenation of cyclic alkanes	19-01	from halo-azides	15-45
deoxygenation of aryl ethers	11-37	from hydroxy-amines	10-32
desulfonylation of aryl sulfonic acids	11-38	from imines	16-32
from aldehydes	11-34	from triazolines	15-58
from aromatic compounds	11-33	imines + diazo compounds	16-32
from aromatic compounds	18-28		
hydrolysis of aromatic organometallics	11-41	AZIRINES	
protonation of aryl organometallics	11-41	alkynes + amino nitrenes	15-54
pyrolysis of bicyclic dienones	17-28		
reduction aryl diazonium salts	19-69	AZO COMPOUNDS	
reduction of aryl halides	11-39	aryl amines + nitroso compounds	13-24
reduction of phenols	19-55	aryl diazonium salts + aromatic compounds	11-04
reduction of quinones	19-01	from aryldiazonium salts	13-28
		oxidation of hydrazines	19-05
		rearrangement of aryl triazenes	11-30
		rearrangement of azoxy compounds	18-43
		reduction of azoxy compounds	19-68
		reduction of nitro compounds	19-80
		Wallach rearrangement	18-43
AZIDES			
aldehydes + metal azides	16-78	AZOXY COMPOUNDS	
alkenes + hydrazoic acid	15-10	from alkyl halides	10-45
alkenes + metal azides	15-53	nitroso compounds + hydroxylamines	12-51
amides + sulfonyl azides	12-11	reduction of nitro compounds	19-79
from acyl halides	10-43		
from alkyl halides	10-43	BIARYLS	
hydrazines + HONO or nitrosyl compounds	12-49	aromatic compounds + aryl halides (<i>h</i> ν)	14-18
AZIDO ALCOHOLS		aromatic compounds + aryl organometallics	11-16
from epoxides	10-43		

aromatic compounds + aryl organometallics	14-17	BUNTE SALTS from alkyl halides	10-28
aromatic compounds + arylboronates	11-16	CARBAMATES alkyl halides + amines	10-17
aryl halides + alkyl or aryl organometallics	13-09	amines + alkyl halides + CO ₂	12-53
aryl halides + arylboronic acids	13-09	amines + CO ₂	12-53
aryl halides + arylboronic acids	13-12	from aziridines	12-53
aryl halides + metals	13-11	haloformates + amines	16-72
aryl halides + trifluoroborates	13-12	isocyanates + alcohols	16-08
aryldiazonium salts + aromatic compounds	13-27	CARBONATES alcohols + phosphine	16-10
aryldiazonium salts + metal salts	13-28	CARBOXYLIC ACIDS acyl halides + diazo compounds	18-08
arylsulfonic acid + arylboronic acids	13-05	acyl peroxides + alkyl organometallics	12-26
by benzidine rearrangement	18-36	alkylation of carboxylic acids	10-70
coupling 2 aryldiazonium salts	13-28	aromatic compounds + CO ₂	11-20
coupling aryl halides	13-11	aromatic compounds + CO ₂	11-20
coupling of aromatic compounds	11-15	aromatic compounds-carboxylation	11-19
coupling of aryl sulfonates	13-12	aryl nitro compounds + cyanide	13-30
Scholl Reaction	11-15	Barbier–Wieland procedure	19-10
Suzuki–Miyaura coupling	13-12	boranes + ether-acids	18-24
Ullmann coupling	13-11	by decarboxylation	12-40
BIS(AMINES)		by Favorskii rearrangement	18-07
by benzidine rearrangement	18-36	by malonic ester synthesis	10-67
BIS(AMIDES)		by Michael addition	15-24
aldehydes + amides	16-18	by the Cannizzaro reaction	19-81
BISULFITES		carboxylation of alkenes	15-35
metal bisulfite + carbonyl compounds	16-12	cleavage of diketones	12-43
BORANES		cleavage of ketoesters	12-43
alkenes + borane or alkyl boranes	15-16	cleavage of ketones	12-45
thermal migration of boron in boranes	18-11	cleavage of methyl ketones	12-44
BORATES (TRIFLUORO)		deacyloxylation	19-59
boranes + KHF ₂	12-28	esters + metal halides	10-51
BORATES		from carboxylic acids	10-70
alcohols + boranes	12-28	from lactones	10-51
oxidation of boranes	12-27	from oxazolones	10-72
BORONIC ACIDS		from RM + arenes	10-57
alkyl borates + alkyl organometallics	12-28	haloform reaction	12-44
		hydrolysis of acyl halides	16-57
		hydrolysis of amides	16-60
		hydrolysis of anhydrides	16-58
		hydrolysis of carboxylic esters	16-59
		hydrolysis of diazo ketones	18-08
		hydrolysis of nitriles	16-04

hydrolysis of ortho esters	10-06	by the Tishchenko reaction	19-82
hydrolysis of trihalide	10-03	carbonylation of alkyl halides and	
ketones + peroxy acids	18-19	alcohols	10-77
organometallics + CO ₂	16-30	carboxylic acids + diazo	
oxidation of aldehydes	19-23	compounds	10-19
oxidation of aromatic rings	19-10	cleavage of keto-esters	12-43
oxidation of aromatic side chains	19-11	condensation of aldehydes	19-82
oxidation of organoiron compounds	10-77	condensation of ketones	19-84
oxidation of primary alcohols	19-22	conjugate addition of	
oxidative cleavage of alkenes	19-10	allylic silanes	15-26
oxidative cleavage of alkynes	19-10	esterification of carboxylic acids	16-63
ozonolysis of alkenes	19-09	esters + ethers	10-18
phenoxides + CO ₂	11-20	ethers + anhydrides	10-18
phosphoranes + CO ₂	16-44	from alcohols	10-77
pyrolysis of esters	17-04	from alkanes	14-09
rearrangement of ketones	18-19	from alkyl halides	10-17
		from alkyl halides	10-77

ketones + alcohols	16-07	from aldehydes + aromatics	10-14
Michael addition with O nucleophiles	15-31	from alkyl halides	10-46
Organometallics + peroxides	12-26	from amines	10-53
oxidative cyclization of alcohols	14-06	from esters	10-51
phenols + diazo compounds	10-11	from inorganic esters	10-47
rearrangement of aryl sulfones	13-33	from silyl ethers	10-48
reduction of esters	19-62	from sulfonate esters	10-47
reduction of lactones	19-62	halide exchange with alkyl halides	10-46
reductive cleavage of acetals or ketals	19-56	halo-decarboxylation of acids	16-71
Smiles rearrangement	13-33	halogens + alkyl organometallics	12-31
transetherification	10-13	halogens + boranes	12-31
		halo-methylation of arenes	11-14
		Hunsdiecker reaction	14-30
ETHERS, SILYL		HALIDES, ALLYLIC	
Brook rearrangement	18-44	alkanes + halo-succinimides	14-03
cleavage of ethers	10-49	alkenes + halogens	14-03
from alcohols and silyl halides	10-08	HALIDES, ARYL	
rearrangement of hydroxy-silanes	18-44	aromatic compounds + halogen	11-10
		aromatic compounds + halo-succinimides	11-10
FORMAMIDES		aryl ammonium salts + halide ion	11-32
amines + trihalides	10-40	aryl halides + halogenating agent	13-07

aryldiazonium salts + metal halides	14-20	HALOAMINES	
aryldiazonium salts + metal iodides	13-22	alkenes + <i>N</i> -haloamines	15-43
by Sandmeyer reaction	14-20	from amines	12-52
from aryl amines	14-20		
from phenols	13-22	HALOAZIDES	
heating aryldiazonium		alkenes + X-N ₃	15-45
tetrafluoroborates	13-23		
phenols + phosphonium halides	13-07	HALOCARBOXYLIC ACIDS	
rearrangement of <i>N</i> -haloamides	11-31	carboxylic acid + halogen	12-05
sulfonyl halides + transition metal		carboxylic acid + halogenating	
halides	11-38	agents	12-05
		from amino acids	10-52
HALIDES, Silyl			
From silanes	14-02	HALOESTERS	
		from epoxides	10-50
HALIDES, SULFONYL			
alkanes + SO ₂ + halogens	14-10	HALOETHERS	
aromatic compounds + sulfonyl		from alkene-alcohols	15-51
halides	11-08		
aryldiazonium salts + sulfur dioxide	14-22	HALOKETONES	
sulfonic acids + halogenating agents	16-103	alkenes + acyl halides	15-47
		from diazoketones	10-52
		from enol borinates	12-04
		ketone + halogen	12-04
		ketone + halogenating agents	12-04
HALIDES, VINYL			
elimination of dihalides	17-22	HALOLACTAMS	
elimination of halides (by base)	17-13	halolactamization	15-41
from aldehydes or ketones	11-23		
from alkynes	12-31	HALOLACTONES	
halide exchange with vinyl halides	10-46	halolactonization	15-41
halogens + vinyl boranes	12-31		
halogens + vinyl-M (M = a metal)	12-31		
HALOALCOHOLS (Halohydrins)			
cleavage of cyclic ethers	10-49	HALONITRO COMPOUNDS	
from aldehydes or ketones	16-24	alkenes + NOX	15-44
from alkenes	15-40	HALONITROSO COMPOUNDS	
		alkenes + NOX	15-44
HALOALDEHYDES			
aldehydes + halogen	12-04	HALOSILANES	
aldehydes + halogenating agent	12-04	from silanes	10-16
alkenes + formamides	15-47	silanes + halogens	14-02
HALOALKYNES			
from alkynes	12-31	HALOSULFONES	
		sulfones + halogenation agents	12-06
HALOAMIDES		HALOSULFOXIDES	
from amides	12-53	sulfoxides + halogenating	
from aziridines	10-50	agents	12-06

HALOHYDRINS

alkenes + alcohols + halogens	15-40
alkenes + hypohalous acids	15-40
from epoxides	10-50

HETEROCYCLES

acylation of amines	16-77
aromatization of six-membered rings	19-01
by [3 + 2]-cycloaddition	15-58
by the heteroatom Diels–Alder reaction	15-61
by the Paterno–Büchi reaction	15-63
condensation of aldehydes	16-92
cyclization of amino-ketones or aldehydes	16-13
cyclization of haloamines	18-40
dehydrogenation reactions	19-02
dinitriles + ammonia or amines	16-21
rearrangement of acyl aziridines	18-31
thermal rearrangement of azides	18-14
furans: from diketones	16-05
indoles: Fischer indole synthesis	18-34
oxetanes: alkenes + aldehydes or ketones	16-95
oxetanes: Paterno–Büchi reaction	16-95
oxetanes: alkenes + ketones	15-63
pyrans: from diketones	16-05
pyrazoles: hydrazines + diketones	16-14
pyrazolines: alkenes + diazoalkanes	15-58
pyrazolines: hydrazines + keto-esters	16-14
pyridine derivatives: by the heteroatom Diels–Alder reaction	15-61
pyrazolidines: alkenes + azomethine imines	15-58
pyrrolidines: cleavage of aziridines	15-58
pyrrolines: rearrangement of cyclopropyl imines	18-31
quinolines (dihydro): cyclodehydration of imines	11-13
quinolines (dihydro): from amines	11-13
quinolines (tetrahydro):	
cyclodehydration of amides	11-13
quinolines (tetrahydro): from amines	11-13

HYDRATES

from ketones or aldehydes	16-01
---------------------------	-------

HYDRAZIDES

Imides + hydrazine	10-41
carboxylic esters + hydrazine	16-75

HYDRAZINES

reduction of azo compounds	19-51
reduction of diazo compounds	19-51

HYDRAZONES

active methylene compounds + aryldiazonium	12-07
exchange of hydrazine + hydrazones	16-14
from azo compounds	12-07
from ketones	12-07
hydrazines + aldehydes or ketones	16-14

HYDROXAMIC ACIDS

carboxylic esters + hydroxylamine	16-75
-----------------------------------	-------

HYDROXY-ALDEHYDES

aldol condensation	16-34
dihydrooxazines + epoxides	10-72
imines + ketones	16-34
Mukaiyama aldol	16-35
oxidation of epoxides	19-20
silyl enol ethers + aldehydes	16-35

HYDROXY-AMIDES

aldehydes + amides	16-18
alkenes + amides	15-52
alkenes + sulfonyl amines	15-52

HYDROXY-AMINES: See amino alcohols**HYDROXY-AZIRIDINES**

from amino epoxides	10-36
---------------------	-------

HYDROXY-CARBOXYLIC ACIDS

by the Cannizzaro reaction	19-81
rearrangement of 1,2-diketones	18-06

HYDROXY-ESTERS

Baylis–Hillman reaction	16-27
-------------------------	-------

Claisen condensation	16-36	Claisen condensation	16-36
epoxides + carboxylate anions	10-14	from epoxides	10-26
from epoxides and RCOOH	10-18		
Reformatsky reaction	16-28	HYDROXYLAMINES	
transesterification of lactones	16-64	addition of organometallics to oximes	16-31
HYDROXY-ETHERS		oxidation of amines	19-27
epoxides + alcohols	10-14	rearrangement of amine oxides	18-21
		reduction of nitro compounds	19-46
HYDROXY-KETONES		IMIDES	
acyloin condensation	19-78	acylation of amines	16-77
aldehydes + cyanide	16-55	alkyl halides + imides	10-41
aldehydes and cyanide	15-32	anhydrides + ammonia or amines	16-73
Baylis–Hillman reaction	16-27	from alcohols	10-41
by aldol condensation	16-34	from aryl acyl isothiocyanates	11-21
by rearrangement of hydroxy ketones	18-04	isocyanates + phosphine oxides	16-93
by the Tollens reaction	16-43		
coupling of carboxylic esters	19-78	IMIDINES	
hydrolysis of diazo ketones	10-05	dinitriles + ammonia or amines	16-21
ketones + formaldehyde	16-43		
Mukaiyama aldol	16-35	IMINES	
oxidation epoxides	19-20	active methylene compound + nitroso compound	12-08
oxidation of methylene	19-15	addition of organometallics to nitriles	16-33
photolysis of epoxy ketones	10-07	aldehydes + amines or ammonia	16-13
rearrangement of silyloxy epoxides	18-02	alkynes + amines	15-08
reduction of epoxy ketones	19-35	dehydrogenation of amines	19-05
silyl enol ethers + ketones	16-35	from imines + RMgX	10-69
		ketones + amines or ammonia	16-13
HYDROXY-NITRILES: See cyanohydrins		oxidation of primary amines	19-21
HYDROXY-NITRO COMPOUNDS		rearrangement of cyclopropyl	18-31
from epoxides	10-35	reductive alkylation of aldehydes or ketones	16-17
Henry reaction	16-37	thermal rearrangement of alkyl azides	18-14
		via Bischler–Napieralski reaction	10-13
HYDROXY-PHOSPHONATES		IMINO ESTERS	
phosphonate esters + carbonyl compounds	16-44	haloimines + aroxides	18-42
HYDROXY-PHOSPHORAMIDES		ISOCYANATES	
phosphoramides + carbonyl compounds	16-44	amides + hypohalites	18-13
HYDROXY-THIOCYANATES		amines + CO	12-53
epoxides + thiocyanate	10-14	base induced rearrangement of hydroxamic acids	18-15
HYDROXY-THIOETHERS		carboxylic acids + HN ₃	18-16
alkenes + disulfides + carboxylic acids	15-51		

Curtius rearrangement	18-14	KETO-CARBOXYLIC ACIDS	
from acyl halides	10-44	active H compounds + CO ₂ or CS ₂	16-42
from alkyl halides	10-44	carboxylic acids + esters	16-87
from nitrile oxides	18-44		
Hofmann rearrangement	18-13	KETO-ESTERS	
phosgene + amines	16-72	acyl halides + active H compounds	16-84
the Schmidt reaction	18-16	aldehydes + diazoketones	12-18
thermal rearrangement of acyl azides	18-14	alkenes + acyloxy salts	15-56
		alkylation reactions	10-67
		Claisen condensation	16-85
		haloesters + esters	16-28
		haloesters + nitriles	16-28
ISONITRILES (ISOCYANIDES)		KETO-ESTERS, CONJUGATED	
alkyl halides + cyanide	10-75	by the Knoevenagel reaction	16-38
amines + trihalides	10-40		
dehydration of formamides	17-31		
from oxetanes	10-40		
		KETO-NITRILES	
ISOTHIOCYANATES		acyl halides + active H compounds	16-84
from acyl halides	10-44	by the Thorpe reaction	16-50
from alkyl halides	10-44	condensation of nitriles	16-50
		esters + nitriles	16-86
ISOTHIOURONIUM SALTS		from ketones	12-19
from alkyl halides	10-25		
		KETO-SULFIDES	
KETALS		Ketones + disulfides	12-14
ketals + RM	10-64		
ketones + alcohols	16-05		
reductive cleavage of ortho esters	19-56	KETO-SULFONES	
		acyl halides + active H compounds	16-84
		KETO-SULFONIC ACIDS	
KETENES		ketones + sulfur trioxide	12-14
base-induced elimination of acyl halides	17-14		
dehydration of carboxylic acids	17-01	KETONES	
elimination of haloacyl halides	17-23	acyl halides + aromatic compounds	11-17
		acyl halides + organometallic compounds	16-81
KETENIMINES		addition of organometallics to nitriles	16-33
by the Wittig reaction	16-44	aldehydes + alkenes	15-34
dehydration of amides	17-01	aldehydes + boranes	12-18
		aldehydes + heterocycles	14-19
KETO-ALDEHYDES		aldehydes + transition metal complexes	12-18
ketals + formamides	12-16	alkenes + aldehydes	15-34
		alkenes + alkenes + CO	15-36
KETO-ALKYNES		alkenes + ketones	15-33
elimination of epoxy-hydrazones	17-27	alkyl halides + organoiron compounds	10-76
KETO-AMIDES			
alkenes + acyloxy salts + nitriles	15-56		
amino acids + anhydrides	12-42		

alkylation of enamines	10-69	from dithioketals	10-06
alkylation of hydrazones	10-68	from dithioketals	16-11
alkylation of ketones	10-68	from enamines	10-69
alkylation reactions	10-67	from halo-ketones	10-73
amines + HONO	12-50	from imines	10-69
and keto-enol tautomerism	12-03	from ketones	10-68
aromatic compounds + acyl halides	11-17	from keto-sulfoxides	10-67
aromatic compounds + aldehydes	14-19	from nitriles	11-24
aromatic compounds + anhydrides	11-17	from organometallics	12-33
aromatic compounds + carboxylic acids	11-17	haloketones + boranes	10-73
aromatic compounds + nitriles	11-24	homologation of ketones	18-09
aryl diazonium salts + oximes	14-23	hydration of alkynes	15-04
arylation of ketones	13-14	hydration of allenes	15-04
arylation	13-14	hydrolysis of C=N compounds	16-02
by cleavage of alkoxides	12-41	hydrolysis of dithioketals	10-06
by decarboxylation	12-40	hydrolysis of dithioketals	10-71
by Michael addition	15-24	hydrolysis of enol ethers	10-06
carbonyl transposition	12-14	hydrolysis of furans	10-06
carbonylation of metal alkyls	13-15	hydrolysis of <i>gem</i> -dihalides	10-02
carboxylic acids + organolithium reagents	16-29	hydrolysis of imines	16-33
cleavage of diketones	12-43	hydrolysis of ketals	10-05
conjugate addition of alkyl halides	15-28	hydrolysis of nitro compounds	16-03
conjugate addition of allylic slanes	15-26	hydrolysis of orthoesters	10-06
conjugate addition of boranes	15-27	hydrolysis of vinyl ethers	10-06
conjugate addition of boranes	15-27	hydrolysis of vinyl halides	10-01
conjugate addition of organometallics	15-25	imines + RM	10-69
cyanoboranes + anhydrides	18-23	insertion of diazo ketones	12-21
decarboxylative alkylation	14-31	ketenes + alkenes	15-63
decarboxylative coupling of 2 acids	16-90	keto esters + alkyl halides	10-67
diazo ketones + boranes	10-73	ketones + diazomethane	18-09
elimination (1,3) of halo-amines	17-25	Nef reaction	16-03
elimination (1,3) of diols	17-25	oxidation alkenes	19-25
elimination (1,3) of halohydrins	17-25	oxidation of alcohols	19-03
Friedel-Crafts acylation	11-17	oxidation of dicarboxylic acids	19-13
Fries rearrangement	11-27	oxidation of methylene	19-17
from aldehydes	12-18	oxidation of nitro compounds	19-21
from alkyl halides	10-76	oxidation of primary amines	19-21
from anhydrides	11-17	oxidation of vinyl boranes	18-26
from aryl halides	13-15	oxidative cleavage of alkenes	19-10
from boranes	10-73	oxidative cleavage of diols	19-07
from cyanohydrins	10-68	oxidative cleavage of enamines	19-10
from diazoketones	10-73	ozonolysis of alkenes	19-09
from dihaloalkenes	10-02	pinacol rearrangement	18-02
from dihydrooxazines	10-72	pyrolysis of hydroxy-alkenes	17-32
from dithianes	10-71	radical addition to conjugated ketones	15-28
		rearrangement of aryl esters	11-27
		rearrangement of diols	18-02

rearrangement of epoxides	18-02
rearrangement of ketones	18-04
rearrangement of peroxides	18-20
ring expansion of amino alcohols	18-03
ring expansion of halohydrins	18-03
Sakurai reaction	15-26
silyl enol ethers + alkyl halides	10-68
tautomerization of enols	12-03
transesterification of vinyl esters	16-64
transition metal carbonyls + RM (M = metal)	12-33
Wacker process	19-25
Weinreb amides + organometallic compounds	16-82

KETONES, CONJUGATED

aldol condensation	16-34
alkenes + acyl halides	12-16
carbonylation of vinyl-M (M = metal)	12-33
coupling of dienones	15-20
oxidation of methylene	19-17
Pauson-Khand reaction	15-36

LACTAMS

alkyl halides from amides	10-41
and Michael addition	15-31
by Beckmann rearrangement	18-17
cyclic ketones + HN ₃	18-16
cyclic ketones + silyl azides	18-16
from amino carboxylic acids	16-74
from haloamides	10-41
lactams + amines	16-76
lactones + ammonia or amines	16-75
N-arylation	10-41
N-vinylation	10-41
oxidation of methylene in amines	19-17
rearrangement of oximes	18-17
reduction of imides	19-64
Schmidt reaction	18-16

LACTAMS, β

diazo-[2 + 2]-cycloaddition	15-63
enamines + ketenimines	16-96
ketenes + C=N compounds	16-96
ketones + C=N compounds	16-96
rearrangement of hydroxy-haloamines	18-18

LACTONES

alkenes + carboxylic acids	15-57
and Michael addition	15-31
Baeyer-Villiger rearrangement	18-19
condensation of dialdehydes	19-81
cyclization of allene carboxylic acids	15-06
from halocarboxylic acids	10-17
from hydroxy-carboxylic acids	16-63
oxidation of methylene in ethers	19-17
photolysis of halo-amides	18-40
rearrangement of cyclic ketones	18-19
rearrangement of lactones	18-44
reduction of anhydrides	19-63

LACTONES, β

ketones + aldehydes or ketones	16-95
--------------------------------	-------

NITRATES: See inorganic esters

NITRILES

aldehydes + hydroxylamines	16-16
alkenes + HCN	15-38
alkyl halides + cyanide	10-75
aromatic compounds + trihalo nitriles	11-25
aryl diazonium salts and metal cyanides	14-20
aryl halides + metal cyanides	13-08
aryl triflates + metal cyanides	11-25
by decarboxylation	12-40
by Sandmeyer reaction	14-20
carboxylic acids + cyanogen halides	16-94
cyanation α to active hydrogen compounds	12-19
cyanation α to nitrogen	12-19
cyanoborates + metal cyanide	12-34
dehydration of amides	17-30
dehydration of oximes	17-29
dehydrogenation of amines	19-05
elimination (base) of hydrazones	17-29
from iminium salts	11-25
from aldehydes	17-29
from alkyl halides	10-75
metal cyanides + alkyl organometallics	12-34
metal cyanides + aryl organometallics	13-08

Michael addition	15-24	alkenes + metal hydrides	15-17
oxidation of hydrazones	19-06	alkyl halides + alkyl organometallics	12-39
rearrangement of isonitriles	18-21	alkyl halides + metals	12-38
reduction of nitro compounds	19-49	alkynes + metal hydrides	15-17
NITRILES, CONJUGATED		aryl halides + metals	11-40
by the Knoevenagel reaction	16-38	aryl halides + R-M (M = a metal)	11-40
NITRITES: See inorganic esters		formation of enolate anions	12-23
NITRO COMPOUNDS		isonitriles + organolithium reagents	16-99
alkanes + alkyl nitrates	12-09	metal halides + RM (where M = metals)	12-36
alkanes + nitronium salts	12-09	metalation of aromatic compounds	13-17
alkenes + nitric acid	12-09	metals + RM (where M = metals)	12-35
aryldiazonium salts + metal nitrites	14-21	thioethers + organometallics	14-28
by Michael addition	15-24	transmetalation	12-35–12-37
from alcohols	10-42	ORTHO ESTERS	
from alkyl halides	10-42	by transesterification	10-13
from aromatics	11-02	carboxylic acids + alcohols	16-05
from aromatics	14-20	from trihalides	10-08
from conjugated carboxylic acids	14-13	OSAZONES	
nitration of aromatic rings	11-02	hydrazines + hydroxy aldehydes or ketones	16-14
oxidation of amines	19-28	OXIMES	
oxidation of isocyanates	19-28	alcohols + NOCl	18-40
oxidation of oximes	19-28	aldehydes or ketones + hydroxylamine	16-15
rearrangement of nitroamines	11-28	alkenes + NOX	15-44
NITROALCOHOLS: See hydroxy-nitro compounds		aryldiazonium salts + oximes	14-23
NITRONES		Barton rearrangement	18-40
from oximes	10-24	carbonyl compounds + nitrous acid	12-08
oxidation of hydroxylamines	19-06	O-alkylation of oximes	10-24
NITROSO COMPOUNDS		reduction of nitro compounds	19-49
Barton reaction	18-40	OXONIUM SALTS	
from active methylene compounds	12-08	alkyl halides + ethers	10-20
nitrosation of aromatic rings	11-03	OXIRANES: See Epoxides	
oxidation of amines	19-27	PEROXIDES	
rearrangement of nitroso-amines	11-29	acid halides + alkyl hydroperoxides	10-21
NITROSOAMINES		acid halides + hydrogen peroxide	10-21
amines + HONO	12-50	alkanes + oxygen	14-07
ORGANOMETALLICS		alkanes + peroxides	14-08
alkanes + alkyl organometallics	12-22	alkenes + oxygen	15-62
alkanes + metals	12-23	alkyl halides + hydroperoxide anion	10-21
alkenes + alkyl organometallics	15-21		

alkyl halides + hydroperoxide anion	10-21	SELENIDES	
anhydrides + hydrogen peroxide	10-21	aryl halides + selenide	13-04
dienes + oxygen	15-62	from alkyl halides	10-26
from organometallics	12-29	SELENOCARBONATES	
oxidation of carboxylic acids	19-24	from isocyanates	16-08
oxygen + alkyl organometallics	12-25	SELENOETHER-ALDEHYDES	
oxygen + organoboranes	12-25	aldehyde + diselenide	12-14
photooxidation of dienes	15-62		
PHENOLS		SELENOETHER-KETONES	
aromatic compounds + peroxides	14-05	ketone + diselenide	12-14
aromatic compounds + peroxyacids	11-26		
aryl halides + hydroxide	13-01	SELENOXIDES	
aryl sulfonic acids + hydroxide	13-02	alkylation of selenoxides	10-71
aryldiazonium salts + water	13-20		
Claisen rearrangement	18-33	SILANES	
Fries rearrangement	11-27	addition of silanes to alkenes	15-19
oxidation of aromatic compounds	11-26	and dyotropic rearrangement	18-44
oxidation of aryl borates	13-01	aryl halides + silanes	13-16
oxidation of arylboronic acids	13-01	from metallated aryls	10-55
rearrangement of allyl aryl ethers	18-33		
rearrangement of aryl esters	11-27	SULFIDES: See Thioethers	
rearrangement of aryl hydroxylamines	13-32	SULFINIC ACIDS	
rearrangement of dienones	18-05	RM (M = a metal) + sulfonating agents	12-30
Wallach rearrangement	18-43		
PHOSPHINES		SULFONAMIDES	
alkenes + phosphines	15-08	addition or arylboronates to C=N	16-31
phosphines + aryl halides	13-05	dealkylation of sulfonamides	19-73
reduction of phosphine oxides	19-68	reduction of acyl sulfonamides	19-64
		reduction of sulfonyl azides	19-50
PHOSPHONATE ESTERS: See inorganic esters		sulfonyl halides + ammonia or amines	16-102
PHOSPHONIUM SALTS		SULFONATE ESTERS	
alkyl halides + amines	10-31	alkenes + sulfonic acids	15-06
phosphines + ammonium salts	10-31	from ethers	10-22
		sulfonamides + alcohols	16-101
PHOSPHORANES		sulfonyl halides + alcohols	16-101
and the Wittig reaction	16-43		
QUINONES		SULFONES	
dyotropic rearrangement	18-44	alkenes + sulfonyl halides	15-42
oxidation of aromatic compounds	19-04	alkyl halides + sulfinic acid salts	10-29
oxidation of aromatic compounds	19-19	alkyl halides + sulfonyl halides	10-29
oxidation of phenols	19-04	alkylation of sulfones	10-67
		alkylation of sulfones	10-71

and Michael addition	15-31	alkenes + sulfur reagents	15-50
aromatic compounds + sulfonic acids	11-09	from epoxides	10-26
aromatic compounds + sulfonyl halides	11-09	from halo-alcohols	10-09
aryl halides + sulfonate	13-04	from halo-ketones	10-09
oxidation of sulfoxides	19-31	thioketones + sulfur ylids	16-48
oxidation of thioethers	19-31	THIOAMIDES	
sulfones + organometallics	10-61	amides + sulfur reagents	16-11
sulfonyl halides + arylboronic acids	16-105	amides + sulfur reagents	16-70
sulfonyl halides + organometallics	16-105	from nitriles	16-04
SULFONIC ACIDS		THIOCARBAMATES	
aromatic compounds + sulfuric acid	11-07	from isocyanates	16-08
aromatic compounds + sulfuric acid	11-36	hydrolysis of thiocyanates	16-04
aryl halides + sulfonates	13-04	THIOCARBOXYLIC ACIDS	
hydrolysis of sulfonyl halides	16-100	acyl halides + sulfur reagents	16-69
oxidation of sulfur compounds	19-30	THIOCYANATES	
oxidation of thiols	19-30	aryl halides + thiocyanate	13-04
rearrangement of aryl sulfones	13-33	aryldiazonium salts + thiocyanate	13-21
reduction of sulfonyl halides	16-104	from alkyl halides	10-30
sulfonation of aromatic compounds	11-07	from alkenes	15-42
sulfonation of aromatic compounds	11-36	from amines	10-30
sulfonation of methylene	19-16	THIOESTERS	
SULFONIUM SALTS		acyl halides + thiols	16-69
alkyl halides + thioethers	10-26	esters + sulfur reagents	16-11
SULFONYL IMINES: See halides, sulfonyl		THIOETHER-ALDEHYDES	
SULFONYL IMINES		aldehyde + disulfides	12-14
sulfonamides + aldehydes	16-18	THIOETHER-KETONES	
SULFOXIDES		enol ethers + disulfides	12-14
alkylation of sulfoxides	10-67	ketone + disulfides	12-14
aromatic compounds + sulfonyl halides	11-09	THIOETHERS (SULFIDES)	
oxidation of thioethers	19-31	alcohols + thiols	10-26
TELLURIDES		alkenes + thiols	15-07
from alkyl halides	10-26	alkyl halides + thiolate anions	10-26
THIIRANES (EPISULFIDES)		aromatic compounds + sulfones	11-23
diazo compounds + sulfur	16-48	aryl halides + alkyl sulfides	13-04
		aryldiazonium salts + sulfide	13-21
		aryldiazonium salts + thiols	13-21
		from alcohols	10-26
		from alkyl halides	10-26
		from ammonium salts	10-26
		from dihalides	10-26

from organometallics	12-30	TRIHALIDES	
from phenols	11-23	acyl halides + halogenating agents	16-23
Michael addition with S-nucleophiles	15-31	cleavage of methyl ketones	12-44
rearrangement of sulfonium salts	18-21		
reduction of sulfones	19-72	TRIOXANES	
reduction of sulfoxides	19-72	from aldehydes	16-92
sulfur + alkyl organometallics	12-30		
thiols + arylboronic acids	13-04	UREAS	
thiomethylation of aromatics	11-23	amines + CO ₂	16-22
thiophenols + aromatic compounds	13-04	isocyanates + amines	16-20
THIOKETONES		VINYL ETHERS (including silyl enol ethers)	
ketones + sulfur reagents	16-11	alcohol + alkyne	15-05
		alcohol + enol ester	10-13
THIOLACTAMS		alcohol + enol ether	10-13
lactam + sulfur reagents	16-11	by the Wittig reaction	16-44
lactone + sulfur reagents	16-11	cleavage of acetals or ketones	17-02
		from aldehydes	12-17
THIOLS		from enol esters or enol ethers	10-13
alkyl halides + hydrogen sulfide or HS ⁻	10-25	from esters	16-45
aryl halides + sulfide	13-04	from ketones	12-17
aryldiazonium salts + H ₂ S	13-21	from phenols	10-08
from alcohols	10-25	peroxides + vinyl-M (M = a metal)	12-26
from Bunte salts	10-28	Petasis alkenylation	16-45
hydrolysis of Bunte salts	10-28	Tebbe alkenylation	16-45
reduction of disulfides	19-75		
reduction of sulfonyl halides	19-71	VINYL PHOSPHINES	
sulfur + alkyl organometallics	12-30	alkynes + phosphines	15-08
THIOUREAS		VINYL SILANES	
amines + CS ₂	16-22	addition of silanes to alkynes	15-19
isothiocyanates + amines	16-20		
TRIAZOLES		VINYL SULFIDES	
alkenes + alkyl halides	15-58	alkynes + thiols	15-07
		ketones + thiols	16-11
TRIAZOLINES		VINYL SULFONES	
alkenes + alkyl azides	15-58	alkynes + sulfonyl halides	15-42
		from sulfinic acid salts	10-29
TRIENES		XANTHATES	
aromatic compounds + carbenes	15-64	carbon disulfide + alcohols	16-10
cycloaddition of dienes	15-66		
ring opening of cyclic dienes	18-27		

AUTHOR INDEX

Note that only initials are used with each surname. Therefore, several different authors may be represented by a single entry. There are several authors named Smith, M.B., for example, and citations for all are listed after the single entry.

Entries in the index refer to chapter number (**boldface**) and reference number.
