smaller diameter or side to the distance of separation. Curves 2 through 4 of Fig. 5-13, for opposed rectangles, can be computed with Eq. (5-114*b*). The view factors for two finite coaxial coextensive cylinders of radii $r \le R$ and height $L$ are shown in Fig. 5-14. The direct view factors for an infinite plane parallel to a system of rows of parallel tubes (see Fig. 5-16) are given as curves 1 and 3 of Fig. 5-15. The view factors for this two-dimensional geometry can be readily calculated by using the **crossed-strings method.**

The crossed-strings method, due to Hottel (*Radiative Transfer*, McGraw-Hill, New York, 1967), is stated as follows: "The exchange area for two-dimensional surfaces, $A_1$ and $A_2$, per unit length (in the infinite dimension) is given by the sum of the lengths of crossed strings from the ends of $A_1$ to the ends of $A_2$ less the sum of the uncrossed strings from and to the same points all divided by 2." The strings must be drawn so that all the flux from one surface to the other must cross each of a pair of crossed strings and neither of the pair of uncrossed strings. If one surface can see the other around both sides of an obstruction, two more pairs of strings are involved. The calculation procedure is demonstrated by evaluation of the tube-to-tube view factor for one row of a tube bank, as illustrated in Example 7.

***Example 7: The Crossed-Strings Method*** Figure 5-16 depicts the transverse cross section of two infinitely long, parallel circular tubes of diameter $D$ and center-to-center distance of separation $C$. Use the crossed-strings method to formulate the tube-to-tube direct exchange area and view factor $\overline{s_t s_t}$ and $F_{t,t}$, respectively.

*Solution:* The circumferential area of each tube is $A_t = \pi D$ per unit length in the infinite dimension for this two-dimensional geometry. Application of the crossed-strings procedure then yields simply

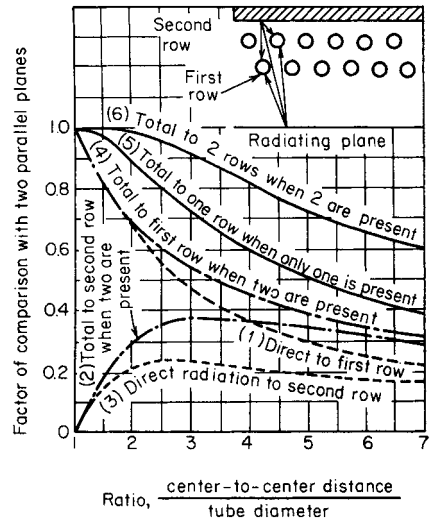

**FIG. 5-15** Distribution of radiation to rows of tubes irradiated from one side. Dashed lines: direct view factor $F$ from plane to tubes. Solid lines: total view factor $\bar{F}$ for black tubes backed by a refractory surface.

$$\overline{s_t s_t} = \frac{2(EFGH - HJ)}{2} = D[\sin^{-1}(1/R) + \sqrt{R^2 - 1} - R]$$

and

$$F_{t,t} = \overline{s_t s_t}/A_t = [\sin^{-1}(1/R) + \sqrt{R^2 - 1} - R]/\pi$$

where $EFGH$ and $HJ = C$ are the indicated line segments and $R \equiv C/D \ge 1$. Curve 1 of Fig. 5-15, denoted by $F_{p,t}$, is a function of $F_{t,t}$, that is, $F_{p,t} = (\pi/R)(\frac{1}{2} - F_{t,t})$.

The **Yamauti principle** [Yamauti, *Res. Electrotech Lab. (Tokyo)*, **148** (1924); **194** (1927); **250** (1929)] is stated as follows; *The exchange areas between two pairs of surfaces are equal when there is a one-to-one correspondence for all sets of symmetrically positioned pairs of differential elements in the two surface combinations*. Figure 5-17 illustrates the Yamauti principle applied to surfaces in perpendicular planes having a common edge. With reference to Fig. 5-17, the Yamauti principle states that the diagonally opposed exchange areas are equal, that is, $\overline{(1)(4)} = \overline{(2)(3)}$. Figure 5-17 also shows a more complex geometric construction for displaced cylinders for which the Yamauti principle also applies. Collectively the three terms *reciprocity* or *symmetry principle, conservation*

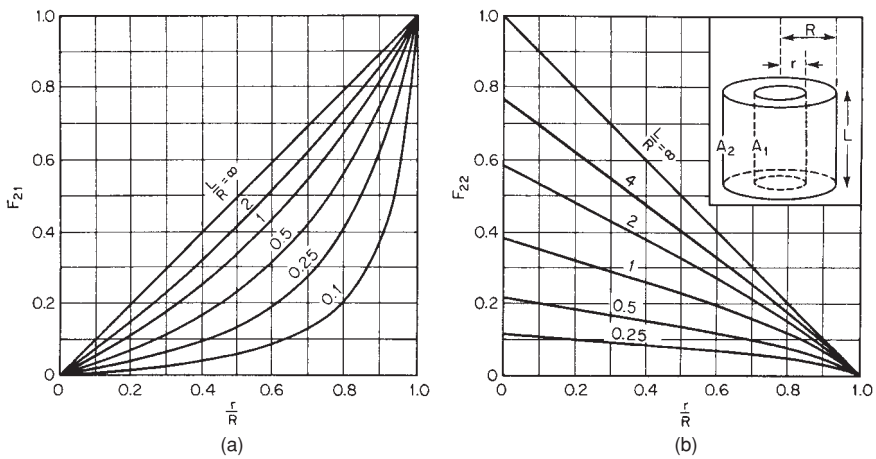

**FIG. 5-14** View factors for a system of two concentric coaxial cylinders of equal length. (*a*) Inner surface of outer cylinder to inner cylinder. (*b*) Inner surface of outer cylinder to itself.

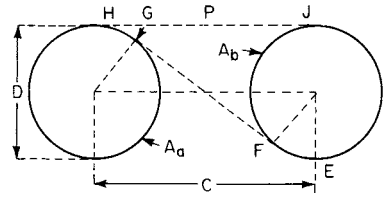

**FIG. 5-16** Direct exchange between parallel circular tubes.

*principle*, and *Yamauti principle* are referred to as **view factor or exchange area algebra.**

***Example 8: Illustration of Exchange Area Algebra*** Figure 5-17 shows a graphical construction depicting four perpendicular opposed rectangles with a common edge. *Numerically* evaluate the direct exchange areas and view factors for the diagonally opposed (shaded) rectangles $A_1$ and $A_4$, that is, $\overline{(1)(4)}$, as well as $\overline{(1)(3+4)}$. The dimensions of the rectangular construction are shown in Fig. 5-17 as $x = 3$, $y = 2$, and $z = 1$.

*Solution:* Using shorthand notation for direct exchange areas, the conservation principle yields

$$\overline{(1+2)(3+4)} = \overline{(1+2)(3)} + \overline{(1+2)(4)} = \overline{(1)(3)} + \overline{(2)(3)} + \overline{(1)(4)} + \overline{(2)(4)}$$

Now by the Yamauti principle we have $\overline{(1)(4)} \equiv \overline{(2)(3)}$. Combination of these two relations yields the first result $\overline{(1)(4)} = [\overline{(1+2)(3+4)} - \overline{(1)(3)} - \overline{(2)(4)}]/2$. For $\overline{(1)(3+4)}$, again conservation yields $\overline{(1)(3+4)} = \overline{(1)(3)} + \overline{(1)(4)}$, and substitution of the expression for $\overline{(1)(4)}$ just obtained yields the second result, that is, $\overline{(1)(3+4)} = [\overline{(1+2)(3+4)} + \overline{(1)(3)} - \overline{(2)(4)}]/2.0$. All three required direct exchange areas in these two relations are readily evaluated from Eq. (5-114*a*). Moreover, these equations apply to opposed *parallel* rectangles as well as rectangles with a common edge oriented at *any angle*. Numerically it follows from Eq. (5-114*a*) that for $X = \frac{1}{3}$, $Y = \frac{2}{3}$, and $z = 3$ that $\overline{(1+2)(3+4)} = 0.95990$; for $X = 1$, $Y = 2$, and $z = 1$ that $\overline{(1)(3)} = 0.23285$; and for $X = \frac{1}{2}$, $Y = 1$, and $z = 2$ that $\overline{(2)(4)} = 0.585747$. Since $A_1 = 1.0$, this leads to $\overline{s_1 s_4} = F_{1,4} = (0.95990 - 0.23285 - 0.584747)/2.0 = 0.07115$ and $\overline{s_1 s_{3+4}} = F_{1,3+4} = (0.95990 + 0.23285 - 0.584747)/2.0 = 0.30400$.

Many literature sources document closed-form algebraic expressions for view factors. Particularly comprehensive references include the compendia by Modest (op. cit., App. D) and Siegel and Howell (op. cit., App. C). The appendices for both of these textbooks also provide a wealth of resource information for radiative transfer. Appendix F of Modest, e.g., references an extensive listing of Fortan computer codes for a variety of radiation calculations which include view factors. These codes are archived in the dedicated Internet web site maintained by the publisher. The textbook by Siegel and Howell also includes an extensive database of view factors archived on a CD-ROM and includes a reference to an author-maintained Internet web site. Other historical sources for view factors include Hottel and Sarofim (op. cit., Chap. 2) and Hamilton and Morgan (NACA-TN 2836, December 1952).

## RADIATIVE EXCHANGE IN ENCLOSURES—THE ZONE METHOD

**Total Exchange Areas** When an enclosure contains *reflective* surface zones, allowance must be made for not only the radiant energy transferred *directly* between any two zones but also the additional transfer attendant to *however many multiple reflections* which occur among the intervening reflective surfaces. Under such circumstances, it can be shown that the *net* radiative flux $Q_{i,j}$ between all such surface zone pairs $A_i$ and $A_j$, making full allowance for all multiple reflections, may be computed from

$$Q_{i,j} = \sigma(A_i \mathcal{F}_{i,j} T_j^4 - A_j \mathcal{F}_{j,i} T_i^4) \tag{5-115}$$

Here, $\mathcal{F}_{i,j}$ is defined as the **total surface-to-surface view factor** *from* $A_i$ to $A_j$, and the quantity $S_i S_j \equiv A_i \mathcal{F}_{i,j}$ is defined as the corresponding **total surface-to-surface exchange area**. In analogy with the direct exchange areas, the total surface-to-surface exchange areas are also symmetric and thus obey reciprocity, that is, $A_i \mathcal{F}_{i,j} = A_j \mathcal{F}_{j,i}$ or $S_i S_j = S_j S_i$. When applied to an enclosure, *total* exchange areas and view factors also must satisfy appropriate conservation relations. Total exchange areas are functions of the *geometry and radiative properties of the entire enclosure.* They are also independent of temperature if all surfaces and any radiatively participating media are gray. The following subsection presents a general **matrix method** for the *explicit* evaluation of total exchange areas from direct exchange areas and other enclosure parameters.

In what follows, conventional matrix notation is strictly employed as in $\mathbf{A} = [a_{i,j}]$ wherein the scalar subscripts always denote the row and column indices, respectively, and all **matrix entities** defined here are denoted by **boldface** notation. Section 3 of this handbook, "Mathematics," provides an especially convenient reference for introductory matrix algebra and matrix computations.

**General Matrix Formulation** The **zone method** is perhaps the simplest numerical quadrature of the governing *integral equations* for radiative transfer. It may be derived from first principles by starting with the *equation of transfer* for radiation intensity. The zone method *always conserves radiant energy* since the spatial discretization utilizes macroscopic energy balances involving *spatially averaged* radiative flux quantities. Because large sets of linear algebraic equations can arise in this process, *matrix algebra* provides the most compact notation and the most expeditious methods of solution. The mathematical approach presented here is a matrix generalization of the original *(scalar)* development of the zone method due to Hottel and Sarofim (op. cit.). The present matrix development is abstracted from that introduced by Noble [Noble, J. J., *Int. J. Heat Mass Transfer*, **18,** 261–269 (1975)].

Consider an arbitrary three-dimensional enclosure of total volume $V$ and surface area $A$ which confines an absorbing-emitting medium (gas). Let the enclosure be subdivided (zoned) into $M$ finite surface area and $N$ finite volume elements, each small enough that all such *zones* are substantially isothermal. The mathematical development in this section is restricted by the following conditions and/or assumptions:

1. The gas temperatures are given a priori.
2. Allowance is made for gas-to-surface radiative transfer.
3. Radiative transfer with respect to the confined gas is either monochromatic or gray. The gray gas absorption coefficient is denoted here by $K(\mathrm{m}^{-1})$. In subsequent sections the monochromatic absorption coefficient is denoted by $K_\lambda(\lambda)$.
4. All surface emissivities are assumed to be gray and thus independent of temperature.
5. Surface emission and reflection are isotropic or diffuse.
6. The gas does not scatter.

Noble (op. cit.) has extended the present matrix methodology to the case where the gaseous absorbing-emitting medium also *scatters isotropically*.

In matrix notation the blackbody emissive powers for all surface and volume zones comprising the zoned enclosure are designated as $\mathbf{E} = [E_i] = [\sigma T_i^4]$, an $M \times 1$ vector, and $\mathbf{E}_g = [E_{g,i}] = [\sigma T_{g,i}^4]$, an $N \times 1$ vector, respectively. Moreover, all surface zones are characterized by three $M \times M$ diagonal matrices for zone area $\mathbf{AI} = [A_i \cdot \delta_{i,j}]$, diffuse emissivity $\boldsymbol{\varepsilon}\mathbf{I} = [\varepsilon_i \cdot \delta_{i,j}]$, and diffuse reflectivity, $\boldsymbol{\rho}\mathbf{I} = [(1 - \varepsilon_i) \cdot \delta_{i,j}]$, respectively . Here $\delta_{i,j}$ is the **Kronecker delta** (that is, $\delta_{i,j} = 1$ for $i = j$ and $\delta_{i,j} = 0$ for $i \neq j$).

Two arrays of direct exchange areas are now defined; i.e., the matrix $\overline{\mathbf{ss}} = [\overline{s_i s_j}]$ is the $M \times M$ array of **direct surface-to-surface exchange areas,** and the matrix $\overline{\mathbf{sg}} = [\overline{s_i g_j}]$ is the $M \times N$ array of **direct gas-to-surface exchange areas.** Here the scalar elements of $\overline{\mathbf{ss}}$ and $\overline{\mathbf{sg}}$ are computed from the integrals

$$\overline{s_i s_j} = \iint_{A_i} \iint_{A_j} \frac{e^{-Kr}}{\pi r^2} \cos\phi_i \cos\phi_j \, dA_j \, dA_i \tag{5-116a}$$

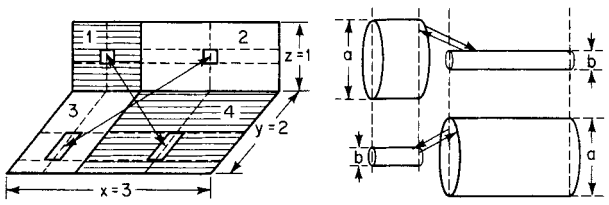

**FIG. 5-17** Illustration of the Yamauti principle.

$$\overline{s_i g_j} = \iint_{A_i} \iint_{V_j} K \frac{e^{-Kr}}{\pi r^2} \cos\phi i \, dV_j \, dA_i \qquad (5\text{-}116b)$$

Equation (5-116*a*) is a generalization of Eq. (5-112) for the case $K \neq 0$ while $\overline{s_i g_j}$ is a new quantity, which arises *only* for the case $K \neq 0$.

Matrix characterization of the radiative energy balance at each surface zone is facilitated via definition of three $M \times 1$ vectors; the radiative surface fluxes $\mathbf{Q} = [Q_i]$, with units of watts; and the vectors $\mathbf{H} = [H_i]$ and $\mathbf{W} = [W_i]$ both having units of W/m$^2$. The arrays **H** and **W** define the *incident* and *leaving* flux *densities*, respectively, at each surface zone. The variable **W** is also referred to in the literature as the **radiosity** or **exitance.** Since $\mathbf{W} \equiv \boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{E} + \boldsymbol{\rho}\mathbf{I}\cdot\mathbf{H}$, the radiative flux at each surface zone is also defined in terms of **E, H,** and **W** by three equivalent matrix relations, namely,

$$\mathbf{Q} = \mathbf{AI}\cdot[\mathbf{W} - \mathbf{H}] = \boldsymbol{\varepsilon}\mathbf{AI}\cdot[\mathbf{E} - \mathbf{H}] = \boldsymbol{\rho}\mathbf{I}^{-1}\cdot\boldsymbol{\varepsilon}\mathbf{AI}\cdot[\mathbf{E} - \mathbf{W}] \qquad (5\text{-}117)$$

where the third form is valid *if and only if the matrix inverse* $\boldsymbol{\rho}\mathbf{I}^{-1}$ *exists*. Two other ancillary matrix expressions are

$$\boldsymbol{\varepsilon}\mathbf{AI}\cdot\mathbf{E} = \boldsymbol{\rho}\mathbf{I}\cdot\mathbf{Q} + \boldsymbol{\varepsilon}\mathbf{AI}\cdot\mathbf{W} \quad \text{and} \quad \mathbf{AI}\cdot\mathbf{H} = \overline{\mathbf{ss}}\cdot\mathbf{W} + \overline{\mathbf{sg}}\cdot\mathbf{E}_g \qquad (5\text{-}117a,b)$$

which lead to

$$\boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{E} = [\mathbf{I} - \boldsymbol{\rho}\mathbf{I}\cdot\mathbf{AI}^{-1}\cdot\overline{\mathbf{ss}}]\cdot\mathbf{W} - \boldsymbol{\rho}\mathbf{I}\cdot\mathbf{AI}^{-1}\,\overline{\mathbf{sg}}\cdot\mathbf{E}_g. \qquad (5\text{-}117c)$$

The latter relation is especially useful in radiation pyrometry where true wall temperatures must be computed from wall radiosities.

**Explicit Matrix Solution for Total Exchange Areas** For gray or monochromatic transfer, the **primary working relation** for zoning calculations via the matrix method is

$$\mathbf{Q} = \boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{E} - \overline{\mathbf{SS}}\cdot\mathbf{E} - \overline{\mathbf{SG}}\cdot\mathbf{E}_g \qquad [M \times 1] \qquad (5\text{-}118)$$

Equation (5-118) makes full allowance for multiple reflections in an enclosure of any degree of complexity. To apply Eq. (5-118) for design or simulation purposes, the gas temperatures must be known and surface boundary conditions must be specified for each and every surface zone in the form of *either* $E_i$ or $Q_i$. In application of Eq. (5-118), *physically impossible values* of $E_i$ may well result if *physically unrealistic* values of $Q_i$ are specified.

In Eq. (5-118), $\overline{\mathbf{SS}}$ and $\overline{\mathbf{SG}}$ are defined as the *required* arrays of **total surface-to-surface exchange areas** and **total gas-to-surface exchange areas,** respectively. The matrices for total exchange areas are calculated *explicitly* from the corresponding arrays of direct exchange areas and the other enclosure parameters by the following matrix formulas:

Surface-to-surface exchange $\quad \overline{\mathbf{SS}} = \boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{R}\cdot\overline{\mathbf{ss}}\cdot\boldsymbol{\varepsilon}\mathbf{I} \quad [M \times M] \qquad (5\text{-}118a)$

Gas-to-surface exchange $\quad \overline{\mathbf{SG}} = \boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{R}\cdot\overline{\mathbf{sg}} \quad [M \times N] \qquad (5\text{-}118b)$

where in Eqs. (5-118), **R** is the explicit **inverse reflectivity matrix,** defined as

$$\mathbf{R} = [\mathbf{AI} - \overline{\mathbf{ss}}\cdot\boldsymbol{\rho}\mathbf{I}]^{-1} \qquad [M \times M] \qquad (5\text{-}118c)$$

While the **R** matrix is generally not symmetric, the matrix product $\boldsymbol{\rho}\mathbf{I}\cdot\mathbf{R}$ is *always* symmetric. This fact proves useful for error checking.

The most computationally significant aspect of the matrix method is that the inverse reflectivity matrix **R** *always exists* for any physically meaningful enclosure problem. More precisely, **R** always exists provided that $K \neq 0$. For a transparent medium, **R** exists provided that there *formally* exists at least one surface zone $A_i$ such that $\varepsilon_i \neq 0$. An important computational corollary of this statement for *transparent media* is that the matrix $[\mathbf{AI} - \overline{\mathbf{ss}}]$ is *always singular* and demonstrates *matrix rank* $M - 1$ (Noble, op. cit.).

Finally, the four matrix arrays $\overline{\mathbf{ss}}$, $\overline{\mathbf{gs}}$, $\overline{\mathbf{SS}}$, and $\overline{\mathbf{SG}}$ of direct and total exchange areas must satisfy **matrix conservation relations,** i.e.,

Direct exchange areas $\quad \mathbf{AI}\cdot\mathbf{1}_M = \overline{\mathbf{ss}}\cdot\mathbf{1}_M + \overline{\mathbf{sg}}\cdot\mathbf{1}_N \qquad (5\text{-}119a)$

Total exchange areas $\quad \boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{1}_M = \overline{\mathbf{SS}}\cdot\mathbf{1}_M + \overline{\mathbf{SG}}\cdot\mathbf{1}_N \qquad (5\text{-}119b)$

Here $\mathbf{1}_M$ is an $M \times 1$ column vector all of whose elements are unity. If $\boldsymbol{\varepsilon}\mathbf{I} = \mathbf{I}$ or equivalently, $\boldsymbol{\rho}\mathbf{I} = \mathbf{0}$, Eq. (5-118*c*) reduces to $\mathbf{R} = \mathbf{AI}^{-1}$ with the result that Eqs. (5-118*a*) and (5-118*b*) degenerate to simply $\overline{\mathbf{SS}} = \overline{\mathbf{ss}}$ and $\overline{\mathbf{SG}} = \overline{\mathbf{sg}}$. Further, while the array $\overline{\mathbf{SS}}$ is always symmetric, the array $\overline{\mathbf{SG}}$ is generally not square.

For purposes of digital computation, it is good practice to enter all data for direct exchange surface-to-surface areas $\overline{\mathbf{ss}}$ with a precision of *at least* five significant figures. This need arises because all the scalar elements of $\overline{\mathbf{sg}}$ can be calculated *arithmetically* from appropriate direct surface-to-surface exchange areas by using view factor algebra rather than via the definition of the defining integral, Eq. (5-116*b*). This process often involves small arithmetic differences between two numbers of nearly equal magnitude, and numerical significance is easily lost.

Computer implementation of the matrix method proves straightforward, given the availability of modern software applications. In particular, several especially user-friendly GUI mathematical utilities are available that perform matrix computations using *essentially algebraic notation*. Many simple zoning problems may be solved with spreadsheets. For large $M$ and $N$, the matrix method can involve management of a large amount of data. Error checks based on symmetry and conservation by calculation of the row sums of the four arrays of direct and total exchange areas then prove indispensable.

**Zone Methodology and Conventions** For a transparent medium, no more than $\Sigma = M(M-1)/2$ of the $M^2$ elements of the $\overline{\mathbf{ss}}$ array are *unique*. Further, surface zones are characterized into two generic types. **Source-sink zones** are defined as those for which temperature is specified and whose radiative flux $Q_i$ is to be determined. For **flux zones,** conversely, these conditions are reversed. When both types of zone are present in an enclosure, Eq. (5-118) may be *partitioned* to produce a more efficient computational algorithm. Let $M = M_s + M_f$ represent the total number of surface zones where $M_s$ is the number of source-sink zones and $M_f$ is the number of flux zones. The flux zones are the *last to be numbered.* Equation (5-118) is then partitioned as follows:

$$\begin{bmatrix}\mathbf{Q}_1\\ \mathbf{Q}_2\end{bmatrix} = \begin{bmatrix}\boldsymbol{\varepsilon}\mathbf{AI}_{1,1} & \mathbf{0}\\ \mathbf{0} & \boldsymbol{\varepsilon}\mathbf{AI}_{2,2}\end{bmatrix}\cdot\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \begin{bmatrix}\overline{\mathbf{SS}}_{1,1} & \overline{\mathbf{SS}}_{1,2}\\ \overline{\mathbf{SS}}_{2,1} & \overline{\mathbf{SS}}_{2,2}\end{bmatrix}\cdot\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \begin{bmatrix}\overline{\mathbf{SG}}_1\\ \overline{\mathbf{SG}}_2\end{bmatrix}\cdot\mathbf{E}_g \qquad (5\text{-}120)$$

Here the dimensions of the submatrices $\boldsymbol{\varepsilon}\mathbf{AI}_{1,1}$ and $\overline{\mathbf{SS}}_{1,1}$ are both $M_s \times M_s$ and $\mathbf{SG}_1$ has dimensions $M_s \times N$. Partition algebra then yields the following two matrix equations for $\mathbf{Q}_1$, the $M_s \times 1$ vector of unknown source-sink fluxes and $\mathbf{E}_2$, the $M_f \times 1$ vector of unknown emissive powers for the flux zones, i.e.,

$$\mathbf{E}_2 = [\boldsymbol{\varepsilon}\mathbf{AI}_{2,2} - \overline{\mathbf{SS}}_{2,2}]^{-1}\cdot[\mathbf{Q}_2 + \overline{\mathbf{SS}}_{2,1}\cdot\mathbf{E}_1 + \overline{\mathbf{SG}}_2\cdot\mathbf{E}_g] \qquad (5\text{-}120a)$$

$$\mathbf{Q}_1 = \boldsymbol{\varepsilon}\mathbf{AI}_{1,1}\cdot\mathbf{E}_1 - \overline{\mathbf{SS}}_{1,1}\cdot\mathbf{E}_1 - \overline{\mathbf{SS}}_{1,2}\cdot\mathbf{E}_2 - \overline{\mathbf{SG}}_1\cdot\mathbf{E}_g \qquad (5\text{-}120b)$$

The inverse matrix in Eq. (5-120*a*) formally does not exist if there is at least one flux zone such that $\varepsilon_i = 0$. However, well-behaved results are usually obtained with Eq. (5-120*a*) by utilizing a *notional zero*, say, $\varepsilon_i \approx 10^{-5}$, to simulate $\varepsilon_i = 0$. Computationally, $\mathbf{E}_2$ is first obtained from Eq. (5-120*a*) and then substituted into either Eq. (5-120*b*) or Eq. (5-118).

Surface zones need not be *contiguous.* For example, in a symmetric enclosure, zones on opposite sides of the plane of symmetry may be "lumped" into a single zone for computational purposes. Lumping nonsymmetrical zones is also possible as long as the zone temperatures and emissivities are equal.

An **adiabatic refractory surface** of area $A_r$ and emissivity $\varepsilon_r$, for which $Q_r = 0$, proves quite important in practice. A nearly radiatively adiabatic refractory surface occurs when differences between internal conduction and convection and external heat losses through the refractory wall are small compared with the *magnitude* of the *incident* and *leaving* radiation fluxes. For *any* surface zone, the radiant flux is given by $Q = A(W - H) = \varepsilon A(E - H)$ and $Q = \varepsilon A/\rho(E - W)$ (if $\rho \neq 0$). These equations then lead to the result that if $Q_r = 0$, $E_r = H_r = W_r$ *for all* $0 \leq \varepsilon_r \leq 1$. *Sufficient conditions* for modeling an adiabatic refractory zone are thus *either* to put $\varepsilon_r = 0$ *or* to specify *directly* that $Q_r = 0$ with $\varepsilon_r \neq 0$. If $\varepsilon_r = 0$, $S_r S_j = 0$ for all $1 \leq j \leq M$ which leads directly *by definition* to $Q_r = 0$. For $\varepsilon_r = 0$, the refractory emissive power $E_r$ *never enters the zoning calculations.* For the special case of $\underline{K} = 0$ and $M_r = 1$, a single (lumped) refractory, with $Q_r = 0$ and $\varepsilon_r \neq 0$, $S_r S_j \neq 0$ and the refractory emissive power may be calculated from Eq. (5-120*a*) as a weighted sum of all *other known blackbody emissive powers* which

characterize the enclosure, i.e.,

$$E_r = \frac{\sum_{j=1}^{M_S} \overline{S_r S_j} \cdot E_j}{\sum_{j=1}^{M_S} \overline{S_r S_j}} \qquad \text{with } j \neq r \tag{5-121}$$

Equation (5-121) specifically *includes* those zones which may not have a *direct* view of the refractory. When $Q_r = 0$, the refractory surface is said to be in **radiative equilibrium** with the entire enclosure. Equation (5-121) is indeterminate if $\varepsilon_r = 0$. If $\varepsilon_r = 0$, $E_r$ does indeed exist and may be evaluated with use of the statement $E_r = H_r = W_r$. It transpires, however, that $E_r$ is *independent of* $\varepsilon_r$ *for all* $0 \le \varepsilon_r \le 1$. Moreover, since $W_r = H_r$ when $Q_r = 0$, for all $0 \le \varepsilon_r \le 1$, the value specified for $\varepsilon_r$ is irrelevant to radiative transfer in the *entire enclosure*. In particular it follows that if $Q_r = 0$, then the *vectors* **W, H,** and **Q** *for the entire enclosure* are also independent of all $0 \le \varepsilon_r \le 1.0$. A surface zone for which $\varepsilon_i = 0$ is termed a **perfect diffuse mirror.** A perfect diffuse mirror is thus also an adiabatic surface zone. The matrix method automatically deals with *all* options for flux and adiabatic refractory surfaces.

**The Limiting Case of a Transparent Medium** For the special case of a transparent medium, $K = 0$, many practical engineering applications can be modeled with the zone method. These include combustion-fired muffle furnaces and electrical resistance furnaces. When $K \to 0$, $\overline{\mathbf{sg}} \to \mathbf{0}$ and $\overline{\mathbf{SG}} \to \mathbf{0}$. Equations (5-118) through (5-119) then reduce to three simple matrix relations

$$\mathbf{Q} = \varepsilon\mathbf{I}\cdot\mathbf{A}\mathbf{I}\cdot\mathbf{E} - \overline{\mathbf{SS}}\cdot\mathbf{E} \tag{5-122a}$$

$$\overline{\mathbf{SS}} = \varepsilon\mathbf{I}\cdot\mathbf{A}\mathbf{I}\cdot\mathbf{R}\cdot\overline{\mathbf{ss}}\cdot\varepsilon\mathbf{I} \tag{5-122b}$$

with again

$$\mathbf{R} \equiv [\mathbf{A}\mathbf{I} - \overline{\mathbf{ss}}\cdot\rho\mathbf{I}]^{-1} \tag{5-122c}$$

The radiant surface flux vector **Q,** as computed from Eq. (5-122*a*), *always* satisfies the (scalar) conservation condition $\mathbf{I}_M^T\cdot\mathbf{Q} = \mathbf{0}$ or $\sum_{i=1}^{M} Q_i = 0$, which is a statement of the overall *radiant* energy balance. The matrix conservation relations also simplify to

$$\mathbf{A}\mathbf{I}\cdot\mathbf{1}_M = \overline{\mathbf{ss}}\cdot\mathbf{1}_M \tag{5-123a}$$

$$\varepsilon\mathbf{I}\cdot\mathbf{A}\mathbf{I}\cdot\mathbf{1}_M = \overline{\mathbf{SS}}\cdot\mathbf{1}_M \tag{5-123b}$$

And the $M \times M$ arrays for *all* the direct and total view factors can be readily computed from

$$\mathbf{F} = \mathbf{A}\mathbf{I}^{-1}\cdot\overline{\mathbf{ss}} \tag{5-124a}$$

and

$$\mathcal{F} = \mathbf{A}\mathbf{I}^{-1}\cdot\overline{\mathbf{SS}} \tag{5-124b}$$

where the following matrix conservation relations must also be satisfied,

$$\mathbf{F}\cdot\mathbf{1}_M = \mathbf{1}_M \tag{5-125a}$$

and

$$\mathcal{F}\cdot\mathbf{1}_M = \varepsilon\mathbf{I}\cdot\mathbf{1}_M \tag{5-125b}$$

**The Two-Zone Enclosure** Figure 5-18 depicts four simple enclosure geometries which are particularly useful for engineering calculations characterized by only *two* surface zones. For $M = 2$, the reflectivity matrix **R** is readily evaluated in *closed form* since an explicit algebraic inversion formula is available for a $2 \times 2$ matrix. In this case knowledge of only $\Sigma = 1$ direct exchange area is required. Direct evaluation of Eqs. (5-122) then leads to

$$\overline{\mathbf{SS}} = \begin{bmatrix} \varepsilon_1 A_1 - \overline{S_1 S_2} & \overline{S_1 S_2} \\ \overline{S_1 S_2} & \varepsilon_2 A_2 - \overline{S_1 S_2} \end{bmatrix} \tag{5-126}$$

where

$$\overline{S_1 S_2} = \frac{1}{\left(\dfrac{1}{\overline{s_1 s_2}} + \dfrac{\rho_1}{\varepsilon_1 A_1} + \dfrac{\rho_2}{\varepsilon_2 A_2}\right)} \tag{5-127}$$

Equation (5-127) is of general utility for any two-zone system for which $\varepsilon_i \neq 0$.

The total exchange areas for the four geometries shown in Fig. 5-18 follow directly from Eqs. (5-126) and (5-127).

1. A planar surface $A_1$ completely surrounded by a second surface $A_2 > A_1$. Here $F_{1,1} = 0$, $F_{1,2} = 1$, and $\overline{s_1 s_2} = A_1$, resulting in

$$\overline{\mathbf{SS}} = \begin{bmatrix} \varepsilon_1\rho_2 A_1^2 + \varepsilon_2\rho_1 A_1 A_2 & \varepsilon_1\varepsilon_2 A_1 A_2 \\ \varepsilon_1\varepsilon_2 A_1 A_2 & \varepsilon_2 A_2^2 + \varepsilon_1(\rho_2 - \varepsilon_2) A_1 A_2 \end{bmatrix} / [\varepsilon_1\rho_2 A_1 + \varepsilon_2 A_2]$$

and in particular $$\overline{S_1 S_2} = \frac{A_1}{1/\varepsilon_1 + (A_1/A_2)(\rho_2/\varepsilon_2)} \tag{5-127a}$$

In the limiting case, where $A_1$ has no negative curvature and is completely surrounded by a very much larger surface $A_2$ such that $A_1 \ll A_2$, Eq. (5-127*a*) leads to the even simpler result that $\overline{S_1 S_2} = \varepsilon_1 \cdot A_1$.

2. Two parallel plates of equal area which are large compared to their distance of separation (infinite parallel plates). Case 2 is a limiting form of case 1 with $A_1 = A_2$. Algebraic manipulation then results in

$$\overline{\mathbf{SS}} = \begin{bmatrix} (\varepsilon_1 + \varepsilon_2 - 2\varepsilon_1\varepsilon_2)\cdot A_1 & \varepsilon_1\varepsilon_2 A_1 \\ \varepsilon_1\varepsilon_2 A_1 & (\varepsilon_1 + \varepsilon_2 - 2\varepsilon_1\varepsilon_2) A_1 \end{bmatrix} / [\varepsilon_1 + \varepsilon_2 - \varepsilon_1\varepsilon_2]$$

and in particular

$$\overline{S_1 S_2} = \frac{A_1}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} \tag{5-127b}$$

| Case 1 | Case 2 | Case 3 | Case 4 |
|---|---|---|---|
|   |   |   |   |
| A planar surface $A_1$ completely surrounded by a second surface $A_2 > A_1$. | Two infinite parallel plates where $A_1 = A_2$. | Concentric spheres or infinite cylinders where $A_1 < A_2$. Identical to Case 1. | A speckled enclosure with two surface zones. |
| $\mathbf{F} = \begin{bmatrix} 0 & 1 \\ A_1/A_2 & 1 - A_1/A_2 \end{bmatrix}$ | $\mathbf{F} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ | $\mathbf{F} = \begin{bmatrix} 0 & 1 \\ A_1/A_2 & 1 - A_1/A_2 \end{bmatrix}$ | $\mathbf{F} = \dfrac{1}{(A_1 + A_2)} \begin{bmatrix} A_1 & A_2 \\ A_1 & A_2 \end{bmatrix}$ |

**FIG. 5-18** Four enclosure geometries characterized by two surface zones and one volume zone. (Marks' Standard Handbook for Mechanical Engineers, *McGraw-Hill, New York, 1999, p. 4-73, Table 4.3.5.*)

3. Concentric spheres or cylinders where $A_2 > A_1$. Case 3 is mathematically identical to case 1.

4. A **speckled enclosure** with two surface zones. Here $\mathbf{F} = \frac{1}{A_1 + A_2}\begin{bmatrix} A_1 & A_2 \\ A_1 & A_2 \end{bmatrix}$ such that $\overline{\mathbf{ss}} = \frac{1}{A_1 + A_2}\begin{bmatrix} A_1^2 & A_1A_2 \\ A_1A_2 & A_2 \end{bmatrix}$ and Eqs. (5-126) and (5-127) then produce

$$\overline{\mathbf{SS}} = \begin{bmatrix} \varepsilon_1^2 A_1^2 & \varepsilon_1\varepsilon_2 A_1 A_2 \\ \varepsilon_1\varepsilon_2 A_1 A_2 & \varepsilon_2^2 A_2^2 \end{bmatrix} / [\varepsilon_1 A_1 + \varepsilon_2 A_2]$$

with the particular result

$$\overline{S_1 S_2} = \frac{1}{1/(\varepsilon_1 A_1) + 1/(\varepsilon_2 A_2)} \tag{5-127c}$$

Physically, a two-zone speckled enclosure is characterized by the fact that the view factor from any point on the enclosure surface to the sink zone is identical to that from any other point on the bounding surface. This is only possible when the two zones are "intimately mixed." The seemingly simplistic concept of a speckled enclosure provides a surprisingly useful *default option* in engineering calculations when the *actual* enclosure geometries are quite complex.

**Multizone Enclosures [M ≥ 3]** Again assume $K = 0$. The major numerical effort involved in implementation of the zone method is the evaluation of the inverse reflection matrix **R**. For $M = 3$, explicit closed-form algebraic formulas *do indeed exist* for the nine scalar elements of the inverse of any arbitrary nonsingular matrix. These formulas are so algebraically complex, however, that it proves impractical to present universal closed-form expressions for the total exchange areas, as has been done for the case $M = 2$. Fortunately, many practical furnace configurations can be idealized with zoning such that only relatively simple *hand calculation procedures are required*. Here the enclosure is modeled with only $M = 3$ surface zones, e.g., a single source, a single sink, and a lumped adiabatic refractory zone. This approach is sometimes termed the **SSR model.** The SSR model assumes that all adiabatic refractory surfaces are *perfect diffuse mirrors*. To implement the SSR procedure, it is necessary to develop *specialized algebraic formulas* and to define a *third black view factor* $\overline{F}_{ij}$ with an *overbar* as follows.

***Refractory Augmented Black View Factors*** $\overline{F}_{ij}$ Let $M = M_r + M_b$, where $M_b$ is the number of black surface zones and $M_r$ is the number of adiabatic refractory zones. Assume $\varepsilon_r = 0$ or $\rho_r = 1$ or, equivalently, that all adiabatic refractory surfaces are *perfect diffuse mirrors*. The view factor $\overline{F}_{ij}$ is then defined as the **refractory augmented black view factor**, i.e., the direct view factor between *any two* black source-sink zones, $A_i$ **and** $A_j$, *with full allowance for reflections from all intervening refractory surfaces*. The quantity $\overline{F}_{ij}$ shall be referred to as ***F*-bar,** for expediency.

Consider the special situation where $M_b = 2$, with any number of refractory zones $M_r \geq 1$. By use of appropriate row and column reduction of the reflectivity matrix **R,** an especially useful relation can be derived that allows computation of the conventional total exchange area $\overline{S_i S_j}$ from the *corresponding refractory augmented black view factor* $\overline{F}_{ij}$

$$\overline{S_1 S_2} = \frac{1}{\left(\dfrac{\rho_1}{\varepsilon_1 A_1} + \dfrac{\rho_2}{\varepsilon_2 A_2} + \dfrac{1}{A_1 \overline{F}_{1,2}}\right)} \tag{5-128a}$$

or

$$\mathcal{F}_{1,2} = \frac{1}{\left(\dfrac{\rho_1}{\varepsilon_1} + \left(\dfrac{A_1}{A_2}\right)\dfrac{\rho_2}{\varepsilon_2} + \dfrac{1}{\overline{F}_{1,2}}\right)} \tag{5-128b}$$

where $\varepsilon_i \neq 0$. Notice that Eq. (5-128*a*) appears *deceptively similar* to Eq. (5-127). Collectively, Eqs. (5-128) along with various formulas to compute $\overline{F}_{ij}$ (*F*-bar) are sometimes called the three-zone source/sink/refractory **SSR model.**

The following formulas permit the calculation of $\overline{F}_{ij}$ from requisite *direct* exchange areas. For the special case where the enclosure is divided into *any number of* black source-sink zones, $M_b \geq 2$, and the remainder of the enclosure is lumped together into a single refractory zone ($M_r = 1$) with total area $A_r$ and uniform average temperature $T_r$, then the direct refractory augmented exchange area for the black zone pairs is given by

$$A_i \overline{F}_{ij} = A_j \overline{F}_{ji} = \overline{s_i s_j} + \frac{\overline{s_i s_r}\cdot\overline{s_r s_j}}{A_r - \overline{s_r s_r}} \qquad \text{for } 1 \leq i,j \leq M_b \tag{5-129}$$

For the special case $M_b = 2$ and $M_r = 1$, Eq. (5-129) then simplifies to

$$A_1 \overline{F}_{1,2} = A_2 \overline{F}_{2,1} = \overline{s_1 s_2} + \frac{1}{1/\overline{s_1 s_r} + 1/\overline{s_2 s_r}} \tag{5-130}$$

and if $\overline{s_1 s_1} = \overline{s_2 s_2} = 0$, Eq. (5-130) further reduces to

$$A_1 \overline{F}_{1,2} = \overline{s_1 s_2} + \frac{1}{1/(A_1 - \overline{s_1 s_2}) + 1/(A_2 - \overline{s_2 s_1})} = \frac{A_1 A_2 - (\overline{s_1 s_2})^2}{A_1 + A_2 - 2\overline{s_1 s_2}} \tag{5-131}$$

which necessitates the evaluation of only one direct exchange area. Let the $M_r$ refractory zones be numbered *last*. Then the $M_b \times M_b$ *array* of refractory augmented direct exchange areas $[A_i \overline{F}_{ij}]$ is symmetric and satisfies and the conservation relation

$$[A_i \cdot \overline{F}_{ij}] \cdot \mathbf{1}_{M_b} = \mathbf{AI} \cdot \mathbf{1}_{M_b} \tag{5-132a}$$

with

$$\overline{\mathbf{F}} \cdot \mathbf{1}_{M_b} = \mathbf{1}_{M_b} \tag{5-132b}$$

Temporarily denote $\overline{S_1 S_2}]_R$ as the value of $\overline{S_1 S_2}$ computed from Eq. (5-128*a*) which assumes $\varepsilon_r = 0$. It remains to demonstrate the relationship between $\overline{S_1 S_2}]_R$ and the total exchange area $\overline{S_1 S_2}$ computed from the matrix method for $M = 3$ when zone 3 is an adiabatic refractory for which $Q_3 = 0$ and $\varepsilon_3 \neq 0$. Let $\Theta_i = (E_i - E_2)/(E_1 - E_2)$ denote the dimensionless emissive power where $E_1 > E_2$ such that $\Theta_1 = 1$ and $\Theta_2 = 0$. The dimensionless refractory emissive power may then be calculated from Eq. (5-121) as $\Theta_3 = \overline{S_3 S_1}/[\overline{S_3 S_1} + \overline{S_3 S_2}]$, which when substituted into Eq. (5-122*a*) leads to $\overline{S_1 S_2}]_R = \overline{S_1 S_2} + \overline{S_2 S_3}\cdot\Theta_3 = \overline{S_1 S_2} + \overline{S_1 S_3}\cdot\overline{S_3 S_2}/[\overline{S_3 S_1} + \overline{S_3 S_2}]$. Thus $\overline{S_1 S_2}]_R$ is clearly the *refractory-aided* total exchange area between zone 1 and zone 2 and *not* $\overline{S_1 S_2}$ as calculated by the matrix method in general. That is, $\overline{S_1 S_2}]_R$ includes not only the radiant energy originating at zone 1 and arriving at zone 2 directly and by reflection from zones 2 and 3, but also radiation originating at zone 1 that is *absorbed* by zone 3 and then wholly reemitted to zone 2; that is, $H_3 = W_3 = E_3$.

Evaluation of any total view factor $\mathcal{F}_{ij}$ using the requisite refractory augmented black view factor $\overline{F}_{ij}$ obviously requires that the latter be readily available and/or capable of calculation. The refractory augmented view factor $\overline{F}_{ij}$ is documented for a few geometrically simple cases and can be calculated or approximated for others. If $A_1$ and $A_2$ are equal parallel disks, squares, or rectangles, connected by nonconducting but reradiating refractory surfaces, then $\overline{F}_{ij}$ is given by Fig. 5-13 in curves 5 to 8. Let $A_1$ represent an infinite plane and $A_2$ represent one or two rows of infinite parallel tubes. If the only other surface is an adiabatic refractory surface located behind the tubes, $\overline{F}_{2,1}$ is then given by curve 5 or 6 of Fig. 5-15.

Experience has shown that the simple SSR model can yield quite useful results for a host of practical engineering applications without resorting to digital computation. The error due to representation of the source and sink by single zones is often small, even if the views of the enclosure from different parts of the same zone are dissimilar, provided the surface emissivities are near unity. The error is also small if the temperature variation of the refractory is small. Any degree of accuracy can, of course, be obtained via the matrix method for arbitrarily large $M$ and $N$ by using a digital computer. From a computational viewpoint, when $M \geq 4$, the matrix method *must be used*. The matrix method must also be used for finer-scale calculations such as more detailed wall *temperature and flux density profiles*.

***The Electrical Network Analog*** At each surface zone the *total* radiant flux is proportional to the difference between $E_i$ and $W_i$, as indicated by the equation $Q_i = (\varepsilon_i A_i \rho_i)(E_i - W_i)$. The *net* flux between zones $i$ and $j$ is also given by $Q_{ij} = \overline{s_i s_j}(W_i - W_j)$, where $Q_i = \sum_{j=1}^{M} Q_{ij}$, for all $1 \leq i \leq M$, is the *total* heat flux leaving each zone. These relations

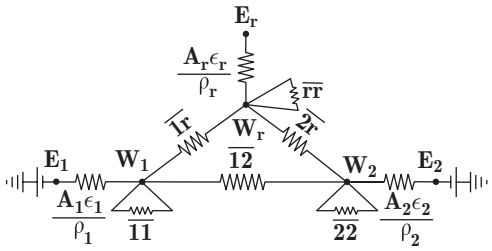

**FIG. 5-19** Generalized electrical network analog for a three-zone enclosure. Here $A_1$ and $A_2$ are gray surfaces and $A_r$ is a radiatively adiabatic surface. (*Hottel, H. C., and A. F. Sarofim*, Radiative Transfer, *McGraw-Hill, New York, 1967, p. 91.*)

suggest a *visual* electrical analog in which $E_i$ and $W_i$ are analogous to voltage potentials. The quantities $\varepsilon_i A_i/\rho_i$ and $\overline{s_i s_j}$ are analogous to conductances (reciprocal impedances), and $Q_i$ or $Q_{i,j}$ is analogous to electric currents. Such an electrical analog has been developed by Oppenheim [Oppenheim, A. K., *Trans. ASME*, **78,** 725–735 (1956)].

Figure 5-19 illustrates a generalized electrical network analogy for a three-zone enclosure consisting of one refractory zone and two gray zones $A_1$ and $A_2$. The potential points $E_i$ and $W_i$ are separated by conductances $\varepsilon_i A_i/\rho_i$. The emissive powers $E_1$, $E_2$ represent potential sources or sinks, while $W_1$, $W_2$, and $W_r$ are internal node points. In this construction the nodal point representing each surface is connected to that of every other surface it can see directly. Figure 5-19 can be used to formulate the total exchange area $\overline{S_1S_2}$ for the SSR model virtually by inspection. The refractory zone is first characterized by a floating potential such that $E_r = W_r$. Next, the resistance for the parallel "current paths" between the internal nodes $W_1$ and $W_2$ is defined by $\dfrac{1}{A_1\overline{F}_{1,2}} \equiv \dfrac{1}{\overline{s_1s_2} + 1/(1/\overline{s_1s_r} + 1/\overline{s_2s_r})}$ which is identical to Eq. (5-130). Finally, the overall impedance between the source $E_1$ and the sink $E_2$ is represented simply by three resistors in series and is thus given by

$$\frac{1}{\overline{S_1S_2}} = \frac{\rho_1}{\varepsilon_1 A_1} + \frac{1}{A_1\overline{F}_{1,2}} + \frac{\rho_2}{\varepsilon_2 A_2}$$

or

$$\overline{S_1S_2} = \frac{1}{\dfrac{\rho_1}{\varepsilon_1 A_1} + \dfrac{\rho_2}{\varepsilon_2 A_2} + \dfrac{1}{A_1\overline{F}_{1,2}}} \tag{5-133}$$

This result is identically that for the SSR model as obtained previously in Eq. (5-128*a*). This equation is also valid for $M_r \geq 1$ as long as $M_b = 2$. The electrical network analog methodology can be generalized for enclosures having $M > 3$.

**Some Examples from Furnace Design** The theory of the past several subsections is best understood in the context of two engineering examples involving furnace modeling. The engineering idealization of the **equivalent gray plane concept** is introduced first. Figure 5-20 depicts a common furnace configuration in which the heating source is two refractory-backed, internally fired tube banks. Clearly the overall geometry for even this common furnace configuration is too complex to be modeled in an expeditious manner by anything other than *a simple engineering idealization*. Thus the furnace shown in Fig. 5-20 is modeled in Example 10, by *partitioning* the entire enclosure into two subordinate furnace compartments. The approach first defines an imaginary gray plane $A_2$, located on the inward-facing side of the tube assemblies. Second, the total exchange area between the tubes to this *equivalent* gray plane is calculated, making full allowance for the reflection from the refractory tube backing. The plane-to-tube view factor is then *defined* to be the emissivity of the required equivalent gray plane whose temperature is further assumed to be that of the tubes. This procedure guarantees continuity of the radiant flux *into* the interior radiant portion of the furnace arising from a moderately complicated *external* source.

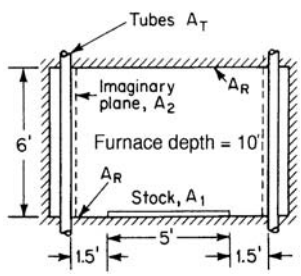

**FIG. 5-20** Furnace chamber cross section. To convert feet to meters, multiply by 0.3048.

Example 9 demonstrates classical zoning calculations for radiation pyrometry in furnace applications. Example 10 is a classical furnace design calculation via zoning an enclosure with a *diathermanous* atmosphere and $M = 4$. The latter calculation can only be addressed with the matrix method. The results of Example 10 demonstrate the relative insensitivity of zoning to $M > 3$ and the engineering utility of the SSR model.

***Example 9: Radiation Pyrometry*** A long tunnel furnace is heated by electrical resistance coils embedded in the ceiling. The stock travels on a floor-mounted conveyer belt and has an estimated emissivity of 0.7. The sidewalls are unheated refractories with emissivity 0.55, and the ceiling emissivity is 0.8. The furnace cross section is rectangular with height 1 m and width 2 m. A total radiation pyrometer is sighted on the walls and indicates the following apparent temperatures: ceiling, 1340°C; sidewall readings average about 1145°C; and the load indicates about 900°C. (*a*) What are the true temperatures of the furnace walls and stock? (*b*) What is the net heat flux at each surface? (*c*) How do the matrix method and SSR models compare?

*Three-zone model, M = 3:*

Zone 1: Source (top)

Zone 2: Sink (bottom)

Zone 3: Refractory (lumped sides)

*Physical constants:*

$$T_0 \equiv 273.15\ \text{K} \quad \sigma \equiv 5.670400 \times 10^{-8}\ \frac{\text{W}}{\text{m}^2\cdot\text{K}^4}$$

*Enclosure input parameters:*

$H_e := 1\ \text{m}$ $W_e := 2\ \text{m}$ $L_e := 1\ \text{m}$ $A_1 := W_e \cdot L_e$ $A_2 := A_1$ $A_3 := 2H_e \cdot L_e$

$\varepsilon_1 := .8$ $\varepsilon_2 := .7$ $\varepsilon_3 := .55$ $\rho_1 := 1 - \varepsilon_1$ $\rho_2 := 1 - \varepsilon_2$ $\rho_3 := 1 - \varepsilon_3$

$$\mathbf{AI} := \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{bmatrix} \quad \boldsymbol{\varepsilon}\mathbf{I} := \begin{bmatrix} \varepsilon_1 & 0 & 0 \\ 0 & \varepsilon_2 & 0 \\ 0 & 0 & \varepsilon_3 \end{bmatrix} \quad \boldsymbol{\rho}\mathbf{I} := \begin{bmatrix} \rho_1 & 0 & 0 \\ 0 & \rho_2 & 0 \\ 0 & 0 & \rho_3 \end{bmatrix}$$

$$\mathbf{AI} := \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix} \text{m}^2 \quad \boldsymbol{\varepsilon}\mathbf{I} := \begin{bmatrix} 0.8 & 0 & 0 \\ 0 & 0.7 & 0 \\ 0 & 0 & 0.55 \end{bmatrix} \quad \boldsymbol{\rho}\mathbf{I} := \begin{bmatrix} 0.2 & 0 & 0 \\ 0 & 0.3 & 0 \\ 0 & 0 & 0.45 \end{bmatrix}$$

*Compute direct exchange areas by using crossed strings ($\Sigma = 3$):*

$ss_{11} := 0$ $ss_{22} := 0$ $ss_{33} := 2(\sqrt{H_e^2 + W_e^2} - W_e)L_e$ $ss_{33} = 0.4721\ \text{m}^2$

From symmetry and conservation, there are three linear simultaneous results for the off-diagonal elements of **ss:**

$$\begin{bmatrix} \overline{12} \\ \overline{13} \\ \overline{23} \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}^{-1} \begin{bmatrix} A_1 - \overline{11} \\ A_2 - \overline{22} \\ A_3 - \overline{33} \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 & 1 & -1 \\ 1 & -1 & 1 \\ -1 & 1 & 1 \end{bmatrix}$$

$$\times \begin{bmatrix} A_1 - \overline{11} \\ A_2 - \overline{22} \\ A_3 - \overline{33} \end{bmatrix} = \frac{1}{2} \begin{bmatrix} +A_1 + A_2 - A_3 - \overline{11} - \overline{22} + \overline{33} \\ +A_1 - A_2 + A_3 - \overline{11} + \overline{22} - \overline{33} \\ -A_1 + A_2 + A_3 + \overline{11} - \overline{22} - \overline{33} \end{bmatrix}$$

Thus $ss_{12} := 0.5\,(A_1 + A_2 - A_3 + ss_{33})$

$ss_{13} := 0.5\,(A_1 - A_2 + A_3 - ss_{33})$ $ss_{23} := 0.5\,(-A_1 + A_2 + A_3 - ss_{33})$

$$\overline{\mathbf{ss}} := \begin{bmatrix} ss_{11} & ss_{12} & ss_{13} \\ ss_{12} & ss_{22} & ss_{23} \\ ss_{13} & ss_{23} & ss_{33} \end{bmatrix} \quad \overline{\mathbf{ss}} := \begin{bmatrix} 0 & 1.2361 & 0.7639 \\ 1.2361 & 0 & 0.7639 \\ 0.7639 & 0.7639 & 0.4721 \end{bmatrix} \text{m}^2 \quad (\mathbf{AI} - \overline{\mathbf{ss}}) \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \text{m}^2$$

*Compute radiosities W from pyrometer temperature readings:*

$$\mathbf{T_{we}} := \begin{bmatrix} 1340.0 \\ 900.0 \\ 1145.0 \end{bmatrix} \text{C} \quad \mathbf{W} := \sigma\left(\mathbf{T_{we}} \cdot \frac{\text{K}}{\text{C}} + \text{T}_0\right)^4 \quad \mathbf{W} := \begin{bmatrix} 384.0 \\ 107.4 \\ 229.4 \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

*Matrix wall flux density relations and heat flux calculations based on W:*

$$\mathbf{H} := \mathbf{AI}^{-1}\mathbf{ss}\cdot\mathbf{W} \qquad \mathbf{Q} := \mathbf{AI}(\mathbf{W} - \mathbf{H}) \qquad \mathbf{E} := (\boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI})^{-1}\cdot\mathbf{Q} + \mathbf{H}$$

$$\mathbf{H} := \begin{bmatrix} 154.0 \\ 324.9 \\ 241.8 \end{bmatrix} \frac{\text{kW}}{\text{m}^2} \quad \mathbf{Q} := \begin{bmatrix} 460.0 \\ -435.0 \\ -25.0 \end{bmatrix} \text{kW} \quad \mathbf{E} := \begin{bmatrix} 441.5 \\ 14.2 \\ 219.1 \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

The sidewalls act as near-adiabatic surfaces since the heat loss through each sidewall is only about 2.7 percent of the total heat flux originating at the source.

*Actual temperatures versus pyrometer readings:*

$$\mathbf{T}: = \left[\left(\frac{\text{E}}{\sigma}\right)^{0.25} - T_0\right]\frac{\text{C}}{\text{K}} \quad \mathbf{T} = \begin{bmatrix} 1397.3 \\ 434.1 \\ 1128.9 \end{bmatrix} \text{C} \quad \text{versus} \quad \mathbf{T_{we}} = \begin{bmatrix} 1340.0 \\ 900.0 \\ 1145.0 \end{bmatrix} \text{C}$$

*Compare SSR model versus matrix method* [use Eqs. (5-128*a*) and (5-130)]: From Eq. (5-130)

$$\text{ssbar}_{12} := \text{ss}_{1,2} + \frac{1}{\frac{1}{\text{ss}_{1,3}} + \frac{1}{\text{ss}_{2,3}}} \qquad \text{ssbar}_{12} = 1.6180\ \text{m}^2$$

And from Eq. (5-128*a*)

$$\text{SSR}_{12} := \frac{1}{\frac{\rho_1}{\varepsilon_1\cdot\text{A}_1} + \frac{\rho_2}{\varepsilon_2\cdot\text{A}_2} + \frac{1}{\text{ssbar}_{12}}} \qquad \text{SSR}_{12} = 1.0446\ \text{m}^2$$

With the numerical result $\text{Q}_{12} := \text{SSR}_{12}(\text{E}_1 - \text{E}_2)$ $\qquad \text{Q}_{12} = 446.3\ \text{kW}$

Thus the SSR model produces $Q_{12} = 446.3$ kW versus the measured value $Q_1 = 460.0$ kW or a discrepency of about 3.0 percent. Mathematically the SSR model assumes a value of $\varepsilon_3 = 0.0$, which precludes the sidewall heat loss of $Q_3 = -25.0$ kW. This assumption accounts for *all* of the difference between the two values. It remains to compare $\text{SSR}_{12}$ and $\text{SS}_{1,2}$ computed by the matrix method.

*Compute total exchange areas ($\varepsilon_3 = 0.55$):*

$$\mathbf{R} := (\mathbf{AI} - \overline{\mathbf{ss}}\cdot\boldsymbol{\rho}\mathbf{I})^{-1}$$

$$\overline{\mathbf{SS}} := \boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{R}\cdot\overline{\mathbf{ss}}\cdot\boldsymbol{\varepsilon}\mathbf{I} \quad \overline{\mathbf{SS}} = \begin{bmatrix} 0.2948 & 0.8284 & 0.4769 \\ 0.8284 & 0.1761 & 0.3955 \\ 0.4769 & 0.3955 & 0.2277 \end{bmatrix} \text{m}^2 \quad (\boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI} - \overline{\mathbf{SS}}) \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \text{m}^2$$

Clearly $\text{SSR}_{21}$ and $\text{SS}_{1,2}$ are unequal. But if

$$\Theta_3 := \frac{\text{SS}_{3,1}}{\text{SS}_{3,1} + \text{SS}_{3,2}}$$

define

$$\text{SSA}_{12} := \text{SS}_{1,2} + \text{SS}_{2,3}\cdot\Theta_3$$

and

$$\Theta_3 := 0.5466 \quad \text{SSA}_{12} = 1.0446\ \text{m}^2 \quad \text{E}_r := \text{E}_2 + (\text{E}_1 - \text{E}_2)\cdot\Theta_3 \quad \text{E}_r = 247.8\ \frac{\text{kW}}{\text{m}^2}$$

Numerically the matrix method predicts $\text{SSA}_{12} = 1.0446$ m$^2$ for $Q_3 = 0$ and $\varepsilon_3 = 0.55$, which is identical to $\text{SSR}_{1,2}$ for the SSR model. Thus $\text{SSR}_{1,2} = \text{SSA}_{12}$ is the *refractory-aided* total exchange area between zone 1 and zone 2. The SSR model also predicts $E_r = 247.8$ kW/m$^2$ versus the experimental value $E_3 = 219.1$ kW/m$^2$ (1172.6C vs. 1128.9C), which is also a consequence of the actual 25.0-kW refractory heat loss.

***Example 10: Furnace Simulation via Zoning*** The furnace chamber depicted in Fig. 5-20 is heated by combustion gases passing through 20 vertical radiant tubes which are backed by refractory sidewalls. The tubes have an outside diameter of D = 5 in (12.7 cm) mounted on C = 12 in (4.72 cm) centers and a gray body emissivity of 0.8. The interior (radiant) portion of the furnace is a $6 \times 8 \times 10$ ft rectangular parallelepiped with a total surface area of 376 ft$^2$ (34.932 m$^2$). A 50-ft$^2$ (4.645-m$^2$) sink is positioned centrally on the floor of the furnace. The tube and sink temperatures are measured with embedded thermocouples as 1500 and 1200°F, respectively. The gray refractory emissivity may be taken as 0.5. While all *other* refractories are assumed to be radiatively adiabatic, the roof of the furnace is estimated to lose heat to the surroundings with a *flux density* (W/m$^2$) equal to 5 percent of the source and sink emissive power difference. An estimate of the radiant flux arriving at the sink is required, as well as estimates for the roof and average refractory temperatures in consideration of refractory service life.

*Part (a): Equivalent Gray Plane Emissivity* Algebraically compute the equivalent gray plane emissivity for the refractory-backed tube bank idealized by the imaginary plane $A_2$, depicted in Fig. 5-15.

*Solution:* Let zone 1 represent *one* tube and zone 2 represent the *effective* plane 2, that is, the *unit cell* for the tube bank. Thus $A_1 = \pi D$ and $A_2 = C$ are the corresponding zone areas, respectively (per unit vertical dimension). This notation is consistent with Example 3. Also put $\varepsilon_1 = 0.8$ with $\varepsilon_2 = 1.0$ and define R = C/D = 12/5 = 2.4. The gray plane effective emissivity is then calculated as the total view factor for the effective plane to tubes, that is, $\mathcal{F}_{2,1} \equiv \overline{\varepsilon}_2$. For R = 2.4, Fig. 5-15, curve 5, yields the refractory augmented view factor $\overline{F}_{2,1} \approx 0.81$. Then $\mathcal{F}_{2,1}$ is calculated from Eq. (5-128*b*) as $\mathcal{F}_{2,1} = \dfrac{1}{0/1 + (2.4/\pi)\cdot 0.2/0.8 + 1/0.81} \approx 0.702$.

A more accurate value is obtained via the matrix method as $\mathcal{F}_{2,1} = 0.70295$.

*Part (b): Radiant Furnace Chamber with Heat Loss*
*Four-zone model, M = 4: Use matrix method.*
Zone 1: Sink (floor)
Zone 2: Source (lumped sides)
Zone 3: Refractory (roof)
Zone 4: Refractory (ends and floor strips)

*Physical constants:*

$$T_0 \equiv 273.15\ \text{K} \quad \sigma \equiv 5.6704 \times 10^{-8}\ \frac{\text{W}}{\text{m}^2\cdot\text{K}^4}$$

*Enclosure input parameters:*

$\text{A}_1 := 50\ \text{ft}^2$ $\text{A}_2 := 120\ \text{ft}^2$ $\text{A}_3 := 80\ \text{ft}^2$ $\text{A}_4 := 126\ \text{ft}^2$ $\text{D} := 5$ in $\text{H} := 6$ ft

$\varepsilon_1 := .9$ $\varepsilon_2 := .70295$ $\varepsilon_3 := .5$ $\varepsilon_4 := .5$ $\mathbf{I_4} :=$ identity(4)

$$\boldsymbol{\varepsilon}\mathbf{I} = \begin{bmatrix} 0.9 & 0 & 0 & 0 \\ 0 & 0.7029 & 0 & 0 \\ 0 & 0 & 0.5 & 0 \\ 0 & 0 & 0 & 0.5 \end{bmatrix} \quad \boldsymbol{\rho}\mathbf{I} := \mathbf{I_4} - \boldsymbol{\varepsilon}\mathbf{I} \quad \boldsymbol{\rho}\mathbf{I} = \begin{bmatrix} 0.1 & 0 & 0 & 0 \\ 0 & 0.2971 & 0 & 0 \\ 0 & 0 & 0.5 & 0 \\ 0 & 0 & 0 & 0.5 \end{bmatrix}$$

*Compute direct exchange areas:* There are $\sum = 6$ unique direct exchange areas. These are obtained from Eqs. (5-114) and view factor algebra. The final array of direct exchange areas is:

$$\overline{\mathbf{ss}} = \begin{bmatrix} 0 & 1.559 & 1.575 & 1.511 \\ 1.559 & 2.078 & 2.839 & 4.673 \\ 1.575 & 2.839 & 0 & 3.018 \\ 1.511 & 4.673 & 3.018 & 2.503 \end{bmatrix} \text{m}^2 \quad \mathbf{AI} = \begin{bmatrix} 4.645 & 0 & 0 & 0 \\ 0 & 11.148 & 0 & 0 \\ 0 & 0 & 7.432 & 0 \\ 0 & 0 & 0 & 11.706 \end{bmatrix} \text{m}^2$$

*Compute total exchange areas:*

$$\mathbf{R} := (\mathbf{AI} - \overline{\mathbf{ss}}\cdot\boldsymbol{\rho}\mathbf{I})^{-1} \qquad \overline{\mathbf{SS}} := \boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{R}\cdot\mathbf{ss}\cdot\boldsymbol{\varepsilon}\mathbf{I} \qquad \overline{\mathbf{SS}} = \begin{bmatrix} 0.405 & 1.669 & 0.955 & 1.152 \\ 1.669 & 2.272 & 1.465 & 2.431 \\ 0.955 & 1.465 & 0.234 & 1.063 \\ 1.152 & 2.431 & 1.063 & 1.207 \end{bmatrix} \text{m}^2$$

*Check matrix conservation via row-sums:*

$$(\mathbf{AI} - \overline{\mathbf{ss}}) \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \text{m}^2 \quad (\boldsymbol{\varepsilon}\mathbf{I}\cdot\mathbf{AI} - \overline{\mathbf{SS}}) \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \text{m}^2$$

*Emissive power and wall flux input data:*

$$\mathbf{T_F} := \begin{bmatrix} 1200 \\ 1500 \\ 32 \\ 32 \end{bmatrix} \text{F} \qquad \mathbf{T} := \frac{5}{9}(\mathbf{T_F} - 32\ \text{F})\frac{\text{C}}{\text{F}} \qquad \mathbf{E} := \sigma\left(\mathbf{T}\cdot\frac{\text{K}}{\text{C}} + T_0\right)^4$$

$$\mathbf{T} = \begin{bmatrix} 648.9 \\ 815.6 \\ 0.0 \\ 0.0 \end{bmatrix} \text{C} \qquad \mathbf{E} = \begin{bmatrix} 40.98 \\ 79.66 \\ 0.32 \\ 0.32 \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

$$\text{Q}_3 := -0.05\cdot\text{A}_3(\text{E}_2 - \text{E}_1) \qquad \text{Q}_3 = -14.37\ \text{kW} \qquad \text{Q}_4 := 0$$

*Compute refractory emissive powers from known flux inputs $Q_3$ and $Q_4$ using partitioned matrix equations [Eq. (5-120b)]:*

$$\mathbf{E_R} := \begin{bmatrix} \varepsilon_3 \cdot A_3 - SS_{3,3} & -SS_{3,4} \\ -SS_{4,3} & \varepsilon_4 \cdot A_4 - SS_{4,4} \end{bmatrix}^{-1} \cdot \begin{bmatrix} Q_3 + SS_{3,1} \cdot E_1 + SS_{3,2} \cdot E_2 \\ Q_4 + SS_{4,1} \cdot E_1 + SS_{4,2} \cdot E_2 \end{bmatrix}$$

$$\mathbf{E_R} = \begin{bmatrix} 60.68 \\ 65.73 \end{bmatrix} \frac{kW}{m^2} \qquad \mathbf{E} := \begin{bmatrix} E_1 \\ E_2 \\ E_{R_1} \\ E_{R_2} \end{bmatrix} \qquad \mathbf{E} = \begin{bmatrix} 40.98 \\ 79.66 \\ 60.68 \\ 65.73 \end{bmatrix} \frac{kW}{m^2}$$

*Compute flux values and final zone temperatures:*

$$\mathbf{Q} := \varepsilon \mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{E} - \overline{\mathbf{SS}} \cdot \mathbf{E} \qquad \mathbf{T} := \left[ \left( \frac{\mathbf{E}}{\sigma} \right)^{0.25} - T_0 \right] \frac{C}{K}$$

$$\mathbf{Q} = \begin{bmatrix} -111.87 \\ 126.24 \\ -14.37 \\ 0.00 \end{bmatrix} kW \qquad \mathbf{T} = \begin{bmatrix} 648.9 \\ 815.6 \\ 743.9 \\ 764.5 \end{bmatrix} C$$

*Auxiliary calculations for tube area and effective tube emissivity:*

$$A_{Tubes} := 20\pi \cdot D \cdot H \qquad \varepsilon_{Tubes} := \frac{Q_2}{A_{Tubes}(E_2 - E_1)} \qquad A_{Tubes} = 14.59\ m^2 \qquad \varepsilon_{Tubes} = 0.2237$$

*Notes:* (1) Results for $Q$ and $T$ here are independent of $\varepsilon_3$ and $\varepsilon_4$ with the exception of $T_3$, which is indeed a function of $\varepsilon_3$. (2) The total surface area of the tubes is $A_{Tubes} = 14.59\ m^2$. Suppose the tubes were totally surrounded by a *black* enclosure at the temperature of the sink. The hypothetical emissivity of the tubes would then be $\varepsilon_{Tubes} = 0.224$. (3) A 5 percent roof heat loss is consistent with practical measurement errors. A sensitivity test was performed with $M = 3$, 4, and 5 with and without roof heat loss. The SSR model corresponds to $M = 3$ with zero heat loss. For $M = 5$, zone 4 corresponded to the furnace ends and zone 5 corresponded to the floor strips. The results are summarized in the following table. With the exception of the temperature of the floor strips, the computed results are seen to be remarkably insensitive to $M$.

Effect of Zone Number $M$ on Computed Results

| | Zero roof heat loss | | | 5 percent roof heat loss | | |
|---|---|---|---|---|---|---|
| | $M = 3$ | $M = 4$ | $M = 5$ | $M = 3$ | $M = 4$ | $M = 5$ |
| | Temperature, °C | | | | | |
| $T_3$ | 765.8 | 762.0 | 762.4 | 756.2 | 743.9 | 744.3 |
| $T_4$ | NA | 768.4 | 765.0 | NA | 764.5 | 761.1 |
| $T_5$ | NA | NA | 780.9 | NA | NA | 776.7 |
| | Heat flux, kW | | | | | |
| $Q_1$ | −117.657 | −117.275 | −116.251 | −112.601 | −111.870 | −110.877 |
| $Q_2$ | 117.657 | 117.275 | 116.251 | 126.975 | 126.244 | 125.251 |

**Allowance for Specular Reflection** If the assumption that all surface zones are diffuse emitters and reflectors is relaxed, the zoning equations become much more complex. Here, all surface parameters become functions of the *angles of incidence and reflection* of the radiation beams at each surface. In practice, such details of reflectance and emission are seldom known. When they are, the Monte Carlo method of tracing a large number of beams emitted from random positions and in random initial directions is probably the best method of obtaining a solution. Siegel and Howell (op. cit., Chap. 10) and Modest (op. cit., Chap. 20) review the utilization of the Monte Carlo approach to a variety of radiant transfer applications. Among these is the Monte Carlo calculation of direct exchange areas for very complex geometries. Monte Carlo techniques are generally *not used* in practice for simpler engineering applications.

A simple *engineering* approach to specular reflection is the so-called **diffuse plus specular reflection model**. Here the total reflectivity $\rho_i = 1 - \varepsilon_i = \rho_{Si} + \rho_{Di}$ is represented as the sum of a *diffuse component* $\rho_{Si}$ and a *specular component* $\rho_{Di}$. The method yields analytical results for a number of two surface zone geometries. In particular, the following equation is obtained for exchange between concentric spheres or infinitely long coaxial cylinders for which $A_1 < A_2$:

$$\overline{S_1 S_2} = \frac{A_1}{\left( \dfrac{1}{\varepsilon_1} + \dfrac{\rho_2}{\varepsilon_2} \cdot \dfrac{A_1}{A_2} + \dfrac{\rho_{S2}}{(1 - \rho_{S2})} [1 - A_1/A_2] \right)} \tag{5-134}$$

For $\rho_{D1} = \rho_{D2} = 0$ (or equivalently $\rho_1 = \rho_{S1}$ with $\rho_2 = \rho_{S2}$), Eq. (5-134) yields the limiting case for wholly specular reflection, i.e.

*Specular limit*

$$\overline{S_1 S_2} = \frac{A_1}{\left( \dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1 \right)} \tag{5-134$a$}$$

which is independent of the area ratio, $A_1/A_2$. It is important to notice that Eq. (5-124*a*) is *similar* to Eq. (5-127*b*) but the emissivities here are defined as $\varepsilon_1 \equiv 1 - \rho_{S1}$ and $\varepsilon_2 \equiv 1 - \rho_{S2}$. When surface reflection is wholly diffuse [$\rho_{S1} = \rho_{S2} = 0$ or $\rho_1 = \rho_{D1}$ with $\rho_2 = \rho_{D2}$], Eq. (5-134) results in a formula *identical* to Eq. (5-127*a*), viz.

*Diffuse limit*

$$\overline{S_1 S_2} = \frac{A_1}{\left[ \dfrac{1}{\varepsilon_1} + \left( \dfrac{A_1}{A_2} \right) \dfrac{\rho_2}{\varepsilon_2} \right]} \tag{5-134$b$, 5-127$a$}$$

For the case of (infinite) parallel flat plates where $A_1 = A_2$, Eq. (5-134) leads to a general formula *similar* to Eq. (5-134*a*) but with the stipulation here that $\varepsilon_1 \equiv 1 - \rho_{D1} - \rho_{S1}$ and $\varepsilon_2 \equiv 1 - \rho_{D2} - \rho_{S2}$.

Another particularly interesting limit of Eq. (5-134) occurs when $A_2 \gg A_1$, which might represent a small sphere irradiated by an infinite surroundings which can reflect radiation originating at $A_1$ back to $A_1$. That is to say, even though $A_2 \to \infty$, the "self" total exchange area does not necessarily vanish, to wit

$$\overline{S_1 S_1} = \frac{\varepsilon_1^2 \cdot \rho_{s2} \cdot A_1}{[1 - \rho_1 \cdot \rho_{s2}]} \quad \text{and} \quad \overline{S_1 S_2} = \frac{\varepsilon_1 (1 - \rho_{s2}) \cdot A_1}{[1 - \rho_1 \cdot \rho_{s2}]} \tag{5-134$c,d$}$$

which again exhibit diffuse and specular limits. The diffuse plus specular reflection model becomes significantly more complex for geometries with $M \geq 3$ where digital computation is usually required.

**An Exact Solution to the Integral Equations—The Hohlraum** Exact solutions of the fundamental *integral equations* for radiative transfer are available for only a few simple cases. One of these is the evaluation of the emittance from a small aperture, of area $A_1$, in the surface of an isothermal spherical cavity of radius $R$. In German, this geometry is termed a *hohlraum* or hollow space. For this special case the radiosity $W$ is constant over the inner surface of the cavity. It then follows that the ratio $W/E$ is given by

$$W/E = \frac{\varepsilon}{1 - \rho[1 - A_1/(4\pi R^2)]} \tag{5-135}$$

where $\varepsilon$ and $\rho = 1 - \varepsilon$ are the diffuse emissivity and reflectivity of the interior cavity surface, respectively. The ratio $W/E$ is the effective emittance of the aperture as sensed by an external narrow-angle receiver (radiometer) viewing the cavity interior. Assume that the cavity is constructed of a rough material whose (diffuse) emissivity is $\varepsilon = 0.5$. As a point of reference, if the cavity is to simulate a blackbody emitter to better than 98 percent of an ideal theoretical blackbody, Eq. (5-135) then predicts that the ratio of the aperture to sphere areas $A_1/(4\pi R^2)$ must be less than 2 percent. Equation (5-135) has practical utility in the experimental design of calibration standards for laboratory radiometers.

## RADIATION FROM GASES AND SUSPENDED PARTICULATE MATTER

**Introduction** Flame radiation originates as a result of emission from water vapor and carbon dioxide in the hot gaseous combustion

products and from the presence of particulate matter. The latter includes emission from burning of microscopic and submicroscopic soot particles, and from large suspended particles of coal, coke, or ash. Thermal radiation owing to the presence of water vapor and carbon dioxide is not visible. The characteristic blue color of clean natural gas flames is due to chemiluminescence of the excited intermediates in the flame which contribute negligibly to the radiation from combustion products.

***Gas Emissivities*** Radiant transfer in a gaseous medium is characterized by three quantities; the gas emissivity, gas absorptivity, and gas transmissivity. Gas emissivity refers to radiation originating within a gas volume which is incident on some reference surface. Gas absorptivity and transmissivity, however, refer to the absorption and transmission of radiation from some *external* surface radiation source characterized by some radiation temperature $T_1$. The sum of the gas absorptivity and transmissivity must, by definition, be unity. Gas absorptivity may be calculated from an appropriate gas emissivity. The gas emissivity is a function only of the gas temperature $T_g$ while the absorptivity and transmissivity are functions of *both* $T_g$ and $T_1$.

The **standard hemispherical monochromatic gas emissivity** is defined as the direct volume-to-surface exchange area for a hemispherical gas volume to an infinitesimal area element located at the center of the planar base. Consider monochromatic transfer in a *black* hemispherical enclosure of radius $R$ that confines an isothermal volume of gas at temperature $T_g$. The temperature of the bounding surfaces is $T_1$. Let $A_2$ denote the area of the finite hemispherical surface and $dA_1$ denote an infinitesimal element of area located at the center of the planar base. The (dimensionless) monochromatic direct exchange area for exchange between the finite hemispherical surface $A_2$ and $dA_1$ then follows from direct integration of Eq. (5-116*a*) as

$$\frac{\partial(\overline{s_1 s_2})_\lambda}{\partial A_1} = \int_{\phi_1=0}^{\pi/2} \frac{e^{-K_\lambda R}}{\pi R^2} \cos\phi_1 \, 2\pi R^2 \sin\phi_1 \, d\phi_1 = e^{-K_\lambda R} \qquad (5\text{-}136a)$$

and from conservation there results

$$\frac{\partial(\overline{s_1 g})_\lambda}{\partial A_1} = 1 - e^{-K_\lambda R} \qquad (5\text{-}136b)$$

Note that Eq. (5-136*b*) is identical to the expression for the gas emissivity for a column of path length $R$. In Eqs. (5-136) the gas absorption coefficient is a function of gas temperature, composition, and wavelength, that is, $K_\lambda = K_\lambda(T,\lambda)$. The net monochromatic radiant flux density at $dA_1$ due to irradiation from the gas volume is then given by

$$q_{1g,\lambda} = \frac{\partial(\overline{s_1 g})_\lambda}{\partial A_1}(E_{1,\lambda} - E_{g,\lambda}) \equiv \alpha_{g1,\lambda} E_{1,\lambda} - \varepsilon_{g,\lambda} E_{g,\lambda} \qquad (5\text{-}137)$$

In Eq. (5-137), $\varepsilon_{g,\lambda}(T,\lambda) = 1 - \exp(-K_\lambda R)$ is defined as the monochromatic or *spectral gas emissivity* and $\alpha_{g,\lambda}(T,\lambda) = \varepsilon_{g,\lambda}(T,\lambda)$.

If Eq. (5-137) is integrated with respect to wavelength over the entire EM spectrum, an expression for the *total* flux density is obtained

$$q_{1,g} = \alpha_{g,1} E_1 - \varepsilon_g E_g \qquad (5\text{-}138)$$

where

$$\varepsilon_g(T_g) = \int_{\lambda=0}^{\infty} \varepsilon_\lambda(T_g,\lambda) \cdot \frac{E_{b,\lambda}(T_g,\lambda)}{E_b(T_g)} \, d\lambda \qquad (5\text{-}138a)$$

and

$$\alpha_{g,1}(T_1,T_g) = \int_{\lambda=0}^{\infty} \alpha_{g,\lambda}(T_g,\lambda) \cdot \frac{E_{b,\lambda}(T_1,\lambda)}{E_b(T_1)} \, d\lambda \qquad (5\text{-}138b)$$

define the *total* gas emissivity and absorptivity, respectively. The notation used here is analogous to that used for surface emissivity and absorptivity as previously defined. For a *real* gas $\varepsilon_g = \alpha_{g,1}$ only if $T_1 = T_g$, while for a *gray* gas mass of arbitrarily shaped volume $\varepsilon_g = \alpha_{g,1} = \partial(\overline{s_1 g})/\partial A_1$ is independent of temperature. Because $K_\lambda(T,\lambda)$ is also a function of the composition of the radiating species, it is necessary in what follows to define a second absorption coefficient $k_{p,\lambda}$, where $K_\lambda = k_{p,\lambda} p$. Here $p$ is the partial pressure of the radiating species, and $k_{p,\lambda}$, with units of $(\text{atm}\cdot\text{m})^{-1}$, is referred to as the *monochromatic line absorption coefficient*.

***Mean Beam Lengths*** It is always possible to represent the emissivity of an arbitrarily shaped volume of gray gas (and thus the corresponding direct gas-to-surface exchange area) with an equivalent sphere of radius $R = L_M$. In this context the hemispherical radius $R = L_M$ is referred to as the **mean beam length** of the arbitrary gas volume. Consider, e.g., an isothermal gas layer at temperature $T_g$ confined by two infinite parallel plates separated by distance $L$. Direct integration of Eq. (5-116*a*) and use of conservation yield a closed-form expression for the requisite surface-gas direct exchange area

$$\frac{\partial(\overline{s_1 g})}{\partial A_1} = [1 - 2E_3(KL)] \qquad (5\text{-}139a)$$

where $E_n(z) = \int_{t=1}^{\infty} \frac{e^{-z\cdot t}}{t^n} \, dt$ is defined as the ***n*th-order exponential integral** which is readily available. Employing the definition of gas emissivity, the **mean beam length** between the plates $L_M$ is then defined by the expression

$$\varepsilon_g = [1 - 2E_3(KL)] \equiv 1 - e^{-KL_M} \qquad (5\text{-}139b)$$

Solution of Eq. (5-139*b*) yields $KL_M = -\ln[2E_3(KL)]$, and it is apparent that $KL_M$ is a function of $KL$. Since $E_n(0) = 1/(n-1)$ for $n > 1$, the mean beam length approximation also correctly predicts the gas emissivity as zero when $K = 0$ and $K \to \infty$.

In the limit $K \to 0$, power series expansion of both sides of the Eq. (5-139*b*) leads to $KL_M \to 2KL \equiv KL_{M0}$, where $L_M \equiv L_{M0} = 2L$. Here $L_{M0}$ is defined as the **optically thin mean beam length** for radiant transfer from the entire *infinite* planar gas layer to a differential element of surface area on one of the plates. The optically thin mean beam length for two infinite parallel plates is thus simply *twice* the plate spacing $L$. In a similar manner it may be shown that for a sphere of diameter $D$, $L_{M0} = \frac{2}{3} D$, and for an infinitely long cylinder $L_{M0} = D$. A useful default formula for an arbitrary enclosure of volume $V$ and area $A$ is given by $L_{M0} = 4V/A$. This expression predicts $L_{M0} = \frac{8}{9} R$ for the standard hemisphere of radius $R$ because the optically thin mean beam length is averaged over the *entire* hemispherical enclosure.

Use of the optically thin value of the mean beam length yields values of gas emissivities or exchange areas that are too high. It is thus necessary to introduce a dimensionless constant $\beta \le 1$ and define some new **average mean beam length** such that $KL_M \equiv \beta KL_{M0}$. For the case of parallel plates, we now require that the mean beam length exactly predict the gas emissivity for a *third* value of $KL$. In this example we find $\beta = -\ln[2E_3(KL)]/2KL$ and for $KL = 0.193095$ there results $\beta = 0.880$. The value $\beta = 0.880$ is not wholly arbitrary. It also happens to minimize the error defined by the so-called shape correction factor $\phi = [\partial(\overline{s_1 g})/\partial A_1]/(1 - e^{-KL_M})$ for all $KL > 0$. The required *average* mean beam length for all $KL > 0$ is then taken simply as $L_M = 0.88 L_{M0} = 1.76L$. The error in this approximation is less than 5 percent.

For an arbitrary geometry, the average mean beam length is defined as the radius of a hemisphere of gas which predicts values of the direct exchange area $\overline{s_1 g}/A_1 = [1 - \exp(-KL_M)]$, subject to the optimization condition indicated above. It is has been found that the error introduced by using average mean beam lengths to approximate direct exchange areas is sufficiently small to be appropriate for many engineering calculations. When $\beta = L_M/L_{M0}$ is evaluated for a large number of geometries, it is found that $0.8 < \beta < 0.95$. It is recommended here that $\beta = 0.88$ be employed in lieu of any further geometric information. For a single-gas zone, all the requisite direct exchange areas can be approximated for engineering purposes in terms of a *single* appropriately defined average mean beam length.

**Emissivities of Combustion Products** Absorption or emission of radiation by the constituents of gaseous combustion products is determined primarily by vibrational and rotational transitions between the energy levels of the gaseous molecules. Changes in both vibrational and rotational energy states gives rise to *discrete* spectral lines. Rotational lines accompanying vibrational transitions usually overlap, forming a so-called vibration-rotation band. These bands are thus associated with the major vibrational frequencies of the molecules.

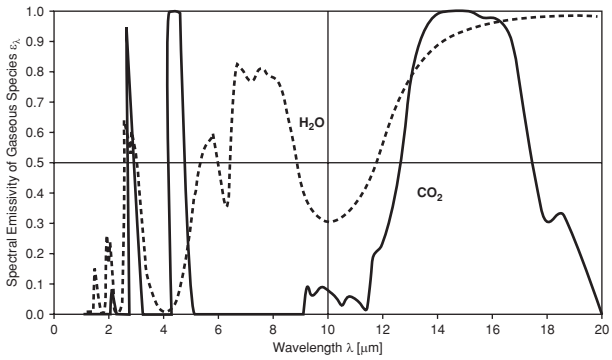

**FIG. 5-21** Spectral emittances for carbon dioxide and water vapor after RADCAL. $p_cL = p_wL = 0.36$ atm·m, $T_g = 1500$ K.

Each spectral line is characterized by an absorption coefficient $k_{p,\lambda}$ which exhibits a maximum at some central characteristic wavelength or wave number $\eta_0 = 1/\lambda_0$ and is described by a Lorentz* probability distribution. Since the widths of spectral lines are dependent on collisions with other molecules, the absorption coefficient will also depend upon the composition of the combustion gases and the total system pressure. This brief discussion of gas spectroscopy is intended as an introduction to the factors controlling absorption coefficients and thus the factors which govern the empirical correlations to be presented for gas emissivities and absorptivities.

Figure 5-21 shows computed values of the spectral emissivity $\varepsilon_{g,\lambda} \equiv \varepsilon_{g,\lambda}(T,pL,\lambda)$ as a function of wavelength for an equimolar mixture of carbon dioxide and water vapor for a gas temperature of 1500 K, partial pressure of 0.18 atm, and a path length $L = 2$ m. Three principal absorption-emission bands for $CO_2$ are seen to be centered on 2.7, 4.3, and 15 μm. Two weaker bands at 2 and 9.7 μm are also evident. Three principal absorption-emission bands for water vapor are also identified near 2.7, 6.6, and 20 μm with lesser bands at 1.17, 1.36, and 1.87 μm. The *total* emissivity $\varepsilon_g$ and absorptivity $\alpha_{g,1}$ are calculated by integration with respect to wavelength of the spectral emissivities, using Eqs. (5-138) in a manner similar to the development of total surface properties.

***Spectral Emissivities*** Highly resolved spectral emissivities can be generated at ambient temperatures from the HITRAN database (*hi*gh-resolution *tran*smission molecular absorption) that has been developed for atmospheric models [Rothman, L. S., Chance, K., and Goldman, A., eds., *J. Quant. Spectroscopy & Radiative Trans.*, **82** (1–4), 2003]. This database includes the chemical species: $H_2O$, $CO_2$, $O_3$, $N_2O$, CO, $CH_4$, $O_2$, NO, $SO_2$, $NO_2$, $NH_3$, $HNO_3$, OH, HF, HCl, HBr, ClO, OCS, $H_2CO$, HOCl, $N_2$, HCN, $CH_3C$, HCl, $H_2O_2$, $C_2H_2$, $C_2H_6$, $PH_3$, $COF_2$, $SF_6$, $H_2S$, and $HCO_2H$. These data have been extended to high temperature for $CO_2$ and $H_2O$, allowing for the changes in the population of different energy levels and in the line half width [Denison, M. K., and Webb, B. W., *Heat Transfer*, **2**, 19–24 (1994)]. The resolution in the single-line models of emissivities is far greater than that needed in engineering calculations. A number of models are available that average the emissivities over narrow-wavelength regimes or over the entire band. An extensive set of measurements of narrowband parameters performed at NASA (Ludwig, C., et al., *Handbook of Infrared Radiation from Combustion Gases*, NASA SP-3080, 1973) has been used to develop the RADCAL computer code to obtain spectral emissivities for $CO_2$, $H_2O$, $CH_4$, CO, and soot (Grosshandler, W. L., "RADCAL," NIST Technical Note 1402, 1993). The exponential wideband model is available for emissions averaged over a band for $H_2O$, $CO_2$, CO, $CH_4$, NO, $SO_2$, $N_2O$, $NH_3$, and $C_2H_2$ [Edwards, D. K., and Menard, W. A., *Appl. Optics*, **3,** 621–625 (1964)]. The line and band models have the advantages of being able to account for complexities in determining emissivities of line broadening due to changes in composition and pressure, exchange with spectrally selective walls, and greater accuracy in formulating fluxes in gases with temperature gradients. These models can be used to generate the total emissivities and absorptivies that will be used in this chapter. RADCAL is a command-line FORTRAN code which is available in the public domain on the Internet.

***Total Emissivities and Absorptivities*** Total emissivities and absorptivities for water vapor and carbon dioxide at present are still based on data embodied in the classical **Hottel emissivity charts.** These data have been adjusted with the more recent measurements in RADCAL and used to develop the correlations of emissivities given in Table 5-5. Two empirical correlations which permit hand calculation of emissivities for water vapor, carbon dioxide, and *four* mixtures of the two gases are presented in Table 5-5. The first section of Table 5-5 provides data for the two constants $b$ and $n$ in the empirical relation

$$\overline{\varepsilon_g T_g} = b[pL - 0.015]^n \qquad (5\text{-}140a)$$

while the second section of Table 5-5 utilizes the *four* constants in the empirical correlation

$$\log\left(\overline{\varepsilon_g T_g}\right) = a_0 + a_1 \log(pL) + a_2 \log^2(pL) + a_3 \log^3(pL) \qquad (5\text{-}140b)$$

In both cases the empirical constants are given for the three temperatures of 1000, 1500, and 2000 K. Table 5-5 also includes some six values for the partial pressure ratios $p_W/p_C$ of water vapor to carbon dioxide, namely, 0, 0.5, 1.0, 2.0, 3.0, and ∞. These ratios correspond to composition values of $p_C/(p_C + p_W) = 1/(1 + p_W/p_C)$ of 0, 1/3, 1/2, 2/3, 3/4, and unity. For emissivity calculations at other temperatures and mixture compositions, linear interpolation of the constants is recommended.

The absorptivity can be obtained from the emissivity with aid of Table 5-5 by using the following functional equivalence.

$$\overline{\alpha_{g,1} T_1} = \left[\overline{\varepsilon_g T_1}(pL \cdot T_1/T_g)\right]\left(\frac{T_g}{T_1}\right)^{0.5} \qquad (5\text{-}141)$$

Verbally, the absorptivity computed from Eq. (5-141) by using the correlations in Table 5-5 is based on a value for gas emissivity $\varepsilon_g$ calculated at a temperature $T_1$ and at a partial-pressure path-length product of $(p_C + p_W)LT_1/T_g$. The absorptivity is then equal to this value of gas emissivity multiplied by $(T_g/T_1)^{0.5}$. It is recommended that spectrally based models such as RADCAL (loc. cit.) be used particularly when extrapolating beyond the temperature, pressure, or partial-pressure-length product ranges presented in Table 5-5.

A comparison of the results of the predictions of Table 5-5 with values obtained via the integration of the spectral results calculated from the narrowband model in RADCAL is provided in Fig. 5-22. Here calculations are shown for $p_CL = p_WL = 0.12$ atm·m and a gas temperature of 1500 K. The RADCAL predictions are 20 percent higher than the measurements at low values of $pL$ and are 5 percent higher at the large values of $pL$. An extensive comparison of different sources of emissivity data shows that disparities up to 20 percent are to be expected at the current time [Lallemant, N., Sayre, A., and Weber, R., *Prog. Energy Combust. Sci.*, **22,** 543–574, (1996)]. However, smaller errors result for the range of the total emissivity measurements presented in the Hottel emissivity tables. This is demonstrated in Example 11.

***Example 11: Calculations of Gas Emissivity and Absorptivity*** Consider a slab of gas confined between two infinite parallel plates with a distance of separation of $L = 1$ m. The gas pressure is 101.325 kPa (1 atm), and the gas temperature is 1500 K (2240°F). The gas is an equimolar mixture of $CO_2$ and $H_2O$, each with a partial pressure of 12 kPa ($p_C = p_W = 0.12$ atm). The radiative flux to one of its bounding surfaces has been calculated by using RADCAL for two cases. For case (*a*) the flux to the bounding surface is 68.3 kW/m$^2$ when the emitting gas is backed by a black surface at an ambient temperature of 300 K (80°F). This (cold) back surface contributes less than 1 percent to the flux. In case (*b*), the flux is calculated as 106.2 kW/m$^2$ when the gas is backed by a black surface at a temperature of 1000 K (1340°F). In this example, gas emissivity and

*Spectral lines are conventionally described in terms of wave number $\eta = 1/\lambda$, with each line having a peak absorption at wave number $\eta_0$. The Lorentz distribution is defined as $k_\eta/S = \dfrac{b_c}{\pi[b_c^2 + (\eta - \eta_o)^2]}$ where $S$ is the integral of $k_\eta$ over all wave numbers. The parameter $S$ is known as the integrated line intensity, and $b_c$ is defined as the collision line half-width, i.e., the half-width of the line is one-half of its peak centerline value. The units of $k_\eta$ are m$^{-1}$ atm$^{-1}$.

NOTE: $p_w/(p_w + p_c)$ of ⅓, ½, ⅔, and ¾ may be used to cover the ranges 0.2–0.4, 0.4–0.6, 0.6–0.7, and 0.7–0.8, respectively, with a maximum error in $\varepsilon_g$ of 5 percent at $pL$ = 6.5 m·atm, less at lower $pL$'s. Linear interpolation reduces the error generally to less than 1 percent. Linear interpolation or extrapolation on $T$ introduces an error generally below 2 percent, less than the accuracy of the original data.

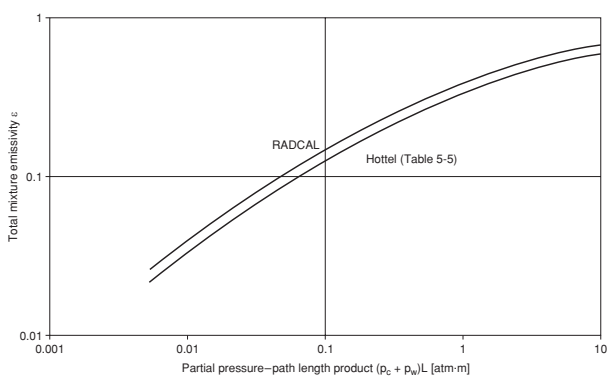

**FIG. 5-22** Comparison of Hottel and RADCAL total gas emissivities. Equimolal gas mixture of $CO_2$ and $H_2O$ with $p_c = p_w = 0.12$ atm and $T_g = 1500$ K.

absorptivity are to be computed from these flux values and compared with values obtained by using Table 5-5.

*Case (a):* The flux incident on the surface is equal to $\varepsilon_g \cdot \sigma \cdot T_g^4 = 68.3$ kW/m$^2$; therefore, $\varepsilon_g = 68{,}300/(5.6704 \times 10^{-8} \cdot 1500^4) = 0.238$. To utilize Table 5-5, the mean beam length for the gas is calculated from the relation $L_M = 0.88 L_{M0} = 0.88 \cdot 2L = 1.76$ m. For $T_g = 1500$ K and $(p_C + p_W)L_M = 0.24(1.76) = 0.422$ atm·m, the two-constant correlation in Table 5-5 yields $\varepsilon_g = 0.230$ and the four-constant correlation yields $\varepsilon_g = 0.234$. These results are clearly in excellent agreement with the predicted value of $\varepsilon_g = 0.238$ obtained from RADCAL.

*Case (b):* The flux incident on the surface (106.2 kW/m$^2$) is the sum of that contributed by (1) gas emission $\varepsilon_g \cdot \sigma \cdot T_g^4 = 68.3$ kW/m$^2$ and (2) emission from the opposing surface corrected for absorption by the intervening gas using the gas transmissivity, that is, $\tau_{g,1} \sigma \cdot T_1^4$ where $\tau_{g,1} = 1 - \alpha_{g,1}$. Therefore $\alpha_{g,1} = [1 - (106{,}200 - 68{,}300)/(5.6704 \times 10^{-8} \cdot 1000^4)] = 0.332$. Using Table 5-5, the two-constant and four-constant gas emissivities evaluated at $T_1 = 1000$ K and $pL = 0.4224 \cdot (1000/1500) = 0.282$ atm·m are $\varepsilon_g = 0.2654$ and $\varepsilon_g = 0.2707$, respectively. Multiplication by the factor $(T_g / T_1)^{0.5} = (1500/1000)^{0.5} = 1.225$ produces the final values of the two corresponding gas absorptivities $\alpha_{g,1} = 0.325$ and $\alpha_{g,1} = 0.332$, respectively. Again the agreement with RADCAL is excellent.

***Other Gases*** The most extensive available data for gas emissivity are those for carbon dioxide and water vapor because of their importance in the radiation from the products of fossil fuel combustion. Selected data for other species present in combustion gases are provided in Table 5-6.

### Flames and Particle Clouds

***Luminous Flames*** Luminosity conventionally refers to soot radiation. At atmospheric pressure, soot is formed in locally fuel-rich portions of flames in amounts that usually correspond to less than 1 percent of the carbon in the fuel. Because soot particles are small relative to the wavelength of the radiation of interest in flames (primary particle diameters of soot are of the order of 20 nm compared to wavelengths of interest of 500 to 8000 nm), the incident radiation permeates the particles, and the absorption is proportional to the volume of the particles. In the limit of $r_p/\lambda << 1$, the Rayleigh limit, the monochromatic emissivity $\varepsilon_\lambda$ is given by

$$\varepsilon_\lambda = 1 - \exp(-K \cdot f_v \cdot L/\lambda) \tag{5-142}$$

where $f_v$ is the volumetric soot concentration, $L$ is the path length in the same units as the wavelength $\lambda$, and $K$ is dimensionless. The value $K$ will vary with fuel type, experimental conditions, and the temperature history of the soot. The values of $K$ for a wide range of systems are within a factor of about 2 of one another. The single most important variable governing the value of $K$ is the hydrogen/carbon ratio of the soot, and the value of $K$ increases as the H/C ratio decreases. A value of $K = 9.9$ is recommended on the basis of seven studies involving 29 fuels [Mulholland, G. W., and Croarkin, C., *Fire and Materials*, **24,** 227–230 (2000)].

The total emissivity of soot $\varepsilon_S$ can be obtained by substituting $\varepsilon_\lambda$ from Eq. (5-142) for $\varepsilon_\lambda$ in Eq. (5-138*a*) to yield

$$\varepsilon_S = \int_{\lambda=0}^{\infty} \varepsilon_\lambda \frac{E_{b,\lambda}(T_g,\lambda)}{E_b(T_g)}\, d\lambda = 1 - \frac{15}{4}[\Psi^{(3)}(1 + K \cdot f_v \cdot L \cdot T/c_2)]$$

$$\cong (1 + K \cdot f_v \cdot L \cdot T/c_2)^{-4} \tag{5-143}$$

Here $\Psi^{(3)}(x)$ is defined as the pentagamma function of $x$ and $c_2$ (m·K) is again Planck's second constant. The approximate relation in Eq. (5-143) is accurate to better than 1 percent for arguments yielding values of $\varepsilon_S < 0.7$. At present, the largest uncertainty in estimating total soot emissivities is in the estimation of the soot volume fraction $f_v$. Soot forms in the fuel-rich zones of flames. Soot formation rates are a function of fuel type, mixing rate, local equivalence ratio $\Phi$, temperature, and pressure. The equivalence ratio is defined as the quotient of the actual to stoichiometric fuel-to-oxidant ratio $\Phi = [F/O]_{Act}/[F/O]_{Stoich}$. Soot formation increases with the aromaticity or C/H ratio of fuels with benzene, α-methyl naphthalene, and acetylene having a high propensity to form soot and methane having a low soot formation propensity. Oxygenated fuels, such as alcohols, emit little soot. In practical turbulent diffusion flames, soot forms on the fuel side of the flame front. In premixed flames, at a given temperature, the rate of soot formation increases rapidly for $\Phi > 2$. For temperatures above 1500 K, soot burns out rapidly (in less than 0.1s) under fuel-lean conditions, $\Phi < 1$. Because of this rapid soot burnout, soot is usually localized in a relatively small fraction of a furnace or combustor volume. Long, poorly mixed diffusion flames promote soot formation while highly backmixed combustors can burn soot-free. In a typical flame at atmospheric pressure, maximum volumetric soot concentrations are found to be in the range $10^{-7} < f_v < 10^{-6}$. This corresponds to a soot formation of about 1.5 to 15 percent of the carbon in the fuel. When $f_v$ is to be calculated at high pressures, allowance must be made for the significant increase in soot formation with pressure and for the inverse proportionality of $f_v$ with respect to pressure. Great progress is being made in the ability to calculate soot in premixed flames. For example, predicted and measured soot concentration have been compared in a well-stirred reactor operated over a wide range of temperatures and equivalence ratios [Brown, N.J. Revzan, K. L., Frenklach, M., *Twenty-seventh Symposium (International) on Combustion*, pp. 1573–1580, 1998]. Moreover, CFD (computational fluid dynamics) and population dynamics modeling have been used to simulate soot formation in a turbulent non-premixed ethylene-air flame [Zucca, A., Marchisio, D. L., Barresi, A. A., Fox, R. O., *Chem. Eng. Sci.,* 2005]. The importance of soot radiation varies widely between combustors. In large boilers the soot is confined to small volumes and is of only local importance. In gas turbines, cooling the combustor liner is of primary importance so that only small incremental soot radiation is of concern. In high-temperature glass tanks, the presence of soot adds 0.1 to 0.2 to emissivities of oil-fired flames. In natural gas-fired flames, efforts to augment flame emissivities with soot generation have generally been unsuccessful. The contributions of soot to the radiation from pool fires often dominates, and thus the presence of soot in such flames directly impacts the safe separation distances from dikes around oil tanks and the location of flares with respect to oil rigs.

***Clouds of Large Black Particles*** The emissivity $\varepsilon_M$ of a cloud of black particles with a large perimeter-to-wavelength ratio is

$$\varepsilon_M = 1 - \exp[-(a/v)L] \tag{5-144}$$

where $a/v$ is the projected area of the particles per unit volume of space. If the particles have no negative curvature (the particle does not "see" any of itself) and are randomly oriented, $a = a'/4$, where $a'$ is the actual surface area. If the particles are uniform, $a/v = cA = cA'/4$, where $A$ and $A'$ are the projected and total areas of each particle and $c$ is the number concentration of particles. For spherical particles this leads to

$$\varepsilon_M = 1 - \exp[-(\pi/4)cd_p^2L] = 1 - \exp(-1.5f_vL/d_p) \tag{5-145}$$

As an example, consider a heavy fuel oil ($CH_{1.5}$, specific gravity, 0.95) atomized to a mean surface particle diameter of $d_p$ burned with

20 percent excess air to produce coke-residue particles having the original drop diameter and suspended in combustion products at 1204°C (2200°F). The flame emissivity due to the particles along a path of $L$ m, with $d_p$ measured in micrometers, is

$$\varepsilon_M = 1 - \exp(-24.3L/d_p) \tag{5-146}$$

For 200-μm particles and $L = 3.05$ m, the particle contribution to emissivity is calculated as 0.31.

***Clouds of Nonblack Particles*** For nonblack particles, emissivity calculations are complicated by multiple scatter of the radiation reflected by each particle. The emissivity $\varepsilon_M$ of a cloud of gray particles of individual emissivity $\varepsilon_1$ can be estimated by the use of a simple modification Eq. (5-144), i.e.,

$$\varepsilon_M = 1 - \exp[-\varepsilon_1(a/v)L] \tag{5-147}$$

Equation (5-147) predicts that $\varepsilon_M \to 1$ as $L \to \infty$. This is *impossible* in a scattering system, and use of Eq. (5-147) is restricted to values of the optical thickness $(a/v)\ L < 2$. Instead, the asymptotic value of $\varepsilon_M$ is obtained from Fig. 5-12 as $\varepsilon_M = \varepsilon_h\ (\lim L \to \infty)$, where the albedo $\omega$ is replaced by the particle-surface reflectance $\omega = 1 - \varepsilon_1$. Particles with perimeter-to-wavelength ratios of 0.5 to 5.0 can be analyzed, with significant mathematical complexity, by use of the the *Mie equations* (Bohren, C. F., and Huffman, D. R., *Absorption and Scattering of Light by Small Particles*, Wiley, 1998).

***Combined Gas, Soot, and Particulate Emission*** In a mixture of emitting species, the emission of each constituent is attenuated on its way to the system boundary by absorption by all other constituents. The transmissivity of a mixture is the product of the transmissivities of its component parts. This statement is a corollary of Beer's law. For present purposes, the transmissivity of "species $k$" is defined as $\tau_k = 1 - \varepsilon_k$. For a mixture of combustion products consisting of carbon dioxide, water vapor, soot, and oil coke or char particles, the total emissivity $\varepsilon_T$ at any wavelength can therefore be obtained from

$$(1 - \varepsilon_T)_\lambda = (1 - \varepsilon_C)_\lambda(1 - \varepsilon_W)_\lambda(1 - \varepsilon_S)_\lambda(1 - \varepsilon_M)_\lambda \tag{5-148}$$

where the subscripts denote the four flame species. The total emissivity is then obtained by integrating Eq. (5-148) over the entire EM energy spectrum, taking into account the variability of $\varepsilon_C$, $\varepsilon_W$, and $\varepsilon_S$ with respect to wavelength. In Eq. (5-148), $\varepsilon_M$ is independent of wavelength because absorbing char or coke particles are effectively blackbody absorbers. Computer programs for spectral emissivity, such as RADCAL (loc. cit.), perform the integration with respect to wavelength for obtaining total emissivity. Corrections for the overlap of vibration-rotation bands of $CO_2$ and $H_2O$ are automatically included in the correlations for $\varepsilon_g$ for mixtures of these gases. The monochromatic soot emissivity is higher at shorter wavelengths, resulting in higher attenuations of the bands at 2.7 μm for $CO_2$ and $H_2O$ than at longer wavelengths. The following equation is recommended for calculating the emissivity $\varepsilon_{g+S}$ of a mixture of $CO_2$, $H_2O$, and soot

$$\varepsilon_{g+S} = \varepsilon_g + \varepsilon_S - M{\cdot}\varepsilon_g\varepsilon_S \tag{5-149}$$

where $M$ can be represented with acceptable error by the dimensionless function

$$M = 1.12 - 0.27{\cdot}(T/1000) + 2.7 \times 10^5 f_v{\cdot}L \tag{5-150}$$

In Eq. (5-150), $T$ has units of kelvins and $L$ is measured in meters. Since coke or char emissivities are gray, their addition to those of the $CO_2$, $H_2O$, and soot follows simply from Eq. (5-148) as

$$\varepsilon_T = \varepsilon_{g+S} + \varepsilon_M - \varepsilon_{g+S}\varepsilon_M \tag{5-151}$$

with the definition $1 - \varepsilon_{g+S} \equiv (1 - \varepsilon_C)(1 - \varepsilon_W)(1 - \varepsilon_S)$.

## RADIATIVE EXCHANGE WITH PARTICIPATING MEDIA

**Energy Balances for Volume Zones—The Radiation Source Term** Reconsider a generalized enclosure with $N$ volume zones confining a *gray* gas. When the $N$ gas temperatures are *unknown*, an *additional* set of $N$ equations is required in the form of radiant energy balances for each volume zone. These $N$ equations are given by the *definition* of the $N$-vector for the **net radiant volume absorption** $\mathbf{S'} = [S'_j]$ for each volume zone

$$\mathbf{S'} = \overline{\mathbf{GS}}{\cdot}\mathbf{E} + \overline{\mathbf{GG}}{\cdot}\mathbf{E_g} - 4K\mathbf{VI}{\cdot}\mathbf{E_g} \qquad [N \times 1] \tag{5-152}$$

The radiative source term is a discretized formulation of the *net radiant absorption* for each volume zone which may be incorporated as a *source term* into numerical approximations for the generalized *energy equation*. As such, it permits formulation of energy balances on each zone that may include conductive and convective heat transfer. For $K \to 0$, $\overline{\mathbf{GS}} \to 0$, and $\overline{\mathbf{GG}} \to 0$ leading to $\mathbf{S'} \to \mathbf{0_N}$. When $K \neq 0$ and $\mathbf{S'} = \mathbf{0_N}$, the gas is said to be in a state of *radiative equilibrium*. In the notation usually associated with the discrete ordinate (DO) and finite volume (FV) methods, see Modest (op. cit., Chap. 16), one would write $S'_i/V_i = K[G - 4{\cdot}E_g] = -\nabla{\cdot}\vec{q}_r$. Here $H_g = G/4$ is the average flux density incident on a given volume zone from all other surface and volume zones. The DO and FV methods are currently available options as "RTE-solvers" in complex simulations of combustion systems using *computational fluid dynamics* (CFD).*

Implementation of Eq. (5-152) necessitates the definition of two additional *symmetric* $N \times N$ arrays of exchange areas, namely, $\overline{\mathbf{gg}} = [\overline{g_ig_j}]$ and $\overline{\mathbf{GG}} = [\overline{G_iG_j}]$. In Eq. (5-152) $\mathbf{VI} = [Vj{\cdot}\boldsymbol{\delta}_{ij}]$ is an $N \times N$ diagonal matrix of zone volumes. The total exchange areas in Eq. (5-151) are *explicit* functions of the direct exchange areas as follows:

Surface-to-gas exchange

$$\overline{\mathbf{GS}} = \overline{\mathbf{SG}}^T \qquad [N \times M] \tag{5-153a}$$

Gas-to-gas exchange

$$\overline{\mathbf{GG}} = \overline{\mathbf{gg}} + \overline{\mathbf{sg}}^T{\cdot}\rho\mathbf{I}{\cdot}\mathbf{R}{\cdot}\overline{\mathbf{sg}} \quad [N \times M] \tag{5-153b}$$

The matrices $\overline{\mathbf{gg}} = [\overline{g_ig_j}]$ and $\overline{\mathbf{GG}} = [\overline{G_iG_j}]$ must also satisfy the following **matrix conservation relations:**

Direct exchange areas: $4K\mathbf{VI}{\cdot}\mathbf{1}_N = \overline{\mathbf{gs}}{\cdot}\mathbf{1}_M + \overline{\mathbf{gg}}{\cdot}\mathbf{1}_N$ (5-154a)

Total exchange areas: $4K\mathbf{VI}{\cdot}\mathbf{1}_N = \overline{\mathbf{GS}}{\cdot}\mathbf{1}_M + \overline{\mathbf{GG}}\ {\cdot}\mathbf{1}_N$ (5-154b)

The formal integral definition of the direct gas-gas exchange area is

$$\overline{g_ig_j} = \iiint_{V_i}\iiint_{V_j} K^2\frac{e^{-Kr}}{\pi r^2}\,dV_j\,dV_i \tag{5-155}$$

Clearly, when $K = 0$, the two direct exchange areas involving a gas zone $\overline{\mathbf{g_is_j}}$ and $\overline{\mathbf{g_ig_j}}$ vanish. Computationally it is *never* necessary to make resort to Eq. (5-155) for calculation of $\overline{g_ig_j}$. This is so because $\overline{s_ig_j}$, $\overline{g_is_j}$, and $\overline{g_ig_j}$ may *all* be calculated *arithmetically* from appropriate values of $\overline{s_is_j}$ by using associated conservation relations and view factor algebra.

**Weighted Sum of Gray Gas (WSGG) Spectral Model** Even in simple engineering calculations, the assumption of a gray gas is almost never a good one. The zone method is now further generalized to make allowance for nongray radiative transfer via incorporation of the **weighted sum of gray gas** (WSGG) spectral model. Hottel has shown that the emissivity $\varepsilon_g(T,L)$ of an absorbing-emitting gas mixture containing $CO_2$ and $H_2O$ of known composition can be approximated by a *weighted sum of P gray gases*

$$\varepsilon_g(T,L) \approx \sum_{p=1}^{P} a_p(T)(1 - e^{-K_pL}) \tag{5-156a}$$

where

$$\sum_{p=1}^{P} a_p(T) = 1.0 \tag{5-156b}$$

In Eqs. (5-156), $K_p$ is some gray gas absorption coefficient and $L$ is some appropriate path length. In practice, Eqs. (5-156) usually yield acceptable accuracy for $P \leq 3$. For $P = 1$, Eqs. (5-156) degenerate to the case of a single gray gas.

*To further clarify the mathematical differences between zoning and the DO and FV methods recognize that (neglecting scatter) the matrix expressions $\mathbf{H} = \mathbf{AI^{-1}}{\cdot}\overline{\mathbf{ss}}{\cdot}\mathbf{W} + \mathbf{AI^{-1}}{\cdot}\overline{\mathbf{sg}}{\cdot}\mathbf{E_g}$ and $4K{\cdot}\mathbf{H_g} = \mathbf{VI^{-1}}{\cdot}\overline{\mathbf{gs}}{\cdot}\mathbf{W} + \mathbf{VI^{-1}}{\cdot}\overline{\mathbf{gg}}\ {\cdot}\ \mathbf{E_g}$ represent spatial discretizations of the integral form(s) of the RTE applied at any point (zone) on the boundary or interior of an enclosure, respectively, for a gray gas.

***The Clear plus Gray Gas WSGG Spectral Model*** In principle, the emissivity of all gases approaches unity for infinite path length $L$. In practice, however, the gas emissivity may fall considerably short of unity for representative values of $pL$. This behavior results because of the *band* nature of real gas spectral absorption and emission whereby there is usually no significant overlap between dominant absorption bands. Mathematically, this physical phenomenon is modeled by defining one of the gray gas components in the WSGG spectral model to be *transparent*.

For $P = 2$ and path length $L_M$, Eqs. (5-156) yield the following expression for the gas emissivity

$$\varepsilon_g = a_1(1 - e^{-K_1 L_M}) + a_2(1 - e^{-K_2 L_M}) \tag{5-157}$$

In Eq. (5-157) if $K_1 = 0$ and $a_2 \neq 0$, the limiting value of gas emissivity is $\varepsilon_g(T,\infty) \to a_2$. Put $K_1 = 0$ in Eq. (5-157), $a_g = a_2$, and define $\tau_g = e^{-K_2 L_M}$ as the gray gas transmissivity. Equation (5-157) then simplifies to

$$\varepsilon_g = a_g(1 - \tau_g) \tag{5-158}$$

It is important to note in Eq. (5-158) that $0 \le a_g,\ \tau_g \le 1.0$ while $0 \le \varepsilon_g \le a_g$.

Equation (5-158) constitutes a two-parameter model which may be fitted with only *two* empirical emissivity data points. To obtain the constants $a_g$ and $\tau_g$ in Eq. (5-158) at fixed composition and temperature, denote the two emissivity data points as $\varepsilon_{g,2} = \varepsilon_g(2pL) > \varepsilon_{g,1} = \varepsilon_g(pL)$ and recognize that $\varepsilon_{g,1} = a_g(1 - \tau_g)$ and $\varepsilon_{g,2} = a_g(1 - \tau_g^2) = a_g(1 - \tau_g)(1 + \tau_g) = \varepsilon_{g,1}(1 + \tau_g)$. These relations lead directly to the final emissivity fitting equations

$$\tau_g = \frac{\varepsilon_{g,2}}{\varepsilon_{g,1}} - 1 \tag{5-159a}$$

and

$$a_g = \frac{\varepsilon_{g,1}}{2 - \varepsilon_{g,2}/\varepsilon_{g,1}} \tag{5-159b}$$

The clear plus gray WSGG spectral model also readily leads to values for gas *absorptivity* and *transmissivity*, with respect to some appropriate surface radiation source at temperature $T_1$, for example,

$$\alpha_{g,1} = a_{g,1}(1 - \tau_g) \tag{5-160a}$$

and

$$\tau_{g,1} = a_{g,1} \cdot \tau_g \tag{5-160b}$$

In Eqs. (5-160) the *gray* gas transmissivity $\tau_g$ is taken to be identical to that obtained for the gas emissivity $\varepsilon_g$. The constant $a_{g,1}$ in Eq. (5-160*a*) is then obtained with knowledge of *one additional empirical value* for $\alpha_{g,1}$ which may also be obtained from the correlations in Table 5-5. Notice further in the definitions of the three parameters $\varepsilon_g$, $\alpha_{g,1}$, and $\tau_{g,1}$ that *all* the temperature dependence is forced into the *two* WSGG constants $a_g$ and $a_{g,1}$.

The *three* clear plus gray WSGG constants $a_g$, $a_{g,1}$, and $\tau_g$ are functions of total pressure, temperature, and mixture composition. It is not necessary to ascribe any particular physical significance to them. Rather, they may simply be visualized as three constants that happen to fit the gas emissivity data. It is noteworthy that *three* constants are far fewer than the number required to calculate gas emissivity data from fundamental spectroscopic data. The two constants $a_g$ and $a_{g,1}$ defined in Eqs. (5-158) and (5-160) can, however, be interpreted *physically* in a particularly simple manner. Suppose the gas absorption spectrum is idealized by *many* absorption bands (boxes), *all* of which are characterized by the *identical* absorption coefficient $K$. The a's might then be calculated from the total blackbody energy fraction $F_b(\lambda T)$ defined in Eqs. (5-105) and (5-106). That is, $a_g$ simply represents the total *energy fraction* of the blackbody energy distribution in which the gas *absorbs*. This concept may be further generalized to real gas absorption spectra via the *wideband stepwise gray spectral box model* (Modest, op. cit., Chap. 14).

When $P \ge 3$, exponential curve-fitting procedures for the WSGG spectral model become significantly more difficult for hand computation but are quite routine with the aid of a variety of readily available mathematical software utilities. The clear plus gray WSGG fitting procedure is demonstrated in Example 8.

**The Zone Method and Directed Exchange Areas** Spectral dependence of real gas spectral properties is now introduced into the zone method via the WSGG spectral model. It is still assumed, however, that all surface zones are gray isotropic emitters and absorbers.

***General Matrix Representation*** We first define a new set of four **directed exchange areas $\overleftarrow{\mathbf{SS}}$, $\overleftarrow{\mathbf{SG}}$, $\overleftarrow{\mathbf{GS}}$,** and $\overleftarrow{\mathbf{GG}}$ which are denoted by an overarrow. The directed exchange areas are obtained from the total exchange areas for gray gases by simple matrix multiplication using weighting factors derived from the WSGG spectral model. The directed exchange areas are denoted by an overarrow to indicate the "sending" and "receiving" zone. The a-weighting factors for transfer originating at a gas zone $a_{g,i}$ are derived from WSGG gas *emissivity* calculations, while those for transfers originating at a surface zone, $a_i$ are derived from appropriate WSGG gas *absorptivity* calculations. Let $\mathbf{agI}_p = [a_{p,g,i}\delta_{ij}]$ and $\mathbf{aI}_p = [a_{p,i}\delta_{ij}]$ represent the $P$ $[M \times M]$ and $[N \times N]$ *diagonal* matrices comprised of the appropriate WSGG $a$ constants. The *directed* exchange areas are then computed from the associated *total* gray gas exchange areas via simple *diagonal* matrix multiplication.

$$\overleftarrow{\mathbf{SS}} = \sum_{p=1}^{P} \overline{\mathbf{SS}}_p \cdot \mathbf{aI}_p \qquad [M \times M] \tag{5-161a}$$

$$\overleftarrow{\mathbf{SG}} = \sum_{p=1}^{P} \overline{\mathbf{SG}}_p \cdot \mathbf{agI}_p \qquad [M \times N] \tag{5-161b}$$

$$\overleftarrow{\mathbf{GS}} = \sum_{p=1}^{P} \overline{\mathbf{GS}}_p \cdot \mathbf{aI}_p \qquad [M \times N] \tag{5-161c}$$

$$\overleftarrow{\mathbf{GG}} = \sum_{p=1}^{P} \overline{\mathbf{GG}}_p \cdot \mathbf{agI}_p \qquad [N \times N] \tag{5-161d}$$

with

$$\overleftarrow{\mathbf{KI}} = \sum_{p=1}^{P} \mathbf{KI}_p \cdot \mathbf{agI}_p \qquad [N \times N] \tag{5-161e}$$

In contrast to the *total* exchange areas which are always independent of temperature, the four *directed* arrays $\overleftarrow{\mathbf{SS}}$, $\overleftarrow{\mathbf{SG}}$, $\overleftarrow{\mathbf{GS}}$, and $\overleftarrow{\mathbf{GG}}$ are dependent on the temperatures of each and every zone, i.e., as in $a_{p,i} = a_p(T_i)$. Moreover, in contrast to *total* exchange areas, the *directed* arrays $\overleftarrow{\mathbf{SS}}$ and $\overleftarrow{\mathbf{GG}}$ are generally not symmetric and $\overleftarrow{\mathbf{GS}} \neq \overleftarrow{\mathbf{SG}}^T$. Finally, since the directed exchange areas are temperature-*dependent*, iteration may be required to update the $\mathbf{aI}_p$ and $\mathbf{a_gI}_p$ arrays during the course of a calculation. There is a great deal of latitude with regard to fitting the WSGG $a$ constants in these matrix equations, especially if $N > 1$ and composition variations are to be allowed for in the gas. An extensive discussion of $a$ fitting for $N > 1$ is beyond the scope of this presentation. Details of the fitting procedure, however, are presented in Example 12 in the context of a single-gas zone.

Having formulated the directed exchange areas, the governing matrix equations for the radiative flux equations at each surface zone and the radiant source term are then given as follows:

$$\mathbf{Q} = \varepsilon\mathbf{AI} \cdot \mathbf{E} - \overleftarrow{\mathbf{SS}} \cdot \mathbf{E} - \overleftarrow{\mathbf{SG}} \cdot \mathbf{E}_g \tag{5-162a}$$

$$\mathbf{S}' = \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g + \overleftarrow{\mathbf{GS}} \cdot \mathbf{E} - 4\overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} \cdot \mathbf{E}_g \tag{5-162b}$$

or the alternative forms

$$\mathbf{Q} = [\mathbf{EI} \cdot \overrightarrow{\mathbf{SS}} - \overleftarrow{\mathbf{SS}} \cdot \mathbf{EI}] \cdot \mathbf{1}_M + [\mathbf{EI} \cdot \overrightarrow{\mathbf{SG}} - \overleftarrow{\mathbf{SG}} \cdot \mathbf{E}_g\mathbf{I}] \cdot \mathbf{1}_N \tag{5-163a}$$

$$\mathbf{S}' = -[\mathbf{E}_g\mathbf{I} \cdot \overrightarrow{\mathbf{GS}} - \overleftarrow{\mathbf{GS}} \cdot \mathbf{EI}] \cdot \mathbf{1}_M - [\mathbf{E}_g\mathbf{I} \cdot \overrightarrow{\mathbf{GG}} - \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g\mathbf{I}] \cdot \mathbf{1}_N \tag{5-163b}$$

It may be *proved* that the $\mathbf{Q}$ and $\mathbf{S}'$ vectors computed from Eqs. (5-162) and (5-163) always *exactly* satisfy the overall (scalar) *radiant* energy balance $\mathbf{1}_M^T \cdot \mathbf{Q} = \mathbf{1}_N^T \cdot \mathbf{S}'$. In words, the total radiant gas emission for all gas zones in the enclosure must always exactly equal the total radiant energy received at all surface zones which comprise the enclosure. In Eqs. (5-162) and (5-163), the following definitions are employed for the *four forward-directed* exchange areas

$$\overrightarrow{\mathbf{SS}} = \overleftarrow{\mathbf{SS}}^T \qquad \overrightarrow{\mathbf{SG}} = \overleftarrow{\mathbf{GS}}^T \qquad \overrightarrow{\mathbf{GS}} = \overleftarrow{\mathbf{SG}}^T \qquad \overrightarrow{\mathbf{GG}} = \overleftarrow{\mathbf{GG}}^T \tag{5-64a,b,c,d}$$

such that formally there are some *eight* matrices of directed exchange areas. The four *backward-directed* arrays of directed exchange areas must satisfy the following conservation relations

$$\overleftarrow{\mathbf{SS}}\cdot\mathbf{1}_M + \overleftarrow{\mathbf{SG}}\cdot\mathbf{1}_N = \varepsilon\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{1}_M \tag{5-165a}$$

$$4\overleftarrow{\mathbf{KI}}\cdot\mathbf{VI}\cdot\mathbf{1}_N = \overleftarrow{\mathbf{GS}}\cdot\mathbf{1}_M + \overleftarrow{\mathbf{GG}}\cdot\mathbf{1}_N \tag{5-165b}$$

Subject to the restrictions of no scatter and diffuse surface emission and reflection, the above equations are the most general matrix statement possible for the zone method. When $P = 1$, the *directed* exchange areas all reduce to the *total* exchange areas for a single gray gas. If, in addition, $K = 0$, the much simpler case of radiative transfer in a transparent medium results. If, in addition, all surface zones are *black*, the direct, total, and directed exchange areas are all identical.

***Allowance for Flux Zones*** As in the case of a transparent medium, we now distinguish between source and flux surface zones. Let $M = M_s + M_f$ represent the total number of surface zones where $M_s$ is the number of source-sink zones and $M_f$ is the number of flux zones. The flux zones are the *last to be numbered.* To accomplish this, partition the surface emissive power and flux vectors as $\mathbf{E} = \begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix}$ and $\mathbf{Q} = \begin{bmatrix}\mathbf{Q}_1\\ \mathbf{Q}_2\end{bmatrix}$, where the subscript 1 denotes surface source/sink zones whose emissive power $\mathbf{E}_1$ is specified a priori, and subscript 2 denotes surface flux zones of unknown emissive power vector $\mathbf{E}_2$ and known radiative flux vector $\mathbf{Q}_2$. Suppose the radiative source vector $\mathbf{S}'$ is *known*. Appropriate partitioning of Eqs. (5-162) then produces

$$\begin{bmatrix}\mathbf{Q}_1\\ \mathbf{Q}_2\end{bmatrix} = \begin{bmatrix}\varepsilon\mathbf{AI}_{1,1} & \mathbf{0}\\ \mathbf{0} & \varepsilon\mathbf{AI}_{2,2}\end{bmatrix}\cdot\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix}\begin{bmatrix}\overleftarrow{\mathbf{SS}}_{1,2} & \overleftarrow{\mathbf{SS}}_{1,2}\\ \overleftarrow{\mathbf{SS}}_{2,1} & \overleftarrow{\mathbf{SS}}_{2,2}\end{bmatrix}\cdot\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \begin{bmatrix}\overleftarrow{\mathbf{SG}}_1\\ \overleftarrow{\mathbf{SG}}_1\end{bmatrix}\cdot\mathbf{E}_g \tag{5-166a}$$

and

$$\mathbf{S}' = \overleftarrow{\mathbf{GG}}\cdot\mathbf{E}_g + \begin{bmatrix}\overleftarrow{\mathbf{GS}}_1 & \overleftarrow{\mathbf{GS}}_2\end{bmatrix}\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - 4\overleftarrow{\mathbf{KI}}\cdot\mathbf{VI}\cdot\mathbf{E}_g \tag{5-166b}$$

where the definitions of the matrix partitions follow the conventions with respect to Eq. (5-120). Simultaneous solution of the *two* unknown vectors in Eqs. (5-166) then yields

$$\mathbf{E}_2 = \mathbf{RP}\cdot\left[\overleftarrow{\mathbf{SS}}_{2,1} + \overleftarrow{\mathbf{SG}}_2\cdot\mathbf{PP}\cdot\overleftarrow{\mathbf{GS}}_1\right]\cdot\mathbf{E}_1 + \mathbf{RP}\cdot\left[\mathbf{Q}_2 - \overleftarrow{\mathbf{SG}}_2\cdot\mathbf{PP}\cdot\mathbf{S}'\right] \tag{5-167a}$$

and

$$\mathbf{E}_g = \mathbf{PP}\cdot\begin{bmatrix}\overleftarrow{\mathbf{GS}}_1 & \overleftarrow{\mathbf{GS}}_2\end{bmatrix}\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \mathbf{PP}\cdot\mathbf{S}' \tag{5-167b}$$

where two auxiliary inverse matrices **RP** and **PP** are defined as

$$\mathbf{PP} = \left[4\overleftarrow{\mathbf{KI}}\cdot\mathbf{VI} - \overleftarrow{\mathbf{GG}}\right]^{-1} \tag{5-168a}$$

$$\mathbf{RP} = \left[\varepsilon\mathbf{AI}_{2,2} - \overleftarrow{\mathbf{SS}}_{2,2} - \overleftarrow{\mathbf{SG}}_2\cdot\mathbf{PP}\cdot\overleftarrow{\mathbf{GS}}_2\right]^{-1} \tag{5-168b}$$

The emissive power vectors **E** and $\mathbf{E}_g$ are then both *known* quantities for purposes of subsequent calculation.

**Algebraic Formulas for a Single Gas Zone** As shown in Fig. 5-10, the three-zone system with $M = 2$ and $N = 1$ can be employed to simulate a surprisingly large number of useful engineering geometries. These include two infinite parallel plates confining an absorbing-emitting medium; *any* two-surface zone system where a nonconvex surface zone is completely surrounded by a second zone (this includes concentric spheres and cylinders), and the speckled two-surface enclosure. As in the case of a transparent medium, the inverse reflectivity matrix **R** is capable of explicit matrix inversion for $M = 2$. This allows derivation of *explicit* algebraic equations for all the required *directed* exchange areas for the clear plus gray WSGG spectral model with $M = 1$ and 2 and $N = 1$.

***The Limiting Case M = 1 and N = 1*** The directed exchange areas for this special case correspond to a single well-mixed gas zone completely surrounded by a single surface zone $A_1$. Here the reflectivity matrix is a $1 \times 1$ scalar quantity which follows directly from the general matrix equations as $\mathbf{R} = [1/(A_1 - \overline{s_1s_1}\cdot\rho_1)]$. There are *two* WSCC clear plus gray constants $a_1$ and $a_g$, and only *one* unique direct exchange area which satisfies the conservation relation $\overline{s_1s_1} + \overline{s_1g} = A_1$. The only two physically meaningful directed exchange areas are those between the surface zone $A_1$ and the gas zone

$$\overleftarrow{S_1G} = \frac{a_g\cdot\varepsilon_1A_1\cdot\overline{s_1g}}{\varepsilon_1\cdot A_1 + \rho_1\cdot\overline{s_1g}} \tag{5-169a}$$

$$\overleftarrow{GS_1} = \frac{a_1\cdot\varepsilon_1A_1\cdot\overline{s_1g}}{\varepsilon_1\cdot A_1 + \rho_1\cdot\overline{s_1g}} \tag{5-169b}$$

The total radiative flux $Q_1$ at surface $A_1$ and the radiative source term $Q_1 = S$ are given by

$$Q_1 = \overleftarrow{GS_1}\cdot E_1 - \overleftarrow{S_1G}\cdot E_g \tag{5-169}$$

***Directed Exchange Areas for M = 2 and N = 1*** For this case there are *four* WSGG constants, i.e., $a_1$, $a_2$, $a_g$, and $\tau_g$. There is one required value of $K$ that is readily obtained from the equation $K = -\ln(\tau_g)/L_M$, where $\tau_g = \exp(-KL_M)$. For an enclosure with $M = 2$, $N = 1$, and $K \neq 0$, only *three unique* direct exchange areas are required because conservation stipulates $A_1 = \overline{s_1s_2} + \overline{s_1s_2} + \overline{s_1g}$ and $A_2 = \overline{s_1s_2} + \overline{s_2s_2} + \overline{s_2g}$. For $M = 2$ and $N = 1$, the matrix Eqs. (5-118) readily lead to the *general* gray gas matrix solution for $\overleftarrow{\mathbf{SS}}$ and $\overleftarrow{\mathbf{SG}}$ with $K \neq 0$ as

$$\overleftarrow{\mathbf{SS}} = \begin{bmatrix}\varepsilon_1A_1 - \overline{S_1S_2} - \overline{S_1G} & \overline{S_1S_2}\\ \overline{S_1S_1} & \varepsilon_2A_2 - \overline{S_1S_2} - \overline{S_2G}\end{bmatrix} \tag{5-170a}$$

where

$$\overleftarrow{S_1S_2} = \varepsilon_1\varepsilon_2A_1A_2\overline{s_1s_2}\,/\det\mathbf{R}^{-1} \tag{5-170b}$$

and

$$\overleftarrow{\mathbf{SG}} = \begin{bmatrix}\varepsilon_1A_1[(A_2 - \rho_2\cdot\overline{s_2s_2})\cdot\overline{s_1g} + \rho_2\cdot\overline{s_1s_2}\cdot\overline{s_2g}]\\ \varepsilon_2A_2[(A_1 - \rho_1\cdot\overline{s_1s_1})\cdot\overline{s_2g} + \rho_1\cdot\overline{s_1s_2}\cdot\overline{s_1g}]\end{bmatrix}\Big/\det\mathbf{R}^{-1} \tag{5-170c}$$

with $\overleftarrow{\mathbf{GS}} = \overleftarrow{\mathbf{SG}}^{\mathrm{T}}$ and the indicated determinate of $\mathbf{R}^{-1}$ is evaluated algebraically as

$$\det\mathbf{R}^{-1} = (A_1 - \overline{s_1s_1}\cdot\rho_1)\cdot(A_2 - \overline{s_2s_2}\cdot\rho_2) - \rho_1\cdot\rho_2\cdot\overline{s_1s_2}^2 \tag{5-170d}$$

For the WSGG clear gas components we denote $\overleftarrow{\mathbf{SS}}\,\big|_{K=0} \equiv \overleftarrow{\mathbf{SS}}_0$ and $\overleftarrow{\mathbf{SG}}\,\big|_{K=0} \equiv \overleftarrow{\mathbf{SG}}_0 = \mathbf{0}$. Finally the WSGG arrays of directed exchange areas are computed simply from $a$-weighted sums of the gray gas total exchange areas as

$$\overleftarrow{\mathbf{SS}} = \overleftarrow{\mathbf{SS}}_0\cdot\begin{bmatrix}1-a_1 & 0\\ 0 & 1-a_2\end{bmatrix} + \overleftarrow{\mathbf{SS}}\cdot\begin{bmatrix}a_1 & 0\\ 0 & a_2\end{bmatrix}$$

$$\overleftarrow{\mathbf{SG}} = \overleftarrow{\mathbf{SG}}\cdot a_g \tag{5-171a,b,c}$$

$$\overleftarrow{\mathbf{GS}} = \overleftarrow{\mathbf{GS}}\cdot\begin{bmatrix}a_1 & 0\\ 0 & a_2\end{bmatrix} \neq \overleftarrow{\mathbf{SG}}^{T}$$

and finally

$$\overleftarrow{\mathbf{GG}} = a_g\cdot 4KV - \overleftarrow{\mathbf{GS}}\cdot\begin{bmatrix}1\\ 1\end{bmatrix} \tag{5-171d}$$

The results of this development may be further expanded into algebraic form with the aid of Eq. (5-127) to yield the following

$$\overleftarrow{S_2S_1} = \frac{\varepsilon_1\varepsilon_2A_1A_2\cdot\overline{s_2s_1}]_0(1-a_1)}{\varepsilon_1\varepsilon_1A_1A_2 + (\varepsilon_1A_1\rho_2 + \varepsilon_2A_2\rho_1)\overline{s_2s_1}]_0} + \frac{\varepsilon_1\varepsilon_2A_1A_2\overline{s_2s_1}\cdot a_1}{\det\mathbf{R}^{-1}} \tag{5-171e}$$

$$\overleftarrow{\mathbf{SG}} = \begin{bmatrix}\varepsilon_1A_1[(A_2 - \rho_2\cdot\overline{s_2s_2})\cdot\overline{s_1g} + \rho_2\cdot\overline{s_1s_2}\cdot\overline{s_2g}]a_g\\ \varepsilon_2A_2[(A_1 - \rho_1\cdot\overline{s_1s_1})\cdot\overline{s_2g} + \rho_1\cdot\overline{s_1s_2}\cdot\overline{s_1g}]a_g\end{bmatrix}\Big/\det\mathbf{R}^{-1} \tag{5-171f}$$

and

$$\overleftarrow{\mathbf{GS}} = \begin{bmatrix}\overleftarrow{GS_1} & \overleftarrow{GS_2}\end{bmatrix} \tag{5-171g}$$

whose matrix elements are given by $\overleftarrow{GS}_1 \equiv \varepsilon_1 A_1[(A_2 - \rho_2 \cdot \overline{s_1 s_1}) \cdot \overline{s_1 g} + \rho_2 \cdot \overline{s_1 s_2} \cdot \overline{s_2 g}] a_1 / \det \mathbf{R}^{-1}$ and $\overleftarrow{GS}_2 \equiv \varepsilon_2 A_2[(A_1 - \rho_1 \cdot \overline{s_1 s_1}) \cdot \overline{s_2 g} + \rho_1 \cdot \overline{s_1 s_2} \cdot \overline{s_1 g}] a_2 / \det \mathbf{R}^{-1}$. Derivation of the scalar (algebraic) forms for the directed exchange areas here is done primarily for pedagogical purposes. Computationally, the only advantage is to obviate the need for a digital computer to evaluate a $[2 \times 2]$ matrix inverse.

***Allowance for an Adiabatic Refractory with N = 1 and M = 2*** Put $N = 1$ and $M = 2$, and let zone 2 represent the refractory surface. Let $Q_2 = 0$ and $\varepsilon_2 \neq 0$, and it then follows that we may define a *refractory-aided* directed exchange area $\overleftarrow{S_1 G_R}$ by

$$\overleftarrow{S_1 G_R} = \overleftarrow{S_1 G} + \frac{\overleftarrow{S_1 S_2} \cdot \overleftarrow{S_2 G}}{\overleftarrow{S_1 S_2} + \overleftarrow{S_2 G}} \tag{5-172a}$$

Assuming radiative equilibrium, the emissive power of the refractory may also be calculated from the companion equation

$$E_2 = \frac{\overleftarrow{S_2 S_1} \cdot E_1 + \overleftarrow{S_2 G} \cdot E_g}{\overleftarrow{S_2 S_1} + \overleftarrow{S_2 G}} \tag{5-172b}$$

In this circumstance, *all* the radiant energy originating in the gas volume is transferred to the *sole* sink zone $A_1$. Equation (5-172*a*) is thus tantamount to the statement that $Q_1 = S'$ or that the net emission from the source ultimately must arrive at the sink. Notice that if $\varepsilon_1 = 0$, Eq. (5-172*a*) leads to a physically incongruous statement since *all* the directed exchange areas would vanish and *no sink* would exist. Even for the simple case of $M = 2$, $N = 1$, the algebraic complexity of Eqs. (5-171) suggests that *numerical matrix manipulation* of directed exchange areas is to be preferred rather than calculations using algebraic formulas.

**Engineering Approximations for Directed Exchange Areas** Use of the preceding equations for directed exchange areas with $M = 2$, $N = 1$ and the WSGG clear plus gray gas spectral approximation requires knowledge of three independent direct exchange areas. It also formally requires evaluation of three WSGG weighting constants $a_1$, $a_2$, and $a_g$ with respect to the three temperatures $T_1$, $T_2$, and $T_g$. Further simplifications may be made by assuming that radiant transfer for the *entire* enclosure is characterized by the *single* mean beam length $L_M = 0.88 \cdot 4 \cdot V/A$. The requisite direct exchange areas are then approximated by

$$\overline{\mathbf{ss}} = \tau_g \begin{bmatrix} A_1 \cdot F_{1,1} & A_1 \cdot F_{1,2} \\ A_2 \cdot F_{2,1} & A_2 \cdot F_{2,2} \end{bmatrix} \tag{5-173a}$$

with

$$\overline{\mathbf{sg}} = (1 - \tau_g) \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \tag{5-173b}$$

and for the particular case of a speckled enclosure

$$\overline{\mathbf{ss}} = \frac{\tau_g}{A_1 + A_2} \begin{bmatrix} A_1^2 & A_1 \cdot A_2 \\ A_1 \cdot A_2 & A_2^2 \end{bmatrix} \tag{5-174a}$$

also with

$$\overline{\mathbf{sg}} = (1 - \tau_g) \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \tag{5-174b}$$

where again $\tau_g$ is obtained from the WSGG fit of gas emissivity. These approximate formulas clearly obviate the need for *exact* values of the direct exchange areas and may be used in conjunction with Eqs. (5-171).

For engineering calculations, an additional simplification is sometimes warranted. Again characterize the system by a single mean beam length $L_M = 0.88 \cdot 4 \cdot V/A$ and employ the *identical* value of $\tau_g = KL_M$ for all surface-gas transfers. The three *a* constants *might* then be obtained by a WSGG data-fitting procedure for gas emissivity and gas absorptivity which utilizes the three different temperatures $T_g$, $T_1$, and $T_2$. For engineering purposes we choose a simpler method, however. First calculate values of $\varepsilon_g$ and $\alpha_{g1}$ for gas temperature $T_g$ with respect to the *dominant* (sink) temperature $T_1$. The *net* radiative flux between an isothermal gas mass at temperature $T_g$ and a black isothermal bounding surface $A_1$ at temperature $T_1$ (the sink) is given by Eq. (5-138) as

$$Q_{1,g} = A_1 \sigma(\alpha_{g,1} T_1^4 - \varepsilon_g T_g^4) \tag{5-175}$$

It is clear that transfer from the gas to the surface and transfer from the surface into the gas are characterized by two different constants of proportionality, $\varepsilon_g$ and $\alpha_{g,1}$. To allow for the difference between gas emissivity and absorptivity, it proves convenient to introduce a single *mean gas emissivity* defined by

$$\sigma[\varepsilon_g T_g^4 - \alpha_{g,1} T_1^4] = \varepsilon_m \sigma(T_g^4 - T_1^4) \tag{5-176a}$$

or

$$\varepsilon_m \equiv \frac{\varepsilon_g - \alpha_{g,1}(T_1/T_g)^4}{1 - (T_1/T_g)^4} \tag{5-176b}$$

The calculation then proceeds by computing *two* values of $\varepsilon_m$ at the given $T_g$ and $T_1$ temperature pair and the two values of $pL_M$ and $2pL_M$. We thereby obtain the expression $\varepsilon_m = a_m(1 - \tau_m)$. It is then assumed that $a_1 = a_2 = a_g = a_m$ for use in Eqs. (5-171). This simplification may be used for $M > 2$ as long as $N = 1$. This simplification is illustrated in Example 12.

***Example 12: WSGG Clear plus Gray Gas Emissivity Calculations*** Methane is burned to completion with 20 percent excess air (50 percent relative humidity at 298 K or 0.0088 mol water/mol dry air) in a furnace chamber of floor dimensions $3 \times 10$ m and height 5 m. The entire surface area of the enclosure is a gray sink with emissivity of 0.8 at temperature 1000 K. The confined gas is well stirred at a temperature of 1500 K. Evaluate the clear plus gray WSGG constants and the mean effective gas emissivity, and calculate the average radiative flux density to the enclosure surface.

*Two-zone model, M = 1, N = 1:* A single volume zone completely surrounded by a single sink surface zone.

*Function definitions:*

Gas emissivity: Eq. (5-140*a*)
$$\varepsilon gF(T_g, pL, b, n) := b \cdot (pL - 0.015)^n \div T_g$$

Gas absorptivity: Eq. (5-141)
$$\alpha g1F(T_g, T_1, pL, b, n) := \frac{\varepsilon gF(T_1, pL \cdot T_1 \div T_g, b, n) \cdot T_1 \cdot (T_g \div T_1)^{0.5}}{T_1}$$

Mean effective gas emissivity: Eq. (5-176*a*)
$$\varepsilon_{gm}(\varepsilon_g, \alpha_g, T_g, T_1) := \frac{\varepsilon_g - \alpha_g \cdot (T_1 \div T_g)^4}{1 - (T_1 \div T_g)^4}$$

*Physical constants:*
$$\sigma \equiv 5.670400 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}$$

*Enclosure input parameters:*

$T_g := 1500$ K  $T_1 := 1000$ K  $A_1 := 190$ m$^2$  $V := 150$ m$^3$

$\varepsilon_1 := 0.8$  $\rho_1 := 1 - \varepsilon_1$  $\rho_1 = 0.2$

$E_1 := \sigma \cdot T_1^4$  $E_g := \sigma \cdot T_g^4$  $E_1 = 56.70 \dfrac{\text{kW}}{\text{m}^2}$  $E_g = 287.06 \dfrac{\text{kW}}{\text{m}^2}$

Stoichiometry yields the following mole table:

Mole Table: Basis 1.0 mol Methane

| Species | MW | Moles in | Mass in | Moles out | Y out |
|---|---|---|---|---|---|
| $CH_4$ | 16.04 | 1.00000 | 16.04 | 0.00000 | 0.00000 |
| $O_2$ | 32.00 | 2.40000 | 76.80 | 0.40000 | 0.03193 |
| $N_2$ | 28.01 | 9.02857 | 252.93 | 9.02857 | 0.72061 |
| $CO_2$ | 44.01 | 0.00000 | 0.00 | 1.00000 | 0.07981 |
| $H_2O$ | 18.02 | 0.10057 | 1.81 | 2.10057 | 0.16765 |
| Totals | 27.742 | 12.52914 | 347.58 | 1.52914 | 1.00000 |

$p_W := .16765$ atm  $p_C := 0.07981$ atm  $p := p_W + p_C$  $p = 0.2475$ atm
$p_W \div p_C = 2.101$

The mean beam length is approximated by

$$L_M := 0.88 \cdot 4 \cdot V \div A_1 \qquad L_M = 2.7789 \text{ m}$$

and $pL_M := p \cdot L_M$  $pL_M = 0.6877$ atm·m  $pL_M := 0.6877$

The gas emissivities and absorptivities are then calculated from the two constant correlation in Table 5-5 (column 5 with $p_w/p_c = 2.0$) as follows:

$\varepsilon_{g1} := \varepsilon gF(1500, pL_M, 540, .42)$  $\varepsilon_{g1} = 0.3048$

$\varepsilon_{g2} := \varepsilon gF(1500, 2pL_M, 540, .42)$ $\varepsilon_{g2} = 0.4097$

$\alpha_{g11} := \alpha g1F(1500, 1000, pL_M, 444, .34)$ $\alpha_{g11} = 0.4124$

$\alpha_{g12} := \alpha g1F(1500, 1000, 2pL_M, 444, .34)$ $\alpha_{g12} = 0.5250$

*Case (a): Compute Flux Density Using Exact Values of the WSGG Constants*

$$\tau_g := \frac{\varepsilon_{g2}}{\varepsilon_{g1}} - 1 \qquad a_g := \frac{\varepsilon_{g1}}{1-\tau_g} \qquad \varepsilon_g := a_g \cdot (1-\tau_g) \qquad a_{g1} := \frac{\alpha_{g11}}{1-\tau_g}$$

$\tau_g = 0.3442$ $a_g = 0.4647$ $\varepsilon_g = 0.3048$ $a_{g1} = 0.6289$

and the WSGG gas absorption coefficient (which is necessary for calculation of direct exchange areas) is calculated as $K_1 := \dfrac{-(\ln \tau_g)}{L_M}$ or $K_1 = 0.3838 \ \dfrac{1}{\text{m}}$

*Compute directed exchange areas:*
Eqs. (5-169)

$$s1g := (1-\tau_g)\cdot A_1 \qquad s1g = 124.61 \text{ m}^2$$

$$DS1G := \frac{a_g \cdot \varepsilon_1 \cdot A_1 \cdot s1g}{\varepsilon_1 \cdot A_1 + \rho_1 \cdot s1g} \qquad DGS1 := \frac{a_{g1} \cdot \varepsilon_1 \cdot A_1 \cdot s1g}{\varepsilon_1 \cdot A_1 + \rho_1 \cdot s1g}$$

$DS1G = 49.75 \text{ m}^2$ $DGS1 = 67.32 \text{ m}^2$

And finally the gas to sink flux density is computed as

$$Q_1 := DGS1 \cdot E_1 - DS1G \cdot E_g \qquad Q_1 = -10464.0 \text{ kW} \qquad \frac{Q_1}{A_1} = -55.07 \ \frac{\text{kW}}{\text{m}^2}$$

*Case (b): Compute the Flux Density Using Mean Effective Gas Emissivity Approximation*

$$\varepsilon_{gm1} := \varepsilon_{gm}(\varepsilon_{g1}, \alpha_{g11}, T_g, T_1) \qquad \varepsilon_{gm1} = 0.2783$$
$$\varepsilon_{gm2} := \varepsilon_{gm}(\varepsilon_{g2}, \alpha_{g12}, T_g, T_1) \qquad \varepsilon_{gm2} = 0.3813$$

$$\tau_m := \frac{\varepsilon_{gm2}}{\varepsilon_{gm1}} - 1 \qquad a_m := \frac{\varepsilon_{gm1}}{1-\tau_m} \qquad \varepsilon_{gm} := a_m \cdot (1-\tau_m)$$

$\tau_m = 0.3701$ $a_m = 0.4418$ $\varepsilon_{gm} = 0.2783$ $s1g_m := (1-\tau_m)\cdot A_1$

$$S1G_m := \frac{\varepsilon_1 \cdot a_m \cdot s1g_m \cdot A_1}{\varepsilon_1 \cdot A_1 + \rho_1 \cdot s1g_m} \qquad S1G_m = 45.68 \text{ m}^2 \qquad s1g_m = 119.67 \text{ m}^2$$

$$q_{1m} := \frac{S1G_m \cdot (E_1 - E_g)}{A_1} \qquad q_{1m} = -55.38 \ \frac{\text{kW}}{\text{m}^2}$$

$$\text{compared with } \frac{Q_1}{A_1} = -55.07 \ \frac{\text{kW}}{\text{m}^2}$$

The computed flux densities are nearly equal because there is a *single* sink zone $A_1$.

## ENGINEERING MODELS FOR FUEL-FIRED FURNACES

Modern digital computation has evolved methodologies for the design and simulation of fuel-fired combustion chambers and furnaces which incorporate virtually *all* the transport phenomena, chemical kinetics, and thermodynamics studied by chemical engineers. Nonetheless, there still exist many furnace design circumstances where such computational sophistication is not always appropriate. Indeed, a practical need still exists for simple engineering models for purposes of conceptual process design, cost estimation, and the correlation of test performance data. In this section, the zone method is used to develop perhaps the simplest **computational template** available to address some of these practical engineering needs.

**Input/Output Performance Parameters for Furnace Operation** The term **firing density** is typically used to define the basic *operational input parameter* for fuel-fired furnaces. In practice, firing density is often defined as the input fuel feed rate per unit area (or volume) of furnace heat-transfer surface. Thus defined, the firing density is a *dimensional quantity*. Since the feed enthalpy rate $H_f$ is proportional to the feed rate, we employ the sink area $A_1$ to define a **dimensionless firing density** as $N_{FD} = H_f/\sigma T_{\text{Ref}}^4 \cdot A_1$ where $T_{\text{Ref}}$ is some characteristic reference temperature. In practice, gross furnace *output performance* is often described by using one of several *furnace efficiencies*. The most common is the **gas or gas-side furnace efficiency** $\eta_g$, defined as the total enthalpy transferred to furnace internals divided by the total available feed enthalpy. Here the total available feed enthalpy is defined to include the lower heating value (LHV) of the fuel plus any air preheat above an arbitrary ambient datum temperature. Under certain conditions the definition of furnace efficiency reduces to some variant of the simple equation $\eta_g = (T_{\text{Ref}} - T_{\text{out}})/(T_{\text{Ref}} - T_0)$ where again $T_{\text{Ref}}$ is some reference temperature appropriate to the system in question.

**The Long Plug Flow Furnace (LPFF) Model** If a combustion chamber of cross-sectional area $A_{\text{Duct}}$ and perimeter $P_{\text{Duct}}$ is sufficiently long in the direction of flow, compared to its mean hydraulic radius, $L \gg R_h = A_{\text{Duct}}/P_{\text{Duct}}$, the radiative flux from the gas to the bounding surfaces can sometimes be adequately characterized by the *local* gas temperature. The physical rationale for this is that the *magnitudes* of the opposed upstream and downstream radiative fluxes through a cross section transverse to the direction of flow are sufficiently large as to substantially balance each other. Such a situation is not unusual in engineering practice and is referred to as the *long furnace approximation*. As a result, the radiative flux from the gas to the bounding surface may then be approximated using *two-dimensional* directed exchange areas, $\overleftarrow{S_1G}/A_1 \equiv \dfrac{\partial(\overleftarrow{S_1G})}{\partial A_1}$, calculated using methods as described previously.

Consider a duct of length $L$ and perimeter $P$, and assume plug flow in the direction of flow $z$. Further assume high-intensity mixing at the entrance end of the chamber such that combustion is *complete* as the combustion products enter the duct. The duct then acts as a long heat exchanger in which heat is transferred to the walls at constant temperature $T_1$ by the combined effects of radiation and convection. Subject to the long furnace approximation, a differential energy balance on the duct then yields

$$\dot{m}\,\overline{C}_p \frac{dT_g}{dz} = P\left[\frac{\overleftarrow{S_1G}}{A_1}\sigma\left(T_g^4 - T_1^4\right) + h(T_g - T_1)\right] \qquad (5\text{-}177)$$

where $\dot{m}$ is the mass flow rate and $\overline{C}_p$ is the heat capacity per unit mass. Equation (5-177) is nonlinear with respect to temperature. To solve Eq. (5-177), first linearize the convective heat-transfer term in the right-hand side with the approximation $\Delta T = T_2 - T_1 \approx (T_2^4 - T_1^4)/4\overline{T}_{1,2}^3$ where $\overline{T}_{1,2} = (T_1 + T_2)/2$. This linearization underestimates $\Delta T$ by no more than 5 percent when $T_2/T_1 < 1.59$. Integration of Eq. (5-177) then leads to the solution

$$\ln\left[\frac{(T_{g,\text{out}} - T_1)(T_{g,\text{in}} + T_1)}{(T_{g,\text{out}} + T_1)(T_{g,\text{in}} - T_1)}\right] + 2.0\,\tan^{-1}\left[\frac{(T_{g,\text{in}} - T_{g,\text{out}})\cdot T_1}{\left(\overline{T}_1^3 + T_{g,\text{in}} \cdot T_{g,\text{out}}\right)}\right] = -\frac{4}{D_{\text{eff}}} \qquad (5\text{-}178)$$

The LPFF model is described by only two dimensionless parameters, namely an *effective* firing density and a dimensionless sink temperature, viz.,

$$D_{\text{eff}} = \frac{N_{\text{FD}}}{\left(\dfrac{\overleftarrow{S_1G}}{A_1}\right) + N_{\text{CR}}} \quad \text{and} \quad \Theta_1 = T_1/T_{g,\text{in}} \qquad (5\text{-}178a,b)$$

Here the dimensionless firing density, $N_{\text{FD}}$, and a dimensionless convection-radiation namber $N_{\text{CR}}$ are defined as

$$N_{\text{FD}} = \frac{\dot{m}\,\overline{C}_p}{\sigma \cdot T_1^3 A_1} \quad \text{and} \quad N_{\text{CR}} = \frac{h}{4\sigma \overline{T}_{g,1}^3} \qquad (5\text{-}178c,d)$$

where $A_1 = PL$ is the duct surface area (the sink area), and $\overline{T}_{g,1} = (\overline{T}_g + T_1)/2$ is treated as a constant. This definition of the effective dimensionless firing density, $D_{\text{eff}}$, clearly delineates the relative

roles of radiation and convective heat transfer since radiation and convection are identified as *parallel* (*electrical*) *conductances*.

In analogy with a conventional heat exchanger, Eq. (5-178) displays two asymptotic limits. First define

$$\eta_f = \frac{T_{g,\text{in}} - T_{g,\text{out}}}{T_{g,\text{in}} - T_1} = 1 - \frac{T_{g,\text{out}} - T_1}{T_{g,\text{in}} - T_1} \tag{5-179}$$

as the efficiency of the long furnace. The two asymptotic limits with respect to firing density are then given by

$$D_{\text{eff}} \ll 1, \qquad T_{g,\text{out}} \to T_1 \qquad \eta_f \to 1 \tag{5-179a}$$

and

$$D_{\text{eff}} \gg 1, \qquad T_{g,\text{out}} \to T_{g,\text{in}}$$

$$\eta_f \to \frac{4}{D_{\text{eff}}\left[1 - \frac{R-1}{R+1} - 2\frac{R-1}{R^2+1}\right]} \tag{5-179b}$$

where $R \equiv T_{g,\text{in}}/T_1 = 1/\Theta_1$.

For low firing rates, the exit temperature of the furnace gases approaches that of the sink; i.e., sufficient residence time is provided for nearly complete heat removal from the gases. When the combustion chamber is overfired, only a small fraction of the available feed enthalpy heat is removed within the furnace. The exit gas temperature then remains essentially that of the inlet temperature, and the furnace efficiency tends asymptotically to zero.

It is important to recognize that the two-dimensional exchange area $\overleftarrow{S_1G}/A_1 \equiv \partial(\overleftarrow{S_1G})/\partial A_1$ in the definition of $D_{\text{eff}}$ can represent a *lumped* two-dimensional exchange area of somewhat arbitrary complexity. This quantity also contains *all* the information concerning furnace geometry and gas and surface emissivities. To compare the relative importance of radiation with respect to convection, suppose $h = 10$ Btu/(hr·ft²·°R) = 0.057 kW/(K·m²) and $\overline{T}_{g,1} = 1250$ K, which leads to the numerical value $N_{\text{CR}} = 0.128$; or, in general, $N_{\text{CR}}$ is of order 0.1 or less. The importance of the radiation contribution is estimated by bounding the magnitude of the dimensionless directed exchange area. For the case of a single gas zone completely surrounded by a black enclosure, Eq. (5-169) reduces to simply $\overleftarrow{S_1G}/A_1 = \varepsilon_g \le 1.0$, and it is evident that the magnitude of the radiation contribution never exceeds unity. At high temperatures, radiative effects can easily dominate other modes of heat transfer by an order of magnitude or more. When mean beam length calculations are employed, use $L_M/D = 0.94$ for a cylindrical cross section of diameter $D$, and

$$L_{M0} = \frac{2H \cdot W}{H + W}$$

for a rectangular duct of height $H$ and width $W$.

**The Well-Stirred Combustion Chamber (WSCC) Model** Many combustion chambers utilize high-momentum feed conditions with associated high-intensity mixing. The **well-stirred combustion chamber (WSCC) model** assumes a single gas zone and high-intensity mixing. Moreover, combustion and heat transfer are visualized to occur *simultaneously* within the combustion chamber. The WSCC model is characterized by some *six* temperatures which are listed in rank order as $T_0$, $T_{\text{air}}$, $T_1$, $T_e$, $T_g$, and $T_f$. Even though the combustion chamber is well mixed, it is *arbitrarily* assumed that the gas temperature within the enclosure $T_g$ is *not necessarily equal* to the gas exit temperature $T_e$. Rather the two temperatures are related by the simple relation $\Delta T_{ge} \equiv T_g - T_e$, where $\Delta T_{ge} \approx 170$ K (as a representative value) is introduced as an *adjustable parameter* for purposes of data fitting and to make allowance for nonideal mixing. In addition, $T_0$ is the ambient temperature, $T_{\text{air}}$ is the air preheat temperature, and $T_f$ is a *pseudoadiabatic flame temperature*, as shall be explained in the following development. The condition $\Delta T_{ge} \equiv 0$ is intended to simulate a perfect continuous well-stirred reactor (CSTR).

***Dimensional WSCC Approach*** A macroscopic enthalpy balance on the well-stirred combustion chamber is written as

$$-\Delta H = H_{\text{In}} - H_{\text{Out}} = Q_{\text{Rad}} + Q_{\text{Con}} + Q_{\text{Ref}} \tag{5-180}$$

Here $Q_{\text{Rad}} = \overleftarrow{S_1G}_R \sigma (T_g^4 - T_1^4)$ represents radiative heat transfer to the sink (with due allowance for the presence of any refractory surfaces). And the two terms $Q_{\text{Con}} = h_1 A_1 (T_g - T_1)$ and $Q_{\text{Ref}} = UA_R(T_g - T_0)$ formulate the convective heat transfer to the sink and *through* the refractory, respectively.

Formulation of the left-hand side of Eq. (5-180) requires representative thermodynamic data and information on the combustion stoichiometry. In particular, the former includes the lower heating value of the fuel, the temperature-dependent molal heat capacity of the inlet and outlet streams, and the air preheat temperature $T_{\text{air}}$. It proves especially convenient now to introduce the definition of a pseudoadiabatic flame temperature $T_f$, which is *not* the true adiabatic flame temperature, but rather is an adiabatic flame temperature based on the average heat capacity of the combustion products over the temperature interval $T_0 < T < T_e$. The calculation of $T_f$ does not allow for dissociation of chemical species and is a surrogate for the total enthalpy content of the input fuel-air mixture. It also proves to be an especially convenient system *reference temperature*. Details for the calculation of $T_f$ are illustrated in Example 13.

In terms of this particular definition of the pseudoadiabatic flame temperature $T_f$, the total enthalpy change and gas efficiency are given simply as

$$\Delta H = \dot{H}_f - \dot{m} \cdot \overline{C}_{P,\text{Prod}}(T_e - T_0) = \dot{m}\overline{C}_{P,\text{Prod}}(T_f - T_e) \tag{5-181a,b}$$

where $\dot{H}_f \equiv \dot{m} \cdot \overline{C}_{p,\text{Prod}}(T_f - T_0)$ and $T_e = T_g - \Delta T_{ge}$. This particular definition of $T_f$ leads to an especially convenient formulation of furnace efficiency

$$\eta_g = Q/\dot{H}_f = \frac{\dot{m} \cdot \overline{C}_{P,\text{Prod}}(T_f - T_e)}{\dot{m} \cdot \overline{C}_{P,\text{Prod}}(T_f - T_0)} = \frac{T_f - T_e}{T_f - T_0} \tag{5-182}$$

In Eq. (5-182), $\dot{m}$ is the total mass flow rate and $\overline{C}_{P,\text{Prod}}$ [J/(kg·K)] is defined as the average heat capacity of the product stream over the temperature interval $T_0 < T < T_e$.

The final overall enthalpy balance is then written as

$$\dot{m} \cdot \overline{C}_{P,\text{Prod}}(T_f - T_e) = \overleftarrow{S_1G}_R \sigma \left(T_g^4 - T_1^4\right) + h_1 A_1 (T_g - T_1) + UA_R(T_g - T_0) \tag{5-183}$$

with $T_e = T_g - \Delta T_{ge}$.

Equation (5-183) is a nonlinear algebraic equation which may be solved by a variety of iterative methods. The *sole* unknown quantity, however, in Eq. (5-183) is the gas temperature $T_g$. It should be recognized, in particular, that $T_f$, $T_e$, $\overline{C}_{P,\text{Prod}}$, and the directed exchange area are all explicit functions of $T_g$. The method of solution of Eq. (5-183) is demonstrated in some detail in Example 13.

***Dimensionless WSCC Approach*** In Eq. (5-183), assume the convective heat loss through the refractory is negligible, and linearize the convective heat transfer to the sink. These approximations lead to the result

$$\dot{m} \cdot \overline{C}_{P,\text{Prod}}(T_f - T_g + \Delta T_{ge}) = \overleftarrow{S_1G}_R \sigma \left(T_g^4 - T_1^4\right) + h_1 A_1 \left(T_g^4 - T_1^4\right)/4\overline{T}_{g,1}^3 \tag{5-184}$$

where $\overline{T}_{g,1} = (T_g + T_1)/2$ is some characteristic average temperature which is taken as constant. Now normalize all temperatures based on the pseudoadiabatic temperature as in $\Theta_i = T_i/T_f$. Equation (5-184) then leads to the dimensionless equation

$$D_{\text{eff}}(1 - \Theta_g + \Delta^\circ) = \left(\Theta_g^4 - \Theta_1^4\right) \tag{5-185}$$

where again $D_{\text{eff}} = N_{FD}/\left(\overleftarrow{S_1G}/A_1 + N_{CR}\right)$ is defined *exactly* as in the case of the LPFF model, with the proviso that the WSCC dimensionless firing density is defined here as $N_{FD} = \dot{m}\overline{C}_{P,\text{Prod}}/(\sigma\, T_f^3 \cdot A_1)$. The dimensionless furnace efficiency follows directly from Eq. (5-182) as

$$\eta_g = \frac{1 - \Theta_e}{1 - \Theta_0} = \frac{1 - \Theta_g + \Delta^\circ}{1 - \Theta_0} \tag{5-186a}$$

We also define a **reduced furnace efficiency** $\eta'_g$

$$\eta'_g \equiv (1 - \Theta_0)\eta_g = 1 - \Theta_g + \Delta^* \qquad (5\text{-}186b)$$

Since Eq. (5-186*b*) may be rewritten as $\Theta_g = (1 + \Delta^* - \eta'_g)$, combination of Eqs. (5-185) and (5-186*b*) then yields the final result

$$D_{\text{eff}}\eta'_g = (1 + \Delta^* - \eta'_g)^4 - \Theta_1^4 \qquad (5\text{-}187)$$

Equation (5-187) provides an *explicit* relation between the modified furnace efficiency and the effective firing density directly in which the gas temperature is eliminated.

Equation (5-187) has two asymptotic limits

$$D_{\text{eff}} \ll 1 \qquad \Theta_g \to \Theta_1$$
$$\eta'_g \to 1 - \Theta_1 + \Delta^* \qquad (5\text{-}188a)$$

and

$$D_{\text{eff}} \gg 1 \qquad \Theta_g \to 1 + \Delta^* \qquad \text{and} \qquad \Theta_e \to 1$$

$$\eta'_g \to \frac{(1 + \Delta^*)^4 - \Theta_1^4}{D_{\text{eff}} + 4(1 + \Delta^*)^3} \qquad (5\text{-}188b)$$

Figure 5-23 is a plot of $\eta'_g$ versus $D_{\text{eff}}$ computed from Eq. (5-187) for the case $\Delta^* = 0$.

The asymptotic behavior of Eq. (5-189) mirrors that of the LPFF model. Here, however, for low firing densities, the exit temperature of the furnace exit gases approaches $\Theta_e = \Theta_1 - \Delta^*$ rather than the sink temperature. Moreover, for $D_{\text{eff}} \ll 1$ the reduced furnace efficiency adopts the constant value $\eta'_g = 1 - \Theta_e = 1 + \Delta^* - \Theta_1$. Again at very high firing rates, only a very small fraction of the available feed enthalpy heat is recovered within the furnace. Thus the exit gas temperature remains nearly unchanged from the pseudoadiabatic flame temperature [$T_e \approx T_f$,] and the gas-side efficiency necessarily approaches zero.

***Example 13: WSCC Furnace Model Calculations*** Consider the furnace geometry and combustion stoichiometry described in Example 12. The end-fired furnace is 3 m wide, 5 m tall, and 10 m long. Methane at a firing rate of 2500 kg/h is burned to completion with 20 percent excess air which is preheated to 600°C. The speckled furnace model is to be used. The sink (zone 1) occupies 60 percent of the total interior furnace area and is covered with two rows of 5-in (0.127-m) tubes mounted on equilateral centers with a center-to-center distance of twice the tube diameter. The sink temperature is 1000 K, and the tube emissivity is 0.7. Combustion products discharge from a 10-m$^2$ duct in the roof which is also tube-screen covered and is to be considered part of the sink. The refractory (zone 2) with emissivity 0.6 is radiatively adiabatic but demonstrates a small convective heat loss to be calculated with an overall heat transfer coefficient $U$. Compute all unknown furnace temperatures, the gas-side furnace efficiency, and the mean heat flux density through the tube surface. Use the *dimensional* solution approach for the well-stirred combustor model and compare computed results with the *dimensionless* WSCC and LPFF models. Computed values for mean equivalent gas emissivity obtained from Eq. (5-174*b*) and Table 5-5 for $T_g = 2000$ K for $L_M = 2.7789$ m and $T_1 = 1000$ K are found to be

$T_g = 1500$ K $\quad a_m = 0.44181 \quad \tau_m = 0.37014 \quad \varepsilon_m = 0.27828$

$T_g = 2000$ K $\quad a_m = 0.38435 \quad \tau_m = 0.41844 \quad \varepsilon_m = 0.22352$

Over this temperature range the gas emissivity may be calculated by linear interpolation. Additional heat-transfer and thermodynamic data are supplied in context.

*Three-zone speckled furnace model, M = 2, N = 1:*

Zone 1: Sink (60 percent of total furnace area)

Zone 2: Refractory surface (40 percent of total furnace area)

*Physical constants:*

$$\sigma \equiv 5.670400 \times 10^{-8}\ \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}$$

*Linear interpolation function for mean effective gas emissivity constants:*

$$\text{LINTF}(T, Y2, Y1) := \frac{Y1 \cdot (2000\ \text{K} - T) + Y2 \cdot (T - 1500\ \text{K})}{500\ \text{K}} \quad (1500\ \text{K} < T < 2000\ \text{K})$$

*Enclosure input parameters:*

$$V_{\text{tot}} := 150\ \text{m}^3 \quad A_{\text{tot}} := 190\ \text{m}^2 \quad C_1 := 0.6 \quad C_2 := 1 - C_1$$

$$A_1 := C_1 \cdot A_{\text{tot}} \quad A_2 := C_2 \cdot A_{\text{tot}} \quad D_{\text{tube}} := .127\ \text{m}$$

*Direct exchange areas for WSGG clear gas component (temperature independent):*

$$F := \begin{pmatrix} C_1 & C_2 \\ C_1 & C_2 \end{pmatrix} \quad AI := \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix} \quad ss1 := AI \cdot F \quad ss1 = \begin{pmatrix} 68.40 & 45.60 \\ 45.60 & 30.40 \end{pmatrix} \text{m}^2$$

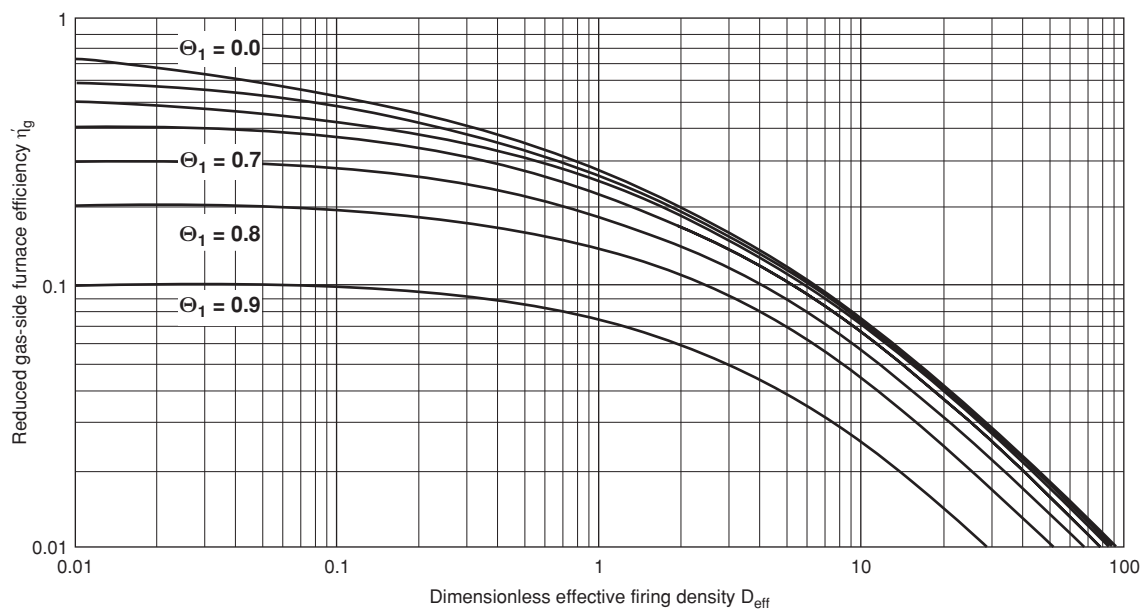

**FIG. 5-23** Reduced gas-side furnace efficiency versus effective firing density for well-stirred combustion chamber model. $\Delta^* = 0$, $\Theta_1 = 0.0, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9$.

*Equivalent gray plane emissivity calculations for sink:*

$\varepsilon_{tube} := 0.7 \quad F_{bar} := 0.987$ (from Fig. 5-13, curve 6 with ratio = 2.0)

$$\varepsilon 1_{eq} := \frac{1}{\left(\frac{1}{1}-1\right)+2\cdot\frac{D_{tube}}{2\cdot\pi\cdot D_{tube}}\cdot\left(\frac{1}{\varepsilon_{tube}}-1\right)+\frac{1}{F_{bar}}} \qquad \varepsilon 1_{eq} = 0.86988$$

$$\varepsilon_1 := \varepsilon 1_{eq} \quad \varepsilon_2 := 0.6 \quad \varepsilon I := \begin{pmatrix}\varepsilon_1 & 0\\ 0 & \varepsilon_2\end{pmatrix} \quad \rho I := \text{identity}(2) - \varepsilon I$$

*Total exchange areas for WSGG clear gas component:*

$$R1 := (AI - ss1\cdot\rho I)^{-1} \quad SS1 := \varepsilon I\cdot AI\cdot R1\cdot ss1\cdot\varepsilon I \quad SS1 = \begin{pmatrix}67.93 & 31.24\\ 31.24 & 14.36\end{pmatrix}\text{m}^2$$

*Temperature and emissive power input data:*

$T_1 := 1000.0\text{ K} \qquad T_{air} := 873.15\text{ K}$

$$T_0 := 298.15\text{ K} \qquad \Delta T_{ge} := 170\text{ K} \qquad E_1 := \sigma\cdot T_1^4 \qquad E_1 = 56.704\ \frac{\text{kW}}{\text{m}^2}$$

*Mean beam length calculations:*

$$L_{M0} := 4\cdot\frac{V_{tot}}{A_{tot}} \quad L_{M0} = 3.1579\text{ m} \quad L_M := 0.88L_{M0} \quad L_M = 2.7789\text{ m}$$

*Stoichiometric and thermodynamic input data:*

$$MCH4_{dot} := 2500\frac{\text{kg}}{\text{h}} \quad MW_{CH4} := 16.04\frac{\text{g}}{\text{mol}} \quad MW_{in} := 27.742\frac{\text{g}}{\text{mol}}$$

$$\sum\text{Mols} := 12.52914 \quad \text{LHV} := 191760\frac{\text{cal}}{\text{mol}} \quad MCp_{air} := 7.31\frac{\text{cal}}{\text{mol}\cdot\text{K}}$$

$$MCp(T) := \left[7.01 + 0.875\left(\frac{T}{1000\text{ K}}\right)\right]\frac{\text{cal}}{\text{mol}\cdot\text{K}} \quad (800\text{ K} < T < 1200\text{ K})$$

$M_{dot}$ is the total mass flowrate and $NCH4_{dot}$ is the molal flowrate of $CH_4$.

$$M_{dot} := \frac{MCH4_{dot}\cdot MW_{in}\cdot\Sigma\text{Mols}}{MW_{CH4}} \qquad NCH4_{dot} := \frac{MCH4_{dot}}{MW_{CH4}}$$

$$M_{dot} = 54174.5\frac{\text{kg}}{\text{h}} \quad NCH4_{dot} = 155860.3\frac{\text{mol}}{\text{h}}$$

*Overall refractory heat-transfer coefficient:*

$$D_r := 0.343\text{ m} \quad k_r := 0.00050\ \frac{\text{kW}}{\text{m}\cdot\text{K}}$$

$$h_0 := 0.0114\cdot\frac{\text{kW}}{\text{m}^2\cdot\text{K}} \quad h_0 = 2.0077\ \frac{\text{Btu}}{\text{h}\cdot\text{ft}^2\text{R}} \quad h_1 := 0.0170\frac{\text{kW}}{\text{m}^2\cdot\text{K}}$$

$$h_1 = 2.9939\frac{\text{Btu}}{\text{h}\cdot\text{ft}^2\text{R}} \qquad U := \frac{1}{\frac{1}{h_0}+\frac{1}{h_1}+\frac{D_r}{k_r}}$$

$$U = 0.001201\frac{\text{kW}}{\text{m}^2\cdot\text{K}} \qquad U = 0.2115\frac{\text{Btu}}{\text{h}\cdot\text{ft}^2\text{R}}$$

*START OF ITERATION LOOP: Successive Substitution with $T_g$ as the Trial Variable*

Assume $T_g := 1759.1633222447\text{ K} \qquad T_e := T_g - \Delta T_{ge} \qquad T_e = 1589.2\text{ K}$

$$E_g := \sigma\cdot T_g^4 \qquad E_g = 543.05\ \frac{\text{kW}}{\text{m}^2}$$

*Compute temperature-dependent mean effective gas emissivity via linear interpolation:*

$\tau_m := \text{LINTF}(T_g, 0.37014, 0.418442) \quad a_m := \text{LINTF}(T_g, 0.44181, 0.38435)$

$\tau_m = 0.3934 \qquad a_m = 0.4141 \qquad \varepsilon_m := a_m\cdot(1-\tau_m) \qquad \varepsilon_m = 0.2512$

Compare interpolated value:

$$\varepsilon_{com} := \text{LINTF}(T_g, 0.27828, 0.22352) \qquad \varepsilon_{com} = 0.2519$$

*Direct and total exchange areas for WSGG gray gas component:*

$$ss2 := \tau_m\cdot ss1 \qquad sg2 := (AI - ss2)\begin{bmatrix}1\\1\end{bmatrix} \quad R2 := (AI - ss2\cdot\rho I)^{-1}$$

$$ss2 = \begin{pmatrix}26.91 & 17.94\\ 17.94 & 11.96\end{pmatrix}\text{m}^2 \qquad sg2 = \begin{pmatrix}69.15\\ 46.10\end{pmatrix}\text{m}^2 \qquad SS2 := \varepsilon I\cdot AI\cdot R2\cdot ss2\cdot\varepsilon I$$

*Compute directed exchange areas:*

$\text{DSS} := (1 - a_m)\cdot SS1 + a_m\cdot SS2 \qquad \text{DSG} := a_m\cdot\varepsilon I\cdot AI\cdot R2\cdot sg2$

*Refractory augmented directed gas-sink exchange area:*

$$\text{DS1GR} := \text{DSG}_1 + \frac{\text{DSS}_{1,2}\cdot\text{DSG}_2}{\text{DSS}_{1,2} + \text{DSG}_2} \quad \text{DS1GR} = 35.59\text{ m}^2 \quad \text{Eq. (5-172}a\text{)}$$

*Compute refractory temperature ($T_2$); assume radiative equilibrium:*

Equation (5-172$b$): $$E_2 := \frac{\text{DSS}_{2,1}\cdot E_1 + \text{DSG}_2\cdot E_g}{\text{DSS}_{2,1} + \text{DSG}_2}$$

$$E_2 = 231.24\ \frac{\text{kW}}{\text{m}^2}$$

$$T_2 := \left(\frac{E_2}{\sigma}\right)^{0.25} \qquad T_2 = 1421.1\text{ K}$$

*Enthalpy balance: Basis: 1 mole $CH_4$:*

$$h_{in} := LHV + (\Sigma\text{Mols} - 1)\cdot MCp_{air}\cdot(T_{air} - T_0) \qquad h_{in} = 240219.9\ \frac{\text{cal}}{\text{mol}}$$

*Compute pseudoadiabatic flame temperature $T_f$:*

$$T_f := T_0 + \frac{h_{in}}{\Sigma\text{Mols}\ MCp(T_e)} \qquad h_{out} := \Sigma\text{Mols}\cdot MCp(T_e)\cdot(T_e - T_0)$$

$T_f = 2580.5\text{ K} \qquad h_{out} = 135880.8\ \frac{\text{cal}}{\text{mol}}$

$H_{in} := NCH4_{dot}\cdot h_{in} \qquad H_{out} := NCH4_{dot}\cdot h_{out} \qquad \Delta H := H_{out} - H_{in}$

$H_{in} = 43543.59\text{ kW} \qquad H_{out} = 24630.51\text{ kW} \qquad \Delta H = -18913.08\text{ kW}$

*Overall enthalpy balance:*

$Q1_g := \text{DS1GR}\cdot(E_g - E_1) \qquad Q1_g = 17308.45\text{ kW}$

$Q1_{Con} := h_1\cdot A_1\cdot(T_g - T_1) \qquad Q1_{Con} = 1471.26\text{ kW}$

$Q2_{Con} := U\cdot A_2\cdot(T_g - T_0) \qquad Q2_{Con} = 133.37\text{ kW}$

$\text{ERROR} := Q1_g + Q1_{Con} + Q2_{Con} + \Delta H \qquad \%\text{ERROR1} := 100\ \frac{\text{ERROR}}{\Delta H}$

$\text{ERROR} = -0.0000\text{ kW} \qquad \%\text{ERROR1} = 0.00000$

$$T_{gcalc} := \left[\frac{\text{DS1GR}\cdot E_1 - (\Delta H + Q1_{Con} + Q2_{Con})}{\text{DS1GR}\cdot\sigma}\right]^{0.25} \qquad T_{gcalc} = 1759.16332\text{ K}$$

*Average assumed and calculated temperatures for next iteration*

$$T_{gnew} := \frac{T_g + T_{gcalc}}{2} \qquad T_{gnew} = 1759.1633222935\text{ K} \qquad \text{Go to Start}$$

*END OF ITERATION LOOP: Final Gas Temperature* $T_g = 1759.16\text{ K}$

$$\eta_g := \frac{H_{in} - H_{out}}{H_{in}} \quad \text{or} \quad \eta 1_g := \frac{T_f - T_e}{T_f - T_0} \qquad \eta_g = 0.43435 \quad \eta 1_g = 0.43435$$

*Heat flux density calculations:*

$$q_1 := \frac{Q1_g + Q1_{Con}}{A_1} \qquad q_{tube} := q_1\cdot\left(2\cdot\frac{D_{tube}}{2\cdot\pi\cdot D_{tube}}\right)$$

$$q_1 = 164.7\ \frac{\text{kW}}{\text{m}^2} \qquad q_{tube} = 52.44\ \frac{\text{kW}}{\text{m}^2}$$

*Note:* This example was also solved with $\Delta T_{ge} = 0$. The results were as follows: $T_f = 2552.8$ K, $T_g = T_e = 1707.1$ K, $T_2 = 1381.1$ K, $\eta_g = 37.51$ percent, $D_{eff} = 0.53371$, and $\Delta H = 16332.7$ kW. The WSCC model with $\Delta T_{ge} = 0$ predicts a lower performance bound.

*Compare dimensionless WSCC model:*

$$\Theta_0 := \frac{T_0}{T_f} \qquad \Theta_1 := \frac{T_1}{T_f} \qquad \Delta T_{star} := \frac{\Delta T_{ge}}{T_f}$$

$$T_{g1} := \frac{T_1 + T_g}{2}$$

$$\Theta_0 = 0.1155 \quad \Theta_1 = 0.3875 \quad \Delta T_{star} = 0.06588 \quad T_{g1} = 1379.58\ \text{K}$$

$$Cp_{Prod} := \frac{MCp(T_e)}{MW_{in}} \qquad Cp_{Prod} = 0.000352\ \text{kW}\cdot\frac{\text{h}}{\text{kg}\cdot\text{K}}$$

$$N_{FD} := M_{dot}\cdot\frac{Cp_{prod}}{\sigma\cdot T_f^{\,3}\cdot A_1} \qquad N_{CR} := \frac{h_1}{4\cdot\sigma\cdot T_{g1}^{\,3}} \qquad D_{eff} := \frac{N_{FD}}{\frac{DS1GR}{A_1} + N_{CR}}$$

$$N_{FD} = 0.17176 \quad N_{CR} = 0.02855 \quad D_{eff} = 0.50409 \quad \frac{DS1GR}{A_1} = 0.31218$$

$$\eta_{prime} := \eta_g\cdot(1-\Theta_0) \qquad D1_{eff} := \frac{(1+\Delta T_{star}-\eta_{prime})^4 - \Theta_1^{\,4}}{\eta_{prime}}$$

$$D1_{eff} = 0.50350 \quad \text{versus} \quad D_{eff} = 0.50409$$

This small discrepancy is due to linearization and neglect of convective refractory heat losses in the dimensionless WSCC model.

*Compare dimensionless LPFF model:*

$$R_{in} := \frac{1}{\Theta_1} \qquad R_{in} = 2.58050$$

*Trial and error calculation to match effective firing densities:*
Assume:

$$T_{out} := 1000.13763\ \text{K} \quad R_{out} := \frac{T_{out}}{T_1} \quad R_{out} = 1.00014 \quad \frac{4}{D_{eff}} = 7.93513$$

$$CLong := -\ln\left[\frac{(R_{out}-1)\cdot(R_{in}+1)}{(R_{in}-1)\cdot(R_{out}+1)}\right] - 2\cdot\text{atan}\left(\frac{R_{in}-R_{out}}{1+R_{in}\cdot R_{out}}\right) \quad CLong = 7.93514$$

$$\eta L_f := \frac{R_{in}-R_{out}}{R_{in}-1} \quad \eta L_f = 0.99991292 \quad \text{versus} \quad \eta_g = 0.43435$$

*Note*: The long plug flow furnace Model is so efficient that it would be grossly underfired using the computed WSCC effective firing density. Of the two models, the LPFF model always predicts an upper theoretical performance limit.

(This example was developed as a MATHCAD 14® worksheet. Mathcad is registered trademark of Parametric Technology Corporation.)

**WSCC Model Utility and More Complex Zoning Models** Despite its simplicity, the WSCC construct has a wide variety of practical uses and is of significant pedagogical value. Here an engineering situation of inordinate complexity is described by the definition of only eight dimensionless quantities $D_{eff}$, $N_{FD}$, $\overleftarrow{S_1 G_R}/A_1$, $N_{CR}$, $\eta_g$, $\Delta^*$, $\Theta_0$, and $\Theta_1$. The first three are related by the simple algebraic definition $D_{eff} = N_{FD}/(\overleftarrow{S_1 G_R}/A_1 + N_{CR})$. These dimensionless quantities contain all the physical input information for the model, namely, furnace parameters and geometry, radiative properties of the combustion products, and the stoichiometry and thermodynamics of the combustion process. The WSCC model leads to a dimensionless two-dimensional plot of *reduced* effective furnace efficiency versus dimensionless effective firing density (Fig. 5-23), which is characterized by only two additional parameters, namely, $\Delta^*$ and $\Theta_1$.

Of the models presented here, the WSCC model with $\Delta T_{ge} = 0$ produces the lowest furnace efficiencies. The long furnace model usually produces the highest furnace efficiency. This is really not a fair statement because two distinctly different pieces of process equipment are compared. In this regard, a more appropriate definition of the dimensionless firing density for the LPFF model might be $N'_{FD} = \dot{m}\,\overline{C}_p/(\sigma\cdot T_{g,in}^3\cdot A_1)$. It may be counterintuitive, but the WSCC and LPFF models *generally do not* characterize the extreme conditions for the performance of combustors as in the case of chemical reactors.

Figure 5-23 has been used to correlate furnace performance data for a multitude of industrial furnaces and combustors. Typical operational domains for a variety of fuel-fired industrial furnaces are summarized in Table 5-7. The WSCC approach (or "speckled" furnace model) is a classic contribution to furnace design methodology which was first due to Hottel [op. cit.]. The WSCC model provides a simple *furnace design template* which leads to a host of more complex furnace models. These models include an obvious extension to a tanks-in-series model as well as multizone models utilizing empirical cold-flow velocity patterns. For more information on practical furnace design models, reference is made to Hottel and Sarofim (op. cit., Chap. 14). Qualitative aspects of process equipment have been treated in some detail elsewhere (Baukal, C. E., ed., *The John Zink Combustion Handbook,* CRC Press, Boca Raton, Fla., 2001).

**TABLE 5-7 Operational Domains for Representative Process Furnaces and Combustors**

| Domain | Furnace or combustor type | Dimensionless sink temperature | Dimensionless firing density |
|---|---|---|---|
| A | Oil processing furnaces; radiant section of oil tube stills and cracking coils | $\Theta_1 \approx 0.4$ | $0.1 < D_{eff} < 1.0$ |
| B | Domestic boiler combustion chambers | $\Theta_1 \approx 0.2$ | $0.5 < D_{eff} < 1.1$ |
| C | Glass furnaces | $0.7 < \Theta_1 < 0.8$ | $0.035 < D_{eff} < 0.8$ |
| D | Soaking pits | $\Theta_1 \approx 0.6$ | $0.7 < D_{eff} < 1.1$ |
| E | Gas-turbine combustors | $0.4 < \Theta_1 < 0.7$ | $4.0 < D_{eff} < 25.0$ |

## INTRODUCTION

This part of Sec. 5 provides a concise guide to solving problems in situations commonly encountered by chemical engineers. It deals with diffusivity and mass-transfer coefficient estimation and common flux equations, although material balances are also presented in typical coordinate systems to permit a wide range of problems to be formulated and solved.

Mass-transfer calculations involve transport properties, such as diffusivities, and other empirical factors that have been found to relate mass-transfer rates to measured "driving forces" in myriad geometries and conditions. The context of the problem dictates whether the fundamental or more applied coefficient should be used. One key distinction is that, whenever there is flow parallel to an interface through which mass transfer occurs, the relevant coefficient is an empirical combination of properties and conditions. Conversely, when diffusion occurs in stagnant media or in creeping flow without transverse velocity gradients, ordinary diffusivities may be suitable for solving the problem. In either case, it is strongly suggested to employ data, whenever available, instead of relying on correlations.

Units employed in diffusivity correlations commonly followed the cgs system. Similarly, correlations for mass transfer correlations used the cgs or English system. In both cases, only the most recent correlations employ SI units. Since most correlations involve other properties and physical parameters, often with mixed units, they are repeated here as originally stated. Common conversion factors are listed in Table 1-4.

**Fick's First Law** This law relates flux of a component to its composition gradient, employing a constant of proportionality called a diffusivity. It can be written in several forms, depending on the units and frame of reference. Three that are related but not identical are

$$ {}_{V}J_A = -D_{AB}\frac{dc_A}{dz} \approx {}_{M}J_A = -cD_{AB}\frac{dx_A}{dz} \propto {}_{m}J_A = -\rho D_{AB}\frac{dw_A}{dz} \quad (5\text{-}189) $$

The first equality (on the left-hand side) corresponds to the molar flux with respect to the volume average velocity, while the equality in the center represents the molar flux with respect to the molar average velocity and the one on the right is the mass flux with respect to the mass average velocity. These must be used with consistent flux expressions for fixed coordinates and for $N_C$ components, such as:

$$ N_A = {}_{V}J_A + c_A\sum_{i=1}^{N_C} N_i\overline{V}_i = {}_{M}J_A + x_A\sum_{i=1}^{N_C} N_i = \frac{{}_{m}J_A + w_A\sum_{i=1}^{N_C} n_i}{M_A} \quad (5\text{-}190) $$

In each case, the term containing the summation accounts for *conveyance,* which is the amount of component *A* carried by the net flow in the direction of diffusion. Its impact on the total flux can be as much as 10 percent. In most cases it is much less, and it is frequently ignored. Some people refer to this as the "convective" term, but that conflicts with the other sense of convection which is promoted by flow perpendicular to the direction of flux.

**Mutual Diffusivity, Mass Diffusivity, Interdiffusion Coefficient Diffusivity** is denoted by $D_{AB}$ and is defined by Fick's first law as the ratio of the flux to the concentration gradient, as in Eq. (5-189). It is analogous to the thermal diffusivity in Fourier's law and to the kinematic viscosity in Newton's law. These analogies are flawed because both heat and momentum are conveniently defined with respect to fixed coordinates, irrespective of the direction of transfer or its magnitude, while mass diffusivity most commonly requires information about bulk motion of the medium in which diffusion occurs. For liquids, it is common to refer to the limit of infinite dilution of *A* in *B* using the symbol, $D^{\circ}_{AB}$.

When the flux expressions are consistent, as in Eq. (5-190), the diffusivities in Eq. (5-189) are identical. As a result, experimental diffusivities are often measured under constant volume conditions but may be used for applications involving open systems. It turns out that the two versions are very nearly equivalent for gas-phase systems because there is negligible volume change on mixing. That is not usually true for liquids, however.

**Self-Diffusivity Self-diffusivity** is denoted by $D_{A'A}$ and is the measure of mobility of a species in itself; for instance, using a small concentration of molecules tagged with a radioactive isotope so they can be detected. Tagged and untagged molecules presumably do not have significantly different properties. Hence, the solution is ideal, and there are practically no gradients to "force" or "drive" diffusion. This kind of diffusion is presumed to be purely statistical in nature.

In the special case that *A* and *B* are similar in molecular weight, polarity, and so on, the self-diffusion coefficients of pure *A* and *B* will be approximately equal to the mutual diffusivity, $D_{AB}$. Second, when *A* and *B* are the less mobile and more mobile components, respectively, their self-diffusion coefficients can be used as rough lower and upper bounds of the mutual diffusion coefficient. That is, $D_{A'A} \le D_{AB} \le D_{B'B}$. Third, it is a common means for evaluating diffusion for gases at high pressure. Self-diffusion in liquids has been studied by many [Easteal, *AIChE J.* **30,** 641 (1984), Ertl and Dullien, *AIChE J.* **19,** 1215 (1973), and Vadovic and Colver, *AIChE J.* **18,** 1264 (1972)].

**Tracer Diffusivity Tracer diffusivity,** denoted by $D_{A'B}$ is related to both mutual and self-diffusivity. It is evaluated in the presence of a second component *B,* again using a tagged isotope of the first component. In the dilute range, tagging *A* merely provides a convenient method for indirect composition analysis. As concentration varies, tracer diffusivities approach mutual diffusivities at the dilute limit, and they approach self-diffusivities at the pure component limit. That is, at the limit of dilute *A* in *B*, $D_{A'B} \to D^{\circ}_{AB}$ and $D_{B'A} \to D_{B'B}$; likewise at the limit of dilute *B* in *A*, $D_{B'A} \to D^{\circ}_{BA}$ and $D_{A'B} \to D_{A'A}$.

Neither the tracer diffusivity nor the self-diffusivity has much practical value except as a means to understand ordinary diffusion and as order-of-magnitude estimates of mutual diffusivities. Darken's equation [Eq. (5-230)] was derived for tracer diffusivities but is often used to relate mutual diffusivities at moderate concentrations as opposed to infinite dilution.

**Mass-Transfer Coefficient** Denoted by $k_c$, $k_x$, $K_x$, and so on, the mass-transfer coefficient is the ratio of the flux to a concentration (or composition) difference. These coefficients generally represent rates of transfer that are much greater than those that occur by diffusion alone, as a result of convection or turbulence at the interface where mass transfer occurs. There exist several principles that relate that coefficient to the diffusivity and other fluid properties and to the intensity of motion and geometry. Examples that are outlined later are the film theory, the surface renewal theory, and the penetration theory, all of which pertain to idealized cases. For many situations of practical interest like investigating the flow inside tubes and over flat surfaces as well as measuring external flow through banks of tubes, in fixed beds of particles, and the like, correlations have been developed that follow the same forms as the above theories. Examples of these are provided in the subsequent section on mass-transfer coefficient correlations.

**Problem Solving Methods** Most, if not all, problems or applications that involve mass transfer can be approached by a systematic course of action. In the simplest cases, the unknown quantities are obvious. In more complex (e.g., multicomponent, multiphase, multidimensional, nonisothermal, and/or transient) systems, it is more subtle to resolve the known and unknown quantities. For example, in multicomponent systems, one must know the fluxes of the components before predicting their effective diffusivities and vice versa. More will be said about that dilemma later. Once the known and unknown quantities are resolved, however, a combination of conservation equations, definitions, empirical relations, and properties are

**Nomenclature and Units—Mass Transfer**

| Symbols | Definition | SI units | U.S. Customary units |
|---|---|---|---|
| $a$ | Effective interfacial mass transfer area per unit volume | $m^2/m^3$ | $ft^2/ft^3$ |
| $A_{cs}$ | Cross-sectional area of vessel | $m^2$ or $cm^2$ | $ft^2$ |
| $A'$ | Constant (see Table 5-24-K) | | |
| $a_p$ | See $a$ | | |
| $c$ | Concentration = $P/RT$ for an ideal gas | mol/$m^3$ or mol/l or gequiv/l | lbmol/$ft^3$ |
| $c_i$ | Concentration of component $i = x_i c$ at gas-liquid interface | mol/$m^3$ or mol/l or gequiv/l | lbmol/$ft^3$ |
| $c_P$ | Specific heat | kJ/(kg·K) | Btu/(lb·°F) |
| $d$ | Characteristic length | m or cm | ft |
| $d_b$ | Bubble diameter | m | ft |
| $d_c$ | Column diameter | m or cm | ft |
| $d_{drop}$ | Sauter mean diameter | m | ft |
| $d_{imp}$ | Impeller diameter | m | ft |
| $d_{pore}$ | Pore diameter | m or cm | ft |
| $D_{A'A}$ | Self-diffusivity (= $D_A$ at $x_A = 1$) | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D_{AB}$ | Mutual diffusivity | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D^\circ_{AB}$ | Mutual diffusivity at infinite dilution of $A$ in $B$ | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D_{eff}$ | Effective diffusivity within a porous solid = $\varepsilon_p D/\tau$ | $m^2/s$ | $ft^2/h$ |
| $D_K$ | Knudson diffusivity for gases in small pores | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D_L$ | Liquid phase diffusion coefficient | $m^2/s$ | $ft^2/h$ |
| $D_S$ | Surface diffusivity | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $E$ | Energy dissipation rate/mass | | |
| $E_S$ | Activation energy for surface diffusion | J/mol or cal/mol | |
| $f$ | Friction factor for fluid flow | Dimensionless | Dimensionless |
| $F$ | Faraday's constant | 96,487 Coulomb/gequiv | |
| $g$ | Acceleration due to gravity | $m/s^2$ | $ft/h^2$ |
| $g_c$ | Conversion factor | 1.0 | $4.17 \times 10^8$ lb ft/[lbf·$h^2$] |
| $G$ | Gas-phase mass flux | kg/(s·$m^2$) | lb/(h·$ft^2$) |
| $G_a$ | Dry air flux | kg/(s·$m^2$) | lb/(h·$ft^2$) |
| $G_M$ | Molar gas-phase mass flux | kmol/(s·$m^2$) | (lbmol)/(h·$ft^2$) |
| $h'$ | Heat transfer coefficient | W/($m^2$·K) = J/(s·$m^2$·K) | Btu/(h·$ft^2$·°F) |
| $h_T$ | Total height of tower packing | m | ft |
| $H$ | Compartment height | m | ft |
| $H$ | Henry's law constant | kPa/(mole-fraction solute in liquid phase) | ($lbf/in^2$)/(mole-fraction solute in liquid phase) |
| $H'$ | Henry's law constant | kPa/[kmol/($m^3$ solute in liquid phase)] | ($lbf/in^2$)/[(lbmol)/($ft^3$ solute in liquid phase)] or atm/[(lbmole)/($ft^3$ solute in liquid phase)] |
| $H_G$ | Height of one transfer unit based on gas-phase resistance | m | ft |
| $H_{OG}$ | Height of one overall gas-phase mass-transfer unit | m | ft |
| $H_L$ | Height of one transfer unit based on liquid-phase resistance | m | ft |
| $H_{OL}$ | Height of one overall liquid-phase mass-transfer unit | m | ft |
| $HTU$ | Height of one transfer unit (general) | m | ft |
| $j_D$ | Chilton-Colburn factor for mass transfer, Eq. (5-289) | Dimensionless | Dimensionless |
| $j_H$ | Chilton-Colburn factor for heat transfer | Dimensionless | Dimensionless |
| $j_M$ | See $j_D$ | | |
| ${}_mJ_A$ | Mass flux of $A$ by diffusion with respect to the mean mass velocity | kmol/($m^2$·s) or mol/($cm^2$·s) | lbmol/($ft^2$·h) |
| ${}_MJ_A$ | Molar flux of $A$ by diffusion with respect to mean molar velocity | kmol/($m^2$·s) or mol/($cm^2$·s) | lbmol/($ft^2$·h) |
| ${}_vJ_A$ | Molar flux of A with respect to mean volume velocity | kmol/($m^2$·s) | lbmol/($ft^2$·h) |
| $J_{Si}$ | Molar flux by surface diffusion | kmol/($m^2$·s) or gmol/($cm^2$·s) | lbmol/($ft^2$·h) |
| $k$ | Boltzmann's constant | $8.9308 \times 10^{-10}$ gequiv ohm/s | |
| $k$ | Film mass transfer coefficient | m/s or cm/s | ft/hr |
| $k$ | Thermal conductivity | (J·m)/(s·$m^2$·K) | Btu/(h·ft·°F) |
| $k'$ | Mass-transfer coefficient for dilute systems | kmol/[(s·$m^2$)(kmol/$m^3$)] or m/s | lbmol/[(h·$ft^2$)(lbmol/$ft^3$)] or ft/hr |
| $k_G$ | Gas-phase mass-transfer coefficient for dilute systems | kmol/[(s·$m^2$)(kPa solute partial pressure)] | lbmol/[(h·$ft^2$)lbf/$in^2$ solute partial pressure)] |
| $k'_G$ | Gas-phase mass-transfer coefficient for dilute systems | kmol/[(s·$m^2$)(mole fraction in gas)] | lbmol/[(h·$ft^2$)(mole fraction in gas)] |
| $k_Ga$ | Volumetric gas-phase mass-transfer | kmol/[(s·$m^3$)(mole fraction)] | (lbmol)/[(h·$ft^3$)(mole fraction)] |
| $\hat{k}_Ga$ | Overall volumetric gas-phase mass-transfer coefficient for concentrated systems | kmol/(s·$m^3$) | lbmol/(h·$ft^3$) |
| $\hat{k}^\circ_L$ | Liquid phase mass transfer coefficient for pure absorption (no reaction) | kmol/(s·$m^2$) | lbmol/(h·$ft^2$) |
| $k_L$ | Liquid-phase mass-transfer coefficient for dilute systems | kmol/[(s·$m^2$)(mole-fraction solution in liquid)] | (lbmol)/[(h·$ft^2$)(mole-fraction solute in liquid)] |
| $k'_L$ | Liquid-phase mass-transfer coefficient for dilute systems | kmol/[(s·$m^2$)(kmol/$m^3$)] or m/s | (lbmol)/[(h·$ft^2$)(lbmol/$ft^3$)] or ft/h |
| $\hat{k}_L$ | Liquid-phase mass-transfer coefficient for concentrated systems | kmol/(s·$m^2$) | lbmol/(h·$ft^2$) |
| $k_La$ | Volumetric liquid-phase mass-transfer coefficient for dilute systems | kmol/[(s·$m^3$)(mole fraction)] | (lbmol)/[(h·$ft^3$)(mole fraction)] |
| $K$ | Overall mass transfer coefficient | m/s or cm/s | ft/h |
| $K$ | $\alpha/R$ = specific conductance | ohm/cm | |
| $K_G$ | Overall gas-phase mass-transfer coefficient for dilute systems | kmol/[(s·$m^2$)(mole fraction)] | (lbmol)/[(h·$ft^2$)(mole fraction)] |

**Nomenclature and Units—Mass Transfer** (*Continued*)

| Symbols | Definition | SI units | U.S. Customary units |
|---|---|---|---|
| $\hat{K}_G$ | Overall gas-phase mass-transfer coefficient for concentrated systems | kmol/(s·m$^2$) | lbmol/(h·ft$^2$) |
| $K_Ga$ | Overall volumetric gas-phase mass-transfer dilute systems | kmol/[(s·m$^3$)(mole-fraction solute in gas)] | (lbmol)/[(h·ft$^3$(mole-fraction solute in gas)] |
| $K'_Ga$ | Overall volumetric gas-phase mass-transfer dilute systems | kmol/[(s·m$^3$)(kPa solute partial pressure)] | (lbmol)/[(h·ft$^3$)(lbf/in$^2$ solute partial pressure)] |
| $(Ka)_H$ | Overall enthalpy mass-transfer coefficient | kmol/[(s·m$^2$)(mole fraction)] | lb/[(h·ft$^3$)(lb water/lb dry air)] |
| $K_L$ | Overall liquid-phase mass-transfer coefficient | kmol/[(s·m$^2$)(mole fraction)] | (lbmol)/[(h·ft$^2$)(mole fraction)] |
| $\hat{K}_L$ | Liquid-phase mass-transfer coefficient for concentrated systems | kmol/(s·m$^2$) | (lbmol)/(h·ft$^2$) |
| $K_La$ | Overall volumetric liquid-phase mass-transfer coefficient for dilute systems | kmol/[(s·m$^3$)(mole-fraction solute in liquid)] | (lbmol)/[(h·ft$^3$)(mole-fraction solute in liquid)] |
| $\hat{K}_La$ | Overall volumetric liquid-phase mass-transfer coefficient for concentrated systems | kmol/(s·m$^3$) | (lbmol)/(h·ft$^3$) |
| $L$ | Liquid-phase mass flux | kg/(s·m$^2$) | lb/(h·ft$^2$) |
| $L_M$ | Molar liquid-phase mass flux | kmol/(s·m$^2$) | (lbmol)/(h·ft$^2$) |
| $m$ | Slope of equilibrium curve = $dy/dx$ (mole-fraction solute in gas)/(mole-fraction solute in liquid) | Dimensionless | Dimensionless |
| $m$ | Molality of solute | mol/1000 g solvent | |
| $M_i$ | Molecular weight of species $i$ | kg/kmol or g/mol | lb/lbmol |
| M | Mass in a control volume $V$ | kg or g | lb |
| $\lvert n_+ \rVert n_- \rvert$ | Valences of cationic and anionic species | Dimensionless | Dimensionless |
| $n'$ | See Table 5-24-K | Dimensionless | Dimensionless |
| $n_A$ | Mass flux of $A$ with respect to fixed coordinates | kg/(s·m$^2$) | lb/(h·ft$^2$) |
| $N$ | Impeller speed | Revolution/s | Revolution/min |
| $N'$ | Number deck levels | Dimensionless | Dimensionless |
| $N_A$ | Interphase mass-transfer rate of solute $A$ per interfacial area with respect to fixed coordinates | kmol/(s·m$^2$) | (lbmol)/(h·ft$^2$) |
| $N_c$ | Number of components | Dimensionless | Dimensionless |
| $N_{Fr}$ | Froude Number ($d_{\text{imp}}N^2$/g) | Dimensionless | Dimensionless |

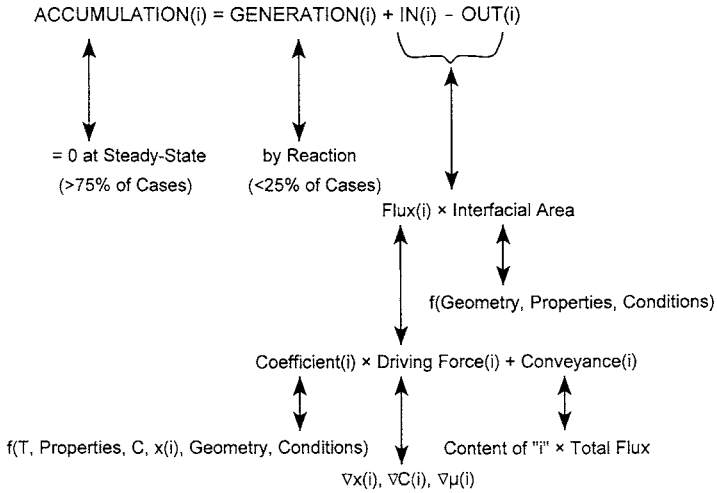

**FIG. 5-24** Flowchart illustrating problem solving approach using mass-transfer rate expressions in the context of mass conservation.

applied to arrive at an answer. Figure 5-24 is a flowchart that illustrates the primary types of information and their relationships, and it applies to many mass-transfer problems.

## CONTINUITY AND FLUX EXPRESSIONS

**Material Balances** Whenever mass-transfer applications involve equipment of specific dimensions, flux equations alone are inadequate to assess results. A material balance or continuity equation must also be used. When the geometry is simple, macroscopic balances suffice. The following equation is an overall mass balance for such a unit having $N_m$ bulk-flow ports and $N_n$ ports or interfaces through which diffusive flux can occur:

$$\frac{dM}{dt} = \sum_{i=1}^{N_m} m_i + \sum_{i=1}^{N_n} n_i A_{cs_i} \tag{5-191}$$

where $M$ represents the mass in the unit volume $V$ at any time $t$; $m_i$ is the mass flow rate through the $i$th port; and $n_i$ is the mass flux through the $i$th port, which has a cross-sectional area of $A_{cs_i}$. The corresponding balance equation for individual components includes a reaction term:

$$\frac{dM_j}{dt} = \sum_{i=1}^{N_m} m_{ij} + \sum_{i=1}^{N_n} n_{ij} A_{cs_i} + r_j V \tag{5-192}$$

For the $j$th component, $m_{ij} = m_i w_{ij}$ is the component mass flow rate in stream $i$; $w_{ij}$ is the mass fraction of component $j$ in stream $i$; and $r_j$ is the net reaction rate (mass generation minus consumption) per unit volume $V$ that contains mass $M$. If it is inconvenient to measure mass flow rates, the product of density and volumetric flow rate is used instead.

In addition, most situations that involve mass transfer require material balances, but the pertinent area is ambiguous. Examples are packed columns for absorption, distillation, or extraction. In such cases, flow rates through the discrete ports (nozzles) must be related to the mass-transfer rate in the packing. As a result, the mass-transfer rate is determined via flux equations, and the overall material balance incorporates the stream flow rates $m_i$ and integrated fluxes. In such instances, it is common to begin with the most general, differential material balance equations. Then, by eliminating terms that are negligible, the simplest applicable set of equations remains to be solved. Table 5-8 provides material balances for Cartesian, cylindrical, and spherical coordinates. The generic form applies over a unit cross-sectional area and constant volume:

$$\frac{\partial \rho_j}{\partial t} = -\nabla \cdot n_j + r_j \tag{5-193a}$$

where $n_j = \rho v_j$. Applying Fick's law and expressing composition as concentration gives

$$\frac{\partial c_j}{\partial t} = -v \cdot \nabla c_j + D_j \nabla^2 c_j + r_j \tag{5-193b}$$

**Flux Expressions: Simple Integrated Forms of Fick's First Law** Simplified flux equations that arise from Eqs. (5-189) and (5-190) can be used for unidimensional, steady-state problems with binary mixtures. The boundary conditions represent the compositions $x_{A_L}$ and $x_{A_R}$ at the left-hand and right-hand sides of a hypothetical layer having thickness $\Delta z$. The principal restriction of the following equations is that the concentration and diffusivity are assumed to be constant. As written, the flux is positive from left to right, as depicted in Fig. 5-25.

1. Equimolar counterdiffusion ($N_A = -N_B$)

$$N_A = {}_M J_A = -D_{AB}\, c\, \frac{dx_A}{dz} = \frac{D_{AB}}{\Delta z}\, c\, (x_{A_L} - x_{A_R}) \tag{5-197}$$

**TABLE 5-8 Continuity Equation in Various Coordinate Systems**

| Coordinate System | Equation |
|---|---|
| Cartesian | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{\partial n_{x_j}}{\partial x} + \frac{\partial n_{y_j}}{\partial y} + \frac{\partial n_{z_j}}{\partial z}\right) + r_j$ (5-194) |
| Cylindrical | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{1}{r}\frac{\partial r n_{r_j}}{\partial r} + \frac{1}{r}\frac{\partial n_{\theta_j}}{\partial \theta} + \frac{\partial n_{z_j}}{\partial z}\right) + r_j$ (5-195) |
| Spherical | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{1}{r^2}\frac{\partial r^2 n_{r_j}}{\partial r} + \frac{1}{r \sin\theta}\frac{\partial n_{\theta_j} \sin\theta}{\partial \theta} + \frac{1}{r \sin\theta}\frac{\partial n_{\phi_j}}{\partial \phi}\right) + r_j$ (5-196) |

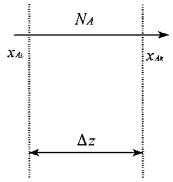

**FIG. 5-25** Hypothetical film and boundary conditions.

2. Unimolar diffusion ($N_A \neq 0$, $N_B = 0$)

$$N_A = {}_M J_A + x_A N_A = \frac{D_{AB}}{\Delta z} c \ln \frac{1 - x_{A_R}}{1 - x_{A_L}} \tag{5-198}$$

3. Steady state diffusion ($N_A \neq -N_B \neq 0$)

$$N_A = {}_M J_A + x_A(N_A + N_B) = \frac{N_A}{N_A + N_B} \frac{D_{AB}}{\Delta z} c \ln \frac{\dfrac{N_A}{N_A + N_B} - x_{A_R}}{\dfrac{N_A}{N_A + N_B} - x_{A_L}} \tag{5-199}$$

The unfortunate aspect of the last relationship is that one must know a priori the ratio of the fluxes to determine the magnitudes. It is not possible to solve simultaneously the pair of equations that apply for components *A* and *B* because the equations are not independent.

**Stefan-Maxwell Equations** Following Eq. (5-190), a simple and intuitively appealing flux equation for applications involving $N_c$ components is

$$N_i = -cD_{im} \nabla x_i + x_i \sum_{j=1}^{N_c} N_j \tag{5-200}$$

In the late 1800s, the development of the kinetic theory of gases led to a method for calculating multicomponent gas diffusion (e.g., the flux of each species in a mixture). The methods were developed simultaneously by Stefan and Maxwell. The problem is to determine the diffusion coefficient $D_{im}$. The Stefan-Maxwell equations are simpler in principle since they employ binary diffusivities:

$$\nabla x_i = \sum_{j=1}^{N_c} \frac{1}{cD_{ij}} (x_i N_j - x_j N_i) \tag{5-201}$$

If Eqs. (5-200) and (5-201) are combined, the multicomponent diffusion coefficient may be assessed in terms of binary diffusion coefficients [see Eq. (5-214)]. For gases, the values $D_{ij}$ of this equation are approximately equal to the binary diffusivities for the *ij* pairs. The Stefan-Maxwell diffusion coefficients may be negative, and the method may be applied to liquids, even for electrolyte diffusion [Kraaijeveld, Wesselingh, and Kuiken, *Ind. Eng. Chem. Res.*, **33,** 750 (1994)]. Approximate solutions have been developed by linearization [Toor, H.L., *AIChE J.*, **10,** 448 and 460 (1964); Stewart and Prober, *Ind. Eng. Chem. Fundam.*, **3,** 224 (1964)]. Those differ in details but yield about the same accuracy. More recently, efficient algorithms for solving the equations exactly have been developed (see Taylor and Krishna, Krishnamurthy and Taylor [*Chem. Eng. J.*, **25,** 47 (1982)], and Taylor and Webb [*Comput. Chem. Eng.*, **5,** 61 (1981)].

Useful studies of multicomponent diffusion were presented by Vrentas and Vrentas [*Ind. Eng. Chem. Res.* **44,** 1112 (2005)], Curtis and Bird [*Ind. Eng. Chem. Res.* **38,** 2515 (1999)], and Amundson, Pan, and Paulson [*AIChE J.* **48,** 813 (2003)]. Vrentas and Vrentas treated only ternary mixtures, such as restrictions due to the entropy inequality, application of the Onsager reciprocal relations, and stability. Curtis and Bird reconciled the multicomponent Fick's law approach with the more elegant Stefan-Maxwell theory. They also provided interrelationships of multicomponent diffusivities devised for various situations, i.e., binary, ternary, and quaternary mixtures. Amundson et al. presented numerical methods for coping with mixtures having four or more components, which are nearly intractable via the analytical S-M method, due to the difficult inversion. Related studies were performed by Ghorayeb and Firoozabadi [*AIChE J.* **46,** 883 (2000)] and Firoozabadi, Ghorayeb, and Saukla [*AIChE J.* **46,** 892 (2000)]. The former covered ordinary molecular diffusion as well as pressure and thermal diffusion for multicomponent mixtures. The latter covered thermal diffusion in multicomponent mixtures.

## DIFFUSIVITY ESTIMATION—GASES

Whenever measured values of diffusivities are available, they should be used. Typically, measurement errors are less than those associated with predictions by empirical or even semitheoretical equations. A few general sources of data are Sec. 2 of this handbook; e.g., experimental values for gas mixtures are listed in Table 2-371. Estimation methods for some gaseous applications appear in Eqs. (2-150) through (2-154). Other pertinent references are Schwartzberg and Chao; Poling et al.; Gammon et al.; and Daubert and Danner. Many other more restricted sources are listed under specific topics later in this subsection.

Before using diffusivities from either data or correlations, it is a good idea to check their reasonableness with respect to values that have been commonly observed in similar situations. Table 5-9 is a compilation of several rules of thumb. These values are not authoritative; they simply represent guidelines based on experience.

Diffusivity correlations for gases are outlined in Table 5-10. Specific parameters for individual equations are defined in the specific text regarding each equation. References are given at the beginning of the "Mass Transfer" subsection. The errors reported for Eqs. (5-202) through (5-205) were compiled by Poling et al., who compared the predictions with 68 experimental values of $D_{AB}$. Errors cited for Eqs. (5-206) to (5-212) were reported by the authors.

**Binary Mixtures—Low Pressure—Nonpolar Components** Many evaluations of correlations are available [Elliott and Watts, *Can. J. Chem.*, **50,** 31 (1972); Lugg, *Anal. Chem.*, **40,** 1072 (1968); Marrero and Mason, *AIChE J.*, **19,** 498 (1973)]. The differences in accuracy of the correlations are minor, and thus the major concern is ease of calculation. The Fuller-Schettler-Giddings equation is usually the simplest correlation to use and is recommended by Poling et al.

***Chapman-Enskog (Bird et al.) and Wilke and Lee [31]*** The inherent assumptions of these equations are quite restrictive (i.e., low density, spherical atoms), and the intrinsic potential function is empirical. Despite that, they provide good estimates of $D_{AB}$ for many polyatomic gases and gas mixtures, up to about 1000 K and a maximum of 70 atm. The latter constraint is because observations for many gases indicate that $D_{AB}P$ is constant up to 70 atm.

The characteristic length is $\sigma_{AB} = (\sigma_A + \sigma_B)/2$ in Å. In order to estimate $\Omega_D$ for Eq. (5-202) or (5-203), two empirical equations are

**TABLE 5-9 Rules of Thumb for Diffusivities (See Cussler, Poling et al., Schwartzberg and Chao)**

| | $D_i$ magnitude | | $D_i$ range | | |
|---|---|---|---|---|---|
| Continuous phase | $m^2/s$ | $cm^2/s$ | $m^2/s$ | $cm^2/s$ | Comments |
| Gas at atmospheric pressure | $10^{-5}$ | 0.1 | $10^{-4}$–$10^{-6}$ | 1–$10^{-2}$ | Accurate theories exist, generally within ±10%; $D_i P \cong$ constant; $D_i \propto T^{1.66 \text{ to } 2.0}$ |
| Liquid | $10^{-9}$ | $10^{-5}$ | $10^{-8}$–$10^{-10}$ | $10^{-4}$–$10^{-6}$ | Approximate correlations exist, generally within ±25% |
| Liquid occluded in solid matrix | $10^{-10}$ | $10^{-6}$ | $10^{-8}$–$10^{-12}$ | $10^{-4}$–$10^{-8}$ | Hard cell walls: $D_{eff}/D_i = 0.1$ to 0.2. Soft cell walls: $D_{eff}/D_i = 0.3$ to 0.9 |
| Polymers and glasses | $10^{-12}$ | $10^{-8}$ | $10^{-10}$–$10^{-14}$ | $10^{-6}$–$10^{-10}$ | Approximate theories exist for dilute and concentrated limits; strong composition dependence |
| Solid | $10^{-14}$ | $10^{-10}$ | $10^{-10}$–$10^{-34}$ | $10^{-6}$–$10^{-30}$ | Approximate theories exist; strong temperature dependence |

**TABLE 5-10 Correlations of Diffusivities for Gases**

| Authors* | Equation | | Error, % |
|---|---|---|---|
| | 1. Binary Mixtures—Low Pressure—Nonpolar | | |
| Chapman-Enskog | $D_{AB} = \dfrac{0.001858 T^{3/2} M_{AB}^{1/2}}{P\sigma_{AB}^2 \Omega_D}$ | (5-202) | 7.3 |
| Wilke-Lee [31] | $D_{AB} = \dfrac{(0.00217 - 0.0005 M_{AB}^{1/2})\, T^{3/2} M_{AB}^{1/2}}{P\sigma_{AB}^2 \Omega_D}$ | (5-203) | 7.0 |
| Fuller-Schettler-Giddings [10] | $D_{AB} = \dfrac{0.001 T^{1.75} M_{AB}^{1/2}}{P\,[(\sum v)_A^{1/3} + (\sum v)_B^{1/3}]^2}$ | (5-204) | 5.4 |
| | 2. Binary Mixtures—Low Pressure—Polar | | |
| Brokaw [4] | $D_{AB} = \dfrac{0.001858 T^{3/2} M_{AB}^{1/2}}{P\sigma_{AB}^2 \Omega_D}$ | (5-205) | 9.0 |
| | 3. Self-Diffusivity | | |
| Mathur-Thodos [18] | $D_{AA} = \dfrac{10.7 \times 10^{-5} T_r}{\beta \rho_r}$ $\{\rho_r \le 1.5\}$ | (5-206) | 5 |
| Lee-Thodos [14] | $D_{AA} = \dfrac{0.77 \times 10^{-5} T_r}{\rho_r \delta}$ $\{\rho_r \le 1\}$ | (5-207) | 0.5 |
| Lee-Thodos [15] | $D_{AA} = \dfrac{(0.007094G + 0.001916)^{2.5} T_r}{\delta}$, $[\rho_r > 1, G < 1]$ | (5-208) | 17 |
| | 4. Supercritical Mixtures | | |
| Sun and Chen [25] | $D_{AB} = \dfrac{1.23 \times 10^{-10} T}{\mu^{0.799} V_{C_A}^{0.49}}$ | (5-209) | 5 |
| Catchpole and King [6] | $D_{AB} = 5.152\, D_c T_r \dfrac{(\rho^{-0.667} - 0.4510)\,(1 + M_A/M_B)\, R}{(1 + (V_{cB}/V_{cA})^{0.333})^2}$ | (5-210) | 10 |
| Liu and Ruckenstein [17] | $D_{AB} = \dfrac{kT}{f\pi\mu_A\sigma_{AB}} \left[ \dfrac{1}{1 + \frac{2}{3}\left(1 - \frac{1}{2}\theta_{AB}^{\infty}\right)^{1/2}} + \dfrac{\sigma_{AB}}{3\sigma_A} \right]$ | (5-211) | 5.7 |
| | $D_{AB} = \alpha\left(V_A^k - \beta\right)\sqrt{\dfrac{T}{M_B}}$, $\alpha = 10^{-5}\left[0.56392 + 2.1417 \exp\left(\dfrac{-0.95088\sqrt{M_A V_{C_A}}}{P_{C_A}}\right)\right]$ | (5-212) | 6.9 |
| | $\beta = 8.9061 + 0.93858 \dfrac{\sqrt{M_A V_{C_A}}}{P_{C_A}}$ | | |
| | $k = \dfrac{2}{3}\left[1 - 0.28 \exp\left(-0.3\sqrt{M_A}\rho_{r_A}\right)\right]$ | | |

*References are listed at the beginning of the "Mass Transfer" subsection.

available. The first is:

$$\Omega_D = (44.54 T^{*-4.909} + 1.911 T^{*-1.575})^{0.10} \qquad (5\text{-}213a)$$

where $T^* = kT/\varepsilon_{AB}$ and $\varepsilon_{AB} = (\varepsilon_A \varepsilon_B)^{1/2}$. Estimates for $\sigma_i$ and $\varepsilon_i$ are given in Table 5-11. This expression shows that $\Omega_D$ is proportional to temperature roughly to the –0.49 power at low temperatures and to the –0.16 power at high temperature. Thus, gas diffusivities are proportional to temperatures to the 2.0 power and 1.66 power, respectively, at low and high temperatures. The second is:

$$\Omega_D = \frac{A}{T^{*B}} + \frac{C}{\exp(DT^*)} + \frac{E}{\exp(FT^*)} + \frac{G}{\exp(HT^*)} \qquad (5\text{-}213b)$$

**TABLE 5-11 Estimates for $\varepsilon_i$ and $\sigma_i$ (K, Å, atm, cm³, mol)**

| | | |
|---|---|---|
| Critical point | $\varepsilon/k = 0.75\, T_c$ | $\sigma = 0.841\, V_c^{1/3}$ or $2.44\,(T_c/P_c)^{1/3}$ |
| Critical point | $\varepsilon/k = 65.3\, T_c z_c^{3.6}$ | $\sigma = \dfrac{1.866\, V_c^{1/3}}{z_c^{1.2}}$ |
| Normal boiling point | $\varepsilon/k = 1.15\, T_b$ | $\sigma = 1.18\, V_b^{1/3}$ |
| Melting point | $\varepsilon/k = 1.92\, T_m$ | $\sigma = 1.222\, V_m^{1/3}$ |
| Acentric factor | $\varepsilon/k = (0.7915 + 0.1693\,\omega)\, T_c$ | $\sigma = (2.3551 - 0.087\,\omega)\left(\dfrac{T_c}{P_c}\right)^{1/3}$ |

NOTE: These values may not agree closely, so usage of a consistent basis is suggested (e.g., data at the normal boiling point).

**TABLE 5-12 Atomic Diffusion Volumes for Use in Estimating $D_{AB}$ by the Method of Fuller, Schettler, and Giddings [10]**

| Atomic and Structural Diffusion–Volume Increments, $v_i$ (cm³/mol) | | | |
|---|---|---|---|
| C | 16.5 | (Cl) | 19.5 |
| H | 1.98 | (S) | 17.0 |
| O | 5.48 | Aromatic ring | −20.2 |
| (N) | 5.69 | Heterocyclic ring | −20.2 |
| **Diffusion Volumes for Simple Molecules, $\Sigma v_i$ (cm³/mol)** | | | |
| $H_2$ | 7.07 | CO | 18.9 |
| $D_2$ | 6.70 | $CO_2$ | 26.9 |
| He | 2.88 | $N_2O$ | 35.9 |
| $N_2$ | 17.9 | $NH_3$ | 14.9 |
| $O_2$ | 16.6 | $H_2O$ | 12.7 |
| Air | 20.1 | $(CCl_2F_2)$ | 114.8 |
| Ar | 16.1 | $(SF_5)$ | 69.7 |
| Kr | 22.8 | $(Cl_2)$ | 37.7 |
| (Xe) | 37.9 | $(Br_2)$ | 67.2 |
| Ne | 5.59 | $(SO_2)$ | 41.1 |

Parentheses indicate that the value listed is based on only a few data points.

where $A = 1.06036$, $B = 0.15610$, $C = 0.1930$, $D = 0.47635$, $E = 1.03587$, $F = 1.52996$, $G = 1.76474$, and $H = 3.89411$.

***Fuller, Schettler, and Giddings [10]*** The parameters and constants for this correlation were determined by regression analysis of 340 experimental diffusion coefficient values of 153 binary systems. Values of $\sum v_i$ used in this equation are in Table 5-12.

**Binary Mixtures—Low Pressure—Polar Components** The *Brokaw* [4] correlation was based on the Chapman-Enskog equation, but $\sigma_{AB^*}$ and $\Omega_{D^*}$ were evaluated with a modified Stockmayer potential for polar molecules. Hence, slightly different symbols are used. That potential model reduces to the Lennard-Jones 6-12 potential for interactions between nonpolar molecules. As a result, the method should yield accurate predictions for polar as well as nonpolar gas mixtures. Brokaw presented data for 9 relatively polar pairs along with the prediction. The agreement was good: an average absolute error of 6.4 percent, considering the complexity of some of the gas pairs [e.g., $(CH_3)_2O$ and $CH_3Cl$]. Despite that, Poling, (op. cit.) found the average error was 9.0 percent for combinations of mixtures (including several polar-nonpolar gas pairs), temperatures and pressures. In this equation, $\Omega_D$ is calculated as described previously, and other terms are:

$$\Omega_{D^*} = \Omega_D + 0.19\,\delta_{AB}^2/T^* \qquad T^* = kT/\varepsilon_{AB^*}$$
$$\sigma_{AB^*} = (\sigma_{A^*}\,\sigma_{B^*})^{1/2} \qquad \sigma_{i^*} = [1.585\,V_{bi}/(1 + 1.3\,\delta_i^2)]^{1/3}$$
$$\delta_{AB} = (\delta_A\,\delta_B)^{1/2} \qquad \delta_i = 1.94 \times 10^3\,\mu_i^2/V_{bi}T_{bi}$$
$$\varepsilon_{AB^*} = (\varepsilon_{A^*}\varepsilon_{B^*})^{1/2} \qquad \varepsilon_{i^*}/k = 1.18\,(1 + 1.3\,\delta_i^2)T_{bi}$$

**Binary Mixtures—High Pressure** Of the various categories of gas-phase diffusion, this is the least studied. This is so because of the effects of diffusion being easily distorted by even a slight pressure gradient, which is difficult to avoid at high pressure. Harstad and Bellan [*Ind. Eng. Chem. Res.* **43,** 645 (2004)] developed a corresponding-states expression that extends the Chapman-Enskog method, covered earlier. They express the diffusivity at high pressure by accounting for the reduced temperature, and they suggest employing an equation of state and shifting from $D_{AB}^o = f(T, P)$ to $D_{AB} = g(T, V)$.

**Self-Diffusivity** Self-diffusivity is a property that has little intrinsic value, e.g., for solving separation problems. Despite that, it reveals quite a lot about the inherent nature of molecular transport, because the effects of discrepancies of other physical properties are eliminated, except for those that constitute isotopic differences, which are necessary to ascertain composition differences. Self-diffusivity has been studied extensively under high pressures, e.g., greater than 70 atm. There are few accurate estimation methods for mutual diffusivities at such high pressures, because composition measurements are difficult.

The general observation for gas-phase diffusion $D_{AB}\,P$ = constant, which holds at low pressure, is not valid at high pressure. Rather, $D_{AB}\,P$ decreases as pressure increases. In addition, composition effects, which frequently are negligible at low pressure, are very significant at high pressure.

*Liu and Ruckenstein* [*Ind. Eng. Chem. Res.* **36**, 3937 (1997)] studied self-diffusion for both liquids and gases. They proposed a semiempirical equation, based on hard-sphere theory, to estimate self-diffusivities. They extended it to Lennard-Jones fluids. The necessary energy parameter is estimated from viscosity data, but the molecular collision diameter is estimated from diffusion data. They compared their estimates to 26 pairs, with a total of 1822 data points, and achieved a relative deviation of 7.3 percent.

*Zielinski and Hanley* [*AIChE J.* **45**, 1 (1999)] developed a model to predict multicomponent diffusivities from self-diffusion coefficients and thermodynamic information. Their model was tested by estimated experimental diffusivity values for ternary systems, predicting drying behavior of ternary systems, and reconciling ternary self-diffusion data measured by pulsed-field gradient NMR.

*Mathur and Thodos* [18] showed that for reduced densities less than unity, the product $D_{AA}\rho$ is approximately constant at a given temperature. Thus, by knowing the value of the product at low pressure, it is possible to estimate its value at a higher pressure. They found at higher pressures the density increases, but the product $D_{AA}\rho$ decreases rapidly. In their correlation, $\beta = M_A^{1/2}P_C^{1/3}/T_C^{5/6}$.

*Lee and Thodos* [14] presented a generalized treatment of self-diffusivity for gases (and liquids). These correlations have been tested for more than 500 data points each. The average deviation of the first is 0.51 percent, and that of the second is 17.2 percent. $\delta = M_A^{1/2}/P_c^{1/2}V_c^{5/6}$, s/cm², and where $G = (X^* - X)/(X^* - 1)$, $X = \rho_r/T_r^{0.1}$, and $X^* = \rho_r/T_r^{0.1}$ evaluated at the solid melting point.

Lee and Thodos [15] expanded their earlier treatment of self-diffusivity to cover 58 substances and 975 data points, with an average absolute deviation of 5.26 percent. Their correlation is too involved to repeat here, but those interested should refer to the original paper.

*Liu, Silva, and Macedo* [*Chem. Eng. Sci.* **53**, 2403 (1998)] present a theoretical approach incorporating hard-sphere, square-well, and Lennard-Jones models. They compared their resulting estimates to estimates generated via the Lee-Thodos equation. For 2047 data points with nonpolar species, the Lee-Thodos equation was slightly superior to the Lennard-Jones fluid-based model, that is, 5.2 percent average deviation versus 5.5 percent, and much better than the square-well fluid-based model (10.6 percent deviation). For over 467 data points with polar species, the Lee-Thodos equation yielded 36 percent average deviation, compared with 25 percent for the Lennard-Jones fluid-based model, and 19 percent for the square-well fluid-based model.

*Silva, Liu, and Macedo* [*Chem. Eng. Sci.* **53**, 2423 (1998)] present an improved theoretical approach incorporating slightly different Lennard-Jones models. For 2047 data points with nonpolar species, their best model yielded 4.5 percent average deviation, while the Lee-Thodos equation yielded 5.2 percent, and the prior Lennard-Jones fluid-based model produced 5.5 percent. The new model was much better than all the other models for over 424 data points with polar species, yielding 4.3 percent deviation, while the Lee-Thodos equation yielded 34 percent and the Lennard-Jones fluid-based model yielded 23 percent.

**Supercritical Mixtures** *Debenedetti and Reid* [*AIChE J.,* **32,** 2034 (1986) and **33,** 496 (1987)] showed that conventional correlations based on the Stokes-Einstein relation (for liquid phase) tend to overpredict diffusivities in the supercritical state. Nevertheless, they observed that the Stokes-Einstein group $D_{AB}\mu/T$ was constant. Thus, although no general correlation applies, only one data point is necessary to examine variations of fluid viscosity and/or temperature effects. They explored certain combinations of aromatic solids in $SF_6$ and $CO_2$.

*Sun and Chen* [25] examined tracer diffusion data of aromatic solutes in alcohols up to the supercritical range and found their data correlated with average deviations of 5 percent and a maximum deviation of 17 percent for their rather limited set of data.

*Catchpole and King* [6] examined binary diffusion data of near-critical fluids in the reduced density range of 1 to 2.5 and found that their data correlated with average deviations of 10 percent and a maximum deviation of 60 percent. They observed two classes of behavior. For the first, no correction factor was required ($R = 1$). That class was comprised of alcohols as solvents with aromatic or aliphatic solutes, or

carbon dioxide as a solvent with aliphatics except ketones as solutes, or ethylene as a solvent with aliphatics except ketones and naphthalene as solutes. For the second class, the correction factor was $R = X^{0.17}$. The class was comprised of carbon dioxide with aromatics; ketones and carbon tetrachloride as solutes; and aliphatics (propane, hexane, dimethyl butane), sulfur hexafluoride, and chlorotrifluoromethane as solvents with aromatics as solutes. In addition, sulfur hexafluoride combined with carbon tetrachloride, and chlorotrifluoromethane combined with 2-propanone were included in that class. In all cases, $X = (1 + (V_{cB}/V_{cA})^{1/3})^2/(1 + M_A/M_B)$ was in the range of 1 to 10.

*Liu and Ruckenstein* [17] presented a semiempirical equation to estimate diffusivities under supercritical conditions that is based on the Stokes-Einstein relation and the long-range correlation, respectively. The parameter $2\theta^{\circ}_{AB}$ was estimated from the Peng-Robinson equation of state. In addition, $f = 2.72 - 0.3445\ T_{cB}/T_{cA}$ for most solutes, but for $C_5$ through $C_{14}$ linear alkanes, $f = 3.046 - 0.786\ T_{cB}/T_{cA}$. In both cases $T_{ci}$ is the species critical temperature. They compared their estimates to 33 pairs, with a total of 598 data points, and achieved lower deviations (5.7 percent) than the Sun-Chen correlation (13.3 percent) and the Catchpole-King equation (11.0 percent).

*He and Yu* [13] presented a semiempirical equation to estimate diffusivities under supercritical conditions that is based on hard-sphere theory. It is limited to $\rho_r \geq 0.21$, where the reduced density is $\rho_r = \rho_A(T, P)/\rho_{cA}$. They compared their estimates to 107 pairs, with a total of 1167 data points, and achieved lower deviations (7.8 percent) than the Catchpole-King equation (9.7 percent), which was restricted to $\rho_r \geq 1$.

*Silva and Macedo* [*Ind. Eng. Chem. Res.* **37,** 1490 (1998)] measured diffusivities of ethers in $CO_2$ under supercritical conditions and compared them to the Wilke-Chang [Eq. (5-218)], Tyn-Calus [Eq. (5-219)], Catchpole-King [Eq. (5-210)], and their own equations. They found that the Wilke-Chang equation provided the best fit.

*Gonzalez, Bueno, and Medina* [*Ind. Eng. Chem. Res.* **40**, 3711 (2001)] measured diffusivities of aromatic compounds in $CO_2$ under supercritical conditions and compared them to the Wilke-Chang [Eq. (5-218)], Hayduk-Minhas [Eq. (5-226)], and other equations. They recommended the Wilke-Chang equation (which yielded a relative error of 10.1 percent) but noted that the He-Yu equation provided the best fit (5.5 percent).

**Low-Pressure/Multicomponent Mixtures** These methods are outlined in Table 5-13. Stefan-Maxwell equations were discussed earlier. *Smith and Taylor* [23] compared various methods for predicting multicomponent diffusion rates and found that Eq. (5-214) was superior among the effective diffusivity approaches, though none is very good. They also found that linearized and exact solutions are roughly equivalent and accurate.

*Blanc* [3] provided a simple limiting case for dilute component *i* diffusing in a stagnant medium (i.e., $N \approx 0$), and the result, Eq. (5-215), is known as Blanc's law. The restriction basically means that the compositions of all the components, besides component *i,* are relatively large and uniform.

*Wilke* [29] obtained solutions to the Stefan-Maxwell equations. The first, Eq. (5-216), is simple and reliable under the same conditions as Blanc's law. This equation applies when component *i* diffuses through a stagnant mixture. It has been tested and verified for diffusion of toluene in hydrogen + air + argon mixtures and for diffusion of ethyl propionate in hydrogen + air mixtures [Fairbanks and Wilke *Ind. Eng. Chem.,* **42,** 471 (1950)]. When the compositions vary from one boundary to the other, Wilke recommends that the arithmetic average mole fractions be used. Wilke also suggested using the Stefan-Maxwell equation, which applies when the fluxes of two or more components are significant. In this situation, the mole fractions are arithmetic averages of the boundary conditions, and the solution requires iteration because the ratio of fluxes is not known a priori.

## DIFFUSIVITY ESTIMATION—LIQUIDS

Many more correlations are available for diffusion coefficients in the liquid phase than for the gas phase. Most, however, are restricted to binary diffusion at infinite dilution $D^{\circ}_{AB}$ or to self-diffusivity $D_{A'A}$. This reflects the much greater complexity of liquids on a molecular level. For example, gas-phase diffusion exhibits negligible composition effects and deviations from thermodynamic ideality. Conversely, liquid-phase diffusion almost always involves volumetric and thermodynamic effects due to composition variations. For concentrations greater than a few mole percent of *A* and *B,* corrections are needed to obtain the true diffusivity. Furthermore, there are many conditions that do not fit any of the correlations presented here. Thus, careful consideration is needed to produce a reasonable estimate. Again, if diffusivity data are available at the conditions of interest, then they are strongly preferred over the predictions of any correlations. Experimental values for liquid mixtures are listed in Table 2-325.

**Stokes-Einstein and Free-Volume Theories** The starting point for many correlations is the Stokes-Einstein equation. This equation is derived from continuum fluid mechanics and classical thermodynamics for the motion of large spherical particles in a liquid. For this case, the need for a molecular theory is cleverly avoided. The Stokes-Einstein equation is (Bird et al.)

$$D_{AB} = \frac{kT}{6\pi r_A \mu_B} \tag{5-217}$$

where *A* refers to the solute and *B* refers to the solvent. This equation is applicable to very large unhydrated molecules ($M > 1000$) in low-molecular-weight solvents or where the molar volume of the solute is greater than 500 $cm^3$/mol (Reddy and Doraiswamy, *Ind. Eng. Chem. Fundam.,* **6,** 77 (1967); Wilke and Chang [30]). Despite its intellectual appeal, this equation is seldom used "as is." Rather, the following principles have been identified: (1) The diffusion coefficient is inversely proportional to the size $r_A \simeq V_A^{1/3}$ of the solute molecules. Experimental observations, however, generally indicate that the exponent of the solute molar volume is larger than one-third. (2) The term $D_{AB}\mu_B/T$ is approximately constant only over a 10-to-15 K interval. Thus, the dependence of liquid diffusivity on properties and conditions does not generally obey the interactions implied by that grouping. For example, Robinson, Edmister, and Dullien [*Ind. Eng. Chem. Fundam.,* **5,** 75 (1966)] found that $\ln D_{AB} \propto -1/T$. (3) Finally, pressure does not affect liquid-phase diffusivity much, since $\mu_B$ and $V_A$ are only weakly pressure-dependent. Pressure does have an impact at very high levels.

**TABLE 5-13 Relationships for Diffusivities of Multicomponent Gas Mixtures at Low Pressure**

| Authors* | Equation |
|---|---|
| Stefan-Maxwell, Smith and Taylor [23] | $D_{im} = \left[1 - x_i \left(\sum_{j=1}^{NC} N_j\right)\Big/ N_i\right]\Big/ \sum_{j=1}^{NC} \left[\left(x_j - \frac{x_i N_i}{N_i}\right)\Big/ D_{ij}\right]$ (5-214) |
| Blanc [2] | $D_{im} = \left(\sum_{j=1}^{NC} \frac{x_j}{D_{ij}}\right)^{-1}$ (5-215) |
| Wilke [29] | $D_{im} = \left(\sum_{\substack{j=1 \\ j \neq i}}^{NC} \frac{x_j}{D_{ij}}\right)^{-1}$ (5-216) |

*References are listed at the beginning of the "Mass Transfer" subsection.

Another advance in the concepts of liquid-phase diffusion was provided by Hildebrand [*Science,* **174,** 490 (1971)] who adapted a theory of viscosity to self-diffusivity. He postulated that $D_{A'A} = B(V - V_{ms})/V_{ms}$, where $D_{A'A}$ is the self-diffusion coefficient, $V$ is the molar volume, and $V_{ms}$ is the molar volume at which fluidity is zero (i.e., the molar volume of the solid phase at the melting temperature). The difference $(V - V_{ms})$ can be thought of as the free volume, which increases with temperature; and $B$ is a proportionality constant.

Ertl and Dullien (ibid.) found that Hildebrand's equation could not fit their data with $B$ as a constant. They modified it by applying an empirical exponent $n$ (a constant greater than unity) to the volumetric ratio. The new equation is not generally useful, however, since there is no means for predicting $n$. The theory does identify the free volume as an important physical variable, since $n > 1$ for most liquids implies that diffusion is more strongly dependent on free volume than is viscosity.

**Dilute Binary Nonelectrolytes: General Mixtures** These correlations are outlined in Table 5-14.

***Wilke-Chang* [30]** This correlation for $D^{\circ}_{AB}$ is one of the most widely used, and it is an empirical modification of the Stokes-Einstein equation. It is not very accurate, however, for water as the solute. Otherwise, it applies to diffusion of very dilute $A$ in $B$. The average absolute error for 251 different systems is about 10 percent. $\phi_B$ is an association factor of solvent $B$ that accounts for hydrogen bonding.

| Component $B$ | $\phi_B$ |
|---|---|
| Water | 2.26 |
| Methanol | 1.9 |
| Ethanol | 1.5 |
| Propanol | 1.2 |
| Others | 1.0 |

The value of $\phi_B$ for water was originally stated as 2.6, although when the original data were reanalyzed, the empirical best fit was 2.26. Random comparisons of predictions with 2.26 versus 2.6 show no consistent advantage for either value, however. Kooijman [*Ind. Eng. Chem. Res.* **41,** 3326 (2002)] suggests replacing $V_A$ with $\theta_A V_A$, in which $\theta_A = 1$ except when $A$ = water, $\theta_A = 4.5$. This modification leads to an overall error of 8.7 percent for 41 cases he compared. He suggests retaining $\Phi_B = 2.6$ when $B$ = water. It has been suggested to replace the exponent of 0.6 with 0.7 and to use an association factor of 0.7 for systems containing aromatic hydrocarbons. These modifications, however, are not recommended by Umesi and Danner [27]. Lees and Sarram [*J. Chem. Eng. Data,* **16,** 41 (1971)] present a comparison of the association parameters. The average absolute error for 87 different solutes in water is 5.9 percent.

***Tyn-Calus* [26]** This correlation requires data in the form of molar volumes and parachors $\psi_i = V_i\sigma_i^{1/4}$ (a property which, over moderate temperature ranges, is nearly constant), measured at the same temperature (not necessarily the temperature of interest). The parachors for the components may also be evaluated at different temperatures from each other. Quale [Chem. Rev. **53,** 439 (1953)] has compiled values of $\psi_i$ for many chemicals. Group contribution methods are available for estimation purposes (Poling et al.). The following suggestions were made by Poling et al.: The correlation is constrained to cases in which $\mu_B < 30$ cP. If the solute is water or if the solute is an organic acid and the solvent is not water or a short-chain alcohol, dimerization of the solute $A$ should be assumed for purposes of estimating its volume and parachor. For example, the appropriate values for water as solute at 25°C are $V_W = 37.4$ cm$^3$/mol and $\psi_W = 105.2$ cm$^3$g$^{1/4}$/s$^{1/2}$mol. Finally, if the solute is nonpolar, the solvent volume and parachor should be multiplied by $8\mu_B$. According to Kooijman (ibid.), if the Brock-Bird method (described in Poling et al.) is used to

**TABLE 5-14 Correlations for Diffusivities of Dilute, Binary Mixtures of Nonelectrolytes in Liquids**

| Authors* | Equation | | Error |
|---|---|---|---|
| 1. General Mixtures | | | |
| Wilke-Chang [30] | $D^{\circ}_{AB} = \dfrac{7.4 \times 10^{-8}\,(\phi_B M_B)^{1/2}\,T}{\mu_B\,V_A^{0.6}}$ | (5-218) | 20% |
| Tyn-Calus [26] | $D^{\circ}_{AB} = \dfrac{8.93 \times 10^{-8}\,(V_A/V_B^2)^{1/6}\,(\psi_B/\psi_A)^{0.6}\,T}{\mu_B}$ | (5-219) | 10% |
| Umesi-Danner [27] | $D^{\circ}_{AB} = \dfrac{2.75 \times 10^{-8}\,(R_B/R_A^{2/3})\,T}{\mu_B}$ | (5-220) | 16% |
| Siddiqi-Lucas [22] | $D^{\circ}_{AB} = \dfrac{9.89 \times 10^{-8}\,V_B^{0.265}\,T}{V_A^{0.45}\,\mu_B^{0.907}}$ | (5-221) | 13% |
| 2. Gases in Low Viscosity Liquids | | | |
| Sridhar-Potter [24] | $D^{\circ}_{AB} = D_{BB}\left(\dfrac{V_{c_B}}{V_{c_A}}\right)^{2/3}\left(\dfrac{V_B}{V_{ml_B}}\right)$ | (5-222) | 18% |
| Chen-Chen [7] | $D^{\circ}_{AB} = 2.018 \times 10^{-9}\,\dfrac{(\beta V_{c_B})^{2/3}(RT_{c_B})^{1/2}}{M_A^{1/6}\,(M_B V_{c_A})^{1/3}}\,(V_r - 1)\left(\dfrac{T}{T_{c_B}}\right)^{1/2}$ | (5-223) | 6% |
| 3. Aqueous Solutions | | | |
| Hayduk-Laudie [11] | $D^{\circ}_{AW} = \dfrac{13.16 \times 10^{-5}}{\mu_w^{1.14}\,V_A^{0.589}}$ | (5-224) | 18% |
| Siddiqi-Lucas [22] | $D^{\circ}_{AW} = 2.98 \times 10^{-7}\,V_A^{-0.5473}\,\mu_w^{-1.026}\,T$ | (5-225) | 13% |
| 4. Hydrocarbon Mixtures | | | |
| Hayduk-Minhas [12] | $D^{\circ}_{AB} = 13.3 \times 10^{-8}\,T^{1.47}\,\mu_B^{(10.2/V_A - 0.791)}\,V_A^{-0.71}$ | (5-226) | 5% |
| Matthews-Akgerman [19] | $D^{\circ}_{AB} = 32.88\,M_A^{-0.61}V_D^{-1.04}\,T^{0.5}\,(V_B - V_D)$ | (5-227) | 5% |
| Riazi-Whitson [21] | $D_{AB} = 1.07\,\dfrac{(\rho D_{AB})^{\circ}}{\rho}\left(\dfrac{\mu}{\mu^{\circ}}\right)^{-0.27 - 0.38\,\omega + (-0.05 + 0.1\,\omega)P_r}$ | (5-228) | 15% |

*References are listed at the beginning of the "Mass Transfer" subsection.

estimate the surface tension, the error is only increased by about 2 percent, relative to employing experimentally measured values.

***Umesi-Danner [27]*** They developed an equation for nonaqueous solvents with nonpolar and polar solutes. In all, 258 points were involved in the regression. $R_i$ is the radius of gyration in Å of the component molecule, which has been tabulated by Passut and Danner [*Chem. Eng. Progress Symp. Ser.,* **140,** 30 (1974)] for 250 compounds. The average absolute deviation was 16 percent, compared with 26 percent for the Wilke-Chang equation.

***Siddiqi-Lucas [22]*** In an impressive empirical study, these authors examined 1275 organic liquid mixtures. Their equation yielded an average absolute deviation of 13.1 percent, which was less than that for the Wilke-Chang equation (17.8 percent). Note that this correlation does not encompass aqueous solutions; those were examined and a separate correlation was proposed, which is discussed later.

**Binary Mixtures of Gases in Low-Viscosity, Nonelectrolyte Liquids** *Sridhar and Potter* [24] derived an equation for predicting gas diffusion through liquid by combining existing correlations. Hildebrand had postulated the following dependence of the diffusivity for a gas in a liquid: $D^\circ_{AB} = D_{B'B}(V_{cB}/V_{cA})^{2/3}$, where $D_{B'B}$ is the solvent self-diffusion coefficient and $V_{ci}$ is the critical volume of component $i$, respectively. To correct for minor changes in volumetric expansion, Sridhar and Potter multiplied the resulting equation by $V_B/V_{mlB}$, where $V_{mlB}$ is the molar volume of the liquid $B$ at its melting point and $D_{B'B}$ can be estimated by the equation of Ertl and Dullien (see p. 5-54). Sridhar and Potter compared experimentally measured diffusion coefficients for twenty-seven data points of eleven binary mixtures. Their average absolute error was 13.5 percent, but Chen and Chen [7] analyzed about 50 combinations of conditions and 3 to 4 replicates each and found an average error of 18 percent. This correlation does not apply to hydrogen and helium as solutes. However, it demonstrates the usefulness of self-diffusion as a means to assess mutual diffusivities and the value of observable physical property changes, such as molar expansion, to account for changes in conditions.

***Chen-Chen [7]*** Their correlation was based on diffusion measurements of 50 combinations of conditions with 3 to 4 replicates each and exhibited an average error of 6 percent. In this correlation, $V_r = V_B/[0.9724\ (V_{mlB} + 0.04765)]$ and $V_{mlB}$ = the liquid molar volume at the melting point, as discussed previously. Their association parameter $\beta$ [which is different from the definition of that symbol in Eq. (5-229)] accounts for hydrogen bonding of the solvent. Values for acetonitrile and methanol are: $\beta = 1.58$ and 2.31, respectively.

**Dilute Binary Mixtures of a Nonelectrolyte in Water** The correlations that were suggested previously for general mixtures, unless specified otherwise, may also be applied to diffusion of miscellaneous solutes in water. The following correlations are restricted to the present case, however.

***Hayduk and Laudie [11]*** They presented a simple correlation for the infinite dilution diffusion coefficients of nonelectrolytes in water. It has about the same accuracy as the Wilke-Chang equation (about 5.9 percent). There is no explicit temperature dependence, but the 1.14 exponent on $\mu_w$ compensates for the absence of $T$ in the numerator. That exponent was misprinted (as 1.4) in the original article and has been reproduced elsewhere erroneously.

***Siddiqi and Lucas [227]*** These authors examined 658 aqueous liquid mixtures in an empirical study. They found an average absolute deviation of 19.7 percent. In contrast, the Wilke-Chang equation gave 35.0 percent and the Hayduk-Laudie correlation gave 30.4 percent.

**Dilute Binary Hydrocarbon Mixtures** *Hayduk and Minhas* [12] presented an accurate correlation for normal paraffin mixtures that was developed from 58 data points consisting of solutes from $C_5$ to $C_{32}$ and solvents from $C_5$ to $C_{16}$. The average error was 3.4 percent for the 58 mixtures.

***Matthews and Akgerman [19]*** The free-volume approach of Hildebrand was shown to be valid for binary, dilute liquid paraffin mixtures (as well as self-diffusion), consisting of solutes from $C_8$ to $C_{16}$ and solvents of $C_6$ and $C_{12}$. The term they referred to as the "diffusion volume" was simply correlated with the critical volume, as $V_D = 0.308\ V_c$. We can infer from Table 5-11 that this is approximately related to the volume at the melting point as $V_D = 0.945\ V_m$. Their correlation was valid for diffusion of linear alkanes at temperatures up to 300°C and pressures up to 3.45 MPa. Matthews, Rodden, and Akgerman [*J. Chem. Eng. Data,* **32,** 317 (1987)] and Erkey and Akgerman [*AIChE J.,* **35,** 443 (1989)] completed similar studies of diffusion of alkanes, restricted to *n*-hexadecane and *n*-octane, respectively, as the solvents.

***Riazi and Whitson [21]*** They presented a generalized correlation in terms of viscosity and molar density that was applicable to both gases and liquids. The average absolute deviation for gases was only about 8 percent, while for liquids it was 15 percent. Their expression relies on the Chapman-Enskog correlation [Eq. (5-202)] for the low-pressure diffusivity and the Stiel-Thodos [*AIChE J.,* **7,** 234 (1961)] correlation for low-pressure viscosity:

$$\mu^\circ = \frac{x_A \mu^\circ_A M_A^{1/2} + x_B \mu^\circ_B M_B^{1/2}}{x_A M_A^{1/2} + x_B M_B^{1/2}}$$

where $\mu^\circ_i \xi_i = 3.4 \times 10^{-4}\ T_{r^i}^{0.94}$ for $T_{r^i} < 1.5$ or $\mu^\circ_i \xi_i = 1.778 \times 10^{-4}\ (4.58\ T_{r^i} - 1.67)^{5/8}$ for $T_{r^i} > 1.5$. In these equations, $\xi_i = T_{c^i}^{1/6}/P_{c^i}^{2/3}\ M_i^{1/2}$, and units are in cP, atm, K, and mol. For dense gases or liquids, the Chung et al; [*Ind. Eng. Chem. Res.,* **27,** 671 (1988)] or Jossi-Stiel-Thodos [*AIChE J.,* **8,** 59 (1962)] correlation may be used to estimate viscosity. The latter is:

$$(\mu - \mu^\circ)\,\xi + 10^{-4} = (0.1023 + 0.023364\ \rho_r + 0.058533\ \rho_r^2 - 0.040758\ \rho_r^3 + 0.093324\ \rho_r^4)^4$$

where

$$\xi = \frac{(x_A\ T_{c_A} + x_B T_{c_B})^{1/6}}{(x_A M_A + x_B M_B)^{1/2}\ (x_A\ P_{c_A} + x_B\ P_{c_B})}$$

and

$$\rho_r = (x_A\ V_{c_A} + x_B\ V_{c_B})\rho.$$

**Dilute Binary Mixtures of Nonelectrolytes with Water as the Solute** *Olander* [*AIChE J.,* **7,** 175 (1961)] modified the Wilke-Chang equation to adapt it to the infinite dilution diffusivity of water as the solute. The modification he recommended is simply the division of the right-hand side of the Wilke-Chang equation by 2.3. Unfortunately, neither the Wilke-Chang equation nor that equation divided by 2.3 fit the data very well. A reasonably valid generalization is that the Wilke-Chang equation is accurate if water is very insoluble in the solvent, such as pure hydrocarbons, halogenated hydrocarbons, and nitro-hydrocarbons. On the other hand, the Wilke-Chang equation divided by 2.3 is accurate for solvents in which water is very soluble, as well as those that have low viscosities. Such solvents include alcohols, ketones, carboxylic acids, and aldehydes. Neither equation is accurate for higher-viscosity liquids, especially diols.

**Dilute Dispersions of Macromolecules in Nonelectrolytes** The Stokes-Einstein equation has already been presented. It was noted that its validity was restricted to large solutes, such as spherical macromolecules and particles in a continuum solvent. The equation has also been found to predict accurately the diffusion coefficient of spherical latex particles and globular proteins. Corrections to Stokes-Einstein for molecules approximating spheroids is given by Tanford *Physical Chemistry of Macromolecules,* Wiley, New York, (1961). Since solute-solute interactions are ignored in this theory, it applies in the dilute range only.

***Hiss and Cussler*** *[*AIChE J., ***19,*** *698 (1973)]* Their basis is the diffusion of a small solute in a fairly viscous solvent of relatively large molecules, which is the opposite of the Stokes-Einstein assumptions. The large solvent molecules investigated were not polymers or gels but were of moderate molecular weight so that the macroscopic and microscopic viscosities were the same. The major conclusion is that $D^\circ_{AB}\,\mu^{2/3} =$ constant at a given temperature and for a solvent viscosity from $5 \times 10^{-3}$ to 5 Pa·s or greater (5 to $5 \times 10^3$ cP). This observation is useful if $D^\circ_{AB}$ is known in a given high-viscosity liquid (oils, tars, etc.). Use of the usual relation of $D^\circ_{AB} \propto 1/\mu$ for such an estimate could lead to large errors.

**Concentrated, Binary Mixtures of Nonelectrolytes** Several correlations that predict the composition dependence of $D_{AB}$ are summarized in Table 5-15. Most are based on known values of $D^\circ_{AB}$ and $D^\circ_{BA}$. In fact, a rule of thumb states that, for many binary systems, $D^\circ_{AB}$ and $D^\circ_{BA}$ bound the $D_{AB}$ vs. $x_A$ curve. Cullinan's [8] equation predicts diffusivities even in lieu of values at infinite dilution, but requires accurate density, viscosity, and activity coefficient data.

**TABLE 5-15 Correlations of Diffusivities for Concentrated, Binary Mixtures of Nonelectrolyte Liquids**

| Authors* | Equation | |
|---|---|---|
| Caldwell-Babb [5] | $D_{AB} = (x_A D^\circ_{BA} + x_B D^\circ_{AB})\beta_A$ | (5-231) |
| Rathbun-Babb [20] | $D_{AB} = (x_A D^\circ_{BA} + x_B D^\circ_{AB})\beta_A^n$ | (5-232) |
| Vignes [28] | $D_{AB} = D_{AB}^{\circ x_B} D_{BA}^{\circ x_A} \beta_A$ | (5-233) |
| Leffler-Cullinan [16] | $D_{AB}\mu_{mix} = (D^\circ_{AB}\mu_B)^{x_B}(D^\circ_{BA}\mu_A)^{x_A}\beta_A$ | (5-234) |
| Cussler [9] | $D_{AB} = D_0\left[1 + \dfrac{K}{x_A x_B}\left(\dfrac{\partial \ln x_A}{\partial \ln a_A} - 1\right)\right]^{-1/2}$ | (5-235) |
| Cullinan [8] | $D_{AB} = \dfrac{kT}{2\pi\mu_{mix}(V/A)^{1/3}}\left[\dfrac{2\pi x_A x_B \beta_A}{1 + \beta_A(2\pi x_A x_B - 1)}\right]^{1/2}$ | (5-236) |
| Asfour-Dullien [1] | $D_{AB} = \left(\dfrac{D^\circ_{AB}}{\mu_B}\right)^{x_B}\left(\dfrac{D^\circ_{BA}}{\mu_A}\right)^{x_A}\zeta\mu\beta_A$ | (5-237) |
| Siddiqi-Lucas [22] | $D_{AB} = (C_B\overline{V}_B D^\circ_{AB} + C_A\overline{V}_A D^\circ_{BA})\beta_A$ | (5-238) |
| Bosse and Bart no. 1 [3] | $D_{AB} = (D^\infty_{AB})^{X_B}(D^\infty_{AB})^{X_A}\exp\left(-\dfrac{g^E}{RT}\right)$ | (5-239) |
| Bosse and Bart no. 2 [3] | $\mu D_{AB} = (\mu_\beta D^\infty_{AB})^{X_B}(\mu_A D^\infty_{BA})^{X_A}\exp\left(-\dfrac{g^E}{RT}\right)$ | (5-240) |

Relative errors for the correlations in this table are very dependent on the components of interest and are cited in the text.
*See the beginning of the "Mass Transfer" subsection for references.

Since the infinite dilution values $D^\circ_{AB}$ and $D^\circ_{BA}$ are generally unequal, even a thermodynamically ideal solution like $\gamma_A = \gamma_B = 1$ will exhibit concentration dependence of the diffusivity. In addition, nonideal solutions require a thermodynamic correction factor to retain the true "driving force" for molecular diffusion, or the gradient of the chemical potential rather than the composition gradient. That correction factor is:

$$\beta_A = 1 + \frac{\partial \ln \gamma_A}{\partial \ln x_A} \tag{5-229}$$

***Caldwell and Babb [5]*** Darken [*Trans. Am. Inst. Mining Met. Eng.*, **175,** 184 (1948)] observed that solid-state diffusion in metallurgical applications followed a simple relation. His equation related the tracer diffusivities and mole fractions to the mutual diffusivity:

$$D_{AB} = (x_A D_B + x_B D_A)\beta_A \tag{5-230}$$

Caldwell and Babb used virtually the same equation to evaluate the mutual diffusivity for concentrated mixtures of common liquids.

Van Geet and Adamson [*J. Phys. Chem.* **68,** 238 (1964)] tested that equation for the *n*-dodecane (*A*) and *n*-octane (*B*) system and found the average deviation of $D_{AB}$ from experimental values to be –0.68 percent. In addition, that equation was tested for benzene + bromobenzene, *n*-hexane + *n*-dodecane, benzene + $CCl_4$, octane + decane, heptane + cetane, benzene + diphenyl, and benzene + nitromethane with success. For systems that depart significantly from thermodynamic ideality, it breaks down, sometimes by a factor of eight. For example, in the binary systems acetone + $CCl_4$, acetone + chloroform, and ethanol + $CCl_4$, it is not accurate. Thus, it can be expected to be fairly accurate for nonpolar hydrocarbons of similar molecular weight but not for polar-polar mixtures. Siddiqi, Krahn, and Lucas [*J. Chem. Eng. Data,* **32,** 48 (1987)] found that this relation was superior to those of Vignes and Leffler and Cullinan for a variety of mixtures. Umesi and Danner [27] found an average absolute deviation of 13.9 percent for 198 data points.

*Rathbun and Babb* [20] suggested that Darken's equation could be improved by raising the thermodynamic correction factor $\beta_A$ to a power, *n*, less than unity. They looked at systems exhibiting negative deviations from Raoult's law and found $n = 0.3$. Furthermore, for polar-nonpolar mixtures, they found $n = 0.6$. In a separate study, Siddiqi and Lucas [22] followed those suggestions and found an average absolute error of 3.3 percent for nonpolar-nonpolar mixtures, 11.0 percent for polar-nonpolar mixtures, and 14.6 percent for polar-polar mixtures. Siddiqi, Krahn, and Lucas (ibid.) examined a few other mixtures and found that $n = 1$ was probably best. Thus, this approach is, at best, highly dependent on the type of components being considered.

*Vignes* [28] empirically correlated mixture diffusivity data for 12 binary mixtures. Later Ertl, Ghai, and Dollon [*AIChE J.,* **20,** 1 (1974)] evaluated 122 binary systems, which showed an average absolute deviation of only 7 percent. None of the latter systems, however, was very nonideal.

*Leffler and Cullinan* [16] modified Vignes' equation using some theoretical arguments to arrive at Eq. (5-234), which the authors compared to Eq. (5-233) for the 12 systems mentioned above. The average absolute maximum deviation was only 6 percent. Umesi and Danner [27], however, found an average absolute deviation of 11.4 percent for 198 data points. For normal paraffins, it is not very accurate. In general, the accuracies of Eqs. (5-233) and (5-234) are not much different, and since Vignes' is simpler to use, it is suggested. The application of either should be limited to nonassociating systems that do not deviate much from ideality ($0.95 < \beta_A < 1.05$).

*Cussler* [9] studied diffusion in concentrated associating systems and has shown that, in associating systems, it is the size of diffusing clusters rather than diffusing solutes that controls diffusion. $D_o$ is a reference diffusion coefficient discussed hereafter; $a_A$ is the activity of component *A*; and *K* is a constant. By assuming that $D_o$ could be predicted by Eq. (5-233) with $\beta = 1$, *K* was found to be equal to 0.5 based on five binary systems and validated with a sixth binary mixture. The limitations of Eq. (5-235) using $D_o$ and *K* defined previously have not been explored, so caution is warranted. Gurkan [*AIChE J.,* **33,** 175 (1987)] showed that *K* should actually be closer to 0.3 (rather than 0.5) and discussed the overall results.

*Cullinan* [8] presented an extension of Cussler's cluster diffusion theory. His method accurately accounts for composition and temperature dependence of diffusivity. It is novel in that it contains no adjustable constants, and it relates transport properties and solution thermodynamics. This equation has been tested for six very different mixtures by Rollins and Knaebel [*AIChE J.,* **37,** 470 (1991)], and it was found to agree remarkably well with data for most conditions, considering the absence of adjustable parameters. In the dilute region (of either *A* or *B*), there are systematic errors probably caused by the breakdown of certain implicit assumptions (that nevertheless appear to be generally valid at higher concentrations).

*Asfour and Dullien* [1] developed a relation for predicting alkane diffusivities at moderate concentrations that employs:

$$\zeta = \left(\frac{V_{f_m}}{V_{fx_A} V_{fx_B}}\right)^{2/3} \frac{M_{x_A} M_{x_B}}{M_m} \tag{5-241}$$

where $V_{fx_i} = V_{fi}^{x_i}$; the fluid free volume is $V_{f^i} = V_i - V_{ml^i}$ for $i = A$, $B$, and $m$, in which $V_{ml^i}$ is the molar volume of the liquid at the melting point and

$$V_{ml_m} = \left( \frac{x_A^2}{V_{ml_A}} + \frac{2x_A x_B}{V_{ml_{AB}}} + \frac{x_B^2}{V_{ml_B}} \right)^{-1}$$

and

$$V_{ml_{AB}} = \left[ \frac{V_{ml_A}^{1/3} + V_{ml_B}^{1/3}}{2} \right]^3$$

and $\mu$ is the mixture viscosity; $M_m$ is the mixture mean molecular weight; and $\beta_A$ is defined by Eq. (5-229). The average absolute error of this equation is 1.4 percent, while the Vignes equation and the Leffler-Cullinan equation give 3.3 percent and 6.2 percent, respectively.

*Siddiqi and Lucas* [22] suggested that component volume fractions might be used to correlate the effects of concentration dependence. They found an average absolute deviation of 4.5 percent for nonpolar-nonpolar mixtures, 16.5 percent for polar-nonpolar mixtures, and 10.8 percent for polar-polar mixtures.

*Bosse and Bart* added a term to account for excess Gibbs free energy, involved in the activation energy for diffusion, which was previously omitted. Doing so yielded minor modifications of the Vignes and Leffler-Cullinan equations [Eqs. (5-233) and (5-234), respectively]. The UNIFAC method was used to assess the excess Gibbs free energy. Comparing predictions of the new equations with data for 36 pairs and 326 data points yielded relative deviations of 7.8 percent and 8.9 percent, respectively, but which were better than the closely related Vignes (12.8 percent) and Leffler-Cullinan (10.4 percent) equations.

**Binary Electrolyte Mixtures** When electrolytes are added to a solvent, they dissociate to a certain degree. It would appear that the solution contains at least three components: solvent, anions, and cations. If the solution is to remain neutral in charge at each point (assuming the absence of any applied electric potential field), the anions and cations diffuse effectively as a single component, as for molecular diffusion. The diffusion of the anionic and cationic species in the solvent can thus be treated as a binary mixture.

***Nernst-Haskell*** The theory of dilute diffusion of salts is well developed and has been experimentally verified. For dilute solutions of a single salt, the well-known Nernst-Haskell equation (Poling et al.) is applicable:

$$D_{AB}^\circ = \frac{RT}{F^2} \frac{\left|\frac{1}{n_+}\right| + \left|\frac{1}{n_-}\right|}{\frac{1}{\lambda_+^0} + \frac{1}{\lambda_-^0}} = 8.9304 \times 10^{-10}\, T \frac{\left|\frac{1}{n_+}\right| + \left|\frac{1}{n_-}\right|}{\frac{1}{\lambda_+^0} + \frac{1}{\lambda_-^0}} \quad (5\text{-}242)$$

where $D_{AB}^\circ$ = diffusivity based on molarity rather than normality of dilute salt $A$ in solvent $B$, cm$^2$/s.

The previous definitions can be interpreted in terms of ionic-species diffusivities and conductivities. The latter are easily measured and depend on temperature and composition. For example, the equivalent conductance $\Lambda$ is commonly tabulated in chemistry handbooks as the limiting (infinite dilution) conductance $\Lambda_o$ and at standard concentrations, typically at 25°C. $\Lambda = 1000K/C = \lambda_+ + \lambda_- = \Lambda_o + f(C)$, (cm$^2$/ohm gequiv); $K = \alpha/\boldsymbol{R}$ = specific conductance, (ohm cm)$^{-1}$; $C$ = solution concentration, (gequiv/$\ell$); $\alpha$ = conductance cell constant (measured), (cm$^{-1}$); $\boldsymbol{R}$ = solution electrical resistance, which is measured (ohm); and $f(C)$ = a complicated function of concentration. The resulting equation of the electrolyte diffusivity is

$$D_{AB} = \frac{|z_+| + |z_-|}{(|z_-| / D_+) + (|z_+| / D_-)} \quad (5\text{-}243)$$

where $|z_\pm|$ represents the magnitude of the ionic charge and where the cationic or anionic diffusivities are $D_\pm = 8.9304 \times 10^{-10}\, T\lambda_\pm / |z_\pm|$ cm$^2$/s. The coefficient is $kN_0/F^2 = R/F^2$. In practice, the equivalent conductance of the ion pair of interest would be obtained and supplemented with conductances of permutations of those ions and one independent cation and anion. This would allow determination of all the ionic conductances and hence the diffusivity of the electrolyte solution.

***Gordon*** *[*J. Phys. Chem. ***5,*** *522 (1937)]* Typically, as the concentration of a salt increases from infinite dilution, the diffusion coefficient decreases rapidly from $D_{AB}^\circ$. As concentration is increased further, however, $D_{AB}$ rises steadily, often becoming greater than $D_{AB}^\circ$. Gordon proposed the following empirical equation, which is applicable up to concentrations of 2$N$:

$$D_{AB} = D_{AB}^\circ \frac{1}{C_B \bar{V}_B} \frac{\mu_B}{\mu} \left( 1 + \frac{\ln \gamma_\pm}{\ln m} \right) \quad (5\text{-}244)$$

where $D_{AB}^\circ$ is given by the Nernst-Haskell equation. References that tabulate $\gamma_\pm$ as a function of $m$, as well as other equations for $D_{AB}$, are given by Poling et al.

***Morgan, Ferguson, and Scovazzo*** *[*Ind. Eng. Chem. Res. ***44,*** *4815 (2005)]* They studied diffusion of gases in ionic liquids having moderate to high viscosity (up to about 1000 cP) at 30°C. Their range was limited, and the empirical equation they found was

$$D_{AB} = 3.7 \times 10^{-3} \left( \frac{1}{\mu_B^{0.59} V_A \rho_B^2} \right) \quad (5\text{-}245)$$

which yielded a correlation coefficient of 0.975. Of the estimated diffusivities 90 percent were within ±20 percent of the experimental values. The exponent for viscosity approximately confirmed the observation of Hiss and Cussler (ibid).

**Multicomponent Mixtures** No simple, practical estimation methods have been developed for predicting multicomponent liquid-diffusion coefficients. Several theories have been developed, but the necessity for extensive activity data, pure component and mixture volumes, mixture viscosity data, and tracer and binary diffusion coefficients have significantly limited the utility of the theories (see Poling et al.).

The generalized Stefan-Maxwell equations using binary diffusion coefficients are not easily applicable to liquids since the coefficients are so dependent on conditions. That is, in liquids, each $D_{ij}$ can be strongly composition dependent in binary mixtures and, moreover, the binary $D_{ij}$ is strongly affected in a multicomponent mixture. Thus, the convenience of writing multicomponent flux equations in terms of binary coefficients is lost. Conversely, they apply to gas mixtures because each $D_{ij}$ is practically independent of composition by itself and in a multicomponent mixture (see Taylor and Krishna for details).

One particular case of multicomponent diffusion that has been examined is the dilute diffusion of a solute in a homogeneous mixture (e.g., of $A$ in $B + C$). Umesi and Danner [27] compared the three equations given below for 49 ternary systems. All three equations were equivalent, giving average absolute deviations of 25 percent.

***Perkins and Geankoplis*** *[*Chem. Eng. Sci., ***24,*** *1035 (1969)]*

$$D_{am}\, \mu_m^{0.8} = \sum_{\substack{j=1 \\ j \neq A}}^{n} x_j\, D_{Aj}^\circ\, \mu_j^{0.8} \quad (5\text{-}246)$$

***Cullinan*** *[*Can. J. Chem. Eng. ***45,*** *377 (1967)]* This is an extension of Vignes' equation to multicomponent systems:

$$D_{am} = \prod_{\substack{j=1 \\ j \neq A}}^{n} (D_{Aj}^\circ)^{x_j} \quad (5\text{-}247)$$

***Leffler and Cullinan [16]*** They extended their binary relation to an arbitrary multicomponent mixture, as follows:

$$D_{am}\, \mu_m = \prod_{\substack{j=1 \\ j \neq A}}^{n} (D_{Aj}^\circ\, \mu_j)^{x_j} \quad (5\text{-}248)$$

where $D_{Aj}$ is the dilute binary diffusion coefficient of $A$ in $j$; $D_{Am}$ is the dilute diffusion of $A$ through $m$; $x_j$ is the mole fraction; $\mu_j$ is the viscosity of component $j$; and $\mu_m$ is the mixture viscosity.

***Akita*** *[*Ind. Eng. Chem. Fundam., ***10,*** *89 (1981)]* Another case of multicomponent dilute diffusion of significant practical interest is that of gases in aqueous electrolyte solutions. Many gas-absorption processes use electrolyte solutions. Akita presents experimentally tested equations for this case.

***Graham and Dranoff*** *[*Ind. Eng. Chem. Fundam., ***21,*** *360 and 365 (1982)]* They studied multicomponent diffusion of electrolytes in ion exchangers. They found that the Stefan-Maxwell interaction coefficients reduce to limiting ion tracer diffusivities of each ion.

***Pinto and Graham*** *[*AIChE J. **32,** *291 (1986) and* **33,** *436 (1987)]* They studied multicomponent diffusion in electrolyte solutions. They focused on the Stefan-Maxwell equations and corrected for solvation effects. They achieved excellent results for 1-1 electrolytes in water at 25°C up to concentrations of 4*M*.

***Anderko and Lencka*** *[*Ind. Eng. Chem. Res. **37,** *2878 (1998)]* These authors present an analysis of self-diffusion in multicomponent aqueous electrolyte systems. Their model includes contributions of long-range (Coulombic) and short-range (hard-sphere) interactions. Their mixing rule was based on equations of nonequilibrium thermodynamics. The model accurately predicts self-diffusivities of ions and gases in aqueous solutions from dilute to about 30 mol/kg water. It makes it possible to take single-solute data and extend them to multicomponent mixtures.

## DIFFUSION OF FLUIDS IN POROUS SOLIDS

Diffusion in porous solids is usually the most important factor controlling mass transfer in adsorption, ion exchange, drying, heterogeneous catalysis, leaching, and many other applications. Some of the applications of interest are outlined in Table 5-16. Applications of these equations are found in Secs. 16, 22, and 23.

Diffusion within the largest cavities of a porous medium is assumed to be similar to ordinary or bulk diffusion except that it is hindered by the pore walls (see Eq. 5-249). The tortuosity $\tau$ that expresses this hindrance has been estimated from geometric arguments. Unfortunately, measured values are often an order of magnitude greater than those estimates. Thus, the effective diffusivity $D_{\text{eff}}$ (and hence $\tau$) is normally determined by comparing a diffusion model to experimental measurements. The normal range of tortuosities for silica gel, alumina, and other porous solids is $2 \le \tau \le 6$, but for activated carbon, $5 \le \tau \le 65$.

In small pores and at low pressures, the mean free path $\ell$ of the gas molecule (or atom) is significantly greater than the pore diameter $d_{\text{pore}}$. Its magnitude may be estimated from

$$\ell = \frac{3.2\,\mu}{P}\left(\frac{RT}{2\pi M}\right)^{1/2} \quad \text{m}$$

As a result, collisions with the wall occur more frequently than with other molecules. This is referred to as the Knudsen mode of diffusion and is contrasted with ordinary or bulk diffusion, which occurs by intermolecular collisions. At intermediate pressures, both ordinary diffusion and Knudsen diffusion may be important [see Eqs. (5-252) and (5-253)].

For gases and vapors that adsorb on the porous solid, surface diffusion may be important, particularly at high surface coverage [see Eqs. (5-254) and (5-257)]. The mechanism of surface diffusion may be viewed as molecules hopping from one surface site to another. Thus, if adsorption is too strong, surface diffusion is impeded, while if adsorption is too weak, surface diffusion contributes insignificantly to the overall rate. Surface diffusion and bulk diffusion usually occur in parallel [see Eqs. (5-258) and (5-259)]. Although $D_s$ is expected to be less than $D_{\text{eff}}$, the solute flux due to surface diffusion may be larger

**TABLE 5-16 Relations for Diffusion in Porous Solids**

| Mechanism | Equation | | Applies to | References* |
|---|---|---|---|---|
| Bulk diffusion in pores | $D_{\text{eff}} = \dfrac{\varepsilon_p D}{\tau}$ | (5-249) | Gases or liquids in large pores. $N_{Kn} = \ell/d_{\text{pore}} < 0.01$ | [33] |
| Knudsen diffusion | $D_K = 48.5\, d_{\text{pore}} \left(\dfrac{T}{M}\right)^{1/2}$ in m²/s | (5-250) | Dilute (low pressure) gases in small pores. $N_{Kn} = \ell/d_{\text{pore}} > 10$ | Geankoplis, [34, 35] |
| | $D_{K\text{eff}} = \dfrac{\varepsilon_p D_K}{\tau}$ | | | |
| | $N_i = -D_K \dfrac{dC_i}{dz}$ | (5-251) | " " " " | |
| Combined bulk and Knudsen diffusion | $D_{\text{eff}} = \left(\dfrac{1 - \alpha x_A}{D_{\text{eff}}} + \dfrac{1}{D_{K\text{eff}}}\right)^{-1}$ | (5-252) | " " " " $N_A \ne N_B$ | Geankoplis, [32, 35] |
| | $\alpha = 1 + \dfrac{N_B}{N_A}$ | | | |

| | $D_S = D_S'(q) \exp\left(\dfrac{-E_S}{RT}\right)$ | (5-257) | " " " " | |
| Parallel bulk and surface diffusion | $J = -\left[D_{\text{eff}} \left(\dfrac{dp_i}{dz}\right) + D_{S\text{eff}}\, \rho_p \left(\dfrac{dq_i}{dz}\right)\right]$ | (5-258) | " " " " | [34] |
| | $J = -D_{\text{app}} \left(\dfrac{dp_i}{dz}\right)$ | (5-259) | " " " " | |
| | $D_{\text{app}} = D_{\text{eff}} + D_{S\text{eff}}\, \rho_p \left(\dfrac{dq_i}{dp_i}\right)$ | (5-260) | " " " " | |

*See the beginning of the "Mass Transfer" subsection for references.

than that due to bulk diffusion if $\partial q_i/\partial z >> \partial C_i/\partial z$. This can occur when a component is strongly adsorbed and the surface coverage is high. For all that, surface diffusion is not well understood. The references in Table 5-16 should be consulted for further details.

## INTERPHASE MASS TRANSFER

Transfer of material between phases is important in most separation processes in which two phases are involved. When one phase is pure, mass transfer in the pure phase is not involved. For example, when a pure liquid is being evaporated into a gas, only the gas-phase mass transfer need be calculated. Occasionally, mass transfer in one of the two phases may be neglected even though pure components are not involved. This will be the case when the resistance to mass transfer is much larger in one phase than in the other. Understanding the nature and magnitudes of these resistances is one of the keys to performing reliable mass transfer. In this section, mass transfer between gas and liquid phases will be discussed. The principles are easily applied to the other phases.

**Mass-Transfer Principles: Dilute Systems** When material is transferred from one phase to another across an interface that separates the two, the resistance to mass transfer in each phase causes a concentration gradient in each, as shown in Fig. 5-26 for a gas-liquid interface. The concentrations of the diffusing material in the two phases immediately adjacent to the interface generally are unequal, even if expressed in the same units, but usually are assumed to be related to each other by the laws of thermodynamic equilibrium. Thus, it is assumed that the thermodynamic equilibrium is reached at the gas-liquid interface almost immediately when a gas and a liquid are brought into contact.

For systems in which the solute concentrations in the gas and liquid phases are dilute, the rate of transfer may be expressed by equations which predict that the rate of mass transfer is proportional to the difference between the bulk concentration and the concentration at the gas-liquid interface. Thus

$$N_A = k'_G(p - p_i) = k'_L(c_i - c) \tag{5-261}$$

where $N_A$ = mass-transfer rate, $k'_G$ = gas-phase mass-transfer coefficient, $k'_L$ = liquid-phase mass-transfer coefficient, $p$ = solute partial pressure in bulk gas, $p_i$ = solute partial pressure at interface, $c$ = solute concentration in bulk liquid, and $c_i$ = solute concentration in liquid at interface.

The mass-transfer coefficients $k'_G$ and $k'_L$ by definition are equal to the ratios of the molal mass flux $N_A$ to the concentration driving forces $(p - p_i)$ and $(c_i - c)$ respectively. An alternative expression for the rate of transfer in dilute systems is given by

$$N_A = k_G(y - y_i) = k_L(x_i - x) \tag{5-262}$$

where $N_A$ = mass-transfer rate, $k_G$ = gas-phase mass-transfer coefficient, $k_L$ = liquid-phase mass-transfer coefficient, $y$ = mole-fraction solute in bulk-gas phase, $y_i$ = mole-fraction solute in gas at interface, $x$ = mole-fraction solute in bulk-liquid phase, and $x_i$ = mole-fraction solute in liquid at interface.

The mass-transfer coefficients defined by Eqs. (5-261) and (5-262) are related to each other as follows:

$$k_G = k'_G p_T \tag{5-263}$$

$$k_L = k'_L \overline{\rho}_L \tag{5-264}$$

where $p_T$ = total system pressure employed *during the experimental determinations* of $k'_G$ values and $\overline{\rho}_L$ = average molar density of the liquid phase. The coefficient $k_G$ is relatively independent of the total system pressure and therefore is more convenient to use than $k'_G$, which is inversely proportional to the total system pressure.

The above equations may be used for finding the interfacial concentrations corresponding to any set of values of $x$ and $y$ provided the ratio of the individual coefficients is known. Thus

$$(y - y_i)/(x_i - x) = k_L/k_G = k'_L\overline{\rho}_L/k'_G p_T = L_M H_G/G_M H_L \tag{5-265}$$

where $L_M$ = molar liquid mass velocity, $G_M$ = molar gas mass velocity, $H_L$ = height of one transfer unit based on liquid-phase resistance, and $H_G$ = height of one transfer unit based on gas-phase resistance. The last term in Eq. (5-265) is derived from Eqs. (5-284) and (5-286).

Equation (5-265) may be solved graphically if a plot is made of the equilibrium vapor and liquid compositions and a point representing the bulk concentrations $x$ and $y$ is located on this diagram. A construction of this type is shown in Fig. 5-27, which represents a gas-absorption situation.

The interfacial mole fractions $y_i$ and $x_i$ can be determined by solving Eq. (5-265) simultaneously with the equilibrium relation $y_i^\circ = F(x_i)$ to obtain $y_i$ and $x_i$. The rate of transfer may then be calculated from Eq. (5-262).

If the equilibrium relation $y_i^\circ = F(x_i)$ is sufficiently simple, e.g., if a plot of $y_i^\circ$ versus $x_i$ is a straight line, not necessarily through the origin, the rate of transfer is proportional to the difference between the bulk concentration in one phase and the concentration (in that same phase) which would be in equilibrium with the bulk concentration in the second phase. One such difference is $y - y^\circ$, and another is $x^\circ - x$. In this case, there is no need to solve for the interfacial compositions, as may be seen from the following derivation.

The rate of mass transfer may be defined by the equation

$$N_A = K_G(y - y^\circ) = k_G(y - y_i) = k_L(x_i - x) = K_L(x^\circ - x) \tag{5-266}$$

where $K_G$ = overall gas-phase mass-transfer coefficient, $K_L$ = overall liquid-phase mass-transfer coefficient, $y^\circ$ = vapor composition in equilibrium with $x$, and $x^\circ$ = liquid composition in equilibrium with vapor of composition $y$. This equation can be rearranged to the formula

$$\frac{1}{K_G} = \frac{1}{k_G}\left(\frac{y - y^\circ}{y - y_i}\right) = \frac{1}{k_G} + \frac{1}{k_G}\left(\frac{y_i - y^\circ}{y - y_i}\right) = \frac{1}{k_G} + \frac{1}{k_L}\left(\frac{y_i - y^\circ}{x_i - x}\right) \tag{5-267}$$

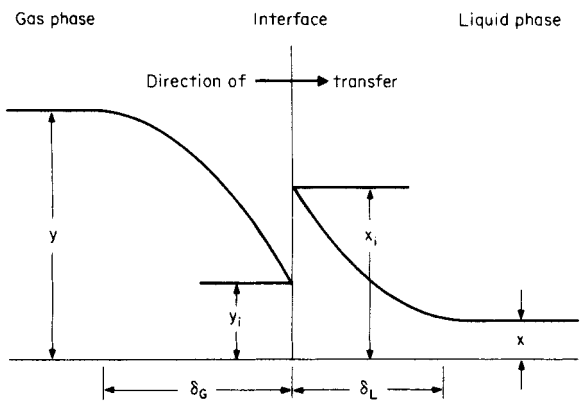

**FIG. 5-26** Concentration gradients near a gas-liquid interface.

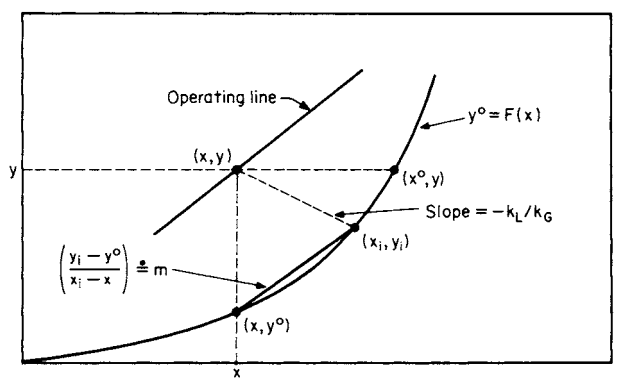

**FIG. 5-27** Identification of concentrations at a point in a countercurrent absorption tower.

in view of Eq. (5-265). Comparison of the last term in parentheses with the diagram of Fig. 5-27 shows that it is equal to the slope of the chord connecting the points $(x,y^\circ)$ and $(x_i,y_i)$. If the equilibrium curve is a straight line, then this term is the slope $m$. Thus

$$1/K_G = (1/k_G + m/k_L) \tag{5-268}$$

When Henry's law is valid ($p_A = Hx_A$ or $p_A = H'C_A$), the slope $m$ can be computed according to the relationship

$$m = H/p_T = H'\overline{\rho}_L/p_T \tag{5-269}$$

where $m$ is defined in terms of mole-fraction driving forces compatible with Eqs. (5-262) through (5-268), i.e., with the definitions of $k_L$, $k_G$, and $K_G$.

If it is desired to calculate the rate of transfer from the overall concentration difference based on bulk-liquid compositions $(x^\circ - x)$, the appropriate overall coefficient $K_L$ is related to the individual coefficients by the equation

$$1/K_L = [1/k_L + 1/(mk_G)] \tag{5-270}$$

Conversion of these equations to a $k'_G$, $k'_L$ basis can be accomplished readily by direct substitution of Eqs. (5-263) and (5-264).

Occasionally one will find $k'_L$ or $K'_L$ values reported in units (SI) of meters per second. The correct units for these values are kmol/[(s·m$^2$)(kmol/m$^3$)], and Eq. (5-264) is the correct equation for converting them to a mole-fraction basis.

When $k'_G$ and $K'_G$ values are reported in units (SI) of kmol/[(s·m$^2$)(kPa)], one must be careful in converting them to a mole-fraction basis to multiply by the total pressure actually employed in the original experiments and *not* by the total pressure of the system to be designed. This conversion is valid for systems in which Dalton's law of partial pressures $(p = yp_T)$ is valid.

Comparison of Eqs. (5-268) and (5-270) shows that for systems in which the equilibrium line is straight, the overall mass transfer coefficients are related to each other by the equation

$$K_L = mK_G \tag{5-271}$$

When the equilibrium curve is not straight, there is no strictly logical basis for the use of an overall transfer coefficient, since the value of $m$ will be a function of position in the apparatus, as can be seen from Fig. 5-27. In such cases the rate of transfer must be calculated by solving for the interfacial compositions as described above.

Experimentally observed rates of mass transfer often are expressed in terms of overall transfer coefficients even when the equilibrium lines are curved. This procedure is empirical, since the theory indicates that in such cases the rates of transfer may not vary in direct proportion to the overall bulk concentration differences $(y - y^\circ)$ and $(x^\circ - x)$ at all concentration levels even though the rates may be proportional to the concentration difference in each phase taken separately, i.e., $(x_i - x)$ and $(y - y_i)$.

In most types of separation equipment such as packed or spray towers, the interfacial area that is effective for mass transfer cannot be accurately determined. For this reason it is customary to report experimentally observed rates of transfer in terms of transfer coefficients based on a unit volume of the apparatus rather than on a unit of interfacial area. Such volumetric coefficients are designated as $K_Ga$, $k_La$, etc., where $a$ represents the interfacial area per unit volume of the apparatus. Experimentally observed variations in the values of these volumetric coefficients with variations in flow rates, type of packing, etc., may be due as much to changes in the effective value of $a$ as to changes in $k$. Calculation of the overall coefficients from the individual volumetric coefficients is made by means of the equations

$$1/K_Ga = (1/k_Ga + m/k_La) \tag{5-272}$$

$$1/K_La = (1/k_La + 1/mk_Ga) \tag{5-273}$$

Because of the wide variation in equilibrium, the variation in the values of $m$ from one system to another can have an important effect on the overall coefficient and on the selection of the type of equipment to use. For example, if $m$ is large, the liquid-phase part of the overall resistance might be extremely large where $k_L$ might be relatively small. This kind of reasoning must be applied with caution, however, since species with different equilibrium characteristics are separated under different operating conditions. Thus, the effect of changes in $m$ on the overall resistance to mass transfer may partly be counterbalanced by changes in the individual specific resistances as the flow rates are changed.

**Mass-Transfer Principles: Concentrated Systems** When solute concentrations in the gas and/or liquid phases are large, the equations derived above for dilute systems no longer are applicable. The correct equations to use for concentrated systems are as follows:

$$\begin{aligned} N_A &= \hat{k}_G(y - y_i)/y_{BM} = \hat{k}_L(x_i - x)/x_{BM} \\ &= \hat{K}_G(y - y^\circ)/y^\circ_{BM} = \hat{K}_L(x^\circ - x)/x^\circ_{BM} \end{aligned} \tag{5-274}$$

where $(N_B = 0)$

$$y_{BM} = \frac{(1-y) - (1-y_i)}{\ln[(1-y)/(1-y_i)]} \tag{5-275}$$

$$y^\circ_{BM} = \frac{(1-y) - (1-y^\circ)}{\ln[(1-y)/(1-y^\circ)]} \tag{5-276}$$

$$x_{BM} = \frac{(1-x) - (1-x_i)}{\ln[(1-x)/(1-x_i)]} \tag{5-277}$$

$$x^\circ_{BM} = \frac{(1-x) - (1-x^\circ)}{\ln[(1-x)/(1-x^\circ)]} \tag{5-278}$$

and where $\hat{k}_G$ and $\hat{k}_L$ are the gas-phase and liquid-phase mass-transfer coefficients for concentrated systems and $\hat{K}_G$ and $\hat{K}_L$ are the overall gas-phase and liquid-phase mass-transfer coefficients for concentrated systems. These coefficients are defined later in Eqs. (5-281) to (5-283).

The factors $y_{BM}$ and $x_{BM}$ arise from the fact that, in the diffusion of a solute through a second stationary layer of insoluble fluid, the resistance to diffusion varies in proportion to the concentration of the insoluble stationary fluid, approaching zero as the concentration of the insoluble fluid approaches zero. See Eq. (5-198).

The factors $y^\circ_{BM}$ and $x^\circ_{BM}$ cannot be justified on the basis of mass-transfer theory since they are based on overall resistances. These factors therefore are included in the equations by analogy with the corresponding film equations.

In dilute systems the logarithmic-mean insoluble-gas and nonvolatile-liquid concentrations approach unity, and Eq. (5-274) reduces to the dilute-system formula. For equimolar counter diffusion (e.g., binary distillation), these log-mean factors should be omitted. See Eq. (5-197).

Substitution of Eqs. (5-275) through (5-278) into Eq. (5-274) results in the following simplified formula:

$$\begin{aligned} N_A &= \hat{k}_G \ln[(1-y_i)/(1-y)] \\ &= \hat{K}_G \ln[(1-y^\circ)/(1-y)] \\ &= \hat{k}_L \ln[(1-x)/(1-x_i)] \\ &= \hat{K}_L \ln[(1-x)/(1-x^\circ)] \end{aligned} \tag{5-279}$$

Note that the units of $\hat{k}_G$, $\hat{K}_G$, $\hat{k}_L$, and $\hat{K}_L$ are all identical to each other, i.e., kmol/(s·m$^2$) in SI units.

The equation for computing the interfacial gas and liquid compositions in concentrated systems is

$$\begin{aligned} (y - y_i)/(x_i - x) &= \hat{k}_L y_{BM}/\hat{k}_G x_{BM} \\ &= L_M H_G y_{BM}/G_M H_L x_{BM} = k_L/k_G \end{aligned} \tag{5-280}$$

This equation is identical to the one for dilute systems since $\hat{k}_G = k_G y_{BM}$ and $\hat{k}_L = k_L x_{BM}$. Note, however, that when $\hat{k}_G$ and $\hat{k}_L$ are given, the equation must be solved by trial and error, since $x_{BM}$ contains $x_i$ and $y_{BM}$ contains $y_i$.

The overall gas-phase and liquid-phase mass-transfer coefficients for concentrated systems are computed according to the following equations:

$$\frac{1}{\hat{K}_G} = \frac{y_{BM}}{y^\circ_{BM}}\frac{1}{\hat{k}_G} + \frac{x_{BM}}{y^\circ_{BM}}\frac{1}{\hat{k}_L}\left(\frac{y_i - y^\circ}{x_i - x}\right) \tag{5-281}$$

$$\frac{1}{\hat{K}_L} = \frac{x_{BM}}{x^\circ_{BM}}\frac{1}{\hat{k}_L} + \frac{y_{BM}}{x^\circ_{BM}}\frac{1}{\hat{k}_G}\left(\frac{x^\circ - x_i}{y - y_i}\right) \tag{5-282}$$

When the equilibrium curve is a straight line, the terms in parentheses can be replaced by the slope $m$ or 1/m as before. In this case the

overall mass-transfer coefficients for concentrated systems are related to each other by the equation

$$\hat{K}_L = m\hat{K}_G(x^\circ_{BM}/y^\circ_{BM}) \tag{5-283}$$

All these equations reduce to their dilute-system equivalents as the inert concentrations approach unity in terms of mole fractions of inert concentrations in the fluids.

**HTU (Height Equivalent to One Transfer Unit)** Frequently the values of the individual coefficients of mass transfer are so strongly dependent on flow rates that the quantity obtained by dividing each coefficient by the flow rate of the phase to which it applies is more nearly constant than the coefficient itself. The quantity obtained by this procedure is called the height equivalent to one transfer unit, since it expresses in terms of a single length dimension the height of apparatus required to accomplish a separation of standard difficulty.

The following relations between the transfer coefficients and the values of HTU apply:

$$H_G = G_M/k_G a y_{BM} = G_M/\hat{k}_G a \tag{5-284}$$

$$H_{OG} = G_M/K_G a y^\circ_{BM} = G_M/\hat{K}_G a \tag{5-285}$$

$$H_L = L_M/k_L a x_{BM} = L_M/\hat{k}_L a \tag{5-286}$$

$$H_{OL} = L_M/K_L a x^\circ_{BM} = L_M/\hat{K}_L a \tag{5-287}$$

The equations that express the addition of individual resistances in terms of HTUs, applicable to either dilute or concentrated systems, are

$$H_{OG} = \frac{y_{BM}}{y^\circ_{BM}} H_G + \frac{mG_M}{L_M}\frac{x_{BM}}{y^\circ_{BM}} H_L \tag{5-288}$$

$$H_{OL} = \frac{x_{BM}}{x^\circ_{BM}} H_L + \frac{L_M}{mG_M}\frac{y_{BM}}{x^\circ_{BM}} H_G \tag{5-289}$$

These equations are strictly valid only when $m$, the slope of the equilibrium curve, is constant, as noted previously.

**NTU (Number of Transfer Units)** The NTU required for a given separation is closely related to the number of theoretical stages or plates required to carry out the same separation in a stagewise or plate-type apparatus. For equimolal counterdiffusion, such as in a binary distillation, the number of overall gas-phase transfer units $N_{OG}$ required for changing the composition of the vapor stream from $y_1$ to $y_2$ is

$$N_{OG} = \int_{y_2}^{y_1} \frac{dy}{y - y^\circ} \tag{5-290}$$

When diffusion is in one direction only, as in the absorption of a soluble component from an insoluble gas,

$$N_{OG} = \int_{y_2}^{y_1} \frac{y^\circ_{BM}\, dy}{(1-y)(y-y^\circ)} \tag{5-291}$$

The total height of packing required is then

$$h_T = H_{OG}N_{OG} \tag{5-292}$$

When it is known that $H_{OG}$ varies appreciably within the tower, this term must be placed inside the integral in Eqs. (5-290) and (5-291) for accurate calculations of $h_T$. For example, the packed-tower design equation in terms of the overall gas-phase mass-transfer coefficient for absorption would be expressed as follows:

$$h_T = \int_{y_2}^{y_1} \left[\frac{G_M}{K_G a y^\circ_{BM}}\right] \frac{y^\circ_{BM}\, dy}{(1-y)(y-y^\circ)} \tag{5-293}$$

where the first term under the integral can be recognized as the HTU term. Convenient solutions of these equations for special cases are discussed later.

**Definitions of Mass-Transfer Coefficients $\hat{k}_G$ and $\hat{k}_L$** The mass-transfer coefficient is defined as the ratio of the molal mass flux $N_A$ to the concentration driving force. This leads to many different ways of defining these coefficients. For example, gas-phase mass-transfer rates may be defined as

$$N_A = k_G(y - y_i) = k'_G(p - p_i) = \hat{k}_G(y - y_i)/y_{BM} \tag{5-294}$$

where the units (SI) of $k_G$ are kmol/[(s·m$^2$)(mole fraction)], the units of $k'_G$ are kmol/[(s·m$^2$)(kPa)], and the units of $\hat{k}_G$ are kmol/(s·m$^2$). These coefficients are related to each other as follows:

$$k_G = k_G y_{BM} = k'_G p_T y_{BM} \tag{5-295}$$

where $p_T$ is the total system pressure (it is assumed here that Dalton's law of partial pressures is valid).

In a similar way, liquid-phase mass-transfer rates may be defined by the relations

$$N_A = k_L(x_i - x) = k'_L(c_i - c) = \hat{k}_L(x_i - x)/x_{BM} \tag{5-296}$$

where the units (SI) of $k_L$ are kmol/[(s·m$^2$)(mole fraction)], the units of $k'_L$ are kmol/[(s·m$^2$)(kmol/m$^3$)] or meters per second, and the units of $\hat{k}_L$ are kmol/(s·m$^2$). These coefficients are related as follows:

$$\hat{k}_L = k_L x_{BM} = k'_L \overline{\rho}_L x_{BM} \tag{5-297}$$

where $\overline{\rho}_L$ is the molar density of the liquid phase in units (SI) of kilomoles per cubic meter. Note that, for dilute solutions where $x_{BM} \doteq 1$, $k_L$ and $\hat{k}_L$ will have identical numerical values. Similarly, for dilute gases $\hat{k}_G \doteq k_G$.

**Simplified Mass-Transfer Theories** In certain simple situations, the mass-transfer coefficients can be calculated from first principles. The film, penetration, and surface-renewal theories are attempts to extend these theoretical calculations to more complex situations. Although these theories are often not accurate, they are useful to provide a physical picture for variations in the mass-transfer coefficient.

For the special case of steady-state unidirectional diffusion of a component through an inert-gas film in an ideal-gas system, the rate of mass transfer is derived as

$$N_A = \frac{D_{AB}p_T}{RT\,\delta_G}\frac{(y - y_i)}{y_{BM}} = \frac{D_{AB}p_T}{RT\,\delta_G}\ln\frac{1-y_i}{1-y} \tag{5-298}$$

where $D_{AB}$ = the diffusion coefficient or "diffusivity," $\delta_G$ = the "effective" thickness of a stagnant-gas layer which would offer a resistance to molecular diffusion equal to the experimentally observed resistance, and $R$ = the gas constant. [Nernst, *Z. Phys. Chem.*, **47,** 52 (1904); Whitman, *Chem. Mat. Eng.*, **29,** 149 (1923), and Lewis and Whitman, *Ind. Eng. Chem.*, **16,** 1215 (1924)].

The film thickness $\delta_G$ depends primarily on the hydrodynamics of the system and hence on the Reynolds number and the Schmidt number. Thus, various correlations have been developed for different geometries in terms of the following dimensionless variables:

$$N_{Sh} = \hat{k}_G RTd/D_{AB}p_T = f(N_{Re}, N_{Sc}) \tag{5-299}$$

where $N_{Sh}$ is the Sherwood number, $N_{Re}$ (= $Gd/\mu_G$) is the Reynolds number based on the characteristic length $d$ appropriate to the geometry of the particular system; and $N_{Sc}$ (= $\mu_G/\rho_G D_{AB}$) is the Schmidt number.

According to this analysis one can see that for gas-absorption problems, which often exhibit unidirectional diffusion, the most appropriate driving-force expression is of the form $(y - y_i)/y_{BM}$, and the most appropriate mass-transfer coefficient is therefore $\hat{k}_G$. This concept is to be found in all the key equations for the design of mass-transfer equipment.

The Sherwood-number relation for gas-phase mass-transfer coefficients as represented by the film diffusion model in Eq. (5-299) can be rearranged as follows:

$$N_{Sh} = (\hat{k}_G/G_M)N_{Re}N_{Sc} = N_{St}N_{Re}N_{Sc} = f(N_{Re}, N_{Sc}) \tag{5-300}$$

where $N_{St} = \hat{k}_G/G_M = k'_G p_{BM}/G_M$ is known as the Stanton number. This equation can now be stated in the alternative functional forms

$$N_{St} = \hat{k}_G/G_M = g(N_{Re}, N_{Sc}) \tag{5-301}$$

$$j_D = N_{St} \cdot N_{Sc}^{2/3} \tag{5-302}$$

where $j$ is the Chilton-Colburn "$j$ factor" for mass transfer (discussed later).

The important point to note here is that the gas-phase mass-transfer coefficient $\hat{k}_G$ depends principally upon the transport properties of the fluid ($N_{Sc}$) and the hydrodynamics of the particular system involved ($N_{Re}$). It also is important to recognize that specific mass-transfer correlations can be derived only in conjunction with the

investigator's particular assumptions concerning the numerical values of the effective interfacial area $a$ of the packing.

The stagnant-film model discussed previously assumes a steady state in which the local flux across each element of area is constant; i.e., there is no accumulation of the diffusing species within the film. Higbie [*Trans. Am. Inst. Chem. Eng.*, **31,** 365 (1935)] pointed out that industrial contactors often operate with repeated brief contacts between phases in which the contact times are too short for the steady state to be achieved. For example, Higbie advanced the theory that in a packed tower the liquid flows across each packing piece in laminar flow and is remixed at the points of discontinuity between the packing elements. Thus, a fresh liquid surface is formed at the top of each piece, and as it moves downward, it absorbs gas at a decreasing rate until it is mixed at the next discontinuity. This is the basis of penetration theory.

If the velocity of the flowing stream is uniform over a very deep region of liquid (total thickness, $\delta_T >> \sqrt{Dt}$), the time-averaged mass-transfer coefficient according to penetration theory is given by

$$k'_L = 2\sqrt{D_l/\pi t} \tag{5-303}$$

where $k'_L$ = liquid-phase mass-transfer coefficient, $D_L$ = liquid-phase diffusion coefficient, and $t$ = contact time.

In practice, the contact time $t$ is not known except in special cases in which the hydrodynamics are clearly defined. This is somewhat similar to the case of the stagnant-film theory in which the unknown quantity is the thickness of the stagnant layer $\delta$ (in film theory, the liquid-phase mass-transfer coefficient is given by $k'_L = D_L/\delta$).

The penetration theory predicts that $k'_L$ should vary by the square root of the molecular diffusivity, as compared with film theory, which predicts a first-power dependency on $D$. Various investigators have reported experimental powers of $D$ ranging from 0.5 to 0.75, and the Chilton-Colburn analogy suggests a ⅔ power.

Penetration theory often is used in analyzing absorption with chemical reaction because it makes no assumption about the depths of penetration of the various reacting species, and it gives a more accurate result when the diffusion coefficients of the reacting species are not equal. When the reaction process is very complex, however, penetration theory is more difficult to use than film theory, and the latter method normally is preferred.

Danckwerts [*Ind. Eng. Chem.*, **42,** 1460 (1951)] proposed an extension of the penetration theory, called the surface renewal theory, which allows for the eddy motion in the liquid to bring masses of fresh liquid continually from the interior to the surface, where they are exposed to the gas for finite lengths of time before being replaced. In his development, Danckwerts assumed that every element of fluid has an equal chance of being replaced regardless of its age. The Danckwerts model gives

$$k'_L = \sqrt{Ds} \tag{5-304}$$

where $s$ = fractional rate of surface renewal.

Note that both the penetration and the surface-renewal theories predict a square-root dependency on $D$. Also, it should be recognized that values of the surface-renewal rate $s$ generally are not available, which presents the same problems as do $\delta$ and $t$ in the film and penetration models.

The predictions of correlations based on the film model often are nearly identical to predictions based on the penetration and surface-renewal models. Thus, in view of its relative simplicity, the film model normally is preferred for purposes of discussion or calculation. It should be noted that none of these theoretical models has proved adequate for making a priori predictions of mass-transfer rates in packed towers, and therefore empirical correlations such as those outlined later in Table 5-24 must be employed.

**Mass-Transfer Correlations** Because of the tremendous importance of mass transfer in chemical engineering, a very large number of studies have determined mass-transfer coefficients both empirically and theoretically. Some of these studies are summarized in Tables 5-17 to 5-24. Each table is for a specific geometry or type of contactor, starting with flat plates, which have the simplest geometry (Table 5-17); then wetted wall columns (Table 5-18); flow in pipes and ducts (Table 5-19); submerged objects (Table 5-20); drops and bubbles (Table 5-21); agitated systems (Table 5-22); packed beds of particles for adsorption, ion exchange, and chemical reaction (Table 5-23); and finishing with packed bed two-phase contactors for distillation, absorption and other unit operations (Table 5-24). Although extensive, these tables are not meant to be encyclopedic, but a variety of different configurations are shown to provide a flavor of the range of correlations available. These correlations include transfer to or from one fluid and either a second fluid or a solid. Many of the correlations are for $k_L$ and $k_G$ values obtained from dilute systems where $x_{BM} \approx 1.0$ and $y_{BM} \approx 1.0$. The most extensive source for older mass-transfer correlations in a variety of geometries is Skelland (*Diffusional Mass Transfer,* 1974). The extensive review of bubble column systems (see Table 5-21) by Shah et al. [*AIChE J.* **28,** 353 (1982)] includes estimation of bubble size, gas holdup, interfacial area $k_La$, and liquid dispersion coefficient. For correlations for particle-liquid mass transfer in stirred tanks (part of Table 5-22) see the review by Pangarkar et al. [*Ind. Eng. Chem. Res.* **41,** 4141 (2002)]. For mass transfer in distillation, absorption, and extraction in packed beds (Table 5-24), see also the appropriate sections in this handbook and the review by Wang, Yuan, and Yu [*Ind. Eng. Chem. Res.* **44,** 8715 (2005)]. For simple geometries, one may be able to determine a theoretical (T) form of the mass-transfer correlation. For very complex geometries, only an empirical (E) form can be found. In systems of intermediate complexity, semiempirical (S) correlations where the form is determined from theory and the coefficients from experiment are often useful. Although the major limitations and constraints in use are usually included in the tables, obviously many details cannot be included in this summary form. Readers are strongly encouraged to check the references before using the correlations in important situations. Note that even authoritative sources occasionally have typographical errors in the fairly complex correlation equations. Thus, it is a good idea to check several sources, including the original paper. The references will often include figures comparing the correlations with data. These figures are very useful since they provide a visual picture of the scatter in the data.

Since there are often several correlations that are applicable, how does one choose the correlation to use? First, the engineer must determine which correlations are closest to the current situation. This involves recognizing the similarity of geometries, which is often challenging, and checking that the range of parameters in the correlation is appropriate. For example, the Bravo, Rocha, and Fair correlation for distillation with structured packings with triangular cross-sectional channels (Table 5-24-H) uses the Johnstone and Pigford correlation for rectification in vertical wetted wall columns (Table 5-18-F). Recognizing that this latter correlation pertains to a rather different application and geometry was a nontrivial step in the process of developing a correlation. If several correlations appear to be applicable, check to see if the correlations have been compared to each other and to the data. When a detailed comparison of correlations is not available, the following heuristics may be useful:

1. Mass-transfer coefficients are derived from models. They must be employed in a similar model. For example, if an arithmetic concentration difference was used to determine $k$, that $k$ should only be used in a mass-transfer expression with an arithmetic concentration difference.
2. Semiempirical correlations are often preferred to purely empirical or purely theoretical correlations. Purely empirical correlations are dangerous to use for extrapolation. Purely theoretical correlations may predict trends accurately, but they can be several orders of magnitude off in the value of $k$.
3. Correlations with broader data bases are often preferred.
4. The analogy between heat and mass transfer holds over wider ranges than the analogy between mass and momentum transfer. Good heat transfer data (without radiation) can often be used to predict mass-transfer coefficients.
5. More recent data is often preferred to older data, since end effects are better understood, the new correlation often builds on earlier data and analysis, and better measurement techniques are often available.
6. With complicated geometries, the product of the interfacial area per volume and the mass-transfer coefficient is required. Correlations of $ka_p$ or of HTU are more accurate than individual correlations of $k$ and

**TABLE 5-18 Mass-Transfer Correlations for Falling Films with a Free Surface in Wetted Wall Columns—Transfer between Gas and Liquid**

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. Laminar, vertical wetted wall column | $N_{Sh,avg} = \dfrac{k'_m x}{D} \approx 3.41 \dfrac{x}{\delta_{film}}$ (first term of infinite series) | [T] Low rates M.T. Use with log mean concentration difference. Parabolic velocity distribution in films. | [138] p. 78 |
| | $\delta_{film} = \left(\dfrac{3\mu Q}{w\rho g}\right)^{1/3}$ = film thickness | $w$ = film width (circumference in column) | [141] p. 137 |
| | $N_{Re,film} = \dfrac{4Q\rho}{w\mu} < 20$ | Derived for flat plates, used for tubes if $r_{tube}\left(\dfrac{\rho g}{2\sigma}\right)^{1/2} > 3.0$. $\sigma$ = surface tension | [152] p. 50 |
| | | If $N_{Re,film} > 20$, surface waves and rates increase. An approximate solution $D_{apparent}$ can be used. Ripples are suppressed with a wetting agent good to $N_{Re}$ = 1200. | |
| B. Turbulent, vertical wetted wall column | $N_{Sh,avg} = \dfrac{k'_m d_t}{D} = 0.023 N_{Re}^{0.83} N_{Sc}^{0.44}$ | [E] Use with log mean concentration difference for correlations in B and D. $N_{Re}$ is for gas. $N_{Sc}$ for vapor in gas. $2000 < N_{Re} \le 35{,}000$, $0.6 \le N_{Sc} \le 2.5$. Use for gases, $d_t$ = tube diameter. | [68] [77] p.181 [138] p. 211 [141] p. 265 [149] p. 212 [152] p. 71 |
| | A coefficient 0.0163 has also been reported using $N_{Re'}$, where $v = v$ of gas relative to liquid film. | | |
| Better fit | $N_{Sh,avg} = 0.0318 N_{Re}^{0.790} N_{Sc}^{0.5}$ | [S] Reevaluated data | [58] |
| C. Turbulent, very short column | $N_{Sh} = 0.00283 N_{Re,g} N_{Sc,g}^{0.5} N_{Re,liq}^{0.08}$ | [E] Evaporation data | [56] |
| | $N_{Sh} = k_g(d_{tube} - 2\delta)/D$ | $N_{Sh,g}$ = 11 to 65, $N_{Re,g}$ = 2400 to 9100 | |
| | $N_{Re,g} = \rho_g u_g (d_{tube} - 2\delta)/\mu_g$ | $N_{Re,liq}$ = 110 to 480, $N_{Sc,g}$ = 0.62 to 1.93 | |
| | $N_{Re,liq} = \rho_{liq} Q_{liq}/[\pi\mu(d_{tube} - 2\delta)]$ | $\delta$ = film thickness | |
| D. Turbulent, vertical wetted wall column with ripples | $N_{Sh,avg} = \dfrac{k'_m d_t}{D} = 0.00814 N_{Re}^{0.83} N_{Sc}^{0.44} \left(\dfrac{4Q\rho}{w\mu}\right)^{0.15}$ | [E] For gas systems with rippling. | [85] |
| | $30 \le \left(\dfrac{4Q\rho}{w\mu}\right) < 1200$ | Fits 5-18-*B* for $\left(\dfrac{4Q\rho}{w\mu}\right) = 1000$ | [138] p. 213 |
| | $N_{Sh,avg} = \dfrac{k'_m d_t}{D} = 0.023 N_{Re}^{0.8} N_{Sc}^{1/3}$ | [E] "Rounded" approximation to include ripples. Includes solid-liquid mass-transfer data to find ⅓ coefficient on $N_{Sc}$. May use $N_{Re}^{0.83}$. Use for liquids. See also Table 5-19. | |
| E. Turbulent, with ripples | $N_{Sh} = \left(\dfrac{2}{\pi}\right)^{0.5} N_{Re,\dot{\varepsilon}}^{0.5} N_{Sc}^{0.5}$ | [E] $\dot{\varepsilon}$ = dilation rate of surface = $\dfrac{\partial v_x^s}{\partial x} + \dfrac{\partial v_y^s}{\partial y}$ | [150] |
| | $N_{Re,\dot{\varepsilon}} = \dot{\varepsilon} L^2/\nu$ | | |
| F. Rectification in vertical wetted wall column with turbulent vapor flow, Johnstone and Pigford correlation | $N_{Sh,avg} = \dfrac{k'_G d_{col} p_{BM}}{D_v p} = 0.0328 (N'_{Re})^{0.77} N_{Sc}^{0.33}$ | [E] Use logarithmic mean driving force at two ends of column. Based on four systems with gas-side resistance only. $p_{BM}$ = logarithmic mean partial pressure of nondiffusing species $B$ in binary mixture. $p$ = total pressure | [84] |
| | $3000 < N'_{Re} < 40{,}000$, $0.5 < N_{Sc} < 3$ | | [138] p. 214 |
| | $N'_{Re} = \dfrac{d_{col} v_{rel} \rho_v}{\mu_v}$, $v_{rel}$ = gas velocity relative to liquid film = $\dfrac{3}{2} u_{avg}$ in film | Modified form is used for structured packings (See Table 5-24-H). | [156] |

*See the beginning of the "Mass Transfer" subsection for references.

$a_p$ since the measurements are simpler to determine the product $ka_p$ or HTU.

7. Finally, if a mass-transfer coefficient looks too good to be true, it probably is incorrect.

To determine the mass-transfer rate, one needs the interfacial area in addition to the mass-transfer coefficient. For the simpler geometries, determining the interfacial area is straightforward. For packed beds of particles $a$, the interfacial area per volume can be estimated as shown in Table 5-23-A. For packed beds in distillation, absorption, and so on in Table 5-24, the interfacial area per volume is included with the mass-transfer coefficient in the correlations for HTU. For agitated liquid-liquid systems, the interfacial area can be estimated from the dispersed phase holdup and mean drop size correlations. Godfrey, Obi, and Reeve [*Chem. Engr. Prog.* **85,** 61 (Dec. 1989)] summarize these correlations. For many systems, $\bar{d}_{drop}/d_{imp}$ = (const)$N_{We}^{-0.6}$ where $N_{We} = \rho_c N^2 d_{imp}^3/\sigma$. Piché, Grandjean, and Larachi [*Ind. Eng. Chem. Res.* **41**, 4911 (2002)] developed two correlations for reconciling the gas-liquid mass-transfer coefficient and interfacial area in randomly packed towers. The correlation for the interfacial area was a function of five dimensionless groups, and yielded a relative error of 22.5 percent for 325 data points. That equation, when combined with a correlation for $N_{Sh}$ as a function of four dimensionless groups, achieved a relative error of 24.4 percent, for 3455 data points for the product $k'_G a$.

**TABLE 5-19 Mass-Transfer Correlations for Flow in Pipes and Ducts—Transfer Is from Wall to Fluid**

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. Tubes, laminar, fully developed parabolic velocity profile, developing concentration profile, constant wall concentration | $N_{Sh} = \dfrac{k'd_t}{D} = 3.66 + \dfrac{0.0668(d_t/x)N_{Re}N_{Sc}}{1 + 0.04[(d_t/x)N_{Re}N_{Sc}]^{2/3}}$ | [T] Use log mean concentration difference. For $\dfrac{x/d_t}{N_{Re}N_{Sc}} < 0.10$, $N_{Re} < 2100$. $x$ = distance from tube entrance. Good agreement with experiment at values $10^4 > \dfrac{\pi}{4}\dfrac{d_t}{x}N_{Re}N_{Sc} > 10$ | [77] p. 176<br>[87] p. 525<br>[141] p. 159 |

*See the beginning of the "Mass Transfer" subsection for references.

**Effects of Total Pressure on $\hat{k}_G$ and $\hat{k}_L$** The influence of total system pressure on the rate of mass transfer from a gas to a liquid or to a solid has been shown to be the same as would be predicted from stagnant-film theory as defined in Eq. (5-298), where

$$\hat{k}_G = D_{AB}p_T/RT\,\delta_G \tag{5-305}$$

Since the quantity $D_{AB}p_T$ is known to be relatively independent of the pressure, it follows that the rate coefficients $\hat{k}_G$, $k_G y_{BM}$, and $k'_G p_T y_{BM}$ $(= k'_G p_{BM})$ do not depend on the total pressure of the system, subject to the limitations discussed later.

Investigators of tower packings normally report $k'_G a$ values measured at very low inlet-gas concentrations, so that $y_{BM} = 1$, and at total pressures close to 100 kPa (1 atm). Thus, the correct rate coefficient for use in packed-tower designs involving the use of the driving force $(y - y_i)/y_{BM}$ is obtained by multiplying the reported $k'_G a$ values by the value of $p_T$ employed in the actual test unit (e.g., 100 kPa) and *not* the total pressure of the system to be designed.

From another point of view one can correct the reported values of $k'_G a$ in kmol/[(s·m$^3$)(kPa)], valid for a pressure of 101.3 kPa (1 atm), to some other pressure by dividing the quoted values of $k'_G a$ by the design pressure and multiplying by 101.3 kPa, i.e., ($k'_G a$ at design pressure $p_T$) = ($k'_G a$ at 1 atm) × 101.3/$p_T$.

One way to avoid a lot of confusion on this point is to convert the experimentally measured $k'_G a$ values to values of $\hat{k}_G a$ straightaway, before beginning the design calculations. A design based on the rate coefficient $\hat{k}_G a$ and the driving force $(y - y_i)/y_{BM}$ will be independent of the total system pressure with the following limitations: caution should be employed in assuming that $\hat{k}_G a$ is independent of total pressure for systems having significant vapor-phase nonidealities, for systems that operate in the vicinity of the critical point, or for total pressures higher than about 3040 to 4050 kPa (30 to 40 atm).

Experimental confirmations of the relative independence of $\hat{k}_G$ with respect to total pressure have been widely reported. Deviations do occur at extreme conditions. For example, Bretsznajder (*Prediction of Transport and Other Physical Properties of Fluids,* Pergamon Press, Oxford, 1971, p. 343) discusses the effects of pressure on the $D_{AB}p_T$ product and presents experimental data on the self-diffusion of $CO_2$ which show that the $D$-$p$ product begins to decrease at a pressure of approximately 8100 kPa (80 atm). For reduced temperatures higher than about 1.5, the deviations are relatively modest for pressures up to the critical pressure. However, deviations are large near the critical point (see also p. 5-52). The effect of pressure on the gas-phase viscosity also is negligible for pressures below about 5060 kPa (50 atm).

For the liquid-phase mass-transfer coefficient $\hat{k}_L$, the effects of total system pressure can be ignored for all practical purposes. Thus, when using $\hat{k}_G$ and $\hat{k}_L$ for the design of gas absorbers or strippers, the primary pressure effects to consider will be those which affect the equilibrium curves and the values of $m$. If the pressure changes affect the hydrodynamics, then $\hat{k}_G$, $\hat{k}_L$, and $a$ can all change significantly.

**Effects of Temperature on $\hat{k}_G$ and $\hat{k}_L$** The Stanton-number relationship for gas-phase mass transfer in packed beds, Eq. (5-301), indicates that for a given system geometry the rate coefficient $\hat{k}_G$ depends only on the Reynolds number and the Schmidt number. Since the Schmidt number for a gas is approximately independent of temperature, the principal effect of temperature upon $\hat{k}_G$ arises from changes in the gas viscosity with changes in temperature. For normally encountered temperature ranges, these effects will be small owing to the fractional powers involved in Reynolds-number terms (see Tables 5-17 to 5-24). It thus can be concluded that for all

**TABLE 5-20 Mass-Transfer Correlations for Flow Past Submerged Objects**

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. Single sphere | $N_{Sh} = \dfrac{k'_G p_{BLM} RT d_s}{PD} = \dfrac{2r}{r - r_s}$<br>$r/r_s$: 2 \| 5 \| 10 \| 50 \| ∞ (asymptotic limit)<br>$N_{Sh}$: 4.0 \| 2.5 \| 2.22 \| 2.04 \| 2.0 | [T] Use with log mean concentration difference. $r$ = distance from sphere, $r_s$, $d_s$ = radius and diameter of sphere. No convection. | [141] p. 18 |
| B. Single sphere, creeping flow with forced convection | $N_{Sh} = \dfrac{k'd}{D} = [4.0 + 1.21(N_{Re}N_{Sc})^{2/3}]^{1/2}$ | [T] Use with log mean concentration difference. Average over sphere. Numerical calculations. $(N_{Re}N_{Sc}) < 10{,}000$ $N_{Re} < 1.0$. Constant sphere diameter. Low mass-transfer rates. | [46][88] p. 114<br>[105]<br>[138] p. 214 |
| | $N_{Sh} = \dfrac{k'd}{D} = a(N_{Re}N_{Sc})^{1/3}$ | [T] Fit to above ignoring molecular diffusion. | [101] p. 80 |
| | $a = 1.00 \pm 0.01$ | $1000 < (N_{Re}N_{Sc}) < 10{,}000$. | [138] p. 215 |
| C. Single spheres, molecular diffusion, and forced convection, low flow rates | $N_{Sh} = 2.0 + AN_{Re}^{1/2}N_{Sc}^{1/3}$<br>$A = 0.5$ to $0.62$ | [E] Use with log mean concentration difference. Average over sphere. | [39] |
| | | Frössling Eq. ($A = 0.552$), $2 \le N_{Re} \le 800$, $0.6 \le N_{sc} \le 2.7$. | [77], p. 194<br>[88] p. 114 |
| | | $N_{Sh}$ lower than experimental at high $N_{Re}$. | [141] p. 276 |
| | $A = 0.60$. | [E] Ranz and Marshall $2 \le N_{Re} \le 200$, $0.6 \le N_{sc} \le 2.5$. Modifications recommended [110] See also Table 5-23-O. | [39] p. 409, 647<br>[121] [110]<br>[138] p. 217<br>[141] p. 276 |
| | $A = 0.95$. | [E] Liquids $2 \le N_{Re} \le 2{,}000$. Graph in Ref. 138, p. 217–218. | [65][66] p. 482<br>[138] p. 217 |
| | $A = 0.95$. | [E] $100 \le N_{Re} \le 700$; $1{,}200 \le N_{Sc} \le 1525$. | [126][141] p. 276 |
| | $A = 0.544$. | [E] Use with arithmetic concentration difference. $N_{Sc} = 1$; $50 \le N_{Re} \le 350$. | [81][141] p. 276 |
| D. Same as 5-20-C | $N_{Sh} = \dfrac{k'd_s}{D} = 2.0 + 0.575N_{Re}^{1/2}N_{Sc}^{0.35}$ | [E] Use with log mean concentration difference. $N_{Sc} \le 1$, $N_{Re} < 1$. | [70][141] p. 276 |
| E. Same as 5-20-C | $N_{Sh} = \dfrac{k'd_s}{D} = 2.0 + 0.552N_{Re}^{0.53}N_{Sc}^{1/3}$ | [E] Use with log mean concentration difference. $1.0 < N_{Re} \le 48{,}000$ Gases: $0.6 \le N_{Sc} \le 2.7$. | [66] p. 482 |
| F. Single spheres, forced concentration, any flow rate | $N_{Sh} = \dfrac{k'_c d_s}{D} = 2.0 + 0.59\left[\dfrac{E^{1/3}d_p^{4/3}\rho}{\mu}\right]^{0.57}N_{Sc}^{1/3}$<br>Energy dissipation rate per unit mass of fluid (ranges $570 < N_{Sc} < 1420$):<br>$E = \left(\dfrac{C_{Dr}}{2}\right)\left(\dfrac{v_r^3}{d_p}\right)\dfrac{m^2}{s^3}$ | [S] Correlates large amount of data and compares to published data. $v_r$ = relative velocity between fluid and sphere, m/s. $C_{Dr}$ = drag coefficient for single particle fixed in fluid at velocity $v_r$. See 5-23-F for calculation details and applications.<br>$2 < \left(\dfrac{E^{1/3}d_p^{4/3}\rho}{\mu}\right) < 63{,}000$ | [108] |
| G. Single spheres, forced convection, high flow rates, ignoring molecular diffusion | $N_{Sh} = \dfrac{k'd_s}{D} = 0.347N_{Re}^{0.62}N_{Sc}^{1/3}$ | [E] Use with arithmetic concentration difference. Liquids, $2000 < N_{Re} < 17{,}000$. | [66] p. 482<br>[147] |
| | | High $N_{Sc}$, graph in Ref. 138, p. 217–218. | [138] p. 217 |
| | $N_{Sh} = \dfrac{k'd_s}{D} = 0.33N_{Re}^{0.6}N_{Sc}^{1/3}$ | [E] $1500 \le N_{Re} \le 12{,}000$. | [141] p. 276 |
| | $N_{Sh} = \dfrac{k'd_s}{D} = 0.43N_{Re}^{0.56}N_{Sc}^{1/3}$ | [E] $200 \le N_{Re} \le 4 \times 10^4$, "air" $\le N_{Sc} \le$ "water." | [141] p. 276 |
| | $N_{Sh} = \dfrac{k'd_s}{D} = 0.692N_{Re}^{0.514}N_{Sc}^{1/3}$ | [E] $500 \le N_{Re} \le 5000$. | [112]<br>[141] p. 276 |
| H. Single sphere immersed in bed of smaller particles. For gases. | $N_{Sh,avg} = \dfrac{kd_1}{D'} = \varepsilon\left[4 + \dfrac{4}{5}N_{Pe'}^{2/3} + \dfrac{4}{\pi}N_{Pe'}\right]\left(1 + \dfrac{1}{9}N_{Pe'}\right)^{1/2}$<br>Limit $N_{Pe'} \to 0, N_{Sh,avg} = 2\varepsilon$ | [T] Compared to experiment. $N_{Pe'} = \dfrac{u_o d_1}{D'}$,<br>$D' = D/\tau$, $D$ = molecular diffusivity, $d_1$ = diameter large particle, $\tau$ = tortuosity. Arithmetic conc. difference fluid flow in inert bed follows Darcy's law. | [71] |
| I. Single cylinders, perpendicular flow | $N_{Sh} = \dfrac{k'd_s}{D} = AN_{Re}^{1/2}N_{Sc}^{1/3}$, $A = 0.82$ | [E] $100 < N_{Re} \le 3500$, $N_{Sc} = 1560$. | [141] p. 276 |
| | $A = 0.74$ | [E] $120 \le N_{Re} \le 6000$, $N_{Sc} = 2.44$. | [141] p. 276 |
| | $A = 0.582$ | [E] $300 \le N_{Re} \le 7600$, $N_{Sc} = 1200$. | [142] |
| | $j_D = 0.600(N_{Re})^{-0.487}$ | [E] Use with arithmetic concentration difference. | [141] p. 276 |
| | $N_{Sh} = \dfrac{k'd_{cyl}}{D}$ | $50 \le N_{Re} \le 50{,}000$; gases, $0.6 \le N_{Sc} \le 2.6$; liquids; $1000 \le N_{Sc} \le 3000$. Data scatter ± 30%. | [66] p. 486 |

**TABLE 5-20 Mass-Transfer Correlations for Flow Past Submerged Objects** (*Concluded*)

| Situation | Correlation | Comments<br>E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| J. Rotating cylinder in an infinite liquid, no forced flow | $j'_D = \frac{k'}{v} N_{Sc}^{0.644} = 0.0791 N_{Re}^{-0.30}$<br>Results presented graphically to $N_{Re} = 241{,}000$.<br>$N_{Re} = \frac{v d_{cyl} \mu}{\rho}$ where $v = \frac{\omega d_{cyl}}{2}$ = peripheral velocity | [E] Used with arithmetic concentration difference. Useful geometry in electrochemical studies.<br>$112 < N_{Re} \le 100{,}000$. $835 < N_{Sc} < 11490$<br>$k'$ = mass-transfer coefficient, cm/s; $\omega$ = rotational speed, radian/s. | [60]<br>[138] p. 238 |
| K. Stationary or rotating cylinder for air | Stationary:<br>$N_{Sh,avg} = A N_{Re}^{c} S_c^{1/3}$<br>$2.0 \times 10^4 \le N_{Re} \le 2.5 \times 10^5$; $d/H = 0.3$, Tu = 0.6%<br>$A = 0.0539$, $c = 0.771$ [114]<br>$A$ and $c$ depend on geometry [37]<br>Rotating in still air:<br>$N_{Sh,avg} = 0.169 N_{Re,\omega}^{2/3}$<br>$1.0E4 \le N_{Re,\omega} \le 1.0E5$; $N_{Sc} \approx 2.0$; $N_{Cr} \approx 2.0 \times 10^6$ | [E] Reasonable agreement with data of other investigators. $d$ = diameter of cylinder, $H$ = height of wind tunnel, Tu of = turbulence level, $N_{Re}$w = rotational Reynold's number = $u_\omega d\rho/\mu$, $u_\omega$ = cylinder surface velocity. Also correlations for two-dimensional slot jet flow [114]. For references to other correlations see [37]. | [37]<br>[114] |
| L. Oblate spheroid, forced convection | $j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}} = 0.74 N_{Re}^{-0.5}$<br>$N_{Re} = \frac{d_{ch} v \rho}{\mu}$, $d_{ch} = \frac{\text{total surface area}}{\text{perimeter normal to flow}}$<br>e.g., for cube with side length $a$, $d_{ch} = 1.27a$.<br>$N_{Sh} = \frac{k' d_{ch}}{D}$ | [E] Used with arithmetic concentration difference.<br>$120 \le N_{Re} \le 6000$; standard deviation 2.1%.<br>Eccentricities between 1:1 (spheres) and 3:1. Oblate spheroid is often approximated by drops. | [141] p. 284<br>[142] |
| M. Other objects, including prisms, cubes, hemispheres, spheres, and cylinders; forced convection | $j_D = 0.692 N_{Re,p}^{-0.486}$, $N_{Re,p} = \frac{v d_{ch} \rho}{\mu}$<br>Terms same as in 5-20-J. | [E] Used with arithmetic concentration difference. Agrees with cylinder and oblate spheroid results, $\pm 15\%$. Assumes molecular diffusion and natural convection are negligible.<br>$500 \le N_{Re,p} \le 5000$. Turbulent. | [88] p. 115<br>[141] p. 285<br>[111] [112] |
| N. Other objects, molecular diffusion limits | $N_{Sh} = \frac{k' d_{ch}}{D} = A$ | [T] Use with arithmetic concentration difference. Hard to reach limits in experiments. Spheres and cubes $A = 2$, tetrahedrons $A = 2\sqrt{6}$ octahedrons $2\sqrt{2}$. | [88] p. 114 |
| O. Shell side of microporous hollow fiber module for solvent extraction | $N_{Sh} = \beta [d_h (1 - \varphi)/L] N_{Re}^{0.6} N_{Sc}^{0.33}$<br>$N_{Sh} = \frac{\overline{K} d_h}{D}$<br>$N_{Re} = \frac{d_h v \rho}{\mu}$, $\overline{K}$ = overall mass-transfer coefficient<br>$\beta = 5.8$ for hydrophobic membrane.<br>$\beta = 6.1$ for hydrophilic membrane. | [E] Use with logarithmic mean concentration difference.<br>$d_h$ = hydraulic diameter<br>$= \frac{4 \times \text{cross-sectional area of flow}}{\text{wetted perimeter}}$<br>$\varphi$ = packing fraction of shell side.<br>$L$ = module length.<br>Based on area of contact according to inside or outside diameter of tubes depending on location of interface between aqueous and organic phases. Can also be applied to gas-liquid systems with liquid on shell side. | [118] |

**TABLE 5-21 Mass-Transfer Correlations for Drops, Bubbles, and Bubble Columns**

| Conditions | Correlations | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. Single liquid drop in immiscible liquid, drop formation, discontinuous (drop) phase coefficient | $\hat{k}_{d,f} = A\left(\frac{\rho_d}{M_d}\right)_{av}\left(\frac{D_d}{\pi t_f}\right)^{1/2}$<br>$A = \frac{24}{7}$ (penetration theory)<br>$A = 1.31$ (semiempirical value)<br>$A = \left[\frac{24}{7}(0.8624)\right]$ (extension by fresh surface elements) | [T,S] Use arithmetic mole fraction difference.<br>Fits some, but not all, data. Low mass transfer rate. $M_d$ = mean molecular weight of dispersed phase; $t_f$ = formation time of drop. $k_{L,d}$ = mean dispersed liquid phase M.T. coefficient kmole/[s·m$^2$ (mole fraction)]. | [141] p. 399 |
| B. Same as 5-21-A | $\hat{k}_{df} = 0.0432 \times \frac{d_p}{t_f}\left(\frac{\rho_d}{M_d}\right)_{av}\left(\frac{u_o}{d_p g}\right)^{0.089}\left(\frac{d_p^2}{t_f D_d}\right)^{-0.334}\left(\frac{\mu_d}{\sqrt{\rho_d d_p \sigma g_c}}\right)^{-0.601}$ | [E] Use arithmetic mole fraction difference. Based on 23 data points for 3 systems. Average absolute deviation 26%. Use with surface area of drop after detachment occurs. $u_o$ = velocity through nozzle; $\sigma$ = interfacial tension. | [141] p. 401<br>[144] p. 434 |
| C. Single liquid drop in immiscible liquid, drop formation, continuous phase coefficient | $\hat{k}_{cf} = 4.6\left(\frac{\rho_c}{M_c}\right)_{av}\sqrt{\frac{D_c}{\pi t_f}}$ | [T] Use arithmetic mole fraction difference. Based on rate of bubble growth away from fixed orifice. Approximately three times too high compared to experiments. | [141] p. 402 |
| D. Same as 5-21-C | $k_{L,c} = 0.386 \times \left(\frac{\rho_c}{M_c}\right)_{av}\left(\frac{D_c}{t_f}\right)^{0.5}\left(\frac{\rho_c \sigma g_c}{\Delta\rho g t_f \mu_c}\right)^{0.407}\left(\frac{g t_f^2}{d_p}\right)^{0.148}$ | [E] Average absolute deviation 11% for 20 data points for 3 systems. | [141] p. 402<br>[144] p. 434 |
| E. Single liquid drop in immiscible liquid, free rise or fall, discontinuous phase coefficient, stagnant drops | $k_{L,d,m} = \frac{-d_p}{6t}\left(\frac{\rho_d}{M_d}\right)_{av}\ln\left\{\frac{6}{\pi^2}\sum_{j=1}^{\infty}\frac{1}{j^2}\exp\left[\left(\frac{-D_d j^2 \pi^2 t}{(d_p/2)^2}\right)\right]\right\}$ | [T] Use with log mean mole fraction differences based on ends of column. $t$ = rise time. No continuous phase resistance. Stagnant drops are likely if drop is very viscous, quite small, or is coated with surface active agent. $k_{L,d,m}$ = mean dispersed liquid M.T. coefficient. | [141] p. 404<br>[144] p. 435 |
| F. Same as 5-21-E | $\hat{k}_{L,d,m} = \frac{-d_p}{6t}\left(\frac{\rho_d}{M_d}\right)_{av}\ln\left[1 - \frac{\pi D_d^{1/2} t^{1/2}}{d_p/2}\right]$ | [S] See 5-21-E. Approximation for fractional extractions less than 50%. | [141] p. 404<br>[144] p. 435 |
| G. Same as 5-21-E, continuous phase coefficient, stagnant drops, spherical | $N_{Sh} = \frac{k_{L,c,m} d_c}{D_c} = 0.74\left(\frac{\rho_c}{M_c}\right)_{av} N_{Re}^{1/2}(N_{Sc})^{1/3}$ | [E] $N_{Re} = \frac{v_s d_p \rho_c}{\mu_c}$, $v_s$ = slip velocity between drop and continuous phase. | [141] p. 407<br>[142][144] p. 436 |
| H. Single bubble or drop with surfactant. Stokes flow. | $N_{Sh} = 2.0 + \alpha N_{Pe}^{\beta}$, $N_{Sh} = 2rk/D$<br>$\alpha = \frac{5.49}{A + 6.10} + \frac{A}{A + 28.64}$<br>$\beta = \frac{0.35A + 17.21}{A + 34.14}$<br>$2r = 2$ to 50 μm, $A = 2.8\text{E}4$ to $7.0\text{E}5$<br>$0.0026 < N_{Pe,s} < 340$, $2.1 < N_{Ma} < 1.3\text{E}6$<br>$N_{Pe} = 1.0$ to $2.5 \times 10^4$,<br>$N_{Re} = 2.2 \times 10^{-6}$ to 0.034 | [T] $A$ = surface retardation parameter<br>$A = B\Gamma_o r/\mu D_s = N_{Ma} N_{Pe,s}$<br>$N_{Ma} = B\Gamma_o/\mu u$ = Marangoni no.<br>$\Gamma$ = surfactant surface conc.<br>$N_{Pe,s}$ = surface Peclet number = $ur/D_s$<br>$D_s$ = surface diffusivity<br>$N_{Pe}$ = bulk Peclet number<br>For $A >> 1$ acts like rigid sphere:<br>$\beta \to 0.35$, $\alpha \to 1/2864 = 0.035$ | [120] |
| I. 5-21-E, oblate spheroid | $N_{Sh} = \frac{k_{L,c,m} d_3}{D_c} = 0.74\left(\frac{\rho_c}{M_c}\right)_{av}(N_{Re,3})^{1/2}(N_{Sc,c})^{1/3}$<br>$N_{Re,3} = \frac{v_s d_3 \rho_c}{\mu_c}$ | [E] Used with log mean mole fraction. Differences based on ends of extraction column; 100 measured values ±2% deviation. Based on area oblate spheroid.<br>$v_s$ = slip velocity, $d_3 = \frac{\text{total drop surface area}}{\text{perimeter normal to flow}}$ | [141] p. 285, 406, 407 |
| J. Single liquid drop in immiscible liquid, Free rise or fall, discontinuous phase coefficient, circulating drops | $k_{dr,\text{circ}} = -\frac{d_p}{6\theta}\ln\left[\frac{3}{8}\sum_{j=1}^{\infty}B_j^2\exp\left(-\frac{\lambda_j 64 D_d \theta}{d_p^2}\right)\right]$<br>Eigenvalues for Circulating Drop<br>$k_d d_p/D_d$ \| $\lambda_1$ \| $\lambda_2$ \| $\lambda_3$ \| $B_1$ \| $B_2$ \| $B_3$<br>3.20 \| 0.262 \| 0.424 \| \| 1.49 \| 0.107 \|<br>10.7 \| 0.680 \| 4.92 \| \| 1.49 \| 0.300 \|<br>26.7 \| 1.082 \| 5.90 \| 15.7 \| 1.49 \| 0.495 \| 0.205<br>107 \| 1.484 \| 7.88 \| 19.5 \| 1.39 \| 0.603 \| 0.384<br>320 \| 1.60 \| 8.62 \| 21.3 \| 1.31 \| 0.583 \| 0.391<br>∞ \| 1.656 \| 9.08 \| 22.2 \| 1.29 \| 0.596 \| 0.386 | [T] Use with arithmetic concentration difference.<br>$\theta$ = drop residence time. A more complete listing of eigenvalues is given by Refs. 62 and 76.<br>$k'_{L,d,\text{circ}}$ is m/s. | [62][76][141] p. 405<br>[152] p. 523 |

| Conditions | Correlations | Comments<br>E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| U. Single liquid drops in gas, gas side coefficient | $\frac{\hat{k}_g M_g d_p P}{D_{gas}\rho_g} = 2 + AN_{Re,g}^{1/2} N_{Sc,g}^{1/3}$<br>$A = 0.552$ or 0.60.<br>$N_{Re,g} = \frac{d_p \rho_g v_s}{\mu_g}$ | [E] Used for spray drying (arithmetic partial pressure difference).<br>$v_s$ = slip velocity between drop and gas stream.<br>Sometimes written with $M_g P/\rho_g = RT$. | [90] p. 388<br>[121] |
| V. Single water drop in air, liquid side coefficient | $k_L = 2\left(\frac{D_L}{\pi t}\right)^{1/2}$, short contact times<br>$k_L = 10\,\frac{D_L}{d_p}$, long contact times | [T] Use arithmetic concentration difference. Penetration theory. $t$ = contact time of drop. Gives plot for $k_G a$ also. Air-water system. | [90] p. 389 |
| W. Single bubbles of gas in liquid, continuous phase coefficient, very small bubbles | $N_{Sh} = \frac{k_c' d_b}{D_c} = 1.0(N_{Re} N_{Sc})^{1/3}$ | [T] Solid-sphere Eq. (see Table 5-20-B). $d_b < 0.1$ cm, $k_c'$ is average over entire surface of bubble. | [105]<br>[138] p. 214 |
| X. Same as 5-21-W, medium to large bubbles | $N_{Sh} = \frac{k_c' d_b}{D_c} = 1.13(N_{Re} N_{Sc})^{1/2}$ | [T] Use arithmetic concentration difference. Droplet equation: $d_b > 0.5$ cm. | [138] p. 231 |
| Y. Same as 5-21-X | $N_{Sh} = \frac{k_c' d_b}{D_c} = 1.13(N_{Re} N_{Sc})^{1/2}\left[\frac{d_b}{0.45 + 0.2 d_b}\right]$<br>$500 \le N_{Re} \le 8000$ | [S] Use arithmetic concentration difference. Modification of above ($X$), $d_b > 0.5$ cm. No effect SAA for $d_p > 0.6$ cm. | [83][138] p. 231 |
| Z. Taylor bubbles in single capillaries (square or circular) | $k_L a = 4.5\left(\frac{D u_G}{L_{uc}}\right)^{1/2} \frac{1}{d_c}$<br>Applicable $\left(\frac{u_G + u_L}{L_{slug}}\right)^{0.5} > 3 s^{-0.5}$ | [E] Air-water<br>$L_{uc}$ = unit cell length, $L_{slug}$ = slug length, $d_c$ = capillary i.d.<br>For most data $k_L a \pm 20\%$. | [153] |
| AA. Gas-liquid mass transfer in monoliths | $k_L a \approx 0.1\left(\frac{P}{V}\right)^{1/4}$<br>$P/V$ = power/volume (kW/m$^3$), range = 100 to 10,000 | [E] Each channel in monolith is a capillary. Results are in expected order of magnitude for capillaries based on 5-21-Z.<br>$k_L$ is larger than in stirred tanks. | [93] |
| AB. Rising small bubbles of gas in liquid, continuous phase. Calderbank and Moo-Young correlation | $N_{Sh} = \frac{k_c' d_b}{D_c} = 2 + 0.31(N_{Gr})^{1/3} N_{Sc}^{1/3}$, $d_b < 0.25$ cm<br>$N_{Ra} = \frac{d_b^3 \rho_G - \rho_L \lvert g}{\mu_L D_L}$ = Raleigh number | [E] Use with arithmetic concentration difference. Valid for single bubbles or swarms. Independent of agitation as long as bubble size is constant. Recommended by [136].<br>Note that $N_{Ra} = N_{Gr} N_{Sc}$. | [47][66] p. 451<br>[88] p. 119<br>[152] p. 156<br>[136] |
| AC. Same as 5-21-AB, large bubbles | $N_{Sh} = \frac{k_c' d_b}{D_c} = 0.42\,(N_{Gr})^{1/3} N_{Sc}^{1/2}$, $d_b > 0.25$ cm<br>$\frac{\text{Interfacial area}}{\text{volume}} = a = \frac{6\,H_g}{d_b}$ | [E] Use with arithmetic concentration difference. For large bubbles, $k_c'$ is independent of bubble size and independent of agitation or liquid velocity. Resistance is entirely in liquid phase for most gas-liquid mass transfer.<br>$H_g$ = fractional gas holdup, volume gas/total volume. | [47][66] p. 452<br>[88] p. 119<br>[97] p. 249<br>[136] |
| AD. Bubbles in bubble columns. Hughmark correlation | $N_{Sh} = \frac{k_L d}{D} = 2 + bN_{Sc}^{0.546} N_{Re}^{0.779}\left(\frac{d g^{1/3}}{D^{2/3}}\right)^{0.116}$<br>$b = 0.061$ single gas bubbles;<br>$b = 0.0187$ swarms of bubbles,<br>$V_s = \frac{V_g}{\varphi_G} - \frac{V_L}{1 - \varphi_G}$ | [E] $d$ = bubble diameter<br>Air–liquid. Recommended by [136, 152]. For swarms, calculate<br>$N_{Re}$ with slip velocity $V_s$.<br>$\varphi_G$ = gas holdup<br>$V_G$ = superficial gas velocity<br>Col. diameter = 0.025 to 1.1 m<br>$\rho_L'$ = 776 to 1696 kg/m$^3$<br>$\mu_L$ = 0.0009 to 0.152 Pa·s | [55]<br>[82]<br>[152] p. 144 |
| AE. Bubbles in bubble column | $k_L a = 0.00315 u_G^{0.59}\,\mu_{eff}^{-0.84}$ | [E] Recommended by [136]. | [57] |

| AF. Bubbles in bubble column | $k_L = \frac{0.15D}{d_{Vs}}\left(\frac{\nu}{D}\right)^{1/2} N_{Re}^{3/4}$ | [E] $d_{Vs}$ = Sauter mean bubble diameter, $N_{Re} = d_{Vs}u_G\rho_L/\mu_L$. Recommended by [49] based on experiments in industrial system. | [49] [133] |
| AG. High-pressure bubble column | $k_La = 1.77\sigma^{-0.22}\exp(1.65u_\ell - 65.3\mu_\ell)\varepsilon_g^{1.2}$<br>$790 < \rho_L < 1580$ kg/m$^3$<br>$0.00036 < \mu_\ell < 0.0383$ Pa·s<br>$0.0232 < \sigma_\ell < 0.0726$ N/m<br>$0.028 < u_g < 0.678$ m/s<br>$0 < u_\ell < 0.00089$ m/s | [E] Pressure up to 4.24 MPa.<br>$T$ up to 92°C.<br>$\varepsilon_g$ = gas holdup. Correlation to estimate $\varepsilon_g$ is given.<br>$0.045 < d_{col} < 0.45$ m, $d_{col}/H_{col} > 5$<br>$0.97 < \rho_g < 33.4$ kg/m$^3$ | [96] |
| AH. Three phase (gas-liquid-solid) bubble column to solid spheres | $N_{sh} = \frac{k_s d_p}{D} = 2.0 + 0.545N_{Sc}^{1/3}\left(\frac{ed_p^4}{\nu^3}\right)^{0.264}$<br>$N_{Sc}$ = 137 to 50,000 (very wide range)<br>$d_p$ = particle diameter (solids) | [E] $e$ = local energy dissipation rate/unit mass, $e = u_g g$<br>$N_{Sc} = \mu_L/(\rho_L D)$<br>Recommended by [136]. | [129] [136] |

See Table 5-22 for agitated systems.
*See the beginning of the "Mass Transfer" subsection for references.

practical purposes $\hat{k}_G$ is independent of temperature and pressure in the normal ranges of these variables.

For modest changes in temperature the influence of temperature upon the interfacial area $a$ may be neglected. For example, in experiments on the absorption of $SO_2$ in water, Whitney and Vivian [*Chem. Eng. Prog.*, **45,** 323 (1949)] found no appreciable effect of temperature upon $k'_Ga$ over the range from 10 to 50°C.

With regard to the liquid-phase mass-transfer coefficient, Whitney and Vivian found that the effect of temperature upon $k_La$ could be explained entirely by variations in the liquid-phase viscosity and diffusion coefficient with temperature. Similarly, the oxygen-desorption data of Sherwood and Holloway [*Trans. Am. Inst. Chem. Eng.*, **36,** 39 (1940)] show that the influence of temperature upon $H_L$ can be explained by the effects of temperature upon the liquid-phase viscosity and diffusion coefficients (see Table 5-24-A).

It is important to recognize that the effects of temperature on the liquid-phase diffusion coefficients and viscosities can be very large and therefore must be carefully accounted for when using $\hat{k}_L$ or $H_L$ data. For liquids the mass-transfer coefficient $\hat{k}_L$ is correlated as either the Sherwood number or the Stanton number as a function of the Reynolds and Schmidt numbers (see Table 5-24). Typically, the general form of the correlation for $H_L$ is (Table 5-24)

$$H_L = bN_{Re}^a N_{Sc}^{1/2} \tag{5-306}$$

where $b$ is a proportionality constant and the exponent $a$ may range from about 0.2 to 0.5 for different packings and systems. The liquid-phase diffusion coefficients may be corrected from a base temperature $T_1$ to another temperature $T_2$ by using the Einstein relation as recommended by Wilke [*Chem. Eng. Prog.*, **45,** 218 (1949)]:

$$D_2 = D_1(T_2/T_1)(\mu_1/\mu_2) \tag{5-307}$$

The Einstein relation can be rearranged to the following equation for relating Schmidt numbers at two temperatures:

$$N_{Sc2} = N_{Sc1}(T_1/T_2)(\rho_1/\rho_2)(\mu_2/\mu_1)^2 \tag{5-308}$$

Substitution of this relation into Eq. (5-306) shows that for a given geometry the effect of temperature on $H_L$ can be estimated as

$$H_{L2} = H_{L1}(T_1/T_2)^{1/2}(\rho_1/\rho_2)^{1/2}(\mu_2/\mu_1)^{1-a} \tag{5-309}$$

In using these relations it should be noted that for equal liquid flow rates

$$H_{L2}/H_{L1} = (\hat{k}_La)_1/(\hat{k}_La)_2 \tag{5-310}$$

**Effects of System Physical Properties on $\hat{k}_G$ and $\hat{k}_L$** When designing packed towers for nonreacting gas-absorption systems for which no experimental data are available, it is necessary to make corrections for differences in composition between the existing test data and the system in question. The ammonia-water test data (see Table 5-24-B) can be used to estimate $H_G$, and the oxygen desorption data (see Table 5-24-A) can be used to estimate $H_L$. The method for doing this is illustrated in Table 5-24-E. There is some conflict on whether the value of the exponent for the Schmidt number is 0.5 or 2/3 [Yadav and Sharma, *Chem. Eng. Sci.* **34,** 1423 (1979)]. Despite this disagreement, this method is extremely useful, especially for absorption and stripping systems.

It should be noted that the influence of substituting solvents of widely differing viscosities upon the interfacial area $a$ can be very large. One therefore should be cautious about extrapolating $\hat{k}_La$ data to account for viscosity effects between different solvent systems.

**Effects of High Solute Concentrations on $\hat{k}_G$ and $\hat{k}_L$** As discussed previously, the stagnant-film model indicates that $\hat{k}_G$ should be independent of $y_{BM}$ and $k_G$ should be inversely proportional to $y_{BM}$. The data of Vivian and Behrman [*Am. Inst. Chem. Eng. J.*, **11,** 656 (1965)] for the absorption of ammonia from an inert gas strongly suggest that the film model's predicted trend is correct. This is another indication that the most appropriate rate coefficient to use in concentrated systems is $\hat{k}_G$ and the proper driving-force term is of the form $(y - y_i)/y_{BM}$.

The use of the rate coefficient $\hat{k}_L$ and the driving force $(x_i - x)/x_{BM}$ is believed to be appropriate. For many practical situations the liquid-phase solute concentrations are low, thus making this assumption unimportant.

**Influence of Chemical Reactions on $\hat{k}_G$ and $\hat{k}_L$** When a chemical reaction occurs, the transfer rate may be influenced by the chemical reaction as well as by the purely physical processes of diffusion and convection within the two phases. Since this situation is common in gas absorption, gas absorption will be the focus of this discussion. One must consider the impacts of chemical equilibrium and reaction kinetics on the absorption rate in addition to accounting for the effects of gas solubility, diffusivity, and system hydrodynamics.

There is no sharp dividing line between pure physical absorption and absorption controlled by the rate of a chemical reaction. Most cases fall in an intermediate range in which the rate of absorption is limited both by the resistance to diffusion and by the finite velocity of the reaction. Even in these intermediate cases the equilibria between the various diffusing species involved in the reaction may affect the rate of absorption.

**TABLE 5-23 Mass-Transfer Correlations for Fixed and Fluidized Beds**

Transfer is to or from particles

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. For gases, fixed and fluidized beds, Gupta and Thodos correlation | $j_H = j_D = \dfrac{2.06}{\varepsilon N_{Re}^{0.575}}$, $90 \le N_{Re} \le A$<br>Equivalent:<br>$N_{Sh} = \dfrac{2.06}{\varepsilon} N_{Re}^{0.425} N_{Sc}^{1/3}$<br>For other shapes:<br>$\dfrac{\varepsilon j_D}{(\varepsilon j_D)_{\text{sphere}}} = 0.79$ (cylinder) or 0.71 (cube) | [E] For spheres. $N_{Re} = \dfrac{v_{\text{super}} d_p \rho}{\mu}$<br>$A = 2453$ [Ref. 141], $A = 4000$ [Ref. 77].<br>For $N_{Re} > 1900$, $j_H = 1.05 j_D$.<br>Heat transfer result is in absence of radiation.<br>$N_{Sh} = \dfrac{k' d_s}{D}$<br>Graphical results are available for $N_{Re}$ from 1900 to 10,300.<br>$a = \dfrac{\text{surface area}}{\text{volume}} = 6(1-\varepsilon)/d_p$<br>For spheres, $d_p$ = diameter.<br>For nonspherical: $d_p = 0.567 \sqrt{\text{Part. Surf. Area}}$ | [72] [73]<br>[77] p. 195<br>[141] |
| B. For gases, for fixed beds, Petrovic and Thodos correlation | $N_{Sh} = \dfrac{0.357}{\varepsilon} N_{Re}^{0.641} N_{Sc}^{1/3}$<br>$3 < N_{Re} < 900$ can be extrapolated to $N_{Re} < 2000$. | [E] Packed spheres, deep beds. Corrected for axial dispersion with axial Peclet number = 2.0. Prediction is low at low $N_{Re}$. $N_{Re}$ defined as in 5-23-A. | [116][128] p. 214 [155] |
| C. For gases and liquids, fixed and fluidized beds | $j_D = \dfrac{0.4548}{\varepsilon N_{Re}^{0.4069}}$, $10 \le N_{Re} \le 2000$<br>$j_D = \dfrac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}$, $N_{Sh} = \dfrac{k' d_s}{D}$ | [E] Packed spheres, deep bed. Average deviation $\pm 20\%$, $N_{Re} = d_p v_{\text{super}} \rho/\mu$. Can use for fluidized beds. $10 \le N_{Re} \le 4000$. | [60][66] p. 484 |
| D. For gases, fixed beds | $j_D = \dfrac{0.499}{\varepsilon N_{Re}^{0.382}}$ | [E] Data on sublimination of naphthalene spheres dispersed in inert beads. $0.1 < N_{Re} < 100$, $N_{Sc} = 2.57$. Correlation coefficient = 0.978. | [80] |
| E. For liquids, fixed bed, Wilson and Geankoplis correlation | $j_D = \dfrac{1.09}{\varepsilon N_{Re}^{2/3}}$, $0.0016 < N_{Re} < 55$<br>$165 \le N_{Sc} \le 70{,}600$, $0.35 < \varepsilon < 0.75$<br>Equivalent:<br>$N_{Sh} = \dfrac{1.09}{\varepsilon} N_{Re}^{1/3} N_{Sc}^{1/3}$<br>$j_D = \dfrac{0.25}{\varepsilon N_{Re}^{0.31}}$, $55 < N_{Re} < 1500$, $165 \le N_{Sc} \le 10{,}690$<br>Equivalent: $N_{Sh} = \dfrac{0.25}{\varepsilon} N_{Re}^{0.69} N_{Sc}^{1/3}$ | [E] Beds of spheres,<br>$N_{Re} = \dfrac{d_p V_{\text{super}} \rho}{\mu}$<br>Deep beds.<br>$N_{Sh} = \dfrac{k' d_s}{D}$ | [66] p. 484<br>[77] p. 195<br>[141] p. 287 [158] |
| F. For liquids, fixed beds, Ohashi et al. correlation | $N_{Sh} = \dfrac{k' d_s}{D} = 2 + 0.51 \left( \dfrac{E^{1/3} d_p^{4/3} \rho}{\mu} \right)^{0.60} N_{Sc}^{1/3}$<br>$E$ = Energy dissipation rate per unit mass of fluid<br>$= 50(1-\varepsilon)\varepsilon^2 C_{Do} \left( \dfrac{v_r^3}{d_p} \right)$, m²/s³<br>$= \left[ \dfrac{50(1-\varepsilon) C_D}{\varepsilon} \right] \left( \dfrac{v_{\text{super}}^3}{d_p} \right)$<br>General form:<br>$N_{Sh} = 2 + K \left( \dfrac{E^{1/3} D_p^{4/3} \rho}{\mu} \right)^{\alpha} N_{Sc}^{\beta}$<br>applies to single particles, packed beds, two-phase tube flow, suspended bubble columns, and stirred tanks with different definitions of $E$. | [S] Correlates large amount of published data. Compares number of correlations, $v_r$ = relative velocity, m/s. In packed bed, $v_r = v_{\text{super}}/\varepsilon$.<br>$C_{Do}$ = single particle drag coefficient at $v_{\text{super}}$ calculated from $C_{Do} = A N_{Re_i}^{-m}$.<br>$N_{Re}$ / $A$ / $m$<br>0 to 5.8 / 24 / 1.0<br>5.8 to 500 / 10 / 0.5<br>>500 / 0.44 / 0<br>Ranges for packed bed:<br>$0.001 < N_{Re} < 1000$, $505 < N_{Sc} < 70{,}600$,<br>$0.2 < \dfrac{E^{1/3} d_p^{4/3} \rho}{\mu} < 4600$<br>Compares different situations versus general correlation. See also 5-20-F. | [108] |

**TABLE 5-23 Mass Transfer Correlations for Fixed and Fluidized Beds** (*Continued*)

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| G. Electrolytic system. Pall rings. Transfer from fluid to rings. | Full liquid upflow: $N_{sh} = k_L d_e/D = 4.1 N_{Re}^{0.39} N_{Sc}^{1/3}$ $N_{Re} d_e u/\nu = 80$ to 550 Irrigated liquid downflow (no gas flow): $N_{Sh} = 5.1 N_{Re}^{0.44} N_{Sc}^{1/3}$ | [E] $d_e$ = diameter of sphere with same surface area as Pall ring. Full liquid upflow agreed with literature values. Schmidt number dependence was assumed from literature values. In downflow, $N_{Re}$ used superficial fluid velocity. | [69] |
| H. For liquids, fixed and fluidized beds | $\varepsilon j_D = \dfrac{1.1068}{N_{Re}^{0.72}}$, $1.0 < N_{Re} \le 10$ $\varepsilon j_D = \dfrac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}$, $N_{Sh} = \dfrac{k' d_s}{D}$ | [E] Spheres: $N_{Re} = \dfrac{d_p v_{\text{super}} \rho}{\mu}$ | [59][66] p. 484 |
| I. For gases and liquids, fixed and fluidized beds, Dwivedi and Upadhyay correlation | $\varepsilon j_D = \dfrac{0.765}{N_{Re}^{0.82}} + \dfrac{0.365}{N_{Re}^{0.386}}$ Gases: $10 \le N_{Re} \le 15{,}000$. Liquids: $0.01 \le N_{Re} \le 15{,}000$. $N_{Re} = \dfrac{d_p v_{\text{super}} \rho}{\mu}$, $N_{Sh} = \dfrac{k' d_s}{D}$ | [E] Deep beds of spheres, $j_D = \dfrac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}$ Best fit correlation at low conc. [52] Based on 20 gas studies and 17 liquid studies. Recommended instead of 5-23-C or E. | [59] [77] p. 196 [52] |
| J. For gases and liquids, fixed bed | $j_D = 1.17 N_{Re}^{-0.415}$, $10 \le N_{Re} \le 2500$ $j_D = \dfrac{k'}{v_{av}} \dfrac{p_{BM}}{P} N_{Sc}^{2/3}$ | [E] Spheres: Variation in packing that changes $\varepsilon$ not allowed for. Extensive data referenced. $0.5 < N_{Sc} < 15{,}000$. Comparison with other results are shown. $N_{Re} = \dfrac{d_p v_{\text{super}} \rho}{\mu}$ | [138] p. 241 |
| K. For liquids, fixed and fluidized beds, Rahman and Streat correlation | $N_{Sh} = \dfrac{0.86}{\varepsilon} N_{Re} N_{Sc}^{1/3}$, $2 \le N_{Re} \le 25$ | [E] Can be extrapolated to $N_{Re} = 2000$. $N_{Re} = d_p v_{\text{super}} \rho/\mu$. Done for neutralization of ion exchange resin. | [119] |
| L. Size exclusion chromatography of proteins | $N_{Sh} = \dfrac{k_L d}{D} = \dfrac{1.903}{\varepsilon} N_{Re}^{1/3} N_{Sc}^{1/3}$ | [E] Slow mass transfer with large molecules. Aqueous solutions. Modest increase in $N_{Sh}$ with increasing velocity. | [79] |
| M. Liquid-free convection with fixed bed Raschig rings. Electrochemical. | $N_{Sh} = kd/D = 0.15 (N_{Sc} N_{Gr})^{0.32}$ $N_{Gr}$ = Grashof no. = $g d^3 \Delta\rho/(\nu^2 \rho)$ If forced convection superimposed, $N_{Sh,\text{ overall}} = (N_{Sh,\text{forced}}^3 + N_{Sh,\text{free}}^3)^{1/3}$ | [E] $d$ = Raschig ring diameter, $h$ = bed height $1810 < N_{Sc} < 2532$, $0.17 < d/h < 1.0$ $10.6 \times 10^6 < N_{Sc} N_{Gr} < 21 \times 10^7$ | [135] |
| N. Oscillating bed packed with Raschig rings. Dissolution of copper rings. | Batch (no net solution flow): $N_{Sh} = 0.76 N_{Sc}^{0.33} N_{Re,v}^{0.7} (d_c/h)^{0.35}$ $503 < N_{Re,v} < 2892$ $960 < N_{Sc} < 1364$, $2.3 < d_c/h < 7.6$ | [E] $N_{Sh} = kd_c/D$, $N_{Re,v}$ = vibrational Re = $\rho v_v d_c/\mu$ $v_v$ = vibrational velocity (intensity) $d_c$ = col. diameter, $h$ = column height Average deviation is ± 12%. | [61] |
| O. For liquids and gases, Ranz and Marshall correlation | $N_{Sh} = \dfrac{k' d}{D} = 2.0 + 0.6 N_{Sc}^{1/3} N_{Re}^{1/2}$ $N_{Re} = \dfrac{d_p v_{\text{super}} \rho}{\mu}$ | [E] Based on freely falling, evaporating spheres (see 5-20-C). Has been applied to packed beds, prediction is low compared to experimental data. Limit of 2.0 at low $N_{Re}$ is too high. Not corrected for axial dispersion. | [121][128] p. 214 [155] [110] |
| P. For liquids and gases, Wakao and Funazkri correlation | $N_{Sh} = 2.0 + 1.1 N_{Sc}^{1/3} N_{Re}^{0.6}$, $3 < N_{Re} < 10{,}000$ $N_{Sh} = \dfrac{k'_{\text{film}}\, d_p}{D}$, $N_{Re} = \dfrac{\rho_f v_{\text{super}} \rho}{\mu}$ $\dfrac{\varepsilon D_{\text{axial}}}{D} = 10 + 0.5 N_{Sc} N_{Re}$ | [E] Correlate 20 gas studies and 16 liquid studies. Corrected for axial dispersion with: Graphical comparison with data shown [128], p. 215, and [155]. $D_{\text{axial}}$ is axial dispersion coefficient. | [128] p. 214 [155] |
| Q. Acid dissolution of limestone in fixed bed | $N_{Sh} = 1.77 N_{Re}^{0.56} N_{Sc}^{1/3} (1 - \varepsilon)^{0.44}$ $20 < N_{Re} < 6000$ | [E] Best fit was to correlation of Chu et al., *Chem. Eng. Prog.*, **49**(3), 141(1953), even though no reaction in original. | [94] |
| R. Semifluidized or expanded bed. Liquid-solid transfer. | $N_{Sh} = \dfrac{k_{\text{film}}\, d_p}{D} = 2 + 1.5 (1 - \varepsilon_L) N_{Re}^{1/3} N_{Sc}^{1/3}$ $N_{Re} = \rho_p d_p u/\mu\varepsilon_L$; $N_{Sc} = \mu/\rho D$ | [E] $\varepsilon_L$ = liquid-phase void fraction, $\rho_p$ = particle density, $\rho$ = fluid density, $d_p$ = particle diameter. Fits expanded bed chromatography in viscous liquids. | [64] [159] |

*See the beginning of the "Mass Transfer" subsection for references.

The gas-phase rate coefficient $\hat{k}_G$ is not affected by the fact that a chemical reaction is taking place in the liquid phase. If the liquid-phase chemical reaction is extremely fast and irreversible, the rate of absorption may be governed completely by the resistance to diffusion in the gas phase. In this case the absorption rate may be estimated by knowing only the gas-phase rate coefficient $\hat{k}_G$ or else the height of one gas-phase transfer unit $H_G = G_M/(\hat{k}_G a)$.

It should be noted that the highest possible absorption rates will occur under conditions in which the liquid-phase resistance is negligible and the equilibrium back pressure of the gas over the solvent is zero.

Such situations would exist, for instance, for $NH_3$ absorption into an acid solution, for $SO_2$ absorption into an alkali solution, for vaporization of water into air, and for $H_2S$ absorption from a dilute-gas stream into a strong alkali solution, provided there is a large excess of reagent in solution to consume all the dissolved gas. This is known as the gas-phase mass-transfer limited condition, when both the liquid-phase resistance and the back pressure of the gas equal zero. Even when the reaction is sufficiently reversible to allow a small back pressure, the absorption may be gas-phase-controlled, and the values of $\hat{k}_G$ and $H_G$ that would apply to a physical-absorption process will govern the rate.

The liquid-phase rate coefficient $\hat{k}_L$ is strongly affected by fast chemical reactions and generally increases with increasing reaction rate. Indeed, the condition for zero liquid-phase resistance ($m/\hat{k}_L$) implies that either the equilibrium back pressure is negligible, or that $\hat{k}_L$ is very large, or both. Frequently, even though reaction consumes the solute as it is dissolving, thereby enhancing both the mass-transfer coefficient and the driving force for absorption, the reaction rate is slow enough that the liquid-phase resistance must be taken into account. This may be due either to an insufficient supply of a second reagent or to an inherently slow chemical reaction.

In any event the value of $\hat{k}_L$ in the presence of a chemical reaction normally is larger than the value found when only physical absorption occurs, $\hat{k}_L^0$. This has led to the presentation of data on the effects of chemical reaction in terms of the "reaction factor" or "enhancement factor" defined as

$$\phi = \hat{k}_L/\hat{k}_L^0 \geq 1 \tag{5-311}$$

where $\hat{k}_L$ = mass-transfer coefficient with reaction and $\hat{k}_L^0$ = mass-transfer coefficient for pure physical absorption.

It is important to understand that when chemical reactions are involved, this definition of $\hat{k}_L$ is based on the driving force defined as the difference between the concentration of *unreacted* solute gas at the interface and in the bulk of the liquid. A coefficient based on the total of both unreacted and reacted gas could have values *smaller* than the physical-absorption mass-transfer coefficient $\hat{k}_L^0$.

When liquid-phase resistance is important, particular care should be taken in employing any given set of experimental data to ensure that the equilibrium data used conform with those employed by the original author in calculating values of $\hat{k}_L$ or $H_L$. Extrapolation to widely different concentration ranges or operating conditions should be made with caution, since the mass-transfer coefficient $\hat{k}_L$ may vary in an unexpected fashion, owing to changes in the apparent chemical-reaction mechanism.

Generalized prediction methods for $\hat{k}_L$ and $H_L$ do not apply when chemical reaction occurs in the liquid phase, and therefore one must use actual operating data for the particular system in question. A discussion of the various factors to consider in designing gas absorbers and strippers when chemical reactions are involved is presented by Astarita, Savage, and Bisio, *Gas Treating with Chemical Solvents,* Wiley (1983) and by Kohl and Nielsen, *Gas Purification,* 5th ed., Gulf (1997).

**Effective Interfacial Mass-Transfer Area *a*** In a packed tower of constant cross-sectional area $S$ the differential change in solute flow per unit time is given by

$$-d(G_M S y) = N_A a\, dV = N_A a S\, dh \tag{5-312}$$

where $a$ = interfacial area effective for mass transfer per unit of packed volume and $V$ = packed volume. Owing to incomplete wetting of the packing surfaces and to the formation of areas of stagnation in the liquid film, the effective area normally is significantly less than the total external area of the packing pieces.

The effective interfacial area depends on a number of factors, as discussed in a review by Charpentier [*Chem. Eng. J.,* **11,** 161 (1976)]. Among these factors are (1) the shape and size of packing, (2) the packing material (for example, plastic generally gives smaller interfacial areas than either metal or ceramic), (3) the liquid mass velocity, and (4), for small-diameter towers, the column diameter.

Whereas the interfacial area generally increases with increasing liquid rate, it apparently is relatively independent of the superficial gas mass velocity below the flooding point. According to Charpentier's review, it appears valid to assume that the interfacial area is independent of the column height when specified in terms of unit packed volume (i.e., as $a$). Also, the existing data for chemically reacting gas-liquid systems (mostly aqueous electrolyte solutions) indicate that the interfacial area is independent of the chemical system. However, this situation may not hold true for systems involving large heats of reaction.

Rizzuti et al. [*Chem. Eng. Sci.,* **36,** 973 (1981)] examined the influence of solvent viscosity upon the effective interfacial area in packed columns and concluded that for the systems studied the effective interfacial area $a$ was proportional to the kinematic viscosity raised to the 0.7 power. Thus, the hydrodynamic behavior of a packed absorber is strongly affected by viscosity effects. Surface-tension effects also are important, as expressed in the work of Onda et al. (see Table 5-24-C).

In developing correlations for the mass-transfer coefficients $\hat{k}_G$ and $\hat{k}_L$, the various authors have assumed different but internally compatible correlations for the effective interfacial area $a$. It therefore would be inappropriate to mix the correlations of different authors unless it has been demonstrated that there is a valid area of overlap between them.

**Volumetric Mass-Transfer Coefficients $\hat{K}_G a$ and $\hat{K}_L a$** Experimental determinations of the individual mass-transfer coefficients $\hat{k}_G$ and $\hat{k}_L$ and of the effective interfacial area $a$ involve the use of extremely difficult techniques, and therefore such data are not plentiful. More often, column experimental data are reported in terms of overall volumetric coefficients, which normally are defined as follows:

$$K'_G a = n_A/(h_T S p_T \Delta y^\circ_{1m}) \tag{5-313}$$

and

$$K_L a = n_A/(h_T S\, \Delta x^\circ_{1m}) \tag{5-314}$$

where $K'_G a$ = overall volumetric gas-phase mass-transfer coefficient, $K_L a$ = overall volumetric liquid-phase mass-transfer coefficient, $n_A$ = overall rate of transfer of solute $A$, $h_T$ = total packed depth in tower, $S$ = tower cross-sectional area, $p_T$ = total system pressure employed during the experiment, and $\Delta x^\circ_{1m}$ and $\Delta y^\circ_{1m}$ are defined as

$$\Delta y^\circ_{1m} = \frac{(y - y^\circ)_1 - (y - y^\circ)_2}{\ln\,[(y - y^\circ)_1/(y - y^\circ)_2]} \tag{5-315}$$

and

$$\Delta x^\circ_{1m} = \frac{(x^\circ - x)_2 - (x^\circ - x)_1}{\ln\,[(x^\circ - x)_2/(x^\circ - x)_1]} \tag{5-316}$$

where subscripts 1 and 2 refer to the bottom and top of the tower respectively.

Experimental $K'_G a$ and $K_L a$ data are available for most absorption and stripping operations of commercial interest (see Sec. 14). The solute concentrations employed in these experiments normally are very low, so that $K_L a \doteq \hat{K}_L a$ and $K'_G a p_T \doteq \hat{K}_G a$, where $p_T$ is the total pressure employed in the actual experimental-test system. Unlike the individual gas-film coefficient $\hat{k}_G a$, the overall coefficient $\hat{K}_G a$ will vary with the total system pressure except when the liquid-phase resistance is negligible (i.e., when either $m = 0$, or $\hat{k}_L a$ is very large, or both).

Extrapolation of $K_G a$ data for absorption and stripping to conditions other than those for which the original measurements were made can be extremely risky, especially in systems involving chemical reactions in the liquid phase. One therefore would be wise to restrict the use of overall volumetric mass-transfer-coefficient data to conditions not too far removed from those employed in the actual tests. The most reliable data for this purpose would be those obtained from an operating commercial unit of similar design.

Experimental values of $H_{OG}$ and $H_{OL}$ for a number of distillation systems of commercial interest are also readily available. Extrapolation of the data or the correlations to conditions that differ significantly from those used for the original experiments is risky. For example, pressure has a major effect on vapor density and thus can affect the hydrodynamics significantly. Changes in flow patterns affect both mass-transfer coefficients and interfacial area.

**Chilton-Colburn Analogy** On occasion one will find that heat-transfer-rate data are available for a system in which mass-transfer-rate data are not readily available. The Chilton-Colburn analogy [90, 53] (see Tables 5-17-G and 5-19-T) provides a procedure for developing estimates of the mass-transfer rates based on heat-transfer data. Extrapolation of experimental $j_M$ or $j_H$ data obtained with gases to predict liquid systems (and vice versa) should be approached with caution, however. When pressure-drop or friction-factor data are available, one may be able to place an upper bound on the rates of heat and mass transfer of $f/2$. The Chilton-Colburn analogy can be used for simultaneous heat and mass transfer as long as the concentration and temperature fields are independent [Venkatesan and Fogler, *AIChE J.* **50,** 1623 (2004)].

## Nomenclature and Units*

In this listing, symbols used in this section are defined in a general way and appropriate SI units are given. Specific definitions, as denoted by subscripts, are stated at the place of application in the section. Some specialized symbols used in the section are defined only at the place of application. Some symbols have more than one definition; the appropriate one is identified at the place of application.

| Symbol | Definition | SI units | U.S. customary units |
|---|---|---|---|
| $a$ | Pressure wave velocity | m/s | ft/s |
| $A$ | Area | $m^2$ | $ft^2$ |
| $b$ | Wall thickness | m | in |
| $b$ | Channel width | m | ft |
| $c$ | Acoustic velocity | m/s | ft/s |
| $c_f$ | Friction coefficient | Dimensionless | Dimensionless |
| $C$ | Conductance | $m^3/s$ | $ft^3/s$ |
| Ca | Capillary number | Dimensionless | Dimensionless |
| $C_0$ | Discharge coefficient | Dimensionless | Dimensionless |
| $C_D$ | Drag coefficient | Dimensionless | Dimensionless |
| $d$ | Diameter | m | ft |
| $D$ | Diameter | m | ft |
| De | Dean number | Dimensionless | Dimensionless |
| $D_{ij}$ | Deformation rate tensor components | 1/s | 1/s |
| $E$ | Elastic modulus | Pa | $lbf/in^2$ |
| $\dot{E}_v$ | Energy dissipation rate | J/s | ft · lbf/s |
| Eo | Eotvos number | Dimensionless | Dimensionless |
| $f$ | Fanning friction factor | Dimensionless | Dimensionless |
| $f$ | Vortex shedding frequency | 1/s | 1/s |
| $F$ | Force | N | lbf |
| $F$ | Cumulative residence time distribution | Dimensionless | Dimensionless |
| Fr | Froude number | Dimensionless | Dimensionless |
| $g$ | Acceleration of gravity | $m/s^2$ | $ft/s^2$ |
| $G$ | Mass flux | $kg/(m^2 \cdot s)$ | $lbm/(ft^2 \cdot s)$ |
| $h$ | Enthalpy per unit mass | J/kg | Btu/lbm |
| $h$ | Liquid depth | m | ft |
| $k$ | Ratio of specific heats | Dimensionless | Dimensionless |
| $k$ | Kinetic energy of turbulence | J/kg | ft · lbf/lbm |
| $K$ | Power law coefficient | $kg/(m \cdot s^{2-n})$ | $lbm/(ft \cdot s^{2-n})$ |
| $l_v$ | Viscous losses per unit mass | J/kg | ft · lbf/lbm |
| $L$ | Length | m | ft |
| $\dot{m}$ | Mass flow rate | kg/s | lbm/s |
| $M$ | Mass | kg | lbm |
| $M$ | Mach number | Dimensionless | Dimensionless |
| $M$ | Morton number | Dimensionless | Dimensionless |
| $M_w$ | Molecular weight | kg/kgmole | lbm/lbmole |
| $n$ | Power law exponent | Dimensionless | Dimensionless |
| $N_b$ | Blend time number | Dimensionless | Dimensionless |
| $N_D$ | Best number | Dimensionless | Dimensionless |
| $N_P$ | Power number | Dimensionless | Dimensionless |
| $N_Q$ | Pumping number | Dimensionless | Dimensionless |
| $p$ | Pressure | Pa | $lbf/in^2$ |
| $q$ | Entrained flow rate | $m^3/s$ | $ft^3/s$ |
| $Q$ | Volumetric flow rate | $m^3/s$ | $ft^3/s$ |
| $Q$ | Throughput (vacuum flow) | $Pa \cdot m^3/s$ | $lbf \cdot ft^3/s$ |
| $\delta Q$ | Heat input per unit mass | J/kg | Btu/lbm |
| $r$ | Radial coordinate | m | ft |
| $R$ | Radius | m | ft |
| $R$ | Ideal gas universal constant | J/(kgmole · K) | Btu/(lbmole · R) |
| $R_i$ | Volume fraction of phase $i$ | Dimensionless | Dimensionless |
| Re | Reynolds number | Dimensionless | Dimensionless |
| $s$ | Density ratio | Dimensionless | Dimensionless |
| $s$ | Entropy per unit mass | J/(kg · K) | Btu/(lbm · R) |
| $S$ | Slope | Dimensionless | Dimensionless |
| $S$ | Pumping speed | $m^3/s$ | $ft^3/s$ |
| $S$ | Surface area per unit volume | l/m | l/ft |
| St | Strouhal number | Dimensionless | Dimensionless |
| $t$ | Time | s | s |
| $t$ | Force per unit area | Pa | $lbf/in^2$ |
| $T$ | Absolute temperature | K | R |
| $u$ | Internal energy per unit mass | J/kg | Btu/lbm |
| $u$ | Velocity | m/s | ft/s |
| $U$ | Velocity | m/s | ft/s |
| $v$ | Velocity | m/s | ft/s |
| $V$ | Velocity | m/s | ft/s |
| $V$ | Volume | $m^3$ | $ft^3$ |
| We | Weber number | Dimensionless | Dimensionless |
| $\dot{W}_s$ | Rate of shaft work | J/s | Btu/s |
| $\delta W_s$ | Shaft work per unit mass | J/kg | Btu/lbm |
| $x$ | Cartesian coordinate | m | ft |
| $y$ | Cartesian coordinate | m | ft |
| $z$ | Cartesian coordinate | m | ft |
| $z$ | Elevation | m | ft |
| | Greek Symbols | | |
| $\alpha$ | Velocity profile factor | Dimensionless | Dimensionless |
| $\alpha$ | Included angle | Radians | Radians |
| $\beta$ | Velocity profile factor | Dimensionless | Dimensionless |
| $\beta$ | Bulk modulus of elasticity | Pa | $lbf/in^2$ |
| $\dot{\gamma}$ | Shear rate | l/s | l/s |
| $\Gamma$ | Mass flow rate per unit width | $kg/(m \cdot s)$ | $lbm/(ft \cdot s)$ |
| $\delta$ | Boundary layer or film thickness | m | ft |
| $\delta_{ij}$ | Kronecker delta | Dimensionless | Dimensionless |
| $\epsilon$ | Pipe roughness | m | ft |
| $\epsilon$ | Void fraction | Dimensionless | Dimensionless |
| $\epsilon$ | Turbulent dissipation rate | $J/(kg \cdot s)$ | $ft \cdot lbf/(lbm \cdot s)$ |
| $\theta$ | Residence time | s | s |
| $\theta$ | Angle | Radians | Radians |
| $\lambda$ | Mean free path | m | ft |
| $\mu$ | Viscosity | $Pa \cdot s$ | $lbm/(ft \cdot s)$ |
| $\nu$ | Kinematic viscosity | $m^2/s$ | $ft^2/s$ |
| $\rho$ | Density | $kg/m^3$ | $lbm/ft^3$ |
| $\sigma$ | Surface tension | N/m | lbf/ft |
| $\sigma$ | Cavitation number | Dimensionless | Dimensionless |
| $\sigma_{ij}$ | Components of total stress tensor | Pa | $lbf/in^2$ |
| $\tau$ | Shear stress | Pa | $lbf/in^2$ |
| $\tau$ | Time period | s | s |
| $\tau_{ij}$ | Components of deviatoric stress tensor | Pa | $lbf/in^2$ |
| $\Phi$ | Energy dissipation rate per unit volume | $J/(m^3 \cdot s)$ | $ft \cdot lbf/(ft^3 \cdot s)$ |
| $\phi$ | Angle of inclination | Radians | Radians |
| $\omega$ | Vorticity | 1/s | 1/s |

* Note that with U.S. Customary units, the conversion factor $g_c$ may be required to make equations in this section dimensionally consistent; $g_c = 32.17$ (lbm·ft)/(lbf·s$^2$).

## NATURE OF FLUIDS

**Deformation and Stress** A **fluid** is a substance which undergoes continuous deformation when subjected to a shear stress. Figure 6-1 illustrates this concept. A fluid is bounded by two large parallel plates, of area $A$, separated by a small distance $H$. The bottom plate is held fixed. Application of a force $F$ to the upper plate causes it to move at a velocity $U$. The fluid continues to deform as long as the force is applied, unlike a solid, which would undergo only a finite deformation.

The force is directly proportional to the area of the plate; the shear stress is $\tau = F/A$. Within the fluid, a linear velocity profile $u = Uy/H$ is established; due to the **no-slip condition,** the fluid bounding the lower plate has zero velocity and the fluid bounding the upper plate moves at the plate velocity $U$. The velocity gradient $\dot{\gamma} = du/dy$ is called the **shear rate** for this flow. Shear rates are usually reported in units of reciprocal seconds. The flow in Fig. 6-1 is a **simple shear flow.**

**Viscosity** The ratio of shear stress to shear rate is the viscosity, $\mu$.

$$\mu = \frac{\tau}{\dot{\gamma}} \tag{6-1}$$

The SI units of viscosity are kg/(m · s) or Pa · s (pascal second). The cgs unit for viscosity is the poise; 1 Pa · s equals 10 poise or 1000 centipoise (cP) or 0.672 lbm/(ft · s). The terms *absolute viscosity* and *shear viscosity* are synonymous with the viscosity as used in Eq. (6-1). **Kinematic viscosity** $\nu \equiv \mu/\rho$ is the ratio of viscosity to density. The SI units of kinematic viscosity are $m^2/s$. The cgs stoke is 1 $cm^2/s$.

**Rheology** In general, fluid flow patterns are more complex than the one shown in Fig. 6-1, as is the relationship between fluid deformation and stress. Rheology is the discipline of fluid mechanics which studies this relationship. One goal of rheology is to obtain **constitutive equations** by which stresses may be computed from deformation rates. For simplicity, fluids may be classified into rheological types in reference to the simple shear flow of Fig. 6-1. Complete definitions require extension to multidimensional flow. For more information, several good references are available, including Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977); Metzner ("Flow of Non-Newtonian Fluids" in Streeter, *Handbook of Fluid Dynamics,* McGraw-Hill, New York, 1971); and Skelland (*Non-Newtonian Flow and Heat Transfer*, Wiley, New York, 1967).

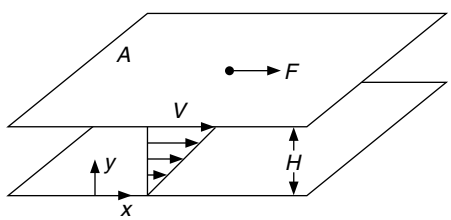

**FIG. 6-1** Deformation of a fluid subjected to a shear stress.

Fluids without any solidlike elastic behavior do not undergo any reverse deformation when shear stress is removed, and are called **purely viscous** fluids. The shear stress depends only on the rate of deformation, and not on the extent of deformation (strain). Those which exhibit both viscous and elastic properties are called **viscoelastic** fluids.

Purely viscous fluids are further classified into time-independent and time-dependent fluids. For time-independent fluids, the shear stress depends only on the instantaneous shear rate. The shear stress for time-dependent fluids depends on the past history of the rate of deformation, as a result of structure or orientation buildup or breakdown during deformation.

A **rheogram** is a plot of shear stress versus shear rate for a fluid in simple shear flow, such as that in Fig. 6-1. Rheograms for several types of time-independent fluids are shown in Fig. 6-2. The **Newtonian** fluid rheogram is a straight line passing through the origin. The slope of the line is the viscosity. For a Newtonian fluid, the viscosity is independent of shear rate, and may depend only on temperature and perhaps pressure. By far, the Newtonian fluid is the largest class of fluid of engineering importance. Gases and low molecular weight liquids are generally Newtonian. Newton's law of viscosity is a rearrangement of Eq. (6-1) in which the viscosity is a constant:

$$\tau = \mu\dot{\gamma} = \mu \frac{du}{dy} \tag{6-2}$$

All fluids for which the viscosity varies with shear rate are **non-Newtonian fluids.** For non-Newtonian fluids the viscosity, defined as the ratio of shear stress to shear rate, is often called the **apparent viscosity** to emphasize the distinction from Newtonian behavior. Purely viscous, time-independent fluids, for which the apparent viscosity may be expressed as a function of shear rate, are called **generalized Newtonian fluids.**

Non-Newtonian fluids include those for which a finite stress $\tau_y$ is required before continuous deformation occurs; these are called **yield-stress** materials. The **Bingham plastic** fluid is the simplest yield-stress material; its rheogram has a constant slope $\mu_\infty$, called the *infinite shear* viscosity.

$$\tau = \tau_y + \mu_\infty\dot{\gamma} \tag{6-3}$$

Highly concentrated suspensions of fine solid particles frequently exhibit Bingham plastic behavior.

**Shear-thinning** fluids are those for which the slope of the rheogram decreases with increasing shear rate. These fluids have also been called *pseudoplastic,* but this terminology is outdated and discouraged. Many polymer melts and solutions, as well as some solids suspensions, are shear-thinning. Shear-thinning fluids without yield stresses typically obey a power law model over a range of shear rates.

$$\tau = K\dot{\gamma}^n \tag{6-4}$$

The apparent viscosity is

$$\mu = K\dot{\gamma}^{n-1} \tag{6-5}$$

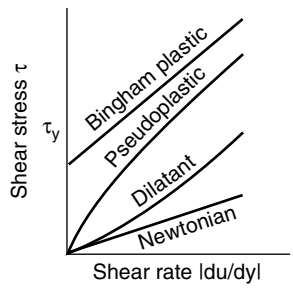

**FIG. 6-2** Shear diagrams.

The factor $K$ is the consistency index or power law coefficient, and $n$ is the power law exponent. The exponent $n$ is dimensionless, while $K$ is in units of kg/(m · $s^{2-n}$). For shear-thinning fluids, $n < 1$. The power law model typically provides a good fit to data over a range of one to two orders of magnitude in shear rate; behavior at very low and very high shear rates is often Newtonian. Shear-thinning power law fluids with yield stresses are sometimes called *Herschel-Bulkley fluids.* Numerous other rheological model equations for shear-thinning fluids are in common use.

**Dilatant,** or shear-thickening, fluids show increasing viscosity with increasing shear rate. Over a limited range of shear rate, they may be described by the power law model with $n > 1$. Dilatancy is rare, observed only in certain concentration ranges in some particle suspensions (Govier and Aziz, pp. 33–34). Extensive discussions of dilatant suspensions, together with a listing of dilatant systems, are given by Green and Griskey (*Trans. Soc. Rheol,* **12**[1], 13–25 [1968]); Griskey and Green (*AIChE J.,* **17,** 725–728 [1971]); and Bauer and Collins ("Thixotropy and Dilatancy," in Eirich, *Rheology,* vol. 4, Academic, New York, 1967).

**Time-dependent** fluids are those for which structural rearrangements occur during deformation at a rate too slow to maintain equilibrium configurations. As a result, shear stress changes with duration of shear. **Thixotropic** fluids, such as mayonnaise, clay suspensions used as drilling muds, and some paints and inks, show decreasing shear stress with time at constant shear rate. A detailed description of thixotropic behavior and a list of thixotropic systems is found in Bauer and Collins (ibid.).

**Rheopectic** behavior is the opposite of thixotropy. Shear stress increases with time at constant shear rate. Rheopectic behavior has been observed in bentonite sols, vanadium pentoxide sols, and gypsum suspensions in water (Bauer and Collins, ibid.) as well as in some polyester solutions (Steg and Katz, *J. Appl. Polym. Sci.,* **9,** 3, 177 [1965]).

**Viscoelastic** fluids exhibit elastic recovery from deformation when stress is removed. Polymeric liquids comprise the largest group of fluids in this class. A property of viscoelastic fluids is the *relaxation time,* which is a measure of the time required for elastic effects to decay. Viscoelastic effects may be important with sudden changes in rates of deformation, as in flow startup and stop, rapidly oscillating flows, or as a fluid passes through sudden expansions or contractions where accelerations occur. In many fully developed flows where such effects are absent, viscoelastic fluids behave as if they were purely viscous. In viscoelastic flows, normal stresses perpendicular to the direction of shear are different from those in the parallel direction. These give rise to such behaviors as the *Weissenberg effect,* in which fluid climbs up a shaft rotating in the fluid, and *die swell,* where a stream of fluid issuing from a tube may expand to two or more times the tube diameter.

A parameter indicating whether viscoelastic effects are important is the **Deborah number,** which is the ratio of the characteristic relaxation time of the fluid to the characteristic time scale of the flow. For small Deborah numbers, the relaxation is fast compared to the characteristic time of the flow, and the fluid behavior is purely viscous. For very large Deborah numbers, the behavior closely resembles that of an elastic solid.

Analysis of viscoelastic flows is very difficult. Simple constitutive equations are unable to describe all the material behavior exhibited by viscoelastic fluids even in geometrically simple flows. More complex constitutive equations may be more accurate, but become exceedingly difficult to apply, especially for complex geometries, even with advanced numerical methods. For good discussions of viscoelastic fluid behavior, including various types of constitutive equations, see Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* vol. 2: *Kinetic Theory,* Wiley, New York, 1977); Middleman (*The Flow of High Polymers,* Interscience (Wiley) New York, 1968); or Astarita and Marrucci (*Principles of Non-Newtonian Fluid Mechanics,* McGraw-Hill, New York, 1974).

**Polymer processing** is the field which depends most on the flow of non-Newtonian fluids. Several excellent texts are available, including Middleman (*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977) and Tadmor and Gogos (*Principles of Polymer Processing,* Wiley, New York, 1979).

There is a wide variety of instruments for measurement of Newtonian viscosity, as well as rheological properties of non-Newtonian fluids. They are described in Van Wazer, Lyons, Kim, and Colwell (*Viscosity and Flow Measurement,* Interscience, New York, 1963); Coleman, Markowitz, and Noll (*Viscometric Flows of Non-Newtonian Fluids,* Springer-Verlag, Berlin, 1966); Dealy and Wissbrun (*Melt Rheology and Its Role in Plastics Processing,* Van Nostrand Reinhold, 1990). Measurement of rheological behavior requires well-characterized flows. Such *rheometric* flows are thoroughly discussed by Astarita and Marrucci (*Principles of Non-Newtonian Fluid Mechanics,* McGraw-Hill, New York, 1974).

## KINEMATICS OF FLUID FLOW

**Velocity** The term *kinematics* refers to the quantitative description of fluid motion or deformation. The rate of deformation depends on the distribution of velocity within the fluid. Fluid velocity **v** is a vector quantity, with three cartesian components $v_x$, $v_y$, and $v_z$. The velocity vector is a function of spatial position and time. A **steady** flow is one in which the velocity is independent of time, while in **unsteady** flow **v** varies with time**.**

**Compressible and Incompressible Flow** An incompressible flow is one in which the density of the fluid is constant or nearly constant. Liquid flows are normally treated as incompressible, except in the context of hydraulic transients (see following). Compressible fluids, such as gases, may undergo incompressible flow if pressure and/or temperature changes are small enough to render density changes insignificant. Frequently, compressible flows are regarded as flows in which the density varies by more than 5 to 10 percent.

**Streamlines, Pathlines, and Streaklines** These are curves in a flow field which provide insight into the flow pattern. *Streamlines* are tangent at every point to the local instantaneous velocity vector. A *pathline* is the path followed by a material element of fluid; it coincides with a streamline if the flow is steady. In unsteady flow the pathlines generally do not coincide with streamlines. *Streaklines* are curves on which are found all the material particles which passed through a particular point in space at some earlier time. For example, a streakline is revealed by releasing smoke or dye at a point in a flow field. For steady flows, streamlines, pathlines, and streaklines are indistinguishable. In two-dimensional incompressible flows, streamlines are contours of the **stream function.**

**One-dimensional Flow** Many flows of great practical importance, such as those in pipes and channels, are treated as one-dimensional flows. There is a single direction called the *flow direction;* velocity components perpendicular to this direction are either zero or considered unimportant. Variations of quantities such as velocity, pressure, density, and temperature are considered only in the flow direction. The fundamental conservation equations of fluid mechanics are greatly simplified for one-dimensional flows. A broader category of one-dimensional flow is one where there is only one nonzero velocity component, which depends on only one coordinate direction, and this coordinate direction may or may not be the same as the flow direction.

**Rate of Deformation Tensor** For general three-dimensional flows, where all three velocity components may be important and may vary in all three coordinate directions, the concept of deformation previously introduced must be generalized. The rate of deformation tensor $D_{ij}$ has nine components. In Cartesian coordinates,

$$D_{ij} = \left( \frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right) \tag{6-6}$$

where the subscripts $i$ and $j$ refer to the three coordinate directions. Some authors define the deformation rate tensor as one-half of that given by Eq. (6-6).

**Vorticity** The relative motion between two points in a fluid can be decomposed into three components: rotation, dilatation, and deformation. The rate of deformation tensor has been defined. Dilatation refers to the volumetric expansion or compression of the fluid, and vanishes for incompressible flow. Rotation is described by a tensor $\omega_{ij} = \partial v_i/\partial x_j - \partial v_j/\partial x_i$. The vector of vorticity given by one-half the

curl of the velocity vector is another measure of rotation. In two-dimensional flow in the $x$-$y$ plane, the vorticity $\omega$ is given by

$$\omega = \frac{1}{2}\left(\frac{\partial v_y}{\partial x} - \frac{\partial v_x}{\partial y}\right) \tag{6-7}$$

Here $\omega$ is the magnitude of the vorticity vector, which is directed along the $z$ axis. An **irrotational** flow is one with zero vorticity. Irrotational flows have been widely studied because of their useful mathematical properties and applicability to flow regions where viscous effects may be neglected. Such flows without viscous effects are called **inviscid** flows.

**Laminar and Turbulent Flow, Reynolds Number** These terms refer to two distinct types of flow. In *laminar flow,* there are smooth streamlines and the fluid velocity components vary smoothly with position, and with time if the flow is unsteady. The flow described in reference to Fig. 6-1 is laminar. In *turbulent flow,* there are no smooth streamlines, and the velocity shows chaotic fluctuations in time and space. Velocities in turbulent flow may be reported as the sum of a time-averaged velocity and a velocity fluctuation from the average. For any given flow geometry, a dimensionless **Reynolds number** may be defined for a Newtonian fluid as $\mathrm{Re} = LU\rho/\mu$ where $L$ is a characteristic length. Below a critical value of Re the flow is laminar, while above the critical value a transition to turbulent flow occurs. The geometry-dependent critical Reynolds number is determined experimentally.

## CONSERVATION EQUATIONS

**Macroscopic and Microscopic Balances** Three postulates, regarded as laws of physics, are fundamental in fluid mechanics. These are *conservation of mass, conservation of momentum,* and *conservation of energy.* In addition, two other postulates, *conservation of moment of momentum* (angular momentum) and the *entropy inequality* (second law of thermodynamics) have occasional use. The conservation principles may be applied either to material systems or to control volumes in space. Most often, control volumes are used. The control volumes may be either of finite or differential size, resulting in either **algebraic** or **differential** conservation equations, respectively. These are often called **macroscopic** and **microscopic** balance equations.

**Macroscopic Equations** An arbitrary control volume of finite size $V_a$ is bounded by a surface of area $A_a$ with an outwardly directed unit normal vector **n.** The control volume is not necessarily fixed in space. Its boundary moves with velocity **w.** The fluid velocity is **v.** Figure 6-3 shows the arbitrary control volume.

**Mass Balance** Applied to the control volume, the principle of conservation of mass may be written as (Whitaker, *Introduction to Fluid Mechanics,* Prentice-Hall, Englewood Cliffs, N.J., 1968, Krieger, Huntington, N.Y., 1981)

$$\frac{d}{dt}\int_{V_a} \rho\, dV + \int_{A_a} \rho(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\, dA = 0 \tag{6-8}$$

This equation is also known as the **continuity** equation.

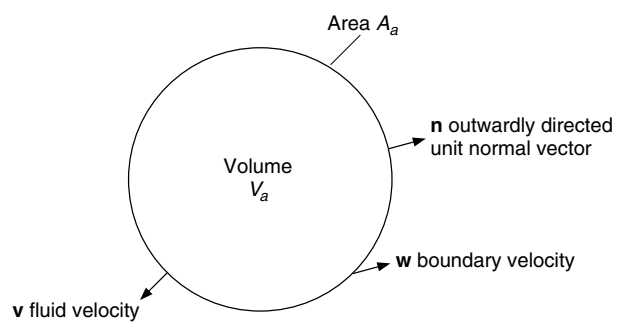

**FIG. 6-3** Arbitrary control volume for application of conservation equations.

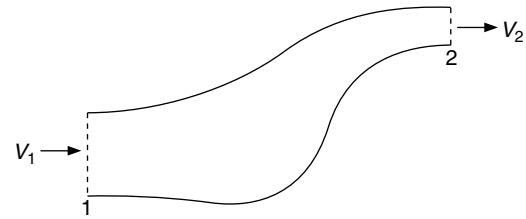

**FIG. 6-4** Fixed control volume with one inlet and one outlet.

Simplified forms of Eq. (6-8) apply to special cases frequently found in practice. For a control volume fixed in space with one inlet of area $A_1$ through which an incompressible fluid enters the control volume at an average velocity $V_1$, and one outlet of area $A_2$ through which fluid leaves at an average velocity $V_2$, as shown in Fig. 6-4, the continuity equation becomes

$$V_1A_1 = V_2A_2 \tag{6-9}$$

The average velocity across a surface is given by

$$V = (1/A)\int_A v\, dA$$

where $v$ is the local velocity component perpendicular to the inlet surface. The volumetric flow rate $Q$ is the product of average velocity and the cross-sectional area, $Q = VA$. The average **mass velocity** is $G = \rho V$. For steady flows through fixed control volumes with multiple inlets and/or outlets, conservation of mass requires that the sum of inlet mass flow rates equals the sum of outlet mass flow rates. For incompressible flows through fixed control volumes, the sum of inlet flow rates (mass or volumetric) equals the sum of exit flow rates, whether the flow is steady or unsteady.

**Momentum Balance** Since momentum is a vector quantity, the momentum balance is a vector equation. Where gravity is the only body force acting on the fluid, the linear momentum principle, applied to the arbitrary control volume of Fig. 6-3, results in the following expression (Whitaker, ibid.).

$$\frac{d}{dt}\int_{V_a} \rho\mathbf{v}\, dV + \int_{A_a} \rho\mathbf{v}(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\, dA = \int_{V_a} \rho\mathbf{g}\, dV + \int_{A_a} \mathbf{t_n}\, dA \tag{6-10}$$

Here $\mathbf{g}$ is the gravity vector and $\mathbf{t_n}$ is the force per unit area exerted by the surroundings on the fluid in the control volume. The integrand of the area integral on the left-hand side of Eq. (6-10) is nonzero only on the entrance and exit portions of the control volume boundary. For the special case of steady flow at a mass flow rate $\dot{m}$ through a control volume fixed in space with one inlet and one outlet (Fig. 6-4), with the inlet and outlet velocity vectors perpendicular to planar inlet and outlet surfaces, giving average velocity vectors $\mathbf{V}_1$ and $\mathbf{V}_2$, the momentum equation becomes

$$\dot{m}(\beta_2\mathbf{V}_2 - \beta_1\mathbf{V}_1) = -p_1\mathbf{A}_1 - p_2\mathbf{A}_2 + \mathbf{F} + M\mathbf{g} \tag{6-11}$$

where $M$ is the total mass of fluid in the control volume. The factor $\beta$ arises from the averaging of the velocity across the area of the inlet or outlet surface. It is the ratio of the area average of the square of velocity magnitude to the square of the area average velocity magnitude. For a uniform velocity, $\beta = 1$. For turbulent flow, $\beta$ is nearly unity, while for laminar pipe flow with a parabolic velocity profile, $\beta = 4/3$. The vectors $\mathbf{A}_1$ and $\mathbf{A}_2$ have magnitude equal to the areas of the inlet and outlet surfaces, respectively, and are outwardly directed normal to the surfaces. The vector $\mathbf{F}$ is the force exerted on the fluid by the nonflow boundaries of the control volume. It is also assumed that the stress vector $\mathbf{t_n}$ is normal to the inlet and outlet surfaces, and that its magnitude may be approximated by the pressure $p$. Equation (6-11) may be generalized to multiple inlets and/or outlets. In such cases, the mass flow rates for all the inlets and outlets are not equal. A distinct flow rate $\dot{m}_i$ applies to each inlet or outlet $i$. To generalize the equation, $-\mathbf{pA}$ terms for each inlet and outlet, $-\dot{m}\beta\mathbf{V}$ terms for each inlet, and $\dot{m}\beta\mathbf{V}$ terms for each outlet are included.

Balance equations for angular momentum, or moment of momentum, may also be written. They are used less frequently than the linear momentum equations. See Whitaker (*Introduction to Fluid Mechanics,* Prentice-Hall, Englewood Cliffs, N.J., 1968, Krieger, Huntington, N.Y., 1981) or Shames (*Mechanics of Fluids,* 3d ed., McGraw-Hill, New York, 1992).

**Total Energy Balance** The total energy balance derives from the first law of thermodynamics. Applied to the arbitrary control volume of Fig. 6-3, it leads to an equation for the rate of change of the sum of internal, kinetic, and gravitational potential energy. In this equation, $u$ is the internal energy per unit mass, $v$ is the magnitude of the velocity vector $\mathbf{v}$, $z$ is elevation, $g$ is the gravitational acceleration, and $\mathbf{q}$ is the heat flux vector:

$$\frac{d}{dt}\int_{V_a}\rho\left(u+\frac{v^2}{2}+gz\right)dV+\int_{A_a}\rho\left(u+\frac{v^2}{2}+gz\right)(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\,dA = \int_{A_a}(\mathbf{v}\cdot\mathbf{t_n})\,dA-\int_{A_a}(\mathbf{q}\cdot\mathbf{n})\,dA \quad (6\text{-}12)$$

The first integral on the right-hand side is the rate of work done on the fluid in the control volume by forces at the boundary. It includes both work done by moving solid boundaries and work done at flow entrances and exits. The work done by moving solid boundaries also includes that by such surfaces as pump impellers; this work is called **shaft work;** its rate is $\dot{W}_S$.

A useful simplification of the total energy equation applies to a particular set of assumptions. These are a control volume with fixed solid boundaries, except for those producing shaft work, steady state conditions, and mass flow at a rate $\dot{m}$ through a single planar entrance and a single planar exit (Fig. 6-4), to which the velocity vectors are perpendicular. As with Eq. (6-11), it is assumed that the stress vector $\mathbf{t_n}$ is normal to the entrance and exit surfaces and may be approximated by the pressure $p$. The **equivalent pressure,** $p+\rho gz$, is assumed to be uniform across the entrance and exit. The average velocity at the entrance and exit surfaces is denoted by $V$. Subscripts 1 and 2 denote the entrance and exit, respectively.

$$h_1+\alpha_1\frac{V_1^2}{2}+gz_1=h_2+\alpha_2\frac{V_2^2}{2}+gz_2-\delta Q-\delta W_S \quad (6\text{-}13)$$

Here, $h$ is the enthalpy per unit mass, $h=u+p/\rho$. The shaft work per unit of mass flowing through the control volume is $\delta W_S=\dot{W}_s/\dot{m}$. Similarly, $\delta Q$ is the heat input per unit of mass. The factor $\alpha$ is the ratio of the cross-sectional area average of the cube of the velocity to the cube of the average velocity. For a uniform velocity profile, $\alpha=1$. In turbulent flow, $\alpha$ is usually assumed to equal unity; in turbulent pipe flow, it is typically about 1.07. For laminar flow in a circular pipe with a parabolic velocity profile, $\alpha=2$.

**Mechanical Energy Balance, Bernoulli Equation** A balance equation for the sum of kinetic and potential energy may be obtained from the momentum balance by forming the scalar product with the velocity vector. The resulting equation, called the *mechanical energy balance,* contains a term accounting for the dissipation of mechanical energy into thermal energy by viscous forces. The mechanical energy equation is also derivable from the total energy equation in a way that reveals the relationship between the dissipation and entropy generation. The macroscopic mechanical energy balance for the arbitrary control volume of Fig. 6-3 may be written, with $p$ = thermodynamic pressure, as

$$\frac{d}{dt}\int_{V_a}\rho\left(\frac{v^2}{2}+gz\right)dV+\int_{A_a}\rho\left(\frac{v^2}{2}+gz\right)(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\,dA = \int_{V_a}p\,\boldsymbol{\nabla}\cdot\mathbf{v}\,dV+\int_{A_a}(\mathbf{v}\cdot\mathbf{t}_n)\,dA-\int_{V_a}\Phi\,dV \quad (6\text{-}14)$$

The last term is the rate of viscous energy dissipation to internal energy, $\dot{E}_v=\int_{V_a}\Phi\,dV$, also called the rate of viscous losses. These losses are the origin of frictional pressure drop in fluid flow. Whitaker and Bird, Stewart, and Lightfoot provide expressions for the dissipation function $\Phi$ for Newtonian fluids in terms of the local velocity gradients. However, when using macroscopic balance equations the local velocity field within the control volume is usually unknown. For such cases additional information, which may come from empirical correlations, is needed.

For the same special conditions as for Eq. (6-13), the mechanical energy equation is reduced to

$$\alpha_1\frac{V_1^2}{2}+gz_1+\delta W_S=\alpha_2\frac{V_2^2}{2}+gz_2+\int_{p_1}^{p_2}\frac{dp}{\rho}+l_v \quad (6\text{-}15)$$

Here $l_v=\dot{E}_v/\dot{m}$ is the energy dissipation per unit mass. This equation has been called the **engineering Bernoulli equation.** For an incompressible flow, Eq. (6-15) becomes

$$\frac{p_1}{\rho}+\alpha_1\frac{V_1^2}{2}+gz_1+\delta W_S=\frac{p_2}{\rho}+\alpha_2\frac{V_2^2}{2}+gz_2+l_v \quad (6\text{-}16)$$

The Bernoulli equation can be written for incompressible, inviscid flow along a streamline, where no shaft work is done.

$$\frac{p_1}{\rho}+\frac{V_1^2}{2}+gz_1=\frac{p_2}{\rho}+\frac{V_2^2}{2}+gz_2 \quad (6\text{-}17)$$

Unlike the momentum equation (Eq. [6-11]), the Bernoulli equation is not easily generalized to multiple inlets or outlets.

**Microscopic Balance Equations** Partial differential balance equations express the conservation principles at a point in space. Equations for mass, momentum, total energy, and mechanical energy may be found in Whitaker (ibid.), Bird, Stewart, and Lightfoot (*Transport Phenomena,* Wiley, New York, 1960), and Slattery (*Momentum, Heat and Mass Transfer in Continua,* 2d ed., Krieger, Huntington, N.Y., 1981), for example. These references also present the equations in other useful coordinate systems besides the cartesian system. The coordinate systems are fixed in inertial reference frames. The two most used equations, for mass and momentum, are presented here.

**Mass Balance, Continuity Equation** The continuity equation, expressing conservation of mass, is written in cartesian coordinates as

$$\frac{\partial\rho}{\partial t}+\frac{\partial\rho v_x}{\partial x}+\frac{\partial\rho v_y}{\partial y}+\frac{\partial\rho v_z}{\partial z}=0 \quad (6\text{-}18)$$

In terms of the **substantial derivative,** $D/Dt$,

$$\frac{D\rho}{Dt}\equiv\frac{\partial\rho}{\partial t}+v_x\frac{\partial\rho}{\partial x}+v_y\frac{\partial\rho}{\partial y}+v_z\frac{\partial\rho}{\partial z}=-\rho\left(\frac{\partial v_x}{\partial x}+\frac{\partial v_y}{\partial y}+\frac{\partial v_z}{\partial z}\right) \quad (6\text{-}19)$$

The substantial derivative, also called the **material derivative,** is the rate of change in a Lagrangian reference frame, that is, following a material particle. In vector notation the continuity equation may be expressed as

$$\frac{D\rho}{Dt}=-\rho\nabla\cdot\mathbf{v} \quad (6\text{-}20)$$

For incompressible flow,

$$\nabla\cdot\mathbf{v}=\frac{\partial v_x}{\partial x}+\frac{\partial v_y}{\partial y}+\frac{\partial v_z}{\partial z}=0 \quad (6\text{-}21)$$

**Stress Tensor** The stress tensor is needed to completely describe the stress state for microscopic momentum balances in multidimensional flows. The components of the stress tensor $\sigma_{ij}$ give the force in the $j$ direction on a plane perpendicular to the $i$ direction, using a sign convention defining a positive stress as one where the fluid with the greater $i$ coordinate value exerts a force in the positive $i$ direction on the fluid with the lesser $i$ coordinate. Several references in fluid mechanics and continuum mechanics provide discussions, to various levels of detail, of stress in a fluid (Denn; Bird, Stewart, and Lightfoot; Schlichting; Fung [*A First Course in Continuum Mechanics,* 2d. ed., Prentice-Hall, Englewood Cliffs, N.J., 1977]; Truesdell and Toupin [in Flügge, *Handbuch der Physik,* vol. 3/1, Springer-Verlag, Berlin, 1960]; Slattery [*Momentum, Energy and Mass Transfer in Continua,* 2d ed., Krieger, Huntington, N.Y., 1981]).

The stress has an isotropic contribution due to fluid pressure and dilatation, and a **deviatoric** contribution due to viscous deformation effects. The deviatoric contribution for a Newtonian fluid is the three-dimensional generalization of Eq. (6-2):

$$\tau_{ij}=\mu D_{ij} \quad (6\text{-}22)$$

The total stress is

$$\sigma_{ij} = (-p + \lambda \nabla \cdot \mathbf{v})\delta_{ij} + \tau_{ij} \tag{6-23}$$

The identity tensor $\delta_{ij}$ is zero for $i \neq j$ and unity for $i = j$. The coefficient $\lambda$ is a material property related to the **bulk viscosity,** $\kappa = \lambda + 2\mu/3$. There is considerable uncertainty about the value of $\kappa$. Traditionally, Stokes' hypothesis, $\kappa = 0$, has been invoked, but the validity of this hypothesis is doubtful (Slattery, ibid.). For incompressible flow, the value of bulk viscosity is immaterial as Eq. (6-23) reduces to

$$\sigma_{ij} = -p\delta_{ij} + \tau_{ij} \tag{6-24}$$

Similar generalizations to multidimensional flow are necessary for non-Newtonian constitutive equations.

**Cauchy Momentum and Navier-Stokes Equations** The differential equations for conservation of momentum are called the **Cauchy momentum equations.** These may be found in general form in most fluid mechanics texts (e.g., Slattery [ibid.]; Denn; Whitaker; and Schlichting). For the important special case of an incompressible Newtonian fluid with constant viscosity, substitution of Eqs. (6-22) and (6-24) leads to the **Navier-Stokes equations,** whose three Cartesian components are

$$\rho\left(\frac{\partial v_x}{\partial t} + v_x\frac{\partial v_x}{\partial x} + v_y\frac{\partial v_x}{\partial y} + v_z\frac{\partial v_x}{\partial z}\right) = -\frac{\partial p}{\partial x} + \mu\left(\frac{\partial^2 v_x}{\partial x^2} + \frac{\partial^2 v_x}{\partial y^2} + \frac{\partial^2 v_x}{\partial z^2}\right) + \rho g_x \tag{6-25}$$

$$\rho\left(\frac{\partial v_y}{\partial t} + v_x\frac{\partial v_y}{\partial x} + v_y\frac{\partial v_y}{\partial y} + v_z\frac{\partial v_y}{\partial z}\right) = -\frac{\partial p}{\partial y} + \mu\left(\frac{\partial^2 v_y}{\partial x^2} + \frac{\partial^2 v_y}{\partial y^2} + \frac{\partial^2 v_y}{\partial z^2}\right) + \rho g_y \tag{6-26}$$

$$\rho\left(\frac{\partial v_z}{\partial t} + v_x\frac{\partial v_z}{\partial x} + v_y\frac{\partial v_z}{\partial y} + v_z\frac{\partial v_z}{\partial z}\right) = -\frac{\partial p}{\partial z} + \mu\left(\frac{\partial^2 v_z}{\partial x^2} + \frac{\partial^2 v_z}{\partial y^2} + \frac{\partial^2 v_z}{\partial z^2}\right) + \rho g_z \tag{6-27}$$

In vector notation,

$$\rho\frac{D\mathbf{v}}{Dt} = \frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{v} = -\nabla p + \mu\nabla^2\mathbf{v} + \rho\mathbf{g} \tag{6-28}$$

The pressure and gravity terms may be combined by replacing the pressure $p$ by the equivalent pressure $P = p + \rho g z$. The left-hand side terms of the Navier-Stokes equations are the **inertial terms,** while the terms including viscosity $\mu$ are the **viscous terms.** Limiting cases under which the Navier-Stokes equations may be simplified include **creeping flows** in which the inertial terms are neglected, **potential flows** (inviscid or irrotational flows) in which the viscous terms are neglected, and **boundary layer** and **lubrication** flows in which certain terms are neglected based on scaling arguments. Creeping flows are described by Happel and Brenner (*Low Reynolds Number Hydrodynamics,* Prentice-Hall, Englewood Cliffs, N.J., 1965); potential flows by Lamb (*Hydrodynamics,* 6th ed., Dover, New York, 1945) and Milne-Thompson (*Theoretical Hydrodynamics,* 5th ed., Macmillan, New York, 1968); boundary layer theory by Schlichting (*Boundary Layer Theory,* 8th ed., McGraw-Hill, New York, 1987); and lubrication theory by Batchelor (*An Introduction to Fluid Dynamics,* Cambridge University, Cambridge, 1967) and Denn (*Process Fluid Mechanics,* Prentice-Hall, Englewood Cliffs, N.J., 1980).

Because the Navier-Stokes equations are first-order in pressure and second-order in velocity, their solution requires one pressure boundary condition and two velocity boundary conditions (for each velocity component) to completely specify the solution. The **no slip** condition, which requires that the fluid velocity equal the velocity of any bounding solid surface, occurs in most problems. Specification of velocity is a type of boundary condition sometimes called a *Dirichlet condition.* Often boundary conditions involve stresses, and thus velocity gradients, rather than the velocities themselves. Specification of velocity derivatives is a *Neumann boundary condition.* For example, at the boundary between a viscous liquid and a gas, it is often assumed that the liquid shear stresses are zero. In numerical solution of the Navier-Stokes equations, Dirichlet and Neumann, or **essential** and **natural,** boundary conditions may be satisfied by different means.

**Fluid statics,** discussed in Sec. 10 of the *Handbook* in reference to pressure measurement, is the branch of fluid mechanics in which the fluid velocity is either zero or is uniform and constant relative to an inertial reference frame. With velocity gradients equal to zero, the momentum equation reduces to a simple expression for the pressure field, $\nabla p = \rho\mathbf{g}$. Letting $z$ be directed vertically upward, so that $g_z = -g$ where $g$ is the gravitational acceleration (9.806 m²/s), the pressure field is given by

$$dp/dz = -\rho g \tag{6-29}$$

This equation applies to any incompressible or compressible static fluid. For an incompressible liquid, pressure varies linearly with depth. For compressible gases, $p$ is obtained by integration accounting for the variation of $\rho$ with $z$.

The **force exerted on a submerged planar surface** of area $A$ is given by $F = p_c A$ where $p_c$ is the pressure at the geometrical **centroid** of the surface. The **center of pressure,** the point of application of the net force, is always lower than the centroid. For details see, for example, Shames, where may also be found discussion of forces on **curved surfaces, buoyancy,** and **stability of floating bodies.**

**Examples** Four examples follow, illustrating the application of the conservation equations to obtain useful information about fluid flows.

***Example 1: Force Exerted on a Reducing Bend*** An incompressible fluid flows through a reducing elbow (Fig. 6-5) situated in a horizontal plane. The inlet velocity $V_1$ is given and the pressures $p_1$ and $p_2$ are measured. Selecting the inlet and outlet surfaces 1 and 2 as shown, the continuity equation Eq. (6-9) can be used to find the exit velocity $V_2 = V_1A_1/A_2$. The mass flow rate is obtained by $\dot{m} = \rho V_1 A_1$.

Assume that the velocity profile is nearly uniform so that $\beta$ is approximately unity. The force exerted on the fluid by the bend has $x$ and $y$ components; these can be found from Eq. (6-11). The $x$ component gives

$$F_x = \dot{m}(V_{2x} - V_{1x}) + p_1A_{1x} + p_2A_{2x}$$

while the $y$ component gives

$$F_y = \dot{m}(V_{2y} - V_{1y}) + p_1A_{1y} + p_2A_{2y}$$

The velocity components are $V_{1x} = V_1$, $V_{1y} = 0$, $V_{2x} = V_2\cos\theta$, and $V_{2y} = V_2\sin\theta$. The area vector components are $A_{1x} = -A_1$, $A_{1y} = 0$, $A_{2x} = A_2\cos\theta$, and $A_{2y} = A_2\sin\theta$. Therefore, the force components may be calculated from

$$F_x = \dot{m}(V_2\cos\theta - V_1) - p_1A_1 + p_2A_2\cos\theta$$

$$F_y = \dot{m}V_2\sin\theta + p_2A_2\sin\theta$$

The force acting on the fluid is **F;** the equal and opposite force exerted by the fluid on the bend is **−F.**

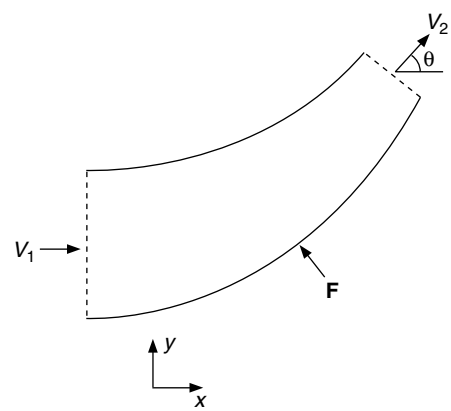

**FIG. 6-5** Force at a reducing bend. **F** is the force exerted by the bend on the fluid. The force exerted by the fluid on the bend is **−F.**

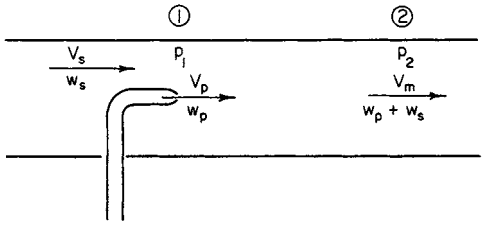

**FIG. 6-6** Draft-tube ejector.

***Example 2: Simplified Ejector*** Figure 6-6 shows a very simplified sketch of an ejector, a device that uses a high velocity primary fluid to pump another (secondary) fluid. The continuity and momentum equations may be applied on the control volume with inlet and outlet surfaces 1 and 2 as indicated in the figure. The cross-sectional area is uniform, $A_1 = A_2 = A$. Let the mass flow rates and velocities of the primary and secondary fluids be $\dot{m}_p$, $\dot{m}_s$, $V_p$ and $V_s$. Assume for simplicity that the density is uniform. Conservation of mass gives $\dot{m}_2 = \dot{m}_p + \dot{m}_s$. The exit velocity is $V_2 = \dot{m}_2/(\rho A)$. The principle momentum exchange in the ejector occurs between the two fluids. Relative to this exchange, the force exerted by the walls of the device are found to be small. Therefore, the force term $F$ is neglected from the momentum equation. Written in the flow direction, assuming uniform velocity profiles, and using the extension of Eq. (6-11) for multiple inlets, it gives the pressure rise developed by the device:

$$(p_2 - p_1)A = (\dot{m}_p + \dot{m}_s)V_2 - \dot{m}_p V_p - \dot{m}_s V_s$$

Application of the momentum equation to ejectors of other types is discussed in Lapple (*Fluid and Particle Dynamics,* University of Delaware, Newark, 1951) and in Sec. 10 of the *Handbook.*

***Example 3: Venturi Flowmeter*** An incompressible fluid flows through the venturi flowmeter in Fig. 6-7. An equation is needed to relate the flow rate $Q$ to the pressure drop measured by the manometer. This problem can be solved using the mechanical energy balance. In a well-made venturi, viscous losses are negligible, the pressure drop is entirely the result of acceleration into the throat, and the flow rate predicted neglecting losses is quite accurate. The inlet area is $A$ and the throat area is $a$.

With control surfaces at 1 and 2 as shown in the figure, Eq. (6-17) in the absence of losses and shaft work gives

$$\frac{p_1}{\rho} + \frac{V_1^2}{2} = \frac{p_2}{\rho} + \frac{V_2^2}{2}$$

The continuity equation gives $V_2 = V_1 A/a$, and $V_1 = Q/A$. The pressure drop measured by the manometer is $p_1 - p_2 = (\rho_m - \rho)g\Delta z$. Substituting these relations into the energy balance and rearranging, the desired expression for the flow rate is found.

$$Q = \frac{1}{A}\sqrt{\frac{2(\rho_m - \rho)g\Delta z}{\rho[(A/a)^2 - 1]}}$$

***Example 4: Plane Poiseuille Flow*** An incompressible Newtonian fluid flows at a steady rate in the $x$ direction between two very large flat plates, as shown in Fig. 6-8. The flow is laminar. The velocity profile is to be found. This example is found in most fluid mechanics textbooks; the solution presented here closely follows Denn.

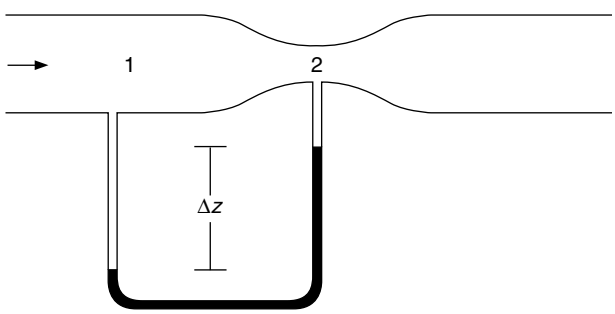

**FIG. 6-7** Venturi flowmeter.

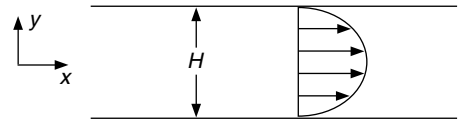

**FIG. 6-8** Plane Poiseuille flow.

This problem requires use of the microscopic balance equations because the velocity is to be determined as a function of position. The boundary conditions for this flow result from the no-slip condition. All three velocity components must be zero at the plate surfaces, $y = H/2$ and $y = -H/2$.

Assume that the flow is **fully developed,** that is, all velocity derivatives vanish in the $x$ direction. Since the flow field is infinite in the $z$ direction, all velocity derivatives should be zero in the $z$ direction. Therefore, velocity components are a function of $y$ alone. It is also assumed that there is no flow in the $z$ direction, so $v_z = 0$. The continuity equation Eq. (6-21), with $v_z = 0$ and $\partial v_x/\partial x = 0$, reduces to

$$\frac{dv_y}{dy} = 0$$

Since $v_y = 0$ at $y = \pm H/2$, the continuity equation integrates to $v_y = 0$. This is a direct result of the assumption of fully developed flow.

The Navier-Stokes equations are greatly simplified when it is noted that $v_y = v_z = 0$ and $\partial v_x/\partial x = \partial v_x/\partial z = \partial v_x/\partial t = 0$. The three components are written in terms of the equivalent pressure $P$:

$$0 = -\frac{\partial P}{\partial x} + \mu\frac{\partial^2 v_x}{\partial y^2}$$

$$0 = -\frac{\partial P}{\partial y}$$

$$0 = -\frac{\partial P}{\partial z}$$

The latter two equations require that $P$ is a function only of $x$, and therefore $\partial P/\partial x = dP/dx$. Inspection of the first equation shows one term which is a function only of $x$ and one which is only a function of $y$. This requires that both terms are constant. The pressure gradient $-dP/dx$ is constant. The $x$-component equation becomes

$$\frac{d^2 v_x}{dy^2} = \frac{1}{\mu}\frac{dP}{dx}$$

Two integrations of the $x$-component equation give

$$v_x = \frac{1}{2\mu}\frac{dP}{dx}y^2 + C_1 y + C_2$$

where the constants of integration $C_1$ and $C_2$ are evaluated from the boundary conditions $v_x = 0$ at $y = \pm H/2$. The result is

$$v_x = \frac{H^2}{8\mu}\left(-\frac{dP}{dx}\right)\left[1 - \left(\frac{2y}{H}\right)^2\right]$$

This is a **parabolic** velocity distribution. The average velocity $V = (1/H)\int_{-H/2}^{H/2} v_x\,dy$ is

$$V = \frac{H^2}{12\mu}\left(-\frac{dP}{dx}\right)$$

This flow is one-dimensional, as there is only one nonzero velocity component, $v_x$, which, along with the pressure, varies in only one coordinate direction.

## INCOMPRESSIBLE FLOW IN PIPES AND CHANNELS

**Mechanical Energy Balance** The mechanical energy balance, Eq. (6-16), for **fully developed** incompressible flow in a straight circular pipe of constant diameter $D$ reduces to

$$\frac{p_1}{\rho} + gz_1 = \frac{p_2}{\rho} + gz_2 + l_v \tag{6-30}$$

In terms of the equivalent pressure, $P \equiv p + \rho gz$,

$$P_1 - P_2 = \rho l_v \tag{6-31}$$

The pressure drop due to frictional losses $l_v$ is proportional to pipe length $L$ for fully developed flow and may be denoted as the (positive) quantity $\Delta P \equiv P_1 - P_2$.

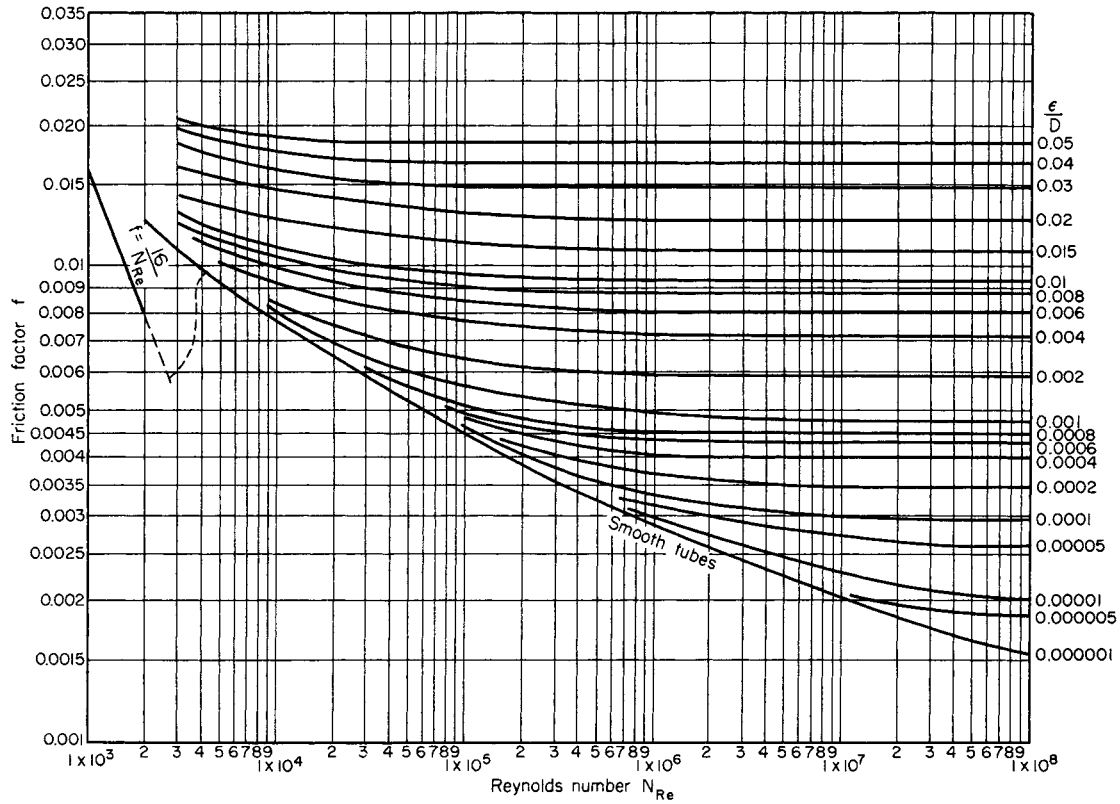

**FIG. 6-9** Fanning Friction Factors. Reynolds number Re = $DV\rho/\mu$, where $D$ = pipe diameter, $V$ = velocity, $\rho$ = fluid density, and $\mu$ = fluid viscosity. (*Based on Moody,* Trans. ASME, ***66,*** *671 [1944].*)

**Friction Factor and Reynolds Number** For a Newtonian fluid in a smooth pipe, dimensional analysis relates the frictional pressure drop per unit length $\Delta P/L$ to the pipe diameter $D$, density $\rho$, viscosity $\mu$, and average velocity $V$ through two dimensionless groups, the **Fanning friction factor** $f$ and the **Reynolds number Re.**

$$f \equiv \frac{D\Delta P}{2\rho V^2 L} \tag{6-32}$$

$$\text{Re} \equiv \frac{DV\rho}{\mu} \tag{6-33}$$

For smooth pipe, the friction factor is a function only of the Reynolds number. In rough pipe, the relative roughness $\epsilon/D$ also affects the friction factor. Figure 6-9 plots $f$ as a function of Re and $\epsilon/D$. Values of $\epsilon$ for various materials are given in Table 6-1. The Fanning friction factor should not be confused with the Darcy friction factor used by Moody (*Trans. ASME,* **66,** 671 [1944]), which is four times greater. Using the momentum equation, the stress at the wall of the pipe may be expressed in terms of the friction factor:

$$\tau_w = f\,\frac{\rho V^2}{2} \tag{6-34}$$

**Laminar and Turbulent Flow** Below a **critical Reynolds number** of about 2,100, the flow is laminar; over the range 2,100 < Re < 5,000 there is a transition to turbulent flow. Reliable correlations for the friction factor in transitional flow are not available. For laminar flow, the Hagen-Poiseuille equation

$$f = \frac{16}{\text{Re}} \qquad \text{Re} \le 2{,}100 \tag{6-35}$$

**TABLE 6-1 Values of Surface Roughness for Various Materials***

| Material | Surface roughness $\epsilon$, mm |
|---|---|
| Drawn tubing (brass, lead, glass, and the like) | 0.00152 |
| Commercial steel or wrought iron | 0.0457 |
| Asphalted cast iron | 0.122 |
| Galvanized iron | 0.152 |
| Cast iron | 0.259 |
| Wood stove | 0.183–0.914 |
| Concrete | 0.305–3.05 |
| Riveted steel | 0.914–9.14 |

* From Moody, *Trans. Am. Soc. Mech. Eng.,* **66,** 671–684 (1944); *Mech. Eng.,* **69,** 1005–1006 (1947). Additional values of $\varepsilon$ for various types or conditions of concrete wrought-iron, welded steel, riveted steel, and corrugated-metal pipes are given in Brater and King, *Handbook of Hydraulics,* 6th ed., McGraw-Hill, New York, 1976, pp. 6-12–6-13. To convert millimeters to feet, multiply by $3.281 \times 10^{-3}$.

may be derived from the Navier-Stokes equation and is in excellent agreement with experimental data. It may be rewritten in terms of volumetric flow rate, $Q = V\pi D^2/4$, as

$$Q = \frac{\pi \Delta P D^4}{128\mu L} \qquad \text{Re} \le 2{,}100 \tag{6-36}$$

For turbulent flow in smooth tubes, the Blasius equation gives the friction factor accurately for a wide range of Reynolds numbers.

$$f = \frac{0.079}{\text{Re}^{0.25}} \qquad 4{,}000 < \text{Re} < 10^5 \tag{6-37}$$

The Colebrook formula (Colebrook, *J. Inst. Civ. Eng.* [*London*], **11,** 133–156 [1938–39]) gives a good approximation for the $f$-Re-($\epsilon/D$) data for rough pipes over the entire turbulent flow range:

$$\frac{1}{\sqrt{f}} = -4 \log \left[ \frac{\epsilon}{3.7D} + \frac{1.256}{\mathrm{Re}\sqrt{f}} \right] \qquad \mathrm{Re} > 4{,}000 \qquad (6\text{-}38)$$

Equation (6-38) was used to construct the curves in the turbulent flow regime in Fig. 6-9.

An equation by Churchill (*Chem. Eng.,* **84**[24], 91–92 [Nov. 7, 1977]) approximating the Colebrook formula offers the advantage of being explicit in $f$:

$$\frac{1}{\sqrt{f}} = -4 \log \left[ \frac{0.27\epsilon}{D} + \left( \frac{7}{\mathrm{Re}} \right)^{0.9} \right] \qquad \mathrm{Re} > 4{,}000 \qquad (6\text{-}39)$$

Churchill also provided a single equation that may be used for Reynolds numbers in laminar, transitional, and turbulent flow, closely fitting $f = 16/\mathrm{Re}$ in the laminar regime, and the Colebrook formula, Eq. (6-38), in the turbulent regime. It also gives unique, reasonable values in the transition regime, where the friction factor is uncertain.

$$f = 2 \left[ \left( \frac{8}{\mathrm{Re}} \right)^{12} + \frac{1}{(A+B)^{3/2}} \right]^{1/12} \qquad (6\text{-}40)$$

where

$$A = \left[ 2.457 \ln \frac{1}{(7/\mathrm{Re})^{0.9} + 0.27\epsilon/D} \right]^{16}$$

and

$$B = \left( \frac{37{,}530}{\mathrm{Re}} \right)^{16}$$

In laminar flow, $f$ is independent of $\epsilon/D$. In turbulent flow, the friction factor for rough pipe follows the smooth tube curve for a range of Reynolds numbers (hydraulically smooth flow). For greater Reynolds numbers, $f$ deviates from the smooth pipe curve, eventually becoming independent of Re. This region, often called *complete turbulence,* is frequently encountered in commercial pipe flows.

Two common pipe flow problems are calculation of pressure drop given the flow rate (or velocity) and calculation of flow rate (or velocity) given the pressure drop. When flow rate is given, the Reynolds number may be calculated directly to determine the flow regime, so that the appropriate relations between $f$ and Re (or pressure drop and flow rate or velocity) can be selected. When flow rate is specified and the flow is turbulent, Eq. (6-39) or (6-40), being explicit in $f$, may be preferable to Eq. (6-38), which is implicit in $f$ and pressure drop.

When the pressure drop is given and the velocity and flow rate are to be determined, the Reynolds number cannot be computed directly, since the velocity is unknown. Instead of guessing and checking the flow regime, it may be useful to observe that the quantity $\mathrm{Re}\sqrt{f} = (D^{3/2}/\mu)\sqrt{\rho \Delta P/(2L)}$, appearing in the Colebrook equation (6-38), does not include velocity and so can be computed directly. The upper limit Re = 2,100 for laminar flow and use of Eq. (6-35) corresponds to $\mathrm{Re}\sqrt{f} = 183$. For smooth pipe, the lower limit Re = 4,000 for the Colebrook equation corresponds to $\mathrm{Re}\sqrt{f} = 400$. Thus, at least for smooth pipes, the flow regime can be determined without trial and error from $\Delta P/L$, $\mu$, $\rho$, and $D$. When pressure drop is given, Eq. (6-38), being explicit in velocity, is preferable to Eqs. (6-39) and (6-40), which are implicit in velocity.

As Fig. 6-9 suggests, the friction factor is uncertain in the transition range, and a conservative choice should be made for design purposes.

**Velocity Profiles** In laminar flow, the solution of the Navier-Stokes equation, corresponding to the Hagen-Poiseuille equation, gives the velocity $v$ as a function of radial position $r$ in a circular pipe of radius $R$ in terms of the average velocity $V = Q/A$. The **parabolic** profile, with centerline velocity twice the average velocity, is shown in Fig. 6-10.

$$v = 2V \left( 1 - \frac{r^2}{R^2} \right) \qquad (6\text{-}41)$$

In turbulent flow, the velocity profile is much more blunt, with most of the velocity gradient being in a region near the wall, described by a **universal** velocity profile. It is characterized by a **viscous sublayer,** a **turbulent core,** and a **buffer zone** in between.

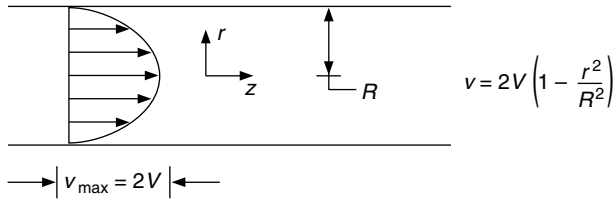

**FIG. 6-10** Parabolic velocity profile for laminar flow in a pipe, with average velocity $V$.

Viscous sublayer

$$u_+ = y_+ \qquad \text{for} \qquad y_+ < 5 \qquad (6\text{-}42)$$

Buffer zone

$$u_+ = 5.00 \ln y_+ - 3.05 \qquad \text{for} \qquad 5 < y_+ < 30 \qquad (6\text{-}43)$$

Turbulent core

$$u_+ = 2.5 \ln y_+ + 5.5 \qquad \text{for} \qquad y_+ > 30 \qquad (6\text{-}44)$$

Here, $u_+ = v/u_*$ is the dimensionless, time-averaged axial velocity, $u_* = \sqrt{\tau_w/\rho}$ is the **friction velocity** and $\tau_w = f\rho V^2/2$ is the wall stress. The friction velocity is of the order of the root mean square velocity fluctuation perpendicular to the wall in the turbulent core. The dimensionless distance from the wall is $y_+ = yu_*\rho/\mu$. The universal velocity profile is valid in the wall region for any cross-sectional channel shape. For incompressible flow in constant diameter circular pipes, $\tau_w = D\Delta P/4L$ where $\Delta P$ is the pressure drop in length $L$. In circular pipes, Eq. (6-44) gives a surprisingly good fit to experimental results over the entire cross section of the pipe, even though it is based on assumptions which are valid only near the pipe wall.

For rough pipes, the velocity profile in the turbulent core is given by

$$u_+ = 2.5 \ln y/\epsilon + 8.5 \qquad \text{for} \qquad y_+ > 30 \qquad (6\text{-}45)$$

when the dimensionless roughness $\epsilon_+ = \epsilon u_* \rho/\mu$ is greater than 5 to 10; for smaller $\epsilon_+$, the velocity profile in the turbulent core is unaffected by roughness.

For velocity profiles in the transition region, see Patel and Head (*J. Fluid Mech.,* **38,** part 1, 181–201 [1969]) where profiles over the range 1,500 < Re < 10,000 are reported.

**Entrance and Exit Effects** In the entrance region of a pipe, some distance is required for the flow to adjust from upstream conditions to the fully developed flow pattern. This distance depends on the Reynolds number and on the flow conditions upstream. For a uniform velocity profile at the pipe entrance, the computed length in laminar flow required for the centerline velocity to reach 99 percent of its fully developed value is (Dombrowski, Foumeny, Ookawara, and Riza, *Can. J. Chem. Engr.,* **71,** 472–476 [1993])

$$L_{\mathrm{ent}}/D = 0.370 \exp(-0.148\mathrm{Re}) + 0.0550\mathrm{Re} + 0.260 \qquad (6\text{-}46)$$

In turbulent flow, the entrance length is about

$$L_{\mathrm{ent}}/D = 40 \qquad (6\text{-}47)$$

The frictional losses in the entrance region are larger than those for the same length of fully developed flow. (See the subsection, "Frictional Losses in Pipeline Elements," following.) At the pipe exit, the velocity profile also undergoes rearrangement, but the exit length is much shorter than the entrance length. At low Re, it is about one pipe radius. At Re > 100, the exit length is essentially 0.

**Residence Time Distribution** For laminar Newtonian pipe flow, the cumulative residence time distribution $F(\theta)$ is given by

$$F(\theta) = 0 \qquad \text{for} \qquad \theta < \frac{\theta_{\mathrm{avg}}}{2}$$

$$F(\theta) = 1 - \frac{1}{4} \left( \frac{\theta_{\mathrm{avg}}}{\theta} \right)^2 \qquad \text{for} \qquad \theta \geq \frac{\theta_{\mathrm{avg}}}{2} \qquad (6\text{-}48)$$

where $F(\theta)$ is the fraction of material which resides in the pipe for less than time $\theta$ and $\theta_{\mathrm{avg}}$ is the average residence time, $\theta = V/L$.

The residence time distribution in long transfer lines may be made narrower (more uniform) with the use of **flow inverters** or **static mixing elements.** These devices exchange fluid between the wall and central regions. Variations on the concept may be used to provide effective mixing of the fluid. See Godfrey ("Static Mixers," in Harnby, Edwards, and Nienow, *Mixing in the Process Industries,* 2d ed., Butterworth Heinemann, Oxford, 1992); Etchells and Meyer ("Mixing in Pipelines, in Paul, Atiemo-Obeng, and Kresta, *Handbook of Industrial Mixing*, Wiley Interscience, Hoboken, N.J., 2004).

A theoretically derived equation for laminar flow in helical pipe coils by Ruthven (*Chem. Eng. Sci.,* **26,** 1113–1121 [1971]; **33,** 628–629 [1978]) is given by

$$F(\theta) = 1 - \left(\frac{1}{4}\right)\left[\frac{\theta_{avg}}{\theta}\right]^{2.81} \qquad \text{for} \qquad 0.5 < \frac{\theta_{avg}}{\theta} < 1.63 \qquad (6\text{-}49)$$

and was substantially confirmed by Trivedi and Vasudeva (*Chem. Eng. Sci.,* **29,** 2291–2295 [1974]) for $0.6 < De < 6$ and $0.0036 < D/D_c < 0.097$ where $De = Re\sqrt{D/D_c}$ is the Dean number and $D_c$ is the diameter of curvature of the coil. Measurements by Saxena and Nigam (*Chem. Eng. Sci.,* **34,** 425–426 [1979]) indicate that such a distribution will hold for $De > 1$. The residence time distribution for helical coils is narrower than for straight circular pipes, due to the secondary flow which exchanges fluid between the wall and center regions.

In turbulent flow, axial mixing is usually described in terms of turbulent diffusion or dispersion coefficients, from which cumulative residence time distribution functions can be computed. Davies (*Turbulence Phenomena,* Academic, New York, 1972, p. 93) gives $D_L = 1.01\nu Re^{0.875}$ for the longitudinal dispersion coefficient. Levenspiel (*Chemical Reaction Engineering,* 2d ed., Wiley, New York, 1972, pp. 253–278) discusses the relations among various residence time distribution functions, and the relation between dispersion coefficient and residence time distribution.

**Noncircular Channels** Calculation of frictional pressure drop in noncircular channels depends on whether the flow is laminar or turbulent, and on whether the channel is full or open. For **turbulent flow** in **ducts running full,** the **hydraulic diameter** $D_H$ should be substituted for $D$ in the friction factor and Reynolds number definitions, Eqs. (6-32) and (6-33). The hydraulic diameter is defined as **four times the channel cross-sectional area divided by the wetted perimeter.** For example, the hydraulic diameter for a circular pipe is $D_H = D$, for an annulus of inner diameter $d$ and outer diameter $D$, $D_H = D - d$, for a rectangular duct of sides $a, b$, $D_H = ab/[2(a+b)]$. The **hydraulic radius** $R_H$ is defined as **one-fourth** of the hydraulic diameter.

With the hydraulic diameter subsititued for $D$ in $f$ and Re, Eqs. (6-37) through (6-40) are good approximations. Note that $V$ appearing in $f$ and Re is the actual average velocity $V = Q/A$; for noncircular pipes; it is **not** $Q/(\pi D_H^2/4)$. The pressure drop should be calculated from the friction factor for noncircular pipes. Equations relating $Q$ to $\Delta P$ and $D$ for circular pipes **may not be used** for noncircular pipes with $D$ replaced by $D_H$ because $V \neq Q/(\pi D_H^2/4)$.

Turbulent flow in noncircular channels is generally accompanied by secondary flows perpendicular to the axial flow direction (Schlichting). These flows may cause the pressure drop to be slightly greater than that computed using the hydraulic diameter method. For data on pressure drop in annuli, see Brighton and Jones (*J. Basic Eng.,* **86,** 835–842 [1964]); Okiishi and Serovy (*J. Basic Eng.,* **89,** 823–836 [1967]); and Lawn and Elliot (*J. Mech. Eng. Sci.,* **14,** 195–204 [1972]). For rectangular ducts of large aspect ratio, Dean (*J. Fluids Eng.,* **100,** 215–233 [1978]) found that the numerator of the exponent in the Blasius equation (6-37) should be increased to 0.0868. Jones (*J. Fluids Eng.,* **98,** 173–181 [1976]) presents a method to improve the estimation of friction factors for rectangular ducts using a modification of the hydraulic diameter–based Reynolds number.

The hydraulic diameter method does not work well for **laminar flow** because the shape affects the flow resistance in a way that cannot be expressed as a function only of the ratio of cross-sectional area to wetted perimeter. For some shapes, the Navier-Stokes equations have been integrated to yield relations between flow rate and pressure drop. These relations may be expressed in terms of **equivalent diameters** $D_E$ defined to make the relations reduce to the second form of the Hagen-Poiseulle equation, Eq. (6-36); that is, $D_E \equiv (128Q\mu L/\pi\Delta P)^{1/4}$. **Equivalent diameters are not the same as hydraulic diameters.** Equivalent diameters yield the correct relation between flow rate and pressure drop when substituted into Eq. (6-36), but not Eq. (6-35) because $V \neq Q/(\pi D_E/4)$. Equivalent diameter $D_E$ is not to be used in the friction factor and Reynolds number; $f \neq 16/\text{Re}$ using the equivalent diameters defined in the following. This situation is, by arbitrary definition, opposite to that for the hydraulic diameter $D_H$ used for turbulent flow.

**Ellipse,** semiaxes $a$ and $b$ (Lamb, *Hydrodynamics,* 6th ed., Dover, New York, 1945, p. 587):

$$D_E = \left(\frac{32a^3b^3}{a^2+b^2}\right)^{1/4} \qquad (6\text{-}50)$$

**Rectangle,** width $a$, height $b$ (Owen, *Trans. Am. Soc. Civ. Eng.,* **119,** 1157–1175 [1954]):

$$D_E = \left(\frac{128ab^3}{\pi K}\right)^{1/4} \qquad (6\text{-}51)$$

| $a/b =$ | 1 | 1.5 | 2 | 3 | 4 | 5 | 10 | ∞ |
|---|---|---|---|---|---|---|---|---|
| $K =$ | 28.45 | 20.43 | 17.49 | 15.19 | 14.24 | 13.73 | 12.81 | 12 |

**Annulus,** inner diameter $D_1$, outer diameter $D_2$ (Lamb, op. cit., p. 587):

$$D_E = \left\{(D_2^2 - D_1^2)\left[D_2^2 + D_1^2 - \frac{D_2^2 - D_1^2}{\ln(D_2/D_1)}\right]\right\}^{1/4} \qquad (6\text{-}52)$$

For isosceles triangles and regular polygons, see Sparrow (*AIChE J.,* **8,** 599–605 [1962]), Carlson and Irvine (*J. Heat Transfer,* **83,** 441–444 [1961]), Cheng (*Proc. Third Int. Heat Transfer Conf.,* New York, **1,** 64–76 [1966]), and Shih (*Can. J. Chem. Eng.,* **45,** 285–294 [1967]).

The critical Reynolds number for **transition from laminar to turbulent flow** in noncircular channels varies with channel shape. In rectangular ducts, $1{,}900 < Re_c < 2{,}800$ (Hanks and Ruo, *Ind. Eng. Chem. Fundam.,* **5,** 558–561 [1966]). In triangular ducts, $1{,}600 < Re_c < 1{,}800$ (Cope and Hanks, *Ind. Eng. Chem. Fundam.,* **11,** 106–117 [1972]; Bandopadhayay and Hinwood, *J. Fluid Mech.,* **59,** 775–783 [1973]).

**Nonisothermal Flow** For nonisothermal flow of **liquids,** the friction factor may be increased if the liquid is being cooled or decreased if the liquid is being heated, because of the effect of temperature on viscosity near the wall. In shell and tube heat-exchanger design, the recommended practice is to first estimate $f$ using the bulk mean liquid temperature over the tube length. Then, in laminar flow, the result is divided by $(\mu_a/\mu_w)^{0.23}$ in the case of cooling or $(\mu_a/\mu_w)^{0.38}$ in the case of heating. For turbulent flow, $f$ is divided by $(\mu_a/\mu_w)^{0.11}$ in the case of cooling or $(\mu_a/\mu_w)^{0.17}$ in case of heating. Here, $\mu_a$ is the viscosity at the average bulk temperature and $\mu_w$ is the viscosity at the average wall temperature (Seider and Tate, *Ind. Eng. Chem.,* **28,** 1429–1435 [1936]). In the case of rough commercial pipes, rather than heat-exchanger tubing, it is common for flow to be in the "complete" turbulence regime where $f$ is independent of Re. In such cases, the friction factor should not be corrected for wall temperature. If the liquid density varies with temperature, the average bulk density should be used to calculate the pressure drop from the friction factor. In addition, a (usually small) correction may be applied for acceleration effects by adding the term $G^2[(1/\rho_2) - (1/\rho_1)]$ from the mechanical energy balance to the pressure drop $\Delta P = P_1 - P_2$, where $G$ is the mass velocity. This acceleration results from small compressibility effects associated with temperature-dependent density. Christiansen and Gordon (*AIChE J.,* **15,** 504–507 [1969]) present equations and charts for frictional loss in laminar nonisothermal flow of Newtonian and non-Newtonian liquids heated or cooled with constant wall temperature.

Frictional dissipation of mechanical energy can result in significant heating of fluids, particularly for very viscous liquids in small channels. Under adiabatic conditions, the bulk liquid temperature rise is given by $\Delta T = \Delta P/C_v\rho$ for incompressible flow through a channel of constant cross-sectional area. For flow of polymers, this amounts to about 4°C per 10 MPa pressure drop, while for hydrocarbon liquids it is about

6°C per 10 MPa. The temperature rise in laminar flow is highly nonuniform, being concentrated near the pipe wall where most of the dissipation occurs. This may result in significant viscosity reduction near the wall, and greatly increased flow or reduced pressure drop, and a flattened velocity profile. Compensation should generally be made for the heat effect when $\Delta P$ exceeds 1.4 MPa (203 psi) for adiabatic walls or 3.5 MPa (508 psi) for isothermal walls (Gerard, Steidler, and Appeldoorn, *Ind. Eng. Chem. Fundam.,* **4,** 332–339 [1969]).

**Open Channel Flow** For flow in **open channels,** the data are largely based on experiments with water in turbulent flow, in channels of sufficient roughness that there is no Reynolds number effect. The hydraulic radius approach may be used to estimate a friction factor with which to compute friction losses. Under conditions of **uniform flow** where liquid depth and cross-sectional area do not vary significantly with position in the flow direction, there is a balance between gravitational forces and wall stress, or equivalently between frictional losses and potential energy change. The mechanical energy balance reduces to $l_v = g(z_1 - z_2)$. In terms of the friction factor and hydraulic diameter or hydraulic radius,

$$l_v = \frac{2fV^2L}{D_H} = \frac{fV^2L}{2R_H} = g(z_1 - z_2) \tag{6-53}$$

The hydraulic radius is the cross-sectional area divided by the wetted perimeter, where the wetted perimeter *does not include the free surface.* Letting $S = \sin\theta$ = channel slope (elevation loss per unit length of channel, $\theta$ = angle between channel and horizontal), Eq. (6-53) reduces to

$$V = \sqrt{\frac{2gSR_H}{f}} \tag{6-54}$$

The most often used friction correlation for open channel flows is due to Manning (*Trans. Inst. Civ. Engrs. Ireland,* **20,** 161 [1891]) and is equivalent to

$$f = \frac{29n^2}{R_H^{1/3}} \tag{6-55}$$

where $n$ is the channel roughness, with dimensions of $(\text{length})^{1/6}$. Table 6-2 gives roughness values for several channel types.

For gradual changes in channel cross section and liquid depth, and for slopes less than 10°, the momentum equation for a rectangular channel of width $b$ and liquid depth $h$ may be written as a differential equation in the flow direction $x$.

$$\frac{dh}{dx}(1 - \text{Fr}) - \text{Fr}\left(\frac{h}{b}\right)\frac{db}{dx} = S - \frac{fV^2(b + 2h)}{2gbh} \tag{6-56}$$

For a given fixed flow rate $Q = Vbh$, and channel width profile $b(x)$, Eq. (6-56) may be integrated to determine the liquid depth profile $h(x)$. The dimensionless Froude number is $\text{Fr} = V^2/gh$. When $\text{Fr} = 1$, the flow is **critical,** when $\text{Fr} < 1$, the flow is **subcritical,** and when $\text{Fr} > 1$, the flow is **supercritical.** Surface disturbances move at a wave velocity $c = \sqrt{gh}$; they cannot propagate upstream in supercritical flows. The **specific energy** $E_{sp}$ is nearly constant.

$$E_{sp} = h + \frac{V^2}{2g} \tag{6-57}$$

This equation is cubic in liquid depth. Below a minimum value of $E_{sp}$ there are no real positive roots; above the minimum value there are two positive real roots. At this minimum value of $E_{sp}$ the flow is critical; that is, $\text{Fr} = 1$, $V = \sqrt{gh}$, and $E_{sp} = (3/2)h$. Near critical flow conditions, wave motion and sudden depth changes called **hydraulic jumps** are likely. Chow (*Open Channel Hydraulics,* McGraw-Hill, New York, 1959) discusses the numerous surface profile shapes which may exist in nonuniform open channel flows.

For flow over a sharp-crested weir of width $b$ and height $L$, from a liquid depth $H$, the flow rate is given approximately by

$$Q = \frac{2}{3}C_d b\sqrt{2g}(H - L)^{3/2} \tag{6-58}$$

where $C_d \approx 0.6$ is a discharge coefficient. Flow through notched weirs is described under flow meters in Sec. 10 of the *Handbook.*

**Non-Newtonian Flow** For **isothermal laminar flow** of time-independent non-Newtonian liquids, integration of the Cauchy momentum equations yields the fully developed velocity profile and flow rate–pressure drop relations. For the **Bingham plastic** fluid described by Eq. (6-3), in a pipe of diameter $D$ and a pressure drop per unit length $\Delta P/L$, the flow rate is given by

$$Q = \frac{\pi D^3\tau_w}{32\mu_\infty}\left[1 - \frac{4\tau_y}{3\tau_w} + \frac{\tau_y^4}{3\tau_w^4}\right] \tag{6-59}$$

where the wall stress is $\tau_w = D\Delta P/(4L)$. The velocity profile consists of a central nondeforming plug of radius $r_P = 2\tau_y/(\Delta P/L)$ and an annular deforming region. The velocity profile in the annular region is given by

$$v_z = \frac{1}{\mu_\infty}\left[\frac{\Delta P}{4L}(R^2 - r^2) - \tau_y(R - r)\right] \qquad r_P \le r \le R \tag{6-60}$$

where $r$ is the radial coordinate and $R$ is the pipe radius. The velocity of the central, nondeforming plug is obtained by setting $r = r_P$ in Eq. (6-60). When $Q$ is given and Eq. (6-59) is to be solved for $\tau_w$ and the pressure drop, multiple positive roots for the pressure drop may be found. The root corresponding to $\tau_w < \tau_y$ is physically unrealizable, as it corresponds to $r_p > R$ and the pressure drop is insufficient to overcome the yield stress.

For a **power law fluid,** Eq. (6-4), with constant properties $K$ and $n$, the flow rate is given by

$$Q = \pi\left(\frac{\Delta P}{2KL}\right)^{1/n}\left(\frac{n}{1 + 3n}\right)R^{(1+3n)/n} \tag{6-61}$$

and the velocity profile by

$$v_z = \left(\frac{\Delta P}{2KL}\right)^{1/n}\left(\frac{n}{1 + n}\right)[R^{(1+n)/n} - r^{(1+n)/n}] \tag{6-62}$$

Similar relations for other non-Newtonian fluids may be found in Govier and Aziz and in Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977).

For steady-state laminar flow of any time-independent viscous fluid, at average velocity $V$ in a pipe of diameter $D$, the Rabinowitsch-Mooney relations give a general relationship for the shear rate at the pipe wall.

$$\dot{\gamma}_w = \frac{8V}{D}\left(\frac{1 + 3n'}{4n'}\right) \tag{6-63}$$

where $n'$ is the slope of a plot of $D\Delta P/(4L)$ versus $8V/D$ on logarithmic coordinates,

$$n' = \frac{d\ln[D\Delta P/(4L)]}{d\ln(8V/D)} \tag{6-64}$$

**TABLE 6-2 Average Values of *n* for Manning Formula, Eq. (6-55)**

| Surface | $n$, $\text{m}^{1/6}$ | $n$, $\text{ft}^{1/6}$ |
|---|---|---|
| Cast-iron pipe, fair condition | 0.014 | 0.011 |
| Riveted steel pipe | 0.017 | 0.014 |
| Vitrified sewer pipe | 0.013 | 0.011 |

SOURCE: Brater and King, *Handbook of Hydraulics,* 6th ed., McGraw-Hill, New York, 1976, p. 7-22. For detailed information, see Chow, *Open-Channel Hydraulics,* McGraw-Hill, New York, 1959, pp. 110–123.

By plotting capillary viscometry data this way, they can be used directly for pressure drop design calculations, or to construct the rheogram for the fluid. For pressure drop calculation, the flow rate and diameter determine the velocity, from which $8V/D$ is calculated and $D\Delta P/(4L)$ read from the plot. For a Newtonian fluid, $n' = 1$ and the shear rate at the wall is $\dot{\gamma} = 8V/D$. For a power law fluid, $n' = n$. To construct a rheogram, $n'$ is obtained from the slope of the experimental plot at a given value of $8V/D$. The shear rate at the wall is given by Eq. (6-63) and the corresponding shear stress at the wall is $\tau_w = D\Delta P/(4L)$ read from the plot. By varying the value of $8V/D$, the shear rate versus shear stress plot can be constructed.

The generalized approach of Metzner and Reed (*AIChE J.*, **1,** 434 [1955]) for time-independent non-Newtonian fluids defines a modified Reynolds number as

$$\mathrm{Re}_{\mathrm{MR}} \equiv \frac{D^{n'}V^{2-n'}\rho}{K'8^{n'-1}} \tag{6-65}$$

where $K'$ satisfies

$$\frac{D\Delta P}{4L} = K'\left(\frac{8V}{D}\right)^{n'} \tag{6-66}$$

With this definition, $f = 16/\mathrm{Re}_{\mathrm{MR}}$ is automatically satisfied at the value of $8V/D$ where $K'$ and $n'$ are evaluated. Equation (6-66) may be obtained by integration of Eq. (6-64) only when $n'$ is a constant, as, for example, the cases of Newtonian and power law fluids. For Newtonian fluids, $K' = \mu$ and $n' = 1$; for power law fluids, $K' = K[(1 + 3n)/(4n)]^n$ and $n' = n$. For Bingham plastics, $K'$ and $n'$ are variable, given as a function of $\tau_w$ (Metzner, *Ind. Eng. Chem.*, **49,** 1429–1432 [1957]).

$$K = \tau_w^{1-n'}\left[\frac{\mu_\infty}{1 - 4\tau_y/3\tau_w + (\tau_y/\tau_w)^4/3}\right]^{n'} \tag{6-67}$$

$$n' = \frac{1 - 4\tau_y/(3\tau_w) + (\tau_y/\tau_w)^4/3}{1 - (\tau_y/\tau_w)^4} \tag{6-68}$$

For laminar flow of power law fluids in channels of noncircular cross section, see Schecter (*AIChE J.*, **7,** 445–448 [1961]), Wheeler and Wissler (*AIChE J.*, **11,** 207–212 [1965]), Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids*, vol. 1: *Fluid Mechanics*, Wiley, New York, 1977), and Skelland (*Non-Newtonian Flow and Heat Transfer*, Wiley, New York, 1967).

Steady-state, fully developed laminar flows of viscoelastic fluids in straight, constant-diameter pipes show no effects of viscoelasticity. The viscous component of the constitutive equation may be used to develop the flow rate–pressure drop relations, which apply downstream of the entrance region after viscoelastic effects have disappeared. A similar situation exists for time-dependent fluids.

The **transition to turbulent flow** begins at $\mathrm{Re}_{\mathrm{MR}}$ in the range of 2,000 to 2,500 (Metzner and Reed, *AIChE J.*, **1,** 434 [1955]). For Bingham plastic materials, $K'$ and $n'$ must be evaluated for the $\tau_w$ condition in question in order to determine $\mathrm{Re}_{\mathrm{MR}}$ and establish whether the flow is laminar. An alternative method for Bingham plastics is by Hanks (Hanks, *AIChE J.*, **9,** 306 [1963]; **14,** 691 [1968]; Hanks and Pratt, *Soc. Petrol. Engrs. J.*, **7,** 342 [1967]; and Govier and Aziz, pp. 213–215). The transition from laminar to turbulent flow is influenced by **viscoelastic** properties (Metzner and Park, *J. Fluid Mech.*, **20,** 291 [1964]) with the critical value of $\mathrm{Re}_{\mathrm{MR}}$ increased to beyond 10,000 for some materials.

For **turbulent flow of non-Newtonian fluids,** the design chart of Dodge and Metzner (*AIChE J.*, **5,** 189 [1959]), Fig. 6-11, is most widely used. For Bingham plastic materials in turbulent flow, it is generally assumed that stresses greatly exceed the yield stress, so that the friction factor–Reynolds number relationship for Newtonian fluids applies, with $\mu_\infty$ substituted for $\mu$. This is equivalent to setting $n' = 1$ and $\tau_y/\tau_w = 0$ in the Dodge-Metzner method, so that $\mathrm{Re}_{\mathrm{MR}} = DV\rho/\mu_\infty$. Wilson and Thomas (*Can. J. Chem. Eng.*, **63,** 539–546 [1985]) give friction factor equations for turbulent flow of power law fluids and Bingham plastic fluids.

Power law fluids:

$$\frac{1}{\sqrt{f}} = \frac{1}{\sqrt{f_N}} + 8.2\,\frac{1-n}{1+n} + 1.77\ln\left(\frac{1+n}{2}\right) \tag{6-69}$$

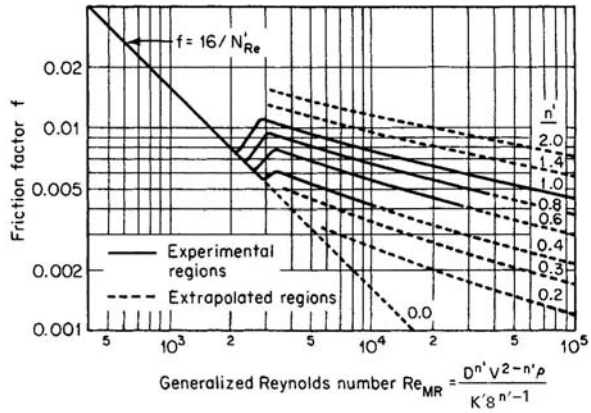

**FIG. 6-11** Fanning friction factor for non-Newtonian flow. The abscissa is defined in Eq. (6-65). (*From Dodge and Metzner,* Am. Inst. Chem. Eng. J., **5,** *189 [1959].*)

where $f_N$ is the friction factor for Newtonian fluid evaluated at $\mathrm{Re} = DV\rho/\mu_{\mathrm{eff}}$ where the effective viscosity is

$$\mu_{\mathrm{eff}} = K\left(\frac{3n+1}{4n}\right)^{n-1}\left(\frac{8V}{D}\right)^{n-1} \tag{6-70}$$

Bingham fluids:

$$\frac{1}{\sqrt{f}} = \frac{1}{\sqrt{f_N}} + 1.77\ln\left(\frac{(1-\xi)^2}{1+\xi}\right) + \xi(10 + 0.884\xi) \tag{6-71}$$

where $f_N$ is evaluated at $\mathrm{Re} = DV\rho/\mu_\infty$ and $\xi = \tau_y/\tau_w$. Iteration is required to use this equation since $\tau_w = f\rho V^2/2$.

**Drag reduction** in turbulent flow can be achieved by adding soluble high molecular weight polymers in extremely low concentration to Newtonian liquids. The reduction in friction is generally believed to be associated with the viscoelastic nature of the solutions effective in the wall region. For a given polymer, there is a minimum molecular weight necessary to initiate drag reduction at a given flow rate, and a critical concentration above which drag reduction will not occur (Kim, Little, and Ting, *J. Colloid Interface Sci.*, **47,** 530–535 [1974]). Drag reduction is reviewed by Hoyt (*J. Basic Eng.*, **94,** 258–285 [1972]); Little, et al. (*Ind. Eng. Chem. Fundam.*, **14,** 283–296 [1975]) and Virk (*AIChE J.*, **21,** 625–656 [1975]). At maximum possible drag reduction in smooth pipes,

$$\frac{1}{\sqrt{f}} = -19\log\left(\frac{50.73}{\mathrm{Re}\sqrt{f}}\right) \tag{6-72}$$

or, approximately,

$$f = \frac{0.58}{\mathrm{Re}^{0.58}} \tag{6-73}$$

for $4{,}000 < \mathrm{Re} < 40{,}000$. The actual drag reduction depends on the polymer system. For further details, see Virk (ibid.).

**Economic Pipe Diameter, Turbulent Flow** The economic optimum pipe diameter may be computed so that the last increment of investment reduces the operating cost enough to produce the required minimum return on investment. For long cross-country pipelines, alloy pipes of appreciable length and complexity, or pipelines with control valves, detailed analyses of investment and operating costs should be made. Peters and Timmerhaus (*Plant Design and Economics for Chemical Engineers*, 4th ed., McGraw-Hill, New York, 1991) provide a detailed method for determining the economic optimum size. For pipelines of the lengths usually encountered in chemical plants and petroleum refineries, simplified selection charts are often adequate. In many cases there is an economic optimum velocity that is nearly independent of diameter, which may be used to estimate the economic diameter from the flow rate. For low-viscosity liquids in schedule 40 steel pipe, economic optimum velocity is typically in the range of 1.8 to 2.4 m/s (5.9 to 7.9 ft/s). For gases with density ranging

from 0.2 to 20 kg/m$^3$ (0.013 to 1.25 lbm/ft$^3$), the economic optimum velocity is about 40 m/s to 9 m/s (131 to 30 ft/s). Charts and rough guidelines for economic optimum size do not apply to multiphase flows.

**Economic Pipe Diameter, Laminar Flow** Pipelines for the transport of high-viscosity liquids are seldom designed purely on the basis of economics. More often, the size is dictated by operability considerations such as available pressure drop, shear rate, or residence time distribution. Peters and Timmerhaus (ibid., Chap. 10) provide an economic pipe diameter chart for laminar flow. For non-Newtonian fluids, see Skelland (*Non-Newtonian Flow and Heat Transfer,* Chap. 7, Wiley, New York, 1967).

**Vacuum Flow** When gas flows under high vacuum conditions or through very small openings, the continuum hypothesis is no longer appropriate if the channel dimension is not very large compared to the mean free path of the gas. When the mean free path is comparable to the channel dimension, flow is dominated by collisions of molecules with the wall, rather than by collisions between molecules. An approximate expression based on Brown, et al. (*J. Appl. Phys.,* **17,** 802–813 [1946]) for the mean free path is

$$\lambda = \left(\frac{2\mu}{p}\right)\sqrt{\frac{8RT}{\pi M_w}} \tag{6-74}$$

The Knudsen number Kn is the ratio of the mean free path to the channel dimension. For pipe flow, Kn = $\lambda/D$. **Molecular flow** is characterized by Kn > 1.0; continuum viscous (laminar or turbulent) flow is characterized by Kn < 0.01. **Transition** or **slip** flow applies over the range 0.01 < Kn < 1.0.

Vacuum flow is usually described with flow variables different from those used for normal pressures, which often leads to confusion. **Pumping speed** $S$ is the actual volumetric flow rate of gas through a flow cross section. **Throughput** $Q$ is the product of pumping speed and absolute pressure. In the SI system, $Q$ has units of Pa·m$^3$/s.

$$Q = Sp \tag{6-75}$$

The mass flow rate $w$ is related to the throughput using the ideal gas law.

$$w = \frac{M_w}{RT}Q \tag{6-76}$$

Throughput is therefore proportional to mass flow rate. For a given mass flow rate, throughput is independent of pressure. The relation between throughput and pressure drop $\Delta p = p_1 - p_2$ across a flow element is written in terms of the **conductance** $C$. **Resistance** is the reciprocal of conductance. Conductance has dimensions of volume per time.

$$Q = C\Delta p \tag{6-77}$$

The conductance of a series of flow elements is given by

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots \tag{6-78}$$

while for elements in parallel,

$$C = C_1 + C_2 + C_3 + \cdots \tag{6-79}$$

For a vacuum pump of speed $S_p$ withdrawing from a vacuum vessel through a connecting line of conductance $C$, the pumping speed at the vessel is

$$S = \frac{S_p C}{S_p + C} \tag{6-80}$$

**Molecular Flow** Under molecular flow conditions, conductance is independent of pressure. It is proportional to $\sqrt{T/M_w}$, with the proportionality constant a function of geometry. For fully developed pipe flow,

$$C = \frac{\pi D^3}{8L}\sqrt{\frac{RT}{M_w}} \tag{6-81}$$

For an orifice of area $A$,

$$C = 0.40A\sqrt{\frac{RT}{M_w}} \tag{6-82}$$

**TABLE 6-3 Constants for Circular Annuli**

| $D_2/D_1$ | $K$ | $D_2/D_1$ | $K$ |
|---|---|---|---|
| 0 | 1.00 | 0.707 | 1.254 |
| 0.259 | 1.072 | 0.866 | 1.430 |
| 0.500 | 1.154 | 0.966 | 1.675 |

Conductance equations for several other geometries are given by Ryans and Roper (*Process Vacuum System Design and Operation,* Chap. 2, McGraw-Hill, New York, 1986). For a circular annulus of outer and inner diameters $D_1$ and $D_2$ and length $L$, the method of Guthrie and Wakerling (*Vacuum Equipment and Techniques,* McGraw-Hill, New York, 1949) may be written

$$C = 0.42K\frac{(D_1 - D_2)^2(D_1 + D_2)}{L}\sqrt{\frac{RT}{M_w}} \tag{6-83}$$

where $K$ is a dimensionless constant with values given in Table 6-3.

For a short pipe of circular cross section, the conductance as calculated for an orifice from Eq. (6-82) is multiplied by a correction factor $K$ which may be approximated as (Kennard, *Kinetic Theory of Gases,* McGraw-Hill, New York, 1938, pp. 306–308)

$$K = \frac{1}{1 + (L/D)} \qquad \text{for} \quad 0 \le L/D \le 0.75 \tag{6-84}$$

$$K = \frac{1 + 0.8(L/D)}{1 + 1.90(L/D) + 0.6(L/D)^2} \qquad \text{for} \quad L/D > 0.75 \tag{6-85}$$

For $L/D > 100$, the error in neglecting the end correction by using the fully developed pipe flow equation (6-81) is less than 2 percent. For rectangular channels, see Normand (*Ind. Eng. Chem.,* **40,** 783–787 [1948]).

Yu and Sparrow (*J. Basic Eng.,* **70,** 405–410 [1970]) give a theoretically derived chart for slot seals with or without a sheet located in or passing through the seal, giving mass flow rate as a function of the ratio of seal plate thickness to gap opening.

**Slip Flow** In the transition region between molecular flow and continuum viscous flow, the conductance for fully developed pipe flow is most easily obtained by the method of Brown, et al. (*J. Appl. Phys.,* **17,** 802–813 [1946]), which uses the parameter

$$X = \sqrt{\frac{8}{\pi}}\left(\frac{\lambda}{D}\right) = \left(\frac{2\mu}{p_m D}\right)\sqrt{\frac{RT}{M}} \tag{6-86}$$

where $p_m$ is the arithmetic mean absolute pressure. A correction factor $F$, read from Fig. 6-12 as a function of $X$, is applied to the conductance

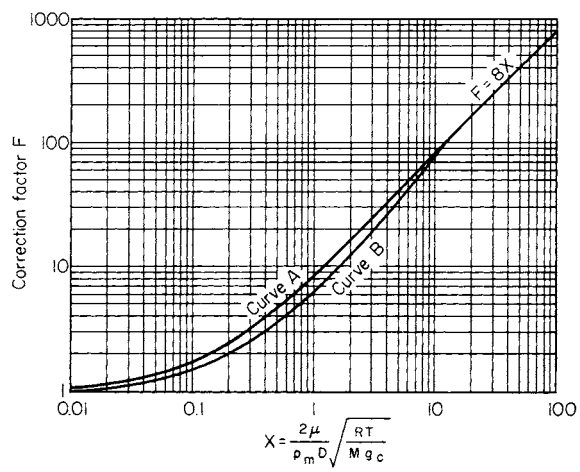

**FIG. 6-12** Correction factor for Poiseuille's equation at low pressures. Curve *A:* experimental curve for glass capillaries and smooth metal tubes. (*From Brown, et al.,* J. Appl. Phys., **17,** 802 [1946].) Curve *B:* experimental curve for iron pipe (*From Riggle, courtesy of E. I. du Pont de Nemours & Co.*)

for viscous flow.

$$C = F\frac{\pi D^4 p_m}{128\mu L} \tag{6-87}$$

For slip flow through **square channels,** see Milligan and Wilkerson (*J. Eng. Ind.,* **95,** 370–372 [1973]). For slip flow through **annuli,** see Maegley and Berman (*Phys. Fluids,* **15,** 780–785 [1972]).

The **pump-down time** $\theta$ for evacuating a vessel in the absence of air in-leakage is given approximately by

$$\theta = \left(\frac{V_t}{S_0}\right)\ln\left(\frac{p_1 - p_0}{p_2 - p_0}\right) \tag{6-88}$$

where $V_t$ = volume of vessel plus volume of piping between vessel and pump; $S_0$ = system speed as given by Eq. (6-80), assumed independent of pressure; $p_1$ = initial vessel pressure; $p_2$ = final vessel pressure; and $p_0$ = lowest pump intake pressure attainable with the pump in question. See Dushman and Lafferty (*Scientific Foundations of Vacuum Technique,* 2d ed., Wiley, New York, 1962).

The amount of inerts which has to be removed by a pumping system after the pump-down stage depends on the in-leakage of air at the various fittings, connections, and so on. Air leakage is often correlated with system volume and pressure, but this approach introduces uncertainty because the number and size of leaks does not necessily correlate with system volume, and leakage is sensitive to maintenance quality. Ryans and Roper (*Process Vacuum System Design and Operation,* McGraw-Hill, New York, 1986) present a thorough discussion of air leakage.

## FRICTIONAL LOSSES IN PIPELINE ELEMENTS

The viscous or frictional loss term in the mechanical energy balance for most cases is obtained experimentally. For many common fittings found in piping systems, such as expansions, contractions, elbows, and valves, data are available to estimate the losses. Substitution into the energy balance then allows calculation of pressure drop. A common error is to assume that pressure drop and frictional losses are equivalent. Equation (6-16) shows that in addition to frictional losses, other factors such as shaft work and velocity or elevation change influence pressure drop.

Losses $l_v$ for incompressible flow in sections of straight pipe of constant diameter may be calculated as previously described using the Fanning friction factor:

$$l_v = \frac{\Delta P}{\rho} = \frac{2fV^2L}{D} \tag{6-89}$$

where $\Delta P$ = drop in equivalent pressure, $P = p + \rho gz$, with $p$ = pressure, $\rho$ = fluid density, $g$ = acceleration of gravity, and $z$ = elevation. Losses in the fittings of a piping network are frequently termed *minor losses* or *miscellaneous losses.* These descriptions are misleading because in process piping fitting losses are often much greater than the losses in straight piping sections.

**Equivalent Length and Velocity Head Methods** Two methods are in common use for estimating fitting loss. One, the **equivalent length** method, reports the losses in a piping element as the length of straight pipe which would have the same loss. For turbulent flows, the equivalent length is usually reported as a number of diameters of pipe of the same size as the fitting connection; $L_e/D$ is given as a fixed quantity, independent of $D$. This approach tends to be most accurate for a single fitting size and loses accuracy with deviation from this size. For laminar flows, $L_e/D$ correlations normally have a size dependence through a Reynolds number term.

The other method is the **velocity head** method. The term $V^2/2g$ has dimensions of length and is commonly called a *velocity head.* Application of the Bernoulli equation to the problem of frictionless discharge at velocity $V$ through a nozzle at the bottom of a column of liquid of height $H$ shows that $H = V^2/2g$. Thus $H$ is the liquid head corresponding to the velocity $V$. Use of the velocity head to scale pressure drops has wide application in fluid mechanics. Examination of the Navier-Stokes equations suggests that when the inertial terms dominate the viscous terms, pressure gradients are expected to be proportional to $\rho V^2$ where $V$ is a characteristic velocity of the flow.

In the velocity head method, the losses are reported as a number of velocity heads $K$. Then, the engineering Bernoulli equation for an incompressible fluid can be written

$$p_1 - p_2 = \alpha_2\frac{\rho V_2^2}{2} - \alpha_1\frac{\rho V_1^2}{2} + \rho g(z_2 - z_1) + K\frac{\rho V^2}{2} \tag{6-90}$$

where $V$ is the reference velocity upon which the velocity head loss coefficient $K$ is based. For a section of straight pipe, $K = 4fL/D$.

**Contraction and Entrance Losses** For a **sudden contraction** at a sharp-edged entrance to a pipe or sudden reduction in cross-sectional area of a channel, as shown in Fig. 6-13*a,* the loss coefficient based on the downstream velocity $V_2$ is given for **turbulent flow** in Crane Co. Tech Paper 410 (1980) approximately by

$$K = 0.5\left(1 - \frac{A_2}{A_1}\right) \tag{6-91}$$

***Example 5: Entrance Loss*** Water, $\rho = 1{,}000$ kg/m$^3$, flows from a large vessel through a sharp-edged entrance into a pipe at a velocity in the pipe of 2 m/s. The flow is turbulent. Estimate the pressure drop from the vessel into the pipe.

With $A_2/A_1 \sim 0$, the viscous loss coefficient is $K = 0.5$ from Eq. (6-91). The mechanical energy balance, Eq. (6-16) with $V_1 = 0$ and $z_2 - z_1 = 0$ and assuming uniform flow ($\alpha_2 = 1$) becomes

$$p_1 - p_2 = \frac{\rho V_2^2}{2} + 0.5\frac{\rho V_2^2}{2} = 4{,}000 + 2{,}000 = 6{,}000 \text{ Pa}$$

Note that the total pressure drop consists of 0.5 velocity heads of frictional loss contribution, and 1 velocity head of velocity change contribution. The frictional contribution is a permanent loss of mechanical energy by viscous dissipation. The acceleration contribution is reversible; if the fluid were subsequently decelerated in a frictionless diffuser, a 4,000 Pa pressure rise would occur.

For a **trumpet-shaped** rounded entrance, with a radius of rounding greater than about 15 percent of the pipe diameter (Fig. 6-13*b*), the turbulent flow loss coefficient $K$ is only about 0.1 (Vennard and Street, *Elementary Fluid Mechanics,* 5th ed., Wiley, New York, 1975, pp. 420–421). Rounding of the inlet prevents formation of the **vena contracta,** thereby reducing the resistance to flow.

For **laminar flow** the losses in sudden contraction may be estimated for area ratios $A_2/A_1 < 0.2$ by an equivalent additional pipe length $L_e$ given by

$$L_e/D = 0.3 + 0.04\text{Re} \tag{6-92}$$

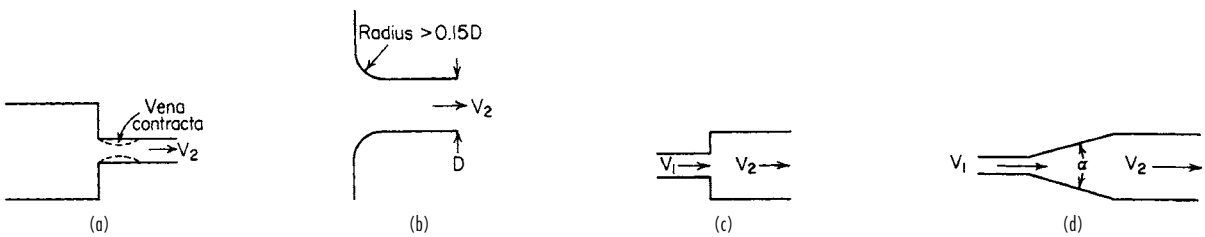

**FIG. 6-13** Contractions and enlargements: (*a*) sudden contraction, (*b*) rounded contraction, (*c*) sudden enlargement, and (*d*) uniformly diverging duct.

where $D$ is the diameter of the smaller pipe and Re is the Reynolds number in the smaller pipe. For laminar flow in the entrance to rectangular ducts, see Shah (*J. Fluids Eng.,* **100,** 177–179 [1978]) and Roscoe (*Philos. Mag.,* **40,** 338–351 [1949]). For creeping flow, Re < 1, of power law fluids, the entrance loss is approximately $L_e/D = 0.3/n$ (Boger, Gupta, and Tanner, *J. Non-Newtonian Fluid Mech.,* **4,** 239–248 [1978]). For viscoelastic fluid flow in circular channels with sudden contraction, a toroidal vortex forms upstream of the contraction plane. Such flows are reviewed by Boger (*Ann. Review Fluid Mech.,* **19,** 157–182 [1987]).

For creeping flow through **conical converging channels,** inertial acceleration terms are negligible and the viscous pressure drop $\Delta p = \rho l_v$ may be computed by integration of the differential form of the Hagen-Poiseuille equation Eq. (6-36), provided the angle of convergence is small. The result for a power law fluid is

$$\Delta p = 4K\left(\frac{3n+1}{4n}\right)^n \left(\frac{8V_2}{D_2}\right)^n \left\{\frac{1}{6n\tan(\alpha/2)}\left[1-\left(\frac{D_2}{D_1}\right)^{3n}\right]\right\} \quad (6\text{-}93)$$

where $D_1$ = inlet diameter
$D_2$ = exit diameter
$V_2$ = velocity at the exit
$\alpha$ = total included angle

Equation (6-93) agrees with experimental data (Kemblowski and Kiljanski, *Chem. Eng. J.* (*Lausanne*), **9,** 141–151 [1975]) for $\alpha < 11°$. For Newtonian liquids, Eq. (6-93) simplifies to

$$\Delta p = \mu\left(\frac{32V_2}{D_2}\right)\left\{\frac{1}{6\tan(\alpha/2)}\left[1-\left(\frac{D_2}{D_1}\right)^3\right]\right\} \quad (6\text{-}94)$$

For creeping flow through noncircular converging channels, the differential form of the Hagen-Poiseulle equation with equivalent diameter given by Eqs. (6-50) to (6-52) may be used, provided the convergence is gradual.

**Expansion and Exit Losses** For ducts of any cross section, the frictional loss for a **sudden enlargement** (Fig. 6-13*c*) with turbulent flow is given by the Borda-Carnot equation:

$$l_v = \frac{V_1^2 - V_2^2}{2} = \frac{V_1^2}{2}\left(1-\frac{A_1}{A_2}\right)^2 \quad (6\text{-}95)$$

where $V_1$ = velocity in the smaller duct
$V_2$ = velocity in the larger duct
$A_1$ = cross-sectional area of the smaller duct
$A_2$ = cross-sectional area of the larger duct

Equation (6-95) is valid for incompressible flow. For compressible flows, see Benedict, Wyler, Dudek, and Gleed (*J. Eng. Power,* **98,** 327–334 [1976]). For an infinite expansion, $A_1/A_2 = 0$, Eq. (6-95) shows that the **exit loss** from a pipe is 1 velocity head. This result is easily deduced from the mechanical energy balance Eq. (6-90), noting that $p_1 = p_2$. This exit loss is due to the dissipation of the discharged jet; there is no pressure drop at the exit.

For creeping Newtonian flow (Re < 1), the frictional loss due to a sudden enlargement should be obtained from the same equation for a sudden contraction (Eq. [6-92]). Note, however, that Boger, Gupta, and Tanner (ibid.) give an exit friction equivalent length of 0.12 diameter, increasing for power law fluids as the exponent decreases. For laminar flows at higher Reynolds numbers, the pressure drop is twice that given by Eq. (6-95). This results from the velocity profile factor $\alpha$ in the mechanical energy balance being 2.0 for the parabolic laminar velocity profile.

If the transition from a small to a large duct of any cross-sectional shape is accomplished by a **uniformly diverging duct** (see Fig. 6-13*d*) with a straight axis, the total frictional pressure drop can be computed by integrating the differential form of Eq. (6-89), $dl_v/dx = 2fV^2/D$ over the length of the expansion, provided the total angle $\alpha$ between the diverging walls is less than 7°. For angles between 7 and 45°, the loss coefficient may be estimated as $2.6\sin(\alpha/2)$ times the loss coefficient for a sudden expansion; see Hooper (*Chem. Eng.,* Nov. 7, 1988). Gibson (*Hydraulics and Its Applications,* 5th ed., Constable, London 1952, p. 93) recommends multiplying the sudden enlargement loss by 0.13 for $5° < \alpha < 7.5°$ and by $0.0110\alpha^{1.22}$ for $7.5° < \alpha <$ 35°. For angles greater than 35 to 45°, the losses are normally considered equal to those for a sudden expansion, although in some cases the losses may be greater. Expanding flow through standard pipe reducers should be treated as sudden expansions.

**Trumpet-shaped enlargements** for **turbulent flow** designed for constant decrease in velocity head per unit length were found by Gibson (ibid., p. 95) to give 20 to 60 percent less frictional loss than straight taper pipes of the same length.

A special feature of expansion flows occurs when **viscoelastic** liquids are extruded through a die at a low Reynolds number. The extrudate may expand to a diameter several times greater than the die diameter, whereas for a Newtonian fluid the diameter expands only 10 percent. This phenomenon, called **die swell,** is most pronounced with short dies (Graessley, Glasscock, and Crawley, *Trans. Soc. Rheol.,* **14,** 519–544 [1970]). For velocity distribution measurements near the die exit, see Goulden and MacSporran (*J. Non-Newtonian Fluid Mech.,* **1,** 183–198 [1976]) and Whipple and Hill (*AIChE J.,* **24,** 664–671 [1978]). At high flow rates, the extrudate becomes distorted, suffering **melt fracture** at wall shear stresses greater than $10^5$ N/m$^2$. This phenomenon is reviewed by Denn (*Ann. Review Fluid Mech.,* **22,** 13–34 [1990]). Ramamurthy (*J. Rheol.,* **30,** 337–357 [1986]) has found a dependence of apparent stick-slip behavior in melt fracture to be dependent on the material of construction of the die.

**Fittings and Valves** For **turbulent flow,** the frictional loss for fittings and valves can be expressed by the equivalent length or velocity head methods. As fitting size is varied, $K$ values are relatively more constant than $L_e/D$ values, but since fittings generally do not achieve geometric similarity between sizes, $K$ values tend to decrease with increasing fitting size. Table 6-4 gives $K$ values for many types of fittings and valves.

Manufacturers of valves, especially control valves, express valve capacity in terms of a flow coefficient $C_v$, which gives the flow rate through the valve in gal/min of water at 60°F under a pressure drop of 1 lbf/in$^2$. It is related to $K$ by

$$C_v = \frac{C_1 d^2}{\sqrt{K}} \quad (6\text{-}96)$$

where $C_1$ is a dimensional constant equal to 29.9 and $d$ is the diameter of the valve connections in inches.

For **laminar flow,** data for the frictional loss of valves and fittings are meager (Beck and Miller, *J. Am. Soc. Nav. Eng.,* **56,** 62–83 [1944]; Beck, ibid., **56,** 235–271, 366–388, 389–395 [1944]; De Craene, *Heat. Piping Air Cond.,* **27**[10], 90–95 [1955]; Karr and Schutz, *J. Am. Soc. Nav. Eng.,* **52,** 239–256 [1940]; and Kittredge and Rowley, *Trans. ASME,* **79,** 1759–1766 [1957]). The data of Kittredge and Rowley indicate that $K$ is constant for Reynolds numbers above 500 to 2,000, but increases rapidly as Re decreases below 500. Typical values for $K$ for laminar flow Reynolds numbers are shown in Table 6-5.

Methods to calculate losses for **tee and wye junctions** for dividing and combining flow are given by Miller (*Internal Flow Systems,* 2d ed., Chap. 13, BHRA, Cranfield, 1990), including effects of Reynolds number, angle between legs, area ratio, and radius. Junctions with more than three legs are also discussed. The sources of data for the loss coefficient charts are Blaisdell and Manson (*U.S. Dept. Agric. Res. Serv. Tech. Bull.* 1283 [August 1963]) for combining flow and Gardel (*Bull. Tech. Suisses Romande,* **85**[9], 123–130 [1957]; **85**[10], 143–148 [1957]) together with additional unpublished data for dividing flow.

Miller (*Internal Flow Systems,* 2d ed., Chap. 13, BHRA, Cranfield, 1990) gives the most complete information on losses in **bends and curved pipes.** For turbulent flow in circular cross-section bends of constant area, as shown in Fig. 6-14*a*, a more accurate estimate of the loss coefficient $K$ than that given in Table 6-4 is

$$K = K^* C_{\mathrm{Re}} C_o C_f \quad (6\text{-}97)$$

where $K^*$, given in Fig. 6-14*b*, is the loss coefficient for a smooth-walled bend at a Reynolds number of $10^6$. The Reynolds number correction factor $C_{\mathrm{Re}}$ is given in Fig. 6-14*c*. For $0.7 < r/D < 1$ or for $K^* < 0.4$, use the $C_{\mathrm{Re}}$ value for $r/D = 1$. Otherwise, if $r/D < 1$, obtain $C_{\mathrm{Re}}$ from

$$C_{\mathrm{Re}} = \frac{K^*}{K^* + 0.2(1 - C_{\mathrm{Re},\, r/D=1})} \quad (6\text{-}98)$$

**TABLE 6-4 Additional Frictional Loss for Turbulent Flow through Fittings and Valves[a]**

SOURCE: From curves by Kittredge and Rowley, *Trans. Am. Soc. Mech. Eng.*, **79,** 1759–1766 (1957).

The correction $C_o$ (Fig. 6-14*d*) accounts for the extra losses due to developing flow in the outlet tangent of the pipe, of length $L_o$. The total loss for the bend plus outlet pipe includes the bend loss $K$ plus the straight pipe frictional loss in the outlet pipe $4fL_o/D$. Note that $C_o = 1$ for $L_o/D$ greater than the termination of the curves on Fig. 6-14*d*, which indicate the distance at which fully developed flow in the outlet pipe is reached. Finally, the roughness correction is

$$C_f = \frac{f_{\text{rough}}}{f_{\text{smooth}}} \tag{6-99}$$

where $f_{\text{rough}}$ is the friction factor for a pipe of diameter $D$ with the roughness of the bend, at the bend inlet Reynolds number. Similarly, $f_{\text{smooth}}$ is the friction factor for smooth pipe. For $\text{Re} > 10^6$ and $r/D \geq 1$, use the value of $C_f$ for $\text{Re} = 10^6$.

***Example 6: Losses with Fittings and Valves*** It is desired to calculate the liquid level in the vessel shown in Fig. 6-15 required to produce a discharge velocity of 2 m/s. The fluid is water at 20°C with $\rho = 1{,}000$ kg/m$^3$ and $\mu = 0.001$ Pa · s, and the butterfly valve is at $\theta = 10°$. The pipe is 2-in Schedule 40, with an inner diameter of 0.0525 m. The pipe roughness is 0.046 mm. Assuming the flow is turbulent and taking the velocity profile factor $\alpha = 1$, the engineering Bernoulli equation Eq. (6-16), written between surfaces 1 and 2, where the pressures are both atmospheric and the fluid velocities are 0 and $V = 2$ m/s, respectively, and there is no shaft work, simplifies to

$$gZ = \frac{V^2}{2} + l_v$$

Contributing to $l_v$ are losses for the entrance to the pipe, the three sections of straight pipe, the butterfly valve, and the 90° bend. Note that no exit loss is used because the discharged jet is outside the control volume. Instead, the $V^2/2$ term accounts for the kinetic energy of the discharging stream. The Reynolds number in the pipe is

$$\text{Re} = \frac{DV\rho}{\mu} = \frac{0.0525 \times 2 \times 1000}{0.001} = 1.05 \times 10^5$$

From Fig. 6-9 or Eq. (6-38), at $\epsilon/D = 0.046 \times 10^{-3}/0.0525 = 0.00088$, the friction factor is about 0.0054. The straight pipe losses are then

$$l_{v(\text{sp})} = \left(\frac{4fL}{D}\right)\frac{V^2}{2}$$

$$= \left(\frac{4 \times 0.0054 \times (1 + 1 + 1)}{0.0525}\right)\frac{V^2}{2}$$

$$= 1.23\,\frac{V^2}{2}$$

The losses from Table 6-4 in terms of velocity heads $K$ are $K = 0.5$ for the sudden contraction and $K = 0.52$ for the butterfly valve. For the 90° standard radius ($r/D = 1$), the table gives $K = 0.75$. The method of Eq. (6-94), using Fig. 6-14, gives

$$K = K^* C_{\text{Re}} C_o C_f$$
$$= 0.24 \times 1.24 \times 1.0 \times \left(\frac{0.0054}{0.0044}\right)$$
$$= 0.37$$

This value is more accurate than the value in Table 6-4. The value $f_{\text{smooth}} = 0.0044$ is obtainable either from Eq. (6-37) or Fig. 6-9.

The total losses are then

$$l_v = (1.23 + 0.5 + 0.52 + 0.37)\,\frac{V^2}{2} = 2.62\,\frac{V^2}{2}$$

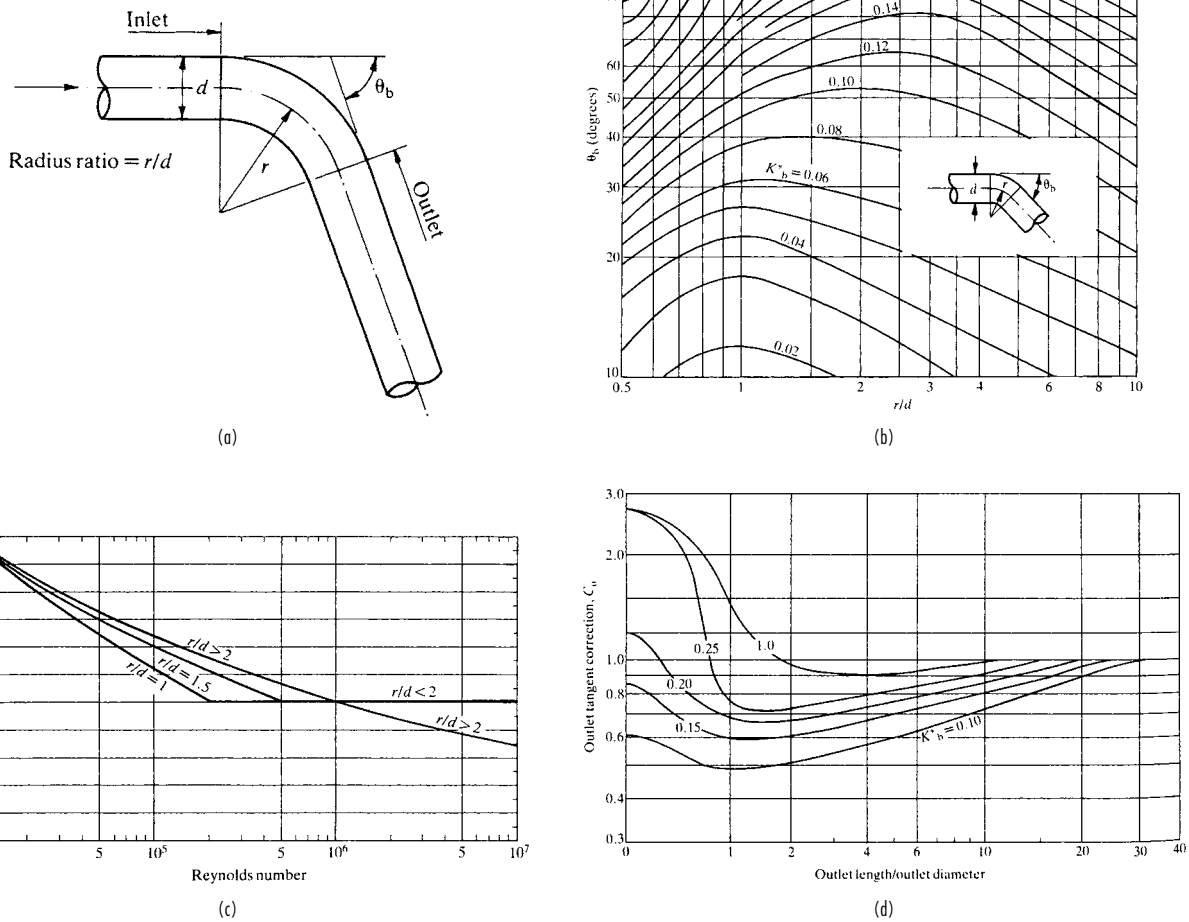

**FIG. 6-14** Loss coefficients for flow in bends and curved pipes: (*a*) flow geometry, (*b*) loss coefficient for a smooth-walled bend at Re = $10^6$, (*c*) Re correction factor, (*d*) outlet pipe correction factor. (*From D. S. Miller,* Internal Flow Systems, 2*d ed., BHRA, Cranfield, U.K., 1990.*)

and the liquid level Z is

$$Z = \frac{1}{g}\left(\frac{V^2}{2} + 2.62\,\frac{V^2}{2}\right) = 3.62\,\frac{V^2}{2g}$$

$$= \frac{3.62 \times 2^2}{2 \times 9.81} = 0.73 \text{ m}$$

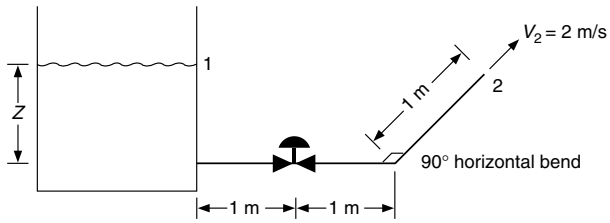

**FIG. 6-15** Tank discharge example.

**Curved Pipes and Coils** For flow through curved pipe or coil, a secondary circulation perpendicular to the main flow called the **Dean effect** occurs. This circulation increases the friction relative to straight pipe flow and stabilizes laminar flow, delaying the transition Reynolds number to about

$$\text{Re}_{\text{crit}} = 2{,}100\left(1 + 12\sqrt{\frac{D}{D_c}}\right) \tag{6-100}$$

where $D_c$ is the coil diameter. Equation (6-100) is valid for $10 < D_c/D < 250$. The **Dean number** is defined as

$$\text{De} = \frac{\text{Re}}{(D_c/D)^{1/2}} \tag{6-101}$$

In laminar flow, the friction factor for curved pipe $f_c$ may be expressed in terms of the straight pipe friction factor $f = 16/\text{Re}$ as (Hart, *Chem. Eng. Sci.*, **43,** 775–783 [1988])

$$f_c/f = 1 + 0.090\left(\frac{\text{De}^{1.5}}{70 + \text{De}}\right) \tag{6-102}$$

For turbulent flow, equations by Ito (*J. Basic Eng.* **81,** 123 [1959]) and Srinivasan, Nandapurkar, and Holland (*Chem. Eng.* [*London*] no. 218, CE113-CE119 [May 1968]) may be used, with probable accuracy of ±15 percent. Their equations are similar to

$$f_c = \frac{0.079}{\mathrm{Re}^{0.25}} + \frac{0.0073}{\sqrt{(D_c/D)}} \tag{6-103}$$

The pressure drop for flow in **spirals** is discussed by Srinivasan, et al. (loc. cit.) and Ali and Seshadri (*Ind. Eng. Chem. Process Des. Dev.*, **10,** 328–332 [1971]). For friction loss in laminar flow through **semicircular ducts,** see Masliyah and Nandakumar (*AIChE J.*, **25,** 478–487 [1979]); for curved channels of **square cross section,** see Cheng, Lin, and Ou (*J. Fluids Eng.*, **98,** 41–48 [1976]).

For **non-Newtonian** (**power law**) **fluids** in coiled tubes, Mashelkar and Devarajan (*Trans. Inst. Chem. Eng.* (*London*), **54,** 108–114 [1976]) propose the correlation

$$f_c = (9.07 - 9.44n + 4.37n^2)(D/D_c)^{0.5}(\mathrm{De}')^{-0.768 + 0.122n} \tag{6-104}$$

where De′ is a modified Dean number given by

$$\mathrm{De}' = \frac{1}{8}\left(\frac{6n+2}{n}\right)^n \mathrm{Re}_{\mathrm{MR}}\sqrt{\frac{D}{D_c}} \tag{6-105}$$

where $\mathrm{Re}_{\mathrm{MR}}$ is the Metzner-Reed Reynolds number, Eq. (6-65). This correlation was tested for the range De′ = 70 to 400, $D/D_c$ = 0.01 to 0.135, and $n$ = 0.35 to 1. See also Oliver and Asghar (*Trans. Inst. Chem. Eng.* [*London*], **53,** 181–186 [1975]).

**Screens** The pressure drop for incompressible flow across a screen of fractional free area α may be computed from

$$\Delta p = K\frac{\rho V^2}{2} \tag{6-106}$$

where ρ = fluid density
$V$ = superficial velocity based upon the gross area of the screen
$K$ = velocity head loss

$$K = \left(\frac{1}{C^2}\right)\left(\frac{1-\alpha^2}{\alpha^2}\right) \tag{6-107}$$

The discharge coefficient for the screen $C$ with aperture $D_s$ is given as a function of screen Reynolds number $\mathrm{Re} = D_s(V/\alpha)\rho/\mu$ in Fig. 6-16 for **plain square-mesh screens,** α = 0.14 to 0.79. This curve fits most of the data within ±20 percent. In the laminar flow region, Re < 20, the discharge coefficient can be computed from

$$C = 0.1\sqrt{\mathrm{Re}} \tag{6-108}$$

Coefficients greater than 1.0 in Fig. 6-16 probably indicate partial pressure recovery downstream of the minimum aperture, due to rounding of the wires.

Grootenhuis (*Proc. Inst. Mech. Eng.* [*London*], **A168,** 837–846 [1954]) presents data which indicate that for a series of screens, the total pressure drop equals the number of screens times the pressure drop for one screen, and is not affected by the spacing between screens or their orientation with respect to one another, and presents a correlation for frictional losses across plain square-mesh screens and sintered gauzes. Armour and Cannon (*AIChE J.*, **14,** 415–420 [1968]) give a correlation based on a packed bed model for plain, twill, and "dutch" weaves. For losses through monofilament fabrics see Pedersen (*Filtr. Sep.*, **11,** 586–589 [1975]). For screens **inclined at an angle** θ, use the normal velocity component $V'$

$$V' = V\cos\theta \tag{6-109}$$

(Carothers and Baines, *J. Fluids Eng.*, **97,** 116–117 [1975]) in place of $V$ in Eq. (6-106). This applies for Re > 500, $C$ = 1.26, α ≤ 0.97, and 0 < θ < 45°, for square-mesh screens and diamond-mesh netting. Screens inclined at an angle to the flow direction also experience a tangential stress.

For **non-Newtonian** fluids in slow flow, friction loss across a square-woven or full-twill-woven screen can be estimated by considering the screen as a set of parallel tubes, each of diameter equal to the average minimal opening between adjacent wires, and length twice the diameter, without entrance effects (Carley and Smith, *Polym. Eng. Sci.*, **18,** 408–415 [1978]). For screen stacks, the losses of individual screens should be summed.

## JET BEHAVIOR

A **free jet,** upon leaving an outlet, will entrain the surrounding fluid, expand, and decelerate. To a first approximation, total momentum is conserved as jet momentum is transferred to the entrained fluid. For practical purposes, a jet is considered free when its cross-sectional area is less than one-fifth of the total cross-sectional flow area of the region through which the jet is flowing (Elrod, *Heat. Piping Air Cond.*, **26**[3], 149–155 [1954]), and the surrounding fluid is the same as the jet fluid. A **turbulent jet** in this discussion is considered to be a free jet with Reynolds number greater than 2,000. Additional discussion on the relation between Reynolds number and turbulence in jets is given by Elrod (ibid.). Abramowicz (*The Theory of Turbulent Jets,* MIT Press, Cambridge, 1963) and Rajaratnam (*Turbulent Jets,* Elsevier, Amsterdam, 1976) provide thorough discourses on turbulent jets. Hussein, et al. (*J. Fluid Mech.*, **258,** 31–75 [1994]) give extensive

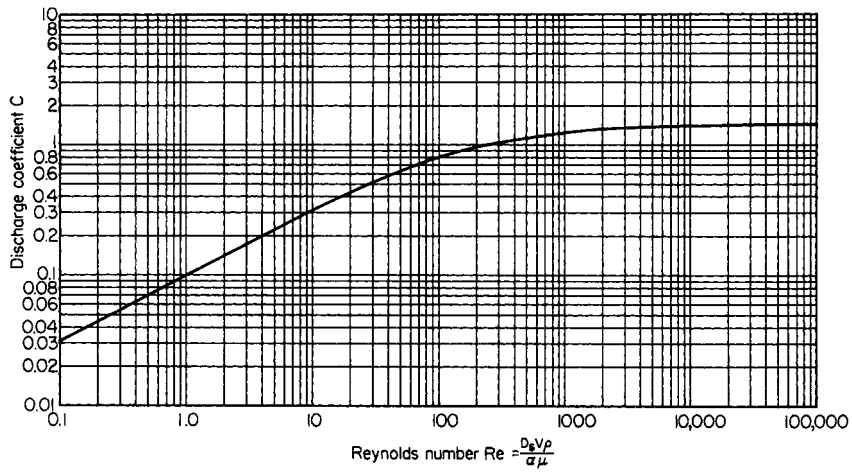

**FIG. 6-16** Screen discharge coefficients, plain square-mesh screens. (*Courtesy of E. I. du Pont de Nemours & Co.*)

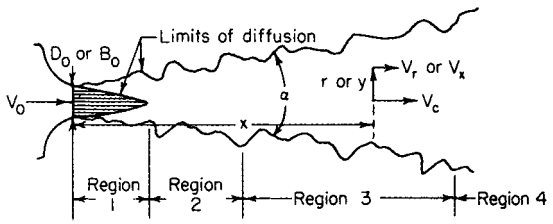

**FIG. 6-17** Configuration of a turbulent free jet.

velocity data for a free jet, as well as an extensive discussion of free jet experimentation and comparison of data with momentum conservation equations.

A turbulent free jet is normally considered to consist of four flow regions (Tuve, *Heat. Piping Air Cond.*, **25**[1], 181–191 [1953]; Davies, *Turbulence Phenomena,* Academic, New York, 1972) as shown in Fig. 6-17:

1. Region of flow establishment—a short region whose length is about 6.4 nozzle diameters. The fluid in the conical core of the same length has a velocity about the same as the initial discharge velocity. The termination of this *potential core* occurs when the growing mixing or boundary layer between the jet and the surroundings reaches the centerline of the jet.
2. A transition region that extends to about 8 nozzle diameters.
3. Region of established flow—the principal region of the jet. In this region, the velocity profile transverse to the jet is self-preserving when normalized by the centerline velocity.
4. A terminal region where the residual centerline velocity reduces rapidly within a short distance. For air jets, the residual velocity will reduce to less than 0.3 m/s, (1.0 ft/s) usually considered still air.

Several references quote a length of 100 nozzle diameters for the length of the established flow region. However, this length is dependent on initial velocity and Reynolds number.

Table 6-6 gives characteristics of **rounded-inlet circular jets** and **rounded-inlet infinitely wide slot jets** (aspect ratio > 15). The information in the table is for a homogeneous, incompressible air system under isothermal conditions. The table uses the following nomenclature:

$B_0$ = slot height
$D_0$ = circular nozzle opening
$q$ = total jet flow at distance $x$
$q_0$ = initial jet flow rate
$r$ = radius from circular jet centerline
$y$ = transverse distance from slot jet centerline
$V_c$ = centerline velocity
$V_r$ = circular jet velocity at $r$
$V_y$ = velocity at $y$

Witze (*Am. Inst. Aeronaut. Astronaut. J.,* **12,** 417–418 [1974]) gives equations for the centerline velocity decay of different types of subsonic and supersonic circular free jets. Entrainment of surrounding fluid in the region of flow establishment is lower than in the region of established flow (see Hill, *J. Fluid Mech.*, **51,** 773–779 [1972]). Data of Donald and Singer (*Trans. Inst. Chem. Eng.* [*London*], **37,** 255–267 [1959]) indicate that jet angle and the coefficients given in Table 6-6 depend upon the fluids; for a water system, the jet angle for a circular jet is 14° and the entrainment ratio is about 70 percent of that for an air system. Most likely these variations are due to Reynolds number effects which are not taken into account in Table 6-6. Rushton (*AIChE J.,* **26,** 1038–1041 [1980]) examined available published results for circular jets and found that the centerline velocity decay is given by

$$\frac{V_c}{V_0} = 1.41\mathrm{Re}^{0.135}\left(\frac{D_0}{x}\right) \tag{6-110}$$

where $\mathrm{Re} = D_0V_0\rho/\mu$ is the initial jet Reynolds number. This result corresponds to a jet angle tan $\alpha/2$ proportional to $\mathrm{Re}^{-0.135}$.

**TABLE 6-6 Turbulent Free-Jet Characteristics**

Where both jet fluid and entrained fluid are air

Rounded-inlet circular jet

Longitudinal distribution of velocity along jet center line*†

$$\frac{V_c}{V_0} = K\frac{D_0}{x} \qquad \text{for } 7 < \frac{x}{D_0} < 100$$

$K = 5$ for $V_0 = 2.5$ to 5.0 m/s
$K = 6.2$ for $V_0 = 10$ to 50 m/s

Radial distribution of longitudinal velocity†

Characteristics of **rectangular jets** of various aspect ratios are given by Elrod (*Heat., Piping, Air Cond.*, **26**[3], 149–155 [1954]). For **slot jets discharging into a moving fluid,** see Weinstein, Osterle, and Forstall (*J. Appl. Mech.*, **23,** 437–443 [1967]). **Coaxial jets** are discussed by Forstall and Shapiro (*J. Appl. Mech.*, **17,** 399–408 [1950]), and **double concentric jets** by Chigier and Beer (*J. Basic Eng.*, **86,** 797–804 [1964]). **Axisymmetric confined jets** are described by Barchilon and Curtet (*J. Basic Eng.*, **777–787** [1964]). **Restrained** turbulent jets of liquid discharging into air are described by Davies (*Turbulence Phenomena,* Academic, New York, 1972). These jets are inherently unstable and break up into drops after some distance. Lienhard and Day (*J. Basic Eng. Trans. AIME*, p. 515 [September 1970]) discuss the breakup of superheated liquid jets which flash upon discharge.

**Density gradients** affect the spread of a single-phase jet. A jet of lower density than the surroundings spreads more rapidly than a jet of the same density as the surroundings, and, conversely, a denser jet spreads less rapidly. Additional details are given by Keagy and Weller (*Proc. Heat Transfer Fluid Mech. Inst., ASME*, pp. 89–98, June 22–24 [1949]) and Cleeves and Boelter (*Chem. Eng. Prog.*, **43,** 123–134 [1947]).

Few experimental data exist on **laminar jets** (see Gutfinger and Shinnar, *AIChE J.*, **10,** 631–639 [1964]). Theoretical analysis for velocity distributions and entrainment ratios are available in Schlichting and in Morton (*Phys. Fluids,* **10,** 2120–2127 [1967]).

Theoretical analyses of jet flows for power law **non-Newtonian fluids** are given by Vlachopoulos and Stournaras (*AIChE J.*, **21,** 385–388 [1975]), Mitwally (*J. Fluids Eng.*, **100,** 363 [1978]), and Sridhar and Rankin (*J. Fluids Eng.*, **100,** 500 [1978]).

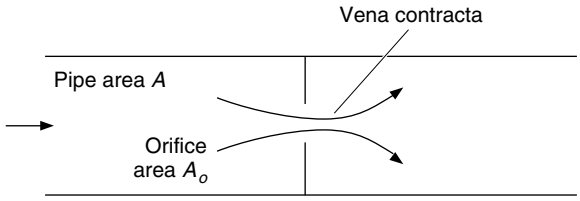

**FIG. 6-18** Flow through an orifice.

## FLOW THROUGH ORIFICES

Section 10 of this *Handbook* describes the use of orifice meters for flow measurement. In addition, **orifices** are commonly found within pipelines as flow-restricting devices, in perforated pipe distributing and return manifolds, and in perforated plates. Incompressible flow through an orifice in a pipeline, as shown in Fig. 6-18, is commonly described by the following equation for flow rate $Q$ in terms of the pressures $P_1$, $P_2$, and $P_3$; the orifice area $A_o$; the pipe cross-sectional area $A$; and the density $\rho$.

$$Q = v_o A_o = C_o A_o \sqrt{\frac{2(P_1 - P_2)}{\rho[1 - (A_o/A)^2]}}$$

$$= C_o A_o \sqrt{\frac{2(P_1 - P_3)}{\rho(1 - A_o/A)\,[1 - (A_o/A)^2]}} \qquad (6\text{-}111)$$

The velocity based on the hole area is $v_o$. The pressure $P_1$ is the pressure upstream of the orifice, typically about 1 pipe diameter upstream, the pressure $P_2$ is the pressure at the **vena contracta,** where the flow passes through a minimum area which is less than the orifice area, and the pressure $P_3$ is the pressure downstream of the vena contracta after pressure recovery associated with deceleration of the fluid. The velocity of approach factor $1 - (A_o/A)^2$ accounts for the kinetic energy approaching the orifice, and the **orifice coefficient** or **discharge coefficient** $C_o$ accounts for the vena contracta. The location of the vena contracta varies with $A_0/A$, but is about 0.7 pipe diameter for $A_o/A < 0.25$. The factor $1 - A_o/A$ accounts for pressure recovery. Pressure recovery is complete by about 4 to 8 pipe diameters downstream of the orifice. The permanent pressure drop is $P_1 - P_3$. When the orifice is at the end of pipe, discharging directly into a large chamber, there is negligible pressure recovery, the permanent pressure drop is $P_1 - P_2$, and the last equality in Eq. (6-111) does not apply. Instead, $P_2 = P_3$. Equation (6-111) may also be used for flow across a perforated plate with open area $A_o$ and total area $A$. The location of the vena contracta and complete recovery would scale not with the vessel or pipe diameter in which the plate is installed, but with the hole diameter and pitch between holes.

The orifice coefficient has a value of about 0.62 at large Reynolds numbers ($\mathrm{Re} = D_o V_o \rho/\mu > 20{,}000$), although values ranging from 0.60 to 0.70 are frequently used. At lower Reynolds numbers, the orifice coefficient varies with both Re and with the area or diameter ratio. See Sec. 10 for more details.

When liquids discharge vertically downward from a pipe of diameter $D_p$, through orifices into gas, gravity increases the discharge coefficient. Figure 6-19 shows this effect, giving the discharge coefficient in terms of a modified Froude number, $\mathrm{Fr} = \Delta p/(\rho g D_p)$.

The orifice coefficient deviates from its value for sharp-edged orifices when the orifice wall thickness exceeds about 75 percent of the orifice diameter. Some pressure recovery occurs within the orifice and the orifice coefficient increases. Pressure drop across **segmental orifices** is roughly 10 percent greater than that for concentric circular orifices of the same open area.

## COMPRESSIBLE FLOW

Flows are typically considered **compressible** when the density varies by more than 5 to 10 percent. In practice compressible flows are normally limited to gases, supercritical fluids, and multiphase flows containing gases. Liquid flows are normally considered incompressible, except for certain calculations involved in **hydraulic transient** analysis (see following) where compressibility effects are important even for nearly incompressible liquids with extremely small density variations. Textbooks on compressible gas flow include Shapiro (*Dynamics and Thermodynamics of Compressible Fluid Flow,* vols. I and II, Ronald Press, New York [1953]) and Zucrow and Hofmann (*Gas Dynamics,* vols. I and II, Wiley, New York [1976]).

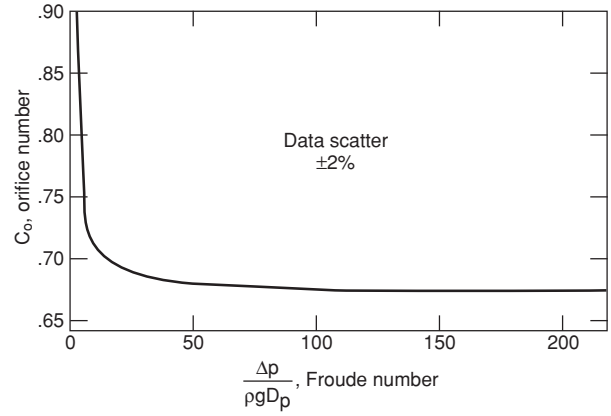

**FIG. 6-19** Orifice coefficient vs. Froude number. (*Courtesy E. I. duPont de Nemours & Co.*)

In chemical process applications, one-dimensional gas flows through nozzles or orifices and in pipelines are the most important applications of compressible flow. Multidimensional external flows are of interest mainly in aerodynamic applications.

**Mach Number and Speed of Sound** The **Mach number** $M = V/c$ is the ratio of fluid velocity, $V$, to the **speed of sound** or **acoustic velocity,** $c$. The speed of sound is the propagation velocity of infinitesimal pressure disturbances and is derived from a momentum balance. The compression caused by the pressure wave is adiabatic and frictionless, and therefore isentropic.

$$c = \sqrt{\left(\frac{\partial p}{\partial \rho}\right)_s} \qquad (6\text{-}112)$$

The derivative of pressure $p$ with respect to density $\rho$ is taken at constant entropy $s$. For an ideal gas,

$$\left(\frac{\partial p}{\partial \rho}\right)_s = \frac{kRT}{M_w}$$

where $k$ = ratio of specific heats, $C_p/C_v$
$R$ = universal gas constant (8,314 J/kgmol K)
$T$ = absolute temperature
$M_w$ = molecular weight

Hence for an ideal gas,

$$c = \sqrt{\frac{kRT}{M_w}} \qquad (6\text{-}113)$$

Most often, the Mach number is calculated using the speed of sound evaluated at the local pressure and temperature. When $M = 1$, the flow is **critical** or **sonic** and the velocity equals the local speed of sound. For **subsonic** flow $M < 1$ while **supersonic** flows have $M > 1$. Compressibility effects are important when the Mach number exceeds 0.1 to 0.2. A common error is to assume that compressibility effects are always negligible when the Mach number is small. The proper assessment of whether compressibility is important should be based on relative density changes, not on Mach number.

**Isothermal Gas Flow in Pipes and Channels** Isothermal compressible flow is often encountered in long transport lines, where there is sufficient heat transfer to maintain constant temperature. Velocities and Mach numbers are usually small, yet compressibility

effects are important when the total pressure drop is a large fraction of the absolute pressure. For an ideal gas with $\rho = pM_w/RT$, integration of the differential form of the momentum or mechanical energy balance equations, assuming a constant friction factor $f$ over a length $L$ of a channel of constant cross section and hydraulic diameter $D_H$, yields,

$$p_1^2 - p_2^2 = G^2 \frac{RT}{M_w}\left[\frac{4fL}{D_H} + 2\ln\left(\frac{p_1}{p_2}\right)\right] \tag{6-114}$$

where the mass velocity $G = w/A = \rho V$ is the mass flow rate per unit cross-sectional area of the channel. The logarithmic term on the right-hand side accounts for the pressure change caused by acceleration of gas as its density decreases, while the first term is equivalent to the calculation of frictional losses using the density evaluated at the average pressure $(p_1 + p_2)/2$.

Solution of Eq. (6-114) for $G$ and differentiation with respect to $p_2$ reveals a maximum mass flux $G_{max} = p_2\sqrt{M_w/(RT)}$ and a corresponding exit velocity $V_{2,max} = \sqrt{RT/M_w}$ and exit Mach number $M_2 = 1/\sqrt{k}$. This apparent **choking** condition, though often cited, is not physically meaningful for isothermal flow because at such high velocities, and high rates of expansion, isothermal conditions are not maintained.

**Adiabatic Frictionless Nozzle Flow** In process plant pipelines, compressible flows are usually more nearly adiabatic than isothermal. Solutions for adiabatic flows through frictionless nozzles and in channels with constant cross section and constant friction factor are readily available.

Figure 6-20 illustrates adiabatic discharge of a **perfect** gas through a frictionless nozzle from a large chamber where velocity is effectively zero. A perfect gas obeys the ideal gas law $\rho = pM_w/RT$ and also has constant specific heat. The subscript 0 refers to the **stagnation** conditions in the chamber. More generally, stagnation conditions refer to the conditions which would be obtained by isentropically decelerating a gas flow to zero velocity. The minimum area section, or *throat,* of the nozzle is at the nozzle exit. The flow through the nozzle is isentropic because it is frictionless (reversible) and adiabatic. In terms of the exit Mach number $M_1$ and the upstream stagnation conditions, the flow conditions at the nozzle exit are given by

$$\frac{p_0}{p_1} = \left(1 + \frac{k-1}{2}M_1^2\right)^{k/(k-1)} \tag{6-115}$$

$$\frac{T_0}{T_1} = 1 + \frac{k-1}{2}M_1^2 \tag{6-116}$$

$$\frac{\rho_0}{\rho_1} = \left(1 + \frac{k-1}{2}M_1^2\right)^{1/(k-1)} \tag{6-117}$$

The mass velocity $G = w/A$, where $w$ is the mass flow rate and $A$ is the nozzle exit area, at the nozzle exit is given by

$$G = p_0\sqrt{\frac{kM_w}{RT_0}}\,\frac{M_1}{\left(1 + \frac{k-1}{2}M_1^2\right)^{(k+1)/2(k-1)}} \tag{6-118}$$

These equations are consistent with the isentropic relations for a perfect gas $p/p_0 = (\rho/\rho_0)^k$, $T/T_0 = (p/p_0)^{(k-1)/k}$. Equation (6-116) is valid for adiabatic flows with or without friction; it does not require isentropic flow. However, Eqs. (6-115) and (6-117) do require isentropic flow.

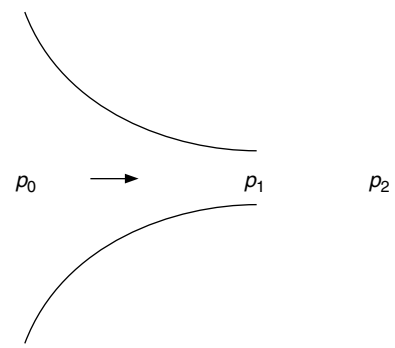

**FIG. 6-20** Isentropic flow through a nozzle.

**The exit Mach number $M_1$ may not exceed unity.** At $M_1 = 1$, the flow is said to be **choked, sonic,** or **critical.** When the flow is choked, the pressure at the exit is greater than the pressure of the surroundings into which the gas flow discharges. The pressure drops from the exit pressure to the pressure of the surroundings in a series of shocks which are highly nonisentropic. Sonic flow conditions are denoted by *; sonic exit conditions are found by substituting $M_1 = M_1^* = 1$ into Eqs. (6-115) to (6-118).

$$\frac{p^*}{p_0} = \left(\frac{2}{k+1}\right)^{k/(k-1)} \tag{6-119}$$

$$\frac{T^*}{T_0} = \frac{2}{k+1} \tag{6-120}$$

$$\frac{\rho^*}{\rho_0} = \left(\frac{2}{k+1}\right)^{1/(k-1)} \tag{6-121}$$

$$G^* = p_0\sqrt{\left(\frac{2}{k+1}\right)^{(k+1)/(k-1)}\left(\frac{kM_w}{RT_0}\right)} \tag{6-122}$$

Note that under choked conditions, the exit velocity is $V = V^* = c^* = \sqrt{kRT^*/M_w}$, not $\sqrt{kRT_0/M_w}$. Sonic velocity must be evaluated at the exit temperature. For air, with $k = 1.4$, the critical pressure ratio $p^*/p_0$ is 0.5285 and the critical temperature ratio $T^*/T_0 = 0.8333$. Thus, for air discharging from 300 K, the temperature drops by 50 K (90 R). This large temperature decrease results from the conversion of internal energy into kinetic energy and is reversible. As the discharged jet decelerates in the external stagant gas, it recovers its initial enthalpy.

When it is desired to determine the discharge rate through a nozzle from upstream pressure $p_0$ to external pressure $p_2$, Equations (6-115) through (6-122) are best used as follows. The critical pressure is first determined from Eq. (6-119). If $p_2 > p^*$, then the flow is subsonic (subcritical, unchoked). Then $p_1 = p_2$ and $M_1$ may be obtained from Eq. (6-115). Substitution of $M_1$ into Eq. (6-118) then gives the desired mass velocity $G$. Equations (6-116) and (6-117) may be used to find the exit temperature and density. On the other hand, if $p_2 \le p^*$, then the flow is choked and $M_1 = 1$. Then $p_1 = p^*$, and the mass velocity is $G^*$ obtained from Eq. (6-122). The exit temperature and density may be obtained from Eqs. (6-120) and (6-121).

When the flow is choked, $G = G^*$ is independent of external downstream pressure. Reducing the downstream pressure will not increase the flow. The mass flow rate under choking conditions is directly proportional to the upstream pressure.

***Example 7: Flow through Frictionless Nozzle*** Air at $p_0$ and temperature $T_0 = 293$ K discharges through a frictionless nozzle to atmospheric pressure. Compute the discharge mass flux $G$, the pressure, temperature, Mach number, and velocity at the exit. Consider two cases: (1) $p_0 = 7 \times 10^5$ Pa absolute, and (2) $p_0 = 1.5 \times 10^5$ Pa absolute.

1. $p_0 = 7.0 \times 10^5$ Pa. For air with $k = 1.4$, the critical pressure ratio from Eq. (6-119) is $p^*/p_0 = 0.5285$ and $p^* = 0.5285 \times 7.0 \times 10^5 = 3.70 \times 10^5$ Pa. Since this is greater than the external atmospheric pressure $p_2 = 1.01 \times 10^5$ Pa, the flow is choked and the exit pressure is $p_1 = 3.70 \times 10^5$ Pa. The exit Mach number is 1.0, and the mass flux is equal to $G^*$ given by Eq. (6-118).

$$G^* = 7.0 \times 10^5 \times \sqrt{\left(\frac{2}{1.4+1}\right)^{(1.4+1)/(1.4-1)}\left(\frac{1.4 \times 29}{8314 \times 293}\right)} = 1{,}650 \text{ kg/m}^2 \cdot \text{s}$$

The exit temperature, since the flow is choked, is

$$T^* = \left(\frac{T^*}{T_0}\right)T_0 = \left(\frac{2}{1.4+1}\right) \times 293 = 244 \text{ K}$$

The exit velocity is $V = Mc = c^* = \sqrt{kRT^*/M_w} = 313$ m/s.

2. $p_0 = 1.5 \times 10^5$ Pa. In this case $p^* = 0.79 \times 10^5$ Pa, which is less than $p_2$. Hence, $p_1 = p_2 = 1.01 \times 10^5$ Pa. The flow is unchoked (subsonic). Equation (6-115) is solved for the Mach number.

$$\frac{1.5 \times 10^5}{1.01 \times 10^5} = \left(1 + \frac{1.4-1}{2}M_1^2\right)^{1.4/(1.4-1)}$$

$$M_1 = 0.773$$

Substitution into Eq. (6-118) gives $G$.

$$G = 1.5 \times 10^5 \times \sqrt{\frac{1.4 \times 29}{8{,}314 \times 293}} \times \frac{0.773}{\left(1 + \left(\frac{1.4-1}{2}\right) \times 0.773^2\right)^{(1.4+1)/2(1.4-1)}} = 337 \text{ kg/m}^2 \cdot \text{s}$$

The exit temperature is found from Eq. (6-116) to be 261.6 K or −11.5°C. The exit velocity is

$$V = Mc = 0.773 \times \sqrt{\frac{1.4 \times 8314 \times 261.6}{29}} = 250 \text{ m/s}$$

**Adiabatic Flow with Friction in a Duct of Constant Cross Section** Integration of the differential forms of the continuity, momentum, and total energy equations for a perfect gas, assuming a constant friction factor, leads to a tedious set of simultaneous algebraic equations. These may be found in Shapiro (*Dynamics and Thermodynamics of Compressible Fluid Flow,* vol. I, Ronald Press, New York, 1953) or Zucrow and Hofmann (*Gas Dynamics,* vol. I, Wiley, New York, 1976). Lapple's (*Trans. AIChE.,* **39,** 395–432 [1943]) widely cited graphical presentation of the solution of these equations contained a subtle error, which was corrected by Levenspiel (*AIChE J.,* **23,** 402–403 [1977]). Levenspiel's graphical solutions are presented in Fig. 6-21. These charts refer to the physical situation illustrated in Fig. 6-22, where a perfect gas discharges from stagnation conditions in a large chamber through an isentropic nozzle followed by a duct of length $L$. The resistance parameter is $N = 4fL/D_H$, where $f$ = Fanning friction factor and $D_H$ = hydraulic diameter.

The exit Mach number $M_2$ may not exceed unity. $M_2 = 1$ corresponds to choked flow; sonic conditions may exist only at the pipe exit. The mass velocity $G^*$ in the charts is the choked **mass flux for an isentropic nozzle** given by Eq. (6-118). For a pipe of finite length, the mass flux is less than $G^*$ under choking conditions. The curves in Fig. 6-21 become vertical at the choking point, where flow becomes independent of downstream pressure.

The equations for nozzle flow, Eqs. (6-114) through (6-118), remain valid for the nozzle section even in the presence of the discharge pipe. Equations (6-116) and (6-120), for the temperature variation, may also be used for the pipe, with $M_2$, $p_2$ replacing $M_1$, $p_1$ since they are valid for adiabatic flow, with or without friction.

The graphs in Fig. 6-21 are based on accurate calculations, but are difficult to interpolate precisely. While they are quite useful for rough estimates, precise calculations are best done using the equations for one-dimensional adiabatic flow with friction, which are suitable for computer programming. Let subscripts 1 and 2 denote two points along a pipe of diameter $D$, point 2 being downstream of point 1. From a given point in the pipe, where the Mach number is $M$, the additional length of pipe required to accelerate the flow to sonic velocity ($M = 1$) is denoted $L_{max}$ and may be computed from

$$\frac{4fL_{max}}{D} = \frac{1 - M^2}{kM^2} + \frac{k+1}{2k} \ln \left( \frac{\frac{k+1}{2} M^2}{1 + \frac{k-1}{2} M^2} \right) \qquad (6\text{-}123)$$

With $L$ = length of pipe between points 1 and 2, the change in Mach number may be computed from

$$\frac{4fL}{D} = \left(\frac{4fL_{max}}{D}\right)_1 - \left(\frac{4fL_{max}}{D}\right)_2 \qquad (6\text{-}124)$$

Equations (6-116) and (6-113), which are valid for adiabatic flow with friction, may be used to determine the temperature and speed of sound at points 1 and 2. Since the mass flux $G = \rho v = \rho c M$ is constant, and $\rho = PM_w/RT$, the pressure at point 2 (or 1) can be found from $G$ and the pressure at point 1 (or 2).

The additional frictional losses due to pipeline fittings such as elbows may be added to the velocity head loss $N = 4fL/D_H$ using the same velocity head loss values as for incompressible flow. This works well for fittings which do not significantly reduce the channel cross-sectional area, but may cause large errors when the flow area is greatly reduced, as, for example, by restricting orifices. Compressible flow across restricting orifices is discussed in Sec. 10 of this *Handbook.* Similarly, elbows near the exit of a pipeline may choke the flow even though the Mach number is less than unity due to the nonuniform velocity profile in the elbow. For an abrupt contraction rather than rounded nozzle inlet, an additional 0.5 velocity head should be added to $N$. This is a reasonable approximation for $G$, but note that it allocates the additional losses to the pipeline, even though they are actually incurred in the entrance. It is an error to include one velocity head exit loss in $N$. The kinetic energy at the exit is already accounted for in the integration of the balance equations.

***Example 8: Compressible Flow with Friction Losses*** Calculate the discharge rate of air to the atmosphere from a reservoir at $10^6$ Pa gauge and 20°C through 10 m of straight 2-in Schedule 40 steel pipe (inside diameter = 0.0525 m), and 3 standard radius, flanged 90° elbows. Assume 0.5 velocity heads lost for the elbows.

For commercial steel pipe, with a roughness of 0.046 mm, the friction factor for fully rough flow is about 0.0047, from Eq. (6-38) or Fig. 6-9. It remains to be verified that the Reynolds number is sufficiently large to assume fully rough flow. Assuming an abrupt entrance with 0.5 velocity heads lost,

$$N = 4 \times 0.0047 \times \frac{10}{0.0525} + 0.5 + 3 \times 0.5 = 5.6$$

The pressure ratio $p_3/p_0$ is

$$\frac{1.01 \times 10^5}{(1 \times 10^6 + 1.01 \times 10^5)} = 0.092$$

From Fig. 6-21*b* at $N = 5.6$, $p_3/p_0 = 0.092$ and $k = 1.4$ for air, the flow is seen to be choked. At the choke point with $N = 5.6$ the critical pressure ratio $p_2/p_0$ is about 0.25 and $G/G^*$ is about 0.48. Equation (6-122) gives

$$G^* = 1.101 \times 10^6 \times \sqrt{\left(\frac{2}{1.4+1}\right)^{(1.4+1)/(1.4-1)} \left(\frac{1.4 \times 29}{8{,}314 \times 293.15}\right)} = 2{,}600 \text{ kg/m}^2 \cdot \text{s}$$

Multiplying by $G/G^* = 0.48$ yields $G = 1{,}250$ kg/m$^2 \cdot$ s. The discharge rate is $w = GA = 1{,}250 \times \pi \times 0.0525^2/4 = 2.7$ kg/s.

Before accepting this solution, the Reynolds number should be checked. At the pipe exit, the temperature is given by Eq. (6-120) since the flow is choked. Thus, $T_2 = T^* = 244.6$ K. The viscosity of air at this temperature is about $1.6 \times 10^{-5}$ Pa · s. Then

$$\text{Re} = \frac{DV\rho}{\mu} = \frac{DG}{\mu} = \frac{0.0525 \times 1{,}250}{1.6 \times 10^{-5}} = 4.1 \times 10^6$$

At the beginning of the pipe, the temperature is greater, giving greater viscosity and a Reynolds number of $3.6 \times 10^6$. Over the entire pipe length the Reynolds number is very large and the fully rough flow friction factor choice was indeed valid.

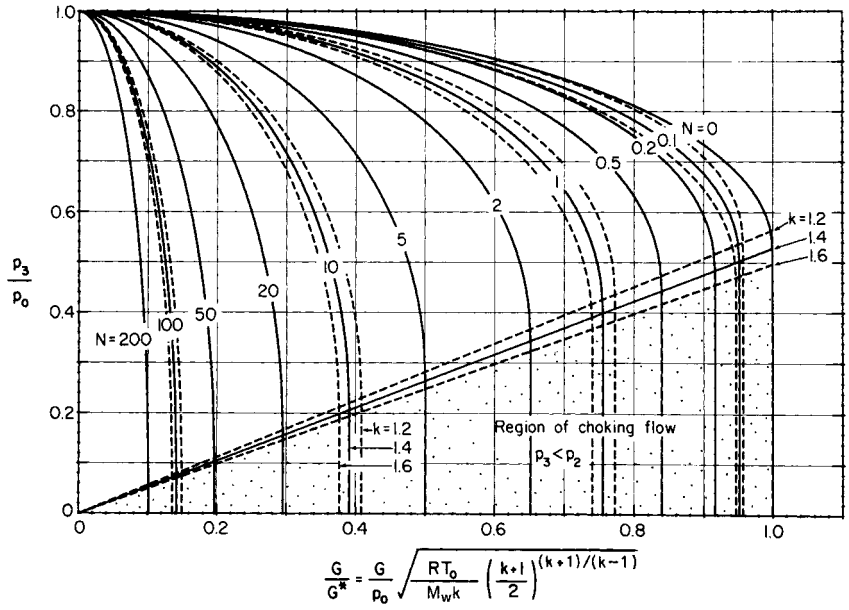
Once the mass flux $G$ has been determined, Fig. 6-21*a* or 6-21*b* can be used to determine the pressure at any point along the pipe, simply by reducing $4fL/D_H$ and computing $p_2$ from the figures, given $G$, instead of the reverse. Charts for calculation between two points in a pipe with known flow and known pressure at either upstream or downstream locations have been presented by Loeb (*Chem. Eng.,* **76**[5], 179–184 [1969]) and for known downstream conditions by Powley (*Can. J. Chem. Eng.,* **36,** 241–245 [1958]).

**Convergent/Divergent Nozzles (De Laval Nozzles)** During frictionless adiabatic one-dimensional flow with changing cross-sectional area $A$ the following relations are obeyed:

$$\frac{dA}{A} = \frac{dp}{\rho V^2}(1 - M^2) = \frac{1 - M^2}{M^2} \frac{d\rho}{\rho} = -(1 - M^2) \frac{dV}{V} \qquad (6\text{-}125)$$

Equation (6-125) implies that in converging channels, subsonic flows are accelerated and the pressure and density decrease. In diverging channels, subsonic flows are decelerated as the pressure and density increase. In subsonic flow, the converging channels act as nozzles and diverging channels as diffusers. In supersonic flows, the opposite is true. Diverging channels act as nozzles accelerating the flow, while converging channels act as diffusers decelerating the flow.

Figure 6-23 shows a converging/diverging nozzle. When $p_2/p_0$ is less than the critical pressure ratio ($p^*/p_0$), the flow will be subsonic in the converging portion of the nozzle, sonic at the throat, and supersonic in the diverging portion. At the throat, where the flow is critical and the velocity is sonic, the area is denoted $A^*$. The cross-sectional



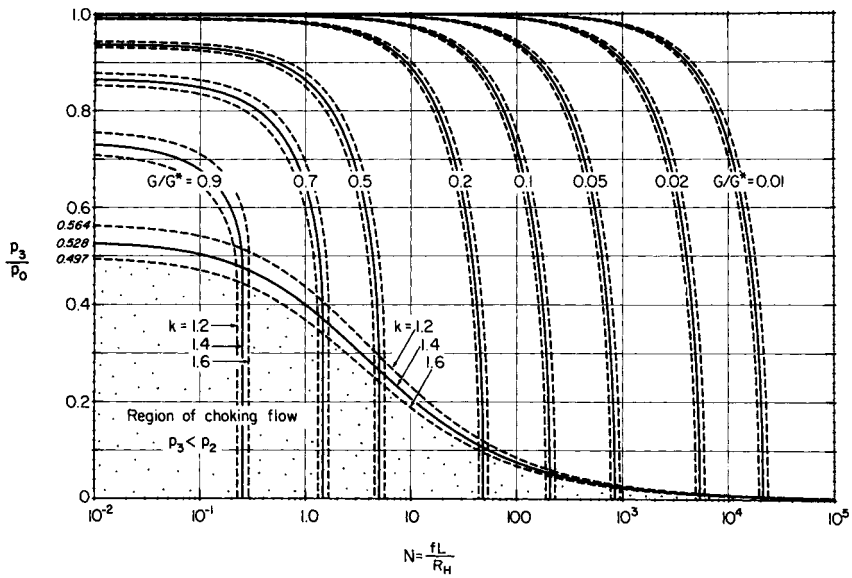


**FIG. 6-21** Design charts for adiabatic flow of gases; (*a*) useful for finding the allowable pipe length for given flow rate; (*b*) useful for finding the discharge rate in a given piping system. (*From Levenspiel,* Am. Inst. Chem. Eng. J., **23,** *402* [*1977*].)

area and pressure vary with Mach number along the converging/diverging flow path according to the following equations for isentropic flow of a perfect gas:

$$\frac{A}{A^*} = \frac{1}{M}\left[\frac{2}{k+1}\left(1+\frac{k-1}{2}M^2\right)\right]^{(k+1)/2(k-1)} \tag{6-126}$$

$$\frac{p_0}{p} = \left(1+\frac{k-1}{2}M^2\right)^{k/(k-1)} \tag{6-127}$$

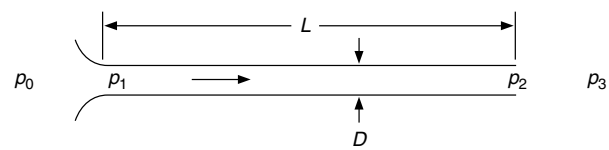

**FIG. 6-22** Adiabatic compressible flow in a pipe with a well-rounded entrance.

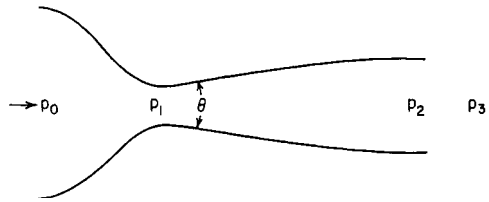

**FIG. 6-23** Converging/diverging nozzle.

The temperature obeys the adiabatic flow equation for a perfect gas,

$$\frac{T_0}{T} = 1 + \frac{k-1}{2} M^2 \qquad (6\text{-}128)$$

Equation (6-128) does not require frictionless (isentropic) flow. The sonic mass flux through the throat is given by Eq. (6-122). With $A$ set equal to the nozzle exit area, the exit Mach number, pressure, and temperature may be calculated. Only if the exit pressure equals the ambient discharge pressure is the ultimate expansion velocity reached in the nozzle. Expansion will be incomplete if the exit pressure exceeds the ambient discharge pressure; shocks will occur outside the nozzle. If the calculated exit pressure is less than the ambient discharge pressure, the nozzle is overexpanded and compression shocks within the expanding portion will result.

The shape of the converging section is a smooth trumpet shape similar to the simple converging nozzle. However, special shapes of the diverging section are required to produce the maximum supersonic exit velocity. Shocks result if the divergence is too rapid and excessive boundary layer friction occurs if the divergence is too shallow. See Liepmann and Roshko (*Elements of Gas Dynamics,* Wiley, New York, 1957, p. 284). If the nozzle is to be used as a thrust device, the diverging section can be conical with a total included angle of 30° (Sutton, *Rocket Propulsion Elements,* 2d ed., Wiley, New York, 1956). To obtain large exit Mach numbers, slot-shaped rather than axisymmetric nozzles are used.

## MULTIPHASE FLOW

Multiphase flows, even when restricted to simple pipeline geometry, are in general quite complex, and several features may be identified which make them more complicated than single-phase flow. Flow pattern description is not merely an identification of laminar or turbulent flow. The relative quantities of the phases and the topology of the interfaces must be described. Because of phase density differences, vertical flow patterns are different from horizontal flow patterns, and horizontal flows are not generally axisymmetric. Even when phase equilibrium is achieved by good mixing in two-phase flow, the changing equilibrium state as pressure drops with distance, or as heat is added or lost, may require that interphase mass transfer, and changes in the relative amounts of the phases, be considered.

Wallis (*One-dimensional Two-phase Flow,* McGraw-Hill, New York, 1969) and Govier and Aziz present mass, momentum, mechanical energy, and total energy balance equations for two-phase flows. These equations are based on one-dimensional behavior for each phase. Such equations, for the most part, are used as a framework in which to interpret experimental data. Reliable prediction of multiphase flow behavior generally requires use of data or correlations. **Two-fluid modeling,** in which the full three-dimensional microscopic (partial differential) equations of motion are written for each phase, treating each as a continuum, occupying a volume fraction which is a continuous function of position, is a rapidly developing technique made possible by improved computational methods. For some relatively simple examples not requiring numerical computation, see Pearson (*Chem. Engr. Sci.,* **49,** 727–732 [1994]). Constitutive equations for two-fluid models are not yet sufficiently robust for accurate general-purpose two-phase flow computation, but may be quite good for particular classes of flows.

**Liquids and Gases** For cocurrent flow of liquids and gases in vertical (upflow), horizontal, and inclined pipes, a very large literature of experimental and theoretical work has been published, with less work on countercurrent and cocurrent vertical downflow. Much of the effort has been devoted to predicting flow patterns, pressure drop, and volume fractions of the phases, with emphasis on fully developed flow. In practice, many two-phase flows in process plants are not fully developed.

The most reliable methods for fully developed gas/liquid flows use **mechanistic models** to predict flow pattern, and use different pressure drop and void fraction estimation procedures for each flow pattern. Such methods are too lengthy to include here, and are well suited to incorporation into computer programs; commercial codes for gas/liquid pipeline flows are available. Some key references for mechanistic methods for flow pattern transitions and flow regime–specific pressure drop and void fraction methods include Taitel and Dukler (*AIChE J.,* **22,** 47–55 [1976]), Barnea, et al. (*Int. J. Multiphase Flow,* **6,** 217–225 [1980]), Barnea (*Int. J. Multiphase Flow,* **12,** 733–744 [1986]), Taitel, Barnea, and Dukler (*AIChE J.,* **26,** 345–354 [1980]), Wallis (*One-dimensional Two-phase Flow,* McGraw-Hill, New York, 1969), and Dukler and Hubbard (*Ind. Eng. Chem. Fundam.,* **14,** 337–347 [1975]). For preliminary or approximate calculations, **flow pattern maps** and flow regime–independent empirical correlations, are simpler and faster to use. Such methods for horizontal and vertical flows are provided in the following.

In **horizontal pipe,** flow patterns for fully developed flow have been reported in numerous studies. Transitions between flow patterns are gradual, and subjective owing to the visual interpretation of individual investigators. In some cases, statistical analysis of pressure fluctuations has been used to distinguish flow patterns. Figure 6-24 (Alves, *Chem. Eng. Progr.,* **50,** 449–456 [1954]) shows seven flow patterns for horizontal gas/liquid flow. **Bubble flow** is prevalent at high ratios of liquid to gas flow rates. The gas is dispersed as bubbles which move at velocity similar to the liquid and tend to concentrate near the top of the pipe at lower liquid velocities. **Plug flow** describes a pattern in which alternate plugs of gas and liquid move along the upper part of the pipe. In **stratified flow,** the liquid flows along the bottom of the pipe and the gas flows over a smooth liquid/gas interface. Similar to stratified flow, **wavy flow** occurs at greater gas velocities and has waves moving in the flow direction. When wave crests are sufficiently high to bridge the pipe, they form frothy slugs which move at much greater than the average liquid velocity. **Slug flow** can cause severe and sometimes dangerous vibrations in equipment because of impact of the high-velocity slugs against bends or other fittings. Slugs may also flood gas/liquid separation equipment.

In **annular flow,** liquid flows as a thin film along the pipe wall and gas flows in the core. Some liquid is entrained as droplets in the gas

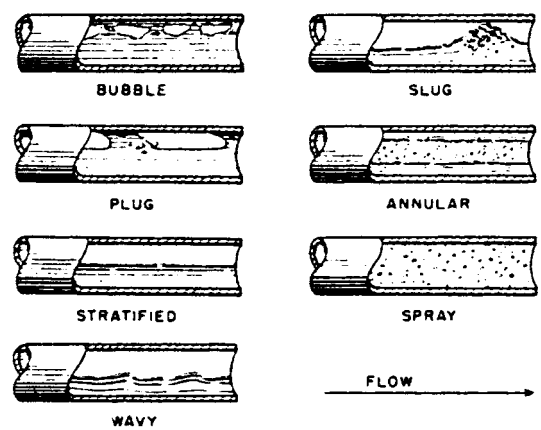

**FIG. 6-24** Gas/liquid flow patterns in horizontal pipes. (*From Alves,* Chem. Eng. Progr., ***50,*** *449–456 [1954].*)

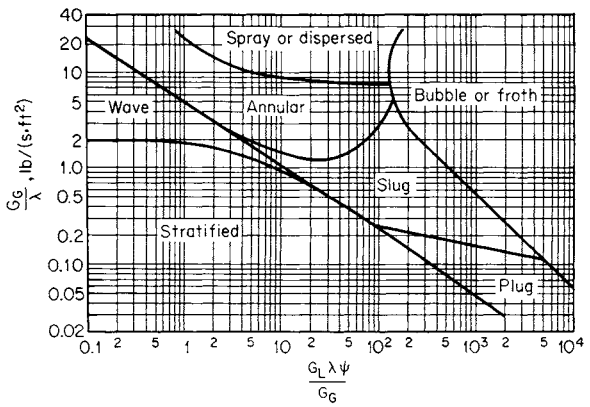

**FIG. 6-25** Flow-pattern regions in cocurrent liquid/gas flow through horizontal pipes. To convert lbm/(ft² · s) to kg/(m² · s), multiply by 4.8824. (*From Baker,* Oil Gas J., ***53****[12], 185–190, 192, 195 [1954].*)

core. At very high gas velocities, nearly all the liquid is entrained as small droplets. This pattern is called **spray, dispersed,** or **mist flow.**

Approximate prediction of flow pattern may be quickly done using **flow pattern maps,** an example of which is shown in Fig. 6-25 (Baker, *Oil Gas J.,* **53**[12], 185–190, 192–195 [1954]). The Baker chart remains widely used; however, for critical calculations the mechanistic model methods referenced previously are generally preferred for their greater accuracy, especially for large pipe diameters and fluids with physical properties different from air/water at atmospheric pressure. In the chart,

$$\lambda = (\rho'_G \rho'_L)^{1/2} \tag{6-129}$$

$$\psi = \frac{1}{\sigma'} \left[ \frac{\mu'_L}{(\rho'_L)^2} \right]^{1/3} \tag{6-130}$$

$G_L$ and $G_G$ are the liquid and gas mass velocities, $\mu'_L$ is the ratio of liquid viscosity to water viscosity, $\rho'_G$ is the ratio of gas density to air density, $\rho'_L$ is the ratio of liquid density to water density, and $\sigma'$ is the ratio of liquid surface tension to water surface tension. The reference properties are at 20°C (68°F) and atmospheric pressure, water density 1,000 kg/m³ (62.4 lbm/ft³), air density 1.20 kg/m³ (0.075 lbm/ft³), water viscosity 0.001 Pa · s (1.0 cP), and surface tension 0.073 N/m (0.0050 lbf/ft). The empirical parameters $\lambda$ and $\psi$ provide a crude accounting for physical properties. The Baker chart is dimensionally inconsistent since the dimensional quantity $G_G/\lambda$ is plotted against a dimensionless one, $G_L\lambda\psi/G_G$, and so must be used with $G_G$ in lbm/(ft² · s) units on the ordinate. To convert to kg/(m² · s), multiply by 4.8824.

Rapid approximate predictions of **pressure drop** for fully developed, incompressible horizontal gas/liquid flow may be made using the method of Lockhart and Martinelli (*Chem. Eng. Prog.,* **45,** 39–48 [1949]). First, the pressure drops that would be expected for each of the two phases as if flowing alone in single-phase flow are calculated. The Lockhart-Martinelli parameter $X$ is defined in terms of the ratio of these pressure drops:

$$X = \left[ \frac{(\Delta p/L)_L}{(\Delta p/L)_G} \right]^{1/2} \tag{6-131}$$

The two-phase pressure drop may then be estimated from either of the single-phase pressure drops, using

$$\left( \frac{\Delta p}{L} \right)_{TP} = Y_L \left( \frac{\Delta p}{L} \right)_L \tag{6-132}$$

or

$$\left( \frac{\Delta p}{L} \right)_{TP} = Y_G \left( \frac{\Delta p}{L} \right)_G \tag{6-133}$$

where $Y_L$ and $Y_G$ are read from Fig. 6-26 as functions of $X$. The curve labels refer to the flow regime (laminar or turbulent) found for each of

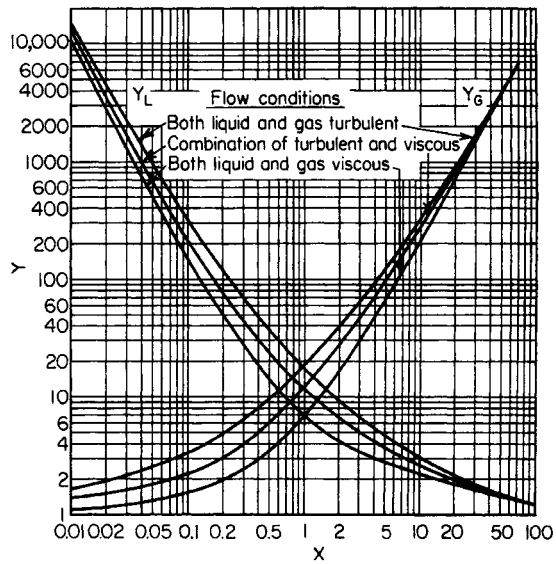

**FIG. 6-26** Parameters for pressure drop in liquid/gas flow through horizontal pipes. (*Based on Lockhart and Martinelli,* Chem. Engr. Prog., ***45,*** *39 [1949].*)

the phases flowing alone. The common turbulent-turbulent case is approximated well by

$$Y_L = 1 + \frac{20}{X} + \frac{1}{X^2} \tag{6-134}$$

Lockhart and Martinelli (ibid.) correlated pressure drop data from pipes 25 mm (1 in) in diameter or less within about ±50 percent. In general, the predictions are high for stratified, wavy, and slug flows and low for annular flow. The correlation can be applied to pipe diameters up to about 0.1 m (4 in) with about the same accuracy.

The **volume fraction,** sometimes called **holdup,** of each phase in two-phase flow is generally not equal to its volumetric flow rate fraction, because of velocity differences, or **slip,** between the phases. For each phase, denoted by subscript $i$, the relations among superficial velocity $V_i$, in situ velocity $v_i$, volume fraction $R_i$, total volumetric flow rate $Q_i$, and pipe area $A$ are

$$Q_i = V_i A = v_i R_i A \tag{6-135}$$

$$v_i = \frac{V_i}{R_i} \tag{6-136}$$

The **slip velocity** between gas and liquid is $v_s = v_G - v_L$. For two-phase gas/liquid flow, $R_L + R_G = 1$. A very common mistake in practice is to assume that in situ phase volume fractions are equal to input volume fractions.

For fully developed incompressible horizontal gas/liquid flow, a quick estimate for $R_L$ may be obtained from Fig. 6-27, as a function of the Lockhart-Martinelli parameter $X$ defined by Eq. (6-131). Indications are that liquid volume fractions may be overpredicted for liquids more viscous than water (Alves, *Chem. Eng. Prog.,* **50,** 449–456 [1954]), and underpredicted for pipes larger than 25 mm diameter (Baker, *Oil Gas J.,* **53**[12], 185–190, 192–195 [1954]).

A method for predicting pressure drop and volume fraction for **non-Newtonian fluids** in annular flow has been proposed by Eisenberg and Weinberger (*AIChE J.,* **25,** 240–245 [1979]). Das, Biswas, and Matra (*Can. J. Chem. Eng.,* **70,** 431–437 [1993]) studied holdup in both horizontal and vertical gas/liquid flow with non-Newtonian liquids. Farooqi and Richardson (*Trans. Inst. Chem. Engrs.,* **60,** 292–305, 323–333 [1982]) developed correlations for holdup and pressure drop for gas/non-Newtonian liquid horizontal flow. They used a modified Lockhart-Martinelli parameter for non-Newtonian

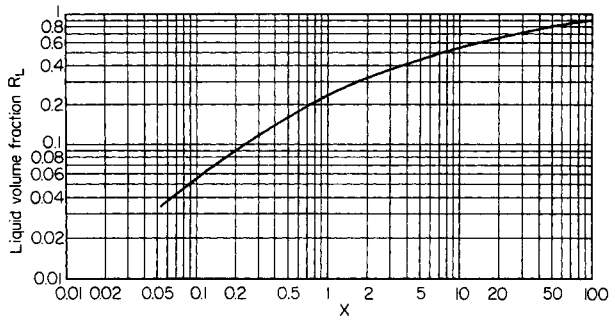

**FIG. 6-27** Liquid volume fraction in liquid/gas flow through horizontal pipes. (*From Lockhart and Martinelli,* Eng. Prog., ***45,*** *39 [1949].*)

liquid holdup. They found that two-phase pressure drop may actually be less than the single-phase liquid pressure drop with shear thinning liquids in laminar flow.

Pressure drop data for a 1-in **feed tee** with the liquid entering the run and gas entering the branch are given by Alves (*Chem. Eng. Progr.,* **50,** 449–456 [1954]). Pressure drop and division of two-phase **annular flow in a tee** are discussed by Fouda and Rhodes (*Trans. Inst. Chem. Eng.* [*London*], **52,** 354–360 [1974]). Flow through tees can result in unexpected flow splitting. Further reading on gas/liquid flow through tees may be found in Mudde, Groen, and van den Akker (*Int. J. Multiphase Flow,* **19,** 563–573 [1993]); Issa and Oliveira (*Computers and Fluids,* **23,** 347–372 [1993]) and Azzopardi and Smith (*Int. J. Multiphase Flow,* **18,** 861–875 [1992]).

Results by Chenoweth and Martin (*Pet. Refiner,* **34**[10], 151–155 [1955]) indicate that single-phase data for **fittings** and **valves** can be used in their correlation for two-phase pressure drop. Smith, Murdock, and Applebaum (*J. Eng. Power,* **99,** 343–347 [1977]) evaluated existing correlations for two-phase flow of steam/water and other gas/liquid mixtures through sharp-edged **orifices** meeting ASTM standards for flow measurement. The correlation of Murdock (*J. Basic Eng.,* **84,** 419–433 [1962]) may be used for these orifices. See also Collins and Gacesa (*J. Basic Eng.,* **93,** 11–21 [1971]), for measurements with steam and water beyond the limits of this correlation.

For pressure drop and holdup in **inclined pipe** with upward or downward flow, see Beggs and Brill (*J. Pet. Technol.,* **25,** 607–617 [1973]); the mechanistic model methods referenced above may also be applied to inclined pipes. Up to 10° from horizontal, upward pipe inclination has little effect on holdup (Gregory, *Can. J. Chem. Eng.,* **53,** 384–388 [1975]).

For fully developed incompressible **cocurrent upflow** of gases and liquids in **vertical pipes,** a variety of flow pattern terminologies and descriptions have appeared in the literature; some of these have been summarized and compared by Govier, Radford, and Dunn (*Can. J. Chem. Eng.,* **35,** 58–70 [1957]). One reasonable classification of patterns is illustrated in Fig. 6-28.

In **bubble flow,** gas is dispersed as bubbles throughout the liquid, but with some tendency to concentrate toward the center of the pipe. In **slug flow,** the gas forms large **Taylor bubbles** of diameter nearly equal to the pipe diameter. A thin film of liquid surrounds the Taylor bubble. Between the Taylor bubbles are liquid slugs containing some bubbles. **Froth** or **churn flow** is characterized by strong intermittency and intense mixing, with neither phase easily described as continuous or dispersed. There remains disagreement in the literature as to whether churn flow is a real fully developed flow pattern or is an indication of large entry length for developing slug flow (Zao and Dukler, *Int. J. Multiphase Flow,* **19,** 377–383 [1993]; Hewitt and Jayanti, *Int. J. Multiphase Flow,* **19,** 527–529 [1993]).

**Ripple flow** has an upward-moving wavy layer of liquid on the pipe wall; it may be thought of as a transition region to **annular, annular mist,** or **film flow,** in which gas flows in the core of the pipe while an annulus of liquid flows up the pipe wall. Some of the liquid is entrained as droplets in the gas core. **Mist flow** occurs when all the liquid is carried as fine drops in the gas phase; this pattern occurs at high gas velocities, typically 20 to 30 m/s (66 to 98 ft/s).

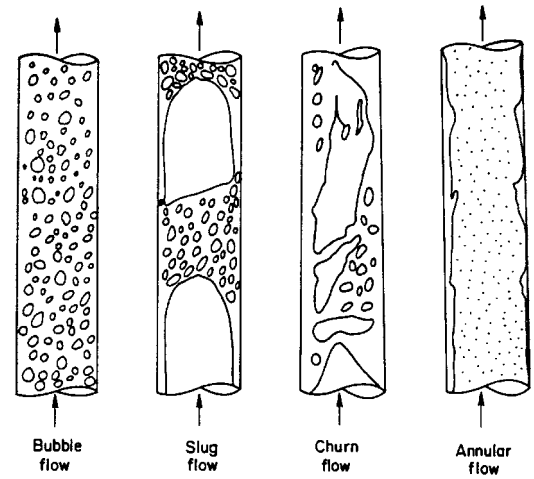

**FIG. 6-28** Flow patterns in cocurrent upward vertical gas/liquid flow. (*From Taitel, Barnea, and Dukler,* AIChE J., ***26,*** *345–354 [1980]. Reproduced by permission of the American Institute of Chemical Engineers © 1980 AIChE. All rights reserved.*)

The correlation by Govier, et al. (*Can. J. Chem. Eng.,* **35,** 58–70 [1957]), Fig. 6-29, may be used for quick estimate of flow pattern.

**Slip,** or relative velocity between phases, occurs for vertical flow as well as for horizontal. No completely satisfactory, flow regime–independent correlation for volume fraction or holdup exists for vertical flow. Two frequently used flow regime–independent methods are those by Hughmark and Pressburg (*AIChE J.,* **7,** 677 [1961]) and Hughmark (*Chem. Eng. Prog.,* **58**[4], 62 [April 1962]). **Pressure drop** in **upflow** may be calculated by the procedure described in Hughmark (*Ind. Eng. Chem. Fundam.,* **2,** 315–321 [1963]). The mechanistic, flow regime–based methods are advisable for critical applications.

For **upflow** in **helically coiled tubes,** the flow pattern, pressure drop, and holdup can be predicted by the correlations of Banerjee, Rhodes, and Scott (*Can. J. Chem. Eng.,* **47,** 445–453 [1969]) and

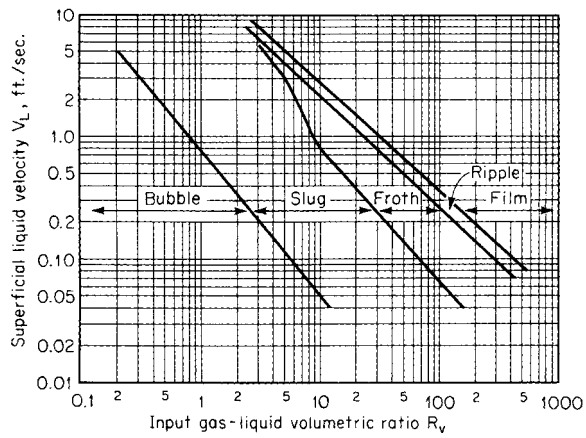

**FIG. 6-29** Flow-pattern regions in cocurrent liquid/gas flow in upflow through vertical pipes. To convert ft/s to m/s, multiply by 0.3048. (*From Govier, Radford, and Dunn,* Can. J. Chem. Eng., **35,** *58–70 [1957].*)

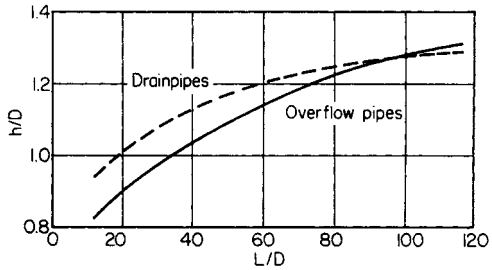

**FIG. 6-30** Critical head for drain and overflow pipes. (*From Kalinske,* Univ. Iowa Stud. Eng., *Bull.* **26** [*1939–1940*].)

Akagawa, Sakaguchi, and Ueda (*Bull JSME,* **14,** 564–571 [1971]). Correlations for flow patterns in **downflow** in vertical pipe are given by Oshinowo and Charles (*Can. J. Chem. Eng.,* **52,** 25–35 [1974]) and Barnea, Shoham, and Taitel (*Chem. Eng. Sci.,* **37,** 741–744 [1982]). Use of **drift flux theory** for void fraction modeling in downflow is presented by Clark and Flemmer (*Chem. Eng. Sci.,* **39,** 170–173 [1984]). **Downward inclined** two-phase flow data and modeling are given by Barnea, Shoham, and Taitel (*Chem. Eng. Sci.,* **37,** 735–740 [1982]). Data for **downflow** in **helically coiled tubes** are presented by Casper (*Chem. Ing. Tech.,* **42,** 349–354 [1970]).

The entrance to a **drain** is flush with a horizontal surface, while the entrance to an **overflow** pipe is above the horizontal surface. When such pipes do not run full, considerable amounts of gas can be drawn down by the liquid. The amount of gas entrained is a function of pipe diameter, pipe length, and liquid flow rate, as well as the drainpipe outlet boundary condition. Extensive data on air entrainment and liquid head above the entrance as a function of water flow rate for pipe diameters from 43.9 to 148.3 mm (1.7 to 5.8 in) and lengths from about 1.22 to 5.18 m (4.0 to 17.0 ft) are reported by Kalinske (*Univ. Iowa Stud. Eng.,* Bull. 26, pp. 26–40 [1939–1940]). For heads greater than the critical, the pipes will run full with no entrainment. The critical head $h$ for flow of water in drains and overflow pipes is given in Fig. 6-30. Kalinske's results show little effect of the height of protrusion of overflow pipes when the protrusion height is greater than about one pipe diameter. For conservative design, McDuffie (*AIChE J.,* **23,** 37–40 [1977]) recommends the following relation for minimum liquid height to prevent entrainment.

$$\mathrm{Fr} \le 1.6\left(\frac{h}{D}\right)^2 \tag{6-137}$$

where the Froude number is defined by

$$\mathrm{Fr} \equiv \frac{V_L}{\sqrt{g(\rho_L - \rho_G)D/\rho_L}} \tag{6-138}$$

where $g$ = acceleration due to gravity
$V_L$ = liquid velocity in the drain pipe
$\rho_L$ = liquid density
$\rho_G$ = gas density
$D$ = pipe inside diameter
$h$ = liquid height

For additional information, see Simpson (*Chem. Eng.,* **75**[6], 192–214 [1968]). A critical Froude number of 0.31 to ensure vented flow is widely cited. Recent results (Thorpe, *3d Int. Conf. Multi-phase Flow,* The Hague, Netherlands, 18–20 May 1987, paper K2, and *4th Int. Conf. Multi-phase Flow,* Nice, France, 19–21 June 1989, paper K4) show hysteresis, with different critical Froude numbers for flooding and unflooding of drain pipes, and the influence of end effects. Wallis, Crowley, and Hagi (*Trans. ASME J. Fluids Eng.,* 405–413 [June 1977]) examine the conditions for horizontal discharge pipes to run full.

**Flashing flow** and **condensing flow** are two examples of multiphase flow with **phase change.** Flashing flow occurs when pressure drops below the bubble point pressure of a flowing liquid. A frequently used one-dimensional model for flashing flow through nozzles and pipes is the **homogeneous equilibrium model** which assumes that both phases move at the same in situ velocity, and maintain vapor/liquid equilibrium. It may be shown that a **critical flow** condition, analogous to sonic or critical flow during compressible gas flow, is given by the following expression for the mass flux $G$ in terms of the derivative of pressure $p$ with respect to mixture density $\rho_m$ at constant entropy:

$$G_{\mathrm{crit}} = \rho_m \sqrt{\left(\frac{\partial p}{\partial \rho_m}\right)_s} \tag{6-139}$$

The corresponding acoustic velocity $\sqrt{(\partial p/\partial \rho_m)_s}$ is normally much less than the acoustic velocity for gas flow. The mixture density is given in terms of the individual phase densities and the **quality** (mass flow fraction vapor) $x$ by

$$\frac{1}{\rho_m} = \frac{x}{\rho_G} + \frac{1-x}{\rho_L} \tag{6-140}$$

Choked and unchoked flow situations arise in pipes and nozzles in the same fashion for homogeneous equilibrium flashing flow as for gas flow. For nozzle flow from stagnation pressure $p_0$ to exit pressure $p_1$, the mass flux is given by

$$G^2 = -2\rho_{m1}^2 \int_{p_0}^{p_1} \frac{dp}{\rho_m} \tag{6-141}$$

The integration is carried out over an isentropic flash path: flashes at constant entropy must be carried out to evaluate $\rho_m$ as a function of $p$. Experience shows that isenthalpic flashes provide good approximations unless the liquid mass fraction is very small. Choking occurs when $G$ obtained by Eq. (6-141) goes through a maximum at a value of $p_1$ greater than the external discharge pressure. Equation (6-139) will also be satisfied at that point. In such a case the pressure at the nozzle exit equals the choking pressure and flashing shocks occur outside the nozzle exit.

For homogeneous flow in a pipe of diameter $D$, the differential form of the Bernoulli equation (6-15) rearranges to

$$\frac{dp}{\rho_m} + g\,dz + \frac{G^2}{\rho_m}\,d\frac{1}{\rho_m} + 2f\frac{dx'}{D}\frac{G^2}{\rho_m^2} = 0 \tag{6-142}$$

where $x'$ is distance along the pipe. Integration over a length $L$ of pipe assuming constant friction factor $f$ yields

$$G^2 = \frac{-\int_{p_1}^{p_2} \rho_m\,dp - g\int_{z_1}^{z_2} \rho_m^2\,dz}{\ln(\rho_{m1}/\rho_{m2}) + 2fL/D} \tag{6-143}$$

Frictional pipe flow is not isentropic. Strictly speaking, the flashes must be carried out at constant $h + V^2/2 + gz$, where $h$ is the enthalpy per unit mass of the two-phase flashing mixture. The flash calculations are fully coupled with the integration of the Bernoulli equation; the velocity $V$ must be known at every pressure $p$ to evaluate $\rho_m$. Computational routines, employing the thermodynamic and material balance features of flowsheet simulators, are the most practical way to carry out such flashing flow calculations, particularly when multicompent systems are involved. Significant simplification arises when the mass fraction liquid is large, for then the effect of the $V^2/2$ term on the flash splits may be neglected. If elevation effects are also negligible, the flash computations are decoupled from the Bernoulli equation integration. For many horizontal flashing flow calculations, this is satisfactory and the flash computatations may be carried out first, to find $\rho_m$ as a function of $p$ from $p_1$ to $p_2$, which may then be substituted into Eq. (6-143).

With flashes carried out along the appropriate thermodynamic paths, the formalism of Eqs. (6-139) through (6-143) applies to all homogeneous equilibrium compressible flows, including, for example, flashing flow, ideal gas flow, and nonideal gas flow. Equation (6-118), for example, is a special case of Eq. (6-141) where the quality $x = 1$ and the vapor phase is a perfect gas.

Various **nonequilibrium** and **slip flow** models have been proposed as improvements on the homogeneous equilibrium flow model. See, for example, Henry and Fauske (*Trans. ASME J. Heat Transfer,* 179–187 [May 1971]). Nonequilibrium and slip effects both increase

computed mass flux for fixed pressure drop, compared to homogeneous equilibrium flow. For flow paths greater than about 100 mm, homogeneous equilibrium behavior appears to be the best assumption (Fischer, et al., *Emergency Relief System Design Using DIERS Technology,* AIChE, New York [1992]). For shorter flow paths, the best estimate may sometimes be given by linearly interpolating (as a function of length) between **frozen flow** (constant quality, no flashing) at 0 length and equilibrium flow at 100 mm.

In a series of papers by Leung and coworkers (*AIChE J.,* **32,** 1743–1746 [1986]; **33,** 524–527 [1987]; **34,** 688–691 [1988]; *J. Loss Prevention Proc. Ind.,* **2**[2], 78–86 [April 1989]; **3**[1], 27–32 [January 1990]; *Trans. ASME J. Heat Transfer,* **112,** 524–528, 528–530 [1990]; **113,** 269–272 [1991]) approximate techniques have been developed for homogeneous equilibrium calculations based on pseudo–equation of state methods for flashing mixtures.

Relatively less work has been done on **condensing flows.** Slip effects are more important for condensing than for flashing flows. Soliman, Schuster, and Berenson (*J. Heat Transfer,* **90,** 267–276 [1968]) give a model for condensing vapor in **horizontal pipe.** They assume the condensate flows as an annular ring. The Lockhart-Martinelli correlation is used for the frictional pressure drop. To this pressure drop is added an acceleration term based on homogeneous flow, equivalent to the $G^2 d(1/\rho_m)$ term in Eq. (6-142). Pressure drop is computed by integration of the incremental pressure changes along the length of pipe.

For **condensing vapor** in **vertical downflow,** in which the liquid flows as a thin annular film, the frictional contribution to the pressure drop may be estimated based on the gas flow alone, using the friction factor plotted in Fig. 6-31, where $Re_G$ is the Reynolds number for the gas flowing alone (Bergelin et al., *Proc. Heat Transfer Fluid Mech. Inst.,* ASME, June 22–24, 1949, pp. 19–28).

$$-\frac{dp}{dz} = \frac{2f'_G \rho_G V_G^2}{D} \tag{6-144}$$

To this should be added the $G_G^2 d(1/\rho_G)/dx$ term to account for velocity change effects.

**Gases and Solids** The flow of gases and solids in **horizontal** pipe is usually classified as either **dilute phase** or **dense phase** flow. Unfortunately, there is no clear dilineation between the two types of flow, and the *dense phase* description may take on more than one meaning, creating some confusion (Knowlton et al., *Chem. Eng. Progr.,* **90**[4], 44–54 [April 1994]). For dilute phase flow, achieved at low solids-to-gas weight ratios (loadings), and high gas velocities, the solids may be fully suspended and fairly uniformly dispersed over the pipe cross section (homogeneous flow), particularly for low-density or small particle size solids. At lower gas velocities, the solids may bounce along the bottom of the pipe. With higher loadings and lower gas velocities, the particles may settle to the bottom of the pipe, forming dunes, with the particles moving from dune to dune. In dense phase conveying, solids tend to concentrate in the lower portion of the pipe at high gas velocity. As gas velocity decreases, the solids may first form dense moving strands, followed by slugs. Discrete plugs of solids may be created intentionally by timed injection of solids, or the plugs may form spontaneously. Eventually the pipe may become blocked. For more information on flow patterns, see Coulson and Richardson (*Chemical Engineering,* vol. 2, 2d ed., Pergamon, New York, 1968, p. 583); Korn (*Chem. Eng.,* **57**[3], 108–111 [1950]); Patterson (*J. Eng. Power,* **81,** 43–54 [1959]); Wen and Simons (*AIChE J.,* **5,** 263–267 [1959]); and Knowlton et al. (*Chem. Eng. Progr.,* **90**[4], 44–54 [April 1994]).

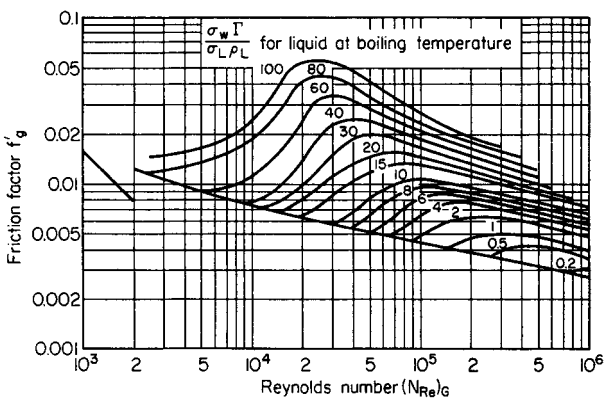

**FIG. 6-31** Friction factors for condensing liquid/gas flow downward in vertical pipe. In this correlation $\Gamma/\rho L$ is in $ft^2/h$. To convert $ft^2/h$ to $m^2/s$, multiply by 0.00155. (*From Bergelin et al.,* Proc. Heat Transfer Fluid Mech. Inst., *ASME, 1949, p. 19.*)

For the **minimum velocity** required to prevent formation of dunes or settled beds in **horizontal flow,** some data are given by Zenz (*Ind. Eng. Chem. Fundam.,* **3,** 65–75 [1964]), who presented a correlation for the minimum velocity required to keep particles from depositing on the bottom of the pipe. This rather tedious estimation procedure may also be found in Govier and Aziz, who provide additional references and discussion on transition velocities. In practice, the actual conveying velocities used in systems with loadings less than 10 are generally over 15 m/s, (49 ft/s) while for high loadings (>20) they are generally less than 7.5 m/s (24.6 ft/s) and are roughly twice the actual solids velocity (Wen and Simons, *AIChE J.,* **5,** 263–267 [1959]).

Total **pressure drop** for **horizontal gas/solid** flow includes acceleration effects at the entrance to the pipe and frictional effects beyond the entrance region. A great number of correlations for pressure gradient are available, none of which is applicable to all flow regimes. Govier and Aziz review many of these and provide recommendations on when to use them.

For **upflow** of gases and solids in **vertical pipes,** the **minimum conveying velocity** for low loadings may be estimated as twice the terminal settling velocity of the largest particles. Equations for terminal settling velocity are found in the "Particle Dynamics" subsection, following. **Choking** occurs as the velocity is dropped below the minimum conveying velocity and the solids are no longer transported, collapsing into solid plugs (Knowlton, et al., *Chem. Eng. Progr.,* **90**[4], 44–54 [April 1994]). See Smith (*Chem. Eng. Sci.,* **33,** 745–749 [1978]) for an equation to predict the onset of choking.

Total **pressure drop** for vertical upflow of gases and solids includes acceleration and frictional affects also found in horizontal flow, plus potential energy or hydrostatic effects. Govier and Aziz review many of the pressure drop calculation methods and provide recommendations for their use. See also Yang (*AIChE J.,* **24,** 548–552 [1978]).

**Drag reduction** has been reported for low loadings of small diameter particles (<60 μm diameter), ascribed to damping of turbulence near the wall (Rossettia and Pfeffer, *AIChE J.,* **18,** 31–39 [1972]).

For **dense phase** transport in **vertical pipes** of small diameter, see Sandy, Daubert, and Jones (*Chem. Eng. Prog.,* **66,** *Symp. Ser.,* 105, 133–142 [1970]).

The **flow of bulk solids through restrictions and bins** is discussed in symposium articles (*J. Eng. Ind.,* **91**[2] [1969]) and by Stepanoff (*Gravity Flow of Bulk Solids and Transportation of Solids in Suspension,* Wiley, New York, 1969). Some problems encountered in discharge from bins include (Knowlton et al., *Chem. Eng. Progr.,* **90**[4], 44–54 [April 1994]) flow stoppage due to **ratholing** or **arching, segregation** of fine and coarse particles, **flooding** upon collapse of ratholes, and poor **residence time distribution** when **funnel flow** occurs.

**Solid and Liquids** Slurry flow may be divided roughly into two categories based on settling behavior (see Etchells in Shamlou, *Processing of Solid-Liquid Suspensions,* Chap. 12, Butterworth-Heinemann, Oxford, 1993). **Nonsettling** slurries are made up of very fine, highly concentrated, or neutrally buoyant particles. These slurries are normally treated as pseudohomogeneous fluids. They may be quite viscous and are frequently non-Newtonian. Slurries of particles that tend to settle out rapidly are called **settling slurries** or **fast-settling slurries.** While in some cases positively buoyant solids are encountered, the present discussion will focus on solids which are more dense than the liquid.

For **horizontal flow** of **fast-settling slurries,** the following rough description may be made (Govier and Aziz). Ultrafine particles, 10 μm

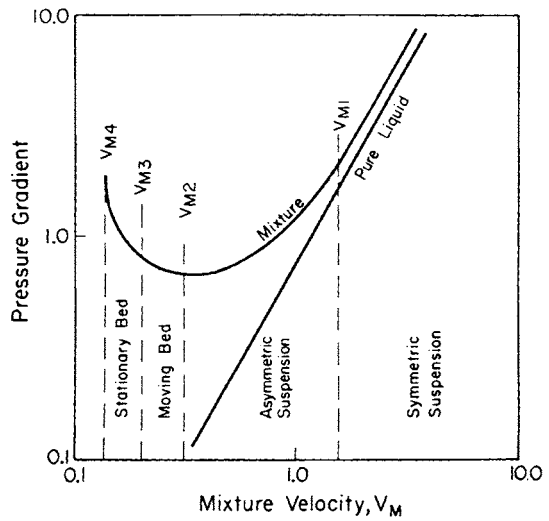

**FIG. 6-32** Flow pattern regimes and pressure gradients in horizontal slurry flow. (*From Govier and Aziz,* The Flow of Complex Mixtures in Pipes, *Van Nostrand Reinhold, New York, 1972.*)

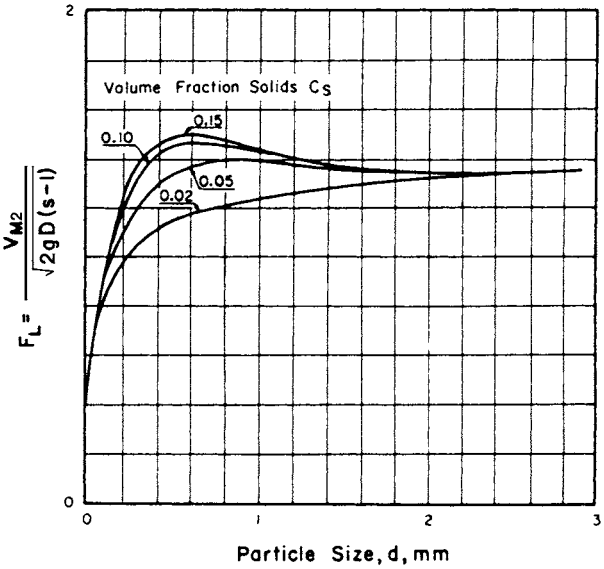

**FIG. 6-33** Durand factor for minimum suspension velocity. (*From Govier and Aziz,* The Flow of Complex Mixtures in Pipes, *Van Nostrand Reinhold, New York, 1972.*)

or smaller, are generally fully syspended and the particle distributions are not influenced by gravity. Fine particles 10 to 100 μm ($3.3 \times 10^{-5}$ to $33 \times 10^{-5}$ ft) are usually fully suspended, but gravity causes concentration gradients. Medium-size particles, 100 to 1000 μm, may be fully suspended at high velocity, but often form a moving deposit on the bottom of the pipe. Coarse particles, 1,000 to 10,000 μm (0.0033 to 0.033 ft), are seldom fully suspended and are usually conveyed as a moving deposit. Ultracoarse particles larger than 10,000 μm (0.033 ft) are not suspended at normal velocities unless they are unusually light.

Figure 6-32, taken from Govier and Aziz, schematically indicates four flow pattern regions superimposed on a plot of pressure gradient vs. mixture velocity $V_M = V_L + V_S = (Q_L + Q_S)/A$ where $V_L$ and $V_S$ are the superficial liquid and solid velocities, $Q_L$ and $Q_S$ are liquid and solid volumetric flow rates, and $A$ is the pipe cross-sectional area. $V_{M4}$ is the transition velocity above which a bed exists in the bottom of the pipe, part of which is stationary and part of which moves by **saltation,** with the upper particles tumbling and bouncing over one another, often with formation of dunes. With a broad particle-size distribution, the finer particles may be fully suspended. Near $V_{M4}$, the pressure gradient rapidly increases as $V_M$ decreases. Above $V_{M3}$, the entire bed moves. Above $V_{M2}$, the solids are fully suspended; that is, there is no deposit, moving or stationary, on the bottom of the pipe. However, the concentration distribution of solids is asymmetric. This flow pattern is the most frequently used for fast-settling slurry transport. Typical mixture velocities are in the range of 1 to 3 m/s (3.3 to 9.8 ft/s). The minimum in the pressure gradient is found to be near $V_{M2}$. Above $V_{M1}$, the particles are symmetrically distributed, and the pressure gradient curve is nearly parallel to that for the liquid by itself.

The most important transition velocity, often regarded as the minimum transport or conveying velocity for settling slurries, is $V_{M2}$. The Durand equation (Durand, Minnesota Int. Hydraulics Conf., *Proc.,* 89, Int. Assoc. for Hydraulic Research [1953]; Durand and Condolios, *Proc. Colloq. On the Hyd. Transport of Solids in Pipes, Nat. Coal Board* [*UK*], Paper IV, 39–35 [1952]) gives the minimum transport velocity as

$$V_{M2} = F_L[2gD(s-1)]^{0.5} \tag{6-145}$$

where $g$ = acceleration of gravity
$D$ = pipe diameter
$s = \rho_S/\rho_L$ = ratio of solid to liquid density
$F_L$ = a factor influenced by particle size and concentration

Probably $F_L$ is a function of particle Reynolds number and concentration, but Fig. 6-33 gives Durand's empirical correlation for $F_L$ as a function of particle diameter and the input, feed volume fraction solids, $C_S = Q_S/(Q_S + Q_L)$. The form of Eq. (6-145) may be derived from turbulence theory, as shown by Davies (*Chem. Eng. Sci.,* **42,** 1667–1670 [1987]).

No single correlation for **pressure drop** in horizontal solid/liquid flow has been found satisfactory for all particle sizes, densities, concentrations, and pipe sizes. However, with reference to Fig. 6-32, the following simplifications may be considered. The minimum pressure gradient occurs near $V_{M2}$ and for conservative purposes it is generally desirable to exceed $V_{M2}$. When $V_{M2}$ is exceeded, a rough guide for pressure drop is 25 percent greater than that calculated assuming that the slurry behaves as a psuedohomogeneous fluid with the density of the mixture and the viscosity of the liquid. Above the transition velocity to symmetric suspension, $V_{M1}$, the pressure drop closely approaches the pseudohomogeneous pressure drop. The following correlation by Spells (*Trans. Inst. Chem. Eng.* [*London*], **33,** 79–84 [1955]) may be used for $V_{M1}$.

$$V_{M1}^2 = 0.075\left(\frac{DV_{M1}\rho_M}{\mu}\right)^{0.775} gD_S(s-1) \tag{6-146}$$

where $D$ = pipe diameter
$D_S$ = particle diameter (such that 85 percent by weight of particles are smaller than $D_S$)
$\rho_M$ = the slurry mixture density
$\mu$ = liquid viscosity
$s = \rho_S/\rho_L$ = ratio of solid to liquid density

Between $V_{M2}$ and $V_{M1}$ the concentration of solids gradually becomes more uniform in the vertical direction. This transition has been modeled by several authors as a concentration gradient where turbulent diffusion balances gravitational settling. See, for example, Karabelas (*AIChE J.,* **23,** 426–434 [1977]).

Published correlations for pressure drop are frequently very complicated and tedious to use, may not offer significant accuracy advantages over the simple guide given here, and many of them are applicable only for velocities above $V_{M2}$. One which does include the effect of sliding beds is due to Gaessler (Doctoral Dissertation, Technische Hochshule, Karlsruhe, Germany [1967]; reproduced by Govier and Aziz, pp. 668–669). Turian and Yuan (*AIChE J.,* **23,** 232–243 [1977]; see also Turian and Oroskar, *AIChE J.,* **24,** 1144 [1978]) segregated a large body of data into four flow regime groups

and developed empirical correlations for predicting pressure drop in each flow regime.

Pressure drop data for the flow of **paper stock** in pipes are given in the data section of *Standards of the Hydraulic Institute* (Hydraulic Institute, 1965). The flow behavior of fiber suspensions is discussed by Bobkowicz and Gauvin (*Chem. Eng. Sci.,* **22,** 229–241 [1967]), Bugliarello and Daily (*TAPPI,* **44,** 881–893 [1961]), and Daily and Bugliarello (*TAPPI,* **44,** 497–512 [1961]).

In **vertical flow** of fast-settling slurries, the in situ concentration of solids with density greater than the liquid will exceed the feed concentration $C = Q_S/(Q_S + Q_L)$ for upflow and will be smaller than $C$ for downflow. This results from slip between the phases. The **slip velocity,** the difference between the in situ average velocities of the two phases, is roughly equal to the terminal settling velocity of the solids in the liquid. Specification of the slip velocity for a pipe of a given diameter, along with the phase flow rates, allows calculation of in situ volume fractions, average velocities, and holdup ratios by simple material balances. Slip velocity may be affected by particle concentration and by turbulence conditions in the liquid. **Drift-flux theory,** a framework incorporating certain functional forms for empirical expressions for slip velocity, is described by Wallis (*One-Dimensional Two-Phase Flow,* McGraw-Hill, New York, 1969). **Minimum transport velocity** for upflow for design purposes is usually taken as twice the particle settling velocity. **Pressure drop** in vertical pipe flow includes the effects of kinetic and potential energy (elevation) changes and friction. Rose and Duckworth (*The Engineer,* **227**[5,903], 392 [1969]; **227**[5,904], 430 [1969]; **227**[5,905], 478 [1969]; see also Govier and Aziz, pp. 487–493) have developed a calculation procedure including all these effects, which may be applied not only to vertical solid/liquid flow, but also to gas/solid flow and to horizontal flow.

For fast-settling slurries, ensuring conveyance is usually the key design issue while pressure drop is somewhat less important. For **nonsettling slurries** conveyance is not an issue, because the particles do not separate from the liquid. Here, viscous and rheological behavior, which control pressure drop, take on critical importance.

Fine particles, often at high concentration, form nonsettling slurries for which useful design equations can be developed by treating them as homogeneous fluids. These fluids are usually very viscous and often non-Newtonian. Shear-thinning and Bingham plastic behavior are common; dilatancy is sometimes observed. Rheology of such fluids must in general be empirically determined, although theoretical results are available for some very limited circumstances. Further discussion of both fast-settling and nonsettling slurries may be found in Shook (in Shamlou, *Processing of Solid-Liquid Suspensions,* Chap. 11, Butterworth-Heinemann, Oxford, 1993).

## FLUID DISTRIBUTION

Uniform fluid distribution is essential for efficient operation of chemical-processing equipment such as contactors, reactors, mixers, burners, heat exchangers, extrusion dies, and textile-spinning chimneys. To obtain optimum distribution, proper consideration must be given to flow behavior in the distributor, flow conditions upstream and downstream of the distributor, and the distribution requirements of the equipment. Even though the principles of fluid distribution have been well developed for more than three decades, they are frequently overlooked by equipment designers, and a significant fraction of process equipment needlessly suffers from maldistribution. In this subsection, guides for the design of various types of fluid distributors, taking into account only the flow behavior within the distributor, are given.

**Perforated-Pipe Distributors** The simple perforated pipe or sparger (Fig. 6-34) is a common type of distributor. As shown, the flow distribution is uniform; this is the case in which pressure recovery due to kinetic energy or momentum changes, frictional pressure drop along the length of the pipe, and pressure drop across the outlet holes have been properly considered. In typical turbulent flow applications, inertial effects associated with velocity changes may dominate frictional losses in determining the pressure distribution along the pipe, unless the length between orifices is large. Application of the momentum or mechanical energy equations in such a case shows that the pressure inside the pipe increases with distance from the entrance of the pipe. If the outlet holes are uniform in size and spacing, the discharge flow will be biased toward the closed end. Disturbances upstream of the distributor, such as pipe bends, may increase or decrease the flow to the holes at the beginning of the distributor. When frictional pressure drop dominates the inertial pressure recovery, the distribution is biased toward the feed end of the distributor.

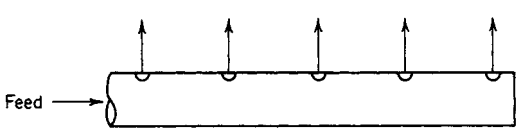

**FIG. 6-34** Perforated-pipe distributor.

For turbulent flow, with roughly uniform distribution, assuming a constant friction factor, the combined effect of friction and inertial (momentum) pressure recovery is given by

$$\Delta p = \left(\frac{4fL}{3D} - 2K\right)\frac{\rho V_i^2}{2} \qquad \text{(discharge manifolds)} \qquad (6\text{-}147)$$

where $\Delta p$ = net pressure drop over the length of the distributor
$L$ = pipe length
$D$ = pipe diameter
$f$ = Fanning friction factor
$V_i$ = distributor inlet velocity

The factor $K$ would be 1 in the case of full momentum recovery, or 0.5 in the case of negligible viscous losses in the portion of flow which remains in the pipe after the flow divides at a takeoff point (Denn, pp. 126–127). Experimental data (Van der Hegge Zijnen, *Appl. Sci. Res.,* **A3,** 144–162 [1951–1953]; and Bailey, *J. Mech. Eng. Sci.,* **17,** 338–347 [1975]), while scattered, show that $K$ is probably close to 0.5 for discharge manifolds. For inertially dominated flows, $\Delta p$ will be negative. For **return manifolds** the recovery factor $K$ is close to 1.0, and the pressure drop between the first hole and the exit is given by

$$\Delta p = \left(\frac{4fL}{3D} + 2K\right)\frac{\rho V_e^2}{2} \qquad \text{(return manifolds)} \qquad (6\text{-}148)$$

where $V_e$ is the pipe exit velocity.

One means to obtain a desired uniform distribution is to make the average pressure drop across the holes $\Delta p_o$ large compared to the pressure variation over the length of pipe $\Delta p$. Then, the relative variation in pressure drop across the various holes will be small, and so will be the variation in flow. When the area of an individual hole is small compared to the cross-sectional area of the pipe, hole pressure drop may be expressed in terms of the discharge coefficient $C_o$ and the velocity across the hole $V_o$ as

$$\Delta p_o = \frac{1}{C_o^2}\frac{\rho V_o^2}{2} \qquad (6\text{-}149)$$

Provided $C_o$ is the same for all the holes, the *percent maldistribution,* defined as the percentage variation in flow between the first and last holes, may be estimated reasonably well for small maldistribution by (Senecal, *Ind. Eng. Chem.,* **49,** 993–997 [1957])

$$\text{Percent maldistribution} = 100\left(1 - \sqrt{\frac{\Delta p_o - |\Delta p|}{\Delta p_o}}\right) \qquad (6\text{-}150)$$

This equation shows that for 5 percent maldistribution, the pressure drop across the holes should be about 10 times the pressure drop over the length of the pipe. For discharge manifolds with $K = 0.5$ in Eq. (6-147), and with $4fL/3D \ll 1$, the pressure drop across the holes should be 10 times the inlet velocity head, $\rho V_i^2/2$ for 5 percent maldistribution. This leads to a simple design equation.

Discharge manifolds, $4fL/3D \ll 1$, 5% maldistribution:

$$\frac{V_o}{V_i} = \frac{A_p}{A_o} = \sqrt{10}C_o \qquad (6\text{-}151)$$

Here $A_p$ = pipe cross-sectional area and $A_o$ is the *total* hole area of the distributor. Use of large hole velocity to pipe velocity ratios promotes perpendicular discharge streams. In practice, there are many cases where the $4fL/3D$ term will be less than unity but not close to zero. In such cases, Eq. (6-151) will be conservative, while Eqs. (6-147), (6-149), and (6-150) will give more accurate design calculations. In cases where $4fL/(3D) > 2$, friction effects are large enough to render Eq. (6-151) nonconservative. When significant variations in $f$ along the length of the distributor occur, calculations should be made by dividing the distributor into small enough sections that constant $f$ may be assumed over each section.

For return manifolds with $K = 1.0$ and $4fL/(3D) \ll 1$, 5 percent maldistribution is achieved when hole pressure drop is 20 times the pipe exit velocity head.

Return manifolds, $4fL/3D \ll 1$, 5% maldistribution:

$$\frac{V_o}{V_e} = \frac{A_p}{A_o} = \sqrt{20}C_o \tag{6-152}$$

When $4fL/3D$ is not negligible, Eq. (6-152) is not conservative and Eqs. (6-148), (6-149), and (6-150) should be used.

One common misconception is that good distribution is always provided by high pressure drop, so that increasing flow rate improves distribution by increasing pressure drop. Conversely, it is mistakenly believed that turndown of flow through a perforated pipe designed using Eqs. (6-151) and (6-152) will cause maldistribution. However, when the distribution is nearly uniform, decreasing the flow rate decreases $\Delta p$ and $\Delta p_o$ in the same proportion, and Eqs. (6-151) and (6-152) are still satisfied, preserving good distribution independent of flow rate, as long as friction losses remain small compared to inertial (velocity head change) effects. Conversely, increasing the flow rate through a distributor with severe maldistribution will not generally produce good distribution.

Often, the pressure drop required for design flow rate is unacceptably large for a distributor pipe designed for uniform velocity through uniformly sized and spaced orifices. Several measures may be taken in such situations. These include the following:

1. Taper the diameter of the distributor pipe so that the pipe velocity and velocity head remain constant along the pipe, thus substantially reducing pressure variation in the pipe.
2. Vary the hole size and/or the spacing between holes to compensate for the pressure variation along the pipe. This method may be sensitive to flow rate and a distributor optimized for one flow rate may suffer increased maldistribution as flow rate deviates from design rate.
3. Feed or withdraw from both ends, reducing the pipe flow velocity head and required hole pressure drop by a factor of 4.

The orifice discharge coefficient $C_o$ is usually taken to be about 0.62. However, $C_o$ is dependent on the ratio of hole diameter to pipe diameter, pipe wall thickness to hole diameter ratio, and pipe velocity to hole velocity ratio. As long as all these are small, the coefficient 0.62 is generally adequate.

***Example 9: Pipe Distributor*** A 3-in schedule 40 (inside diameter 7.793 cm) pipe is to be used as a distributor for a flow of 0.010 $m^3/s$ of water ($\rho = 1{,}000$ $kg/m^3$, $\mu = 0.001$ Pa · s). The pipe is 0.7 m long and is to have 10 holes of uniform diameter and spacing along the length of the pipe. The distributor pipe is submerged. Calculate the required hole size to limit maldistribution to 5 percent, and estimate the pressure drop across the distributor.

The inlet velocity computed from $V_i = Q/A = 4Q/(\pi D^2)$ is 2.10 m/s, and the inlet Reynolds number is

$$\mathrm{Re} = \frac{DV_i\rho}{\mu} = \frac{0.07793 \times 2.10 \times 1{,}000}{0.001} = 1.64 \times 10^5$$

For commercial pipe with roughness $\epsilon = 0.046$ mm, the friction factor is about 0.0043. Approaching the last hole, the flow rate, velocity, and Reynolds number are about one-tenth their inlet values. At Re = 16,400 the friction factor $f$ is about 0.0070. Using an average value of $f = 0.0057$ over the length of the pipe, $4fL/3D$ is 0.068 and may reasonably be neglected so that Eq. (6-151) may be used. With $C_o = 0.62$,

$$\frac{V_o}{V_i} = \frac{A_p}{A_o} = \sqrt{10}C_o = \sqrt{10} \times 0.62 = 1.96$$

With pipe cross-sectional area $A_p = 0.00477$ $m^2$, the total hole area is $0.00477/1.96 = 0.00243$ $m^2$. The area and diameter of each hole are then $0.00243/10 = 0.000243$ $m^2$ and 1.76 cm. With $V_o/V_i = 1.96$, the hole velocity is $1.96 \times 2.10 = 4.12$ m/s and the pressure drop across the holes is obtained from Eq. (6-149).

$$\Delta p_o = \frac{1}{C_o^2}\frac{\rho V_o^2}{2} = \frac{1}{0.62^2} \times \frac{1{,}000(4.12)^2}{2} = 22{,}100 \text{ Pa}$$

Since the hole pressure drop is 10 times the pressure variation in the pipe, the total pressure drop from the inlet of the distributor may be taken as approximately 22,100 Pa.

Further detailed information on pipe distributors may be found in Senecal (*Ind. Eng. Chem.*, **49,** 993–997 [1957]). Much of the information on tapered manifold design has appeared in the pulp and paper literature (Spengos and Kaiser, *TAPPI*, **46**[3], 195–200 [1963]; Madeley, *Paper Technology*, **9**[1], 35–39 [1968]; Mardon, et al., *TAPPI*, **46**[3], 172–187 [1963]; Mardon, et al., *Pulp and Paper Magazine of Canada*, **72**[11], 76–81 [November 1971]; Trufitt, *TAPPI*, **58**[11], 144–145 [1975]).

**Slot Distributors** These are generally used in sheeting dies for extrusion of films and coatings and in air knives for control of thickness of a material applied to a moving sheet. A simple slotted pipe for turbulent flow conditions may give severe maldistribution because of nonuniform discharge velocity, but also because this type of design does not readily give perpendicular discharge (Koestel and Tuve, *Heat. Piping Air Cond.*, **20**[1], 153–157 [1948]; Senecal, *Ind. Eng. Chem.*, **49,** 993–997 [1957]; Koestel and Young, *Heat. Piping Air Cond.*, **23**[7], 111–115 [1951]). For slots in tapered ducts where the duct cross-sectional area decreases linearly to zero at the far end, the discharge angle will be constant along the length of the duct (Koestel and Young, ibid.). One way to ensure an almost perpendicular discharge is to have the ratio of the area of the slot to the cross-sectional area of the pipe equal to or less than 0.1. As in the case of perforated-pipe distributors, pressure variation within the slot manifold and pressure drop across the slot must be carefully considered.

In practice, the following methods may be used to keep the diameter of the pipe to a minimum consistent with good performance (Senecal, *Ind. Eng. Chem.*, **49,** 993–997 [1957]):

1. Feed from both ends.
2. Modify the cross-sectional design (Fig. 6-35); the slot is thus farther away from the influence of feed-stream velocity.
3. Increase pressure drop across the slot; this can be accomplished by lengthening the lips (Fig. 6-35).
4. Use screens (Fig. 6-35) to increase overall pressure drop across the slot.

Design considerations for air knives are discussed by Senecal (ibid.). Design procedures for extrusion dies when the flow is laminar, as with highly viscous fluids, are presented by Bernhardt (*Processing of Thermoplastic Materials*, Rheinhold, New York, 1959, pp. 248–281).

**Turning Vanes** In applications such as ventilation, the discharge profile from slots can be improved by turning vanes. The tapered duct is the most amenable for turning vanes because the discharge angle remains constant. One way of installing the vanes is shown in Fig. 6-36. The vanes should have a depth twice the spacing (*Heating, Ventilating, Air Conditioning Guide*, vol. 38, American Society of Heating, Refrigerating and Air-Conditioning Engineers, 1960, pp. 282–283) and a curvature at the upstream end of the vanes of a circular arc which is tangent to the discharge angle $\theta$ of a slot without vanes and perpendicular at the downstream or discharge end of the vanes (Koestel and Young, *Heat. Piping Air Cond.*, **23**[7], 111–115 [1951]). Angle $\theta$ can be estimated from

$$\cot\theta = \frac{C_d A_s}{A_d} \tag{6-153}$$

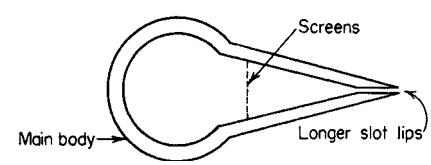

**FIG. 6-35** Modified slot distributor.

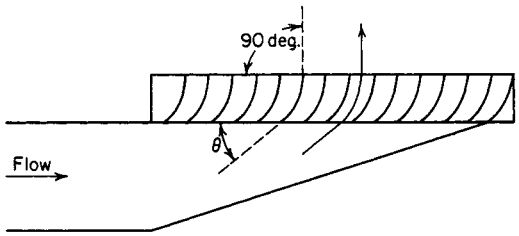

**FIG. 6-36** Turning vanes in a slot distributor.

where $A_s$ = slot area
$A_d$ = duct cross-sectional area at upstream end
$C_d$ = discharge coefficient of slot

Vanes may be used to improve velocity distribution and reduce frictional loss in bends, when the ratio of bend turning radius to pipe diameter is less than 1.0. For a miter bend with low-velocity flows, simple circular arcs (Fig. 6-37) can be used, and with high-velocity flows, vanes of special airfoil shapes are required. For additional details and references, see Ower and Pankhurst (*The Measurement of Air Flow,* Pergamon, New York, 1977, p. 102); Pankhurst and Holder (*Wind-Tunnel Technique,* Pitman, London, 1952, pp. 92–93); Rouse (*Engineering Hydraulics,* Wiley, New York, 1950, pp. 399–401); and Jorgensen (*Fan Engineering,* 7th ed., Buffalo Forge Co., Buffalo, 1970, pp. 111, 117, 118).

**Perforated Plates and Screens** A nonuniform velocity profile in turbulent flow through channels or process equipment can be smoothed out to any desired degree by adding sufficient uniform resistance, such as perforated plates or screens across the flow channel, as shown in Fig. 6-38. Stoker (*Ind. Eng. Chem.,* **38,** 622–624 [1946]) provides the following equation for the effect of a uniform resistance on velocity profile:

$$\frac{V_{2,\max}}{V} = \sqrt{\frac{(V_{1,\max}/V)^2 + \alpha_2 - \alpha_1 + \alpha_2 K}{1 + K}} \qquad (6\text{-}154)$$

Here, $V$ is the area average velocity, $K$ is the number of velocity heads of pressure drop provided by the uniform resistance, $\Delta p = K\rho V^2/2$, and $\alpha$ is the velocity profile factor used in the mechanical energy balance, Eq. (6-13). It is the ratio of the area average of the cube of the velocity, to the cube of the area average velocity $V$. The shape of the exit velocity profile appears twice in Eq. (6-154), in $V_{2,\max}/V$ and $\alpha_2$. Typically, $K$ is on the order of 10, and the desired exit velocity profile

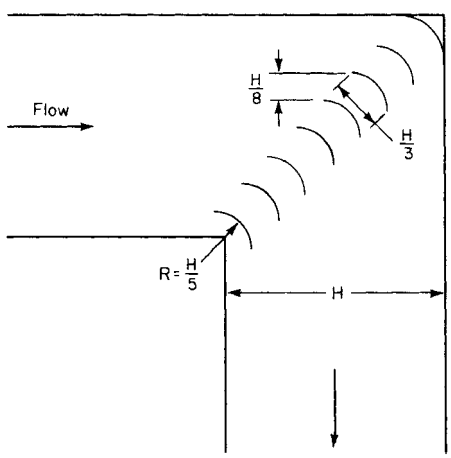

**FIG. 6-37** Miter bend with vanes.

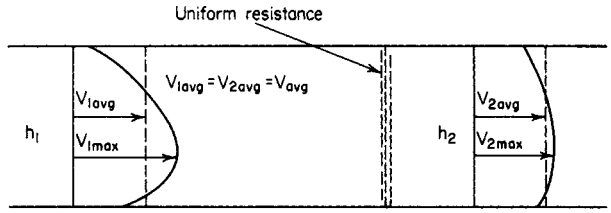

**FIG. 6-38** Smoothing out a nonuniform profile in a channel.

is fairly uniform so that $\alpha_2 \sim 1.0$ may be appropriate. Downstream of the resistance, the velocity profile will gradually reestablish the fully developed profile characteristic of the Reynolds number and channel shape. The screen or perforated plate open area required to produce the resistance $K$ may be computed from Eqs. (6-107) or (6-111).

Screens and other flow restrictions may also be used to suppress stream swirl and turbulence (Loehrke and Nagib, *J. Fluids Eng.,* **98,** 342–353 [1976]). Contraction of the channel, as in a venturi, provides further reduction in turbulence level and flow nonuniformity.

**Beds of Solids** A suitable depth of solids can be used as a fluid distributor. As for other types of distribution devices, a pressure drop of 10 velocity heads is typically used, here based on the superficial velocity through the bed. There are several substantial disadvantages to use of particle beds for flow distribution. Heterogeneity of the bed may actually worsen rather than improve distribution. In general, uniform flow may be found only downstream of the point in the bed where sufficient pressure drop has occurred to produce uniform flow. Therefore, inefficiency results when the bed also serves reaction or mass transfer functions, as in catalysts, adsorbents, or tower packings for gas/liquid contacting, since portions of the bed are bypassed. In the case of trickle flow of liquid downward through column packings, inlet distribution is critical since the bed itself is relatively ineffective in distributing the liquid. Maldistribution of flow through packed beds also arises when the ratio of bed diameter to particle size is less than 10 to 30.

**Other Flow Straightening Devices** Other devices designed to produce uniform velocity or reduce swirl, sometimes with reduced pressure drop, are available. These include both commercial devices of proprietary design and devices discussed in the literature. For pipeline flows, see the references under flow inverters and static mixing elements previously discussed in the "Incompressible Flow in Pipes and Channels" subsection. For large area changes, as at the entrance to a vessel, it is sometimes necessary to diffuse the momentum of the inlet jet discharging from the feed pipe in order to produce a more uniform velocity profile within the vessel. Methods for this application exist, but remain largely in the domain of proprietary, commercial design.

## FLUID MIXING

Mixing of fluids is a discipline of fluid mechanics. Fluid motion is used to accelerate the otherwise slow processes of diffusion and conduction to bring about uniformity of concentration and temperature, blend materials, facilitate chemical reactions, bring about intimate contact of multiple phases, and so on. As the subject is too broad to cover fully, only a brief introduction and some references for further information are given here.

Several texts are available. These include Paul, Atiemo-Obeng, and Kresta (*Handbook of Industrial Mixing,* Wiley-Interscience, Hoboken N.J., 2004); Harnby, Edwards, and Nienow (*Mixing in the Process Industries,* 2d ed., Butterworths, London, 1992); Oldshue (*Fluid Mixing Technology,* McGraw-Hill, New York, 1983); Tatterson (*Fluid Mixing and Gas Dispersion in Agitated Tanks,* McGraw-Hill, New York, 1991); Uhl and Gray (*Mixing,* vols. I–III, Academic, New York, 1966, 1967, 1986); and Nagata (*Mixing: Principles and Applications,* Wiley, New York, 1975). A good overview of stirred tank agitation is given in the series of articles from *Chemical Engineering* (110–114, Dec. 8, 1975; 139–145, Jan. 5, 1976; 93–100, Feb. 2, 1976; 102–110,

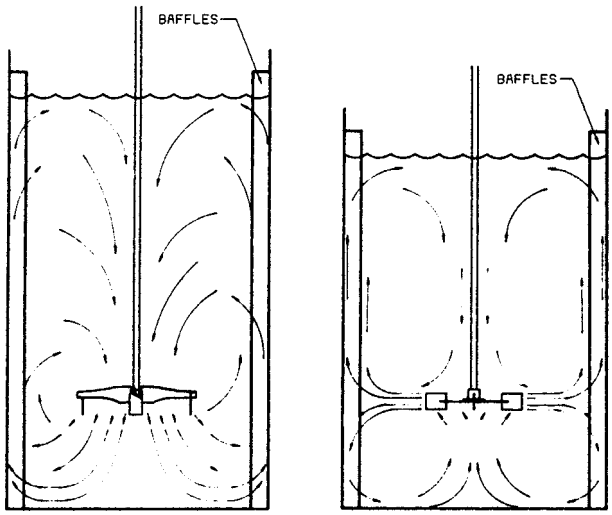

**FIG. 6-39** Typical stirred tank configurations, showing time-averaged flow patterns for axial flow and radial flow impellers. (*From Oldshue,* Fluid Mixing Technology, *McGraw-Hill, New York, 1983.*)

Apr. 26, 1976; 144–150, May 24, 1976; 141–148, July 19, 1976; 89–94, Aug. 2, 1976; 101–108, Aug. 30, 1976; 109–112, Sept. 27, 1976; 119–126, Oct. 25, 1976; 127–133, Nov. 8, 1976).

Process mixing is commonly carried out in pipeline and vessel geometries. The terms **radial mixing** and **axial mixing** are commonly used. Axial mixing refers to mixing of materials which pass a given point at different times, and thus leads to **backmixing.** For example, backmixing or axial mixing occurs in stirred tanks where fluid elements entering the tank at different times are intermingled. Mixing of elements initially at different axial positions in a pipeline is axial mixing. Radial mixing occurs between fluid elements passing a given point at the same time, as, for example, between fluids mixing in a pipeline tee.

**Turbulent flow,** by means of the chaotic eddy motion associated with velocity fluctuation, is conducive to rapid mixing and, therefore, is the preferred flow regime for mixing. **Laminar mixing** is carried out when high viscosity makes turbulent flow impractical.

**Stirred Tank Agitation** Turbine impeller agitators, of a variety of shapes, are used for stirred tanks, predominantly in turbulent flow. Figure 6-39 shows typical stirred tank configurations and time-averaged flow patterns for axial flow and radial flow impellers. In order to prevent formation of a **vortex,** four vertical baffles are normally installed. These cause top-to-bottom mixing and prevent mixing-ineffective swirling motion.

For a given impeller and tank geometry, the impeller Reynolds number determines the flow pattern in the tank:

$$\mathrm{Re}_I = \frac{D^2 N \rho}{\mu} \tag{6-155}$$

where $D$ = impeller diameter, $N$ = rotational speed, and $\rho$ and $\mu$ are the liquid density and viscosity. Rotational speed $N$ is typically reported in revolutions per minute, or revolutions per second in SI units. Radians per second are almost never used. Typically, $\mathrm{Re}_I > 10^4$ is required for fully turbulent conditions throughout the tank. A wide transition region between laminar and turbulent flow occurs over the range $10 < \mathrm{Re}_I < 10^4$.

The power $P$ drawn by the impeller is made dimensionless in a group called the power number:

$$\mathrm{N}_P = \frac{P}{\rho N^3 D^5} \tag{6-156}$$

Figure 6-40 shows power number vs. impeller Reynolds number for a typical configuration. The similarity to the friction factor vs. Reynolds number behavior for pipe flow is significant. In laminar flow, the power number is inversely proportional to Reynolds number, reflecting the dominance of viscous forces over inertial forces. In

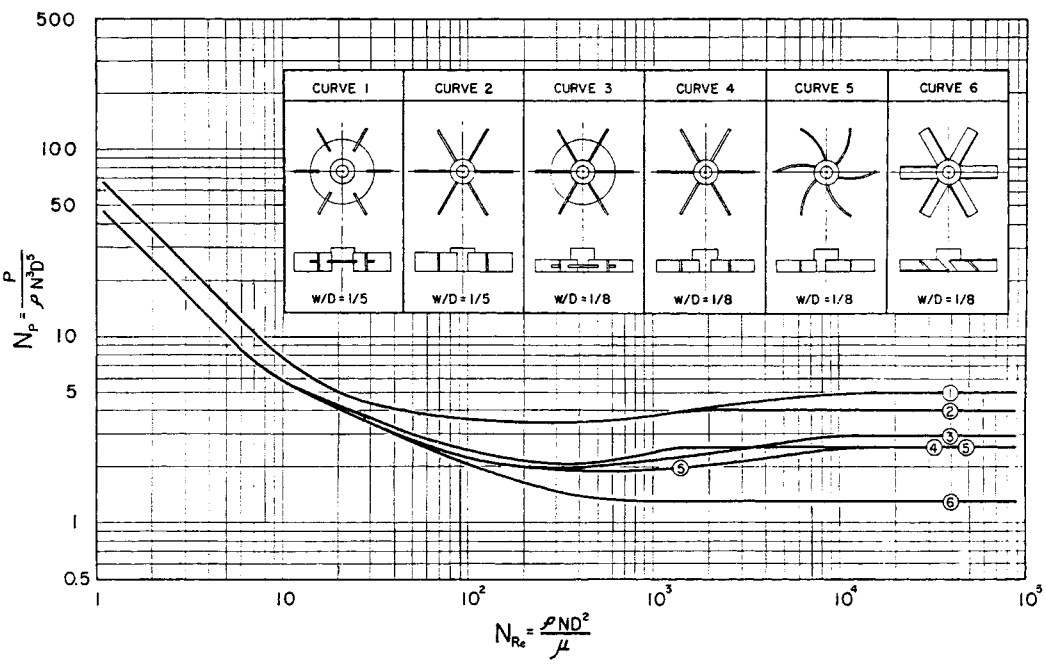

**FIG. 6-40** Dimensionless power number in stirred tanks. (*Reprinted with permission from Bates, Fondy, and Corpstein,* Ind. Eng. Chem. Process Design Develop., **2,** *310 [1963].*)

turbulent flow, where inertial forces dominate, the power number is nearly constant.

Impellers are sometimes viewed as pumping devices; the total volumetric flow rate $Q$ discharged by an impeller is made dimensionless in a pumping number:

$$N_Q = \frac{Q}{ND^3} \tag{6-157}$$

Blend time $t_b$, the time required to achieve a specified maximum standard deviation of concentration after injection of a tracer into a stirred tank, is made dimensionless by multiplying by the impeller rotational speed:

$$N_b = t_b N \tag{6-158}$$

Dimensionless pumping number and blend time are independent of Reynolds number under fully turbulent conditions. The magnitude of concentration fluctuations from the final well-mixed value in batch mixing decays exponentially with time.

The design of mixing equipment depends on the desired process result. There is often a tradeoff between operating cost, which depends mainly on power, and capital cost, which depends on agitator size and torque. For some applications bulk flow throughout the vessel is desired, while for others high local turbulence intensity is required. Multiphase systems introduce such design criteria as solids suspension and gas dispersion. In very viscous systems, helical ribbons, extruders, and other specialized equipment types are favored over turbine agitators.

**Pipeline Mixing** Mixing may be carried out with **mixing tees, inline** or **motionless mixing elements,** or in empty pipe. In the latter case, large pipe lengths may be required to obtain adequate mixing. Coaxially injected streams require lengths on the order of 100 pipe diameters. Coaxial mixing in turbulent single-phase flow is characterized by the turbulent diffusivity (eddy diffusivity) $D_E$ which determines the rate of radial mixing. Davies (*Turbulence Phenomena,* Academic, New York, 1972) provides an equation for $D_E$ which may be rewritten as

$$D_E \sim 0.015 DV\mathrm{Re}^{-0.125} \tag{6-159}$$

where $D$ = pipe diameter
$V$ = average velocity
Re = pipe Reynolds number, $DV\rho/\mu$
$\rho$ = density
$\mu$ = viscosity

Properly designed tee mixers, with due consideration given to main stream and injected stream momentum, are capable of producing high degrees of uniformity in just a few diameters. Forney (*Jet Injection for Optimum Pipeline Mixing,* in "Encyclopedia of Fluid Mechanics," vol. 2., Chap. 25, Gulf Publishing, 1986) provides a thorough discussion of tee mixing. Inline or motionless mixers are generally of proprietary commercial design, and may be selected for viscous or turbulent, single or multiphase mixing applications. They substantially reduce required pipe length for mixing.

## TUBE BANKS

Pressure drop across tube banks may not be correlated by means of a single, simple friction factor—Reynolds number curve, owing to the variety of tube configurations and spacings encountered, two of which are shown in Fig. 6-41. Several investigators have allowed for configuration and spacing by incorporating spacing factors in their friction factor expressions or by using multiple friction factor plots. Commercial computer codes for heat-exchanger design are available which include features for estimating pressure drop across tube banks.

**Turbulent Flow** The correlation by Grimison (*Trans. ASME,* **59,** 583–594 [1937]) is recommended for predicting pressure drop for turbulent flow (Re ≥ 2,000) across staggered or in-line tube banks for tube spacings [$(a/D_t)$, $(b/D_t)$] ranging from 1.25 to 3.0. The pressure drop is given by

$$\Delta p = \frac{4fN_r\rho V_{\max}^2}{2} \tag{6-160}$$

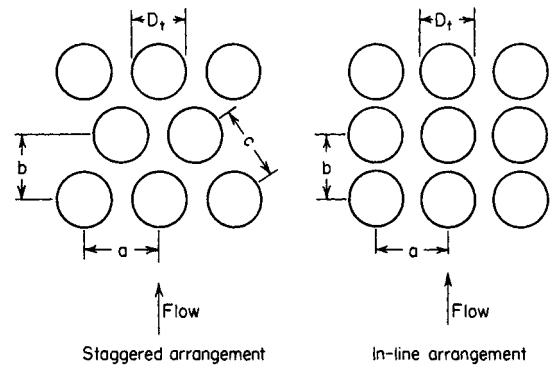

**FIG. 6-41** Tube-bank configurations.

where $f$ = friction factor
$N_r$ = number of rows of tubes in the direction of flow
$\rho$ = fluid density
$V_{\max}$ = fluid velocity through the minimum area available for flow

For banks of **staggered tubes,** the friction factor for isothermal flow is obtained from Fig. (6-42). Each "fence" (group of parametric curves) represents a particular Reynolds number defined as

$$\mathrm{Re} = \frac{D_t V_{\max}\rho}{\mu} \tag{6-161}$$

where $D_t$ = tube outside diameter and $\mu$ = fluid viscosity. The numbers along each fence represent the transverse and inflow-direction spacings. The upper chart is for the case in which the minimum area for flow is in the transverse openings, while the lower chart is for the case in which the minimum area is in the diagonal openings. In the latter case, $V_{\max}$ is based on the area of the diagonal openings and $N_r$ is the number of rows in the direction of flow minus 1. A critical comparison of this method with all the data available at the time showed an average deviation of the order of ±15 percent (Boucher and Lapple, *Chem. Eng. Prog.,* **44,** 117–134 [1948]). For tube spacings greater than 3 tube diameters, the correlation by Gunter and Shaw (*Trans. ASME,* **67,** 643–660 [1945]) can be used as an approximation. As an **approximation,** the pressure drop can be taken as 0.72 velocity head (based on $V_{\max}$ per row of tubes for tube spacings commonly encountered in practice (Lapple, et al., *Fluid and Particle Mechanics,* University of Delaware, Newark, 1954).

For banks of **in-line tubes,** $f$ for isothermal flow is obtained from Fig. 6-43. Average deviation from available data is on the order of ±15 percent. For tube spacings greater than $3D_t$, the charts of Gram, Mackey, and Monroe (*Trans. ASME,* **80,** 25–35 [1958]) can be used. As an **approximation,** the pressure drop can be taken as 0.32 velocity head (based on $V_{\max}$) per row of tubes (Lapple, et al., *Fluid and Particle Mechanics,* University of Delaware, Newark, 1954).

For turbulent flow through **shallow** tube banks, the average friction factor per row will be somewhat greater than indicated by Figs. 6-42 and 6-43, which are based on 10 or more rows depth. A 30 percent increase per row for 2 rows, 15 percent per row for 3 rows, and 7 percent per row for 4 rows can be taken as the maximum likely to be encountered (Boucher and Lapple, *Chem. Eng. Prog.,* **44,** 117–134 [1948]).

For a **single row of tubes,** the friction factor is given by Curve B in Fig. 6-44 as a function of tube spacing. This curve is based on the data of several experimenters, all adjusted to a Reynolds number of 10,000. The values should be substantially independent of Re for $1{,}000 < \mathrm{Re} < 100{,}000$.

For **extended surfaces,** which include fins mounted perpendicularly to the tubes or spiral-wound fins, pin fins, plate fins, and so on, friction data for the specific surface involved should be used. For

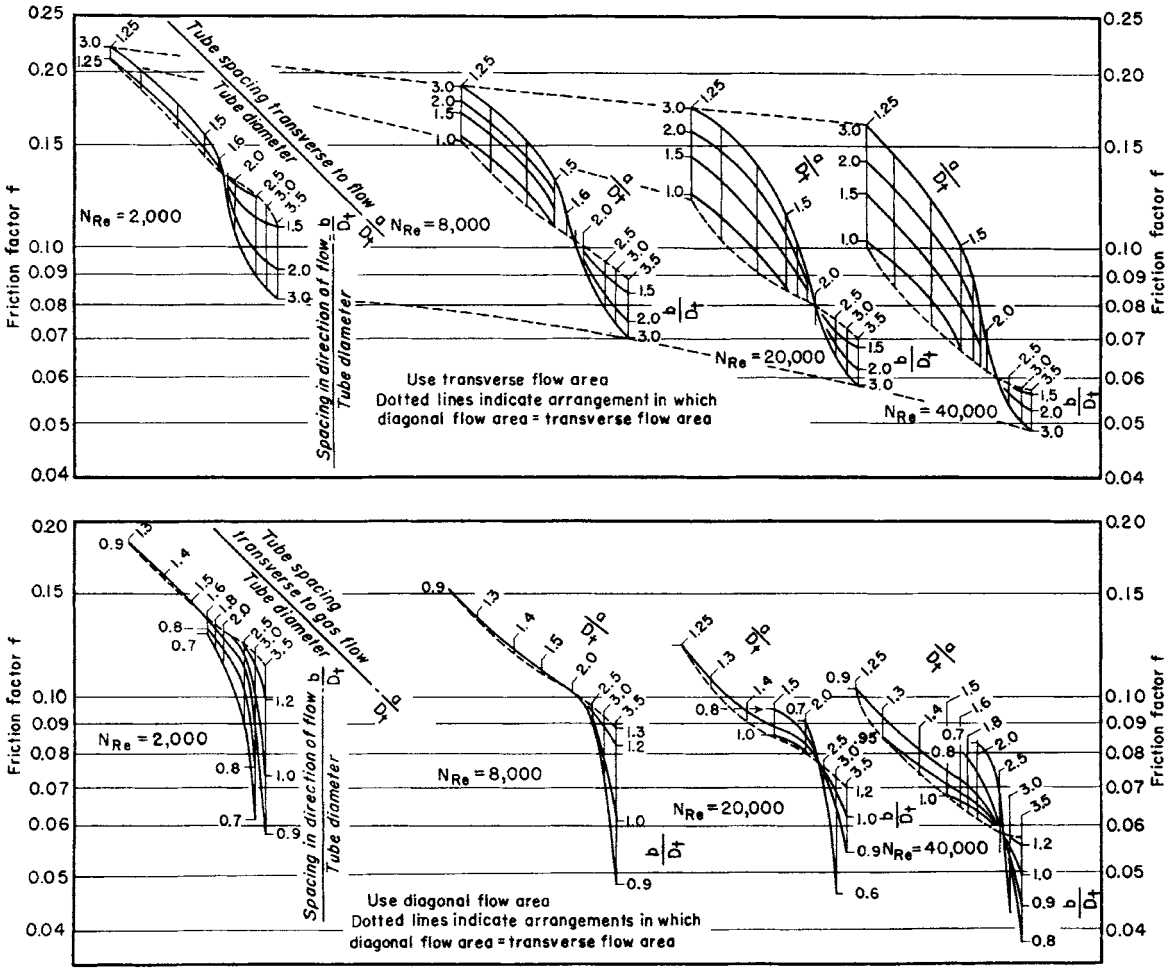

**FIG. 6-42** Upper chart: Friction factors for staggered tube banks with minimum fluid flow area in transverse openings. Lower chart: Friction factors for staggered tube banks with minimum fluid flow area in diagonal openings. (*From Grimison,* Trans. ASME, **59,** 583 [1937].)

details, see Kays and London (*Compact Heat Exchangers,* 2d ed., McGraw-Hill, New York, 1964). If specific data are unavailable, the correlation by Gunter and Shaw (*Trans. ASME,* **67,** 643–660 [1945]) may be used as an approximation.

When a large temperature change occurs in a gas flowing across a tube bundle, gas properties should be evaluated at the mean temperature

$$T_m = T_t + K\,\Delta T_{lm} \tag{6-162}$$

where $T_t$ = average tube-wall temperature
$K$ = constant
$\Delta T_{lm}$ = log-mean temperature difference between the gas and the tubes

Values of $K$ averaged from the recommendations of Chilton and Genereaux (*Trans. AIChE,* **29,** 151–173 [1933]) and Grimison (*Trans. ASME,* **59,** 583–594 [1937]) are as follows: for in-line tubes, 0.9 for cooling and –0.9 for heating; for staggered tubes, 0.75 for cooling and –0.8 for heating.

For nonisothermal flow of **liquids** across tube bundles, the friction factor is increased if the liquid is being cooled and decreased if the liquid is being heated. The factors previously given for nonisothermal flow of liquids in pipes ("Incompressible Flow in Pipes and Channels") should be used.

For two-phase gas/liquid horizontal cross flow through tube banks, the method of Diehl and Unruh (*Pet. Refiner,* **37**[10], 124–128 [1958]) is available.

**Transition Region** This region extends roughly over the range 200 < Re < 2,000. Figure 6-45 taken from Bergelin, Brown, and Doberstein (*Trans. ASME,* **74,** 953–960 [1952]) gives curves for friction factor $f_T$ for five different configurations. Pressure drop for liquid flow is given by

$$\Delta p = \frac{4 f_T N_r \rho V_{\max}^2}{2}\left(\frac{\mu_s}{\mu_b}\right)^{0.14} \tag{6-163}$$

where $N_r$ = number of major restrictions encountered in flow through the bank (equal to number of rows when minimum flow area occurs in transverse openings, and to number of rows minus 1 when it occurs in the diagonal openings); $\rho$ = fluid density; $V_{\max}$ = velocity through minimum flow area; $\mu_s$ = fluid viscosity at tube-surface temperature and $\mu_b$ = fluid viscosity at average bulk temperature. This method gives the friction factor within about ±25 percent.

**Laminar Region** Bergelin, Colburn, and Hull (*Univ. Delaware Eng. Exp. Sta. Bull.,* **2** [1950]) recommend the following equations for

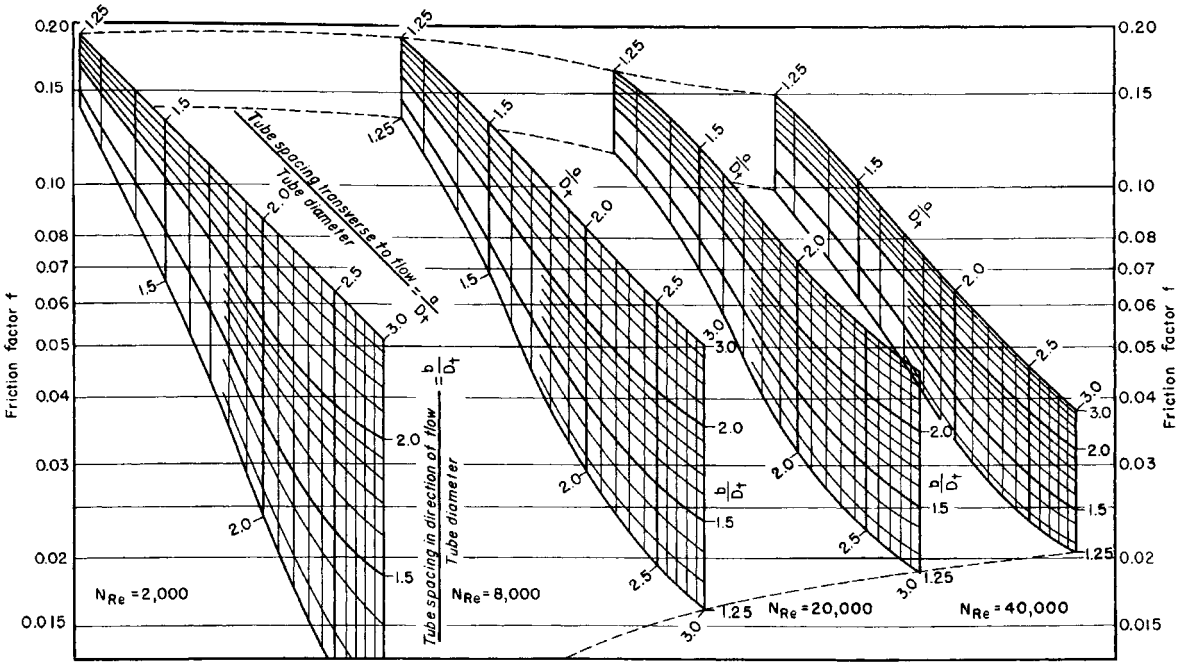

**FIG. 6-43** Friction factors for in-line tube banks. (*From Grimison,* Trans. ASME, ***59,*** *583 [1937].*)

pressure drop with laminar flow ($Re_v < 100$) of liquids across banks of plain tubes with pitch ratios $P/D_t$ of 1.25 and 1.50:

$$\Delta p = \frac{280 N_r}{Re_v}\left(\frac{D_t}{P}\right)^{1.6}\left(\frac{\mu_s}{\mu_b}\right)^m\left(\frac{\rho V_{max}^2}{2}\right) \tag{6-164}$$

$$m = \frac{0.57}{(Re_v)^{0.25}} \tag{6-165}$$

where $Re_v = D_v V_{max}\rho/\mu_b$; $D_v$ = volumetric hydraulic diameter [(4 × free-bundle volume)/(exposed surface area of tubes)]; $P$ = pitch (= $a$ for in-line arrangements, = $a$ or $c$ [whichever is smaller] for staggered arrangements), and other quantities are as defined following Eq. (6-163). Bergelin, et al. (ibid.) show that pressure drop per row is independent of the number of rows in the bank with laminar flow. The pressure drop is predicted within about ±25 percent.

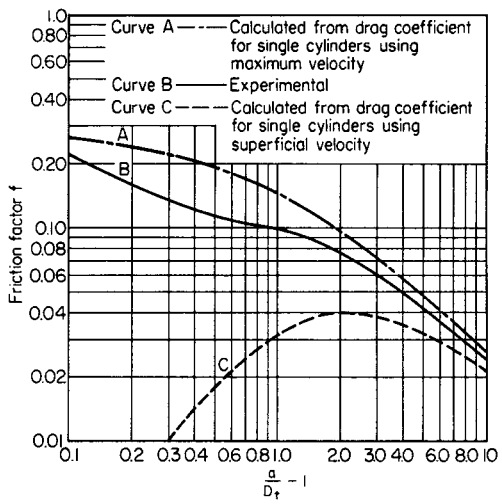

**FIG. 6-44** Friction factors vs. transverse spacing for single row of tubes. (*From Boucher and Lapple,* Chem. Eng. Prog., ***44,*** *117 [1948].*)

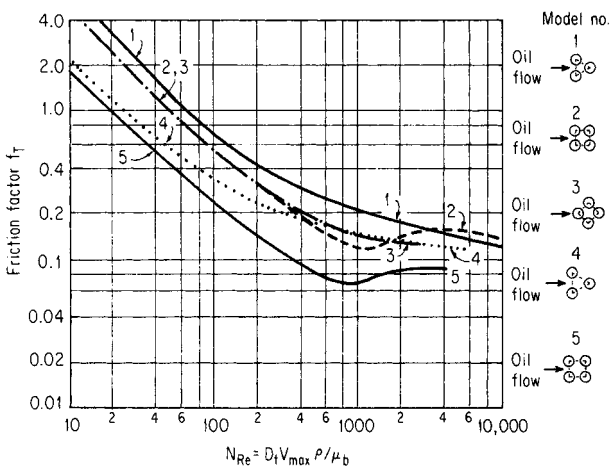

| Model | Rows | $D_t$, in | Pitch/$D_t$ |
|---|---|---|---|
| 1 | 10 | ¾ | 1.25 |
| 2 | 10 | ¾ | 1.25 |
| 3 | 14 | ¾ | 1.25 |
| 4 | 10 | ¾ | 1.50 |
| 5 | 10 | ¾ | 1.50 |

**FIG. 6-45** Friction factors for transition region flow across tube banks. (Pitch is the minimum center-to-center tube spacing.) (*From Bergelin, Brown, and Doberstein,* Trans. ASME, ***74,*** *953 [1952].*)

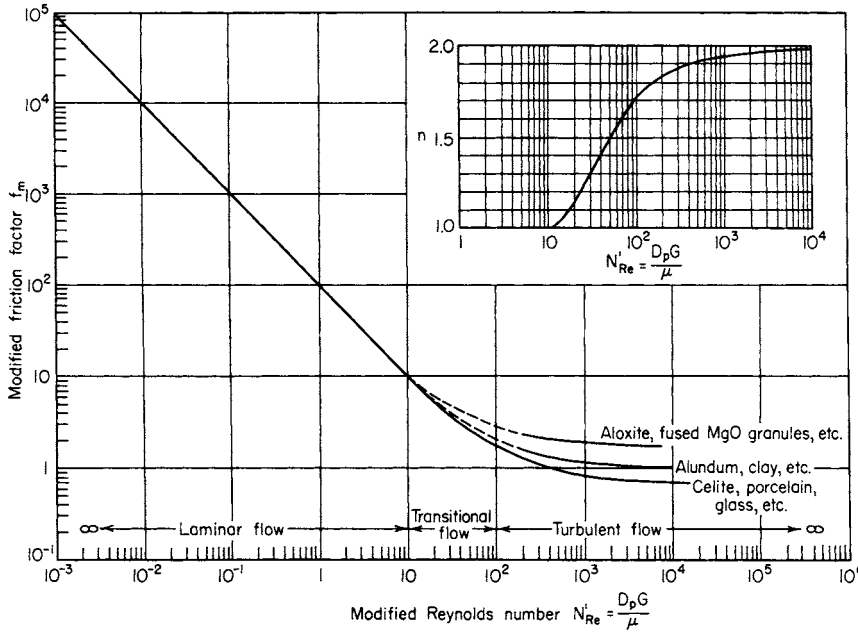

**FIG. 6-46** Friction factor for beds of solids. (*From Leva,* Fluidization, *McGraw-Hill, New York, 1959, p. 49.*)

The validity of extrapolating Eq. (6-164) to pitch ratios larger than 1.50 is unknown. The correlation of Gunter and Shaw (*Trans. ASME,* **67,** 643–660 [1945]) may be used as an approximation in such cases.

For laminar flow of non-Newtonian fluids across tube banks, see Adams and Bell (*Chem. Eng. Prog.,* **64,** *Symp. Ser.,* **82,** 133–145 [1968]).

Flow-induced **tube vibration** occurs at critical fluid velocities through tube banks, and is to be avoided because of the severe damage that can result. Methods to predict and correct vibration problems may be found in Eisinger (*Trans. ASME J. Pressure Vessel Tech.,* **102,** 138–145 [May 1980]) and Chen (*J. Sound Vibration,* **93,** 439–455 [1984]).

## BEDS OF SOLIDS

**Fixed Beds of Granular Solids** Pressure-drop prediction is complicated by the variety of granular materials and of their packing arrangement. For flow of a **single incompressible fluid** through an incompressible bed of granular solids, the pressure drop may be estimated by the correlation given in Fig. 6-46 (Leva, *Chem. Eng.,* **56**[5], 115–117 [1949]), or *Fluidization,* McGraw-Hill, New York, 1959). The modified friction factor and Reynolds number are defined by

$$f_m \equiv \frac{D_p \rho \phi_s^{3-n} \epsilon^3 |\Delta p|}{2G^2 L (1-\epsilon)^{3-n}} \tag{6-166}$$

$$\mathrm{Re}' \equiv \frac{D_p G}{\mu} \tag{6-167}$$

where $-\Delta p$ = pressure drop
$L$ = depth of bed
$D_p$ = average particle diameter, defined as the diameter of a sphere of the same volume as the particle
$\epsilon$ = void fraction
$n$ = exponent given in Fig. 6-46 as a function of Re′
$\phi_s$ = shape factor defined as the area of sphere of diameter $D_p$ divided by the actual surface area of the particle
$G$ = fluid superficial mass velocity based on the empty chamber cross section
$\rho$ = fluid density
$\mu$ = fluid viscosity

As for any incompressible single-phase flow, the equivalent pressure $P = p + \rho g z$ where $g$ = acceleration of gravity $z$ = elevation, may be used in place of $p$ to account for gravitational effects in flows with vertical components.

In creeping flow (Re′ < 10),

$$f_m = \frac{100}{\mathrm{Re}'} \tag{6-168}$$

At high Reynolds numbers the friction factor becomes nearly constant, approaching a value of the order of unity for most packed beds.

In terms of $S$, particle surface area per unit volume of bed,

$$D_p = \frac{6(1-\epsilon)}{\phi_s S} \tag{6-169}$$

**Porous Media** Packed beds of granular solids are one type of the general class referred to as **porous media,** which include geological formations such as petroleum reservoirs and aquifers, manufactured materials such as sintered metals and porous catalysts, burning coal or char particles, and textile fabrics, to name a few. Pressure drop for incompressible flow across a porous medium has the same qualitative behavior as that given by Leva's correlation in the preceding. At low Reynolds numbers, viscous forces dominate and pressure drop is proportional to fluid viscosity and superficial velocity, and at high Reynolds numbers, pressure drop is proportional to fluid density and to the square of superficial velocity.

Creeping flow (Re′ <~ 1) through porous media is often described in terms of the **permeability** $k$ and Darcy's law:

$$\frac{-\Delta P}{L} = \frac{\mu}{k} V \tag{6-170}$$

where $V$ = superficial velocity. The SI units for permeability are $m^2$. Creeping flow conditions generally prevail in geological porous media. For **multidimensional flows** through **isotropic** porous media, the superficial velocity **V** and pressure gradient $\nabla P$ vectors replace the corresponding one-dimensional variables in Eq. (6-170).

$$\nabla P = -\frac{\mu}{k} \mathbf{V} \tag{6-171}$$

For isotropic homogeneous porous media (uniform permeability and porosity), the pressure for creeping incompressible single phase-flow may be shown to satisfy the LaPlace equation:

$$\nabla^2 P = 0 \tag{6-172}$$

For **anisotropic** or **oriented** porous media, as are frequently found in geological media, permeability varies with direction and a **permeability tensor K,** with nine components $K_{ij}$ giving the velocity compenent in the $i$ direction due to a pressure gradient in the $j$ direction, may be introduced. For further information, see Slattery (*Momentum, Energy and Mass Transfer in Continua,* Krieger, Huntington, New York, 1981, pp. 193–218). See also Dullien (*Chem. Eng. J.* [*Laussanne*], **10,** 1,034 [1975]) for a review of pressure-drop methods in single-phase flow. Solutions for Darcy's law for several geometries of interest in petroleum reservoirs and aquifers, for both incompressible and compressible flows, are given in Craft and Hawkins (*Applied Petroleum Reservoir Engineering,* Prentice-Hall, Englewood Cliffs, N.J., 1959). See also Todd (*Groundwater Hydrology,* 2nd ed., Wiley, New York, 1980).

For granular solids of **mixed sizes** the average particle diameter may be calculated as

$$\frac{1}{D_p} = \sum_i \frac{x_i}{D_{p,i}} \tag{6-173}$$

where $x_i$ = weight fraction of particles of size $D_{p,i}$.

For **isothermal compressible flow** of a gas with constant compressibility factor Z through a packed bed of granular solids, an equation similar to Eq. (6-114) for pipe flow may be derived:

$$p_1^2 - p_2^2 = \frac{2ZRG^2T}{M_w}\left[\ln\frac{v_2}{v_1} + \frac{2f_mL(1-\epsilon)^{3-n}}{\phi_s^{3-n}\epsilon^3 D_p}\right] \tag{6-174}$$

where $p_1$ = upstream absolute pressure
$p_2$ = downstream absolute pressure
$R$ = gas constant
$T$ = absolute temperature
$M_w$ = molecular weight
$v_1$ = upstream specific volume of gas
$v_2$ = downstream specific volume of gas

For creeping flow of **power law** non-Newtonian fluids, the method of Christopher and Middleton (*Ind. Eng. Chem. Fundam.,* **4,** 422–426 [1965]) may be used:

$$-\Delta p = \frac{150HLV^n(1-\epsilon)^2}{D_p^2\phi_s^2\epsilon^3} \tag{6-175}$$

$$H = \frac{K}{12}\left(9 + \frac{3}{n}\right)^n\left[\frac{D_p^2\phi_s^2\epsilon^4}{(1-\epsilon)^2}\right]^{(1-n)/2} \tag{6-176}$$

where $V = G/\rho$ = superficial velocity, $K$, $n$ = power law material constants, and all other variables are as defined in Eq. (6-166). This correlation is supported by data from Christopher and Middleton (ibid.), Gregory and Griskey (*AIChE J.,* **13,** 122–125 [1967]), Yu, Wen, and Bailie (*Can. J. Chem. Eng.,* **46,** 149–154 [1968]), Siskovic, Gregory, and Griskey (*AIChE J.,* **17,** 176–187 [1978]), Kemblowski and Mertl (*Chem. Eng. Sci.,* **29,** 213–223 [1974]), and Kemblowski and Dziuminski (*Rheol. Acta,* **17,** 176–187 [1978]). The measurements cover the range $n = 0.50$ to 1.60, and modified Reynolds number $\mathrm{Re}' = 10^{-8}$ to 10, where

$$\mathrm{Re}' = \frac{D_pV^{2-n}\rho}{H} \tag{6-177}$$

For the case $n = 1$ (Newtonian fluid), Eqs. (6-175) and (6-176) give a pressure drop 25 percent less than that given by Eqs. (6-166) through (6-168).

For **viscoelastic fluids** see Marshall and Metzner (*Ind. Eng. Chem. Fundam.,* **6,** 393–400 [1967]), Siskovic, Gregory, and Griskey (*AIChE J.,* **13,** 122–125 [1967]) and Kemblowski and Dziubinski (*Rheol. Acta,* **17,** 176–187 [1978]).

For gas flow through porous media with small pore diameters, the slip flow and molecular flow equations previously given (see the "Vacuum Flow" subsection) may be applied when the pore is of the same or smaller order as the mean free path, as described by Monet and Vermeulen (*Chem. Eng. Prog.,* **55,** *Symp. Ser.,* **25** [1959]).

**Tower Packings** For the flow of a **single fluid** through a bed of tower packing, pressure drop may be estimated using the preceding methods. See also Sec. 14 of this *Handbook.* For **countercurrent gas/liquid flow** in commercial tower packings, both structured and unstructured, several sources of data and correlations for pressure drop and flooding are available. See, for example, Strigle (*Random Packings and Packed Towers, Design and Applications,* Gulf Publishing, Houston, 1989; *Chem. Eng. Prog.,* **89**[8], 79–83 [August 1993]), Hughmark (*Ind. Eng. Chem. Fundam.,* **25,** 405–409 [1986]), Chen (*Chem. Eng. Sci.,* **40,** 2139–2140 [1985]), Billet and Mackowiak (*Chem. Eng. Technol.,* **11,** 213–217 [1988]), Krehenwinkel and Knapp (*Chem. Eng. Technol.,* **10,** 231–242 [1987]), Mersmann and Deixler (*Ger. Chem. Eng.,* **9,** 265–276 [1986]), and Robbins (*Chem. Eng. Progr.,* **87**[5], 87–91 [May 1991]). Data and correlations for flooding and pressure drop for structured packings are given by Fair and Bravo (*Chem. Eng. Progr.,* **86**[1], 19–29 [January 1990]).

**Fluidized Beds** When gas or liquid flows upward through a vertically unconstrained bed of particles, there is a minimum fluid velocity at which the particles will begin to move. Above this minimum velocity, the bed is said to be *fluidized.* Fluidized beds are widely used, in part because of their excellent mixing and heat and mass transfer characteristics. See Sec. 17 of this *Handbook* for detailed information.

## BOUNDARY LAYER FLOWS

Boundary layer flows are a special class of flows in which the flow far from the surface of an object is inviscid, and the effects of viscosity are manifest only in a thin region near the surface where steep velocity gradients occur to satisfy the no-slip condition at the solid surface. The thin layer where the velocity decreases from the inviscid, potential flow velocity to zero (relative velocity) at the solid surface is called the *boundary layer.* The thickness of the boundary layer is indefinite because the velocity asymptotically approaches the free-stream velocity at the outer edge. The boundary layer thickness is conventionally taken to be the distance for which the velocity equals 0.99 times the free-stream velocity. The boundary layer may be either laminar or turbulent. Particularly in the former case, the equations of motion may be simplified by scaling arguments. Schlichting (*Boundary Layer Theory,* 8th ed., McGraw-Hill, New York, 1987) is the most comprehensive source for information on boundary layer flows.

**Flat Plate, Zero Angle of Incidence** For flow over a wide, thin flat plate at zero angle of incidence with a uniform free-stream velocity, as shown in Fig. 6-47, the **critical Reynolds number** at which the boundary layer becomes turbulent is normally taken to be

$$\mathrm{Re}_x = \frac{xV\rho}{\mu} = 500{,}000 \tag{6-178}$$

where $V$ = free-stream velocity
$\rho$ = fluid density
$\mu$ = fluid viscosity
$x$ = distance from leading edge of the plate

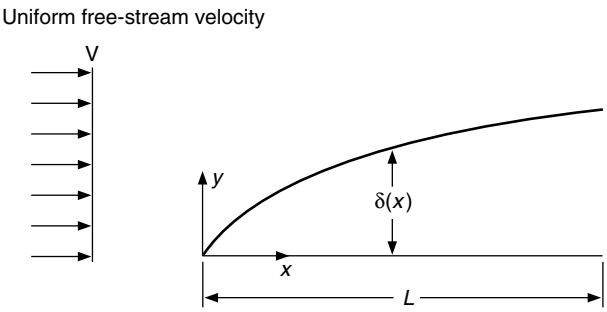

**FIG. 6-47** Boundary layer on a flat plate at zero angle of incidence.

However, the transition Reynolds number depends on free-stream turbulence and may range from $3 \times 10^5$ to $3 \times 10^6$. The **laminar boundary layer** thickness $\delta$ is a function of distance from the leading edge:

$$\delta \approx 5.0x\mathrm{Re}_x^{-0.5} \tag{6-179}$$

The total drag on the plate of length $L$ and width $b$ for a laminar boundary layer, including the drag on both surfaces, is:

$$F_D = 1.328bL\rho V^2\mathrm{Re}_L^{-0.5} \tag{6-180}$$

For **non-Newtonian power law fluids** (Acrivos, Shah, and Peterson, *AIChE J.*, **6,** 312–317 [1960]; Hsu, *AIChE J.*, **15,** 367–370 [1969]),

$$F_D = CbL\rho V^2\mathrm{Re}_L'^{-1/(1+n)} \tag{6-181}$$

| $n$ = | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | 0.8 | 0.9 | 1 |
|---|---|---|---|---|---|---|---|---|---|
| $C$ = | 2.075 | 1.958 | 1.838 | 1.727 | 1.627 | 1.538 | 1.460 | 1.390 | 1.328 |

where $\mathrm{Re}'_L = \rho V^{2-n}L^n/K$ and $K$ and $n$ are the power law material constants (see Eq. [6-4]).

For a **turbulent boundary layer,** the thickness may be estimated as

$$\delta \approx 0.37x\mathrm{Re}_x^{-0.2} \tag{6-182}$$

and the total drag force on both sides of the plate of length $L$ is

$$F_D = \left[\frac{0.455}{(\log \mathrm{Re}_L)^{2.58}} - \frac{1{,}700}{\mathrm{Re}_L}\right]\rho bLV^2 \qquad 5 \times 10^5 < \mathrm{Re}_L < 10^9 \tag{6-183}$$

Here the second term accounts for the laminar leading edge of the boundary layer and assumes that the critical Reynolds number is 500,000.

**Cylindrical Boundary Layer** Laminar boundary layers on cylindrical surfaces, with flow parallel to the cylinder axis, are described by Glauert and Lighthill (*Proc. R. Soc.* [*London*], **230A,** 188–203 [1955]), Jaffe and Okamura (*Z. Angew. Math. Phys.*, **19,** 564–574 [1968]), and Stewartson (*Q. Appl. Math.*, **13,** 113–122 [1955]). For a turbulent boundary layer, the total drag may be estimated as

$$F_D = \overline{c_j}\pi rL\rho V^2 \tag{6-184}$$

where $r$ = cylinder radius, $L$ = cylinder length, and the average friction coefficient is given by (White, *J. Basic Eng.*, **94,** 200–206 [1972])

$$\overline{c_j} = 0.0015 + \left[0.30 + 0.015\left(\frac{L}{r}\right)^{0.4}\right]\mathrm{Re}_L^{-1/3} \tag{6-185}$$

for $\mathrm{Re}_L = 10^6$ to $10^9$ and $L/r < 10^6$.

**Continuous Flat Surface** Boundary layers on continuous surfaces drawn through a stagnant fluid are shown in Fig. 6-48. Figure 6-48*a* shows the continuous flat surface (Sakiadis, *AIChE J.*, **7,** 26–28, 221–225, 467–472 [1961]). The critical Reynolds number for transition to turbulent flow may be greater than the 500,000 value for the finite flat-plate case discussed previously (Tsou, Sparrow, and Kurtz, *J. Fluid Mech.*, **26,** 145–161 [1966]). For a laminar boundary layer, the thickness is given by

$$\delta = 6.37x\mathrm{Re}_x^{-0.5} \tag{6-186}$$

and the total drag exerted on the two surfaces is

$$F_D = 1.776bL\rho V^2\mathrm{Re}_L^{-0.5} \tag{6-187}$$

The total flow rate of fluid entrained by the surface is

$$q = 3.232bLV\mathrm{Re}_L^{-0.5} \tag{6-188}$$

The theoretical velocity field was experimentally verified by Tsou, Sparrow, and Goldstein (*Int. J. Heat Mass Transfer,* **10,** 219–235 [1967]) and Szeri, Yates, and Hai (*J. Lubr. Technol.*, **98,** 145–156 [1976]). For **non-Newtonian power law fluids** see Fox, Erickson, and Fan (*AIChE J.*, **15,** 327–333 [1969]).

For a turbulent boundary layer, the thickness is given by

$$\delta = 1.01x\mathrm{Re}_x^{-0.2} \tag{6-189}$$

and the total drag on both sides by

$$F_D = 0.056bL\rho V^2\mathrm{Re}_L^{-0.2} \tag{6-190}$$

and the total entrainment by

$$q = 0.252bLV\mathrm{Re}_L^{-0.2} \tag{6-191}$$

When the laminar boundary layer is a significant part of the total length of the object, the total drag should be corrected by subtracting a calculated turbulent drag for the length of the laminar section and then adding the laminar drag for the laminar section. Tsou, Sparrow, and Goldstein (*Int. J. Heat Mass Transfer,* **10,** 219–235 [1967]) give an improved analysis of the turbulent boundary layer; their data indicate that Eq. (6-190) underestimates the drag by about 15 percent.

**Continuous Cylindrical Surface** The continuous surface shown in Fig. 6-48*b* is applicable, for example, for a wire drawn through a stagnant fluid (Sakiadis, *AIChE J.*, **7,** 26–28, 221–225, 467–472 [1961]); Vasudevan and Middleman, *AIChE J.*, **16**, 614 [1970]). The critical-length Reynolds number for transition is $\mathrm{Re}_x$ = 200,000. The laminar boundary layer thickness, total drag, and entrainment flow rate may be obtained from Fig. 6-49. The normalized boundary layer thickness and integral friction coefficient are from Vasudevan and Middleman, who used a similarity solution of the boundary layer equations. The drag force over a length $x$ is given by

$$F_D = \overline{C_f}^x \frac{\rho V^2}{2} 2\pi r_o \tag{6-192}$$

The entrainment flow rate is from Sakiadis, who used an integral momentum approximation rather than the exact similarity solution.

$$q = V\Delta \tag{6-193}$$

Further laminar boundary layer analysis is given by Crane (*Z. Angew. Math. Phys.*, **23,** 201–212 [1972]).

For a turbulent boundary layer, the total drag may be roughly estimated using Eqs. (6-184) and (6-185) for finite cylinders. Measured forces by Kwon and Prevorsek (*J. Eng. Ind.*, **101,** 73–79 [1979]) are greater than predicted this way.

The laminar boundary layer on **deforming continuous surfaces** with velocity varying with axial position is discussed by Vleggaar (*Chem. Eng. Sci.*, **32,** 1517–1525 [1977] and Crane (*Z. Angew. Math. Phys.*, **26,** 619–622 [1975]).

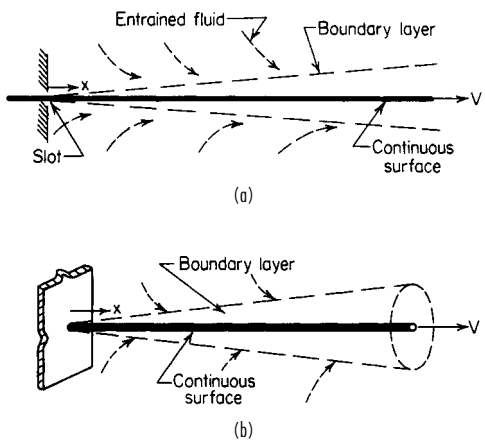

**FIG. 6-48** Continuous surface: (*a*) continuous flat surface, (*b*) continuous cylindrical surface. (*From Sakiadis,* Am. Inst. Chem. Eng. J., **7,** *221, 467 [1961].*)

## VORTEX SHEDDING

When fluid flows past objects or through orifices or similar restrictions, vortices may periodically be shed downstream. Objects such as smokestacks, chemical-processing columns, suspended pipelines, and electrical transmission lines can be subjected to damaging vibrations and forces due to the vortices, especially if the shedding frequency is close to a natural vibration frequency of the object. The shedding can

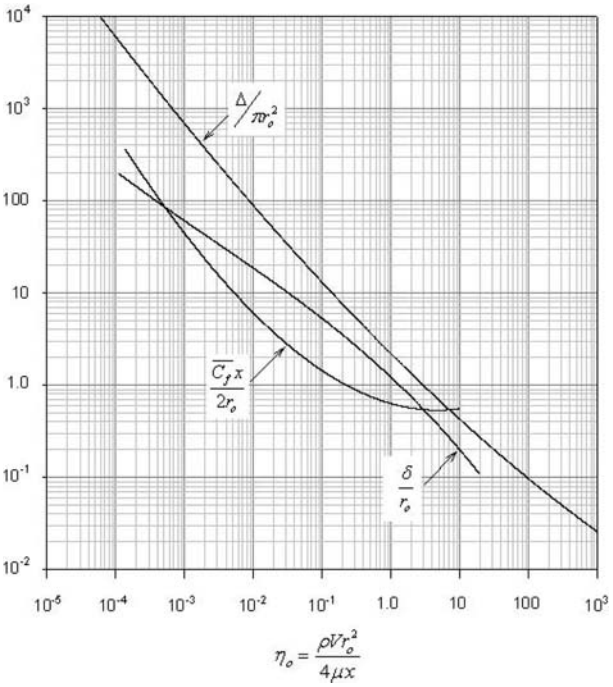

**FIG 6-49** Boundary layer parameters for continuous cylindrical surfaces. ($\Delta/\pi r_o^2$ *is from Sakiadis,* Am. Inst. Chem. Engr. J., **7,** *467 [1961];* $\overline{C_f}x/2r_o$ and $\delta/r_o$ *are from Vasudevan and Middleman,* Am. Inst. Chem. Eng. J., ***16****, 614 [1970].*)

also produce sound. See Krzywoblocki (*Appl. Mech. Rev.,* **6,** 393–397 [1953]) and Marris (*J. Basic Eng.,* **86,** 185–196 [1964]).

Development of a vortex street, or *von Kármán vortex street* is shown in Fig. 6-50. Discussions of the vortex street may be found in Panton (pp. 387–393). The Reynolds number is

$$\mathrm{Re} = \frac{DV\rho}{\mu} \tag{6-194}$$

where $D$ = diameter of cylinder or effective width of object
$V$ = free-stream velocity
$\rho$ = fluid density
$\mu$ = fluid viscosity

For flow past a cylinder, the vortex street forms at Reynolds numbers above about 40. The vortices initially form in the wake, the point of formation moving closer to the cylinder as Re is increased. At a Reynolds number of 60 to 100, the vortices are formed from eddies attached to the cylinder surface. The vortices move at a velocity slightly less than $V$. The frequency of vortex shedding $f$ is given in terms of the Strouhal number, which is approximately constant over a wide range of Reynolds numbers.

$$\mathrm{St} \equiv \frac{fD}{V} \tag{6-195}$$

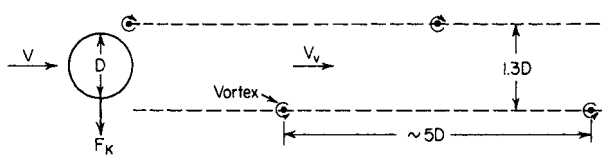

**FIG. 6-50** Vortex street behind a cylinder.

For $40 < \mathrm{Re} < 200$ the vortices are laminar and the Strouhal number has a nearly constant value of 0.2 for flow past a cylinder. Between Re = 200 and 400 the Strouhal number is no longer constant and the wake becomes irregular. Above about Re = 400 the vortices become turbulent, the wake is once again stable, and the Strouhal number remains constant at about 0.2 up to a Reynolds number of about $10^5$. Above $\mathrm{Re} = 10^5$ the vortex shedding is difficult to see in flow visualization experiments, but velocity measurements still show a strong spectral component at St = 0.2 (Panton, p. 392). Experimental data suggest that the vortex street disappears over the range $5 \times 10^5 < \mathrm{Re} < 3.5 \times 10^6$, but is reestablished at above $3.5 \times 10^6$ (Schlichting).

Vortex shedding exerts alternating lateral forces on a cylinder, perpendicular to the flow direction. Such forces may lead to severe vibration or mechanical failure of cylindrical elements such as heat-exchanger tubes, transmission lines, stacks, and columns when the vortex shedding frequency is close to resonant bending frequency. According to Den Hartog (*Proc. Nat. Acad. Sci.,* **40,** 155–157 [1954]), the vortex shedding and cylinder vibration frequency will shift to the resonant frequency when the calculated shedding frequency is within 20 percent of the resonant frequency. The well-known Tacoma Narrows bridge collapse resulted from resonance between a torsional oscillation and vortex shedding (Panton, p. 392). Spiral strakes are sometimes installed on tall stacks so that vortices at different axial positions are not shed simultaneously. The alternating lateral force $F_K$, sometimes called the *von Kármán force,* is given by (Den Hartog, *Mechanical Vibrations,* 4th ed., McGraw-Hill, New York, 1956, pp. 305–309):

$$F_K = C_K A \frac{\rho V^2}{2} \tag{6-196}$$

where $C_K$ = von Kármán coefficient
$A$ = projected area perpendicular to the flow
$\rho$ = fluid density
$V$ = free-stream fluid velocity

For a cylinder, $C_K = 1.7$. For a vibrating cylinder, the effective projected area exceeds, but is always less than twice, the actual cylinder projected area (Rouse, *Engineering Hydraulics,* Wiley, New York, 1950).

The following references pertain to discussions of vortex shedding in specific structures: steel stacks (Osker and Smith, *Trans. ASME,* **78,** 1381–1391 [1956]; Smith and McCarthy, *Mech. Eng.,* **87,** 38–41 [1965]); chemical-processing columns (Freese, *J. Eng. Ind.,* **81,** 77–91 [1959]); heat exchangers (Eisinger, *Trans. ASME J. Pressure Vessel Tech.,* **102,** 138–145 [May 1980]; Chen, *J. Sound Vibration,* **93,** 439–455 [1984]; Gainsboro, *Chem. Eng. Prog.,* **64**[3], 85–88 [1968]; "Flow-Induced Vibration in Heat Exchangers," *Symp. Proc.,* ASME, New York, 1970); suspended pipe lines (Baird, *Trans. ASME,* **77,** 797–804 [1955]); and suspended cable (Steidel, *J. Appl. Mech.,* **23,** 649–650 [1956]).

## COATING FLOWS

In coating flows, liquid films are entrained on moving solid surfaces. For general discussions, see Ruschak (*Ann. Rev. Fluid Mech.,* **17,** 65–89 [1985]), Cohen and Gutoff (*Modern Coating and Drying Technology,* VCH Publishers, New York, 1992), and Middleman (*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977). It is generally important to control the thickness and uniformity of the coatings.

In **dip coating,** or free withdrawal coating, a solid surface is withdrawn from a liquid pool, as shown in Fig. 6-51. It illustrates many of the features found in other coating flows, as well. Tallmadge and Gutfinger (*Ind. Eng. Chem.,* **59**[11], 19–34 [1967]) provide an early review of the theory of dip coating. The coating flow rate and film thickness are controlled by the withdrawal rate and the flow behavior in the meniscus region. For a withdrawal velocity $V$ and an angle of inclination from the horizontal $\phi$, the film thickness $h$ may be

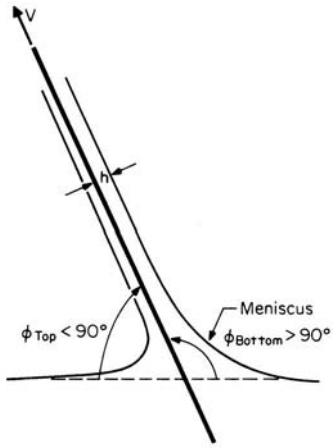

**FIG. 6-51** Dip coating.

estimated for low withdrawal velocities by

$$h\left(\frac{\rho g}{\sigma}\right)^{1/2} = \frac{0.944}{(1-\cos\phi)^{1/2}}\,\mathrm{Ca}^{2/3} \tag{6-197}$$

where $g$ = acceleration of gravity
$\mathrm{Ca} = \mu V/\sigma$ = capillary number
$\mu$ = viscosity
$\sigma$ = surface tension

Equation (6-197) is asymptotically valid as $\mathrm{Ca} \to 0$ and agrees with experimental data up to capillary numbers in the range of 0.01 to 0.03. In practice, where high production rates require high withdrawal speeds, capillary numbers are usually too large for Eq. (6-197) to apply. Approximate analytical methods for larger capillary numbers have been obtained by numerous investigators, but none appears wholly satisfactory, and some are based on questionable assumptions (Ruschak, *Ann. Rev. Fluid Mech.*, **17,** 65–89 [1985]). With the availability of high-speed computers and the development of the field of computational fluid dynamics, numerical solutions accounting for two-dimensional flow aspects, along with gravitational, viscous, inertial, and surface tension forces are now the most effective means to analyze coating flow problems.

Other common coating flows include premetered flows, such as **slide** and **curtain coating,** where the film thickness is an independent parameter that may be controlled within limits, and the curvature of the mensiscus adjusts accordingly; the closely related **blade coating;** and **roll coating** and **extrusion coating.** See Ruschak (ibid.), Cohen and Gutoff (*Modern Coating and Drying Technology,* VCH Publishers, New York, 1992), and Middleman (*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977). For dip coating of wires, see Taughy (*Int. J. Numerical Meth. Fluids,* **4,** 441–475 [1984]).

Many coating flows are subject to instabilities that lead to unacceptable coating defects. Three-dimensional flow instabilities lead to such problems as **ribbing.** Air entrainment is another common defect.

## FALLING FILMS

**Minimum Wetting Rate** The minimum liquid rate required for complete wetting of a vertical surface is about 0.03 to 0.3 kg/m · s for water at room temperature. The minimum rate depends on the geometry and nature of the vertical surface, liquid surface tension, and mass transfer between surrounding gas and the liquid. See Ponter, et al. (*Int. J. Heat Mass Transfer,* **10,** 349–359 [1967]; *Trans. Inst. Chem. Eng.* [*London*], **45,** 345–352 [1967]), Stainthorp and Allen (*Trans. Inst. Chem. Eng.* [*London*], **43,** 85–91 [1967]) and Watanabe, et al. (*J. Chem. Eng.* [*Japan*], **8**[1], 75 [1975]).

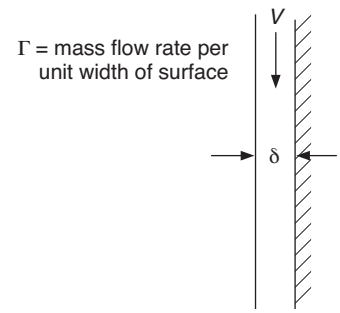

**FIG. 6-52** Falling film.

**Laminar Flow** For films falling down **vertical flat surfaces,** as shown in Fig. 6-52, or vertical tubes with small film thickness compared to tube radius, laminar flow conditions prevail for Reynolds numbers less than about 2,000, where the Reynolds number is given by

$$\mathrm{Re} = \frac{4\Gamma}{\mu} \tag{6-198}$$

where $\Gamma$ = liquid mass flow rate per unit width of surface and $\mu$ = liquid viscosity. For a flat film surface, the following equations may be derived. The film thickness $\delta$ is

$$\delta = \left(\frac{3\Gamma\mu}{\rho^2 g}\right)^{1/3} \tag{6-199}$$

The average film velocity is

$$V = \frac{\Gamma}{\rho\delta} = \frac{g\rho\delta^2}{3\mu} \tag{6-200}$$

The downward velocity profile $u(x)$ where $x = 0$ at the solid surface and $x = \delta$ at the liquid/gas interface is given by

$$u = 1.5V\left[\frac{2x}{\delta} - \left(\frac{x}{\delta}\right)^2\right] \tag{6-201}$$

These equations assume that there is no drag force at the gas/liquid interface, such as would be produced by gas flow. For a flat surface **inclined** at an angle $\theta$ with the horizontal, the preceding equations may be modified by replacing $g$ by $g \sin\theta$. For films falling inside vertical tubes with film thickness up to and including the full pipe radius, see Jackson (*AIChE J.,* **1,** 231–240 [1955]).

These equations have generally given good agreement with experimental results for low-viscosity liquids (<0.005 Pa · s) (< 5 cP) whereas Jackson (ibid.) found film thicknesses for higher-viscosity liquids (0.01 to 0.02 Pa·s (10 to 20 cP) were significantly less than predicted by Eq. (6-197). At Reynolds numbers of 25 or greater, **surface waves** will be present on the liquid film. West and Cole (*Chem. Eng. Sci.,* **22,** 1388–1389 [1967]) found that the surface velocity $u(x = \delta)$ is still within ±7 percent of that given by Eq. (6-201) even in wavy flow.

For laminar non-Newtonian film flow, see Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977, p. 215, 217), Astarita, Marrucci, and Palumbo (*Ind. Eng. Chem. Fundam.,* **3,** 333–339 [1964]) and Cheng (*Ind. Eng. Chem. Fundam.,* **13,** 394–395 [1974]).

**Turbulent Flow** In turbulent flow, Re > 2,000, for vertical surfaces, the film thickness may be estimated to within ±25 percent using

$$\delta = 0.304\left(\frac{\Gamma^{1.75}\mu^{0.25}}{\rho^2 g}\right)^{1/3} \tag{6-202}$$

Replace $g$ by $g \sin \theta$ for a surface inclined at angle $\theta$ to the horizontal. The average film velocity is $V = \Gamma/\rho\delta$.

Tallmadge and Gutfinger (*Ind. Eng. Chem.*, **59**[11], 19–34 [1967]) discuss prediction of drainage rates from liquid films on flat and cylindrical surfaces.

**Effect of Surface Traction** If a drag is exerted on the surface of the film because of motion of the surrounding fluid, the film thickness will be reduced or increased, depending upon whether the drag acts with or against gravity. Thomas and Portalski (*Ind. Eng. Chem.*, **50,** 1081–1088 [1958]), Dukler (*Chem. Eng. Prog.*, **55**[10], 62–67 [1959]), and Kosky (*Int. J. Heat Mass Transfer*, **14,** 1220–1224 [1971]) have presented calculations of film thickness and film velocity. Film thickness data for falling water films with cocurrent and countercurrent air flow in pipes are given by Zhivaikin (*Int. Chem. Eng.*, **2,** 337–341 [1962]). Zabaras, Dukler, and Moalem-Maron (*AIChE J.*, **32,** 829–843 [1986]) and Zabaras and Dukler (*AIChE J.*, **34,** 389–396 [1988]) present studies of film flow in vertical tubes with both cocurrent and countercurrent gas flow, including measurements of film thickness, wall shear stress, wave velocity, wave amplitude, pressure drop, and flooding point for countercurrent flow.

**Flooding** With countercurrent gas flow, a condition is reached with increasing gas rate for which flow reversal occurs and liquid is carried upward. The mechanism for this flooding condition has been most often attributed to waves either bridging the pipe or reversing direction to flow upward at flooding. However, the results of Zabaras and Dukler (ibid.) suggest that flooding may be controlled by flow conditions at the liquid inlet and that wave bridging or upward wave motion does not occur, at least for the 50.8-mm diameter pipe used for their study. Flooding mechanisms are still incompletely understood. Under some circumstances, as when the gas is allowed to develop its normal velocity profile in a "calming length" of pipe beneath the liquid draw-off, the gas superficial velocity at flooding will be increased, and increases with decreasing length of wetted pipe (Hewitt, Lacy, and Nicholls, *Proc. Two-Phase Flow Symp.*, University of Exeter, paper 4H, AERE-4 4614 [1965]). A bevel cut at the bottom of the pipe with an angle 30° from the vertical will increase the flooding velocity in small-diameter tubes at moderate liquid flow rates. If the gas approaches the tube from the side, the taper should be oriented with the point facing the gas entrance. Figures 6-53 and 6-54 give correlations for flooding in tubes with square and slant bottoms (courtesy Holmes, DuPont Co.) The superficial mass velocities of gas and liquid $G_G$ and $G_L$, and the physical property parameters $\lambda$ and $\psi$ are the same as those defined for the Baker chart ("Multiphase Flow" subsection, Fig. 6-25). For tubes larger than 50 mm (2 in), flooding velocity appears to be relatively insensitive to diameter and the flooding curves for 1.98-in diameter may be used.

## HYDRAULIC TRANSIENTS

Many transient flows of liquids may be analyzed by using the full time-dependent equations of motion for incompressible flow. However,

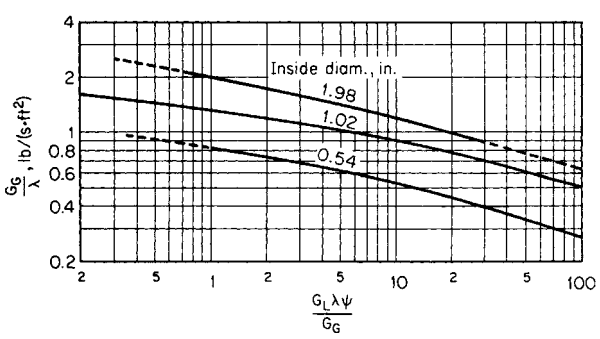

**FIG. 6-53** Flooding in vertical tubes with square top and square bottom. To convert lbm/(ft²·s) to kg/(m²·s), multiply by 4.8824; to convert in to mm, multiply by 25.4. (*Courtesy of E. I. du Pont de Nemours & Co.*)

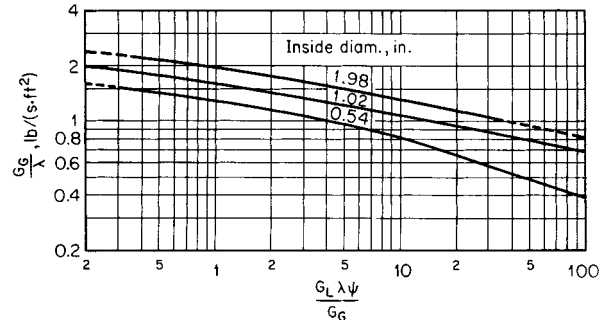

**FIG. 6-54** Flooding in vertical tubes with square top and slant bottom. To convert lbm/(ft²·s) to kg/(m²·s), multiply by 4.8824; to convert in to mm, multiply by 25.4. (*Courtesy of E. I. du Pont de Nemours & Co.*)

there are some phenomena that are controlled by the small compressibility of liquids. These phenomena are generally called **hydraulic transients.**

**Water Hammer** When liquid flowing in a pipe is suddenly decelerated to zero velocity by a fast-closing valve, a pressure wave propagates upstream to the pipe inlet, where it is reflected; a pounding of the line commonly known as **water hammer** is often produced. For an instantaneous flow stoppage of a truly incompressible fluid in an inelastic pipe, the pressure rise would be infinite. Finite compressibility of the fluid and elasticity of the pipe limit the pressure rise to a finite value. The Joukowski formula gives the maximum pressure rise as

$$\Delta p = \rho a \Delta V \tag{6-203}$$

where $\rho$ = liquid density
$\Delta V$ = change in liquid velocity
$a$ = pressure wave velocity

The wave velocity is given by

$$a = \frac{\sqrt{\beta/\rho}}{\sqrt{1 + (\beta/E)(D/b)}} \tag{6-204}$$

where $\beta$ = liquid bulk modulus of elasticity
$E$ = elastic modulus of pipe wall
$D$ = pipe inside diameter
$b$ = pipe wall thickness

The numerator gives the wave velocity for perfectly rigid pipe, and the denominator corrects for wall elasticity. This formula is for thin-walled pipes; for thick-walled pipes, the factor $D/b$ is replaced by

$$2\,\frac{D_o^2 + D_i^2}{D_o^2 - D_i^2}$$

where $D_o$ = pipe outside diameter
$D_i$ = pipe inside diameter

***Example 10: Response to Instantaneous Valve Closing*** Compute the wave speed and maximum pressure rise for instantaneous valve closing, with an initial velocity of 2.0 m/s, in a 4-in Schedule 40 steel pipe with elastic modulus $207 \times 10^9$ Pa. Repeat for a plastic pipe of the same dimensions, with $E = 1.4 \times 10^9$ Pa. The liquid is water with $\beta = 2.2 \times 10^9$ Pa and $\rho = 1{,}000$ kg/m³.

For the steel pipe, $D = 102.3$ mm, $b = 6.02$ mm, and the wave speed is

$$a = \frac{\sqrt{\beta/\rho}}{\sqrt{1 + (\beta/E)(D/b)}}$$

$$= \frac{\sqrt{2.2 \times 10^9/1000}}{\sqrt{1 + (2.2 \times 10^9/207 \times 10^9)(102.3/6.02)}}$$

$$= 1365 \text{ m/s}$$

The maximum pressure rise is

$$\Delta p = \rho a \Delta V$$
$$= 1{,}000 \times 1{,}365 \times 2.0 = 2.73 \times 10^6 \text{ Pa}$$

For the plastic pipe,

$$a = \frac{\sqrt{2.2 \times 10^9/1000}}{\sqrt{1 + (2.2 \times 10^9/1.4 \times 10^9)(102.3/6.02)}}$$
$$= 282 \text{ m/s}$$
$$\Delta p = \rho a \Delta V = 1{,}000 \times 282 \times 2.0 = 5.64 \times 10^5 \text{ Pa}$$

The maximum pressure surge is obtained when the valve closes in less time than the period $\tau$ required for the pressure wave to travel from the valve to the pipe inlet and back, a total distance of $2L$.

$$\tau = \frac{2L}{a} \tag{6-205}$$

The pressure surge will be reduced when the time of flow stoppage exceeds the pipe period $\tau$, due to cancellation between direct and reflected waves. Wood and Jones (*Proc. Am. Soc. Civ. Eng., J. Hydraul. Div.*, **99,** (HY1), 167–178 [1973]) present charts for reliable estimates of water-hammer pressure for different valve closure modes. Wylie and Streeter (*Hydraulic Transients,* McGraw-Hill, New York, 1978) describe several solution methods for hydraulic transients, including the method of characteristics, which is well suited to computer methods for accurate solutions. A rough approximation for the peak pressure for cases where the valve closure time $t_c$ exceeds the pipe period $\tau$ is (Daugherty and Franzini, *Fluid Mechanics with Engineering Applications,* McGraw-Hill, New York, 1985):

$$\Delta p \approx \left(\frac{\tau}{t_c}\right)\rho a \Delta V \tag{6-206}$$

Successive reflections of the pressure wave between the pipe inlet and the closed valve result in alternating pressure increases and decreases, which are gradually attenuated by fluid friction and imperfect elasticity of the pipe. Periods of reduced pressure occur while the reflected pressure wave is traveling from inlet to valve. Degassing of the liquid may occur, as may vaporization if the pressure drops below the vapor pressure of the liquid. Gas and vapor bubbles decrease the wave velocity. Vaporization may lead to what is often called *liquid column separation;* subsequent collapse of the vapor pocket can result in pipe rupture.

In addition to water hammer induced by changes in valve setting, including closure, numerous other hydraulic transient flows are of interest, as, for example (Wylie and Streeter, *Hydraulic Transients,* McGraw-Hill, New York, 1978), those arising from starting or stopping of pumps; changes in power demand from turbines; reciprocating pumps; changing elevation of a reservoir; waves on a reservoir; turbine governor hunting; vibration of impellers or guide vanes in pumps, fans, or turbines; vibration of deformable parts such as valves; draft-tube instabilities due to vortexing; and unstable pump or fan characteristics. Tube failure in heat exhangers may be added to this list.

**Pulsating Flow** Reciprocating machinery (pumps and compressors) produces flow pulsations, which adversely affect flow meters and process control elements and can cause vibration and equipment failure, in addition to undesirable process results. Vibration and damage can result not only from the fundamental frequency of the pulse producer but also from higher harmonics. Multipiston double-acting units reduce vibrations. Pulsation dampeners are often added. Damping methods are described by M. W. Kellogg Co. (*Design of Piping Systems,* rev. 2d ed., Wiley, New York, 1965). For liquid phase pulsation damping, gas-filled surge chambers, also known as accumulators, are commonly used; see Wylie and Streeter (*Hydraulic Transients,* McGraw-Hill, New York, 1978).

Software packages are commercially available for simulation of hydraulic transients. These may be used to analyze piping systems to reveal unsatisfactory behavior, and they allow the assessment of design changes such as increases in pipe-wall thickness, changes in valve actuation, and addition of check valves, surge tanks, and pulsation dampeners.

**Cavitation** Loosely regarded as related to water hammer and hydraulic transients because it may cause similar vibration and equipment damage, **cavitation** is the phenomenon of collapse of vapor bubbles in flowing liquid. These bubbles may be formed anywhere the local liquid pressure drops below the vapor pressure, or they may be injected into the liquid, as when steam is sparged into water. Local low-pressure zones may be produced by local velocity increases (in accordance with the Bernoulli equation; see the preceding "Conservation Equations" subsection) as in eddies or vortices, or near boundary contours; by rapid vibration of a boundary; by separation of liquid during water hammer; or by an overall reduction in static pressure, as due to pressure drop in the suction line of a pump.

Collapse of vapor bubbles once they reach zones where the pressure exceeds the vapor pressure can cause objectionable noise and vibration and extensive erosion or pitting of the boundary materials. The critical cavitation number at inception of cavitation, denoted $\sigma_i$, is useful in correlating equipment performance data:

$$\sigma_i = \frac{p - p_v}{\rho V^2/2} \tag{6-207}$$

where $p$ = static pressure in undisturbed flow
$p_v$ = vapor pressure
$\rho$ = liquid density
$V$ = free-stream velocity of the liquid

The value of the cavitation number for incipient cavitation for a specific piece of equipment is a characteristic of that equipment. Cavitation numbers for various head forms of cylinders, for disks, and for various hydrofoils are given by Holl and Wislicenus (*J. Basic Eng.,* **83,** 385–398 [1961]) and for various surface irregularities by Arndt and Ippen (*J. Basic Eng.,* **90,** 249–261 [1968]), Ball (*Proc. ASCE J. Constr. Div.,* **89**(C02), 91–110 [1963]), and Holl (*J. Basic Eng.,* **82,** 169–183 [1960]). As a guide only, for blunt forms the cavitation number is generally in the range of 1 to 2.5, and for somewhat streamlined forms the cavitation number is in the range of 0.2 to 0.5. Critical cavitation numbers generally depend on a characteristic length dimension of the equipment in a way that has not been explained. This renders scale-up of cavitation data questionable.

For cavitation in flow through orifices, Fig. 6-55 (Thorpe, *Int. J. Multiphase Flow,* **16,** 1023–1045 [1990]) gives the critical cavitation number for inception of cavitation. To use this cavitation number in Eq. (6-207), the pressure $p$ is the orifice backpressure downstream of the vena contracta after full pressure recovery, and $V$ is the average velocity through the orifice. Figure 6-55 includes data from Tullis and Govindarajan (*ASCE J. Hydraul. Div.,* **HY13,** 417–430 [1973]) modified to use the same cavitation number definition; their data also include critical cavitation numbers for 30.50- and 59.70-cm pipes

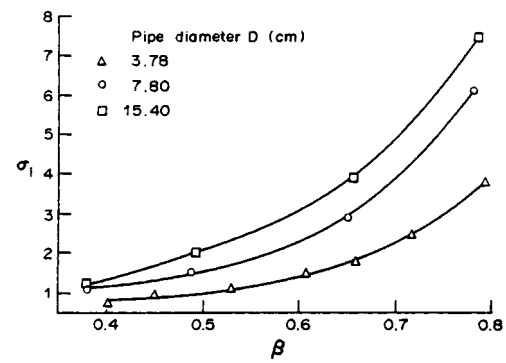

**FIG. 6-55** Critical cavitation number vs. diameter ratio $\beta$. (*Reprinted from Thorpe, "Flow regime transitions due to cavitation in the flow through an orifice,"* Int. J. Multiphase Flow, ***16,** 1023–1045. Copyright © 1990, with kind permission from Elsevier Science, Ltd., The Boulevard, Langford Lane, Kidlington OX5 1GB, United Kingdom.*)

(12.00- to 23.50-in). Very roughly, compared with the 15.40-cm pipe, the cavitation number is about 20 percent greater for the 30.50-cm (12.01-in) pipe and about 40 percent greater for the 59.70-cm (23.50-in) diameter pipe. Inception of cavitation appears to be related to release of dissolved gas and not merely vaporization of the liquid. For further discussion of cavitation, see Eisenberg and Tulin (Streeter, *Handbook of Fluid Dynamics,* Sec. 12, McGraw-Hill, New York, 1961).

## TURBULENCE

Turbulent flow occurs when the Reynolds number exceeds a critical value above which laminar flow is unstable; the critical Reynolds number depends on the flow geometry. There is generally a transition regime between the critical Reynolds number and the Reynolds number at which the flow may be considered fully turbulent. The transition regime is very wide for some geometries. In turbulent flow, variables such as velocity and pressure fluctuate chaotically; statistical methods are used to quantify turbulence.

**Time Averaging** In turbulent flows it is useful to define time-averaged and fluctuation values of flow variables such as velocity components. For example, the $x$-component velocity fluctuation $v_x'$ is the difference between the actual instantaneous velocity $v_x$ and the time-averaged velocity $\overline{v_x}$:

$$v_x'(x, y, z, t) = v_x(x, y, z, t) - \overline{v_x}(x, y, z) \tag{6-208}$$

The actual and fluctuating velocity components are, in general, functions of the three spatial coordinates $x$, $y$, and $z$ and of time $t$. The time-averaged velocity $\overline{v_x}$ is independent of time for a **stationary** flow. Nonstationary processes may be considered where averages are defined over time scales long compared to the time scale of the turbulent fluctuations, but short compared to longer time scales over which the time-averaged flow variables change due, for example, to time-varying boundary conditions. The time average over a time interval $2T$ centered at time $t$ of a turbulently fluctuating variable $\zeta(t)$ is defined as

$$\overline{\zeta(t)} = \frac{1}{2T}\int_{t-T}^{t+T} \zeta(\tau)\, d\tau \tag{6-209}$$

where $\tau$ = dummy integration variable. For stationary turbulence, $\overline{\zeta}$ does not vary with time.

$$\overline{\zeta} = \lim_{T\to\infty} \frac{1}{2T}\int_{t-T}^{t+T} \zeta(\tau)\, d\tau \tag{6-210}$$

The time average of a fluctuation $\overline{\zeta'} = \overline{\zeta - \overline{\zeta}} = 0$. Fluctuation magnitudes are quantified by root mean squares.

$$\tilde{v}_x' = \sqrt{\overline{(v_x')^2}} \tag{6-211}$$

In **isotropic** turbulence, statistical measures of fluctuations are equal in all directions.

$$\tilde{v}_x' = \tilde{v}_y' = \tilde{v}_z' \tag{6-212}$$

In **homogeneous** turbulence, turbulence properties are independent of spatial position. **The kinetic energy of turbulence** $k$ is given by

$$k = \frac{1}{2}\left(\tilde{v}_x'^2 + \tilde{v}_y'^2 + \tilde{v}_z'^2\right) \tag{6-213}$$

Turbulent velocity fluctuations ultimately dissipate their kinetic energy through viscous effects. Macroscopically, this energy dissipation requires pressure drop, or velocity decrease. The **energy dissipation rate** per unit mass is usually denoted $\epsilon$. For steady flow in a pipe, the average energy dissipation rate per unit mass is given by

$$\epsilon = \frac{2fV^3}{D} \tag{6-214}$$

where $\rho$ = fluid density
$f$ = Fanning friction factor
$D$ = pipe inside diameter

When the continuity equation and the Navier-Stokes equations for incompressible flow are time averaged, equations for the time-averaged velocities and pressures are obtained which appear identical to the original equations (6-18 through 6-28), except for the appearance of additional terms in the Navier-Stokes equations. Called **Reynolds stress** terms, they result from the nonlinear effects of momentum transport by the velocity fluctuations. In each $i$-component ($i = x, y, z$) Navier-Stokes equation, the following additional terms appear on the right-hand side:

$$\sum_{j=1}^{3} \frac{\partial \tau_{ji}^{(t)}}{\partial x_j}$$

with $j$ components also being $x$, $y$, $z$. The Reynolds stresses are given by

$$\tau_{ij}^{(t)} = -\rho\overline{v_i' v_j'} \tag{6-215}$$

The Reynolds stresses are nonzero because the velocity fluctuations in different coordinate directions are correlated so that $\overline{v_i' v_j'}$ in general is nonzero.

Although direct numerical simulations under limited circumstances have been carried out to determine (unaveraged) fluctuating velocity fields, in general the solution of the equations of motion for turbulent flow is based on the time-averaged equations. This requires semiempirical models to express the Reynolds stresses in terms of time-averaged velocities. This is the **closure** problem of turbulence. In all but the simplest geometries, numerical methods are required.

**Closure Models** Many closure models have been proposed. A few of the more important ones are introduced here. Many employ the Boussinesq approximation, simplified here for incompressible flow, which treats the Reynolds stresses as analogous to viscous stresses, introducing a scalar quantity called the turbulent or eddy viscosity $\mu_t$.

$$-\rho\overline{v_i' v_j'} = \mu_t\left(\frac{\partial \overline{v_i}}{\partial x_j} + \frac{\partial \overline{v_j}}{\partial x_i}\right) \tag{6-216}$$

An additional *turbulence pressure* term equal to $-\frac{2}{3}k\delta_{ij}$, where $k$ = turbulent kinetic energy and $\delta_{ij} = 1$ if $i = j$ and $\delta_{ij} = 0$ if $i \neq j$, is sometimes included in the right-hand side. To solve the equations of motion using the Boussinesq approximation, it is necessary to provide equations for the single scalar unknown $\mu_t$ (and $k$, if used) rather than the nine unknown tensor components $\tau_{ij}^{(t)}$. With this approximation, and using the effective viscosity $\mu_{\text{eff}} = \mu + \mu_t$, the time-averaged momentum equation is similar to the original Navier-Stokes equation, with time-averaged variables and $\mu_{\text{eff}}$ replacing the instantaneous variables and molecular viscosity. However, solutions to the time-averaged equations for turbulent flow are not identical to those for laminar flow because $\mu_{\text{eff}}$ is not a constant.

The universal turbulent velocity profile near the pipe wall presented in the preceding subsection "Incompressible Flow in Pipes and Channels" may be developed using the Prandtl mixing length approximation for the eddy viscosity,

$$\mu_t = \rho l_P^2 \left|\frac{d\overline{v_x}}{dy}\right| \tag{6-217}$$

where $l_P$ is the Prandtl mixing length. The turbulent core of the universal velocity profile is obtained by assuming that the mixing length is proportional to the distance from the wall. The proportionality constant is one of two constants adjusted to fit experimental data.

The Prandtl mixing length concept is useful for shear flows parallel to walls, but is inadequate for more general three-dimensional flows. A more complicated semiempirical model commonly used in numerical computations, and found in most commercial software for computational fluid dynamics (CFD; see the following subsection), is the $k$–$\epsilon$ model described by Launder and Spaulding (*Lectures in Mathematical Models of Turbulence,* Academic, London, 1972). In this model the eddy viscosity is assumed proportional to the ratio $k^2/\epsilon$.

$$\mu_t = \rho C_\mu \frac{k^2}{\epsilon} \tag{6-218}$$

where the value $C_\mu = 0.09$ is normally used. Semiempirical partial differential conservation equations for $k$ and $\epsilon$ derived from the

Navier-Stokes equations with simplifying closure assumptions are coupled with the equations of continuity and momentum:

$$\frac{\partial}{\partial t}(\rho k) + \frac{\partial}{\partial x_i}(\rho \overline{v_i} k) = \frac{\partial}{\partial x_i}\left(\frac{\mu_t}{\sigma_k}\frac{\partial k}{\partial x_i}\right) + \mu_t\left(\frac{\partial \overline{v_i}}{\partial x_j} + \frac{\partial \overline{v_j}}{\partial x_i}\right)\frac{\partial \overline{v_i}}{\partial x_j} - \rho\epsilon \quad (6\text{-}219)$$

$$\frac{\partial}{\partial t}(\rho\epsilon) + \frac{\partial}{\partial x_i}(\rho \overline{v_i}\epsilon) = \frac{\partial}{\partial x_i}\left(\frac{\mu_t}{\sigma_\epsilon}\frac{\partial \epsilon}{\partial x_i}\right) + C_{1\epsilon}\frac{\epsilon\mu_t}{k}\left(\frac{\partial \overline{v_i}}{\partial x_j} + \frac{\partial \overline{v_j}}{\partial x_i}\right)\frac{\partial \overline{v_i}}{\partial x_j} - C_{2\epsilon}\frac{\rho\epsilon^2}{k} \quad (6\text{-}220)$$

In these equations summations over repeated indices are implied. The values for the empirical constants $C_{1\epsilon} = 1.44$, $C_{2\epsilon} = 1.92$, $\sigma_k = 1.0$, and $\sigma_\epsilon = 1.3$ are widely accepted (Launder and Spaulding, *The Numerical Computation of Turbulent Flows,* Imperial Coll. Sci. Tech. London, NTIS N74-12066 [1973]). The $k$–$\epsilon$ model has proved reasonably accurate for many flows without highly curved streamlines or significant swirl. It usually underestimates flow separation and overestimates turbulence production by normal straining. The $k$–$\epsilon$ model is suitable for high Reynolds number flows. See Virendra, Patel, Rodi, and Scheuerer (*AIAA J.,* **23,** 1308–1319 [1984]) for a review of low Reynolds number $k$–$\epsilon$ models.

More advanced models, more complex and computationally intensive, are being developed. For example, the renormalization group theory (Yakhot and Orszag, *J. Scientific Computing,* **1,** 1–51 [1986]; Yakhot, Orszag, Thangam, Gatski, and Speziale, *Phys. Fluids A,* **4,** 1510–1520 [1992]) modification of the $k$–$\epsilon$ model provides theoretical values of the model constants and provides substantial improvement in predictions of flows with stagnation, separation, normal straining, transient behavior such as vortex shedding, and relaminarization. Stress transport models provide equations for all nine Reynolds stress components, rather than introducing eddy viscosity. Algebraic closure equations for the Reynolds stresses are available, but are no longer in common use. Differential Reynolds stress models (e.g., Launder, Reece, and Rodi, *J. Fluid Mech.,* **68,** 537–566 [1975]) use differential conservation equations for all nine Reynolds stress components.

In **direct numerical simulation** of turbulent flows, the solution of the unaveraged equations of motion is sought. Due to the extreme computational intensity, solutions to date have been limited to relatively low Reynolds numbers in simple geometries. Since computational grids must be sufficiently fine to resolve even the smallest eddies, the computational difficulty rapidly becomes prohibitive as Reynolds number increases. **Large eddy simulations** use models for subgrid turbulence while solving for larger-scale fluctuations.

**Eddy Spectrum** The energy that produces and sustains turbulence is extracted from velocity gradients in the mean flow, principally through vortex stretching. At Reynolds numbers well above the critical value there is a wide spectrum of eddy sizes, often described as a cascade of energy from the largest down to the smallest eddies. The largest eddies are of the order of the equipment size. The smallest are those for which viscous forces associated with the eddy velocity fluctuations are of the same order as inertial forces, so that turbulent fluctuations are rapidly damped out by viscous effects at smaller length scales. Most of the turbulent kinetic energy is contained in the larger eddies, while most of the dissipation occurs in the smaller eddies. Large eddies, which extract energy from the mean flow velocity gradients, are generally anisotropic. At smaller length scales, the directionality of the mean flow exerts less influence, and **local isotropy** is approached. The range of eddy scales for which local isotropy holds is called the **equilibrium range.**

Davies (*Turbulence Phenomena,* Academic, New York, 1972) presents a good discussion of the spectrum of eddy lengths for well-developed isotropic turbulence. The smallest eddies, usually called *Kolmogorov eddies* (Kolmogorov, *Compt. Rend. Acad. Sci. URSS,* **30,** 301; **32,** 16 [1941]), have a characteristic velocity fluctuation $\tilde{v}'_K$ given by

$$\tilde{v}'_K = (\nu\epsilon)^{1/4} \quad (6\text{-}221)$$

where $\nu$ = kinematic viscosity and $\epsilon$ = energy dissipation per unit mass. The size of the Kolmogorov eddy scale is

$$l_K = (\nu^3/\epsilon)^{1/4} \quad (6\text{-}222)$$

The Reynolds number for the Kolmogorov eddy, $\mathrm{Re}_K = l_K \tilde{v}'_k/\nu$, is equal to unity by definition. In the equilibrium range, which exists for well-developed turbulence and extends from the medium eddy sizes down to the smallest, the energy dissipation at the smaller length scales is supplied by turbulent energy drawn from the bulk flow and passed down the spectrum of eddy lengths according to the scaling rule

$$\epsilon = \frac{(\tilde{v}')^3}{l} \quad (6\text{-}223)$$

which is consistent with Eqs. (6-221) and (6-222). For the medium, or energy-containing, eddy size,

$$\epsilon = \frac{(\tilde{v}'_e)^3}{l_e} \quad (6\text{-}224)$$

For turbulent pipe flow, the friction velocity $u_* = \sqrt{\tau_w/\rho}$ used earlier in describing the universal turbulent velocity profile may be used as an estimate for $\tilde{v}'_e$. Together with the Blasius equation for the friction factor from which $\epsilon$ may be obtained (Eq. 6-214), this provides an estimate for the energy-containing eddy size in turbulent pipe flow:

$$l_e = 0.05D\mathrm{Re}^{-1/8} \quad (6\text{-}225)$$

where $D$ = pipe diameter and Re = pipe Reynolds number. Similarly, the Kolmogorov eddy size is

$$l_K = 4D\mathrm{Re}^{-0.78} \quad (6\text{-}226)$$

Most of the energy dissipation occurs on a length scale about 5 times the Kolmogorov eddy size. The characteristic fluctuating velocity for these energy-dissipating eddies is about 1.7 times the Kolmogorov velocity.

The eddy spectrum is normally described using Fourier transform methods; see, for example, Hinze (*Turbulence,* McGraw-Hill, New York, 1975), and Tennekes and Lumley (*A First Course in Turbulence,* MIT Press, Cambridge, 1972). The spectrum $E(\kappa)$ gives the fraction of turbulent kinetic energy contained in eddies of wavenumber between $\kappa$ and $\kappa + d\kappa$, so that $k = \int_0^\infty E(\kappa)\, d\kappa$. The portion of the equilibrium range excluding the smallest eddies, those which are affected by dissipation, is the **inertial subrange.** The Kolmogorov law gives $E(\kappa) \propto \kappa^{-5/3}$ in the inertial subrange.

Several texts are available for further reading on turbulent flow, including Pope (*Turbulent Flows,* Cambridge University Press, Cambridge, U.K., 2000), Tennekus and Lumley (ibid.), Hinze (*Turbulence,* McGraw-Hill, New York, 1975), Landau and Lifshitz (*Fluid Mechanics,* 2d ed., Chap. 3, Pergamon, Oxford, 1987) and Panton (*Incompressible Flow,* Wiley, New York, 1984).

## COMPUTATIONAL FLUID DYNAMICS

Computational fluid dynamics (CFD) emerged in the 1980s as a significant tool for fluid dynamics both in research and in practice, enabled by rapid development in computer hardware and software. Commercial CFD software is widely available. Computational fluid dynamics is the numerical solution of the equations of continuity and momentum (Navier-Stokes equations for incompressible Newtonian fluids) along with additional conservation equations for energy and material species in order to solve problems of nonisothermal flow, mixing, and chemical reaction.

Textbooks include Fletcher (*Computational Techniques for Fluid Dynamics,* vol. 1: *Fundamental and General Techniques,* and vol. 2: *Specific Techniques for Different Flow Categories,* Springer-Verlag, Berlin, 1988), Hirsch (*Numerical Computation of Internal and External Flows,* vol. 1: *Fundamentals of Numerical Discretization,* and vol. 2: *Computational Methods for Inviscid and Viscous Flows,* Wiley, New York, 1988), Peyret and Taylor (*Computational Methods for Fluid*

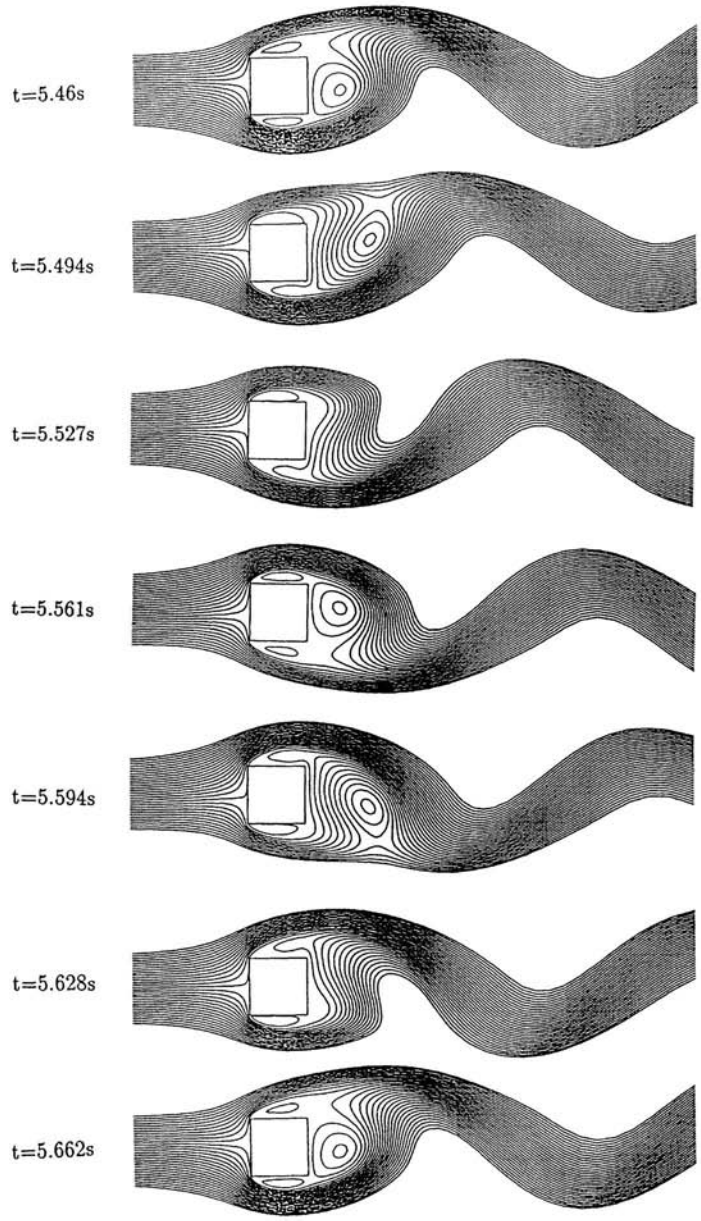

**FIG. 6-56** Computational fluid dynamic simulation of flow over a square cylinder, showing one vortex shedding period. (*From Choudhury et al.,* Trans. ASME Fluids Div., *TN-076* [*1994*].)

*Flow,* Springer-Verlag, Berlin, 1990), Canuto, Hussaini, Quarteroni, and Zang (*Spectral Methods in Fluid Dynamics,* Springer-Verlag, Berlin, 1988), Anderson, Tannehill, and Pletcher (*Computational Fluid Mechanics and Heat Transfer,* Hemisphere, New York, 1984), and Patankar (*Numerical Heat Transfer and Fluid Flow,* Hemisphere, Washington, D.C., 1980).

A wide variety of numerical methods has been employed, but three basic steps are common.

1. **Subdivision or discretization of the flow domain into cells or elements.** There are methods, called *boundary element methods,* in which the surface of the flow domain, rather than the volume, is discretized, but the vast majority of CFD work uses volume discretization. Discretization produces a set of **grid** lines or curves which define a **mesh** and a set of **nodes** at which the flow variables are to be calculated. The equations of motion are solved approximately on a domain defined by the grid. Curvilinear or **body-fitted** coordinate system grids may be used to ensure that the discretized domain accurately represents the true problem domain.

2. **Discretization of the governing equations.** In this step, the exact partial differential equations to be solved are replaced by approximate algebraic equations written in terms of the nodal values of the dependent variables. Among the numerous discretization methods, **finite difference, finite volume,** and **finite element** methods are the most common. The *finite difference* method estimates spatial derivatives in terms of the nodal values and spacing between nodes. The governing equations are then written in terms of the nodal unknowns at each interior node. *Finite volume* methods, related to finite difference methods, may be derived by a volume integration of the equations of motion, with application of the divergence theorem, reducing by one the order of the differential equations. Equivalently, macroscopic balance equations are written on each cell. *Finite element* methods are weighted residual techniques in which the unknown dependent variables are expressed in terms of **basis functions** interpolating among the nodal values. The basis functions are substituted into the equations of motion, resulting in error residuals which are multiplied by the weighting functions, integrated over the control volume, and set to zero to produce algebraic equations in terms of the nodal unknowns. Selection of the weighting functions defines the various finite element methods. For example, Galerkin's method uses the nodal interpolation basis functions as weighting functions. Each method also has its own method for implementing **boundary conditions.** The end result after discretization of the equations and application of the boundary conditions is a set of algebraic equations for the nodal unknown variables. Discretization in time is also required for the $\partial/\partial t$ time derivative terms in unsteady flow; finite differencing in time is often used. The discretized equations represent an approximation of the exact equations, and their solution gives an approximation for the flow variables. The accuracy of the solution improves as the grid is **refined;** that is, as the number of nodal points is increased.

3. **Solution of the algebraic equations.** For creeping flows with constant viscosity, the algebraic equations are linear and a linear matrix equation is to be solved. Both direct and iterative solvers have been used. For most flows, the nonlinear inertial terms in the momentum equation are important and the algebraic discretized equations are therefore nonlinear. Solution yields the nodal values of the unknowns.

A CFD method called the lattice Boltzmann method is based on modeling the fluid as a set of particles moving with discrete velocities on a discrete grid or lattice, rather than on discretization of the governing continuum partial differential equations. Lattice Boltzmann approximations can be constructed that give the same macroscopic behavior as the Navier-Stokes equations. The method is currently used mainly in academic and research codes, rather than in general-purpose commercial CFD codes. There appear to be significant computational advantages to the lattice Boltzmann method. Lattice Boltzmann simulations incorporating turbulence models, and of multiphase flows and flows with heat transfer, species diffusion, and reaction, have been carried out. For a review of the method, see Chen and Doolen [*Ann. Rev. Fluid Mech.,* **30,** 329 (1998)].

CFD solutions, especially for complex three-dimensional flows, generate very large quantities of solution data. Computer graphics have greatly improved the ability to examine CFD solutions and visualize flow.

CFD methods are used for incompressible and compressible, creeping, laminar and turbulent, Newtonian and non-Newtonian, and isothermal and nonisothermal flows. Chemically reacting flows, particularly in the field of combustion, have been simulated. Solution accuracy must be considered from several perspectives. These include convergence of the algorithms for solving the nonlinear discretized equations and convergence with respect to refinement of the mesh so that the discretized equations better approximate the exact equations and, in some cases, so that the mesh more accurately fits the true geometry. The possibility that steady-state solutions are unstable must always be considered. In addition to numerical sources of error, modeling errors are introduced in turbulent flow, where semiempirical closure models are used to solve time-averaged equations of motion, as discussed previously. Most commercial CFD codes include the $k$–$\epsilon$ turbulence model, which has been by far the most widely used. More accurate models, such as differential Reynolds stress and renormalization group theory models, are also becoming available. Significant solution error is known to result in some problems from inadequacy of the turbulence model. Closure models for nonlinear chemical reaction source terms may also contribute to inaccuracy.

Large eddy simulation (LES) methods for turbulent flow are available in some commercial CFD codes. LES methods are based on filtering fluctuating variables, so that lower-frequency eddies, with scales larger than the grid spacing, are resolved, while higher-frequency eddies, the subgrid fluctuations, are filtered out. The subgrid-scale Reynolds stress is estimated by a turbulence model. The Smagorinsky model, a one-equation mixing length model, is used in most commercial codes that offer LES options and is also used in many academic and research CFD codes. See Wilcox (*Turbulence Modeling for CFD,* 2d ed., DCW Industries, La Cañada, Calif., 1998).

In its general sense, multiphase flow is not currently solvable by computational fluid dynamics. However, in certain cases reasonable solutions are possible. These include well-separated flows where the phases are confined to relatively well-defined regions separated by one or a few interfaces and flows in which a second phase appears as discrete particles of known size and shape whose motion may be approximately computed with drag coefficient formulations, or rigorously computed with refined meshes applying boundary conditions at the particle surface. **Two-fluid modeling,** in which the phases are treated as overlapping continua, with each phase occupying a volume fraction that is a continuous function of position (and time) is a useful approximation which is becoming available in commercial software. See Elghobashi and Abou-Arab (*J. Physics Fluids,* **26,** 931–938 [1983]) for a $k$–$\epsilon$ model for two-fluid systems.

Figure 6-56 gives an example CFD calculation for time-dependent flow past a square cylinder at a Reynolds number of 22,000 (Choudhury, et al., *Trans. ASME Fluids Div.,* Lake Tahoe, Nev. [1994]). The computation was done with an implementation of the renormalization group theory $k$–$\epsilon$ model. The series of contour plots of stream function shows a sequence in time over about 1 vortex-shedding period. The calculated Strouhal number (Eq. [6-195]) is 0.146, in excellent agreement with experiment, as is the time-averaged drag coefficient, $C_D = 2.24$. Similar computations for a circular cylinder at Re = 14,500 have given excellent agreement with experimental measurements for St and $C_D$ (*Introduction to the Renormalization Group Method and Turbulence Modeling,* Fluent, Inc., 1993).

## DIMENSIONLESS GROUPS

For purposes of data correlation, model studies, and scale-up, it is useful to arrange variables into dimensionless groups. Table 6-7 lists many of the dimensionless groups commonly found in fluid mechanics problems, along with their physical interpretations and areas of application. More extensive tabulations may be found in Catchpole and Fulford (*Ind. Eng. Chem.,* **58**[3], 46–60 [1966]) and Fulford and Catchpole (*Ind. Eng. Chem.,* **60**[3], 71–78 [1968]).

**TABLE 6-7 Dimensionless Groups and Their Significance**

| Name | Symbol | Formula | Physical interpretation | Comments |
|---|---|---|---|---|
| Archimedes number | Ar | $\frac{gL^3(\rho_p-\rho)\rho}{\mu^2}$ | $\frac{\text{inertial forces} \times \text{buoyancy forces}}{(\text{viscous forces})^2}$ | Particle settling |
| Bingham number | Bm | $\frac{\tau_y L}{\mu_\infty V}$ | $\frac{\text{yield stress}}{\text{viscous stress}}$ | Flow of Bingham plastics = yield number, Y |
| Bingham Reynolds number | $Re_B$ | $\frac{LV\rho}{\mu_\infty}$ | $\frac{\text{inertial force}}{\text{viscous force}}$ | Flow of Bingham plastics |
| Blake number | B | $\frac{V\rho}{\mu(1-\epsilon)s}$ | $\frac{\text{inertial force}}{\text{viscous force}}$ | Beds of solids |
| Bond number | Bo | $\frac{(\rho_L-\rho_G)L^2g}{\sigma}$ | $\frac{\text{gravitational force}}{\text{surface-tension force}}$ | Atomization = Eotvos number, Eo |
| Capillary number | Ca | $\frac{\mu V}{\sigma}$ | $\frac{\text{viscous force}}{\text{surface-tension force}}$ | Two-phase flows, free surface flows |
| Cauchy number | C | $\frac{\rho V^2}{\beta}$ | $\frac{\text{inertial force}}{\text{compressibility force}}$ | Compressible flow, hydraulic transients |
| Cavitation number | $\sigma$ | $\frac{p-p_v}{\rho V^2/2}$ | $\frac{\text{excess pressure above vapor pressure}}{\text{velocity head}}$ | Cavitation |
| Dean number | $D_e$ | $\frac{\text{Re}}{(Dc/D)^{1/2}}$ | $\text{Reynolds number} \times \frac{\text{inertial force}}{\text{centrifugal force}}$ | Flow in curved channels |
| Deborah number | De | $\lambda\omega$ | $\frac{\text{fluid relaxation time}}{\text{flow characteristic time}}$ | Viscoelastic flow |
| Drag coefficient | $C_D$ | $\frac{F_D}{A\rho V^2/2}$ | $\frac{\text{drag force}}{\text{projected area} \times \text{velocity head}}$ | Flow around objects, particle settling |
| Elasticity number | El | $\frac{\lambda\mu}{\rho L^2}$ | $\frac{\text{elastic force}}{\text{inertial force}}$ | Viscoelastic flow |
| Euler number | Eu | $\frac{\Delta p}{\rho V^2}$ | $\frac{\text{frictional pressure loss}}{2 \times \text{velocity head}}$ | Fluid friction in conduits |
| Fanning friction factor | $f$ | $\frac{D\Delta p}{2\rho V^2 L} = \frac{2\tau_w}{\rho V^2}$ | $\frac{\text{wall shear stress}}{\text{velocity head}}$ | Fluid friction in conduits Darcy friction factor = $4f$ |
| Froude number | Fr | $\frac{V^2}{gL}$ | $\frac{\text{inertial force}}{\text{gravity force}}$ | Often defined as $\text{Fr} = V/\sqrt{gL}$ |
| Densometric Froude number | Fr′ | $\frac{\rho V^2}{(\rho_d-\rho)gL}$ | $\frac{\text{inertial force}}{\text{gravity force}}$ | or $\text{Fr}' = \frac{V}{\sqrt{(\rho_d-\rho)gL/\rho}}$ |
| Hedstrom number | He | $\frac{L^2\tau_Y\rho}{\mu_\infty^2}$ | Bingham Reynolds number × Bingham number | Flow of Bingham plastics |
| Hodgson number | H | $\frac{V'\omega\Delta p}{\bar{q}\bar{p}}$ | $\frac{\text{time constant of system}}{\text{period of pulsation}}$ | Pulsating gas flow |
| Mach number | M | $\frac{V}{c}$ | $\frac{\text{fluid velocity}}{\text{sonic velocity}}$ | Compressible flow |
| Newton number | Ne | $\frac{\Delta PD}{\rho V^2 L}$ | 2 × Fanning friction factor | |
| Ohnesorge number | Z | $\frac{\mu}{(\rho L\sigma)^{1/2}}$ | $\frac{\text{viscous force}}{(\text{inertial force} \times \text{surface tension force})^{1/2}}$ | $\text{Atomization} = \frac{\text{Weber number}}{\text{Reynolds number}}$ |
| Peclet number | Pe | $\frac{LV}{D}$ | $\frac{\text{convective transport}}{\text{diffusive transport}}$ | Heat, mass transfer, mixing |
| Pipeline parameter | Pn | $\frac{aV_o}{2gH}$ | $\frac{\text{maximum water-hammer pressure rise}}{2 \times \text{static pressure}}$ | Water hammer |

# PARTICLE DYNAMICS

**General References:** Brodkey, *The Phenomena of Fluid Motions,* Addison-Wesley, Reading, Mass., 1967; Clift, Grace, and Weber, *Bubbles, Drops and Particles,* Academic, New York, 1978; Govier and Aziz, *The Flow of Complex Mixtures in Pipes,* Van Nostrand Reinhold, New York, 1972, Krieger, Huntington, N.Y., 1977; Lapple, et al., *Fluid and Particle Mechanics,* University of Delaware, Newark, 1951; Levich, *Physicochemical Hydrodynamics,* Prentice-Hall, Englewood Cliffs, N.J., 1962; Orr, *Particulate Technology,* Macmillan, New York, 1966; Shook and Roco, *Slurry Flow,* Butterworth-Heinemann, Boston, 1991; Wallis, *One-dimensional Two-phase Flow,* McGraw-Hill, New York, 1969.

## DRAG COEFFICIENT

Whenever relative motion exists between a particle and a surrounding fluid, the fluid will exert a drag upon the particle. In steady flow, the drag force on the particle is

$$F_D = \frac{C_D A_P \rho u^2}{2} \tag{6-227}$$

where $F_D$ = drag force
$C_D$ = drag coefficient
$A_P$ = projected particle area in direction of motion
$\rho$ = density of surrounding fluid
$u$ = relative velocity between particle and fluid

The drag force is exerted in a direction parallel to the fluid velocity. Equation (6-227) defines the **drag coefficient.** For some solid bodies, such as aerofoils, a lift force component perpendicular to the liquid velocity is also exerted. For free-falling particles, lift forces are generally not important. However, even spherical particles experience lift forces in shear flows near solid surfaces.

## TERMINAL SETTLING VELOCITY

A particle falling under the action of gravity will accelerate until the drag force balances gravitational force, after which it falls at a constant **terminal** or **free-settling velocity** $u_t$, given by

$$u_t = \sqrt{\frac{2gm_p(\rho_p - \rho)}{\rho\rho_p A_P C_D}} \tag{6-228}$$

where $g$ = acceleration of gravity
$m_p$ = particle mass
$\rho_p$ = particle density

and the remaining symbols are as previously defined.

Settling particles may undergo fluctuating motions owing to vortex shedding, among other factors. Oscillation is enhanced with increasing separation between the mass and geometric centers of the particle. Variations in mean velocity are usually less than 10 percent. The drag force on a particle fixed in space with fluid moving is somewhat lower than the drag force on a particle freely settling in a stationary fluid at the same relative velocity.

**Spherical Particles** For spherical particles of diameter $d_p$, Eq. (6-228) becomes

$$u_t = \sqrt{\frac{4gd_p(\rho_p - \rho)}{3\rho C_D}} \tag{6-229}$$

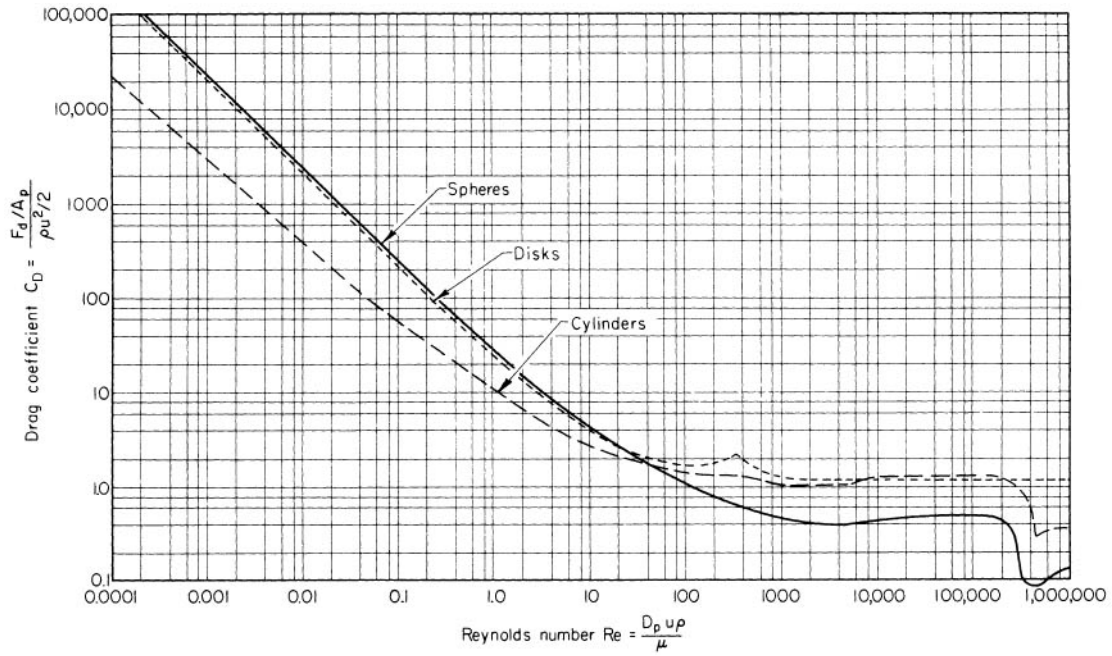

**FIG. 6-57** Drag coefficients for spheres, disks, and cylinders: $A_p$ = area of particle projected on a plane normal to direction of motion; $C$ = overall drag coefficient, dimensionless; $D_p$ = diameter of particle; $F_d$ = drag or resistance to motion of body in fluid; Re = Reynolds number, dimensionless; $u$ = relative velocity between particle and main body of fluid; $\mu$ = fluid viscosity; and $\rho$ = fluid density. (*From Lapple and Shepherd,* Ind. Eng. Chem., **32,** *605 [1940].*)

The drag coefficient for rigid spherical particles is a function of particle Reynolds number, $Re_p = d_p \rho u/\mu$ where $\mu$ = fluid viscosity, as shown in Fig. 6-57. At low Reynolds number, **Stokes' law** gives

$$C_D = \frac{24}{Re_p} \qquad Re_p < 0.1 \tag{6-230}$$

which may also be written

$$F_D = 3\pi\mu u d_p \qquad Re_p < 0.1 \tag{6-231}$$

and gives for the terminal settling velocity

$$u_t = \frac{g d_p^2 (\rho_p - \rho)}{18\mu} \qquad Re_p < 0.1 \tag{6-232}$$

In the **intermediate regime** ($0.1 < Re_p < 1{,}000$), the drag coefficient may be estimated within 6 percent by

$$C_D = \left(\frac{24}{Re_p}\right)\left(1 + 0.14 Re_p^{0.70}\right) \qquad 0.1 < Re_p < 1{,}000 \tag{6-233}$$

In the **Newton's law** regime, which covers the range $1{,}000 < Re_p < 350{,}000$, $C_D = 0.445$, within 13 percent. In this region, Eq. (6-227) becomes

$$u_t = 1.73\sqrt{\frac{g d_p (\rho_p - \rho)}{\rho}} \qquad 1{,}000 < Re_p < 350{,}000 \tag{6-234}$$

Between about $Re_p = 350{,}000$ and $1 \times 10^6$, the drag coefficient drops dramatically in a **drag crisis** owing to the transition to turbulent flow in the boundary layer around the particle, which delays aft separation, resulting in a smaller wake and less drag. Beyond $Re = 1 \times 10^6$, the drag coefficient may be estimated from (Clift, Grace, and Weber):

$$C_D = 0.19 - \frac{8 \times 10^4}{Re_p} \qquad Re_p > 1 \times 10^6 \tag{6-235}$$

Drag coefficients may be affected by turbulence in the free-stream flow; the drag crisis occurs at lower Reynolds numbers when the free stream is turbulent. Torobin and Guvin (*AIChE J.,* **7,** 615–619 [1961]) found that the drag crisis Reynolds number decreases with increasing free-stream turbulence, reaching a value of 400 when the relative turbulence intensity, defined as $\sqrt{u'}/U_R$ is 0.4. Here $\sqrt{u'}$ is the rms fluctuating velocity and $U_R$ is the relative velocity between the particle and the fluid.

For computing the terminal settling velocity, correlations for drag coefficient as a function of Archimedes number

$$Ar = \frac{g d_p^3 (\rho_\rho - \rho)\rho}{\mu^2} \tag{6-236}$$

may be more convenient than $C_D$-Re correlations, because the latter are implicit in terminal velocity, and the settling regime is unknown. Karamanev [*Chem. Eng Comm.* **147,** 75 (1996)] provided a correlation for drag coefficient for settling solid spheres in terms of Ar.

$$C_D = \frac{432}{Ar}(1 + 0.0470 Ar^{2/3}) + \frac{0.517}{1 + 154 Ar^{-1/3}} \tag{6-237}$$

This equation reduces to Stokes' law $C_D = 24/Re$ in the limit $Ar \to 0$ and is a fit to data up to about $Ar = 2 \times 10^{10}$, where it gives $C_D = 0.50$, slightly greater than the Newton's law value above. For rising light spheres, which exhibit more energy dissipating lateral motion than do falling dense spheres, Karamanev found that Eq. (6-237) is followed up to Ar = 13,000 and that for Ar > 13,000, the drag coefficient is $C_D = 0.95$.

For particles settling in **non-Newtonian** fluids, correlations are given by Dallon and Christiansen (Preprint 24C, *Symposium on Selected Papers,* part III, 61st Ann. Mtg. AIChE, Los Angeles, Dec. 1–5, 1968) for spheres settling in shear-thinning liquids, and by Ito and Kajiuchi (*J. Chem. Eng. Japan,* **2**[1], 19–24 [1969]) and Pazwash and Robertson (*J. Hydraul. Res.,* **13,** 35–55 [1975]) for spheres settling in Bingham plastics. Beris, Tsamopoulos, Armstrong, and Brown (*J. Fluid Mech.,* **158** [1985]) present a finite element calculation for creeping motion of a sphere through a Bingham plastic.

**Nonspherical Rigid Particles** The drag on a nonspherical particle depends upon its shape and orientation with respect to the

**TABLE 6-8 Free-Fall Orientation of Particles**

| Reynolds number* | Orientation |
|---|---|
| 0.1–5.5 | All orientations are stable when there are three or more perpendicular axes of symmetry. |
| 5.5–200 | Stable in position of maximum drag. |
| 200–500 | Unpredictable. Disks and plates tend to wobble, while fuller bluff bodies tend to rotate. |
| 500–200,000 | Rotation about axis of least inertia, frequently coupled with spiral translation. |

SOURCE: From Becker, *Can. J. Chem. Eng.*, **37,** 85–91 (1959).
*Based on diameter of a sphere having the same surface area as the particle.

direction of motion. The orientation in free fall as a function of Reynolds number is given in Table 6-8.

The drag coefficients for **disks** (flat side perpendicular to the direction of motion) and for **cylinders** (infinite length with axis perpendicular to the direction of motion) are given in Fig. 6-57 as a function of Reynolds number. The effect of length-to-diameter ratio for cylinders in the Newton's law region is reported by Knudsen and Katz (*Fluid Mechanics and Heat Transfer,* McGraw-Hill, New York, 1958).

Pettyjohn and Christiansen (*Chem. Eng. Prog.,* **44,** 157–172 [1948]) present correlations for the effect of particle shape on free-settling velocities of **isometric particles.** For $Re < 0.05$, the terminal or free-settling velocity is given by

$$u_t = K_1 \frac{g d_s^2(\rho_p - \rho)}{18\mu} \tag{6-238}$$

$$K_1 = 0.843 \log\left(\frac{\psi}{0.065}\right) \tag{6-239}$$

where $\psi$ = sphericity, the surface area of a sphere having the same volume as the particle, divided by the actual surface area of the particle; $d_s$ = equivalent diameter, equal to the diameter of the equivalent sphere having the same volume as the particle; and other variables are as previously defined.

In the **Newton's law region,** the terminal velocity is given by

$$u_t = \sqrt{\frac{4d_s(\rho_p - \rho)g}{3K_3\rho}} \tag{6-240}$$

$$K_3 = 5.31 - 4.88\psi \tag{6-241}$$

Equations (6-238) to (6-241) are based on experiments on cube-octahedrons, octahedrons, cubes, and tetrahedrons for which the sphericity $\psi$ ranges from 0.906 to 0.670, respectively. See also Clift, Grace, and Weber. A graph of drag coefficient vs. Reynolds number with $\psi$ as a parameter may be found in Brown, et al. (*Unit Operations,* Wiley, New York, 1950) and in Govier and Aziz.

For particles with $\psi < 0.67$, the correlations of Becker (*Can. J. Chem. Eng.,* **37,** 85–91 [1959]) should be used. Reference to this paper is also recommended for **intermediate region** flow. Settling characteristics of nonspherical particles are discussed by Clift, Grace, and Weber, Chaps. 4 and 6.

The terminal velocity of **axisymmetric particles in axial motion** can be computed from Bowen and Masliyah (*Can. J. Chem. Eng.,* **51,** 8–15 [1973]) for low–Reynolds number motion:

$$u_t = \frac{V'}{K_2} \frac{g D_s^2(\rho_p - \rho)}{18\mu} \tag{6-242}$$

$$K_2 = 0.244 + 1.035\Sigma - 0.712\Sigma^2 + 0.441\Sigma^3 \tag{6-243}$$

where $D_s$ = diameter of sphere with perimeter equal to maximum particle projected perimeter
$V'$ = ratio of particle volume to volume of sphere with diameter $D_s$
$\Sigma$ = ratio of surface area of particle to surface area of a sphere with diameter $D_s$

and other variables are as defined previously.

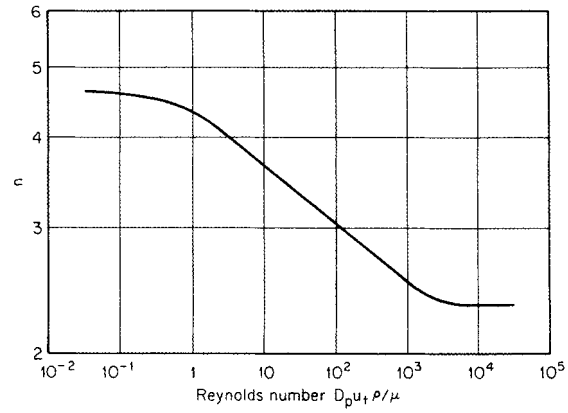

**FIG. 6-58** Values of exponent $n$ for use in Eq. (6-242). (*From Maude and Whitmore,* Br. J. Appl. Phys., **9,** *481 [1958]. Courtesy of the Institute of Physics and the Physical Society.*)

**Hindered Settling** When particle concentration increases, particle settling velocities decrease because of hydrodynamic interaction between particles and the upward motion of displaced liquid. The suspension viscosity increases. Hindered settling is normally encountered in sedimentation and transport of concentrated slurries. Below 0.1 percent volumetric particle concentration, there is less than a 1 percent reduction in settling velocity. Several expressions have been given to estimate the effect of particle volume fraction on settling velocity. Maude and Whitmore (*Br. J. Appl. Phys.,* **9,** 477–482 [1958]) give, for uniformly sized spheres,

$$u_t = u_{t0}(1 - c)^n \tag{6-244}$$

where $u_t$ = terminal settling velocity
$u_{t0}$ = terminal velocity of a single sphere (infinite dilution)
$c$ = volume fraction solid in the suspension
$n$ = function of Reynolds number $Re_p = d_p u_{t0}\rho/\mu$ as given Fig. 6-58

In the Stokes' law region ($Re_p < 0.3$), $n = 4.65$ and in the Newton's law region ($Re_p > 1{,}000$), $n = 2.33$. Equation (6-244) may be applied to particles of any size in a polydisperse system, provided the volume fraction corresponding to all the particles is used in computing terminal velocity (Richardson and Shabi, *Trans. Inst. Chem. Eng.* [*London*], **38,** 33–42 [1960]). The concentration effect is greater for nonspherical and angular particles than for spherical particles (Steinour, *Ind. Eng. Chem.,* **36,** 840–847 [1944]). Theoretical developments for low–Reynolds number flow assemblages of spheres are given by Happel and Brenner (*Low Reynolds Number Hydrodynamics,* Prentice-Hall, Englewood Cliffs, N.J., 1965) and Famularo and Happel (*AIChE J.,* **11,** 981 [1965]) leading to an equation of the form

$$u_t = \frac{u_{t0}}{1 + \gamma c^{1/3}} \tag{6-245}$$

where $\gamma$ is about 1.3. As particle concentration increases, resulting in interparticle contact, hindered settling velocities are difficult to predict. Thomas (*AIChE J.,* **9,** 310 [1963]) provides an empirical expression reported to be valid over the range $0.08 < u_t/u_{t0} < 1$:

$$\ln\left(\frac{u_t}{u_{t0}}\right) = -5.9c \tag{6-246}$$

**Time-dependent Motion** The time-dependent motion of particles is computed by application of Newton's second law, equating the rate of change of particle motion to the net force acting on the particle. Rotation of particles may also be computed from the net torque. For large particles moving through low-density gases, it is usually sufficient to compute the force due to fluid drag from the

relative velocity and the drag coefficient computed for steady flow conditions. For two- and three-dimensional problems, the velocity appearing in the particle Reynolds number and the drag coefficient is the amplitude of the relative velocity. The drag force, not the relative velocity, is to be resolved into vector components to compute the particle acceleration components. Clift, Grace, and Weber (*Bubbles, Drops and Particles,* Academic, London, 1978) discuss the complexities that arise in the computation of transient drag forces on particles when the transient nature of the flow is important. Analytical solutions for the case of a single particle in creeping flow ($Re_p = 0$) are available. For example, the creeping motion of a sphericial particle released from rest in a stagnant fluid is described by

$$\rho_p V \frac{dU}{dt} = g(\rho_p - \rho)V - 3\pi\mu d_p U - \frac{\rho}{2} V \frac{dU}{dt} - \left(\frac{3}{2}\right) d_p^2 \sqrt{\pi\rho\mu} \int_0^t \frac{(dU/dt)_{t=s}\, ds}{\sqrt{t-s}} \quad (6\text{-}247)$$

Here, $U$ = particle velocity, positive in the direction of gravity, and $V$ = particle volume. The first term on the right-hand side is the net gravitational force on the particle, accounting for buoyancy. The second is the steady-state Stokes drag (Eq. 6-231). The third is the **added mass** or **virtual mass** term, which may be interpreted as the inertial effect of the fluid which is accelerated along with the particle. The volume of the added mass of fluid is half the particle volume. The last term, the **Basset force,** depends on the entire history of the transient motion, with past motions weighted inversely with the square root of elapsed time. Clift, et al. provide integrated solutions. In **turbulent flows,** particle velocity will closely follow fluid eddy velocities when (Clift et al.)

$$\tau_0 >> \frac{d_p^2[(2\rho_p/\rho) + 1]}{36\nu} \quad (6\text{-}248)$$

where $\tau_0$ = oscillation period or eddy time scale, the right-hand side expression is the **particle relaxation time,** and $\nu$ = kinematic viscosity.

**Gas Bubbles** Fluid particles, unlike rigid solid particles, may undergo deformation and internal circulation. Figure 6-59 shows rise velocity data for air bubbles in stagnant water. In the figure, Eo = Eotvos number, $g(\rho_L - \rho_G)d_e/\sigma$, where $\rho_L$ = liquid density, $\rho_G$ = gas density, $d_e$ = bubble diameter, $\sigma$ = surface tension, and the equivalent diameter $d_e$ is the diameter of a sphere with volume equal to that of the bubble. Small bubbles (<1-mm [0.04-in] diameter) remain spherical and rise in straight lines. The presence of surface active materials generally renders small bubbles rigid, and they rise roughly according to the drag coefficient and terminal velocity equations for spherical solid particles. Bubbles roughly in the range 2- to 8-mm (0.079- to 0.32-in) diameter assume flattened, ellipsoidal shape, and rise in a zigzag or spiral pattern. This motion increases dissipation and drag, and the rise velocity may actually decrease with increasing bubble diameter in this region, characterized by rise velocities in the range of 20 to 30 cm/s (0.7 to 1.0 ft/s). Large bubbles, >8-mm (0.32-in) diameter, are greatly deformed, assuming a mushroomlike, spherical cap shape. These bubbles are unstable and may break into smaller bubbles. Carefully purified water, free of surface active materials, allows bubbles to freely circulate even when they are quite small. Under creeping flow conditions $Re_b = d_b u_r \rho_L/\mu_L < 1$, where $u_r$ = bubble rise velocity and $\mu_L$ = liquid viscosity, the bubble rise velocity may be computed analytically from the Hadamard-Rybczynski formula (Levich, *Physicochemical Hydrodynamics,* Prentice-Hall, Englewood Cliffs, N.J., 1962, p. 402). When $\mu_G/\mu_L << 1$, which is normally the case, the rise velocity is 1.5 times the rigid sphere Stokes law velocity. However, in practice, most liquids, including ordinary distilled water, contain sufficient surface active materials to render small bubbles rigid. Larger bubbles undergo deformation in both purified and ordinary liquids; however, the variation in rise velocity for large bubbles with degree of purity is quite evident in Fig. 6-59. For additional discussion, see Clift, et al., Chap. 7.

Karamanev [op. cit.] provided equations for bubble rise velocity based on the Archimedes number and on use of the bubble projected diameter $d_h$ in the drag coefficient and the bubble equivalent diameter in Ar. The Archimedes number is as defined in Eq. (6-236) except that the density difference is liquid density minus gas density, and $d_p$ is replaced by $d_e$.

$$u_t = 40.3 \frac{d_e}{d_h} \sqrt{\frac{V^{1/3}}{C_D}} = 40.3 \frac{d_e}{d_h} \sqrt{\frac{(\pi d_e^3/6)^{1/3}}{C_D}} \quad (6\text{-}249)$$

$$C_D = \frac{432}{\mathrm{Ar}}(1 + 0.0470\mathrm{Ar}^{2/3}) + \frac{0.517}{1 + 154\mathrm{Ar}^{-1/3}} \quad \mathrm{Ar} < 13{,}000 \quad (6\text{-}250)$$

$$C_D = 0.95 \quad \mathrm{Ar} > 13{,}000 \quad (6\text{-}251)$$

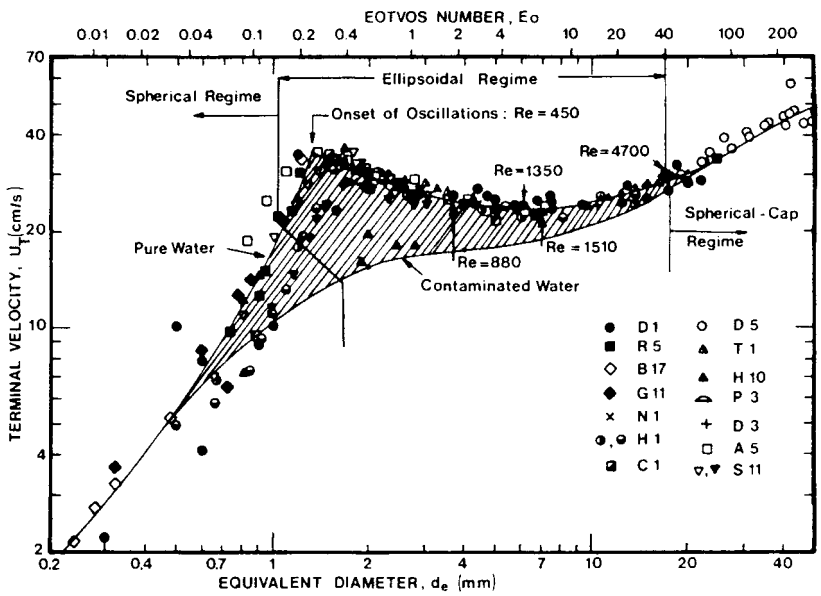

**FIG. 6-59** Terminal velocity of air bubbles in water at 20°C. (*From Clift, Grace, and Weber,* Bubbles, Drops and Particles, *Academic, New York, 1978*).

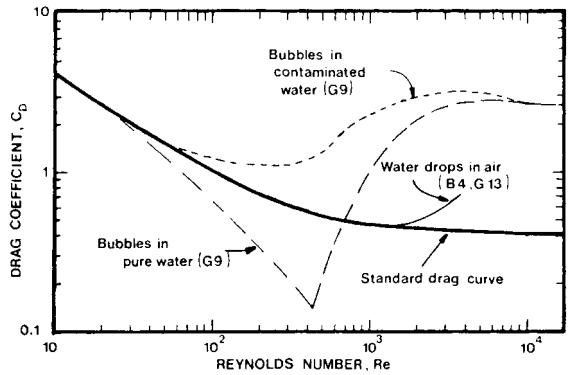

**FIG. 6-60** Drag coefficient for water drops in air and air bubbles in water. Standard drag curve is for rigid spheres. (*From Clift, Grace, and Weber,* Bubbles, Drops and Particles, *Academic, New York, 1978.*)

$$\frac{d_e}{d_h} = (1 + 0.163\text{Eo}^{0.757})^{-1/3} \quad \text{Eo} < 40 \tag{6-252}$$

$$\frac{d_e}{d_h} = 0.62 \quad \text{Eo} > 40 \tag{6-253}$$

Applied to air bubbles in water, these expressions give reasonable agreement with the contaminated water curve in Fig. 6-59.

Figure 6-60 gives the drag coefficient as a function of bubble or drop Reynolds number for air bubbles in water and water drops in air, compared with the standard drag curve for rigid spheres. Information on bubble motion in **non-Newtonian** liquids may be found in Astarita and Apuzzo (*AIChE J.*, **11,** 815–820 [1965]); Calderbank, Johnson, and Loudon (*Chem. Eng. Sci.*, **25,** 235–256 [1970]); and Acharya, Mashelkar, and Ulbrecht (*Chem. Eng. Sci.*, **32,** 863–872 [1977]).

**Liquid Drops in Liquids** Very small liquid drops in immisicibile liquids behave like rigid spheres, and the terminal velocity can be approximated by use of the drag coefficient for solid spheres up to a Reynolds number of about 10 (Warshay, Bogusz, Johnson, and Kintner, *Can. J. Chem. Eng.*, **37,** 29–36 [1959]). Between Reynolds numbers of 10 and 500, the terminal velocity exceeds that for rigid spheres owing to internal circulation. In normal practice, the effect of drop phase viscosity is neglected. Grace, Wairegi, and Nguyen (*Trans. Inst. Chem. Eng.*, **54,** 167–173 [1976]; Clift, et al., op. cit., pp. 175–177) present a correlation for terminal velocity valid in the range

$$M < 10^{-3} \qquad \text{Eo} < 40 \qquad \text{Re} > 0.1 \tag{6-254}$$

where $M$ = Morton number = $g\mu^4\Delta\rho/\rho^2\sigma^3$
Eo = Eotvos number = $g\Delta\rho d^2/\sigma$
Re = Reynolds number = $du\rho/\mu$
$\Delta\rho$ = density difference between the phases
$\rho$ = density of continuous liquid phase
$d$ = drop diameter
$\mu$ = continuous liquid viscosity
$\sigma$ = surface tension
$u$ = relative velocity

The correlation is represented by

$$J = 0.94H^{0.757} \qquad (2 < H \le 59.3) \tag{6-255}$$

$$J = 3.42H^{0.441} \qquad (H > 59.3) \tag{6-256}$$

where

$$H = \frac{4}{3}\text{Eo}M^{-0.149}\left(\frac{\mu}{\mu_w}\right)^{-0.14} \tag{6-257}$$

$$J = \text{Re}M^{0.149} + 0.857 \tag{6-258}$$

Note that the terminal velocity may be evaluated explicitly from

$$u = \frac{\mu}{\rho d} M^{-0.149}(J - 0.857) \tag{6-259}$$

In Eq. (6-257), $\mu$ = viscosity of continuous liquid and $\mu_w$ = viscosity of water, taken as 0.9 cP (0.0009 Pa · s).

For drop velocities in non-Newtonian liquids, see Mhatre and Kinter (*Ind. Eng. Chem.*, **51,** 865–867 [1959]); Marrucci, Apuzzo, and Astarita (*AIChE J.*, **16,** 538–541 [1970]); and Mohan, et al. (*Can. J. Chem. Eng.*, **50,** 37–40 [1972]).

**Liquid Drops in Gases** Liquid drops falling in stagnant gases appear to remain spherical and follow the rigid sphere drag relationships up to a Reynolds number of about 100. Large drops will deform,

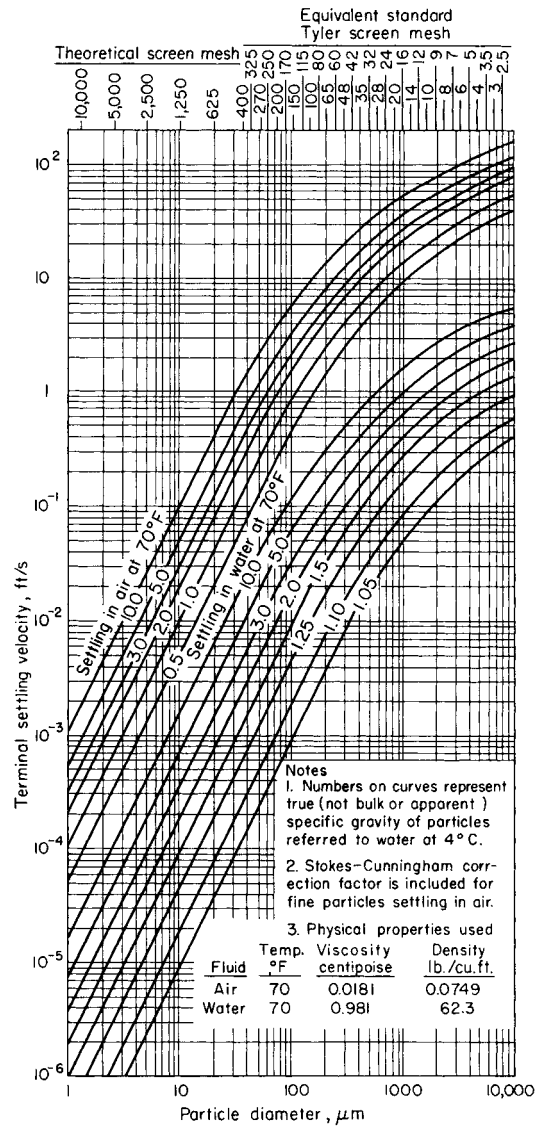

**FIG. 6-61** Terminal velocities of spherical particles of different densities settling in air and water at 70°F under the action of gravity. To convert ft/s to m/s, multiply by 0.3048. (*From Lapple, et al.,* Fluid and Particle Mechanics, *University of Delaware, Newark, 1951, p. 292.*)

with a resulting increase in drag, and in some cases will shatter. The largest water drop which will fall in air at its terminal velocity is about 8 mm (0.32 in) in diameter, with a corresponding velocity of about 9 m/s (30 ft/s). Drops shatter when the Weber number defined as

$$\mathrm{We} = \frac{\rho_G u^2 d}{\sigma} \tag{6-260}$$

exceeds a critical value. Here, $\rho_G$ = gas density, $u$ = drop velocity, $d$ = drop diameter, and $\sigma$ = surface tension. A value of $\mathrm{We}_c = 13$ is often cited for the critical Weber number.

Terminal velocities for water drops in air have been correlated by Berry and Prnager (*J. Appl. Meteorol.*, **13,** 108–113 [1974]) as

$$\mathrm{Re} = \exp\left[-3.126 + 1.013 \ln N_D - 0.01912(\ln N_D)^2\right] \tag{6-261}$$

for $2.4 < N_D < 10^7$ and $0.1 < \mathrm{Re} < 3{,}550$. The dimensionless group $N_D$ (often called the *Best* number [Clift et al.]) is given by

$$N_D = \frac{4\rho\Delta\rho g d^3}{3\mu^2} \tag{6-262}$$

and is proportional to the similar Archimedes and Galileo numbers.

Figure 6-61 gives calculated settling velocities for solid spherical particles settling in air or water using the standard drag coefficient curve for spherical particles. For fine particles settling in air, the **Stokes-Cunningham correction** has been applied to account for particle size comparable to the mean free path of the gas. The correction is less than 1 percent for particles larger than 16 μm settling in air. Smaller particles are also subject to **Brownian motion.** Motion of particles smaller than 0.1 μm is dominated by Brownian forces and gravitational effects are small.

**Wall Effects** When the diameter of a settling particle is significant compared to the diameter of the container, the settling velocity is reduced. For rigid spherical particles settling with $\mathrm{Re} < 1$, the correction given in Table 6-9 may be used. The factor $k_w$ is multiplied by the settling velocity obtained from Stokes' law to obtain the corrected settling rate. For values of diameter ratio $\beta$ = particle diameter/vessel diameter less than 0.05, $k_w = 1/(1 + 2.1\beta)$ (Zenz and Othmer, *Fluidization and Fluid-Particle Systems*, Reinhold, New York, 1960, pp. 208–209). In the range $100 < \mathrm{Re} < 10{,}000$, the computed terminal velocity for rigid spheres may be multiplied by $k'_w$ to account for wall effects, where $k'_w$ is given by (Harmathy, *AIChE J.*, **6,** 281 [1960])

$$k'_w = \frac{1 - \beta^2}{\sqrt{1 + \beta^4}} \tag{6-263}$$

For gas bubbles in liquids, there is little wall effect for $\beta < 0.1$. For $\beta > 0.1$, see Uto and Kintner (*AIChE J.*, **2,** 420–424 [1956]), Maneri and Mendelson (*Chem. Eng. Prog.*, **64,** *Symp. Ser.*, **82,** 72–80 [1968]), and Collins (*J. Fluid Mech.*, **28,** part 1, 97–112 [1967]).

**TABLE 6-9 Wall Correction Factor for Rigid Spheres in Stokes' Law Region**

| β* | $k_w$ | β | $k_w$ |

## Nomenclature and Units

The component A is identified by the subscript $a$. Thus, the number of moles is $n_a$; the fractional conversion is $X_a$; the extent of reaction is $\zeta_a$; the partial pressure is $p$; the rate of consumption is $r_a$; the molar flow rate is $N_a$; the volumetric flow rate is $q$; reactor volume is $V_r$ or simply $V$ for batch reactors; the volumetric concentration is $C_a = n_a/V$ or $C_a = N_a/q$; the total pressure is $P$; and the temperature is $T$. Throughout this section, equations are presented without specification of units. Use of any consistent unit set is appropriate.

Following is a listing of typical nomenclature expressed in SI and U.S. Customary System units.

| Symbol | Definition | SI units | U.S. Customary System units |
|---|---|---|---|
| $A, B, C, \ldots$ | Names of substances | | |
| $A$ | Free radical, as $CH_3$ | | |
| $a$ | Activity | | |
| BR | Batch reactor | | |
| $b$ | Estimate of kinetic parameters, vector | | |
| $C_a$ | Concentration of substance A | kg·mol/m$^3$ | lb·mol/ft$^3$ |
| CSTR | Continuous stirred tank reactor | | |
| $C_0$ | Initial concentration | kg·mol/m$^3$ | lb·mol/ft$^3$ |
| $c_p$ | Heat capacity at constant pressure | kJ/(kg·K) | Btu/(lbm·°F) |
| $\Delta c_p$ | Heat capacity change in a reaction | kJ/(kg·K) | Btu/(lbm·°F) |
| $D$ | Diffusivity, dispersion coefficient | m$^2$/s | ft$^2$/s |
| $D_e$ | Effective diffusivity | m$^2$/s | ft$^2$/s |
| $D_K$ | Knudsen diffusivity | m$^2$/s | ft$^2$/s |
| DP | Degree of polymerization | | |
| $E$ | Activation energy, enhancement factor for gas-liquid mass transfer with reaction, electrochemical cell potential | | |
| $F$ | Faraday constant, $F$ statistic | | |
| $f$ | Efficiency of initiation in polymerization | | |
| $f_a$ | $C_a/C_{a0}$ or $n_a/n_{a0}$, fraction of $A$ remaining unconverted | | |
| Ha | Hatta number | | |
| He | Henry constant for absorption of gas in liquid | | |
| $\Delta G$ | Free energy change | kJ/kg·mol | Btu/lb·mol |
| $\Delta H_r$ | Heat of reaction | kJ/kg·mol | Btu/lb·mol |
| $I$ | Initiator for polymerization, modified Bessel functions, electric current | | |
| $j$ | Electric current density | A/m$^2$ | |
| $K_a$ | Adsorption constant | | |
| $K_e$ | Chemical equilibrium constant | | |
| $k$ | Specific rate constant of reaction, mass-transfer coefficient | | |
| $L$ | Length of path in reactor | m | ft |
| LFSS | Lack of fit sum of squares | | |
| $M$ | Average molecular weight in polymers, dead polymer species, monomer | | |
| $m$ | Number of moles in electrochemical reaction | kg·mol | lb·mol |
| $N$ | Molar flow rate, molar flux | | |
| NCLD | Number chain length distribution | | |
| NMWD | Number molecular weight distribution | | |
| $n$ | Number of stages in a CSTR battery, reaction order, number of electrons in electrochemical reaction, number of experiments | | |
| $n_a$ | Number of moles of $A$ present | kg·mol | lb·mol |
| $n_t$ | Total number of moles | kg·mol | lb·mol |
| $P$ | Total pressure, live polymer species | | |
| PESS | Pure error sum of squares | | |
| PFR | Plug flow reactor | | |
| $p$ | Number of kinetic parameters | | |

| Symbol | Definition | SI units | U.S. Customary System units |
|---|---|---|---|
| $p_a$ | Partial pressure of substance $A$ | Pa | psi |
| $q$ | Volumetric flow rate | m$^3$/s | ft$^3$/s |
| $Q$ | Electric charge | Coulomb | |
| $R$ | Radial position, radius, universal gas constant | | |
| Re | Reynolds number | | |
| RgSS | Regression sum of squares | | |
| RSS | Residual sum of squares | | |
| $r_a$ | Rate of reaction of $A$ per unit volume | | |
| $S$ | Selectivity, stoichiometric matrix, objective function for parameter estimation | | |
| SBR | Semibatch reactor | | |
| Sc | Schmidt number | | |
| Sh | Sherwood number | | |
| $\Delta S$ | Entropy change | kJ/(kg·mol·K) | Btu/(lb·mol·R$_r$) |
| $s$ | Estimate of variance | | |
| $t$ | Time, $t$ statistic | | |
| $u$ | Linear velocity | m/s | ft/s |
| $V$ | Volume of reactor, variance-covariance matrix | | |
| $v$ | Molar volume | m$^3$/kg·mol | ft$^3$/lb·mol |
| WCLD | Weight chain length distribution | | |
| WMMD | Weight molecular weight distribution | | |
| $X$ | Linear model matrix for parameter estimation, fractional conversion | | |
| $X_a$ | $1 - f_a = 1 - C_a/C_{a0}$ or $1 - n_a/_{a0}$, fraction of $A$ converted | | |
| $x$ | Axial position in a reactor, mole fraction in liquid | Variable | |
| $Y$ | Yield; yield coefficient for biochemical reactions | | |
| $y$ | Mole fraction in gas, predicted dependent variable | | |
| $z$ | $x/L$, normalized axial position | | |

### Greek letters

| | |
|---|---|
| $\alpha$ | Fraction of initial catalyst activity, probability of propagation for chain polymerization, confidence level |
| $\beta$ | $r/R$, normalized radial position, fraction of poisoned catalyst, kinetic parameter vector |
| $\delta$ | Film thickness or boundary layer thickness, relative change in number of moles by reaction |
| $\delta(t)$ | Unit impulse input, Dirac function |
| $\varepsilon$ | Fraction void space in a packed bed, relative change in number of moles by reaction, residual error, porosity, current efficiency |
| $\Phi$ | Weisz Prater parameter |
| $\phi$ | Thiele modulus |

**Nomenclature and Units** (*Concluded*)

| Symbol | Definition | SI units | U.S. Customary System units |
|---|---|---|---|
| | **Greek letters** | | |
| η | Effectiveness factor of porous catalyst, overpotential in electrochemical reactions | | |
| λ | Parameter for instantaneous gas-liquid reaction, moments in polymer chain length | | |
| μ | Viscosity, biomass growth rate, average chain length in polymers | | |
| ν | μ/ρ, kinematic viscosity, stoichiometric coefficient, fraction of surface covered by adsorbed species | | |
| θ | Dimensionless time | | |
| ρ | Density | $kg/m^3$ | $lbm/ft^3$ |
| σ | Variance | | |
| τ | Residence time, tortuosity factor | | |
| ζ | Extent of reaction | | |
| | **Subscripts** | | |
| act | Activation | | |
| anode | At anode | | |
| *B* | Bed | | |
| cathode | At cathode | | |
| cell | Electrochemical cell | | |
| current, *j* | Current, species *j* | | |
| *D* | Diffusion, dispersion | | |

| Subscripts | |
|---|---|
| *d* | Deactivation |
| *e* | Equilibrium |
| *f* | Forward reaction, final, formation |
| *G* | Gas |
| *i* | Component *i* |
| *j* | Reaction *j* |
| *L* | Liquid |
| *m* | Based on mass, mass transfer |
| max | Maximum biomass growth, maximum extent of reaction |
| *n* | Chain length in polymers |
| *o* | Oxidized |
| obs | observed |
| *p* | Particle |
| projected | Electrode projected area |
| *r* | Reverse reaction, reduced |
| *S* | Substrate |
| *s* | Solid or catalyst, saturation, surface |
| surf | Surface |
| *v* | Based on volume |
| *x* | Biomass |
| 0 | At initial or inlet conditions, as in $C_{a0}$, $n_{g0}$, $V'_0$, at reference temperature |
| ½ | Half-life |

| Superscripts | |
|---|---|
| eq | Equilibrium |
| *o* | At reference temperature |
| *T* | Transposed matrix |

The mechanism and corresponding kinetics provide the rate at which the chemical or biochemical species in the reactor system react at the prevailing conditions of temperature, pressure, composition, mixing, flow, heat, and mass transfer. Observable kinetics represent the true intrinsic chemical kinetics only when competing phenomena such as transport of mass and heat are not limiting the rates. The intrinsic chemical mechanism and kinetics are unique to the reaction system. Knowledge of the intrinsic kinetics therefore facilitates reactor selection, choice of optimal operating conditions, and reactor scale-up and design, when combined with understanding of the associated physical and transport phenomena for different reactor scales and types.

This section covers the following key aspects of reaction kinetics:

- Chemical mechanism of a reaction system and its relation to kinetics
- Intrinsic rate data using equations that can be correlative, lumped, or based on detailed elementary kinetics
- Catalytic kinetics
- Effect of mass transfer on kinetics in heterogeneous systems
- Intrinsic kinetic rates from experimental data and/or from theoretical calculations
- Kinetic parameter estimation

The use of reaction kinetics for analyzing and designing suitable reactors is discussed in Sec. 19.

# BASIC CONCEPTS

## MECHANISM

The mechanism describes the reaction steps and the relationship between the reaction rates of the chemical components. A single chemical reaction includes reactants $A, B, \ldots$ and products $R, S, \ldots$

$$\nu_a A + \nu_b B + \cdots \Leftrightarrow \nu_r R + \nu_s S + \cdots \tag{7-1}$$

where $\nu_i$ are the *stoichiometric coefficients* of components $A, B, \ldots$, i.e., the relative number of molecules of $A, B, \ldots$ that participate in the reaction. For instance, the HBr synthesis has the global stoichiometry $H_2 + Br_2 \Leftrightarrow 2HBr$.

The *stoichiometry* of the reaction defines the reaction elemental balance (atoms of H and Br, for instance) and therefore relates the number of molecules of reactants and products participating in the reaction. The stoichiometric coefficients are not unique for a given reaction, but their ratios are unique. For instance, for the HBr synthesis above we could have written the stoichiometric equation $\frac{1}{2}H_2 + \frac{1}{2}Br_2 \Leftrightarrow HBr$ as well.

Often several reactions occur simultaneously, resulting in a *network of reactions*. When the network is broken down into *elementary* or *single-event* steps (such as a single electron transfer), the network represents the *true mechanism* of the chemical transformations leading from initial reactants to final products through intermediates. The intermediates can be molecules, ions, free radicals, transition state complexes, and other moieties. A network of *global reactions*, with each reaction representing the combination of a number of elementary steps, does not represent the true mechanism of the chemical transformation but is still useful for global reaction rate calculations, albeit empirically. The stoichiometry can only be written in a unique manner for elementary reactions, since as shown later, the reaction rate for elementary reactions is determined directly by the stoichiometry through the concept of the law of mass action.

## REACTION RATE

The *specific rate* of consumption or production of any reaction species $i$, $r_i$, is the rate of change of the number of molecules of species $i$ with time per unit volume of reaction medium:

$$r_i = \frac{1}{V}\frac{dn_i}{dt} \tag{7-2}$$

The rate is negative when $i$ represents a *reactant* ($dn_i/dt$ is negative since $n_i$ is decreasing with time) and positive when $i$ represents a *product* ($dn_i/dt$ positive since $n_i$ is increasing with time). The specific rate of a reaction, e.g., that in Eq. (7-1) is defined as

$$\begin{aligned} r &= -r_i/\nu_I \qquad \text{for reactants} \\ r &= r_i/\nu_I \qquad \text{for products} \end{aligned} \tag{7-3}$$

By this definition, the specific rate of reaction is uniquely defined, and its sign is always positive. Inversely, the rate of reaction of each component or species participating in the reaction is the specific reaction rate multiplied by the species' stoichiometric coefficient with the corrected sign (negative for reactants, positive for products).

## CLASSIFICATION OF REACTIONS

Reactions can be classified in several ways. On the basis of *mechanism* they may be

1. *Irreversible*, i.e., the reverse reaction rate is negligible: $A + B \Rightarrow C + D$, e.g., CO oxidation $CO + \frac{1}{2}O_2 \Rightarrow CO_2$
2. *Reversible*: $A + B \Leftrightarrow C + D$, e.g., the water-gas shift $CO + H_2O \Leftrightarrow CO_2 + H_2$
3. *Equilibrium*, a special case with zero net rate, i.e., with the forward and reverse reaction rates of a reversible reaction being equal. All reversible reactions, if left to go to completion, end in equilibrium.
4. *Networks of simultaneous reactions*, i.e., consecutive, parallel, complex (combination of consecutive and parallel reactions):

$$A + B \Rightarrow C + D \qquad C + E \Rightarrow F + G$$

e.g., two-step hydrogenation of acetylene to ethane

$$CH{\equiv}CH + H_2 \Rightarrow CH_2{=}CH_2 \qquad CH_2{=}CH_2 + H_2 \Rightarrow CH_3CH_3$$

A further classification is from the point of view of the number of reactant molecules participating in the reaction, or the *molecularity:*

1. *Unimolecular*: $A \Rightarrow B$, e.g., isomerization of ortho-xylene to para-xylene, *O*-xylene $\Rightarrow$ *P*-xylene, or $A \Rightarrow B + C$, e.g., decomposition $CaCO_3 \Rightarrow CaO + CO_2$
2. *Bimolecular*: $A + B \Rightarrow C$ or $2A \Rightarrow B$ or $A + B \Rightarrow C + D$, e.g., $C_2H_4 + H_2 \Rightarrow C_2H_6$
3. *Trimolecular*: $A + B + C \Rightarrow D$ or $3A \Rightarrow B$

This last classification has fundamental meaning only when considering elementary reactions, i.e., reactions that constitute a single chemical transformation or a single event, such as a single electron transfer. For elementary reactions, molecularity is rarely higher than 2. Often elementary reactions are not truly unimolecular, since in order for the reaction to occur, energy is required and it is obtained through collision with other molecules such as an inert solvent or gas.

Thus the unimolecular reaction $A \Rightarrow B$ could in reality be represented as a bimolecular reaction $A + X \Rightarrow B + X$, i.e., $A$ collides with $X$ to produce $B$ and $X$, and thus no net consumption of $X$ occurs.

Reactions can be further classified according to the *phases* present. Examples for the more common cases are

1. *Homogeneous gas,* e.g., methane combustion
2. *Homogeneous liquid,* e.g., acid/base reactions to produce soluble salts
3. *Heterogeneous gas-solid,* e.g., HCN synthesis from $NH_3$, $CH_4$, and air on a solid catalyst
4. *Heterogeneous gas-liquid,* e.g., absorption of $CO_2$ in amine solutions
5. *Heterogeneous liquid-liquid,* e.g., reaction in immiscible organic and aqueous phases such as synthesis of adipic acid from cyclohexanone and nitric acid
6. *Heterogeneous liquid-solid,* e.g., reaction of limestone with sulfuric acid to make gypsum
7. *Heterogeneous solid-solid,* e.g., self-propagating, high-temperature synthesis of inorganic pure oxides (SHS)
8. *Heterogeneous gas-liquid-solid,* e.g., catalytic Fischer-Tropsch synthesis of hydrocarbons from CO and $H_2$
9. *Heterogeneous gas-liquid-liquid,* e.g., oxidations or hydrogenations with phase transfer catalysts

Reactions can also be classified with respect to the *mode of operation* in the reaction system as

1. *Isothermal constant volume* (batch)
2. *Isothermal constant pressure* (continuous)
3. *Adiabatic*
4. *Nonisothermal* temperature-controlled (by cooling or heating), batch or continuous

## EFFECT OF CONCENTRATION ON RATE

The *concentration* of the reaction components determines the rate of reaction. For instance, for the irreversible reaction

$$pA + qB \Rightarrow rC + sD \tag{7-4}$$

the rate can be represented *empirically* as a power law function of the reactant concentrations such as

$$r = kC_a^a C_b^b \qquad C_i = \frac{n_i}{V} \tag{7-5}$$

The exponents $a$ and $b$ represent the *order of the reaction* with respect to components $A$ and $B$, and the *sum* $a + b$ represents the *overall order of the reaction*. The order can be a positive, zero, or negative number indicating that the rate increases, is independent of, or decreases with an increase in a species concentration, respectively. The exponents can be whole (integral order) or fraction (fractional order). In Eq. (7-5) $k$ is the *specific rate constant* of the reaction, and it is independent of concentrations for elementary reactions only. For global reactions consisting of several elementary steps, $k$ may still be constant over a narrow range of compositions and operating conditions and therefore can be considered constant for limited practical purposes. A further complexity arises for nonideal chemical solutions where activities have to be used instead of concentrations. In this case the rate constant can be a function of composition even for elementary steps (see, for instance, Froment and Bischoff, *Chemical Reactor Analysis and Design,* Wiley, 1990).

When Eq. (7-4) represents a global reaction combining a number of elementary steps, then rate equation (7-5) represents an empirical correlation of the global or overall reaction rate. In this case exponents $a$ and $b$ have no clear physical meaning other than indicating the overall effect of the various concentrations on rate, and they do not have any obvious relationship to the stoichiometric coefficients $p$ and $q$. This is not so for elementary reactions, as shown in the next subsection. Also, as shown later, power law and rate expressions other than power law (e.g., hyperbolic) can be developed for specific reactions by starting with the mechanism of the elementary steps and making simplifying assumptions that are valid under certain conditions.

## LAW OF MASS ACTION

As indicated above, the dependence of rate on concentration can be shown to be of the general form

$$r = kf(C_a, C_b, \ldots) \tag{7-6}$$

For elementary reactions, the *law of mass action* states that the rate is proportional to the concentrations of the reactants raised to the power of their respective molecularity. Thus for an elementary irreversible reaction such as (7-4) the rate equation is

$$r = kC_a^p C_b^q \tag{7-7}$$

Hence, the exponents $p$ *and* $q$ of Eq. (7-7) are the stoichiometric coefficients when the stoichiometric equation truly represents the mechanism of reaction, i.e., when the reactions are elementary. As discussed above, the exponents $a$ and $b$ in Eq. (7-5) identify the order of the reaction, while the stoichiometric coefficients $p$ and $q$ in Eq. (7-7) also identify the molecularity—for elementary reactions these are the same.

## EFFECT OF TEMPERATURE

The *Arrhenius equation* relates the specific rate constant to the absolute temperature

$$k = k_0 \exp\left(-\frac{E}{RT}\right) \tag{7-8}$$

where $E$ is called the *activation energy* and $k_0$ is the *preexponential* factor. As seen from Eq. (7-8), the rate can be a very strongly increasing (exponential) function of temperature, depending on the magnitude of the activation energy $E$. This equation works well for elementary reactions, and it also works reasonably well for global reactions over a relatively narrow range of temperatures in the absence of mass-transfer limitations. The Arrhenius form represents an energy barrier on the reaction pathway between reactants and products that has to be overcome by the reactant molecules.

The Arrhenius equation can be derived from theoretical considerations using either of two competing theories, the *collision theory* and the *transition state theory*. A more accurate form of Eq. (7-8) includes an additional temperature factor

$$k = k_0 T^m \exp\left(-\frac{E}{RT}\right) \qquad 0 < m < 1 \tag{7-9}$$

but the $T^m$ factor is often neglected because of the usually much stronger dependence on temperature of the exponential factor in Eq. (7-9), as $m$ is usually small. When $m$ is larger, as it can be for complex molecules, then the $T^m$ term has to be taken into consideration. For more details, see Masel, *Chemical Kinetics and Catalysis,* Wiley, 2001; Levenspiel, *Chemical Reaction Engineering,* 3d ed., Wiley, 1999).

## HEAT OF REACTION

Chemical reactions are accompanied by evolution or absorption of energy. The enthalpy change (difference between the total enthalpy of formation of the products and that of the reactants) is called the *heat of reaction* $\Delta H_r$:

$$\Delta H_r = (\nu_r H_{fr} + \nu_s H_{fs} + \cdots) - (\nu_a H_{fa} + \nu_b H_{fb} + \cdots) \tag{7-10}$$

where $H_{fi}$ are the *enthalpies of formation* of components $i$. The reaction is *exothermic* if heat is produced by the reaction (negative heat of reaction) and *endothermic* if heat is consumed (positive heat of reaction). The magnitude of the effective heat of reaction depends upon temperature and the phases of the reactants and product. To estimate the dependence of the heat of reaction on temperature relative to a

reference temperature $T_0$, the following expression can be used, provided there is no phase change:

$$\Delta H_r(T) = \Delta H_r(T_0) + \int_{T_0}^{T} \Delta c_p \, dT$$
$$\Delta c_p = (\nu_r c_{pr} + \nu_s c_{ps} + \cdots) - (\nu_a c_{pa} + \nu_b c_{pb} + \cdots) \tag{7-11}$$

where $c_{pi}$ are the *heat capacities* of component $i$. The heat of reaction can be measured by using calorimetry, or it can be calculated by using a variety of thermodynamic methods out of the scope of this chapter (see relevant sections of this handbook, thermodynamic texts, and Bird, Stewart, and Lightfoot, *Transport Phenomena,* 2d ed., John Wiley & Sons, New York, 2002). It is important to accurately capture the energy balance and its relation to the heat of reaction and heat capacities (see also Denn, *Process Modeling,* Langman, New York, 1986, for correct formulations). The coupling of the heat of reaction with the reaction rate through the Arrhenius equation often has a dominating effect on reactor selection and control, and on the laboratory reactor setup required to obtain accurate intrinsic kinetics and mechanism. More on this can be found in Sec. 19.

## CHEMICAL EQUILIBRIUM

Often reactions or reaction steps in a network of reactions are at chemical equilibrium; i.e., the rate of the forward reaction equals the rate of the reverse reaction. For instance, for the reversible reaction

$$\nu_a A + \nu_b B \underset{k_r}{\overset{k_f}{\Leftrightarrow}} \nu_r R + \nu_s S \tag{7-12}$$

with mass action kinetics, the rate may be written as

$$r = r_f - r_r = k_f C_a^{\nu_a} C_b^{\nu_b} - k_r C_r^{\nu_r} C_s^{\nu_s} \tag{7-13}$$

At chemical equilibrium the forward and reverse reaction rates are equal according to the principle of *microscopic reversibility*:

$$r = r_f - r_r = 0 \tag{7-14}$$

The equilibrium constant $K_e$ (based on volumetric concentrations) is defined as the ratio of the forward and reverse rate constants and is related to the composition at equilibrium as follows:

$$K_e = \frac{k_f}{k_r} = \frac{C_{r,e}^{\nu_r} C_{s,e}^{\nu_s}}{C_{a,e}^{\nu_a} C_{b,e}^{\nu_b}} \tag{7-15}$$

$K_e$ can be calculated from the free energy change of the reaction. Using the van't Hoff relation, we obtain the dependence of $K_e$ on temperature:

$$\frac{d(\ln K_e)}{dT} = \frac{\Delta H_r}{RT^2} \tag{7-16}$$

Integrating with respect to temperature, we obtain a form similar to the Arrhenius expression of the rate constant for a narrow range of temperature:

$$K_e = K_{e0} \exp\left(\frac{\Delta H_r}{RT}\right) \tag{7-17}$$

A more general integral form of Eq. (7-16) is

$$\ln K_e(T) = \ln K_e(T_0) + \frac{1}{R} T \int_{T_0}^{T} \frac{\Delta H_r(T_0) + \int_{T_0}^{T} \Delta c_p dT}{T^2} \, dt \tag{7-18}$$

When a reversible reaction is not at equilibrium, knowledge of $K_e$ can be used to eliminate the rate constant of the reverse reaction by using Eq. (7-15) as follows:

$$r = k_f (C_a^{\nu_a} C_b^{\nu_b} - C_r^{\nu_r} C_s^{\nu_s} / K_e) \tag{7-19}$$

When several reversible reactions occur simultaneously, each reaction $r_j$ is characterized by its equilibrium constant $K_{ej}$. When the $K_{ej}$ are known, the composition at equilibrium can be calculated from a set of equations such as Eq. (7-15) for each reaction.

## CONVERSION, EXTENT OF REACTION, SELECTIVITY, AND YIELD

*Conversion* of a reactant is the number of moles converted per initial or feed moles of a reactant. Thus for component $A$

$$X_a = 1 - \frac{n_a}{n_{a0}} \tag{7-20}$$

A *limiting reactant* is a reactant whose concentration at the start of the reaction is the least of all reactants relative to the required stoichiometric amount needed for complete conversion. For instance, for the single reaction (7-12), $A$ is the limiting reactant if the initial molar ratio of concentrations of $A$ and $B$ is less than the ratio of their stoichiometric coefficients:

$$\frac{n_{a0}}{n_{b0}} < \frac{\nu_a}{\nu_b} \tag{7-21}$$

Once the limiting reactant is depleted, the respective reaction stops even though other (nonlimiting) reactants may still be abundant.

For each reaction or each step in a network of reactions, a unique *extent of reaction* $\xi$ that relates the composition of components that participate in the reaction to each other can be defined. For instance, for the single reaction (7-1):

$$\xi = \frac{n_{a0} - n_a}{\nu_a} = \frac{n_{b0} - n_b}{\nu_b} = \cdots = -\frac{n_{r0} - n_r}{\nu_r} = -\frac{n_{s0} - n_s}{\nu_s} = \cdots \tag{7-22}$$

The extent of reaction is related to conversion as follows:

$$\xi = \frac{X_a n_{ao}}{\nu_a} = \frac{X_b n_{bo}}{\nu_b} = \cdots \tag{7-23}$$

When $A$ is the limiting reactant as in Eq. (7-21), the maximum extent of reaction (with $A$ fully converted) is

$$\xi_{\max} = \frac{n_{a0}}{\nu_a} \tag{7-24}$$

For multiple reactions with reactants participating in more than one reaction, it is more difficult to determine the limiting reactant and often it is necessary to calculate the concentration as the reactions proceed to determine which reactant is consumed first. When the limiting reactant is depleted, all reactions that use this component as reactant stop, and the corresponding rates become zero.

*Selectivity* $S$ of a product is the ratio of the rate of production of that product to the rate of production of all products combined. For a single reaction selectivity is trivial—if more than one product occurs, then the selectivity of each product is the ratio of the stoichiometric coefficient of that product to the sum of stoichiometric coefficients of all the products. Thus for reaction (7-1)

$$S_r = \frac{\nu_r}{\nu_r + \nu_s + \cdots} \tag{7-25}$$

The selectivity of product $R$ for a network of reactions, with all the reactions making the various products included, is

$$S_r = \frac{r_r}{\sum_{\text{all products } i} r_i} \tag{7-26}$$

For instance, for the network of reactions $A + B \overset{1}{\Rightarrow} C + D$ $C + E \overset{2}{\Rightarrow} F + G$, the selectivity to product $C$ is

$$S_c = \frac{r_c}{r_c + r_d + r_f + r_g} = \frac{r_1 - r_2}{(r_1 - r_2) + r_1 + r_2 + r_2} = \frac{r_1 - r_2}{2r_1 + r_2}$$

The *yield* $Y$ of a product $R$ with respect to a reactant $A$ is the ratio of the rate of production of $R$ to that of consumption of $A$:

$$Y_r = \frac{r_r}{-r_a} \tag{7-27}$$

For a single reaction the yield is trivial and Eq. (7-27) simplifies to the ratio of the respective stoichiometric coefficients:

$$Y_r = \frac{\nu_r}{\nu_a} \tag{7-28}$$

The yield quantifies the efficiency of the respective reactant utilization to make the desired products.

## CONCENTRATION TYPES

Different concentration types are used for different reaction systems. For gas-phase reactions, *volumetric concentration* or *partial pressures* are equally useful and can be related by the thermodynamic equation of state. For instance, for ideal gases (approximation valid for gases at very low pressure)

$$PV = nRT \tag{7-29}$$

When applied to individual components in a constant-volume system,

$$p_i V = n_i RT \tag{7-30}$$

Using Eq. (7-5), we obtain the relationship between the volumetric concentrations and partial pressures:

$$C_i = \frac{p_i}{RT} \tag{7-31}$$

For an ideal gas the total concentration is

$$C = \frac{P}{RT} \tag{7-32}$$

For higher pressure and nonideal gases, a *compressibility factor* $z_i$ can be used:

$$p_i V = z_i n_i RT \qquad \text{and} \qquad C_i = \frac{p_i}{z_i RT} \tag{7-33}$$

Other relevant equations of state can also be used for both gases and liquids. This aspect is not in the scope of this section, and the reader is referred to the relevant section of this handbook.

Other concentration units include *mole fractions* for liquid $x_i$:

$$x_i = \frac{n_i}{\Sigma n_i} = \frac{C_i}{\Sigma C_i} = \frac{C_i}{C} \tag{7-34}$$

and for gas $y_i$

$$y_i = \frac{n_i}{\Sigma n_i} = \frac{C_i}{\Sigma C_i} = \frac{C_i}{C} = \frac{p_i}{\Sigma p_i} = \frac{p_i}{P} \tag{7-35}$$

The last two terms are only valid for an ideal gas.

## STOICHIOMETRIC BALANCES

**Single Reactions** Equation (7-22) shows that for a single reaction, the number of moles and concentration of all other components can be calculated from the extent of reaction $\zeta$ or the conversion based on the limiting reactant, say $A$, $X_a$. In terms of number of moles $n_i$,

$$\begin{aligned}
n_a &= n_{a0} - \nu_a \xi = n_{a0}(1 - X_a) \\
n_b &= n_{b0} - \nu_b \xi = n_{b0}(1 - X_b) = n_{b0} - \frac{\nu_b}{\nu_a} n_{a0} X_a \\
&\cdots \\
n_r &= n_{r0} + \nu_r \xi = n_{r0} - \frac{\nu_r}{\nu_a} n_{a0} X_a \\
n_s &= n_{s0} + \nu_s \xi = n_{s0} - \frac{\nu_s}{\nu_a} n_{a0} X_a \\
&\cdots
\end{aligned} \tag{7-36}$$

Similarly the number of moles of each component in terms of moles of $A$, $n_a$, is

$$\begin{aligned}
n_b &= n_{b0} - \frac{\nu_b}{\nu_a}(n_{a0} - n_a) \\
&\cdots \\
n_r &= n_{r0} + \frac{\nu_r}{\nu_a}(n_{a0} - n_a) \\
n_s &= n_{s0} + \frac{\nu_s}{\nu_a}(n_{a0} - n_a) \\
&\cdots
\end{aligned} \tag{7-37}$$

Change in number of moles by the reaction and change in temperature, pressure, and density affect the translation of stoichiometric balances from number of moles to volumetric concentrations. These relationship are different for gases and liquids. For instance, for *constant density* systems (such as many liquid-phase isothermal reactions) or for *constant temperature*, *constant pressure* gas reaction with no change in number of moles, Eqs. (7-36) and (7-37) can be changed to volumetric concentration $C_i$ by dividing each equation by the constant reaction volume $V$ (e.g., in a batch reactor) and using Eq. (7-5). For example, for the single reaction (7-4) with rate (7-5):

$$\begin{aligned}
C_b &= C_{b0} - \frac{q}{p}(C_{a0} - C_a) \\
C_r &= C_{r0} + \frac{r}{p}(C_{a0} - C_a) \\
C_s &= C_{s0} + \frac{s}{p}(C_{a0} - C_a)
\end{aligned} \tag{7-38}$$

$$r = kC_a^a \left[ C_{b0} - \frac{q}{p}(C_{a0} - C_a) \right]^b = k[C_{a0}(1 - X_a)]^a \left( C_{b0} - \frac{q}{p} C_{a0} X_a \right)^b \tag{7-39}$$

It is best to represent all concentrations in terms of that of the limiting reactant.

Often there is a change in total number of moles due to reaction. Taking the general reaction (7-1), in the gas phase the change in

number of moles relative to moles of component $A$ converted, $\delta_a$, and the total number of moles can be calculated as follows:

$$\delta_a = \frac{\nu_q + \nu_s + \cdots - \nu_a - \nu_b - \cdots}{\nu_a}$$

$$n_0 = \sum n_{i0} \qquad n = \sum n_i \tag{7-40}$$

$$\frac{n}{n_0} = 1 + y_{a0}\delta_a X_a = 1 + \varepsilon_a X_a$$

$$\varepsilon_a = y_{a0}\delta_a$$

Using the ideal gas law, Eq. (7-29), the volume change depends on conversion as follows:

$$\frac{V}{V_0} = \frac{T}{T_0}\frac{P_0}{P}\frac{n}{n_0} = \frac{T}{T_0}\frac{P_0}{P}(1 + \varepsilon_a X_a) \tag{7-41}$$

Hence, for an isothermal constant-pressure ideal gas reaction system,

$$C_a = \frac{n_a}{V} = \frac{C_{a0}(1 - X_a)}{1 + \varepsilon_a X_a}$$

$$C_b = \frac{n_b}{V} = \frac{C_{b0} - \frac{\nu_b}{\nu_a}C_{a0}X_a}{1 + \varepsilon_a X_a}$$

$$\cdots \tag{7-42}$$

$$C_r = \frac{n_b}{V} = \frac{C_{r0} - \frac{\nu_r}{\nu_a}C_{a0}X_a}{1 + \varepsilon_a X_a}$$

$$C_s = \frac{n_b}{V} = \frac{C_{s0} - \frac{\nu_s}{\nu_a}C_{a0}X_a}{1 + \varepsilon_a X_a}$$

$$\cdots$$

Applying this to reaction (7-4) and rate (7-5) gives

$$r = k\left[\frac{C_{a0}(1 - X_a)}{1 + \varepsilon_a X_a}\right]^a \left[\frac{C_{b0} - (q/p)C_{a0}X_a}{1 + \varepsilon_a X_a}\right]^b \tag{7-43}$$

Compare this to Eq. (7-39) where there is no change in number of moles.

**Reaction Networks** The analysis for single reactions can be extended to a network of reactions by defining an extent of reaction for each reaction, or by choosing a representative reactant concentration for each reaction step. For a complex network, the number of independent extents of reaction required to calculate the concentration of all components is equal to the number *of independent reactions*, which is less than or equal to the total number of reactions in the network. To calculate the number of independent reactions, and to form a set of independent reactions and corresponding independent set of concentrations or extents of reaction, we need to construct the *stoichiometric matrix* and determine its *rank*. The stoichiometric matrix is used to derive a relationship between the concentrations and the independent extents of reaction similar to that of a single reaction.

The stoichiometric matrix is the matrix of the stoichiometric coefficients of the reaction network with negative signs for reactants and positive signs for products. For instance, the hydrodechlorination of Freon 12 ($CF_2Cl_2$) can proceed with the following consecutive mechanism [Bonarowska et al., "Hydrodechlorination of $CCl_2F_2$ (CFC-12) over Silica-Supported Palladium-Gold Catalysts," *Appl. Catal. B: Environmental,* **30:**187–193, 2001]:

$$CF_2Cl_2 + H_2 \Rightarrow CF_2ClH + HCl \qquad CF_2ClH + H_2 \Rightarrow CF_2H_2 + HCl$$

The stoichiometric matrix $S$ for this network is

$$S = \begin{pmatrix} -1 & 1 & 0 & -1 & 1 \\ 0 & -1 & 1 & -1 & 1 \end{pmatrix}$$

The first row refers to the first reaction and the second row to the second reaction. The columns (species) are in the following order: 1-$CF_2Cl_2$, 2-$CF_2ClH$, 3-$CF_2H_2$, 4-$H_2$, and 5-HCl. The rank of a matrix is the largest square submatrix obtained by deleting rows and columns, whose determinant is not zero. The rank equals the number of independent reactions. This is also equivalent to stating that there are reactions in the network that are linear combinations of the independent reactions. The rank of $S$ above is 2, since the *determinant* of the first $2 \times 2$ *submatrix* is not zero (there are other $2 \times 2$ submatrices that are not zero as well but it is sufficient to have at least one that is not zero):

$$S_1 = \begin{pmatrix} -1 & 1 \\ 0 & -1 \end{pmatrix} \qquad \det(S_1) = 1 \neq 0$$

Hence the two reactions are independent. Now if we add another step, which converts Freon 12 directly into the final hydrofluorocarbon $CF_2H_2$; $CF_2Cl_2 + 2H_2 \Rightarrow CF_2H_2 + 2HCl$, then the stoichiometric matrix becomes

$$S = \begin{pmatrix} -1 & 1 & 0 & -1 & 1 \\ 0 & -1 & 1 & -1 & 1 \\ -1 & 0 & 1 & -2 & 2 \end{pmatrix}$$

Since the last reaction is a linear combination of the first two (sum), it can be easily proved that the rank remains unchanged at 2. So to conclude, the concentrations of all components in this network can be expressed in terms of two, say $H_2$ and Freon 12, and the first two reactions form an independent reaction set. In case of more complicated networks it may be difficult to determine the independent reactions by observation alone. In this case the *Gauss-Jordan decomposition* leads to a set of independent reactions (see, e.g., Amundson, *Mathematical Methods in Chemical Engineering—Matrices and Their Application,* Prentice-Hall International, New York, 1966).

For a network of reactions the general procedure is as follows:

1. Generate the reaction network by including all known reaction steps.
2. Generate the corresponding stoichiometric matrix.
3. Calculate the rank of the stoichiometric matrix which equals the number of independent reactions and independent component concentrations required to calculate all the remaining component concentrations.
4. For relatively simple networks, observation allows selection of reactions that are independent—for more complex systems use the Gauss-Jordan elimination to reduce the network to a set of independent (nonzero rows) reactions.
5. Select the independent concentration variables and independent reactions, and use these to calculate all other concentrations and reaction rates.

## CATALYSIS

A catalyst is a material that increases the rate of both the forward and reverse reactions of a reaction step, with no net consumption or generation of catalyst by the reaction. A catalyst does not affect the reaction thermodynamics, i.e., the equilibrium composition or the heat of reaction. It does, however, affect the temperature sensitivity of the reaction rate by lowering the activation energy or the energy barrier on the reaction pathway from reactants to products. This allows the reaction to occur faster than the corresponding uncatalyzed reaction at a given temperature. Alternatively, catalytic reactions can proceed at lower temperatures than the corresponding noncatalytic reactions. For a network of reactions, the catalyst is often used to speed up desired reactions and/or to slow down undesired reactions for improved selectivity. On the basis of catalysis, reactions can be further classified into

1. Noncatalytic reactions, e.g., free-radical gas-phase reactions such as combustion of hydrocarbons.

2. Homogeneous catalytic reactions with the catalyst being dissolved in the same phase as the reactants and products in a homogeneous reaction medium. Here the catalyst is uniformly distributed throughout the system, e.g., the hydroformylation of olefins in the presence of dissolved Co or Rh carbonyls.

3. Heterogeneous catalytic reactions, with the catalyst, for instance, being a solid in contact with reactants and products in a gas-solid, gas-liquid-solid, or a liquid-solid reaction system. Here the catalyst is not uniformly distributed, and the reaction occurring on the catalyst surface requires, for instance, adsorption of reactants and desorption of products from the solid surface, e.g., the catalytic cracking of gasoil to gasoline and lighter hydrocarbons.

Table 7-1 illustrates the enhancement of the reaction rates by the catalyst—this enhancement can be of many orders of magnitude.

**TABLE 7-1 The Rate of Enhancement of Some Reactions in the Presence of a Catalyst**

| Reaction | Catalyst | Rate enhancement | Temperature, K |
|---|---|---|---|
| Ortho $H_2 \Rightarrow$ para $H_2$ | Pt (solid) | $10^{40}$ | 300 |
| $2NH_3 \Rightarrow N_2 + 3H_2$ | Mo (solid) | $10^{20}$ | 600 |
| $C_2H_4 + H_2 \Rightarrow C_2H_6$ | Pt (solid) | $10^{42}$ | 300 |
| $H_2 + Br_2 \Rightarrow 2HBr$ | Pt (solid) | $1 \times 10^8$ | 300 |
| $2NO + 2H_2 \Rightarrow N_2 + 2H_2O$ | Ru (solid) | $3 \times 10^{16}$ | 500 |
| $CH_3COH \Rightarrow CH_4 + CO$ | $I_2$ (gas) | $4 \times 10^6$ | 500 |
| $CH_3CH_3 \Rightarrow C_2H_4 + H_2$ | $NO_2$ (gas) | $1 \times 10^9$ | 750 |
| $(CH_3)_3COH \Rightarrow (CH_3)_2CH_2CH_2 + H_2O$ | HBr (gas) | $3 \times 10^8$ | 750 |

## IDEAL REACTORS

Reactions occur in reactors, and in addition to the intrinsic kinetics, observed reaction rates depend on the reactor type, scale, geometry, mode of operation, and operating conditions. Similarly, understanding of the reactor system used in the kinetic experiments is required to determine the reaction mechanism and intrinsic kinetics. In this section we address the effect of reactor type on observed rates. In Sec. 19 the effect of reactor type on performance (rates, selectivity, yield) is discussed in greater detail.

Material, energy, and momentum balances are essential to fully describe the performance of reactors, and often simplifying assumptions and phenomenological assumptions are needed especially for energy and momentum terms, as indicated in greater detail in Sec. 19 (see also Bird, Stewart, and Lightfoot, *Transport Phenomena,* 2d ed., John Wiley & Sons, New York, 2002). Ideal reactors allow us to simplify the energy, momentum, and material balances, thus focusing the analysis on intrinsic kinetics. A useful classification of ideal reactor types is in terms of their concentration distributions versus reaction time and space. Three types of ideal reactors are considered in this section:

1. Ideal *batch reactors (BRs)* including *semibatch reactors* (*SBRs*)
2. Ideal *continuously stirred tank reactor (CSTR),* including single and multiple stages
3. *Plug flow reactor (PFR)* with and without *recycle*

Figure 7-1 shows these types of ideal reactors. Other types of ideal and nonideal reactors are treated in detail in Sec. 19.

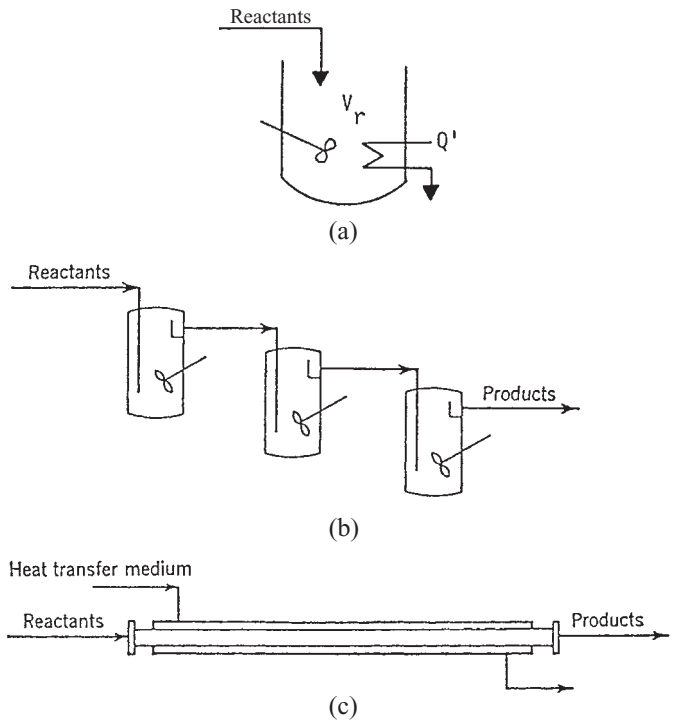

**FIG. 7-1** Types of ideal reactors: (*a*) Batch or semibatch. (*b*) CSTR or series of CSTRs. (*c*) Plug flow.

The general form of a balance equation is

$$\text{Input} + \text{sources} - \text{outputs} = \text{accumulation} \tag{7-44}$$

## IDEAL BATCH REACTOR

**Batch Reactor (BR)** Ideal batch reactors (Fig. 7-1*a*) are tanks provided with agitation for uniform composition and temperature at all times. An ideal batch reactor can be operated under isothermal conditions (constant temperature), temperature-programmed mode (by controlling cooling rate according to a protocol), or adiabatic mode with no heat crossing the reactor boundaries). In adiabatic mode the temperature is increasing, decreasing, or constant as the reaction proceeds for exothermic, endothermic, and thermally neutral reactions, respectively. In the ideal batch reactor, all the reactants are loaded into the reactor and well mixed by agitation before the conditions for reaction initiation (temperature and pressure) are reached; as the reaction proceeds, the concentration varies with time, but at any one time it is uniform throughout due to agitation.

Laboratory batch reactors can be single-phase (e.g., gas or liquid), multiphase (e.g., gas-liquid or gas-liquid-solid), and catalytic or noncatalytic. In this section we limit the discussion to operation at isothermal conditions. This eliminates the need to consider energy, and due to the uniform composition the component material balances are simple ordinary differential equations with time as the independent variable.

An ideal isothermal single-phase batch reactor in which a general reaction network takes place has the following general material balance equation:

$$\frac{dn_i}{dt} = V\sum_j \nu_{ij} r_j \qquad n_i = n_{i0} \qquad \text{at } t = 0 \tag{7-45}$$

The left-hand side is the accumulation term in moles per second of component $i$, and the right-hand side is the source term due to chemical reaction also in moles per second, which includes all reactions $j$ that consume or produce component $i$, and the corresponding stoichiometric coefficients are represented in matrix form as $\nu_{ij}$ with a positive sign for products and a negative sign for reactants. This molar balance is valid for each component since we can multiply each side of the equation by the component molecular weight to obtain the true mass balance equation. In terms of conversion, Eq. (7-45) can be rewritten as

$$\frac{n_{i0}\, dX_i}{dt} = -V\sum \nu_{ij} r_j \qquad n_i = n_{i0} \qquad \text{at } t = 0 \tag{7-46}$$

and we can integrate this equation to get the *batch reaction time* or *batch residence time* $\tau_{BR}$ required to obtain a conversion $X_i$, starting with initial conversion $X_{i0}$ and ending with final conversion $X_{if}$:

$$\tau_{BR} = -n_{i0}\int_{X_{i0}}^{X_{if}} \frac{dX_i}{V\sum \nu_{ij} r_j} \tag{7-47}$$

To integrate we need to represent all reaction rates $r_j$ in terms of the conversion $X_i$. For a single reaction this is straightforward [see, e.g., Eq. (7-43)]. However, for a network of reactions, integration of a system of often nonlinear differential equations is required using implicit or semi-implicit integration. For references please see the relevant section of this handbook or any textbook on ordinary differential equations.

A special case of batch reactors is constant-volume or constant-density operation typical of liquid-phase reactions, with volume invariant with time:

$$\frac{dC_i}{dt} = \sum \nu_{ij} r_j \qquad C_i = C_{i0} \qquad \text{at } t = 0 \tag{7-48}$$

A typical concentration profile versus time for a reactant is shown in Fig. 7-2*a*. Integration of Eq. (7-48) gives the batch residence time

$$\tau_{BR} = \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum \nu_{ij} r_j} \tag{7-49}$$

For instance, for a single reaction, Eq. (7-43) can be used to describe the reaction rate $r_i$ in terms of one reactant concentration. For reaction networks integration of a system of ordinary differential equations is required.

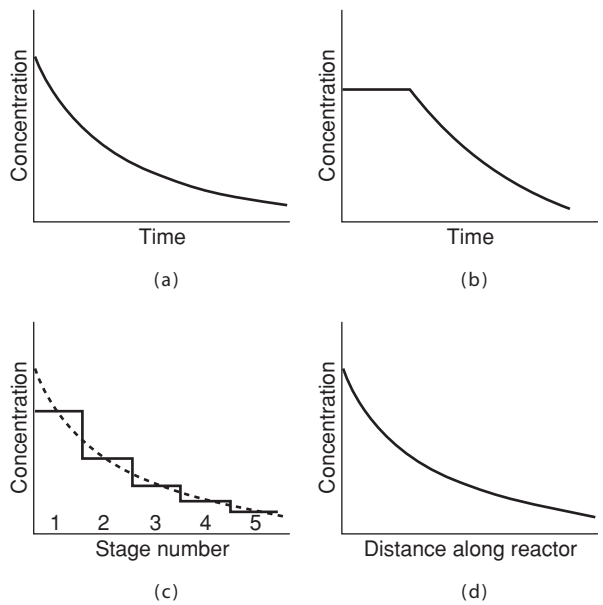

**FIG. 7-2** Concentration profiles in batch and continuous flow: (*a*) Batch time profile. (*b*) Semibatch time profile. (*c*) Five-stage CSTRs distance profile. (*d*) Tubular flow distance profile.

**Semibatch Reactor (SBR)** In semibatch operation, a gas of limited solubility or a liquid reactant may be fed in gradually as it is used up. An ideal isothermal single-phase semibatch reactor in which a general reaction network takes place has the following general material balance equation:

$$\frac{dn_i}{dt} = N_{i0} + V\sum \nu_{ij} r_j \qquad n_i = n_{i0} \qquad \text{at } t = 0$$
$$N_{i0} = N_{i0}(t) \qquad \text{for } t_{s0i} \le t \le t_{s1i} \tag{7-50}$$

The first term on the right-hand side of Eq. (7-50) is the molar feed rate of the components, which can be different for each component, hence the subscript $i$, and can vary with time. A typical concentration profile versus time for a reactant whose concentration is kept constant initially by controlling the feed rate is shown in Fig. 7-2*b*. Knowledge of the reaction kinetics allows these ordinary differential equations to be integrated to obtain the reactor composition versus time.

## IDEAL CONTINUOUS STIRRED TANK REACTOR (CSTR)

In an ideal continuous stirred tank reactor, composition and temperature are uniform throughout just as in the ideal batch reactor. But this reactor also has a continuous feed of reactants and a continuous withdrawal of products and unconverted reactants, and the effluent composition and temperature are the same as those in the tank (Fig. 7-1*b*). A CSTR can be operated under transient conditions (due to variation in feed composition, temperature, cooling rate, etc., with time), or it can be operated under steady-state conditions. In this section we limit the discussion to isothermal conditions. This eliminates the need to consider energy balance equations, and due to the uniform composition the component material balances are simple ordinary differential equations with time as the independent variable:

$$\frac{dn_i}{dt} = N_{i0} - N_i + V\sum \nu_{ij} r_j \qquad n_i = n_{i0} \qquad \text{at } t = 0 \tag{7-51}$$

At steady state the differential equations simplify to algebraic equations as indicated below:

$$V = -\frac{N_{i0} - N_i}{\sum \nu_{ij} r_j} \tag{7-52}$$

Equation (7-52) can be expressed in terms of volumetric concentration or in terms of conversions just as we did with the batch reactor. An *apparent residence time* based on feed conditions can be defined for a single-phase CSTR as follows:

$$\tau_{\text{CSTR}} = \frac{V}{q_0} \qquad N_{i0} = q_0 C_{i0} \qquad N_i = qC_i \tag{7-53}$$

In Eq. (7-53) the feed and effluent molar rates $N_{i0}$ and $N_i$ are expressed in terms of volumetric flow rates $q_0$ and $q$ (inlet and outlet, respectively) and concentrations. Thus Eq. (7-52) can be rewritten as

$$\tau_{\text{CSTR}} = \frac{C_{i0} - (q/q_0)C_i}{\sum \nu_{ij} r_j} \tag{7-54}$$

Equation (7-54) allows calculation of the residence time required to achieve a given conversion or effluent composition. In the case of a network of reactions, knowing the reaction rates as a function of volumetric concentrations allows solution of the set of often nonlinear algebraic material balance equations using an implicit solver such as the multi variable Newton-Raphson method to determine the CSTR effluent concentration as a function of the residence time. As for batch reactors, for a single reaction all compositions can be expressed in terms of a component conversion or volumetric concentration, and Eq. (7-54) then becomes a single nonlinear algebraic equation solved by the Newton-Raphson method (for more details on this method see the relevant section this handbook).

A special case of Eq. (7-54) is a constant-density system (e.g., a liquid-phase reaction), with the true average residence time $\tau_{\text{CSTR}}$

$$\tau_{\text{CSTR}} = \frac{C_{i0} - C_i}{\sum \nu_{ij} r_j} \qquad q = q_0 \tag{7-55}$$

When a number of such CSTRs are employed in series, the concentration profile is step-shaped if the abscissa is the total residence time or the stage number as indicated by a typical reactant concentration profile in Fig. 7-2*c*.

## PLUG FLOW REACTOR (PFR)

In a *plug flow reactor* all portions of the feed stream move with the same radially uniform velocity along parallel streamlines and therefore have the same residence time; that is, there is no mixing in the axial direction but complete mixing radially (Fig. 7-1*c*). As the reaction proceeds, the concentration falls off with distance. A PFR can be operated under either transient conditions or steady-state conditions. In this section we limit the discussion to steady-state conditions. This eliminates the need to consider partial differential equations in time and space. We further limit the discussion to isothermal operation, which together with the defined plug flow also eliminates the need for energy and momentum balance equations. Due to the radially uniform composition, the component material balances are simple ordinary differential equations with axial distance from inlet as the independent variable. An isothermal single-phase steady-state PFR in which a general reaction network takes place has the following general material balance equation:

$$\frac{dN_i}{dV} = \sum \nu_{ij} r_j \qquad N_i = N_{i0} \qquad \text{at } V = 0 \tag{7-56}$$

Note the similarity between the ideal batch and the plug flow reactors, Eqs. (7-45) and (7-56), respectively. In terms of conversion, Eq. (7-56) can be written as

$$N_{i0}\frac{dX_i}{dV} = -\sum \nu_{ij} r_j \tag{7-57}$$

Equation (7-57) can be integrated to calculate the reactor volume required to achieve a given conversion $X_i$:

$$V = -N_{i0}\int_{X_{i0}}^{X_{if}} \frac{dX_i}{\sum \nu_{ij} r_j} \tag{7-58}$$

An *apparent residence time* based on feed conditions can be defined for a single-phase PFR as follows:

$$\tau_{\text{PFR}} = \frac{V}{q_0} \tag{7-59}$$

Equation (7-58) becomes

$$\tau_{\text{PFR}} = -C_{i0}\int_{X_{i0}}^{X_{if}} \frac{dX_i}{\sum \nu_{ij} r_j} \tag{7-60}$$

Equation (7-60) is identical to that of the ideal batch reactor, Eq. (7-47), and the two reactor systems can be modeled in identical fashion.

For a constant-density system with no change in number of moles, with the true residence time $\tau_{\text{PFR}}$:

$$\tau_{\text{PFR}} = \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum \nu_{ij} r_j} \tag{7-61}$$

This is identical to the corresponding ideal batch reactor, Eq. (7-49).

**Ideal Recycle Reactor** All reactor modes can sometimes be advantageously operated with recycling part of the product or intermediate streams. Heated or cooled recycle streams serve to moderate undesirable temperature gradients, and they can be processed for changes in composition such as separating products to remove equilibrium limitations, before being returned. Say the recycle flow rate in

**TABLE 7-2 Consecutive and Parallel First-Order Reactions in an Isothermal Constant-Volume Ideal Batch or Plug Flow Reactor.**

The independent variable $t$ is either the batch time or the plug flow residence time.

| Reaction network | Material balances | Concentration profiles |
|---|---|---|
| $A \overset{1}{\Rightarrow} B \overset{2}{\Rightarrow} C$ | $\frac{dC_a}{dt} = -k_1 C_a$ | $C_a = C_{a0} e^{-k_1 t}$ |
| | $\frac{dC_b}{dt} = k_1 C_a - k_2 C_b$ | $C_b = C_{b0} e^{-k_2 t} + \frac{k_1 C_{a0}}{k_2 - k_1}(e^{-k_1 t} - e^{-k_2 t})$ |
| | $\frac{dC_c}{dt} = k_2 C_b$ | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_b$ |
| $A \overset{1}{\Rightarrow} B$ <br> $A \overset{2}{\Rightarrow} C$ | $\frac{dC_a}{dt} = -(k_1 + k_2) C_a$ | $Ca = C_{a0} e^{-(k_1 + k_2)r}$ |
| | $\frac{dc_b}{dt} = k_1 C_a$ | $C_b = C_{b0} + \frac{k_1 C_{a0}}{k_2 + k_1}(1 - e^{(k_1 + k_2)r})$ |
| | $\frac{dC_c}{dt} = k_2 C_a$ | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_b$ |

a PFR is $q_R$ and the fresh feed rate is $q_0$. With a fresh feed concentration of $C_0$ and a product concentration of $C_2$, the composite reactor feed concentration $C_1$ and the recycle ratio $R$ are

$$C_1 = \frac{C_0 + RC_2}{1 + R} \qquad R = \frac{q_R}{q_0} \tag{7-62}$$

The change in concentration across the reactor becomes

$$\Delta C = C_1 - C_2 = \frac{C_2 - C_0}{1 + R} \tag{7-63}$$

Accordingly, the change in concentration (or in temperature) across the reactor can be made as small as desired by increasing the recycle ratio. Eventually, the reactor can become a well-mixed unit with essentially constant concentration and temperature, while substantial differences in composition will concurrently arise between the fresh feed inlet and the product withdrawal outlet, similar to a CSTR. Such an operation is useful for obtaining experimental data for analysis of rate equations. In the simplest case, where the product is recycled without change in composition, the flow reactor equation at constant density is

$$\tau_{\text{PFR}} = (1 + R) \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum \nu_{ij} r_j} \tag{7-64}$$

Hence, recycling increases the residence time or reactor size required to achieve a given conversion, since $1 + R > 1$.

## EXAMPLES FOR SOME SIMPLE REACTIONS

Table 7-2 and Figs. 7-3 and 7-4 show the analytical solution of the integrals for two simple first-order reaction systems in an isothermal constant-volume batch reactor or plug flow reactor. Table 7-3 shows the analytical solution for the same reaction systems in an isothermal constant-density CSTR.

Section 19 provides discussion about advantages and disadvantages of CSTRs versus PFR and BR for various reaction systems.

**TABLE 7-3 Consecutive and Parallel First-Order Reactions in an Isothermal Constant-Volume Ideal CSTR**

| Reaction network | Material balances | Concentration profiles |
|---|---|---|
| $A \overset{1}{\Rightarrow} B \overset{2}{\Rightarrow} C$ | $C_{a0} - C_a - \tau k_1 C_a = 0$ | $C_a = \frac{C_{a0}}{1 + \tau k_1}$ |
| | $C_{b0} - C_b + \tau(k_1 C_a - k_2 C_b)$ | $C_b = \frac{C_{b0}}{1 + \tau k_2} + \frac{\tau k_1 C_{a0}}{(1 + \tau k_1)(1 + \tau k_2)}$ |
| | $C_{c0} - C_c + \tau k_2 C_b = 0$ | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_b$ |
| $A \overset{1}{\Rightarrow} B$ <br> $A \overset{2}{\Rightarrow} C$ | $C_{a0} - C_a - \tau(k_1 + k_2) C_a = 0$ | $C_a = \frac{C_{a0}}{1 + \tau(k_1 + k_2)}$ |
| | $C_{b0} - C_b + \tau k_1 C_a = 0$ | $C_b = C_{b0} \frac{\tau k_1 C_{a0}}{1 + \tau(k_1 + k_2)}$ |
| | $C_{c0} - C_c + \tau k_2 C_a = 0$ | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_c$ |

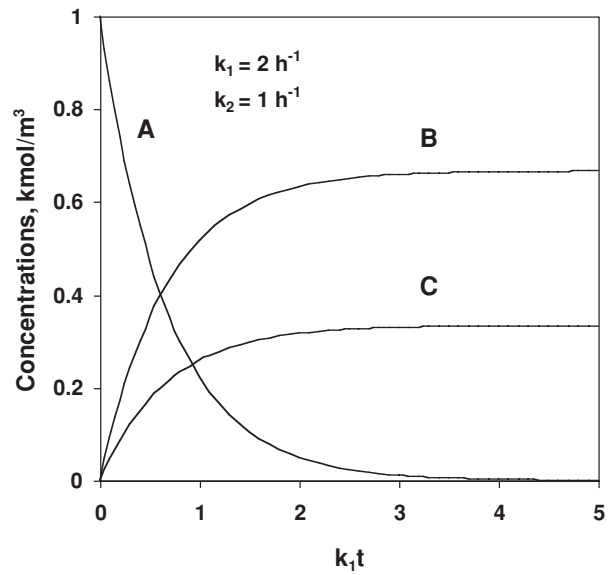

**FIG. 7-4** Concentration profiles for the reaction $A \rightarrow B$ and $A \rightarrow C$.

## KINETICS OF COMPLEX HOMOGENEOUS REACTIONS

Global or complex reactions are not usually well represented by mass action kinetics because the rate results from the combined effect of several simultaneous elementary reactions (each subject to mass action kinetics) that underline the global reaction. The elementary steps include short-lived and unstable intermediate components such as free radicals, ions, molecules, transition complexes, etc.

The reason many global reactions between stable reactants and products have complex mechanisms is that these unstable intermediates have to be produced in order for the reaction to proceed at reasonable rates. Often simplifying assumptions lead to closed-form kinetic rate expressions even for very complex global reactions, but care must be taken when using these since the simplifying assumptions are valid over limited ranges of compositions, temperature, and pressure. These assumptions can fail completely—in that case the full elementary reaction network has to be considered, and no closed-form kinetics can be derived to represent the complex system as a global reaction.

Typical simplifying assumptions include these:

- *Pseudo-steady-state* approximation for the unstable intermediate; i.e., the concentration of these does not change during reaction
- Equilibrium for certain fast reversible reactions and completion of very fast irreversible steps
- *Rate-determining step(s)*; i.e., the global reaction rate is determined by the rate(s) of the slowest step(s) in the reaction network composing the overall or global reaction

These simplifying assumptions allow elimination of some reaction steps, and representation of free radical and short-lived intermediates concentrations in terms of the concentration of the stable measurable components, resulting in complex non–mass action rate expressions.

Complex reactions can proceed through *chain* or *nonchain* mechanisms. In a *chain reaction*, the active unstable components are produced in an *initiation* step and are repeatedly regenerated through *propagation* steps, and only a small fraction of these are converted to stable components through a *termination* step. Free radicals are examples of such unstable components frequently encountered in chain reactions: free radicals are molecular fragments having one or more unpaired electrons, are usually short-lived (milliseconds), and are highly reactive. They are detectable spectroscopically, and some have been isolated. They occur as initiators and intermediates in such basic phenomena as oxidation, combustion, photolysis, and polymerization. Several examples of free radical mechanisms possessing nonintegral power law or hyperbolic rate equations are cited below. In a *nonchain reaction,* the unstable intermediate, such as an *activated complex* or *transition state complex*, reacts further to produce the products, and it is not regenerated through propagation but is continually made from reactants in stoichiometric quantities.

### CHAIN REACTIONS

**Phosgene Synthesis** The global reaction $CO + Cl_2 \Rightarrow COCl_2$ proceeds through the following free radical mechanism:

$$Cl_2 \Leftrightarrow 2Cl\bullet$$

$$Cl\bullet + CO \Leftrightarrow COCl\bullet$$

$$COCl\bullet + Cl_2 \Rightarrow COCl_2 + Cl\bullet$$

Assuming the first two reactions are in equilibrium, expressions are found for the concentrations of the free radicals Cl• and COCl• in terms of the species CO, $Cl_2$, and $COCL_2$, and when these are substituted into the mass action rate expression of the third reaction, the rate becomes

$$r_{COCl_2} = k(CO)(Cl_2)^{3/2} \tag{7-65}$$

**Ozone Conversion to Oxygen in Presence of Chlorine** The global reaction $2O_3 \overset{Cl_2}{\Rightarrow} 3O_2$ in the presence of $Cl_2$ proceeds through the following sequence:

$$Cl_2 + O_3 \Rightarrow ClO\bullet + ClO_2\bullet$$

$$ClO_2\bullet + O_3 \Rightarrow ClO_3\bullet + O_2$$

$$ClO_3\bullet + O_3 \Rightarrow ClO_2\bullet + 2O$$

$$ClO_3\bullet + ClO_3\bullet \Rightarrow Cl_2 + 3O_2$$

The chain carriers ClO•, $ClO_2$•, and $ClO_3$• are assumed to attain pseudo-steady state. Then,

$$r_{O_3} = k(Cl_2)^{1/2}(O_3)^{3/2} \tag{7-66}$$

**Hydrogen Bromide Synthesis** The global reaction $H_2 + Br_2 \Rightarrow 2HBr$ proceeds through the following chain of reactions:

$$Br_2 \Leftrightarrow 2Br\bullet$$

$$Br\bullet + H_2 \Leftrightarrow HBr + H\bullet$$

$$H\bullet + Br_2 \Rightarrow HBr + Br\bullet$$

Assuming pseudo-steady state for the concentrations of the free radicals H• and Br•, the global rate equation becomes

$$r_{HBr} = \frac{k_1(H_2)(Br_2)^{1/2}}{k_2 + HBr/Br_2} \tag{7-67}$$

**Chain Polymerization** For free radical polymerization, the following generic mechanism can be postulated:
Initiation:

$$1 \overset{1}{\Rightarrow} 2R\bullet$$

$$R\bullet + M \overset{2}{\Rightarrow} RM\bullet$$

Propagation:

$$RM\bullet + M \overset{k_p}{\Rightarrow} RM_2\bullet$$

$$RM_n\bullet + M \overset{k_p}{\Rightarrow} RM_{n+1}\bullet$$

Termination:

$$RM_n\bullet + RM_m\bullet \overset{k_t}{\Rightarrow} RM_{n+m}$$

$$RM_n\bullet + RM_m\bullet \overset{k_t}{\Rightarrow} RM_n + RM_m$$

The rates of formation of the free radicals $R$• and $M$• reach pseudo-steady states, resulting in the following polymerization rate:

$$r_p = k_p(M)(M*) = k_p\left(\frac{k_I}{k_t}\right)^{1/2}(M)(I)^{1/2} \tag{7-68}$$

## NONCHAIN REACTIONS

Nonchain reactions proceed through an active intermediate to the products. Many homogeneous nonchain reactions are also homogeneously catalyzed reactions, discussed below.

## HOMOGENEOUS CATALYSIS

Homogeneous catalysts proceed through an activated or transition state complex between reactant(s) and catalysts, which decomposes into products. Homogeneous catalysts are dissolved in the homogeneous reaction mixture and include among others acids/bases, metal salts, radical initiators, solvents, and enzymes.

**Acid-Catalyzed Isomerization of Butene-1** Butene-1 isomerizes to butene-2 in the presence of an acid according to the global reaction

$$CH_3CH_2HC{=}CH_2 \overset{H^+}{\Rightarrow} CH_3HC{=}CHCH_2$$

Even though this appears to be a monomolecular reaction, it is not, as it proceeds through the following mechanism:

$$CH_3CH_2HC{=}CH_2 + H^+ \overset{1}{\Leftrightarrow} \{CH_3CH_2\overset{H}{\overset{\wedge}{HC}}{-}CH_2\}^+$$

$$\overset{2}{\Rightarrow} CH_3HC{=}CHCH_2 + H^+$$

Assuming reaction 1 is in equilibrium, the reaction rate is

$$r = k_2K_1[H^+][CH_3CH_2HC{=}CH_2] \tag{7-69}$$

**Enzyme Kinetics** Enzymes are homogeneous catalysts for cellular and enzymatic reactions. The enzyme $E$ and the reactant $S$ are

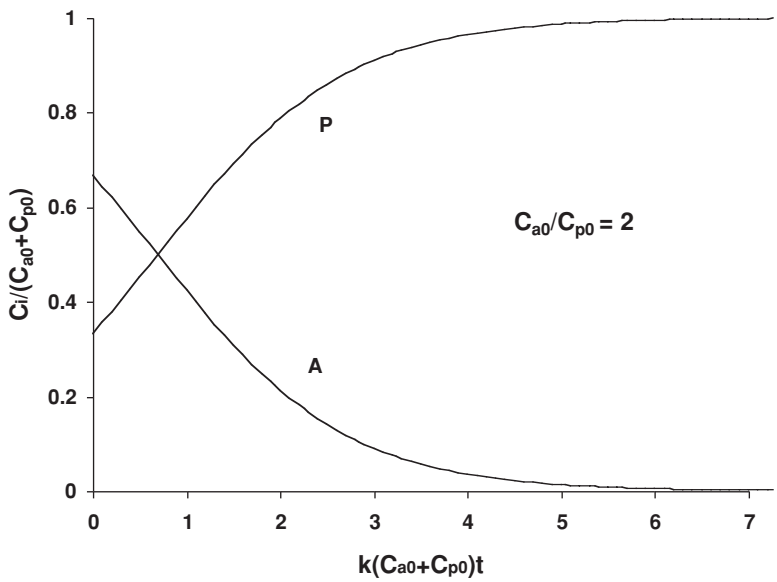

**FIG. 7-5** Product concentration profile for the autocatalytic reaction $A + P \Rightarrow 2P$ with rate $r = kC_aC_p$.

assumed to form a complex $ES$ that then dissociates into product $P$ and releases the enzyme:

$$S + E \Leftrightarrow ES$$

$$ES \Rightarrow E + P$$

Assuming equilibrium for the first step results in the following rate, developed by Michaelis and Menten [*Biochem. Zeit.*, **49:**333 (1913)] and named Michaelis-Menten kinetics,

$$r_p = -r_s = \frac{k(S)}{K_m + (S)} \tag{7-70}$$

Here $K_m$ is the inverse of the equilibrium constant for the first reaction.

### AUTOCATALYSIS

In an autocatalytic reaction, a reactant reacts with a product to make more product. For the reaction to proceed, therefore, product must be present initially in a batch or in the feed of a continuous reactor. Examples are cell growth in fermentation and combustion of fuels. For instance, the irreversible elementary reaction $A + P \Rightarrow 2P$ has the mass action kinetics

$$r = kC_aC_p \tag{7-71}$$

For an ideal batch reactor (see, e.g., Steinfeld, Francisco, and Hase, *Chemical Kinetics and Dynamics*, Prentice-Hall, 1989):

$$\frac{dC_a}{dt} = -kC_aC_p \qquad \frac{dC_p}{dt} = kC_aC_p \qquad C_a + C_p = C_{a0} + C_{p0} \tag{7-72}$$

Integration results in the following concentration profile:

$$C_P = \frac{C_{a0} + C_{p0}}{1 + (C_{a0}/C_{p0})e^{-k(Ca0 + Cp0)t}} \qquad C_a = C_{a0} + C_{p0} - C_p \tag{7-73}$$

Figure 7-5 illustrates the dimensionless concentration profile for the reactant $A$ and product $P$, $C_i/(C_{a0} + C_{p0})$, for $C_{a0}/C_{p0} = 2$, indicative of a maximum rate at the inflexion point (maximum in slope of the concentration-time curve), typical to autocatalytic reactions.

## INTRINSIC KINETICS FOR FLUID-SOLID CATALYTIC REACTIONS

There are a large number of fluid-solid catalytic reactions, mostly gas-solid, including catalytic cracking, oxidation of polluting gases in automotive and power generation catalytic converters, partial oxidation synthesis reactions such as HCN synthesis, chemical vapor deposition, etc. (see, e.g., Sec. 19 for more examples). Examples of solid catalysts include, among others, supported metals, transition metal oxides and sulfides, solid acids and bases, and immobilized homogeneous catalysts and enzymes. Solid catalysts can be a fine powder (suspended in a liquid or fluidized by a flowing gas), cylindrical, spherical, and more-complex-shaped particles (in a packed bed), a thin layer of active components (on the walls of a monolith or a foam) and gauzes. The solid catalyst can be porous with active component distributed throughout the particle volume, or nonporous with active component present on the exposed catalyst external surface alone.

The analysis of Langmuir [*J. Am. Chem. Soc.* **40:**1361 (1918)] and Hinshelwood (*Kinetics of Chemical Change*, Oxford, 1940) form the basis for the simplified treatment of kinetics on heterogeneous catalysts. For a solid catalyzed reaction between gas phase reactants $A$ and $B$, the postulated mechanism consists of the following steps in series:

1. The reactants from the gas adsorb to bond to active sites on the catalyst surface as molecules or dissociated atoms. The rate of adsorption is proportional to the partial pressure of reactants and to the fraction of uncovered surface sites $\vartheta_v$. More than one type of active site can be present. The adsorption isotherms such as the Langmuir isotherm relate the partial pressure of an adsorbed species to its surface coverage, and the form of this relationship is indicative of the type of adsorption process taking place (see, for more details, Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001).
2. The adsorbed species react on the surface to form adsorbed products. The rate of reaction between adsorbed species is proportional to their adsorbed concentrations on the surface.
3. The adsorbed products desorb into the gas. The rate of desorption of species $A$ is proportional to the fraction of the surface covered by $A$, $\vartheta_a$.

For instance, for the simple irreversible reaction $A + B \Rightarrow C + D$, the postulated mechanism is

$$\begin{aligned} &A + \sigma \Leftrightarrow A\sigma \\ &B + \sigma \Leftrightarrow B\sigma \\ &A\sigma + B\sigma \Rightarrow C\sigma + D\sigma \\ &C\sigma \Leftrightarrow C + \sigma \\ &D\sigma \Leftrightarrow D + \sigma \end{aligned} \tag{7-74}$$

$A\sigma$, $B\sigma$, $C\sigma$, and $D\sigma$ above are adsorbed species on the catalyst surface, and $\sigma$ is an available active site. We will consider a variety of possible scenarios for this simple solid-catalyzed system. Note that the intrinsic specific reaction rate for such systems is often expressed on a unit mass catalyst basis ($r_m$) instead of unit reaction volume basis ($r_V$), and the latter is related to the former through the catalyst loading (mass catalyst/reaction volume) or bed density:

$$r_v = \frac{r_m M_{\text{cat}}}{V} = r_m \rho_B \tag{7-75}$$

### ADSORPTION EQUILIBRIUM

Assuming equilibrium for all adsorption steps (e.g., the surface reaction is rate-limiting), the net rates of adsorption of reactants and product are all zero.

$$r_i = k_i p_i \vartheta_v - k_{-i}\vartheta_i \Rightarrow 0 \qquad i = a, b, c, d \tag{7-76}$$

A material balance on all sites yields

$$\vartheta_v = 1 - \vartheta_a - \vartheta_b - \vartheta_c - \vartheta_d \tag{7-77}$$

and solving for the surface coverages gives

$$\begin{aligned} &\vartheta_a = \left(\frac{k_a}{k_{-a}}\right)p_a\vartheta_v = K_a p_a \vartheta_v \qquad \vartheta_b = \left(\frac{k_b}{k_{-b}}\right)p_b\vartheta_v = K_b p_b \vartheta_v \\ &\vartheta_c = \left(\frac{k_c}{k_{-c}}\right)p_c\vartheta_v = K_c p_c \vartheta_v \qquad \vartheta_d = \left(\frac{k_d}{k_{-d}}\right)p_d\vartheta_v = K_d p_d \vartheta_v \end{aligned} \tag{7-78}$$

The fraction of surface not covered is

$$\vartheta_v = \frac{1}{1 + K_a p_a + K_b p_b + K_c p_c + K_d p_d} \tag{7-79}$$

In the denominator, terms may be added for adsorbed inerts (e.g., $K_I p_I$) that may be present, and analogous expressions for the other participants. The rate of reaction or the rate-determining step is that between adsorbed reactant species:

$$r = k p_a p_b \vartheta_v^2 = \frac{k p_a p_b}{(1 + K_a p_a + K_b p_b + K_c p_c + K_d p_d)^2} \tag{7-80}$$

## DISSOCIATION

A diatomic molecule $A_2$ may adsorb dissociatively as atoms

$$A_2 + 2\sigma \Rightarrow 2A\sigma \tag{7-81}$$

with the result

$$\vartheta_a = \frac{\sqrt{K_a p_a}}{1 + \sqrt{K_a p_a} + K_b p_b + \cdots} = \sqrt{K_a p_a}\,\vartheta_v \tag{7-82}$$

and the rate-determining step and its rate are

$$2A\sigma + B\sigma \Rightarrow \text{products} + 3\sigma \qquad r = k'\vartheta_a^2\vartheta_b = k p_a p_b \vartheta_v^2 \tag{7-83}$$

## DIFFERENT SITES

When $A$ and $B$ adsorb on chemically different sites $\sigma_1$ and $\sigma_2$, the rate of the reaction, with surface reaction controlling,

$$A + B \Rightarrow \text{unadsorbed products} \tag{7-84}$$

is

$$r = \frac{k p_a p_b}{(1 + K_a p_a)(1 + K_b p_b)} \tag{7-85}$$

## CHANGE IN NUMBER OF MOLES

When the numbers of moles of product is larger than that of the reactants, extra sites are required:

$$A \Leftrightarrow M + N \tag{7-86}$$

$$A\sigma + \sigma \Rightarrow M\sigma + N\sigma \tag{7-87}$$

and the rate is

$$r = k\left(\vartheta_a\vartheta_v - \frac{\vartheta_m\vartheta_n}{K}\right) = \left(p_a - \frac{p_m p_n}{K}\right)\vartheta_v^2 = \frac{k(p_a - p_m p_n/K)}{(1 + K_a p_a + K_m p_m + K_n p_n)^2} \tag{7-88}$$

## REACTANT IN THE GAS PHASE

When $A$ in the gas phase reacts directly with adsorbed $B$:

$$A + B\sigma \Rightarrow \text{products}$$

$$r = k p_a \vartheta_b = k p_a p_b \vartheta_v = \frac{k p_a p_b}{1 + \sum K_i p_i} \tag{7-89}$$

This mechanism is called the *Ely-Rideal kinetics*.

## CHEMICAL EQUILIBRIUM IN GAS PHASE

When $A$ is not in adsorbtive equilibrium but it is in chemical equilibrium in the gas phase according to

$$A + B \Leftrightarrow M + N \qquad p_a = \frac{p_m p_n}{K_e p_b} \tag{7-90}$$

this expression is substituted for $p_a$ wherever it appears in the rate equation. If the rate-determining step is the surface reaction between adsorbed species, then

$$r = k p_a p_b \vartheta_v^2 = \frac{k p_m p_n / K_e}{1 + Ka(p_m p_n/K_e p_b) + K_b p_b + K_m p_m + K_n p_n} \tag{7-91}$$

Table 7-4 summarizes some examples of reactions where all substances are in adsorptive equilibrium and the surface reaction controls the rate. In Table 7-5, substance $A$ is not in adsorptive equilibrium, and its adsorption rate is controlling. Details of the derivations of these and some other equations are presented by Yang and Hougen [*Chem. Eng.*

**TABLE 7-4 Surface-Reaction Controlling.**

Adsorptive equilibrium maintained for all participants.

| Reaction | Special condition | Basic rate equation | Driving force | Adsorption term |
|---|---|---|---|---|
| 1. $A \rightarrow M + N$ | General case | $r = k\theta_a$ | $p_a$ | $1 + K_a p_a + K_m p_m + K_n p_n$ |
| $A \rightarrow M + N$ | Sparsely covered surface | $r = k\theta_a$ | $p_a$ | 1 |
| $A \rightarrow M + N$ | Fully covered surface | $r = k\theta_a$ | 1 | 1 |
| 2. $A \rightleftharpoons M$ | | $r = k_1\theta_a - k_{-1}\theta_m$ | $p_a - \frac{p_m}{K}$ | $1 + K_a p_a + K_m p_m$ |
| 3. $A \rightleftharpoons M + N$ | Adsorbed $A$ reacts with vacant site | $r = k_1\theta_a\theta_v - k_{-1}\theta_m\theta_n$ | $p_a - \frac{p_m p_n}{K}$ | $(1 + K_a p_a + K_m p_m + K_n p_n)^2$ |
| 4. $A_2 \rightleftharpoons M$ | Dissociation of $A_2$ upon adsorption | $r = k_1\theta_a^2 - k_{-1}\theta_m\theta_v$ | $p_a - \frac{p_m}{K}$ | $(1 + \sqrt{K_a p_a} + K_m p_m)^2$ |
| 5. $A + B \rightarrow M + N$ | Adsorbed $B$ reacts with $A$ in gas but not | $r = k\theta_a\theta_b$ | $p_a p_b$ | $(1 + K_a p_a + K_b p_b + K_m p_m + K_n p_n)^2$ |
| $A + B \rightarrow$ M + N | with adsorbed $A$ | $r = k p_a\theta_b$ | $p_a p_b$ | $1 + K_a p_a + K_b p_b + K_m p_m + K_n p_n$ |
| 6. $A + B \rightleftharpoons M$ | | $r = k_1\theta_a\theta_b - k_{-1}\theta_m\theta_v$ | $p_a p_b - \frac{p_m}{K}$ | $(1 + K_a p_a + K_b p_b + K_m p_m)^2$ |
| 7. $A + B \rightleftharpoons M + N$ | | $r = k_1\theta_a\theta_b - k_{-1}\theta_m\theta_n$ | $p_a p_b - \frac{p_m p_n}{K}$ | $(1 + K_a p_a + K_b p_b + K_m p_m + K_n p_n)^2$ |
| 8. $A_2 + B \rightleftharpoons M + N$ | Dissociation of $A_2$ upon adsorption | $r = k_1\theta_a^2\theta_b - k_{-1}\theta_m\theta_n\theta_v$ | $p_a p_b - \frac{p_m p_n}{K}$ | $(1 + \sqrt{K_a p_a} + K_b p_b + K_m p_m + K_n p_n)^3$ |

NOTE: The rate equation is:

$$r = \frac{k\ (\text{driving force})}{\text{adsorption term}}$$

When an inert substance $I$ is adsorbed, the term $K_I p_I$ is to be added to the adsorption term.

## NO RATE-CONTROLLING STEP

All the relations developed above assume that only one step is controlling. In a reaction system, changing the operating conditions may shift the control from one step to another. It is therefore also obvious that at certain conditions there is no single step controlling. In that case all the reactions and their respective rates have to be considered, and the adsorbed species cannot be eliminated from the rate expressions to obtain a single closed-form kinetic rate.

## LIQUID-SOLID CATALYTIC REACTIONS

An analogous treatment for liquid-solid catalysis can be derived, with partial pressures replaced by liquid volumetric concentrations. Otherwise all the analyses hold.

## BIOCATALYSIS

Biochemical reactions such as *aerobic* and *anaerobic fermentations* occur in the presence of living organisms or *cells*, such as bacteria, algae, and yeast. These reactions can be considered as *biocatalyzed* by the organism. Thus in a typical bioreactor a *substrate* (such as glucose) is fed into the *fermenter* or *bioreactor* in the presence of an initial amount of cells. The desired product can be the cells themselves or a secreted chemical called a *metabolite*. In either case the cells multiply in the presence of the substrate, and the rate of production of cells is proportional to the concentration of the cells—hence this process is autocatalytic. In a batch reactor with ample supply of substrate, this results in *exponential growth* of the culture. A typical cell or biomass growth rate function, called the *Monod kinetics*, is identical in form to the Michaelis-Menten enzyme kinetics in Eq. (7-70):

$$\mu = \frac{\mu_{\max} C_s}{K_s + C_s} \tag{7-92}$$

In Eq. (7-92) $\mu$ is the *specific growth rate* of the culture. It is measured in units of reciprocal time ($h^{-1}$). Growth rate $\mu$ is related to the *volumetric growth rate* $r_x$ of the culture: $r_x = C_x\mu$. This means that the true unit of $\mu$ is, e.g., (g biomass formed/h)/(g biomass present), where *g biomass* is the *dry-weight* (DW) of the biomass, obtained after evaporation of the water content of the cell (which constitutes about 80 percent of the *wet biomass* weight). Similarly $C_x$ has the unit, e.g., (g DW)/(L medium volume). The variable $C_s$ in Eq. (7-92) is the concentration of *the limiting substrate* in the medium (g/L). There are many substrates (including micronutrients) in the medium, but there is usually just one that determines the specific growth rate. This substrate is often a sugar (most likely glucose) but it could also be a metal ion ($Mg^{2+}$ etc.), or $PO_4^{3-}$, $NH_4^+$, . . . , or perhaps a hormone. The limiting substrate may easily change during a fermentation, and then the rate expression will change.

The two parameters in Eq. (7-92) are the *maximum specific growth rate* $\mu_{\max}$ ($h^{-1}$) and the *saturation constant* $K_s$ (g substrate/L). The value of $K_s$ is obtained as the substrate concentration at which $\mu = {}^1/_2\,\mu_{\max}$ (see Fig. 7-6). The form of Eq. (7-92) is entirely empirical, but it incorporates two important features: (1) At high substrate concentration the whole cell machinery is involved in cell synthesis, and the specific growth rate reaches a maximum $\mu_{\max}$; (2) at low substrate concentration formation of biomass is a first-order rate process (as in any other chemical reaction) and $\mu \rightarrow (\mu_{\max}/K_s)C_s$. Note that for many commonly used microorganisms $K_s$ is much

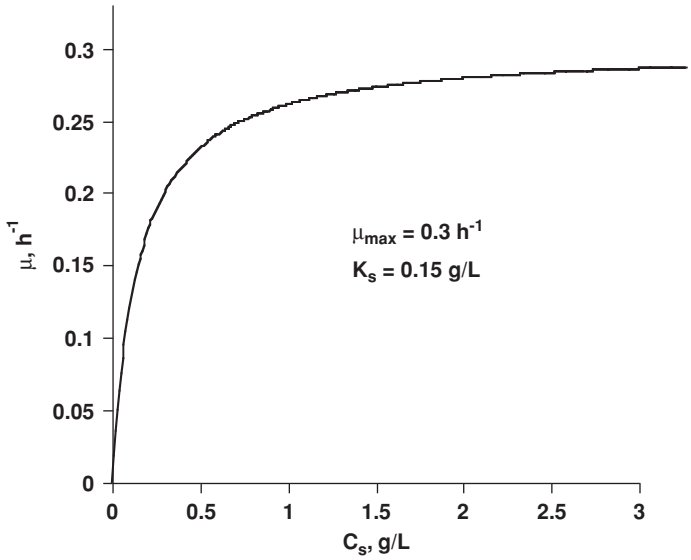

**FIG. 7-6** The effect of substrate concentration on specific growth rate.

smaller than the substrate concentration $C_s$.Thus in batch cultivations $K_s$ is several orders of magnitude smaller than $C_s$ until the very end of the batch, and this is what gives the well-known *exponential growth* [see Eq. (7-93)]. Equation (7-93) applies for batch cultures after an initial *lag phase* when cell machinery is synthesized. Typical values for $K_s$ are 150 mg/L (*Saccharomyces cerevisiae)*, 5 to 10 mg/L (lactic bacteria and *E. coli*), and less than 1 mg/L (filamentous fungi).

$$\frac{dC_x}{dt} = \mu C_x \qquad C_x = C_{x0}e^{\mu t} \tag{7-93}$$

Equation (7-93) may have to be modified by subtraction of a *death-rate* term $\mu_d C_x$. $\mu_d$ may well increase during the batch fermentation in which case the net growth rate of (viable) cells eventually becomes negative, and the concentration of (viable) cells will start to decrease.

# FLUID-SOLID REACTIONS WITH MASS AND HEAT TRANSFER

## GAS-SOLID CATALYTIC REACTIONS

The Langmuir-Hinshelwood mechanism of adsorption/reaction described above allowed us to relate the gas concentrations and partial pressures in the vicinity of the catalyst surface to the adsorbed species concentration at the active sites, which in turn determined the surface reaction rates. In practice, two additional mass-transfer processes may need to be considered:

1. Diffusion to and from the bulk gas to the external catalyst surface, represented as an external mass-transfer process across a film or boundary layer concentration gradient. For nonporous catalyst this is the only mass-transfer step.
2. Diffusion to and from the catalyst external surface through pores in a porous catalyst particle to active sites inside the catalyst particle where the adsorption and reaction occur, represented as intraparticle diffusion and modeled as a diffusion-reaction process.

**External Mass Transfer** In a reactor, the solid catalyst is deposited on the surface of narrow tubes (such as monolith or foams), is packed as particles in a tube, or is suspended in slurry or in a fluidized bed as fine particles. For these systems, the bulk concentration of the gas phase approaches that on the catalyst surface if the mass-transfer rate from bulk to surface is substantially larger than the reaction rates on the surface. This, however, is often not the case. The mechanism of mass transfer and reaction on the external catalyst surface includes the following consecutive steps:

1. Mass transfer of gas reactants from the bulk gas to the solid catalyst surface, also called external mass transfer
2. Adsorption, reaction on the surface, and desorption of products, e.g., Langmuir-Hinshelwood kinetics
3. Mass transfer of products from the catalyst surface to the bulk gas

At steady state all these rates are equal.

For example, for a first-order irreversible reaction $A \Rightarrow B$, the rate of mass transfer equals the rate of intrinsic reaction:

$$k_s a_s(C_a - C_{as}) = kC_{as} \tag{7-94}$$

Here $a_s$ is, for instance, the external particle surface area/volume of reactor. Eliminating the surface concentration $C_{as}$ in terms of the observable bulk gas concentration $C_a$ yields the overall specific rate of consumption of $A$:

$$r_{\text{obs}} = kC_a = \frac{C_a}{1/(k_s a_s) + 1/k}$$

$$k_{\text{obs}} = \frac{1}{1/(k_s a_s) + 1/k} \tag{7-95}$$

Hence the observable overall rate constant $k_{\text{obs}}$ is actually a combination of the mass-transfer coefficient and the intrinsic rate

coefficient; or in terms of resistances (in units of time) the overall resistance is the sum of the mass transfer and intrinsic kinetic resistance. For this first-order rate case, the overall behavior remains first order in bulk gas concentration. The two limiting cases are mass transfer and reaction control, respectively:

$$\begin{aligned} k_{obs} &= k_s a_s \quad \text{and } r_{obs} = k_s a_s C_a \quad \text{for } k_s a_s \ll k \quad \text{Mass transfer control} \\ k_{obs} &= k \quad \text{and } r_{obs} = kC_a \quad \text{for } k_s a_s \gg k \quad \text{Kinetic control} \end{aligned} \tag{7-96}$$

The mass-transfer coefficient depends on the geometry of the solid surface, on the hydrodynamic conditions in the vicinity of the catalyst (which are a function, e.g., of the reactor type, geometry, operating conditions, flow regime), and it also depends on the diffusivity of the gas species. Correlations for the mass-transfer coefficient are a large topic and outside the scope of this section. For more details see Bird, Stewart, and Lightfoot, *Transport Phenomena,* 2d ed., John Wiley & Sons, New York, 2002, and relevant sections in this handbook. For non-first-order kinetics a closed-form relationship such as the series of resistances cannot always be derived, but the steady-state assumption of the consecutive mass and reaction steps still applies.

**Intraparticle Diffusion** As indicated above, the larger the catalyst surface area per unit reaction volume $a_s$, the larger the overall reaction rate. For a fixed mass of catalyst, decreasing the particle size increases the total external surface area available for the reaction. Another way to increase the surface area is by providing a porous catalyst with lots of internal surface area. The internal structure of the catalyst determines how accessible these internal sites are to the gas-phase reactant and how easily can the products escape back to the gas. The analysis is based on the pseudo-homogeneous reaction diffusion equation, with the gas reactant diffusing through the pores and reacting at active sites inside the catalyst particle. For a first-order irreversible reaction of species $A$ in an infinite slab geometry, the diffusion-reaction equations describe the decreasing reactant concentration from the external surface to the center of the slab:

$$D_{ea}\frac{d^2C_{ay}}{dy^2} - kC_{ay} = 0 \qquad C_{ay}(L) = C_{as}$$
$$\frac{dC_{ay}}{dy}\,(0) \tag{7-97}$$

The concept of effectiveness factor has been developed to calculate the overall reaction rate in terms of the concentration at the external surface $C_{as}$:

$$r = \eta k C_{as} \tag{7-98}$$

Hence the effectiveness factor is the ratio of the actual rate to that if the reactions were to occur at the external surface concentration, i.e., in absence of intraparticle diffusion resistance:

$$\eta = \frac{(1/L)\int_0^L r(C_{ay})\,dy}{r(C_{as})} = \frac{\text{rate with pore diffusion resistance}}{\text{rate at external surface conditions}} \tag{7-99}$$

The effectiveness factor can be written as a function of a dimensionless independent variable called the Thiele modulus, which for a first-order reaction is defined below together with the corresponding effectiveness factor derived by integration of the corresponding diffusion-reaction equation (7-97):

$$\phi_{slab} = L\sqrt{\frac{k}{D_{ea}}} \qquad \eta = \frac{\tanh\phi_{slab}}{\phi_{slab}} \tag{7-100}$$

Since the model is pseudo-homogeneous, there is no distinction between the gas-filled pores and the solid parts of the particle. For most catalysts (except for straight channel monoliths), the diffusion path is not straight and has varying cross section. Hence, the effective diffusivity of $A$ is defined based on the catalyst internal structure and the gas diffusivity of $A$ in the gas mixture as follows:

$$D_{ea} = \frac{\varepsilon_s}{\tau} D_a \tag{7-101}$$

The parameters that describe the pore structure are the porosity $\varepsilon_s$, accounting for the fact that diffusion only occurs through the gas-filled part of the particle, and the tortuosity $\tau$ accounting for the effect of diffusion path length and contraction/expansion of pores along the diffusion path. The diffusion regime depends on the diffusing molecule, pore size, and operating conditions (concentration, temperature, pressure), and this can be visualized in Fig. 7-7. As indicated, the effective diffusion coefficient ranges over many orders of magnitude from very low values in the configurational regime (e.g., in zeolites) to high values in the regular regime.

There is a large body of literature that deals with the proper definition of the diffusivity used in the intraparticle diffusion-reaction model, especially in multicomponent mixtures found in many practical reaction systems. The reader should consult references, e.g., Bird, Stewart, and Lightfoot, *Transport Phenomena,* 2d ed., John Wiley & Sons, New York, 2002; Taylor and Krishna, *Multicomponent Mass Transfer,* Wiley, 1993; and Cussler, *Diffusion Mass Transfer in Fluid Systems,* Cambridge University Press, 1997.

The larger the *characteristic length L,* the larger the Thiele modulus, the smaller the effectiveness factor, and the steeper the reactant concentration profile in the catalyst particle. A generalized characteristic length definition $V_p/S_{px}$ (particle volume/external particle surface area) brings together the $\eta$-$\phi$ curves for a variety of particle shapes, as illustrated in Table 7-6 and Fig. 7-8 for for slabs, cylinders, and spheres. Here $I_0$ and $I_1$ are the corresponding modified Bessel functions of the first kind.

Further generalization of the Thiele modulus and effectiveness factor for a general global reaction and various shapes is

$$\phi = \frac{(V_p/S_{px})r_a(C_{as})}{\sqrt{\frac{1}{2}\int_{C_{ae}}^{Cas} D_{ea}(C_{ay})r_a(C_{ay})\,dC_{ay}}} \tag{7-102}$$

In Eq. (7-102) component $A$ is the limiting reactant. For example, for an $n$th-order irreversible reaction

$$\phi = \frac{V_p}{S_{px}}\sqrt{\frac{(n+1)}{2}\frac{kC_{as}^{n-1}}{D_{ea}}} \tag{7-103}$$

This generalized Thiele modulus works well with the effectiveness factors for low and high values of the Thiele modulus, but it is not as accurate for intermediate values. However, these differences are not significant, given the uncertainties associated with measuring some of the other key parameters that go into the calculation of the Thiele modulus, e.g., the effective diffusivity and the intrinsic rate constant.

***Effect of Intraparticle Diffusion on Observed Order and Activation Energy*** Taking the $n$th-order reaction case in the limit of intraparticle diffusion control, i.e., large Thiele modulus, the effectiveness factor is

$$\eta = \frac{1}{\phi} \tag{7-104}$$

the observed rate is

$$r_{obs} = \eta r = \frac{S_{px}}{V_p}\sqrt{\frac{2D_{ea}k}{(n+1)}}C_{as}^{(n+1)/2} \tag{7-105}$$

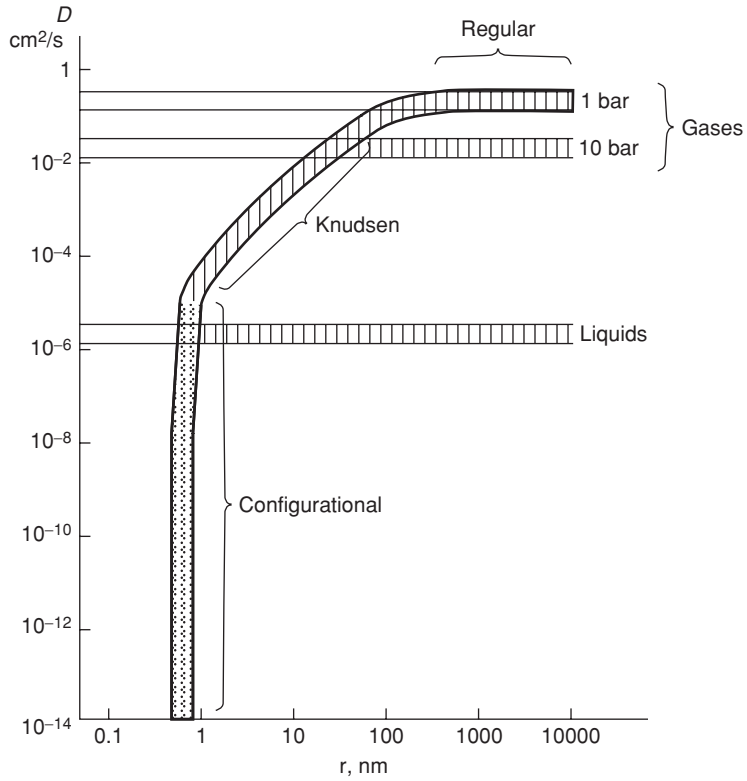

**FIG. 7-7** Diffusion regimes in heterogeneous catalysts. [*From Weisz,* Trans. Fara. Soc. ***69:*** *1696–1705 (1973); Froment and Bischoff,* Chemical Reactor Analysis and Design, *Wiley, 1990, Figure 3.5.1-1.*]

and the observed rate constant is

$$k_{\text{obs}} = \eta k = \frac{S_{px}}{V_p}\sqrt{\frac{2}{n+1} D_{ea0} e^{(E_D/RT)} k_0 e^{(E/RT)}} \qquad (7\text{-}106)$$

Hence, the observed order and activation energy differ from those of the intrinsic $n$th-order kinetics:

$$n_{\text{obs}} = \frac{n+1}{2} \qquad E_{\text{obs}} = \frac{E+E_D}{2} \simeq \frac{E}{2} \qquad (7\text{-}107)$$

Here $E_D$ is the activation energy for diffusion.

**TABLE 7-6 Effectiveness Factors for Different Shapes for a First-Order Reaction**

| Shape | $V_p/S_{px}$ | Effectiveness factor $\eta$ |
|---|---|---|
| Infinite slab | $R$ | $\dfrac{\tanh \phi}{\phi}$ |
| Infinite cylinder | $R/2$ | $\dfrac{I_1(2\phi)}{\phi\, I_0(2\phi)}$ |
| Sphere | $R/3$ | $\dfrac{1}{\phi}\left(\dfrac{3}{\tanh 3\phi} - \dfrac{1}{\phi}\right)$ |

The observed and intrinsic reaction order is the same under intraparticle diffusion control only for a first-order reaction. Weisz and Prater ["Interpretation of Measurements in Experimental Catalysis," *Adv. Catal.* **6:** 144 (1954)] developed general estimates for the observed order and activation energy over the entire range of $\phi$:

$$n_{\text{obs}} = n + \frac{n-1}{2}\frac{d\ln\eta}{d\ln\phi} \qquad E_{\text{obs}} = E + \frac{E-E_D}{2}\frac{d\ln\eta}{d\ln\phi} \qquad (7\text{-}108)$$

Weisz and Prater ["Interpretation of Measurements in Experimental Catalysis," *Adv. Catal.* **6:** 144 (1954)] also developed a general criterion for diffusion limitations, which can guide the lab analysis of rate data:

$$\text{If } \Phi = \left(\frac{3V_p}{S_{px}}\right)^2 \frac{r_{\text{obs}}}{D_{ea}C_{as}} \gg 1 \quad \text{then diffusion-limited} \qquad \ll 1 \quad \text{then no diffusional resistance} \qquad (7\text{-}109)$$

***Effect of Intraparticle Diffusion for Reaction Networks*** For multiple reactions, intraparticle diffusion resistance can also affect the observed selectivity and yield. For example, for consecutive reactions intraparticle diffusion resistance reduces the yield of the intermediate (often desired) product if both reactions have the same order. For parallel reactions diffusion resistance reduces the selectivity to the higher-order reaction. For more details see, e.g., Carberry, *Chemical and Catalytic Reaction Engineering,* McGraw-Hill, 1976; and Levenspiel, *Chemical Reaction Engineering,* 3d ed., Wiley, 1999.

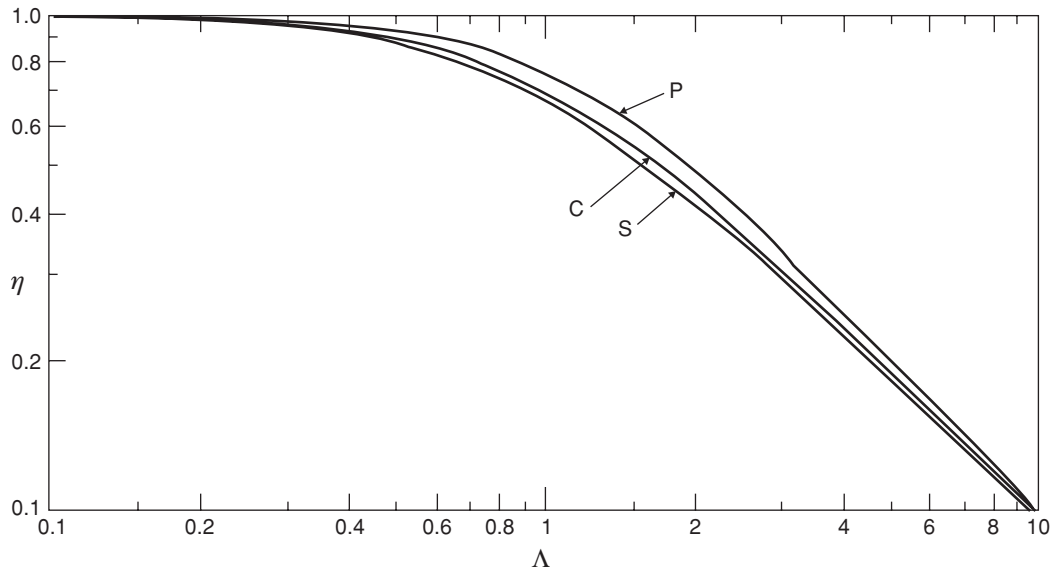

**FIG. 7-8** Effectiveness factors for a slab (P), a cylinder (C), and a sphere (S). [*Adapted from Fig. 1 in Aris and Rester, "The Effect of Shape on the Effectiveness Factor,"* Chem. Eng. Sci. **24:** 793 (1969).]

For more complex reactions, the effect of intraparticle diffusion resistance on rate, selectivity, and yield depends on the particulars of the network. Also, the use of the Thiele modulus–effectiveness factor relationships is not as easily applicable, and numerical solution of the diffusion-reaction equations may be required.

**Intraparticle Diffusion and External Mass-Transfer Resistance** For typical industrial conditions, external mass transfer is important only if there is substantial intraparticle diffusion resistance. This subject has been discussed by Luss, "Diffusion-Reaction Interactions in Catalyst Pellets," in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering,* Dekker, 1987. This, however, may not be the case for laboratory conditions, and care must be exerted in including the proper data interpretation. For instance, for a spherical particle with both external and internal mass-transfer limitations and first-order reaction, an overall effectiveness factor $\eta_t$ can be derived, indicating the series-of-resistances nature of external mass transfer followed by intraparticle diffusion-reaction:

$$\frac{1}{\eta_t} = \frac{1}{\eta} + \frac{\phi^2}{3Sh'} \tag{7-110}$$

$$Sh' = \frac{\varepsilon_s k_s R}{D_{ea}} \tag{7-111}$$

As indicated above, intraparticle diffusion lowers the apparent activation energy. The apparent activation energy is even further lowered under external mass-transfer control. Figure 7-9 illustrates how the rate-controlling step changes with temperature, and as a result the dependence of the apparent first-order rate constant on temperature also changes, from a very strong dependence under kinetic control to virtual independence under external mass-transfer control.

Note that in the limit of external diffusion control, the activation energy $E_{obs} \to 0$, as can be shown when substituting Eq. (7-110) in Eq. (7-108). For more details on how to represent the combined effect of external and intraparticle diffusion on effectiveness factor for more complex systems, see Luss, "Diffusion-Rection Interactions in Catalyst Pellets."

**Heat-Transfer Resistances** A similar analysis regarding external and intraparticle heat-transfer limitations leads to temperature gradients which add further complexity to the behavior of heterogeneous catalytic systems, including steady-state multiplicity. More details are given in Sec. 19.

**Catalyst Deactivation** The catalyst life ranges from seconds to minutes to a few days to several years, as the active surface of a catalyst is degraded by chemical, thermal, or mechanical factors. *Chemical deactivation* occurs due to feed or product *poisoning* or *masking*. Poisoning may be due to compounds such as P, S, As, Na, and Bi that have free electron pairs and is generally considered irreversible. In some cases a reduced life is simply accepted, as in the case of slow accumulation of trace metals from feed to catalytic cracking; but in other cases the deactivation is too rapid. Sulfur and water are removed from feed to ammonia synthesis, sulfur from feed to platinum reforming, and arsenic from feed to $SO_2$ oxidation with platinum. Masking may be due to covering of the active sites by contaminants in either the feed or products. Examples of feed masking agents can include Si (from organic silicons) and rust. An example of product masking is coking. Reactivation sometimes is done in place;

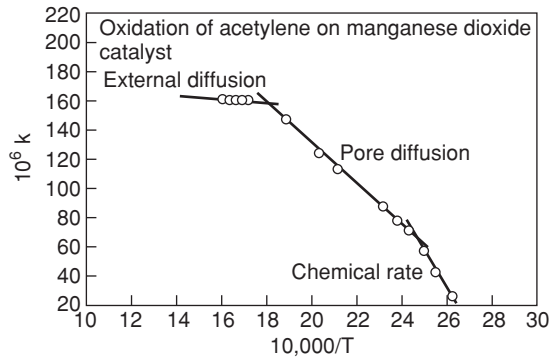

**FIG. 7-9** Dependence of the rate-controlling step on temperature.

for instance, coke is burned off cracking catalyst or off nickel and nickel-molybdenum catalysts in a fluidized reactor/regenerator system. *Thermal deactivation* is primarily due to rearrangement of the active sites at high temperature due to *sintering*. Sintering results in agglomeration of active ingredients (lower dispersion). In most cases sintering is irreversible; however $Pt/Al_2O_3$ catalysts have been regenerated in place by $Cl_2$ treatment. The catalyst also can be modified by additives, for instance, chromia to nickel to prevent sintering, rhenium to platinum to reduce coking, and so on. *Mechanical deactivation* may be caused by attrition or erosion and subsequent loss of catalyst as fines. The attrition resistance of catalysts is related to the nature of the support and its porosity.

For additional references, see, e.g., Thomas, *Catalytic Processes and Proven Catalysts,* Academic Press, 1970; Butt and Petersen, *Activation, Deactivation and Poisoning of Catalysts,* Academic Press, 1988; and Delmon and Froment, *Catalyst Deactivation,* Elsevier, 1980.

The *activity* $\alpha$ at any time on stream may be simply defined as the ratio of the rate at time $t$ to the rate with fresh catalyst

$$\alpha = \frac{r(t)}{r(t=0)} \tag{7-112}$$

The rate of destruction of active sites and pore structure can be expressed as a kinetic relation that can be generally first- or second-order. For instance, for a second-order dependence,

$$\frac{d\alpha}{dt} = -k_d\alpha^2 \tag{7-113}$$

the corresponding integral is

$$\alpha = \frac{1}{1+k_d t} \tag{7-114}$$

This type of deactivation mechanism often applies catalyst sintering and coke deactivation. The deactivation rate constant is expected to have an Arrhenius dependence on temperature.

When the feedstock contains constant proportions of reactive impurities, the rate of decline may also depend on the concentration of the main reactant, e.g., for a power law rate

$$\frac{d\alpha}{dt} = -k_d\alpha^p C^q \tag{7-115}$$

Such a differential equation must be solved simultaneously with a rate equation for the main reactant.

The deactivation rate constants are estimated by methods like those for finding constants of any rate equation, given suitable ($\alpha$, $t$) data. There are different chemical deactivation mechanisms—two of the most common are described below. For more details see Butt and Petersen, *Activation, Deactivation and Poisoning of Catalysts,* Academic Press, 1988; and Froment and Bischoff, *Chemical Reactor Analysis and Design,* Wiley, 1990. In *uniform deactivation*, the poison is distributed uniformly throughout the pellet and degrades it gradually. In *pore mouth (shell progressive) poisoning*, the poison is so effective that it kills the active site as it enters the pore; hence complete deactivation begins at the mouth and moves gradually inward.

***Uniform Deactivation*** When uniform deactivation occurs, the specific rate declines by a factor $1-\beta$, where $\beta$ is the fractional poisoning. $\beta$ is calculated from the poisoning rate, and it is often assumed to be proportional to the concentration of the poison in the bulk fluid. Then a power law rate equation becomes

$$r = k(1-\beta)\eta C_s^n \tag{7-116}$$

The effectiveness depends on $\beta$ through the Thiele modulus

$$\phi = L\sqrt{\frac{k(1-\beta)C_s^{n-1}}{D_e}} \tag{7-117}$$

To find the effectiveness under poisoned conditions, this form of the Thiele modulus is substituted into the appropriate relation for effectiveness. For example, for a first-order reaction in slab geometry, the effectiveness factor is

$$\eta = \frac{\tanh\phi}{\phi} = \frac{\tanh[L\sqrt{k(1-\beta)/D_e}]}{L\sqrt{k(1-\beta)/D_e}} \tag{7-118}$$

Figure 7-10*a* shows the ratio of the effectiveness factor with uniform poisoning to that without poisoning versus the fraction poisoned for the above case of first-order reaction in a slab.

***Pore Mouth (or Shell Progressive) Poisoning*** This mechanism occurs when the poisoning of a pore surface begins at the mouth of the pore and moves gradually inward. This is a moving boundary problem, and the pseudo-steady-state assumption is made that the boundary moves slowly compared with diffusion of poison and reactants and reaction on the active surface. $\beta$ is the fraction of the pore that is deactivated. The poison diffuses through the dead zone and deposits at the interface between the dead and active zones. The reactants diffuse across the dead zone without reaction, followed by diffusion-reaction in the active zone.

Figure 7-10*b* shows simulation results for the ratio of the effectiveness factor with pore mouth poisoning to that without poisoning for a first-order reaction in a slab.

## GAS-SOLID NONCATALYTIC REACTIONS

Examples of gas-solid noncatalytic reactions include production of iron from iron ores, roasting of sulfide oxides, combustion of solid fuels, chlorination of Ti ores to make $TiCl_4$ in the production of $TiO_2$ pigments, incineration of waste, decomposition of solids to produce gases, e.g., solid propellants and explosives. The kinetic treatment of these reactions has to take into consideration external mass transfer and intraparticle diffusion just as in the case of gas-solid catalytic reactions. However there are major differences, the primary one being consumption of the solid reactant, making the conditions inside the solid particle transient in nature, including change in unreacted particle size, particle density, porosity, etc. For more details see, e.g., Wen ["Noncatalytic Heterogeneous Solid-Fluid Reaction Models," *Ind. Eng. Chem.* **60**(9):34–54 (1968)], Szekely (in Lapidus and Amundson (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977), Doraiswamy and Kulkarni [in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987], and Levenspiel (*Chemical Reaction Engineering*, 3d ed., Wiley, 1999).

The basic steps are identical to those of catalytic gas-solid reactions. However, as indicated above, the process is transient (non-steady-state) due to change in particle size and properties as the reaction progresses.

Several models that describe gas-solid noncatalytic reactions are summarized in Table 7-7. The first two, the sharp interface and volume reaction models, are pseudo-homogeneous, form part of the class of shrinking core models, and can be treated by using the Thiele modulus and effectiveness factor concept. The last three are heterogeneous models.

**Sharp Interface Model** For a first-order reaction in gas reactant,

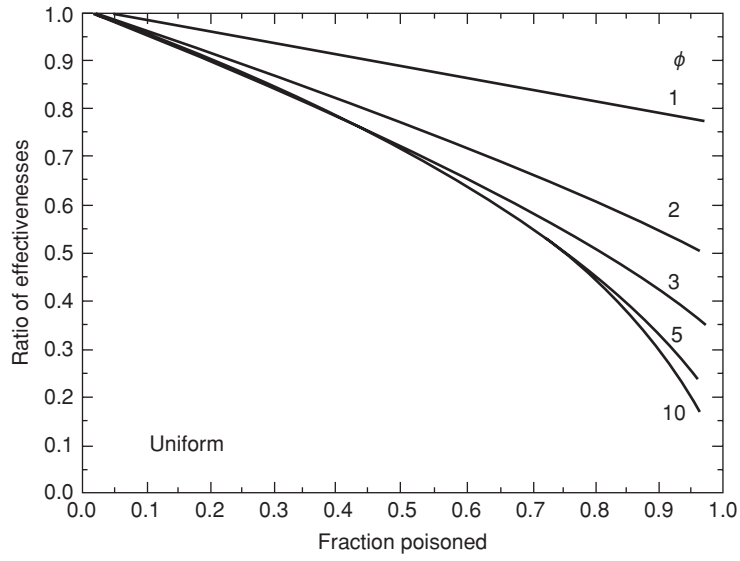
$$A(g) + bB(s) \Rightarrow \text{products} \tag{7-119}$$

a rate of conversion of the solid $B$ per unit particle volume of

$$r_b = kC_{as}C_s \tag{7-120}$$

and assuming pseudo-steady state for the gas-phase component, it can be shown that

$$r_{\text{obs}} = \frac{C_{a0}}{\dfrac{1}{k_p a_p} + \dfrac{R_p^2}{D_{ea}}\left(\dfrac{R_p}{R_s} - 1\right) + \dfrac{b}{kC_{s0}}} \tag{7-121}$$



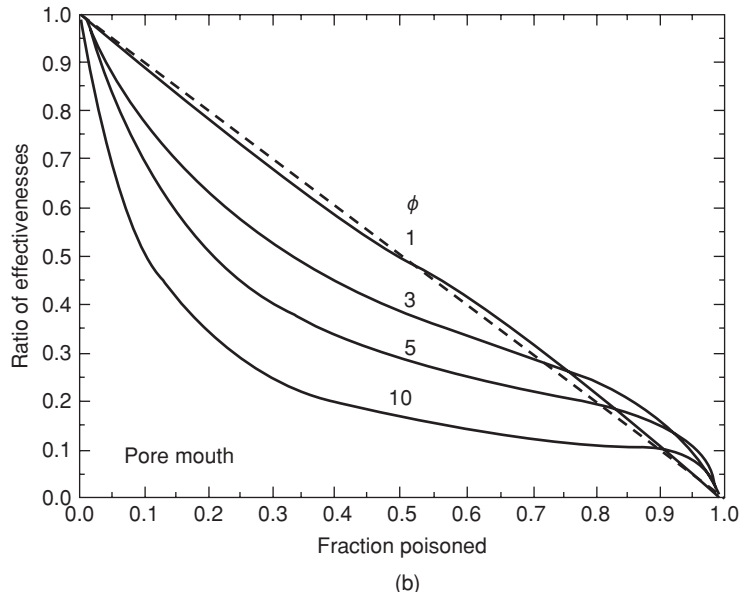


**FIG. 7-10** Poisoning of a first-order reaction. (*a*) Uniform poisoning. (*b*) Pore mouth poisoning.

where $R_p$ and $R_s$ are the particle and solid core radii, $a_p$ is the external particle diameter-based interfacial area per particle volume, and $k$ is based on particle volume. Equation (7-121) represents three resistances in series—external mass transfer, diffusion in the reacted (ash) zone, and reaction at the unreacted solid-ash interface.

The conversion of the solid reactant $B$ is obtained from integration of the pseudo-steady-state diffusion model with reaction at the boundary:

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left(D_{ea}r^2\frac{\partial C_{as}}{\partial r}\right)=0$$

$$D_{ea}\frac{\partial C_{as}}{\partial r}=\frac{1}{b}kC_{as}C_s \qquad \text{at } r=R_s \tag{7-122}$$

$$D_{ea}\frac{\partial C_{as}}{\partial r}=k_s(C_{a0}-C_{as}) \qquad \text{at } r=R_p$$

**TABLE 7-7 Noncatalytic Gas-Solid Reaction-Diffusion Models**

| Model | Main features |
|---|---|
| Sharp interface model (SIM) | Reacting solid is nonporous.<br>Reacted solid ash is porous.<br>Reaction occurs at the ash-unreacted solid interface. |
| Volume reaction model | Reacting solid is also porous.<br>Reaction occurs everywhere in the particle. |
| Grain model | Particle is divided into identical solid spherical grains.<br>Each grain reacts according to the sharp interface model. |
| Crackling core model | Combination of SIM and grain model. |
| Nucleation model | Nucleation of metals in metal reduction reactions. |

The moving boundary radius $R_c$ is determined from a material balance that relates the unreacted solid volume to the reaction rate. Integration gives the time $\tau$ required to achieve a given conversion of the solid $B$, $X_b$:

$$\tau = \frac{R_p C_{s0}}{bC_{a0}}\left\{\frac{1}{3}\left(\frac{1}{k_s} - \frac{R_p}{D_{ea}}\right)X_b + \frac{R_p}{2D_{ea}}\left[1-(1-X_b)^{2/3}\right] + \frac{3b}{C_{s0}R_p k}\left[1-(1-X_b)^{1/3}\right]\right\} \qquad X_b = 1-\left(\frac{R_s}{R_p}\right)^3 \tag{7-123}$$

Similar solutions can be obtained for other shapes (Doraiswamy and Kulkarni, in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987). Figure 7-11 shows typical concentration profiles for this case.

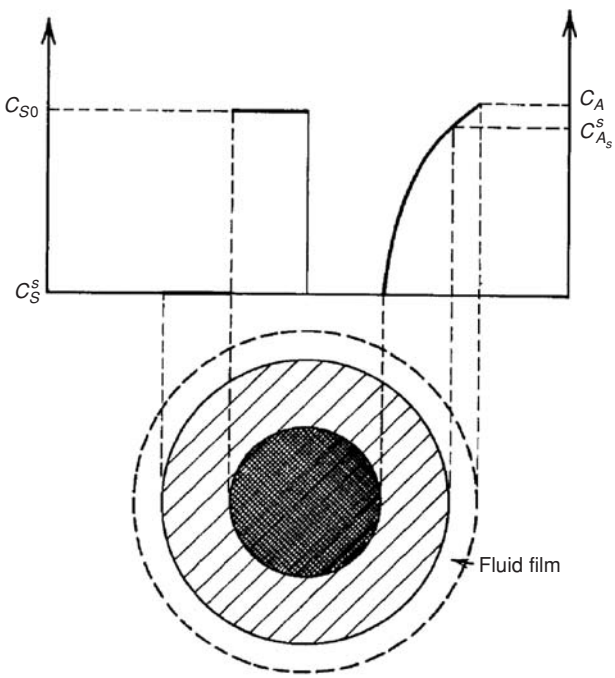

**FIG. 7-11** Sharp interface model—concentration profiles. [*From Wen, "Noncatalytic Heterogeneous Solid-Fluid Reaction Models,"* Ind. Eng. Chem. ***60****(9): 34–54 (1968), Fig. 1.*]

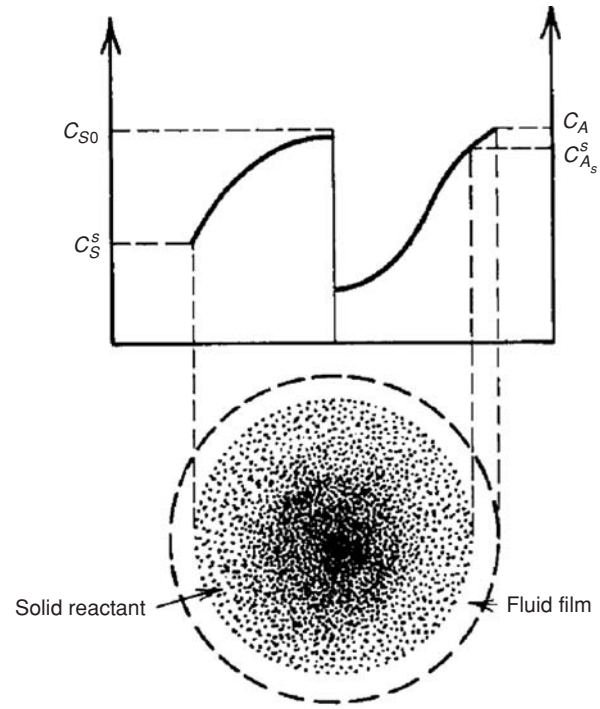

**FIG. 7-12** Typical concentration profiles for the volume reaction model. [*From Wen, "Noncatalytic Heterogeneous Solid-Fluid Reaction Models,"* Ind. Eng. Chem. ***60****(9): 34–54 (1968), Fig. 3.*]

**Volume Reaction Model** A typical concentration profile for the volume reaction model is shown in Fig. 7-12.

A general transient model of diffusion-reaction that uses the effective diffusivity concept described for gas-solid catalytic reactions can be derived here as well, e.g., for a spherical particle:

$$\frac{\partial(\varepsilon_s C_{as})}{\partial t} = \frac{1}{r^2}\frac{\partial}{\partial r}\left(D_{ea}r^2\frac{\partial C_{as}}{\partial r}\right) - r_a \qquad \frac{\partial C_s}{\partial t} = -r_s$$

$$C_{as} = C_{as0} \qquad C_s = C_{s0} \qquad \text{at } t = 0 \qquad\qquad \frac{\partial C_{as}}{\partial r} = 0 \qquad \text{at } r = 0$$

$$D_{ea}\frac{\partial C_{as}}{\partial r}\Big|_{r=R} = k_s(C_a - C_{as}|_{r=R}) \tag{7-124}$$

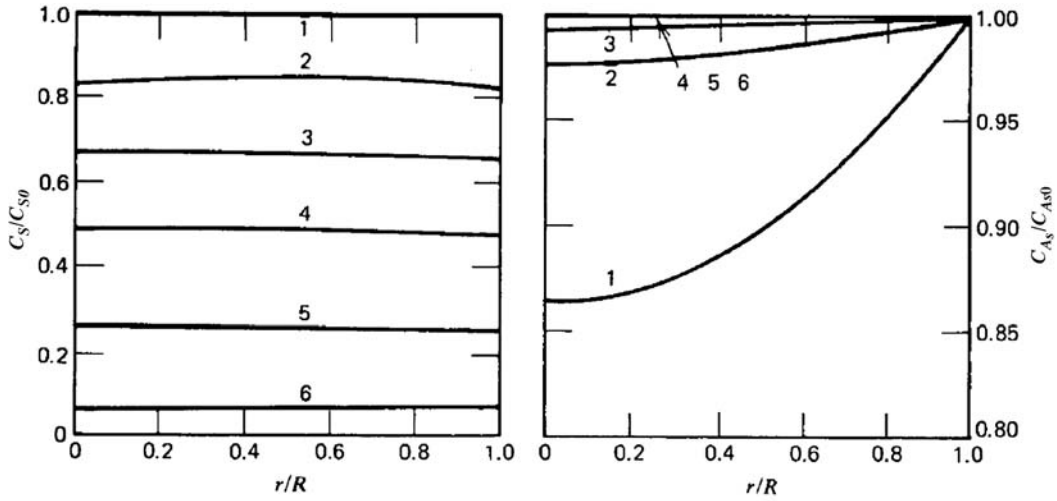
$$\varepsilon_s = \varepsilon_{s0} + C_{s0}(v_s - v_p)\left(1 - \frac{C_s}{C_{s0}}\right) \qquad \frac{D_{ea}}{D_{ea0}} = \left(\frac{\varepsilon_s}{\varepsilon_{s0}}\right)^\beta, \ \beta = 2-3 \tag{7-125}$$

Here the porosity and the diffusivity vary with conversion of solid; $v_s$ and $v_p$ are the reactant and product molar volumes. A Thiele modulus $\phi$ and dimensionless time $\theta$ can be defined, e.g., for a rate second-order in $A$ and first-order in $S$:

$$r = kC_{as}^2 C_s \tag{7-126}$$

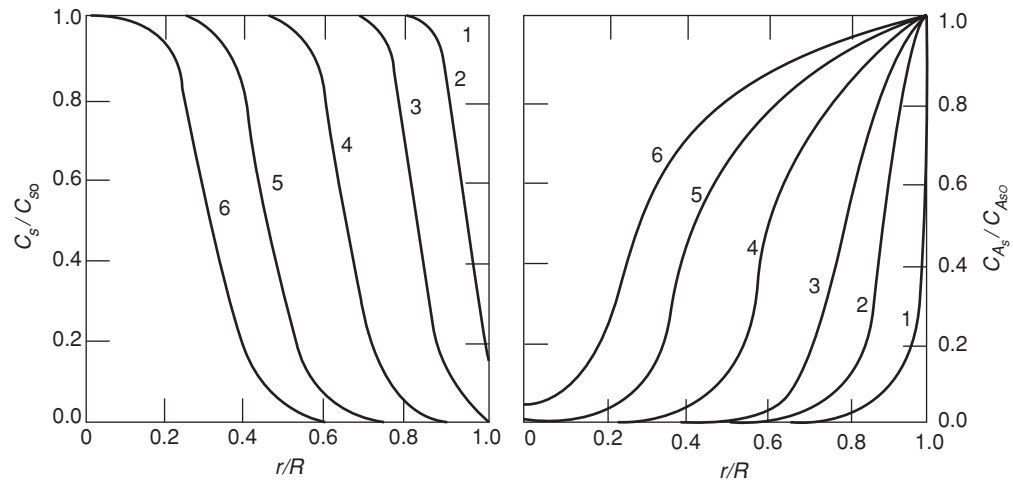
$$\phi = R\sqrt{\frac{kC_{as}(R_s)C_{s0}}{D_{ea0}}} \qquad \theta = bkC_{as0}^2 t \tag{7-127}$$

For the given rate expression, equations (7-124) to (7-127) can be numerically integrated, e.g., in Fig. 7-13 for reaction control and Fig. 7-14 for intraparticle diffusion control, both with negligible external mass-transfer resistance; $x$ is the fractional conversion.



| Curve | $\theta$ | $x$ |
|---|---|---|
| 1 | 0 | 0 |
| 2 | 0.189 | 0.165 |
| 3 | 0.429 | 0.341 |
| 4 | 0.749 | 0.521 |
| 5 | 1.389 | 0.748 |
| 6 | 2.669 | 0.930 |

**FIG. 7-13** Concentration profiles with reaction control $\phi = 1$, in absence of gas particle mass-transfer resistance. [*From Wen, "Noncatalytic Heterogeneous Solid-Fluid Reaction Models,"* Ind. Eng. Chem. ***60****(9): 34–54 (1968), Fig. 11.*]



| Curve | $\theta$ | $x$ |

**FIG. 7-14** Concentration profiles with intraparticle diffusion control, $\phi = 70$, in absence of gas particle mass-transfer resistance. [*From Wen, "Noncatalytic Heterogeneous Solid-Fluid Reaction Models,"* Ind. Eng. Chem. ***60****(9): 34–54 (1968), Fig. 12.*]

# GAS-LIQUID REACTIONS

Many industrial processes employ gas-liquid reactions that can be either noncatalytic or homogeneously catalyzed. These include, for instance, absorption of acid gases ($SO_3$, $NO_2$, $CO_2$), chlorinations (benzene, dodecane, toluene), oxidations (P-Xylene to terephthalic acid, cyclohexane to cyclohenanone and cyclohexanol, acetaldehyde to acetic acid), hydrogenations (olefins, esters to fatty acids), and hydroformylation of olefins to alcohols, to name a few. See also Sec. 19 and Shah (*Gas-Liquid-Solid Reactor Design,* McGraw-Hill, 1979). These reactions include gas reactants dissolving in a liquid and reacting there with a liquid reactant. When determining the kinetics of such reactions from lab data, one needs to understand the mechanism and the controlling steps, just as was the case for heterogeneous gas-solid reactions. The simplest model is the two-film model, and it involves the following consecutive steps for the gaseous reactant:

1. Mass transfer of gas reactant from bulk gas to the gas-liquid interface across the gas film.
2. At the gas-liquid interface, the liquid and gas concentrations of the gaseous reactant are assumed to be at thermodynamic equilibrium.
3. Mass transfer of the dissolved gas reactant to the bulk liquid across the liquid film—if the reaction is fast, the reaction will occur both in the liquid film (in parallel with diffusion) and in the bulk liquid.

For a volatile liquid reactant or a volatile product, these steps are essentially reversed. For a nonvolatile liquid reactant or product, only the reaction and diffusion in the liquid take place. Figure 7-15 describes the absorbing gas concentration profiles in a gas-liquid system.

For a general gas-liquid reaction:

$$A(g) + bB(\text{l}) \rightarrow \text{products} \tag{7-128}$$

the two-film pseudo-steady-state model is described by the following fluxes across the interface for the gaseous reactant *A:*

$$N_{aG} = \frac{D_{aG}}{\delta_G}(P_a - P_{ai}) = k_G(P_a - P_{ai}) = N_{aL} = \frac{D_{aL}}{\delta_L}(C_{Lai} - C_{La}) = k_L(C_{Lai} - C_{La}) \tag{7-129}$$

Here the subscript $L$ denotes liquid, $G$ denotes gas, $i$ denotes the gas-liquid interface (where the gas and liquid concentrations are in equilibrium). The thickness of the liquid and gas films is not a directly measurable quantity, and instead mass-transfer coefficients are defined as indicated above. These depend on the diffusivity of the molecule, geometry, flow, and operating conditions; and typical values can be viewed in Sec. 19. In addition to the two-film steady-state model, other more accurate, non-steady-state models have also been developed such as the surface renewal and penetration models (see, e.g., Astarita, *Mass Transfer with Chemical Reaction*, Elsevier, 1967). In many industrial cases of interest, mass-transfer resistance in the gas-film is negligible, especially considering that gas-phase diffusivities are 2 to 3 orders of magnitude larger for the same species than those in the liquid. Hence we drop the subscripts $L$ and $G$ from the concentrations since the concentrations considered are in the liquid phase only.

## REACTION-DIFFUSION REGIMES

Depending on the relative rates of diffusion and reaction, the following diffusion-reaction regimes occur:

$$\begin{aligned} t_D &\ll t_r && \text{slow reaction regime with reaction control} \\ t_D &\gg t_r && \text{fast reaction regime with diffusion control} \\ t_D &\simeq t_r && \text{both reaction and diffusion are important} \end{aligned} \tag{7-130}$$

$$t_D = \frac{D_a}{k_L^2} \qquad t_r = \frac{C_{ai} - C_{ae}}{r(C_{ai})}$$

Here $t_D$ and $t_r$ are the diffusion and reaction times, respectively, and $k_L$ is the mass-transfer coefficient in the absence of reaction. For the *fast reaction regime*, diffusion and reaction occur in parallel in the liquid film, while for the *slow reaction regime*, there is no reaction in the liquid film and the mass transfer can be considered to occur independently of reaction in a consecutive manner. For the slow reaction regime, the following subregimes can be defined:

$$\begin{aligned} t_m &\ll t_r && \text{slow reaction kinetic control} \\ t_m &\gg t_r && \text{slow reaction mass-transfer control} \\ t_m &\simeq t_r && \text{both reaction and mass transfer are important} \end{aligned} \tag{7-131}$$

$$t_m = \frac{1}{k_L a}$$

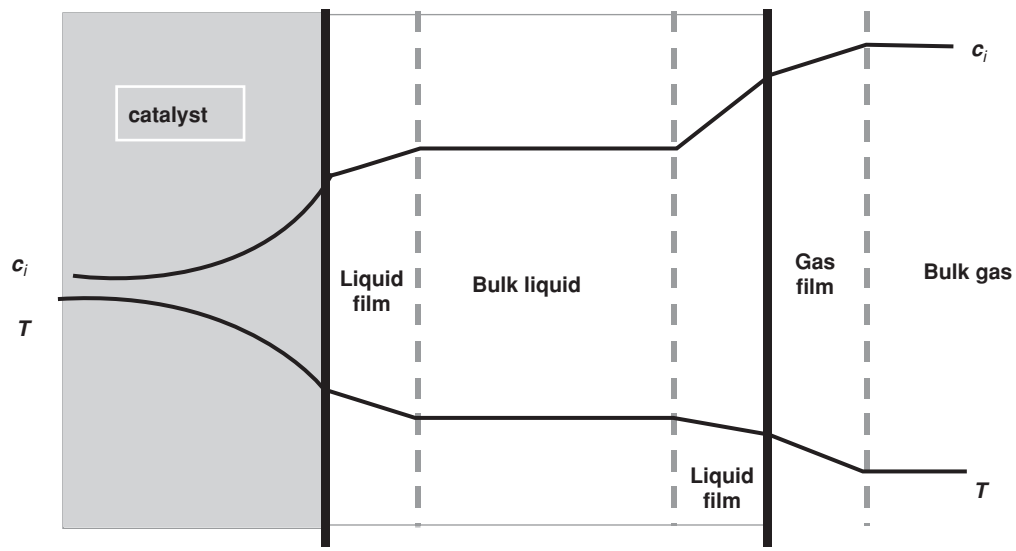

**FIG. 7-15** Absorbing gas concentration and temperature profiles (exothermic reaction) in gas-liquid and gas-liquid-solid reactions.

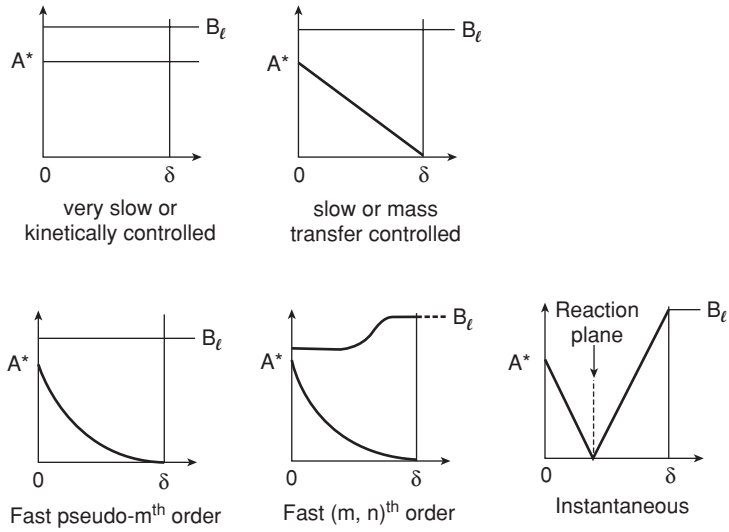

**FIG. 7-16** Concentration profiles for the general reaction $A(g) + bB(l) \rightarrow$ products with the rate $r = kC_a^m C_b^n$. [*Adapted from Mills, Ramachandran, and Chaudhari, "Multiphase Reaction Engineering for Fine Chemicals and Pharmaceuticals,"* Rev. Chem. Eng. *8(1–2):1 (1992), Figs. 19 and 20.*]

Here $t_m$ is the mass-transfer time. Only under *slow reaction kinetic control regime* can intrinsic kinetics be derived directly from lab data. Otherwise the intrinsic kinetics have to be extracted from the observed rate by using the mass-transfer and diffusion-reaction equations, in a manner similar to those defined for catalytic gas-solid reactions. For instance, in the *slow reaction regime*,

$$r_{a,\text{obs}} = \frac{C_{ai}}{\text{He}_a/k_G a + 1/k_L a + 1/k} \tag{7-132}$$

$$k_{\text{obs}} = \frac{1}{\text{He}_a/k_G a + 1/k_L a + 1/k} \tag{7-133}$$

Here $\text{He}_a$ is the Henry constant for the solute *a*. For the fast reaction regime, instead of the effectiveness factor adjustment for the intrinsic reaction rate, it is customary to define an *enhancement factor* for mass-transfer enhancement by the reaction, defined as the ratio of mass transfer in presence of reaction in the liquid, to mass transfer in absence of reaction:

$$E = k_L/k_{L0} \tag{7-134}$$

Solving the diffusion-reaction equation in the liquid, the enhancement factor can be related to the *Hatta numbe*r Ha, which is similar to the Thiele modulus defined for heterogeneous gas-solid catalysts. Thus, the Hatta number and its relation to the controlling regime are

$$\text{Ha} = \frac{t_D}{t_R} = \sqrt{\frac{\text{maximum reaction rate in the film}}{\text{maximum mass transfer rate through film}}}$$

$$\text{Ha} << 1 \qquad \text{slow reaction regime} \tag{7-135}$$

$$\text{Ha} >> 1 \qquad \text{fast reaction regime}$$

For instance, for a first-order reaction in the gaseous reactant *A* (e.g., with large excess of liquid reactant *B*), the following relates the enhancement factor to the Hatta number:

$$\text{Ha} = \delta_L \sqrt{\frac{k}{D_a}} = \frac{\sqrt{kD_a}}{k_{L0}} \qquad \text{for } C_b >> C_{ai} \tag{7-136}$$

$$E = \frac{\text{Ha}}{\tanh \text{Ha}} \left(1 - \frac{C_a}{C_{ai}} \frac{1}{\cosh \text{Ha}}\right) > 1 \tag{7-137}$$

When both *A* and *B* have comparable concentrations, then the enhancement factor is an increasing function of an additional parameter:

$$\lambda = \frac{D_b C_b}{b D_a C_{ai}} \tag{7-138}$$

In the limit of an instantaneous reaction, the reaction occurs at a plane where the concentration of both reactants *A* and *B* is zero and the flux of *A* equals the flux of *B*. The criterion for an instantaneous reaction is

$$\text{Ha}^{1/2} >> \frac{C_b}{bC_{ai}} \qquad E_\infty = 1 + \lambda >> 1 \tag{7-139}$$

Figure 7-16 illustrates typical concentration profiles of *A* and *B* for the various diffusion-reaction regimes.

# GAS-LIQUID-SOLID REACTIONS

## GAS-LIQUID-SOLID CATALYTIC REACTIONS

Many solid catalyzed reactions take place with one of the reactants absorbing from the gas phase into the liquid and reacting with a liquid reactant on the surface or inside the pores of a solid catalyst (see Fig. 7-15). Examples include the Fischer-Tropsch synthesis of hydrocarbons from synthesis gas (CO and $H_2$) in the presence of Fe or Co-based heterogeneous catalysts, methanol synthesis from synthesis gas ($H_2$ + CO) in the presence of heterogeneous CuO/ZnO catalyst, and a large number of noble metal catalyzed hydrogenations among others. For a slow first-order reaction of a gaseous reactant, the concept of resistances in series can be expanded as follows, e.g., for a slurry reactor with fine catalyst powder:

$$r_{a,\text{obs}} = \frac{C_{ai}}{\dfrac{\text{He}}{k_G a} + \dfrac{1}{k_L a} + \dfrac{1}{k_s a_s} + \dfrac{1}{k}} \qquad k_{\text{obs}} = \frac{1}{\dfrac{\text{He}}{k_G a} + \dfrac{1}{k_L a} + \dfrac{1}{k_s a_s} + \dfrac{1}{k}} \tag{7-140}$$

Intraparticle diffusion resistance may become important when the particles are larger than the powders used in slurry reactors, such as for catalytic packed beds operating in trickle flow mode (gas and liquid downflow), in upflow gas-liquid mode, or countercurrent gas-liquid mode. For these the effectiveness factor concept for intraparticle diffusion resistance has to be considered in addition to the other resistances present. See more details in Sec. 19.

## POLYMERIZATION REACTIONS

Polymers are high-molecular-weight compounds assembled by the linking of small molecules called monomers. Most polymerization reactions involve two or three phases, as indicated below. There are several excellent references dealing with *polymerization kinetics* and reactors, including Ray in Lapidus and Amundson, (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977; Tirrel et al. in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987; and Meyer and Keurentjes (eds.), *Handbook of Polymer Reaction Engineering*, Wiley, 2005.

Polymerization can be classified according to the main phase in which the reaction occurs as liquid (most polymerizations), vapor (e.g., Ziegler Natta polymerization of olefins), and solid phase (e.g., finishing of melt step polymerization). Polymerization reactions occur in liquid phase and can be further subclassified into

1. Bulk mass polymerization:
   *a.* Polymer soluble in monomer
   *b.* Polymer insoluble in monomer
   *c.* Polymer swollen by monomer
2. Solution polymerization
   *a.* Polymer soluble in solvent
   *b.* Polymer insoluble in solvent
3. Suspension polymerization with initiator dissolved in monomer
4. Emulsion polymerization with initiator dissolved in dispersing medium

Polymerization can be catalytic or noncatalytic, and can be homogeneously or heterogeneously catalyzed. Polymers that form from the liquid phase may remain dissolved in the remaining monomer or solvent, or they may precipitate. Sometimes beads are formed and remain in suspension; sometimes emulsions form. In some processes solid polymers precipitate from a fluidized gas phase. Polymerization processes are also characterized by extremes in temperature, viscosity, and reaction times. For instance, many industrial polymers are mixtures with molecular weights of $10^4$ to $10^7$. In polymerization of styrene the viscosity increased by a factor of $10^6$ as conversion increased from 0 to 60 percent. The adiabatic reaction temperature for complete polymerization of ethylene is 1800 K (3240°R). Initiators of the chain reactions have concentration as low as $10^{-8}$ g·mol/L, so they are highly sensitive to small concentrations of poisons and impurities.

Polymerization mechanism and kinetics require special treatment and special mathematical tools due to the very large number of similar reaction steps. Some polymerization types are briefly described next.

**Bulk Polymerization** The monomer and initiators are reacted with or without mixing, e.g., without mixing to make useful shapes directly. Because of viscosity limitations, stirred bulk polymerization is not carried to completion. For instance, for addition polymerization conversions as low as 30 to 60 percent are achieved, with the remaining monomer stripped out and recycled (e.g., in the case of polystyrene).

**Bead Polymerization** Bulk reaction proceeds in droplets of 10- to 1000-μm diameter suspended in water or other medium and insulated from each other by some colloid. A typical suspending agent is polyvinyl alcohol dissolved in water. The polymerization can be done to high conversion. Temperature control is easy because of the moderating thermal effect of the water and its low viscosity. The suspensions sometimes are unstable and agitation may be critical. Examples are polyvinyl acetate in methanol, copolymers of acrylates and methacrylates, and polyacrylonitrile in aqueous $ZnCl_2$ solution.

**Emulsion Polymerization** Emulsions have particles of 0.05- to 5.0-μm diameter. The product is a stable latex, rather than a filterable suspension. Some latexes are usable directly, as in paints, or they may be coagulated by various means to produce very high-molecular-weight polymers. Examples are polyvinyl chloride and butadiene-styrene rubber.

**Solution Polymerization** These processes may retain the polymer in solution or precipitate it. Examples include polyethylene, the copolymerization of styrene and acrylonitrile in methanol, the aqueous solution of acrylonitrile to precipitate polyacrylonitrile.

**Polymer Characterization** The physical properties of polymers depend largely on the *molecular weight distribution* (*MWD*), which can cover a wide range. Since it is impractical to fractionate the products and reformulate them into desirable ranges of molecular weights, immediate attainment of desired properties must be achieved through the correct choice of reactor type and operating conditions, notably of distributions of residence time and temperature. High viscosities influence those factors. For instance, high viscosities prevalent in bulk and melt polymerizations can be avoided with solution, bead, or emulsion operations. The interaction between the flow pattern in the reactor and the type of reaction affects the MWD. If the period during which the molecule is growing is short compared with the residence time in the reactor, the MWD in a batch reactor is broader than in a CSTR. This situation holds for many free radical and ionic polymerization processes where the reaction intermediates are very short lived. In cases where the growth period is the same as the residence time in the reactor, the MWD is narrower in batch than in CSTR. Polymerizations that have no termination step—for instance, polycondensations—are of this type. This topic is treated by Denbigh [*J. Applied Chem.*, **1:**227(1951)].

Four types of MWD can be defined: (1) The *number chain length distribution* (*NCLD*), relating the chain length distribution to the number of molecules per unit volume; (2) the *weight chain length distribution* (*WCLD*) relating the chain length distribution to the weight of molecules per unit volume; (3) the *number molecular weight distribution* (*NMWD*) relating the chain length distribution to molecular weight; and (4) the *weight molecular weight distribution* (*WMWD*) relating the weight distribution to molecular weight. Two average molecular weights and corresponding average chain lengths are typically defined: the *number average molecular weight* $M_n$ and the corresponding *number average chain length* $\mu_n$; and the *weight average molecular weight* $M_w$ and the corresponding *weight average chain length* $\mu_w$. Their ratio is called *polydispersity* and describes the width of the molecular weight distribution.

$$M_n = \frac{w\sum_{j=1}^{\infty} jP_j}{\sum_{j=1}^{\infty} P_j} \qquad \mu_n = \frac{\sum_{j=1}^{\infty} jP_j}{\sum_{j=1}^{\infty} P_j} \qquad M_w = \frac{w\sum_{j=1}^{\infty} j^2P_j}{\sum_{j=1}^{\infty} jP_j} \qquad \mu_w = \frac{\sum_{j=1}^{\infty} j^2P_j}{\sum_{j=1}^{\infty} jP_j}$$

$$\text{polydispersity} = \frac{M_w}{M_n} = \frac{\mu_w}{\mu_n} \tag{7-141}$$

The average chain lengths can be related to the *moments* $\lambda_k$ of the distribution as follows:

$$\mu_n = \frac{\lambda_1}{\lambda_0} \qquad \mu_w = \frac{\lambda_2}{\lambda_1} \qquad \text{polydispersity} = \frac{\lambda_0\lambda_2}{\lambda_1^2} \qquad \lambda_k = \sum_{j=1}^{\infty} j^k P_j \tag{7-142}$$

Here $P_j$ is the concentration of the polymer with chain length $j$—the same symbol is also used for representing the polymer species $P_j$; $w$ is the molecular weight of the repeating unit in the chain.

A factor in addition to the residence time distribution and temperature distribution that affects the molecular weight distribution is the type of the chemical reaction (e.g., step or addition polymerization).

Two major polymerization mechanisms are considered: *chain growth* and *step growth*. In addition, polymerization can be *homopolymerization*—a single monomer is used—and *copolymerization* usually with two monomers with complementary functional groups.

**Chain Homopolymerization Mechanism and Kinetics** Free radical and ionic polymerizations proceed through this type of mechanism, such as styrene polymerization. Here one monomer molecule is added to the chain in each step. The general reaction steps and corresponding rates can be written as follows:

$$\begin{aligned}
&I \xrightarrow{k_d} 2fR && && \text{initiation}\\
&R + M \xrightarrow{k_i} P_1 && && \\
&P_j + M \xrightarrow{k_p} P_{j+1} && n = 1, 2, \ldots && \text{propagation} \qquad (7\text{-}143)\\
&P_j + M \xrightarrow{k_f} P_1 + M_n && && \text{transfer}\\
&P_j + P_k \xrightarrow{k_{td}} M_j + M_k && && \text{termination}\\
&P_j + P_k \xrightarrow{k_{tc}} M_{j+k} && &&
\end{aligned}$$

Here $P_j$ is the *growing* or *live polymer*, and $M_j$ is the *dead* or *product polymer*. Assuming reaction steps independent of chain length and assuming pseudo-steady-state approximation for the radicals lead to the following rates for monomer and initiator conversion and live polymer distribution. The growing chains distribution is the most probable distribution [see, e.g., Ray in Lapidus and Amundson (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977; Tirrel et al. in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987]:

$$P_n = (1-\alpha)P\alpha^{n-1} \qquad \alpha = \frac{k_p M}{(k_p + k_f)M + (k_{tc} + k_{td})P}$$

$$P = \left(\frac{2fk_dI}{k_{tc} + k_{td}}\right)^{1/2} \qquad \frac{dI}{dt} = -k_dI \qquad (7\text{-}144)$$

$$r = \frac{dM}{dt} = -k_p\left(\frac{2fk_d}{k_{tc} + k_{td}}\right)^{1/2} I^{1/2}M \qquad DP_n^{\text{inst}} = \frac{k_pM}{(0.5k_{tc} + k_{td})}P$$

Here $r$ is the rate of polymerization, $\alpha$ is *the probability of propagation*, $DP_n^{\text{inst}}$ is *the instantaneous degree of polymerization*, i.e., the number of monomer units on the dead polymer, and $f$ is the *initiation efficiency*. Compare $r$ in Eq. (7-144) with the simpler Eq. (7-68). When chain transfer is the primary termination mechanism, such as in anionic polymerization, then the polydispersity is 2.

Mathematically, the infinite set of equations describing the rate of each chain length can be solved by using the $z$ transform method (a discrete method), *continuous variable approximation method*, or the *method of moments* [see, e.g., Ray in Lapidus and Amundson (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977].

Typical ranges of the kinetic parameters for low conversion homopolymerization are given in Table 7-8. For more details see Hutchenson in Meyer and Keurentjes (eds.), *Handbook of Polymer Reaction Engineering*, Wiley, 2005.

**Step Growth Homopolymerization Mechanism and Kinetics** Here any two growing chains can react with each other. The propagation mechanism is an infinite set of reactions:

$$P_j + P_k \xrightarrow{k_p} P_{j+k} \qquad (7\text{-}145)$$

**TABLE 7-8 Typical Ranges of Kinetic Parameters**

| Coefficient/concentration | Typical range |
|---|---|
| $k_d$, 1/s | $10^{-6}$–$10^{-4}$ |
| $f$ | 0.4–0.9 |
| $k_p$, L /(mol/s) | $10^2$–$10^4$ |
| $k_t$, L /(mol/s) | $10^6$–$10^8$ |
| $k_{tr}/k_p$ | $10^{-6}$–$10^{-4}$ |
| $I$, mol/L | $10^{-4}$–$10^{-2}$ |
| $M$, mol/L | 1–10 |

SOURCE: Hutchenson, "Typical Ranges of Kinetic Parameters," in *Handbook of Reaction Engineering*, Wiley, 2005, Table 4.1.

For instance, some nylons are produced through this mechanism. This is usually modeled under the simplifying assumption that the rate constants are independent of chain length. This assumption was proved pretty accurate, and by using the $z$ transform it results in the *Flory distribution*:

$$P_n = \frac{P_{10}(P_{10}\tau)^{n-1}}{(P_{10}\tau + 1)^{n+1}} \quad n \geq 1 \quad k_{pnm} = k_p \quad \text{for all } n, m \quad \tau = \int_0^t k_pM\,dt$$

$$\mu_n = \frac{2-\alpha}{1-\alpha} \quad \mu_w = \frac{2}{(1-\alpha)(2-\alpha)} \quad \text{polydispersity} = \frac{\mu_w}{\mu_n} = \frac{2}{(2-\alpha)^2}$$

$$\alpha = \frac{P_{10}\tau}{P_{10}\tau + 1} \qquad (7\text{-}146)$$

**Copolymerization** Copolymerization involves more than one monomer, usually two comonomers, as opposed to the single monomer involved in the chain growth and step homopolymerization schemes above. Examples are some nylons, polyesters, and aramids. Here as well there are step growth and chain growth mechanisms, and these are much more complex [see, e.g., Ray in Lapidus and Amundson (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977].

## BIOCHEMICAL REACTIONS

Mechanism and kinetics in biochemical systems describe the cellular reactions that occur in living cells. Biochemical reactions involve two or three phases. For example, aerobic fermentation involves gas (air), liquid (water and dissolved nutrients), and solid (cells), as described in the "Biocatalysis" subsection above. Bioreactions convert feeds called *substrates* into more *cells* or *biomass* (cell growth), proteins, and *metabolic* products. Any of these can be the desired product in a commercial *fermentation*. For instance, methane is converted to biomass in a commercial process to supply fish meal to the fish farming industry. Ethanol, a metabolic product used in transportation fuels, is obtained by fermentation of corn-based or sugar-cane-based sugars. There is a substantial effort to develop genetically modified biocatalysts that produce a desired metabolite at high yield.

Bioreactions follow the same general laws that govern conventional chemical reactions, but the complexity of the mechanism is higher due to the close coupling of bioreactions and *enzymes* that are turned on (*expressed*) or off (*repressed*) by the cell depending on the conditions in the fermenter and in the cell. Thus the rate expression (7-92) can mainly be used to design bioreaction processes when the culture is in *balanced growth*, i.e., for steady-state cultivations or batch growth for as long as the substrate concentration is much higher than $C_s$. After a sudden process upset (e.g., a sudden change in substrate concentration or pH), the *control network* of the cell that lies under the *mass flow network* is activated, and dramatic changes in the kinetics of product formation can occur. Table 7-9 summarizes key differences between biochemical and conventional chemical systems [see, e.g., Leib, Pereira, and Villadsen, "Bioreactors, A Chemical Engineering Perspective," *Chem. Eng. Sci.* **56:** 5485–5497 (2001)].

**TABLE 7-9 Biological versus Chemical Systems**

- There is tighter control on conditions (e.g., pH, temperature, substrate and product concentrations, dissolved $O_2$ concentration, avoidance of contamination by foreign organisms).
- Pathways can be turned on/off by the microorganism through expression of certain enzymes depending on the substrate type and concentration and operating conditions, leading to a richness of behavior unparalleled in chemical systems.
- The global stoichiometry changes with operating conditions and feed composition; kinetics and stoichiometry obtained from steady-state (chemostat) data cannot be used reliably over a wide range of conditions, unless fundamental models are employed.
- Long-term adaptations (mutations) may occur in response to environment changes that can alter completely the product distribution.
- Only the substrates that maximize biomass growth are utilized even in the presence of multiple substrates.
- Cell energy balance requirements pose additional constraints on the stoichiometry that can make it very difficult to predict flux limitations.

**TABLE 7-10 Heirarchy of Kinetic Models in Biological Systems**

- Stoichiometric black box models (similar to a single global chemical reaction) represent the biochemistry by a single global reaction with fixed stoichiometric or *yield coefficients* (limited to a narrow range of conditions). Black box models can be used over a wider range of conditions by establishing different sets of yield coefficient for different conditions. These are also needed to establish the quantitative amounts of various nutrients needed for the completion of the bioreaction.
- Unstructured models view the cell as a single component interacting with the fermentation medium, and each bioreaction is considered to be a global reaction, with a corresponding empirical rate expression.
- Structured models include information on individual reactions or groups of reactions occurring in the cell, and cell components such as DNA, RNA, and proteins are included in addition to the primary metabolites and substrates (see, e.g., the active cell model of Nielsen and Villadsen, *Bioreaction Engineering Principles*, 2d ed., Kluwer Academic/Plenum Press, 2003).
- Fundamental models include cell dimensions, transport of substrates and metabolites across the cell membrane, and the elementary cell bioreaction steps and their corresponding enzyme induction mechanism. In recent years further kinetic steps have been added to the above models which are based on the conversion of substrates to metabolites. Thus the kinetics of protein synthesis by *transcription* and *translation* from the *genome* add much further complexity to cell kinetics.

The network of bioreactions is called the *metabolic network*, the series of consecutive steps between key intermediates in the network are called *metabolic pathways*, and the determination of the mechanism and kinetics is called *metabolic flux analysis*. As for chemical systems, there are several levels of mechanistic and kinetic representation and analysis, listed in order of increasing complexity in Table 7-10.

Additional complexity can be included through cell population balances that account for the distribution of cell generation present in the fermenter through use of stochastic models. In this section we limit the discussion to simple black box and unstructured models. For more details on bioreaction systems, see, e.g., Nielsen, Villadsen, and Liden, *Bioreaction Engineering Principles*, 2d ed., Kluwer, Academic/Plenum Press, 2003; Bailey and Ollis, *Biochemical Engineering Fundamentals*, 2d ed., McGraw-Hill, 1986; Blanch and Clark, *Biochemical Engineering*, Marcel Dekker, 1997; and Sec. 19.

**Mechanism** Stoichiometric balances are done on a C atom basis called *C-moles*, e.g., relative to the substrate (denoted by subscript *s*), and the corresponding stoichiometric coefficients $Y_{si}$ (based on C-mole of the primary substrate) are called *yield coefficients*. For instance,

$$CH_2O + Y_{so}O_2 + Y_{sn}NH_3 + Y_{ss1}S_1 + \cdots \Rightarrow Y_{sx}X + Y_{sc}CO_2 + Y_{sp1}P_1 + \cdots + Y_{sw}H_2O \qquad (7\text{-}147)$$

Here the reactants (substrates) are glucose ($CH_2O$), $O_2$, $NH_3$, and a sulfur-providing nutrient $S_1$, and the products are biomass X, $CO_2$, metabolic product $P_1$, and $H_2O$.

The products of bioreactions can be reduced or oxidized, and all feasible pathways have to be *redox neutral*. There are several cofactors that transfer redox power in a pathway or between pathways, each equivalent to the reducing power of a molecule of $H_2$, e.g., nicotinamide adenine dinucleotide (NADH), and these have to be included in the stoichiometric balances as H equivalents through redox balancing. For instance, for the reaction of glucose to glycerol ($CH_{8/3}O$), $\frac{1}{3}$ NADH equivalent is consumed:

$$CH_2O + \frac{1}{3}NADH \Rightarrow CH_{8/3}O \qquad (7\text{-}148)$$

The stoichiometry in the biochemical literature often does not show $H_2O$ produced by the reaction; however, for complete elemental balance, water has to be included, and this is easily done once an $O_2$ requirement has been determined based on a redox balance. Likewise for simplicity, the other form of the cofactor [e.g., the oxidized form of the cofactor NADH in Eq. (7-148)] is usually left out. In addition to C balances, for aerobic systems cell respiration has to be accounted for as well through a stoichiometric equation:

$$NADH + 0.5O_2 \Rightarrow H_2O + \gamma ATP \qquad (7\text{-}149)$$

The associated free energy produced or consumed in each reaction is captured in units of adenosine triphosphate (ATP). The ATP stoichiometry is usually obtained from biochemical tables since the energy has to be also balanced for the cell. Thus for Eq. (7-148) the stoichiometric ATP requirement to convert one C-mole of glucose to one C-mole of glycerol is $\frac{1}{3}$. In calculations of the carbon flux distribution in different pathways this ATP requirement has to be added on the left-hand side of the equation. Again the other form of the cofactor ATP is usually left out to simplify the reaction equation.

There are several metabolic pathways that are repeated for many living cells, and these are split into two: *catabolic* or energy-producing and *anabolic* or energy-consuming, the later producing building blocks such as amino acids and the resulting macromolecules such as proteins. Of course the energy produced in catabolic steps has to be balanced by the energy consumed in anabolic steps. Catabolic pathways include the well-studied *glycolysis*, *TCA cycle*, *oxidative phosphorylation,* and *fermentative pathways*. For more details see Stephanopoulos, Aristidou, and Nielsen, *Metabolic Engineering: Principles and Methodologies*, Academic Press, 1998; and Nielsen, Villadsen, and Liden, *Bioreaction Engineering Principles*, 2d ed., Kluwer, Academic/Plenum Press, 2003; Bailey and Ollis, *Biochemical Engineering Fundamentals*, 2d ed., McGraw-Hill, 1986.

**Monod-Type Empirical Kinetics** Many bioreactions show increased biomass growth rate with increasing substrate concentration at low substrate concentration for the limiting substrate, but no effect of substrate concentration at high concentrations. This behavior can be represented by the Monod equation (7-92). Additional variations on the Monod equation are briefly illustrated below. For two essential substrates the Monod equation can be modified as

$$\mu = \frac{\mu_{max} C_{s1} C_{s2}}{(K_{s1} + C_{s2})(K_{s2} + C_{s2})} \qquad (7\text{-}150)$$

This type of rate expression is often used in models for water treatment, and many environmental factors can be included (the effect of, e.g., phosphate, ammonia, volatile fatty acids, etc.). The correlation between parameters in such complicated models is, however, severe, and very often a simple Monod model (7-92) with only one limiting substrate is sufficient.

When *substrate inhibition* occurs,

$$\mu = \frac{\mu_{max} C_s}{K_s + C_s + K_1/C_s^2} \qquad (7\text{-}151)$$

$O_2$ is typically a substrate that in high concentrations leads to substrate inhibition, but a high concentration of the carbon source can also be inhibiting (e.g., in bioremediation of toxic waste a high concentration of the organic substrate can well lead to severe inhibition or death of the microorganism).

When *product inhibition* is present,

$$\mu = \frac{\mu_{max} C_s}{K_s + C_s}\left(1 - \frac{C_p}{C_{pmax}}\right) \qquad (7\text{-}152)$$

Here the typical example is the inhibitor effect of ethanol on yeast growth. Considerable efforts are made by the biocompanies to develop yeast strains that are tolerant to high ethanol concentrations since this will give considerable savings in, e.g., production of biofuel by fermentation.

The various component reaction rates for a single reaction can be related to the growth rate by using the stoichiometric (yield) coefficients, e.g., from Eq. (7-147):

$$r_i = Y_{xi}\mu C_x = \frac{Y_{si}}{Y_{sx}}\mu C_x \qquad (7\text{-}153)$$

**Chemostat with Empirical Kinetics** Using the CSTR equation (7-54) for a constant-volume single reaction [Eq. (7-147)], the substrate, biomass, and product material balances are

$$\begin{aligned} &\frac{1}{Y_{sx}}\mu C_x + D(C_{s0} - C_s) = 0 \\ &\mu C_x - DC_x = 0 \rightarrow D = \mu \\ &\frac{Y_{sp}}{Y_{sx}}\mu C_x - DC_p = 0 \end{aligned} \tag{7-154}$$

Here $C_{s0}$ is the feed substrate concentration, and $D$ is the *dilution rate*, which at steady-state constant volume is equal to both the feed and effluent volumetric flow rates and to the specific growth rate. The effluent concentrations of substrate, biomass, and products can be calculated by using a suitable expression for the specific growth rate $\mu$ such as one of the relevant variants of the Monod kinetics described above.

## ELECTROCHEMICAL REACTIONS

Electrochemical reactions involve coupling between chemical reactions and electric charge transfer and may have two or three phases, for instance, a gas (e.g., $H_2$ or $O_2$ evolved at the electrodes or fed as reactants), a liquid (the electrolyte solution), and solids (electrodes). Electrocatalysts may be employed to enhance the reaction for a particular desired product. Hence, electrochemical reactions are heterogeneous reactions that occur at the surface of electrodes and involve the transfer of charge in the form of electrons as part of a chemical reaction. The electrochemical reaction can produce a chemical change by passing an electric current through the system (e.g., electrolysis), or reversely a chemical change can produce electric energy (e.g., using a battery or fuel cell to power an appliance). There are a variety of practical electrochemical reactions, some occurring naturally, such as corrosion, and others used in production of chemicals (e.g., the decomposition of HCl to produce $Cl_2$ and $H_2$, the production of caustic soda and chlorine, the smelting of aluminum), electroplating, and energy generation (e.g., fuel cells and photovoltaics). Electrochemical reactions are reversible and can be generally written as a *reduction-oxidation* (*redox*) couple:

$$O + ne^- \rightleftarrows R$$

where $O$ is an oxidized and $R$ is a reduced species. For instance, the corrosion process includes oxidation at the *anode*:

$$Fe \rightleftarrows Fe^{2+} + 2e^-$$

and reduction at the *cathode*:

$$O_2 + H_2O + 4e^- \rightleftarrows 4OH^-$$

The overall electrochemical reaction is the stoichiometric sum of the anode and cathode reactions:

$$2Fe + O_2 + H_2O \rightleftarrows 2Fe^{2+} + 4OH^- \quad \text{(four electron transfer process, } n = 4\text{)}$$

The anode and cathode reactions are close coupled in that the electric charge is conserved; therefore, the overall production rate is a direct function of the electric charge passed per unit time, the electric current $I$.

For references on electrochemical reaction kinetics and mechanism, see, e.g., Newman and Thomas-Alvea, *Electrochemical Systems*, 3d ed., Wiley Interscience, 2004; Bard and Faulkner, *Electrochemical Methods: Fundamentals and Applications*, 2d ed., Wiley, 2001; Bethune and Swendeman, "Table of Electrode Potentials and Temperature Coefficients," *Encyclopedia of Electrochemistry*, Van Nostrand Reinhold, New York 1964, pp. 414–424; and Bethune and Swendeman, *Standard Aqueous Electrode Potentials and Temperature Coefficients*, C. A. Hampel Publisher, 1964.

*Faraday's law* relates the charge transferred by ions in the electrolyte and electrons in the external circuit, to the moles of chemical species reacted (Newman and Thomas-Alvea, *Electrochemical Systems*, 3d ed., Wiley Interscience, 2004):

$$\begin{aligned} &Q = nmF \qquad F = 96{,}485 \text{ C/equiv} \\ &I = \frac{Q}{t} = \frac{\text{charge}}{\text{time}} \qquad \text{A} \end{aligned} \tag{7-155}$$

where $n$ is the number of equivalents per mole, $m$ is the number of moles, $F$ is the Faraday constant, $Q$ is the charge, and $t$ is time. The total current passed may represent several parallel electrochemical reactions; therefore, we designate a current efficiency for each chemical species. The chemical species production rate (mass/time) is related to the total current passed $I$, the species *current efficiency* $\varepsilon_{\text{current},i}$, and the molecular weight of the chemical species $MW_i$:

$$\begin{aligned} &\dot{m} = \frac{I \times \varepsilon_{\text{current},i} \times MW_i}{nF} = \frac{\text{mass}}{\text{time}} \\ &j = \frac{\text{current}}{\text{area}} = \frac{I}{A_{\text{projected}}} \end{aligned} \tag{7-156}$$

Since electrochemical reactions are heterogeneous at electrode surfaces, the current $I$ is generally normalized by dividing it by the geometric or projected area of the electrode, resulting in the quantity known as the *current density* $j$, in units of kA/m$^2$.

The overall electrochemical cell *equilibrium potential* $E^o_{\text{cell}}$, as measured between the cathode and the anode, is related to the Gibbs free energy change for the overall electrochemical reaction:

$$\begin{aligned} &\Delta G^o = \Delta H^o - T\,\Delta S^o = -nFE^o_{\text{cell}} \\ &E^o_{\text{cell}} = -\frac{\Delta G^o}{nF} = E^o_{\text{cathode}} - E^o_{\text{anode}} \end{aligned} \tag{7-157}$$

Each electrode reaction, anode and cathode, or half-cell reaction has an associated energy level or electrical potential (volts) associated with it. Values of the standard equilibrium electrode reduction potentials $E^o$ at unit activity and 25°C may be obtained from the literature (de Bethune and Swendeman Loud, *Encyclopedia of Electrochemistry*, Van Nostrand Reinhold, 1964). The overall electrochemical cell *equilibrium potential* either can be obtained from $\Delta G$ values or is equal to the cathode half-cell potential minus the anode half-cell potential, as shown above.

The *Nernst equation* allows one to calculate the *equilibrium potential* $E^{\text{eq}}$ when the activity of the reactants or products is not at unity:

$$\begin{aligned} &\sum_i \nu_i M_i^{n_i} \rightarrow ne^- \\ &E^{\text{eq}} = E^o - \frac{RT}{nF}\ln(\Pi a_i^{\nu_i}) \\ &\left(\frac{\partial E}{\partial T}\right)_P = \frac{\Delta S}{nF} \end{aligned} \tag{7-158}$$

where $\nu_i$ is the stoichiometric coefficient of chemical species $i$ (positive for products; negative for reactants), $M_i$ is the symbol for species $i$, $n_i$ is the charge number of the species, $a_i$ is the activity of the chemical species, $E$ is the *formal potential*, and $\Pi$ represents the product of all respective activities raised to their stiochiometric powers as required by the reaction. Please note that if the value of the equilibrium potential is desired at another temperature, $E^o$ must also be evaluated at the new temperature as indicated.

**Kinetic Control** In 1905, Julius Tafel experimentally observed that when mass transport was not limiting, the *current density* $j$ of electrochemical reactions exhibited the following behavior:

$$j = a' e^{\eta_{\text{act}}/b'} \qquad \text{or} \qquad \eta_{\text{act}} = a + b \log j$$

where the quantity $\eta_{\text{act}}$ is known as the *activation overpotential* $E - E^{\text{eq}}$, and is the difference between the actual electrode potential

$E$ and the reversible equilibrium potential of the electrochemical reaction $E^{eq}$. Thus the driving force for the electrochemical reaction is not the absolute potential; it is the activation overpotential $\eta_{act}$.

This relationship between the current density and activation overpotential has been further developed and resulted in the Butler-Volmer equation:

$$r = \frac{j}{nF} = k_f C_o - k_r C_r \qquad j = j_0(e^{-(\alpha_a F/RT)\eta_{act}} - e^{[(1-\alpha)nF/RT]\eta_{act}})$$

$$\eta_{act} = E - E^{eq} \tag{7-159}$$

Here the reaction rate $r$ is defined per unit electrode area, moles per area per time, $j_0$ is the *equilibrium exchange current* when $E = E^{eq}$, $\eta_{act}$ is the *activation overpotential*, and $\alpha$ is the *transfer coefficient*. For large activation overpotentials, the *Tafel empirical equation* applies:

$$\eta_{act} = a + b \log j \qquad \text{for } \eta_{act} > 100 \text{ mV}, b = \text{Tafel slope} \tag{7-160}$$

For small activation overpotentials, linearization gives

$$j = j_0 \frac{nF}{RT} \eta_{act} \tag{7-161}$$

**Mass-Transfer Control** The surface concentration at the electrodes differs significantly from the bulk electrolyte concentration. The Nernst equation applies to the surface concentrations (or activities in case of nonideal solutions):

$$E^{eq} = E^o - \frac{RT}{nF} \ln(\Pi a_{i,\text{surf}}^{\nu_i}) \tag{7-162}$$

If mass transfer is limiting, then a *limiting current* is obtained for each chemical species $i$:

$$j_{i,\text{lim}} = \frac{nFD_i C_i}{\delta} = nFk_{L,i}C_i \tag{7-163}$$

where $D_i$ is the diffusion coefficient, $\delta$ is the boundary layer thickness, and $k_{L,i}$ is the mass-transfer coefficient of species $i$. The effect of mass transfer is included as follows:

$$j = j_0\left[\left(1 - \frac{j}{j_{a,\text{lim}}}\right)e^{-(\alpha_a F/RT)\eta_{act}} - \left(1 - \frac{j}{j_{c,\text{lim}}}\right)e^{[(1-\alpha)nF/RT]\eta_{act}}\right]$$

$$\frac{C_{i,\text{surf}}}{C_i} = \left(1 - \frac{j}{j_{i,\text{lim}}}\right) \qquad i = o,r \tag{7-164}$$

**Ohmic Control** The overall electrochemical reactor cell voltage may be dependent on the kinetic and mass-transfer aspects of the electrochemical reactions; however, a third factor is the potential lost within the electrolyte as current is passing through this phase. The potential drops may become dominant and limit the electrochemical reactions requiring an external potential to be applied to drive the reactions or significantly lower the delivered electrical potential in power generation applications such as batteries and fuel cells.

**Multiple Reactions** With multiple reactions, the total current is the sum of the currents from the individual reactions with anodic currents positive and cathodic currents negative. This is called the *mixed potential principle*. For more details see Bard and Faulkner, *Electrochemical Methods: Fundamentals and Applications*, 2d ed., Wiley, 2001.

# DETERMINATION OF MECHANISM AND KINETICS

Laboratory data are the predominant source for reaction mechanism and kinetics in industrial practice. However, often laboratory data intended for scoping and demonstration studies rather than for kinetic evaluation have to be used, thus reducing the effectiveness and accuracy of the resulting kinetic model. The following are the steps required to obtain kinetics from laboratory data:

1. Develop initial guesses on mechanism, reaction time scale, and potential kinetic models from the literature, scoping experiments, similar chemistries, and computational chemistry calculations, when possible.
2. Select a suitable laboratory reactor type and scale, and analytical tools for kinetic measurements.
3. Develop à priori factorial experimental design or sequential experimental design.
4. When possible, provide ideal reactor conditions, e.g., good mechanical agitation in batch and CSTR, high velocity flow in PFR.
5. Estimate the limiting diffusion-reaction regimes under the prevailing lab reactor conditions for heterogeneous reactions, and use the appropriate lab reactor model. When possible, operate the reactor under kinetic control.
6. Discriminate between competing mechanisms and kinetic rates by forcing maximum differentiation between competing hypotheses through the experimental design, and by obtaining the best fit of the kinetic data to the proposed kinetic forms.

## LABORATORY REACTORS

Selection of the laboratory reactor type and size, and associated feed and product handling, control, and analytical schemes depends on the type of reaction, reaction time scales, and type of analytical methods required. The criteria for selection include equipment cost, ease of operation, ease of data analysis, accuracy, versatility, temperature uniformity, and controllability, suitability for mixed phases, and scale-up feasibility. Many configurations of laboratory reactors have been employed. Rase (*Chemical Reactor Design for Process Plants,* Wiley, 1977) and Shah (*Gas-Liquid-Solid Reactor Design,* McGraw-Hill, 1979) each have about 25 sketches, and Shah's bibliography has 145 items classified into 22 categories of reactor types. Jankowski et al. [*Chemische Technik* **30:** 441–446 (1978)] illustrate 25 different kinds of gradientless laboratory reactors for use with solid catalysts.

Laboratory reactors are of two main types:

1. Reactors used to obtain fundamental data on intrinsic chemical rates free of mass-transfer resistances or other complications. Some of the gas-liquid lab reactors, for instance, employ known interfacial areas, thus avoiding the uncertainty regarding the area for gas to liquid mass transfer. When ideal behavior cannot be achieved, intrinsic kinetic estimates need to account for mass- and heat-transfer effects.
2. Reactors used to obtain scale-up data due to their similarity to the reactor intended for the pilot or commercial plant scale. How to scale down from the conceptual commercial or pilot scale to lab scale is a difficult problem in itself, and it is not possible to maintain all key features while scaling down.

The first type is often the preferred one—once the intrinsic kinetics are obtained at "ideal" lab conditions, scale-up is done by using models or correlations that describe large-scale reactor hydrodynamics coupled with the intrinsic kinetics. However, in some cases ideal conditions cannot be achieved, and the laboratory reactor has to be adequately modeled to account for mass and heat transfer and nonideal mixing effects to enable extraction of intrinsic kinetics. In addition, with homogeneous reactions, attention must be given to prevent wall-catalyzed reactions, which can result in observed kinetics that are fundamentally different from intrinsic homogeneous kinetics. This is a problem for scale-up, due to the high surface/volume ratio in small reactors versus the low surface/volume ratio in large-scale systems, resulting in widely different contributions of wall effects at different scales. Similar issues arise in bioreactors with the potential of

undesirable wall growth of the biocatalyst cells masking the homogeneous growth kinetics. In catalytic reactions certain reactor configurations may enhance undesirable homogeneous reactions, and the importance of these reactions may be different at larger scale, causing potential scale-up pitfalls.

The reaction rate is expressed in terms of chemical compositions of the reacting species, so ultimately the variation of composition with time or space must be found. The composition is determined in terms of a property that is measured by some instrument and calibrated. Among the measures that have been used are titration, pressure, refractive index, density, chromatography, spectrometry, polarimetry, conductimetry, absorbance, and magnetic resonance. Therefore, batch or semibatch data are converted to composition as a function of time ($C$, $t$), or to composition and temperature as functions of time ($C$, $T$, $t$), to prepare for kinetic analysis. In a steady CSTR and PFR, the rate and compositions in the effluent are observed as a function of residence time.

When a reaction has many reactive species (which may be the case even for apparently simple processes such as pyrolysis of ethane or synthesis of methanol), a factorial or sequential experimental design should be developed and the data can be subjected to a *response surface analysis* (Box, Hunter, and Hunter, *Statistics for Experimenters,* 2d ed., Wiley Interscience, 2005; Davies, *Design and Analysis of Industrial Experiments,* Oliver & Boyd, 1954). This can result in a black box correlation or statistical model, such as a quadratic (limited to first- and second-order effects) for the variables $x_1$, $x_2$, and $x_3$:

$$r = k_1x_1 + k_2x_2 + k_3x_3 + k_{12}x_1x_2 + k_{13}x_1x_3 + k_{23}x_2x_3$$

Analysis of such statistical correlations may reveal the significant variables and interactions and may suggest potential mechanisms and kinetic models, say, of the Langmuir-Hinshelwood type, that could be analyzed in greater detail by a regression process. The variables $x_i$ could be various parameters of heterogeneous processes as well as concentrations. An application of this method to isomerization of *n*-pentane is given by Kittrel and Erjavec [*Ind. Eng. Chem. Proc. Des. Dev.* **7:** 321 (1968)].

Table 7-11 summarizes laboratory reactor types that approach the three ideal concepts BR, CSTR and PFR, classified according to reaction types.

**TABLE 7-11 Laboratory Reactors**

| Reaction | Reactor |
|---|---|
| Homogeneous gas | Isothermal U-tube in temperature-controlled batch |
| Homogeneous liquid | Mechanically agitated batch or CSTR with jacketed cooling/heating |
| Catalytic gas-solid | Packed tube in furnace |
| | Isothermal U-tube in temperature-controlled bath |
| | Rotating basket with jacketed cooling/heating |
| | Internal recirculation (Berty) reactor with jacketed cooling/heating |
| Noncatalytic gas-solid | Packed tube in furnace |
| Liquid-solid | Packed tube in furnace |
| Gas-liquid | CSTR with jacketed cooling/heating |
| | Fixed interface CSTR |
| | Wetted wall |
| | Laminar jet |
| Gas-liquid-solid | Slurry CSTR with jacketed cooling/heating |
| | Packed bed with downflow, upflow, or countercurrent |
| Solid-solid | Packed tube in furnace |

For instance, Fig. 7-17 summarizes laboratory reactor types and hydrodynamics for gas-liquid reactions.

**Batch Reactors** In the simplest kind of investigation, reactants can be loaded into a number of sealed tubes, kept in a thermostatic bath for various periods, shaken mechanically to maintain uniform composition, and analyzed. In terms of cost and versatility, the stirred batch reactor is the unit of choice for homogeneous or heterogeneous slurry reactions including gas-liquid and gas-liquid-solid systems. For multiphase systems the reactants can be semibatch or continuous. The BR is especially suited to reactions with half-lives in excess of 10 min. Samples are taken at time intervals, and the reaction is stopped by cooling, by dilution, or by destroying a residual reactant such as an acid or base; analysis can then be made at a later time. Analytic methods that do not necessitate termination of reaction include nonintrusive measurements of (1) the amount of gas produced, (2) the gas pressure in a constant-volume vessel, (3) absorption of light, (4) electrical or thermal conductivity, (5) polarography, (6) viscosity of polymerization, (7) pH and DO probes, and so on. Operation may be isothermal, with the important effect of temperature determined from several isothermal runs, or the composition and temperature may be recorded simultaneously and the

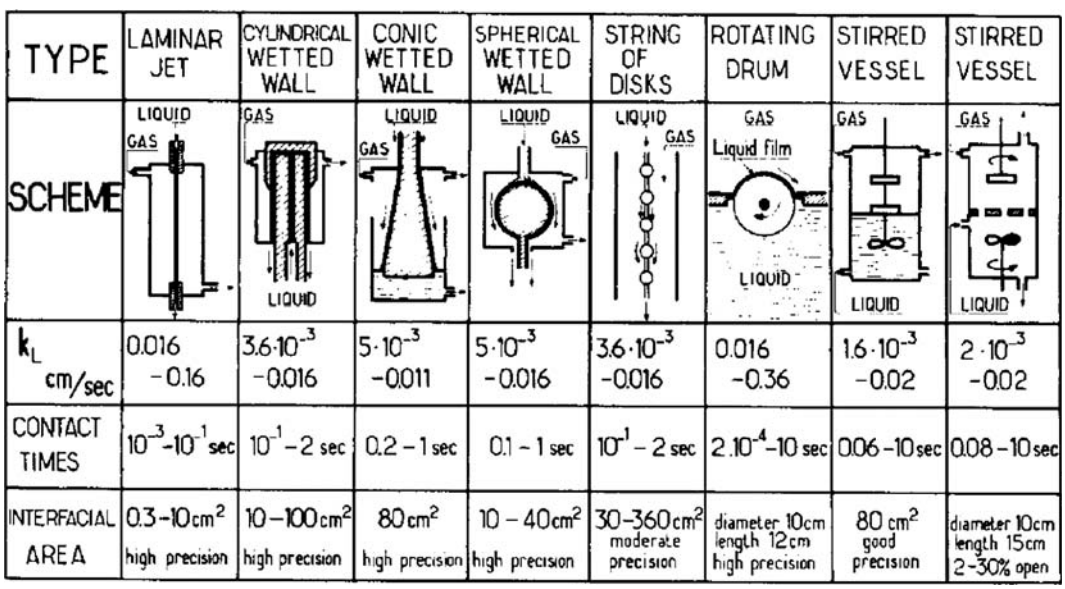

**FIG. 7-17** Principal types of laboratory reactors for gas-liquid reactions. [From *Fig. 8 in J. C. Charpentier, "Mass Transfer Rates in Gas-Liquid Absorbers and Reactors," in Drew et al. (eds.),* Advances in Chemical Engineering, *vol. 11, Academic Press, 1981.*]

data regressed. On the laboratory scale, it is essential to ensure that a BR is stirred to uniform composition, and for critical cases such as high viscosities this should be checked with tracer tests.

**Flow Reactors** CSTRs and other devices that require flow control are more expensive and difficult to operate. However, CSTRs and PFRs are the preferred laboratory reactors for steady operation. One of the benefits of CSTRs is their isothermicity and the fact that their mathematical representation is algebraic, involving no differential equations, thus making data analysis simpler. For laboratory research purposes, CSTRs are considered feasible for holding times of 1 to 4000 s, reactor volumes of 2 to 1000 $cm^3$ (0.122 to 61 $in^3$), and flow rates of 0.1 to 2.0 $cm^3/s$. Fast reactions and those in the gas phase are generally done in tubular flow reactors, just as they are often done on the commercial scale. Usually it is not possible to measure compositions along a PFR, although temperatures can be measured using a thermowell with fixed or mobile thermocouple bundle. PFRs can be kept at nearly constant temperatures; small-diameter tubes immersed in a fluidized sand bed or molten salt can hold quite constant temperatures of a few hundred degrees. Other PFRs are operated at near adiabatic conditions by providing dual radial temperature control to minimize the radial heat flux, with multiple axial zones. A recycle unit can be operated as a differential reactor with arbitrarily small conversion and temperature change. Test work in a tubular flow unit may be desirable if the intended commercial unit is of that type.

**Multiphase Reactors** Reactions between gas-liquid, liquid-liquid, and gas-liquid-solid phases are often tested in CSTRs. Other laboratory types are suggested by the commercial units depicted in appropriate sketches in Sec. 19 and in Fig. 7-17 [Charpentier, *Mass Transfer Rates in Gas-Liquid Absorbers and Reactors*, in Drew et al. (eds.), *Advances in Chemical Engineering*, vol. 11, Academic Press, 1981]. Liquids can be reacted with gases of low solubilities in stirred vessels, with the liquid charged first and the gas fed continuously at the rate of reaction or dissolution. Some of these reactors are designed to have known interfacial areas. Most equipment for gas absorption without reaction is adaptable to absorption with reaction. The many types of equipment for liquid-liquid extraction also are adaptable to reactions of immiscible liquid phases.

**Solid Catalysts** Processes with solid catalysts are affected by diffusion of heat and mass (1) within the pores of the pellet, (2) between the fluid and the particle, and (3) axially and radially within the packed bed. Criteria in terms of various dimensionless groups have been developed to tell when these effects are appreciable, and some of these were discussed above. For more details see Mears [*Ind. Eng. Chem. Proc. Des. Devel.* **10:** 541–547 (1971); *Ind. Eng. Chem. Fund.* **15:** 20–23 (1976)] and Satterfield (*Heterogeneous Catalysis in Practice*, McGraw-Hill, 1991, p. 491). For catalytic investigations, the rotating basket or fixed basket with internal recirculation is the standard device, usually more convenient and less expensive than equipment with external recirculation. In the fixed-basket type, an internal recirculation rate of 10 to 15 or so times the feed rate effectively eliminates external diffusional resistance, and temperature gradients (see, e.g., Berty, *Experiments in Catalytic Reaction Engineering*, Elsevier, 1999). A unit holding 50 $cm^3$ (3.05 $in^3$) of catalyst can operate up to 800 K (1440°R) and 50 bar (725 psi). When deactivation occurs rapidly (in a few seconds during catalytic cracking, for instance), the fresh activity can be maintained with a transport reactor through which both reactants and fresh catalyst flow without slip and with short contact time. Since catalysts often are sensitive to traces of impurities, the time deactivation of the catalyst usually can be evaluated only with commercial feedstock. Physical properties of catalysts also may need to be checked periodically, including pellet size, specific surface, porosity, pore size and size distribution, effective diffusivity, and active metals content and dispersion. The effectiveness of a porous catalyst is found by measuring conversions with successively smaller pellets until no further change occurs. These topics are touched on by Satterfield (*Heterogeneous Catalysis in Industrial Practice*, McGraw-Hill, 1991).

To determine the deactivation kinetics, long-term deactivation studies at constant conditions and at different temperatures are required. In some cases, accelerated aging can be induced to reduce the time required for the experimental work, by either increasing the feed flow rate (if the deactivation is a result of feed or product poisoning) or increasing the temperature above the standard reaction temperature. These require a good understanding of how the higher-temperature or rate-accelerated deactivation correlates with deactivation at the operating reaction temperature and rate.

**Bioreactors** There are several types of laboratory bioreactors used with live organisms as biocatalysts:

1. Mechanically agitated batch/semibatch with pH control and nutrients or other species either fed at the start or added continuously based on a recipe or protocol.
2. CSTR to maintain a constant *dilution rate* (the feed rate). These require some means to separate the biocatalyst from the product and recycle to the reactor, such as centrifuge or microfiltration:

*a. Chemostat* controls the flow to maintain a constant fermentation volume.

*b. Turbidostat* controls the biomass or cells concentration.

*c. pH-auxostat* controls pH in the effluent (same as pH in reactor).

*d. Productostat* controls the effluent concentration of one of the metabolic products.

The preferred reactor for kinetics is the chemostat, but semibatch reactors are more often used owing to their simpler operation.

**Calorimetry** Another category of laboratory systems that can be used for kinetics includes *calorimeters*. These are primarily used to establish temperature effects and thermal runaway conditions, but can also be employed to determine reaction kinetics. Types of calorimeters are summarized in Table 7-12; for more details see Reid, "Differential Microcalorimeters," *J. Physics E: Scientific Instruments*, **9** (1976).

Additional methods of laboratory data acquisition are described in Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001.

## KINETIC PARAMETERS

The kinetic parameters are constants that appear in the intrinsic kinetic rate expressions and are required to describe the rate of a reaction or reaction network. For instance, for the simple global *n*th-order reaction with Arrhenius temperature dependence:

$$A \Rightarrow B \qquad r = kC_a^n \qquad k = k_0 e^{-E/RT} \tag{7-165}$$

The kinetic parameters are $k_0$, $E$, and $n$, and knowledge of these parameters and the prevailing concentration and temperature fully determines the reaction rate.

For a more complex expression such as the Langmuir-Hinshelwood rate for gas reaction on heterogeneous catalyst surface with equilibrium adsorption of reactants $A$ and $B$ on two different sites and nonadsorbing products, Eq. (7-85) can be rewritten as

$$r = \frac{k_0 e^{-E/RT} P_a P_b}{(1 + K_{a0} e^{-E_{aa}/RT})(1 + K_{b0} e^{-E_{ab}/RT})} \tag{7-166}$$

and the kinetic parameters are $k_0$, $E$, $K_{a0}$, $E_{aa}$, $K_{b0}$, and $E_{ab}$.

A number of factors limit the accuracy with which parameters needed for the design of commercial equipment can be determined. The kinetic parameters may be affected by inaccurate accounting for laboratory reactor heat and mass transport, and hydrodynamics; correlations for these are typically determined under nonreacting conditions at ambient temperature and pressure and with nonreactive model fluids and may not be applicable or accurate at reaction conditions. Experimental uncertainty including errors in analysis, measurement,

and control is also a contributing factor (see, e.g., Hoffman, "Kinetic Data Analysis and Parameter Estimation," in de Lasa (ed.), *Chemical Reactor Design and Technology,* Martinus Nijhoff, 1986.

## DATA ANALYSIS METHODS

In this section we focus on the three main types of ideal reactors: BR, CSTR, and PFR. Laboratory data are usually in the form of concentrations or partial pressures versus batch time (batch reactors), concentrations or partial pressures versus distance from reactor inlet or residence time (PFR), or rates versus residence time (CSTR). Rates can also be calculated from batch and PFR data by differentiating the concentration versus time or distance data, usually by numerical curve fitting first. It follows that a general classification of experimental methods is based on whether the data measure rates directly (differential or direct method) or indirectly (integral of indirect method). Table 7-13 shows the pros and cons of these methods.

Some simple reaction kinetics are amenable to analytical solutions and graphical linearized analysis to calculate the kinetic parameters from rate data. More complex systems require numerical solution of nonlinear systems of differential and algebraic equations coupled with nonlinear parameter estimation or regression methods.

**Differential Data Analysis** As indicated above, the rates can be obtained either directly from differential CSTR data or by differentiation of integral data. A common way of evaluating the kinetic parameters is by rearrangement of the rate equation, to make it linear in parameters (or some transformation of parameters) where possible. For instance, using the simple *n*th-order reaction in Eq. (7-165) as an example, taking the natural logarithm of both sides of the equation results in a linear relationship between the variables ln *r,* 1/*T,* and ln $C_a$:

$$\ln r = \ln k_0 - \frac{E}{RT} + n \ln C_a \tag{7-167}$$

Multilinear regression can be used to find the constants $k_0$, $E$, and $n$. For constant-temperature (isothermal) data, Eq. (7-167) can be simplified by using the Arrhenius form as

$$\ln r = \ln k + n \ln C_a \tag{7-168}$$

and the kinetic parameters $n$ and $k$ can be determined as the intercept and slope of the best straight-line fit to the data, respectively, as shown in Fig. 7-18.

The preexponential $k_0$ and activation energy $E$ can be obtained from multiple isothermal data sets at different temperatures by using the linearized form of the Arrhenius equation

$$\ln k = \ln k_0 - \frac{E}{RT} \tag{7-169}$$

as shown in Fig. 7-19.

**Integral Data Analysis** Integral data such as from batch and PFR relate concentration to time or distance. Integration of the BR equation for an *n*th-order homogeneous constant-volume reaction yields

**TABLE 7-13 Comparison of Direct and Indirect Methods**

| Direct method | Indirect method |
|---|---|
| Advantages | Disadvantages |
| Get rate equation directly | Must infer rate equation |
| Easy to fit data to a rate law | Hard to analyze rate data |
| High confidence on final rate equation | Low confidence on final rate equation |
| Disadvantages | Advantages |
| Difficult experiment | Easier experiment |
| Need many runs | Can do a few runs and get important information |
| Not suitable for very fast or very slow reactions | Suitable for all reactions including very fast or very slow ones |

SOURCE: Masel, *Chemical Kinetics and Catalysis,* Wiley, 2001, Table 3.2.

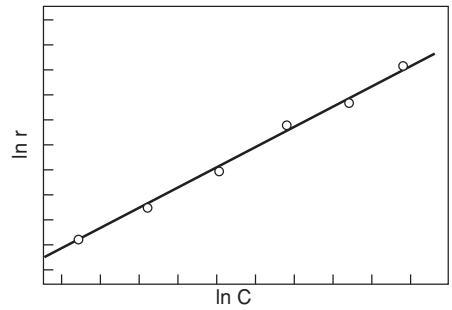

**FIG. 7-18** Determination of the rate constant and reaction order.

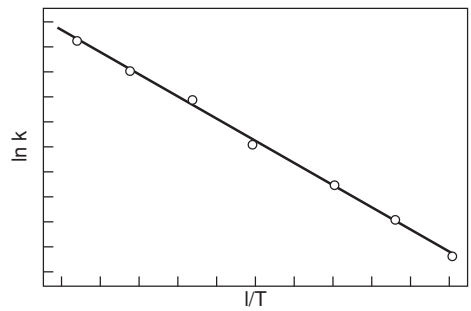

**FIG. 7-19** Determination of the activation energy.

$$\ln \frac{C_{a0}}{C_a} = k\tau \qquad \text{for } n = 1$$
$$\left(\frac{C_{a0}}{C_a}\right)^{n-1} = 1 + k\tau(n-1)C_{a0}^{n-1} \qquad \text{for } n \neq 1 \tag{7-170}$$

For the first-order case, the rate constant $k$ can be obtained directly from the slope of the graph of the left-hand side of Eq. (7-170) versus batch time, as shown in Fig. 7-20.

For orders other than first, plotting the natural log of Eq. (7-170) can at least indicate if the order is larger or smaller than 1, as shown in Fig. 7-21.

**The Half-Life Method** The half-life is the batch time required to get 50 percent conversion. For an *n*th-order reaction,

$$\tau_{1/2} = \frac{\ln 2}{k} \qquad \text{for } n = 1$$
$$\tau_{1/2} = \frac{2^{n-1} - 1}{(n-1)\,kC_{a0}^{n-1}} \qquad \text{for } n \neq 1 \tag{7-171}$$

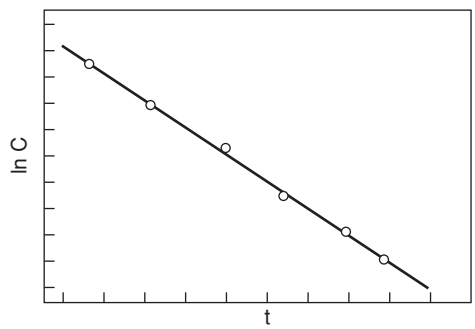

**FIG. 7-20** Determination of first-order rate constant from integral data.

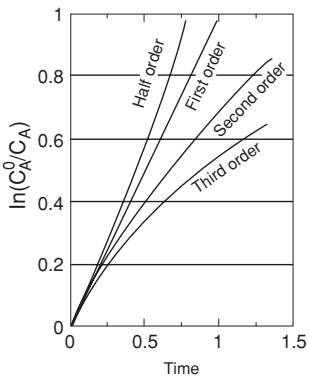

**FIG. 7-21** Reaction behavior for *n*th-order reaction. (*Masel,* Chemical Kinetics and Catalysis, *Wiley, 2001, Fig. 3.15.*)

Thus for first-order reactions, the *half-life* is constant and independent of the initial reactant concentration and can be used directly to calculate the rate constant $k$. For non-first-order reactions, Eq. (7-171) can be linearized as follows:

$$\ln\tau_{1/2} = \ln\frac{2^{n-1}-1}{(n-1)k} - (n-1)\ln C_{a0} \qquad \text{for } n \neq 1 \quad (7\text{-}172)$$

The reaction order $n$ can be obtained from the slope and the rate constant $k$ from the intercept of the plot of Eq. (7-172), shown in Fig. 7-22.

**Complex Rate Equations** The examples above are for special cases amenable to simple treatment. Complex rate equations and reaction networks with complex kinetics require individual treatment, which often includes both numerical solvers for the differential and algebraic equations describing the laboratory reactor used to obtain the data and linear or nonlinear parameter estimation.

## PARAMETER ESTIMATION

The straightforward method to obtain kinetic parameters from data is the numerical fitting of the concentration data (e.g., from BR or PFR) to integral equations, or the rate data (e.g., from a CSTR or from differentiation of BR or PFR) to rate equations. This is done by parameter estimation methods described here. An excellent reference for experimental design and parameter estimation (illustrated for heterogeneous gas-solid reactions) is the review paper of Froment and Hosten, "Catalytic Kinetics—Modeling," in *Catalysis—Science and Technology,* Springer-Verlag, New York, 1981. Two previous papers devoted to this topic by Hofmann [in *Chemical Reaction Engineering, ACS Advances in Chemistry,* **109:** 519–534 (1972); in de Lasa (ed.), *Chemical Reactor Design and Technology,* Martinus Nijhoff, 1985, pp. 69–105] are also very useful. As indicated above, the acquisition of kinetic data and parameter estimation can be a complex endeavor. It includes statistical design of experiments, laboratory equipment, computer-based data acquisition, complex analytical methods, and statistical evaluation of the data.

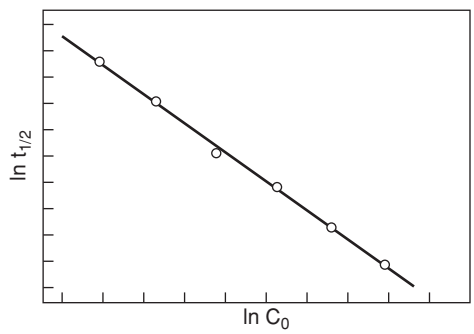

**FIG. 7-22** Determination of reaction order and rate constant from half-life data.

*Regression* is the procedure used to estimate the kinetic parameters by fitting kinetic model predictions to experimental data. When the parameters can be made to appear linear in the kinetic model (through transformations, grouping of parameters, and rearrangement), the regression is linear, and an accurate fit to data can be obtained, provided the form of the kinetic model represents well the reaction kinetics and the data provide enough width in temperature, pressure, and composition for statistically significant estimates. Often such linearization is not possible.

**Linear Models in Parameters, Single Reaction** We adopt the terminology from Froment and Hosten, "Catalytic Kinetics—Modeling," in *Catalysis—Science and Technology,* Springer-Verlag, New York, 1981. For $n$ *observations* (experiments) of the concentration vector $y$ for a model linear in the parameter vector $\beta$ of length $p < n$, the *residual error* $\varepsilon$ is the difference between the kinetic model-predicted values and the measured data values:

$$\varepsilon = y - X\beta = y - \hat{y} \qquad (7\text{-}173)$$

The linear model is represented as a linear transformation of the parameter vector $\beta$ through the model matrix $X$. Estimates $b$ of the true parameters $\beta$ are obtained by minimizing the *objective function* $S(\beta)$, *the sum of squares of the residual errors*, while varying the values of the parameters:

$$S(\beta) = \varepsilon^T\varepsilon = \sum_{i=1}^{n}(y-\hat{y})^2 \xrightarrow{\beta} \text{Min} \qquad (7\text{-}174)$$

This linear optimization problem, subject to constraints on the possible values of the parameters (e.g., requiring positive preexponentials, activation energies, etc.) can be solved to give the estimated parameters:

$$b = (X^TX)^{-1}X^Ty \qquad (7\text{-}175)$$

When the error is *normally distributed* and has zero *mean* and *variance* $\sigma^2$, then the *variance-covariance matrix* $V(b)$ is defined as

$$V(b) = (X^TX)^{-1}\sigma^2 \qquad (7\text{-}176)$$

An estimate for $\sigma^2$, denoted $s^2$, is

$$s^2 = \frac{\sum_{i=1}^{n}(y-\hat{y}_i)^2}{n-p} \qquad (7\text{-}177)$$

When $V(b)$ is known from experimental observations, a *weighted objective function* should be used for optimization of the objective function:

$$S(\beta) = \varepsilon^TV^{-1}\varepsilon \xrightarrow{\beta} \text{Min} \qquad (7\text{-}178)$$

and the estimates $b$ are obtained as

$$b = (X^TV^{-1}X)^{-1}X^TV^{-1}y \qquad (7\text{-}179)$$

The parameter fit is adequate if the *F test* is satisfied, that is, $F_c$, the calculated $F$, is larger than the tabulated statistical one at the *confidence level* of $1-\alpha$:

$$F_c = \frac{\dfrac{\text{LFSS}}{n-p-n_e+1}}{\dfrac{\text{PESS}}{n_e-1}} \geq F(n-p-n_e+1, n_e-1; 1-\alpha) \qquad (7\text{-}180)$$

$$\text{LFSS} = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2 - \sum_{i=1}^{ne}(y_i - \bar{y}_i)^2 \qquad \text{PESS} = \sum_{i=1}^{ne}(y_i - \bar{y}_i)^2$$

Here $\bar{y}_i$ are the averaged values of the data for replicates. Equation (7-180) is valid if there are $n$ replicate experiments and the pure error sum of squares (PESS) is known. Without replicates,

$$F_c = \frac{\dfrac{\text{RgSS}}{p}}{\dfrac{\text{RSS}}{n-p}} \geq F(p,n-p;1-\alpha) \qquad \text{RgSS} = \sum_{i=1}^{n}\hat{y}_i^2$$

$$\text{RSS} = \sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \qquad (7\text{-}181)$$

The *bounds* on the parameter estimates are given by the *t statistics*:

$$b_i - t\left(n-p;1-\frac{\alpha}{2}\right) \leq \beta_i \leq b_i + t\left(n-p;1-\frac{\alpha}{2}\right) \qquad (7\text{-}182)$$

An example of a linear model in parameters is Eq. (7-167), where the parameters are ln $k_0$, $E$, and $n$, and the linear regression can be used directly to estimate these.

**Nonlinear Models in Parameters, Single Reaction** In practice, the parameters appear often in nonlinear form in the rate expressions, requiring nonlinear regression. Nonlinear regression does not guarantee optimal parameter estimates even if the kinetic model adequately represents the true kinetics and the data width is adequate. Further, the statistical tests of model adequacy apply rigorously only to models linear in parameters, and can only be considered approximate for nonlinear models.

For a general nonlinear model $f(x_i, \beta)$, where $x$ is the vector of the independent model variables and $\beta$ is the vector of parameters,

$$\varepsilon = y - f(x, \beta) \qquad (7\text{-}183)$$

An example of a model nonlinear in parameters is Eq. (7-166). Here it is not possible through any number of transformations to obtain a linear form in all the parameters $k_0$, $E$, $K_{a0}$, $E_{aa}$, $K_{b0}$, $E_{ab}$. Note that for some Langmuir-Hinshelwood rate expressions it is possible to linearize the model in parameters at isothermal conditions and obtain the kinetic constants for each temperature, followed by Arrhenius-type plots to obtain activation energies (see, e.g., Churchill, *The Interpretation and Use of Rate Data: The Rate Concept,* McGraw-Hill, 1974).

Minimization of the sum of squares of residuals does not result in a closed form for nonlinear parameter estimates as for the linear case; rather it requires an iterative numerical solution, and having a reasonable initial estimate for the parameter values and their feasible ranges is critical for success. Also, the minima in the residual sum of squares are local and not global. To obtain global minima that better represent the kinetics over a wide range of conditions, parameter estimation has to be repeated with a wide range of initial parameter guesses to increase the chance of reaching the global minimum. The nonlinear regression procedure typically involves a *steepest descent* optimization search combined with *Newton's linearization* method when a minimum is approached, enhancing the convergence speed [e.g., the *Marquardt-Levenberg* or *Newton-Gauss* method; Marquardt, *J. Soc. Ind. Appl. Math.* **2:** 431 (1963)].

An integral part of the parameter estimation methodology is *mechanism discrimination*, i.e., selection of the best mechanism that would result in the best kinetic model. Nonlinear parameter estimation is an extensive topic and will not be further discussed here. For more details see Froment and Hosten, "Catalytic Kinetics—Modeling," in *Catalysis—Science and Technology*, Springer-Verlag, New York, 1981.

**Network of Reactions** The statistical parameter estimation for multiple reactions is more complex than for a single reaction. As indicated before, a single reaction can be represented by a single concentration [e.g., Eq. 7-39]. With a network of reactions, there are a number of dependent variables equal to the number of stoichiometrically independent reactions, also called *responses*. In this case the objective function has to be modified. For details see Froment and Hosten, "Catalytic Kinetics—Modeling," in *Catalysis—Science and Technology*, Springer-Verlag, New York, 1981.

## THEORETICAL METHODS

**Prediction of Mechanism and Kinetics** Reaction mechanisms for a variety of reaction systems can be predicted to some extent by following a set of heuristic rules derived from experience with a wide range of chemistries. For instance, Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001, chapter 5, enumerates the rules for gas-phase chain and nonchain reactions including limits on activation energies for various elementary steps. Other reaction systems such as ionic reactions, and reactions on metal and acid surfaces, are also discussed by Masel, although these mechanisms are not as well understood. Nevertheless, the rules can lead to computer-generated mechanisms for complex systems such as homogeneous gas-phase combustion and partial oxidation of methane and higher hydrocarbons. Developments in computational chemistry methods allow, in addition to the derivation of most probable elementary mechanisms, prediction of thermodynamic and kinetic reaction parameters for relatively small molecules in homogeneous gas-phase and liquid-phase reactions, and even for some heterogeneous catalytic systems. This is especially useful for complex kinetics where there is no easily discernible rate-determining step, and therefore no simple closed-form global reaction rate can be determined. In particular, estimating a large number of kinetic parameters from laboratory data requires a large number of experiments and use of intermediate reaction components that are not stable or not readily available. The nonlinear parameter estimation with many parameters is difficult, with no assurance that global minima are actually obtained. For such complex systems, computational chemistry estimates are an attractive starting point, requiring experimental validation.

Computational chemistry includes a wide range of methods of varying accuracy and complexity, summarized in Table 7-14. Many of these methods have been implemented as software packages that require high-speed supercomputers or parallel computers to solve realistic reactions. For more details on computational chemistry, see, e.g., Cramer, *Essentials of Computational Chemistry: Theories and Models*, 2d ed., Wiley, 2004.

**Lumping and Mechanism Reduction** It is often useful to reduce complex reaction networks to a smaller reaction set which still maintains the key features of the detailed reaction network but with a much smaller number of representative species, reactions, and kinetic parameters. Simple examples were already given above for reducing simple networks into global reactions through assumptions such as pseudo-steady state, rate-limiting step, and equilibrium reactions.

In general, *mechanism reduction* can only be used over a limited range of conditions for which the simplified system simulates the original complete reaction network. This reduces the number of kinetic parameters that have to be either estimated from data or calculated by

**TABLE 7-14 Computational Chemistry Methods**

using computational chemistry. The simplified system also reduces the computation load for reactor scale-up, design, and optimization.

A type of mechanism reduction called *lumping* is typically performed on a reaction network that consists of a large number of similar reactions occurring between similar species, such as homologous series or molecules having similar functional groups. Such situations occur, for instance, in the oil refining industry, examples including catalytic reforming, catalytic cracking, hydrocracking, and hydrotreating. Lumping is done by grouping similar species, or molecules with similar functional groups, into pseudo components called lumped species. The behavior of the lumped system depends on the initial composition, the distribution of the rate constants in the detailed system, and the form of the rate equation. The two main issues in lumping are

1. Determination of the lump structure that simulates the detailed system over the required range of conditions
2. Determination of the kinetics of the lumped system from general knowledge about the type of kinetics and the overall range of parameters of the detailed system

Lumping has been applied extensively to first-order reaction networks [e.g., Wei and Kuo, "A Lumping Analysis in Monomolecular Reaction Systems," *I&EC Fundamentals* **8**(1): 114–123 (1969); Golikeri and Luss, "Aggregation of Many Coupled Consecutive First Order Reactions," *Chem. Eng. Sci.* **29:** 845–855 (1974)]. For instance, it has been shown that a lumped reaction network of first-order reactions can behave under certain conditions as a global second-order reaction. Where analytical solutions were not available, others, such as Golikeri and Luss, "Aggregation of Many Coupled Consecutive First Order Reactions," *Chem. Eng. Sci.* **29:** 845–855 (1974), developed bounds that bracketed the behavior of the lump for first-order reactions as a function of the initial composition and the rate constant distribution. Lumping has not been applied as successfully to nonlinear or higher-order kinetics. More recent applications of lumping were published, including structure-oriented lumping that lumps similar structural groups, by Quann and Jaffe, "Building Useful Models of Complex Reaction Systems in Petroleum Refining," *Chem. Eng. Sci.* **51**(10): 1615–1635 (1996).

For other types of systems such as highly branched reaction networks for homogeneous gas-phase combustion and combined homogeneous and catalytic partial oxidation, mechanism reduction involves pruning branches and pathways of the reaction network that do not contribute significantly to the overall reaction. This pruning is done by using *sensitivity analysis*. See, e.g., Bui et al., "Hierarchical Reduced Models for Catalytic Combustion: $H_2$/Air Mixtures near Platinum Surfaces," *Combustion Sci. Technol.* **129**(1–6):243–275 (1997).

**Multiple Steady States, Oscillations, and Chaotic Behavior** There are reaction systems whose steady-state behavior depends on the initial or starting conditions; i.e., for different starting conditions, different steady states can be reached at the same final operating conditions. This behavior is called steady-state multiplicity and is often the result of the interaction of kinetic and transport phenomena having distinct time scales. For some cases, the cause of the multiplicity is entirely reaction-related, as shown below. Associated with steady-state multiplicity is hysteresis, and higher-order instabilities such as self-sustained oscillations and chaotic behavior. The existence of multiple steady states may be relevant to analysis of laboratory data, since faster of slower rates may be observed at the same conditions depending on how the lab reactor is started up.

For example, CO oxidation on heterogeneous Rh catalyst exhibits hysteresis and multiple steady states, and one of the explained causes is the existence of two crystal structures for Rh, each with a different reactivity (Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001, p. 38).

Another well-known example of chemistry-related instability includes the oscillatory behavior of the Bhelousov-Zhabotinsky reaction of malonic acid and bromate in the presence of homogeneous Ce catalyst having the overall reaction

$$HOOCCH_2COOH + HBrO \overset{Ce^{4+}}{\Rightarrow} \text{products}$$

Ce can be in two oxidation states, $Ce^{3+}$ and $Ce^{4+}$, and there are competing reaction pathways. Complex kinetic models are required to predict the oscillatory behavior, the most well known being that of Noyes [e.g., Showalter, Noyes, and Bar-Eli, *J. Chem. Phys.* **69**(6): 2514–2524 (1978)].

A large body of work has been done to develop criteria that determine the onset of chemistry and transport chemistry-based instabilities. More details and transport-reaction coupling-related examples are discussed in Sec. 19.

## SOFTWARE TOOLS

There are a number of useful software packages that enable efficient analysis of laboratory data for developing the mechanism and kinetics of reactions and for testing the kinetics by using simple reactor models. The reader is referred to search the Internet as some of these software packages change ownership or name. Worth mentioning are the Aspen Engineering Suite (Aspen), the Thermal Safety Software suite (Cheminform St. Petersburg), the Matlab suite (Mathworks), the Chemkin software suite (Reaction Design), the NIST Chemical Kinetics database (NIST), and Gepasi for biochemical kinetics (freeware). The user is advised to experiment and validate any software package with known data and kinetics to ensure robustness and reliability.

**Nomenclature**

| Symbol | Definition |
|---|---|
| $A$ | Area |
| $A_a$ | Actuator area |
| $A_c$ | Output amplitude limits |
| $A_v$ | Amplitude of controlled variable |
| $A_1$ | Cross-sectional area of tank |
| $b$ | Controller output bias |
| $B$ | Bottoms flow rate |
| $B_i^*$ | Limit on control |
| $c_A$ | Concentration of $A$ |
| $C$ | Cumulative sum |
| $C_d$ | Discharge coefficient |
| $C_i$ | Inlet concentration |
| $C_i^*$ | Limit on control move |
| $C_L$ | Specific heat of liquid |
| $C_0$ | Integration constant |
| $C_p$ | Process capability |
| $C_r$ | Heat capacity of reactants |
| $C_V$ | Valve flow coefficient |
| $D$ | Distillate flow rate, disturbance |
| $D_i^*$ | Limit on output |
| $e$ | Error |
| $E$ | Economy of evaporator |
| $f$ | Function of time |
| $F, f$ | Feed flow rate |
| $F_L$ | Pressure recovery factor |
| $g_c$ | Unit conversion constant |
| $g_i$ | Algebraic inequality constraint |
| $G$ | Transfer function |
| $G_c$ | Controller transfer function |
| $G_d$ | Disturbance transfer function |
| $G_f$ | Feedforward controller transfer function |
| $G_m$ | Sensor transfer function |
| $G_p$ | Process transfer function |
| $G_t$ | Transmitter transfer function |
| $G_v$ | Valve transfer function |
| $h_i$ | Algebraic equality constraints |
| $h_1$ | Liquid head in tank |
| $H$ | Latent heat of vaporization, control limit or threshold |
| $i$ | Summation index |
| $I_i$ | Impulse response coefficient |
| $j$ | Time index |
| $J$ | Objective function or performance index |
| $k$ | Time index |
| $k_f$ | Flow coefficient |
| $k_r$ | Kinetic rate constant |
| $K$ | Gain, slack parameter |
| $K_c$ | Controller gain |
| $K_d$ | Disturbance transfer function gain |
| $K_m$ | Measurement gain |
| $K_p$ | Process gain |
| $K_u$ | Ultimate controller gain (stability) |
| $L$ | Load variable |
| $L_p$ | Sound pressure level |
| $M$ | Manipulated variable |
| $m_c$ | Number of constraints |
| $M_v$ | Mass flow |
| $M_r$ | Mass of reactants |
| $M_w$ | Molecular weight |
| $n$ | Number of data points, number of stages or effects |
| $N$ | Number of inputs/outputs, model horizon |
| $p$ | Proportional band (%) |
| $p_c$ | Vapor pressure |
| $p_d$ | Actuator pressure |
| $p_i$ | Pressure |
| $p_u$ | Proportional band (ultimate) |
| $q$ | Radiated energy flux |
| $q_b$ | Energy flux to a black body |
| $Q$ | Flow rate |
| $r_c$ | Number of constraints |
| $R$ | Equal-percentage valve characteristic |
| $R_T$ | Resistance in temperature sensor |
| $R_1$ | Valve resistance |
| $s$ | Laplace transform variable |
| $s$ | Search direction |
| $S_i$ | Step response coefficient |
| $t$ | Time |
| $T$ | Temperature, target |
| $T(s)$ | Decoupler transfer function |
| $T_b$ | Base temperature |
| $T_f$ | Exhaust temperature |
| $T_R$ | Reset time |
| $U$ | Heat-transfer coefficient |
| $u$, $U$ | Manipulated variable, controller output |
| $V$ | Volume |
| $V_s$ | Product value |
| $w$ | Mass flow rate |
| $w_i$ | Weighting factor |
| $W$ | Steam flow rate |
| $x$ | Mass fraction |
| $\bar{x}$ | Sample mean |
| $x_i$ | Optimization variable |
| $x_T$ | Pressure drop ratio factor |
| $X$ | Transform of deviation variable |
| $y$, $Y$ | Process output, controlled variable, valve travel |
| $Y_{sp}$ | Set point |
| $z$ | Controller tuning law, expansion factor |
| $z_i$ | Feed mole fraction (distillation) |
| $Z$ | Compressibility factor |

Greek Symbols

| | |
|---|---|
| $\alpha$ | Digital filter coefficient |
| $a_T$ | Temperature coefficient of resistance |
| $\beta$ | Resistance thermometer parameter |
| $\gamma$ | Ratio of specific heats |
| $\delta$ | Move suppression factor, shift in target value |
| $\Delta q$ | Load step change |
| $\Delta t$ | Time step |
| $\Delta T$ | Temperature change |
| $\Delta u$ | Control move |
| $\varepsilon$ | Spectral emissivity, step size |
| $\zeta$ | Damping factor (second-order system) |
| $\theta$ | Time delay |
| $\lambda$ | Relative gain array parameter, wavelength |
| $\Lambda$ | Relative gain array |
| $\xi$ | Deviation variable |
| $\rho$ | Density |
| $\sigma$ | Stefan-Boltzmann constant, standard deviation |
| $\Sigma_t$ | Total response time |
| $\tau$ | Time constant |
| $\tau_d$ | Natural period of closed loop, disturbance time constant |
| $\tau_D$ | Derivative time (PID controller) |
| $\tau_F$ | Filter time constant |
| $\tau_I$ | Integral time (PID controller) |
| $\tau_p$ | Process time constant |
| $\tau_o$ | Period of oscillation |
| $\phi_{PI}$ | Phase lag |

Subscripts

# FUNDAMENTALS OF PROCESS DYNAMICS AND CONTROL

## THE GENERAL CONTROL SYSTEM

A process is shown in Fig. 8-1 with a manipulated input $U$, a load input $D$, and a controlled output $Y$, which could be flow, pressure, liquid level, temperature, composition, or any other inventory, environmental, or quality variable that is to be held at a desired value identified as the set point $Y_{sp}$. The load may be a single variable or an aggregate of variables either acting independently or manipulated for other purposes, affecting the controlled variable much as the manipulated variable does. Changes in load may occur randomly as caused by changes in weather, diurnally with ambient temperature, manually when operators change production rate, stepwise when equipment is switched into or out of service, or cyclically as the result of oscillations in other control loops. Variations in load will drive the controlled variable away from the set point, requiring a corresponding change in the manipulated variable to bring it back. The manipulated variable must also change to move the controlled variable from one set point to another.

An open-loop system positions the manipulated variable either manually or on a programmed basis, without using any process measurements. This operation is acceptable for well-defined processes without disturbances. An automated transfer switch is provided to allow manual adjustment of the manipulated variable in case the process or the control system is not performing satisfactorily.

A closed-loop system uses the measurement of one or more process variables to move the manipulated variable to achieve control. Closed-loop systems may include feedforward, feedback, or both.

**Feedback Control** In a feedback control loop, the controlled variable is compared to the set point $Y_{sp}$, with the error $E$ acted upon by the controller to move $U$ in such a way as to minimize the error. This action is specifically negative feedback, in that an increase in error moves $U$ so as to decrease the error. (Positive feedback would cause the error to expand rather than diminish and therefore does not regulate.) The action of the controller is selectable to allow use on process gains of both signs.

The controller has tuning parameters related to proportional, integral, derivative, lag, dead time, and sampling functions. A negative feedback loop will oscillate if the controller gain is too high; but if it is too low, control will be ineffective. The controller parameters must be properly related to the process parameters to ensure closed-loop stability while still providing effective control. This relationship is accomplished, first, by the proper selection of control modes to satisfy the requirements of the process and, second, by the appropriate tuning of those modes.

**Feedforward Control** A feedforward system uses measurements of disturbance variables to position the manipulated variable in such a way as to minimize any resulting deviation. The disturbance variables could be either measured loads or the set point, the former being more common. The feedforward gain must be set precisely to reduce the deviation of the controlled variable from the set point.

Feedforward control is usually combined with feedback control to eliminate any offset resulting from inaccurate measurements and calculations and unmeasured load components. The feedback controller can be used as a bias on the feedforward controller or in a multiplicative form.

**Computer Control** Computers have been used to replace analog PID controllers, either by setting set points of lower-level controllers in supervisory control or by driving valves directly in direct digital control. Single-station digital controllers perform PID control in one or two loops, including computing functions such as mathematical operations, characterization, lags, and dead time, with digital logic and alarms. Distributed control systems provide all these functions, with the digital processor shared among many control loops; separate processors may be used for displays, communications, file servers, and the like. A host computer may be added to perform high-level operations such as scheduling, optimization, and multivariable control. More details on computer control are provided later in this section.

## PROCESS DYNAMICS AND MATHEMATICAL MODELS

**General References:** Seborg, Edgar, and Mellichamp, *Process Dynamics and Control,* Wiley, New York, 2004; Marlin, *Process Control,* McGraw-Hill, New York, 2000; Ogunnaike and Ray, *Process Dynamics Modeling and Control,* Oxford University Press, New York, 1994; Smith and Corripio, *Principles and Practices of Automatic Process Control,* Wiley, New York, 1997.

**Open-Loop versus Closed-Loop Dynamics** It is common in industry to manipulate coolant in a jacketed reactor in order to control conditions in the reactor itself. A simplified schematic diagram of such a reactor control system is shown in Fig. 8-2. Assume that the reactor temperature is adjusted by a controller that increases the coolant flow in proportion to the difference between the desired reactor temperature and the temperature that is measured. The proportionality constant is $K_c$. If a small change in the temperature of the inlet stream occurs, then

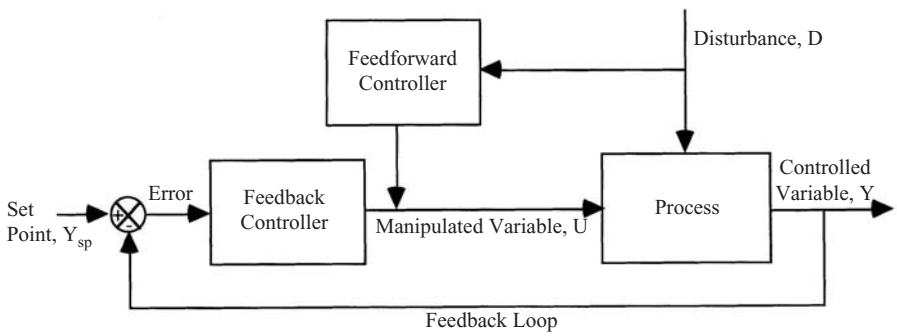

**FIG. 8-1** Block diagram for feedforward and feedback control.

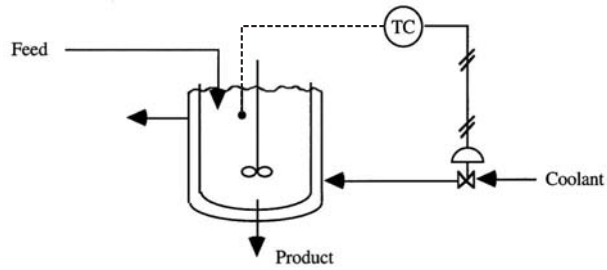

**FIG. 8-2** Reactor control system.

depending on the value of $K_c$, one might observe the reactor temperature responses shown in Fig. 8-3. The top plot shows the case for no control ($K_c = 0$), which is called the open loop, or the normal dynamic response of the process by itself. As $K_c$ increases, several effects can be noted. First, the reactor temperature responds faster and faster. Second, for the initial increases in $K_c$ the maximum deviation in the reactor temperature becomes smaller. Both of these effects are desirable so that disturbances from normal operation have as small an effect as possible on the process under study. As the gain is increased further, eventually a point is reached where the reactor temperature oscillates indefinitely, which is undesirable. This point is called the stability limit, where $K_c = K_u$, the ultimate controller gain. Increasing $K_c$ further causes the magnitude of the oscillations to increase, with the result that the control valve will cycle between full open and closed.

The responses shown in Fig. 8-3 are typical of the vast majority of regulatory loops encountered in the process industries. Figure 8-3 shows that there is an optimal choice for $K_c$, somewhere between 0 (no control) and $K_u$ (stability limit). If one has a dynamic model of a process, then this model can be used to calculate controller settings. In Fig. 8-3, no time scale is given, but rather the figure shows relative responses. A well-designed controller might be able to speed up the response of a process by a factor of roughly 2 to 4. Exactly how fast the control system responds is determined by the dynamics of the process itself.

**Physical Models versus Empirical Models** In developing a dynamic process model, there are two distinct approaches that can be taken. The first involves models based on first principles, called physical or first principles models, and the second involves empirical models. The conservation laws of mass, energy, and momentum form the basis for developing physical models. The resulting models typically involve sets of differential and algebraic equations that must be solved simultaneously. Empirical models, by contrast, involve postulating the form of a dynamic model, usually as a transfer function, which is discussed below. This transfer function contains a number of parameters that need to be estimated from data. For the development of both physical and empirical models, the most expensive step normally involves verification of their accuracy in predicting plant behavior.

To illustrate the development of a physical model, a simplified treatment of the reactor, shown in Fig. 8-2, is used. It is assumed that the reactor is operating isothermally and that the inlet and exit volumetric flows and densities are the same. There are two components, $A$ and $B$, in the reactor, and a single first-order reaction of $A \rightarrow B$ takes place. The inlet concentration of $A$, which we call $c_i$, varies with time. A dynamic mass balance for the concentration of $A$, denoted $c_A$, can be written as follows:

$$V\frac{dc_A}{dt} = Fc_i - Fc_A - k_r V c_A \tag{8-1}$$

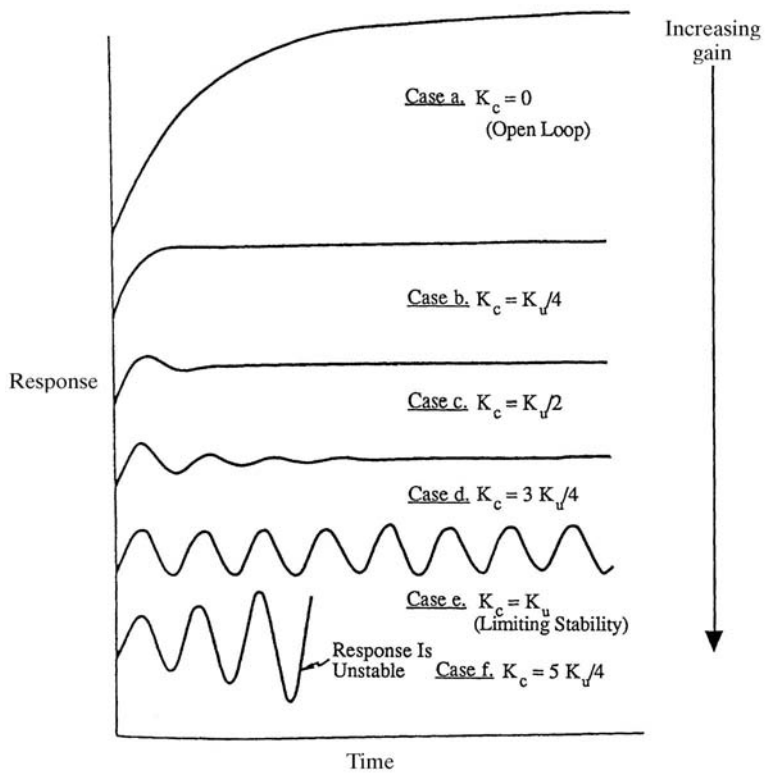

**FIG. 8-3** Typical control system responses.

In Eq. (8-1), the flow in of component $A$ is $Fc_i$, the flow out is $Fc_A$, and the loss via reaction is $k_rVc_A$, where $V$ = reactor volume and $k_r$ = kinetic rate constant. In this example, $c_i$ is the input, or forcing, variable and $c_A$ is the output variable. If $V$, $F$, and $k_r$ are constant, Eq. (8-1) can be rearranged by dividing by $F + k_rV$ so that it contains only two groups of parameters. The result is

$$\tau \frac{dc_A}{dt} = Kc_i - c_A \tag{8-2}$$

where $\tau = V/(F + k_rV)$ and $K = F/(F + k_rV)$. For this example, the resulting model is a first-order differential equation in which $\tau$ is called the time constant and $K$ the process gain.

As an alternative to deriving Eq. (8-2) from a dynamic mass balance, one could simply postulate a first-order differential equation to be valid (empirical modeling). Then it would be necessary to estimate values for $\tau$ and $K$ so that the postulated model described the reactor's dynamic response. The advantage of the physical model over the empirical model is that the physical model gives insight into how reactor parameters affect the values of $\tau$ and $K$, which in turn affects the dynamic response of the reactor.

**Nonlinear versus Linear Models** If $V$, $F$, and $k$ are constant, then Eq. (8-1) is an example of a linear differential equation model. In a linear equation, the output and input variables and their derivatives appear to only the first power. If the rate of reaction were second-order, then the resulting dynamic mass balance would be

$$V \frac{dc_A}{dt} = Fc_i - Fc_A - k_rVc_A^2 \tag{8-3}$$

Since $c_A$ appears in this equation to the second power, the equation is nonlinear.

The difference between linear systems and nonlinear systems can be seen by considering the steady-state behavior of Eq. (8-1) compared to Eq. (8-3) (the left-hand side is zero; that is, $dc_A/dt = 0$). For a given change in $c_i$, $\Delta c_i$, the change in $c_A$ calculated from Eq. (8-1), $\Delta c_A$, is always proportional to $\Delta c_i$, and the proportionality constant is $K$ [see Eq. (8-2)]. The change in the output of a system divided by a change in the input to the system is called the *process gain.* Linear systems have constant process gains for all changes in the input. By contrast, Eq. (8-3) gives a $\Delta c_A$ that varies with $\Delta c_i$, which is a function of the concentration levels in the reactor. Thus, depending on the reactor operating conditions, a change in $c_i$ produces different changes in $c_A$. In this case, the process has a nonlinear gain. Systems with nonlinear gains are more difficult to control than linear systems that have constant gains.

**Simulation of Dynamic Models** Linear dynamic models are particularly useful for analyzing control system behavior. The insight gained through linear analysis is invaluable. However, accurate dynamic process models can involve large sets of nonlinear equations. Analytical solution of these models is not possible. Thus, in these cases, one must turn to simulation approaches to study process dynamics and the effect of process control. Equation (8-3) will be used to illustrate the simulation of nonlinear processes. If $dc_A/dt$ on the left-hand side of Eq. (8-3) is replaced with its finite difference approximation, one gets

$$c_A(t + \Delta t) = \frac{c_A(t) + \Delta t \cdot [Fc_i(t) - Fc_A(t) - k_rVc_A^2(t)]}{V} \tag{8-4}$$

Starting with an initial value of $c_A$ and given $c_i(t)$, Eq. (8-4) can be solved for $c_A(t + \Delta t)$. Once $c_A(t + \Delta t)$ is known, the solution process can be repeated to calculate $c_A(t + 2\Delta t)$, and so on. This approach is called the Euler integration method; while it is simple, it is not necessarily the best approach to numerically integrating nonlinear differential equations. As discussed in Sec. 3, more sophisticated approaches are available that allow much larger step sizes to be taken but require additional calculations. One widely used approach is the fourth-order Runge Kutta method, which involves the following calculations:

Define

$$f(c_At) = \frac{Fc_i(t) - Fc_A - k_rVc_A^2}{V} \tag{8-5}$$

then

$$c_A(t + \Delta t) = c_A(t) + \Delta t(m_1 + 2m_2 + 2m_3 + m_4) \tag{8-6}$$

with

$$m_1 = f[c_A(t), t] \tag{8-7}$$

$$m_2 = f\left[c_A(t) + 2\frac{m_1 \Delta t}{2}, t + \frac{\Delta t}{2}\right] \tag{8-8}$$

$$m_3 = f\left[c_A(t) + 2\frac{m_2 \Delta t}{2}, t + \frac{\Delta t}{2}\right] \tag{8-9}$$

$$m_4 = f[c_A(t) + m_3 \Delta t, t + \Delta t] \tag{8-10}$$

In this method, the $m_i$'s are calculated sequentially in order to take a step in time. Even though this method requires calculation of the four additional $m_i$ values, for equivalent accuracy the fourth-order Runge Kutta method can result in a faster numerical solution, because it permits a larger step $\Delta t$ to be taken. Increasingly sophisticated simulation packages are being used to calculate the dynamic behavior of processes and to test control system behavior. These packages have good user interfaces, and they can handle stiff systems where some variables respond on a time scale that is much much faster or slower than that of other variables. A simple Euler approach cannot effectively handle stiff systems, which frequently occur in chemical process models. See Sec. 3 of this handbook for more details.

**Laplace Transforms** When mathematical models are used to describe process dynamics in conjunction with control system analysis, the models generally involve linear differential equations. Laplace transforms are very effective for solving linear differential equations. The key advantage of using Laplace transforms is that they convert differential equations to algebraic equations. The resulting algebraic equations are easier to solve than the original differential equations. When the Laplace transform is applied to a linear differential equation in time, the result is an algebraic equation in a new variable $s$, called the Laplace variable. To get the solution to the original differential equation, one needs to invert the Laplace transform. Table 8-1 gives a number of useful Laplace transform pairs, and more extensive tables are available (Seborg, Edgar, and Mellichamp, *Process Dynamics and Control,* Wiley, New York, 2004).

To illustrate how Laplace transforms work, consider the problem of solving Eq. (8-2), subject to the initial condition that $c_A = c_i = 0$ at $t = 0$. If $c_A$ were not initially zero, one would define a deviation variable between $c_A$ and its initial value $c_{A0}$. Then the transfer function would be developed by using this deviation variable. If $c_i$ changes from zero to $\bar{c}_i$, taking the Laplace transform of both sides of Eq. (8-2) gives

$$\pounds\left(\frac{\tau dc_A}{dt}\right) = \pounds(K\bar{c}_i) - \pounds(c_A) \tag{8-11}$$

**TABLE 8-1 Frequently Used Laplace Transforms**

| Time function $f(t)$ | Transform $F(s)$ |
|---|---|
| $A$ | $A/s$ |
| $At$ | $A/s^2$ |
| $Ae^{-at}$ | $A/(s + a)$ |
| $A(1 - e^{-t/\tau})$ | $A/[s(\tau s + 1)]$ |
| $A \sin \omega t$ | $A\omega/(s^2 + \omega^2)$ |
| $f(t - \theta)$ | $e^{-\theta}F(s)$ |
| $df/dt$ | $sF(s) - f(0)$ |
| $\int f(t)dt$ | $F(s)/s$ |

Denoting $\mathcal{L}(C_A)$ as $C_A(s)$ and using the relationships in Table 8-1 give

$$\tau s C_A(s) = \frac{K\bar{c}_i}{s} - C_A(s) \tag{8-12}$$

Equation (8-12) can be solved for $C_A$ to give

$$C_A(s) = \frac{K\bar{c}_i/s}{\tau s + 1} \tag{8-13}$$

By using the entries in Table 8-1, Eq. (8-13) can be inverted to give the transient response of $c_A$ as

$$c_A(t) = (K\bar{c}_i)(1 - e^{-1/\tau}) \tag{8-14}$$

Equation (8-14) shows that $c_A$ starts from 0 and builds up exponentially to a final concentration of $Kc_i$. Note that to get Eq. (8-14), it was only necessary to solve the algebraic Eq. (8-12) and then find the inverse of $C_A(s)$ in Table 8-1. The original differential equation was not solved directly. In general, techniques such as partial fraction expansion must be used to solve higher-order differential equations with Laplace transforms.

**Transfer Functions and Block Diagrams** A very convenient and compact method of representing the process dynamics of linear systems involves the use of transfer functions and block diagrams. A transfer function can be obtained by starting with a physical model, as discussed previously. If the physical model is nonlinear, first it needs to be linearized around an operating point. The resulting linearized model is then approximately valid in a region around this operating point. To illustrate how transfer functions are developed, Eq. (8-2) will again be used. First, one defines deviation variables, which are the process variables minus their steady-state values at the operating point. For Eq. (8-2), there would be deviation variables for both $c_A$ and $c_i$, and these are defined as

$$\xi = c_A - \bar{c}_A \tag{8-15}$$

$$\xi_i = c_i - \bar{c}_i \tag{8-16}$$

where the overbar stands for steady state. Substitution of Eqs. (8-15) and (8-16) into Eq. (8-2) gives

$$\tau \frac{d\xi}{dt} = K\xi_i - \xi + (K\bar{c}_i - \bar{c}_A) \tag{8-17}$$

The term in parentheses in Eq. (8-17) is zero at steady state, and thus it can be dropped. Next the Laplace transform is taken, and the resulting algebraic equation is solved.

By denoting $X(s)$ as the Laplace transform of $\xi$ and $X_i(s)$ as the transform of $\xi_i$, the final transfer function can be written as

$$\frac{X}{X_i} = \frac{K}{\tau s + 1} \tag{8-18}$$

Equation (8-18) is an example of a first-order transfer function. As mentioned above, an alternative to formally deriving Eq. (8-18) involves simply postulating its form and then identifying its two parameters, the process gain $K$ and time constant $\tau$, to fit the process under study. In fitting the parameters, data can be generated by forcing the process. If step forcing is used, then the resulting response is called the process reaction curve. Often transfer functions are placed in block diagrams, as shown in Fig. 8-4. Block diagrams show how changes in an input variable affect an output variable. Block diagrams are a means of concisely representing the dynamics of a process under study. Since linearity is assumed in developing a block diagram, if more than one variable affects an output, the contributions from each can be added.

**Continuous versus Discrete Models** The preceding discussion has focused on systems where variables change continuously with time. Most real processes have variables that are continuous, such as temperature, pressure, and flow. However, some processes involve discrete events, such as the starting or stopping of a pump. In addition, modern plants are controlled by digital computers, which are discrete. In controlling a process, a digital system samples variables at a fixed rate, and the resulting system is a sampled data system. From one sampling instant until the next, variables are assumed to remain fixed at their sampled values. Similarly, in controlling a process, a digital computer sends out signals to control elements, usually valves, at discrete instants of time. These signals remain fixed until the next sampling instant.

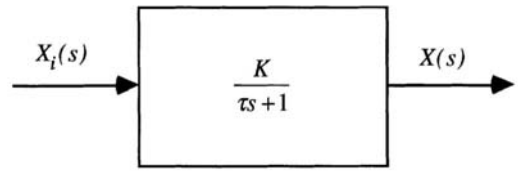

**FIG. 8-4** First-order transfer function.

Figure 8-5 illustrates the concept of sampling a continuous function. At integer values of the sampling rate $\Delta t$, the value of the variable to be sampled is measured and held until the next sampling instant. To deal with sampled data systems, the $z$ transform has been developed. The $z$ transform of the function given in Fig. 8-5 is defined as

$$Z(f) = \sum_{n=0}^{\infty} f(n\,\Delta t) z^{-n} \tag{8-19}$$

In an analogous manner to Laplace transforms, one can develop transfer functions in the $z$ domain as well as block diagrams. Tables of $z$ transform pairs have been published (Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 2004) so that the discrete transfer functions can be inverted back to the time domain. The inverse gives the value of the function at the discrete sampling instants. Sampling a continuous variable results in a loss of information. However, in practical applications, sampling is fast enough that the loss is typically insignificant and the difference between continuous and discrete modeling is small in terms of its effect on control. Increasingly, model predictive controllers that make use of discrete dynamic models are being used in the process industries. The purpose of these controllers is to guide a process to optimum operating points. These model predictive control algorithms are typically run at much slower sampling rates than are used for basic control loops such as flow control or pressure control. The discrete dynamic models used are normally developed from data generated

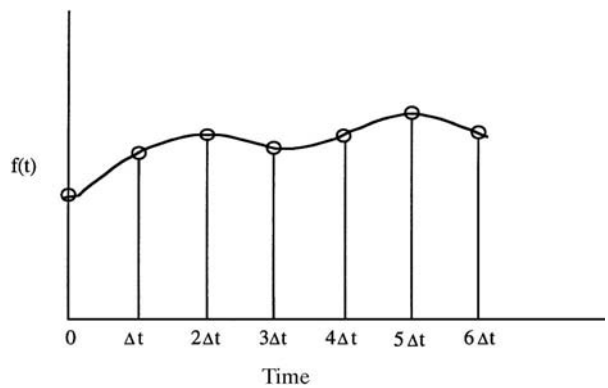

**FIG. 8-5** Sampled data example.

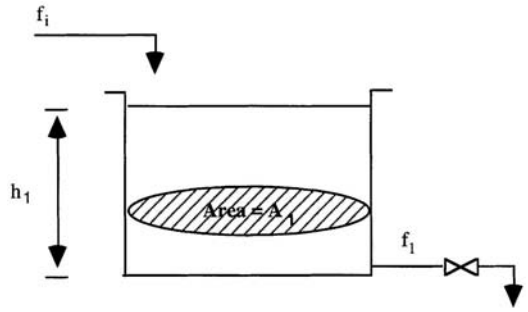

**FIG. 8-6** Single tank with exit valve.

from plant testing, as discussed hereafter. For a detailed discussion of modeling sampled data systems, the interested reader is referred to textbooks on digital control (Astrom and Wittenmark, *Computer Controlled Systems*, Prentice-Hall, Englewood Cliffs, N.J., 1997).

**Process Characteristics in Transfer Functions** In many cases, process characteristics are expressed in the form of transfer functions. In the previous discussion, a reactor example was used to illustrate how a transfer function could be derived. Here, another system involving flow out of a tank, shown in Fig. 8-6, is considered.

***Proportional Element*** First, consider the outflow through the exit valve on the tank. If the flow through the line is turbulent, then Bernoulli's equation can be used to relate the flow rate through the valve to the pressure drop across the valve as

$$f_1 = k_f A_v \sqrt{2g_c(h_1 - h_0)} \tag{8-20}$$

where $f_1$ = flow rate, $k_f$ = flow coefficient, $A_v$ = cross-sectional area of the restriction, $g_c$ = constant, $h_1$ = liquid head in tank (pressure at the base of the tank), and $h_0$ = atmospheric pressure. This relationship between flow and pressure drop across the valve is nonlinear, and it can be linearized around a particular operating point to give

$$f_1 - \bar{f}_1 = \left(\frac{1}{R_1}\right)(h_1 - \bar{h}_1) \tag{8-21}$$

where $R_1 = \bar{f}_1/(g_c k_f^2 A_v^2)$ is called the resistance of the valve in analogy with an electrical resistance. The transfer function relating changes in flow to changes in head is shown in Fig. 8-7, and it is an example of a pure gain system with no dynamics. In this case, the process gain is $K = 1/R_1$. Such a system has an instantaneous dynamic response, and for a step change in head, there is an immediate step change in flow, as shown in Fig. 8-8. The exact magnitude of the step in flow depends on the operating flow $\bar{f}_1$ as the definition of $R_1$ shows.

***First-Order Lag (Time Constant Element)*** Next consider the system to be the tank itself. A dynamic mass balance on the tank gives

$$A_1 \frac{dh_1}{dt} = f_i - f_1 \tag{8-22}$$

where $A_1$ is the cross-sectional area of the tank and $f_i$ is the inlet flow. By substituting Eq. (8-21) into Eq. (8-22) and following the approach

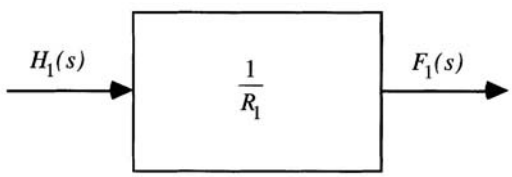

**FIG. 8-7** Proportional element transfer function.

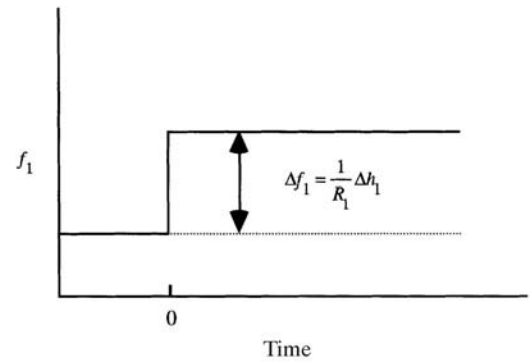

**FIG. 8-8** Response of proportional element.

discussed above for deriving transfer functions, one can develop the transfer function relating changes in $h_1$ to changes in $f_i$. The resulting transfer function is another example of a first-order system, shown in Fig. 8-4, and it has a gain $K = R_1$ and a time constant $\tau_1 = R_1 A_1$. For a step change in $f_i$, $h_1$ follows a decaying exponential response from its initial value $\bar{h}_1$ to a final value of $\bar{h}_1 + R_1 \Delta f_i$ (Fig. 8-9). At a time equal to $\tau_1$, the transient in $h_1$ is 63 percent finished; and at $3\tau_1$, the response is 95 percent finished. These percentages are the same for all first-order processes. Thus, knowledge of the time constant of a first-order process gives insight into how fast the process responds to sudden input changes.

***Capacity Element*** Now consider the case where the valve in Fig. 8-7 is replaced with a pump. In this case, it is reasonable to assume that the exit flow from the tank is independent of the level in the tank. For such a case, Eq. (8-22) still holds, except that $f_1$ no longer depends on $h_1$. For changes in $f_i$, the transfer function relating changes in $h_1$ to changes in $f_i$ is shown in Fig. 8-10. This is an example of a pure capacity process, also called an integrating system. The cross-sectional area of the tank is the chemical process equivalent of an electrical capacitor. If the inlet flow is step forced while the outlet is held constant, then the level builds up linearly, as shown in Fig. 8-11. Eventually the liquid will overflow the tank.

***Second-Order Element*** Because of their linear nature, transfer functions can be combined in a straightforward manner. Consider the two-tank system shown in Fig. 8-12. For tank 1, the transfer function relating changes in $f_1$ to changes in $f_i$ is

$$\frac{F_1(s)}{F_i(s)} = \frac{1}{A_1 R_1 + 1} \tag{8-23}$$

Since $f_1$ is the inlet flow to tank 2, the transfer function relating changes in $h_2$ to changes in $f_1$ has the same form as that given in Fig. 8-4:

$$\frac{H_2(s)}{F_1(s)} = \frac{R_2}{A_2 R_2 s + 1} \tag{8-24}$$

Equations (8-23) and (8-24) can be multiplied to give the final transfer function relating changes in $h_2$ to changes in $f_i$, as shown in Fig. 8-13. This is an example of a second-order transfer function. This transfer function has a gain $R_2$ and two time constants $A_1R_1$ and $A_2R_2$. For two tanks with equal areas, a step change in $f_i$ produces the S-shaped response in level in the second tank shown in Fig. 8-14.

***General Second-Order Element*** Figure 8-3 illustrates the fact that closed-loop systems can exhibit oscillatory behavior. A general second-order transfer function that can exhibit oscillatory behavior is important for the study of automatic control systems. Such a transfer function is given in Fig. 8-15. For a unit step input, the transient responses shown in Fig. 8-16 result. As can be seen, when $\zeta < 1$, the response oscillates; and when $\zeta < 1$, the response is S-shaped. Few open-loop chemical processes exhibit an oscillating response; most exhibit an S-shaped step response.

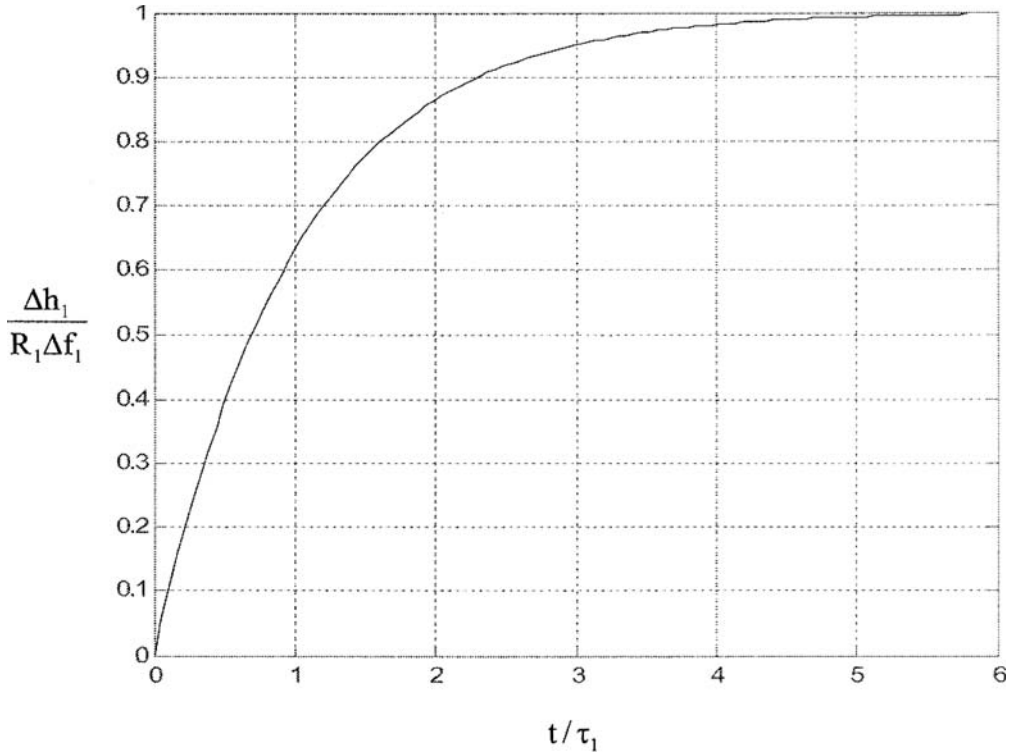

**FIG. 8-9** Response of first-order system.

***Distance-Velocity Lag (Dead-Time Element)*** The dead-time or time-delay element, commonly called a distance-velocity lag, is often encountered in process systems. For example, if a temperature-measuring element is located downstream from a heat exchanger, a time delay occurs before the heated fluid leaving the exchanger arrives at the temperature measurement point. If some element of a system produces a dead time of $\theta$ time units, then an input to that unit $f(t)$ will be reproduced at the output as $f(t - \theta)$. The transfer function for a pure dead-time element is shown in Fig. 8-17, and the transient response of the element is shown in Fig. 8-18.

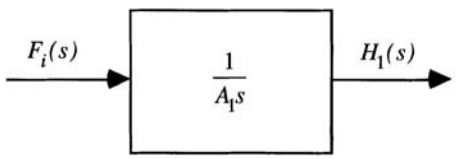

**FIG. 8-10** Pure capacity or integrating transfer function.

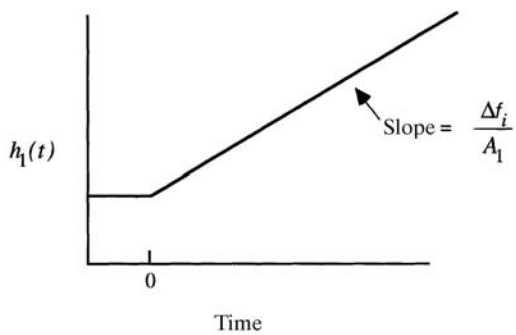

**FIG. 8-11** Response of pure capacity system.

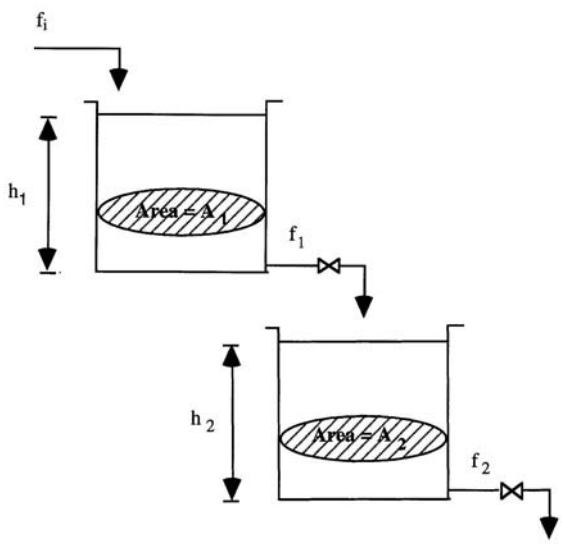

**FIG. 8-12** Two tanks in series.

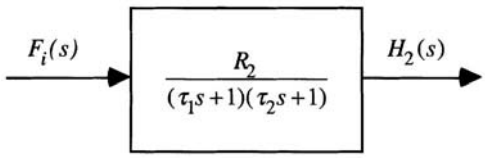

**FIG. 8-13** Second-order transfer function.

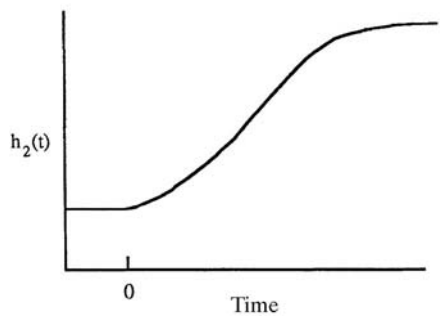

**FIG. 8-14** Response of second-order system.

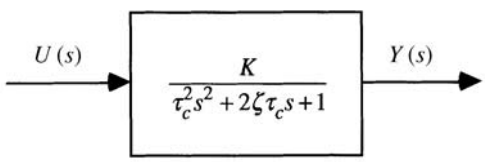

**FIG. 8-15** General second-order transfer function.

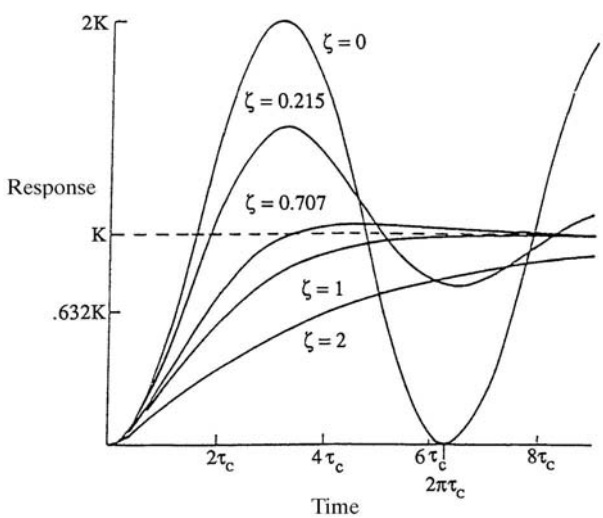

**FIG. 8-16** Response of general second-order system.

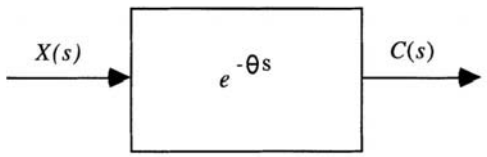

**FIG. 8-17** Dead-time transfer function.

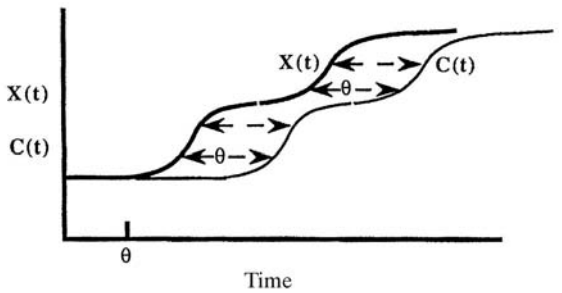

**FIG. 8-18** Response of dead-time system.

***Higher-Order Lags*** If a process is described by a series of $n$ first-order lags, the overall system response becomes proportionally slower with each lag added. The special case of a series of $n$ first-order lags with equal time constants has a transfer function given by

$$G(s) = \frac{K}{(\tau s + 1)^n} \tag{8-25}$$

The step response of this transfer function is shown in Fig. 8-19. Note that all curves reach about 60 percent of their final value at $t = n\tau$.

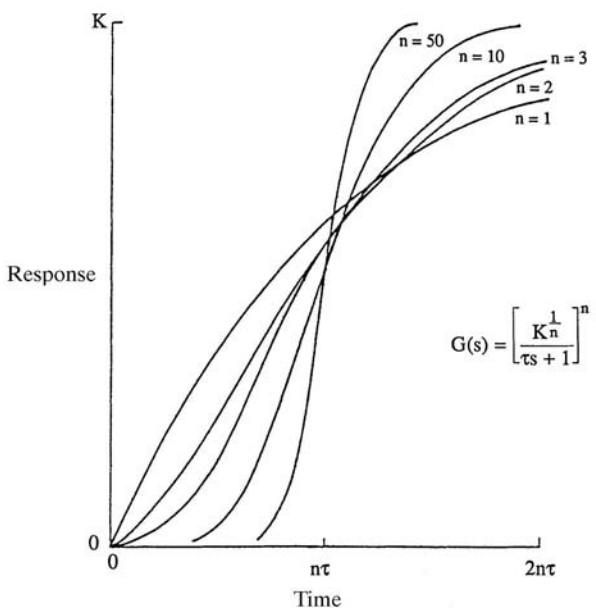

**FIG. 8-19** Response of $n$th-order lags.

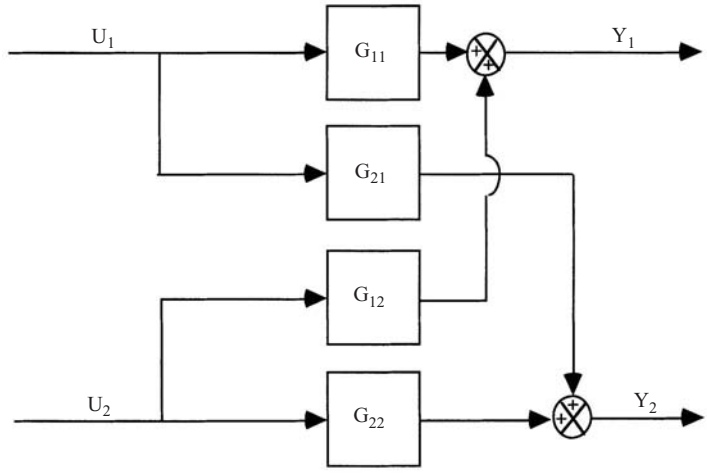

**FIG. 8-20** Example of $2 \times 2$ transfer function.

Higher-order systems can be approximated by a first- or second-order plus dead-time system for control system design.

***Multi-input, Multioutput Systems*** The dynamic systems considered up to this point have been examples of single-input, single-output (SISO) systems. In chemical processes, one often encounters systems where one input can affect more than one output. For example, assume that one is studying a distillation tower in which both reflux and boil-up are manipulated for control purposes. If the output variables are the top and bottom product compositions, then each input affects both outputs. For this distillation example, the process is referred to as a $2 \times 2$ system to indicate the number of inputs and outputs. In general, multi-input, multioutput (MIMO) systems can have $n$ inputs and $m$ outputs with $n \neq m$, and they can be nonlinear. Such a system would be called an $n \times m$ system. An example of a transfer function for a $2 \times 2$ linear system is given in Fig. 8-20. Note that since linear systems are involved, the effects of the two inputs on each output are additive. In many process control systems, one input is selected to control one output in a MIMO system. For $m$ outputs there would be $m$ such selections. For this type of control strategy, one needs to consider which inputs and outputs to couple, and this problem is referred to as loop pairing. Another important issue that arises involves interaction between control loops. When one loop makes a change in its manipulated variable, the change affects the other loops in the system. These changes are the direct result of the multivariable nature of the process. In some cases, the interaction can be so severe that overall control system performance is drastically reduced. Finally, some of the modern approaches to process control tackle the MIMO problem directly, and they simultaneously use all manipulated variables to control all output variables rather than pair one input to one output (see later section on multivariable control).

**Fitting Dynamic Models to Experimental Data** In developing empirical transfer functions, it is necessary to identify model parameters from experimental data. There are a number of approaches to process identification that have been published. The simplest approach involves introducing a step test into the process and recording the response of the process, as illustrated in Fig. 8-21. The $x$'s in the figure represent the recorded data. For purposes of illustration, the process under study will be assumed to be first-order with dead time and have the transfer function

$$G(s) = \frac{Y(s)}{U(s)} = K \exp(-\theta s)/\tau s + 1 \qquad (8\text{-}26)$$

The response $y(t)$, produced by Eq. (8-26) can be found by inverting the transfer function, and it is also shown in Fig. 8-21 for a set of model parameters $K$, $\tau$, and $\theta$ fitted to the data. These parameters are calculated by using optimization to minimize the squared difference between the model predictions and the data, i.e., a least squares approach. Let each measured data point be represented by $y_j$ (measured response), $t_j$ (time of measured response), $j = 1$ to $n$. Then the least squares problem can be formulated as

$$\min_{\tau,\theta,K} \sum_{j=1}^{n} [y_j - \hat{y}(t_j)]^2 \qquad (8\text{-}27)$$

where $\hat{y}(t_j)$ is the predicted value of $y$ at time $t_j$ and $n$ is the number of data points. This optimization problem can be solved to calculate the optimal values of $K$, $\tau$, and $\theta$. A number of software packages such as Excel Solver are available for minimizing Eq. (8-27).

One operational problem caused by step forcing is the fact that the process under study is moved away from its steady-state operating point. Plant managers may be reluctant to allow large steady-state changes, since normal production will be disturbed by the changes. As a result, alternative methods of forcing actual processes have been developed, and these included pulse testing and pseudo-random binary signal (PRBS) forcing, both of which are illustrated in Fig. 8-22. With pulse forcing, one introduces a step, and then after a period of time the input is returned to its original value. The result is that the process dynamics are excited, but after the forcing the process returns to its original steady state. PRBS forcing involves a series of pulses of fixed height and random duration, as shown in Fig. 8-22. The advantage of PRBS is that forcing can be concentrated on particular frequency ranges that are important for control system design.

Transfer function models are linear, but chemical processes are known to exhibit nonlinear behavior. One could use the same type of optimization objective as given in Eq. (8-27) to determine parameters in nonlinear first-principles models, such as Eq. (8-3) presented earlier. Also, nonlinear empirical models, such as neural network models, have recently been proposed for process applications. The key to the use of these nonlinear empirical models is to have high-quality process data, which allows the important nonlinearities to be identified.

## FEEDBACK CONTROL SYSTEM CHARACTERISTICS

**General References:** Shinskey, *Process Control Systems,* 4th ed., McGraw-Hill, New York, 1996; Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 1989.

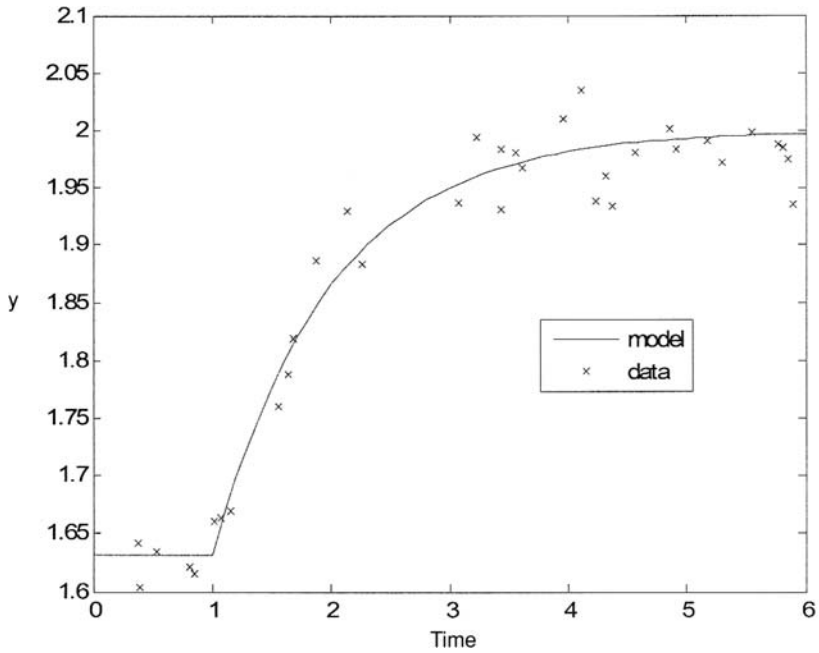

**FIG. 8-21** Plot of experimental data and first-order model fit.

There are two objectives in applying feedback control: (1) regulate the controlled variable at the set point following changes in load and (2) respond to set-point changes, the latter called servo operation. In fluid processes, almost all control loops must contend with variations in load, and therefore regulation is of primary importance. While most loops will operate continuously at fixed set points, frequent changes in set points can occur in flow loops and in batch production. The most common mechanism for achieving both objectives is feedback control, because it is the simplest and most universally applicable approach to the problem.

**Closing the Loop** The simplest representation of the closed feedback loop is shown in Fig. 8-23. The load is shown entering the process at the same point as the manipulated variable because that is the most common point of entry, and because, lacking better information, the elements in the path of the manipulated variable are the best estimates of those in the load path. The load rarely impacts directly on the controlled variable without passing through the dominant lag in the process. Where the load is unmeasured, its current value can be observed as the controller output required to keep the controlled variable $Y$ at set point $Y_{sp}$.

If the loop is opened—either by placing the controller in manual operation or by setting its gains to zero—the load will have complete influence over the controlled variable, and the set point will have none. Only by closing the loop with controller gain as high as possible will the influence of the load be minimized and that of the set point be maximized. There is a practical limit to the controller gain, however, at the point where the controlled variable develops a uniform oscillation. This is defined as the limit of stability, and it is reached when the product of gains in the loop $\Pi G = G_c G_v G_p$ is equal to 1.0 at the period of the oscillation. If the gain of any element in the loop increases from this condition, oscillations will expand, creating a dangerous situation where safe limits of operation could be exceeded in a few cycles. Consequently, control loops should be left in a condition where the loop gain is less than 1.0 by a safe margin that allows for possible variations in process parameters. Figure 8-24 describes a load response under PID (proportional-integral-derivative) control where the loop is well damped at a loop gain of 0.56; loop gain is then increased to 0.93 and to 1.05, creating a lightly damped and then an expanding cycle, respectively.

In controller tuning, a choice must be made between performance and robustness. Performance is a measure of how well a given controller with certain parameter settings regulates a variable, relative to the best response that can be achieved for that particular process. Robustness is a measure of how small a change in a process parameter is required to bring the loop from its current state to the limit of stability ($\Pi G = 1.0$). The well-damped loop in Fig. 8-24 has a robustness of 79 percent, in that increasing the gain of any element in the loop by a factor of 1/0.56, or 1.79, would bring the loop to the limit of stability. Increasing controller performance by raising its gain can therefore be expected to decrease robustness. Both performance and robustness are functions of the dynamics of the process being controlled, the selection of the controller, and the tuning of the controller parameters.

**On/Off Control** An on/off controller is used for manipulated variables having only two states. They commonly control temperatures in homes, electric water heaters and refrigerators, and pressure and liquid level in pumped storage systems. On/off control is satisfactory where slow cycling is acceptable, because it always leads to cycling when the load lies between the two states of the manipulated variable. The cycle will be positioned symmetrically about the set point only if the load happens to be equidistant between the two states of the manipulated variable. The period of the symmetric cycle will be approximately $4\theta$, where $\theta$ is the dead time in the loop. If the load is not centered between the states of the manipulated variable, the period will tend to increase and the cycle will follow a sawtooth pattern.

Every on/off controller has some degree of dead band, also known as lockup, or differential gap. Its function is to prevent erratic switching between states, thereby extending the life of contacts and motors. Instead of changing states precisely when the controlled variable crosses the set point, the controller will change states at two different points for increasing and decreasing signals. The difference between these two switching points is the dead band (see Fig. 8-25); it increases the amplitude and period of the cycle, similar to the effects of dead time.

A three-state controller is used to drive either a pair of independent two-state actuators, such as heating and cooling valves, or a bidirectional motorized actuator. The controller is comprised of two on/off controllers, each with dead band, separated by a dead zone. While the controlled variable lies within the dead zone, neither output is energized. This controller can drive a motorized valve to the point where the manipulated variable matches the load, thereby avoiding cycling.

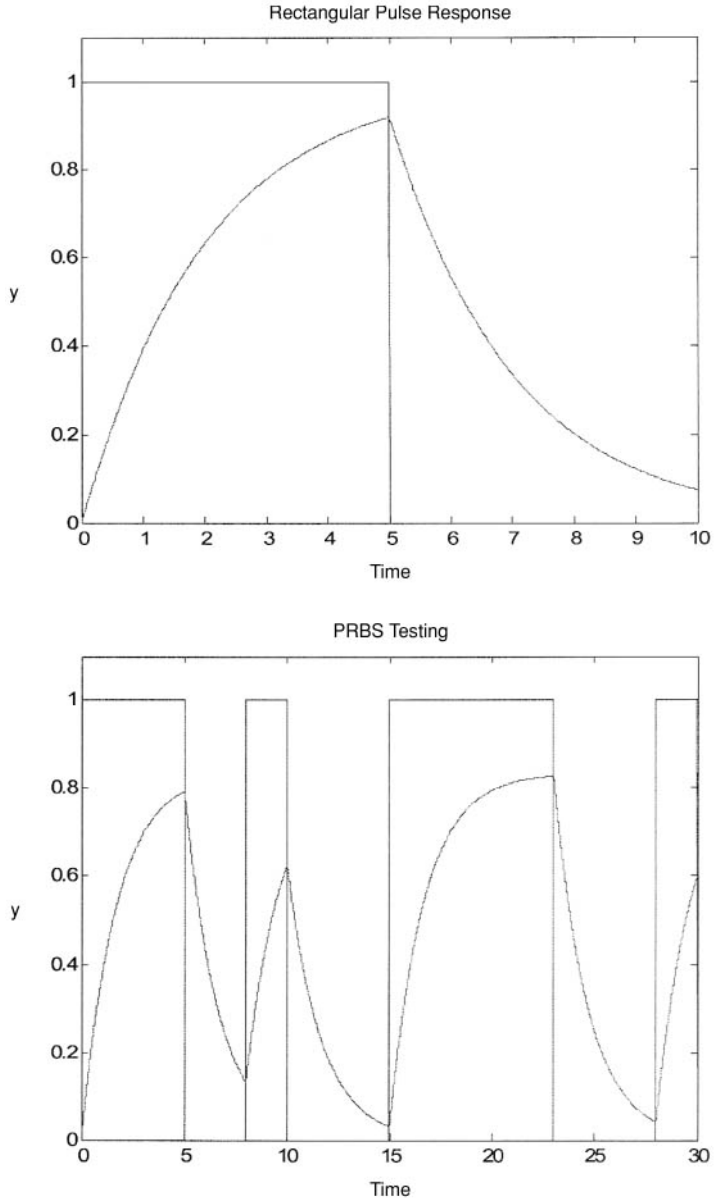

**FIG. 8-22** Rectangular pulse response and PRBS testing.

**Proportional Control** A proportional controller moves its output proportional to the deviation $e$ between the controlled variable $y$ and its set point $y_{sp}$:

$$u = K_c e + b = \frac{100}{P} e + b \tag{8-28}$$

where $e = \pm(y - y_{sp})$, the sign selected to produce negative feedback. In some controllers, proportional gain $K_c$ is introduced as a pure number; in others, it is set as $100/P$, where $P$ is the proportional band in percent. The output bias $b$ of the controller is also known as manual reset. The proportional controller is not a good regulator, because any change in output required to respond to a change in load results in a corresponding change in the controlled variable. To minimize the resulting offset, the bias should be set at the best estimate of the load, and the proportional band set as low as possible. Processes requiring a proportional band of more than a few percent may control with unacceptably large values of offset.

Proportional control is most often used to regulate liquid level, where variations in the controlled variable carry no economic penalty and where other control modes can easily destabilize the loop. It is actually recommended for controlling the level in a surge tank when manipulating the flow of feed to a critical downstream process. By setting the proportional band just under 100 percent, the level is allowed to vary over the full range of the tank capacity as inflow fluctuates, thereby minimizing the resulting rate of change of manipulated outflow. This technique is called averaging level control.

**Proportional-plus-Integral (PI) Control** Integral action eliminates the offset described above by moving the controller output at a

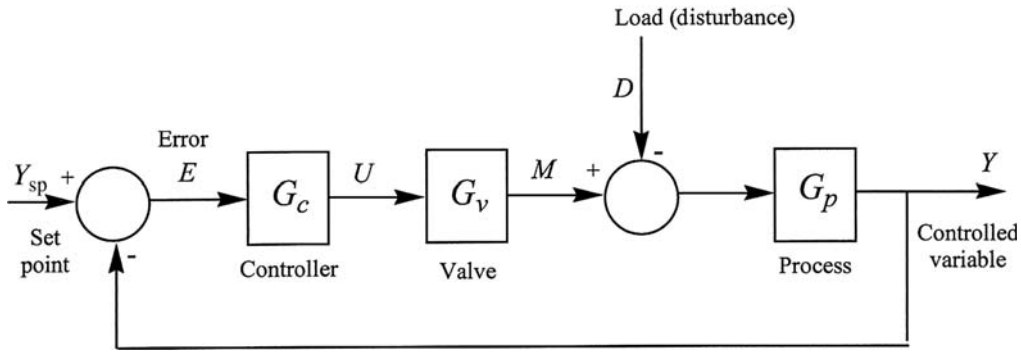

**FIG. 8-23** Both load regulation and set-point response require high gains for the feedback controller.

rate proportional to the deviation from set point—the output will then not stop moving until the deviation is zero. Although available alone in an integral controller, it is most often combined with proportional action in a PI controller:

$$u = \frac{100}{P}\left(e + \frac{1}{\tau_I}\int e dt\right) + C_0 \tag{8-29}$$

where $\tau_I$ is the integral time constant in minutes; in some controllers it is introduced as integral gain or reset rate $1/\tau_I$ in repeats per minute. The last term in the equation is the constant of integration, the value of the controller output when integration begins. The PI controller is by far the most commonly used controller in the process industries.

Because the integral term lags the proportional term by 90° in phase, the PI controller then always produces a phase lag between 0° and 90°:

$$\phi_{PI} = -\tan^{-1}\frac{\tau_o}{2\pi\tau_I} \tag{8-30}$$

where $\tau_o$ is the period of oscillation of the loop. The phase angle should be kept between 15° for lag-dominant processes and 45° for dead-time-dominant processes for optimum results.

**Proportional-plus-Integral-plus-Derivative (PID) Control** The derivative mode moves the controller output as a function of the rate of change of the controlled variable, which adds phase lead to the controller, increasing its speed of response. It is normally combined with proportional and integral modes. The noninteracting or ideal form of the PID controller appears functionally as

$$u = \frac{100}{P}\left(e + \frac{1}{\tau_I}\int e\,dt \pm \tau_D\frac{dy}{dt}\right) + C_0 \tag{8-31}$$

where $\tau_D$ is the derivative time constant. Note that derivative action is applied to the controlled variable rather than to the deviation, as it should not be applied to the set point; the selection of the sign for the derivative term must be consistent with the action of the controller.

In some PID controllers, the integral and derivative terms are combined serially rather than in parallel, as done in the last equation. This results in interaction between these modes, such that the effective values of the controller parameters differ from their set values as follows:

$$\begin{aligned} \tau_{I,\text{eff}} &= \tau_I + \tau_D \\ \tau_{D,\text{eff}} &= \frac{1}{1/\tau_D + 1/\tau_I} \\ K_c &= \frac{100}{P}\left(1 + \frac{\tau_D}{\tau_I}\right) \end{aligned} \tag{8-32}$$

The performance of the interacting controller is almost as high as that of the noninteracting controller on most processes, but the tuning rules differ because of the above relationships. Both controllers are in common use in digital systems.

There is always a gain limit placed upon the derivative vector—a value of 10 is typical. However, interaction decreases the derivative

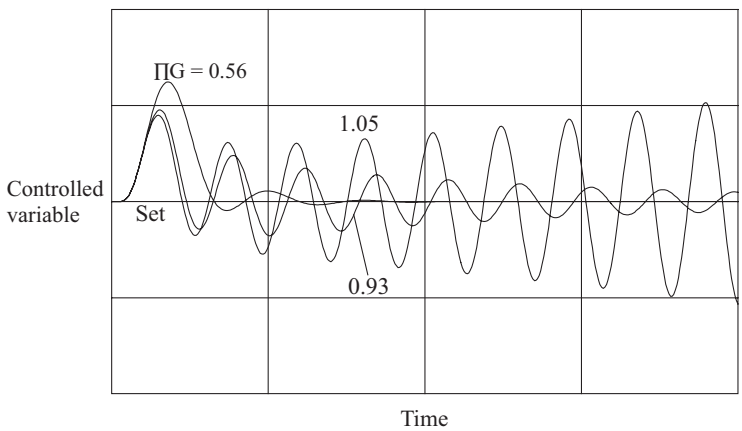

**FIG. 8-24** Transition from well-damped load response to instability develops as loop gain increases.

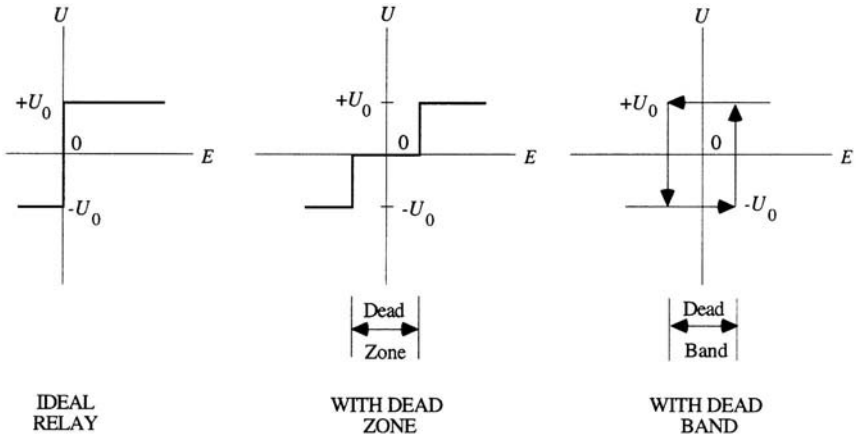

**FIG. 8-25** On/off controller characteristics.

gain below this value by the factor $1 + \tau_D/\tau_I$, which is the reason for the decreased performance of the interacting PID controller. Sampling in a digital controller has a similar effect, limiting derivative gain to the ratio of derivative time to the sample interval of the controller. Noise on the controlled variable is amplified by the derivative gain, preventing its use in controlling flow and liquid level. Derivative action is recommended for control of temperature and composition in multiple-capacity processes with little measurement noise.

**Controller Comparison** Figure 8-26 compares the step load response of a distributed lag without control, and with P, PI, and interacting PID control. A distributed lag is a process whose resistance and capacity are distributed throughout its length—a heat exchanger is characteristic of this class, its heat-transfer surface and heat capacity being uniformly distributed. Other examples include imperfectly stirred tanks and distillation columns—both trayed and packed. The signature of a distributed lag is its open-loop (uncontrolled) step response, featuring a relatively short dead time followed by a dominant lag called $\Sigma\tau$, which is the time required to reach 63.2 percent complete response.

The proportional controller is unable to return the controlled variable to the set point following the step load change, as a deviation is required to sustain its output at a value different from its fixed bias $b$. The amount of proportional offset produced as a fraction of the uncontrolled offset is $1/(1 + KK_c)$, where $K$ is the steady-state process gain—in Fig. 8-26, that fraction is 0.13. Increasing $K_c$ can reduce the offset, but with an accompanying loss in damping.

The PI and PID controller were tuned to produce a minimum *integrated absolute error* (*IAE*). Their response curves are similar in appearance to a gaussian distribution curve, but with a damped cycle in the trailing edge. The peak deviation of the PID response curve is only 0.12 times the uncontrolled offset, occurring at $0.36\Sigma\tau$; the peak deviation of the PI response curve is 0.21 times the uncontrolled offset, occurring at $0.48\Sigma\tau$. These values can be used to predict the load response of any distributed lag whose parameters $K$ and $\Sigma\tau$ are known or can be estimated as described below.

## CONTROLLER TUNING

The performance of a controller depends as much on its tuning as on its design. Tuning must be applied by the end user to fit the controller to the controlled process. There are many different approaches to controller tuning, based on the particular performance criteria selected, whether load or set-point changes are more important, whether the process is lag- or dead-time-dominant, and the availability of information about the process dynamics. The earliest definitive work in this field was done at the Taylor Instrument Company by Ziegler and Nichols (*Trans. ASME*, p. 759, 1942), tuning PI and interacting PID

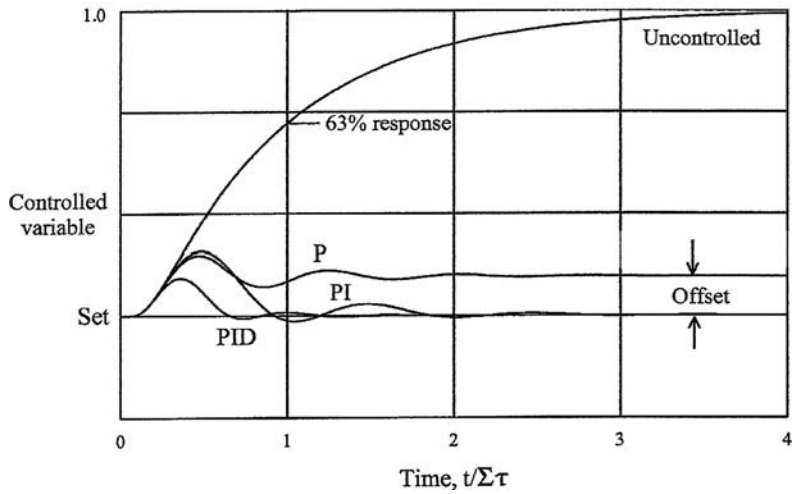

**FIG. 8-26** Minimum-IAE tuning gives very satisfactory load response for a distributed lag.

controllers for optimum response to step load changes applied to lag-dominant processes. While these tuning rules are still in use, they do not apply to set-point changes, dead-time-dominant processes, or noninteracting PID controllers (Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 2004).

**Controller Performance Criteria** The most useful measures of controller performance in an industrial setting are the maximum deviation in the controlled variable resulting from a disturbance, and its integral. The disturbance could be to the set point or to the load, depending on the variable being controlled and its context in the process. The size of the deviation and its integral are proportional to the size of the disturbance (if the loop is linear at the operating point). While actual disturbances arising in a plant may appear to be random, the controller needs a reproducible test to determine how well it is tuned. The disturbance of choice for test purposes is the step, because it can be applied manually, and by containing all frequencies including zero it exercises all modes of the controller. (The step actually has the same frequency distribution as integrated white noise, a "random walk.") When tuned optimally for step disturbances, the controller will be optimally tuned for most other disturbances as well.

A step change in set point, however, may be a poor indicator of a loop's load response. For example, a liquid-level controller does not have to integrate to follow a set-point change, as its steady-state output is independent of the set point. Stepping a flow controller's set point is an effective test of its tuning, however, as its steady-state output is proportional to its set point. Other loops should be load-tested: simulate a load change from a steady state at zero deviation by transferring the controller to manual and stepping its output, and then immediately transferring back to automatic before a deviation develops.

Figure 8-27*a* and *b* shows variations in the response of a distributed lag to a step change in load for different combinations of proportional and integral settings of a PI controller. The maximum deviation is the most important criterion for variables that could exceed safe operating levels, such as steam pressure, drum level, and steam temperature in a boiler. The same rule can apply to product quality if violating specifications causes it to be rejected. However, if the product can be accumulated in a downstream storage tank, its average quality is more important, and this is a function of the deviation integrated over the residence time of the tank. Deviation in the other direction, where the product is better than specification, is safe but increases production costs in proportion to the integrated deviation because quality is given away.

For a PI or PID controller, the integrated deviation—better known as integrated error IE—is related to the controller settings

$$\mathrm{IE} = \Delta u \frac{P\tau_I}{100} \tag{8-33}$$

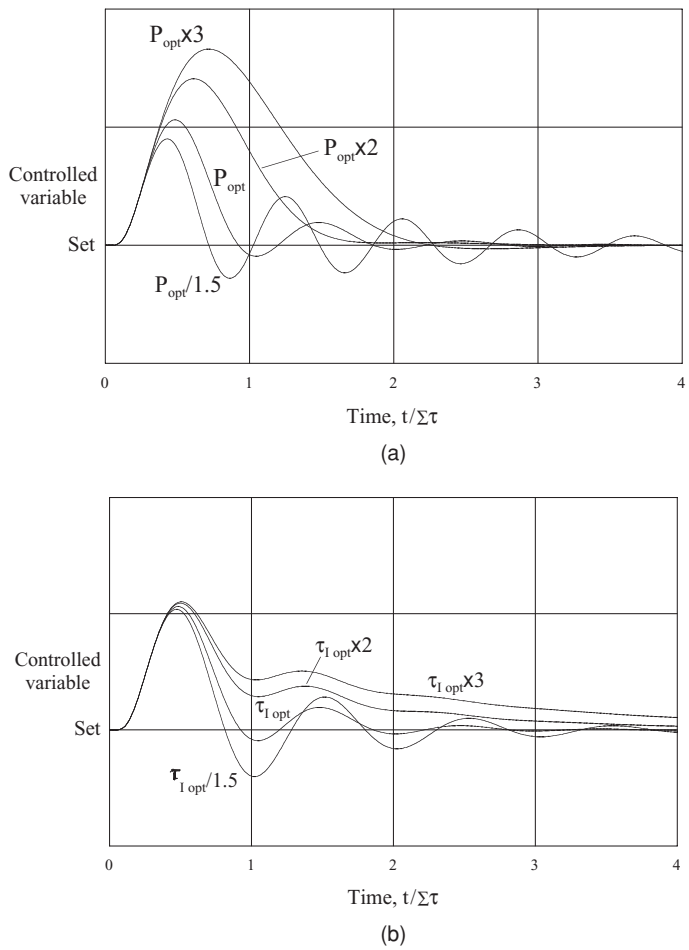

**FIG. 8-27** The optimum settings produce minimum-IAE load response. (*a*) The proportional band primarily affects damping and peak deviation. (*b*) Integral time determines overshoot.

where $\Delta u$ is the difference in controller outputs between two steady states, as required by a change in load or set point. The proportional band $P$ and integral time $\tau_I$ are the indicated settings of the controller for PI and both interacting and noninteracting PID controllers. Although the derivative term does not appear in the relationship, its use typically allows a 50 percent reduction in integral time and therefore in IE. The integral time in the IE expression should be augmented by the sample interval if the controller is digital, the time constant of any filter used, and the value of any dead-time compensator.

It would appear, from the above, that minimizing IE is simply a matter of minimizing the $P$ and $\tau_I$ settings of the controller. However, settings will be reached that produce excessive oscillations, such as shown in the lowest two response curves in Fig. 8-27*a* and *b*. It is preferable instead to find a combination of controller settings that minimizes integrated absolute error IAE, which for both load and set-point changes is a well-damped response with minimal overshoot. The curves designated $P_{opt}$ and $\tau_{I,opt}$ in Fig. 8-27 are the same minimum-IAE response to a step change in load for a distributed-lag process under PI control. Because of the very small overshoot, the IAE will be only slightly larger than the IE. Loops that are tuned to minimize IAE tend to give responses that are close to minimum IE and with minimum peak deviation. The other curves in Fig. 8-27*a* and *b* describe the effects of individual adjustments to $P$ and $\tau_I$, respectively, around those optimum values and can serve as a guide to fine-tuning a PI controller.

The performance of a controller (and its tuning) must be based on what is achievable for a given process. The concept of best practical IE ($IE_b$) for a step change in load $\Delta L$ to a process consisting of dead time and one or two lags can be estimated (Shinskey, *Process Control Systems*, 4th ed., McGraw-Hill, New York, 1996)

$$IE_b = \Delta L K_L \tau_L (1 - e^{-\theta/\tau_L}) \tag{8-34}$$

where $K_L$ is the gain and $\tau_L$ the primary time constant in the load path, and $\theta$ the dead time in the manipulated path to the controlled variable. If the load or its gain is unknown, $\Delta u$ and $K$ ($= K_c K_p$) may be substituted. If the process is non-self-regulating (i.e., an integrator), the relationship is

$$IE_b = \frac{\Delta L \theta^2}{\tau_1} \tag{8-35}$$

where $\tau_1$ is the time constant of the process integrator. The peak deviation of the best practical response curve is

$$e_b = \frac{IE_b}{\theta + \tau_2} \tag{8-36}$$

where $\tau_2$ is the time constant of a common secondary lag (e.g., in the measuring device).

**TABLE 8-2 Tuning Rules Using Known Process Parameters**

| Process | Controller | $P$ | $\tau_I$ | $\tau_D$ |
|---|---|---|---|---|
| Dead-time-dominant | PI | $250K$ | $0.5\theta$ | |
| Lag-dominant | PI | $106K\theta/\tau_m$ | $4.0\theta$ | |
| | $PID_n$ | $77K\theta/\tau_m$ | $1.8\theta$ | $0.45\theta$ |
| | $PID_i$ | $106K\theta/\tau_m$ | $1.5\theta$ | $0.55\theta$ |
| Non-self-regulating | PI | $106\theta/\tau_1$ | $4.0\theta$ | |
| | $PID_n$ | $78\theta/\tau_1$ | $1.9\theta$ | $0.48\theta$ |
| | $PID_i$ | $108\theta/\tau_1$ | $1.6\theta$ | $0.58\theta$ |
| Distributed lags | PI | $20K$ | $0.50\ \Sigma\tau$ | |
| | $PID_n$ | $10K$ | $0.30\ \Sigma\tau$ | $0.09\ \Sigma\tau$ |
| | $PID_i$ | $15K$ | $0.25\ \Sigma\tau$ | $0.10\Sigma\tau$ |

NOTE: $n$ = noninteracting, $i$ = interacting controller modes.

The performance of any controller can be measured against this standard by comparing the IE it achieves in responding to a load change with the best practical IE. Maximum performance levels for PI controllers on lag-dominant processes lie in the 20 to 30 percent range, while for PID controllers they fall between 40 and 60 percent, varying with secondary lags.

**Tuning Methods Based on Known Process Models** The most accurate tuning rules for controllers have been based on simulation, where the process parameters can be specified and IAE and IE can be integrated during the simulation as an indication of performance. Controller settings are then iterated until a minimum IAE is reached for a given disturbance. Next these optimum settings are related to the parameters of the simulated process in tables, graphs, or equations, as a guide to tuning controllers for processes whose parameters are known (Seborg, Edgar, and Mellichamp, *Process Dynamics and* Control, Wiley, New York, 2004). This is a multidimensional problem, however, in that the relationships change as a function of process type, controller type, and source of disturbance.

Table 8-2 summarizes these rules for minimum-IAE load response for the most common controllers. The process gain and time constant $\tau_m$ are obtained from the product of $G_c$ and $G_p$ in Fig. 8-23. Derivative action is not effective for dead-time-dominant processes. Any secondary lag, sampling interval, or filter time constant should be added to dead time $\theta$.

The principal limitation to using these rules is that the true process parameters are often unknown. Steady-state gain $K$ can be calculated from a process model, or determined from the steady-state results of a step test as $\Delta c/\Delta u$, as shown in Fig. 8-28. The test will not be viable, however if the time constant of the process $\tau_m$ is longer than a few minutes, since five time constants must elapse to approach a steady state within 1 percent, and unexpected disturbances may intervene. Estimated dead time $\theta$ is the time from the step to the intercept of a

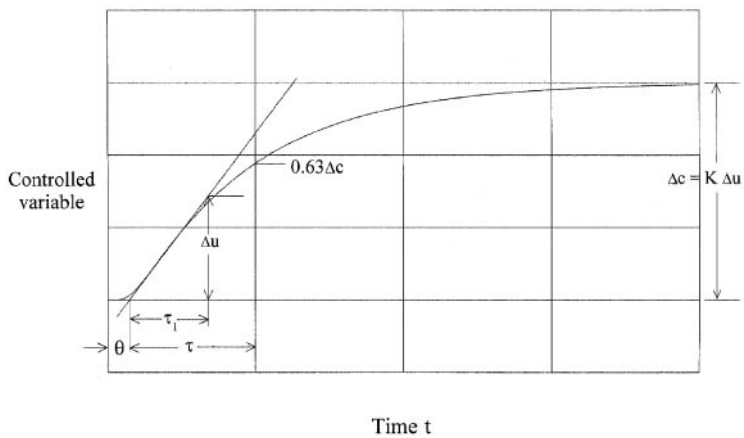

**FIG. 8-28** If a steady state can be reached, gain $K$ and time constant $\tau$ can be estimated from a step response; if not, use $\tau_1$ instead.

**TABLE 8-3 Tuning Rules Using Slope and Intercept**

| Controller | $P$ | $\tau_I$ | $\tau_D$ |
|---|---|---|---|
| PI | $150\theta/\tau_1$ | $3.5\theta$ | |
| $PID_n$ | $75\theta/\tau_1$ | $2.1\theta$ | $0.63\theta$ |
| $PID_i$ | $113\theta/\tau_1$ | $1.8\theta$ | $0.70\theta$ |

NOTE: $n$ = noninteracting, $i$ = interacting controller modes.

straight line tangent to the steepest part of the response curve. The estimated time constant $\tau$ is the time from that point to 63 percent of the complete response. In the presence of a significant secondary lag, these results will not be completely accurate, however. The time for 63 percent response may be more accurately calculated as the residence time of the process: its volume divided by current volumetric flow rate.

**Tuning Methods When Process Model Is Unknown** Ziegler and Nichols developed two tuning methods for processes with unknown parameters. The open-loop method uses a step test without waiting for a steady state to be reached and is therefore applicable to very slow processes. Dead time is estimated from the intercept of the steepest tangent to the response curve in Fig. 8-28, whose slope is also used. If the process is non-self-regulating, the controlled variable will continue to follow this slope, changing by an amount equal to $\Delta u$ in a time equal to its time constant $\tau_1$. This time estimate $\tau_1$ is used along with $\theta$ to tune controllers according to Table 8-3, applicable to lag-dominant processes. If the process is known to be a distributed lag, such as a heat exchanger, distillation column, or stirred tank, then better results will be obtained by converting the estimated values of $\theta$ and $\tau_1$ to $K$ and $\Sigma\tau$ and using Table 8-2. The conversion factors are $K = 7.5\theta/\tau_1$ and $\Sigma\tau = 7.0\theta$.

The Ziegler and Nichols closed-loop method requires forcing the loop to cycle uniformly under proportional control, by setting the integral time to maximum and derivative time to zero and reducing the proportional band until a constant-amplitude cycle results. The natural period $\tau_u$ of the cycle (the proportional controller contributes no phase shift to alter it) is used to set the optimum integral and derivative time constants. The optimum proportional band is set relative to the undamped proportional band $P_u$ which was found to produce the uniform oscillation. Table 8-4 lists the tuning rules for a lag-dominant process.

A uniform cycle can also be forced by using on-off control to cycle the manipulated variable between two limits. The period of the cycle will be close to $\tau_u$ if the cycle is symmetric; the peak-to-peak amplitude $A_c$ of the controlled variable divided by the difference between the output limits $A_u$ is a measure of process gain at that period and is therefore related to $P_u$ for the proportional cycle:

**TABLE 8-4 Tuning Rules Using Proportional Cycle**

| Controller | $P$ | $\tau_I$ | $\tau_D$ |
|---|---|---|---|
| PI | $1.70P_u$ | $0.81\tau_u$ | |
| $PID_n$ | $1.30P_u$ | $0.48\tau_u$ | $0.11\tau_u$ |
| $PID_i$ | $1.80P_u$ | $0.38\tau_u$ | $0.14\tau_u$ |

NOTE: $n$ = noninteracting, $i$ = interacting controller modes.

$$P_u = 100\frac{\pi}{4}\frac{A_c}{A_u} \tag{8-37}$$

The factor $\pi/4$ compensates for the square wave in the output. Tuning rules are given in Table 8-4.

**Set-Point Response** All the above tuning methods are intended to minimize IAE for step load changes. When applied to lag-dominant processes, the resulting controller settings produce excessive overshoot of set-point changes. This behavior has led to the practice of tuning to optimize set-point response, which unfortunately degrades the load response of lag-dominant loops. An option has been available with some controllers to remove proportional action from set-point changes, which eliminates set-point overshoot but lengthens settling time. A preferred solution to this dilemma is available in many modern controllers which feature an independent gain adjustment for the set point, through which set-point response can be optimized after the controller has been tuned to optimize load response.

Figure 8-29 shows set-point and load responses of a distributed lag for both set-point and load tuning, including the effects of fractional set-point gain $K_r$. The set point was stepped at time zero, and the load stepped at time 2.4. With full set-point gain, the PI controller was tuned for minimum-IAE set-point response with $P = 29K$ and $\tau_I = \Sigma\tau$, compared to $P = 20K$ and $\tau_I = 0.50\Sigma\tau$ for minimum-IAE load response. These settings increase its IE for load response by a factor of 2.9, and its peak deviation by 20 percent, over optimum load tuning. However, with optimum load tuning, that same set-point overshoot can be obtained with set-point gain $K_r = 0.54$. The effects of full set-point gain (1.0) and no set-point gain (0) are shown for comparison.

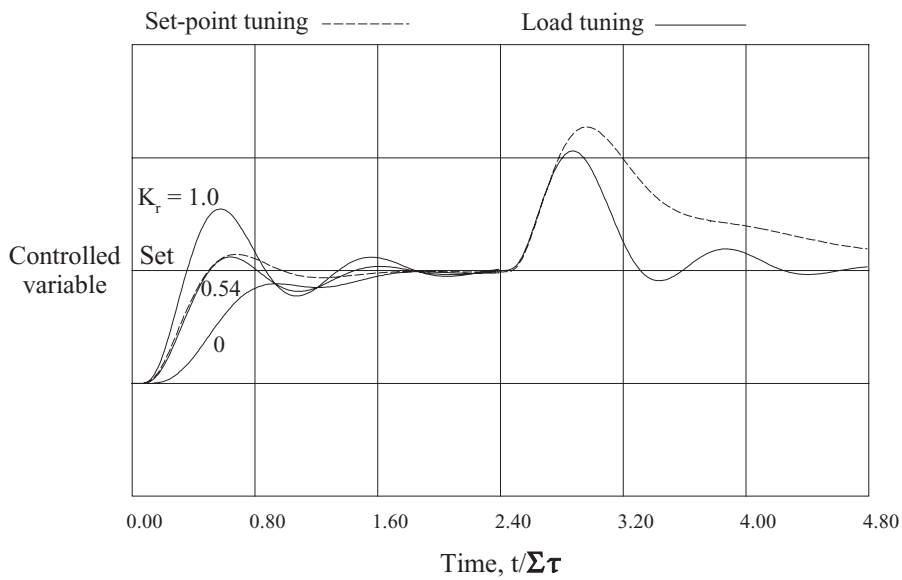

**FIG. 8-29** Tuning proportional and integral settings to optimize set-point response degrades load response; using a separate set-point gain adjustment allows both responses to be optimized.

# ADVANCED CONTROL SYSTEMS

## BENEFITS OF ADVANCED CONTROL

The economics of most processes are determined by the steady-state operating conditions. Excursions from these steady-state conditions usually have a less important effect on the economics of the process, except when the excursions lead to off-specification products. To enhance the economic performance of a process, the steady-state operating conditions must be altered in a manner that leads to more efficient process operation.

The hierarchy shown in Fig. 8-30 indicates that process control activities consist of the following five levels:

Level 1: Measurement devices and actuators
Level 2: Safety, environmental/equipment protection
Level 3: Regulatory control
Level 4: Real-time optimization
Level 5: Planning and scheduling

Levels 4 and 5 clearly affect the process economics, as both levels are directed to optimizing the process in some manner. In contrast, levels 1, 2, and 3 would appear to have no effect on process economics. Their direct effect is indeed minimal, although indirectly they can have a major effect. Basically, these levels provide the foundation for all higher levels. A process cannot be optimized until it can be operated consistently at the prescribed targets. Thus, satisfactory regulatory control must be the first goal of any automation effort. In turn, the measurements and actuators provide the process interface for regulatory control.

For most processes, the optimum operating point is determined by a constraint. The constraint might be a product specification (a product stream can contain no more than 2 percent ethane); violation of this constraint causes off-specification product. The constraint might be an equipment limit (vessel pressure rating is 300 psig); violation of this constraint causes the equipment protection mechanism (pressure

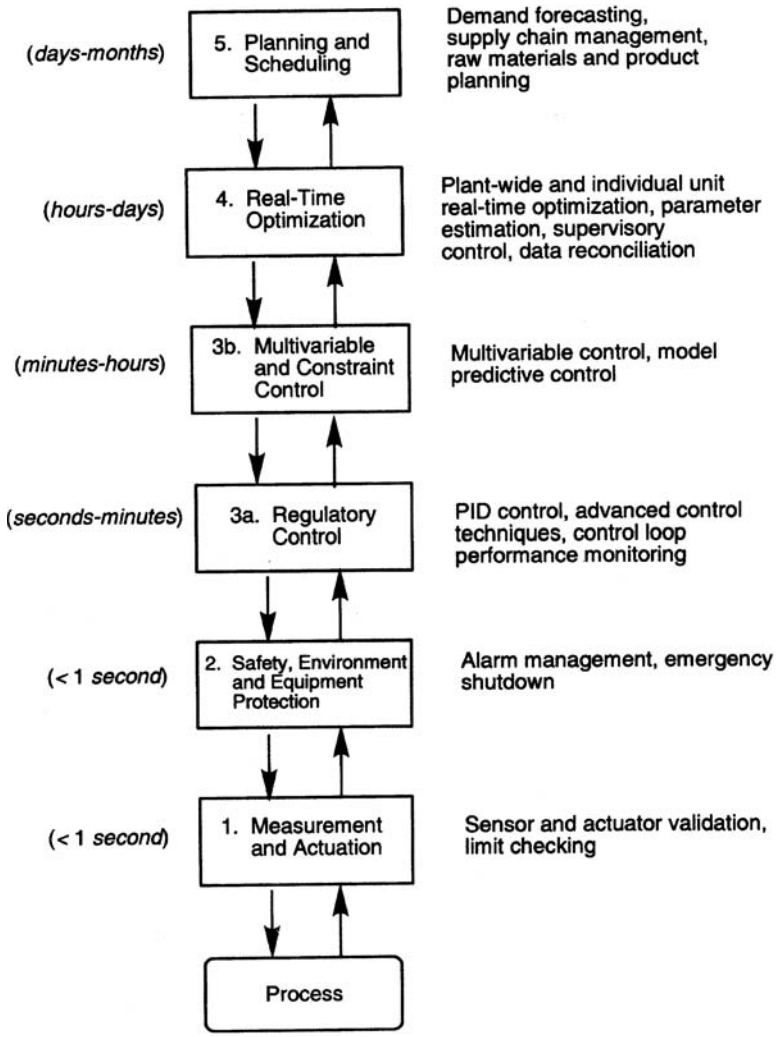

**FIG. 8-30** The five levels of process control and optimization in manufacturing. Time scales are shown for each level. (*Source: Seborg et al.,* Process Dynamics and Control, *2d ed., Wiley, New York, 2004.*)

relief device) to activate. As the penalties are serious, violation of such constraints must be very infrequent.

If the regulatory control system were perfect, the target could be set exactly equal to the constraint (i.e., the target for the pressure controller could be set at the vessel relief pressure). However, no regulatory control system is perfect. Therefore, the value specified for the target must be on the safe side of the constraint, thus allowing the control system some operating margin. How much depends on the following:

1. *The performance of the control system (i.e., how effectively it responds to disturbances).* The faster the control system reacts to a disturbance, the closer the process can be operated to the constraint.
2. *The magnitude of the disturbances to which the control system must respond.* If the magnitude of the major disturbances can be reduced, the process can be operated closer to the constraint.

One measure of the performance of a control system is the variance of the controlled variable from the target. Both improving the control system and reducing the disturbances will lead to a lower variance in the controlled variable.

In a few applications, improving the control system leads to a reduction in off-specification product and thus improved process economics. However, in most situations, the process is operated sufficiently far from the constraint that very little, if any, off-specification product results from control system deficiencies. Management often places considerable emphasis on avoiding off-specification production, so consequently the target is actually set far more conservatively than it should be.

In most applications, simply improving the control system does not directly lead to improved process economics. Instead, the control system improvement must be accompanied by shifting the target closer to the constraint. There is always a cost of operating a process in a conservative manner. The cost may be a lower production rate, a lower process efficiency, a product giveaway, or other. When management places undue emphasis on avoiding off-specification production, the natural reaction is to operate very conservatively, thus incurring other costs.

The immediate objective of an advanced control effort is to reduce the variance in an important controlled variable. However, this effort must be coupled with a commitment to adjust the target for this controlled variable so that the process is operated closer to the constraint. In large-throughput (commodity) processes, very small shifts in operating targets can lead to large economic returns.

## ADVANCED CONTROL TECHNIQUES

**General References:** Seborg, Edgar, and Mellichamp, *Process Dynamics and Control,* Wiley, New York. 2004. Stephanopoulos, *Chemical Process Control: An Introduction to Theory and Practice,* Prentice-Hall, Englewood Cliffs, N.J., 1984. Shinskey, *Process Control Systems,* 4th ed., McGraw-Hill, New York, 1996. Ogunnaike and Ray, *Process Dynamics, Modeling, and Control,* Oxford University Press, New York, 1994.

While the single-loop PID controller is satisfactory in many process applications, it does not perform well for processes with slow dynamics, time delays, frequent disturbances, or multivariable interactions. We discuss several advanced control methods below that can be implemented via computer control, namely, feedforward control, cascade control, time-delay compensation, selective and override control, adaptive control, fuzzy logic control, and statistical process control.

**Feedforward Control** If the process exhibits slow dynamic response and disturbances are frequent, then the application of feedforward control may be advantageous. Feedforward (FF) control differs from feedback (FB) control in that the primary disturbance or load ($D$) is measured via a sensor and the manipulated variable ($U$) is adjusted so that deviations in the controlled variable from the set point are minimized or eliminated (see Fig. 8-31). By taking control action based on measured disturbances rather than controlled variable error, the controller can reject disturbances before they affect the controlled variable $Y$. To determine the appropriate settings for the manipulated variable, one must develop mathematical models that relate

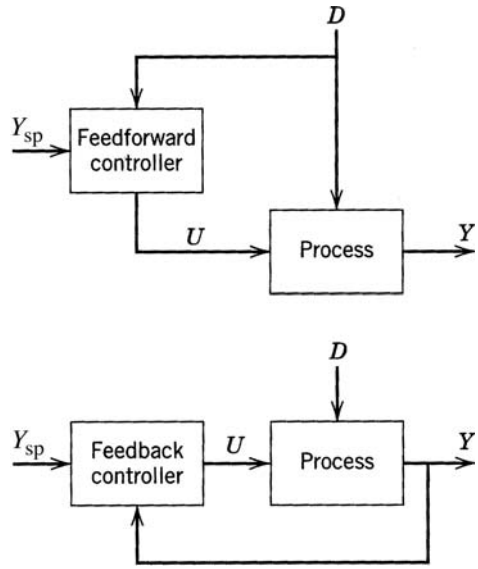

**FIG. 8-31** Simplified block diagrams for feedforward and feedback control.

1. The effect of the manipulated variable $U$ on the controlled variable $Y$
2. The effect of the disturbance $D$ on the controlled variable $Y$

These models can be based on steady-state or dynamic analysis. The performance of the feedforward controller depends on the accuracy of both models. If the models are exact, then feedforward control offers the potential of perfect control (i.e., holding the controlled variable precisely at the set point at all times because of the ability to predict the appropriate control action). However, since most mathematical models are only approximate and since not all disturbances are measurable, it is standard practice to utilize feedforward control in conjunction with feedback control. Table 8-5 lists the relative advantages and disadvantages of feedforward and feedback control. By combining the two control methods, the strengths of both schemes can be utilized.

FF control therefore attempts to eliminate the effects of measurable disturbances, while FB control would correct for unmeasurable disturbances and modeling errors. This latter case is often referred to as feedback trim. These controllers have become widely accepted in the chemical process industries since the 1960s.

***Design Based on Material and Energy Balances*** Consider a heat exchanger example (see Fig. 8-32) to illustrate the use of FF and FB control. The control objective is to maintain $T_2$, the exit liquid temperature, at the desired value (or set point) $T_{2sp}$ despite variations in the inlet liquid flow rate $F$ and inlet liquid temperature $T_l$. This is done by manipulating $W$, the steam flow rate. A feedback control scheme would entail measuring $T_2$, comparing $T_2$ to $T_{2sp}$, and then adjusting $W$. A feedforward control scheme requires measuring $F$ and $T_l$, and adjusting $W$ (knowing $T_{2sp}$), in order to control exit temperature $T_2$.

Figure 8-33*a* and *b* shows the control system diagrams for FB and FF control. A feedforward control algorithm can be designed for the heat exchanger in the following manner. Using a steady-state energy balance and assuming no heat loss from the heat exchanger,

$$WH = FC(T_2 - T_1) \tag{8-38}$$

where $H$ = latent heat of vaporization and $C$ = specific heat of liquid

$$W = \frac{C}{H} F(T_2 - T_1) \tag{8-39}$$

or

$$W = K_1 F(T_2 - T_1) \tag{8-40}$$

**TABLE 8-5 Relative Advantages and Disadvantages of Feedforward and Feedback**

| Advantages | Disadvantages |
|---|---|
| Feedforward | |
| • Acts before the effect of a disturbance has been felt by the system<br>• Is good for systems with large time constant or dead time<br>• Does not introduce instability in the closed-loop response | • Requires direct measurement of all possible disturbances<br>• Cannot cope with unmeasured disturbances<br>• Is sensitive to process/model error |
| Feedback | |
| • Does not require identification and measurement of any disturbance for corrective action<br>• Does not require an explicit process model<br>• Is possible to design controller to be robust to process/model errors | • Control action not taken until the effect of the disturbance has been felt by the system<br>• Is unsatisfactory for processes with large time constants and frequent disturbances<br>• May cause instability in the closed-loop response |

with

$$K_1 = \frac{C_L}{H} \tag{8-41}$$

Replace $T_2$ by $T_{2sp}$

$$W = K_1 F(T_{set} - T_1) \tag{8-42}$$

Equation (8-42) can be used in the FF calculation, assuming one knows the physical properties $C$ and $H$. Of course, it is probable that the model will contain errors (e.g., unmeasured heat losses, incorrect $C$ or $H$). Therefore, $K_1$ can be designated as an adjustable parameter that can be tuned. The use of a physical model for FF control is desirable because it provides a physical basis for the control law and gives an a priori estimate of what the tuning parameters should be. Note that such a model could be nonlinear [e.g., in Eq. (8-42), $F$ and $T_{2sp}$ are multiplied].

***Block Diagram Analysis*** One shortcoming of this feedforward design procedure is that it is based on the steady-state characteristics of the process and, as such, neglects process dynamics (i.e., how fast the controlled variable responds to changes in the load and manipulated variables). Thus, it is often necessary to include "dynamic compensation" in the feedforward controller. The most direct method of designing the FF dynamic compensator is to use a block diagram of a general process, as shown in Fig. 8-34, where $G_t$ represents the disturbance transmitter, $G_f$ is the feedforward controller, $G_d$ relates the disturbance to the controlled variable, $G_v$ is the valve, $G_p$ is the process, $G_m$ is the output transmitter, and $G_c$ is the feedback controller. All blocks correspond to transfer functions (via Laplace transforms).

Using block diagram algebra and Laplace transform variables, the controlled variable $Y(s)$ is given by

$$Y(s) = \frac{G_t G_f L(s) + G_d D(s)}{1 + G_m G_c G_v G_p} \tag{8-43}$$

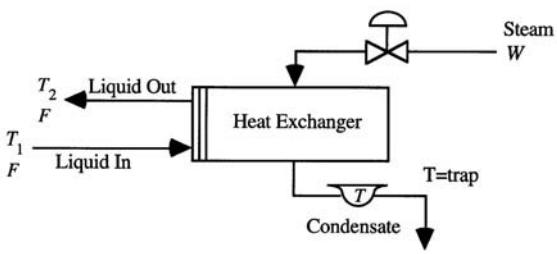

**FIG. 8-32** A heat exchanger diagram.

For disturbance rejection $[D(s) \neq 0]$ we require that $Y(s) = 0$, or zero error. Solving Eq. (8-43) for $G_f$ gives

$$G_f = \frac{-G_L}{G_t G_v G_p} \tag{8-44}$$

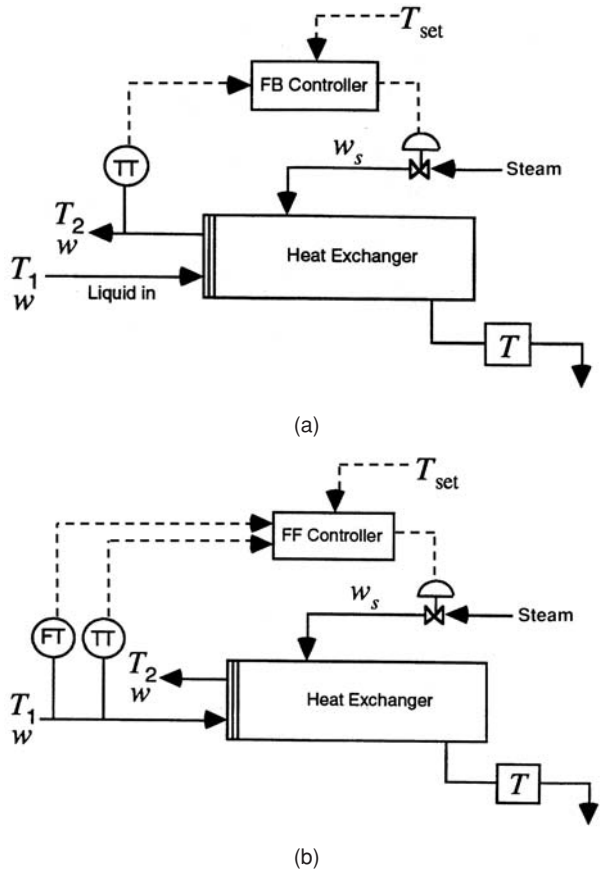

**FIG. 8-33** (*a*) Feedback control of a heat exchanger. (*b*) Feedforward control of a heat exchanger.

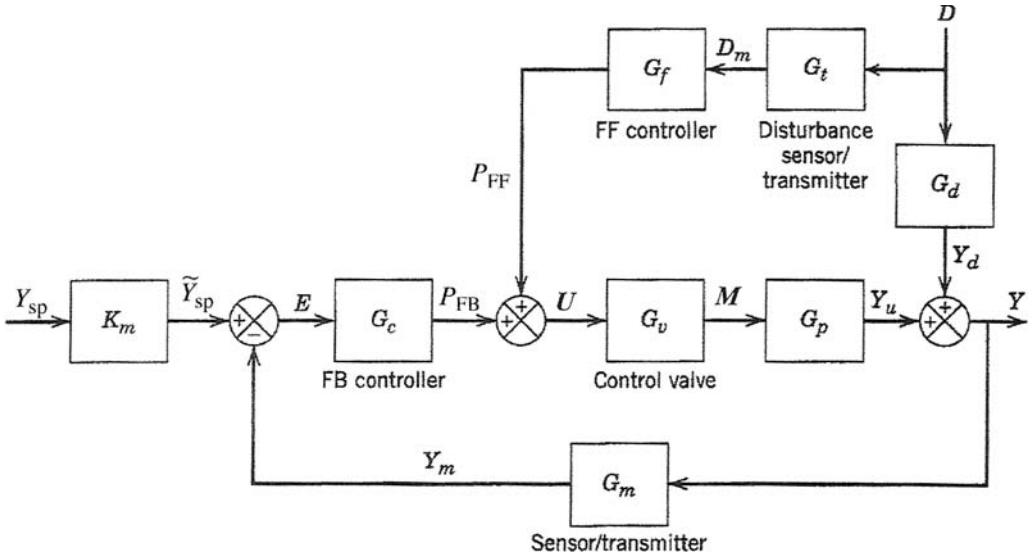

**FIG. 8-34** A block diagram of a feedforward-feedback control system. (*Source: Seborg et al.,* Process Dynamics and Control, *2d ed., Wiley, New York, 2004.*)

Suppose the dynamics of $G_d$ and $G_p$ are first-order; in addition, assume that $G_c = K_c$ and $G_t = K_t$ (constant gains for simplicity).

$$G_d(s) = \frac{K_d}{\tau_d s + 1} = \frac{Y(s)}{D(s)} \tag{8-45}$$

$$G_p(s) = \frac{K_p}{\tau_p s + 1} = \frac{Y(s)}{U(s)} \tag{8-46}$$

Using Eq. (8-44),

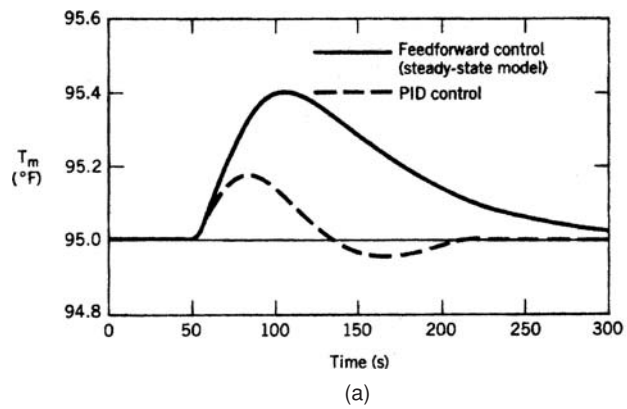
$$G_f(s) = \frac{\tau_p s + 1}{\tau_d s + 1} \cdot \frac{-K_d}{K_p K_c K_t} = \frac{-K(\tau_p s + 1)}{\tau_d s + 1} \tag{8-47}$$

where $K$ is the overall ratio of the gains in Eq. (8-47).

The above FF controller can be implemented by using a digital computer. Figure 8-35*a* and *b* compares typical responses for PID FB control, steady-state FF control ($s = 0$), dynamic FF control, and combined FF/FB control. In practice, the engineer can tune $K$, $\tau_p$, and $\tau_d$ in the field to improve the performance of the FF controller. The feedforward controller can also be simplified to provide steady-state feedforward control. This is done by setting $s = 0$ in $G_f(s)$. This might be appropriate if there is uncertainty in the dynamic models for $G_d$ and $G_p$.

***Other Considerations in Feedforward Control*** The tuning of feedforward and feedback control systems can be performed independently. In analyzing the block diagram in Fig. 8-34, note that $G_f$ is chosen to cancel out the effects of the disturbance $D(s)$, as long as there are no model errors. For the feedback loop, therefore, the effects of $D(s)$ can also be ignored, which for the servo case is

$$\frac{Y(s)}{Y_{sp}(s)} = \frac{G_c G_v G_p K_m}{1 + G_c G_v G_p G_m} \tag{8-48}$$



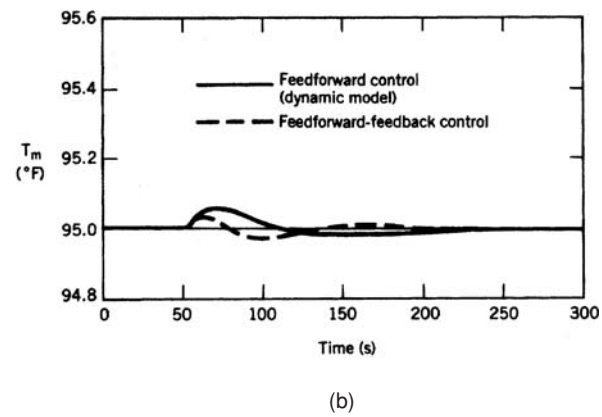


**FIG. 8-35** (*a*) Comparison of FF (steady-state model) and PID FB control for disturbance change. (*b*) Comparison of FF (dynamic model) and combined FF/FB control.

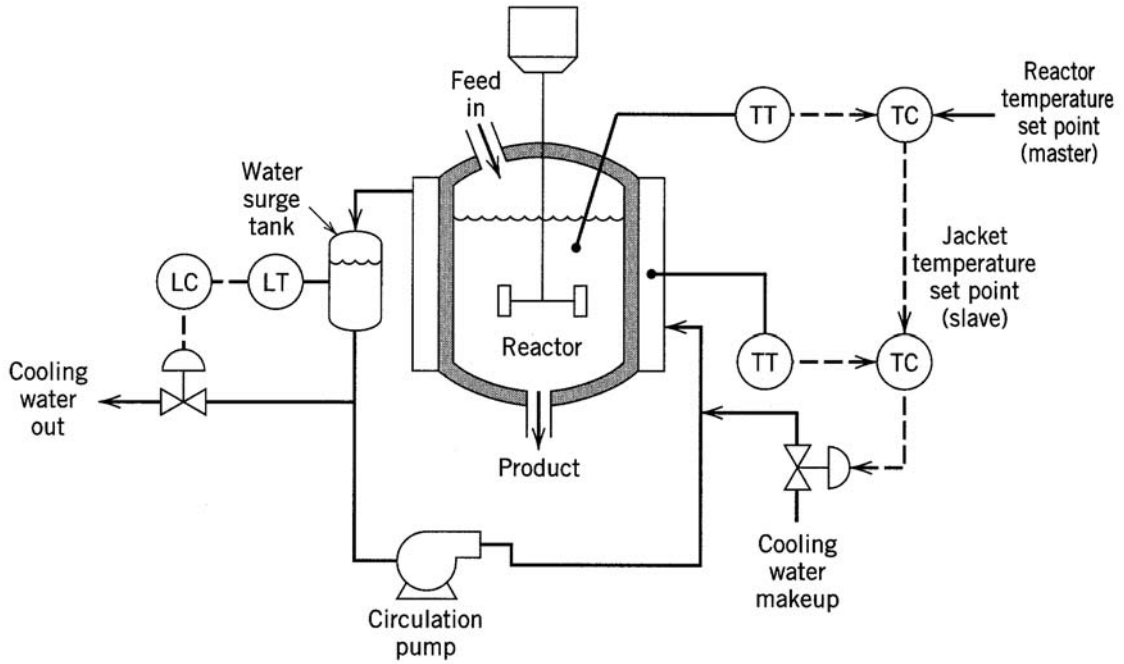

**FIG. 8-36** Cascade control of an exothermic chemical reactor. (*Source: Seborg et al.,* Process Dynamics and Control, *2d ed., Wiley, New York, 2004.*)

Note that the characteristic equation will be unchanged for the FF + FB system; hence system stability will be unaffected by the presence of the FF controller. In general, the tuning of the FF controller can be less conservative than for the case of FB alone, because smaller excursions from the set point will result. This in turn would make the dynamic model $Y(s)$ more accurate.

The tuning of the controller in the feedback loop can be theoretically performed independently of the feedforward loop (i.e., the feedforward loop does not introduce instability in the closed-loop response). For more information on feedforward/feedback control applications and design of such controllers, refer to the general references.

**Cascade Control** One of the disadvantages of using conventional feedback control for processes with large time lags or delays is that disturbances are not recognized until after the controlled variable deviates from its set point. In these processes, correction by feedback control is generally slow and results in long-term deviation from the set point. One way to improve the dynamic response to load changes is by using a secondary measurement point and a secondary controller; the secondary measurement point is located so that it recognizes the upset condition before the primary controlled variable is affected.

One such approach is called cascade control, which is routinely used in most modern computer control systems. Consider a chemical reactor, where reactor temperature is to be controlled by coolant flow to the jacket of the reactor. The reactor temperature can be influenced by changes in disturbance variables such as feed rate or feed temperature; a feedback controller could be employed to compensate for such disturbances by adjusting a valve on the coolant flow to the reactor jacket. However, suppose an increase occurs in the coolant temperature as a result of changes in the plant coolant system. This will cause a change in the reactor temperature measurement, although such a change will not occur quickly, and the corrective action taken by the controller will be delayed.

Cascade control is one solution to this problem (see Fig. 8-36). Here the jacket temperature is measured, and an error signal is sent from this point to the coolant control valve; this reduces coolant flow, maintaining the heat-transfer rate to the reactor at a constant level and rejecting the disturbance. The cascade control configuration will also adjust the setting of the coolant control valve when an error occurs in the reactor temperature. The cascade control scheme shown in Fig. 8-36 contains two controllers. The primary controller is the reactor temperature controller. It measures the reactor temperature, compares it to the set point, and computes an output, which is the set point for the coolant flow rate controller. The secondary controller compares this set point to the coolant temperature measurement and adjusts the valve. The principal advantage of cascade control is that the secondary measurement (jacket temperature) is located closer to a potential disturbance in order to improve the closed-loop response.

Figure 8-37 shows the block diagram for a general cascade control system. In tuning of a cascade control system, the secondary controller (in the inner loop) is tuned first with the primary controller in manual. Often only a proportional controller is needed for the secondary loop, because offset in the secondary loop can be treated by using proportional-plus-integral action in the primary loop. When the primary controller is transferred to automatic, it can be tuned by using the techniques described earlier in this section. For more information on theoretical analysis of cascade control systems, see the general references for a discussion of applications of cascade control.

**Time-Delay Compensation** Time delays are a common occurrence in the process industries because of the presence of recycle loops, fluid-flow distance lags, and dead time in composition measurements resulting from use of chromatographic analysis. The presence of a time delay in a process severely limits the performance of a conventional PID control system, reducing the stability margin of the closed-loop control system. Consequently, the controller gain must be reduced below that which could be used for a process without delay. Thus, the response of the closed-loop system will be sluggish compared to that of the system with no time delay.

To improve the performance of time-delay systems, special control algorithms have been developed to provide time-delay compensation. The Smith predictor technique is the best-known algorithm; a related method is called the analytical predictor. Various investigators have

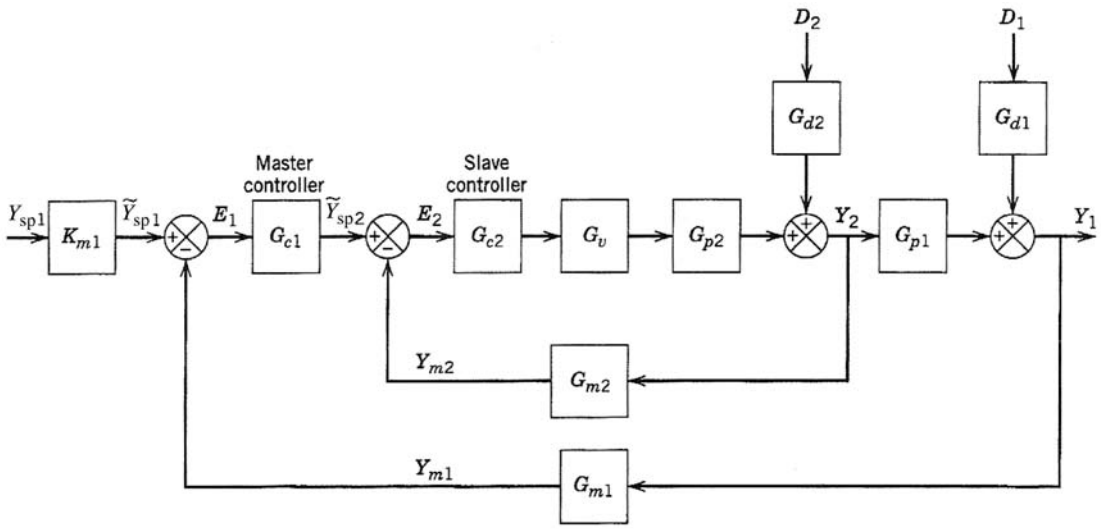

**FIG. 8-37** Block diagram of the cascade control system. For a chemical reactor $G_{d1}$ would correspond to a feed temperature or composition disturbance, while $G_{d2}$ would be a change in the cooling water temperature. (*Source: Seborg et al.,* Process Dynamics and Control, *2d ed., Wiley, New York, 2004.*)

found that, based on integral squared error, the performance of the Smith predictor can be better than that for a conventional controller, as long as the time delay is known accurately.

The Smith predictor is a model-based control strategy that involves a more complicated block diagram than that for a conventional feedback controller, although a PID controller is still central to the control strategy (see Fig. 8-38). The key concept is based on better coordination of the timing of manipulated variable action. The loop configuration takes into account the fact that the current controlled variable measurement is not a result of the current manipulated variable action, but the value taken θ time units earlier. Time-delay compensation can yield excellent performance; however, if the process model parameters change (especially the time delay), the Smith predictor performance will deteriorate and is not recommended unless other precautions are taken.

**Selective and Override Control** When there are more controlled variables than manipulated variables, a common solution to this problem is to use a selector to choose the appropriate process variable from among a number of available measurements. Selectors can be based on multiple measurement points, multiple final control elements, or multiple controllers, as discussed below. Selectors are used to improve the control system performance as well as to protect equipment from unsafe operating conditions.

One type of selector device chooses as its output signal the highest (or lowest) of two or more input signals. This approach is often referred to as auctioneering. On instrumentation diagrams, the symbol

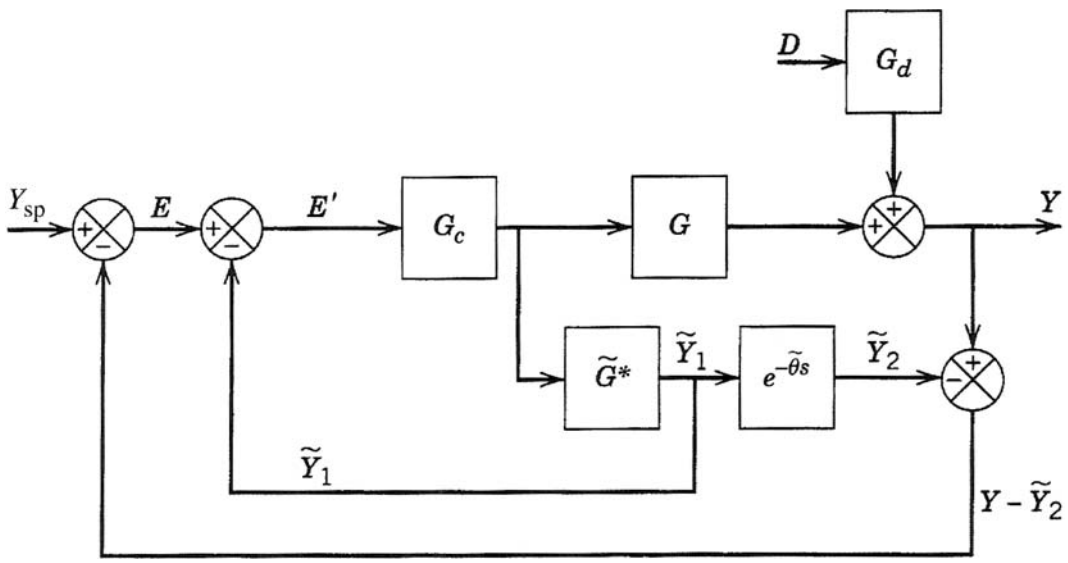

**FIG. 8-38** Block diagram of the Smith predictor. (*Source: Seborg et al.,* Process Dynamics and Control, *2d ed., Wiley, New York, 2004.*)

> denotes a high selector and < a low selector. For example, a high selector can be used to determine the hot-spot temperature in a fixed-bed chemical reactor. In this case, the output from the high selector is the input to the temperature controller. In an exothermic catalytic reaction, the process may run away due to disturbances or changes in the reactor. Immediate action should be taken to prevent a dangerous rise in temperature. Because a hot spot may potentially develop at one of several possible locations in the reactor, multiple (redundant) measurement points should be employed. This approach minimizes the time required to identify when a temperature has risen too high at some point in the bed.

The use of high or low limits for process variables is another type of selective control, called an override. The feature of antireset windup in feedback controllers is a type of override. Another example is a distillation column with lower and upper limits on the heat input to the column reboiler. The minimum level ensures that liquid will remain on the trays, while the upper limit is determined by the onset of flooding. Overrides are also used in forced-draft combustion control systems to prevent an imbalance between airflow and fuel flow, which could result in unsafe operating conditions.

Other types of selective systems employ multiple final control elements or multiple controllers. In some applications, several manipulated variables are used to control a single process variable (also called split-range control). Typical examples include the adjustment of both inflow and outflow from a chemical reactor to control reactor pressure or the use of both acid and base to control pH in wastewater treatment. In this approach, the selector chooses among several controller outputs which final control element should be adjusted.

**Adaptive Control** Process control problems inevitably require online tuning of the controller constants to achieve a satisfactory degree of control. If the process operating conditions or the environment changes significantly, the controller may have to be retuned. If these changes occur quite frequently, then adaptive control techniques should be considered. An adaptive control system is one in which the controller parameters are adjusted automatically to compensate for changing process conditions.

The subject of adaptive control is one of current interest. New algorithms continue to be developed, but these need to be field-tested before industrial acceptance can be expected. An adaptive controller is inherently nonlinear and therefore more complicated than the conventional PID controller.

**Fuzzy Logic Control** The application of fuzzy logic to process control requires the concepts of fuzzy rules and fuzzy inference. A fuzzy rule, also known as a fuzzy IF-THEN statement, has the form

If $x$ then $y$

if input1 = high

and input2 = low

then output = medium

Three functions are required to perform logical inferencing with fuzzy rules. The fuzzy AND is the product of a rule's input membership values, generating a weight for the rule's output. The fuzzy OR is a normalized sum of the weights assigned to each rule that contributes to a particular decision. The third function used is defuzzification, which generates a crisp final output. In one approach, the crisp output is the weighted average of the peak element values.

With a single feedback control architecture, information that is readily available to the algorithm includes the error signal, difference between the process variable and the set-point variable, change in error from previous cycles to the current cycle, changes to the set-point variable, change of the manipulated variable from cycle to cycle, and change in the process variable from past to present. In addition, multiple combinations of the system response data are available. As long as the irregularity lies in that dimension wherein fuzzy decisions are being based or associated, the result should be enhanced performance. This enhanced performance should be demonstrated in both the transient and steady-state response. If the system tends to have changing dynamic characteristics or exhibits nonlinearities, fuzzy logic control should offer a better alternative to using constant PID settings. Most fuzzy logic software begins building its information base during the autotune function. In fact, the majority of the information used in the early stages of system start-up comes from the autotune solutions.

In addition to single-loop process controllers, products that have benefited from the implementation of fuzzy logic are camcorders, elevators, antilock braking systems, and televisions with automatic color, brightness, and sound control. Sometimes fuzzy logic controllers are combined with pattern recognition software such as artificial neural networks (Passino and Yurkovich, *Fuzzy Control*, Addison-Wesley, Reading, Mass., 1998; Kosko, *Neural Networks and Fuzzy Systems,* Prentice-Hall, Englewood Cliffs, N.J., 1992).

## EXPERT SYSTEMS

An expert system is a computer program that uses an expert's knowledge in a particular domain to solve a narrowly focused, complex problem. An offline system uses information entered manually and produces results in visual form to guide the user in solving the problem at hand. An online system uses information taken directly from process measurements to perform tasks automatically or instruct or alert operating personnel to the status of the plant.

Each expert system has a rule base created by the expert to respond as the expert would to sets of input information. Expert systems used for plant diagnostics and management usually have an open rule base, which can be changed and augmented as more experience accumulates and more tasks are automated. The system begins as an empty shell with an assortment of functions such as equation solving, logic, and simulation, as well as input and display tools to allow an expert to construct a proprietary rule base. The "expert" in this case would be the person or persons having the deepest knowledge about the process, its problems, its symptoms, and remedies. Converting these inputs to meaningful outputs is the principal task in constructing a rule base. First-principles models (deep knowledge) produce the most accurate results, although heuristics are always required to establish limits. Often modeling tools such as artificial neural nets are used to develop relationships among the process variables.

A number of process control vendors offer comprehensive, object-oriented software environments for building and deploying expert systems. Advantages of such software include transforming complex real-time data to useful information through knowledge-based reasoning and analysis, monitoring for potential problems before they adversely impact operations, diagnosing root causes of time-critical problems to speed up resolution, and recommending or taking corrective actions to help ensure successful recovery.

## MULTIVARIABLE CONTROL

**General References:** Shinskey, *Process Control Systems*, 4th ed., McGraw-Hill, New York, 1996. Seborg, Edgar, and Mellichamp, *Process Dynamics and Control,* 2d ed., Wiley, New York, 2004. McAvoy, *Interaction Analysis*, lSA, Research Triangle Park, N.C., 1983.

Process control books and journal articles tend to emphasize problems with a single controlled variable. In contrast, many processes require multivariable control with many process variables to be controlled. In fact, for virtually any important industrial process, at least two variables must be controlled: product quality and throughput. In this section, strategies for multivariable control are considered.

Three examples of simple multivariable control systems are shown in Fig. 8-39. The in-line blending system blends pure components $A$ and $B$ to produce a product stream with flow rate $w$ and mass fraction of $A$, $x$. Adjusting either inlet flow rate $w_A$ or $w_B$ affects both of the controlled variables $w$ and $x$. For the pH neutralization process in Fig. 8-39*b*, liquid level $h$ and exit stream pH are to be controlled by adjusting the acid and base flow rates $w_A$ and $w_B$. Each of the manipulated variables affects both of the controlled variables. Thus, both the blending system and the pH neutralization process are said to exhibit

strong process interactions. In contrast, the process interactions for the gas-liquid separator in Fig. 8-39*c* are not as strong because one manipulated variable, liquid flow rate $L$, has only a small and indirect effect on one of the controlled variables, pressure $P$.

Strong process interactions can cause serious problems if a conventional multiloop feedback control scheme (e.g., either PI or PID controllers) is employed. The process interactions can produce undesirable control loop interactions where the controllers fight each other. Also, it may be difficult to determine the best pairing of controlled and manipulated variables. For example, in the in-line blending process in Fig. 8-39*a*, should $w$ be controlled with $w_A$ and $x$ with $w_B$, or vice versa?

**Control Strategies for Multivariable Control** If a conventional multiloop control strategy performs poorly due to control loop interactions, a number of solutions are available:

1. Detune one or more of the control loops.
2. Choose different controlled or manipulated variables (or their pairings).
3. Use a decoupling control system.
4. Use a multivariable control scheme (e.g., model predictive control).

Detuning a controller (e.g., using a smaller controller gain or a larger reset time) tends to reduce control loop interactions by sacrificing the performance for the detuned loops. This approach may be acceptable if some of the controlled variables are faster or less important than others.

The selection of controlled and manipulated variables is of crucial importance in designing a control system. In particular, a judicious choice may significantly reduce control loop interactions. For the blending process in Fig. 8-39*a*, a straightforward control strategy would be to control $x$ by adjusting $w_A$, and $w$ by adjusting $w_B$. But physical intuition suggests that it would be better to control $x$ by adjusting the ratio $w_A/(w_A + w_B)$ and to control product flow rate $w$ by the sum $w_A + w_B$. Thus, the new manipulated variables would be $U_1 = w_A/(w_A + w_B)$ and $U_2 = w_A + w_B$. In this control scheme, $U_1$ affects only $x$, and $U_2$ affects only $w$. Thus, the control loop interactions have been eliminated. Similarly, for the pH neutralization process in Fig. 8-39*b*, the control loop interactions would be greatly reduced if pH were controlled by $U_1 = w_A\ (w_A + w_B)$ and liquid level $h$ were controlled by $U_2 = w_A + w_B$.

**Decoupling Control Systems** Decoupling control systems provide an alternative approach for reducing control loop interactions. The basic idea is to use additional controllers called decouplers to compensate for undesirable process interactions.

As an illustrative example, consider the simplified block diagram for a representative decoupling control system shown in Fig. 8-40. The two controlled variables $Y_1$ and $Y_2$ and two manipulated variables $U_1$ and $U_2$ are related by the four process transfer functions $G_{p11}$, $G_{p12}$, and so on. For example, $G_{p11}$ denotes the transfer function between $U_1$ and $Y_1$:

$$\frac{Y_1(s)}{U_1(s)} = G_{p11}(s) \tag{8-49}$$

Figure 8-40 includes two conventional feedback controllers: $G_{c1}$ controls $Y_1$ by manipulating $U_1$, and $G_{c2}$ controls $Y_2$ by manipulating $U_2$. The output signals from the feedback controllers serve as input signals to the two decouplers $T_{12}$ and $T_{21}$. The block diagram is in a simplified form because the disturbance variables and transfer functions for the final control elements and sensors have been omitted.

The function of the decouplers is to compensate for the undesirable process interactions represented by $G_{p12}$ and $G_{p21}$. Suppose that the process transfer functions are all known. Then the ideal design equations are

$$T_{12}(s) = -\frac{G_{p12}(s)}{G_{p11}(s)} \tag{8-50}$$

$$T_{21}(s) = -\frac{G_{p21}(s)}{G_{p22}(s)} \tag{8-51}$$

These decoupler design equations are very similar to the ones for feedforward control in an earlier section. In fact, decoupling can be interpreted as a type of feedforward control where the input signal is the output of a feedback controller rather than a measured disturbance variable.

In principle, ideal decoupling eliminates control loop interactions and allows the closed-loop system to behave as a set of independent control loops. But in practice, this ideal behavior is not attained for a variety of reasons, including imperfect process models and the presence of saturation constraints on controller outputs and manipulated variables. Furthermore, the ideal decoupler design equations in (8-50) and (8-51) may not be physically realizable and thus would have to be approximated.

In practice, other types of decouplers and decoupling control configurations have been employed. For example, in partial decoupling, only a single decoupler is employed (i.e., either $T_{12}$ or $T_{21}$ in Fig. 8-40

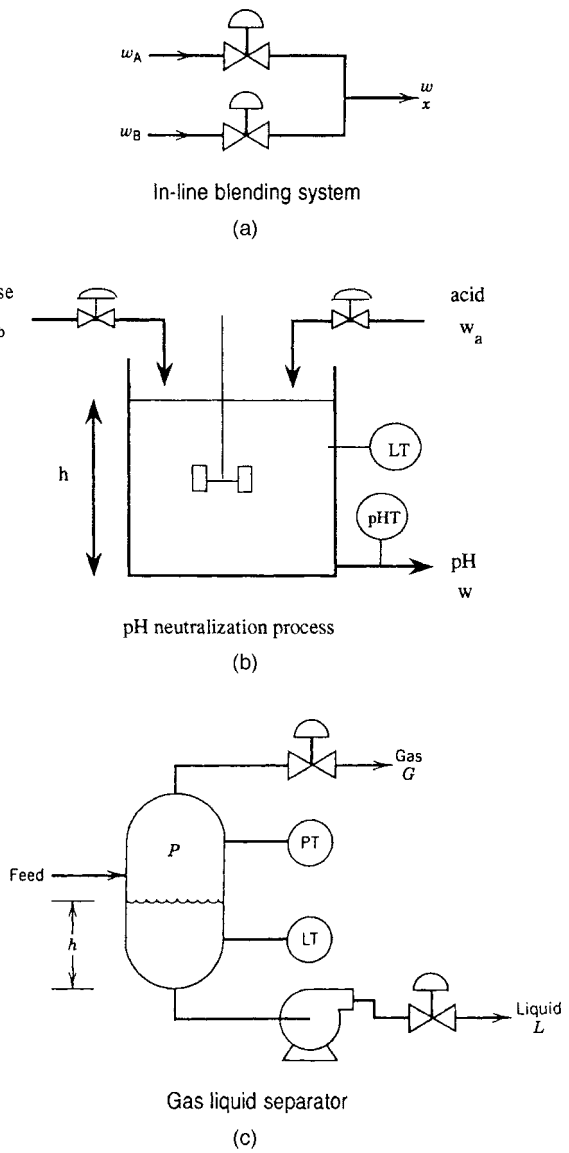

**FIG. 8-39** Physical examples of multivariable control problems.

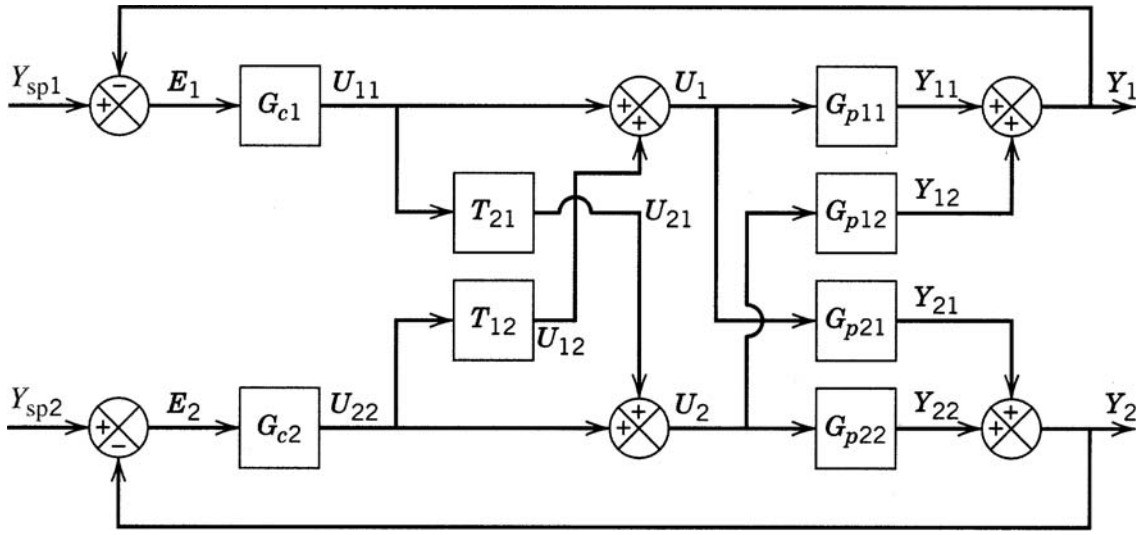

**FIG. 8-40** A decoupling control system.

is set equal to zero). This approach tends to be more robust than complete decoupling and is preferred when one of the controlled variables is more important than the other. Static decouplers can be used to reduce the steady-state interactions between control loops. They can be designed by replacing the transfer functions in Eqs. (8-50) and (8-51) with the corresponding steady-state gains

$$T_{12}(s) = -\frac{K_{p12}}{K_{p11}} \tag{8-52}$$

$$T_{21}(s) = -\frac{K_{p21}}{K_{p22}} \tag{8-53}$$

The advantage of static decoupling is that less process information is required, namely, only steady-state gains. Nonlinear decouplers can be used when the process behavior is nonlinear.

**Pairing of Controlled and Manipulated Variables** A key decision in multiloop control system design is the pairing of manipulated and controlled variables. This is referred to as the controller pairing problem. Suppose there are $N$ controlled variables and $N$ manipulated variables. Then $N!$ distinct control configurations exist. For example, if $N = 5$, then there are 120 different multiloop control schemes. In practice, many would be rejected based on physical insight or previous experience. But a smaller number (say, 5 to 15) may appear to be feasible, and further analysis would be warranted. Thus, it is very useful to have a simple method for choosing the most promising control configuration.

The most popular and widely used technique for determining the best controller pairing is the relative gain array (RGA) method (Bristol, "On a New Measure of Process Interaction," *IEEE Trans. Auto. Control*, **AC-11:** 133, 1966). The RGA method provides two important items of information:

1. A measure of the degree of process interactions between the manipulated and controlled variables
2. A recommended controller pairing

An important advantage of the RGA method is that it requires minimal process information, namely, steady-state gains. Another advantage is that the results are independent of both the physical units used and the scaling of the process variables. The chief disadvantage of the RGA method is that it neglects process dynamics, which can be an important factor in the pairing decision. Thus, the RGA analysis should be supplemented with an evaluation of process dynamics. Although extensions of the RGA method that incorporate process dynamics have been reported, these extensions have not been widely applied.

**RGA Method for $2 \times 2$ Control Problems** To illustrate the use of the RGA method, consider a control problem with two inputs and two outputs. The more general case of $N \times N$ control problems is considered elsewhere (McAvoy, *Interaction Analysis*, ISA, Research Triangle Park, N.C., 1983). As a starting point, it is assumed that a linear, steady-state process model in Eqs. (8-54) and (8-55) is available, where $U_1$ and $U_2$ are steady-state values of the manipulated inputs; $Y_1$ and $Y_2$ are steady-state values of the controlled outputs; and the $K$ values are steady-state gains. The $Y$ and $U$ variables are deviation variables from nominal steady-state values. This process model could be obtained in a variety of ways, such as by linearizing a theoretical model or by calculating steady-state gains from experimental data or a steady-state simulation.

$$Y_1 = K_{11}U_1 + K_{12}U_2 \tag{8-54}$$

$$Y_2 = K_{21}U_1 + K_{22}U_2 \tag{8-55}$$

By definition, the relative gain $\lambda_{ij}$ between the $i$th manipulated variable and the $j$th controlled variable is defined as

$$\lambda_{ij} = \frac{\text{open-loop gain between } Y_i \text{ and } U_j}{\text{closed-loop gain between } Y_i \text{ and } U_j} \tag{8-56}$$

where the open-loop gain is simply $K_{ij}$ from Eqs. (8-54) and (8-55). The closed-loop gain is defined to be the steady-state gain between $U_j$ and $Y_i$ when the other control loop is closed and no offset occurs in the other controlled variable due to the presence of integral control action. The RGA for the $2 \times 2$ process is denoted by

$$\Lambda = \begin{bmatrix} \lambda_{11} & \lambda_{12} \\ \lambda_{21} & \lambda_{22} \end{bmatrix} \tag{8-57}$$

The RGA has the important normalization property that the sum of the elements in each row and each column is exactly 1. Consequently, the RGA in Eq. (8-57) can be written as

$$\Lambda = \begin{bmatrix} \lambda & 1-\lambda \\ 1-\lambda & \lambda \end{bmatrix} \tag{8-58}$$

where $\lambda$ can be calculated from the following formula:

$$\lambda = \frac{1}{1 - K_{12}K_{21}/(K_{11}K_{22})} \tag{8-59}$$

Ideally, the relative gains that correspond to the proposed controller pairing should have a value of 1 because Eq. (8-56) implies that the open- and closed-loop gains are then identical. If a relative gain equals 1, the steady-state operation of this loop will not be affected when the other control loop is changed from manual to automatic, or vice versa. Consequently, the recommendation for the best controller pairing is to pair the controlled and manipulated variables so that the corresponding relative gains are positive and close to 1.

**RGA Example** To illustrate use of the RGA method, consider the following steady-state version of a transfer function model for a pilot-scale, methanol-water distillation column (Wood and Berry, "Terminal Composition Control of a Binary Distillation Column," *Chem. Eng. Sci.*, **28:** 1707, 1973): $K_{11} = 12.8$, $K_{12} = -18.9$, $K_{21} = 6.6$, and $K_{22} = -19.4$. It follows that $\lambda = 2$ and

$$\Lambda = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix} \tag{8-60}$$

Thus it is concluded that the column is fairly interacting and the recommended controller pairing is to pair $Y_1$ with $U_1$ and $Y_2$ with $U_2$.

## MODEL PREDICTIVE CONTROL

**General References:** Qin and Badgwell, *Control Eng. Practice*, **11:** 773, 2003. Rawlings, *IEEE Control Systems Magazine*, **20**(3)**:** 38, 2000). Camacho and Bordons, *Model Predictive Control*, 2d ed., Springer-Verlag, New York, 2004. Maciejowski, *Predictive Control with Constraints*, Prentice-Hall, Upper Saddle River, N.J., 2002. Seborg, Edgar, and Mellichamp, *Process Dynamics and Control,* 2d ed., Wiley, New York, 2004, Chap. 20.

The model-based control strategy that has been most widely applied in the process industries is *model predictive control* (*MPC*). It is a general method that is especially well suited for difficult multi-input, multioutput (MIMO) control problems where there are significant interactions between the manipulated inputs and the controlled outputs. Unlike other model-based control strategies, MPC can easily accommodate inequality constraints on input and output variables such as upper and lower limits and rate-of-change limits.

A key feature of MPC is that future process behavior is predicted by using a dynamic model and available measurements. The controller outputs are calculated so as to minimize the difference between the predicted process response and the desired response. At each sampling instant, the control calculations are repeated and the predictions updated based on current measurements. In typical industrial applications, the set point and target values for the MPC calculations are updated by using online optimization based on a steady-state model of the process.

The current widespread interest in MPC techniques was initiated by pioneering research performed by two industrial groups in the 1970s. Shell Oil (Houston, Tex.) reported its Dynamic Matrix Control (DMC) approach in 1979, while a similar technique, marketed as IDCOM, was published by a small French company ADERSA in 1978. Since then, there have been thousands of applications of these and related MPC techniques in oil refineries and petrochemical plants around the world. Thus, MPC has had a substantial impact and is currently the method of choice for difficult multivariable control problems in these industries. However, relatively few applications have been reported in other process industries, even though MPC is a very general approach that is not limited to a particular industry.

**Advantages and Disadvantages of MPC** Model predictive control offers a number of important advantages in comparison with conventional multiloop PID control:

1. It is a general control strategy for MIMO processes with inequality constraints on input and output variables.
2. It can easily accommodate difficult or unusual dynamic behavior such as large time delays and inverse responses.
3. Because the control calculations are based on optimizing control system performance, MPC can be readily integrated with online optimization strategies to optimize plant performance.
4. The control strategy can be easily updated online to compensate for changes in process conditions, constraints, or performance criteria.

But current versions of MPC have significant disadvantages in comparison with conventional multiloop control:

1. The MPC strategy is very different from conventional multiloop control strategies and thus initially unfamiliar to plant personnel.
2. The MPC calculations can be relatively complicated [e.g., solving a linear programming (LP) or quadratic programming (QP) problem at each sampling instant] and thus require a significant amount of computer resources and effort. These optimization strategies are described in the next section.
3. The development of a dynamic model from plant data is time-consuming, typically requiring days, or even weeks, of around-the-clock plant tests.
4. Because empirical models are generally used, they are valid only over the range of conditions considered during the plant tests.
5. Theoretical studies have demonstrated that MPC can perform poorly for some types of process disturbances, especially when output constraints are employed.

Because MPC has been widely used and has had considerable impact, there is a broad consensus that its advantages far outweigh its disadvantages.

**Economic Incentives for Automation Projects** Industrial applications of advanced process control strategies such as MPC are motivated by the need for improvements regarding safety, product quality, environmental standards, and economic operation of the process. One view of the economics incentives for advanced automation techniques is illustrated in Fig. 8-41. Distributed control systems (DCS) are widely used for data acquisition and conventional single-loop (PID) control. The addition of advanced regulatory control systems such as selective controls, gain scheduling, and time-delay compensation can provide benefits for a modest incremental cost. But

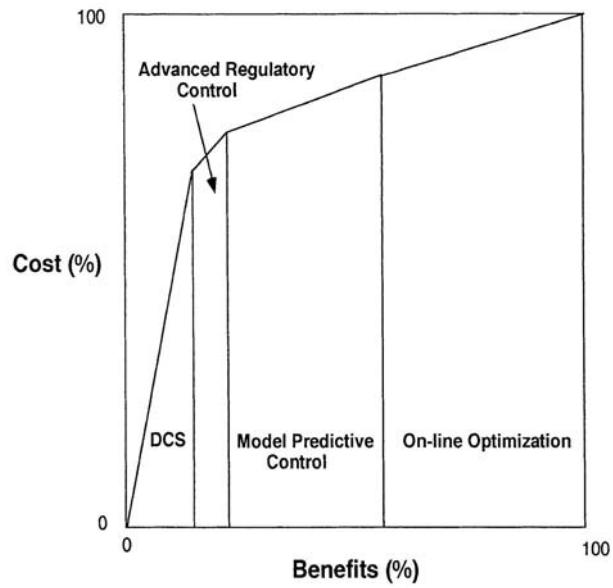

**FIG. 8-41** Economic incentives for automation projects in the process industries.

experience has indicated that the major benefits can be obtained for relatively small incremental costs through a combination of MPC and online optimization. The results in Fig. 8-41 are shown qualitatively, rather than quantitatively, because the actual costs and benefits are application-dependent.

A key reason why MPC has become a major commercial and technical success is that there are numerous vendors who are licensed to market MPC products and install them on a turnkey basis. Consequently, even medium-sized companies are able to take advantage of this new technology. Payout times of 3 to 12 months have been widely reported.

**Basic Features of MPC** Model predictive control strategies have a number of distinguishing features:

1. A dynamic model of the process is used to predict the future outputs over a prediction *horizon* consisting of the next $P$ sampling periods.
2. A reference trajectory is used to represent the desired output response over the prediction horizon.
3. Inequality constraints on the input and output variables can be included as an option.
4. At each sampling instant, a control policy consisting of the next $M$ control moves is calculated. The control calculations are based on minimizing a quadratic or linear performance index over the prediction horizon while satisfying the constraints.
5. The performance index is expressed in terms of future control moves and the predicted deviations from the reference trajectory.
6. A *receding horizon approach* is employed. At each sampling instant, only the first control move (of the $M$ moves that were calculated) is actually implemented.
7. Then the predictions and control calculations are repeated at the next sampling instant.

These distinguishing features of MPC will now be described in greater detail.

***Dynamic Model*** A key feature of MPC is that a dynamic model of the process is used to predict future values of the controlled outputs. There is considerable flexibility concerning the choice of the dynamic model. For example, a physical model based on first principles (e.g., mass and energy balances) or an empirical model developed from data could be employed. Also, the empirical model could be a linear model (e.g., transfer function, step response model, or state space model) or a nonlinear model (e.g., neural net model). However, most industrial applications of MPC have relied on linear empirical models, which may include simple nonlinear transformations of process variables.

The original formulations of MPC (i.e., DMC and IDCOM) were based on empirical linear models expressed in either step response or impulse response form. For simplicity, we consider only a single-input, single-output (SISO) model. However, the SISO model can be easily generalized to the MIMO models that are used in industrial applications. The step response model relating a single controlled variable $y$ and a single manipulated variable $u$ can be expressed as

$$\hat{y}(k+1) = y_0 + \sum_{i=1}^{N-1} S_i \,\Delta u(k-i+1) + S_N u(k-N+1) \qquad (8\text{-}61)$$

where $\hat{y}(k+1)$ is the predicted value of $y$ at the $k+1$ sampling instant, $u(k)$ is the value of the manipulated input at time $k$, and the model parameters $S_i$ are referred to as the *step response coefficients*. The initial value $y_0$ is assumed to be known. The change in the manipulated input from one sampling instant to the next is denoted by

$$\Delta u(k) = u(k) - u(k-1) \qquad (8\text{-}62)$$

The step response model is also referred to as a discrete convolution model.

In principle, the step response coefficients can be determined from the output response to a step change in the input. A typical response to a unit step change in input $u$ is shown in Fig. 8-42. The step response coefficients $S_i$ are simply the values of the output variable at the sampling instants, after the initial value $y_0$ has been subtracted. Theoretically, they can be determined from a single step response, but, in practice, a number of "bump tests" are required to compensate for unanticipated disturbances, process nonlinearities, and noisy measurements.

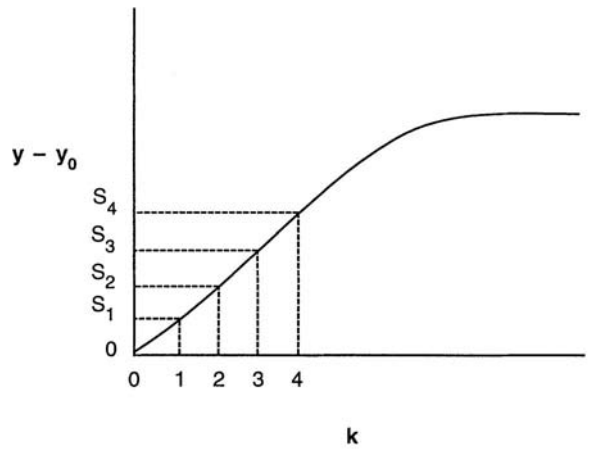

**FIG. 8-42** Step response for a unit step change in the input.

***Horizons*** The step response model in Eq. (8-61) is equivalent to the following impulse response model:

$$\hat{y}(k) = \sum_{i=1}^{N} h_i u(k-i) + y_0 \qquad (8\text{-}63)$$

where the impulse response coefficients $h_i$ are related to the step response coefficients by $h_i = S_i - S_{i-1}$. Step and impulse response models typically contain a large number of parameters because the model horizon $N$ is usually quite large ($30 < N < 120$). In fact, these models are often referred to as nonparametric models.

The receding horizon feature of MPC is shown in Fig. 8-43 with the current sampling instant denoted by $k$. Past and present input signals [$u(i)$ for $i \le k$] are used to predict the output at the next $P$ sampling instants [$y(k+i)$ for $i = 1, 2, \ldots, P$]. The control calculations are performed to generate an $M$-step control policy [$u(k)$, $u(k+1)$, . . . , $u(k+M-1)$], which optimizes a performance index. The first control action $u(k)$ is implemented. Then at the next sampling instant $k+1$, the prediction and control calculations are repeated in order to determine $u(k+1)$. In Fig. 8-43 the reference trajectory (or target) is considered to be constant. Other possibilities include a gradual or step set-point change that can be generated by online optimization.

***Performance Index*** The performance index for MPC applications is usually a linear or quadratic function of the predicted errors and calculated future control moves. For example, the following quadratic performance index has been widely used:

$$\min_{\Delta \mathbf{u}(k)} J = \sum_{i=1}^{P} Q_i e^2(k+i) + \sum_{i=1}^{M} R_i \,\Delta u^2(k+i-1) \qquad (8\text{-}64)$$

The value $e(k+i)$ denotes the predicted error at time $k+i$,

$$e(k+i) = y_{sp}(k+i) - \hat{y}(k+i) \qquad (8\text{-}65)$$

where $y_{sp}(k+i)$ is the set point at time $k+i$ and $\Delta \mathbf{u}(k)$ denotes the column vector of current and future control moves over the next $M$ sampling instants:

$$\Delta \mathbf{u}(k) = [\Delta u(k), \Delta u(k+1), \ldots, \Delta u(k+M-1)]^T \qquad (8\text{-}66)$$

Equation (8-64) contains two types of design parameters that can also be used for tuning purposes. Weighting factor $R_i$ penalizes large control moves, while weighting factor $Q_i$ allows the predicted errors to be weighed differently at each time step, if desired.

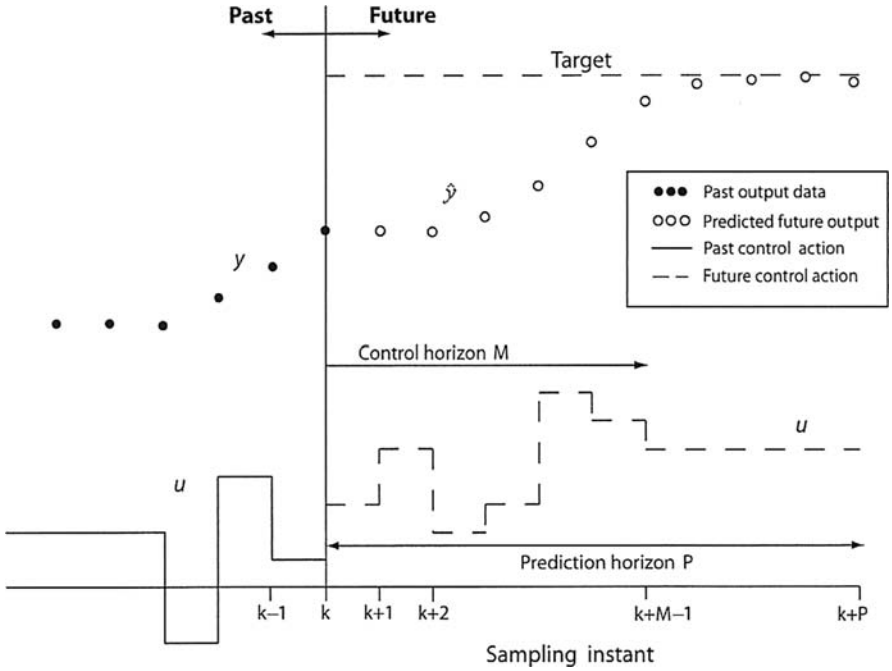

**FIG. 8-43** The "moving horizon" approach of model predictive control. (*Seborg, Edgar, and Mellichamp,* Process Dynamics and Control, *2d ed., Wiley, New York, 2004.*)

***Inequality Constraints*** Inequality constraints on the future inputs or their rates of change are widely used in the MPC calculations. For example, if both upper and lower limits are required, the constraints could be expressed as

$$u^-(k) \le u(k+j) \le u^+(k) \qquad \text{for } j = 0, 1, \ldots, M-1 \qquad (8\text{-}67)$$

$$\Delta u^-(k) \le \Delta u(k+j) \le \Delta u^+(k) \qquad \text{for } j = 0, 1, \ldots, M-1 \qquad (8\text{-}68)$$

where $B_i$ and $C_i$ are constants. Constraints on the predicted outputs are sometimes included as well:

$$y^-(k) \le \hat{y}(k+j) \le y^+(k) \qquad \text{for } j = 0, 1, \ldots, P \qquad (8\text{-}69)$$

The minimization of the quadratic performance index in Eq. (8-64), subject to the constraints in Eqs. (8-67) to (8-69) and the step response model in Eq. (8-61), can be formulated as a standard QP (quadratic programming) problem. Consequently, efficient QP solution techniques can be employed. When the inequality constraints in Eqs. (8-67) to (8-69) are omitted, the optimization problem has an analytical solution (Camacho and Bordons, *Model Predictive Control*, 2d ed., Springer-Verlag, New York, 2004; Maciejowski, *Predictive Control with Constraints*, Prentice-Hall, Upper Saddle River, N.J., 2002). If the quadratic terms in Eq. (8-64) are replaced by linear terms, an LP (linear programming) problem results that can also be solved by using standard methods. This MPC formulation for SISO control problems can easily be extended to MIMO problems.

**Implementation of MPC** For a new MPC application, a cost/benefit analysis is usually performed prior to project approval. Then the steps involved in the implementation of MPC can be summarized as follows (Hokanson and Gerstle, Dynamic Matrix Control Multivariable Controllers, in *Practical Distillation Control*, Luyben (ed.), Van Nostrand Reinhold, New York, 1992, p. 248; Qin and Badgwell, *Control Eng. Practice,* **11:** 773, 2003).

***Step 1: Initial Controller Design*** The first step in MPC design is to select the controlled, manipulated, and measured disturbance variables. These choices determine the structure of the MPC system and should be based on process knowledge and control objectives. In typical applications the number of controlled variables ranges from 5 to 40, and the number of manipulated variables is typically between 5 and 20.

***Step 2: Pretest Activity*** During the pretest activity, the plant instrumentation is checked to ensure that it is working properly and to decide whether additional sensors should be installed. The pretest data can be used to estimate the steady-state gain and approximate settling times for each input/output pair. This information is used to plan the full plant tests of step 3.

As part of the pretest, it is desirable to benchmark the performance of the existing control system for later comparison with MPC performance (step 8).

***Step 3: Plant Tests*** The dynamic model for the MPC calculations is developed from data collected during special plant tests. The excitation for the plant tests usually consists of changing an input variable or a disturbance variable (if possible) from one value to another, using either a series of step changes with different durations or a pseudorandom binary sequence (PRBS). To ensure that sufficient data are obtained for model identification, each input variable is typically moved to a new value, 8 to 15 times during a plant test (Qin and Badgwell, *Control Eng. Practice,* **11:** 773, 2003). Identification during closed-loop operation is becoming more common.

***Step 4: Model Development*** The dynamic model is developed from the plant test data by selecting a model form (e.g., a step response model) and then estimating the model parameters. However, first it is important to eliminate periods of test data where plant upsets or other abnormal situations have occurred. Decisions to omit portions of the test data are based on visual inspection of the data, knowledge of the process, and experience. Parameter estimation is usually based on least squares estimation.

***Step 5: Control System Design and Simulation*** The preliminary control system design from step 1 is critically evaluated and modified, if necessary. Then the MPC design parameters are selected including the sampling periods, weighting factors, and control and prediction horizons. Next, the closed-loop system is simulated, and the MPC design parameters are adjusted, if necessary, to obtain satisfactory control system performance and robustness over the specified range of operating conditions.

***Step 6: Operator Interface Design and Operator Training*** Operator training is important because MPC concepts such as predictive control, multivariable interactions, and constraint handling are very different from conventional regulatory control concepts. Thus, understanding why the MPC system responds the way that it does, especially for unusual operating conditions, can be a challenge for both operators and engineers.

***Step 7: Installation and Commissioning*** After an MPC control system is installed, it is first evaluated in a "prediction mode." Model predictions are compared with measurements, but the process continues to be controlled by the existing control system. After the output predictions are judged to be satisfactory, the calculated MPC control moves are evaluated to determine if they are reasonable. Finally, the MPC software is evaluated during closed-loop operation with the calculated control moves implemented as set points to the DCS control loops. The MPC design parameters are tuned, if necessary. The commissioning period typically requires some troubleshooting and can take as long as, or even longer than, the plant tests of step 3.

***Step 8: Measuring Results and Monitoring Performance*** The evaluation of MPC system performance is not easy, and widely accepted metrics and monitoring strategies are not available. However, useful diagnostic information is provided by basic statistics such as the means and standard deviations for both measured variables and calculated quantities, such as control errors and model residuals. Another useful statistic is the relative amount of time that an input is saturated or a constraint is violated, expressed as a percentage of the total time the MPC system is in service.

**Integration of MPC and Online Optimization** As indicated in Fig. 8-41, significant potential benefits can be realized by using a combination of MPC and online optimization. At present, most commercial MPC packages integrate the two methodologies in a hierarchical configuration such as the one shown in Fig. 8-44. The MPC calculations are performed quite often (e.g., every 1 to 10 min) and implemented as set points for PID control loops at the DCS level. The targets and constraints for the MPC calculations are generated by solving a steady-state optimization problem (LP or QP) based on a linear process model. These calculations may be performed as often as the MPC calculations. As an option, the targets and constraints for the LP or QP optimization can be generated from a nonlinear process model using a nonlinear optimization technique. These calculations tend to be performed less frequently (e.g., every 1 to 24 h) due to the complexity of the calculations and the process models.

The combination of MPC and frequent online optimization has been successfully applied in oil refineries and petrochemical plants around the world.

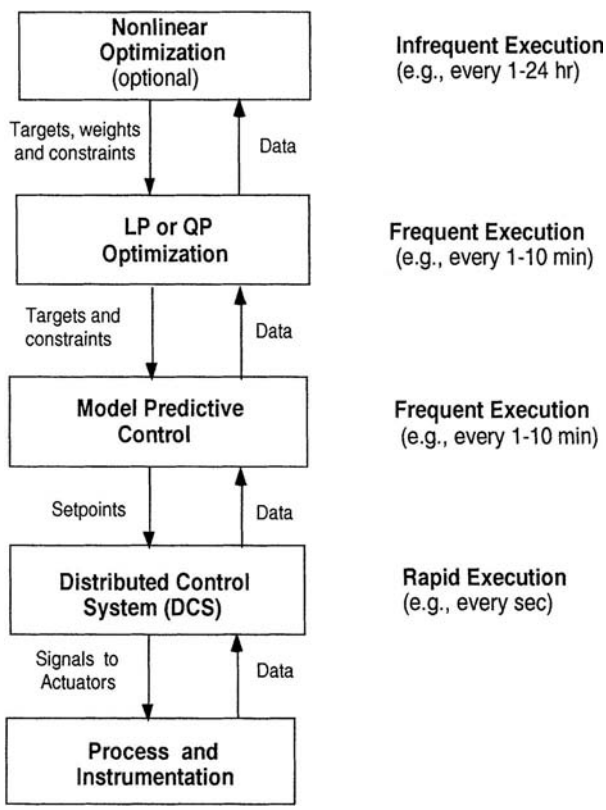

**FIG. 8-44** Hierarchical control configuration for MPC and online optimization.

## REAL-TIME PROCESS OPTIMIZATION

The chemical industry has undergone significant changes during the past 20 years due to the increased cost of energy and raw materials, more stringent environmental regulations, and intense worldwide competition. Modifications of both plant design procedures and plant operating conditions have been implemented to reduce costs and meet constraints. One of the most important engineering tools that can be employed in such activities is optimization. As plant computers have become more powerful, the size and complexity of problems that can be solved by optimization techniques have correspondingly expanded. A wide variety of problems in the operation and analysis of chemical plants (as well as many other industrial processes) can be solved by optimization. Real-time optimization means that the process operating conditions (set points) are evaluated on a regular basis and optimized, as shown earlier in level 4 in Fig. 8-28. Sometimes this is called steady-state optimization or supervisory control. This section examines the basic characteristics of optimization problems and their solution techniques and describes some representative benefits and applications in the chemical and petroleum industries.

Typical problems in chemical engineering process design or plant operation have many possible solutions. Optimization is concerned with selecting the best among the entire set of solutions by efficient quantitative methods. Computers and associated software make the computations involved in the selection manageable and cost-effective. Engineers work to improve the initial design of equipment and strive for enhancements in the operation of the equipment once it is installed in order to realize the greatest production, the greatest profit, the maximum cost, the least energy usage, and so on. In plant operations, benefits arise from improved plant performance, such as improved yields of valuable products (or reduced yields of contaminants), reduced energy consumption, higher processing rates, and longer times between shutdowns. Optimization can also lead to reduced maintenance costs, less equipment wear, and better staff utilization. It is helpful to systematically identify the objective, constraints, and degrees of freedom in a process or a plant if such benefits as improved quality of designs, faster and more reliable troubleshooting, and faster decision making are to be achieved.

Optimization can take place at many levels in a company, ranging from a complex combination of plants and distribution facilities down through individual plants, combinations of units, individual pieces of equipment, subsystems in a piece of equipment, or even smaller entities.

Problems that can be solved by optimization can be found at all these levels.

While process design and equipment specification are usually performed prior to the implementation of the process, optimization of operating conditions is carried out monthly, weekly, daily, hourly, or even every minute. Optimization of plant operations determines the set points for each unit at the temperatures, pressures, and flow rates that are the best in some sense. For example, the selection of the percentage of excess air in a process heater is quite critical and involves a balance on the fuel/air ratio to ensure complete combustion and at the same time make the maximum use of the heating potential of the fuel. Typical day-to-day optimization in a plant minimizes steam consumption or cooling water consumption, optimizes the reflux ratio in a distillation column, or allocates raw materials on an economic basis [Latour, *Hydro. Proc.*, **58**(6): 73, 1979, and **58**(7): 219, 1979].

A real-time optimization (RTO) system determines set-point changes and implements them via the computer control system without intervention from unit operators. The RTO system completes all data transfer, optimization calculations, and set-point implementation before unit conditions change that may invalidate the computed optimum. In addition, the RTO system should perform all tasks without upsetting plant operations. Several steps are necessary for implementation of RTO, including determination of the plant steady state, data gathering and validation, updating of model parameters (if necessary) to match current operations, calculation of the new (optimized) set points, and the implementation of these set points.

To determine if a process unit is at steady state, a program monitors key plant measurements (e.g., compositions, product rates, feed rates, and so on) and determines if the plant is close enough to steady state to start the sequence. Only when all the key measurements are within the allowable tolerances is the plant considered steady and the optimization sequence started. Tolerances for each measurement can be tuned separately. Measured data are then collected by the optimization computer. The optimization system runs a program to screen the measurements for unreasonable data (gross error detection). This validity checking automatically modifies the model updating calculation to reflect any bad data or when equipment is taken out of service. Data validation and reconciliation (online or offline) is an extremely critical part of any optimization system.

The optimization system then may run a parameter-fitting case that updates model parameters to match current plant operation. The integrated process model calculates such items as exchanger heat-transfer coefficients, reactor performance parameters, furnace efficiencies, and heat and material balances for the entire plant. Parameter fitting allows for continual updating of the model to account for plant deviations and degradation of process equipment. After completion of the parameter fitting, the information regarding the current plant constraints, control status data, and economic values for feed products, utilities, and other operating costs is collected. The economic values are updated by the planning and scheduling department on a regular basis. The optimization system then calculates the optimized set points. The steady-state condition of the plant is rechecked after the optimization case is successfully completed. If the plant is still steady, then the values of the optimization targets are transferred to the process control system for implementation. After a line-out period, the process control computer resumes the steady-state detection calculations, restarting the cycle.

**Essential Features of Optimization Problems** The solution of optimization problems involves the use of various tools of mathematics, which is discussed in detail in Sec. 3. The formulation of an optimization problem requires the use of mathematical expressions. From a practical viewpoint, it is important to mesh properly the problem statement with the anticipated solution technique. Every optimization problem contains three essential categories:

1. An objective function to be optimized (revenue function, cost function, etc.)
2. Equality constraints (equations)
3. Inequality constraints (inequalities)

Categories 2 and 3 comprise the model of the process or equipment; category 1 is sometimes called the economic model.

**TABLE 8-6 Six Steps Used to Solve Optimization Problems**

1 Analyze the process itself so that the process variables and specific characteristics of interest are defined (i.e., make a list of all the variables).
2 Determine the criterion for optimization, and specify the objective function in terms of the above variables together with coefficients. This step provides the performance model (sometimes called the economic model, when appropriate).
3 Develop via mathematical expressions a valid process or equipment model that relates the input/output variables of the process and associated coefficients. Include both equality and inequality constraints. Use well-known physical principles (mass balances, energy balances), empirical relations, implicit concepts, and external restrictions. Identify the independent and dependent variables (number of degrees of freedom).
4 If the problem formulation is too large in scope, (*a*) break it up into manageable parts and/or (*b*) simplify the objective function and model.
5 Apply a suitable optimization technique to the mathematical statement of the problem.
6 Check the answers and examine the sensitivity of the result to changes in the coefficients in the problem and the assumptions.

No single method or algorithm of optimization exists that can be applied efficiently to all problems. The method chosen for any particular case will depend primarily on (1) the character of the objective function, (2) the nature of the constraints, and (3) the number of independent and dependent variables. Table 8-6 summarizes the six general steps for the analysis and solution of optimization problems (Edgar, Himmelblau, and Lasdon, *Optimization of Chemical Processes*, 2d ed., McGraw-Hill, New York, 2001). You do not have to follow the cited order exactly, but you should cover all the steps at some level of detail. Shortcuts in the procedure are allowable, and the easy steps can be performed first. Steps 1, 2, and 3 deal with the mathematical definition of the problem: identification of variables, specification of the objective function, and statement of the constraints. If the process to be optimized is very complex, it may be necessary to reformulate the problem so that it can be solved with reasonable effort. Later in this section, we discuss the development of mathematical models for the process and the objective function (the economic model) in typical RTO applications.

Step 5 in Table 8-6 involves the computation of the optimum point. Quite a few techniques exist to obtain the optimal solution for a problem. We describe several classes of methods below. In general, the solution of most optimization problems involves the use of a digital computer to obtain numerical answers. Over the past 15 years, substantial progress has been made in developing efficient and robust computational methods for optimization. Much is known about which methods are most successful. Virtually all numerical optimization methods involve iteration, and the effectiveness of a given technique can depend on a good first guess for the values of the variables at the optimal solution. After the optimum is computed, a sensitivity analysis for the objective function value should be performed to determine the effects of errors or uncertainty in the objective function, mathematical model, or other constraints.

**Development of Process (Mathematical) Models** Constraints in optimization problems arise from physical bounds on the variables, empirical relations, physical laws, and so on. The mathematical relations describing the process also comprise constraints. Two general categories of models exist:

1. Those based on physical theory
2. Those based on strictly empirical descriptions

Mathematical models based on physical and chemical laws (e.g., mass and energy balances, thermodynamics, chemical reaction kinetics) are frequently employed in optimization applications. These models are conceptually attractive because a general model for any system size can be developed before the system is constructed. On the other hand, an empirical model can be devised that simply correlates input/output data without any physiochemical analysis of the process. For these models, optimization is often used to fit a model to process data, using a procedure called parameter estimation. The well-known least squares curve-fitting procedure is based on optimization theory, assuming that the model parameters are contained linearly in the model. One example is the yield matrix, where the percentage yield of each product in a unit operation is estimated for each feed component

by using process data rather than employing a mechanistic set of chemical reactions.

**Formulation of the Objective Function** The formulation of objective functions is one of the crucial steps in the application of optimization to a practical problem. You must be able to translate the desired objective to mathematical terms. In the chemical process industries, the objective function often is expressed in units of currency per unit time (e.g., U.S. dollars per week, month, or year) because the normal industrial goal is to minimize costs or maximize profits subject to a variety of constraints.

A typical economic model involves the costs of raw materials, values of products, and costs of production as functions of operating conditions, projected sales figures, and the like. An objective function can be expressed in terms of these quantities; e.g., annual operating profit ($/yr) might be expressed as

$$J = \sum_N F_s V_s - \sum_r F_r C_r - \text{OC} \tag{8-70}$$

where $J$ = profit/time

$\sum_s F_s V_s$ = sum of product flow rates times respective product values (income)

$\sum_r F_r C_r$ = sum of feed flows times respective unit costs

OC = operating costs/time

**Unconstrained Optimization** *Unconstrained optimization* refers to the case where no inequality constraints are present and all equality constraints can be eliminated by solving for selected dependent variables followed by substitution for them in the objective function. Very few realistic problems in process optimization are unconstrained. However, the availability of efficient unconstrained optimization techniques is important because these techniques must be applied in real time, and iterative calculations may require excessive computer time. Two classes of unconstrained techniques are single-variable optimization and multivariable optimization.

**Single-Variable Optimization** Many real-time optimization problems can be reduced to the variation of a single-variable so as to maximize profit or some other overall process objective function. Some examples of single-variable optimization include optimizing the reflux ratio in a distillation column or the air/fuel ratio in a furnace. While most processes actually are multivariable processes with several operating degrees of freedom, often we choose to optimize only the most important variable in order to keep the strategy uncomplicated. One characteristic implicitly required in a single-variable optimization problem is that the objective function $J$ be unimodal in the variable $x$.

The selection of a method for one-dimensional search is based on the tradeoff between the number of function evaluations and computer time. We can find the optimum by evaluating the objective function at many values of $x$, using a small grid spacing ($\Delta x$) over the allowable range of $x$ values, but this method is generally inefficient. There are three classes of techniques that can be used efficiently for one-dimensional search: indirect, region elimination, and interpolation.

Indirect methods seek to solve the necessary condition $dJ/dx = 0$ by iteration, but these methods are not as popular as the second two classes. Region elimination methods include equal interval search, dichotomous search (or bisecting), Fibonacci search, and golden section. These methods do not use information on the shape of the function (other than its being unimodal) and thus tend to be rather conservative. The third class of techniques uses repeated polynomial fitting to predict the optimum. These interpolation methods tend to converge rapidly to the optimum without being very complicated. Two interpolation methods, quadratic and cubic interpolation, are used in many optimization packages.

**Multivariable Optimization** The numerical optimization of general nonlinear multivariable objective functions requires that efficient and robust techniques be employed. Efficiency is important since iteration is employed. For example, in multivariable "grid" search for a problem with four independent variables, an equally spaced grid for each variable is prescribed. For 10 values of each of the four variables, $10^4$ total function evaluations would be required to find the best answer for the grid intersections, but this result may not be close enough to the true optimum and would require further search. A larger number of variables (say, 20) would require exponentially more computation, so grid search is a very inefficient method for most problems.

In multivariable optimization, the difficulty of dealing with multivariable functions is usually resolved by treating the problem as a series of one-dimensional searches. For a given starting point, a search direction $s$ is specified, and the optimum is found by searching along that direction. The step size $\varepsilon$ is the distance moved along $s$. Then a new search direction is determined, followed by another one-dimensional search. The algorithm used to specify the search direction depends on the optimization method selected.

There are two basic types of unconstrained optimization algorithms: (1) those requiring function derivatives and (2) those that do not. Here we give only an overview and refer the reader to Sec. 3 or the references for more details. The nonderivative methods are of interest in optimization applications because these methods can be readily adapted to the case in which experiments are carried out directly on the process. In such cases, an actual process measurement (such as yield) can be the objective function, and no mathematical model for the process is required. Methods that do not require derivatives are called direct methods and include sequential simplex (Nelder-Meade) and Powell's method. The sequential simplex method is quite satisfactory for optimization with two or three independent variables, is simple to understand, and is fairly easy to execute. Powell's method is more efficient than the simplex method and is based on the concept of conjugate search directions. This class of methods can be used in special cases but is not recommended for optimization involving more than 6 to 10 variables.

The second class of multivariable optimization techniques in principle requires the use of partial derivatives of the objective function, although finite difference formulas can be substituted for derivatives. Such techniques are called indirect methods and include the following classes:

1. Steepest descent (gradient) method
2. Conjugate gradient (Fletcher-Reeves) method
3. Newton's method
4. Quasi-newton methods

The steepest descent method is quite old and utilizes the intuitive concept of moving in the direction in which the objective function changes the most. However, it is clearly not as efficient as the other three. Conjugate gradient utilizes only first-derivative information, as does steepest descent, but generates improved search directions. Newton's method requires second-derivative information but is very efficient, while quasi-newton retains most of the benefits of Newton's method but utilizes only first-derivative information. All these techniques are also used with constrained optimization.

**Constrained Optimization** When constraints exist and cannot be eliminated in an optimization problem, more general methods must be employed than those described above, because the unconstrained optimum may correspond to unrealistic values of the operating variables. The general form of a nonlinear programming problem allows for a nonlinear objective function and nonlinear constraints, or

$$\begin{aligned} &\text{Minimize} && J(x_1, x_2, \ldots, x_n) \\ &\text{Subject to} && h_i(x_1, x_2, \ldots, x_n) = 0 \qquad i = 1, r_c \\ & && g_i(x_1, x_2, \ldots, x_n) > 0 \qquad i = 1, m_c \end{aligned} \tag{8-71}$$

In this case, there are $n$ process variables with $r_c$ equality constraints and $m_c$ inequality constraints. Such problems pose a serious challenge to performing optimization calculations in a reasonable amount of time. Typical constraints in chemical process optimization include operating conditions (temperatures, pressures, and flows have limits), storage capacities, and product purity specifications.

An important class of constrained optimization problems is one in which both the objective function and the constraints are linear. The solution of these problems is highly structured and can be obtained

rapidly. The accepted procedure, linear programming (LP), has become quite popular in the past 20 years, solving a wide range of industrial problems. It is increasingly being used for online optimization. For processing plants, there are several different kinds of linear constraints that may arise, making the LP method of great utility.

1. Production limitation due to equipment throughput restrictions, storage limits, or market constraints
2. Raw material (feedstock) limitation
3. Safety restrictions on allowable operating temperatures and pressures
4. Physical property specifications placed on the composition of the final product. For blends of various products, we usually assume that a composite property can be calculated through the mass-averaging of pure-component physical properties
5. Material and energy balances of the steady-state model

The optimum in linear programming lies at the constraint intersections, which was generalized to any number of variables and constraints by George Dantzig. The simplex algorithm is a matrix-based numerical procedure for which many digital computer codes exist, for both mainframe and microcomputers (Edgar, Himmelblau, and Lasdon, *Optimization of Chemical Processes*, 2d ed., McGraw-Hill, New York, 2001; Nash and Sofer, *Linear and Nonlinear Programming*, McGraw-Hill, New York, 1996). The algorithm can handle virtually any number of inequality constraints and any number of variables in the objective function, and utilizes the observation that only the constraint boundaries need to be examined to find the optimum. In some instances, nonlinear optimization problems even with nonlinear constraints can be linearized so that the LP algorithm can be employed to solve them (called successive linear programming, or SLP). In the process industries, LP and SLP have been applied to a wide range of RTO problems, including refinery scheduling, olefins production, the optimal allocation of boiler fuel, and the optimization of a total plant.

**Nonlinear Programming** The most general case for optimization occurs when both the objective function and the constraints are nonlinear, a case referred to as nonlinear programming. While the ideas behind the search methods used for unconstrained multivariable problems are applicable, the presence of constraints complicates the solution procedure. All the methods discussed below have been utilized to solve nonlinear programming problems in the field of chemical engineering design and operations. Nonlinear programming is now used extensively in the area of real-time optimization.

One of the older and most accessible NLP algorithms uses iterative linearization and is called the *generalized reduced gradient (GRG) algorithm*. The GRG algorithm employs linear or linearized constraints and uses slack variables to convert all constraints to equality constraints. The GRG algorithm is used in the Excel Solver. CONOPT is a reduced gradient algorithm that works well for large-scale problems and nonlinear constraints. CONOPT and GRG work best for problems in which the number of degrees of freedom is small (the number of constraints is nearly equal to the number of variables).

*Successive quadratic programming* (*SQP*) solves a sequence of quadratic programs that approach the solution of the original NLP by linearizing the constraints and using a quadratic approximation to the objective function. Lagrange multipliers are introduced to handle constraints, and the search procedure generally employs some variation of Newton's method, a second-order method that approximates the hessian matrix using first derivatives (Biegler et al., 1997; Edgar et al., 2001). MINOS and NPSOL are software packages that are suitable for problems with large numbers of variables (more variables than equations) and constraints that are linear or nearly linear. *Successive linear programming (SLP)* is used less often for solving RTO problems. It requires linear approximations of both the objective function and the constraints but sometimes exhibits poor convergence to optima that are not located at constraint intersections.

One important class of nonlinear programming techniques is called *quadratic programming (QP)*, where the objective function is quadratic and the constraints are linear. While the solution is iterative, it can be obtained quickly as in linear programming. This is the basis for the newest type of constrained multivariable control algorithms called model predictive control, which is heavily used in the refining industry. See the earlier subsection on model predictive control for more details.

Figure 8-45 gives an overview of which optimization algorithms are appropriate for certain types of RTO problems. Software libraries such as GAMS (General Algebraic Modeling System) or NAG (Numerical Algorithms Group) offer one or more NLP algorithms, but rarely are all algorithms available from a single source. Also there are quite a few good optimization software programs that are free and can be found by a web search. No single NLP algorithm is best for every problem, so several solvers should be tested on a given application. See Edgar, Himmelblau, and Lasdon, *Optimization of Chemical Processes*, McGraw-Hill, New York, 2001.

Linear and nonlinear programming solvers have been interfaced to spreadsheet software for desktop computers. The spreadsheet has become a popular user interface for entering and manipulating numeric data. Spreadsheet software increasingly incorporates analytic tools that are accessible from the spreadsheet interface and permit access to external databases. For example, Microsoft Excel incorporates an optimization-based routine called Solver that operates on the values and formulas of a spreadsheet model. Current versions (4.0 and later) include LP and NLP solvers and mixed integer programming (MIP) capability for both linear and nonlinear problems. The user specifies a set of cell addresses to be independently adjusted (the decision variables), a set of formula cells whose values are to be constrained (the constraints), and a formula cell designated as the optimization objective.

Referring to Fig. 8-30, the highest level of process control, planning and scheduling, also employs optimization extensively, often with variables that are integer. Level 5 sets production goals to meet supply and logistics constraints and addresses time-varying capacity and workforce utilization decisions. Enterprise resource planning (ERP) and supply chain management (SCM) in level 5 refer to the links in a web of relationships involving retailing (sales), distribution, transportation, and manufacturing. Planning and scheduling usually operate over relatively long time scales and tend to be decoupled from the rest of the activities in lower levels. For example, all of the refineries owned by an oil company are usually included in a comprehensive planning and scheduling model. This model can be optimized to obtain target levels and prices for interrefinery transfers, crude oil and product allocations to each refinery, production targets, inventory targets, optimal operating conditions, stream allocations, and blends for each refinery.

Some planning and scheduling problems are mixed-integer optimization problems that involve both continuous and integer problems; whether or not to operate or use a piece of equipment is a binary (on/off) decision that arises in batch processing. Solution techniques for this type of problem include branch and bound methods and global search. This latter approach handles very complex problems with multiple optima by using algorithms such as tabu search, scatter search, simulated annealing, and genetic evolutionary algorithms (see Edgar, Himmelblau, and Lasdon).

## STATISTICAL PROCESS CONTROL

In industrial plants, large numbers of process variables must be maintained within specified limits in order for the plant to operate properly. Excursions of key variables beyond these limits can have significant consequences for plant safety, the environment, product quality, and plant profitability. *Statistical process control* (*SPC*), also called *statistical quality control* (*SQC*), involves the application of statistical techniques to determine whether a process is operating normally or abnormally. Thus, SPC is a process monitoring technique that relies on *quality control charts* to monitor measured variables, especially product quality.

The basic SPC concepts and control chart methodology were introduced by Walter Shewhart in the 1930s. The current widespread interest in SPC techniques began in the 1950s when they were successfully applied first in Japan and then elsewhere. Control chart methodologies are now widely used to monitor product quality and other variables that are measured infrequently or irregularly. The basic SPC methodology is described in introductory statistics textbooks (e.g., Montgomery and Runger, *Applied Statistics and Probability for Engineers,* 3d ed., Wiley, New York, 2002) and some process control textbooks (e.g., Seborg, Edgar, and Mellichamp, *Process Dynamics and Control,* 2d ed., Wiley, New York, 2004).

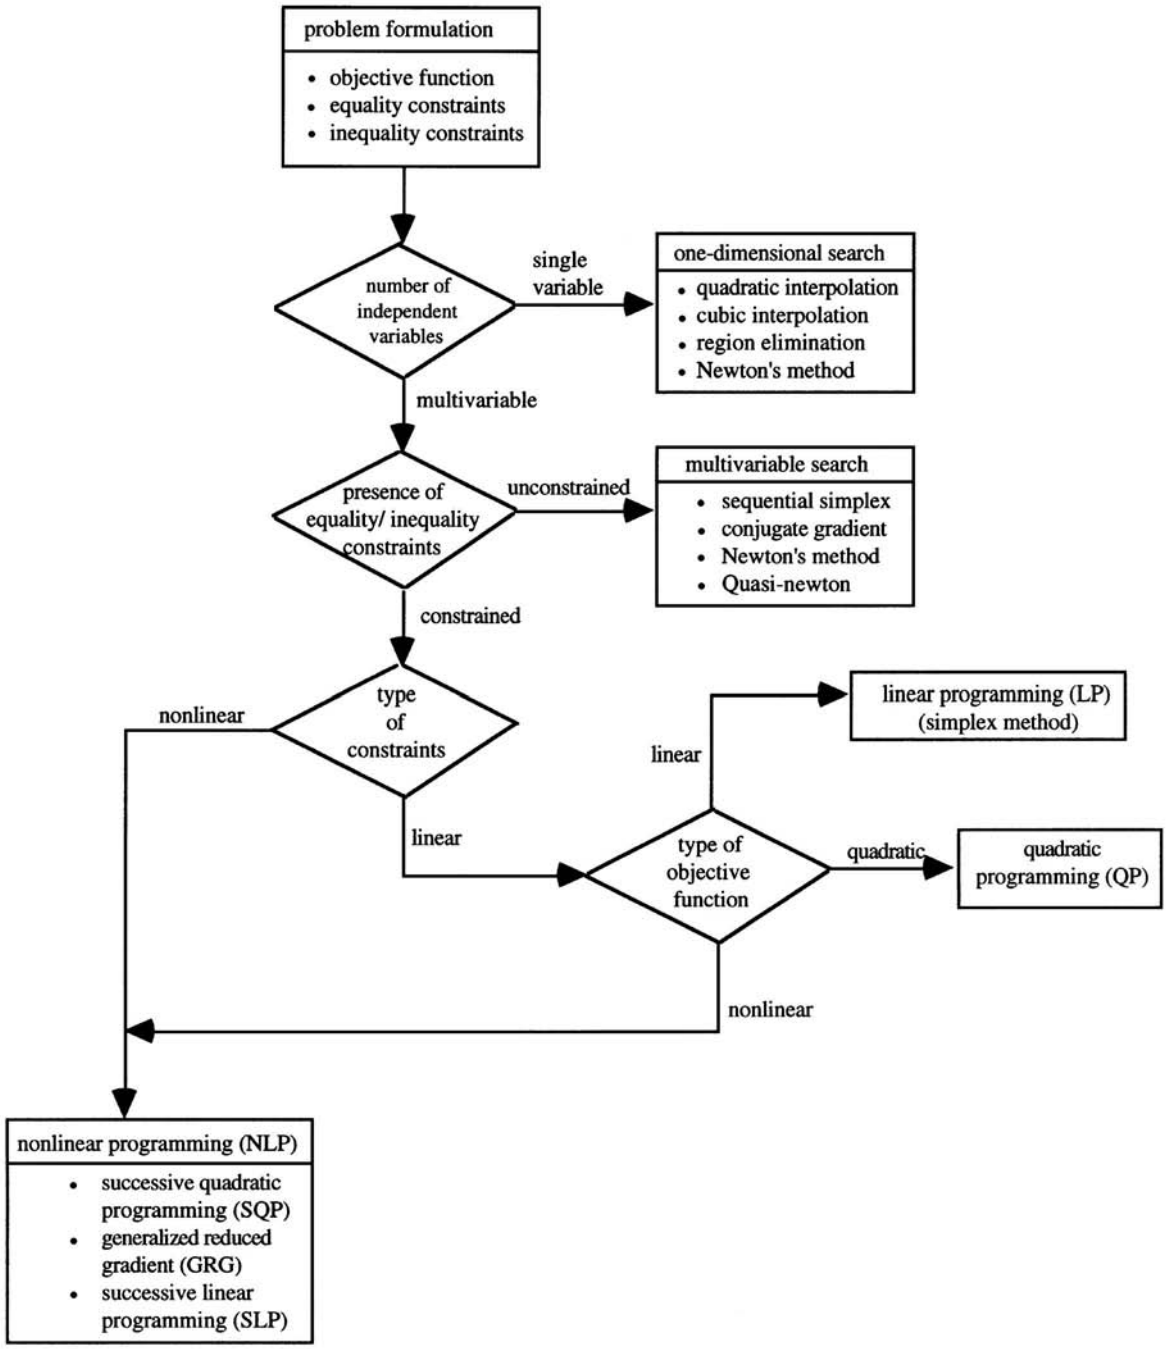

**FIG. 8-45** Diagram for selection of optimization techniques with algebraic constraints and objective function.

An example of the most common control chart, the Shewhart chart, is shown in Fig. 8-46. It merely consists of measurements plotted versus sample number with control limits that indicate the range for normal process operation. The plotted data are either an individual measurement $x$ or the sample mean $\bar{x}$ if more than one sample is measured at each sampling instant. The sample mean for $k$ samples is calculated as,

$$\bar{x} = \frac{1}{n}\sum_{j=1}^{n} x_j \tag{8-72}$$

The Shewhart chart in Fig. 8-46 has a *target (T),* an *upper control limit* (UCL), and a *lower control limit* (LCL). The target (or centerline) is the

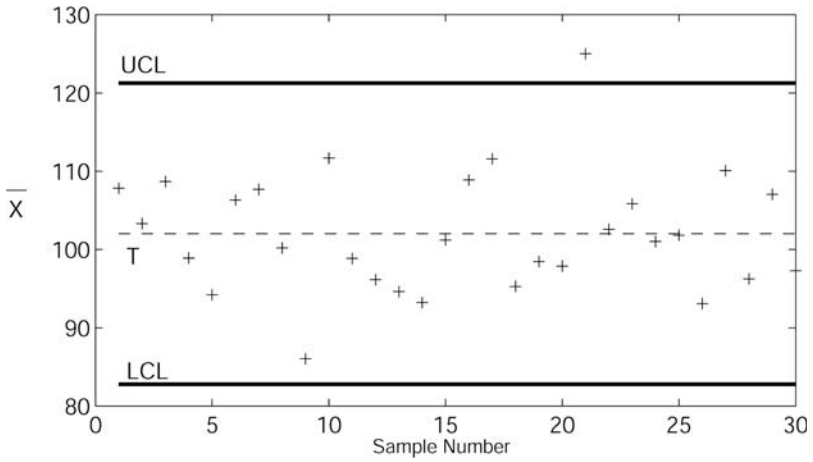

**FIG. 8-46** Shewhart chart for sample mean $\bar{x}$. (*Source: Seborg et al.,* Process Dynamics and Control, *2d ed., Wiley, New York, 2004.*)

desired (or expected) value for $\bar{x}$ while the region between UCL and LCL defines the range of normal variability. If all the $\bar{x}$ data are within the control limits, the process operation is considered to be normal or "in a state of control." Data points outside the control limits are considered to be abnormal, indicating that the process operation is out of control. This situation occurs for the 21st sample. A single measurement slightly beyond a control limit is not necessarily a cause for concern. But frequent or large chart violations should be investigated to determine the root cause.

The major objective in SPC is to use process data and statistical techniques to determine whether the process operation is normal or abnormal. The SPC methodology is based on the fundamental assumption that normal process operation can be characterized by random variations around a mean value. The random variability is caused by the cumulative effects of a number of largely unavoidable phenomena such as electrical measurement noise, turbulence, and random fluctuations in feedstock or catalyst preparation. If this situation exists, the process is said to be *in a state of statistical control* (or *in control*), and the control chart measurements tend to be normally distributed about the mean value. By contrast, frequent control chart violations would indicate abnormal process behavior or an *out-of-control* situation. Then a search would be initiated to attempt to identify the *assignable cause* or the *special cause* of the abnormal behavior

The control limits in Fig. 8-46 (UCL and LCL) are based on the assumption that the measurements follow a normal distribution. Figure 8-47 shows the probability distribution for a normally distributed random variable $x$ with mean $\mu$ and standard deviation $\sigma$. There is a very high probability (99.7 percent) that any measurement is within 3 standard deviations of the mean. Consequently, the control limits for $x$ are typically chosen to be $T \pm 3\hat{\sigma}$, where $\hat{\sigma}$ is an estimate of $\sigma$. This estimate is usually determined from a set of representative data for a period of time when the process operation is believed to be typical. For the common situation in which the plotted variable is the sample mean, its standard deviation is estimated.

Shewhart control charts enable average process performance to be monitored, as reflected by the sample mean. It is also advantageous to monitor process variability. Process variability within a sample of $k$ measurements can be characterized by its range, standard deviation, or sample variance. Consequently, control charts are often used for one of these three statistics.

**Western Electric Rules** Shewhart control charts can detect abnormal process behavior by comparing individual measurements with control chart limits. But the pattern of measurements can also provide useful information. For example, if 10 consecutive measurements are all increasing, then it is very unlikely that the process is in a

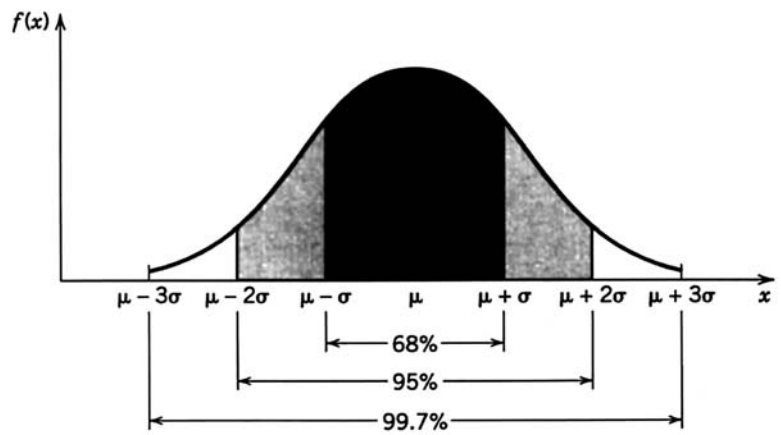

**FIG. 8-47** Probabilities associated with the normal distribution. (*Source: Montgomery and Runger,* Applied Statistics and Probability for Engineers, *3d ed., Wiley, New York, 2002.*)

state of control. A wide variety of *pattern tests* (also called *zone rules*) can be developed based on the properties of the normal distribution. For example, the following excerpts from the *Western Electric Rules* (Western Electric Company, *Statistical Quality Control Handbook*, Delmar Printing Company, Charlotte, N.C., 1956; Montgomery and Runger, *Applied Statistics and Probability for Engineers*, 3d ed., Wiley, New York, 2002) indicate that the process is out of control if one or more of the following conditions occur:

1. One data point outside the 3σ control limits
2. Two out of three consecutive data points beyond a 2σ limit
3. Four out of five consecutive data points beyond a 1σ limit and on one side of the centerline
4. Eight consecutive points on one side of the centerline

Note that the first condition is the familiar Shewhart chart limits. Pattern tests can be used to augment Shewhart charts. This combination enables out-of-control behavior to be detected earlier, but the false-alarm rate is higher than that for Shewhart charts alone.

**CUSUM Control Charts** Although Shewhart charts with 3σ limits can quickly detect large process changes, they are ineffective for small, sustained process changes (e.g., changes smaller than 1.5σ). Alternative control charts have been developed to detect small changes such as the CUSUM control chart. They are often used in conjunction with Shewhart charts. The *cumulative sum* (*CUSUM*) is defined to be a running summation of the deviations of the plotted variable from its target. If the sample mean is plotted, the cumulative sum at sampling instant $k$, $C(k)$, is

$$C(k) = \sum_{j=1}^{k} [\bar{x}(j) - T] \tag{8-73}$$

where $T$ is the target for $\bar{x}$. During normal process operation, $C(k)$ fluctuates about zero. But if a process change causes a small shift in $\bar{x}$, $C(k)$ will drift either upward or downward.

The CUSUM control chart was originally developed using a graphical approach based on *V masks*. However, for computer calculations, it is more convenient to use an equivalent algebraic version that consists of two recursive equations

$$C^+(k) = \max[0, \bar{x}(k) - (T + K) + C^+(k-1)] \tag{8-74}$$

$$C^-(k) = \max[0, (T - K) - \bar{x}(k) + C^-(k-1)] \tag{8-75}$$

where $C^+$ and $C^-$ denote the sums for the high and low directions, and $K$ is a constant, the *slack parameter*. The CUSUM calculations are initialized by setting $C^+(0) = C - 0 = 0$. A deviation from the target that is larger than $K$ increases either $C^+$ or $C^-$. A control limit violation occurs when either $C^+$ or $C^-$ exceeds a specified control limit (or *threshold*) $H$. After a limit violation occurs, that sum is reset to zero or to a specified value.

The selection of the threshold $H$ can be based on considerations of *average run length (ARL)*, the average number of samples required to detect a disturbance of specified magnitude. For example, suppose that the objective is to be able to detect if the sample mean $\bar{x}$ has shifted from the target by a small amount δ. The slack parameter $K$ is usually specified as $K = 0.5\delta$. For the ideal situation (e.g., normally distributed, uncorrelated disturbances), ARL values have been tabulated for different values of δ, $K$, and $H$. Table 8-7 summarizes ARL values for two values of $H$ and different values of δ. (The values of δ are usually expressed as multiples of the standard deviation σ.) The ARL values indicate the average number of samples before a change of δ is detected. Thus the ARL values for $\delta = 0$ indicate the average time between false alarms, i.e., the average time between successive CUSUM alarms when no shift in $\bar{x}$ has occurred. Ideally, we would like the ARL value to be very large for $\delta = 0$ and small for $\delta \neq 0$. Table 8-7 shows that as the magnitude of the shift δ increases, ARL decreases and thus the CUSUM control chart detects the change faster. Increasing the value of $H$ from 4σ to 5σ increases all the ARL values and thus provides a more conservative approach.

**TABLE 8-7 Average Run Lengths for CUSUM Control Charts**

| Shift from target (in multiples of $\sigma$) | ARL for $H = 4\sigma$ | ARL for $H = 5\sigma$ |
|---|---|---|
| 0 | 168. | 465. |
| 0.25 | 74.2 | 139. |
| 0.50 | 26.6 | 38.0 |
| 0.75 | 13.3 | 17.0 |
| 1.00 | 8.38 | 10.4 |
| 2.00 | 3.34 | 4.01 |
| 3.00 | 2.19 | 2.57 |

Adapted from Ryan, *Statistical Methods for Quality Improvement*, 2d ed., Wiley, New York, 2000.

The relative performance of the Shewhart and CUSUM control charts is compared in Fig. 8-48 for a set of simulated data for the tensile strength of a resin. It is assumed that the tensile strength $x$ is normally distributed with a mean of $\mu = 70$ MPa and a standard deviation of $\sigma = 3$ MPa. A single measurement is available at each sampling instant. A constant ($\sigma = 0.5\sigma = 1.5$) was added to $x(k)$ for $k \geq 10$ in order to evaluate each chart's ability to detect a small process shift. The CUSUM chart was designed using $K = 0.5\sigma$ and $H = 5\sigma$.

The Shewhart chart fails to detect the 0.5σ shift in $x$ at $k = 10$. But the CUSUM chart quickly detects this change because a limit violation occurs at $k = 20$. The mean shift can also be detected by applying the Western Electric Rules in the previous section.

**Process Capability Indices** Also known as *process capability ratios*, these provide a measure of whether an in-control process is meeting its product specifications. Suppose that a quality variable $x$ must have a volume between an *upper specification limit (USL)* and a *lower specification limit (LSL)* in order for product to satisfy customer requirements. The *capability index* $C_p$ is defined as

$$C_p = \frac{USL - \text{LSL}}{6\sigma} \tag{8-76}$$

where σ is the standard deviation of $x$. Suppose that $C_p = 1$ and $x$ is normally distributed. Based on the normal distribution, we would expect that 99.7 percent of the measurements satisfy the specification limits, or equivalently, we would expect that only 2700 out of 1 million measurements would lie outside the specification limits. If $C_p < 1$, the product specifications are satisfied; for $C_p > 1$, they are not. However, capability indices are applicable even when the data are not normally distributed.

A second capability index $C_{pk}$ is based on average process performance $\bar{x}$ as well as process variability σ. It is defined as

$$C_{pk} = \frac{\text{Min}[\bar{x} - \text{LSL}, \text{USL} - \bar{x}]}{3\sigma} \tag{8-77}$$

Although both $C_p$ and $C_{pk}$ are used, we consider $C_{pk}$ to be superior to $C_p$ for the following reason. If $\bar{x} = T$, the process is said to be "centered" and $C_{pk} = C_p$. But for $\bar{x} \neq T$, $C_p$ does not change, even though the process performance is worse, while $C_{pk}$ does decrease. For this reason, $C_{pk}$ is preferred.

If the standard deviation σ is not known, it is replaced by an estimate $\hat{\sigma}$ in Eqs. (8-76) and (8-77). For situations where there is only a single specification limit, either USL or LSL, the definitions of $C_p$ and $C_{pk}$ can be modified accordingly.

In practical applications, a common objective is to have a capability index of 2.0 while a value greater than 1.5 is considered to be acceptable. If the $C_{pk}$ value is too low, it can be improved by making a change that either reduces process variability or causes $\bar{x}$ to move closer to the target. These improvements can be achieved in a number of ways that include better process control, better process maintenance, reduced variability in raw materials, improved operator training, and process changes.

**Six-Sigma Approach** Product quality specifications continue to become more stringent as a result of market demands and intense worldwide competition. Meeting quality requirements is especially difficult for products that consist of a very large number of components and for manufacturing processes that consist of hundreds of individual steps. For example, the production of a microelectronic device typically requires 100 to 300 batch processing steps. Suppose

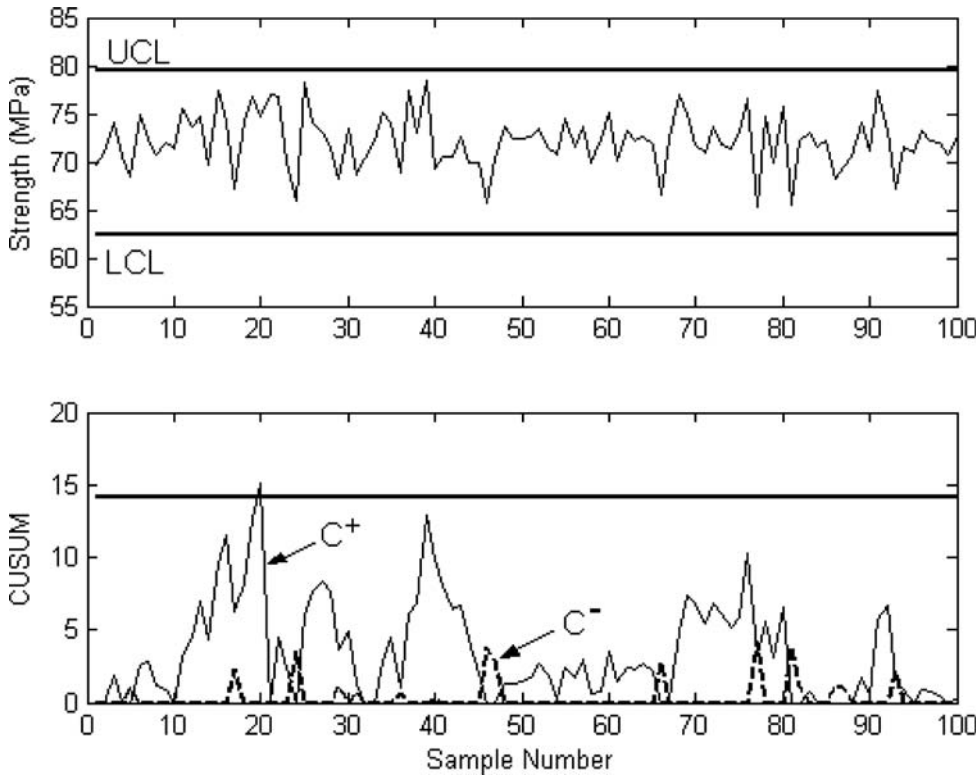

**FIG. 8-48** Comparison of Shewhart and CUSUM control charts for the resin example. (*Source: Seborg et al.,* Process Dynamics and Control, *2d ed., Wiley, New York, 2004.*)

that there are 200 steps and that each one must meet a quality specification for the final product to function properly. If each step is independent of the others and has a 99 percent success rate, the overall yield of satisfactory product is $(0.99)^{200} = 0.134$, or only 13.4 percent. This low yield is clearly unsatisfactory. Similarly, even when a processing step meets $3\sigma$ specifications (99.73 percent success rate), it will still result in an average of 2700 "defects" for every 1 million produced. Furthermore, the overall yield for this 200-step process is still only 58.2 percent.

The six-sigma approach was pioneered by the Motorola Corporation in the early 1980s as a strategy for achieving both six-sigma quality and continuous improvement. Since then, other large corporations have adopted companywide programs that apply the six-sigma approach to all their business operations, both manufacturing and nonmanufacturing. Thus, although the six-sigma approach is "data-driven" and based on statistical techniques, it has evolved into a broader management philosophy that has been implemented successfully by many large corporations. The six-sigma programs have also had a significant financial impact.

**Multivariate Statistical Techniques** For common SPC monitoring problems, two or more quality variables are important, and they can be highly correlated. For these situations, multivariable (or *multivariate)* SPC techniques can offer significant advantages over the single-variable methods discussed earlier. Multivariate monitoring based on the classical Hotelling's $T^2$ statistic (Montgomery, *Introduction to Statistical Quality Control,* 4th ed., Wiley, New York, 2001) can be effective if the data are not highly correlated and the number of variables $p$ is not large (for example, $p < 10$). Fortunately, alternative multivariate monitoring techniques such as *principal-component analysis* (*PCA*) and *partial least squares* (*PLS*) methods have been developed that are very effective for monitoring problems with large numbers of variables and highly correlated data [Piovoso and Hoo (eds.), Special Issue of *IEEE Control Systems Magazine*, **22**(5), 2002].

# UNIT OPERATIONS CONTROL

## PIPING AND INSTRUMENTATION DIAGRAMS

**General References:** Shinskey, *Process Control Systems*, 4th ed., McGraw-Hill, New York, 1996. Luyben, *Practical Distillation Control*, Van Nostrand Reinhold, New York, 1992. Luyben, Tyreus, and Luyben, *Plantwide Process Control*, McGraw-Hill, New York, 1998.

The piping and instrumentation (P&I) diagram provides a graphical representation of the control configuration of the process. P&I diagrams illustrate the measuring devices that provide inputs to the control strategy, the actuators that will implement the results of the control calculations, and the function blocks that provide the control logic. They may also include piping details such as line sizes and the location of hand valves and condensate traps.

The symbology for drawing P&I diagrams generally follows standards developed by the Instrumentation, Systems, and Automation Society (ISA). The chemicals, refining, and food industries generally follow this standard. The standards are updated from time to time, primarily because the continuing evolution in control system hardware and software provides additional capabilities for implementing

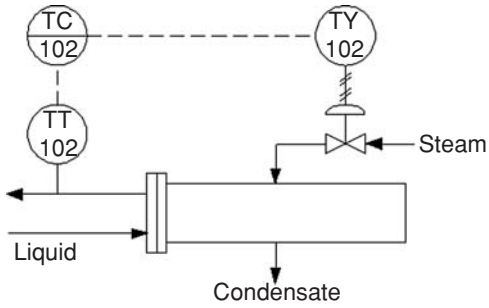

**FIG. 8-49** Example of a simplified piping and instrumentation diagram.

control schemes. The ISA symbols are simple and represent a device or function as a circle containing its tag number and identifying the type of variable being controlled, e.g., pressure, and the function performed, e.g., control: PC-105. Examples of extensions of the ISA standard appear on the pages following.

Figure 8-49 presents a simplified P&I diagram for a temperature control loop that applies the ISA symbology. The measurement devices and most elements of the control logic are shown as circles:

1. TT102 is the temperature transmitter.
2. TC102 is the temperature controller.
3. TY102 is the current-to-pneumatic (I/P) transducer.

The symbol for the control valve in Fig. 8-49 is for a pneumatic modulating valve without a valve positioner.

Electronic (4- to 20-mA) signals are represented by dashed lines. In Fig. 8-49, these include the signal from the transmitter to the controller and the signal from the controller to the I/P transducer. Pneumatic signals are represented by solid lines with double crosshatching at regular intervals. The signal from the I/P transducer to the valve actuator is pneumatic.

The ISA symbology provides different symbols for different types of actuators. Furthermore, variations for the controller symbol distinguish control algorithms implemented in distributed control systems from those in panel-mounted single-loop controllers.

## CONTROL OF HEAT EXCHANGERS

**Steam-Heated Exchangers** Steam, the most common heating medium, transfers its latent heat in condensing, causing heat flow to be proportional to steam flow. Thus a measurement of steam flow is essentially a measure of heat transfer. Consider raising a liquid from temperature $T_1$ to $T_2$ by condensing steam:

$$Q = WH = MC(T_2 - T_1) \tag{8-78}$$

where $W$ and $H$ are the mass flow of steam and its latent heat, $M$ and $C$ are the mass flow and specific heat of the liquid, and $Q$ is the rate of heat transfer. The response of controlled temperature to steam flow is linear:

$$\frac{dT_2}{dW} = \frac{H}{MC} \tag{8-79}$$

However, the steady-state process gain described by this derivative varies inversely with liquid flow: adding a given increment of heat flow to a smaller flow of liquid produces a greater temperature rise.

Dynamically, the response of liquid temperature to a step in steam flow is that of a distributed lag, shown in Fig. 8-26 (uncontrolled). The time required to reach 63 percent complete response, $\Sigma\tau$, is essentially the residence time of the fluid in the exchanger, which is its volume divided by its flow. The residence time then varies inversely with flow. Table 8-2 gives optimum settings for PI and PID controllers for distributed lags, the proportional band varying directly with steady-state gain, and integral and derivative settings directly with $\Sigma\tau$. Since both these parameters vary inversely with liquid flow, fixed settings for the temperature controller are optimal at only one flow rate.

The variability of the process parameters with flow causes variability in load response, as shown in Fig. 8-50. The PID controller was tuned for optimum (minimum-IAE) load response at 50 percent flow. Each curve represents the response of exit temperature to a 10 percent step in liquid flow, culminating at the stated flow. The 60 percent curve is overdamped and the 40 percent curve is underdamped. The differences in gain are reflected in the amplitude of the deviation, and the differences in dynamics are reflected in the period of oscillation.

If steam flow is linear with controller output, as it is in Fig. 8-50, undamped oscillations will be produced when the flow decreases by

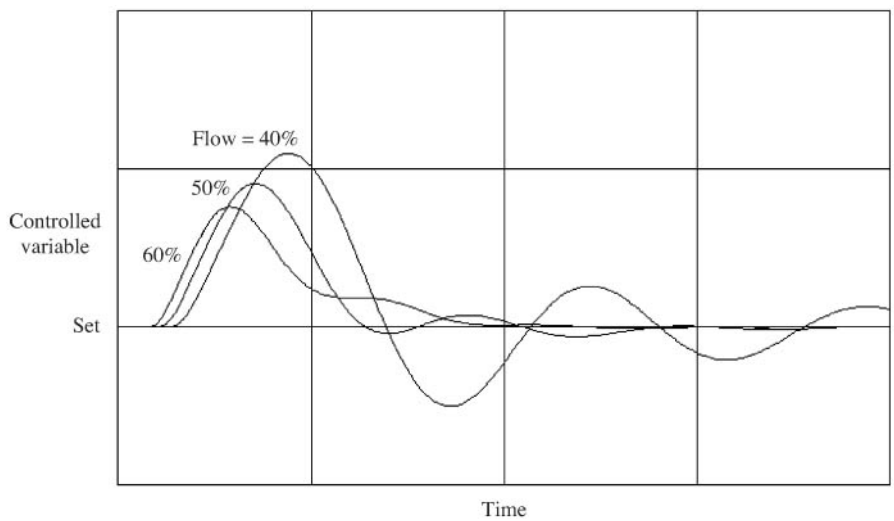

**FIG. 8-50** The response of a heat exchanger varies with flow in both gain and dynamics; here the PID temperature controller was tuned for optimum response at 50 percent flow.

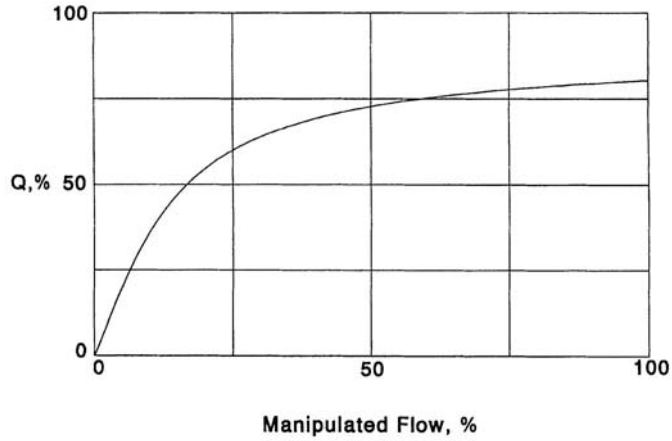

**FIG. 8-51** Heat-transfer rate in sensible-heat exchange varies nonlinearly with flow of the manipulated fluid, requiring equal-percentage valve characterization.

one-third from the value at which the controller was optimally tuned—in this example at 33 percent flow. The stable operating range can be extended to one-half the original flow by using an equal-percentage (logarithmic) steam valve, whose gain varies directly with steam flow, thereby compensating for the variable process gain. Further extension requires increasing the integral setting and reducing the derivative setting from their optimum values. The best solution is to adapt all three PID settings to change inversely with measured flow, thereby keeping the controller optimally tuned for all flow rates.

Feedforward control can also be applied, as described previously under "Advanced Control Techniques." The feedforward system solves Eq. (8-78) for the manipulated set point to the steam flow controller, first by subtracting inlet temperature $T_1$ from the output of the outlet temperature controller (in place of $T_2$), and then by multiplying the result by the dynamically compensated liquid flow measurement. If the inlet temperature is not subject to rapid or wide variation, it can be left out of the calculation. Feedforward is capable of a reduction in integrated error as much as a 100-fold, but requires the use of a steam flow loop and lead-lag compensator to approach this effectiveness. Multiplication of the controller output by liquid flow varies the feedback loop gain directly proportional to flow, extending the stable operating range of the feedback loop much as the equal-percentage steam valve did without feedforward. (This system is eminently applicable to control of fired heaters in oil refineries, which commonly provide a circulating flow of hot oil to several distillation columns and are therefore subject to frequent disturbances).

Steam flow is sometimes controlled by manipulating a valve in the condensate line rather than the steam line, because it is smaller and hence less costly. Heat transfer then is changed by raising or lowering the level of condensate flooding the heat-transfer surface, an operation that is slower than manipulating a steam valve. Protection also needs to be provided against an open condensate valve blowing steam into the condensate system.

**Exchange of Sensible Heat** When there is no change in phase, the rate of heat transfer is no longer linear with the flow of the manipulated stream, but is a function of the mean temperature difference $\Delta T_m$:

$$Q = UA\,\Delta T_m = M_H C_H (T_{H1} - T_{H2}) = M_C C_C (T_{C2} - T_{C1}) \quad (8\text{-}79a)$$

where $U$ and $A$ are the overall heat-transfer coefficient and area and subscripts $H$ and $C$ refer to the hot and cold fluids, respectively. An example would be a countercurrent cooler, where the hot-stream outlet temperature is controlled. Using the logarithmic mean temperature difference and solving for $T_{H2}$ give

$$T_{H2} = T_{C1} + (T_{H1} - T_{C1}) \frac{1 - M_H C_H / M_C C_C}{\varepsilon - M_H C_H / M_C C_C} \quad (8\text{-}79b)$$

where

$$\varepsilon = \exp\left[-UA\left(\frac{1}{M_C C_C} - \frac{1}{M_H C_H}\right)\right] \quad (8\text{-}79c)$$

At a given flow of hot fluid, the heat-transfer rate is plotted as a function of coolant flow in Fig. 8-51, as a percentage of its maximum value (corresponding to $T_{C2} = T_{C1}$). The extreme nonlinearity of this relationship requires the use of an equal-percentage coolant valve for gain compensation. The variable dynamics of the distributed lag also apply, limiting the stable operating range in the same way as for the steam-heated exchanger.

Sensible-heat exchangers are also subject to variations in the temperature of the manipulated stream, an increasingly common problem where heat is being recovered at variable temperatures for reuse. Figure 8-52 shows a temperature controller (TC) setting a heat flow controller (QC) in cascade. A measurement of the manipulated flow is multiplied by its temperature difference across the heat exchanger to calculate the current heat-transfer rate, by using the right side of Eq. (8-78). Variations in supply temperature then appear as variations in calculated heat-transfer rate, which the QC can quickly correct by adjusting the manipulated flow. An equal-percentage valve is still required to linearize the secondary loop, but the primary loop of temperature-setting heat flow is linear. Feedforward can be added by multiplying the dynamically compensated flow measurement of the other fluid by the output of the temperature controller.

When a stream is manipulated whose flow is independently determined, such as the flow of a product or of a heat-transfer fluid from a fired heater, a three-way valve is used to divert the required flow to the heat exchanger. This does not alter the linearity of the process or its sensitivity to supply variations, and it even adds the possibility of independent flow variations. The three-way valve should have equal-percentage characteristics, and heat flow control may be even more beneficial.

## DISTILLATION COLUMN CONTROL

Distillation columns have four or more closed loops—increasing with the number of product streams and their specifications—all of which interact with one another to some extent. Because of this interaction, there are many possible ways to pair manipulated and controlled variables through controllers and other mathematical functions, with widely differing

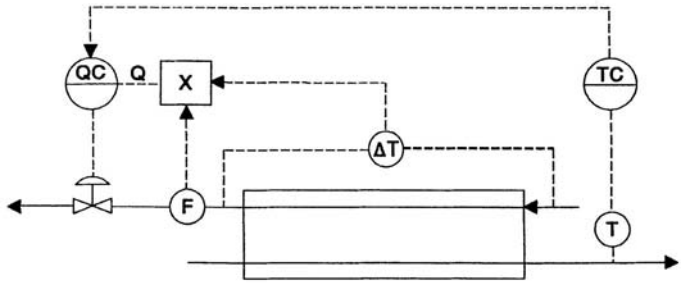

**FIG. 8-52** Manipulating heat flow linearizes the loop and protects against variations in supply temperature.

degrees of effectiveness. Columns also differ from one another, so that no single rule of configuring control loops can be applied successfully to all. The following rules apply to the most common separations.

**Controlling Quality of a Single Product** If one of the products of a column is far more valuable than the other(s), its quality should be controlled to satisfy given specifications, and its recovery should be maximized by minimizing losses of its principal component in other streams. This is achieved by maximizing the reflux ratio consistent with flooding limits on trays, which means maximizing the flow of internal reflux or vapor, whichever is limiting. The same rule should be followed when heating and cooling have little value. A typical example is the separation of high-purity propylene from much lower-valued propane, usually achieved with the waste heat of quench water from the cracking reactors.

The most important factor affecting product quality is the material balance. In separating a feed stream $F$ into distillate $D$ and bottom $B$ products, an overall mole flow balance must be maintained

$$F = D + B \tag{8-80}$$

as well as a balance on each component

$$Fz_i = Dy_i + Bx_i \tag{8-81}$$

where $z$, $y$, and $x$ are mole fractions of component $i$ in the respective streams. Combining these equations gives a relationship between the composition of the products and their relative portion of the feed:

$$\frac{D}{F} = 1 - \frac{B}{F} = \frac{z_i - x_i}{y_i - x_i} \tag{8-82}$$

From the above, it can be seen that control of either $x_i$ or $y_i$ requires both product flow rates to change with feed rate and feed composition.

Figure 8-53 shows a propylene-propane fractionator controlled at maximum boil-up by the differential pressure controller (DPC) across the trays. This loop is fast enough to reject upsets in the temperature

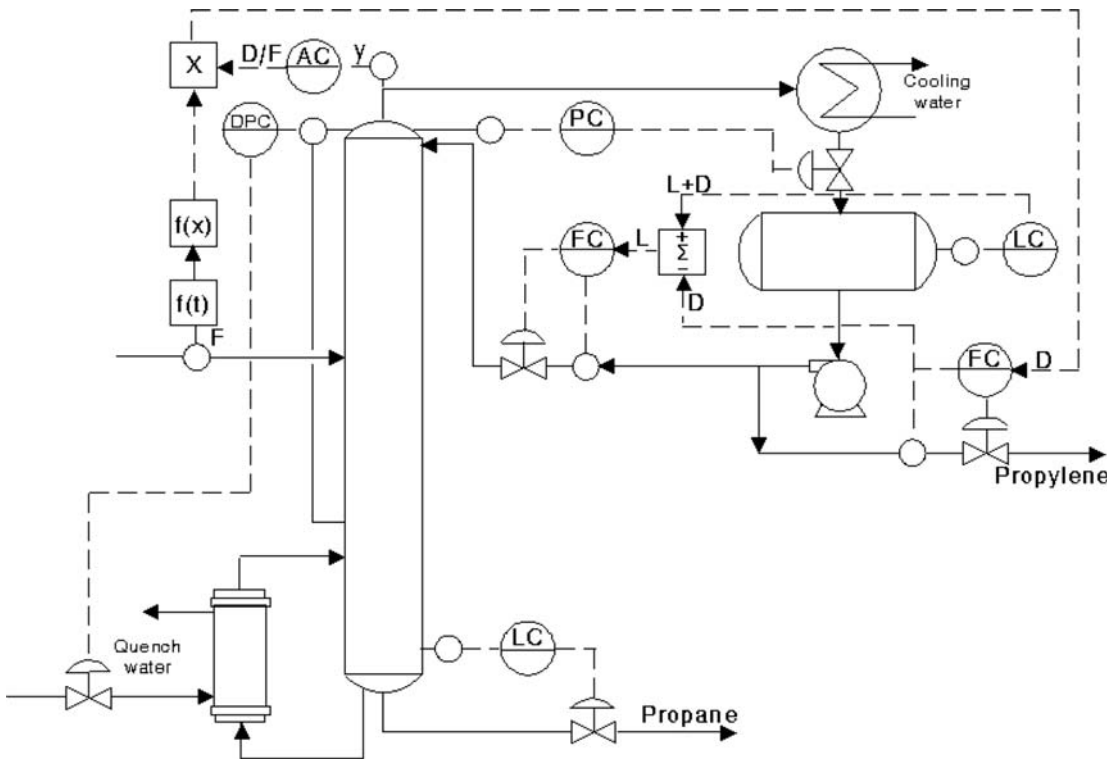

**FIG. 8-53** The quality of high-purity propylene should be controlled by manipulating the material balance.

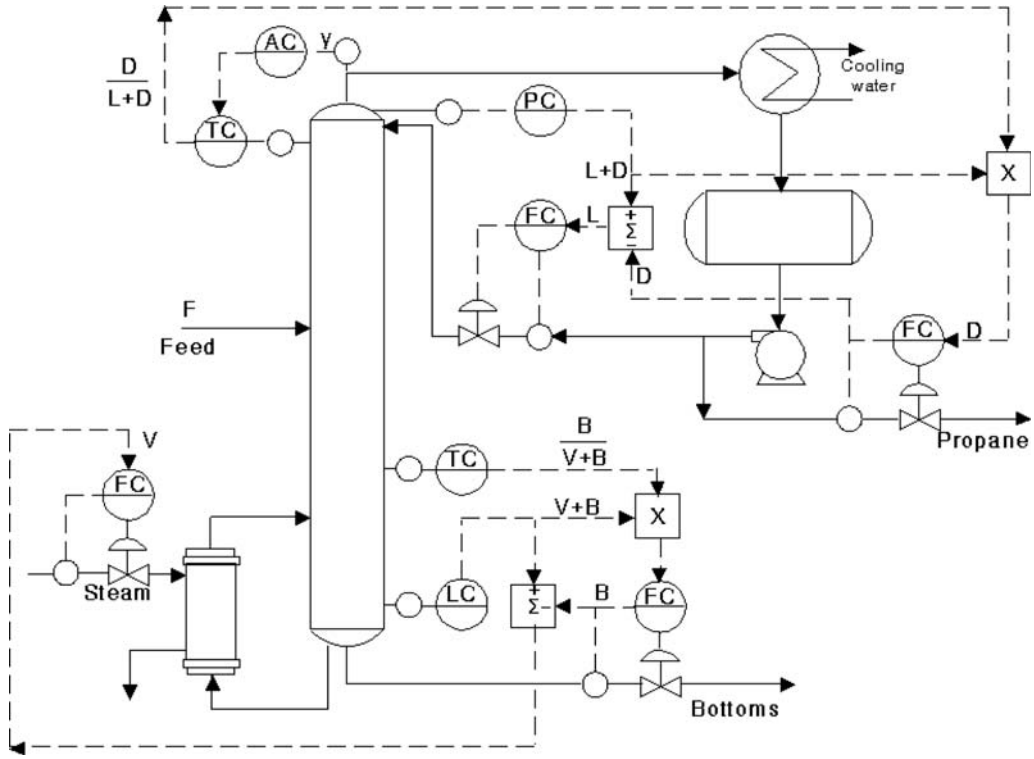

**FIG. 8-54** Depropanizers require control of the quality of both products, here using reflux ratio and boil-up ratio manipulation.

of the quench water quite easily. Pressure is controlled by manipulating the heat-transfer surface in the condenser through flooding. If the condenser should become overloaded, pressure will rise above the set point, but this has no significant effect on the other control loops. Temperature measurements on this column are not helpful, as the difference between the component boiling points is too small. Propane content in the propylene distillate is measured by a chromatographic analyzer sampling the overhead vapor for fast response, and it is controlled by the analyzer controller (AC) manipulating the ratio of distillate to feed rates. The feedforward signal from feed rate is dynamically compensated by $f(t)$ and nonlinearly characterized by $f(x)$ to account for variations in propylene recovery as the feed rate changes. Distillate flow can be measured and controlled more accurately than reflux flow by a factor equal to the reflux ratio, which in this column is typically between 10 and 20. Therefore reflux flow is placed under accumulator level control (LC). Yet composition responds to the difference between internal vapor and reflux flow rates. To eliminate the lag inherent in the response of the accumulator level controller, reflux flow is driven by the subtractor in the direction opposite to distillate flow—this is essential to fast response of the composition loop. The gain of converting distillate flow changes to reflux flow changes can even be increased beyond –1, thereby changing the accumulator level loop from a lag into a dominant lead.

**Controlling Quality of Two Products** Where the two products have similar values, or where heating and cooling costs are comparable to product losses, the compositions of both products should be controlled. This introduces the possibility of strong interaction between the two composition loops, as they tend to have similar speeds of response. Interaction in most columns can be minimized by controlling distillate composition with reflux ratio and bottom composition with boil-up, or preferably boil-up/bottom flow ratio. These loops are insensitive to variations in feed rate, eliminating the need for feedforward control, and they also reject heat balance upsets quite effectively. Figure 8-54 shows a depropanizer controlled by reflux and boil-up ratios. The actual mechanism through which these ratios are manipulated is as $D/(L + D)$ and $B/(V + B)$, where $L$ is reflux flow and $V$ is vapor boil-up, which decouples the temperature loops from the liquid-level loops. Column pressure here is controlled by flooding both the condenser and accumulator; however, there is no level controller on the accumulator, so this arrangement will not function with an overloaded condenser. Temperatures are used as indications of composition in this column because of the substantial difference in boiling points between propane and butanes. However, off-key components such as ethane do affect the accuracy of the relationship, so that an analyzer controller is used to set the top temperature controller (TC) in cascade.

If the products from a column are especially pure, even this configuration may produce excessive interaction between the composition loops. Then the composition of the less pure product should be controlled by manipulating its own flow; the composition of the remaining product should be controlled by manipulating the reflux ratio if it is the distillate, or the boil-up ratio if it is the bottom product.

Most sidestream columns have a small flow dedicated to removing an off-key impurity entering the feed, and that stream must be manipulated to control its content in the major product. For example, an ethylene fractionator separates its feed into a high-purity ethylene sidestream, an ethane-rich bottom product, and a small flow of methane overhead. This small flow must be withdrawn to control the methane content in the ethylene product. The key impurities may then be controlled in the same way as in a two-product column.

Most volatile mixtures have a relative volatility that varies inversely with column pressure. Therefore, their separation requires less energy at lower pressure, and savings in the range of 20 to 40 percent have been achieved. Column pressure can be minimized by floating on the condenser, i.e., by operating the condenser with minimal or no restrictions. In some columns, such as the propylene-propane splitter, pressure can be left uncontrolled. Where it cannot, the set point of the

pressure controller can be indexed by an integral-only controller acting to slowly drive the pressure control valve toward a position just short of maximum cooling. In the case of a flooded condenser, the degree of reflux subcooling can be controlled in place of condenser valve position. Where column temperatures are used to indicate product composition, their measurements must be pressure-compensated.

## CHEMICAL REACTORS

**Composition Control** The first requirement for successful control of a chemical reactor is to establish the proper stoichiometry, i.e., to control the flow rates of the reactants in the proportions needed to satisfy the reaction chemistry. In a continuous reactor, this begins by setting ingredient flow rates in ratio to one another. However, because of variations in the purity of the feed streams and inaccuracy in flow metering, some indication of excess reactant such as pH or a composition measurement should be used to trim the ratios. Many reactions are incomplete, leaving one or more reactants unconverted. They are separated from the products of the reaction and recycled to the reactor, usually contaminated with inert components. While reactants can be recycled to complete conversion (extinction), inerts can accumulate to the point of impeding the reaction and must be purged from the system. Inerts include noncondensible gases that must be vented and nonvolatiles from which volatile products must be stripped.

If one of the reactants differs in phase from the others and the product(s), it may be manipulated to close the material balance on that phase. For example, a gas reacting with liquids to produce a liquid product may be added as it is consumed to control reactor pressure; a gaseous purge would be necessary. Similarly, a liquid reacting with a gas to produce a gaseous product could be added as it is consumed to control the liquid level in the reactor; a liquid purge would be required. Where a large excess of one reactant *A* is used to minimize side reactions, the unreacted excess is sent to a storage tank for recycling. Its flow from the recycle storage tank is set in the desired ratio to the flow of reactant *B*, with the flow of fresh *A* manipulated to control the recycle tank level if the feed is a liquid, or tank pressure if it is a gas. Some catalysts travel with the reactants and must be recycled in the same way.

With batch reactors, it may be possible to add all reactants in their proper quantities initially, if the reaction rate can be controlled by injection of initiator or adjustment of temperature. In semibatch operation, one key ingredient is flow-controlled into the batch at a rate that sets the production. This ingredient should not be manipulated for temperature control of an exothermic reactor, as the loop includes two dominant lags—concentration of the reactant and heat capacity of the reaction mass—and can easily go unstable. It also presents the unfavorable dynamic of inverse response—increasing feed rate may lower temperature by its sensible heat before the increased reaction rate raises temperature.

**Temperature Control** Reactor temperature should always be controlled by heat transfer. Endothermic reactions require heat and therefore are eminently self-regulating. Exothermic reactions produce heat, which tends to raise reaction temperature, thereby increasing the reaction rate and producing more heat. This positive feedback is countered by negative feedback in the cooling system, which removes more heat as the reactor temperature rises. Most continuous reactors have enough heat-transfer surface relative to reaction mass that negative feedback dominates and they are self-regulating. But most batch reactors do not, and they are therefore steady-state unstable. Unstable reactors can be controlled if their temperature controller gain can be set high enough, and if their cooling system has enough margin to accommodate the largest expected disturbance in heat load. Stirred-tank reactors are lag-dominant, and their dynamics allow a high controller gain, but plug flow reactors are dead-time-dominant, preventing their temperature controller from providing enough gain to overcome steady-state instability. Therefore unstable plug flow reactors are also uncontrollable, their temperature tending to limit-cycle in a sawtooth wave. A stable reactor can become unstable as its heat-transfer surface fouls, or as the production rate is increased beyond a critical point (Shinskey, "Exothermic Reactors: The Stable, the Unstable, and the Uncontrollable," *Chem. Eng.*, pp. 54–59, March 2002).

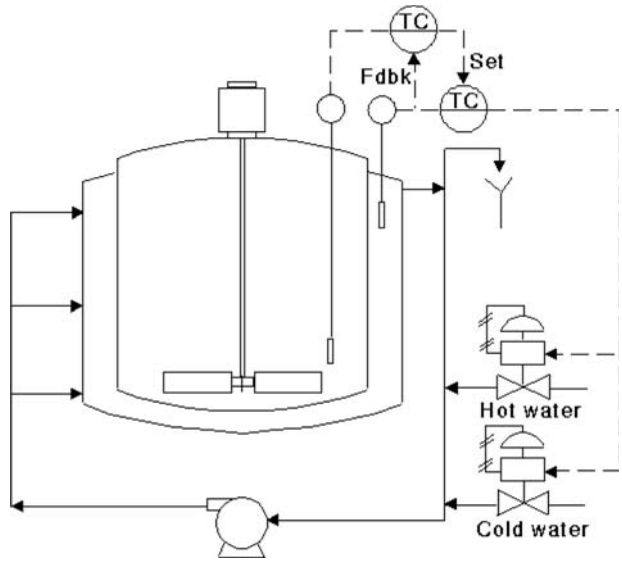

**FIG. 8-55** The stirred-tank reactor temperature controller sets the coolant outlet temperature in cascade, with primary integral feedback taken from the secondary temperature measurement.

Figure 8-55 shows the recommended system for controlling the temperature of an exothermic stirred-tank reactor, either continuous or batch. The circulating pump on the coolant loop is absolutely essential to effective temperature control in keeping dead time minimum and constant—without it, dead time varies inversely with cooling load, causing limit-cycling at low loads. Heating is usually required to raise the temperature to reaction conditions, although it is often locked out of a batch reactor once the initiator is introduced. The valves are operated in split range, the heating valve opening from 50 to 100 percent of controller output and the cooling valve opening from 50 to 0 percent. The cascade system linearizes the reactor temperature loop, speeds its response, and protects it from disturbances in the cooling system. The flow of heat removed per unit of coolant flow is directly proportional to the temperature rise of the coolant, which varies with both the temperature of the reactor and the rate of heat transfer from it. Using an equal-percentage cooling valve helps compensate for this nonlinearity, but incompletely.

The flow of heat across the heat-transfer surface is linear with both temperatures, leaving the primary loop with a constant gain. Using the coolant exit temperature as the secondary controlled variable as shown in Fig. 8-55 places the jacket dynamics in the secondary loop, thereby reducing the period of the primary loop. This is dynamically advantageous for a stirred-tank reactor because of the slow response of its large heat capacity. However, a plug flow reactor cooled by an external heat exchanger lacks this heat capacity, and requires the faster response of the coolant inlet temperature loop.

Performance and robustness are both improved by using the secondary temperature measurement as the feedback signal to the integral mode of the primary controller. (This feature may be available only with controllers that integrate by positive feedback.) This places the entire secondary loop in the integral path of the primary controller, effectively pacing its integral time to the rate at which the secondary temperature is able to respond. It also permits the primary controller to be left in the automatic mode at all times without integral windup.

The primary time constant of the reactor is

$$\tau_1 = \frac{M_r C_r}{UA} \tag{8-83}$$

where $M_r$ and $C_r$ are the mass and heat capacity of the reactants and $U$ and $A$ are the overall heat-transfer coefficient and area, respectively.

The control system of Fig. 8-55 was tested on a pilot reactor where the heat-transfer area and mass could both be changed by a factor of 2, changing $\tau_1$ by a factor of 4 as confirmed by observations of the rates of temperature rise. Yet neither controller required retuning as $\tau_1$ varied. The primary controller should be PID and the secondary controller at least PI in this system (if the secondary controller has no integral mode, the primary will control with offset). Set-point overshoot in batch reactor control can be avoided by setting the derivative time of the primary controller higher than its integral time, but this is effective only with interacting PID controllers.

## CONTROLLING EVAPORATORS

The most important consideration in controlling the quality of concentrate from an evaporator is the forcing of the vapor withdrawal rate to match the flow of excess solvent entering the feed. The mass flow rates of solid material entering and leaving are equal in the steady state

$$M_0 x_0 = M_n x_n \tag{8-84}$$

where $M_0$ and $x_0$ are the mass flow and solid fraction of the feed and $M_n$ and $x_n$ are their values in the product after $n$ effects of evaporation. The total solvent evaporated from all the effects must then be

$$\sum W = M_0 - M_n = M_0\left(1 - \frac{x_0}{x_n}\right) \tag{8-85}$$

For a steam-heated evaporator, each unit of steam $W_0$ applied produces a known amount of evaporation, based on the number of effects and their fractional economy $E$:

$$\sum W = nEW_0 \tag{8-86}$$

(A comparable statement can be made with regard to the power applied to a mechanical recompression evaporator.) In summary, the steam flow required to increase the solid content of the feed from $x_0$ to $x_n$ is

$$W_0 = \frac{M_0(1 - x_0/x_n)}{nE} \tag{8-87}$$

The usual measuring device for feed flow is a magnetic flowmeter, which is a volumetric device whose output $F$ must be multiplied by density $\rho$ to produce mass flow $M_0$. For most aqueous solutions fed to evaporators, the product of density and the function of solid content appearing above is linear with density:

$$F\rho\left(1 - \frac{x_0}{x_n}\right) \approx F[1 - m(\rho - 1)] \tag{8-88}$$

where slope $m$ is determined by the desired product concentration and density is in grams per milliliter. The required steam flow in pounds per hour for feed measured in gallons per minute is then

$$W_0 = \frac{500F[1 - m(\rho - 1)]}{nE} \tag{8-89}$$

where the factor of 500 converts gallons per minute of water to pounds per hour. The factor $nE$ is about 1.74 for a double-effect evaporator and 2.74 for a triple-effect. Using a thermocompressor (ejector) driven with 150 lb/in$^2$ steam on a single-effect evaporator gives an $nE$ of 2.05; it essentially adds the equivalent of one effect to the evaporator train.

A cocurrent evaporator train with its controls is illustrated in Fig. 8-56. The control system applies equally well to countercurrent or mixed-feed evaporators, the principal difference being the tuning of the dynamic compensator $f(t)$, which must be done in the field to minimize the short-term effects of changes in feed flow on product quality. Solid concentration in the product is usually measured as density; feedback trim is applied by the analyzer controller AC adjusting the slope $m$ of the density function, which is the only term related to $x_n$. This recalibrates the system whenever $x_n$ must move to a new set point.

The accuracy of the system depends on controlling heat flow; therefore if steam pressure varies, compensation must be applied to correct

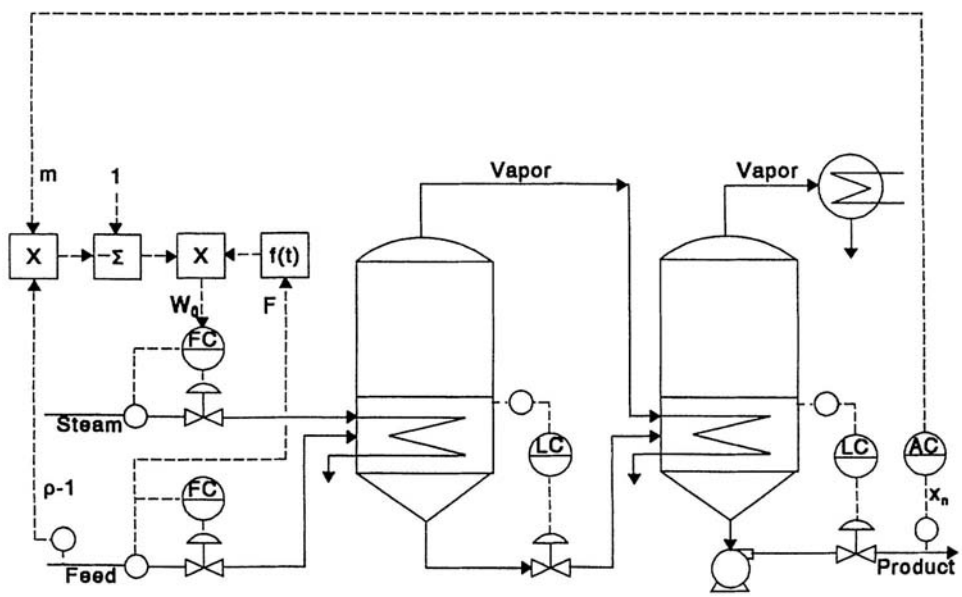

**FIG. 8-56** Controlling the evaporators requires matching steam flow and evaporative load, here using feedforward control.

for both steam density and enthalpy as a function of pressure. Some evaporators must use unreliable sources of low-pressure steam. In this case, the measurement of pressure-compensated steam flow can be used to set feed flow by solving the last equation for $F$, using $W_0$ as a variable. The steam flow controller would be set for a given production rate, but the dynamically compensated steam flow measurement would be the input signal to calculate the feed flow set point. Both of these configurations are widely used in controlling corn syrup concentrators.

## DRYING OPERATIONS

Controlling dryers is much different from controlling evaporators, because online measurements of feed rate and composition and product composition are rarely available. Most dryers transfer moisture from wet feed into hot dry air in a single pass. The process is generally very self-regulating, in that moisture becomes progressively harder to remove from the product as it dries: this is known as falling-rate drying. Controlling the temperature of the air leaving a cocurrent dryer tends to regulate the moisture in the product, as long as the rate and moisture content of the feed and air are reasonably constant. However, at constant outlet air temperature, product moisture tends to rise with all three of these disturbance variables.

In the absence of moisture analyzers, regulation of product quality can be improved by raising the temperature of the exhaust air in proportion to the evaporative load. The evaporative load can be estimated by the loss in temperature of the air passing through the dryer in the steady state. Changes in load are first observed in upsets in exhaust temperature at a given inlet temperature; the controller then responds by returning the exhaust air to its original temperature by changing that of the inlet air.

Figure 8-57 illustrates the simplest application of this principle as the linear relationship

$$T_0 = T_b + K\,\Delta T \tag{8-90}$$

where $T_0$ is the set point for exhaust temperature elevated above a base temperature $T_b$ corresponding to zero-load operation and $\Delta T$ is the drop in air temperature from inlet to outlet. Coefficient $K$ must be set to regulate product moisture over the expected range of evaporative load. If $K$ is set too low, product moisture will increase with increasing load; if $K$ is set too high, product moisture will decrease with increasing load. While $K$ can be estimated from the model of a dryer, it does depend on the rate-of-drying curve for the product, its mean particle size, and whether the load variations are due primarily to changes in feed rate or feed moisture.

It is important to have the most accurate measurement of exhaust temperature attainable. Note that Fig. 8-57 shows the sensor inserted into the dryer upstream of the rotating seal, because air infiltration there could cause the temperature in the exhaust duct to read low—even lower than the wet-bulb temperature, an impossibility without either substantial heat loss or outside-air infiltration.

The calculation of the exhaust temperature set point forms a positive feedback loop capable of destabilizing the dryer. For example, an increase in evaporative load causes the controller to raise the inlet temperature, which will in turn raise the calculated set point, calling for a further increase in inlet temperature. The gain in the set-point loop $K$ is typically well below the gain of the exhaust temperature measurement responding to the same change in inlet temperature. Negative feedback then dominates in the steady state, but the response of the exhaust temperature measurement is delayed by the dryer. A compensating lag $f(t)$ is shown inserted in the set-point loop to prevent positive feedback from dominating in the short term, which could cause cycling. Lag time can be safely set equal to the integral time of the outlet-air temperature controller.

If product moisture is measured offline, analytical results can be used to adjust $K$ and $T_b$ manually. If an online analyzer is used, the analyzer controller would be most effective in adjusting the bias $T_b$, as is done in the figure.

While a rotary dryer is shown, commonly used for grains and minerals, this control system has been successfully applied to fluid-bed drying of plastic pellets, air-lift drying of wood fibers, and spray drying of milk solids. The air may be steam-heated as shown or heated by direct combustion of fuel, provided that a representative measurement of inlet air temperature can be made. If it cannot, then evaporative load can be inferred from a measurement of fuel flow, which then would replace $\Delta T$ in the set-point calculation.

If the feed flows countercurrent to the air, as is the case when drying granulated sugar, the exhaust temperature does not respond to variations in product moisture. For these dryers, the moisture in the product can better be regulated by controlling its temperature at the point of discharge. Conveyor-type dryers are usually divided into a number of zones, each separately heated with recirculation of air, which raises its wet-bulb temperature. Only the last two zones may require indexing of exhaust air temperature as a function of $\Delta T$.

Batch drying, used on small lots such as pharmaceuticals, begins operation by blowing air at constant inlet temperature through saturated product in constant-rate drying, where $\Delta T$ is constant at its maximum value $\Delta T_c$. When product moisture reaches the point where falling-rate drying begins, the exhaust temperature begins to rise. The desired product moisture will be reached at a corresponding exhaust

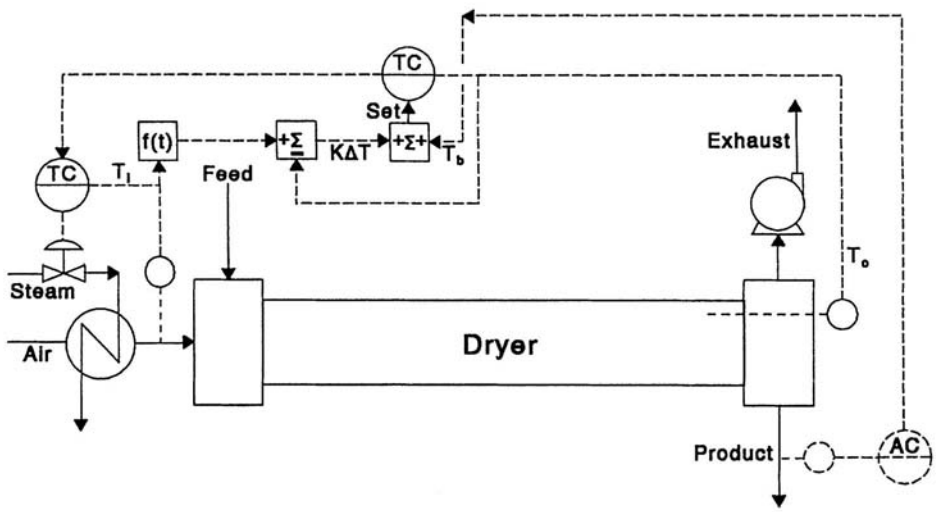

**FIG. 8-57** Product moisture from a cocurrent dryer can be regulated through temperature control indexed to heat load.

temperature $T_f$, which is related to the temperature $T_c$ observed during constant-rate drying, as well as to $\Delta T_c$:

$$T_f = T_c + K\,\Delta T_c \tag{8-91}$$

The control system requires that the values of $T_c$ and $\Delta T_c$ observed during the first minutes of operation be stored as the basis for the above calculation of endpoint. When the exhaust temperature then reaches the calculated value of $T_f$, drying is terminated. Coefficient $K$ can be estimated from models, but requires adjustment online to reach product specifications repeatedly. Products having different moisture specifications or particle size will require different settings of $K$, but the system does compensate for variations in feed moisture, batch size, air moisture, and inlet temperature. Some exhaust air may be recirculated to control the dew point of the inlet air, thereby conserving energy toward the end of the batch and when the ambient air is especially dry.

# BATCH PROCESS CONTROL

## BATCH VERSUS CONTINUOUS PROCESSES

When one is categorizing process plants, the following two extremes can be identified:

1. *Commodity plants.* These plants are custom-designed to produce large amounts of a single product (or a primary product plus one or more secondary products). An example is a chlorine plant, where the primary product is chlorine and the secondary products are hydrogen and sodium hydroxide. Usually the margins (product value less manufacturing costs) for the products from commodity plants are small, so the plants must be designed and operated for best possible efficiencies. Although a few are batch, most commodity plants are continuous. Factors such as energy costs are life-and-death issues for such plants.

2. *Specialty plants.* These plants are capable of producing small amounts of a variety of products. Such plants are common in fine chemicals, pharmaceuticals, foods, and so on. In specialty plants, the margins are usually high, so factors such as energy costs are important but not life-and-death issues. As the production amounts are relatively small, it is not economically feasible to dedicate processing equipment to the manufacture of only one product. Instead, batch processing is utilized so that several products (perhaps hundreds) can be manufactured with the same process equipment. The key issue in such plants is to manufacture consistently each product in accordance with its specifications.

The above two categories represent the extremes in process configurations. The term *semibatch* designates plants in which some processing is continuous but other processing is batch. Even processes that are considered to be continuous can have a modest amount of batch processing. For example, the reformer unit within a refinery is thought of as a continuous process, but the catalyst regeneration is normally a batch process.

In a continuous process, the conditions within the process are largely the same from one day to the next. Variations in feed composition, plant utilities (e.g., cooling water temperature), catalyst activities, and other variables occur, but normally these changes either are about an average (e.g., feed compositions) or exhibit a gradual change over an extended period (e.g., catalyst activities). Summary data such as hourly averages, daily averages, and the like are meaningful in a continuous process.

In a batch process, the conditions within the process are continually changing. The technology for making a given product is contained in the product recipe that is specific to that product. Such recipes normally state the following:

1. *Raw material amounts.* This is the stuff needed to make the product.

2. *Processing instructions.* This is what must be done with the stuff to make the desired product.

This concept of a recipe is quite consistent with the recipes found in cookbooks. Sometimes the term *recipe* is used to designate only the raw material amounts and other parameters to be used in manufacturing a batch. Although appropriate for some batch processes, this concept is far too restrictive for others. For some products, the differences from one product to the next are largely physical as opposed to chemical. For such products, the processing instructions are especially important. The term *formula* is more appropriate for the raw material amounts and other parameters, with *recipe* designating the formula and the processing instructions. The above concept of a recipe permits the following three different categories of batch processes to be identified:

1. *Cyclical batch.* Both the formula and the processing instructions are the same from batch to batch. Batch operations within processes that are primarily continuous often fall into this category. The catalyst regenerator within a reformer unit is a cyclical batch process.

2. *Multigrade.* The processing instructions are the same from batch to batch, but the formula can be changed to produce modest variations in the product. In a batch PVC plant, the different grades of PVC are manufactured by changing the formula. In a batch pulp digester, the processing of each batch or cook is the same, but at the start of each cook, the process operator is permitted to change the formula values for chemical-to-wood ratios, cook time, cook temperature, and so on.

3. *Flexible batch.* Both the formula and the processing instructions can change from batch to batch. Emulsion polymerization reactors are a good example of a flexible batch facility. The recipe for each product must detail both the raw materials required and how conditions within the reactor must be sequenced to make the desired product.

Of these, the flexible batch is by far the most difficult to automate and requires a far more sophisticated control system than either the cyclical batch or the multigrade batch facility.

**Batches and Recipes** Each batch of product is manufactured in accordance with a product recipe, which contains all information (formula and processing instructions) required to make a batch of the product (see Fig. 8-58). For each batch of product, there will be one and only one product recipe. However, a given product recipe is normally used to make several batches of product. To uniquely identify a batch of product, each batch is assigned a unique identifier called the batch ID. Most companies adopt a convention for generating the batch ID, but this convention varies from one company to the next. In most batch facilities, more than one batch of product will be in some stage of production at any given time. The batches in progress may or may not be using the same recipe. The maximum number of batches that can be in progress at any given time is a function of the equipment configuration for the plant.

The existence of multiple batches in progress at a given time presents numerous opportunities for the process operator to make errors, such as charging a material to the wrong batch. Charging a material to the wrong batch is almost always detrimental to the batch to which the material is incorrectly charged. Unless this error is recognized quickly so that the proper charge can be made, the error is also detrimental to the batch to which the charge was supposed to have been made. Such errors usually lead to an off-specification batch, but the consequences could be more serious and could result in a hazardous condition.

*Recipe management* refers to the assumption of such duties by the control system. Each batch of product is tracked throughout its production, which may involve multiple processing operations on various pieces of processing equipment. Recipe management ensures that all actions specified in the product recipe are performed on each batch of product made in accordance with that recipe. As the batch proceeds from one piece of processing equipment to the next, recipe management

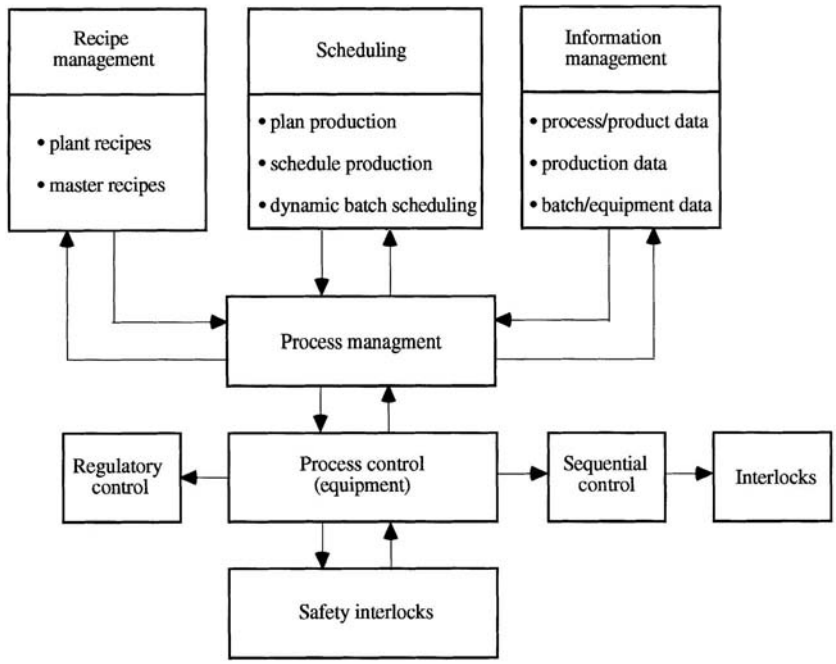

**FIG. 8-58** Batch control overview.

is also responsible for ensuring that the proper type of process equipment is used and that this processing equipment is not currently in use by another batch.

By assuming such responsibilities, the control system greatly reduces the incidences where operator error results in off-specification batches. Such a reduction in error is essential to implement just-in-time production practices, where each batch of product is manufactured at the last possible moment. When a batch (or batches) is made today for shipment by overnight truck, there is insufficient time for producing another batch to make up for an off-specification batch.

**Routing and Production Monitoring** In some facilities, batches are individually scheduled. However, in most facilities, production is scheduled by product runs (also called process orders), where a run is the production of a stated quantity of a given product. From the stated quantity and the standard yield of each batch, the number of batches can be determined. As this is normally more than one batch of product, a production run is normally a sequence of some number of batches of the same product.

In executing a production run, the following issues must be addressed (see Fig. 8-58):

1. *Processing equipment must be dedicated to making the run.* More than one run is normally in progress at a given time. The maximum number of runs simultaneously in progress depends on the equipment configuration of the plant. Routing involves determining which processing equipment will be used for each production run.

2. *Raw material must be utilized.* When a production run is scheduled, the necessary raw materials must be allocated to the production run. As the individual batches proceed, the consumption of raw materials must be monitored for consistency with the allocation of raw materials to the production run.

3. *The production quantity for the run must be achieved by executing the appropriate number of batches.* The number of batches is determined from a standard yield for each batch. However, some batches may achieve yields higher than the standard yield, but other batches may achieve yields lower than the standard yield. The actual yields from each batch must be monitored, and significant deviations from the expected yields must be communicated to those responsible for scheduling production.

The last two activities are key components of production monitoring, although production monitoring may also involve other activities such as tracking equipment utilization.

**Production Scheduling** In this regard, it is important to distinguish between scheduling runs (sometimes called long-term scheduling) and assigning equipment to runs (sometimes called routing or short-term scheduling). As used here production scheduling refers to scheduling runs and is usually a corporate-level as opposed to a plant-level function. Short-term scheduling or routing was previously discussed and is implemented at the plant level. The long-term scheduling is basically a material resources planning (MRP) activity involving the following:

1. *Forecasting.* Orders for long-delivery raw materials are issued at the corporate level based on the forecast for the demand for products. The current inventory of such raw materials is also maintained at the corporate level. This constitutes the resources from which products can be manufactured. Functions of this type are now incorporated into supply chain management.

2. *Orders for products.* Orders are normally received at the corporate level and then assigned to individual plants for production and shipment. Although the scheduling of some products is based on required product inventory levels, scheduling based on orders and shipping directly to the customer (usually referred to as just-in-time) avoids the costs associated with maintaining product inventories.

3. *Plant locations and capacities.* While producing a product at the nearest plant usually lowers transportation costs, plant capacity limitations sometimes dictate otherwise. Any company competing in the world economy needs the flexibility to accept orders on a worldwide basis and then assign them to individual plants to be filled. Such a function is logically implemented within the corporate-level information technology framework.

## BATCH AUTOMATION FUNCTIONS

Automating a batch facility requires a spectrum of functions.

**Interlocks** Some of these are provided for safety and are properly called safety interlocks. However, others are provided to avoid mistakes in processing the batch. When safety is not involved, terms such as *permissives* and *process actions* are sometimes used in lieu of interlocks. Some understand the term *interlock* to have a connection to safety (interlock will be subsequently defined as a protective response initiated on the detection of a process hazard).

**Discrete Device States** Discrete devices such as two-position valves can be driven to either of two possible states. Such devices can be optionally outfitted with limit switches that indicate the state of the device. For two-position valves, the following combinations are possible:

1. No limit switches
2. One limit switch on the closed position
3. One limit switch on the open position
4. Two limit switches

In process control terminology, the discrete device driver is the software routine that generates the output to a discrete device such as a valve and also monitors the state feedback information to ascertain that the discrete device actually attains the desired state. Given the variety of discrete devices used in batch facilities, this logic must include a variety of capabilities. For example, valves do not instantly change states; instead each valve exhibits a travel time for the change from one state to another. To accommodate this characteristic of the field device, the processing logic within the discrete device driver must provide for a user-specified transition time for each field device. When equipped with limit switches, the potential states for a valve are as follows:

1. *Open.* The valve has been commanded to open, and the limit switch inputs are consistent with the open state.
2. *Closed.* The valve has been commanded to close, and the limit switch inputs are consistent with the closed state.
3. *Transition.* This is a temporary state that is only possible after the valve has been commanded to change state. The limit switch inputs are not consistent with the commanded state, but the transition time has not expired.
4. *Invalid.* The transition time has expired, and the limit switch inputs are not consistent with the commanded state for the valve.

The invalid state is an abnormal condition that is generally handled in a manner similar to process alarms. The transition state is not considered to be an abnormal state but may be implemented in either of the following ways:

1. *Drive and wait.* Further actions are delayed until the device attains its commanded state.
2. *Drive and proceed.* Further actions are initiated while the device is in the transition state.

The latter is generally necessary for devices with long travel times, such as flush-fitting reactor discharge valves that are motor-driven. Closing of such valves is normally done via drive and wait; however, drive and proceed is usually appropriate when opening the valve. Although two-state devices are most common, the need occasionally arises for devices with three or more states. For example, an agitator may be on high speed, on slow speed, or off.

**Process States** Batch processing usually involves imposing the proper sequence of states on the process. For example, a simple blending sequence might be as follows:

1. Transfer specified amount of material from tank A to tank R. The process state is "transfer from A."
2. Transfer specified amount of material from tank B to tank R. The process state is "transfer from B."
3. Agitate for specified time. The process state is "agitate without cooling."
4. Cool (with agitation) to specified target temperature. The process state is "agitate with cooling."

For each process state, the various discrete devices are expected to be in a specified device state. For process state "transfer from A," the device states might be as follows:

1. Tank A discharge valve: open
2. Tank R inlet valve: open
3. Tank A transfer pump: running
4. Tank R agitator: off
5. Tank R cooling valve: closed

For many batch processes, process state representations are a very convenient mechanism for representing the batch logic. A grid or table can be constructed, with the process states as rows and the discrete device states as columns (or vice versa). For each process state, the state of every discrete device is specified to be one of the following:

1. Device state 0, which may be valve closed, agitator off, and so on
2. Device state 1, which may be valve open, agitator on, and so on
3. No change or don't care

This representation is easily understandable by those knowledgeable about the process technology and is a convenient mechanism for conveying the process requirements to the control engineers responsible for implementing the batch logic.

Many batch software packages also recognize process states. A configuration tool is provided to define a process state. With such a mechanism, the batch logic does not need to drive individual devices but can simply command that the desired process state be achieved. The system software then drives the discrete devices to the device states required for the target process state. This normally includes the following:

1. Generating the necessary commands to drive each device to its proper state.
2. Monitoring the transition status of each device to determine when all devices have attained their proper states.
3. Continuing to monitor the state of each device to ensure that the devices remain in their proper states. Should any discrete device not remain in its target state, failure logic must be initiated.

**Regulatory Control** For most batch processes, the discrete logic requirements overshadow the continuous control requirements. For many batch processes, the continuous control can be provided by simple loops for flow, pressure, level, and temperature. However, very sophisticated advanced control techniques are occasionally applied. As temperature control is especially critical in reactors, the simple feedback approach is replaced by model-based strategies that rival, if not exceed, the sophistication of advanced control loops in continuous plants.

In some installations, alternative approaches for regulatory control may be required. Where a variety of products are manufactured, the reactor may be equipped with alternative heat removal capabilities, including the following:

1. Jacket filled with cooling water. Most such jackets are once-through, but some are recirculating.
2. Heat exchanger in a pump-around loop.
3. Reflux condenser.

The heat removal capability to be used usually depends on the product being manufactured. Therefore, regulatory loops must be configured for each possible option, and sometimes for certain combinations of the possible options. These loops are enabled and disabled depending on the product being manufactured.

The interface between continuous controls and sequence logic (discussed shortly) is also important. For example, a feed might be metered into a reactor at a variable rate, depending on another feed or possibly on reactor temperature. However, the product recipe calls for a specified quantity of this feed. The flow must be totalized (i.e., integrated), and when the flow total attains a specified value, the feed must be terminated. The sequence logic must have access to operational parameters such as controller modes. That is, the sequence logic must be able to switch a controller to manual, automatic, or cascade. Furthermore, the sequence logic must be able to force the controller output to a specified value.

**Sequence Logic** Sequence logic must not be confused with discrete logic. Discrete logic is especially suitable for interlocks or permissives; e.g., the reactor discharge valve must be closed for the feed valve to be opened. Sequence logic is used to force the process to attain the proper sequence of states. For example, a feed preparation might be to first charge A, then charge B, next mix, and finally cool. Although discrete logic can be used to implement sequence logic, other alternatives are often more attractive.

Sequence logic is often, but not necessarily, coupled with the concept of a process state. Basically, the sequence logic determines when the process should proceed from the current state to the next and sometimes what the next state should be.

Sequence logic must encompass both normal and abnormal process operations. Thus, sequence logic is often viewed as consisting of two distinct but related parts:

1. *Normal logic*. This sequence logic provides for the normal or expected progression from one process state to another.
2. *Failure logic*. This logic provides for responding to abnormal conditions, such as equipment failures.

Of these, the failure logic can easily be the most demanding. The simplest approach is to stop or hold on any abnormal condition and let the process operator sort things out. However, this is not always acceptable. Some failures lead to hazardous conditions that require immediate action; waiting for the operator to decide what to do is not acceptable. The appropriate response to such situations is best determined in conjunction with the process hazards analysis.

No single approach has evolved as the preferred way to implement sequence logic. The approaches utilized include the following:

1. *Discrete logic.* Although sequence logic is different from discrete logic, sequence logic can be implemented using discrete logic capabilities. Simple sequences are commonly implemented as ladder diagrams in programmable logic controllers (PLCs). Sequence logic can also be implemented using the boolean logic functions provided by a distributed control system (DCS), although this approach is now infrequently pursued.
2. *Programming languages*. Traditional procedural languages do not provide the necessary constructs for implementing sequence logic. This necessitates one of the following:

*a. Special languages*. The necessary extensions for sequence logic are provided by extending the syntax of the programming language. This is the most common approach within distributed control systems. The early implementations used BASIC as the starting point for the extensions; the later implementations used C as the starting point. A major problem with this approach is portability, especially from one manufacturer to the next but sometimes from one product version to the next within the same manufacturer's product line.

*b. Subroutine or function libraries*. The facilities for sequence logic are provided via subroutines or functions that can be referenced from programs written in FORTRAN or C. This requires a general-purpose program development environment and excellent facilities to trap the inevitable errors in such programs. Operating systems with such capabilities have long been available on the larger computers, but not for the microprocessors utilized within DCSs. However, such operating systems are becoming more common within DCSs.

3. *State machines*. This technology is commonly applied within the discrete manufacturing industries. However, its migration to process batch applications has been limited.
4. *Graphical implementations.* For sequence logic, the flowchart traditionally used to represent the logic of computer programs must be extended to provide parallel execution paths. Such extensions have been implemented in a graphical representation generally referred to as a sequential function chart, which is a derivative of an earlier technology known as Grafcet. As process engineers have demonstrated a strong dislike for ladder logic, most PLC manufacturers now provide sequential function charts either in addition to or as an alternative to ladder logic. Many DCS manufacturers also provide sequential function charts either in addition to or as an alternative to special sequence languages.

## INDUSTRIAL APPLICATIONS

An industrial example requiring simple sequence logic is the effluent tank with two sump pumps illustrated in Fig. 8-59. There are two sump pumps, A and B. The tank is equipped with three level switches, one for low level (LL), one for high level (LH), and one for high-high level (LHH). All level switches actuate on rising level. The logic is to be as follows:

1. When level switch LH actuates, start one sump pump. This must alternate between the sump pumps. If pump A is started on this occasion, then pump B must be started on the next occasion.

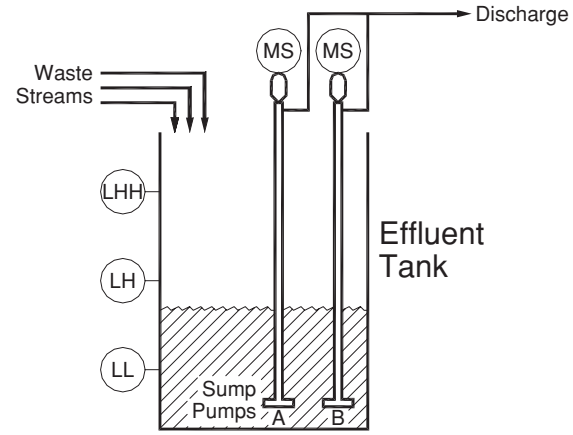

**FIG. 8-59** Effluent tank process.

2. When level switch LHH actuates, start the other sump pump.
3. When level switch LL deactuates, stop all sump pumps.

Once a sump pump is started, it is not stopped until level switch LL deactuates. With this logic, one, both, or no sump pump may be running when the level is between LL and LH. Either one or both sump pumps may be running when the level is between LH and LHH.

Figure 8-60*a* presents the ladder logic implementation of the sequence logic. Ladder diagrams were originally developed for representing hardwired logic, but are now widely used in PLCs. The vertical bar on the left provides the source of power; the vertical bar on the right is ground. If a coil is connected between the power source and ground, the coil will be energized. If a circuit consisting of a set of contacts is inserted between the power source and the coil, the coil will be energized only if power can flow through the circuit. This will depend on the configuration of the circuit and the states of the contacts within the circuit. Ladder diagrams are constructed as rungs, with each rung consisting of a circuit of contacts and an output coil.

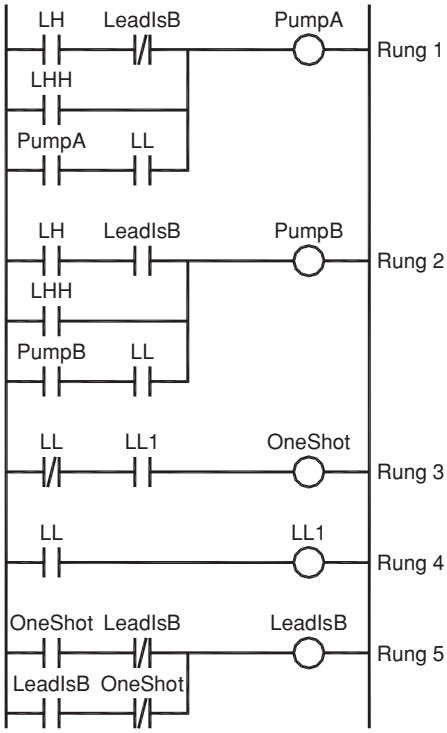
Contacts are represented as vertical bars. A vertical bar represents a normally open contact; power flows through this contact only if the device with which the contact is associated is actuated (energized). Vertical bars separated by a slash represent a normally closed contact; power flows through this contact only if the device with which the contact is associated is not actuated. The level switches actuate on rising level. If the vessel level is below the location of the switch, the normally open contact is open and the normally closed contact is closed. If the level is above the location of the switch, the normally closed contact is closed and the normally open contact is open.

The first rung in Fig. 8-60*a* is for pump A. It will run if one (or more) of the following conditions is true:

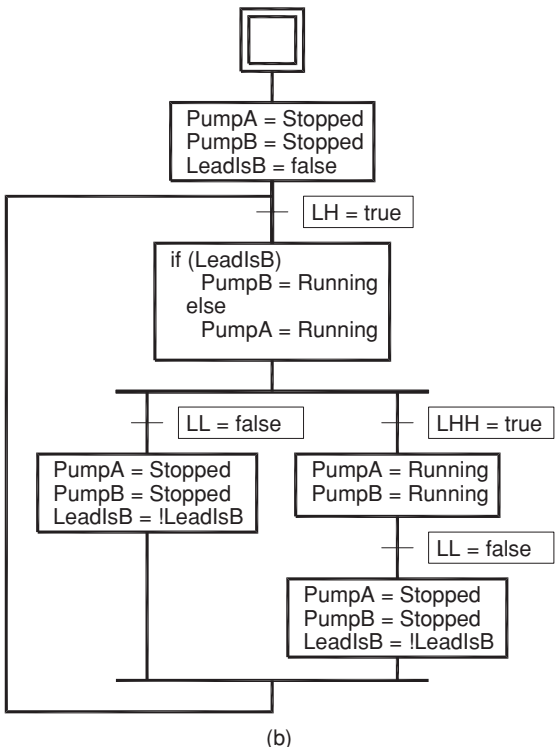
1. Level is above LH and pump A is the lead pump. A coil (designated as LeadIsB) will be subsequently provided to designate the pump to be started next (called the lead pump). If this coil is energized, pump B is the lead pump. Hence, pump A is to be started at LH if this coil is not energized, hence the use of the normally closed contact on coil LeadIsB in the rung of ladder logic for pump A.
2. Level is above LHH.
3. Pump A is running and the level is above LL.

The second rung is an almost identical circuit for pump B. The difference is the use of the normally open contact on the coil LeadIsB.

When implemented as hardwired logic, ladder diagrams are truly parallel logic; i.e., all circuits are active at all instants of time. But when ladder diagrams are implemented in PLCs, the behavior is slightly different. The ladder logic is scanned very rapidly (on the order of 100 times per second), which gives the appearance of parallel logic. But within a scan of ladder logic, the rungs are executed sequentially. This



(a)



(b)

**FIG. 8-60** (*a*) Ladder logic. (*b*) Sequence logic for effluent tank sump pumps.

permits constructs within ladder logic for PLCs that make no sense in hardwired circuits.

One such construct is for a "one-shot." Some PLCs provide this as a built-in function, but here it will be presented in terms of separate components. The one-shot is generated by the third rung of ladder logic in Fig. 8-60*a*. But first examine the fourth rung. The input LL drives the output coil LL1. This coil provides the state of level switch LL on the previous scan of ladder logic. This is used in the third rung to produce the one-shot. Output coil OneShot is energized if

1. LL is not actuated on this scan of ladder logic (note the use of the normally closed contact for LL)
2. LL was actuated on the previous scan of ladder logic (note the use of the normally open contact for LL1)

When LL deactuates, coil OneShot is energized for one scan of ladder logic. OneShot does not energize when LL actuates (a slight modification of the circuit would give a one-shot when LL actuates).

The one-shot is used in the fifth rung of ladder logic to toggle the lead pump. The output coil LeadIsB is energized provided that

1. LeadIsB is energized and OneShot is not energized. Once LeadIsB is energized, it remains energized until the next "firing" of the one-shot.
2. LeadIsB is not energized and OneShot is energized. This causes coil LeadIsB to change states each time the one-shot fires.

Ladder diagrams are ideally suited for representing discrete logic, such as required for interlocks. Sequence logic can be implemented via ladder logic, but usually with some tricks or gimmicks (the one-shot in Fig. 8-60*a* is such a gimmick). These are well known to those "skilled in the art" of PLC programming. But to others, they can be quite confusing.

Figure 8-60*b* provides a sequential function chart for the pumps. Sequential function charts consist of steps and transitions. A step consists of actions to be performed, as represented by statements. A transition consists of a logical expression. As long as the logical expression is false, the sequence logic remains at the transition. When the logical expression is true, the sequence logic proceeds to the step following the transition.

The basic constructs of sequential function charts are presented in Fig. 8-61. The basic construct of a sequential function chart is the step-transition-step. But also note the constructs for OR and AND. At the divergent OR, the logic proceeds on only one of the possible paths, specifically, the one whose transition is the first to attain the true condition. At the divergent AND, the logic proceeds on all paths simultaneously, and all must complete to proceed beyond the convergent AND. This enables sequential function charts to provide parallel logic.

In the sequential function chart in Fig. 8-60*b* for the pumps, the logic is initiated with both pumps stopped and pump A as the lead pump. When LH actuates, the lead pump is started. A divergent OR is used to create two paths:

1. If LL deactuates, both pumps are stopped and the lead pump is swapped.
2. If LHH actuates, both pumps are started (one is already running). Both remain running until LL deactuates, at which time both are stopped. The logic then loops to the transition for LH actuating.

Although not illustrated here, programming languages (either custom sequence languages or traditional languages extended by libraries of real-time functions) are a viable alternative for implementing the logic for the pumps. Graphical constructs such as ladder logic and sequential function charts are appealing to those uncomfortable with traditional programming languages. But in reality, these are programming methodologies.

## BATCH REACTOR CONTROL

The reactors in flexible batch chemical plants usually present challenges. Many reactors have multiple mechanisms for heating and/or cooling. The reactor in Fig. 8-62 has three mechanisms:

1. Heat with steam.
2. Cool with cooling tower water.
3. Cool with chilled water.

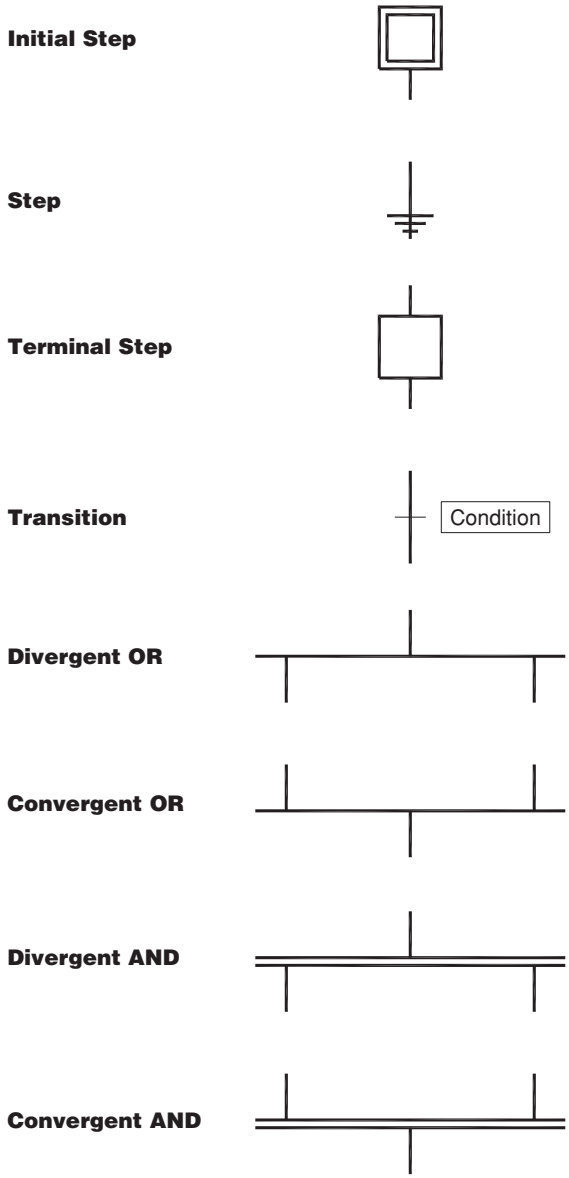


**FIG. 8-61** Elements of sequential function charts.

Sometimes glycol is an option; occasionally liquid nitrogen is used to achieve even lower temperatures. Some jacket configurations require sequences for switching between the various modes for heating and cooling (the jacket has to be drained or depressurized before another medium can be admitted).

The reactor in Fig. 8-62 has three mechanisms for pressure control:

1. Vacuum
2. Atmospheric (using the vent and inert valves)
3. Pressure

Some reactors are equipped with multiple vacuum pumps, with different operating modes for moderate vacuum versus high vacuum. Sequence logic is usually required to start vacuum pumps and establish vacuum.

With three options for heating/cooling and three options for pressure, the reactor in Fig. 8-62 has nine combinations of operating modes.

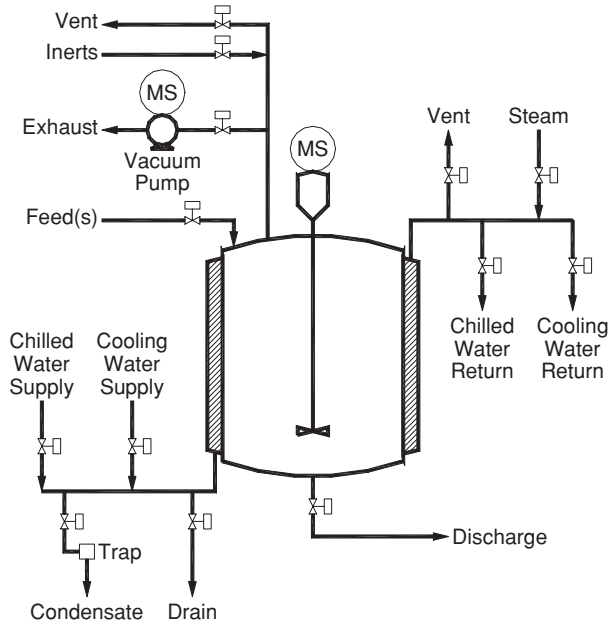

**FIG. 8-62** Chemical reactor schematic.

In practice, this is actually a low number. This number increases with features such as

1. Recirculations or pump-arounds containing a heater and/or cooler
2. Reflux condensers that can be operated at total reflux (providing only cooling) or such that some component is removed from the reacting system

These further increase the number of possible combinations. Some combinations may not make sense, may not be used in current production operations, or otherwise can be eliminated. However, the net number of combinations that must be supported tends to be large.

The order in which the systems are activated usually depends on the product being manufactured. Sometimes heating/cooling and pressure control are established simultaneously; sometimes heating/cooling is established first and then pressure control, and sometimes pressure control is established first and then heating/cooling. One has to be very careful when imposing restrictions. Suppose no current products establish pressure control first and then establish heating/cooling. But what about the next product to be introduced? After all, this is a flexible batch facility.

Such challenging applications for recipe management and sequence logic require a detailed analysis of the production equipment and the operations conducted within that production equipment. While applications such as the sump pumps in the effluent tank can be pursued without it, a structured approach is essential in flexible batch facilities.

## BATCH PRODUCTION FACILITIES

Especially for flexible batch applications, the batch logic must be properly structured in order to be implemented and maintained in a reasonable manner. An underlying requirement is that the batch process equipment be properly structured. The following structure is appropriate for most batch production facilities.

**Plant** A plant is the collection of production facilities at a geographic site. The production facilities at a site normally share warehousing, utilities, and the like.

**Equipment Suite** An equipment suite is the collection of equipment available for producing a group of products. Normally, this

group of products is similar in certain respects. For example, they might all be manufactured from the same major raw materials. Within the equipment suite, material transfer and metering capabilities are available for these raw materials. The equipment suite contains all the necessary types of processing equipment (reactors, separators, and so on) required to convert the raw materials to salable products. A plant may consist of only one suite of equipment, but large plants usually contain multiple equipment suites.

**Process Unit or Batch Unit** A process unit is a collection of processing equipment that can, at least at certain times, be operated in a manner completely independent of the remainder of the plant. A process unit normally provides a specific function in the production of a batch of product. For example, a process unit might be a reactor complete with all associated equipment (jacket, recirculation pump, reflux condenser, and so on). However, each feed preparation tank is usually a separate process unit. With this separation, preparation of the feed for the next batch can be started as soon as the feed tank is emptied for the current batch.

All but the very simplest equipment suites contain multiple process units. The minimum number of process units is one for each type of processing equipment required to make a batch of product. However, many equipment suites contain multiple process units of each type. In such equipment suites, multiple batches and multiple production runs can be in progress at a given time.

**Item of Equipment** An item of equipment is a hardware item that performs a specific purpose. Examples are pumps, heat exchangers, agitators, and the like. A process unit could consist of a single item of equipment, but most process units consist of several items of equipment that must be operated in harmony to achieve the function expected of the process unit.

**Device** A device is the smallest element of interest to batch logic. Examples of devices include measurement devices and actuators.

## STRUCTURED BATCH LOGIC

Flexible batch applications must be pursued by using a structured approach to batch logic. In such applications, the same processing equipment is used to make a variety of products. In most facilities, little or no proprietary technology is associated with the equipment itself; the proprietary technology is how this equipment is used to produce each of the products.

The primary objective of the structured approach is to separate cleanly the following two aspects of the batch logic:

**Product Technology** Basically, this encompasses the product technology, such as how to mix certain molecules to make other molecules. This technology ultimately determines the chemical and physical properties of the final product. The product recipe is the principal source for the product technology.

**Process Technology** The process equipment permits certain processing operations (e.g., heat to a specified temperature) to be undertaken. Each processing operation will involve certain actions (e.g., opening appropriate valves).

The need to keep these two aspects separated is best illustrated by a situation where the same product is to be made at different plants. While it is possible that the processing equipment at the two plants is identical, this is rarely the case. Suppose one plant uses steam for heating its vessels, but the other uses a hot oil system as the source of heat. When a product recipe requires that material be heated to a specified temperature, each plant can accomplish this objective, but each will go about it in quite different ways. The ideal case for a product recipe is as follows:

1. It contains all the product technology required to make a product.
2. It contains no equipment-dependent information, i.e., no process technology.

In the previous example, such a recipe would simply state that the product must be heated to a specified temperature. Whether heating is undertaken with steam or hot oil is irrelevant to the product technology. By restricting the product recipe to a given product technology, the same product recipe can be used to make products at different sites. At a given site, the specific approach to be used to heat a vessel is important. The traditional approach is for an engineer at each site to expand the product recipe into a document that explains in detail how the product is to be made at the specific site. This document goes by various names, although standard operating procedure or SOP is a common one. Depending on the level of detail to which it is written, the SOP could specify exactly which valves must be opened to heat the contents of a vessel. Thus, the SOP is site-dependent and contains both product technology and process technology.

In structuring the logic for a flexible batch application, the following organization permits product technology to be cleanly separated from process technology:

- A recipe consists of a formula and one or more processing operations. Ideally, only product technology is contained in a recipe.
- A processing operation consists of one or more phases. Ideally, only product technology is contained in a processing operation.
- A phase consists of one or more actions. Ideally, only process technology is contained in a phase.

In this structure, the recipe and processing operations would be the same at each site that manufactures the product. However, the logic that comprises each phase would be specific to a given site. In the heating example from above, each site would require a phase to heat the contents of the vessel. However, the logic within the phase at one site would accomplish the heating by opening the appropriate steam valves, while the logic at the other site would accomplish the heating by opening the appropriate hot oil valves.

Usually the critical part of structuring batch logic is the definition of the phases. There are two ways to approach this:

1. Examine the recipes for the current products for commonality, and structure the phases to reflect this commonality.

2 Examine the processing equipment to determine what processing capabilities are possible, and write phases to accomplish each possible processing capability.

There is the additional philosophical issue of whether to have a large number of simple phases with few options each, or a small number of complex phases with numerous options. The issues are analogous to structuring a complex computer program into subprograms. Each possible alternative has advantages and disadvantages.

As the phase contains no product technology, the implementation of a phase must be undertaken by those familiar with the process equipment. Furthermore, they should undertake this on the basis that the result will be used to make a variety of products, not just those that are initially contemplated. The development of the phase logic must also encompass all equipment-related safety issues. The phase should accomplish a clearly defined objective, so the implementers should be able to thoroughly consider all relevant issues in accomplishing this objective. The phase logic is defined in detail, implemented in the control system, and then thoroughly tested. Except when the processing equipment is modified, future modifications to the phase should be infrequent. The result should be a very dependable module that can serve as a building block for batch logic.

Even for flexible batch applications, a comprehensive menu of phases should permit most new products to be implemented by using currently existing phases. By reusing existing phases, numerous advantages accrue:

1. The engineering effort to introduce a new recipe at a site is reduced.
2. The product is more likely to be on-spec the first time, thus avoiding the need to dispose of off-spec product.
3. The new product can be supplied to customers sooner, hopefully before competitors can supply the product.

There is also a distinct advantage in maintenance. When a problem with a phase is discovered and the phase logic is corrected, the correction is effectively implemented in all recipes that use the phase. If a change is implemented in the processing equipment, the affected phases must be modified accordingly and then thoroughly tested. These modifications are also effectively implemented in all recipes that use these phases.

# PROCESS MEASUREMENTS

## GENERAL CONSIDERATIONS

Process measurements encompass the application of the principles of metrology to the process in question. The objective is to obtain values for the current conditions within the process and to make this information available in a form usable by the control system, process operators, or management information systems. The term *measured variable* or *process variable* designates the process condition that is being determined.

Process measurements fall into two categories:

1. *Continuous measurements.* An example of a continuous measurement is a level measurement device that determines the liquid level in a tank (e.g., in meters).
2. *Discrete measurements.* An example of a discrete measurement is a level switch that indicates the presence or absence of liquid at the location at which the level switch is installed.

In continuous processes, most process control applications rely on continuous measurements. In batch processes, many of the process control applications utilize discrete as well as continuous measurements. In both types of processes, the safety interlocks and process interlocks rely largely on discrete measurements.

**Continuous Measurements** In most applications, continuous measurements provide more information than discrete measurements. Basically, discrete measurements involve a yes/no decision, whereas continuous measurements may entail considerable signal processing.

The components of a typical continuous measurement device are as follows:

1. *Sensor.* This component produces a signal that is related in a known manner to the process variable of interest. The sensors in use today are primarily of the electrical analog variety, and the signal is in the form of a voltage, a resistance, a capacitance, or some other directly measurable electrical quantity. Prior to the mid-1970s, instruments tended to use sensors whose signal was mechanical and thus compatible with pneumatic technology. Since that time, the fraction of sensors that are digital has grown considerably, often eliminating the need for analog-to-digital conversion.
2. *Signal processing.* The signal from a sensor is usually related in a nonlinear fashion to the process variable of interest. For the output of the measurement device to be linear with respect to the process variable of interest, linearization is required. Furthermore, the signal from the sensor might be affected by variables other than the process variable. In this case, additional variables must be sensed, and the signal from the sensor compensated to account for the other variables. For example, reference junction compensation is required for thermocouples (except when used for differential temperature measurements).
3. *Transmitter.* The measurement device output must be a signal that can be transmitted over some distance. Where electronic analog transmission is used, the low range on the transmitter output is 4 mA, and the upper range is 20 mA. Microprocessor-based transmitters (often referred to as smart transmitters) are usually capable of transmitting the measured variable digitally in engineering units.

**Accuracy and Repeatability** Definitions of terminology pertaining to process measurements can be obtained from standards available from the Instrumentation, Systems, and Automation Society (ISA) and from the Scientific Apparatus Makers Association [now Measurement, Control, and Automation Association (MCAA)], both of which are updated periodically. An appreciation of accuracy and repeatability is especially important. Some applications depend on the accuracy of the instrument, but other applications depend on repeatability. Excellent accuracy implies excellent repeatability; however, an instrument can have poor accuracy but excellent repeatability. In some applications, this is acceptable, as discussed below.

***Range and Span*** A continuous measurement device is expected to provide credible values of the measured value between a lower range and an upper range. The difference between the upper range and the lower range is the span of the measurement device. The maximum value for the upper range and the minimum value for the lower range depend on the principles on which the measurement device is based and on the design chosen by the manufacturer of the measurement device. If the measured variable is greater than the upper range or less than the lower range, the measured variable is said to be out of range or the measurement device is said to be overranged.

***Accuracy*** Accuracy refers to the difference between the measured value and the true value of the measured variable. Unfortunately, the true value is never known, so in practice accuracy refers to the difference between the measured value and an accepted standard value for the measured variable.

Accuracy can be expressed in four ways:

1. As an absolute difference in the units of the measured variable
2. As a percent of the current reading
3. As a percent of the span of the measured variable
4. As a percent of the upper range of the span

For process measurements, accuracy as a percent of span is the most common.

Manufacturers of measurement devices always state the accuracy of the instrument. However, these statements always specify specific or reference conditions at which the measurement device will perform with the stated accuracy, with temperature and pressure most often appearing in the reference conditions. When the measurement device is applied at other conditions, the accuracy is affected. Manufacturers usually also provide some statements on how accuracy is affected when the conditions of use deviate from the referenced conditions in the statement of accuracy. Although appropriate calibration procedures can minimize some of these effects, rarely can they be totally eliminated. It is easily possible for such effects to cause a measurement device with a stated accuracy of 0.25 percent of span at reference conditions to ultimately provide measured values with accuracies of 1 percent or less. Microprocessor-based measurement devices usually provide better accuracy than do the traditional electronic measurement devices.

In practice, most attention is given to accuracy when the measured variable is the basis for billing, such as in custody transfer applications. However, whenever a measurement device provides data to any type of optimization strategy, accuracy is very important.

***Repeatability*** Repeatability refers to the difference between the measurements when the process conditions are the same. This can also be viewed from the opposite perspective. If the measured values are the same, repeatability refers to the difference between the process conditions.

For regulatory control, repeatability is of major interest. The basic objective of regulatory control is to maintain uniform process operation. Suppose that on two different occasions, it is desired that the temperature in a vessel be 800°C. The regulatory control system takes appropriate actions to bring the measured variable to 800°C. The difference between the process conditions at these two times is determined by the repeatability of the measurement device.

In the use of temperature measurement for control of the separation in a distillation column, repeatability is crucial but accuracy is not. Composition control for the overhead product would be based on a measurement of the temperature on one of the trays in the rectifying section. A target would be provided for this temperature. However, at

periodic intervals, a sample of the overhead product is analyzed in the laboratory and the information is provided to the process operator. Should this analysis be outside acceptable limits, the operator would adjust the set point for the temperature. This procedure effectively compensates for an inaccurate temperature measurement; however, the success of this approach requires good repeatability from the temperature measurement.

**Dynamics of Process Measurements** Especially where the measurement device is incorporated into a closed-loop control configuration, dynamics are important. The dynamic characteristics depend on the nature of the measurement device, and on the nature of components associated with the measurement device (e.g., thermowells and sample conditioning equipment). The term *measurement system* designates the measurement device and its associated components.

The following dynamics are commonly exhibited by measurement systems:

- *Time constants.* Where there is a capacity and a throughput, the measurement device will exhibit a time constant. For example, any temperature measurement device has a thermal capacity (mass times heat capacity) and a heat flow term (heat-transfer coefficient and area). Both the temperature measurement device and its associated thermowell will exhibit behavior typical of time constants.
- *Dead time.* Probably the best example of a measurement device that exhibits pure dead time (time delay) is the chromatograph, because the analysis is not available for some time after a sample is injected. Additional dead time results from the transportation lag within the sample system. Even continuous analyzer installations can exhibit dead time from the sample system.
- *Underdamped.* Measurement devices with mechanical components often have a natural harmonic and can exhibit underdamped behavior. The displacer type of level measurement device is capable of such behavior.

While the manufacturers of measurement devices can supply some information on the dynamic characteristics of their devices, interpretation is often difficult. Measurement device dynamics are quoted on varying bases, such as rise time, time to 63 percent response, settling time, etc. Even where the time to 63 percent response is quoted, it might not be safe to assume that the measurement device exhibits first-order behavior.

Where the manufacturer of the measurement device does not supply the associated equipment (thermowells, sample conditioning equipment, etc.), the user must incorporate the characteristics of these components to obtain the dynamics of the measurement system. An additional complication is that most dynamic data are stated for configurations involving reference materials such as water and air. The nature of the process material will affect the dynamic characteristics. For example, a thermowell will exhibit different characteristics when immersed in a viscous organic emulsion than when immersed in water. It is often difficult to extrapolate the available data to process conditions of interest.

Similarly, it is often impossible, or at least very difficult, to experimentally determine the characteristics of a measurement system under the conditions where it is used. It is certainly possible to fill an emulsion polymerization reactor with water and determine the dynamic characteristics of the temperature measurement system. However, it is not possible to determine these characteristics when the reactor is filled with the emulsion under polymerization conditions.

The primary impact of unfavorable measurement dynamics is on the performance of closed-loop control systems. This explains why most control engineers are very concerned with minimizing measurement dynamics, even though the factors considered in dynamics are often subjective.

**Selection Criteria** The selection of a measurement device entails a number of considerations given below, some of which are almost entirely subjective.

1. *Measurement span.* The measurement span required for the measured variable must lie entirely within the instrument's envelope of performance.

2. *Performance.* Depending on the application, accuracy, repeatability, or perhaps some other measure of performance is appropriate. Where closed-loop control is contemplated, speed of response must be included.

3. *Reliability.* Data available from the manufacturers can be expressed in various ways and at various reference conditions. Often, previous experience with the measurement device within the purchaser's organization is weighted most heavily.

4. *Materials of construction.* The instrument must withstand the process conditions to which it is exposed. This encompasses considerations such as operating temperatures, operating pressures, corrosion, and abrasion. For some applications, seals or purges may be necessary.

5. *Prior use.* For the first installation of a specific measurement device at a site, training of maintenance personnel and purchases of spare parts might be necessary.

6. *Potential for releasing process materials to the environment.* Fugitive emissions are receiving ever-increasing attention. Exposure considerations, both immediate and long-term, for maintenance personnel are especially important when the process fluid is either corrosive or toxic.

7. *Electrical classification.* Article 500 of the National Electric Code provides for the classification of the hazardous nature of the process area in which the measurement device will be installed. If the measurement device is not inherently compatible with this classification, suitable enclosures must be purchased and included in the installation costs.

8. *Physical access.* Subsequent to installation, maintenance personnel must have physical access to the measurement device for maintenance and calibration. If additional structural facilities are required, they must be included in the installation costs.

9. *Invasive or noninvasive.* The insertion of a probe can result in fouling problems and a need for maintenance. Probe location must be selected carefully for good accuracy and minimal fouling.

10. *Cost.* There are two aspects of the cost:

*a.* Initial purchase and installation (capital cost).

*b.* Recurring costs (operational expense). This encompasses instrument maintenance, instrument calibration, consumables (e.g., titrating solutions must be purchased for automatic titrators), and any other costs entailed in keeping the measurement device in service.

**Calibration** Calibration entails the adjustment of a measurement device so that the value from the measurement device agrees with the value from a standard. The International Standards Organization (ISO) has developed a number of standards specifically directed to calibration of measurement devices. Furthermore, compliance with the ISO 9000 standards requires that the working standard used to calibrate a measurement device be traceable to an internationally recognized standard such as those maintained by the National Institute of Standards and Technology (NIST).

Within most companies, the responsibility for calibrating measurement devices is delegated to a specific department. Often, this department may also be responsible for maintaining the measurement device. The specific calibration procedures depend on the type of measurement device. The frequency of calibration is normally predetermined, but earlier action may be dictated if the values from the measurement device become suspect.

Calibration of some measurement devices involves comparing the measured value with the value from the working standard. Pressure and differential pressure transmitters are calibrated in this manner. Calibration of analyzers normally involves using the measurement device to analyze a specially prepared sample whose composition is known. These and similar approaches can be applied to most measurement devices.

Flow is an important measurement whose calibration presents some challenges. When a flow measurement device is used in applications such as custody transfer, provision is made to pass a known flow through the meter. However, such a provision is costly and is not available for most in-process flowmeters. Without such a provision, a true calibration of the flow element itself is not possible. For orifice meters, calibration of the flowmeter normally involves calibration of the differential pressure transmitter, and the orifice plate is usually only inspected for deformation, abrasion, etc. Similarly, calibration of a magnetic flowmeter normally involves calibration of the voltage

**TABLE 8-8 Online Measurement Options for Process Control**

| Temperature | Flow | Pressure | Level | Composition |
|---|---|---|---|---|
| Thermocouple | Orifice | Liquid column | Float-activated | Gas-liquid chromatography (GLC) |
| Resistance temperature detector (RTD) | Venturi | Elastic element | Chain gauge | Mass spectrometry (MS) |
| Filled-system thermometer | Rotameter | Bourdon tube | Lever | Magnetic resonance analysis (MRA) |
| Bimetal thermometer | Turbine | Bellow | Magnetically coupled | Infrared (IR) spectroscopy |
| Pyrometer | Vortex-shedding | Diaphragm | Head devices | Raman spectroscopy |
| Total radiation | Ultrasonic | Strain gauges | Bubble tube | Ultraviolet (uv) spectroscopy |
| Photoelectric | Magnetic | Piezoresistive transducers | Electrical (conductivity) | Thermal conductivity |
| Ratio | Thermal mass | Piezoelectric transducers | Sonic | Refractive index (RI) |
| Laser | Coriolis | Optical fiber | Laser | Capacitance probe |
| Surface acoustic wave | Target | | Radiation | Surface acoustic wave |
| Semiconductor | | | Radar | Electrophoresis |
| | | | | Electrochemical |
| | | | | Paramagnetic |

| | | | | Tunable diode laser absorption |

measurement circuitry, which is analogous to calibration of the differential pressure transmitter for an orifice meter.

In the next section we cover the major types of measurement devices used in the process industries, principally the "big five" measurements: temperature, flow rate, pressure, level, and composition, along with online physical property measurement techniques. Table 8-8 summarizes the different options under each of the principal measurements.

## TEMPERATURE MEASUREMENTS

Measurement of the hotness or coldness of a body or fluid is commonplace in the process industries. Temperature-measuring devices utilize systems with properties that vary with temperature in a simple, reproducible manner and thus can be calibrated against known references (sometimes called secondary thermometers). The three dominant measurement devices used in automatic control are thermocouples, resistance thermometers, and pyrometers, and they are applicable over different temperature regimes.

**Thermocouples** Temperature measurements using thermocouples are based on the discovery by Seebeck in 1821 that an electric current flows in a continuous circuit of two different metallic wires if the two junctions are at different temperatures. The thermocouple may be represented diagrammatically as shown in Fig. 8-63. There A and B are the two metals, and $T_1$ and $T_2$ are the temperatures of the junctions. Let $T_1$ and $T_2$ be the reference junction (cold junction) and the measuring junction, respectively. If the thermoelectric current $i$ flows in the direction indicated in Fig. 8-63, metal A is customarily referred to as thermoelectrically positive to metal B. Metal pairs used for thermocouples include platinum-rhodium (the most popular and accurate), chromel-alumel, copper-constantan, and iron-constantan. The thermal emf is a measure of the difference in temperature between $T_2$ and $T_1$. In control systems the reference junction is usually located at the emf-measuring device. The reference junction may be held at constant temperature such as in an ice bath or a thermostated oven, or it may be at ambient temperature but electrically compensated (cold junction compensated circuit) so that it appears to be held at a constant temperature.

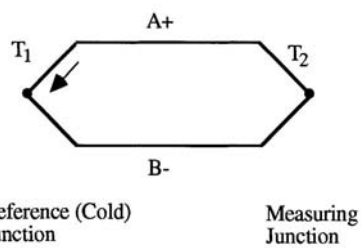

**FIG. 8-63** Basic circuit of Seebeck effect.

**Resistance Thermometers** The resistance thermometer depends upon the inherent characteristics of materials to change in electrical resistance when they undergo a change in temperature. Industrial resistance thermometers are usually constructed of platinum, copper, or nickel, and more recently semiconducting materials such as thermistors are being used. Basically, a resistance thermometer is an instrument for measuring electrical resistance that is calibrated in units of temperature instead of in units of resistance (typically ohms). Several common forms of bridge circuits are employed in industrial resistance thermometry, the most common being the Wheatstone bridge. A resistance thermometer detector (RTD) consists of a resistance conductor (metal) which generally shows an increase in resistance with temperature. The following equation represents the variation of resistance with temperature (°C):

$$R_T = R_0(1 + a_1T + a_2T^2 + \cdots + a_nT^n) \tag{8-92}$$

$R_0$ = resistance at 0°C

The temperature coefficient of resistance, $\alpha_T$ is expressed as

$$\alpha_T = \frac{1}{R_T}\frac{dR_T}{dT} \tag{8-93}$$

For most metals $\alpha_T$ is positive. For many pure metals, the coefficient is essentially constant and stable over large portions of their useful range. Typical resistance versus temperature curves for platinum, copper, and nickel are given in Fig. 8-64, with platinum usually the metal of choice. Platinum has a useful range of –200 to 800°C, while nickel (–80 to 320°C) and copper (–100 to 100°C) are more limited. Detailed resistance versus temperature tables are available from the National Institute of Standards and Technology (NIST) and suppliers of resistance thermometers. Table 8-9 gives recommended temperature measurement ranges for thermocouples and RTDs. Resistance thermometers are receiving increased usage because they are about 10 times more accurate than thermocouples.

**Thermistors** Thermistors are nonlinear temperature-dependent resistors, and normally only the materials with negative temperature coefficient of resistance (NTC type) are used. The resistance is related to temperature as

$$R_T = R_T \exp\left[\beta\left(\frac{1}{T} - \frac{1}{T_r}\right)\right] \tag{8-94}$$

where $\alpha_T$ is a reference temperature, which is generally 298 K. Thus

$$\alpha_T = \frac{1}{R_T}\frac{dR_T}{dT} \tag{8-95}$$

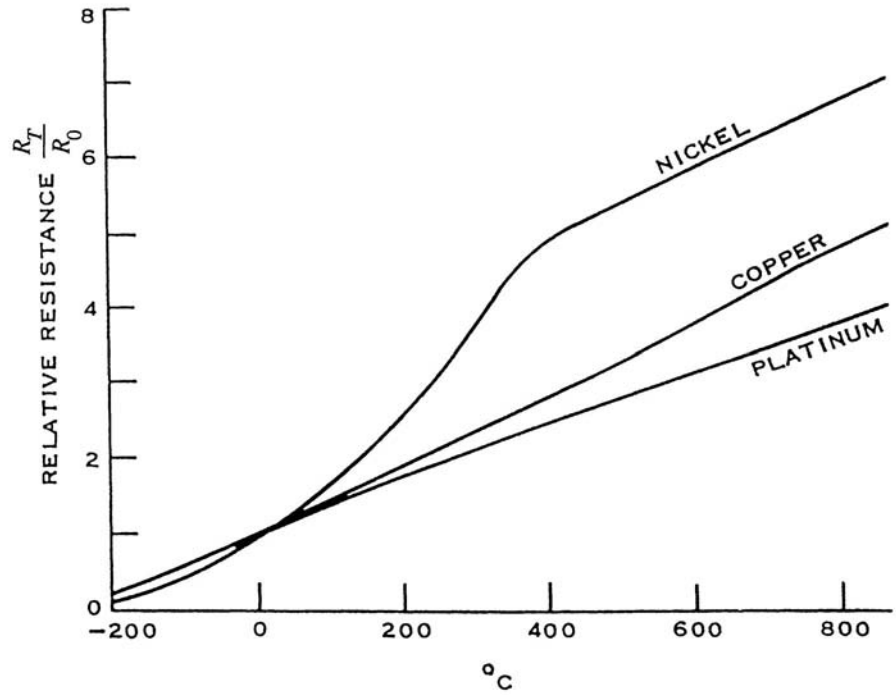

**FIG. 8-64** Typical resistance thermometer curves for platinum, copper, and nickel wire, where $R_T$ = resistance at temperature $T$ and $R_0$ = resistance at 0°C.

The value of β is on the order of 4000, so at room temperature (298 K), $\alpha_T = -0.045$ for thermistor and 0.0035 for 100-Ω platinum RTD. Compared with RTDs, NTC-type thermistors are advantageous in that the detector dimension can be made small, resistance value is higher (less affected by the resistances of the connecting leads), and it has higher temperature sensitivity and low thermal inertia of the sensor. Disadvantages of thermistors to RTDs include nonlinear characteristics and low measuring temperature range.

**Filled-System Thermometers** The filled-system thermometer is designed to provide an indication of temperature some distance removed from the point of measurement. The measuring element (bulb) contains a gas or liquid that changes in volume, pressure, or vapor pressure with temperature. This change is communicated through a capillary tube to a Bourdon tube or other pressure- or volume-sensitive device. The Bourdon tube responds so as to provide a motion related to the bulb temperature. Those systems that respond to volume changes are completely filled with a liquid. Systems that respond to pressure changes either are filled with a gas or are partially filled with a volatile liquid. Changes in gas or vapor pressure with changes in bulb temperatures are carried through the capillary to the Bourdon. The latter bulbs are sometimes constructed so that the capillary is filled with a nonvolatile liquid.

**TABLE 8-9 Recommended Temperature Measurement Ranges for RTDs and Thermocouples**

| | |
|---|---|
| Resistance Thermometer Detectors (RTDs) | |
| 100V Pt | −200–+850°C |
| 120V Ni | −80–+320°C |
| Thermocouples | |
| Type B | 700–+1820°C |
| Type E | −175–+1000°C |
| Type J | −185–+1200°C |
| Type K | −175–+1372°C |
| Type N | 0–+1300°C |
| Type R | 125–+1768°C |
| Type S | 150–+1768°C |
| Type T | −170–+400°C |

Fluid-filled bulbs deliver enough power to drive controller mechanisms and even directly actuate control valves. These devices are characterized by large thermal capacity, which sometimes leads to slow response, particularly when they are enclosed in a thermal well for process measurements. Filled-system thermometers are used extensively in industrial processes for a number of reasons. The simplicity of these devices allows rugged construction, minimizing the possibility of failure with a low level of maintenance, and inexpensive overall design of control equipment. In case of system failure, the entire unit must be replaced or repaired.

As they are normally used in the process industries, the sensitivity and percentage of span accuracy of these thermometers are generally the equal of those of other temperature-measuring instruments. Sensitivity and absolute accuracy are not the equal of those of short-span electrical instruments used in connection with resistance-thermometer bulbs. Also the maximum temperature is somewhat limited.

**Bimetal Thermometers** Thermostatic bimetal can be defined as a composite material made up of strips of two or more metals fastened together. This composite, because of the different expansion rates of its components, tends to change curvature when subjected to a change in temperature. With one end of a straight strip fixed, the other end deflects in proportion to the temperature change, the square of the length, and inversely as the thickness, throughout the linear portion of the deflection characteristic curve. If a bimetallic strip is wound into a helix or a spiral and one end is fixed, the other end will rotate when heat is applied. For a thermometer with uniform scale divisions, a bimetal must be designed to have linear deflection over the desired temperature range. Bimetal thermometers are used at temperatures ranging from 580 down to −180°C and lower. However, at the low temperatures

the rate of deflection drops off quite rapidly. Bimetal thermometers do not have long-time stability at temperatures above 430°C.

**Pyrometers** Planck's distribution law gives the radiated energy flux $q_b(\lambda,T)d\lambda$ in the wavelength range $\lambda$ to $\lambda + d\lambda$ from a black surface:

$$q_b(\lambda,T) = \frac{C_1}{\lambda^5}\frac{1}{e^{C_2/\lambda T}-1} \tag{8-96}$$

where $C_1 = 3.7418 \times 10^{10}\mu W{\cdot}\mu m^4{\cdot}cm^{-2}$ and $C_2 = 14{,}388\ \mu m{\cdot}K$.

If the target object is a black body and if the pyrometer has a detector which measures the specific wavelength signal from the object, the temperature of the object can be exactly estimated from Eq. (8-96). While it is possible to construct a physical body that closely approximates black body behavior, most real-world objects are not black bodies. The deviation from a black body can be described by the spectral emissivity

$$\varepsilon_T = \frac{q(T)}{q_b(T)} \tag{8-97}$$

where $q(\lambda,T)$ is the radiated energy flux from a real body in the wavelength range $\lambda$ to $\lambda + d\lambda$ and $0 < \varepsilon_{\lambda,T} < 1$. Integrating Eq. (8-96) over all wavelengths gives the Stefan-Boltzmann equation

$$q_b(T) = \int_0^\infty q_b(\lambda,T)d\lambda = \sigma T^4 \tag{8-98}$$

where $\sigma$ is the Stefan-Boltzmann constant. Similar to Eq. (8-93), the emissivity $\varepsilon_T$ for the total radiation is

$$\varepsilon_T = \frac{q(T)}{q_b(T)} \tag{8-99}$$

where $q(T)$ is the radiated energy flux from a real body with emissivity $\varepsilon_T$.

***Total Radiation Pyrometers*** In total radiation pyrometers, the thermal radiation is detected over a large range of wavelengths from the object at high temperature. The detector is normally a thermopile, which is built by connecting several thermocouples in series to increase the temperature measurement range. The pyrometer is calibrated for black bodies, so the indicated temperature $T_p$ should be converted for non–black body temperature.

***Photoelectric Pyrometers*** Photoelectric pyrometers belong to the class of band radiation pyrometers. The thermal inertia of thermal radiation detectors does not permit the measurement of rapidly changing temperatures. For example, the smallest time constant of a thermal detector is about 1 ms while the smallest time constant of a photoelectric detector can be about 1 or 2 s. Photoelectric pyrometers may use photoconductors, photodiodes, photovoltaic cells, or vacuum photocells. Photoconductors are built from glass plates with thin film coatings of 1-μm thickness, using PbS, CdS, PbSe, or PbTe. When the incident radiation has the same wavelength as the materials are able to absorb, the captured incident photons free photoelectrons, which form an electric current. Photodiodes in germanium or silicon are operated with a reverse bias voltage applied. Under the influence of the incident radiation, their conductivity as well as their reverse saturation current is proportional to the intensity of the radiation within the spectral response band from 0.4 to 1.7 μm for Ge and from 0.6 to 1.1 μm for Si. Because of the above characteristics, the operating range of a photoelectric pyrometer can be either spectral or in specific band. Photoelectric pyrometers can be applied for a specific choice of the wavelength.

***Disappearing Filament Pyrometers*** Disappearing filament pyrometers can be classified as spectral pyrometers. The brightness of a lamp filament is changed by adjusting the lamp current until the filament disappears against the background of the target, at which point the temperature is measured. Because the detector is the human eye, it is difficult to calibrate for online measurements.

***Ratio Pyrometers*** The ratio pyrometer is also called the two-color pyrometer. Two different wavelengths are utilized for detecting the radiated signal. If one uses Wien's law for small values of $AT$, the detected signals from spectral radiant energy flux emitted at wavelengths $\lambda_1$ and $\lambda_2$ with emissivities $\varepsilon_{\lambda_1}$ and $\varepsilon_{\lambda_2}$ are

$$S_{\lambda_1} = KC_1\varepsilon_{\lambda_1}\lambda_1^{-5}\exp\left(\frac{-C_2}{\lambda_1 T}\right) \tag{8-100}$$

$$S_{\lambda_2} = KC_1\varepsilon_{\lambda_2}\lambda_2^{-5}\exp\left(\frac{-C_2}{\lambda_2 T}\right) \tag{8-101}$$

The ratio of the signals $S_{\lambda_1}$ and $S_{\lambda_2}$ is

$$\frac{S_{\lambda_1}}{S_{\lambda_2}} = \frac{\varepsilon_{\lambda_1}}{\varepsilon_{\lambda_2}}\left(\frac{\lambda_2}{\lambda_1}\right)^5\exp\left[\frac{C_2}{T}\left(\frac{1}{\lambda_2}-\frac{1}{\lambda_1}\right)\right] \tag{8-102}$$

Nonblack or nongray bodies are characterized by the wavelength dependence of their spectral emissivity. Let $T_c$ be defined as the temperature of the body corresponding to the temperature of a black body. If the ratio of its radiant intensities at wavelengths $\lambda_1$ and $\lambda_2$ equals the ratio of the radiant intensities of the non–black body, whose temperature is to be measured at the same wavelength, then Wien's law gives

$$\frac{\varepsilon_{\lambda_1}\exp(-C_2/\lambda_1 T)}{\varepsilon_{\lambda_2}\exp(-C_2/\lambda_2 T)} = \frac{\exp(-C_2/\lambda_1 T_c)}{\exp(-C_2/\lambda_2 T_c)} \tag{8-103}$$

where $T$ is the true temperature of the body. Rearranging Eq. (8-103) gives

$$T = \left[\frac{\ln \varepsilon_{\lambda_1}/\varepsilon_{\lambda_2}}{C_2(1/\lambda_1 - 1/\lambda_2)} + \frac{1}{T_c}\right]^{-1} \tag{8-104}$$

For black or gray bodies, Eq. (8-104) reduces to

$$\frac{S_{\lambda_1}}{S_{\lambda_2}} = \left(\frac{\lambda_2}{\lambda_1}\right)^5\exp\left[\frac{C_2}{T}\left(\frac{1}{\lambda_2}-\frac{1}{\lambda_1}\right)\right] \tag{8-105}$$

Thus by measuring $S_{\lambda_1}$ and $S_{\lambda_2}$, the temperature $T$ can be estimated.

***Accuracy of Pyrometers*** Most of the temperature estimation methods for pyrometers assume that the object is either a gray body or has known emissivity values. The emissivity of the non–black body depends on the internal state or the surface geometry of the objects. Also the medium through which the thermal radiation passes is not always transparent. These inherent uncertainties of the emissivity values make the accurate estimation of the temperature of the target objects difficult. Proper selection of the pyrometer and accurate emissivity values can provide a high level of accuracy.

## PRESSURE MEASUREMENTS

Pressure, defined as force per unit area, is usually expressed in terms of familiar units of weight-force and area or the height of a column of liquid which produces a like pressure at its base. Process pressure-measuring devices may be divided into three groups: (1) those based on the measurement of the height of a liquid column, (2) those based on the measurement of the distortion of an elastic pressure chamber, and (3) electrical sensing devices.

**Liquid-Column Methods** Liquid-column pressure-measuring devices are those in which the pressure being measured is balanced against the pressure exerted by a column of liquid. If the density of the liquid is known, the height of the liquid column is a measure of the pressure. Most forms of liquid-column pressure-measuring devices are commonly called manometers. When the height of the liquid is

observed visually, the liquid columns are contained in glass or other transparent tubes. The height of the liquid column may be measured in length units or calibrated in pressure units. Depending on the pressure range, water and mercury are the liquids most frequently used. Because the density of the liquid used varies with temperature, the temperature must be taken into account for accurate pressure measurements.

**Elastic Element Methods** Elastic element pressure-measuring devices are those in which the measured pressure deforms some elastic material (usually metallic) within its elastic limit, the magnitude of the deformation being approximately proportional to the applied pressure. These devices may be loosely classified into three types: Bourdon tube, bellows, and diaphragm.

***Bourdon Tube Elements*** Probably the most frequently used process pressure-indicating device is the C-spring Bourdon tube pressure gauge. Gauges of this general type are available in a wide variety of pressure ranges and materials of construction. Materials are selected on the basis of pressure range, resistance to corrosion by the process materials, and effect of temperature on calibration. Gauges calibrated with pressure, vacuum, compound (combination pressure and vacuum), and suppressed-zero ranges are available.

***Bellows Element*** The bellows element is an axially elastic cylinder with deep folds or convolutions. The bellows may be used unopposed, or it may be restrained by an opposing spring. The pressure to be measured may be applied either to the inside or to the space outside the bellows, with the other side exposed to atmospheric pressure. For measurement of absolute pressure either the inside or the space outside of the bellows can be evacuated and sealed. Differential pressures may be measured by applying the pressures to opposite sides of a single bellows or to two opposing bellows.

***Diaphragm Elements*** Diaphragm elements may be classified into two principal types: those that utilize the elastic characteristics of the diaphragm and those that are opposed by a spring or other separate elastic element. The first type usually consists of one or more capsules, each composed of two diaphragms bonded together by soldering, brazing, or welding. The diaphragms are flat or corrugated circular metallic disks. Metals commonly used in diaphragm elements include brass, phosphor bronze, beryllium copper, and stainless steel. Ranges are available from fractions of an inch of water to over 800 in (200 kPa) gauge. The second type of diaphragm is used for containing the pressure and exerting a force on the opposing elastic element. The diaphragm is a flexible or slack diaphragm of rubber, leather, impregnated fabric, or plastic. Movement of the diaphragm is opposed by a spring which determines the deflection for a given pressure. This type of diaphragm is used for the measurement of extremely low pressure, vacuum, or differential pressure.

**Electrical Methods** Electrical methods for pressure measurement include strain gauges, piezoresistive transducers, and piezoelectric transducers.

***Strain Gauges*** When a wire or other electrical conductor is stretched elastically, its length is increased and its diameter is decreased. Both of these dimensional changes result in an increase in the electrical resistance of the conductor. Devices utilizing resistance-wire grids for measuring small distortions in elastically stressed materials are commonly called strain gauges. Pressure-measuring elements utilizing strain gauges are available in a wide variety of forms. They usually consist of one of the elastic elements described earlier to which one or more strain gauges have been attached to measure the deformation. There are two basic strain gauge forms: bonded and unbonded. Bonded strain gauges are bonded directly to the surface of the elastic element whose strain is to be measured. The unbonded strain gauge transducer consists of a fixed frame and an armature that moves with respect to the frame in response to the measured pressure. The strain gauge wire filaments are stretched between the armature and frame. The strain gauges are usually connected electrically in a Wheatstone bridge configuration.

Strain gauge pressure transducers are manufactured in many forms for measuring gauge, absolute, and differential pressures and vacuum. Full-scale ranges from 25.4 mm of water to 10,134 MPa are available. Strain gauges bonded directly to a diaphragm pressure-sensitive element usually have an extremely fast response time and are suitable for high-frequency dynamic pressure measurements.

***Piezoresistive Transducers*** A variation of the conventional strain gauge pressure transducer uses bonded single-crystal semiconductor wafers, usually silicon, whose resistance varies with strain or distortion. Transducer construction and electrical configurations are similar to those using conventional strain gauges. A permanent magnetic field is applied perpendicular to the resonating sensor. An alternating current causes the resonator to vibrate, and the resonant frequency is a function of the pressure (tension) of the resonator. The principal advantages of piezoresistive transducers are a much higher bridge voltage output and smaller size. Full-scale output voltages of 50 to 100 mV/V of excitation are typical. Some newer devices provide digital rather than analog output.

***Piezoelectric Transducers*** Certain crystals produce a potential difference between their surfaces when stressed in appropriate directions. Piezoelectric pressure transducers generate a potential difference proportional to a pressure-generated stress. Because of the extremely high electrical impedance of piezoelectric crystals at low frequency, these transducers are usually not suitable for measurement of static process pressures.

## FLOW MEASUREMENTS

*Flow,* defined as volume per unit of time at specified temperature and pressure conditions, is generally measured by positive displacement or rate meters. The term *positive displacement meter* applies to a device in which the flow is divided into isolated measured volumes when the number of fillings of these volumes is counted in some manner. The term *rate meter* applies to all types of flowmeters through which the material passes without being divided into isolated quantities. Movement of the material is usually sensed by a primary measuring element that activates a secondary device. The flow rate is then inferred from the response of the secondary device by means of known physical laws or from empirical relationships.

The principal classes of flow-measuring instruments used in the process industries are variable-head, variable-area, positive-displacement, and turbine instruments; mass flowmeters; vortex-shedding and ultrasonic flowmeters; magnetic flowmeters; and more recently, Coriolis mass flowmeters. Head meters are covered in detail in Sec. 5.

**Orifice Meter** The most widely used flowmeter involves placing a fixed-area flow restriction (an orifice) in the pipe carrying the fluid. This flow restriction causes a pressure drop which can be related to flow rate. The sharp-edge orifice is popular because of its simplicity, low cost, and the large amount of research data on its behavior. For the orifice meter, the flow rate $Q_a$ for a liquid is given by

$$Q_a = \frac{C_d A_2}{\sqrt{1-(A_2/A_1)^2}} \cdot \sqrt{\frac{2(p_1 - p_2)}{\rho}} \qquad (8\text{-}106)$$

where $p_1 - p_2$ is the pressure drop, $\rho$ is the density, $A_1$ is the pipe cross-sectional area, $A_2$ is the orifice cross-sectional area, and $C_d$ is the discharge coefficient. The discharge coefficient $C_d$ varies with the Reynolds number at the orifice and can be calibrated with a single fluid, such as water (typically $C_d \approx 0.6$). If the orifice and pressure taps are constructed according to certain standard dimensions, quite accurate (about 0.4 to 0.8 percent error) values of $C_d$ may be obtained. Also note that the standard calibration data assume no significant flow disturbances such as elbows and valves for a certain minimum distance upstream of the orifice. The presence of such disturbances close to the orifice can cause errors of as much as 15 percent. Accuracy in measurements limits the meter to a flow rate range of 3:1. The orifice has a relatively large permanent pressure loss that must be made up by the pumping machinery.

**Venturi Meter** The venturi tube operates on exactly the same principle as the orifice [see Eq. (8-102)]. Discharge coefficients of venturis are larger than those for orifices and vary from about 0.94 to 0.99. A venturi gives a definite improvement in power losses over an orifice and is often indicated for measuring very large flow rates, where power losses can become economically significant. The initial higher cost of a venturi over an orifice may thus be offset by reduced operating costs.

**Rotameter** A rotameter consists of a vertical tube with a tapered bore in which a float changes position with the flow rate through the tube. For a given flow rate, the float remains stationary because the vertical forces of differential pressure, gravity, viscosity, and buoyancy are balanced. The float position is the output of the meter and can be made essentially linear with flow rate by making the tube area vary linearly with the vertical distance.

**Turbine Meter** If a turbine wheel is placed in a pipe containing a flowing fluid, its rotary speed depends on the flow rate of the fluid. A turbine can be designed whose speed varies linearly with flow rate. The speed can be measured accurately by counting the rate at which turbine blades pass a given point, using magnetic pickup to produce voltage pulses. By feeding these pulses to an electronic pulse rate meter one can measure flow rate by summing the pulses during a timed interval. Turbine meters are available with full-scale flow rates ranging from about 0.1 to 30,000 gal/min for liquids and 0.1 to 15,000 $ft^3$/min for air. Nonlinearity can be less than 0.05 percent in the larger sizes. Pressure drop across the meter varies with the square of flow rate and is about 3 to 10 psi at full flow. Turbine meters can follow flow transients quite accurately since their fluid/mechanical time constant is on the order of 2 to 10 ms.

**Vortex-Shedding Flowmeters** These flowmeters take advantage of vortex shedding, which occurs when a fluid flows past a nonstreamlined object (a blunt body). The flow cannot follow the shape of the object and separates from it, forming turbulent vortices or eddies at the object's side surfaces. As the vortices move downstream, they grow in size and are eventually shed or detached from the object. Shedding takes place alternately at either side of the object, and the rate of vortex formation and shedding is directly proportional to the volumetric flow rate. The vortices are counted and used to develop a signal linearly proportional to the flow rate. The digital signals can easily be totaled over an interval of time to yield the flow rate. Accuracy can be maintained regardless of density, viscosity, temperature, or pressure when the Reynolds number is greater than 10,000. There is usually a low flow cutoff point below which the meter output is clamped at zero. This flowmeter is recommended for use with relatively clean, low-viscosity liquids, gases, and vapors, and rangeability of 10:1 to 20:1 is typical. A sufficient length of straight-run pipe is necessary to prevent distortion in the fluid velocity profile.

**Ultrasonic Flowmeters** An ultrasonic flowmeter is based upon the variable time delays of received sound waves which arise when a flowing liquid's rate of flow is varied. Two fundamental measurement techniques, depending upon liquid cleanliness, are generally used. In the first technique two opposing transducers are inserted in a pipe so that one transducer is downstream from the other. These transducers are then used to measure the difference between the velocity at which the sound travels with the direction of flow and the velocity at which it travels against the direction of flow. The differential velocity is measured either by (1) direct time delays using sound wave burst or (2) frequency shifts derived from beat-together, continuous signals. The frequency measurement technique is usually preferred because of its simplicity and independence of the liquid static velocity. A relatively clean liquid is required to preserve the uniqueness of the measurement path.

In the second technique, the flowing liquid must contain scatters in the form of particles or bubbles which will reflect the sound waves. These scatters should be traveling at the velocity of the liquid. A Doppler method is applied by transmitting sound waves along the flow path and measuring the frequency shift in the returned signal from the scatters in the process fluid. This frequency shift is proportional to liquid velocity.

**Magnetic Flowmeters** The principle behind these flowmeters is Faraday's law of electromagnetic inductance. The magnitude of the voltage induced in a conductive medium moving at right angles through a magnetic field is directly proportional to the product of the magnetic flux density, the velocity of the medium, and the path length between the probes. A minimum value of fluid conductivity is required to make this approach viable. The pressure of multiple phases or undissolved solids can affect the accuracy of the measurement if the velocities of the phases are different from that for straight-run pipe. Magmeters are very accurate over wide flow ranges and are especially accurate at low flow rates. Typical applications include metering viscous fluids, slurries, or highly corrosive chemicals. Because magmeters should be filled with fluid, the preferred installation is in vertical lines with flow going upward. However, magmeters can be used in tight piping schemes where it is impractical to have long pipe runs, typically requiring lengths equivalent to five or more pipe diameters.

**Coriolis Mass Flowmeters** Coriolis mass flowmeters utilize a vibrating tube in which Coriolis acceleration of a fluid in a flow loop can be created and measured. They can be used with virtually any liquid and are extremely insensitive to operating conditions, with pressure ranges over 100:1. These meters are more expensive than volumetric meters and range in size from $\frac{1}{16}$ to 6 in. Due to the circuitous path of flow through the meter, Coriolis flowmeters exhibit higher than average pressure changes. The meter should be installed so that it will remain full of fluid, with the best installation in a vertical pipe with flow going upward. There is no Reynolds number limitation with this meter, and it is quite insensitive to velocity profile distortions and swirl, hence there is no requirement for straight piping upstream.

**Thermal Mass Flowmeters** The trend in the chemical process industries is toward increased usage of mass flowmeters that are independent of changes in pressure, temperature, viscosity, and density. Thermal mass meters are widely used in semiconductor manufacturing and in bioprocessing for control of low flow rates (called mass flow controllers, or MFCs). MFCs measure the heat loss from a heated element, which varies with flow rate, with an accuracy of ± 1 percent. Capacitance probes measure the dielectric constant of the fluid and are useful for flow measurements of slurries and other two-phase flows.

## LEVEL MEASUREMENTS

The measurement of level can be defined as the determination of the location of the interface between two fluids, separable by gravity, with respect to a fixed reference plane. The most common level measurement is that of the interface between a liquid and a gas. Other level measurements frequently encountered are the interface between two liquids, between a granular or fluidized solid and a gas, and between a liquid and its vapor.

A commonly used basis for classification of level devices is as follows: float-actuated, displacer, and head devices, and a miscellaneous group which depends mainly on fluid characteristics.

**Float-Actuated Devices** Float-actuated devices are characterized by a buoyant member which floats at the interface between two fluids. Because a significant force is usually required to move the indicating mechanism, float-actuated devices are generally limited to liquid-gas interfaces. By properly weighting the float, they can be used to measure liquid-liquid interfaces. Float-actuated devices may be classified on the basis of the method used to couple the float motion to the indicating system, as discussed below.

***Chain or Tape Float Gauge*** In these types of gauges, the float is connected to the indicating mechanism by means of a flexible chain or tape. These gauges are commonly used in large atmospheric storage tanks. The gauge-board type is provided with a counterweight to keep the tape or chain taut. The tape is stored in the gauge head on a spring-loaded reel. The float is usually a pancake-shaped hollow metal float, with guide wires from top to bottom of the tank to constrain it.

***Lever and Shaft Mechanisms*** In pressurized vessels, float-actuated lever and shaft mechanisms are frequently used for level measurement. This type of mechanism consists of a hollow metal float and lever attached to a rotary shaft which transmits the float motion to the outside of the vessel through a rotary seal.

***Magnetically Coupled Devices*** A variety of float-actuated level devices which transmit the float motion by means of magnetic coupling have been developed. Typical of this class of devices are magnetically operated level switches and magnetic-bond float gauges. A typical magnetic-bond float gauge consists of a hollow magnet-carrying float which rides along a vertical nonmagnetic guide tube. The follower magnet is connected and drives an indicating dial similar to that on a conventional tape float gauge. The float and guide tube are in contact with the measured fluid and come in a variety of materials for resistance to corrosion and to withstand high pressures or vacuum. Weighted floats for liquid-liquid interfaces are available.

**Head Devices** A variety of devices utilize hydrostatic head as a measure of level. As in the case of displacer devices, accurate level measurement by hydrostatic head requires an accurate knowledge of the densities of both heavier-phase and lighter-phase fluids. The majority of this class of systems utilize standard pressure and differential pressure measuring devices.

***Bubble Tube Systems*** The commonly used bubble tube system sharply reduces restrictions on the location of the measuring element. To eliminate or reduce variations in pressure drop due to the gas flow rate, a constant differential regulator is commonly employed to maintain a constant gas flow rate. Because the flow of gas through the bubble tube prevents entry of the process liquid into the measuring system, this technique is particularly useful with corrosive or viscous liquids, liquids subject to freezing, and liquids containing entrained solids.

**Electrical Methods** Two electrical characteristics of fluids, conductivity and dielectric constant, are frequently used to distinguish between two phases for level measurement purposes. An application of electrical conductivity is the fixed-point level detection of a conductive liquid such as high and low water levels. A voltage is applied between two electrodes inserted into the vessel at different levels. When both electrodes are immersed in the liquid, a current flows. Capacitance-type level measurements are based on the fact that the electrical capacitance between two electrodes varies with the dielectric constant of the material between them. A typical continuous level measurement system consists of a rod electrode positioned vertically in a vessel, the other electrode usually being the metallic vessel wall. The electrical capacitance between the electrodes is a measure of the height of the interface along the rod electrode. The rod is usually conductively insulated from process fluids by a coating of plastic. The dielectric constants of most liquids and solids are markedly higher than those of gases and vapors (by a factor of 2 to 5). The dielectric constant of water and other polar liquids is 10 to 20 times that of hydrocarbons and other nonpolar liquids.

**Thermal Methods** Level-measuring systems may be based on the difference in thermal characteristics between the fluids, such as temperature or thermal conductivity. A fixed-point level sensor based on the difference in thermal conductivity between two fluids consists of an electrically heated thermistor inserted into the vessel. The temperature of the thermistor and consequently its electrical resistance increase as the thermal conductivity of the fluid in which it is immersed decreases. Because the thermal conductivity of liquids is markedly higher than that of vapors, such a device can be used as a point level detector for liquid-vapor interface.

**Sonic Methods** A fixed-point level detector based on sonic propagation characteristics is available for detection of a liquid-vapor interface. This device uses a piezoelectric transmitter and receiver, separated by a short gap. When the gap is filled with liquid, ultrasonic energy is transmitted across the gap, and the receiver actuates a relay. With a vapor filling the gap, the transmission of ultrasonic energy is insufficient to actuate the receiver.

**Laser Level Transmitters** These are designed for bulk solids, slurries, and opaque liquids. A laser near the vessel top fires a short pulse of light down to the surface of the process liquid, where it reflects back to a detector at the vessel top. A timing circuit measures the elapsed time and calculates the fluid depth. Lasers are attractive because lasers have no false echoes and can be directed through tight spaces.

**Radar Level Transmitters** Radar systems operate by beaming microwaves downward, from either a horn or parabolic dish located on top of the vessel. The signal reflects off the fluid surface back to the source after it detects a change in dielectric constant from the vapor to the fluid. The round-trip time is proportional to the distance to the fluid level. Guided-wave radar systems provide a rigid probe or flexible cable to guide the microwave down the height of the tank and back. Guided-wave radar is much more efficient than open-air radar because the guide provides a more focused energy path.

## PHYSICAL PROPERTY MEASUREMENTS

Physical property measurements are sometimes equivalent to composition analyzers, because the composition can frequently be inferred from the measurement of a selected physical property.

**Density and Specific Gravity** For binary or pseudobinary mixtures of liquids or gases or a solution of a solid or gas in a solvent, the density is a function of the composition at a given temperature and pressure. Specific gravity is the ratio of the density of a noncompressible substance to the density of water at the same physical conditions. For nonideal solutions, empirical calibration will give the relationship between density and composition. Several types of measuring devices are described below.

***Liquid Column*** Density may be determined by measuring the gauge pressure at the base of a fixed-height liquid column open to the atmosphere. If the process system is closed, then a differential pressure measurement is made between the bottom of the fixed-height liquid column and the vapor over the column. If vapor space is not always present, the differential pressure measurement is made between the bottom and top of a fixed-height column with the top measurement being made at a point below the liquid surface.

***Displacement*** There are a variety of density measurement devices based on displacement techniques. A hydrometer is a constant-weight, variable-immersion device. The degree of immersion, when the weight of the hydrometer equals the weight of the displaced liquid, is a measure of the density. The hydrometer is adaptable to manual or automatic usage. Another modification includes a magnetic float suspended below a solenoid, the varying magnetic field maintaining the float at a constant distance from the solenoid. Change in position of the float, resulting from a density change, excites an electrical system which increases or decreases the current through the solenoid.

***Direct Mass Measurement*** One type of densitometer measures the natural vibration frequency and relates the amplitude to changes in density. The density sensor is a V-shaped tube held stationary at its node points and allowed to vibrate at its natural frequency. At the curved end of the V is an electrochemical device that periodically strikes the tube. At the other end of the V the fluid is continuously passed through the tube. Between strikes, the tube vibrates at its natural frequency. The frequency changes directly in proportion to changes in density. A pickup device at the curved end of the V measures the frequency and electronically determines the fluid density. This technique is useful because it is not affected by the optical properties of the fluid. However, particulate matter in the process fluid can affect the accuracy.

***Radiation-Density Gauges*** Gamma radiation may be used to measure the density of material inside a pipe or process vessel. The equipment is basically the same as for level measurement, except that here the pipe or vessel must be filled over the effective, irradiated sample volume. The source is mounted on one side of the pipe or vessel and the detector on the other side with appropriate safety radiation shielding surrounding the installation. Cesium 137 is used as the radiation source for path lengths under 610 mm (24 in) and cobalt 60 above 610 mm. The detector is usually an ionization gauge. The absorption of the gamma radiation is a function of density. Since the absorption path includes the pipe or vessel walls, an empirical calibration is used. Appropriate corrections must be made for the source intensity decay with time.

**Viscosity** Continuous viscometers generally measure either the resistance to flow or the drag or torque produced by movement of an element (moving surface) through the fluid. Each installation is normally applied over a narrow range of viscosities. Empirical calibration over this range allows use on both newtonian and nonnewtonian fluids. One such device uses a piston inside a cylinder. The hydrodynamic pressure of the process fluid raises the piston to a preset height. Then the inlet valve closes, the piston is allowed to free-fall, and the time of travel (typically a few seconds) is a measure of viscosity. Other geometries include the rotation of a spindle inside a sample chamber and a vibrating probe immersed in the fluid. Because viscosity depends on temperature, the viscosity measurement must be thermostated with a heater or cooler.

**Refractive Index** When light travels from one medium (e.g., air or glass) into another (e.g., a liquid), it undergoes a change of velocity and, if the angle of incidence is not 90°, a change of direction. For a given interface, angle, temperature, and wavelength of light, the amount of deviation or refraction will depend on the composition of

the liquid. If the sample is transparent, the normal method is to measure the refraction of light transmitted through the glass-sample interface. If the sample is opaque, the reflectance near the critical angle at a glass-sample interface is measured. In an online refractometer the process fluid is separated from the optics by a prism material. A beam of light is focused on a point in the fluid which creates a conic section of light at the prism, striking the fluid at different angles (greater than or less than the critical angle). The critical angle depends on the species concentrations; as the critical angle changes, the proportions of reflected and refracted light change. A photodetector produces a voltage signal proportional to the light refracted, when compared to a reference signal. Refractometers can be used with opaque fluids and in streams that contain particulates.

**Dielectric Constant** The dielectric constant of material represents its ability to reduce the electric force between two charges separated in space. This property is useful in process control for polymers, ceramic materials, and semiconductors. Dielectric constants are measured with respect to vacuum (1.0); typical values range from 2 (benzene) to 33 (methanol) to 80 (water). The value for water is higher than that for most plastics. A measuring cell is made of glass or some other insulating material and is usually doughnut-shaped, with the cylinders coated with metal, which constitute the plates of the capacitor.

**Thermal Conductivity** All gases and vapor have the ability to conduct heat from a heat source. At a given temperature and physical environment, radiation and convection heat losses will be stabilized, and the temperature of the heat source will mainly depend on the thermal conductivity and thus the composition of the surrounding gases. Thermal conductivity analyzers normally consist of a sample cell and a reference cell, each containing a combined heat source and detector. These cells are normally contained in a metal block with two small cavities in which the detectors are mounted. The sample flows through the sample cell cavity past the detector. The reference cell is an identical cavity with a detector through which a known gas flows. The combined heat source and detectors are normally either wire filaments or thermistors heated by a constant current. Because their resistance is a function of temperature, the sample detector resistance will vary with sample composition while the reference detector resistance will remain constant. The output from the detector bridge will be a function of sample composition.

## CHEMICAL COMPOSITION ANALYZERS

Chemical composition is generally the most challenging online measurement. Before the era of online analyzers, messengers were required to deliver samples to the laboratory for analysis and to return the results to the control room. The long time delay involved prevented process adjustment from being made, affecting product quality. The development of online analyzers has automated this approach and reduced the analysis time. However, manual sampling is still frequently employed, especially in the specialty chemical industry where few instruments are commercially available. It is not unusual for a chemical composition analysis system to cost over $100,000, so it is important to assess the payback of such an investment versus the cost of manual sampling. Potential quality improvements can be an important consideration.

A number of composition analyzers used for process monitoring and control require chemical conversion of one or more sample components preceding quantitative measurement. These reactions include formation of suspended solids for turbidimetric measurement, formation of colored materials for colorimetric detection, selective oxidation or reduction for electrochemical measurement, and formation of electrolytes for measurement by electrical conductance. Some nonvolatile materials may be separated and measured by gas chromatography after conversion to volatile derivatives.

**Chromatographic Analyzers** These analyzers are widely used for the separation and measurement of volatile compounds and of compounds that can be quantitatively converted to volatile derivatives. The compounds to be measured are separated by placing a portion of the sample in a chromatographic column and carrying the compounds through the column with a gas stream, called gas chromatography, or GC. As a result of the different affinities of the sample components for the column packing, the compounds emerge successively as binary mixtures with the carrier gas. A detector at the column outlet measures a specific physical property that can be related to the concentrations of the compounds in the carrier gas. Both the concentration peak height and the peak height-time integral, i.e., peak area, can be related to the concentration of the compound in the original sample. The two detectors most commonly used for process chromatographs are the thermal conductivity detector and the hydrogen flame ionization detector. Thermal conductivity detectors, discussed earlier, require calibration for the thermal response of each compound. Hydrogen flame ionization detectors are more complicated than thermal conductivity detectors but are capable of 100 to 10,000 times greater sensitivity for hydrocarbons and organic compounds. For ultrasensitive detection of trace impurities, carrier gases must be specially purified.

Typically, all components can be analyzed in a 5- to 10-min time period (although miniaturized GCs are faster). High-performance liquid chromatography (HPLC) can be used to measure dissolved solute levels, including proteins.

**Infrared Analyzers** Many gaseous and liquid compounds absorb infrared radiation to some degree. The degree of absorption at specific wavelengths depends on molecular structure and concentration. There are two common detector types for nondispersive infrared analyzers. These analyzers normally have two beams of radiation, an analyzing and a reference beam. One type of detector consists of two gas-filled cells separated by a diaphragm. As the amount of infrared energy absorbed by the detector gas in one cell changes, the cell pressure changes. This causes movement in the diaphragm, which in turn causes a change in capacitance between the diaphragm and a reference electrode. This change in electrical capacitance is measured as the output. The second type of detector consists of two thermopiles or two bolometers, one in each of the two radiation beams. The infrared radiation absorbed by the detector is measured by a differential thermocouple output or a resistance thermometer (bolometer) bridge circuit.

There are two common detector types for nondispersive analyzers. These analyzers normally have two beams of radiation, an analyzing and a reference beam. One type of detector consists of two gas-filled cells separated by a diaphragm. As the amount of infrared energy absorbed by the detector gas in one cell changes, the cell pressure changes. This causes movement in the diaphragm, which in turn causes a change in capacitance between the diaphragm and a reference electrode. This change in electrical capacitance is measured as the output. The second type of detector consists of two thermopiles or two bolometers, one in each of the two radiation beams. The infrared radiation absorbed by the detector is measured by a differential thermocouple output or a resistance thermometer (bolometer) bridge circuit. With gas-filled detectors, a chopped light system is normally used in which one side of the detector sees the source through the analyzing beam and the other side sees through the reference beam, alternating at a frequency of a few hertz.

**Ultraviolet and Visible-Radiation Analyzers** Many gas and liquid compounds absorb radiation in the near-ultraviolet or visible region. For example, organic compounds containing aromatic and carbonyl structural groups are good absorbers in the ultraviolet region. Also many inorganic salts and gases absorb in the ultraviolet or visible region. In contrast, straight chain and saturated hydrocarbons, inert gases, air, and water vapor are essentially transparent. Process analyzers are designed to measure the absorbance in a particular wavelength band. The desired band is normally isolated by means of optical filters. When the absorbance is in the visible region, the term *colorimetry* is used. A phototube is the normal detector. Appropriate optical filters are used to limit the energy reaching the detector to the desired level and the desired wavelength region. Because absorption by the sample is logarithmic if a sufficiently narrow wavelength region is used, an exponential amplifier is sometimes used to compensate and produce a linear output.

**Paramagnetism** A few gases including $O_2$, NO, and $NO_2$ exhibit paramagnetic properties as a result of unpaired electrons. In a nonuniform magnetic field, paramagnetic gases, because of their magnetic susceptibility, tend to move toward the strongest part of the

field, thus displacing diamagnetic gases. Paramagnetic susceptibility of these gases decreases with temperature. These effects permit measurement of the concentration of the strongest paramagnetic gas, oxygen. An oxygen analyzer uses a dumbbell suspended in the magnetic field which is repelled or attracted toward the magnetic field depending on the magnetic susceptibility of the gas.

**Other Analyzers** Mass spectroscopy (MS) determines the partial pressures of gases in a mixture of directing ionized gases into a detector under a vacuum ($10^{-6}$ torr), and the gas phase composition is then monitored more or less continuously based on the molecular weight of the species (Nichols, 1988). Sometimes GC is combined with MS to obtain a higher level of discrimination of the components present. Fiber-optic sensors are attractive options (although higher-cost) for acquiring measurements in harsh environments such as high temperature or pressure. The transducing technique used by these sensors is optical and does not involve electric signals, so they are immune to electromagnetic interference. Raman spectroscopy uses fiber optics and involves pulsed light scattering by molecules. It has a wide variety of applications in process control. Workman, Koch, and Veltkamp, *Anal. Chem.*, **75:** 2859, 2003.

Significant advances have occurred during the past decade to miniaturize the size of the measurement system in order to make online analysis economically feasible and to reduce the time delays that often are present in analyzers. Recently, chemical sensors have been placed on microchips, even those requiring multiple physical, chemical, and biochemical steps (such as electrophoresis) in the analysis. This device has been called *lab-on-a-chip*. The measurements of chemical composition can be direct or indirect, the latter case referring to applications where some property of the process stream is measured (such as refractive index) and then related to composition of a particular component.

## ELECTROANALYTICAL INSTRUMENTS

**Conductometric Analysis** Solutions of electrolytes in ionizing solvents (e.g., water) conduct current when an electrical potential is applied across electrodes immersed in the solution. Conductance is a function of ion concentration, ionic charge, and ion mobility. Conductance measurements are ideally suited for measurement of the concentration of a single strong electrolyte in dilute solutions. At higher concentrations conductance becomes a complex, nonlinear function of concentration requiring suitable calibration for quantitative measurements.

**Measurement of pH** The primary detecting element in pH measurement is the glass electrode. A potential is developed at the pH-sensitive glass membrane as a result of differences in hydrogen ion activity in the sample and a standard solution contained within the electrode. This potential measured relative to the potential of the reference electrode gives a voltage which is expressed as pH. Instrumentation for pH measurement is among the most widely used process measurement devices. Rugged electrode systems and highly reliable electronic circuits have been developed for this use.

After installation, the majority of pH measurement problems are sensor-related, mostly on the reference side, including junction plugging, poisoning, and depletion of electrolyte. For the glass (measuring electrode), common difficulties are broken or cracked glass, coating, and etching or abrasion. Symptoms such as drift, sluggish response, unstable readings, and inability to calibrate are indications of measurement problems. Online diagnostics such as impedance measurements, wiring checks, and electrode temperature are now available in most instruments. Other characteristics that can be measured offline include efficiency or slope and asymmetry potential (offset), which indicate whether the unit should be cleaned or changed [Nichols, *Chem. Engr. Prog.,* **90**(12):64, 1994; McMillan, *Chem. Engr. Prog.,* **87**(12):30, 1991].

**Specific-Ion Electrodes** In addition to the pH glass electrode specific for hydrogen ions, a number of electrodes which are selective for the measurement of other ions have been developed. This selectivity is obtained through the composition of the electrode membrane (glass, polymer, or liquid-liquid) and the composition of the electrode. These electrodes are subject to interference from other ions, and the response is a function of the total ionic strength of the solution. However, electrodes have been designed to be highly selective for specific ions, and when properly used, these provide valuable process measurements.

## MOISTURE MEASUREMENT

Moisture measurements are important in the process industries because moisture can foul products, poison reactions, damage equipment, or cause explosions. Moisture measurements include both absolute moisture methods and relative-humidity methods. The absolute methods provide a primary output that can be directly calibrated in terms of dew point temperature, molar concentration, or weight concentration. Loss of weight on heating is the most familiar of these methods. The relative-humidity methods provide a primary output that can be more directly calibrated in terms of percentage of saturation of moisture.

**Dew Point Method** For many applications the dew point is the desired moisture measurement. When concentration is desired, the relation between water content and dew point is well known and available. The dew point method requires an inert surface whose temperature can be adjusted and measured, a sample gas stream flowing past the surface, a manipulated variable for adjusting the surface temperature to the dew point, and a means of detecting the onset of condensation.

Although the presence of condensate can be detected electrically, the original and most often used method is the optical detection of change in light reflection from an inert metallic-surface mirror. Some instruments measure the attenuation of reflected light at the onset of condensation. Others measure the increase of light dispersed and scattered by the condensate instead of, or in addition to, the reflected-light measurement. Surface cooling is obtained with an expendable refrigerant liquid, conventional mechanical refrigeration, or thermoelectric cooling. Surface-temperature measurement is usually made with a thermocouple or a thermistor.

**Piezoelectric Method** A piezoelectric crystal in a suitable oscillator circuit will oscillate at a frequency dependent on its mass. If the crystal has a stable hygroscopic film on its surface, the equivalent mass of the crystal varies with the mass of water sorbed in the film. Thus the frequency of oscillation depends on the water in the film. The analyzer contains two such crystals in matched oscillator circuits. Typically, valves alternately direct the sample to one crystal and a dry gas to the other on a 30-s cycle. The oscillator frequencies of the two circuits are compared electronically, and the output is the difference between the two frequencies. This output is then representative of the moisture content of the sample. The output frequency is usually converted to a variable dc voltage for meter readout and recording. Multiple ranges are provided for measurement from about 1 ppm to near saturation. The dry reference gas is preferably the same as the sample except for the moisture content of the sample. Other reference gases which are adsorbed in a manner similar to the dried sample gas may be used. The dry gas is usually supplied by an automatic dryer. The method requires a vapor sample to the detector. Mist striking the detector destroys the accuracy of measurement until it vaporizes or is washed off the crystals. Water droplets or mist may destroy the hygroscopic film, thus requiring crystal replacement. Vaporization or gas-liquid strippers may sometimes be used for the analysis of moisture in liquids.

**Capacitance Method** Several analyzers utilize the high dielectric constant of water for its detection in solutions. The alternating electric current through a capacitor containing all or part of the sample between the capacitor plates is measured. Selectivity and sensitivity are enhanced by increasing the concentration of moisture in the cell by filling the capacitor sample cell with a moisture-specific sorbent as part of the dielectric. This both increases the moisture content and reduces the amount of other interfering sample components. Granulated alumina is the most frequently used sorbent. These detectors may be cleaned and recharged easily and with satisfactory reproducibility if the sorbent itself is uniform.

**Oxide Sensors** Aluminum oxide can be used as a sensor for moisture analysis. A conductivity call has one electrode node of aluminum,

which is anodized to form a thin film of aluminum oxide, followed by coating with a thin layer of gold (the opposite electrode). Moisture is selectively adsorbed through the gold layer and into the hygroscopic aluminum oxide layer, which in turn determines the electrical conductivity between gold and aluminum oxide. This value can be related to ppm water in the sample. This sensor can operate between near vacuum to several hundred atmospheres, and it is independent of flow rate (including static conditions). Temperature, however, must be carefully monitored. A similar device is based on phosphorous pentoxide. Moisture content influences the electric current between two inert metal electrodes, which are fabricated as a helix on the inner wall of a tubular nonconductive sample cell. For a constant dc voltage applied to the electrodes, a current flows that is proportional to moisture. The moisture is absorbed into the hygroscopic phosphorous pentoxide, where the current electrolyzes the water molecules into hydrogen and oxygen. This sensor will handle moisture up to 1000 ppm and 6-atm pressure. As with the aluminum oxide ion, temperature control is very important.

**Photometric Moisture Analysis** This analyzer requires a light source, a filter wheel rotated by a synchronous motor, a sample cell, a detector to measure the light transmitted, and associated electronics. Water has two absorption bands in the near-infrared region at 1400 and 1900 nm. This analyzer can measure moisture in liquid or gaseous samples at levels from 5 ppm up to 100 percent, depending on other chemical species in the sample. Response time is less than 1 s, and samples can be run up to 300°C and 400 psig.

## OTHER TRANSDUCERS

Other types of transducers used in process measurements include mechanical drivers such as gear trains and electrical drivers such as a differential transformer or a Hall effect (semiconductor-based) sensor.

**Gear Train** Rotary motion and angular position are easily transduced by various types of gear arrangements. A gear train in conjunction with a mechanical counter is a direct and effective way to obtain a digital readout of shaft rotations. The numbers on the counter can mean anything desired, depending on the gear ratio and the actuating device used to turn the shaft. A pointer attached to a gear train can be used to indicate a number of revolutions or a small fraction of a revolution for any specified pointer rotation.

**Differential Transformer** These devices produce an ac electrical output from linear movement of an armature. They are very versatile in that they can be designed for a full range of output with any range of armature travel up to several inches. The transformers have one or two primaries and two secondaries connected to oppose each other. With an ac voltage applied to the primary, the output voltage depends on the position of the armature and the coupling. Such devices produce accuracies of 0.5 to 1.0 percent of full scale and are used to transmit forces, pressures, differential pressures, or weights up to 1500 m. They can also be designed to transmit rotary motion.

**Hall Effect Sensors** Some semiconductor materials exhibit a phenomenon in the presence of a magnetic field which is adaptable to sensing devices. When a current is passed through one pair of wires attached to a semiconductor, such as germanium, another pair of wires properly attached and oriented with respect to the semiconductor will develop a voltage proportional to the magnetic field present and the current in the other pair of wires. Holding the exciting current constant and moving a permanent magnet near the semiconductor produce a voltage output proportional to the movement of the magnet. The magnet may be attached to a process variable measurement device which moves the magnet as the variable changes. Hall effect devices provide high speed of response, excellent temperature stability, and no physical contact.

## SAMPLING SYSTEMS FOR PROCESS ANALYZERS

The sampling system consists of all the equipment required to present a process analyzer with a clean representative sample of a process stream and to dispose of that sample. When the analyzer is part of an automatic control loop, the reliability of the sampling system is as important as the reliability of the analyzer or the control equipment. Sampling systems have several functions. The sample must be withdrawn from the process, transported, conditioned, introduced to the analyzer, and disposed. Probably the most common problem in sample system design is the lack of realistic information concerning the properties of the process material at the sampling point. Another common problem is the lack of information regarding the conditioning required so that the analyzer may utilize the sample without malfunction for long periods. Some samples require enough conditioning and treating that the sampling systems become equivalent to miniature online processing plants. These systems possess many of the same fabrication, reliability, and operating problems as small-scale pilot plants except that the sampling system must generally operate reliably for much longer periods of time.

**Selecting the Sampling Point** The selection of the sampling point is based primarily on supplying the analyzer with a sample whose composition or physical properties are pertinent to the control function to be performed. Other considerations include selecting locations that provide representative homogeneous samples with minimum transport delay, locations which collect a minimum of contaminating material, and locations which are accessible for test and maintenance procedures.

**Sample Withdrawal from Process** A number of considerations are involved in the design of sample withdrawal devices which will provide representative samples. For example, in a horizontal pipe carrying process fluid, a sample point on the bottom of the pipe will collect a maximum count of rust, scale, or other solid materials being carried along by the process fluid. In a gas stream, such a location will also collect a maximum amount of liquid contaminants. A sample point on the top side of a pipe will, for liquid streams, collect a maximum amount of vapor contaminants being carried along. Bends in the piping which produce swirls or cause centrifugal concentration of the denser phase may cause maximum contamination to be at unexpected locations. Two-phase process materials are difficult to sample for a total-composition representative sample.

A typical method for obtaining a sample of process fluid well away from vessel or pipe walls is an eduction tube inserted through a packing gland. This sampling method withdraws liquid sample and vaporizes it for transporting to the analyzer location. The transport lag time from the end of the probe to the vaporizer is minimized by using tubing having a small internal volume compared with pipe and valve volumes.

This sample probe may be removed for maintenance and reinstalled without shutting down the process. The eduction tube is made of material which will not corrode so that it will slide through the packing gland even after long periods of service. There may be a small amount of process fluid leakage until the tubing is withdrawn sufficiently to close the gate valve. A swaged ferrule on the end of the tube prevents accidental ejection of the eduction tube prior to removal of the packing gland. The section of pipe surrounding the eduction tube and extending into the process vessel provides mechanical protection for the eduction tube.

**Sample Transport** Transport time—the time elapsed between sample withdrawal from the process and its introduction into the analyzer—should be minimized, particularly if the analyzer is an automatic analyzer-controller. Any sample transport time in the analyzer-controller loop must be treated as equivalent to process dead time in determining conventional feedback controller settings or in evaluating controller performance. Reduction in transport time usually means transporting the sample in the vapor state.

Design considerations for sample lines are as follows:

1. The structural strength or protection must be compatible with the area through which the sample line runs.
2. Line size and length must be small enough to meet transport time requirements without excessive pressure drop or excessive bypass of sample at the analyzer input.
3. Line size and internal surface quality must be adequate to prevent clogging by the contaminants in the sample.
4. The prevention of a change of state of the sample may require installation, refrigeration, or heating of the sample line.
5. Sample line material must be such as to minimize corrosion due to sample or the environment.

**Sample Conditioning** Sample conditioning usually involves the removal of contaminants or some deleterious component from the sample mixture and/or the adjustment of temperature, pressure, and flow rate of the sample to values acceptable to the analyzer. Some of the more common contaminants which must be removed are rust, scale, corrosion products, deposits due to chemical reactions, and tar. In sampling some process streams, the material to be removed may include the primary process product such as polymer or the main constituent of the stream such as oil. In other cases the material to be removed is present in trace quantities, e.g., water in an online chromatograph sample which can damage the chromatographic column packing. When contaminants or other materials which will hinder analysis represent a large percentage of the stream composition, their removal may significantly alter the integrity of the sample. In some cases, removal must be done as part of the analysis function so that removed material can be accounted for. In other cases, proper calibration of the analyzer output will suffice.

# TELEMETERING AND TRANSMISSION

## ANALOG SIGNAL TRANSMISSION

Modern control systems permit the measurement device, the control unit, and the final control element to be physically separated by several hundred meters, if necessary. This requires the transmission of the measured variable from the measurement device to the control unit, and the transmission of the controller output from the control unit to the final control element. In each case, transmission of a single value in only one direction is required. Such requirements can be met by analog signal transmission. A measurement range is defined for the value to be transmitted, and the value is basically transmitted as a percent of the span. For the measured variable, the logical span is the measurement span. For the controller output, the logical span is the range of the final control element (e.g., valve fully closed to valve fully open).

For pneumatic transmission systems, the signal range used for the transmission is 3 to 15 psig. In each pneumatic transmission system, there can be only one transmitter, but there can be any number of receivers. When most measurement devices were pneumatic, pneumatic transmission was the logical choice. However, with the displacement of pneumatic measurement devices by electronic devices, pneumatic transmission is now limited to applications where the unique characteristics of pneumatics make it the logical choice.

In order for electronic transmission systems to be less susceptible to interference from magnetic fields, current is used for the transmission signal instead of voltage. The signal range is 4 to 20 mA. In each circuit or "current loop," there can be only one transmitter. There can be more than one receiver, but not an unlimited number. For each receiver, a 250-Ω *range resistor* is inserted into the current loop, which provides a 1- to 5-V input to the receiving device. The number of receivers is limited by the power available from the transmitter.

Both pneumatic and electronic transmission use a *live zero.* This enables the receiver to distinguish a transmitted value of 0 percent of span from a transmitter or transmission system failure. Transmission of 0 percent of span provides a signal of 4 mA in electronic transmission. Should the transmitter or the transmission system fail (i.e., an open circuit in a current loop), the signal level would be 0 mA.

For most measurement variable transmissions, the lower range corresponds to 4 mA and the upper range corresponds to 20 mA. On an open circuit, the measured variable would fail to its lower range. In some applications, this is undesirable. For example, in a fired heater that is heating material to a target temperature, failure of the temperature measurement to its lower range value would drive the output of the combustion control logic to the maximum possible firing rate. In such applications, the analog transmission signal is normally inverted, with the upper range corresponding to 4 mA and the lower range corresponding to 20 mA. On an open circuit, the measured variable would fail to its upper range. For the fired heater, failure of the measured variable to its upper range would drive the output of the combustion control logic to the minimum firing rate.

## DIGITAL SYSTEMS

With the advent of the microprocessor, digital technology began to be used for data collection, feedback control, and all other information processing requirements in production facilities. Such systems must acquire data from a variety of measurement devices, and control systems must drive final control elements.

**Analog Inputs and Outputs** Analog inputs are generally divided into two categories:

1. *High level.* Where the source is a process transmitter, the range resistor in the current loop converts the 4- to 20-mA signal to a 1- to 5-V signal. The conversion equipment can be unipolar (i.e., capable of processing only positive voltages).
2. *Low level.* The most common low-level signals are inputs from thermocouples. These inputs rarely exceed 30 mV and could be zero or even negative. The conversion equipment must be bipolar (i.e., capable of processing positive and negative voltages).

Ultimately, such signals are converted to digital values via an analog-to-digital (A/D) converter. However, the A/D converter is normally preceded by two other components:

1. *Multiplexer.* This permits one A/D converter to service multiple analog inputs. The number of inputs to a multiplexer is usually between 8 and 256.
2. *Amplifier.* As A/D converters require high-level signals, a high-gain amplifier is required to convert low-level signals to high-level signals.

One of the important parameters for the A/D converter is its resolution. The resolution is stated in terms of the number of significant binary digits (bits) in the digital value. As the repeatability of most process transmitters is around 0.1 percent, the minimum acceptable resolution for a bipolar A/D converter is 12 bits, which translates to 11 data bits plus 1 bit for the sign. With this resolution, the analog input values can be represented to 1 part in $2^{11}$, or 1 part in 2048. Normally, a 5-V input is converted to a digital value of 2000, which effectively gives a resolution of 1 part in 2000, or 0.05 percent. Very few process control systems utilize resolutions higher than 14 bits, which translates to a resolution of 1 part in 8000, or 0.0125 percent.

For 4- to 20-mA inputs, the resolution is not quite as good as stated above. For a 12-bit bipolar A/D converter, 1 V converts to a digital value of 400. Thus, the range for the digital value is 400 to 2000, making the effective input resolution 1 part in 1600, or 0.0625 percent. Sometimes this is expressed as a resolution of 7.4 bits, where $2^{7.4} = 1600$.

On the output side, dedicated digital-to-analog (D/A) converters are provided for each analog output. Outputs are normally unipolar and require a lower resolution than inputs. A 10-bit resolution is normally sufficient, giving a resolution of 1 part in 1000, or 0.1 percent.

**Pulse Inputs** Where the sensor within the measurement device is digital, analog-to-digital conversion can be avoided. For rotational devices, the rotational element can be outfitted with a shaft encoder that generates a known number of pulses per revolution. The digital system can process such inputs in any of the following ways:

1. Count the number of pulses over a fixed interval of time.
2. Determine the time for a specified number of pulses.
3. Determine the duration of time between the leading (or trailing) edges of successive pulses.

Of these, the first option is the most commonly used in process applications. Turbine flowmeters are probably the most common example where pulse inputs are used. Another example is a watthour meter. Basically any measurement device that involves a rotational element can be interfaced via pulses. Occasionally, a nonrotational measurement device can generate pulse outputs. One example is the

vortex-shedding meter, where a pulse can be generated when each vortex passes over the detector.

**Serial Interfaces** Some very important measurement devices cannot be reasonably interfaced via either analog or pulse inputs. Two examples are the following:

1. Chromatographs can perform a total composition analysis for a sample. It is possible but inconvenient to provide an analog input for each component. Furthermore, it is often desirable to capture other information, such as the time that the analysis was made (normally the time the sample was injected).
2. Load cells are capable of resolutions of 1 part in 100,000. A/D converters for analog inputs cannot even approach such resolutions.

One approach to interfacing with such devices involves serial interfaces. This has two aspects:

1. *Hardware interface.* The RS-232 interface standard is the basis for most serial interfaces.
2. *Protocol.* This is interpreting the sequence of characters transmitted by the measurement device. There are no standards for protocols, which means that custom software is required.

One advantage of serial interfaces is that two-way communication is possible. For example, a "tare" command can be issued to a load cell.

**Microprocessor-Based Transmitters** The cost of microprocessor technology has declined to the point where it is economically feasible to incorporate a microprocessor into each transmitter. Such microprocessor-based transmitters are often referred to as *smart* transmitters. As opposed to conventional or *dumb* transmitters, the smart transmitters offer the following capabilities:

1. They check on the internal electronics, such as verifying that the voltage levels of internal power supplies are within specifications.
2. They check on environmental conditions within the instruments, such as verifying that the case temperature is within specifications.
3. They perform compensation of the measured value for conditions within the instrument, such as compensating the output of a pressure transmitter for the temperature within the transmitter. Smart transmitters are much less affected by temperature and pressure variations than are conventional transmitters.
4. They perform compensation of the measured value for other process conditions, such as compensating the output of a capacitance level transmitter for variations in process temperature.
5. They linearize the output of the transmitter. Functions such as square root extraction of the differential pressure for a head-type flowmeter can be done within the instrument instead of within the control system.
6. They configure the transmitter from a remote location, such as changing the span of the transmitter output.
7. They do automatic recalibration of the transmitter. Although this is highly desired by users, the capabilities, if any, in this respect depend on the type of measurement.

Due to these capabilities, smart transmitters offer improved performance over conventional transmitters.

**Transmitter/Actuator Networks** With the advent of smart transmitters and smart actuators, the limitations of the 4- to 20-mA analog signal transmission retard the full utilization of the capabilities of smart devices. For smart transmitters, the following capabilities are required:

1. *Transmission of more than one value from a transmitter.* Information beyond the measured variable is available from the smart transmitter. For example, a smart pressure transmitter can also report the temperature within its housing. Knowing that this temperature is above normal values permits corrective action to be taken before the device fails. Such information is especially important during the initial commissioning of a plant.
2. *Bidirectional transmission.* Configuration parameters such as span, engineering units, and resolution must be communicated to the smart transmitter.

Similar capabilities are required for smart actuators.

Eventually this technology, generally referred to as field bus, will replace all other forms of transmission (analog, pulse, and serial). Its acceptance by the user community has been slow, mainly due to the absense of a standard. Smart transmitters and smart valves have gained widespread acceptance, but initially the signal transmission continued to be via current loops. During this interim, several manufacturers introduced products based on proprietary communications technologies. Most manufacturers released sufficient information for others to develop products using their communications technologies, but those considering doing so found the costs to be an impediment.

A standard is now available, specifically, IEC 61158, "Digital Data Communications for Measurement and Control." In most industries, a standard defines only one way of doing something, but not in the computer industry. IEC 61158 defines five different communications technologies. Several manufacturers had selected a direction, and standards are not immune to commercial considerations. The net result is that one person's "field bus" might not be the same as another's. Most plants select one technology for their field bus, although it is possible to have multiple field bus interfaces on a control system and not have all the same type.

Although there will be winners and losers, most companies find the appealing features of field bus technologies too great to continue with the older technologies. U.S. manufacturers have generally chosen a field bus technology known as Foundation Fieldbus. In Europe, a field bus technology known as Profibus has gained wide acceptance. Probably the major advantages of these technologies lie in installation and commissioning. There are fewer wires and connections in a field bus installation. In most plants, the cost of the wiring is proving to be a minor issue. With fewer wires and connections, errors in field bus installations are fewer and can be located more quickly. The major cost savings prove to be in configuring and commissioning the system. With time, field bus will largely replace analog, pulse, and serial signal transmissions within industrial facilities.

## FILTERING AND SMOOTHING

A signal received from a process transmitter generally contains the following components distinguished by their frequency [frequencies are measured in hertz (Hz), with 60-cycle ac being a 60-Hz frequency):

1. *Low-frequency process disturbances.* The control system is expected to react to these disturbances.
2. *High-frequency process disturbances.* The frequency of these disturbances is beyond the capability of the control system to effectively react.
3. *Measurement noise.*
4. *Stray electrical pickup, primarily 50- or 60-cycle ac.*

The objective of filtering and smoothing is to remove the last three components, leaving only the low-frequency process disturbances. Normally this has to be accomplished by using the proper combination of analog and digital filters. Sampling a continuous signal results in a phenomenon often referred to as aliasing or foldover. To represent a sinusoidal signal, a minimum of four samples are required during each cycle. Consequently, when a signal is sampled at a frequency $\omega_s$, all frequencies higher than $(\pi/2)\omega_s$ cannot be represented at their original frequency. Instead, they are present in the sampled signal with their original amplitude but at a lower-frequency harmonic. Because of the aliasing or foldover issues, a combination of analog and digital filtering is usually required. The sampler (i.e., the A/D converter) must be preceded by an analog filter that rejects those high-frequency components such as stray electrical pickup that would result in foldover when sampled. In commercial products, analog filters are normally incorporated into the input processing hardware by the manufacturer. The software then permits the user to specify digital filtering to remove any undesirable low-frequency components.

On the analog side, the filter is often the conventional resistor-capacitor or *RC* filter. However, other possibilities exist. For example, one type of A/D converter is called an *integrating A/D* because the converter basically integrates the input signal over a fixed interval of time. By making the interval $\frac{1}{60}$s, this approach provides excellent rejection of any 60-Hz electrical noise.

On the digital side, the input processing software generally provides for smoothing via the exponentially weighted moving average, which is the digital counterpart to the *RC* network analog filter. The smoothing equation is as follows:

$$y_i = \alpha x_i + (1 - \alpha) y_{i-1} \tag{8-107}$$

where $x_i$ = current value of input
$y_i$ = current output from filter

$y_{i-1}$ = previous output from filter
$\alpha$ = filter coefficient

The degree of smoothing is determined by the filter coefficient $\alpha$, with $\alpha = 1$ being no smoothing and $\alpha = 0$ being infinite smoothing (no effect of new measurements). The filter coefficient $\alpha$ is related to the filter time constant $\tau_F$ and the sampling interval $\Delta t$ by

$$\alpha = 1 - \exp\left(\frac{-\Delta t}{\tau_F}\right) \tag{8-108}$$

or by the approximation

$$\alpha = \frac{\Delta t}{\Delta t + \tau_F} \tag{8-109}$$

Another approach to smoothing is to use the arithmetic moving average, which is represented by

$$y_i = \frac{\sum_{j=1}^{n} x_{i+1-j}}{n} \tag{8-110}$$

The term *moving* is used because the filter software maintains a storage array with the previous $n$ values of the input. When a new value is received, the oldest value in the storage array is replaced with the new value, and the arithmetic average is recomputed. This permits the filtered value to be updated each time a new input value is received.

In process applications, determining $\tau_F$ (or $\alpha$) for the exponential filter and $n$ for the moving average filter is often done merely by observing the behavior of the filtered value. If the filtered value is "bouncing," the degree of smoothing (that is, $\tau_F$ or $n$) is increased. This can easily lead to an excessive degree of filtering, which will limit the performance of any control system that uses the filtered value. The degree of filtering is best determined from the frequency spectrum of the measured input, but such information is rarely available for process measurements.

## ALARMS

The purpose of an alarm is to alert the process operator to a process condition that requires immediate attention. An alarm is said to occur whenever the abnormal condition is detected and the alert is issued. An alarm is said to return to normal when the abnormal condition no longer exists. Analog alarms can be defined on measured variables, calculated variables, controller outputs, and the like. For analog alarms, the following possibilities exist:

1. *High/low alarms.* A high alarm is generated when the value is greater than or equal to the value specified for the high-alarm limit. A low alarm is generated when the value is less than or equal to the value specified for the low-alarm limit.

2. *Deviation alarms.* An alarm limit and a target are specified. A high-deviation alarm is generated when the value is greater than or equal to the target plus the deviation alarm limit. A low-deviation alarm is generated when the value is less than or equal to the target minus the deviation alarm limit.

3. *Trend or rate-of-change alarms.* A limit is specified for the maximum rate of change, usually specified as a change in the measured value per minute. A high-trend alarm is generated when the rate of change of the variable is greater than or equal to the value specified for the trend alarm limit. A low-trend alarm is generated when the rate of change of the variable is less than or equal to the negative of the value specified for the trend alarm limit.

Most systems permit multiple alarms of a given type to be configured for a given value. For example, configuring three high alarms provides a high alarm, a high-high alarm, and a high-high-high alarm.

One operational problem with analog alarms is that noise in the variable can cause multiple alarms whenever its value approaches a limit. This can be avoided by defining a dead band on the alarm. For example, a high alarm would be processed as follows:

1. *Occurrence.* The high alarm is generated when the value is greater than or equal to the value specified for the high-alarm limit.

2. *Return to normal.* The high-alarm return to normal is generated when the value is less than or equal to the high-alarm limit less the dead band.

As the degree of noise varies from one input to the next, the dead band must be individually configurable for each alarm.

Discrete alarms can be defined on discrete inputs, limit switch inputs from on/off actuators, and so on. For discrete alarms, the following possibilities exist:

1. *Status alarms.* An expected or normal state is specified for the discrete value. A status alarm is generated when the discrete value is other than its expected or normal state.

2. *Change-of-state alarm.* A change-of-state alarm is generated on any change of the discrete value.

The expected sequence of events on an alarm is basically as follows:

1. The alarm occurs. This usually activates an audible annunciator.
2. The alarm occurrence is acknowledged by the process operator. When all alarms have been acknowledged, the audible annunciator is silenced.
3. Corrective action is initiated by the process operator.
4. The alarm condition returns to normal.

However, additional requirements are imposed at some plants. Sometimes the process operator must acknowledge the alarm's return to normal. Some plants require that the alarm occurrence be reissued if the alarm remains in the occurred state longer than a specified time. Consequently, some "personalization" of the alarming facilities is done.

When alarms were largely hardware-based (i.e., the panel alarm systems), the purchase and installation of the alarm hardware imposed a certain discipline on the configuration of alarms. With digital systems, the suppliers have made it extremely easy to configure alarms. In fact, it is sometimes easier to configure alarms on a measured value than not to configure the alarms. Furthermore, the engineer assigned the responsibility for defining alarms is often paranoid that an abnormal process condition will go undetected because an alarm has not been configured. When alarms are defined on every measured and calculated variable, the result is an excessive number of alarms, most of which are duplicative and unnecessary.

The accident at the Three Mile Island nuclear plant clearly demonstrated that an alarm system can be counterproductive. An excessive number of alarms can distract the operator's attention from the real problem that needs to be addressed. Alarms that merely tell the operator something that is already known do the same. In fact, a very good definition of a nuisance alarm is one that informs the operator of a situation of which the operator is already aware. The only problem with applying this definition lies determining what the operator already knows.

Unless some discipline is imposed, engineering personnel, especially where contractors are involved, will define far more alarms than plant operations require. This situation may be addressed by simply setting the alarm limits to values such that the alarms never occur. However, changes in alarms and alarm limits are changes from the perspective of the process safety management regulations. It is prudent to impose the necessary discipline to avoid an excessive number of alarms. Potential guidelines are as follows:

1. For each alarm, a specific action is expected from the process operator. Operator actions such as call maintenance are inappropriate with modern systems. If maintenance needs to know, modern systems can inform maintenance directly.

2. Alarms should be restricted to abnormal situations for which the process operator is responsible. A high alarm on the temperature in one of the control system cabinets should not be issued to the process operator. Correcting this situation is the responsibility of maintenance, not the process operator.

3. Process operators are expected to be exercising normal surveillance of the process. Therefore, alarms are not appropriate for situations known to the operator either through previous alarms or through normal process surveillance. The "sleeping operator" problem can be addressed by far more effective means than the alarm system.

4. When the process is operating normally, no alarms should be triggered. Within the electric utility industry, this design objective is

known as *darkboard*. Application of darkboard is especially important in batch plants, where much of the process equipment is operated intermittently.

Ultimately, guidelines such as those above will be taken seriously only if production management pays attention to the process alarms. The consequences of excessive and redundant alarms will be felt primarily by those responsible for production operations. Therefore, production management must make adequate resources available for reviewing and analyzing the proposed alarm configurations.

Another serious distraction to a process operator is the multiple-alarm event, where a single event within the process results in multiple alarms. When the operator must individually acknowledge each alarm, considerable time can be lost in silencing the obnoxious annunciator before the real problem is addressed. Air-handling systems are especially vulnerable to this, where any fluctuation in pressure (e.g., resulting from a blower trip) can cause a number of pressure alarms to occur.

Point alarms (high alarms, low alarms, status alarms, etc.) are especially vulnerable to the multiple-alarm event. This can be addressed in one of two ways:

1. *Ganging alarms.* Instead of individually issuing the point alarms, all alarms associated with a certain aspect of the process are configured to give a single trouble alarm. The responsibility rests entirely with the operator to determine the nature of the problem.

2. *Intelligent alarms.* Logic is incorporated into the alarm system to determine the nature of the problem and then issue a single alarm to the process operator.

While the intelligent alarm approach is clearly preferable, substantial process analysis is required to support intelligent alarming. Meeting the following two objectives is quite challenging:

1. The alarm logic must consistently detect abnormal conditions within the process.

2. The alarm logic must not issue an alert to an abnormal condition when in fact none exists.

Often the latter case is more challenging than the former. Logically, the intelligent alarm effort must be linked to the process hazards analysis. Developing an effective intelligent alarming system requires substantial commitments of effort, involving process engineers, control systems engineers, and production personnel. Methodologies such as expert systems can facilitate the implementation of an intelligent alarming system, but they must still be based on a sound analysis of the potential process hazards.

# DIGITAL TECHNOLOGY FOR PROCESS CONTROL

**GENERAL REFERENCES:** Auslander and Ridgely, *Design and Implementation of Real-Time Software for the Control of Mechanical Systems*, Prentice-Hall, Upper Saddle River, N.J., 2002. Since the 1970s, process controls have evolved from pneumatic analog technology to electronic analog technology to microprocessor-based controls. Electronic and pneumatic controllers have now virtually disappeared from process control systems, which are dominated by programmable electronic systems based on microprocessor technology.

## HIERARCHY OF INFORMATION SYSTEMS

Coupling digital controls with networking technology permits information to be passed from level to level within a corporation at high rates of speed. This technology is capable of presenting the measured variable from a flow transmitter installed in a plant in a remote location anywhere in the world to the company headquarters in less than 1 s.

A hierarchical representation of the information flow within a company leads to a better understanding of how information is passed from one layer to the next. Such representations can be developed in varying degrees of detail, and most companies have developed one that describes their specific practices. The following hierarchy consists of five levels, as shown in Fig. 8-30.

**Measurement Devices and Final Control Elements** This lowest layer couples the control and information systems to the process. The measurement devices provide information on the current conditions within the process. The final control elements permit control decisions to be imposed on the process. Although traditionally analog, smart transmitters and smart valves based on microprocessor technology are now beginning to dominate this layer.

**Safety and Environmental/Equipment Protection** The level 2 functions play a critical role by ensuring that the process is operating safely and satisfies environmental regulations. Process safety relies on the principle of multiple protection layers that involve groupings of equipment and human actions. One layer includes process control functions, such as alarm management during abnormal situations, and safety instrumented systems for emergency shutdowns. The safety equipment (including sensors and block valves) operates independently of the regular instrumentation used for regulatory control in level 3. Sensor validation techniques can be employed to confirm that the sensors are functioning properly.

**Regulatory Controls** The objective of this layer is to operate the process at or near the targets supplied by a higher layer in the hierarchy. To achieve consistent process operations, a high degree of automatic control is required from the regulatory layer. The direct result is a reduction in variance in the key process variables. More uniform product quality is an obvious benefit. However, consistent process operation is a prerequisite for optimizing the process operations. To ensure success for the upper-level functions, the first objective of any automation effort must be to achieve a high degree of regulatory control.

**Real-Time Optimization** Determining the most appropriate targets for the regulatory layer is the responsibility of the RTO layer. Given the current production and quality targets for a unit, RTO determines how the process can be best operated to meet them. Usually this optimization has a limited scope, being confined to a single production unit or possibly even a single unit operation within a production unit. RTO translates changes in factors such as current process efficiencies, current energy costs, cooling medium temperatures, and so on to changes in process operating targets so as to optimize process operations.

**Production Controls** The nature of the production control logic differs greatly between continuous and batch plants. A good example of production control in a continuous process is refinery optimization. From the assay of the incoming crude oil, the values of the various possible refined products, the contractual commitments to deliver certain products, the performance measures of the various units within a refinery, and the like, it is possible to determine the mix of products that optimizes the economic return from processing this crude. The solution of this problem involves many relationships and constraints and is solved with techniques such as linear programming.

In a batch plant, production control often takes the form of routing or short-term scheduling. For a multiproduct batch plant, determining the long-term schedule is basically a manufacturing resource planning (MRP) problem, where the specific products to be manufactured and the amounts to be manufactured are determined from the outstanding orders, the raw materials available for production, the production capacities of the process equipment, and other factors. The goal of the MRP effort is the long-term schedule, which is a list of the products to be manufactured over a specified period of time (often one week). For each product on the list, a target amount is also specified. To manufacture this amount usually involves several batches. The term *production run* often refers to the sequence of batches required to make the target amount of product, so in effect the long-term schedule is a list of production runs.

Most multiproduct batch plants have more than one piece of equipment of each type. Routing refers to determining the specific pieces of equipment that will be used to manufacture each run on the long-term

production schedule. For example, the plant might have five reactors, eight neutralization tanks, three grinders, and four packing machines. For a given run, a rather large number of routes are possible. Furthermore, rarely is only one run in progress at a given time. The objective of routing is to determine the specific pieces of production equipment to be used for each run on the long-term production schedule. Given the dynamic nature of the production process (equipment failures, insertion/deletion of runs into the long-term schedule, etc.), the solution of the routing problem continues to be quite challenging.

**Corporate Information Systems** Terms such as *management information systems* (MIS), *enterprise resource planning* (ERP), *supply chain management* (SCM), and *information technology* (IT) are frequently used to designate the upper levels of computer systems within a corporation. From a control perspective, the functions performed at this level are normally long-term and/or strategic. For example, in a processing plant, long-term contracts are required with the providers of the feedstocks. A forecast must be developed for the demand for possible products from the plant. This demand must be translated to needed raw materials, and then contracts executed with the suppliers to deliver these materials on a relatively uniform schedule.

## DIGITAL HARDWARE IN PROCESS CONTROL

Digital control technology was first applied to process control in 1959, using a single central computer (and analog backup for reliability). In the mid-1970s, a microcomputer-based process control architecture referred to as a *distributed control system* (*DCS*) was introduced and rapidly became a commercial success. A DCS consists of some number of microprocessor-based nodes that are interconnected by a digital communications network, often called a data highway. Today the DCS is still dominant, but there are other options for carrying out computer control, such as single-loop controllers, programmable logic controllers, and personal computer controllers. A brief review of each type of controller device is given below; see the following section "Controllers, Final Control Elements, and Regulators" for more details on controller hardware options.

**Single-Loop Controllers** The single-loop controller (SLC) is the digital equivalent of analog single-loop controllers. It is a self-contained microprocessor-based unit that can be rack-mounted. Many manufacturers produce single processor units that handle cascade control or multiple loops, typically 4, 8, or 16 loops per unit, and incorporate self-tuning or auto-tuning PID control algorithms.

**Programmable Logic Controllers** Programmable logic controllers (PLCs) are simple digital devices that are widely used to control sequential and batch processes, although they now have additional functions that implement PID control and other mathematical operations. PLCs can be utilized as stand-alone devices or in conjunction with digital computer control systems. Because the logical functions are stored in main memory, one measure of a PLC's capability is its memory scan rate. Most PLCs are equipped with an internal timing capability to delay an action by a prescribed amount of time, to execute an action at a prescribed time, and so on. Newer PLC models often are networked to serve as one component of a DCS, with operator I/O provided by a separate component in the network. A distinction is made between configurable and programmable PLCs. The term *configurable* implies that logical operations (performed on inputs to yield a desired output) are located in PLC memory, perhaps in the form of ladder diagrams by selecting from a PLC menu or by direct interrogation of the PLC. Most control engineers prefer the simplicity of configuring the PLC to the alternative of programming it. However, some batch applications, particularly those involving complex sequencing, are best handled by a programmable approach.

**Personal Computer Controllers** In comparison with PLCs, PCs have the advantages of lower purchase cost, graphics output, large memory, large selection of software products (including databases and development tools), more programming options (use of C or Java versus ladder logic), richer operating systems, and open networking. PLCs have the following advantages: lower maintenance cost, operating system and hardware optimized for control, fast boot times, ruggedness, low failure rate, longer support for product models, and self-contained units.

A number of vendors have introduced so-called scalable process control systems. Scalable means that the size of the control and instrumentation systems is easily expanded by simply adding more devices. This feature is possible because of the trend toward more openness (i.e., "plug and play" between devices), smaller size, lower cost, greater flexibility, and more off-the-shelf hardware and software in digital control systems. A typical system includes personal computers, an operating system, object-oriented database technology, modular field-mounted controllers, and plug-and-play integration of both system and intelligent field devices. New devices are automatically recognized and configured with the system. Advanced control algorithms can be executed at the PC level.

**Distributed Control System** Figure 8-65 depicts a representative distributed control system. The DCS consists of many commonly

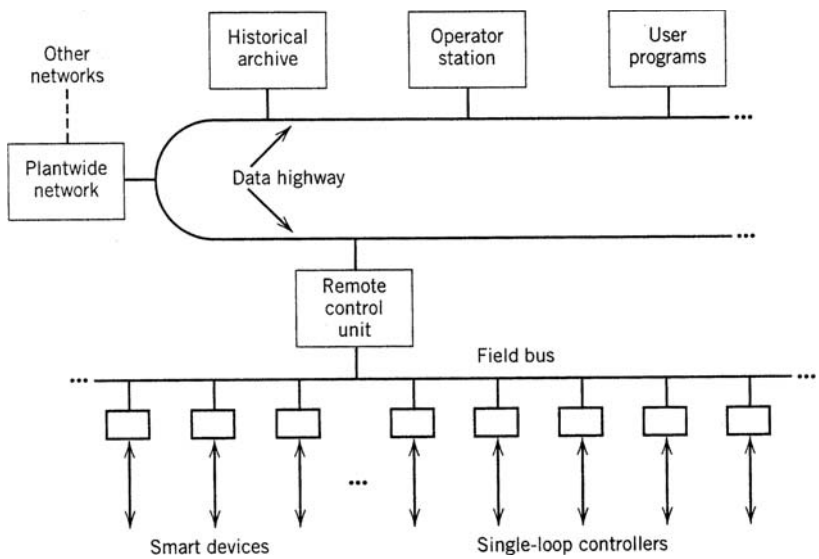

**FIG. 8-65** A DCS using a broadband (high-bandwidth) data highway and field bus connected to a single remote control unit that operates smart devices and single-loop controllers.

used components, including multiplexers (MUXs), single-loop and multiple-loop controllers, PLCs, and smart devices. A system includes some of or all the following components:

1. *Control network.* The control network is the communication link between the individual components of a network. Coaxial cable and, more recently, fiber-optic cable have often been used, sometimes with Ethernet protocols. A redundant pair of cables (dual redundant highway) is normally supplied to reduce the possibility of link failure.
2. *Workstations.* Workstations are the most powerful computers in the system, capable of performing functions not normally available in other units. A workstation acts both as an arbitrator unit to route internodal communications and as the database server. An operator interface is supported, and various peripheral devices are coordinated through the workstations. Computationally intensive tasks, such as real-time optimization or model predictive control, are implemented in a workstation. Operators supervise and control processes from these workstations. Operator stations may be connected directly to printers for alarm logging, printing reports, or process graphics.
3. *Remote control units (RCUs).* These components are used to implement basic control functions such as PID control. Some RCUs may be configured to acquire or supply set points to single-loop controllers. Radio telemetry (wireless) may be installed to communicate with MUX units located at great distances.
4. *Application stations.* These separate computers run application software such as databases, spreadsheets, financial software, and simulation software via an OPC interface. OPC is an acronym for object linking and embedding for process control, a software architecture based on standard interfaces. These stations can be used for e-mail and as web servers, for remote diagnosis configuration, and even for operation of devices that have an IP (Internet Protocol) address. Applications stations can communicate with the main database contained in online mass storage systems. Typically hard disk drives are used to store active data, including online and historical databases and nonmemory resident programs. Memory resident programs are also stored to allow loading at system start-up.
5. *Field buses and smart devices.* An increasing number of field-mounted devices are available that support digital communication of the process I/O in addition to, or in place of, the traditional 4- to 20-mA current signal. These devices have greater functionality, resulting in reduced setup time, improved control, combined functionality of separate devices, and control valve diagnostic capabilities. Digital communication also allows the control system to become completely distributed where, e.g., a PID control algorithm could reside in a valve positioner or in a sensor/transmitter.

## DISTRIBUTED DATABASE AND THE DATABASE MANAGER

A database is a centralized location for data storage. The use of databases enhances system performance by maintaining complex relations between data elements while reducing data redundancy. A database may be built based on the relational model, the entity relationship model, or some other model. The database manager is a system utility program or programs acting as the gatekeeper to the databases. All functions retrieving or modifying data must submit a request to the manager. Information required to access the database includes the tag name of the database entity, often referred to as a point, the attributes to be accessed, and the values, if modifying. The database manager maintains the integrity of the databases by executing a request only when not processing other conflicting requests. Although a number of functions may read the same data item at the same time, writing by a number of functions or simultaneous read and write of the same data item is not permitted.

To allow flexibility, the database manager must also perform point addition or deletion. However, the ability to create a point type or to add or delete attributes of a point type is not normally required because, unlike other data processing systems, a process control system normally involves a fixed number of point types and related attributes. For example, analog and binary input and output types are required for process I/O points. Related attributes for these point types include tag names, values, and hardware addresses. Different system manufacturers may define different point types using different data structures. We will discuss other commonly used point types and attributes as they appear.

**Data Historian** A historical database is built similar to an online database. Unlike their online counterparts, the information stored in a historical database is not normally accessed directly by other subsystems for process control and monitoring. Periodic reports and long-term trends are generated based on the archived data. The reports are often used for planning and system performance evaluations such as statistical process (quality) control. The trends may be used to detect process drifts or to compare process variations at different times.

The historical data are sampled at user-specified intervals. A typical process plant contains a large number of data points, but it is not feasible to store data for all points at all times. The user determines if a data point should be included in the list of archive points. Most systems provide archive-point menu displays. The operators are able to add or delete data points to the archive point lists. The sampling periods are normally some multiples of their base scan frequencies. However, some systems allow historical data sampling of arbitrary intervals. This is necessary when intermediate virtual data points that do not have the scan frequency attribute are involved. The archive point lists are continuously scanned by the historical database software. Online databases are polled for data, and the times of data retrieval are recorded with the data obtained. To conserve storage space, different data compression techniques are employed by various manufacturers.

## DIGITAL FIELD COMMUNICATIONS AND FIELD BUS

Microprocessor-based equipment, such as smart instruments and single-loop controllers with digital communications capability, are now used extensively in process plants. A field bus, which is a low-cost protocol, is necessary to perform efficient communication between the DCS and devices that may be obtained from different vendors. Figure 8-65 illustrates a LAN-based DCS with field buses and smart devices connected to a data highway.

Presently, there are several regional and industry-based field bus standards, including the French standard (FIP), the German standard (Profibus), and proprietary standards by DCS vendors, generally in the United States, led by the Fieldbus Foundation, a not-for-profit corporation. As of 2002, international standards organizations had adopted all these field bus standards rather than a single unifying standard. However, there will likely be further developments in field bus standards in the future. A benefit of standardizing the field bus is that it has encouraged third-party traditional equipment manufacturers to enter the smart equipment market, resulting in increased competition and improved equipment quality.

Several manufacturers have made available field bus controllers that reside in the final control element or measurement transmitter. A suitable communications modem is present in the device to interface with a proprietary PC-based, or hybrid analog/digital bus network. At present, field bus controllers are single-loop controllers containing 8- and 16-bit microprocessors that support the basic PID control algorithm as well as other functionalities. Case studies in implementing such digital systems have shown significant reductions in cost of installation (mostly cabling and connections) versus traditional analog field communication.

A general movement has also begun in the direction of using the high-speed Ethernet standard (100 Mbit/s or higher), allowing data transfer by TCP/IP that is used pervasively in computer networking. This would allow any smart device to communicate directly with others in the network or to be queried by the operator regarding its status and settings.

## INTERNODAL COMMUNICATIONS

For a group of computers to become a network, intercomputer communication is required. Prior to the 1980s, each system vendor used a proprietary protocol to network its computers. Ad hoc approaches were sometimes used to connect third-party equipment but were not cost-effective with regard to system maintenance, upgrade, and expansion.

The recent introduction of standardized communication protocols has led to a decrease in capital cost. Most current DCS network protocol designs are based on the ISO-OSI seven-layer model with physical, data link, network, transport, session, presentation, and application layers.

An effort in standardizing communication protocols for plant automation was initiated by General Motors in the early 1980s. This work culminated in the Manufacturing Automation Protocol (MAP), which adopted the ISO-OSI standards as its basis. MAP specifies a broadband backbone local-area network (LAN) that incorporates a selection of existing standard protocols suitable for discrete component manufacturing. MAP was intended to address the integration of DCSs used in process control. Subsequently, TCP/IP (Transmission Control Protocol/Internet Protocol) was adopted for communication between nodes that have different operating systems.

Communication programs also act as links to the database manager. When data are requested from a remote node, the database manager transfers the request to the remote node database manager via the communication programs. The remote node communication programs then relay the request to the resident database manager and return the requested data. The remote database access and the existence of communications equipment and software are transparent to the user.

### PROCESS CONTROL LANGUAGES

Originally, software for process control utilized high-level programming languages such as FORTRAN and BASIC. Some companies have incorporated libraries of software routines for these languages, but others have developed specialty languages characterized by natural language statements. The most widely adopted user-friendly approach is the fill-in-the-forms or table-driven process control languages (PCLs). Typical PCLs include function block diagrams, ladder logic, and programmable logic. The core of these languages is a number of basic function blocks or software modules, such as analog in, digital in, analog out, digital out, PID, summer, and splitter. Using a module is analogous to calling a subroutine in conventional FORTRAN or C programs.

In general, each module contains one or more inputs and an output. The programming involves connecting outputs of function blocks to inputs of other blocks via the graphical-user interface. Some modules may require additional parameters to direct module execution. Users are required to fill in templates to indicate the sources of input values, the destinations of output values, and the parameters for forms/tables prepared for the modules. The source and destination blanks may specify process I/O channels and tag names when appropriate. To connect modules, some systems require filling in the tag names of modules originating or receiving data.

Many DCSs allow users to write custom code (similar to BASIC) and attach it to data points, so that the code is executed each time the point is scanned. The use of custom code allows many tasks to be performed that cannot be carried out by standard blocks.

All process control languages contain PID control blocks of different forms. Other categories of function blocks include

1. *Logical operators.* AND, OR, and exclusive OR (XOR) functions.
2. *Calculations.* Algebraic operations such as addition, multiplication, square root extraction, or special function evaluation.
3. *Selectors.* Min and max functions, transferring data in a selected input to the output or the input to a selected output.
4. *Comparators.* Comparison of two analog values and transmission of a binary signal to indicate whether one analog value exceeds the other.
5. *Timers.* Delayed activation of the output for a programmed duration after activation by the input signal.
6. *Process dynamics.* Emulation of a first-order process lag (or lead) and time delay.

## CONTROLLERS, FINAL CONTROL ELEMENTS, AND REGULATORS

External control of the process is achieved by devices that are specially designed, selected, and configured for the intended process control application. The text that follows covers three very common function classifications of process control devices: controllers, final control elements, and regulators.

The process controller is the "master" of the process control system. It accepts a set point and other inputs and generates an output or outputs that it computes from a rule or set of rules that is part of its internal configuration. The controller output serves as an input to another controller or, more often, as an input to a final control element. The final control element typically is a device that affects the flow in the piping system of the process. The final control element serves as an interface between the process controller and the process. Control valves and adjustable speed pumps are the principal types discussed.

Regulators, though not controllers or final control elements, perform the combined function of these two devices (controller and final control element) along with the measurement function commonly associated with the process variable transmitter. The uniqueness, control performance, and widespread usage of the regulator make it deserving of a functional grouping of its own.

### PNEUMATIC, ELECTRONIC, AND DIGITAL CONTROLLERS

**Pneumatic Controllers** The pneumatic controller is an automatic controller that uses variable air pressure as input and output signals. An air supply is also required to "power" the mechanical components of the controller and provide an air source for the controller output signal. Pneumatic controllers were first available in the early 1940s but are now rarely used for large-scale industrial control projects. Pneumatic controllers are still used where cost, ruggedness, or the installation requires an all-pneumatic solution.

Pneumatic process transmitters are used to produce a pressure signal that is proportional to the calibrated range of the measuring element. Of the transmitter range 0 to 100 percent is typically represented by a 0.2- to 1.0-bar (3- to 15-psig) pneumatic signal. This signal is sent through tubing to the pneumatic controller process variable feedback connection. The process variable feedback can also be sensed directly in cases where the sensing element has been incorporated into the controller design. Controllers with integral sensing elements are available that sense pressure, differential pressure, temperature, and level.

The pneumatic controller is designed so that 0 to 100 percent output is also represented by 0.2 to 1.0 bar (3 to 15 psig). The output signal is sent through tubing to the control valve or other final control element. Most pneumatic controllers provide a manual control mode where the output pressure is manually set by operating personnel. The controller design also provides a mechanism to adjust the set point.

Early controller designs required "balancing" of the controller output prior to switching to or from automatic and manual modes. This procedure minimized inadvertent disturbance to the process caused by potentially large differences between the automatic and manual output levels. Later designs featured "bumpless" or "procedureless" automatic-to-manual transfer.

Although the pneumatic controller is often used in single-loop control applications, cascade strategies can be implemented where the controller design supports input of external or remote set-point signals. A balancing procedure is typically required to align the remote set point with the local set point before the controller is switched into cascade mode.

Almost all pneumatic controllers include indicators for process variable, set point, and output. Many controller designs also feature integral chart recorders. There are versions of the pneumatic controller that support combinations of proportional, integral, and derivative actions.

The pneumatic controller can be installed into panel boards that are adjacent to the process being controlled or in a centrally located control room. Field-mountable controllers can be installed directly onto the control valve, a nearby pipestand, or wall in close proximity to the control valve and/or measurement transmitter.

If operated on clean, dry plant air, pneumatic controllers offer good performance and are extremely reliable. In many cases, however, plant air is neither clean nor dry. A poor-quality air supply will cause unreliable performance of pneumatic controllers, pneumatic field measurement devices, and final control elements. The main shortcoming of the pneumatic controller is its lack of flexibility when compared to modern electronic controller designs. Increased range of adjustability, choice of alternative control algorithms, the communication link to the control system, and other features and services provided by the electronic controller make it a superior choice in most of today's applications. Controller performance is also affected by the time delay induced by pneumatic tubing runs. For example, a 100-m run of 6.35-mm ($\frac{1}{4}$-in) tubing will typically cause 5 s of apparent process dead time, which will limit the control performance of fast processes such as flows and pressures.

Pneumatic controllers continue to be used in areas where it would be hazardous to use electronic equipment, such as locations with flammable or explosive atmospheres or other locations where compressed air is available but where access to electrical services is limited or restricted.

**Electronic (Digital) Controllers** Almost all the electronic process controllers used today are microprocessor-based, digital devices. In the transition from pneumatic to electronic controllers, a number of analog controller designs were available. Due to the inflexible nature of the analog designs, these controllers have been almost completely replaced by digital designs. The microprocessor-based controllers contain, or have access to, input/output (I/O) interface electronics that allow various types of signals to enter and leave the controller's processor.

The resolution of the analog I/O channels of the controller varies by manufacturer and age of the design. The 12- to 14-bit conversion resolution of the analog input channels is quite common. Conversion resolution of the analog output channels is typically 10- to 12-bit. Newer designs support up to 16 bit input and output resolution. Although 10-bit output resolution had been considered satisfactory for many years, it has recently been identified as a limitation of control performance. This limitation has emerged as the performance of control valve actuators has improved and the use of other high-resolution field devices, such as variable-speed pump drives, has become more prevalent. These improvements have been driven by the need to deliver higher operating efficiencies and improved product specifications through enhanced process control performance.

Sample rates for the majority of digital controllers are adjustable and range from 1 sample every 5 s to 10 samples per second. Some controller designs have fixed sample rates that fall within the same range. Hardwired low-pass filters are usually installed on the analog inputs to the controller to help protect the sampler from aliasing errors.

The real advantage of digital controllers is the substantial flexibility offered by a number of different configuration schemes. The simplest form of configuration is seen in a controller design that features a number of user-selectable control strategies. These strategies are customized by setting "tunable" parameters within the strategy. Another common configuration scheme uses a library of function blocks that can be selected and combined to form the desired control strategy. Each function block has adjustable parameters. Additional configuration schemes include text-based scripting languages, higher-level languages such as Basic or C, and ladder logic.

Some digital controller designs allow the execution rates of control strategy elements to be set independently of each other and independently of the I/O subsystem sample rate. Data passed from control element to subsystems that operate at slower sample or execution rates present additional opportunities for timing and aliasing errors.

***Distributed Control Systems*** Some knowledge of the distributed control system (DCS) is useful in understanding electronic controllers. A DCS is a process control system with sufficient performance to support large-scale, real-time process applications. The DCS has (1) an operations workstation with input devices, such as a keyboard, mouse, track ball, or other similar device, and a display device, such as a CRT or LCD panel; (2) a controller subsystem that supports various types of controllers and controller functions; (3) an I/O subsystem for converting analog process input signals to digital data and digital data back to analog output signals; (4) a higher-level computing platform for performing process supervision, historical data trending and archiving functions, information processing, and analysis; and (5) communication networks to tie the DCS subsystems, plant areas, and other plant systems together. The component controllers used in the controller subsystem portion of the DCS can be of various types and include multiloop controllers, programmable logic controllers, personal computer controllers, single-loop controllers, and field bus controllers. The type of electronic controller utilized depends on the size and functional characteristic of the process application being controlled. Personal computers are increasingly being used as DCS operations workstations or interface stations in place of custom-built machines. This is due to the low cost and high performance of the PC. See the earlier section "Digital Technology for Process Control."

***Multiloop Controllers*** The multiloop controller is a DCS network device that uses a single 32-bit microprocessor to provide control functions to many process loops. The controller operates independently of the other devices on the DCS network and can support from 20 to 500 loops. Data acquisition capability for 1000 analog and discrete I/O channels or more can also be provided by this controller. The I/O is typically processed through a subsystem that is connected to the controller through a dedicated bus or network interface. The multiloop controller contains a variety of function blocks (for example, PID, totalizer, lead/lag compensator, ratio control, alarm, sequencer, and boolean) that can be "soft-wired" together to form complex control strategies. The multiloop controller also supports additional configuration schemes including text-based scripting languages, higher-level languages such as Basic or C, and, to a limited extent, ladder logic. The multiloop controller, as part of a DCS, communicates with other controllers and human/machine interface (HMI) devices also on the DCS network.

***Programmable Logic Controllers*** The programmable logic controller (PLC) originated as a solid-state, and far more flexible, replacement for the hardwired relay control panel and was first used in the automotive industry for discrete manufacturing control. Today, PLCs are primarily used to implement boolean logic functions, timers, and counters. Some PLCs offer a limited number of math functions and PID control. PLCs are often used with on/off input and output devices such as limit or proximity switches, solenoid-actuated process control valves, and motor switch gear. PLCs vary greatly in size with the smallest supporting less than 128 I/O channels and the largest supporting more than 1023 I/O channels. Very small PLCs combine processor, I/O, and communications functions into a single, self-contained unit. For larger PLC systems, hardware modules such as the power supply, processor module, I/O modules, communication module, and backplane are specified based on the application. These systems support multiple I/O backplanes that can be chained together to increase the I/O count available to the processor. Discrete I/O modules are available that support high-current motor loads and general-purpose voltage and current loads. Other modules support analog I/O and special-purpose I/O for servomotors, stepping motors, high-speed pulse counting, resolvers, decoders, displays, and keyboards. PLC I/O modules often come with indicators to determine the status of key I/O channels. When used as an alternative to a DCS, the PLC is programmed with a handheld or computer-based loader. The PLC is typically programmed with ladder logic or a high-level computer language such as BASIC, FORTRAN, or C. Programmable logic controllers use 16- or 32-bit microprocessors and offer some form of point-to-point serial communications such as RS-232C, RS-485, or

networked communication such as Ethernet with proprietary or open protocols. PLCs typically execute the boolean or ladder logic configuration at high rates; 10-ms execution intervals are common. This does not necessarily imply that the analog I/O or PID control functions are executed at the same rate. Many PLCs execute the analog program at a much slower rate. Manufacturers' specifications must be consulted.

***Personal Computer Controller*** Because of its high performance at low cost and its unexcelled ease of use, application of the personal computer (PC) as a platform for process controllers is growing. When configured to perform scan, control, alarm, and data acquisition (SCADA) functions and combined with a spreadsheet or database management application, the PC controller can be a low-cost, basic alternative to the DCS or PLC. Using the PC for control requires installation of a board into the expansion slot in the computer, or the PC can be connected to an external I/O module by using a standard communication port on the PC. The communication is typically achieved through a serial interface (RS-232, RS-422, or IEEE-488), universal serial bus (USB), or Ethernet. The controller card/module supports 16- or 32-bit microprocessors. Standardization and high volume in the PC market have produced a large selection of hardware and software tools for PC controllers.

The PC can also be interfaced to a DCS to perform advanced control or optimization functions that are not available within the standard DCS function library.

***Single-Loop Controller*** The single-loop controller (SLC) is a process controller that produces a single output. SLCs can be pneumatic, analog electronic, or microprocessor-based. Pneumatic SLCs are discussed in the pneumatic controller section, and analog electronic SLC is not discussed because it has been virtually replaced by the microprocessor-based design. The microprocessor-based SLC uses an 8- or 16-bit microprocessor with a small number of digital and analog process input channels with control logic for the I/O incorporated within the controller. Analog inputs and outputs are available in the standard ranges (1 to 5 V dc and 4 to 20 mA dc). Direct process inputs for temperature sensors (thermistor RTD and thermocouple types) are available. Binary outputs are also available. The face of the SLC has some form of visible display and pushbuttons that are used to view or adjust control values and configuration. SLCs are available for mounting in panel openings as small as $48 \times 48$ mm ($1.9 \times 1.9$ in).

The processor-based SLC allows the user to select from a set of predefined control strategies or to create a custom control strategy by using a set of control function blocks. Control function blocks include PID, on/off, lead/lag, adder/subtractor, multiply/divide, filter functions, signal selector, peak detector, and analog track. SLCs feature auto/manual transfer switching, multi-set-point self-diagnostics, gain scheduling, and perhaps also time sequencing. Most processor-based SLCs have self-tuning or auto-tuning PID control algorithms. Sample times for the microprocessor-based SLCs vary from 0.1 to 0.5 s. Low-pass analog electronic filters are usually installed on the process inputs to minimize aliasing errors caused by high-frequency content in the process signal. Input filter time constants are typically in the range of 0.1 to 1 s. Microprocessor-based SLCs may be made part of a DCS by using the communication port (RS-488 is common) on the controller or may be operated in a stand-alone mode independently of the DCS.

***Field Bus Controller*** Field bus technology is a network-based communications system that interconnects measurement and control equipment such as sensors, actuators, and controllers. Advanced field bus systems, intended for process control applications, such as Foundation Fieldbus, enable digital interoperability among these devices and have a built-in capability to distribute the control application across the network. Several manufacturers have made available Foundation Fieldbus devices that support process controller functionality. These controllers, known as field bus controllers, typically reside in the final control element or measurement transmitter, but can be designed into any field bus device. A suitable communications interface connects the Fieldbus segment to the distributed control system. When configuring the control strategy, all or part of the strategy may be loaded into the field bus devices. The remaining part of the control strategy would reside in the DCS itself. The distribution of the control function depends on the processing capacity of the field bus devices, the control strategy, and where it makes sense to perform these functions. Linearization of a control valve could be performed in the digital valve positioner (controller), for example. Temperature and pressure compensation of a flow measurement could be performed in the flow transmitter processor. The capability of field bus devices varies greatly. Some devices will allow instances of control system function blocks to be loaded and executed, while other devices allow the use of only preconfigured function blocks. Field bus controllers are typically configured as single-loop PID controllers, but cascade or other complex control strategies can be configured depending on the capability of the field bus device. Field bus devices that have native support for process control functions do not necessarily implement the PID algorithm in the same way. It is important to understand these differences so that the controller tuning will deliver the desired closed-loop characteristics. The functionality of field bus devices is projected to increase as the controller market develops.

***Controller Reliability and Application Trends*** Critical process control applications demand a high level of reliability from the electronic controller. Some methods that improve the reliability of electronic controllers include (1) focusing on robust circuit design using quality components; (2) using redundant circuits, modules, or subsystems where necessary; (3) using small backup systems when needed; (4) reducing repair time and using more powerful diagnostics; and (5) distributing functionality to more independent modules to limit the impact of a failed module. Currently, the trend in process control is away from centralized process control and toward an increased number of small distributed control or PLC systems. This trend will put emphasis on the evolution of the field bus controller and continued growth of the PC-based controller. Also, as hardware and software improve, the functionality of the controller will increase, and the supporting hardware will be physically smaller. Hence, the traditional lines between the DCS and the PLC will become less distinct as systems become capable of supporting either function set.

***Controller Performance and Process Dynamics*** The design of a control loop must take the control objectives into account. What do you want this loop to do? And under what operating conditions? There may be control applications that require a single control objective and others that have several control objectives. Control objectives may include such requirements as minimum variance control at steady state, maximum speed of recovery from a major disturbance, maximum speed of set-point response where overshoot and ringing are acceptable, critically damped set-point response with no overshoot, robustness issues, and special start-up or shutdown requirements. The control objectives will define not only the tuning requirements of the controller, but also, to a large extent, the allowable dynamic parameters of the field instruments and process design. Process dynamics alone can prevent control objectives from being realized. Tuning of the controller cannot compensate for an incompatible process or unrealistic control objectives. For most controllers, the difference between the set-point and process feedback signal, the error, is the input to the PID algorithm. The calculated PID output is sent back to the final control element. Every component between the controller output and the process feedback is considered by the controller as the "process" and will directly affect the dynamics and ultimately the performance of the system. This includes not only the dynamics of the physical process, but also the dynamics of the field instruments, signal conditioning equipment, and controller signal processing elements such as filters, scaling, and linearization routines. The choice of final control element can significantly affect the dynamics of the system. If the process dynamics are relatively slow, with time constants of a few minutes or longer, most control valves are fast enough that their contribution to the overall process time response will be negligible. In cases where the process time constants are only a few seconds, the control valve dynamics may become the dominant lag in the overall response. Excessive filtering in the field-sensing devices may also mask the true process dynamics and potentially limit control performance. Often, the design of a control loop and the tuning of the controller are a compromise between a number of different control objectives. When a compromise is unacceptable, gain scheduling or other adaptive tuning routine may be necessary to match the controller response to the most appropriate control objective.

When one is tuning a controller, the form of the PID algorithm must be known. The three common forms of the PID algorithm are parallel

or noninteracting, classical or interacting, and the ISA Standard form. In *most* cases, a controller with any of these PID forms can be tuned to produce the desired closed-loop response. The actual tuning parameters will be different. The units of the tuning parameters also affect their value. The controller gain parameter is typically represented as a pure gain ($K_c$), acting on the error, or as proportional band (PB). In cases where the proportional band parameter is used, the equivalent controller gain is equal to 100 divided by the proportional band and represents the percent span that the error must traverse to produce a 100 percent change in the controller output. The proportional band is always applied to the controller error in terms of percent of span and percent of output. Controllers that use a gain tuning parameter commonly scale the error into percent span and use a percent output basis. In some controllers, the error is scaled by using a separate parameter into percent span prior to the PID algorithm. The gain parameter can also be applied to the error in engineering units. Even though most controller outputs are scaled as a percent, in cascade strategies the controller output may need to be scaled to the same span at the slave loop set point. In this case, the controller gain may in fact be required to calculate the controller output in terms of the slave loop engineering units.

The execution rate of a digital controller should be sufficiently fast, compared to the process dynamics, to produce a response that closely approximates that of an analog controller with the same tuning. A general rule of thumb is that the execution interval should be at least 3 times faster than the dominant lag of the process or about 10 times faster than the closed-loop time constant. The controller can be used when the sample rates are slower than this recommendation, but the controller output will consist of a series of coarse steps as compared to a smooth response. This may create stability problems. Some integral and derivative algorithms may not be accurate when the time-based tuning parameters approach the controller execution interval. The analog inputs of the controller are typically protected from aliasing errors through the use of one- or two-pole analog filters. Faster sample rates allow a smaller antialiasing filter and improved input response characteristics. Some controllers or I/O subsystems oversample the analog inputs with respect to the controller execution interval and then process the input data through a digital filter. This technique can produce a more representative measurement with less quantization noise.

Differences in the PID algorithm, controller parameters, units, and other fundamental control functions highlight the importance of understanding the structure of the controller and the requirement of sufficiently detailed documentation. This is especially important for the controller but is also important for the field instruments, final control elements, and device that have the potential to affect the signal characteristics.

## CONTROL VALVES

A control valve consists of a valve, an actuator, and usually one or more valve control devices. The valves discussed in this section are applicable to throttling control (i.e., where flow through the valve is regulated to any desired amount between maximum and minimum limits). Other valves such as check, isolation, and relief valves are addressed in the next subsection. As defined, control valves are automatic control devices that modify the fluid flow rate as specified by the controller.

**Valve Types** Types of valves are categorized according to their design style. These styles can be grouped into type of stem motion—linear or rotary. The valve stem is the rod, shaft, or spindle that connects the actuator with the closure member (i.e., a movable part of the valve that is positioned in the flow path to modify the rate of flow). Movement of either type of stem is known as travel. The major categories are described briefly below.

***Globe and Angle*** The most common linear stem-motion control valve is the globe valve. The name comes from the globular cavities around the port. In general, a port is any fluid passageway, but often the reference is to the passage that is blocked off by the closure member when the valve is closed. In globe valves, the closure member is called a plug. The plug in the valve shown in Fig. 8-66 is guided by a large-diameter port and moves within the port to provide the flow control orifice of the valve. A very popular alternate construction is a cage-guided plug, as illustrated in Fig. 8-67. In many such designs,

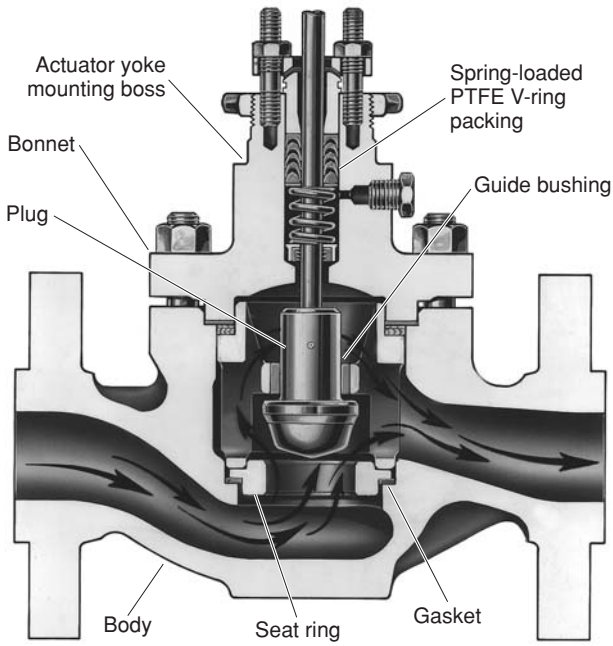

**FIG. 8-66** Post-guided contour plug globe valve with metal seat and raised-face flange end connections. (*Courtesy Fisher Controls International LLC.*)

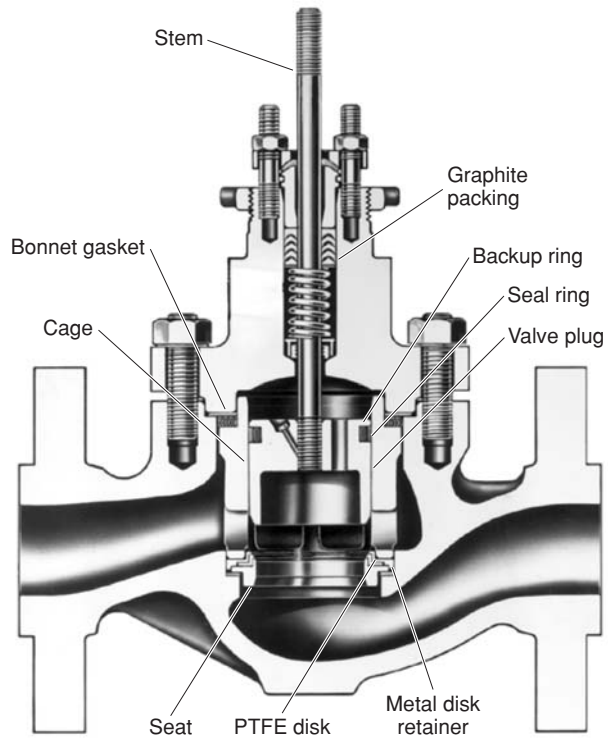

**FIG. 8-67** Cage-guided balanced plug globe valve with polymer seat and plug seal. (*Courtesy Fisher Controls International LLC.*)

openings in the cage provide the flow control orifices. The valve seat is the zone of contact between the moving closure member and the stationary valve body, which shuts off the flow when the valve is closed. Often the seat in the body is on a replaceable part known as a seat ring. This stationary seat can also be designed as an integral part of the cage. Plugs may also be port-guided by wings or a skirt that fits snugly into the seat-ring bore.

One distinct advantage of cage guiding is the use of balanced plugs in single-port designs. The unbalanced plug depicted in Fig. 8-66 is subjected to a static pressure force equal to the port area times the valve pressure differential (plus the stem area times the downstream pressure) when the valve is closed. In the balanced design (Fig. 8-67), note that both the top and bottom of the plug are subjected to the same downstream pressure when the valve is closed. Leakage via the plug-to-cage clearance is prevented by a plug seal. Both plug types are subjected to hydrostatic force due to internal pressure acting on the stem area and to dynamic flow forces when the valve is flowing.

The plug, cage, seat ring, and associated seals are known as the trim. A key feature of globe valves is that they allow maintenance of the trim via a removable bonnet without removing the valve body from the line. Bonnets are typically bolted on but may be threaded in smaller sizes.

Angle valves are an alternate form of the globe valve. They often share the same trim options and have the top-entry bonnet style. Angle valves can eliminate the need for an elbow but are especially useful when direct impingement of the process fluid on the body wall is to be avoided. Sometimes it is not practical to package a long trim within a globe body, so an angle body is used. Some angle bodies are self-draining, which is an important feature for dangerous fluids.

***Butterfly*** The classic design of butterfly valves is shown in Fig. 8-68. Its chief advantage is high capacity in a small package and a very low initial cost. Much of the size and cost advantage is due to the wafer body design, which is clamped between two pipeline flanges. In the simplest design, there is no seal as such, merely a small clearance gap between the disc OD and the body ID. Often a true seal is provided by a resilient material in the body that is engaged via an interference fit with the disc. In a lined butterfly valve, this material covers the entire body ID and extends around the body ends to eliminate the need for pipeline joint gaskets. In a fully lined valve, the disc is also coated to minimize corrosion or erosion.

A high-performance butterfly valve has a disc that is offset from the shaft centerline. This eccentricity causes the seating surface to move away from the seal once the disc is out of the closed position, reducing friction and seal wear. It is also known as an eccentric disc valve; the advantage of the butterfly valve is improved shutoff while maintaining high ultimate capacity at a reasonable cost. This cost advantage relative to other design styles is particularly true in sizes above 6-in nominal pipe size (NPS). Improved shutoff is due to advances in seal technologies, including polymer, flexing metal, combination metal with polymer inserts, and so on, many utilizing pressure assist.

***Ball*** Ball valves get their name from the shape of the closure member. One version uses a full spherical member with a cylindrical bore through it. The ball is rotated one-quarter turn from the full-closed to the full-open position. If the bore is the same diameter as the mating-pipe fitting ID, the valve is referred to as full-bore. If the hole is undersized, the ball valve is considered to be a venturi style. A segmented ball is a portion of a hollow sphere that is large enough to block the port when closed. Segmented balls often have a V-shaped contour along one edge, which provides a desirable flow characteristic (see Fig. 8-69). Both full ball and segmented ball valves are known for

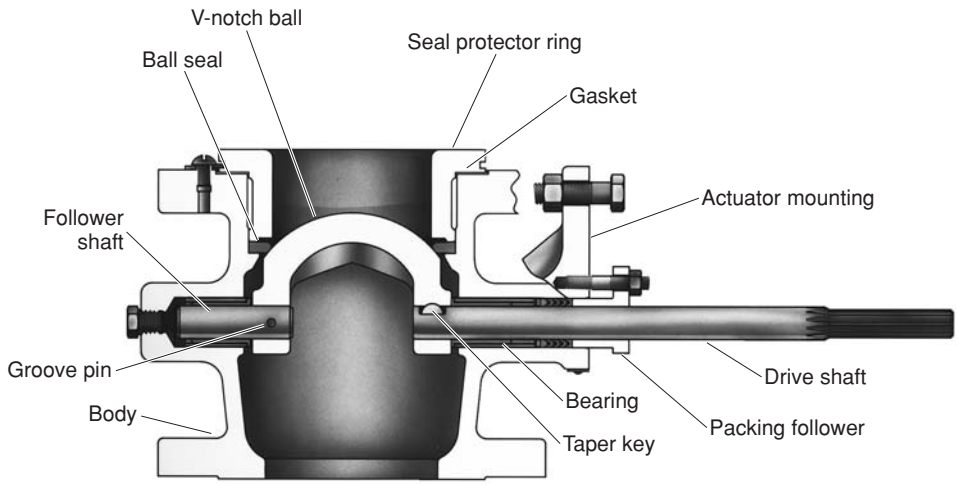

**FIG. 8-69** Segmented ball valve. Partial view of actuator mounting shown 90° out of position. (*Courtesy Fisher Controls International LLC.*)

their low resistance to flow when full open. Shutoff leakage is minimized through the use of flexing or spring-loaded elastomeric or metal seals. Bodies are usually in two or three pieces or have a removable retainer to facilitate installing seals. End connections are usually flanged or threaded in small sizes, although segmented ball valves are offered in wafer style also.

***Plug*** There are two substantially different rotary valve design categories referred to as plug valves. The first consists of a cylindrical or slightly conical plug with a port through it. The plug rotates to vary the flow much as a ball valve does. The body is top-entry but is geometrically simpler than a globe valve and thus can be lined with fluorocarbon polymer to protect against corrosion. These plug valves have excellent shutoff but are generally not for modulating service due to high friction. A variation of the basic design (similar to the eccentric butterfly disc) only makes sealing contact in the closed position and is used for control.

The other rotary plug design is portrayed in Fig. 8-70. The seating surface is substantially offset from the shaft, producing a ball-valve-like motion with the additional cam action of the plug into the seat when closing. In reverse flow, high-velocity fluid motion is directed inward, impinging on itself and only contacting the plug and seat ring.

***Multiport*** This term refers to any valve or manifold of valves with more than one inlet or outlet. For throttling control, the three-way body is used for blending (two inlets, one outlet) or as a diverter (one inlet, two outlets). A three-way valve is most commonly a special globe-like body with special trim that allows flow both over and under the plug. Two rotary valves and a pipe tee can also be used. Special three-, four-, and five-way ball valve designs are used for switching applications.

**Special Application Valves**

***Digital Valves*** True digital valves consist of discrete solenoid-operated flow ports that are sized according to binary weighing. The valve can be designed with sharp-edged orifices or with streamlined nozzles that can be used for flow metering. Precise control of the throttling control orifice is the strength of the digital valve. Digital valves are mechanically complicated and expensive, and they have considerably reduced maximum flow capacities compared to the globe and rotary valve styles.

***Cryogenic Service*** Valves designed to minimize heat absorption for throttling liquids and gases below 80 K are called cryogenic service valves. These valves are designed with small valve bodies to minimize heat absorption and long bonnets between the valve and actuator to allow for extra layers of insulation around the valve. For extreme cases, vacuum jacketing can be constructed around the entire valve to minimize heat influx.

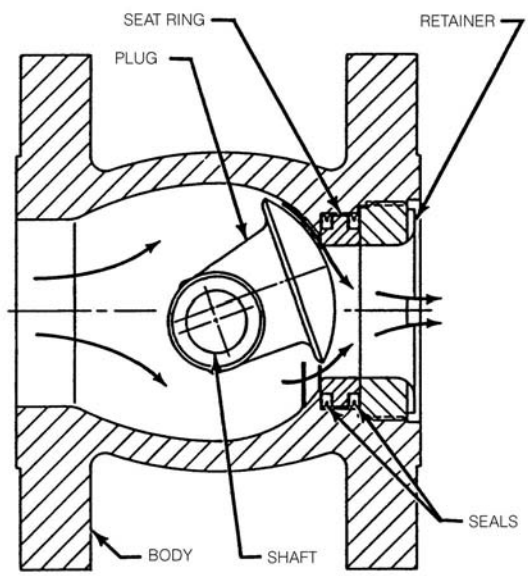

**FIG. 8-70** Eccentric plug valve shown in erosion-resistant reverse flow direction. Shaded components can be made of hard metal or ceramic materials. (*Courtesy Fisher Controls International LLC.*)

***High Pressure*** Valves used for pressures nominally above 760 bar (11,000 psi, pressures above ANSI Class 4500) are often custom-designed for specific applications. Normally, these valves are of the plug type and use specially hardened plug and seat assemblies. Internal surfaces are polished, and internal corners and intersecting bores are smoothed to reduce high localized stresses in the valve body. Steam loops in the valve body are available to raise the body temperature to increase ductility and impact strength of the body material.

***High-Viscous Process*** Used most extensively by the polymer industry, the valve for high-viscous fluids is designed with smooth finished internal passages to prevent stagnation and polymer degradation. These valves are available with integral body passages through which a heat-transfer fluid is pumped to keep the valve and process fluid heated.

***Pinch*** The industrial equivalent of controlling flow by pinching a soda straw is the pinch valve. Valves of this type use fabric-reinforced elastomer sleeves that completely isolate the process fluid from the metal parts in the valve. The valve is actuated by applying air pressure directly to the outside of the sleeve, causing it to contract or pinch. Another method is to pinch the sleeve with a linear actuator with a specially attached foot. Pinch valves are used extensively for corrosive material service and erosive slurry service. This type of valve is used in applications with pressure drops up to 10 bar (145 psi).

***Fire-Rated*** Valves that handle flammable fluids may have additional safety-related requirements for minimal external leakage, minimal internal (downstream) leakage, and operability during and after a fire. Being fire-rated does not mean being totally impervious to fire, but a sample valve must meet particular specifications such as those of American Petroleum Institute (API) 607, Factory Mutual Research Corp. (FM) 7440, or the British Standard 5146 under a simulated fire test. Due to very high flame temperature, metal seating (either primary or as a backup to a burned-out elastomer) is mandatory.

***Solids Metering*** The control valves described earlier are primarily used for the control of fluid (liquid or gas) flow. Sometimes these valves, particularly the ball, butterfly, or sliding gate valves, are used to throttle dry or slurry solids. More often, special throttling mechanisms such as venturi ejectors, conveyers, knife-type gate valves, or rotating vane valves are used. The particular solids-metering valve hardware depends on the volume, density, particle shape, and coarseness of the solids to be handled.

**Actuators** An actuator is a device that applies the force (torque) necessary to cause a valve's closure member to move. Actuators must overcome pressure and flow forces as well as friction from packing, bearings or guide surfaces, and seals; and must provide the seating force. In rotary valves, maximum friction occurs in the closed position, and the moment necessary to overcome it is referred to as breakout torque. The rotary valve shaft torque generated by steady-state flow and pressure forces is called dynamic torque. It may tend to open or close the valve depending on valve design and travel. Dynamic torque per unit pressure differential is largest in butterfly valves at roughly 70° open. In linear stem-motion valves, the flow forces should not exceed the available actuator force, but this is usually accounted for by default when the seating force is provided.

Actuators often provide a fail-safe function. In the event of an interruption in the power source, the actuator will place the valve in a predetermined safe position, usually either full-open or full-closed. Safety systems are often designed to trigger local fail-safe action at specific valves to cause a needed action to occur, which may not be a complete process or plant shutdown.

Actuators are classified according to their power source. The nature of these sources leads naturally to design features that make their performance characteristics distinct.

***Pneumatic*** Despite the availability of more sophisticated alternatives, the pneumatically driven actuator is still by far the most popular type. Historically the most common has been the spring and diaphragm design (Fig. 8-71). The compressed air input signal fills a

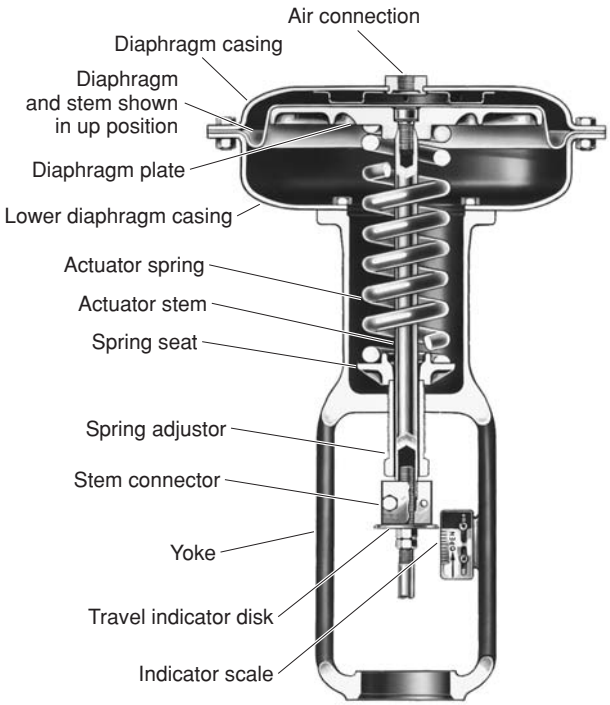

**FIG. 8-71** Spring and diaphragm actuator with an "up" fail-safe mode. Spring adjuster allows slight alteration of bench set. (*Courtesy Fisher Controls International LLC.*)

chamber sealed by an elastomeric diaphragm. The pressure force on the diaphragm plate causes a spring to be compressed and the actuator stem to move. This spring provides the fail-safe function and contributes to the dynamic stiffness of the actuator. If the accompanying valve is "push down to close," the actuator depicted in Fig. 8-71 will be described as "air to close" or synonymously as fail-open. A slightly different design yields "air to open" or fail-closed action. The spring is typically precompressed to provide a significant available force in the failed position (e.g., to provide seating load). The spring also provides a proportional relationship between the force generated by air pressure and stem position. The pressure range over which a spring and diaphragm actuator strokes in the absence of valve forces is known as the bench set. The chief advantages of spring and diaphragm actuators are their high reliability, low cost, adequate dynamic response, and fail-safe action—all of which are inherent in their simple design.

Alternately, the pressurized chamber can be formed by a circular piston with a seal on its outer edge sliding within a cylindrical bore. Higher operating pressure [6 bar (~ 90 psig) is typical] and longer strokes are possible. Piston actuators can be spring-opposed but many times are in a dual-acting configuration (i.e., compressed air is applied to both sides of the piston with the net force determined from the pressure difference—see Fig. 8-72). Dynamic stiffness is usually higher with piston designs than with spring and diaphragm actuators; see "Positioner/Actuator Stiffness." Fail-safe action, if necessary, is achieved without a spring through the use of additional solenoid valves, trip valves, or relays. See "Valve Control Devices."

***Motion Conversion*** Actuator power units with translational output can be adapted to rotary valves that generally need 90° or less rotation. A lever is attached to the rotating shaft, and a link with pivoting means on the end connects to the linear output of the power unit, an arrangement similar to an internal combustion engine crankshaft, connecting rod, and piston. When the actuator piston, or more commonly the diaphragm plate, is designed to tilt, one pivot can be eliminated (see Fig. 8-72). Scotch yoke and rack-and-pinion arrangements are also commonly used, especially with piston power units.

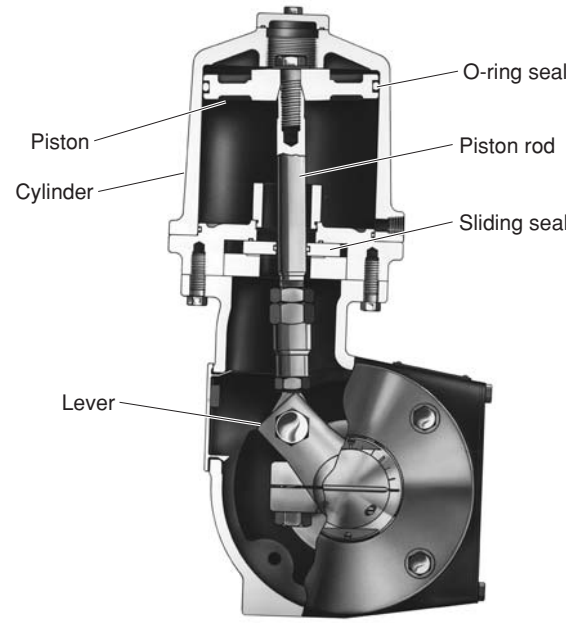

**FIG. 8-72** Double-acting piston rotary actuator with lever and tilting piston for motion conversion. (*Courtesy Fisher Controls International LLC.*)

Friction and the changing mechanical advantage of these motion conversion mechanisms mean the available torque may vary greatly with travel. One notable exception is vane-style rotary actuators whose offset "piston" pivots, giving direct rotary output.

***Hydraulic*** The design of typical hydraulic actuators is similar to that of double-acting piston pneumatic types. One key advantage is the high pressure [typically 35 to 70 bar (500 to 1000 psi)], which leads to high thrust in a smaller package. The incompressible nature of the hydraulic oil means these actuators have very high dynamic stiffness. The incompressibility and small chamber size connote fast stroking speed and good frequency response. The disadvantages include high initial cost, especially when considering the hydraulic supply. Maintenance is much more difficult than with pneumatics, especially on the hydraulic positioner.

Electrohydraulic actuators have similar performance characteristics and cost/maintenance ramifications. The main difference is that they contain their own electric-powered hydraulic pump. The pump may run continuously or be switched on when a change in position is required. Their main application is remote sites without an air supply when a fail-safe spring return is needed.

***Electric*** The most common electric actuators use a typical motor—three-phase ac induction, capacitor-start split-phase induction, or dc. Normally the motor output passes through a large gear reduction and, if linear motion output is required, a ball screw or thread. These devices can provide large thrust, especially given their size. Lost motion in the gearing system does create backlash, but if not operating across a thrust reversal, this type of actuator has very high stiffness. Usually the gearing system is self-locking, which means that forces on the closure member cannot move it by spinning a nonenergized motor. This behavior is called a lock-in-last-position fail-safe mode. Some gear systems (e.g., low-reduction spur gears) can be backdriven. A solenoid-activated mechanical brake or locking current to motor field coils is added to provide lock-in-last-position fail-safe mode. A battery backup system for a dc motor can guard against power failures. Otherwise, an electric actuator is not acceptable if fail-open/closed action is mandatory. Using electric power requires environmental enclosures and explosion protection, especially in hydrocarbon processing facilities; see the full discussion in "Valve Control Devices."

Unless sophisticated speed control power electronics is used, position modulation is achieved via bang-zero-bang control. Mechanical inertia causes overshoot, which is (1) minimized by braking and/or (2) hidden by adding dead band to the position control. Without these provisions, high starting currents would cause motors to overheat from constant "hunting" within the position loop. Travel is limited with power interruption switches or with force (torque) electromechanical cutouts when the closed position is against a mechanical stop (e.g., a globe valve). Electric actuators are often used for on/off service. Stepper motors can be used instead, and they, as their name implies, move in fixed incremental steps. Through gear reduction, the typical number of increments for 90° rotation ranges from 5000 to 10,000; hence positioning resolution at the actuator is excellent.

An electromagnetic solenoid can be used to directly actuate the plug on very small linear stem-motion valves. A solenoid is usually designed as a two-position device, so this valve control is on/off. Special solenoids with position feedback can provide proportional action for modulating control. Force requirements of medium-sized valves can be met with piloted plug designs, which use process pressure to assist the solenoid force. Piloted plugs are also used to minimize the size of common pneumatic actuators, especially when there is need for high seating load.

***Manual*** A manually positioned valve is by definition not an automatic control valve, but it may be involved with process control. For rotary valves, the manual operator can be as simple as a lever, but a wheel driving a gear reduction is necessary in larger valves. Linear motion is normally created with a wheel turning a screw-type device. A manual override is usually available as an option for the powered actuators listed above. For spring-opposed designs, an adjustable travel stop will work as a one-way manual input. In more complex designs, the handwheel can provide loop control override via an engagement means. Some gear reduction systems of electric actuators allow the manual positioning to be independent of the automatic positioning without declutching.

## OTHER PROCESS VALVES

In addition to the throttling control valve, other types of process valves can be used to manipulate a process.

**Valves for On/Off Applications** Valves are often required for service that is primarily nonthrottling. Valves in this category, depending on the service requirements, may be of the same design as the types used for throttling control or, as in the case of gate valves, different in design. Valves in this category usually have tight shutoff when they are closed and low pressure drops when they are wide open. The on/off valve can be operated manually, such as by handwheel or lever; or automatically, with pneumatic or electric actuators.

***Batch*** Batch process operation is an application requiring on/off valve service. Here the valve is opened and closed to provide reactant, catalyst, or product to and from the batch reactor. Like the throttling control valve, the valve used in this service must be designed to open and close thousands of times. For this reason, valves used in this application are often the same valves used in continuous throttling applications. Ball valves are especially useful in batch operations. The ball valve has a straight-through flow passage that reduces pressure drop in the wide-open state and provides tight shutoff capability when closed. In addition, the segmented ball valve provides for shearing action between the ball and the ball seat that promotes closure in slurry service.

***Isolation*** A means for pressure-isolating control valves, pumps, and other piping hardware for installation and maintenance is another common application for an on/off valve. In this application, the valve is required to have tight shutoff so that leakage is stopped when the piping system is under repair. As the need to cycle the valve in this application is far less than that of a throttling control valve, the wear characteristics of the valve are less important. Also, because many are required in a plant, the isolation valve needs to be reliable, simple in design, and simple in operation.

The gate valve, shown in Fig. 8-73, is the most widely used valve in this application. The gate valve is composed of a gatelike disc that moves perpendicular to the flow stream. The disc is moved up and down by a threaded screw that is rotated to effect disc movement. Because the disc is large and at right angles to the process pressure, a large seat loading for tight shutoff is possible. Wear produced by high seat loading during the movement of the disc prohibits the use of the gate valve for throttling applications.

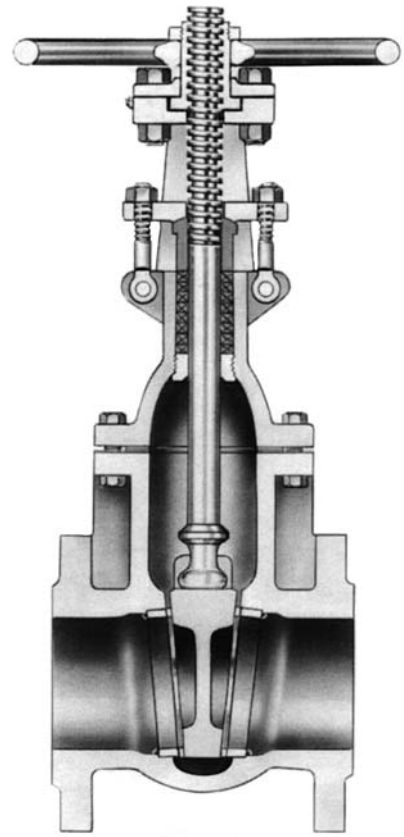

**FIG. 8-73** Gate valve. (*Courtesy Crane Valves.*)

**Pressure Relief Valves** The pressure relief valve is an automatic pressure-relieving device designed to open when normal conditions are exceeded and to close again when normal conditions are restored. Within this class there are relief valves, pilot-operated pressure relief valves, and safety valves. Relief valves (see Fig. 8-74) have spring-loaded discs that close a main orifice against a pressure source. As pressure rises, the disc begins to rise off the orifice and a small amount of fluid passes through the valve. Continued rise in pressure above the opening pressure causes the disc to open the orifice in a proportional fashion. The main orifice reduces and closes when the pressure returns to the set pressure. Additional sensitivity to overpressure conditions can be improved by adding an auxiliary pressure relief valve (pilot) to the basic pressure relief valve. This combination is known as a pilot-operated pressure relief valve.

The safety valve is a pressure relief valve that is designed to open fully, or pop, with only a small amount of pressure over the rated limit. Where conventional safety valves are sensitive to downstream pressure and may have unsatisfactory operating characteristics in variable backpressure applications, pressure-balanced safety relief valve designs are available to minimize the effect of downstream pressure on performance.

Application and sizing of pressure relief valves, pilot-operated pressure relief valves, and safety valves for use on pressure vessels are found in the ASME Boiler and Pressure Vessel Code, Section VIII, Division 1, "Rules for Construction of Pressure Vessels," Paragraphs UG-125 through UG-137.

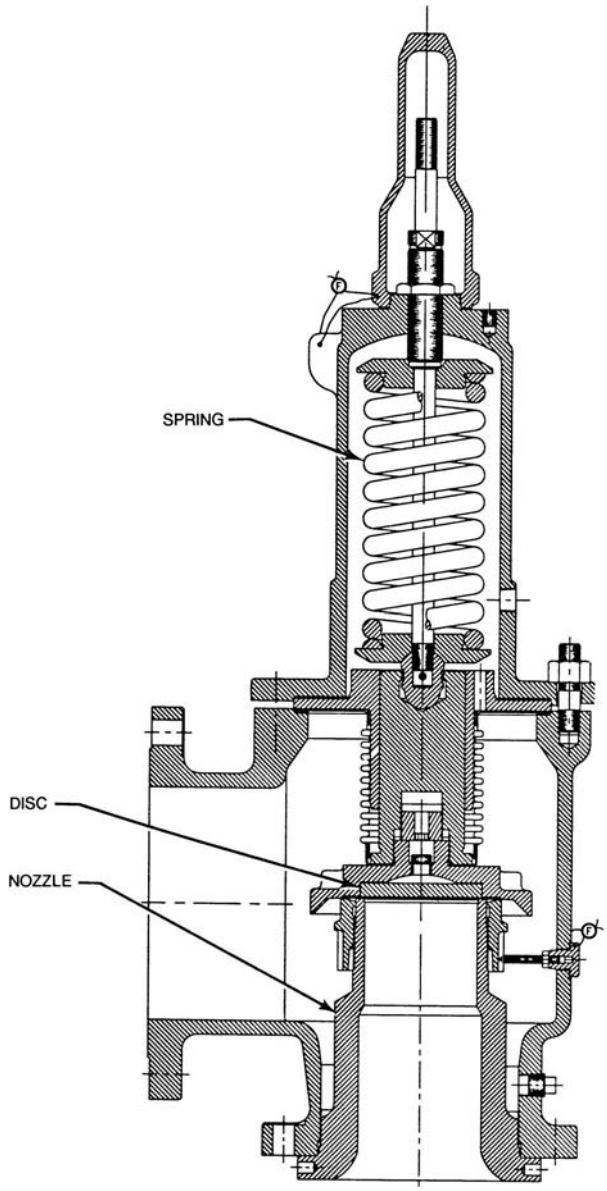

**FIG. 8-74** Relief valve. (*Courtesy of Teledyne Fluid Systems, Farris Engineering.*)

**Check Valves** The purpose of a check valve is to allow relatively unimpeded flow in the desired direction but to prevent flow in the reverse direction. Two common designs are swing-type and lift-type check valves, the names of which denote the motion of the closure member. In the forward direction, flow forces overcome the weight of the member or a spring to open the flow passage. With reverse pressure conditions, flow forces drive the closure member into the valve seat, thus providing shutoff.

## VALVE DESIGN CONSIDERATIONS

Functional requirements and the properties of the controlled fluid determine which valve and actuator types are best for a specific application. If demands are modest and no unique valve features are required, the valve design style selection may be determined solely by cost. If so, general-purpose globe or angle valves provide exceptional value, especially in sizes less than 3-in NPS and hence are very popular. Beyond type selection, there are many other valve specifications that must be determined properly to ultimately yield improved process control.

**Materials and Pressure Ratings** Valves must be constructed from materials that are sufficiently immune to corrosive or erosive action by the process fluid. Common body materials are cast iron, steel, stainless steel, high-nickel alloys, and copper alloys such as bronze. Trim materials need better corrosion and erosion resistance due to the higher fluid velocity in the throttling region. High hardness is desirable in erosive and cavitating applications. Heat-treated and precipitation-hardened stainless steels are common. High hardness is also good for guiding, bearing, and seating surfaces; cobalt-chromium alloys are utilized in cast or wrought form and frequently as welded overlays called hard facing. In less stringent situations, chrome plating, heat-treated nickel coatings, and nitriding are used. Tungsten carbide and ceramic trim are warranted in extremely erosive services. See Sec. 25, "Materials of Construction," for specific material properties.

Since the valve body is a pressurized vessel, it is usually designed to comply with a standardized system of pressure ratings. Two common systems are described in the standards ASME B16.34 and EN 12516. Internal pressure limits under these standards are divided into broad classes, with specific limits being a function of material and temperature. Manufacturers also assign their own pressure ratings based on internal design rules. A common insignia is *250 WOG*, which means a pressure rating of 250 psig (~17 bar) in water, oil, or gas at ambient temperature. "Storage and Process Vessels" in Sec. 10 provides introductory information on compliance of pressure vessel design to industry codes (e.g., ASME Boiler and Pressure Vessel Code, Section VIII; ASME B31.3 Chemical Plant and Petroleum Refinery Piping).

Valve bodies are also standardized to mate with common piping connections: flanged, butt-welded end, socket-welded end, and screwed end. Dimensional information for some of these joints and class pressure-temperature ratings are included in Sec. 10, "Process Plant Piping." Control valves have their own standardized face-to-face dimensions that are governed by ANSI/ISA Standards S75.08 and S75.22. Butterfly valves are also governed by API 609 and Manufacturers Standardization Society (MSS) SP-67 and SP-68.

**Sizing** Throttling control valves must be selected to pass the required flow rate, given expected pressure conditions. Sizing is not merely matching the end connection size with surrounding piping; it is a key step in ensuring that the process can be properly controlled. Sizing methods range from simple models based on elementary fluid mechanics to very complex models when unusual thermodynamics or nonideal behaviors occur. Basic sizing practices have been standardized (for example, ANSI-75.01.01) and are implemented as PC-based programs by manufacturers. The following is a discussion of very basic sizing equations and the associated physics.

Regardless of the particular process variable being controlled (e.g., temperature, level, pH), the output of a control valve is the flow rate. The throttling valve performs its function of manipulating the flow rate by virtue of being an adjustable resistance to flow. Flow rate and pressure conditions are normally known when a process is designed, and the valve resistance range must be matched accordingly. In the tradition of orifice and nozzle discharge coefficients, this resistance is embodied in the valve flow coefficient $C_V$. By applying the principles of conversation of mass and energy, the mass flow rate $w$ kg/h is given for a liquid by

$$w = 27.3C_V\sqrt{\rho(p_1 - p_2)} \tag{8-111}$$

where $p_1$ and $p_2$ are upstream and downstream static pressure, bar, respectively. The density of the fluid $\rho$ is expressed in kilograms per cubic meter. This equation is valid for nonvaporizing, turbulent flow conditions for a valve with no attached fittings.

While the above equation gives the relationship between pressure and flow from a macroscopic point of view, it does not explain what is going on inside the valve. Valves create a resistance to flow by restricting the cross-sectional area of the flow passage and by forcing the fluid to change direction as it passes through the body and trim.

The conservation of mass principle dictates that, for steady flow, the product of density, average velocity, and cross-sectional area remain a constant. The average velocity of the fluid stream at the minimum restriction in the valve is therefore much higher than that at the inlet. Note that due to the abrupt nature of the flow contraction that forms the minimum passage, the main fluid stream may separate from the passage walls and form a jet that has an even smaller cross section, the so-called vena contracta. The ratio of minimum stream area to the corresponding passage area is called the contraction coefficient. As the fluid expands from the minimum cross-sectional area to the full passage area in the downstream piping, large amounts of turbulence are generated. Direction changes can also induce significant amounts of turbulence.

Figure 8-75 is an illustration of how the mean pressure changes as fluid moves through a valve. Some of the potential energy that was stored in the fluid by pressurizing it (e.g., the work done by a pump) is first converted to the kinetic energy of the fast-moving fluid at the vena contracta. Some of that kinetic energy turns into the kinetic energy of turbulence. As the turbulent eddies break down into smaller and smaller structures, viscous effects ultimately convert all the turbulent energy to heat. Therefore, a valve converts fluid energy from one form to another.

For many valve constructions, it is reasonable to approximate the fluid transition from the valve inlet to the minimum cross section of the flow stream as an isentropic or lossless process. Using this approximation, the minimum pressure $p_{VC}$ can be estimated from the Bernoulli relationship. See Sec. 6 ("Fluid and Particle Mechanics") for more background information. Downstream of the vena contracta, the flow is definitely not lossless due to all the turbulence that is generated. As the flow passage area increases and the fluid slows down, some of the kinetic energy of the fluid is converted back to pressure energy as pressure recovers. The energy that is permanently lost via turbulence accounts for the permanent pressure or head loss of the valve. The relative amount of pressure that is recouped determines whether the valve is considered to be high- or low-recovery. The flow passage geometry at and downstream of the vena contracta primarily determines the amount of recovery. The amount of recovery is quantified by the liquid pressure recovery factor $F_L$

$$F_L = \sqrt{\frac{p_1 - p_2}{p_1 - p_{VC}}} \tag{8-112}$$

Under some operating conditions, sufficient pressure differential may exist across the valve to cause the vena contracta pressure to drop to the saturation pressure (also known as the *vapor pressure*) of the liquid. If this occurs, a portion of the liquid will vaporize, forming a two-phase, compressible mixture within the valve. If sufficient vapor forms, the flow may *choke*. When a flow is choked, any increase in pressure differential across the valve no longer produces an increase in flow through the valve.

The vena contracta condition at choked flow for pure liquids has been shown to be

$$p_{VC} = F_F p_v \tag{8-113}$$

where

$$F_F = 0.96 - 0.28\sqrt{\frac{p_v}{p_c}} \tag{8-114}$$

and $p_{VC}$ is the absolute vena contracta pressure under choked conditions, $F_F$ is the liquid critical pressure ratio factor, $p_v$ is the absolute vapor pressure of the liquid at inlet temperature, and $p_c$ is the absolute thermodynamic critical pressure of the fluid.

Equations (8-112) and (8-113) can be used together to determine the pressure differential across the valve at the point where the flow chokes

$$\Delta p_{\text{choked}} = F_L^2(p_1 - F_F p_v) \tag{8-115}$$

The pressure recovery factor is a constant for any given valve at a given opening. The value of this factor can be established by flow test and is published by the valve manufacturer. If the actual pressure differential across the valve is greater than the choked pressure differential of Eq. (8-115), then $\Delta p_{\text{choked}}$ should be used in Eq. (8-111) to determine the correct valve size. A more complete presentation of sizing relationships is given in ANSI 75.01.01, including provisions for pipe reducers and Reynolds number effects.

Equations (8-111) to (8-115) are restricted to incompressible fluids. For gases and vapors, the fluid density is dependent on pressure. For convenience, compressible fluids are often assumed to follow the ideal gas law model. Deviations from ideal behavior are corrected for, to first order, with nonunity values of compressibility factor Z (see Sec. 2, "Physical and Chemical Data," for definitions and data for common fluids). For compressible fluids

$$w = 94.8 C_V p_1 Y \sqrt{\frac{x M_\omega}{T_1 Z}} \tag{8-116}$$

where $p_1$ is in bar absolute, $T_1$ is inlet temperature in kelvins, $M_w$ is the molecular weight, and $x$ is the dimensionless pressure drop ratio $(p_1 - p_2)/p_1$. The expansion factor $Y$ accounts for changes in the fluid density as the fluid passes through the valve. It is dependent on pressure drop and valve geometry. Experimental data have shown that for

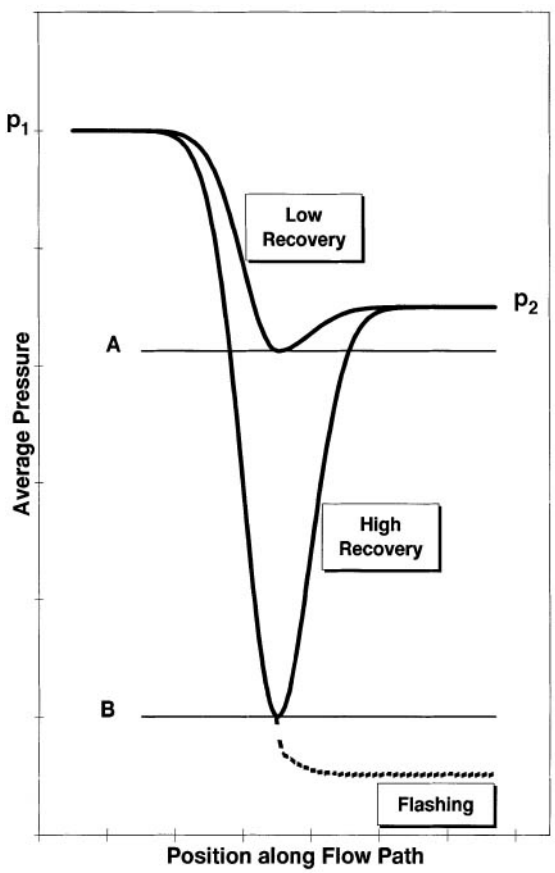

**FIG. 8-75** Generic depictions of average pressure at subsequent cross sections throughout a control valve. The $F_L$ values selected for illustration are 0.9 and 0.63 for low and high recovery, respectively. Internal pressure in the high-recovery valve is shown as a dashed line for flashing conditions ($p_2 < p_v$) with $p_v = B$.

small departures in the ratio of specific heat from that of air (1.4), a simple linear relationship can be used to represent the expansion factor:

$$Y = 1 - \frac{1.4x}{3x_T\gamma} \qquad \text{for} \qquad x \le \frac{x_T\gamma}{1.4} \tag{8-117}$$

where $\gamma$ is the ratio of specific heats and $x_T$ is an experimentally determined factor for a specific valve and is the largest value of $x$ that contributes to flow (i.e., values of $x$ greater than $x_T$ do not contribute to flow).

The terminal value of $x$, $x_T$, results from a phenomenon known as choking. Given a nozzle geometry with fixed inlet conditions, the mass flow rate will increase as $p_2$ is decreased up to a maximum amount at the critical pressure drop. The velocity at the vena contracta has reached sonic, and a standing shock has formed. This shock causes a step change in pressure as flow passes through it, and further reduction in $p_2$ does not increase mass flow. Thus $x_T$ relates to the critical pressure drop ratio and also accounts for valve geometry effects. The value of $x_T$ varies with flow path geometry and is supplied by the valve manufacturer. In the choked case,

$$x > \frac{x_T\gamma}{1.4} \qquad \text{and} \qquad Y = 0.67 \tag{8-118}$$

**Noise Control** Sound is a fluctuation of air pressure that can be detected by the human ear. Sound travels through any fluid (e.g., the air) as a compression/expansion wave. This wave travels radially outward in all directions from the sound source. The pressure wave induces an oscillating motion in the transmitting medium that is superimposed on any other net motion it may have. These waves are reflected, refracted, scattered, and absorbed as they encounter solid objects. Sound is transmitted through solids in a complex array of types of elastic waves. Sound is characterized by its amplitude, frequency, phase, and direction of propagation.

Sound strength is therefore location-dependent and is often quantified as a sound pressure level $L_p$ in decibels based on the root mean square (rms) sound pressure value $p_S$, where

$$L_p = 10 \log\left(\frac{p_S}{p_{\text{reference}}}\right)^2 \tag{8-119}$$

For airborne sound, the reference pressure is $2 \times 10^{-5}$ Pa ($29 \times 10^{-1}$ psi), which is nominally the human threshold of hearing at 1000 Hz. The corresponding sound pressure level is 0 dB. A voice in conversation is about 50 dB, and a jackhammer operator is subject to 100 dB. Extreme levels such as a jet engine at takeoff might produce 140 dB at a distance of 3 m, which is a pressure amplitude of 200 Pa ($29 \times 10^{-3}$ psi). These examples demonstrate both the sensitivity and the wide dynamic range of the human ear.

Traveling sound waves carry energy. Sound intensity $I$ is a measure of the power passing through a unit area in a specified direction and is related to $p_S$. Measuring sound intensity in a process plant gives clues to the location of the source. As one moves away from the source, the fact that the energy is spread over a larger area requires that the sound pressure level decrease. For example, doubling one's distance from a point source reduces $L_p$ by 6 dB. Viscous action from the induced fluid motion absorbs additional acoustic energy. However, in free air, this viscous damping is negligible over short distances (on the order of 1 m).

Noise is a group of sounds with many nonharmonic frequency components of varying amplitudes and random phase. The turbulence generated by a throttling valve creates noise. As a valve converts potential energy to heat, some of the energy becomes acoustic energy as an intermediate step. Valves handling large amounts of compressible fluid through a large pressure change create the most noise because more total power is being transformed. Liquid flows are noisy only under special circumstances, as will be seen in the next subsection. Due to the random nature of turbulence and the broad distribution of length and velocity scales of turbulent eddies, valve-generated sound is usually random, broad-spectrum noise. The total sound pressure level from two such statistically uncorrelated sources is (in decibels)

$$L_p = 10 \log \frac{(p_{S1})^2 + (p_{S2})^2}{(p_{\text{reference}})^2} \tag{8-120}$$

For example, two sources of equal strength combine to create an $L_p$ that is 3 dB higher.

While noise is annoying to listen to, the real reasons for being concerned about noise relate to its impact on people and equipment. Hearing loss can occur due to long-term exposure to moderately high, or even short exposure to very high, noise levels. The U.S. Occupational Safety and Health Act (OSHA) has specific guidelines for permissible levels and exposure times. The human ear has a frequency-dependent sensitivity to sound. When the effect on humans is the criterion, $L_p$ measurements are weighted to account for the ear's response. This so-called A-weighted scale is defined in ANSI S1.4 and is commonly reported as $L_{pA}$. Figure 8-76 illustrates the difference between actual and perceived airborne sound pressure levels. At sufficiently high levels, noise and the associated vibration can damage equipment.

There are two approaches to fluid-generated noise control—source or path treatment. Path treatment means absorbing or blocking the transmission of noise after it has been created. The pipe itself is a barrier. The sound pressure level inside a standard schedule pipe is roughly 40 to 60 dB higher than on the outside. Thicker-walled pipe reduces levels somewhat more, and adding acoustical insulation on the outside of the pipe reduces ambient levels up to 10 dB per inch of thickness. Since noise propagates relatively unimpeded inside the

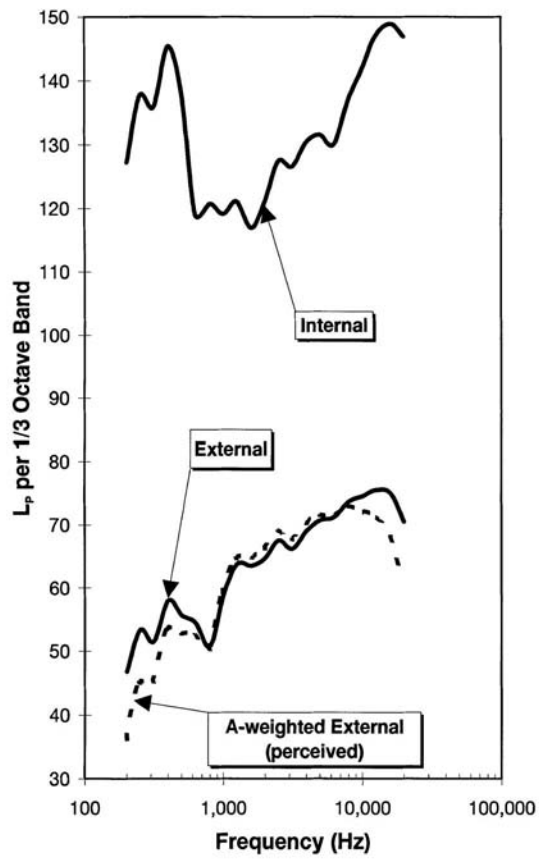

**FIG. 8-76** Valve-generated sound pressure level spectrums.

pipe, barrier approaches require the entire downstream piping system to be treated in order to be totally effective. In-line silencers place absorbent material inside the flow stream, thus reducing the level of the internally propagating noise. Noise reductions up to 25 dB can be achieved economically with silencers.

The other approach to valve noise problems is the use of quiet trim. Two basic strategies are used to reduce the initial production of noise—dividing the flow stream into multiple paths and using several flow resistances in series. Sound pressure level $L_p$ is proportional to mass flow and is dependent on vena contracta velocity. If each path is an independent source, it is easy to show from Eq. (8-120) that $p_S^2$ is inversely proportional to the number of passages; additionally, smaller passage size shifts the predominate spectral content to higher frequencies, where structural resonance may be less of a problem. Series resistances or multiple stages can reduce maximum velocity and/or produce backpressure to keep jets issuing from multiple passages from acting independently. While some of the basic principles are understood, predicting noise for a particle flow passage requires some empirical data as a basis. Valve manufacturers have developed noise prediction methods for the valves they build. ANSI/ISA-75.17 is a public-domain methodology for standard (non-low-noise) valve types, although treatment of some multistage, multipath types is underway. Low-noise hardware consists of special cages in linear stem valves, perforated domes or plates and multichannel inserts in rotary valves, and separate devices that use multiple fixed restrictions.

**Cavitation and Flashing** From the discussion of pressure recovery it was seen that the pressure at the vena contracta can be much lower than the downstream pressure. If the pressure on a liquid falls below its vapor pressure $p_v$, the liquid will vaporize. Due to the effect of surface tension, this vapor phase will first appear as bubbles. These bubbles are carried downstream with the flow, where they collapse if the pressure recovers to a value above $p_v$. This pressure-driven process of vapor bubble formation and collapse is known as cavitation.

Cavitation has three negative side effects in valves—noise and vibration, material removal, and reduced flow. The bubble collapse process is a violent asymmetric implosion that forms a high-speed microjet and induces pressure waves in the fluid. This hydrodynamic noise and the mechanical vibration that it can produce are far stronger than other noise generation sources in liquid flows. If implosions occur adjacent to a solid component, minute pieces of material can be removed, which, over time, will leave a rough, cinderlike surface.

The presence of vapor in the vena contracta region puts an upper limit on the amount of liquid that will pass through a valve. A mixture of vapor and liquid has a lower density than that of the liquid alone. While Eq. (8-111) is not applicable to two-phase flows because pressure changes are redistributed due to varying density and the two phases do not necessarily have the same average velocity, it does suggest that lower density reduces the total mass flow rate. Figure 8-77 illustrates a typical flow rate/pressure drop relationship. As with compressible gas flow at a given $p_1$, flow increases as $p_2$ is decreased until the flow chokes (i.e., no additional fluid will pass). The transition between incompressible and choked flow is gradual because, within the convoluted flow passages of valves, the pressure is actually an uneven distribution at each cross section and consequently vapor formation zones increase gradually. In fact, isolated zones of bubble formation or incipient cavitation often occur at pressure drops well below that at which a reduction in flow is noticeable. The similarity between liquid and gas choking is not serendipitous; it is surmised that the two-phase fluid is traveling at the mixture's sonic velocity in the throat when choked. Complex fluids with components having varying vapor pressures and/or entrained noncondensable gases (e.g., crude oil) will exhibit soft vaporization/implosion transitions.

There are several methods to reduce cavitation or at least its negative side effects. Material damage is slowed by using harder materials and by directing the cavitating stream away from passage walls (e.g., with an angle body flowing down). Sometimes the system can be designed to place the valve in a higher $p_2$ location or add downstream resistance, which creates backpressure. A low recovery valve has a higher minimum pressure for a given $p_2$ and so is a means to eliminate the cavitation itself, not just its side effects. In Fig. 8-75, if $p_v < B$, neither valve will cavitate substantially. For $p_v > B$ but $p_v < A$, the high recovery valve will cavitate substantially, but the low recovery valve will not. Special anticavitation trims are available for globe and angle valves and more recently for some rotary valves. These trims use multiple contraction/expansion stages or other distributed resistances to boost $F_L$ to values sometimes near unity.

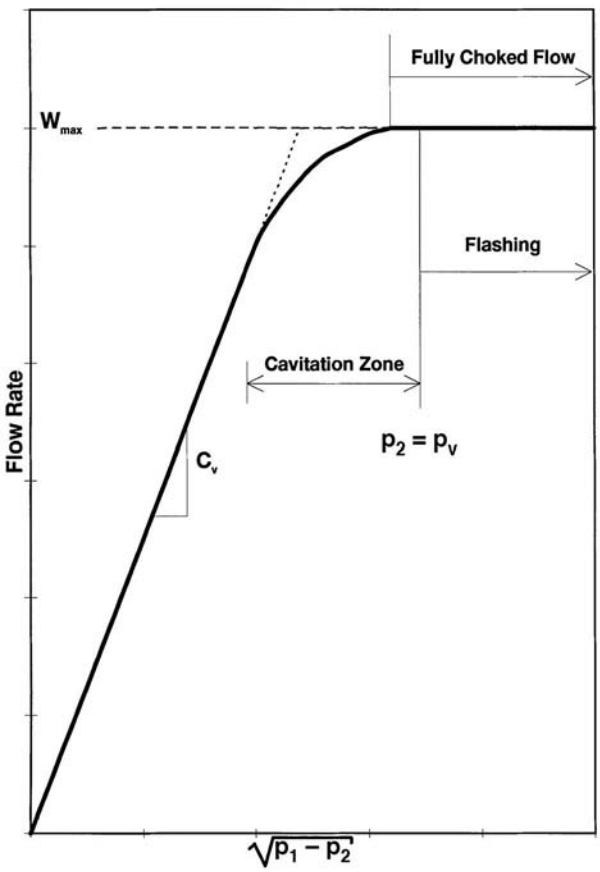

**FIG. 8-77** Liquid flow rate versus pressure drop (assuming constant $p_1$ and $p_v$).

If $p_2$ is below $p_v$, the two-phase mixture will continue to vaporize in the body outlet and/or downstream pipe until all liquid phase is gone, a condition known as flashing. The resulting huge increase in specific volume leads to high velocities, and any remaining liquid droplets acquire much of the higher vapor-phase velocity. Impingement of these droplets can produce material damage, but it differs from cavitation damage because it exhibits a smooth surface. Hard materials and directing the two-phase jets away from solid surfaces are means to avoid this damage.

**Seals, Bearings, and Packing Systems** In addition to their control function, valves often need to provide shutoff. FCI 70-2-1998 and IEC 60534-4 recognize six standard classifications and define their as-shipped qualification tests. Class I is an amount agreed to by user and supplier with no test needed. Classes II, III, and IV are based on an air test with maximum leakage of 0.5 percent, 0.1 percent, and 0.01 percent of rated capacity, respectively. Class V restricts leakage to $5 \times 10^{-6}$ mL of water per second per millimeter of port diameter per bar differential. Class VI allows 0.15 to 6.75 mL/min of air to escape depending on port size; this class implies the need for interference-fit elastomeric seals. With the exception of class V, all classes are based on standardized pressure conditions that may not represent actual conditions. Therefore, it is difficult to estimate leakage in service. Leakage normally increases over time as seals and seating surfaces become nicked or worn. Leak passages across the seat-contact line, known as

wire drawing, may form and become worse over time—even in hard metal seats under sufficiently high-pressure differentials.

Polymers used for seat and plug seals and internal static seals include PTFE (polytetrafluoroethylene) and other fluorocarbons, polyethylene, nylon, polyether-ether-ketone, and acetal. Fluorocarbons are often carbon- or glass-filled to improve mechanical properties and heat resistance. Temperature and chemical compatibility with the process fluid are the key selection criteria. Polymer-lined bearings and guides are used to decrease friction, which lessens dead band and reduces actuator force requirements. See Sec. 25, "Materials of Construction," for properties.

Packing forms the pressure-tight seal, where the stem protrudes through the pressure boundary. Packing is typically made from PTFE or, for high temperature, a bonded graphite. If the process fluid is toxic, more sophisticated systems such as dual packing, live-loaded, or a flexible metal bellows may be warranted. Packing friction can significantly degrade control performance. Pipe, bonnet, and internal-trim joint gaskets are typically a flat sheet composite. Gaskets intended to absorb dimensional mismatch are typically made from filled spiral-wound flat stainless-steel wire with PTFE or graphite filler. The use of asbestos in packing and gaskets has been largely eliminated.

**Flow Characteristics** The relationship between valve flow and valve travel is called the valve flow characteristic. The purpose of flow characterization is to make loop dynamics independent of load, so that a single controller tuning remains optimal for all loads. Valve gain is one factor affecting loop dynamics. In general, gain is the ratio of change in output to change in input. The input of a valve is travel $y$, and the output is flow $w$. Since pressure conditions at the valve can depend on flow (hence travel), valve gain is

$$\frac{dw}{dy} = \frac{\partial w}{\partial C_V}\frac{dC_V}{dy} + \frac{\partial w}{\partial p_1}\frac{dp_1}{dy} + \frac{\partial w}{\partial p_2}\frac{dp_2}{dy} \qquad (8\text{-}121)$$

An inherent valve flow characteristic is defined as the relationship between flow rate and travel, under constant-pressure conditions. Since the rightmost two terms in Eq. (8-121) are zero in this case, the inherent characteristic is necessarily also the relationship between flow coefficient and travel.

Figure 8-78 shows three common inherent characteristics. A linear characteristic has a constant slope, meaning the inherent valve gain is a constant. The most popular characteristic is equal-percentage, which gets its name from the fact that equal changes in travel produce equal-percentage changes in the existing flow coefficient. In other words, the slope of the curve is proportional to $C_V$, or equivalently that inherent valve gain is proportional to flow. The equal-percentage characteristic can be expressed mathematically by

$$C_V(y) = (\text{rated } C_V)\exp\left[\left(\frac{y}{\text{rated } y} - 1\right)\ln R\right] \qquad (8\text{-}122)$$

This expression represents a set of curves parameterized by $R$. Note that $C_V$ ($y = 0$) equals (rated $C_V$)/$R$ rather than zero; real equal-percentage characteristics deviate from theory at some small travel to meet shutoff requirements. An equal-percentage characteristic provides perfect compensation for a process where the gain is inversely proportional to flow (e.g., liquid pressure). *Quick opening* does not have a standardized mathematical definition. Its shape arises naturally from high-capacity plug designs used in on/off service globe valves. Frequently, pressure conditions at the valve will change with flow rate. This so-called process influence [the rightmost two terms on the right-hand side of Eq. (8-121)] combines with inherent gain to express the installed valve gain. The flow versus travel relationship for a specific set of conditions is called the installed flow characteristic. Typically, valve $\Delta p$ decreases with load, since pressure losses in the piping system increase with flow. Figure 8-79 illustrates how allocation of total system head to the valve influences the installed flow characteristics. For a linear or quick-opening characteristic, this transition toward a concave down shape would be more extreme. This effect of typical process pressure variation, which causes equal-percentage characteristics to have fairly constant installed gain, is one reason the equal-percentage characteristic is the most popular.

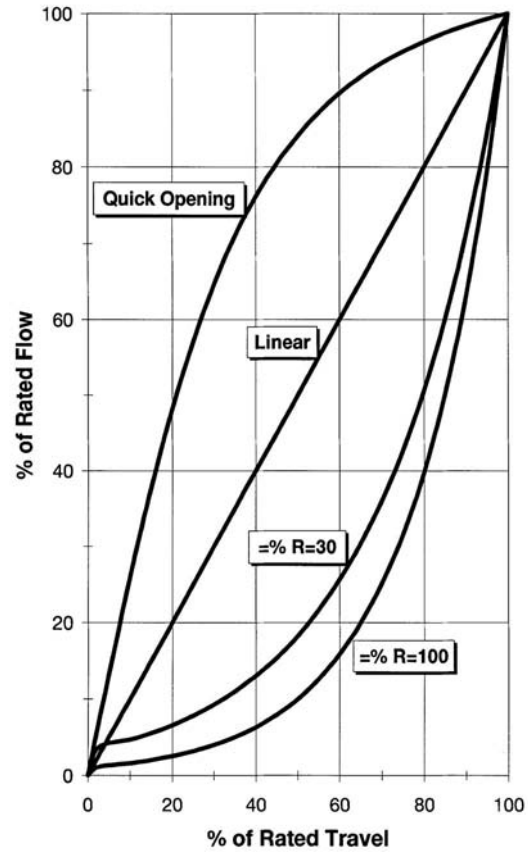

**FIG. 8-78** Typical inherent flow characteristics.

Due to clearance flow, flow force gradients, seal friction, and the like, flow cannot be throttled to an arbitrarily small value. Installed rangeability is the ratio of maximum to minimum controllable flow. The actuator and positioner, as well as the valve, influence the installed rangeability. Inherent rangeability is defined as the ratio of the largest to the smallest $C_V$ within which the characteristic meets specified criteria (see ISA 75.11). The $R$ value in the equal-percentage definition is a theoretical rangeability only. While high installed rangeability is desirable, it is also important not to oversize a valve; otherwise, turndown (ratio of maximum normal to minimum controllable flow) will be limited.

Sliding stem valves are characterized by altering the contour of the plug when the port and plug determine the minimum (controlling) flow area. Passage area versus travel is also easily manipulated in characterized cage designs. Inherent rangeability varies widely, but typical values are 30 for contoured plugs and 20 to 50 for characterized cages. While these types of valves can be characterized, the degree to which manufacturers conform to the mathematical ideal is revealed by plotting measured $C_V$ versus travel. Note that ideal equal-percentage will plot as a straight line on a semilog graph. Custom characteristics that compensate for a specific process are possible.

Rotary stem-valve designs are normally offered only in their naturally occurring characteristic, since it is difficult to appreciably alter this. If additional characterization is required, the positioner or controller may be characterized. However, these approaches are less direct, since it is possible for device nonlinearity and dynamics to distort the compensation.

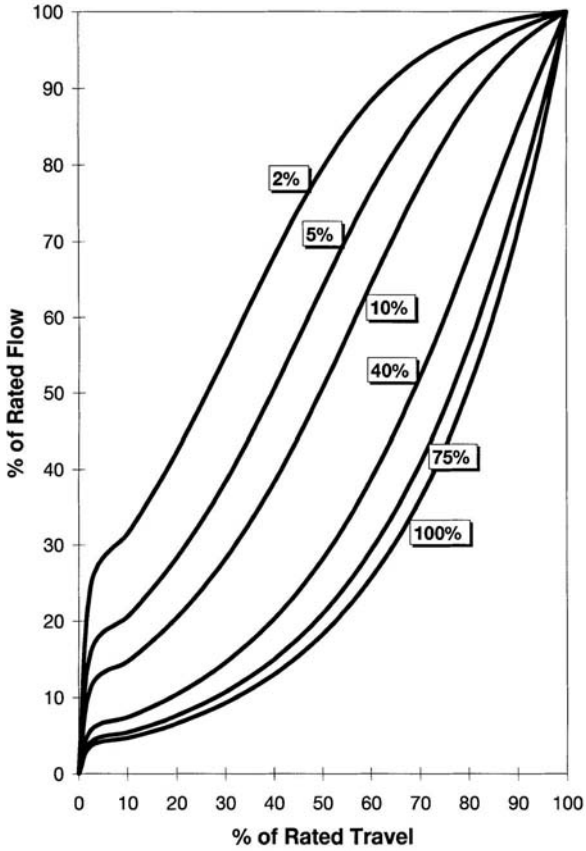

**FIG. 8-79** Installed flow characteristic as a function of percent of total system head allocated to the control valve (assuming constant-head pump, no elevation head loss, and an $R$ equal to 30 equal-percentage inherent characteristic).

**FIG. 8-80** Valve and actuator with valve positioner attached. (*Courtesy Fisher Controls International LLC.*)

## VALVE CONTROL DEVICES

Devices mounted on the control valve that interface various forms of input signals, monitor and transmit valve position, or modify valve response are valve control devices. In some applications, several auxiliary devices are used together on the same control valve. For example, mounted on the control valve, one may find a current-to-pressure transducer, a valve positioner, a volume booster relay, a solenoid valve, a trip valve, a limit switch, a process controller, and/or a stem position transmitter. Figure 8-80 shows a valve positioner mounted on the yoke leg of a spring and diaphragm actuator.

As most throttling control valves are still operated by pneumatic actuators, the control valve device descriptions that follow relate primarily to devices that are used with pneumatic actuators. The functions of hydraulic and electrical counterparts are very similar. Specific details on a particular valve control device are available from the vendor of the device.

**Valve Positioners** The valve positioner, when combined with an appropriate actuator, forms a complete closed-loop valve position control system. This system makes the valve stem conform to the input signal coming from the process controller in spite of force loads that the actuator may encounter while moving the control valve. Usually, the valve positioner is contained in its own enclosure and is mounted on the control valve.

The key parts of the positioner/actuator system, shown in Fig. 8-81*a*, are (1) an input conversion network, (2) a stem position feedback network, (3) a summing junction, (4) an amplifier network, and (5) an actuator.

The input conversion network shown is the interface between the input signal and the summer. This block converts the input current or pressure (from an I/P transducer or a pneumatic process controller) to a voltage, electric current, force, torque, displacement, or other particular variable that can be directly used by the summer. The input conversion usually contains a means to adjust the slope and offset of the block to provide for a means of spanning and zeroing the positioner during calibration. In addition, means for changing the sense (known as "action") of the input/output characteristic are often addressed in this block. Also exponential, logarithmic, or other predetermined characterization can be put in this block to provide a characteristic that is useful in offsetting or reinforcing a nonlinear valve or process characteristic.

The stem position feedback network converts stem travel to a useful form for the summer. This block includes the feedback linkage which varies with actuator type. Depending on positioner design, the stem position feedback network can provide span and zero and characterization functions similar to that described for the input conversion block.

The amplifier network provides signal conversion and suitable static and dynamic compensation for good positioner performance. Control from this block usually reduces to a form of proportional or proportional plus derivative control. The output from this block in the case of a pneumatic positioner is a single connection to the spring and diaphragm actuator or two connections for push/pull operation of a

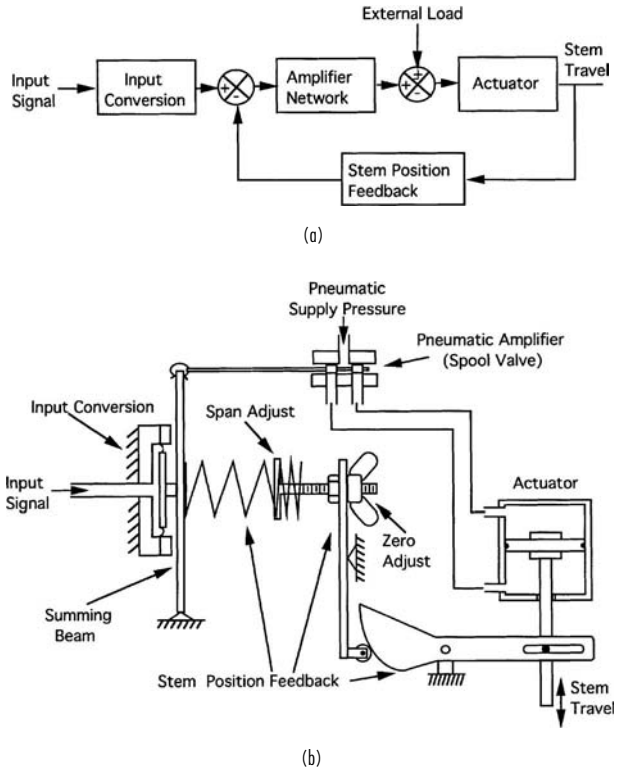

**FIG. 8-81** Positioner/actuators. (*a*) Generic block diagram. (*b*) Example of a pneumatic positioner/actuator.

springless piston actuator. The action of the amplifier network and the action of the stem position feedback can be reversed together to provide for reversed positioner action.

By design, the gain of the amplifier network shown in Fig. 8-81*a* is made very large. Large gain in the amplifier network means that only a small proportional deviation will be required to position the actuator through its active range of travel. This means that the signals into the summer track very closely and that the gain of the input conversion block and the stem position feedback block determine the closed-loop relationship between the input signal and the stem travel.

Large amplifier gain also means that only a small amount of additional stem travel deviation will result when large external force loads are applied to the actuator stem. For example, if the positioner's amplifier network has a gain of 50 (and assuming that high packing box friction loads require 25 percent of the actuator's range of thrust to move the actuator), then only 25 percent/50 (or 0.5 percent deviation) between input signal and output travel will result due to valve friction.

Figure 8-81*b* is an example of a pneumatic positioner/actuator. The input signal is a pneumatic pressure that (1) moves the summing beam, which (2) operates the spool valve amplifier, which (3) provides flow to and from the piston actuator, which (4) causes the actuator to move and continue moving until (5) the feedback force returns the beam to its original position and stops valve travel at a new position. Typical positioner operation is thereby achieved.

Static performance measurements related to positioner/actuator operation include the conformity, measured accuracy, hysteresis, dead band, repeatability, and locked stem pressure gain. Definitions and standardized test procedures for determining these measurements can be found in ISA-S75.13, "Method of Evaluating the Performance of Positioners with Analog Input Signals and Pneumatic Output."

***Dynamics of Positioner-Based Control Valve Assemblies*** Control valve assemblies are complete, functional units that include the valve body, actuator, positioner, if so equipped, associated linkages, and any auxiliary equipment such as current to pneumatic signal transducers and air supply pressure regulators. Although performance information such as frequency response, sensitivity, and repeatability data may be available for a number of these components individually, it is the performance of the entire assembly that will ultimately determine how well the demand signal from the controller output is transferred through the control valve to the process. The valve body, actuator, and positioner combination is typically responsible for the majority of the control valve assembly's dynamic behavior. On larger actuators, the air supply pressure regulator capacity or other airflow restrictions may limit the control valve assembly's speed of response.

The control valve assembly response can usually be characterized quite well by using a first-order plus dead-time response model. The control valve assembly will also exhibit backlash, stiction, and other nonlinear behavior. During normal operation of a control loop, the controller usually makes small output changes from one second to the next. Typically this change is less than 1 percent. With very small controller output changes, e.g., less than 0.1 percent, the control valve assembly may not move at all. As the magnitude of the controller output change increases, eventually the control valve will move. At the threshold of movement, the positional accuracy and repeatability of the control valve are usually quite poor. The speed of response may be quite slow and may occur after a number of seconds of dead time. This poor performance is due to the large backlash and stiction effects relative to the requested movement and the small output change of the positioner. With a further increase in the magnitude of the controller output steps, the behavior of the control valve typically becomes more repeatable and "linear." Dead time usually drops to only a fraction of a second, and the first-order time constant becomes faster. For much larger steps in the controller output, e.g., over 10 percent, the positioner and air supply equipment may be unable to deliver the necessary air volume to maintain the first-order response. In this case, the control valve will exhibit very little dead time, but will be rate-limited and will ramp toward the requested position. It is within the linear region of motion that the potential for the best control performance exists.

When one is specifying a control valve for process control applications, in addition to material, style, and size information, the dynamic response characteristics and maximum allowable dead band (sum of backlash, stiction, and hysteresis effects) *must* be stated. The requirement for the control valve assembly's speed of response is ultimately determined by the dynamic characteristics of the process and the control objectives. Typically, the equivalent first-order time constant specified for the control valve assembly should be at least 5 times faster than the desired controller closed-loop time constant. If this requirement is not met, the tuning of the control loop must be slowed down to accommodate the slow control valve response, otherwise, control robustness and stability may be compromised. The dead band of the control valve assembly is typically the determining factor for control resolution and frequently causes control instability in the form of a "limit" cycle. The controller output will typically oscillate across a range that is 1 to 2 times the magnitude of the control valve dead band. This is very dependent on the nature of the control valve nonlinearities, the process dynamics, and the controller tuning. The magnitude of the process limit cycle is determined by the size of the control valve dead band multiplied by the installed gain of the control valve. For this reason, a high-performance control valve assembly, e.g., with only 0.5 percent dead band, may cause an unacceptably large process limit cycle if the valve is oversized and has a high installed gain. For typical process control applications, the installed gain of the control valve should be in the range of 0.5 to 2 percent of the process variable span per percent of the controller output. The total dead band of the control valve assembly should be less than 1 percent. For applications that require more precise control, the dead band and possibly the installed gain of the control valve must be reduced. Specialized actuators are available that are accurate down to 0.1 percent or less. At this level of performance, however, the design of the valve body, bearings, linkages, and seals starts to become a significant source of dead band.

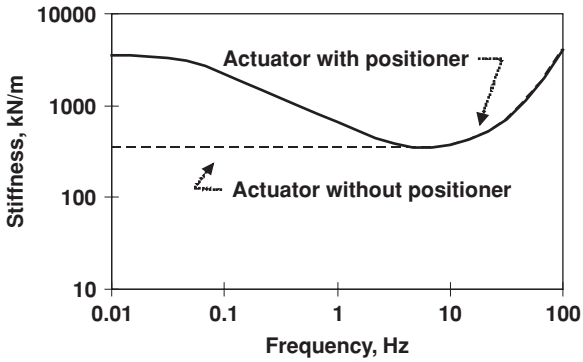

**FIG. 8-82** Actuator stiffness as a function of frequency for a 69-in$^2$ spring and diaphragm pneumatic actuator. Actuator with positioner exhibits higher stiffness over the lower frequency range compared to that of the pneumatic actuator without a positioner.

***Positioner/Actuator Stiffness*** Minimizing the effect of dynamic loads on valve stem travel is an important characteristic of the positioner/actuator. Stem position must be maintained in spite of changing reaction forces caused by valve throttling. These forces can be random (buffeting force) or can result from a negative-slope force/stem travel characteristic (negative gradient); either could result in valve stem instability and loss of control. To reduce and eliminate the effect of these forces, the effective stiffness of the positioner/actuator must be made sufficiently high to maintain stationary control of the valve stem.

The stiffness characteristic of the positioner/actuator varies with the forcing frequency. Figure 8-82 indicates the stiffness of the positioner/actuator is increased at low frequencies and is directly related to the locked-stem pressure gain provided by the positioner. As frequency increases, a dip in the stiffness curve results from dynamic gain attenuation in the pneumatic amplifiers in the positioner. The value at the bottom of the dip is the sum of the mechanical stiffness of the spring in the actuator and the air spring effect produced by air enclosed in the actuator casing. At yet higher frequencies, actuator inertia dominates and causes a corresponding rise in system stiffness.

The air spring effect results from adiabatic expansion and compression of air in the actuator casing. Numerically, the small perturbation value for air spring stiffness in newtons per meter is given by

$$\text{Air spring rate} = \frac{\gamma p_a A_a^2}{V} \tag{8-123}$$

where $\gamma$ is the ratio of specific heats (1.4 for air), $p_a$ is the actuator pressure in pascals absolute, $A_a$ is the actuator pressure area in square meters, and $V$ is the internal actuator volume in cubic meters.

***Positioner Application*** Positioners are widely used on pneumatic valve actuators. Often they provide improved process loop control because they reduce valve-related nonlinearity. Dynamically, positioners maintain their ability to improve control valve performance for sinusoidal input frequencies up to about one-half of the positioner bandwidth. At input frequencies greater than this, the attenuation in the positioner amplifier network gets large, and valve nonlinearity begins to affect final control element performance more significantly. Because of this, the most successful use of the positioner occurs when the positioner response bandwidth is greater than twice that of the most dominant time lag in the process loop.

Some typical examples in which the dynamics of the positioner are sufficiently fast to improve process control are the following:

1. *In a distributed control system (DCS) process loop with an electronic transmitter.* The DCS controller and the electronic transmitter have time constants that are dominant over the positioner response. Positioner operation is therefore beneficial in reducing valve-related nonlinearity.

2. *In a process loop with a pneumatic controller and a large process time constant.* Here the process time constant is dominant, and the positioner will improve the linearity of the final control element. Some common processes with large time constants that benefit from positioner application are liquid level, temperature, large-volume gas pressure, and mixing.

3. *Additional situations in which valve positioners are used:*

*a.* On springless actuators where the actuator is not usable for throttling control without position feedback.

*b.* When split ranging is required to control two or more valves sequentially. In the case of two valves, the smaller control valve is calibrated to open in the lower half of the input signal range, and a larger valve is calibrated to open in the upper half of the input signal range. Calibrating the input command signal range in this way is known as split-range operation and increases the practical range of throttling process flows over that of a single valve.

*c.* In open-loop control applications where best static accuracy is needed. On occasion, positioner use can degrade process control. Such is the case when the process controller, process, and process transmitter have time constants that are similar to or smaller than that of the positioner/actuator. This situation is characterized by low process controller proportional gain (gain < 0.5), and hunting or limit cycling of the process variable is observed.

Improvements here can be made by doing one of the following:

1. Install a dominant first-order, low-pass filter in the loop ahead of the positioner and retune the process loop. This should allow increased proportional gain in the process loop and reduce hunting. Possible means for adding the filter include adding it to the firmware of the DCS controller, by adding an external *RC* network on the output of the process controller or by enabling the filter function in the input of the positioner, if it is available. Also, some transducers, when connected directly to the actuator, form a dominant first-order lag that can be used to stabilize the process loop.

2. Select a positioner with a faster response characteristic.

***Processor-Based Positioners*** When designed around an electronic microcontroller, the valve positioner [now commonly referred to as a *digital valve controller* (DVC)] takes on additional functionality that provides convenience and performance enhancements over the traditional design. The most common form of processor-based positioner, shown in Fig. 8-81, is a digitally communicating stem position controller that operates by using the fundamental blocks shown in Fig. 8-81*a*. A local display is part of the positioner and provides tag information, command input and travel, servo tuning parameters, and diagnostic information. Often auxiliary sensors are integrated into the device to provide increased levels of functionality and performance. Sensed variables can include actuator pressure, relay input pressure, relay valve position, board temperature, or a discrete input. A 4- to 20-mA valve travel readback circuit is also common. The travel sensor is based on a potentiometer or can be a noncontacting type such as a variable capacitance sensor, Hall effect sensor, or GMR device. Some positioners require a separate connection to an ac or dc supply voltage, but the majority of the designs are "loop-powered," which means that they receive power either through the current input (for positioners that require a 4- to 20-mA analog input signal) or through the digital communications link when the control signal is a digital signal.

Processor-based positioners support automatic travel calibration and automatic response tuning for quick commissioning of the final control element. Features of this type of valve positioner include compensators for improved static and dynamic travel response; diagnostics for evaluating positioner, actuator, and valve health; and the capability to be polled from remote locations through a PC-based application or through a handheld communicator attached to the field wiring. Capability to support custom firmware for special valve applications, such as emergency safety shutdown, is also a characteristic of the processor-based design.

***Digital Field Communications*** To provide increased data transmission capability between valve-mounted devices and the host control system, manufacturers are providing digital network means in their devices. The field networks, commonly known as field buses, compete fiercely in the marketplace and have varying degrees of flexibility and specific application strengths. A prospective field bus

customer is advised to study the available bus technologies and to make a selection based on needs, and not be seduced by the technology itself.

Generally, a field bus protocol must be nonproprietary ("open") so that different vendors of valve devices can design their bus interface to operate properly on the selected field bus network. Users demand that the devices be "interoperable" so that the device will work with other devices on the same segment or can be substituted with a device from an alternate manufacturer. International standardization of some of the protocols is currently underway (for example, IEC 61158) whereas others are sponsored by user groups or foundations that provide democratic upgrades to the standard and provide network compliance testing.

The physical wiring typically used is the plant standard twisted-pair wiring for 4- to 20-mA instrumentation. Because of the networking capability of the bus, more than one device can be supported on a single pair of wires, and thus wiring requirements are reduced. Compared to a host level bus such as Ethernet, field buses exhibit slower communication rates, have longer transmission distance capability (1 to 2 km), use standard two-wire installation, are capable of multidrop busing, can support bus-powered devices, do not have redundant modes of bus operation, and are available for intrinsically safe installations. Devices on the field bus network may be either powered by the bus itself or powered separately.

The simplest digital networks available today support discrete sensors and on/off actuators, including limit switches and motor starters. Networks of this type have fast cycle times and are often used as an alternative to PLC discrete I/O. More sophisticated field networks are designed to support process automation, more complex process transmitters, and throttling valve actuators. These process-level networks are fundamentally continuous and analoglike in operation, and data computation is floating-point. They support communication of materials of construction, calibration and commissioning, device and loop level diagnostics (including information displays outlining corrective action), and unique manufacturer-specific functionality. Some process networks are able to automatically detect, identify, and assign an address to a new device added to the network, thus reducing labor, eliminating addressing errors, and indicating proper network function immediately after the connection is made. Final control elements operated by the process-level network include I/P transducers, motorized valves, digital valve controllers, and transmitters.

A particular field network protocol known as HART®* (Highway Addressable Remote Transducer) is the most widely used field network protocol. It is estimated that as of 2004 there are more than 14 million HART-enabled devices installed globally and that 70 percent of all processor-based process measurement and control instruments installed each year use HART communications. HART's popularity is based on its similarity to the traditional 4- to 20-mA field signaling and thus represents a safe, controlled transition to digital field communications without the risk often associated with an abrupt change to a totally digital field bus. With this protocol, the digital communications occur over the same two wires that provide the 4- to 20-mA process control signal without disrupting the process signal. The protocol uses the frequency-shift keying (FSK) technique (see Fig. 8-83) where two individual frequencies, one representing the mark and the other representing the space, are superimposed on the 4- to 20-mA current signal. As the average value of the signals used is zero, there is no dc offset value added to the 4- to 20-mA signal. The HART protocol is principally a master/slave protocol which means that a field device (slave) speaks only when requested by a master device. In this mode of operation, the slave can update the master at a rate of twice per second. An optional communication mode, *burst mode*, allows a HART slave device to continuously broadcast updates without stimulus requests from the master device. Update rates of 3 to 4 updates per second are typical in the burst mode of operation.

HART-enabled devices are provided by the valve device manufacturer at little or no additional cost. The HART network is compatible with existing 4- to 20-mA applications using current plant personnel and practices, provides for a gradual transition from analog to fully digital protocols, and is provided by the valve device manufacturer at little or no additional cost. Contact the HART Communication Foundation for additional information.

Wireless digital communication to and from the final control element is not yet commercially available but is presently being investigated by more than one device manufacturer. The positive attribute of a wireless field network is the reduced cost of a wireless installation compared to a wired installation. Hurdles for wireless transmissions include security from nonnetwork sources, transmission reliability in the plant environment, limited bus speed, and the conservative nature of the process industry relative to change. Initial installations of wireless networks will support secondary variables and diagnostics, then primary control of processes with large time constants, and finally general application to process control. Both point-to-point and mesh architectures are being evaluated for commercialization at the device level. Mesh architectures rely on the other transmitting devices in the area to receive and then pass on any data transmission, thus rerouting communications around sources of interference. Two unlicensed spread spectrum radio bands are the main focus for current wireless development: 900 MHz and 2.4 GHz. The 900-MHz band is unique to North America and has better propagation and penetrating properties than the 2.4-GHz band. The 2.4-GHz band is a worldwide band and has wider channels, allowing much higher data rates. The spread

*HART is a registered trademark of the HART Communication Foundation.

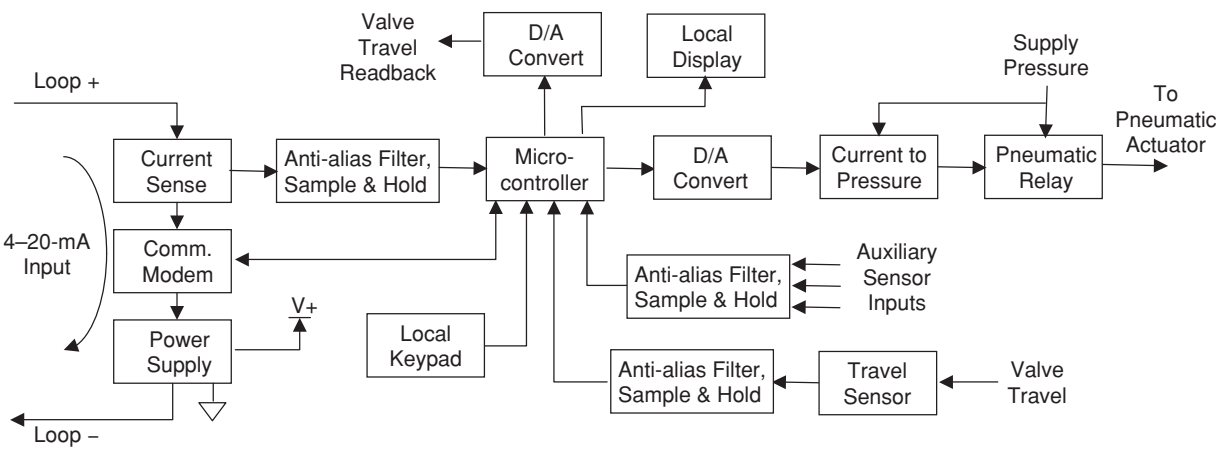

**FIG. 8-83** Generic loop powered digital valve controller.

spectrum technique uses multiple frequencies within the radio band to transmit data. Spread spectrum is further divided into the direct sequence technique, where the device changes frequency many times per data bit, and the frequency-hopping technique, where the device transmits a data packet on one frequency and then changes to a different frequency. Because of the rapid growth expected in this decade, the prospective wireless customer is encouraged to review up-to-date literature to determine the state of field wireless commercialization as it applies to her or his specific application.

***Diagnostic Capability*** The rapid proliferation of communicating, processor-based digital valve controllers over the last decade has led to a corresponding rise in diagnostic capability at the control valve. Diagnosing control valve health is critical to plant operation as maintenance costs can be reduced by identifying the valves that are candidates for repair. Less time is spent during plant shutdown repairing valves that do not need repair, which ultimately results in increased online operating time. Valve diagnostics can detect and flag a failed valve more quickly than by any other means, and can be configured to cause the valve to move to its fail-safe position on detection of specified fault conditions. The diagnostic-enabled positioner, when used with its host-based software application, can pinpoint exact components in a given final control element that have failed, and can recommend precise maintenance procedures to follow to remedy the fault condition.

The state variables that provide valve position control are used to diagnose the health of the final control element. In addition, some digital valve controller designs integrate additional sensors into their construction to provide increased diagnostic capability. For example, pressure sensors are provided to detect supply pressure, actuator pressure (upper and lower cylinder pressures in the case of a springless piston actuator), and internal pilot pressure. Also, the position of the pneumatic relay valve is available in some designs to provide quiescent flow data used for leak detection in the actuator.

Valve diagnostics are divided into two types: online and offline. Offline diagnostics are those diagnostics that occur when the control valve is bypassed or otherwise isolated from the process. The offline diagnostic routine manipulates the travel command to the valve and records the corresponding valve travel, actuator pressure, and servodrive value. These parameters are plotted in various combinations to provide hysteresis plus dead-band information, actuator operating pressure as a function of travel, valve friction, servodrive performance, valve seating load, positioner calibration endpoints, and dynamic response traces. Small- and large-amplitude step inputs as well as large slow ramps (exceeding 100 percent of the input range) are common offline test waveforms generated by the diagnostic as command inputs for offline diagnostic tests. Figure 8-84 is an example of one offline diagnostic test performed on a small globe valve actuated by a spring and diaphragm actuator. During this test the command input, travel, actuator pressure, and servodrive level are recorded and plotted as they result from a command input that is slowly ramped by the diagnostic routine (Fig. 8-85*a*). This diagnostic is extremely useful in detecting problems with the valve/actuator system and can flag potential problems with the final control element before catastrophic failure occurs. For example, Fig. 8-85*b* indicates the overall tracking capability of the control valve, and Fig. 8-85*c* indicates the pressure operating range of the actuator and the amount of frictional force resulting from the combined effects of valve packing and valve plug contact. Figure 8-85*d* displays the level of servodrive required to stroke the valve from one end of travel to the other. The composite operative health of the control valve is determined through comparison of the empirical levels presented in Fig. 8-85 with the manufacturers' recommendations. Recommended maintenance actions result from this comparison.

Online diagnostics are diagnostics that monitor and evaluate conditions at the control valve during normal throttling periods (i.e., during valve-in-service periods). Online diagnostics monitor mean levels and disturbances generated in the normal operation of the valve and typically do not force or generate disturbances on the valve's operation. For example, an online diagnostic can calculate travel deviation relative to the input command and flag a condition where the valve travel has deviated beyond a preset band. Such an event, if it exists for more than a short time, indicates that the valve has lost its ability to track the input

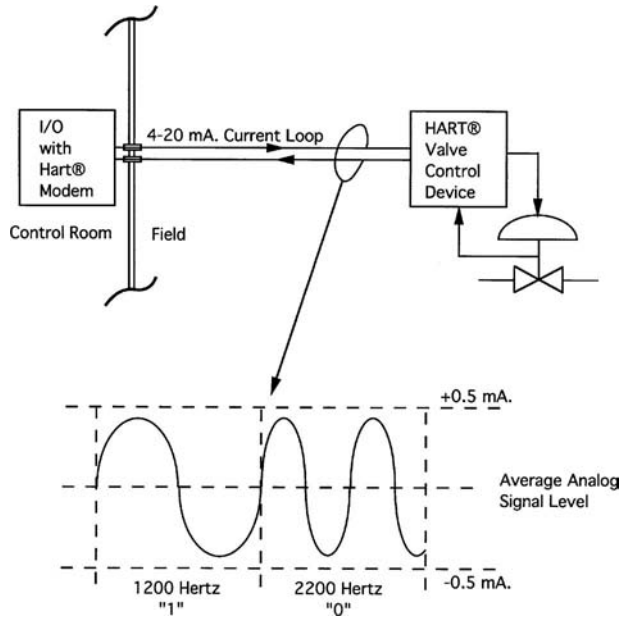

**FIG. 8-84** Hybrid point-to-point communications between the control room and the control valve device.

command within specified limits. Additional diagnostics could suggest that the feedback linkage has ceased functioning, or that the valve has stuck, or that some other specific malfunction is the cause of excess travel deviation. The manufacturer of the positioner diagnostic incorporates default limits into the host software application that are used to determine the relative importance of a specific deviation. To quickly indicate the severity of a problem detected by a diagnostic routine, a red, yellow, or green, or "advise, maintenance now, or failed," indication is presented on the user-interface screen for the valve problem diagnosed. Help notes and recommended remedial action are available by pointing and clicking on the diagnostic icon presented on the user's display.

Event-triggered recording is an online diagnostic technique supported in digital valve controllers (DVCs). Functionally a triggering event, such as a valve coming off a travel stop or a travel deviation alert, starts a time-series recording of selected variables. A collection of variables such as the input command, stem travel, actuator pressure, and drive command are stored for several minutes before and after the triggered event. These variables are then plotted as time series for immediate inspection or are stored in memory for later review. Event-triggering diagnostics are particularly useful in diagnosing valves that are closed or full-open for extended periods. In this case the event-triggered diagnostic focuses on diagnostic rich data at the time the valve is actually in operation and minimizes the recording of flat-line data with little diagnostic content. Other online diagnostics detected by DVC manufacturers include excess valve friction, supply pressure failure, relay operation failure, broken actuator spring, current to pressure module failure, actuator diaphragm leaking, and shifted travel calibration.

Safety shutdown valves, which are normally wide open and operate infrequently, are expected to respond to a safety trip command reliably and without fault. To achieve the level of reliability required in this application, the safety valve must be periodically tested to ensure positive operation under safety trip conditions. To test the operation of the shutdown system without disturbing the process, the traditional method is to physically lock the valve stem in the wide-open position and then to electrically operate the pneumatic shutdown solenoid valve. Observing that the pneumatic solenoid valve has properly vented the actuator pressure to zero, the actuator is seen as capable of applying sufficient spring force to close the valve, and a positive safety valve test is indicated. The

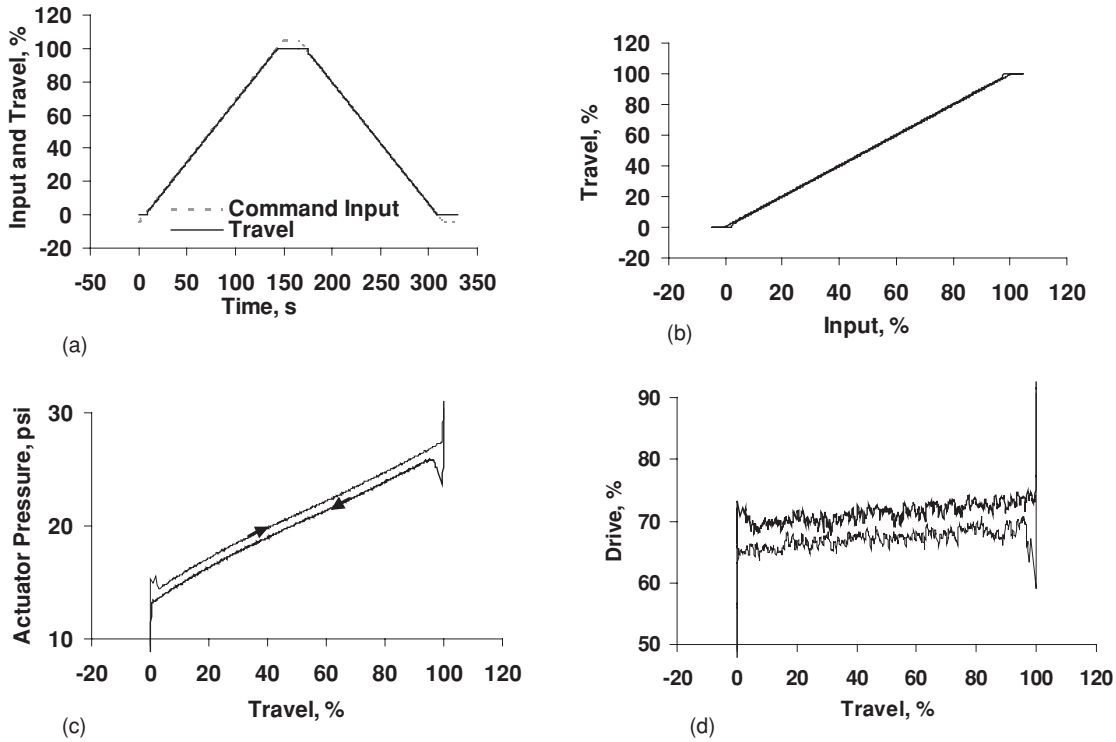

**FIG. 8-85** Offline valve diagnostic scan showing results of a diagnostic ramp. (*a*) The command input and resulting travel. (*b*) The dynamic scan. (*c*) The valve signature. (*d*) The servodrive versus travel plot. The hysteresis shown in the valve signature results from sliding friction due to valve packing and valve plug contact.

pneumatic solenoid valve is then returned to its normal electrical state, the actuator pressure returns to full supply pressure, and the valve stem lock mechanism is removed. This procedure, though necessary to enhance process safety, is time-consuming and takes the valve out of service during the locked stem test. Digital valve controllers are able to validate the operation of a safety shutdown valve by using an online diagnostic referred to as a partial stroke test. The partial stroke test is substituted for the traditional test method described above and does not require the valve to be locked in the wide-open position to perform the test. In a fashion similar to that shown in Fig. 8-85*a* (the partial stroke diagnostic), the system physically ramps the command input to the positioner from the wide-open position to a new position, pauses at the new position for a few seconds, and then ramps the command input back to the wide-open position (see Fig. 8-86*a*). During this time, the valve travel measurement is monitored and compared to the input command. If the travel measurement deviates for the input by more than a fixed amount for the configured period of time, the valve is considered to have failed the test and a failed-test message is communicated to the host system. Also during this test, the actuator pressure required to move the valve is detected via a dedicated pressure sensor (see Fig. 8-86*b*). If the thrust (pressure) required to move the valve during the partial stroke test exceeds the predefined thrust limit for this test, the control valve is determined to have a serious sticking problem, the test is immediately aborted, and the valve is flagged as needing maintenance. The partial stroke test can be automated to perform on a periodic basis, for instance, once a week; or it can be initialized by operator request at any time. The amount of valve travel that occurs during the partial stroke test is typically limited to a minimum valve position of 70 percent open or greater. This limit is imposed to prevent the partial stroking of the safety valve from significantly affecting the process flow through the valve. Comparison of partial stroke curves from past tests can indicate the gradual degradation of valve components. Use of "overlay" graphics, identification of unhealthy shifts in servodrive, increases in valve friction, and changes in dynamic response provide information leading to a diagnosis of needed maintenance.

In addition to device-level diagnostics, networked final control elements, process controllers, and transmitters can provide "loop" level diagnostics that can detect loops that are operating below expectations. Process variability, time in a limit (saturated) condition, and time in the wrong control mode are metrics used to detect problems in process loop operation.

**Transducers** The current-to-pressure transducer (I/P transducer) is a conversion interface that accepts a standard 4- to 20-mA input current from the process controller and converts it to a pneumatic output in a standard pneumatic pressure range [normally 0.2 to 1.0 bar (3 to 15 psig) or, less frequently, 0.4 to 2.0 bar (6 to 30 psig)]. The output pressure generated by the transducer is connected directly to the pressure connection on a spring-opposed diaphragm actuator or to the input of a pneumatic valve positioner.

Figure 8-87*a* is the schematic of a basic I/P transducer. The transducer shown is characterized by (1) an input conversion that generates an angular displacement of the beam proportional to the input current, (2) a pneumatic amplifier stage that converts the resulting angular displacement to pneumatic pressure, and (3) a pressure area that serves as a means to return the beam to very near its original position when the new output pressure is achieved. The result is a device that generates a pressure output that tracks the input current signal. The transducer shown in Fig. 8-88*a* is used to provide pressure to small load volumes (normally 4.0 $in^3$ or less), such as a positioner or booster input. With only one stage of pneumatic amplification, the flow

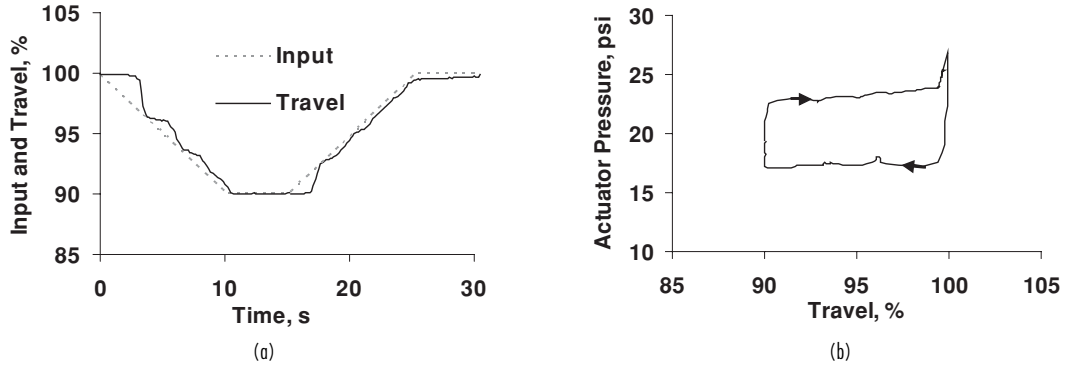

**FIG. 8-86** Online partial stroke diagnostic used to validate the operability of a pneumatically operated safety shutdown valve. (*a*) Input command generated by the diagnostic and resulting travel. (*b*) Actuator pressure measured over the tested range of travel.

capacity of this transducer is limited and not sufficient to provide responsive load pressure directly to a pneumatic actuator.

The flow capacity of the transducer can be increased by adding a booster relay such as the one shown in Fig. 8-87*b*. The flow capacity of the booster relay is nominally 50 to 100 times that of the nozzle amplifier shown in Fig. 8-87*a* and makes the combined transducer/booster suitably responsive to operate pneumatic actuators. This type of transducer is stable for all sizes of load volume and produces measured accuracy (see ANSI/ISA-51.1, "Process Instrumentation Terminology," for the definition of measured accuracy) of 0.5 to 1.0 percent of span.

Better measured accuracy results from the transducer design shown in Fig. 8-87*c*. In this design, pressure feedback is taken at the output of the booster relay stage and fed back to the main summer. This allows the transducer to correct for errors generated in the pneumatic booster as well as errors in the I/P conversion stage. Also, particularly with the new analog electric and digital versions of this design, PID control is used in the transducer control network to give extremely good static accuracy, fast dynamic response, and reasonable stability into a wide range of load volumes (small instrument bellows to large actuators). Also environmental factors such as temperature change, vibration, and supply pressure fluctuation affect this type of transducer the least. Even a perfectly accurate I/P transducer cannot compensate for stem position errors generated by friction, backlash, and varying force loads coming from the actuator and valve. To do this compensation, a different control valve device—the valve positioner—is required.

**Booster Relays** The booster relay is a single-stage power amplifier having a fixed gain relationship between the input and output pressures. The device is packaged as a complete stand-alone unit with pipe thread connections for input, output, and supply pressure. The booster amplifier shown in Fig. 8-87*b* shows the basic construction of the booster relay. Enhanced versions are available that provide specific features such as (1) variable gain to split the output range of a pneumatic controller to operate more than one valve or to provide additional actuator force; (2) low hysteresis for relaying measurement and control signals; (3) high flow capacity for increased actuator stroking speed; and (4) arithmetic, logic, or other compensation functions for control system design.

A particular type of booster relay, called a dead-band booster, is shown in Fig. 8-88. This booster is designed to be used exclusively between the output of a valve positioner and the input to a pneumatic actuator. It is designed to provide extra flow capacity to stroke the actuator faster than with the positioner alone. The dead-band booster is designed intentionally with a large dead band (approximately 5 percent of the input span), elastomer seats for tight shutoff, and an adjustable bypass valve connected between the input and output of the booster. The bypass valve is tuned to provide the best compromise between increased actuator stroking speed and positioner/actuator stability.

With the exception of the dead-band booster, the application of booster relays has diminished somewhat by the increased use of current-to-pressure transducers, electropneumatic positioners, and electronic control systems. Transducers and valve positioners serve much the same functionality as the booster relay in addition to interfacing with the electronic process controller.

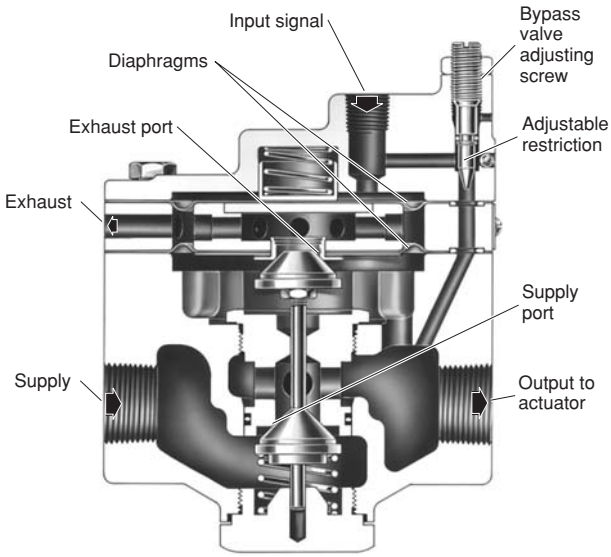

**FIG. 8-88** Dead-band booster relay. (*Courtesy Fisher Controls International LLC.*)

**Solenoid Valves** The electric solenoid valve has two output states. When sufficient electric current is supplied to the coil, an internal armature moves against a spring to an extreme position. This motion causes an attached pneumatic or hydraulic valve to operate. When current is removed, the spring returns the armature and the attached solenoid valve to the deenergized position. An intermediate pilot stage is sometimes used when additional force is required to operate the main solenoid valve. Generally, solenoid valves are used to pressurize or vent the actuator casing for on/off control valve application and safety shutdown applications.

**Trip Valves** The trip valve is part of a system used where a specific valve action (i.e., fail up, fail down, or lock in last position) is required when pneumatic supply pressure to the control valve falls below a preset level. Trip systems are used primarily on springless piston actuators requiring fail-open or fail-closed action. An air storage or "volume" tank and a check valve are used with the trip valve to provide power to stroke the valve when supply pressure is lost. Trip valves are designed with hysteresis around the trip point to avoid instability when the trip pressure and the reset pressure settings are too close to the same value.

**Limit Switches and Stem Position Transmitters** Travel limit switches, position switches, and valve position transmitters are devices that detect the component's relative position, when mounted on the valve, actuator, damper, louver, or other throttling element. The switches are used to operate alarms, signal lights, relays, solenoid valves, or discrete inputs into the control system. The valve position transmitter generates a 4- to 20-mA output that is proportional to the position of the valve.

## FIRE AND EXPLOSION PROTECTION

Electrical equipment and wiring methods can be sources of ignition in environments with combustible concentrations of gas, liquid, dust, fibers, or flyings. Most of the time it is possible to locate the electronic equipment away from these hazardous areas. However, where electric or electronic valve-mounted instruments must be used in areas where there is a hazard of fire or explosion, the equipment and installation must meet requirements for safety. Articles 500 through 504 of the National Electrical Code cover the definitions and requirements for electrical and electronic equipment used in the class I (flammable gases or vapors), divisions 1 and 2; class II (combustible dust), divisions 1 and 2; and class III (ignitable fibers or flyings), divisions 1 and 2. Division 1 locations are locations with hazardous concentrations of gases, vapors, or combustible dust under normal operating conditions; hazardous concentration of gases, vapors, or combustible dust that occur frequently due to repair, maintenance, or leakage; or hazardous due to the presence of easily ignitable fibers or materials producing combustible flyings during handling, manufacturing, or use. Division 2 locations are locations that normally do not have ignitable concentrations of gases, vapors, or combustible dust. Division 2 locations might become hazardous through failure of ventilating equipment; adjacent proximity to a class I, division 1 location where ignitable concentrations of gases or vapors might occasionally exist; through dust accumulations on or in the vicinity of the electrical equipment sufficient to interfere with the safe dissipation of heat or by abnormal operation or failure of electrical equipment; or when easily ignitable fibers are stored or handled other than in the process of manufacture. An alternate method used for class I hazardous locations is the European "zone" method described in IEC 60079-10, "Electrical Apparatus for Explosive Gas Atmospheres." The zone designation for class I locations has been adapted by the NEC as an alternate method and is defined in Article 505 of the NEC.

Acceptable protection techniques for electrical and electronic valve accessories used in specific class and division locations include explosion-proof enclosures; intrinsically safe circuits; nonincendive circuits, equipment, and components; dust-ignition-proof enclosures; dusttight enclosures; purged and pressurized enclosures; oil immersion for current-interrupting contacts; and hermetically sealed equipment. Details of these techniques can be found in the *National Electrical Code Handbook,* available from the *National Fire Protection Association.*

Certified testing and approval for control valve devices used in hazardous locations is normally procured by the manufacturer of the device. The manufacturer typically goes to a third-party laboratory for testing and certification. Applicable approval standards are available from CSA, CENELEC, FM, SAA, and UL.

**Environmental Enclosures** Enclosures for valve accessories are sometimes required to provide protection from specific environmental conditions. The National Electrical Manufacturers Association (NEMA) provides descriptions and test methods for equipment used in specific environmental conditions in NEMA 250. IEC 60529, "Degrees of Protection Provided by Enclosures (IP Code)," describes the European system for classifying the degrees of protection provided by the enclosures of electrical equipment. Rain, windblown dust, hose-directed water, and external ice formation are examples of environmental conditions that are covered by these enclosure standards.

Of growing importance is the electronic control valve device's level of immunity to, and emission of, electromagnetic interference in the chemical valve environment. Electromagnetic compatibility (EMC) for control valve devices is presently mandatory in the European Community and is specified in International Electrotechnical Commission (IEC) 61326, "Electrical Equipment for Measurement Control and Laboratory Use—EMC Requirements." Test methods for EMC testing are found in the series IEC 61000-4, "EMC Compatibility (EMC), Testing and Measurement Techniques." Somewhat more stringent EMC guidelines are found in the German document NAMUR NE21, "Electromagnetic Compatibility of Industrial Process and Laboratory Control Equipment."

## ADJUSTABLE-SPEED PUMPS

An alternative to throttling a process with a process control valve and a fixed-speed pump is by adjusting the speed of the process pump and not using a throttling control valve at all. Pump speed can be varied by using variable-speed prime movers such as turbines, motors with magnetic or hydraulic couplings, and electric motors. Each of these methods of modulating pump speed has its own strengths and weaknesses, but all offer energy savings and dynamic performance advantages over throttling with a control valve.

The centrifugal pump directly driven by a variable-speed electric motor is the most commonly used hardware combination for adjustable-speed pumping. The motor is operated by an electronic motor speed controller whose function is to generate the voltage or current waveform required by the motor to make the speed of the motor track the input command signal from the process controller.

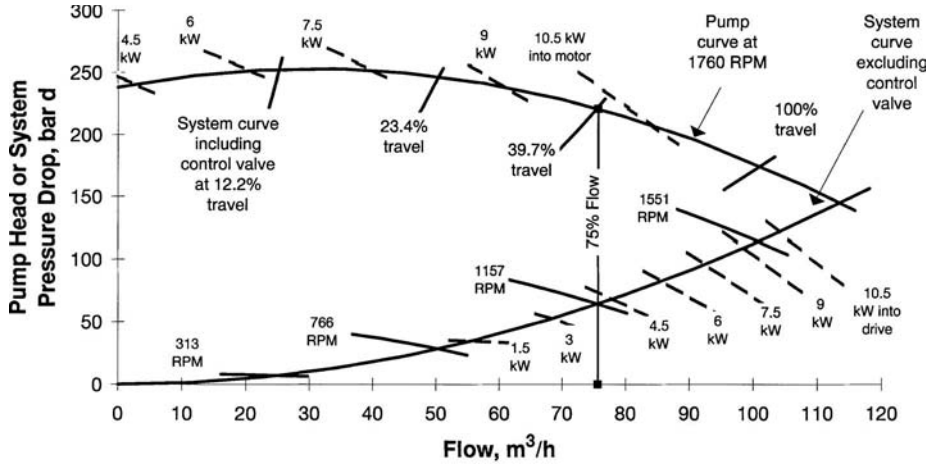

**FIG. 8-89** Pressure, flow, and power for throttling a process using a control valve and a constant-speed pump compared to throttling with an adjustable-speed pump.

The most popular form of motor speed control for adjustable-speed pumping is the voltage-controlled pulse-width-modulated (PWM) frequency synthesizer and ac squirrel-cage induction motor combination. The flexibility of application of the PWM motor drive and its 90+ percent electrical efficiency along with the proven ruggedness of the traditional ac induction motor makes this combination popular.

From an energy consumption standpoint, the power required to maintain steady process flow with an adjustable-speed-pump system (three-phase PWM drive and a squirrel-cage induction motor driving a centrifugal pump on water) is less than that required with a conventional control valve and a fixed-speed pump. Figure 8-89 shows this to be the case for a system where 100 percent of the pressure loss is due to flow velocity losses. At 75 percent flow, the figure shows that using the constant-speed pump/control valve results in a 10.1-kW rate, while throttling with the adjustable-speed pump and not using a control valve results in a 4.1-kW rate. This trend of reduced energy consumption is true for the entire range of flows, although amounts vary.

From a dynamic response standpoint, the electronic adjustable-speed pump has a dynamic characteristic that is more suitable in process control applications than those characteristics of control valves. The small amplitude response of an adjustable-speed pump does not contain the dead band or the dead time commonly found in the small amplitude response of the control valve. Nonlinearities associated with friction in the valve and discontinuities in the pneumatic portion of the control valve instrumentation are not present with electronic variable-speed drive technology. As a result, process control with the adjustable-speed pump does not exhibit limit cycles, problems related to low controller gain, and generally degraded process loop performance caused by control valve nonlinearities.

Unlike the control valve, the centrifugal pump has poor or nonexistent shutoff capability. A flow check valve or an automated on/off valve may be required to achieve shutoff requirements. This requirement may be met by automating an existing isolation valve in retrofit applications.

## REGULATORS

A regulator is a compact device that maintains the process variable at a specific value in spite of disturbances in load flow. It combines the functions of the measurement sensor, controller, and final control element into one self-contained device. Regulators are available to control pressure, differential pressure, temperature, flow, liquid level, and other basic process variables. They are used to control the differential across a filter press, heat exchanger, or orifice plate. Regulators are used for monitoring pressure variables for redundancy, flow check, and liquid surge relief.

Regulators may be used in gas blanketing systems to maintain a protective environment above any liquid stored in a tank or vessel as the liquid is pumped out. When the temperature of the vessel is suddenly cooled, the regulator maintains the tank pressure and protects the walls of the tank from possible collapse. Regulators are known for their fast dynamic response. The absence of time delay that often comes with more sophisticated control systems makes the regulator useful in applications requiring fast corrective action.

Regulators are designed to operate on the process pressures in the pipeline without any other sources of energy. Upstream and downstream pressures are used to supply and exhaust the regulator. Exhausting is connected back to the downstream piping so that no contamination or leakage to the external environment occurs. This makes regulators useful in remote locations where power is not available or where external venting is not allowed.

The regulator is limited to operating on processes with clean, nonslurry process fluids. The small orifice and valve assemblies contained in the regulator can plug and malfunction if the process fluid that operates the regulator is not sufficiently clean.

Regulators are normally not suited to systems that require constant set-point adjustment. Although regulators are available with capability to respond to remote set-point adjustment, this feature adds complexity to the regulator and may be better addressed by a control-valve-based system. In the simplest of regulators, tuning of the regulator for best control is accomplished by changing a spring, an orifice, or a nozzle.

**Self-Operated Regulators** Self-operated regulators are the simplest form of regulator. This regulator (see Fig. 8-90*a*) is composed of a main throttling valve, a diaphragm or piston to sense pressure, and a spring. The self-contained regulator is completely operated by the process fluid, and no outside control lines or pilot stage is used. In general, self-operated regulators are simple in construction, are easy to operate and maintain, and are usually stable devices. Except for some of the pitot-tube types, self-operated regulators have very good dynamic response characteristics. This is so because any change in the controlled variable registers directly and immediately upon the main diaphragm to produce a quick response to the disturbance.

The disadvantage of the self-operated regulator is that it is not generally capable of maintaining a set point as load flow is increased. Because of the proportional nature of the spring and diaphragm-throttling effect, offset from set point occurs in the controlled variable as flow increases. Figure 8-91 shows a typical regulation curve for the self-contained regulator.

Reduced set-point offset with increasing load flow can be achieved by adding a pitot tube to the self-operated regulator. The

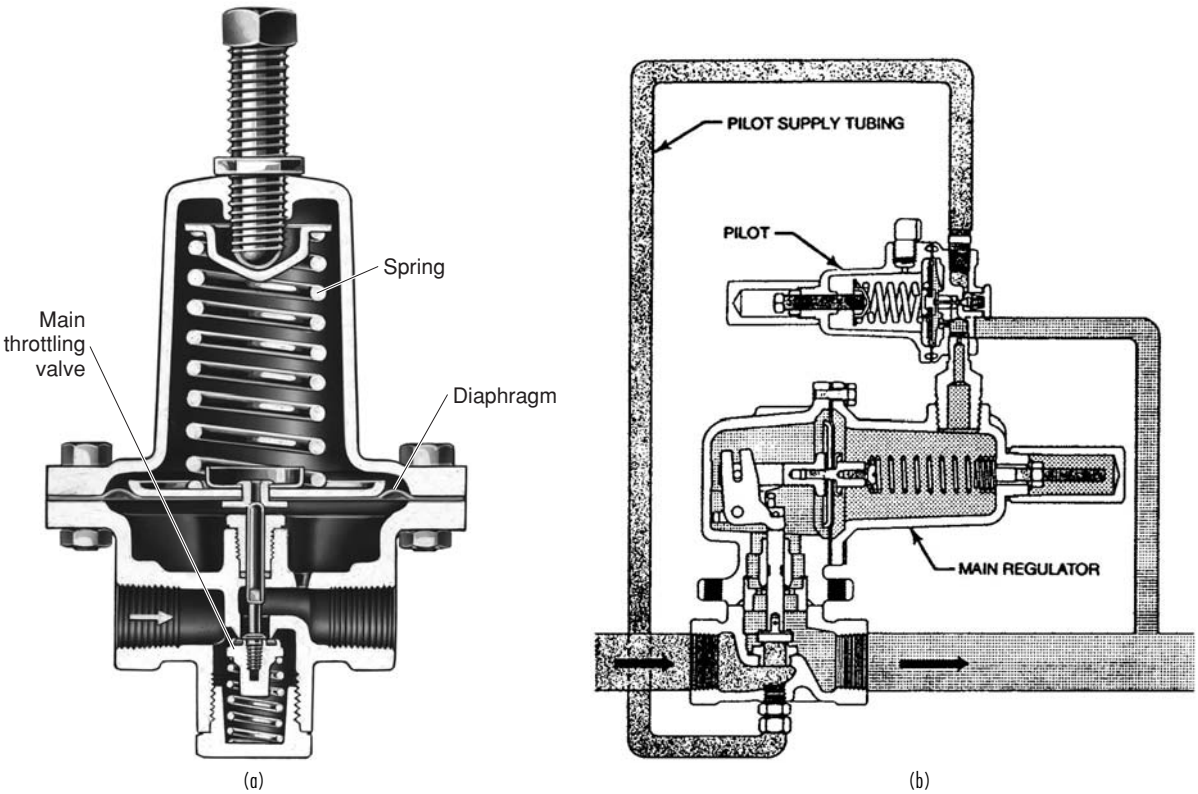

**FIG. 8-90** Regulators. (*a*) Self-operated. (*b*) Pilot-operated. (*Courtesy Fisher Controls International LLC.*)

tube is positioned somewhere near the vena contracta of the main regulator valve. As flow though the valve increases, the measured feedback pressure from the pitot tube drops below the control pressure. This causes the main valve to open or boost more than it would if the static value of control pressure were acting on the diaphragm. The resultant effect keeps the control pressure closer to the set point and thus prevents a large drop in process pressure during high-load-flow conditions. Figure 8-91 shows the improvement that the pitot-tube regulator provides over the regulator without the tube. A side effect of adding a pitot-tube method is that the response of the regulator can be slowed due to the restriction provided by the pitot tube.

**Pilot-Operated Regulators** Another category of regulators uses a pilot stage to provide the load pressure on the main diaphragm. This pilot is a regulator itself that has the ability to multiply a small change in downstream pressure into a large change in pressure applied to the regulator diaphragm. Due to this high-gain feature, pilot-operated

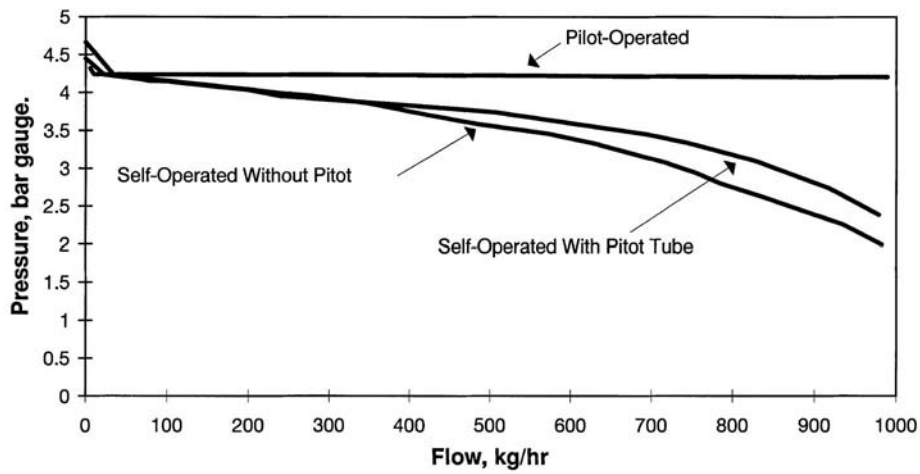

**FIG. 8-91** Pressure regulation curves for three regulator types.

regulators can achieve a dramatic improvement in steady-state accuracy over that achieved with a self-operated regulator. Figure 8-91 shows for regulation at high flows the pilot-operated regulator is the best of the three regulators shown.

The main limitation of the pilot-operated regulator is stability. When the gain in the pilot amplifier is raised too much, the loop can become unstable and oscillate or hunt. The two-path pilot regulator (see Fig. 8-90*b*) is also available. This regulator combines the effects of self-operated and the pilot-operated styles and mathematically produces the equivalent of proportional plus reset control of the process pressure.

**Overpressure Protection** Figure 8-91 shows a characteristic rise in control pressure that occurs at low or zero flow. This lockup tail is due to the effects of imperfect plug and seat alignment and the elastomeric effects of the main throttle valve. If, for some reason, the main throttle valve fails to completely shut off, or if the valve shuts off but the control pressure continues to rise for other reasons, the lockup tail could get very large, and the control pressure could rise to extremely high values. Damage to the regulator or the downstream pressure volume could occur.

To avoid this situation, some regulators are designed with a built-in overpressure relief mechanism. Overpressure relief circuits usually are composed of a spring-opposed diaphragm and valve assembly that vents the downstream piping when the control pressure rises above the set-point pressure.

# PROCESS CONTROL AND PLANT SAFETY

**GENERAL REFERENCE:** *Guidelines for Safe Automation of Chemical Processes,* AIChE Center for Chemical Process Safety, New York, 1993.

Accidents in chemical plants make headline news, especially when there is loss of life or the general public is affected in even the slightest way. This increases the public's concern and may lead to government action. The terms *hazard* and *risk* are defined as follows:

- *Hazard.* A potential source of harm to people, property, or the environment.
- *Risk.* Possibility of injury, loss, or an environmental accident created by a hazard.

Safety is the freedom from hazards and thus the absence of any associated risks. Unfortunately, absolute safety cannot be realized.

The design and implementation of safety systems must be undertaken with a view to two issues:

- *Regulatory.* The safety system must be consistent with all applicable codes and standards as well as "generally accepted good engineering practices."
- *Technical.* Just meeting all applicable regulations and "following the crowd" do not relieve a company of its responsibilities. The safety system must work.

The regulatory environment will continue to change. As of this writing, the key regulatory instrument is OSHA 29 CFR 1910.119, "Process Safety Management of Highly Hazardous Chemicals," which pertains to process safety management within plants in which certain chemicals are present.

In addition to government regulation, industry groups and professional societies are producing documents ranging from standards to guidelines. Two applicable standards are IEC 61508, "Functional Safety of Electrical/Electronic/Programmable Electronic Safety-related Systems," and ANSI/ISA S84.01, "Application of Safety Instrumented Systems for the Process Industries." *Guidelines for Safe Automation of Chemical Processes* from the American Institute of Chemical Engineers' Center for Chemical Process Safety (1993) provides comprehensive coverage of the various aspects of safety; and although short on specifics, it is very useful to operating companies developing their own specific safety practices (i.e., it does not tell you what to do, but it helps you decide what is proper for your plant).

The ultimate responsibility for safety rests with the operating company; OSHA 1910.119 is clear on this. Each company is expected to develop (and enforce) its own practices in the design, installation, testing, and maintenance of safety systems. Fortunately, some companies make these documents public. Monsanto's *Safety System Design Practices* was published in its entirety in the proceedings of the International Symposium and Workshop on Safe Chemical Process Automation, Houston, Texas, September 27–29, 1994 (available from the American Institute of Chemical Engineers' Center for Chemical Process Safety).

## ROLE OF AUTOMATION IN PLANT SAFETY

As microprocessor-based controls displaced hardwired electronic and pneumatic controls, the impact on plant safety has definitely been positive. When automated procedures replace manual procedures for routine operations, the probability of human errors leading to hazardous situations is lowered. The enhanced capability for presenting information to the process operators in a timely manner and in the most meaningful form increases the operator's awareness of current conditions in the process. Process operators are expected to exercise due diligence in the supervision of the process, and timely recognition of an abnormal situation reduces the likelihood that the situation will progress to the hazardous state. Figure 8-92 depicts the layers of safety protection in a typical chemical plant. Although microprocessor-based process controls enhance plant safety, their primary objective is efficient process operation. Manual operations are automated to reduce variability, to minimize the time required, to increase productivity, and so on. Remaining competitive in the world market demands that the plant be operated in the best manner possible, and microprocessor-based process controls provide numerous functions that make this possible. Safety is never compromised in the effort to increase competitiveness, but enhanced safety is a by-product of the process control function and is not a primary objective. By attempting to maintain process conditions at or near their design values, the process controls also attempt to prevent abnormal conditions from developing within the process.

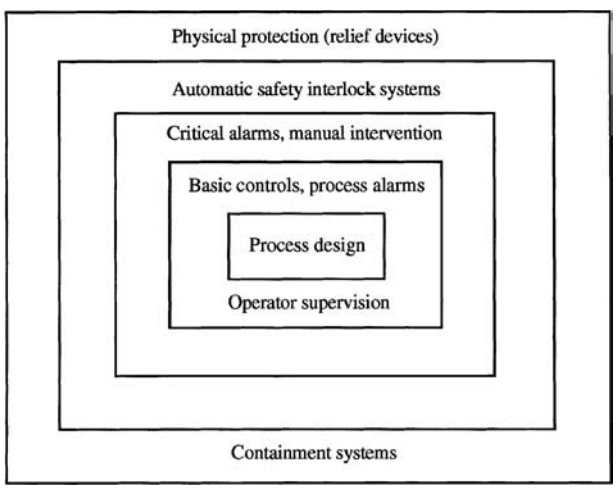

**FIG. 8-92** Layers of safety protection in chemical plants.

Although process controls can be viewed as a protective layer, this is really a by-product and not the primary function. Where the objective of a function is specifically to reduce risk, the implementation is normally not within the process controls. Instead, the implementation is within a separate system specifically provided to reduce risk. This system is generally referred to as the safety interlock system.

As safety begins with the process design, an inherently safe process is the objective of modern plant designs. When this cannot be achieved, process hazards of varying severity will exist. Where these hazards put plant workers and/or the general public at risk, some form of protective system is required. Process safety management addresses the various issues, ranging from assessment of the process hazard to ensuring the integrity of the protective equipment installed to cope with the hazard. When the protective system is an automatic action, it is incorporated into the safety interlock system, not within the process controls.

## INTEGRITY OF PROCESS CONTROL SYSTEMS

Ensuring the integrity of process controls involves hardware issues, software issues, and human issues. Of these, the hardware issues are usually the easiest to assess and the software issues the most difficult.

The hardware issues are addressed by providing various degrees of redundancy, by providing multiple sources of power and/or an uninterruptible power supply, and the like. The manufacturers of process controls provide a variety of configuration options. Where the process is inherently safe and infrequent shutdowns can be tolerated, nonredundant configurations are acceptable. For more-demanding situations, an appropriate requirement might be that no single component failure be able to render the process control system inoperable. For the very critical situations, triple-redundant controls with voting logic might be appropriate. The difficulty lies in assessing what is required for a given process.

Another difficulty lies in assessing the potential for human errors. If redundancy is accompanied with increased complexity, the resulting increased potential for human errors must be taken into consideration. Redundant systems require maintenance procedures that can correct problems in one part of the system while the remainder of the system is in full operation. When maintenance is conducted in such situations, the consequences of human errors can be rather unpleasant.

The use of programmable systems for process control presents some possibilities for failures that do not exist in hardwired electromechanical implementations. Probably of greatest concern are latent defects or "bugs" in the software, either the software provided by the supplier or the software developed by the user. The source of this problem is very simple. There is no methodology available that can be applied to obtain absolute assurance that a given set of software is completely free of defects. Increased confidence in a set of software is achieved via extensive testing, but no amount of testing results in absolute assurance that there are no defects. This is especially true of real-time systems, where the software can easily be exposed to a sequence of events that was not anticipated. Just because the software performs correctly for each event individually does not mean that it will perform correctly when two (or more) events occur at nearly the same time. This is further complicated by the fact that the defect may not be in the programming; it may be in how the software was designed to respond to the events.

The testing of any collection of software is made more difficult as the complexity of the software increases. Software for process control has become progressively complex, mainly because the requirements have become progressively demanding. To remain competitive in the world market, processes must be operated at higher production rates, within narrower operating ranges, closer to equipment limits, and so on. Demanding applications require sophisticated control strategies, which translate to more-complex software. Even with the best efforts of both supplier and user, complex software systems are unlikely to be completely free of defects.

## CONSIDERATIONS IN IMPLEMENTATION OF SAFETY INTERLOCK SYSTEMS

Where hazardous conditions can develop within a process, a protective system of some type must be provided. Sometimes this is in the form of process hardware such as pressure relief devices. However, sometimes logic must be provided for the specific purpose of taking the process to a state where the hazardous condition cannot exist. The term *safety interlock system* is normally used to designate such logic.

The purpose of the logic within the safety interlock system is very different from that of the logic within the process controls. Fortunately, the logic within the safety interlock system is normally much simpler than the logic within the process controls. This simplicity means that a hardwired implementation of the safety interlock system is usually an option. Should a programmable implementation be chosen, this simplicity means that latent defects in the software are less likely to be present. Most safety systems only have to do simple things, but they must do them very, very well.

The difference in the nature of process controls and safety interlock systems leads to the conclusion that these two should be physically separated (see Fig. 8-92). That is, safety interlocks should not be piggybacked onto a process control system. Instead, the safety interlocks should be provided by equipment, either hardwired or programmable, that is dedicated to the safety functions. As the process controls become more complex, faults are more likely. Separation means that faults within the process controls have no consequences in the safety interlock system.

Modifications to the process controls are more frequent than modifications to the safety interlock system. Therefore, physically separating the safety interlock system from the process controls provides the following benefits:

1. The possibility of a change to the process controls leading to an unintentional change to the safety interlock system is eliminated.
2. The possibility of a human error in the maintenance of the process controls having consequences for the safety interlock system is eliminated.
3. Management of change is simplified.
4. Administrative procedures for software version control are more manageable.

Separation also applies to the measurement devices and actuators. Although the traditional point of reference for safety interlock systems is a hardwired implementation, a programmed implementation is an alternative. The potential for latent defects in software implementation is a definite concern. Another concern is that solid-state components are not guaranteed to fail to the safe state. The former is addressed by extensive testing; the latter is addressed by manufacturer-supplied and/or user-supplied diagnostics that are routinely executed by the processor within the safety interlock system. Although issues must be addressed in programmable implementations, the hardwired implementations are not perfect either.

Where a programmed implementation is deemed to be acceptable, the choice is usually a programmable logic controller that is dedicated to the safety function. PLCs are programmed with the traditional relay ladder diagrams used for hardwired implementations. The facilities for developing, testing, and troubleshooting PLCs are excellent. However, for PLCs used in safety interlock systems, administrative procedures must be developed and implemented to address the following issues:

1. Version controls for the PLC program must be implemented and rigidly enforced. Revisions to the program must be reviewed in detail and thoroughly tested before implemention in the PLC. The various versions must be clearly identified so that there can be no doubt as to what logic is provided by each version of the program.
2. The version of the program that is currently being executed by the PLC must be known with absolute certainty. It must be impossible for a revised version of the program undergoing testing to be downloaded to the PLC.

Constant vigilance is required to prevent lapses in such administrative procedures.

## INTERLOCKS

An interlock is a protective response initiated on the detection of a process hazard. The interlock system consists of the measurement devices, logic solvers, and final control elements that recognize the hazard and initiate an appropriate response. Most interlocks consist of one or more logic conditions that detect out-of-limit process conditions and respond by driving the final control elements to the safe states. For example, one must specify that a valve fails open or fails closed.

The potential that the logic within the interlock could contain a defect or bug is a strong incentive to keep it simple. Within process plants, most interlocks are implemented with discrete logic, which means either hardwired electromechanical devices or programmable logic controllers.

The discrete logic within process plants can be broadly classified as follows:

1. *Safety interlocks.* These are designed to protect the public, the plant personnel, and possibly the plant equipment from process hazards. These are implemented within the safety interlock system.
2. *Process actions.* These are designed to prevent process conditions that would unduly stress equipment (perhaps leading to minor damage), lead to off-specification product, and so on. Basically, the process actions address hazards whose consequences essentially lead to a monetary loss, possibly even a short plant shutdown. Although sometimes referred to as interlocks, process actions address situations that are not deemed to be process hazards.

Implementation of process actions within process control systems is perfectly acceptable. Furthermore, it is also permissible (and probably advisable) for responsible operations personnel to be authorized to bypass or ignore a process action. Safety interlocks must be implemented within the separate safety interlock system. Bypassing or ignoring safety interlocks by operations personnel is simply not permitted. When this is necessary for actions such as verifying that the interlock continues to be functional, such situations must be infrequent and incorporated into the design of the interlock.

Safety interlocks are assigned to categories that reflect the severity of the consequences, should the interlock fail to perform as intended. The specific categories used within a company are completely at the discretion of the company. However, most companies use categories that distinguish among the following:

1. *Hazards that pose a risk to the public.* Complete redundancy is normally required.
2. *Hazards that could lead to injury of company personnel.* Partial redundancy is often required (e.g., redundant measurements but not redundant logic).
3. *Hazards that could result in major equipment damage and consequently lengthy plant downtime.* No redundancy is normally required for these, although redundancy is always an option.

Situations resulting in minor equipment damage that can be quickly repaired do not generally require a safety interlock; however, a process action might be appropriate.

A process hazards analysis is intended to identify the safety interlocks required for a process and to provide the following for each:

1. The hazard that is to be addressed by the safety interlock
2. The classification of the safety interlock
3. The logic for the safety interlock, including inputs from measurement devices and outputs to actuators

The process hazards analysis is conducted by an experienced, multidisciplinary team that examines the process design, plant equipment, operating procedures, and so on, using techniques such as hazard and operability studies (HAZOP), failure mode and effect analysis (FMEA), and others. The process hazards analysis recommends appropriate measures to reduce the risk, including (but not limited to) the safety interlocks to be implemented in the safety interlock system.

Diversity is recognized as a useful approach to reduce the number of defects. The team that conducts the process hazards analysis does not implement the safety interlocks but provides the specifications for the safety interlocks to another organization for implementation. This organization reviews the specifications for each safety interlock, seeking clarifications as necessary from the process hazards analysis team and bringing any perceived deficiencies to the attention of the process hazards analysis team.

Diversity can be used to further advantage in redundant configurations. Where redundant measurement devices are required, different technology can be used for each. Where redundant logic is required, one can be programmed and one hardwired. Reliability of the interlock systems has two aspects:

1. It must react, should the hazard arise.
2. It must not react when there is no hazard.

Emergency shutdowns often pose risks in themselves, and therefore they should be undertaken only when truly appropriate. The need to avoid extraneous shutdowns is not motivated by a desire simply to avoid disruption in production operations.

Although safety interlocks can inappropriately initiate shutdowns, the process actions are usually the major source of problems. It is possible to configure so many process actions that it is not possible to operate the plant.

## TESTING

As part of the detailed design of each safety interlock, written test procedures must be developed for the following purposes:

1. Ensure that the initial implementation complies with the requirements defined by the process hazards analysis team.
2. Ensure that the interlock (hardware, software, and I/O) continues to function as designed. The design must also determine the time interval over which this must be done. Often these tests must be done with the plant in full operation.

The former is the responsibility of the implementation team and is required for the initial implementation and following any modification to the interlock. The latter is the responsibility of plant maintenance, with plant management responsible for seeing that it is done at the specified interval of time.

Execution of each test must be documented, showing when it was done, by whom, and the results. Failures must be analyzed for possible changes in the design or implementation of the interlock. These tests must encompass the complete interlock system, from the measurement devices through the final control elements. Merely simulating inputs and checking the outputs is not sufficient. The tests must duplicate the process conditions and operating environments as closely as possible. The measurement devices and final control elements are exposed to process and ambient conditions and thus are usually the most likely to fail. Valves that remain in the same position for extended periods may stick in that position and not operate when needed. The easiest component to test is the logic; however, this is the least likely to fail.

### GLOSSARY

**Nomenclature and Units**

| Symbol | Definition | Units |
|---|---|---|
| $A_1$ | Annual conversion expense at production rate 1 | $ |
| $A_{TC}$ | Annual capital outlay | $ |
| $B$ | Constant | Dimensionless |
| $C$ | Cost of equipment | $ |
| $C_B$ | Base cost of carbon steel exchanger | $ |
| CE | *Chemical Engineering* cost index | Dimensionless |
| $(C_{FC})_{BL}$ | Battery-limits fixed capital investment | $ |
| $(C_{EQ})_{DEL}$ | Delivered equipment cost | $ |
| $C_{HE}$ | Purchased equipment cost, heat exchanger | $ |
| $C_L$ | Cost of labor | $ |
| COE | Cash operating expenses | $ |
| $C_P$ | Equipment cost in base year | $ |
| cP | Viscosity | cP |
| $D$ | Depreciation | $ |
| DCFROR | Discounted cash flow rate of return | % |
| EBIT | Earnings before interest and taxes | $ |
| $e$ | Naperian logarithm base | 2.718 |
| $F$ | Future value, future worth, future amount | $ |
| $F$ | Heat exchanger efficiency factor | Dimensionless |
| $F_B$ | Heat exchanger design type | Dimensionless |
| FCI | Fixed capital investment | $ |
| FE | Fixed expenses | $ |
| FEL | Front-end loading | |
| FIFO | First in, first out (inventory) | lb |
| FOB | Free on board | |
| $F_M$ | Material of construction cost factor | Dimensionless |
| $F_P$ | Design pressure cost factor | Dimensionless |
| $f_1, f_2, f_3$ | Inflation factors for years 1, 2, and 3 | Dimensionless |
| $f$ | Declining-balance factor | Dimensionless |
| $I$ | Investment | $ |
| IRS | Internal Revenue Service | |
| $i$ | Nominal interest | % |
| $i_{eff}$ | Effective interest | % |
| $K$ | Factor for cost index | Dimensionless |
| LIFO | Last in, last out (inventory) | lb |
| $M$ | Annual raw material expense | $ |
| MACRS | Modified Accelerated Cost Recovery System | |
| $m$ | Number of interest periods per year | Varies |
| $m, n, p, q$ | constants or exponent | Dimensionless |
| $N$ | Annual labor requirements | Operators per shift per year |
| $n$ | Number of years, depreciation | Years |
| $P$ | Principal, present value, present worth | $ |
| PC | Personal computer | |
| POP | Payout period (no interest) | Years |
| POP + I | Payout period plus interest | Years |
| $Q$ | Energy transferred | Btu/h |
| $R_1, R_2$ | Annual production rates | lb/yr |
| $S$ | Salvage value or equipment capacity | Various |
| SL | Straight-line depreciation | |
| Sp gr | Specific gravity | Dimensionless |
| TE | Total expenses | $ |
| $T_c$ | Combined incremental tax rate | % |
| $T_f$ | Incremental federal income tax rate | % |
| $T_s$ | Incremental state income tax rate | % |
| $U$ | Annual utility expenses | $ |
| UAC | Uniform annual cost | $ |
| $U_D$ | Overall heat-transfer coefficient | Btu/(h·ft$^2$·°F) |
| $V_e$ | Asset value at end of year | $ |
| $V_i$ | Asset value at beginning of year | $ |
| VE | Variable expenses | $ |
| VIP | Value-improving practice | |
| $X$ | Plant capacity | tons/day |
| $Y$ | Operating labor | operator-hour/ton per processing step |

## GENERAL COMMENTS

One of the most confusing aspects of process engineering economics is the nomenclature used by various authors and companies. In this part of Sec. 9, generic, descriptive terms have been used. Further, an attempt has been made to bring together most of the methods currently in use for project evaluation and to present them in such a way as to make them amenable to modern computational techniques. Most of the calculations can be performed on handheld calculators equipped with scientific function keys. For calculations requiring greater sophistication than that of handheld calculators, algorithms may be solved by using such programs as MATHCAD, TKSOLVER, etc. Spreadsheets are also used whenever the solution to a problem lends itself to this technique.

The nomenclature in process economics has been developed by accountants, engineers, and others such that there is no one correct set of nomenclature. Often it seems confusing, but one must question what is meant by a certain term since companies have adopted their own language. A glossary of terms is included at the end of this section to assist the reader in understanding the nomenclature. Further, abbreviations of terms such as DCFRR (discounted cash flow rate of return) are used to reduce the wordiness. The number of letters and numbers used to define a variable has been limited to five. The parentheses are removed whenever the letter group is used to define a variable for a computer. Also, a general symbol is defined for a type variable and is modified by mnemonic subscript, e.g., an annual cash quantity, annual capital outlay $A_{TC}$, \$/year. Wherever a term like this is introduced, it is defined in the text.

It is impossible to allow for all possible variations of equation requirements, but it is hoped that the nomenclature presented will prove adequate for most purposes and will be capable of logical extension to other more specialized requirements.

## ACCOUNTING AND FINANCIAL CONSIDERATIONS

### PRINCIPLES OF ACCOUNTING

*Accounting* has been defined as the art of recording business transactions in a systematic manner. It is the language of business and is used to communicate financial information. Conventions that govern accounting are fairly simple, but their application is complex. In this section, the basic principles are illustrated by a simple example and applied to analyzing a company report. The fair allocation of costs requires considerable technical knowledge of operations, so a close liaison between process engineers and accountants in a company is desirable.

In simplest terms, assets that are the economic resources of a company are balanced against equities that are claims against the firm. In equation form,

$$\text{Assets} = \text{Equities}$$

or

$$\text{Assets} = \text{Liabilities} + \text{Owners' Equity}$$

This dual aspect has led to the *double-entry* bookkeeping system in use today. Any transaction that takes place causes changes in the accounting equation. An increase in assets must be accompanied by one of the following:

- An increase in liabilities
- An increase in stockholders' equity
- An increase in assets

A change in one part of the equation due to an economic transaction must be accompanied by an equal change in another place—therefore, the term *double-entry* bookkeeping. On a page of an account, the left-hand side is designated the *debit* side and the right-hand side is the *credit* side. This convention holds regardless of the type of account. Therefore, for every economic transaction, there is an entry on the debit side balanced by the same entry on the credit side.

All transactions in their original form (receipts and invoices) are recorded chronologically in a *journal*. The date of the transaction together with an account title and a brief description of the transaction is entered. Table 9-1 is an example of a typical journal page for a company. Journal entries are transferred to a *ledger* in a process called *posting*. Separate ledger accounts, such as a revenue account, expense account, liability account, or asset account, may be set up for each major transaction. Table 9-2 shows an example of a typical ledger page. The number of ledger accounts depends on the information that management needs to make decisions. Periodically, perhaps on a monthly basis but certainly on a yearly basis, the ledger sheets are closed and balanced. The ledger sheets are then intermediate documents between journal records and balance sheets, income statements, and retained earnings statements, and they provide information for management and various government reports. For example, a consolidated income statement can be prepared for the ledger, revenue, and expense accounts. In like manner, the asset and liability accounts provide information for balance sheets.

**TABLE 9-1 Typical Journal Page**

| Date | Explanation | LP | Debit | Credit |
|---|---|---|---|---|
| 200X | | | | |
| Mar 1 | Cash | 1 | $95,000 | |
| | J. Jones, Capital | 2 | | $95,000 |
| Mar 4 | Property | 4 | 5,000 | |
| | Cash | 1 | | 3,000 |

## FINANCIAL STATEMENTS

A basic knowledge of accounting and financial statements is necessary for a chemical professional to be able to analyze a firm's operation and to communicate with accountants, financial personnel, and managers. Financial reports of a company are important sources of information used by management, owners, creditors, investment bankers, and financial analysts. All publicly held companies are required to submit annual reports to the Securities and Exchange Commission. As with any field a certain basic nomenclature is used to be able to understand the financial operation of a company. It should be emphasized that companies may also have their own internal nomenclature, but some terms are universally accepted. In this section, the common terminology is used.

A financial report contains two important documents—the *balance sheet* and the *income statement.* Two other documents that appear in the financial report are the *accumulated retained earnings* and the *changes in working capital.* All these documents are discussed in the following sections using a fictitious company.

**Balance Sheet** The balance sheet represents an accounting view of the financial status of a company on a particular date. Table 9-3 is an example of a balance sheet for a company. The date frequently used by corporations is December 31 of any given year, although some companies are now using June 30 or September 30 as the closing date. It is as if the company's operation were frozen in time on that date. The term *consolidated* means that all the balance sheet and income statement data include information from the parent as well as subsidiary operations. The balance sheet consists of two parts: *assets* are the items that the company owns, and *liabilities and stockholders' equity* are what the company owes to creditors and stockholders. Although the balance sheet has two sides, it is not part of the double-entry accounting system. The balance sheet is not an account but a statement of claims against company assets on the date of the reporting period. The claims are the creditors and the stockholders. Therefore, the total assets must equal the total liabilities plus the stockholders' equity.

*Assets* are classified as current, fixed, or intangibles. *Current assets* include cash, cash equivalents, marketable securities, accounts receivable, inventories, and prepaid expenses. Cash and cash equivalents are those items that can be easily converted to cash. Marketable securities are securities that a company holds that also may be converted to cash. Accounts receivable are the amounts due a company from customers from material that has been delivered but has not been collected as yet. Customers are given 30, 60, or 90 days in which to pay; however, some customers fail to pay bills on time or may not be able to pay at all. An allowance is made for doubtful accounts. The amount is deducted from the accounts receivables. Inventories include the cost of raw materials, goods in process, and product on hand. Prepaid expenses include insurance premiums paid, charges for leased equipment, and charges for advertising that are paid prior to the receipt of the benefit from these items. The sum of all the above items is the *total current assets.* The term *current* refers to the fact that these assets are easily converted within a year, or more likely in a shorter time, say, 90 days.

*Fixed assets* are items that have a relatively long life such as land, buildings, and manufacturing equipment. The sum of these items is the *total property, plant, and equipment.* From this total, *accumulated depreciation* is subtracted and the result is *net property and equipment.* Last, an item referred to as *intangibles* includes a variety of items such as patents, licenses, intellectual capital, and goodwill. Intangibles are difficult to evaluate since they have no physical existence; e.g., goodwill is the value of the company's name and reputation. The sum of the *total current assets, net property,* and *intangibles* is the *total assets.*

*Liabilities* are the obligations that the company owes to creditors and stockholders. *Current liabilities* are obligations that come due within a year and include *accounts payable* (money owed to creditors for goods and services), *notes payable* (money owed to banks, corporations, or other lenders), *accrued expenses* (salaries and wages to employees, interest on borrowed funds, fees due to professionals, etc.), *income taxes payable, current part of long-term debt,* and *other current liabilities* due within the year.

*Long-term liabilities* are the amounts due after 1 year from date of the financial report. They include *deferred income taxes* that a company is permitted to postpone due to accelerated depreciation to encourage investment, (but they must be paid sometime in the future) and *bonds and notes* that do not have to be paid within the year but at some later date. The sum of the *current* and *long-term liabilities* is the *total liabilities.*

*Stockholders' equity* is the interest that all stockholders have in a company and is a liability with respect to the company. This category includes *preferred* and *common stock* as well as additional paid-in capital (the amount that stockholders paid above the par value of the stock) and *retained earnings.* These are earnings from accumulated profit that a company earns and are used for reinvestment in the company. The sum of these items is the *stockholders' equity.*

On a balance sheet, the sum of the *total liabilities* and the *stockholders' equity* must equal the *total assets,* hence the term *balance sheet*. Comparing balance sheets for successive years, one can follow changes in various items that will indicate how well the company manages its assets and meets its obligations.

**Income Statement** An income statement shows the revenue and the corresponding expenses for the year and serves as a guide for how the company may do in the future. Often income statements may show how the company performed for the last two or three years. Table 9-4 is an example of a consolidated income statement.

*Net sales* are the primary source of revenue from goods and services. This figure includes the amount reported after returned goods, discounts, and allowances for price reductions are taken into account. *Cost of sales* represents all the expenses to convert raw materials to finished products. The major components of these expenses are direct material, direct labor, and overhead. If the cost of sales is subtracted from net sales, the result is the *gross margin.* One of the most important items on the income statement is *depreciation* and *amortization.* Depreciation is an allowance the federal government permits for the

**TABLE 9-4 Consolidated Income Statement (December 31)**

| | 2005 | 2004 |
|---|---|---|
| Net sales (revenue) | $932,000 | $850,000 |
| Cost of sales and operating expenses | | |
| Cost of goods sold | 692,000 | 610,000 |
| Depreciation and amortization | 40,000 | 36,000 |
| Sales, general, and administrative expenses | 113,500 | 110,000 |
| Operating profit | $86,500 | $94,000 |
| Other income (expenses) | | |
| Dividends and interest income | 10,000 | 7,000 |
| Interest expense | (22,000) | (22,000) |
| Income before provision for income taxes | $74,500 | $79,000 |
| Provision for federal income taxes | 24,500 | 26,000 |
| **Net profit for year** | $50,000 | $53,000 |

SOURCE: J. R. Couper, *Process Engineering Economics,* Dekker, New York, 2003. By permission of Taylor & Francis Books, Inc., Boca Raton, Fla.

wear and tear as well as the obsolescence of plant and equipment and is treated as an expense. Amortization is the decline in value of intangible assets such as patents, franchises, and goodwill. *Selling, general, and administrative expenses* include the marketing salaries, advertising expenses, travel, executive salaries, as well as office and payroll expenses. When depreciation, amortization, and the sales and administrative expenses are subtracted from the gross margin, the result is the *operating income. Dividends and interest income* received by the company are then added. Next *interest expense* earned by the stockholders and *income taxes* are subtracted, yielding the term *income before extraordinary loss.* It is the expenses a company may incur for unusual and infrequent occasions. When all the above items are added or subtracted from the operating income, *net income* (or *loss*) is obtained. This latter term is the "bottom line" often referred to in various reports.

**Accumulated Retained Earnings** This is an important part of the financial report because it shows how much money has been retained for growth and how much has been paid as dividends to stockholders. When the accumulated retained earnings increase, the company has greater value. The calculation of this value of the retained earnings begins with the previous year's balance. To that figure add the net profit after taxes for the year. Dividends paid to stockholders are then deducted, and the result is the accumulated retained earnings for the year. See Table 9-5.

**Concluding Remarks** One of the most important sections of an annual report is the "notes." These contain any liabilities that a company may have due to impending litigation that could result in charges or expenses not included in the annual report.

## OTHER FINANCIAL TERMS

*Profit margin* is the ratio of net income to total sales, expressed as a percentage or sometimes quoted as the ratio of profit before interest and taxes to sales, expressed as a percentage. *Operating margin* is obtained by subtracting operating expenses from gross profit expressed as a percentage of sales. *Net worth* is the difference between total assets and total liabilities plus stockholders' equity. *Working capital* is the difference between total current assets and current liabilities.

**TABLE 9-5 Accumulated Retained Earnings Statement[a] (December 31)**

| | 2005 | 2004 |
|---|---|---|
| Balance as of January 1 | $172,900 | $141,850 |
| Net profit for year | 50,000 | 53,000 |
| Total for year | $222,900 | $194,850 |
| Less dividends paid on: | | |
| Preferred stock | 700 | 700 |
| Common stock | 14,600 | 21,250 |

## FINANCIAL RATIOS

There are many financial ratios of interest to financial analysts. A brief discussion of some of these ratios follows; however, a more complete discussion may be found in Couper (2003).

*Liquidity ratios* are a measure of a company's ability to pay its short-term debts. *Current ratio* is obtained by dividing the current assets by the current liabilities. Depending on the economic climate, this ratio is 1.5 to 2.0 for the chemical process industries, but some companies operate closer to 1.0. The *quick ratio* is another measure of liquidity and is cash plus marketable securities divided by the current liabilities and is slightly greater than 1.0.

*Leverage ratios* are an indication of the company's overall debt burden. The *debt/total assets ratio* is determined by dividing the total debt by total assets expressed as a percentage. The industry average is 35 percent. *Debt/equity ratio* is another such ratio. The higher these ratios, the greater the financial risk since if an economic downturn did occur, it might be difficult for a company to meet the creditors' demands. The *times interest earned* is a measure of the extent to which profit could decline before a company is unable to pay interest charges. The ratio is calculated by dividing the *earnings before interest and taxes* (*EBIT*) by interest charges. The *fixed-charge coverage* is obtained by dividing the income available for meeting fixed charges by the fixed charges.

*Activity ratios* are a measure of how effectively a firm manages its assets. There are two inventory/turnover ratios in common use today. The *inventory/sales* ratio is found by dividing the inventory by the sales. Another method is to divide the cost of sales by inventory. The *average collection period* measures the number of days that customers' invoices remain unpaid. *Fixed assets* and *total assets turnover* indicate how well the fixed and total assets of the firm are being used.

*Profitability ratios* are used to determine how well income is being managed. The *gross profit margin* is found by dividing the gross profits by the net sales, expressed as a percentage. The *net operating margin* is equal to the earnings before interest and taxes divided by net sales. Another measure, the *profit margin on sales*, is calculated by dividing the net profit after taxes by net sales. The *return on total assets* ratio is the net profit after taxes divided by the total assets expressed as a percentage. The *return on equity* ratio is the net income after taxes and interest divided by stockholders' equity.

Table 9-6 shows the financial ratios for Tables 9-3 and 9-4. Table 9-7 is a summary of selected financial ratios and industry averages.

**TABLE 9-6 Financial Ratios for Tables 9-3 and 9-4**

| |
|---|
| Liquidity |
| Current ratio = \$391,200/\$201,500 = 1.94 |
| Cash ratio = \$391,200 – 149,000/\$201,500 = 1.20 |
| Leverage |
| Debt/assets ratio = [(\$448,100 – 201,500)/\$705,700] × 100 = 35% |
| Times interest earned = \$74,500 – 22,000/\$22,000 = 4.39 |
| Fixed-charge coverage = \$86,500/\$22,000 = 3.93 |
| Activity |
| Inventory turnover = \$932,000/\$149,000 = 6.25 |
| Average collection period = \$135,000/(\$932,000/365) = 52.8 days |
| Fixed-assets turnover = \$932,000/\$438,000 = 2.13 |
| Total-assets turnover = \$932,000/\$705,700 = 1.32 |
| Profitability |
| Gross profit margin = [(\$932,000 – 692,000)/\$932,000] × 100 = 25.8% |
| Net operating margin = \$74,500/\$932,000 × 100 = 7.99% |
| Profit margin on sales = \$50,000/\$932,000 × 100 = 5.36% |
| Return on net worth (return on equity) = [\$50,000/(\$705,700 – 448,100)] × 100 = 19.4% |
| Return on total assets = (\$50,000/\$705,700) × 100 = 7.09% |

## RELATIONSHIP BETWEEN BALANCE SHEETS AND INCOME STATEMENTS

There is a relationship between these two documents because information obtained from each is used to calculate the returns on assets and equity. Figure 9-1 is an operating profitability tree for a fictitious company and contains the fixed and variable expenses as reported on internal company reports, such as the manufacturing expense sheet. Figure 9-2 is a financial family tree for the same company depicting the relationship between values in the income statement and the balance sheet.

## FINANCING ASSETS BY DEBT AND/OR EQUITY

The various options for obtaining funds to finance new projects are not a simple matter. Significant factors such as the state of the economy, inflation, a company's present indebtedness, and the cost of capital will affect the decision. Should a company incur more long-term debt, or should it seek new venture capital from equity sources? A simple yes or no answer will not suffice because the financial decision is complex. One consideration is the company's position with respect to leverage. If a company has a large proportion of its debt in bonds and preferred stock, the common stock is highly leveraged. Should the earnings decline, say, by 10 percent, the dividends available to common stockholders might be wiped out. The company also might not be able to cover the interest on its bonds without dipping into the accumulated earnings. A high debt/equity ratio illustrates the fundamental weakness of companies with a large amount of debt. When low-interest financing is available, such as for large government projects, the return-on-equity evaluations are used. Such leveraging is tantamount to transferring money from one pocket to another; or, to

**TABLE 9-7 Selected Financial Ratios**

| Item | Equation for calculation | Industry average |
|---|---|---|
| Liquidity | | |
| Current ratio | Current assets/current liabilities | 1.5–2.0 |
| Cash ratio | Current assets – inventory/current liabilities | 1.0–1.5 |
| Leverage | | |
| Debt to total assets | Total debt/total assets | 30–40% |
| Times interest earned | Profit before taxes plus interest charges/interest charges | 7.0–8.0 |
| Fixed-charge coverage | Income available for meeting fixed charges/fixed charges | 6.0 |
| Activity | | |
| Inventory turnover | Sales or revenue/inventory | 7.0 |
| Average collection period | Receivables/sales per day | 40–60 days |
| Fixed assets turnover | Sales/fixed assets | 2–4 |
| Total assets turnover | Sales/total assets | 1–2 |
| Profitability | | |
| Gross profit margin | Net sales – cost of goods sold/sales | 25–40% |
| Net operating margin | Net operating profit before taxes/sales | 10–15% |
| Profit margin on sales | Net profit after taxes/sales | 5–8% |
| Return on net worth (return on equity) | Net profit after taxes/net worth | 15% |
| Return on total assets | Net profit after taxes/total assets | 7–10% |

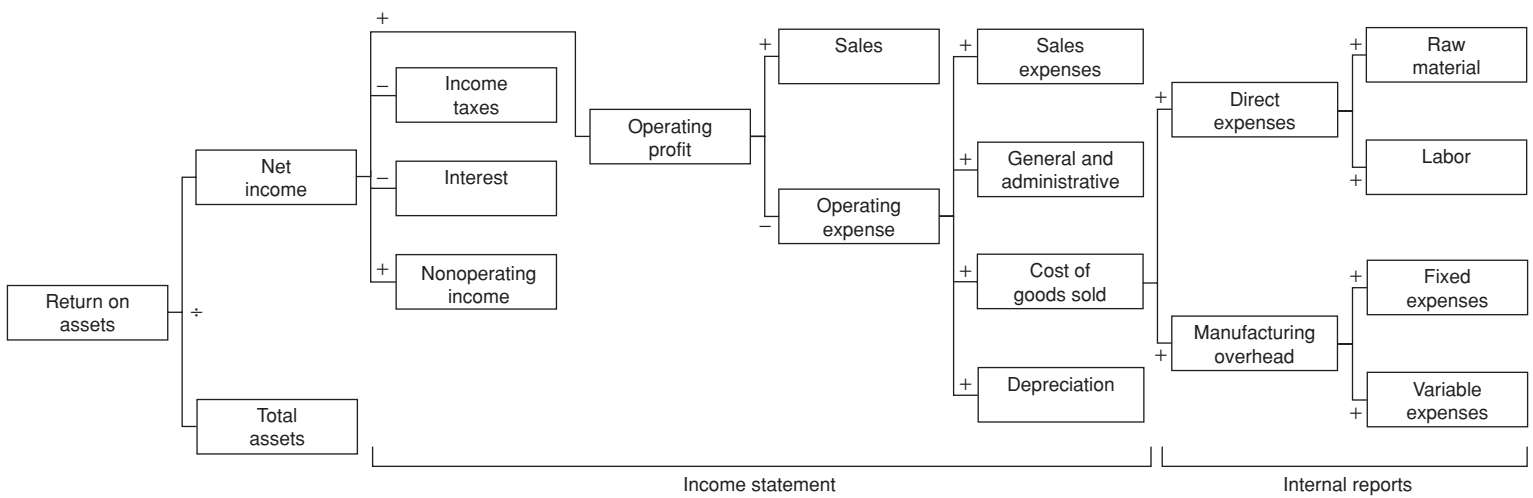

**FIG. 9-1** Operating profitability tree. (*Source: Adapted from Couper, 2003.*)

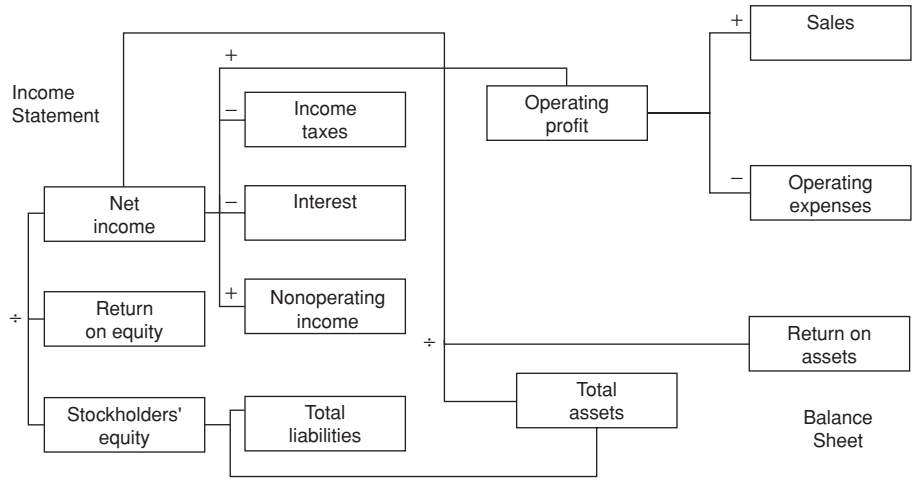

**FIG. 9-2** Financial family tree. (*Source: Adapted from Couper, 2003.*)

put it another way, a company may find itself borrowing from itself. In the chemical process industries, debt/equity ratios of 0.3 to 0.5 are common for industries that are capital-intensive (Couper et al., 2001). Much has been written on the strategies of financing a corporate venture. The correct strategy has to be evaluated from the standpoint of what is best for the company. It must maintain a debt/equity ratio similar to those of successful companies in the same line of business.

## COST OF CAPITAL

The cost of capital is what it costs a company to borrow money from all sources, such as loans, bonds, and preferred and common stock. It is an important consideration in determining a company's minimum acceptable rate of return on an investment. A company must make more than the cost of capital to pay its debts and make a profit. From profits, a company pays dividends to the stockholders. If a company ignores the cost of capital to increase dividends to the stockholders, then management is not meeting its obligations to pay off outstanding debts.

A sample calculation of the after-tax weighted cost of capital is found in Table 9-8. Each debt item is divided by the total debt, and that result is multiplied by the after-tax yield to maturity that equals the after-tax weighted average cost of that debt item contributing to the cost of capital. The information to estimate the cost of capital may be obtained from the annual report, the 10K, or the 10Q reports.

**TABLE 9-8 Cost of Capital Illustration**

| Balance sheet 12/31/XX | Debt, $M | After-tax yield to maturity, % | After-tax weighted average cost, % |
|---|---|---|---|
| Long-term debt | | | |
| Revolving account | 5.0 | 4.5 | 0.02 |
| $4\frac{3}{8}$% debentures | 12.0 | 4.0 | 0.05 |
| $6\frac{1}{2}$% debentures | 3.4 | 4.7 | 0.02 |
| $6\frac{3}{4}$% debentures | 9.4 | 4.2 | 0.04 |
| $7\frac{1}{2}$% debentures | 74.5 | 4.2 | 0.30 |
| $9\frac{3}{8}$% loan | 125.0 | 4.4 | 0.53 |
| Other | 23.2 | 4.4 | 0.10 |
| Total long-term debt | 252.5 | | 1.06 |
| Deferred taxes | 67.7 | 0.0 | 0 |
| Reserves | 16.1 | 0.0 | 0 |
| Preferred stock | 50.0 | 8.6 | 0.42 |
| Shareholders' equity | 653.9 | 15.6 | 9.80 |
| Total debt | 1,040.2 | | 11.28 |

Each debt item in $M divided by the total debt times the after-tax yield to maturity equals the after-tax weighted average cost contributing to the cost of capital.

SOURCE: Private communication.

## WORKING CAPITAL

The accounting definition of *working capital* is total current assets minus total current liabilities. This information can be found from the balance sheet. Current assets consist chiefly of cash, marketable securities, accounts receivable, and inventories; current liabilities include accounts payable, short-term debts, and the part of the long-term debt currently due. The accounting definition is in terms of the entire company.

For economic evaluation purposes, another definition of working capital is used. It is the funds, in addition to the fixed capital, that a company must contribute to a project. It must be adequate to get the plant in operation and to meet subsequent obligations when they come due. Working capital is not a one-time investment that is known at the project inception, but varies with the sales level and other factors. The relationship of working capital to other project elements may be viewed in the cash flow model (see Fig. 9-9). Estimation of an adequate amount of working capital is found in the section "Capital Investment."

## INVENTORY EVALUATION AND COST CONTROL

Under ordinary circumstances, inventories are priced (valued) at some form of cost. The problem in valuating inventory lies in "determining what costs are to be identified with inventories in a given situation" (Nickerson, 1979).

Valuation of materials can be made by using the

- Cost of a specific lot
- Average cost
- Standard cost

Under "cost of a specific lot," those lots to be valuated must be identified by referring to related invoices. Many companies use the average cost for valuating inventories. The average used should be weighted by the quantities purchased rather than by an average purchase price. Average cost method tends to spread the effects of short-run price changes and has a tendency to level out profits in those industries that use raw materials whose prices are volatile. For many manufacturing companies, inventory valuation is an important

consideration varying in degree of importance. Inventories that are large are subject to significant fluctuations from time to time in size and mix and in prices, costs, and values.

Materials are valuated in accordance with their acquisition. Some companies use the first-in, first-out (FIFO) basis. Materials are used in order of their acquisition to minimize losses from deterioration. Another method is last-in, first-out (LIFO) in which materials coming in are the first to leave storage for use. The method used depends on a number of factors. Accounting texts discuss the pros and cons of each method, often giving numerical examples. Some items to consider are income tax considerations and cash flow that motivate management to adopt conservative valuation policies. Tax savings may accrue using one method compared to the other, but they may not be permanent. Whatever method is selected, consistency is important so that comparability of reported figures may be maintained from one time period to another. It is management's responsibility to make the decision regarding the method used. In some countries, government regulations control the method to be used. There are several computer software programs that permit the user to organize, store, search, and manage inventory from a desktop computer.

### BUDGETS AND COST CONTROL

A budget is an objective expressed in monetary terms for planning and controlling the resources of a company. Budgeted numbers are objectives, not achievements. A comparison of actual expenses with budgeted (cost standards) figures is used for control at the company, plant, departmental, or project level. A continuing record of performance should be maintained to provide the data for preparing future budgets (Nickerson, 1979). Often when a company compares actual results with cost standards or budgeted figures, a need for improving operations will surface. For example, if repairs to equipment continuously exceed the budgeted amount, perhaps it is time to consider replacement of that older equipment with a newer, more efficient model. Budgets are usually developed for a 1-year period; however, budgets for various time frames are frequently prepared. For example, in planning future operations, an intermediate time period of, say, 5 years may be appropriate, or for long-range planning the time period selected may be 10 years.

A cost control system is used

- To provide early warning of uneconomical or excessive costs in operations
- To provide relevant feedback to the personnel responsible for developing budgets
- To develop cost standards
- To promote a sense of cost consciousness
- To summarize progress

Budgetary models based upon mathematical equations are available to determine the effect of changes in variables. There are numerous sources extant in the literature for these models.

## CAPITAL COST ESTIMATION

### TOTAL CAPITAL INVESTMENT

The *total capital investment* includes funds required to purchase land, design and purchase equipment, structures, and buildings as well as to bring the facility into operation (Couper, 2003). The following is a list of items constituting the total capital investment:

Land
Fixed capital investment
Offsite capital
Allocated capital
Working capital
Start-up expenses
Other capital items (interest on borrowed funds prior to start-up; catalysts and chemicals; patents, licenses, and royalties; etc.)

**Land** Land is often acquired by a company some time prior to the building of a manufacturing facility. When a project is committed to be built on this land, the value of the land becomes part of that facility's capital investment.

**Fixed Capital Investment** When a firm considers the manufacture of a product, a capital cost estimate is prepared. These estimates are required for a variety of reasons such as feasibility studies, the selection of alternative processes or equipment, etc., to provide information for planning capital appropriations or to enable a contractor to bid on a project. Included in the fixed capital investment is the cost of purchasing, delivery, and installation of manufacturing equipment, piping, automatic controls, buildings, structures, insulation, painting, site preparation, environmental control equipment, and engineering and construction costs. The fixed capital investment is significant in developing the economics of a process since this figure is used in estimating operating expenses and calculating depreciation, cash flow, and project profitability. The estimating method used should be the best, most accurate means consistent with the time and money available to prepare the estimate.

***Classification of Estimates*** There are two broad classes of estimates: grass roots and battery limits. Grass-roots estimates include the entire facility, starting with site preparation, buildings and structures, processing equipment, utilities, services, storage facilities, railroad yards, docks, and plant roads. A battery-limits estimate is one in which an imaginary boundary is drawn around the proposed facility to be estimated. It is assumed that all materials, utilities, and services are available in the quality and quantity required to manufacture a product. Only costs within the boundary are estimated.

***Quality of Estimates*** Capital cost estimation is more art than science. An estimator must use considerable judgment in preparing the estimate, and as the estimator gains experience, the accuracy of the estimate improves. There are several types of fixed capital cost estimates:

- *Order-of-magnitude (ratio estimate).* Rule-of-thumb methods based on cost data from similar-type plants are used. The probable accuracy is –30 percent to +50 percent.
- *Study estimate (factored estimate).* This type requires knowledge of preliminary material and energy balances as well as major equipment items. It has a probable accuracy of –25 to +30 percent.
- *Preliminary estimate (budget authorization estimate).* More details about the process and equipment, e.g., design of major plant items, are required. The accuracy is probably –20 to +25 percent.
- *Definitive estimate (project control estimate).* The data needed for this type of estimate are more detailed than those for a preliminary estimate and include the preparation of specifications and drawings. The probable accuracy is –10 to +15 percent.
- *Detailed estimate (firm estimate).* Complete specifications, drawings, and site surveys for the plant construction are required, and the estimate has an accuracy of –5 to +10 percent.

Detailed information requirements for each type of estimate may be found in Fig. 9-3.

In periods of high inflation, the results of various estimates and accuracy may overlap. At such times, four categories may be more suitable, namely, study, preliminary, definitive, and detailed categories. At present, some companies employing the *front-end loading* (*FEL*) process for project definition and execution use three categories:

| Project stage | Accuracy |
|---|---|
| Conceptual | ±/40% |
| Feasibility | ±/25% |
| Definition | ±/10% |

For more information on the FEL process, see "Capital Project Execution and Analysis" near the end of Sec 9.

***Scope*** The scope is a document that defines a project. It contains words, drawings, and costs. A scope should answer the following questions clearly:

What product is being manufactured?
How much is being produced?

**FIG. 9-3** Information guide for preparing estimates. (*Source*: Perry's Chemical Engineers' Handbook, *5th ed., McGraw-Hill, New York, 1973.*)

What is the quality of the product?
Where is the product to be produced?
What is the quality of the estimate?
What is the basis for the estimate?
What are the knowns and unknowns with respect to the project?

Before an estimate can be prepared, it is essential to prepare a scope. It may be as simple as a single page, such as for an order-of-magnitude estimate, or several large manuals, for a detailed estimate. As the project moves forward from inception to a detailed estimate, the scope must be revised and updated to provide the latest information. Changes during the progress of a project are inevitable, but a well-defined scope prepared in advance can help minimize costly changes. If a scope is properly defined, the following results:

An understanding between those who prepared the scope (engineering) and those who accept it (management)
A document that indicates clearly what is provided in terms of technology, quality, schedule, and cost
A basis in enough detail to be used in controlling the project and its costs to permit proper evaluation of any proposed changes
A device to permit subsequent evaluation of the performance compared to the intended performance
A document to control the detailed estimate for the final design, construction, and design

***Equipment Cost Data*** The foundation of a fixed capital investment estimate is the equipment cost data. From this information, through the application of factors or percentages based upon the estimator's experience, the fixed capital investment is developed.

These cost data are reported as purchased, delivered, or installed cost. Purchased cost is the price of the equipment FOB at the manufacturer's plant, whereas delivered cost is the purchased price plus the delivery charge to the purchaser's plant FOB. Installed cost means the equipment has been purchased, delivered, uncrated, and placed on a foundation in the purchaser's operating department but does not include piping, electrical, instrumentation, insulation, etc., costs. Perhaps a better name might be *set-in-place* cost.

It is essential to have reliable cost data since the engineer producing the estimate starts with this information and develops the fixed capital cost estimate. The estimator must know the source of the data, the basis for the data, its date, potential errors, and the range over which the data apply. There are many sources of graphical equipment cost data in the literature, but some are old and the latest published data were in the early 1990s. There have been no significant cost data published recently. To obtain current cost data, one should solicit bids from vendors; however, it is essential to impress on the vendor that the information is to be used for preliminary estimates. A disadvantage of using vendor sources is that there is a chance of compromising proprietary information.

Cost-capacity plots of equipment indicate a straight-line relationship on a log-log plot. Figure 9-4 is an example of such a plot. A convenient method of presenting these data is in equation format:

$$C_2 = C_1\left(\frac{S_2}{S_1}\right)^n \tag{9-1}$$

where $C_1$ = cost of equipment of capacity $S_1$
$C_2$ = cost of equipment of capacity $S_2$

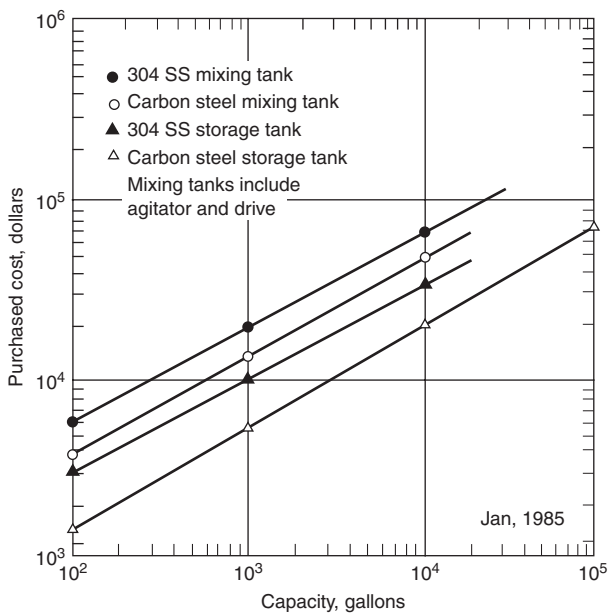

**FIG. 9-4** Cost-capacity plot.

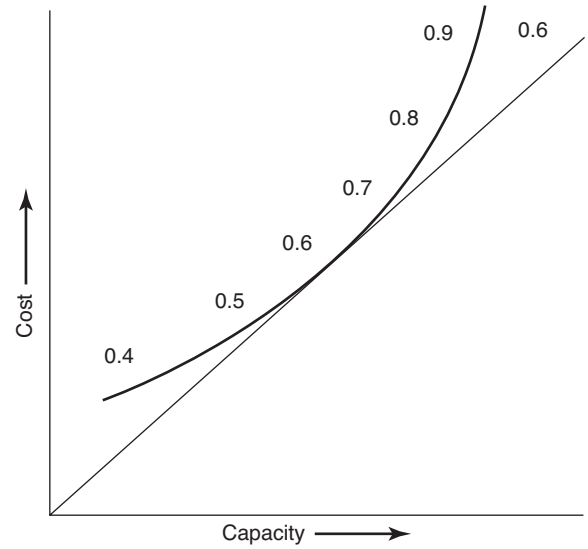

**FIG. 9-5** Variation of $n$ on cost-capacity plot.

$n$ = exponent that may vary between 0.4 and 1.2 depending on type of equipment

Equation (9-1) is known as the *six-tenths rule* since the average value for all equipment is about 0.6. D. S. Remer and L. H. Chai (*Chemical Engineering Progress*, August 1990, pp. 77–82) published an extensive list of six-tenths data. Figure 9-5 shows how the exponent may vary from 0.4 to 0.9 for a given equipment item. Data accuracy is the highest in the narrow, middle-range of capacity, but at either end of the plot, the error is great. These errors occur when one correlates cost data with one independent variable when more than one variable is necessary to represent the data, or when pressure, temperature, materials of construction, or design features vary considerably.

A convenient way to display cost-capacity data is by algorithms. They are readily adaptable for computerized cost estimation programs. Algorithm modifiers in equation format may be used to account for temperature, pressure, material of construction, equipment type, etc. Equation (9-2) is an example of obtaining the cost of a shell-and-tube heat exchanger by using such modifiers.

$$C_{\text{HE}} = KC_BF_DF_MF_P \tag{9-2}$$

where $C_{\text{HE}}$ = purchased equipment cost
$K$ = factor for cost index based upon a base year
$C_B$ = base cost of a carbon-steel floating-head exchanger, 150-psig design pressure
$F_D$ = design-type cost factor if different from that in $C_B$
$F_M$ = material-of-construction cost factor
$F_P$ = design pressure cost factor

Each cost factor is obtained from equations or tables from Couper, 2003, App. C, and have been updated to third-quarter 2002.

***Cost Indices*** Cost data are given as of a specific date and can be converted to more recent costs through the use of cost indices. In general, the indices are based upon constant dollars in a base year and actual dollars in a specific year. In this way, with the proper application of the index, the effect of inflation (or deflation) and price increases by multiplying the historical cost by the ratio of the present cost index divided by the index applicable in the historical year. Labor, material, construction costs, energy prices, and product prices all change at different rates. Most cost indices represent national averages, and local averages may vary considerably. Table 9-9 is a list of selected values of three cost indices of significance in the chemical process industries.

**TABLE 9-9 Selected Cost Indices**

| Year Base | M&S Index[1]a 1926 = 100 | CE index[1] 1957 – 1959 = 100 | Nelson-Farrar index[2] 1946 = 100 |
|---|---|---|---|
| 1990 | 915.1 | 357.6 | 1225.7 |
| 1992 | 943.1 | 358.2 | 1277.3 |
| 1994 | 964.2 | 368.1 | 1349.7 |
| 1996 | 1039.1 | 381.7 | 1418.9 |
| 1998 | 1061.9 | 389.5 | 1477.6 |
| 2000 | 1089.0 | 394.1 | 1542.7 |
| 2001 | 1093.9 | 394.3 | 1579.7 |
| 2002 | 1104.2 | 395.6 | 1642.2 |
| 2003 | 1123.6 | 402.0 | 1710.4 |
| 2004 (3Q) | 1124.7 | 457.4 | 1856.1 |

(1) From 1990 onward, the M&S and CE indices are from *Chemical Engineering* magazine.
(2) The Nelson-Farrar indices from 1990 onward are found in *Oil and Gas Journal.*
[a]Process industry average instead of all industry average.

The chemical engineering (CE) index and the Marshall and Swift index are found in each issue of the magazine *Chemical Engineering.* The *Oil and Gas Journal* reports the *Nelson-Farrar Refinery* indices in the first issue of each quarter. The base years selected for each index are generally periods of low inflation so that the index is stable. The derivation of base values is referred to in the respective publications.

A cost index is used to project a cost from a base year to another selected year. The following equation is used:

$$\text{Cost at } \Theta_2 = \text{cost at } \Theta_2 \left( \frac{\text{index at } \Theta_2}{\text{index at } \Theta_2} \right) \tag{9-3}$$

***Example 1: Use of Cost Index*** A centrifuge cost $95,000 in 1999. What is the cost of the same centrifuge in third quarter of 2004? Use the CE index.

*Solution:*

CE index in 1999 = 390.6

CE index in 3d quarter 2004 = 457.4

Cost in 2004 = cost in 1999 (CE index in 3d quarter 2004/ CE index in 1999)

$$= \$95{,}000\left(\frac{457.4}{390.6}\right) = \$111{,}200$$

***Inflation*** When costs are to be projected into the future due to inflation, it is a highly speculative exercise, but it is necessary for estimating investment costs, operating expenses, etc. Inflation is the increase in price of goods without a corresponding increase in productivity. A method for estimating an inflated cost is

$$C_i = (1 + f_1)\,(1 + f_2)\,(1 + f_3)\,C_P \tag{9-4}$$

where $C_i$ = inflated cost
$f_1$ = inflation rate the first year
$f_2$ = inflation rate the second year
$f_3$ = inflation rate the third year
$C_P$ = cost in a base year

The assumed inflation factors $f$ are obtained from federal economic reports, financial sources such as banks and investment houses, and news media. These factors must be reviewed periodically to update estimates.

***Example 2: Inflation*** A dryer today costs $475,000. The projected inflation rates for the next 3 years are 3, 4.2, and 4.7 percent. Calculate the projected cost in 3 years.

*Solution:*

$$C_i = (1 + f_1)\,(1 + f_2)\,(1 + f_3)\,C_P$$
$$= (1.030)\,(1.042)\,(1.047)\,(\$475{,}000) = \$533{,}800$$

***Equipment Sizing*** Before equipment costs can be obtained, it is necessary to determine equipment size from material and energy balances. For preliminary estimates, rules of thumb may be used; but for definitive and detailed estimates, detailed equipment calculations must be made.

***Example 3: Equipment Sizing and Costing*** Oil at 490,000 lb/h is to be heated from 100 to 170°F with 145,000 lb/h of kerosene initially at 390°F from another section of a plant. The oil enters at 20 psig and the kerosene at 25 psig. The physical properties are

Oil—0.85 sp gr, 3.5 cP at 135°F, 0.49 sp ht

Kerosene—0.82 sp gr, 0.45 cP, 0.61 sp ht

Estimate the cost of an all-carbon-steel exchanger in late 2004. Assume a counterflow shell-and-tube exchanger.

*Solution:*

Energy required to heat oil stream (490,000)(0.49)(170 – 100) = 16,807,000 Btu/h

$$\text{Exit kerosene temperature } T = 390 - \left(\frac{490{,}000}{145{,}000}\right)\left(\frac{0.49}{0.61}\right)(170 - 100)$$

$$= 200^\circ\text{F}$$

$$\text{LMTD} = \frac{220 - 100}{\ln 2.2} = 152^\circ F$$

Calculate the exchanger efficiency factor, *F.*

$$P = \frac{170 - 100}{390 - 100} = 0.241$$

$$R = \frac{390 - 200}{170 - 100} = 2.71$$

From Perry $F = 0.88$. Since the factor must be greater than 0.75, the exchanger is satisfactory. Therefore, $\Delta T = (F)(\text{LMTD}) = (0.88)(152) = 134^\circ$F.

Assume $U_D = 50$ Btu/(h·ft²·°F).

$$Q = U_D A\,\Delta T = 16{,}800{,}000 = (50)(A)(134)$$
$$A = 2510 \text{ ft}^2$$

Use the cost algorithm cited above.

$C_B = \exp\,[8.821 - 0.30863 \ln A + 0.0681(\ln A)^2]$

$= \exp\,[8.821 - 0.30863(7.83) + 0.0681(61.3)] = \$39{,}300$ base cost

$F_D = 1.0$ $F_M =$ for cs/cs material = 1.0

$F_P = 1.00$ since this exchange is operating below 4 bar

$$K = 1.218\ (\text{CE index 4th qtr 2004/CE index 1st qtr 2003}) = 1.218\left(\frac{463}{406}\right)$$

$= 1.389$

Therefore, $C_{\text{HE}} = KC_BF_DF_MF_P = (1.389)(39{,}300)(1.0)(1.0)(1.0) = \$54{,}600$.

### Estimation of Fixed Capital Investment

***Order-of-Magnitude Methods*** The **ratio method** will give the fixed capital investment per gross annual sales; however, most of these data are from the 1960s, and no recent data have been published. The ratio above is called the *capital ratio,* often used by financial analysts. The reciprocal of the capital ratio is the *turnover ratio* that for various businesses ranges from 4 to 0.3. The chemical industry has an average of about 0.4 to 0.5. The ratio method of obtaining fixed capital investment is rapid but suitable only for order-of-magnitude estimates.

The **exponential method** may be used to obtain a rapid capital cost for a plant based upon existing company data or from published sources such as those of D. S. Remer and L. H. Chai, *Chemical Engineering,*

April 1990, pp. 138–175. In the method known as the *seven-tenths rule,* the cost-capacity data for process plants may be correlated by a logarithmic plot similar to the six-tenths plot for equipment. Remer and Chai compiled exponents for a variety of processes and found that the exponents ranged from 0.6 to 0.8. When the data are used to obtain a capital cost for a different-size plant, the estimated capital must be for the same process.

The equation is

$$\text{Cost of plant B} = \text{cost of plant A}\left(\frac{\text{capacity of plant B}}{\text{capacity of plant A}}\right)^{0.7} \quad (9\text{-}5)$$

Cost indices may be used to correct costs for time changes.

***Example 4: Seven-Tenths Rule*** A company is considering the manufacture of 150,000 tons annually of ethylene oxide by the direct oxidation of ethylene. According to Remer and Chai (1990), the cost capacity exponent for such a plant is 0.67. A subsidiary of the company built a 100,000-ton annual capacity plant for $70 million fixed capital investment in 1996. Using the seven-tenths rule, estimate the cost of the proposed new facility in the third quarter 2004.

*Solution:*

$$\text{Cost}_{150} = \text{Cost}_{100}\left(\frac{\text{Cap}_{150}}{\text{Cap}_{100}}\right)^{0.67}\left(\frac{\text{CE index 3Q 2004}}{\text{CE index 1996}}\right)$$

$$= (\$70{,}000{,}000)\left(\frac{150{,}000}{100{,}000}\right)^{0.67}\left(\frac{457.4}{381.7}\right) = \$110{,}000{,}000$$

***Study Method*** The single-factor method begins with collecting the delivered cost of various items of equipment and applying one factor to obtain the battery-limits (BL) fixed capital (FC) investment or total capital investment as follows:

$$(C_{FC})_{BL} = f\,\Sigma(C_{EQ})_{DEL} \quad (9\text{-}6)$$

where $(C_{FC})_{BL}$ = battery-limits fixed capital investment or total capital investment
$(C_{EQ})_{DEL}$ = delivered equipment costs

The single factors include piping, automatic controls, insulation, painting, electrical work, engineering costs, etc. (Couper, 2003). Table 9-10 shows the Lang factors for various types of processing plants. The boundaries between the classifications are not clear-cut, and considerable judgment is required in the selection of the appropriate factors.

***Preliminary Estimate Methods*** A refinement of the Lang factor method is the Hand method. The Hand factors are found in Table 9-11. Equipment is grouped in categories, such as heat exchangers and pumps, and then a factor is applied to each group to obtain the installed cost; finally the groups are summed to give the battery-limits installed cost. Wroth compiled a more detailed list of installation factors; a selection of these can be found in Table 9-12. The Lang and Hand methods start with purchased equipment costs whereas the Wroth method begins with delivered equipment costs, so delivery charges must be included in the Lang and Hand methods. At best the Lang and Hand methods will yield study quality estimates, and the Wroth method might yield a preliminary quality estimate.

***Example 5: Fixed Capital Investment Using the Lang, Hand, and Wroth Methods*** The following is a list of the purchased equipment costs for a proposed processing unit:

| | |
|---|---|
| Heat exchangers | $620,000 |
| Distillation towers and internals | 975,000 |
| Receivers | 320,000 |
| Accumulator drum | 125,000 |
| Pumps and motors | 220,000 |
| Automatic controls | 275,000 |
| Miscellaneous equipment | 150,000 |

Assume delivery charges are 5 percent of the purchased price. Estimate the fixed capital investment 2 years into the future, using the Lang, Hand, and Wroth methods. The inflation rates are 3.5 percent for the first year and 4.0 percent for the second.

*Solution:*

| Equipment | Purchased equipment cost | Delivered equipment cost |
|---|---|---|
| Heat exchangers | $620,000 | $651,000 |
| Distillation towers, internals | 975,000 | 1,024,000 |
| Receivers | 320,000 | 336,000 |
| Accumulator drum | 125,000 | 131,000 |
| Pumps and motors | 220,000 | 231,000 |
| Automatic controls | 275,000 | 289,000 |
| Miscellaneous equipment | 150,000 | 158,000 |
| Total | $2,685,000 | $2,820,000 |

*Lang method:* The Lang factor for a fluid processing unit starting with purchased equipment costs is 5.0. Therefore, fixed capital investment is $2,820,000 × 5.0 × 1.035 × 1.040 = $15,177,000.

*Hand method:* The Hand method begins with purchased equipment costs, and factors are applied from Table 9-11.

**TABLE 9-10 Lang Factors**

| Type of plant | Lang factors: Fixed capital investment | Lang factors: Total capital investment |
|---|---|---|
| Solid processing | 4.0 | 4.7 |
| Solid-fluid processing | 4.3 | 5.0 |
| Fluid processing | 5.0 | 6.0 |

Adapted from M. S. Peters, K. D. Timmerhaus, and R. West, *Plant Design and Economics for Chemical Engineers,* 5th ed., McGraw-Hill, New York, 2004.

**TABLE 9-11 Hand Factors**

| Equipment type | Factor |
|---|---|
| Fractionating columns | 4.0 |
| Pressure vessels | 4.0 |
| Heat exchangers | 3.5 |
| Fired heaters | 2.0 |
| Pumps | 4.0 |
| Compressors | 2.5 |
| Instruments | 4.0 |
| Miscellaneous equipment | 2.5 |

Adapted from W. E. Hand, *Petroleum Refiner,* September 1958, pp. 331–334.

**TABLE 9-12 Selected Wroth Factors**

| Equipment | Factor |
|---|---|
| Blender | 2.0 |
| Blowers and fans | 2.5 |
| Centrifuge | 2.0 |
| Compressors | |
| Centrifugal (motor-driven) | 2.0 |
| Centrifugal (steam-driven, including turbine) | 2.0 |
| Reciprocating (steam and gas) | 2.3 |
| Reciprocating (motor-driven less motor) | 2.3 |
| Ejectors, vacuum | 2.5 |
| Furnaces (packaged units) | 2.0 |
| Heat exchangers | 4.8 |
| Instruments | 4.1 |
| Motors, electric | 3.5 |
| Pumps | |
| Centrifugal (motor-driven less motor) | 7.0 |
| Centrifugal (steam-driven including turbine) | 6.5 |
| Positive-displacement (less motor) | 5.0 |
| Reactors (factor as appropriate, equivalent-type equipment) | — |
| Refrigeration (packaged units) | 2.5 |
| Tanks | |
| Process | 4.1 |
| Storage | 3.5 |
| Fabricated and field-erected 50,000+ gal | 2.0 |
| Towers (columns) | 4.0 |

Abstracted from W. F. Wroth, *Chemical Engineering,* October 17, 1960, p. 204.

Hand method:

| Equipment | Purchased equipment cost | Hand factor | Purchased equipment installed cost |
|---|---|---|---|
| Heat exchangers | $620,000 | 3.5 | $2,170,000 |
| Distillation towers, internals | 975,000 | 4.0 | 3,900,000 |
| Receivers | 320,000 | 2.5* | 800,000 |
| Accumulator drum | 125,000 | 2.5* | 313,000 |
| Pumps and motors | 220,000 | 4.0 | 880,000 |
| Automatic controls | 275,000 | 4.0 | 1,100,000 |
| Miscellaneous | 150,000 | 2.5 | 375,000 |
| TOTAL | $2,685,000 | | $9,538,000 |

The asterisk on the receivers and accumulators indicates that if these vessels are pressure vessels, a factor of 4.0 should be used instead of 2.5. The total purchased equipment installed is $9,538,000 for non–pressure vessels and the delivered cost is $10,015,000. Therefore, the fixed capital investment installed would be $10,015,000 × 1.035 × 1.040 = $10,780,000. Using pressure vessels increases the total purchased equipment cost $667,000; therefore, the fixed capital investment for this case including inflation would be $10,780,000 × 1.05 × 1.035 × 1.04 = $11,534,000.

Wroth method:

| Equipment | Delivered equipment cost | Wroth factor | Delivered equipment installed cost |
|---|---|---|---|
| Heat exchangers | $651,000 | 4.8 | $3,125,000 |
| Distillation towers, internals | 1,024,000 | 4.0 | 4,096,000 |
| Receivers | 336,000 | 3.5 | 1,176,000 |
| Accumulator drum | 131,000 | 3.5 | 459,000 |
| Pumps and motors | 231,000 | 7.0 | 1,617,000 |
| Automatic controls | 289,000 | 4.1 | 1,185,000 |
| Miscellaneous | 158,000 | 4.0 (assumed) | 632,000 |
| TOTAL | $2,820,000 | | $12,290,000 |

The total delivered installed equipment cost is the fixed capital investment and, corrected for 2 years of inflation, will be $12,290,000 × 1.035 × 1.040 = $13,229,000.

Therefore, the summary of the fixed capital investment by the various methods is

| | |
|---|---|
| Lang | $15,177,000 |
| Hand | 11,534,000 |
| Wroth | 13,229,000 |

Experience has shown that the fixed capital investment by the Lang method is generally higher than that of the other methods. Whatever figure is reported to management, it is advisable to state the potential accuracy of these methods.

Brown developed guidelines for the preparation of order-of-magnitude and study capital cost estimates based upon the Lang and Hand methods. Brown modified Lang and Hand methods for materials of construction, instrumentation, and location factors. He found that the modified Hand and Garrett module factor methods gave results within 3.5 percent.

Other multiple-factor methods that have been published in the past are those by C. E. Chilton, *Cost Estimation in the Process Industries,* McGraw-Hill, New York, 1960; M. S. Peters, K. D. Timmerhaus, and R. E. West, *Plant Design and Economics for Chemical Engineers,* 5th ed., McGraw-Hill, New York, 2003; C. A. Miller, *Chemical Engineering,* Sept. 13, 1965, pp. 226–236; and F. A. Holland, F. A. Watson, and V. K. Wilkinson, *Chem. Eng.,* Apr. 1, 1974, pp. 71–76. These methods produced preliminary quality estimates. Most companies have developed their own in-house multiple-factor methods for preliminary cost estimation.

Step-counting methods are based upon a number of processing steps or "functional units." The concept was first introduced by H. E. Wessel, *Chem. Eng.,* 1952, p. 209. Subsequently, R. D. Hill, *Petrol. Refin.,* **35**(8):106–110, August 1956; F. C. Zevnik and R. L. Buchanan, *Chem. Eng. Progress,* **59**(2):70–77, February 1963; and J. H. Taylor, *Eng. Process Econ.,* **2:**259–267, 1977, further developed the step-counting method.

A step or functional unit is a significant process step including all process equipment and ancillary equipment necessary for operating the unit. A functional unit may be a unit operation, unit process, or separation in which mass and energy are transferred. The sum of all functional units is the total fixed capital investment. Pumping and heat exchangers are considered as part of a functional unit. In-process storage is generally ignored except for raw materials, intermediates, or products. Difficulties are encountered in applying the method due to defining a step. This takes practice and experience. If equipment has been omitted from a step, the resulting estimate is seriously affected. These methods are reported to yield estimates of study quality or at best preliminary quality.

***Definitive Estimate Methods*** Modular methods are an extension of the multiple-factor methods and have been proposed by several authors. One of the most comprehensive methods and one of the earliest was that of K. M. Guthrie, *Chem. Eng.,* **76:**114–142, Mar. 24, 1969. It began with equipment FOB equipment costs, and through the use of factors listed in Table 9-13, the module material cost was obtained. Labor for erection and setting equipment was added to the material cost as well as indirect costs for freight, insurance, engineering, and field expenses to give a total module cost. Such items as contingencies, contractors' fees, auxiliaries, site development land, and industrial buildings were added if applicable. Since any plant consists of equipment modules, these are summed to give the total fixed capital investment. Unfortunately, the factors and data are old but the concept is useful. Garrett (1989) developed a similar method based upon a variety of equipment modules, starting with purchased equipment costs obtained from plots and applying factors for materials of construction, instrumentation, and plant location. The method provides for all supporting and connecting equipment to make the equipment installation operational. See Table 9-14. T. R. Brown, *Hydrocarbon Processing,* October 2000, pp. 93–100, made modifications to the Garrett method.

Another method, called the *discipline method*, mentioned by L. R. Dysert, *Cost Eng.* **45**(6), June 6, 2003, is similar to the models of

**TABLE 9-13 Guthrie Method Factors***

| Details | Exchangers | | | Vessels | | Pump and driver | Compressor and driver | Tanks |
|---|---|---|---|---|---|---|---|---|
| | Furnaces | Shell and tube | Air-cooled | Vertical | Horizontal | | | |
| FOB equipment | 1.00 | 1.00 | 1.00 | 1.00 | 1.00 | 1.00 | 1.00 | 1.00 |
| Piping | 0.18 | 0.46 | 0.18 | 0.61 | 0.42 | 0.30 | 0.21 | |
| Concrete | 0.10 | 0.05 | 0.02 | 0.10 | 0.06 | 0.04 | 0.12 | |
| Steel | | 0.03 | | 0.08 | | | | |
| Instruments | 0.04 | 0.10 | 0.05 | 0.12 | 0.06 | 0.03 | 0.08 | |

SOURCE: Private communication.

Guthrie and Garrett. It uses equipment factors to generate separate costs for each of the "disciplines" associated with the installation of equipment, such as installation labor, concrete, structural steel, and piping, to obtain direct field costs for each type of equipment, e.g., heat exchangers, towers, and reactors.

Modular methods, depending on the amount of detail provided, will yield preliminary quality estimates.

***Detailed Estimate Method*** For estimates in the detailed category, a code of account needs to be used to prevent oversight of certain significant items in the capital cost. See Table 9-15. Each item in the code is estimated and provides the capital cost estimate; then this estimate serves for cost control during the construction phase of a project.

**Comments on Significant Cost Items**

***Piping*** This cost includes the cost of the pipe, installation labor, valves, fittings, supports, and miscellaneous items necessary for complete installation of all pipes in the process. The accuracy of the estimates can be seriously in error by the improper application of estimating techniques to this component. Many pipe estimating methods are extant in the literature.

Two general methods have been used to estimate piping costs when detailed flow sheets are not available. One method is to use a percentage of the FOB equipment costs or a percentage of the fixed capital investment. Typical figures are 80 to 100 percent of the FOB equipment costs or 20 to 30 percent of the fixed capital investment. This method is used for preliminary estimates. Another group of methods such as the Dickson "N" method (R. A. Dickson, *Chem. Eng.*, **57:**123–135, Nov. 1947), estimating by weight, estimating by cost per joint, etc., requires a detailed piping takeoff from either PID or piping drawings with piping specifications, material costs, labor expenses, etc. These methods are used for definitive or detailed estimates where accuracy of 10 to 15 percent is required. The takeoff methods must be employed with great care and accuracy by an experienced engineer. A detailed breakdown by plant type for process piping costs is presented in Peters et al. (2003) and in *Perry's Chemical Engineers' Handbook*, 6th ed., 1984.

***Electrical*** This item consists of transformers, wiring, switching gear, as well as instrumentation and control wiring. The installed costs of the electrical items may be estimated as 20 to 40 percent of the delivered equipment costs or 5 to 10 percent of the fixed capital investment for preliminary estimates. As with piping estimation, the process design must be well along toward completion before detailed electrical takeoffs can be made.

***Buildings and Structures*** The cost of the erection of buildings and structures in a chemical process plant as well as the plumbing, heating and ventilation, and miscellaneous building service items may be estimated as 20 to 50 percent of delivered equipment costs or as 10 to 20 percent of the fixed capital investment for a preliminary estimate.

***Yards, Railroad Sidings, Roads, etc.*** This investment includes roads, railroad spurs, docks, and fences. A reasonable figure for preliminary estimates is 15 to 20 percent of the FOB equipment cost or 3 to 7 percent of the fixed capital investment for a preliminary estimate.

***Service Facilities*** For a process plant, utility services such as steam, water, electric power, fuel, compressed air, shop facilities, and a cafeteria require capital expenditures. The cost of these facilities lumped together may be 10 to 20 percent of the fixed capital investment for a preliminary estimate. (*Note:* Buildings, yards, and service facilities must be well defined to obtain a definitive or detailed estimate.)

***Environmental Control and Waste Disposal*** These items are treated as a separate expenditure and are difficult to estimate due to the variety and complexity of the process requirements. Pollution control equipment is generally included as part of the process design. Couper (2003) and Peters et al. (2003) mention that at present there are no general guidelines for estimating these expenditures.

**Computerized Cost Estimation** With the advent of powerful personal computers (PCs) and software packages, capital cost estimates advanced from large mainframe computers to the PCs. The reasons for using computer cost estimation and economic evaluation packages are time saved on repetitive calculations and reduction in mathematical errors. Numerous computer simulation software packages have been developed over the past two decades. Examples of such software are those produced by ASPEN, ICARUS, CHEMCAD, SUPERPRO, PRO II, HYSYS, etc.; but most do not contain cost estimation software packages. ICARUS developed a PC cost estimation and economic evaluation package called Questimate. This system built a cost estimate from design and equipment cost modules, bulk items, site construction, piping and ductwork, buildings, electrical equipment, instruments, etc., developing worker-hours for engineering and fieldwork costs. This process is similar to quantity takeoff methods to which unit costs are applied. A code of accounts is also provided.

ASPEN acquired ICARUS in 2000 and developed Process Evaluator based on Questimate that is used for conceptual design, known as front-end loading (FEL). More information on FEL and value-improving process (VIP) is found later in Sec. 9. Basic and detailed estimates are coupled with a business decision framework in ASPENTECH ICARUS 2000.

EstPro is a process plant cost estimation package for conceptual cost estimation for conceptual design only. It may be obtained from Gulf Publishing, Houston, Tex.

Many companies have developed their own factored estimates using computer spreadsheets based upon their in-house experience and cost database information that they have built from company project history. For detailed estimates, the job is outsourced to design-construction companies that have the staff to perform those estimates.

Whatever package is used, it is recommended that computer-generated costs be spot-checked for reasonable results using a hand-held calculator since errors do occur. Some commercial software companies will develop cost estimation databases in cooperation with a company for site-specific costs.

**Contingency** This is a provision for unforeseen events that experience has demonstrated are likely to occur. Contingencies are of two types: process and project contingency. In the former, there are uncertainties in

- Equipment and performance
- Integration of old and new process steps
- Scaling up to a large-scale plant size
- Accurate definition of certain process parameters, such as severity of process conditions, number of recycles, process blocks and equipment, multiphase streams, and unusual separations

No matter how much time and effort are spent preparing estimates, there is a chance of errors occurring due to

- Engineering errors and omissions
- Cost and labor rate changes
- Construction problems
- Estimating inaccuracies
- Miscellaneous "unforeseens"
- Weather-related problems
- Strikes by fabricators, transportation, and construction personnel

For preliminary estimates, a 15 to 20 percent project contingency should be applied if the process information is firm. As the quality of the estimate moves to definitive and detailed, the contingency value may be lowered to 10 to 15 percent and 5 to 10 percent, respectively. Experience has shown that the smaller the dollar value of the project, the higher the contingency should be.

**Offsite Capital** These facilities include all structures, equipment, and services that do not enter into the manufacture of a product but are important to the functioning of the plant. Such capital items might be steam-generating and electrical-generating and distribution facilities, well-water cooling tower, and pumping stations for water distribution, etc. Service capital might be auxiliary buildings, such as warehouses, service roads, railroad spurs, material storage, fire protection equipment, and security systems. For estimating purposes, the following percentages of the fixed capital investment might be used:

- Small modification of offsites, 1 to 5 percent
- Restructuring of offsites, 5 to 15 percent
- Major expansion of offsites, 15 to 45 percent
- Grass-roots plants, 45 to 150 percent

**Allocated Capital** This is capital that is shared due to its proportionate share use in a new facility. Such items include intermediate chemicals, utilities, services and sales, administration, research, and engineering overhead.

**Working Capital** Working capital is the funds necessary to conduct day-to-day company business. These are funds required to purchase raw materials, supplies, etc. It is continuously liquidated and rejuvenated from the sale of products or services. If an adequate amount of working capital is available, management has the necessary flexibility to cover expenses in case of strikes, delays, fires, etc. Several methods are available for estimating an adequate amount of working capital. They may be broadly classified into percentage and inventory methods. The percentage methods are satisfactory for study and preliminary capital estimates. The percentage methods are of two types: percentage based on capital investment and percentage based upon sales. In the former method, 15 to 25 percent of the total capital investment may be sufficient for preliminary estimates. In the case of certain specialty chemicals where the raw materials are expensive, it is perhaps better to use the percentage of sales method. Such chemicals as flavors, fragrances, perfumes, etc., are in this category. Experience has shown that 15 to 45 percent of sales has been used with 30 to 35 percent being a reasonable average value.

**Start-up Expenses** Start-up expenses are defined as the total costs directly related to bringing a new manufacturing facility onstream. Start-up time is the time span between the end of construction and the beginning of normal operation. Normal operation is operation at a certain percentage of design capacity or a specified number of days of continuous operation or the ability to make product of a specified purity. Start-up costs are part of the total capital investment and include labor, materials, and overhead for design modifications or changes due to errors on the part of engineering, contractors, costs of tests, final alterations and adjustments. These items cannot be included as contingency because it is known that such work will be necessary before the project is completed. Experience has shown that start-up costs are a percentage of the battery-limits fixed capital investment of the order on average of 3 percent.

Depending on the tax laws in effect, not all start-up costs can be expensed and a portion must be capitalized. Start-up costs can reduce the after-tax earnings during the early years of a project because of a delay in the start-up of production causing a loss of earnings. Construction changes are items of capital cost, and production start-up costs are expensed as an operating expense.

**Other Capital Items** Paid-up royalties and licenses are considered part of the capital investment since these are replacements for capital to perform process research and development. The initial catalyst and chemical charge, especially for noble metal catalysts and/or in electrolytic processes, is a large amount. These materials are considered to have a life of 1 year. If funds must be borrowed for a new facility, then the interest on borrowed funds during the construction period is capitalized; otherwise, the interest is part of the operating expense.

# MANUFACTURING-OPERATING EXPENSES

The estimation of manufacturing expenses has received less attention in the open literature than the estimation of capital requirements. Operating expenses are estimated from proprietary company files. In this section, methods for estimating the elements that constitute operating expenses are presented. Operating expenses consist of the expense of manufacturing a product, packaging and shipping, as well as general overhead expense. These are described later in this section. Figure 9-6 shows an example of a typical manufacturing expense sheet.

## RAW MATERIAL EXPENSE

Estimates of the amount of raw material consumed can be obtained from the process material balance. Normally, the raw material expense is the largest expense item in the manufacture of a product. Since yields in a chemical reaction determine the quantity of raw materials consumed, assumed yields may be used to obtain approximate exploratory estimates if possible ranges are given. The prices of the raw materials are published in various trade journals that list material according to form, grade, method of delivery, unit of measure, and cost per unit. The *Chemical Marketing Reporter* is a typical source of these prices. The prices are generally higher than quotations from suppliers, and these latter should be used whenever possible. It may be possible for a company to negotiate the price of a raw material based upon large-quantity use on a long-term basis. With the amount of material used from the material balance and the price of the raw material, the following information can be obtained: annual material consumption, annual material expense, as well as the consumption and expense per unit of product.

Occasionally, by-products may be produced, and if there is a market for these materials, a credit can be given. By-products are treated in the same manner as raw materials and are entered into the manufacturing expense sheet as a credit. If by-products are intermediates for which no market exists, they may be credited to downstream or subsequent operations at a value equivalent to their value as a replacement, or no credit may be obtained.

## DIRECT EXPENSES

These are the expenses that are directly associated with the manufacture of a product, e.g., utilities, labor, and maintenance.

**Utilities** The utility requirements are obtained from the material and energy balances. Utilities include steam, electricity, cooling water, fuel, compressed air, and refrigeration. The current utility prices can be obtained from company plant accounting or from the plant utility supervisor. This person might be able to provide information concerning rate prices for the near future. As requirements increase, the unit cost declines. If large incremental amounts are required, e.g., electricity, it may be necessary to tie the company's utility line to a local utility as a floating source.

With the current energy demands increasing, the unit costs of all utilities are increasing. Any prices quoted need to be reviewed periodically to determine their effect on plant operations. A company utility supervisor is a good source of future price trends. Unfortunately, there are no shortcuts for estimating and projecting utility prices. Utilities are the third largest expense item in the manufacture of a product, behind raw materials and labor.

**Operating Labor** The most reliable method for estimating labor requirements is to prepare a table of shift, weekend, and vacation coverage. For round-the-clock operation of a continuous process, one operator per shift requires 4.2 operators, if it is assumed that 21 shifts cover the operation and each operator works five, 8-h shifts per week. For batch or semicontinuous operation, it is advisable to prepare a labor table, listing the number of tasks and the number of operators required per task, paying particular attention to primary processing steps such as filtration and distillation that may have several items of equipment per step.

Labor rates may be obtained from the union contract or from a company labor relation supervisor. This person will know the current labor rates and any potential labor rate increases in the near future. One should not forget shift differential and overtime charges. Once the number of operators per shift has been established, the annual labor expense and unit expense may be estimated. Wessel (*Chem. Eng.*, **59:**209–210, July 1952) developed a method for estimating labor requirements for various types of chemical processes in the United States. The equation is applicable for a production rate of 2 to 2000 tons/day (2000 lb/ton).

$$\log Y = -0.783 \log X + 1.252 + B \qquad (9\text{-}7)$$

where $Y$ = operating labor, operator h/ton per processing step
$X$ = plant capacity, tons/day
$B$ = constant depending upon type of process
+ 0.132 (for batch operations that have minimum labor requirements)
+ 0 (for operations with average labor requirements)
– 0.167 (for a well-instrumented continuous process)

A processing step is one in which a unit operation occurs; e.g., a filtration step might consist of a feed (precoat) tank, pump, filter, and receiver so a processing step may have several items of equipment. By using a flow sheet, the number of processing steps may be counted. The Wessel equation does not take into account changes in labor productivity, but this information can be obtained from each issue of *Chemical Engineering*. Labor productivity varies widely in various sections of this country but even more widely in foreign countries.

Ulrich (1984) developed a table for estimating labor requirements from flow sheets and drawings of the process. Consideration is given to the type and arrangement of equipment, multiplicity of units, and amount of process control equipment. This method is easier to use than the Wessel method and has been updated in a new edition of the original text.

**Supervision** The approximate expense for supervision of operations depends on process complexity, but 15 to 30 percent of the operating labor expense is reasonable.

**Payroll Charges** This item includes workers' compensation, social security premiums, unemployment taxes, paid vacations, holidays, and some part of health and dental insurance premiums. The figure has steadily declined from 1980 and now is 30 to 40 percent of operating labor plus supervision expenses.

**Maintenance** The maintenance expense consists of two components, namely, materials and labor, approximately 60 and 40 percent, respectively. Company records are the best information sources, however, a value of 6 to 10 percent of the fixed capital investment is a reasonable figure. Processes with a large amount of rotating equipment or that operate at extremes of temperature and/or pressure have higher maintenance requirements.

**Miscellaneous Direct Expenses** These items include operating supplies, clothing and laundry, laboratory expenses, royalties, environmental control expenses, etc.

| Item | Basis | Percentage |
|---|---|---|
| Operating supplies | Operating labor | 5–7 |
| Clothing and laundry | Operating labor | 10–15 |
| Laboratory expenses | Operating labor | 10–20 |
| Royalties and patents | Sales | 1–5 |

**Environmental Control Expense** Wastes from manufacturing operations must be disposed of in an environmentally acceptable manner. This direct expense is borne by each manufacturing department. Some companies have their own disposal facilities, or they may contract with a firm that handles the disposal operation. However the wastes are handled, there is an expense. Published data are found in the open literature, some of which have been published by Couper (2003).

**FIG. 9-6** (*Continued*)

## INDIRECT EXPENSES

These indirect expenses consist of two major items; depreciation and plant indirect expenses.

**Depreciation** The Internal Revenue Service allows a deduction for the "exhaustion, wear and tear and normal obsolescence of equipment used in the trade or business." (This topic is treated more fully later in this section.) Briefly, for manufacturing expense estimates, straight-line depreciation is used, and accelerated methods are employed for cash flow analysis and profitability calculations.

**Plant Indirect Expenses** These expenses cover a wide range of items such as property taxes, personal and property liability insurance premiums, fire protection, plant safety and security, maintenance of plant roads, yards and docks, plant personnel staff, and cafeteria expenses (if one is available). A quick estimate of these expenses based upon company records is on the order of 2 to 4 percent of the fixed capital investment. Hackney presented a method for estimating these expenses based upon a capital investment factor, and a labor factor, but the result is high.

## TOTAL MANUFACTURING EXPENSE

The total manufacturing expense for a product is the sum of the raw materials and direct and indirect expenses.

## PACKAGING AND SHIPPING EXPENSES

The packaging expense depends on how the product is sold. The package may vary from small containers to fiberpacks to leverpacks, or the product may be shipped via tank truck, tank car, or pipeline. Each product must be considered and the expense of the container included on a case-by-case basis. The shipping expense includes the in-plant movement to warehousing facilities. Product delivery expenses are difficult to estimate because products are shipped in various amounts to numerous destinations. Often these expenses come under the heading of freight allowed in the sale of a product.

## TOTAL PRODUCT EXPENSE

The sum of the total manufacturing expense and the packaging and in-plant shipping expense is the total product expense.

## GENERAL OVERHEAD EXPENSE

This expense is often separated from the manufacturing expenses. It includes the expense of maintaining sales offices throughout the country, staff engineering departments, and research and development facilities and administrative offices. All manufacturing departments are expected to share in these expenses so an appropriate charge is made for each product varying between 6 and 15 percent of the product's annual revenue. The wide range in percentage will vary depending on the amount of customer service required due to the nature of the product.

## TOTAL OPERATING EXPENSE

The sum of the total product expense and the general overhead expense is the total operating expense. This item ultimately becomes part of the operating expense on the income statement.

## RAPID MANUFACTURING EXPENSE ESTIMATION

Holland et al. (1953) developed an expression for estimating annual manufacturing expenses for production rates other than the base case based upon fixed capital investment, labor requirements, and utility expense.

$$A_1 = mC_{\text{fci}} + nc_L N_1 + pU_1 \tag{9-8}$$

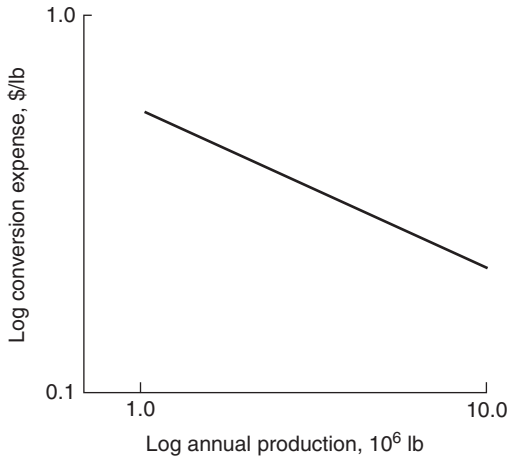

**FIG. 9-7** Annual conversion expense as a function of production rate.

where $C_{fci}$ = fixed capital investment, \$
$C_L$ = cost of labor, \$ per operator per shift
$N_1$ = annual labor requirements, operators/shift/year at rate 1
$U_1$ = annual utility expenses at production rate 1
$A_1$ = annual conversion expense at rate 1
$m, n, p$ = constants obtained from company records in consistent units

Equation (9-8) can be modified to include raw materials by adding a term $qM_1$, where $q$ = a constant and $M_1$ = annual raw material expense at rate 1.

## SCALE-UP OF MANUFACTURING EXPENSES

If it is desired to estimate the annual manufacturing expense at some rate other than a base case, the following modification may be made:

**TABLE 9-16 Typical Labor Requirements for Various Equipment**

| Equipment | Laborers per unit per shift |
|---|---|
| Blowers and compressor | 0.1–0.2 |
| Centrifuge | 0.25–0.50 |
| Crystallizer, mechanical | 0.16 |
| Dryers | |
| Rotary | 0.5 |
| Spray | 1.0 |
| Tray | 0.5 |
| Evaporator | 0.25 |
| Filters | |
| Vacuum | 0.125–0.25 |
| Plate and frame | 1.0 |
| Rotary and belt | 0.1 |
| Heat exchangers | 0.1 |
| Process vessels, towers (including auxiliary pumps and exchangers) | 0.2–0.5 |
| Reactors | |
| Batch | 1.0 |
| Continuous | 0.5 |

Adapted from G. D. Ulrich, *A Guide to Chemical Engineering Process Design and Economics*, Wiley, New York, 1984.

$$A_2 = mC_{fci}\left(\frac{R_2}{R_1}\right)^{0.7} + nC_LN_1\left(\frac{R_2}{R_1}\right)^{0.25} + pU_1\left(\frac{R_2}{R_1}\right) + qM_1\left(\frac{R_2}{R_1}\right) \quad (9\text{-}9)$$

where $A_2$ = annual manufacturing expense at production rate 2
$R_1$ = production rate 1
$R_2$ = production rate 2

Equation (9-9) may also be used to calculate data for a plot of manufacturing expense as a function of annual production rate, as shown in Fig. 9-7. Plots of these data show that the manufacturing expense per unit of production decreases with increasing plant size. The first term in Eq. (9-9) reflects the increase in the capital investment by using the 0.7 power for variations in production rates. Labor varies as the 0.25 power for continuous operations based upon experience. Utilities and raw materials are essentially in direct proportion to the amount of product manufactured, so the exponent of these terms is unity.

# FACTORS THAT AFFECT PROFITABILITY

## DEPRECIATION

According to the Internal Revenue Service (IRS), *depreciation* is defined as an allowance for the decrease in value of a property over a period of time due to wear and tear, deterioration, and normal obsolescence. The intent is to recover the cost of an asset over a period of time. It begins when a property is placed in a business or trade for the production of income and ends when the asset is retired from service or when the cost of the asset is fully recovered, whichever comes first. Depreciation and taxes are irrevocably tied together. It is essential to be aware of the latest tax law changes because the rules governing depreciation will probably change. Over the past 70 years, there have been many changes in the tax laws of which depreciation is a major component. Couper (2003) discussed the history and development of depreciation accounting. Accelerated depreciation was introduced in the early 1950s to stimulate investment and the economy. It allowed greater depreciation rates in the early years of a project when markets were not well established, manufacturing facilities were coming onstream, and expenses were high due to bringing the facility up to design capacity.

The current methods for determining annual depreciation charges are the *straight-line depreciation* and the *Modified Accelerated Cost Recovery System (MACRS).* In the straight-line method, the cost of an asset is distributed over its expected useful life such that the annual charge is

$$D = \frac{I + S}{n} \quad \text{\$ per year} \quad (9\text{-}10)$$

where $D$ = annual depreciation charge
$I$ = investment
$n$ = number of years
$S$ = salvage value

The MACRS went into effect in January 1987 (Couper, 2003) with six asset recovery periods: 3, 5, 7, 10, 15, and 20 years. It is based upon the declining-balance method. The equation for the declining-balance method is

$$V_e = V_i\,(1 - f) \quad (9\text{-}11)$$

where $V_i$ = value of asset at beginning of year
$V_e$ = value of asset at end of year
$f$ = declining-balance factor

For 150 percent declining balance $f = 1.5$, and for 200 percent $f = 2.0$. These factors are applied to the previous year's remaining balance. It is evident that the declining-balance method will not recover the asset that the IRS permits. Therefore, a combination of the declining-balance and straight-line methods forms the basis for the MACRS.

Class lives for selected industries are found in Couper (2003), but most chemical processing equipment falls in the 5-year category and petroleum processing equipment in the 7-year category. For those assets with class lives less than 10 years, a 200 percent declining-balance

**TABLE 9-17 Depreciation Class Lives and MACRS Recovery Periods**

| Asset class | Description of asset | Class life, yr | MACRS recovery period, yr |
|---|---|---|---|
| 00.12 | Information systems | 6 | 5 |
| 00.4 | Industrial steam and electric generation and/or distribution systems | 22 | 15 |
| 13.3 | Petroleum refining | 16 | 10 |
| 20.3 | Manufacture of vegetable oils and vegetable oil products | 18 | 10 |
| 20.5 | Manufacture of food and beverages | 4 | 3 |
| 22.4 | Manufacture of textile yams | 8 | 5 |
| 22.5 | Manufacture of nonwoven fabrics | 10 | 7 |
| 26.1 | Manufacture of pulp and paper | 13 | 7 |
| 28.0 | Manufacture of chemicals and allied products | 9.5 | 5 |
| 30.1 | Manufacture of rubber products | 14 | 7 |
| 30.2 | Manufacture of finished plastic products | 11 | 7 |
| 32.1 | Manufacture of glass products | 14 | 7 |
| 32.2 | Manufacture of cement | 20 | 15 |
| 32.3 | Manufacture of other stone and clay products | 15 | 7 |
| 33.2 | Manufacture of primary nonferrous metals | 14 | 7 |
| 32.4 | Manufacture of primary steel mill products | 15 | 7 |
| 49.223 | Substitute natural gas-coal gasification | 18 | 10 |
| 49.25 | Liquefied natural gas plant | 22 | 15 |

SOURCE: "How to Depreciate Property," Publication 946, Internal Revenue Service, U.S. Department of Treasury, Washington, 1999.

method with a switch to straight-line in the later years is used. The IRS adopted a half-year convention for both depreciation methods. Under this convention, a property placed in service is considered to be only one-half year irrespective of when during the year the property was placed in service. Table 9-17 is a listing of the class lives, and Table 9-18 contains factors with the half-year convention for both the MACRS and straight-line methods.

Depreciation is entered as an indirect expense on the manufacturing expense sheet based upon the straight-line method. However, when one is determining the after-tax cash flow, straight-line depreciation is removed from the manufacturing expense and the MACRS depreciation is entered. This is illustrated under the section on cash flow.

There are certain terms that apply to depreciation:

- *Depreciation reserve* is the accumulated depreciation at a specific time.
- *Book value* is the original investment minus the accumulated depreciation.
- *Service life* is the time period during which an asset is in service and is economically feasible.
- *Salvage value* is the net amount of money obtained from the sale of a used property over and above any charges involved in the removal and sale of the property.
- *Scrap value* implies that the asset has no further useful life and is sold for the amount of scrap material in it.
- *Economic life* is the most likely period of successful operation before a need arises for subsequent investment in additional equipment as the result of product or process obsolescence or equipment due to wear and tear.

## DEPLETION

Depletion is concerned with the diminution of natural resources. Generally depletion does not enter into process economic studies. Rules for determining the amount of depletion are found in the IRS Publication 535.

## AMORTIZATION

Amortization is the ratable deduction for the cost of an intangible property over its useful life, perhaps a 15-year life, via straight-line calculations. An example of an intangible property is a franchise, patent, trademark, etc. Two IRS publications, Form 4562 and Publication 535 (1999), established the regulations regarding amortization.

## TAXES

Corporations pay an income tax based upon gross earnings, as shown in Table 9-19. Most major corporations pay the federal tax rate of 34 percent on their annual gross earnings. In addition, some states have a stepwise corporate income tax rate. State income tax is deductible as an expense item before the calculation of the federal tax. If $T_s$ is the incremental tax rate and $T_f$ is the incremental federal tax, both expressed as decimals, then the combined incremental rate $T_c$ is

**TABLE 9-18 Depreciation Rates for Straight-Line and MACRS Methods**

| | Straight-line half-year convention | | | | | | MACRS* half-year convention | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Year | 3 | 5 | 7 | 10 | 15 | 20 | Year | 3 | 5 | 7 | 10 | 15 | 20 |

| 13 | | | | | 6.67 | 5.0 | 13 | | | | | 5.91 | 4.462 |
| 14 | | | | | 6.66 | 5.0 | 14 | | | | | 5.90 | 4.461 |
| 15 | | | | | 6.67 | 5.0 | 15 | | | | | 5.91 | 4.462 |
| 16 | | | | | 3.33 | 5.0 | 16 | | | | | 2.95 | 4.461 |
| 17 | | | | | | 5.0 | 17 | | | | | | 4.462 |
| 18 | | | | | | 5.0 | 18 | | | | | | 4.461 |
| 19 | | | | | | 5.0 | 19 | | | | | | 4.462 |
| 20 | | | | | | 5.0 | 20 | | | | | | 4.461 |
| 21 | | | | | | 2.5 | 21 | | | | | | 2.231 |

*General depreciation system. Declining-balance switching to straight-line. Recovery periods 3, 5, 7, 10, 15, and 20 years.
SOURCE: "How to Depreciate Property," Publication 946, Internal Revenue Service, U.S. Department of Treasury, Washington, 1999.

**TABLE 9-19 Corporate Federal Income Tax Rates**

| Taxable income | Tax rate, % |
|---|---|
| Annual gross earnings less than $50,000 | 15 |
| Annual gross earnings greater than $50,000 but not over $75,000 | 25 |
| Annual gross earnings greater than $75,000 plus 5% of gross earnings over $100,000 or $11,750, whichever is greater | 34 |
| Corporations with gross earnings of at least $335,000 pay a flat rate of 34% | |

SOURCE: U.S. Corporate Income Tax Return, Form 1120, Internal Revenue Service, U. S. Department of Treasury, Washington, 1999.

$$T_c = T_s + (1 - T_s)T_f \tag{9-12}$$

If the federal rate is 34 percent and the state rate is 7 percent, then the combined rate is

$$T_c = 0.07 + (1 - 0.07)(0.34) = 0.39$$

Therefore, the combined tax rate is 39 percent.

## TIME VALUE OF MONEY

In business, money is either borrowed or loaned. If money is loaned, there is the risk that it may not be repaid. From the lender's standpoint, the funds could have been invested somewhere else and made a profit; therefore, the interest charged for the loan is compensation for the forgone profit. The borrower may look upon this interest as the cost of renting money. The amount of interest charged depends on the scarcity of money, the size of the loan, the length of the loan period, the risk that the lender feels that the loan may not be repaid, and the prevailing economic conditions. Engineers involved in the presentation and/or the evaluation of an investment of funds in a venture, therefore, need to understand the time value of money and how it is applied in the evaluation of projects.

The amount of the loan is called the *principal P.* The longer the time for which the money is loaned, the greater the total amount of interest paid. The *future amount of the money F* is greater than *the principal or present worth P.* The relationship between $F$ and $P$ depends upon the type of interest used. Table 9-20 is a summary of the nomenclature used in time value of money calculations.

**Simple Interest** The relationship between $F$ and $P$ is $F = P(1 + in)$. The interest is charged on the original loan and not on the unpaid balance (Couper and Rader, 1986). The interest is paid at the end of each time interval. Although the simple interest concept still exists, it is seldom used in business.

**Discrete Compound Interest** In financial transactions, loans or deposits are made using compound interest. The interest is not withdrawn but is added to the principal for that time period. In the next time period, the interest is calculated upon the principal plus the interest from the preceding time period. This process illustrates compound interest. In equation format,

$$\text{Year 1:} \quad P + Pi = P(1 + i) = F_1$$

**TABLE 9-20 Interest Nomenclature**

| Symbol | Definition |
|---|---|
| $F$ | Future sum<br>Future value<br>Future worth<br>Future amount |
| $P$ | Principal<br>Present worth<br>Present value<br>Present amount |
| $A$ | End of period payment in a uniform series |

$$\text{Year 2:} \quad P + Pi(1 + i) = P(1 + i)^2 = F_2 \tag{9-13}$$

$$\text{Year } n\text{:} \quad P(1 + i)^n = F$$

An interest rate quoted on an annual basis is called *nominal interest.* However, interest may be payable on a semiannual, quarterly, monthly, or daily basis. To determine the amount compounded, the following equation applies:

$$F = P\left(1 + \frac{i}{m}\right)^{mn} \tag{9-14}$$

where $m$ = number of interest periods per year
$n$ = number of years
$i$ = nominal interest

Interest calculated for a given time period is known as *discrete compound interest*, with *discrete* referring to a discrete time period. Table 9-21 contains 5 and 6 percent discrete interest factors.

Examples of the use of discrete factors for various applications are found in Table 9-22, assuming that the present time is when the first funds are expended.

**Continuous Compound Interest** In some companies, namely, petroleum, petrochemical, and chemical companies, money transactions occur hourly or daily, or essentially continuously. The receipts from sales and services are invested immediately upon receipt. The interest on this cash flow is continuously compounded. To use continuous compounding when evaluating projects or investments, one assumes that cash flows continuously.

In continuous compounding, the year is divided into an infinite number of periods. Mathematically, the limit of the interest term is

$$\lim_{n \to \infty}\left(1 + \frac{r}{m}\right)^{mn} = e^{rn} \tag{9-15}$$

where $n$ = number of years
$m$ = number of interest periods per year
$r$ = nominal interest rate
$e$ = base for naperian logarithms

The numerical difference between discrete compound interest and continuous compound interest is small, but when large sums of money are involved, the difference may be significant. Table 9-23 is an abbreviated continuous interest table, assuming that time zero is when start-up occurs. A summary of the equations for discrete compound and continuous compound interest is found in Table 9-24.

**Compounding-Discounting** When money is moved forward in time from the present to a future time, the process is called *compounding.* The effect of compounding is that the total amount of money increases with time due to interest. *Discounting* is the reverse process, i.e., a sum of money moved backward in time. Figure 9-8 is a

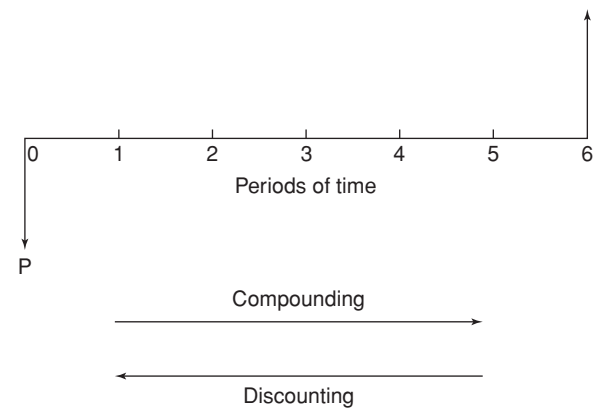

**FIG. 9-8** Compounding-discounting diagram.

*Factors presented for two interest rates only. By using the appropriate formulas, values for other interest rates may be calculated.

**TABLE 9-22 Examples of the Use of Compound Interest Table**

*Given:* \$2500 is invested now at 5 percent.
*Required:* Accumulated value in 10 years (i.e., the amount of a given principal).

*Solution:*

$$F = P(1+i)^n = \$2500 \times 1.05^{10}$$
$$\text{Compound-amount factor} = (1+i)^n = 1.05^{10} = 1.629$$
$$F = \$2500 \times 1.629 = \$4062.50$$

*Given:* \$19,500 will be required in 5 years to replace equipment now in use.
*Required:* With interest available at 3 percent, what sum must be deposited in the bank at present to provide the required capital (i.e., the principal which will amount to a given sum)?

*Solution:*

$$P = F\frac{1}{(1+i)^n} = \$19{,}500\,\frac{1}{1.03^5}$$
$$\text{Present-worth factor} = 1/(1+i)^n = 1/1.03^5 = 0.8626$$
$$P = \$19{,}500 \times 0.8626 = \$16{,}821$$

*Given:* \$50,000 will be required in 10 years to purchase equipment.
*Required:* With interest available at 4 percent, what sum must be deposited each year to provide the required capital (i.e., the annuity which will amount to a given fund)?

*Solution:*

$$A = F\frac{i}{(1+i)^n - 1} = \$50{,}000\,\frac{0.04}{1.04^{10} - 1}$$
$$\text{Sinking-fund factor} = \frac{i}{(1+i)^n - 1} = \frac{0.04}{1.04^{10} - 1} = 0.08329$$
$$A = \$50{,}000 \times 0.08329 = \$4{,}164$$

*Given:* \$20,000 is invested at 10 percent interest.
*Required:* Annual sum that can be withdrawn over a 20-year period (i.e., the annuity provided by a given capital).

*Solution:*

$$A = P\frac{i(1+i)^n}{(1+i)^n - 1} = \$20{,}000\,\frac{0.10 \times 1.10^{20}}{1.10^{20} - 1}$$
$$\text{Capital-recovery factor} = \frac{i(1+i)^n}{(1+i)^n - 1} = \frac{0.10 \times 1.10^{20}}{1.10^{20} - 1} = 0.11746$$
$$A = \$20{,}000 \times 0.11746 = \$2349.20$$

*Given:* \$500 is invested each year at 8 percent interest.
*Required:* Accumulated value in 15 years (i.e., amount of an annuity).

*Solution:*

$$F = A\frac{(1+i)^n - 1}{i} = \$500\,\frac{1.08^{15} - 1}{0.08}$$
$$\text{Compound-amount factor} = \frac{(1-i)^n - 1}{i} = \frac{1.08^{15} - 1}{0.08} = 27.152$$
$$F = \$500 \times 27.152 = \$13{,}576$$

*Given:* \$8000 is required annually for 25 years.
*Required:* Sum that must be deposited now at 6 percent interest.

*Solution:*

$$P = A\frac{(1+i)^n - 1}{i(1+i)^n} = \$8000\,\frac{1.06^{25} - 1}{0.06 \times 1.06^{25}}$$
$$\text{Present-worth factor} = \frac{(1+i)^n - 1}{i(1+i)^n} = \frac{1.06^{25} - 1}{0.06 \times 1.06^{25}} = 12.783$$
$$P = \$8000 \times 12.783 = \$102{,}264$$

sketch of this process. The time periods are years, and the interest is normally on an annual basis using end-of-year money flows. The longer the time before money is received, the less it is worth at present.

**Effective Interest Rates** When an interest rate is quoted, it is *nominal* interest that is stated. These quotes are on an annual basis, however, when compounding occurs that is not the actual or effective interest. According to government regulations, an effective rate APY must be stated also. The effective interest is calculated by

$$i_{\text{eff}} = \left(1 + \frac{i}{m}\right)^{(m)(1)} - 1 \tag{9-16}$$

The time period for calculating the effective interest rate is 1 year.

## TABLE 9-23 Condensed Continuous Interest Table*

Factors for determining zero-time values for cash flows which occur at other than zero time.

| Compounding of Cash Flows Which Occur: | 1% | 5% | 10% | 15% | 20% | 25% | 30% | 35% | 40% | 50% | 60% | 70% | 80% | 90% | 100% |

**TABLE 9-24 Summary of Discrete and Compound Interest Equations**

| Factor | Find | Given | Discrete compounding | | Continuous compounding | |
|---|---|---|---|---|---|---|
| Single payment | | | | | | |
| Compound amount | $F$ | $P$ | $F = P(1+i)^n$ | $P(F/P\ i,n)$ | $F = P(e^{rn})$ | $P(F/P\ r,n)^\infty$ |
| Present worth | $P$ | $F$ | $P = F\left[\frac{1}{(1+i)^n}\right]$ | $F(P/F\ i,n)$ | $P = F(e^{-rn})$ | $F(P/F\ r,n)^\infty$ |
| Uniform series | | | | | | |
| Compound amount | $F$ | $A$ | $F = A\left[\frac{(1+i)^n-1}{i}\right]$ | $A(F/A\ i,n)$ | $F = A\left(\frac{e^{rn}-1}{e^r-1}\right)$ | $F(F/A\ r,n)^\infty$ |
| Sinking fund | $A$ | $F$ | $A = F\left[\frac{i}{(1+i)^n-1}\right]$ | $F(A/F\ i,n)$ | $A = F\left(\frac{e^r-1}{e^{rn}-1}\right)$ | $F(A/F\ r,n)^\infty$ |
| Present worth | $P$ | $A$ | $P = A\left[\frac{(1+i)^n-1}{i(1+i)^n}\right]$ | $A(F/A\ i,n)$ | $P = A\left[\frac{e^{rn}-1}{e^{rn}(e^r-1)}\right]$ | $A(P/A\ r,n)^\infty$ |
| Capital recovery | $A$ | $P$ | $A = P\left[\frac{i(1+i)^n}{(1+i)^n-1}\right]$ | $P(A/P\ i,n)$ | $A = P\left[\frac{e^{rn}(e^r-1)}{e^{rn}-1}\right]$ | $A(P/A\ r,n)^\infty$ |

***Example 6: Effective Interest Rate*** A person is quoted an 8.33 percent nominal interest rate on a 4-year loan compounded monthly. Determine the effective interest rate.

*Solution:*

$$i_{\text{eff}} = \left(\frac{1+i}{m}\right)^{(m)(1)} = \left(\frac{1+0.833}{12}\right)^{(12)(1)} - 1 = (1.00694)^{12} - 1$$

$$= 1.0865 - 1 = 0.0865$$

The effective interest rate is 8.65 percent.

## CASH FLOW

Cash flow is the amount of funds available to a company to meet current operating expenses. Cash flow may be expressed on a before- or after-tax basis. *After-tax cash flow* is defined as the net profit (income) after taxes plus depreciation. It is an integral part of the net present worth (NPW) and discounted cash flow profitability calculations.

The cash flow diagram, also referred to as a cash flow model (Fig. 9-9), shows the relationship between revenue, cash operating expenses, depreciation, and profit. This diagram is similar in many respects to a process flow diagram, but it is in dollars. Revenue is generated from the sale of a product manufactured in "operations." Working capital is replenished from sales and may be considered to be in dynamic equilibrium with operations. Leaving the operations box is a stream, "cash operating expenses." It includes all the cash expenses incurred in the operation but does not include the noncash item depreciation. Since depreciation is an allowance, it is reported on the operating expense sheet, in accordance with the tax laws, as an operating expense item. (See the section "Operating Expense Estimation.") Depreciation is an internal expense, and this allowance is retained within the company. If the cash operating expenses are subtracted from the revenue, the result is the operating income. If depreciation is subtracted from the operating income, the net profit before taxes results. Federal income taxes are then deducted from the net profit before taxes, giving the net profit after taxes. When depreciation and net profit after taxes are summed, the result is the after-tax cash flow. The terminology in Fig. 9-9 is consistent with that found in most company income statements in company annual reports.

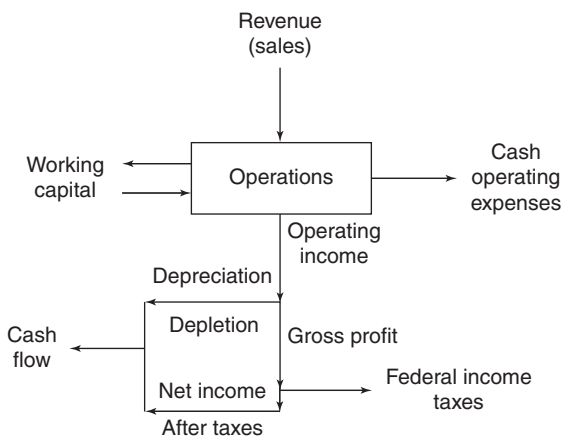

**FIG. 9-9** Cash flow model.

An equation can be developed for cash flow as follows:

$$\text{CF} = (R - C - D)(1 - t) + D \tag{9-17}$$

where $R$ = revenue
$C$ = cash operating expenses
$D$ = depreciation
$t$ = tax rate
CF = after-tax cash flow

Equation (9-17) can be rearranged algebraically to yield Eq. (9-18)

$$\text{CF} = t(D) + (1 - t)(\Delta R) - (1 - t)(\Delta C) \tag{9-18}$$

The term $t \times D$ is only the result of an algebraic manipulation, and no interpretation should be assumed. This term $t \times D$ is the contribution to cash flow from depreciation, and $(1 - t) \times R$ and $(1 - t) \times C$ are the contributions to cash flow from revenues and cash operating expenses, respectively. Example 7 is a sample calculation of the after-tax cash flow and the tabulated results.

***Example 7: After-Tax Cash Flow*** The revenue from the manufacture of a product in the first year of operation is $9.0 million, and the cash operating expenses are $4.5 million. Depreciation on the invested capital is $1.7 million. If the federal income tax rate is 35 percent, calculate the after-tax cash flow.

*Solution*: The resulting after-tax cash flow is $3.52 million. See Fig. 9-10.

**Cumulative Cash Position Table** To organize cash flow calculations, it is suggested that a cumulative cash position table be prepared by using an electronic spreadsheet. For this discussion,

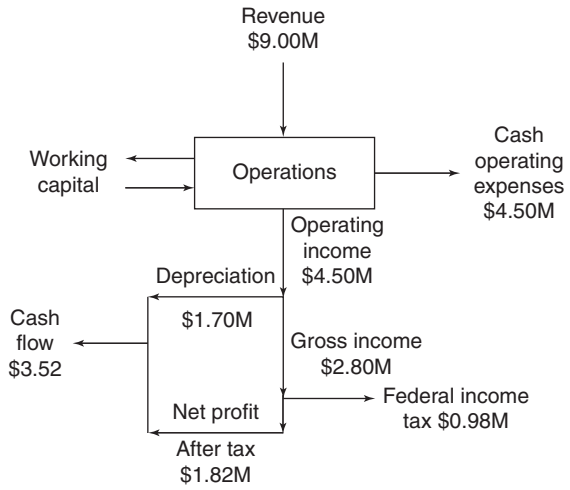

**FIG. 9-10** Cash flow model for Example 7. M = million.

time zero is assumed to be at project start-up. Expenditures for land and equipment occurred prior to time zero and represent negative cash flows. At time zero, working capital is charged to the project as a negative cash flow. Start-up expenses are charged in the first year, and positive cash flow from the sale of product as net income after taxes plus depreciation begins, reducing the negative cash position. This process continues until the project is terminated. At that time, adjustments are made to recover land and working capital. An example of a cumulative cash position table is Table 9-25.

When equipment is added for plant expansions to an existing facility, it may be more convenient to use time zero when the first expenditures occur. The selection of either time base is satisfactory for economic analysis as long as consistency is maintained.

***Example 8: Cumulative Cash Position Table (Time Zero at Start-up)*** A specialty chemical company is considering the manufacture of an additive for use in the plastics industry. The following is a list of production, sales, and cash operating expenses.

| Year | Production, Mlb | Sales, $1,000 | Cash operating expenses, $1,000 |
|---|---|---|---|
| 1 | 40 | 20,000 | 10,320 |
| 2 | 42 | 21,000 | 10,800 |
| 3 | 45 | 23,400 | 11,520 |
| 4 | 48 | 24,960 | 12,240 |
| 5 | 50 | 27,500 | 13,470 |
| 6 | 50 | 28,000 | 13,970 |
| 7 | 47 | 23,500 | 13,175 |
| 8 | 45 | 21,600 | 12,645 |
| 9 | 40 | 18,800 | 11,320 |
| 10 | 35 | 15,750 | 9,995 |

Land for the project is available at $300,000. The fixed capital investment was estimated to be $12,000,000. A working capital of $1,800,000 is needed initially for the venture. Start-up expenses based upon past experience are estimated to be $750,000. The project qualifies under IRS guidelines as a 5-year class life investment. The company uses MACRS depreciation with the half-year convention. At the conclusion of the project, the land and working capital are returned to management. Develop a cash flow analysis for this project, using a cumulative cash position table (Table 9-25).

**Cumulative Cash Position Plot** A pictorial representation of the cumulative cash flows as a function of time is the cumulative cash position plot. All expenditures for capital as well as revenue from sales are plotted as a function of time. Figure 9-11 is such an idealized plot showing time zero at start-up in part *a* and time zero when the first funds are expended in part *b*. It should be understood that the plots have been idealized for illustration purposes. Expenditures are usually stepwise, and accumulated cash flow from sales is seldom a straightline but more likely a curve with respect to time.

**Time Zero at Start-up** Prior to time zero, expenditures are made for land, fixed capital investment, and working capital. It is assumed that land had been purchased by the company at some time in the past, and a parcel is allocated for the project under consideration. Land is allocated instantaneously to the project sometime prior to the purchase of equipment and construction of the plant. The fixed capital investment is purchased and installed over a period of time prior to start-up. For the purpose of this presentation, it is assumed that it occurs uniformly over a period of time. Both land and fixed capital investment are compounded to time zero by using the appropriate compound interest factors. At time zero, working capital is charged to the project. Start-up expenses are entered in the first year of operation after start-up. After time zero, start-up occurs and then manufacturing begins and income is generated, so cash flow begins to accumulate if the process is sound. At the end of the project life, land and working capital are recovered instantaneously.

**TABLE 9-25 Cash Flow Analysis for Example 8**

| Year | −2 | −2 to 0 | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | End 10 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Production Mlb/yr | | | | 40 | 42 | 45 | 48 | 50 | 50 | 47 | 45 | 40 | 35 | |
| All money is $1,000 | | | | | | | | | | | | | | |
| Land | −300 | | | | | | | | | | | | | |
| Fixed capital investment $1000 | | −12,000 | | | | | | | | | | | | |
| Working capital | | | −1,800 | | | | | | | | | | | |
| Start-up expenses | | | −750 | | | | | | | | | | | |
| Total capital investment | | | 14,250 | | | | | | | | | | | |
| Sales | | | | 20,000 | 21,000 | 23,400 | 24,960 | 27,500 | 28,000 | 23,500 | 21,600 | 18,800 | 15,750 | |
| Cash operating expenses | | | | 10,320 | 10,800 | 11,520 | 12,240 | 13,470 | 13,970 | 13,175 | 12,645 | 11,320 | 9,995 | |

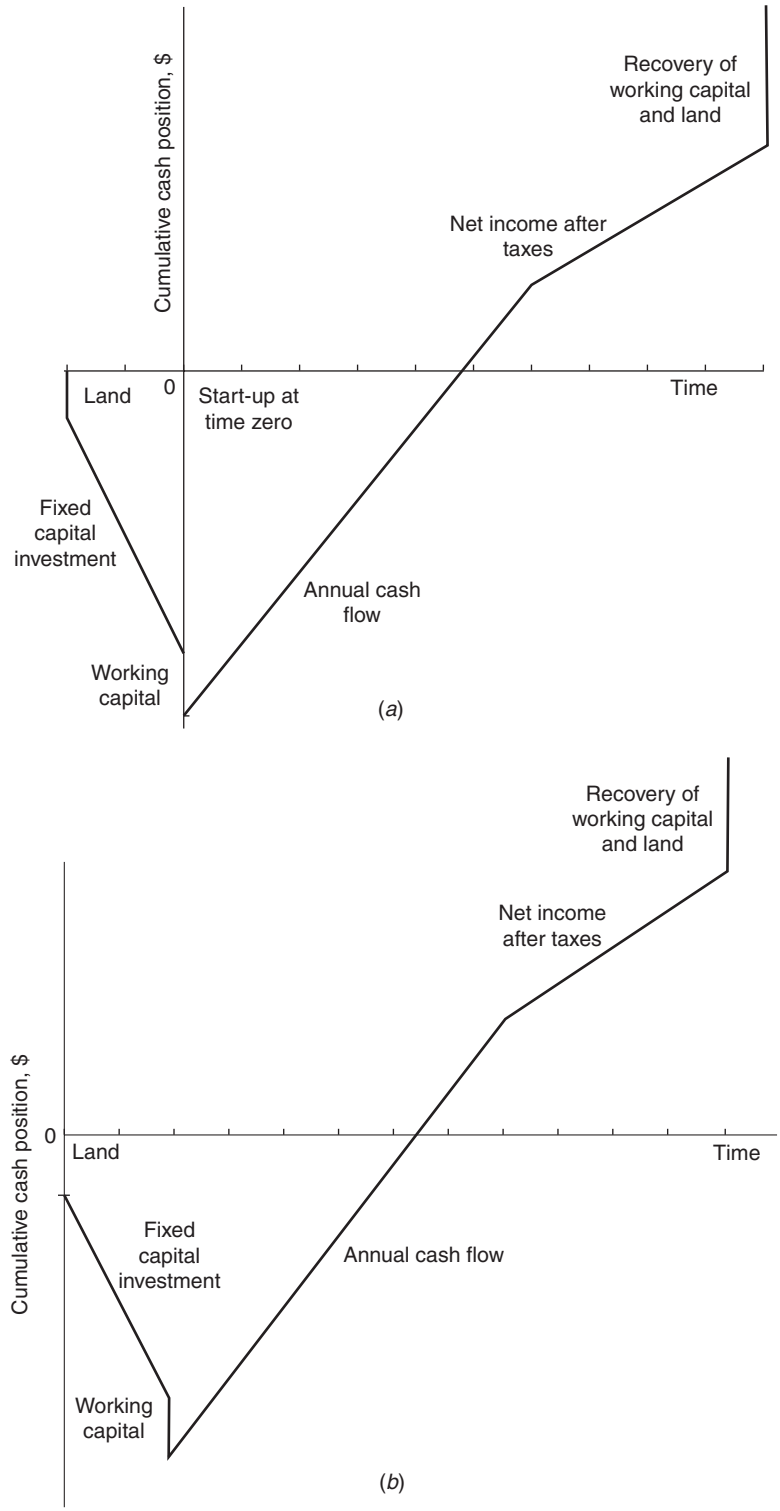

**FIG. 9-11** Typical cumulative cash position plot. (*a*) Time zero is start-up. (*b*) Time zero occurs when first funds are spent.

# PROFITABILITY

In the free enterprise system, companies are in business to make a profit. Management has the responsibility of investing in ventures that are financially attractive by increasing earnings, providing attractive rates of return, and increasing value added. Every viable business has limitations on the capital available for investment; therefore, it will invest in the most economically attractive ventures. The objectives and goals of a company are developed by management. Corporate objectives may include one or several of the following: maximize return on investment, maximize return on stockholders' equity, maximize aggregate earnings, maximize common stock prices, increase market share, increase economic value, increase earnings per share of stock, and increase market value added. These objectives are the ones most frequently listed by executives.

To determine the worthiness of a venture, quantitative and qualitative measures of profitability are considered.

## QUANTITATIVE MEASURES OF PROFITABILITY

When a company invests in a venture, the investment must earn more than the cost of capital for it to be worthwhile. A profitability estimate is an attempt to quantify the desirability of taking a risk in a venture.

The *minimum acceptable rate of return* (*MARR*) for a venture depends on a number of factors such as interest rate, cost of capital, availability of capital, degree of risk, economic project life, and other competing projects. Management will adjust the MARR depending on any of the above factors to screen out the more attractive ventures. When a company invests in a venture, the investment must earn more than the cost of capital and should be able to pay dividends.

Although there have been many quantitative measures suggested through the years, some did not take into account the time value of money. In today's economy, the following measures are the ones most companies use:

Payout period (POP) plus interest
Net present worth (NPW)
Discounted cash flow (DCFROR)

**Payout Period Plus Interest** Payout period (POP) is the time that will be required to recover the depreciable fixed capital investment from the accrued after-tax cash flow of a project with no interest considerations. In equation format

$$\text{Payout period} = \frac{\text{depreciable fixed capital investment}}{\text{after-tax cash flow}} \qquad (9\text{-}19)$$

This model does not take into account the time value of money, and no consideration is given to cash flows that occur in a project's later years after the depreciable investment has been recovered. A variation on this method includes interest, called payout period plus interest (POP + I); and the net effect is to increase the payout period. This variation accounts for the time value of money.

$$\text{Payout period plus interest (POP + I)} = \left(\frac{\text{depreciable fixed capital investment}}{\text{after-tax cash flow}}\right)_i \qquad (9\text{-}20)$$

Neither of these methods makes provision for including land and working capital, and no consideration is given to cash flows that occur in a project's later years after the depreciable fixed investment has been recovered for projects that earn most of their profit in the early years.

**Net Present Worth** In the net present worth method, an arbitrary time frame is selected as the basis of calculation. This method is the measure many companies use, as it reflects properly the time value of money and its effect on profitability. In equation form

$$\text{Net present worth (NPW)} = \text{present worth of all cash inflows} - \text{present worth of all investment items} \qquad (9\text{-}21)$$

When the NPW is calculated according to Eq. (9-21), if the result is positive, the venture will earn more than the interest (discount) rate used; conversely, if the NPW is negative, the venture earns less than that rate.

**Discounted Cash Flow** In the discounted cash flow method, all the yearly after-tax cash flows are discounted or compounded to time zero depending upon the choice of time zero. The following equation is used to solve for the interest rate *i*, which is the discounted cash flow rate of return (DCFROR).

$$\text{DCFROR} = \sum_{0}^{n} (\text{after-tax cash flows}) = 0 \qquad (9\text{-}22)$$

Equation (9-22) may be solved graphically or analytically by an iterative trial-and-error procedure for the value of *i*, which is the discounted cash flow rate of return. It has also been known as the *profitability index*. For a project to be profitable, the interest rate must exceed the cost of capital.

The effect of interest on the cash position of a project is shown in Fig. 9-12. As interest increases, the time to recover the capital expenditures is increased.

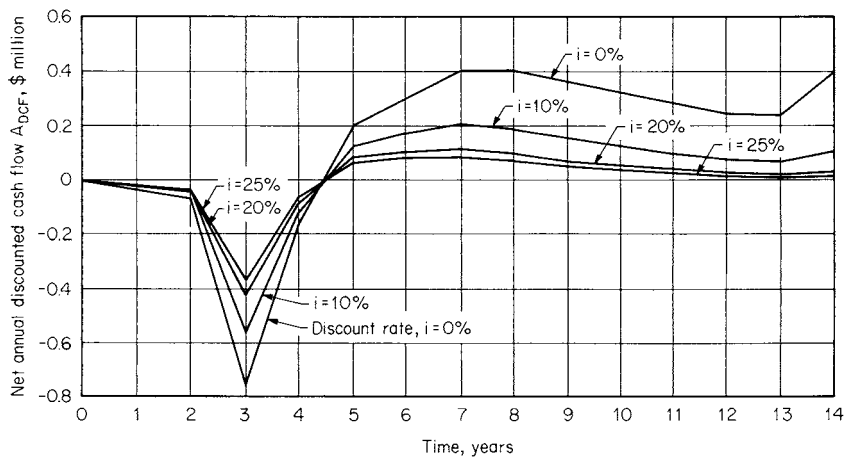

**FIG. 9-12** Effect of interest rate on cash flow (time zero occurs when first funds are expanded).

**TABLE 9-26 Profitability Analysis for Example 9**

| Time | Cash flow | 20% interest factors | Present worth 20% interest | 30% interest factors | Present worth 30% interest | 40% interest factors | Present worth 40% interest |
|---|---|---|---|---|---|---|---|
| –2 | –300 | 1.492 | –448 | 1.822 | –547 | 2.226 | –668 |
| –2 to 0 | –12,000 | 1.230 | –14,760 | 1.370 | –16,440 | 1.532 | –18,384 |
| 0 | –2,250 | 1.000 | –2,250 | 1.000 | –2,250 | 1.000 | –2,250 |
| 1 | 6,040 | 0.906 | 5,472 | 0.864 | 5,219 | 0.824 | 4,977 |
| 2 | 7,974 | 0.742 | 5,917 | 0.640 | 5,103 | 0.552 | 4,402 |
| 3 | 8,527 | 0.608 | 5,184 | 0.474 | 4,042 | 0.370 | 3,155 |
| 4 | 8,754 | 0.497 | 4,351 | 0.351 | 3,073 | 0.248 | 2,171 |
| 5 | 9,602 | 0.407 | 3,908 | 0.260 | 2,497 | 0.166 | 1,594 |
| 6 | 9,361 | 0.333 | 3,117 | 0.193 | 1,807 | 0.112 | 1,048 |
| 7 | 6,711 | 0.273 | 1,832 | 0.143 | 960 | 0.075 | 503 |
| 8 | 5,821 | 0.224 | 1,304 | 0.106 | 617 | 0.050 | 291 |
| 9 | 4,862 | 0.183 | 890 | 0.078 | 379 | 0.034 | 165 |
| 10 | 3,471 | 0.150 | 561 | 0.058 | 217 | 0.022 | 82 |
| End 10 | 2,100 | 0.135 | 284 | 0.050 | 105 | 0.018 | 284 |
| Net present worth | | | 15,362 | | 4,782 | | –2,360 |
| Discounted cash flow rate of return | | | 33.90% | | | | |

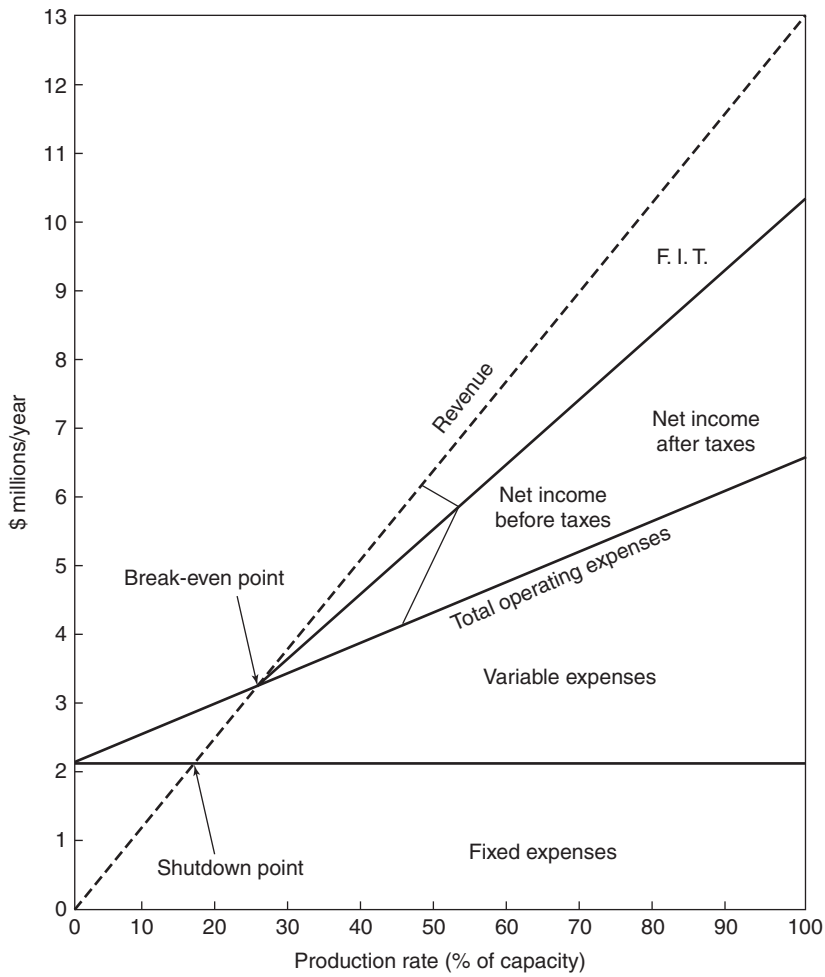

**FIG. 9-13** Break-even plot.

In the chemical business, operating net profit and cash flow are received on a nearly continuous basis, therefore, there is justification for using the condensed continuous interest tables, such as Table 9-23, in discounted cash flow calculations.

***Example 9: Profitability Calculations*** Example 8 data are used to demonstrate these calculations. Calculate the following:

a. Payout period (POP)
b. Payout period with interest (POP + I)
c. NPW at a 30 percent interest rate
d. DCF rate of return

*Solution*:

a. From Table 9-26, the second column is the cash flow by years with no interest. The payout period occurs where the cumulative cash flow is equal to the fixed capital investment, $12,000,000 or 1.7 years.

b. In Table 9-26, the payout period at 30 percent interest occurs at 2.4 years.

c. The results of the present worth calculations for 20, 30, and 40 percent interest rates are tabulated. At 30 percent interest, the net present worth is $4,782,000, and since it is a positive figure, this means the project will earn more than 30 percent interest.

d. Discounted cash flow rate of return is determined by interpolating in Table 9-26. At 30 percent interest the net present worth is positive, and at 40 percent interest it is negative. By definition, the DCFROR occurs when the summation of the net present worth equals zero. This occurs at an interest of 33.9 percent.

## QUALITATIVE MEASURES

In addition to quantitative measures, there are certain qualitative measures or intangible factors that may affect the ultimate investment decision. Those most frequently mentioned by management are employee morale, employee safety, environmental constraints, legal constraints, product liability, corporate image, and management goals. Attempts have been made to quantify these intangibles by using an ordinal or a ranking system, but most have had little or no success. Couper (2003) discussed in greater detail the effect of qualitative measures on the decision-making process.

## SENSITIVITY ANALYSIS

Whenever an economic study is prepared, the marketing, capital investment, and operating expense data used are estimates, and therefore a degree of uncertainty exists. Questions arise such as, What if the capital investment is 15 percent greater than the value reported? A sensitivity analysis is used to determine the effect of percentage changes in pertinent variables on the profitability of the project. Such an analysis indicates which variables are most susceptible to change and need further study.

**Break-Even Analysis** Break-even analysis is a simple form of sensitivity analysis and is a useful concept that can be of value to managers. *Break-even* refers to the point in an operation where income just equals expenses. Figure 9-13 is a pictorial example of the results of a break-even analysis, showing that the break-even point is at 26 percent of production capacity. Management wants to do better than just break even; therefore, such plots can be used as a profit planning tool, for product pricing, production operating level, incremental equipment costs, etc. Another significant point is the *shutdown point* where revenue just equals the fixed expenses. Therefore, if a proposed operation can't make fixed expenses, it should be shut down.

**Strauss Plot** R. Strauss (*Chem. Eng.*, pp. 112–116, Mar. 25, 1968) developed a sensitivity plot, in Fig. 9-14, in which the ordinate is a measure of profitability and the abscissa is the change in a variable greater than (or less than) the value used in the base case. Where the abscissa crosses the ordinate is the result of the base case of NPW, return, annual worth, etc. The slope of a line on this "spider" plot is the degree of change in profitability resulting from a change in a

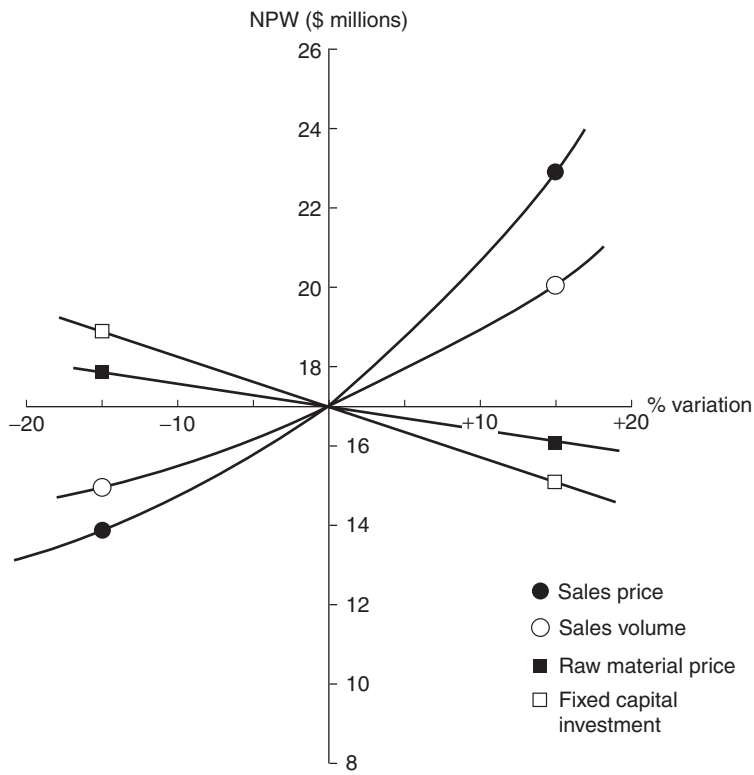

**FIG. 9-14** Strauss plot.

variable, selling price, sales volume, investment, etc. The length of the line represents the sensitivity of the variable and its degree of uncertainty. Positive-slope lines are income-related, and negative-slope lines are expense-related. A spreadsheet is useful in developing data for this "what if" plot since numerous scenarios must be prepared to develop the plot.

**Tornado Plot** Another graphical sensitivity analysis is the "tornado" plot. Its name is derived from the shape of the resulting envelope. As in other methods, a base case is solved first, usually expressing the profitability as the net present worth. In Fig. 9-15, the NPW is a vertical line, and variations in each selected variable above and below the base case are solved and plotted. In this figure, the variables of selling price, sales volume, operating expenses, raw material expenses, share of the market, and investment are plotted. It is apparent that the selling price and sales volume are the critical factors affecting the profitability. A commercial computer program known as @RISK® developed by the Palisade Corporation, Newfield, N.Y., may be used to prepare a tornado plot.

**Relative Sensitivity Plot** Another type of analysis developed by J. C. Agarwal and I. V. Klumpar (*Chem. Eng.*, pp. 66–72, Sept. 29, 1975) is the relative sensitivity plot. The variables studied are related to those in the base case, and the resulting plot is the relative profitability.

Although sensitivity analyses are easy to prepare and they yield useful information for management, there is a serious disadvantage. Only one variable at a time can be studied. Frequently, there are synergistic effects among variables; e.g., in marketing, the variables such as sales volume, selling price, and market share may have a synergistic effect, and that effect cannot be taken into account. Other interrelated variables such as fixed capital investment, maintenance, and other investment-based items also cannot be represented properly. These disadvantages lead to another management tool—uncertainty analysis.

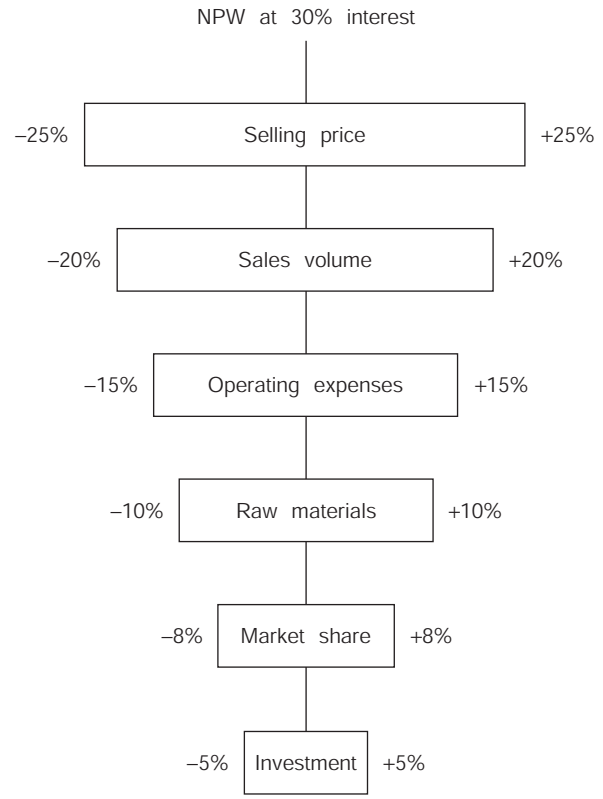

**FIG. 9-15** Typical tornado plot. (*Source: Adapted from Couper, 2003.*)

## UNCERTAINTY ANALYSIS

This analysis allows the user to account for variable interaction that is another level of sophistication. Two terms need clarification—

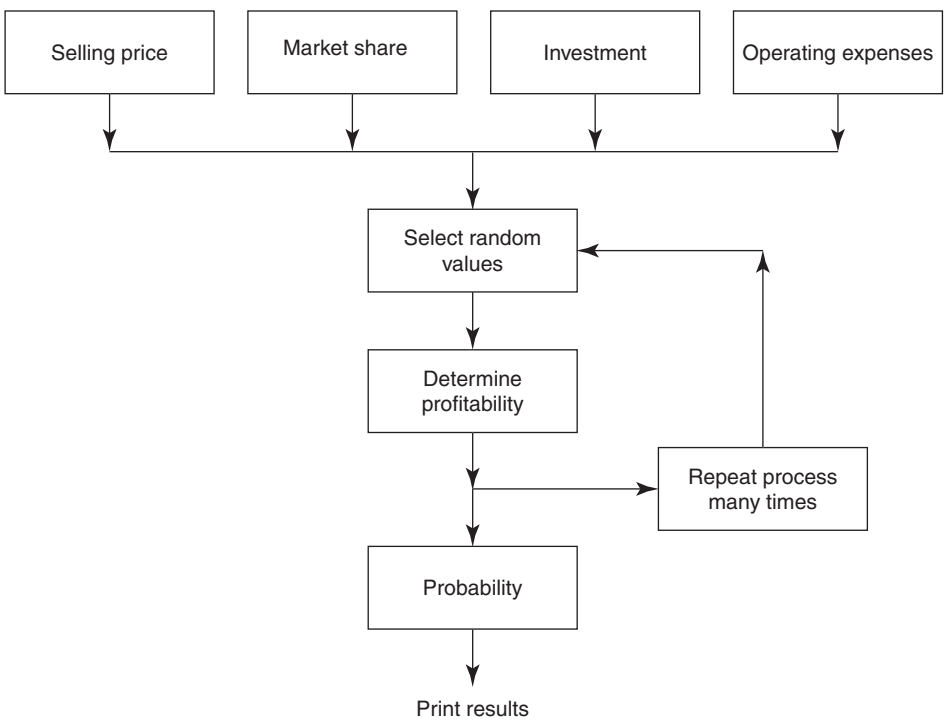

**FIG. 9-16** Schematic diagram of Monte Carlo simulation.

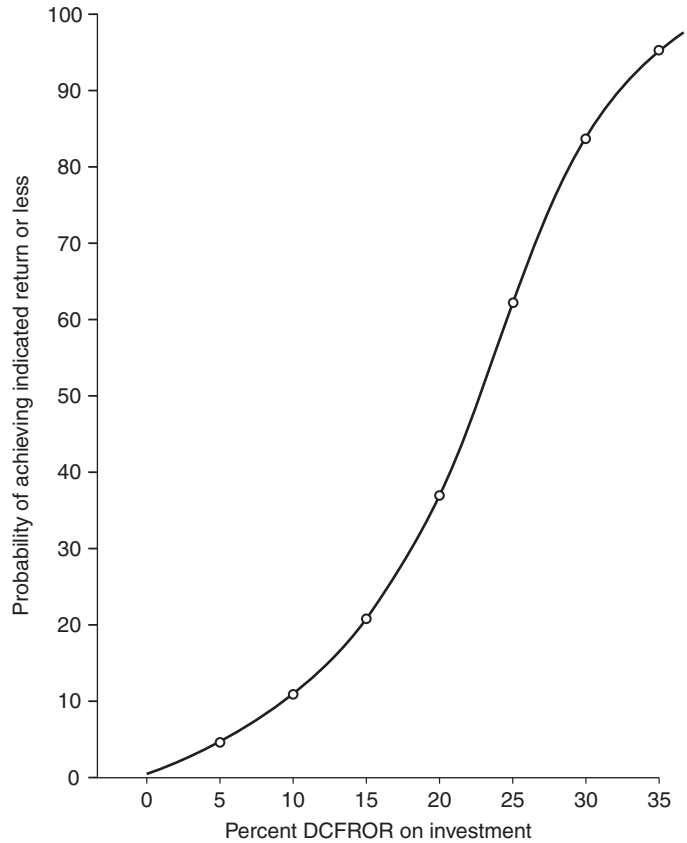

**FIG. 9-17** Probability curve for Monte Carlo simulation.

*uncertainty* and *risk*. Uncertainty is exactly what the word means—not certain. Risk, however, implies that the probability of achieving a specific outcome is known within certain confidence limits.

Since sensitivity analysis has the shortcoming of being able to inspect only one variable at a time, the next step is to use probability risk analysis, generally referred to as the Monte Carlo technique. R. C. Ross (*Chem. Eng.*, pp. 149–155, Sept. 20, 1971), P. Macalusa (*BYTE*, pp. 179–192, March 1984), and D. B. Hertz (*Harvard Bus. Rev.*, pp. 96–108, Jan-Feb 1968) have written classic articles on the use of the Monte Carlo technique in uncertainty analysis. These articles incorporate subjective probabilities and assumptions of the distribution of errors into the analysis. Each variable is represented by a probability distribution model. Figure 9-16 is a pictorial representation of the steps in the Monte Carlo simulation. The first step is to gather enough data to develop a reasonable probability model. Not all variables follow the normal distribution curve, but perhaps sales volume and sales-related variables do. Studies have shown that capital investment estimates are best represented by a beta distribution. Next the task is to select random values from the various models by using a random number generator and from these data calculate a profitability measure such as NPW or rate of return. The procedure is repeated a number of times to generate a plot of the probability of achieving a given profitability versus profitability. Figure 9-17 is a typical plot. Once the analysis has been performed, the next task is to interpret the results. Management must understand what the results mean and the reliability of the results. Experience can be gained only by performing uncertainty analyses, not just one or two attempts, to develop confidence in the process. The stakes may be high enough to spend time and learn the method. Software companies such as @RISK or SAS permit the user to develop probability models and perform the Monte Carlo analysis. The results may be plotted as the probability of achieving at least a given return or of achieving less than the desired profitability.

## FEASIBILITY ANALYSIS

A feasibility analysis is prepared for the purpose of determining that a proposed investment meets the minimum requirements established

by management. It should be in sufficient detail to provide management with the facts required to make an investment decision. All the basic information has been discussed in considerable detail in the earlier parts of Sec. 9.

The minimum information required should include, but not be limited to, that in Table 9-27. Forms and spreadsheets are the most succinct method to present the information. The forms should state clearly the fund amounts and the date that each estimate was performed. The forms may be developed so that data for other scenarios may be reported by extending the tables to the right of the page. It is suggested that blank lines be included for any additional information. Finally the engineer preparing the feasibility analysis should make recommendations based upon management's guidelines.

The development of the information required for Table 9-27 was discussed previously in Sec. 9 with the exception of marketing information. An important document for a feasibility analysis is the marketing data so that the latest income projections can be included for management's consideration. As a minimum, the tabulation of sales volume, sales prices, and market share both domestically and globally should be included. Table 9-28 shows a sample of such marketing information.

Other templates may be prepared for total capital investment, working capital, total product expense, general overhead expense, and cash flow. Table 9-29 may be used to organize cash flow data by showing investment, operating expenses, cash flow, and cumulative cash flow.

# OTHER ECONOMIC TOPICS

## COMPARISON OF ALTERNATIVE INVESTMENTS

Engineers are often confronted with making choices between alternative equipment, designs, procedures, plans or methods. The courses of action require different amounts of capital and different operating expenses. Some basic concepts must be considered before attempting to use mathematical methods for a solution. It is necessary to clearly define the alternatives and their merits. Flow of money takes the form of expenditures or income. Savings from operations are considered as income or as a reduction in operating expenses. Income taxes and inflation as well as a reasonable return on the investment must be included. Money spent is negative and money earned or saved is positive.

Expenditures are of two kinds; instantaneous like land, working capital and capital recovery or uniformly continuous for plant investment, operating expenses, etc. A methodology involving after-tax cash flow is developed to reduce all the above to a manageable format.

In an earlier part of this section, after-tax cash flow was defined as

$$CF = (R - C - D)(1 - t) + D \tag{9-17}$$

where CF = after-tax cash flow
$D$ = depreciation
$t$ = tax rate
$S$ = sales or revenue
$C$ = cash operating expenses (COE)

For the situation in which each case will produce the same revenue or the same benefit, $R$ will equal 0. Rearranging Eq. (9-17) algebraically yields

$$CF = (t)(D) + (1 - t)(S - C) \tag{9-17a}$$

or

$$CF = (t)(D) + (1 - t)(-C) \tag{9-17b}$$

$$CF = (t)(D) - (1 - t)(C) \tag{9-17c}$$

This expression is applied to each alternative. [*Note:* As mentioned under cash flow, the first term in the above equations, $(t)(D)$, is the result of an algebraic rearrangement, and no other significance should be assumed.]

Several methods are available for determining the choice among alternatives:

Net present worth
Rate of return
Capitalized cost
Cash flow
Uniform annual cost

Humphreys in Jelen and Black, *Cost and Optimization Engineering* (1991), has shown that each of these methods would result in the same decision, but the numerical results will differ.

**Net Present Worth Method** The NPW method allows the conversion of all money flows to be discounted to the present time. Appropriate interest factors are applied depending on how and when the cash flow enters a venture. They may be instantaneous, as in the purchase of capital equipment, or uniform, as in operating expenses. The alternative with the more positive NPW is the one to be preferred. In some instances, the alternatives may have different lives so the cost analysis must be for the least common multiple number of years. For example, if alternative A has a 2-year life and alternative B has a 3-year life, then 6 years is the least common multiple. The rate of return, capitalized cost, cash flow, and uniform annual cost methods avoid this complication.

Rate of return and capitalized cost methods are discussed at length in Humphreys (1991).

**Cash Flow Method** Cash flows for each case are determined, and the case that generates the greater cash flow is the preferred one.

**Uniform Annual Cost (UAC) Method** In the uniform annual cost method, the cost is determined over the entire estimated project life. The least common multiple does not have to be calculated, as in the NPW method. This is the advantage of the UAC method; however, the result obtained by this method is more meaningful than the results obtained by other methods.

The UAC method begins with a calculation for each alternative. If discrete interest is used, the annual cost $C$ is found by multiplying the present worth $P$ by the appropriate discrete interest factor, found in Table 9-21, for the number of years $n$ and the interest rate $i$. If continuous interest is preferred, the UAC equation is

$$UAC = \frac{NPW}{(\text{years of life})\,(\text{continuous interest factor})} \tag{9-23}$$

The continuous interest factor may be found from continuous interest equations or from the continuous interest table, Table 9-30. In this table time zero is the present, and all cash flows are discounted back to the present. Note that there are three sections to this table, depending on the cash flow: uniform, instantaneous, or declining uniformly to zero. One enters the table with the argument $R \times T$, where $R$ is the interest rate expressed as a whole number and $T$ is the time in years to obtain a factor. This factor is then used to calculate the present worth of the cash flow item. All cash flows are summed algebraically, giving the net present worth which is substituted in Eq. (9-23). This procedure is followed for both alternatives, and the alternative that yields the more positive UAC (or the least negative) value is the preferred alternative. In Eq. (9-23) the "factor" is always the uniform factor that annualizes all the various cash flows.

This method of comparing alternatives is demonstrated in Example 10.

***Example 10: Choice among Alternatives*** Two filters are considered for installation in a process to remove solids from a liquid discharge stream to meet environmental requirements. The equipment is to be depreciated over a 7-year period by the straight-line method. The income tax rate is 35 percent, and 15 percent continuous interest is to be used. Assume that the service life is 7 years and there is no capital recovery. Data for the two systems are as follows:

| System | B | C |
|---|---|---|
| Fixed investment | $18,000 | $30,000 |
| Annual operating expenses | 14,200 | 4,800 |

Which alternative is preferred?

*Solution*:
System B:

| Year | Item | Cash flow, $ | Factor | PW, $ |
|---|---|---|---|---|
| 0 | Investment | −18,000 | 1.0 | −18,000 |
| 0–7 | Contribution to cash flow from depreciation | (0.35)(18,000) | 0.6191 | +3,900 |
| 0–7 | Contribution to cash flow from operating expense | (1 − 0.35)(7)(14,200) | 0.6191 | −40,000 |
| | | | NPW B | −54,100 |

$$UAC_B = \frac{NPW}{(\text{years of life})(\text{uniform factor})} = \frac{-\$54{,}100}{(7)(0.6191)} = -\$12{,}484$$

System C:

| Year | Item | Cash flow, $ | Factor | PW, $ |
|---|---|---|---|---|
| 0 | Investment | −30,000 | 1.0 | −30,000 |
| 0–7 | Contribution to cash flow from depreciation | (0.35)(30,000) | 0.6191 | +6,500 |
| 0–10 | Contribution to cash flow from operating expense | (1 − 0.35)(10)(4,800) | 0.6191 | −19,316 |
| | | | NPW C | −42,816 |

$$UAC_C = \frac{NPW}{(\text{years of life})(\text{uniform factor})} = \frac{-\$42{,}816}{(10)(0.6191)} = -\$6{,}916$$

Alternative C is preferred because it has the more positive UAC.

## REPLACEMENT ANALYSIS

During the lifetime of a physical asset, continuation of its use may make it a candidate for replacement. In this type of analysis, a replacement is intended to supplant a similar item performing the same service without plant or equipment expansion. In a chemical plant, *replacement* usually refers to a small part of the processing equipment such as a heat exchanger, filter, or compressor. If the replacement is required due to "physical" deterioration, there is no question of whether to replace the item, but the entire plant may be shut down if it is not replaced. The problem then becomes whether the equipment

SOURCE: Adapted and abridged from Couper, 2003.

should be replaced like for like or whether an alternative should be chosen that may be different in cost and/or efficiency. If the replacement is due to technical obsolescence, the timing of the replacement may be important, especially if a plant expansion may be imminent in the near future. Whatever the situation, the replaced item should not present a bottleneck to the processing. The engineer should understand replacement theory to determine if alternative equipment is adequate for the job but with different costs and timing.

Certain terminology has been developed to identify the equipment under consideration. The item in place is called the *defender*, and the candidate for replacement is called the *challenger*. This terminology and methodology was reported by E. L. Grant and W. G. Ireson in *Engineering Economy*, Wiley, New York, 1950. To apply this method, there are certain rules. The value of the defender asset is a sunk cost and is irrelevant except insofar as it affects cash flow from depreciation for the rest of its life and a tax credit for the book loss if it is replaced sooner than its depreciation life. A capital cost for the defender is the net capital recovery forgone and the tax credit from the book loss of the defender asset that was not realized. The UAC method will be used and will be computed for each case, using the time period most favorable to each. For the defender it is 1 year and for the challenger it is the full economic life. The UAC for the challenger is handled in the same manner as in the comparison of alternatives. The method is demonstrated in Example 11.

***Example 11: Replacement Analysis*** A 3-year-old reciprocating compressor is being considered for replacement. Its original cost was $150,000, and it was being depreciated over a 7-year period by the straight-line method. If it is replaced now, the net proceeds from its sale are $50,000, and it is believed that 1 year from now they will be $35,000. A new centrifugal compressor can be installed for $160,000, which would save the company $2000 per year in operating expenses for the 10-year life. At the end of the 10th year, its net proceeds are estimated to be zero. The 7-year depreciation applies also to the centrifugal

compressor. A 35 percent tax rate may be assumed. The company requires a 15 percent after-tax return on an investment of this type. Should the present compressor be replaced now?

*Solution:* The UAC method will be used as a basis for comparison. It is assumed that all money flows are continuous, and continuous interest will be used.

Defender case: The basis for this unit will be 1 year. If it is not replaced now, the rules listed above indicate that there is an equivalent of a capital cost for two benefits forgone (given up). They are

1. Net proceeds now at 3 years of $50,000
2. Tax credit for the loss not realized

Thus net loss forgone = book value at the end of 3 years minus net capital recovery, or

$$NLF_3 = BV_3 - NCR_3$$

where $NLF_3$ = net loss forgone at end of 3 years
$BV_3$ = book value at end of 3 years
$NCR_3$ = net capital recovery at end of 3 years

$$NLF_3 = \$150{,}000\left(1 - \frac{1}{7}\right) - \$50{,}000 = \$35{,}714$$

$$\text{Depreciation for 4th year} = \$150{,}000\left(\frac{1}{7}\right) = \$21{,}429$$

$$NLF_4 = BV_4 - NCR_4 = \$150{,}000\left(1 - \frac{4}{7}\right) - \$35{,}000 = \$29{,}286$$

| Year | Item | Cash flow, $ | Factor | PW, $ |
|---|---|---|---|---|
| At 0[a] | Tax credit for net loss forgone | (0.35)(–35,714) | 1.0 | –12,500 |
| At 0[a] | Net cash recovery forgone | –50,000 | 1.0 | –50,000 |
| 0–1 | Contribution to CF from depreciation | (0.35)(–21,429) | 0.9286[b] | 6,965 |
| 0–1 | Contribution to CF from operting expense | (1 – 0.35)(–15,000) | 0.9286[b] | –9,054 |
| End 1 | Tax credit for net loss | (0.35)(29,286) | 0.8607[c] | 8,822 |
| End 1 | Net cash | 35,000 | 0.8607[c] | 30,125 |
| | | | NPW | –25,642 |

[a]For the defender case, 0 year is the end of the third year.
[b]From Table 9-30, uniform section, for the argument $R \times T = 15 \times 1 = 15$.
[c]From Table 9-30, instantaneous section, for the argument $R \times T = 15 \times 1 = 15$.

$$UAC = \frac{NPW}{(\text{years of life})(\text{uniform factor})} = \frac{-\$25{,}642}{(1)(0.9286)} = -\$27{,}614$$

Challenger case:

| Year | Item | Cash flow, $ | Factor | PW, $ |
|---|---|---|---|---|
| 0 | First cost | –160,000 | 1.0 | –160,000 |
| 0–7 | Contribution to CF from depreciation | (0.35)(160,000) | 0.6191[d] | 56,000 |
| 0–10 | Contribution | (1 – 0.35)(10)(–13,000) | 0.5179[e] | –43,763 |
| | | | NPW | –147,763 |

[d] From Table 9-30, uniform section, $R \times T = 15 \times 7 = 105$.
[e] From Table 9-30, uniform section, $R \times T = 15 \times 10 = 150$.

$$UAC = \frac{NPW}{(\text{years of life})(\text{uniform factor})} = \frac{-\$147{,}763}{(10)(0.5179)} = -\$28{,}531$$

The UAC for the defender case is less negative (more positive) than that for the challenger case; therefore, the defender should not be replaced now. But there will be a time in the near future when the defender should be replaced, as maintenance and deterioration will increase.

## OPPORTUNITY COST

Opportunity cost refers to the cost or value that is forgone or given up because a proposed investment is undertaken, often used as a base case. Perhaps the term should be *lost opportunity*. For example, the profit from production in obsolete facilities is an opportunity cost of replacing them with more efficient ones. In cost analysis on investments, an incremental approach is often used, and if it is applied properly, the correct cost analysis will result.

## ECONOMIC BALANCE

An engineering cost analysis can be used to find either a minimum cost or a maximum profit for a venture. This analysis is called an *economic balance* since it involves the balancing of economic factors to determine optimum design or optimum operating conditions. Such an analysis involves *engineering tradeoffs.* It may be more beneficial to invest more capital to reduce operating expenses or, conversely, incur more operating expenses without the addition of costly capital. An economic balance, then, is a study of all costs, expenses, revenues, and savings that pertain to an operation or perhaps an equipment item size. In this presentation, certain terminology is used; e.g., the term *cost* refers to a one-time purchase of capital equipment. A recurring expense is called an *operating expense,* such as utilities, labor, and maintenance. All costs and operating expenses are related to an arbitrarily designated *controllable* variable such as heat exchanger area, thickness of insulation, or number of units.

There are certain practical considerations that must be recognized in attempting to find the best or optimum condition. Occasionally, a solution may lead to a result for which industrial equipment is not available in the optimum size; therefore, engineering judgment must be exercised. A smaller-diameter pipe might lead to a higher pumping expense but lower pipe costs while a larger-diameter pipe would result in lower pumping expense but higher capital cost. The engineer then encounters an engineering tradeoff that must be resolved.

The essential elements of an economic balance are

- Fixed and variable expenses
- An allowance for depreciation
- An acceptable return on the investment

A total expense equation is

$$TE = FE + VE \tag{9-24}$$

where TE = total expenses
FE = fixed expenses
VE = variable expenses

The guidelines for solving a single-variable economic balance consist of the following steps:

1. Determine all expenses that vary as the controllable variable changes and that need to be considered in the balance.
2. Determine whether any operating limitations exist, such as pressure drop in columns where flooding occurs or limiting heads for pipelines for gravity flow.
3. Mathematically express the expenses as a function of the variables related to the equipment; otherwise use variables that define the operation such as temperature, pressure, and concentration. The final expression should include all pertinent expenses, eliminating those that are not significant. Frequently only one variable is used.
4. Ascertain if the optimum size must be one of a number of discrete sizes commercially available or whether it can be any size.
5. Solve the total expense equation either analytically or graphically.

The solution to Eq. (9-24) may be found analytically or graphically. In the analytical method, the fixed and variable expenses are related in equation format to the controllable variable. Example 12 is an engineering balance example of this method. Equation (9-24) can be differentiated with respect to the controllable variable and that result set equal to zero to find the optimum condition. A graphical method involves determining the fixed and variable expenses for a range of equipment sizes. A plot of TE, FE, and VE as a function of the controllable sizes yields a plot identifying the optimum. Figure 9-18 is a graphical solution to the TE equation. Should the optimum result fall between two commercial sizes, then the engineer must exercise judgment in the tradeoff.

***Example 12: Optimum Number of Evaporator Effects*** Determine the number of evaporator effects for the minimum total annual operating

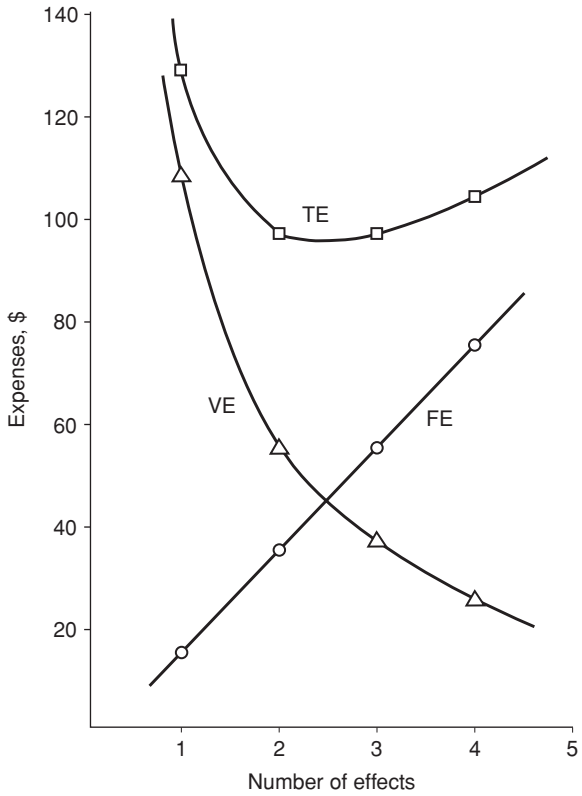

**FIG. 9-18** Optimum number of evaporator effects in Example 12.

expense of a small evaporator system to concentrate a colloidal suspension. Steam costs $3.00 per million Btu (MBtu), and each pound of steam will evaporate $0.8N$ lb water, with $N$ being the number of effects. The total capital cost of each effect is $40,000 and has an estimated life of 10 years. The annual maintenance expense is 10 percent of the capital cost. Labor and other expenses not mentioned may be considered to be independent of the number of effects. The system will operate 300 days/yr with 100,000,000 Btu/day evaporator duty. Depreciation on the equipment is by 7-year straight-line method, and the tax rate is 35 percent. Annual net profit after taxes on the investment must be 15 percent for the installed equipment.

Basis: 1 year of operation, duty $10^8$ Btu/day. Let $N$ equal the number of effects.

*Solution*:

Analytical method:

$$\text{Annual fixed expenses} = \text{FE}$$

$$\text{FE} = \$40{,}000N\left(0.143 + 0.100 + \frac{0.15}{1 - 0.35}\right) = \$18{,}960N$$

dep. maint. profit (return)

Annual variable expenses VE in this example are essentially the steam expenses, and all other variable expenses do not enter into the equation. Therefore

$$\text{VE} = 10^8 \text{ Btu/day} \times 300 \text{ day/yr} \times \$3.00/10^6 \text{ Btu} \times 1/(0.8N) = \frac{\$112{,}500}{N}$$

$$\text{TE} = \text{FE} + \text{VE} = \$18{,}960N + \frac{\$112{,}500}{N}$$

Take the derivative of TE with respect to $N$ and set the result equal to zero.

$$\frac{d\,(\text{TE})}{dN} = 18{,}960 - \frac{112{,}500}{N^2} = 0 \quad N = 2.44 \text{ effects}$$

Therefore 3 effects are required.

Graphical method: Assume the number of effects and calculate the fixed, variable, and total expenses for effect.

| $N$ | 18,960$N$ | 112,500/$N$ | TE |
|---|---|---|---|
| 1 | $18,960 | $112,500 | $131,460 |
| 2 | 37,920 | 56,250 | 94,210 |
| 3 | 56,880 | 37,500 | 94,380 |
| 4 | 75,840 | 28,125 | 103,965 |

The minimum TE occurs between 2 and 3 effects, but 3 effects are recommended to evaporate the colloidal solution. Figure 9-18 is a plot of the graphical solution.

In another example involving the reclaiming of a product using an evaporator and a dryer in series, the product is pumped from the discharge of the evaporator to the dryer. See Fig. 9-19. An economic analysis indicated that a 55 percent slurry is optimum, but perhaps such a slurry is too thick to be pumped. Therefore, engineering judgment must be exercised. The slurry was pumped not at 55 percent but at a lesser concentration of 50 percent, although it was not optimum.

When more than one controllable variable affects the economic balance, the solution approach is essentially the same as that for the single-variable case, but determining the optimum is tedious.

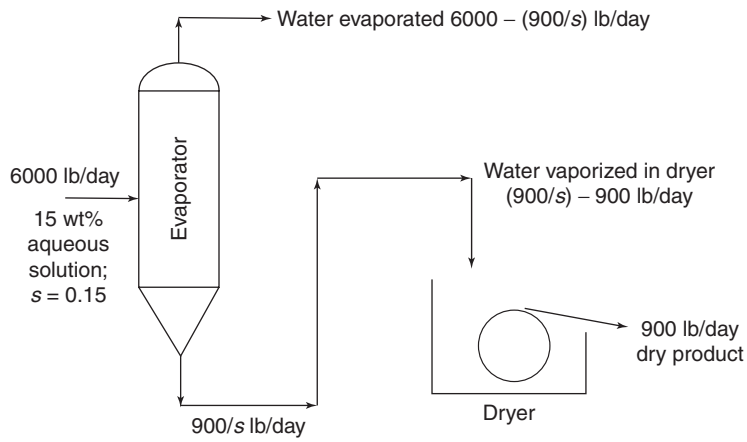

**FIG. 9-19** Evaporator–dryer system. (*Source: Adapted from Couper, 2003.*)

### INTERACTIVE SYSTEMS

If the TE does not pass through a minimum or maximum, but continues to decline or to increase with the number of equipment items or equipment size, the next step is to look at the flow sheet for equipment upstream or downstream from the selected item. It may be necessary to group two or more items and treat them as one in the analysis. Such a system is said to be *interactive*, since more than one item affects the optimum results. An example of such an interactive system is the removal of nitrogen from helium in a natural gas stream. Carbon adsorption is a method for removing nitrogen, but compressors are also required since this is a high-pressure process. If one attempts to find the optimum operating pressure, optimizing on compressor pressure will not result in an optimum condition; and conversely, optimizing on the size of the carbon bed will not yield an optimum. This is an example of an interactive system. Therefore, to find the optimum pressure, both the size of the carbon bed and the compressor pressure must be considered together.

## CAPITAL PROJECT EXECUTION AND ANALYSIS

The demands made on business organizations with the arrival of global free trade have made sophisticated management of capital projects, for the purposes of minimizing capital costs and maximizing project profitability, a necessity. Two elements of such sophisticated project management practice are *front-end loading* (*FEL*) and *value-improving practices* (*VIPs*). These two management practices are, and must be, closely integrated activities, as seen in Fig. 9-20. As shown, they are performed during the early stages of a project life cycle, when they can be, and are, effective at influencing a project's profitability. However, they have very different characteristics, as are detailed in the following sections. Properly performed together, FEL and VIPs maximize project profitability by ensuring that all matters that influence project profitability are considered in the most productive manner and at the most optimal time.

### FRONT-END LOADING

**Introduction** Front-end loading (FEL) is the process by which a company develops a detailed definition of the scope of a capital project that meets corporate business objectives. The term *front-end loading* was first coined by the DuPont company in 1987 and has been used throughout the chemical, refining, and oil and gas industries ever since (Porter, James B., E. I. DuPont de Nemours and

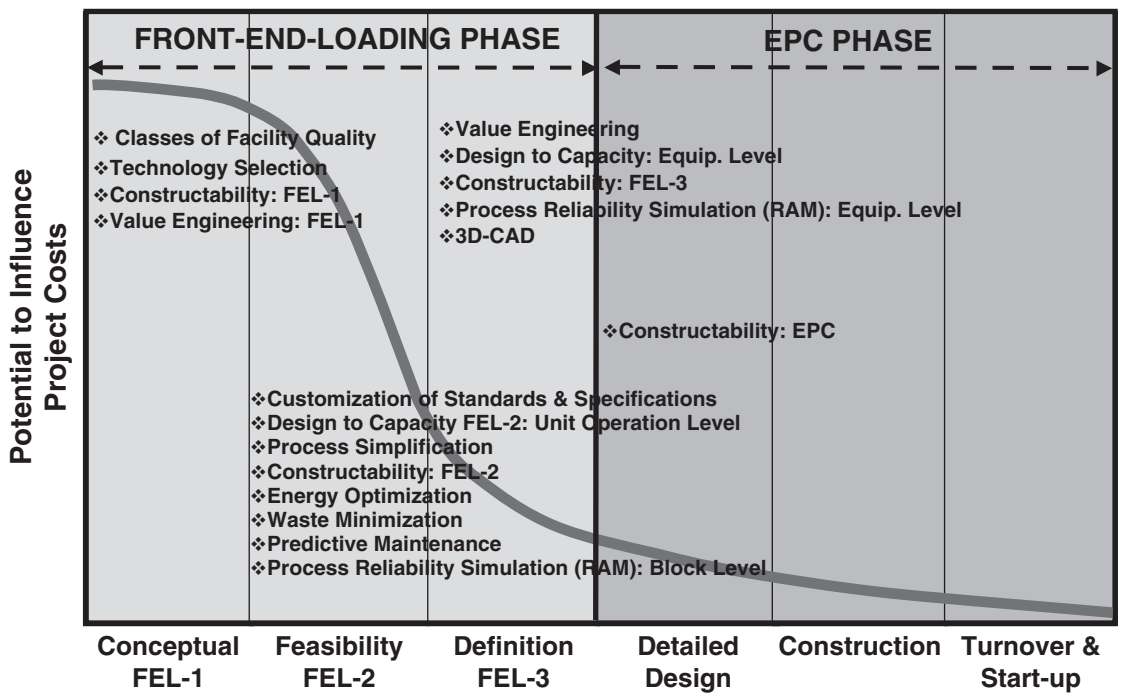

**FIG. 9-20** Front-end loading and the implementation of value-improving practices.

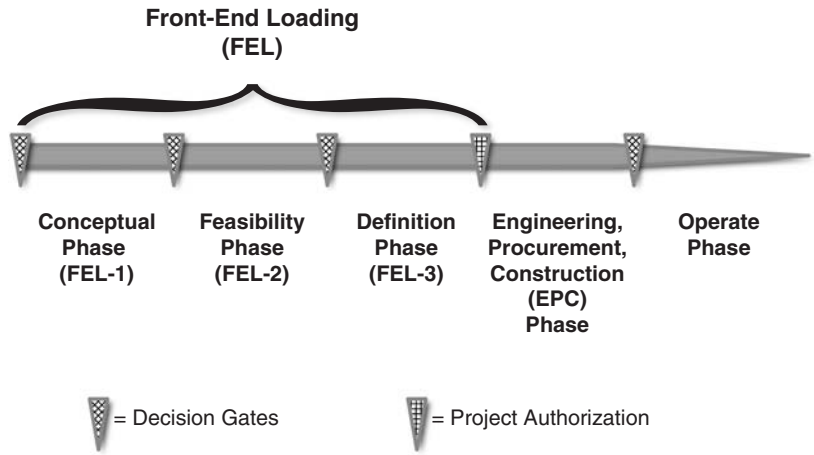

**FIG. 9-21** FEL in the capital project life cycle.

Company). The product of the FEL process is a design-basis package of customized information used to support the production of detailed engineering design documents. Completion of the FEL design-basis package typically coincides with project AFE (Authorization for Expenditure) or project authorization. Project authorization is that point in the project life cycle where the owner organization commits the majority of the project's capital investment and contracts.

FEL starts when an idea for a project is first conceived by a research and development group, project engineering group, plant group, or business unit. FEL activity continues until the project is authorized. After initial conception of an idea, organized interaction is required among the various project stakeholders to assemble the project design-basis package for subsequent authorization.

Within the FEL phases, decision points are formally established by the operating company authorizing the initiation of a capital project development effort. These formal decision gates allow for continuity across the enterprise for authorization of additional funding for the next phase of engineering and project definition. Figure 9-21 illustrates the typical decision gates or stage gates for capital projects.

When the level of project definition is sufficient to support a definitive cost estimate for both the entire project and its projected rate of return, major project funding is authorized for expenditure. This is the conclusion of the FEL process and any significant involvement of the process design engineer. Not until the conclusion of the engineering, procurement, and construction (EPC) phase does the process engineer again become involved. At this time, commissioning and start-up become the focus where the validation occurs for all that was done in the FEL phases many months earlier.

Differing terminology used by companies, engineers, and project management teams is often a point of confusion. Most people seem to think they know what all the terms mean. This is never the case. Confirmation of which terminology will be used by all involved in the project is a must. Nearly every operating company and engineering contractor use differing terminology. FEL terminology is often misunderstood and further confused by differing references to which FEL phase the project is actually in. Figure 9-22 provides some idea of the differing terminology for each project phase used by only a few major oil and gas and chemical companies today. These terms change periodically, so diligence in confirming such terminology is a key task for the process engineers to finish, before beginning their work.

The influence of changes on capital projects is considerably affected by when those changes occur. The earlier a change is considered and incorporated into the project scope, the greater its potential influence on the project's profitability and the greater the ease of incorporating the change. This means that late changes (e.g., in the EPC phase) are far more expensive to implement and are considered very undesirable. Late changes which are potentially advantageous are often not implemented because the cost to implement the change exceeds the benefits of doing so. Conversely, the cost to implement a change at the earlier phases of the project is far lower than making the same change after detailed engineering is underway.

Figure 9-23 shows how quickly this influence curve changes as the typical project progresses (Smith, C. C., Improved Project Definition Insures Value-added Performance—Part 1). This is why proactively seeking changes during FEL is far more advantageous to profitability than is allowing those needed changes to be "discovered" during later project phases. This also means that potentially beneficial changes (value improvements) must be sought during FEL, or else they stand a good chance of not being cost-effective to implement during the EPC phase. This is also why seeking operations, maintenance, and construction experience during FEL offers significant profitability advantages over practices which bring such experience onto the project team following FEL.

**Characteristics of FEL** Front-end loading is a specialized and adaptable work process. This work process translates financial and marketing opportunities to a technical reality in the form of a capital project. It is particularly important that the project be defined in sufficient detail by the engineering deliverables, which are generated by the FEL work process, prior to the point where major funds are authorized. In this manner, overall project risks are identified and sufficiently mitigated to have project funding approved. To achieve this important level of definition, critical decisions must be made and adhered to. In addition, the FEL project team should proactively seek value improvement alternatives and challenge the project premises, scope, and design until such time as implementation of those alternatives loses their profitability and/or technical advantage. By doing so, such value improvements will not develop into costly corrections, which surface later, during the EPC phase.

***Goals and Objectives of FEL*** The FEL work process must enable nearly constant consideration of changes as the work progresses. FEL phases must consider the long-term implications of every aspect of the design. Predictability of equipment and process system life cycle costs must always be balanced with operations and maintenance preferences, as well as the need for the project to maintain its profitability or ROI (return on investment). Additional important goals and objectives of FEL projects are as follows:

- Develop a well-defined and acceptably profitable project.
- Define the primary technical and financial drivers for capital project investment.

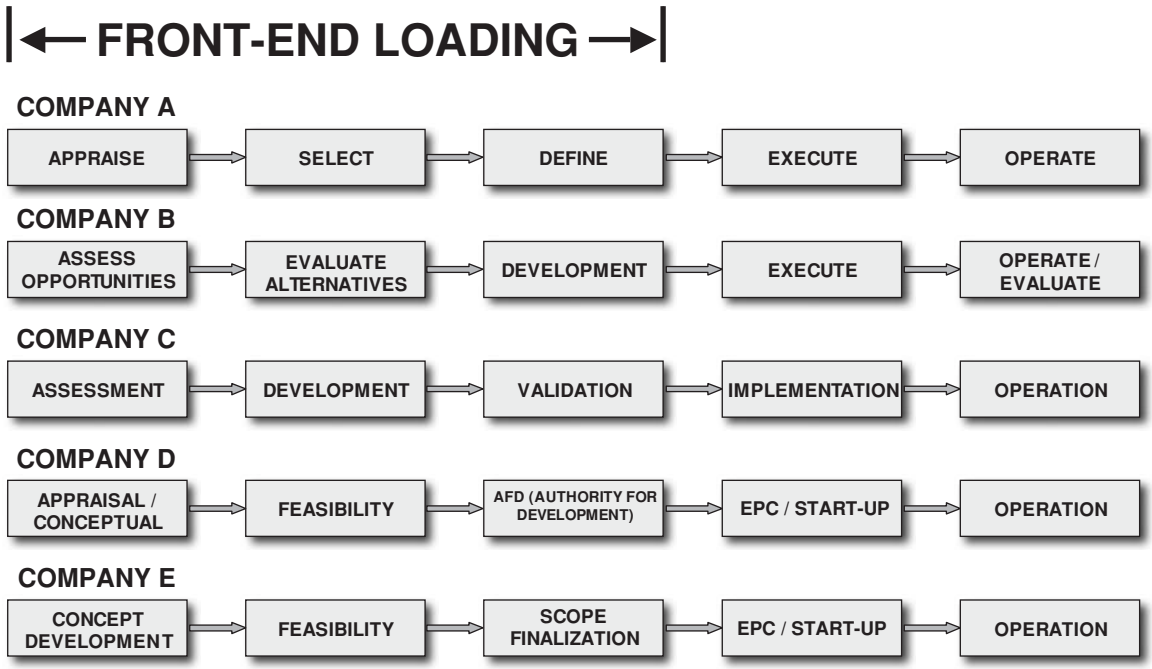

**FIG. 9-22** Project life cycle terminology.

- Challenge baseline premises, and purposely seek out and evaluate alternatives and opportunities.
- Minimize changes during the EPC, turnover, and start-up phases.
- Reduce project schedule and capital cost.
- Reduce the business and project execution risk.
- Balance project technical, financial, and operational profitability drivers.

***Comparison of FEL Projects with EPC Projects*** FEL projects are very different from EPC projects. Engineers and project managers having significant experience only with projects in the EPC phase often are unfamiliar with the significant differences between the philosophies and challenges of the FEL phase and the EPC phase of projects. One of the most important (but most subtle) aspects of FEL is the demand during FEL for more highly experienced staff and

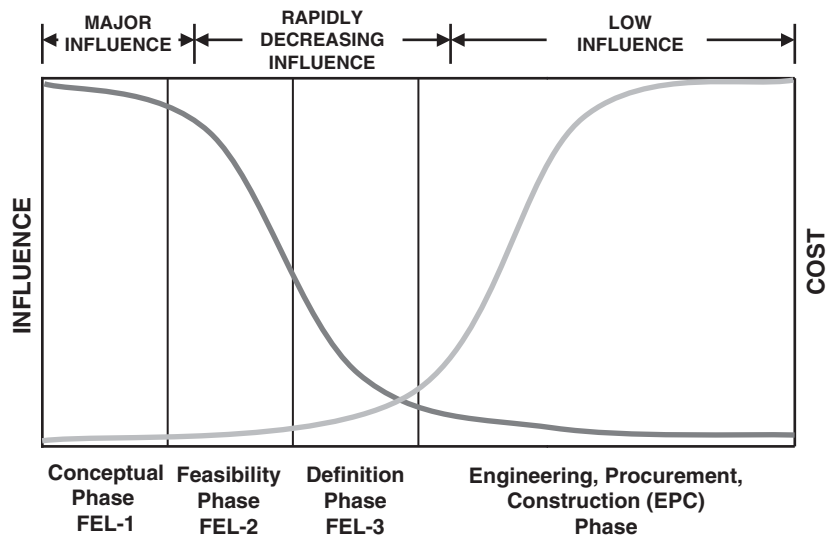

**FIG. 9-23** Project life cycle cost-influence curve.

| | FEL | EPC |
|---|---|---|
| ***Project State*** | Undefined | Defined |
| ***Changes*** | Actively Seeks Changes | Actively Resists Changes |
| ***Impact of Change*** | Low | High |
| ***Opportunity for Change*** | High | Low |
| ***Contract Type*** | Typically Reimbursable | Typically Lump Sum |
| ***Value Improvement Potential*** | High | Low |
| ***Client Participation*** | Encouraged | Discouraged |
| ***Philosophy*** | Information-Driven | Deliverable-Driven |

**FIG. 9-24** FEL projects versus EPC projects.

more sophisticated analysis tools, as compared to EPC projects which have achieved a well-defined project prior to authorization. This is so because of the need in FEL to create, analyze, and implement improvements to what many might consider a "good" design.

In spite of its relatively short duration, FEL proactively seeks to implement the best possible design. The nearly constantly changing environment requires people of many different disciplines and functions to work together to communicate effectively. A well-integrated team always seems to perform best during FEL, if FEL has well-established, informal, and personal interfaces between project groups and organizations. The following describes how the FEL phase is distinguished from the EPC phase:

- FEL proactively seeks data, resources, support, and decision making.
- Projects in the FEL phase place a higher level of importance on close and effective owner-contractor management interfaces.
- FEL demands continuous realignment of client desires and requirements with contractor needs.
- FEL requires greater development of personal relationships that result in respect and trust.
- FEL demands significantly higher frequency of feedback of owner satisfaction.
- FEL emphasizes elimination of low- or zero-value scope.
- FEL improves the capital productivity of projects by using best-available technology.
- FEL focuses on overall project profitability rather than on only cost, schedule, and workhours.
- FEL focuses almost entirely on the owner's business needs.

Figure 9-24 lists further differences between FEL and EPC projects. Understanding these many differences is very important to the process engineer, in that awareness of them, and the driving forces behind them, will prepare the chemical engineer for the challenging and rewarding environment of FEL projects.

***Parameters of FEL Phases*** Important aspects of each phase of FEL are cost estimate accuracy, cumulative engineering hours spent, and the contingency assigned to the cost estimate. Figure 9-25 lists the typical parameters encountered industrywide (KBR Front-end Loading Program, data compiled from selected large projects from 1993 through 2003). For the capital cost estimate, each operating company may request a slightly different accuracy, which is often project-specific. What is important is the level of engineering required to support such estimating accuracy. This determination is the responsibility of both the owner and the engineering contractor. Agreement on this is critical prior to initiating project work.

The engineering hours spent during each phase of FEL vary widely between small and large projects. This is also true for those projects where new or emerging technology is being applied or where higher throughput capacities are being applied than previously commercially demonstrated. Projects such as these may require additional engineering to achieve the desired estimate accuracy and project contingency.

***FEL Project Performance Characteristics*** Overall project performance can be enhanced by ensuring that the following characteristics are emphasized during the FEL phases.

- Methodical business and project execution planning is necessary.
- Effective integration of workforce between owner and contractor staff is important.
- Projects with an integrated management team (owner and engineering contractor) have the lowest number of design changes at any project stage.
- Engineering contractor should be brought into project in early FEL phases.
- Clear roles must exist for project team members that relate to the expertise of both owner and contractor staff.
- Effective personal communication is required between owner and contractor organizations and their project team representatives, ensuring extensive site and manufacturing input.
- Schedule and cost goals are set by integrated business and technical project team composed of owner and contractor representatives.

Figure 9-26 illustrates the benefit of good FEL performance on project costs (Merrow, E. W., Independent Project Analysis, Inc., 32d Annual Engineering & Construction Contracting Conference, Sept. 28–29, 2000). Figure 9-27 illustrates the benefit of good FEL performance on critical path schedule (Merrow, E. W., Independent

| | FEL-1 (CONCEPTUAL) | FEL-2 (FEASIBILITY) | FEL-3 (DEFINITION) |
|---|---|---|---|
| ***Cost Estimate Accuracy*** | ±40% | ±25% | ±10% |
| ***Cumulative Engineering Hours Spent*** | 1–5% | 5–15% | 15–30% |
| ***Contingency*** | 15–20% | 10–15% | 8–12% |

**FIG. 9-25** Parameters of FEL phases.

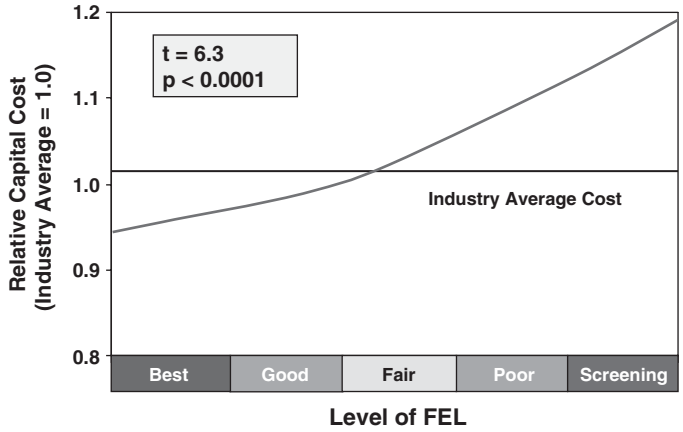

**FIG. 9-26** FEL drives better cost performance.

Project Analysis, Inc., 32d Annual Engineering & Construction Contracting Conference, Sept. 28–29, 2000). IPA statistics indicate that significant project financial and schedule benefits can be realized by implementing a thorough FEL effort prior to the EPC phase.

Figure 9-28 presents the benefits of having an integrated project team during FEL on the overall project performance. This performance impacts overall project costs as well as schedule and operability. An integrated project team produces fewer late changes. This means lower capital costs, better and more predictable schedules, and a slightly better operability, as compared statistically to similar projects lacking an integrated management team (Merrow, E. W., Independent Project Analysis, Inc., 30th Annual Engineering & Construction Contracting Conference, September 1998).

In addition, project data indicate that a well-integrated FEL team can produce significantly better project performance in terms of lower capital investment, as compared to projects where FEL teams were not properly integrated. This illustrates the benefits for each engineering team member working closely together with each other team member, to produce the most profitable project results.

Although project teams, once integrated and functioning with clear roles and responsibilities, perform better, this edge can be quickly lost if key members of that team are changed. The impacts of changes of project managers to a well-integrated FEL team are shown in Fig. 9-29 (HPI Impact, *Hydrocarbon Processing*, p. 23, August 2002, data obtained from Independent Project Analysis, Inc.).

***Investment in FEL for Best Project Performance*** The cost and schedule required to optimally complete the FEL phase of a project are always under pressure and must be justified. This is especially true for "fast-track" projects where the time pressures can be significant. The Construction Industry Institute (CII) has shown that higher levels of preproject planning (i.e., front-end loading) effort can result in significant cost and schedule savings, as seen in Fig. 9-30 (PDRI: Project Definition Rating Index—Industrial Projects, Construction Industry Institute, University of Texas at Austin, July 1996). The process engineer produces the best project performance, when he or she strives, with the entire integrated FEL project team, to define the overall project (not just the process design) as well as possible, prior to AFE.

The level of definition of a project during the FEL phases has a direct influence on the project's ultimate outcome in terms of the number and impacts of changes in the EPC phase. This level of FEL performance translates to fewer major changes in engineering, construction, and during start-up (Merrow, E. W., Independent Project

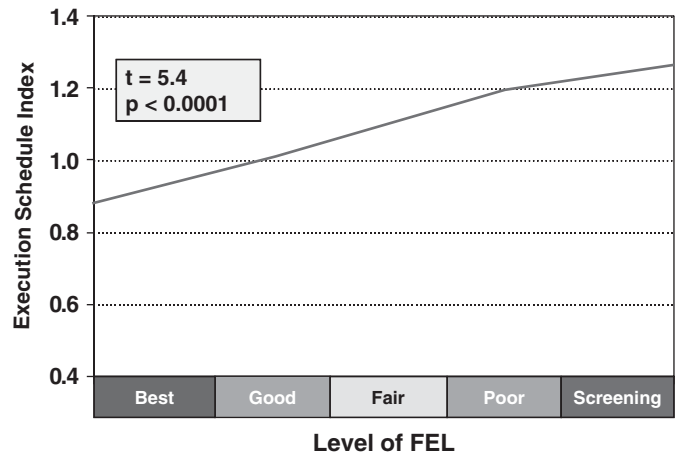

**FIG. 9-27** Good FEL speeds execution time.

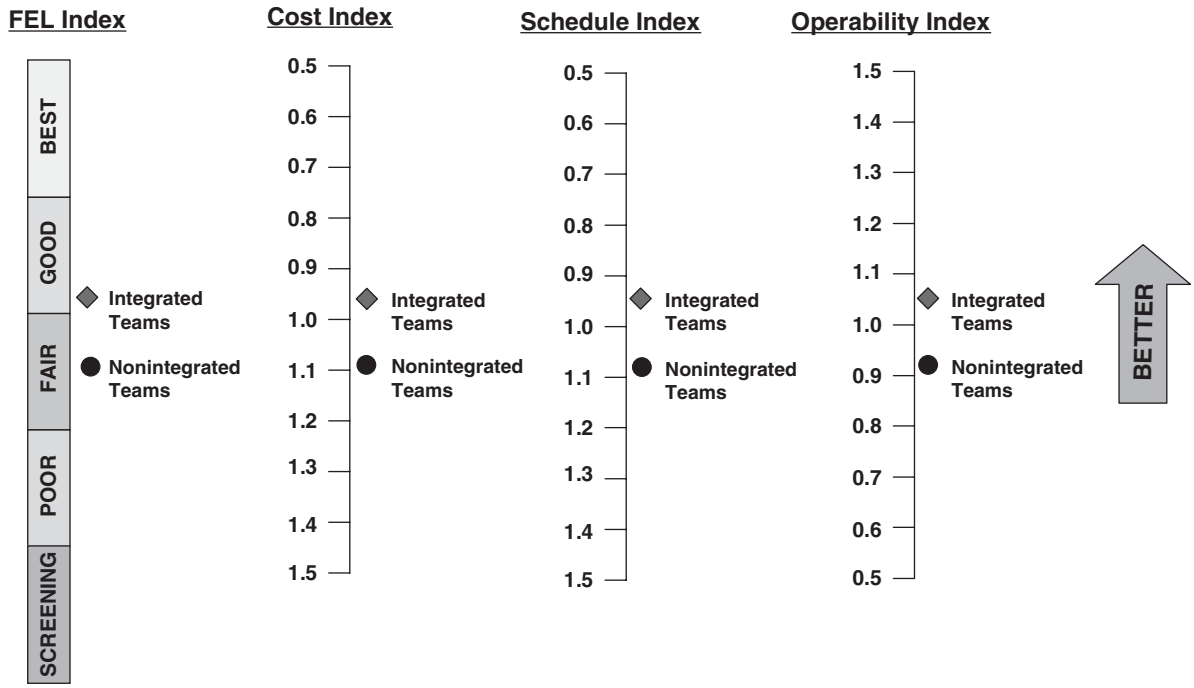

**FIG. 9-28** Integrated teams result In better FEL and better overall performance.

Analysis, Inc., 32d Annual Engineering & Construction Contracting Conference, Sept. 28–29, 2000). These conclusions are depicted by Fig. 9-31. A major late change is defined by IPA's data to mean changes made after the start of detailed engineering and involving impacts greater than either 0.5 percent of the total project capital investment or 1 month in critical path project schedule.

These graphs illustrate why better project performance is produced through proactively seeking profit-improving changes as early as possible. One of the reasons for this observation is that operation, maintenance, and construction expertise is incorporated into the project at the very beginning—during FEL.

This means that the process design engineer should be working closely with these real-world experts as they design processes and their support systems. This also means that to improve overall project performance, achieving the best practical or highest level of definition during FEL is critical. Finally, this high level of definition results in a

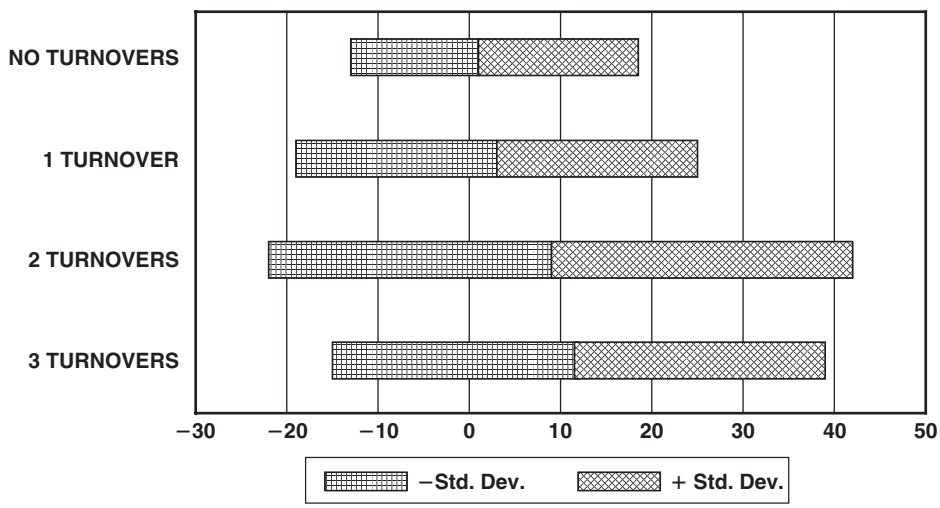

**FIG. 9-29** Effects of project manager turnover on cost growth.

| LEVEL OF FEL EFFORT | COST | SCHEDULE |
|---|---|---|
| *High* | −4% | −13% |
| *Medium* | −2% | +8% |
| *Low* | +16% | +26% |
| *Difference* | 20% | 39% |

**FIG. 9-30** Project performance versus level of FEL effort.

reduced number of changes during the EPC phase. These observations should be the critical goals of all project teams.

The size of capital project also has an influence on FEL outcome based on IPA statistics. IPA's data indicate that small projects benefit more from better project definition prior to the EPC phase than do major projects. The data also indicate that small projects typically have more late changes than do larger projects.

Figure 9-32 illustrates the effect of large projects versus small projects in terms of the impact of late changes (Merrow, E. W., Independent Project Analysis, Inc., 32d Annual Engineering & Construction Contracting Conference, Sept. 28–29, 2000). Figure 9-32 also illustrates that the level of FEL performance directly impacts the number of, and the consequences of, late changes made in projects of any size.

**Typical FEL Deliverables** Every process engineer assigned to a project should be acutely aware of which deliverables or end products are required by those who must commission their work. This should be very well understood by all parties prior to starting the work. Further, the splits of work (who will do which aspect of the work) must be well understood. Today, it is very common to have multiple operating companies form a joint venture to authorize major projects. It is also common for multiple engineering contractors to form joint ventures to execute the engineering for the FEL phases of the project.

***Typical Conceptual Phase (FEL-1) Deliverables*** These are listed below. Each project will customize these deliverables to suit the particular needs of the project. There is no such thing as a "standard" FEL. Therefore, the process engineer must understand what the details are for each deliverable needed, what the *minimum* level is for the engineering required to meet those requirements, and in which formats that information and data will be needed.

- Strategic business assessment
- Key technology selected and risk identified
- Market assessment for feed, products, and capacity
- Potential sites identified and under evaluation
- Cost estimate (±40 percent)
- Preliminary project milestone schedule
- Block flow diagrams completed
- Process cases identified
- Critical long-lead equipment identified
- Value-improving practices reports

***Typical Feasibility Phase (FEL-2) Deliverables*** These are listed below. In this phase, emphasis is on determining the best technical and economic flow scheme, as well as the support systems required to provide the necessary annual production rate at the sales quality required. The focus for the process engineer should be on confirming the number and type of process and technology studies needed, as well as the number of alternate cases required to be evaluated and/or simulated.

- Strategic business assessment
- Project schedule level 1
- Cost estimate (±25 percent)
- Overall project execution strategy
- Contracting and purchasing strategies
- Permitting and regulatory compliance plan
- Soil survey and report
- Project alternatives analysis
- Process flow diagrams for selected option(s)
- Preliminary utility flow diagrams and balances
- Preliminary equipment list and equipment load sheets
- Materials of construction
- Process hazards analysis report
- Value-improving practices reports

***Typical Definition Phase (FEL-3) Deliverables*** These are listed below. In this phase, emphasis is typically on optimizing the best flow scheme and support systems combination. This optimum includes consideration of the plot plan and equipment arrangements for the entire facility. Process optimization cannot be done in isolation. Significant and continuous interaction with operations, maintenance, and construction experts always produces the best results. The emphasis in this phase is on achieving the best practical level of project definition and a good-quality project estimate of +/–10 percent. This level of project definition and cost estimate quality is normally required in order to present to management a candidate project which has the right combination of overall risk and projected economic performance, and thereby secure an AFE.

- Strategic business assessment

**Introduction** Value-improving practices (VIPs) are formal structured practices applied to capital projects to improve profitability (or "value") above that which is attained through the application of proven good engineering and project management practices. VIPs are formal analyses of project characteristics and features performed by small multidisciplinary teams at identified optimum times during the engineering design and development of capital projects.

Application of VIPs to capital projects has been statistically proved to significantly improve project profitability according to Independent Project Analysis, Inc. (IPA) and the Construction Industry Institute (CII). IPA data presented in Fig. 9-33 have been gathered from many capital projects since 1987. These data indicate that about 2.5 percent reduction in the relative capital cost can be expected for high-performing projects due to implementation of good front-end loading work processes. The best-performing projects are often referred to as "Best Practical" or "Best in Class" projects and represent the upper 20 percent of projects.

However, when FEL improvement is combined with rigorous application of VIPs, the project performance improves to about 10 percent in reduction of relative capital cost (Lavingia, Jr., N. J., Improve Profitability Through Effective Project Management and TCM). Experience of at least one major engineering contractor indicates that about a 20 percent capital cost improvement can be expected through judicious use of their modified VIPs (KBR Value Improving Practices Program, 1995 through 2005). These improved results come about from continual adaptation and improvement of the VIPs themselves to maintain their relevance and ability to improve projects above what the project teams can accomplish by themselves.

The VIPs that have been statistically verified by IPA benchmarking of capital projects are listed below. Each has a different purpose and focus, but all produce project profitability improvements that the project team cannot achieve on its own.

- Classes of facility quality
- Technology selection
- Process simplification
- Constructability
- Customization of standards and specifications
- Energy optimization
- Predictive maintenance
- Waste minimization
- Process reliability simulation
- Value engineering
- Design to capacity
- 3D-CAD

Selection of the most applicable VIPs to be performed during a specific project is the focus of the VIP planning session, which should be held just following project kickoff. Figure 9-34 presents the optimal times during a large project for consideration of VIPs. The duration for FEL has been assumed to be 12 months. Every project will have a

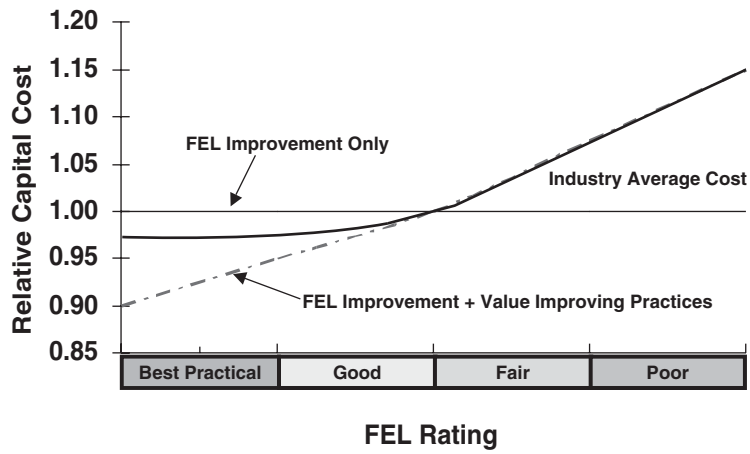

**FIG. 9-33** FEL and VIPs drive lower capital investment.

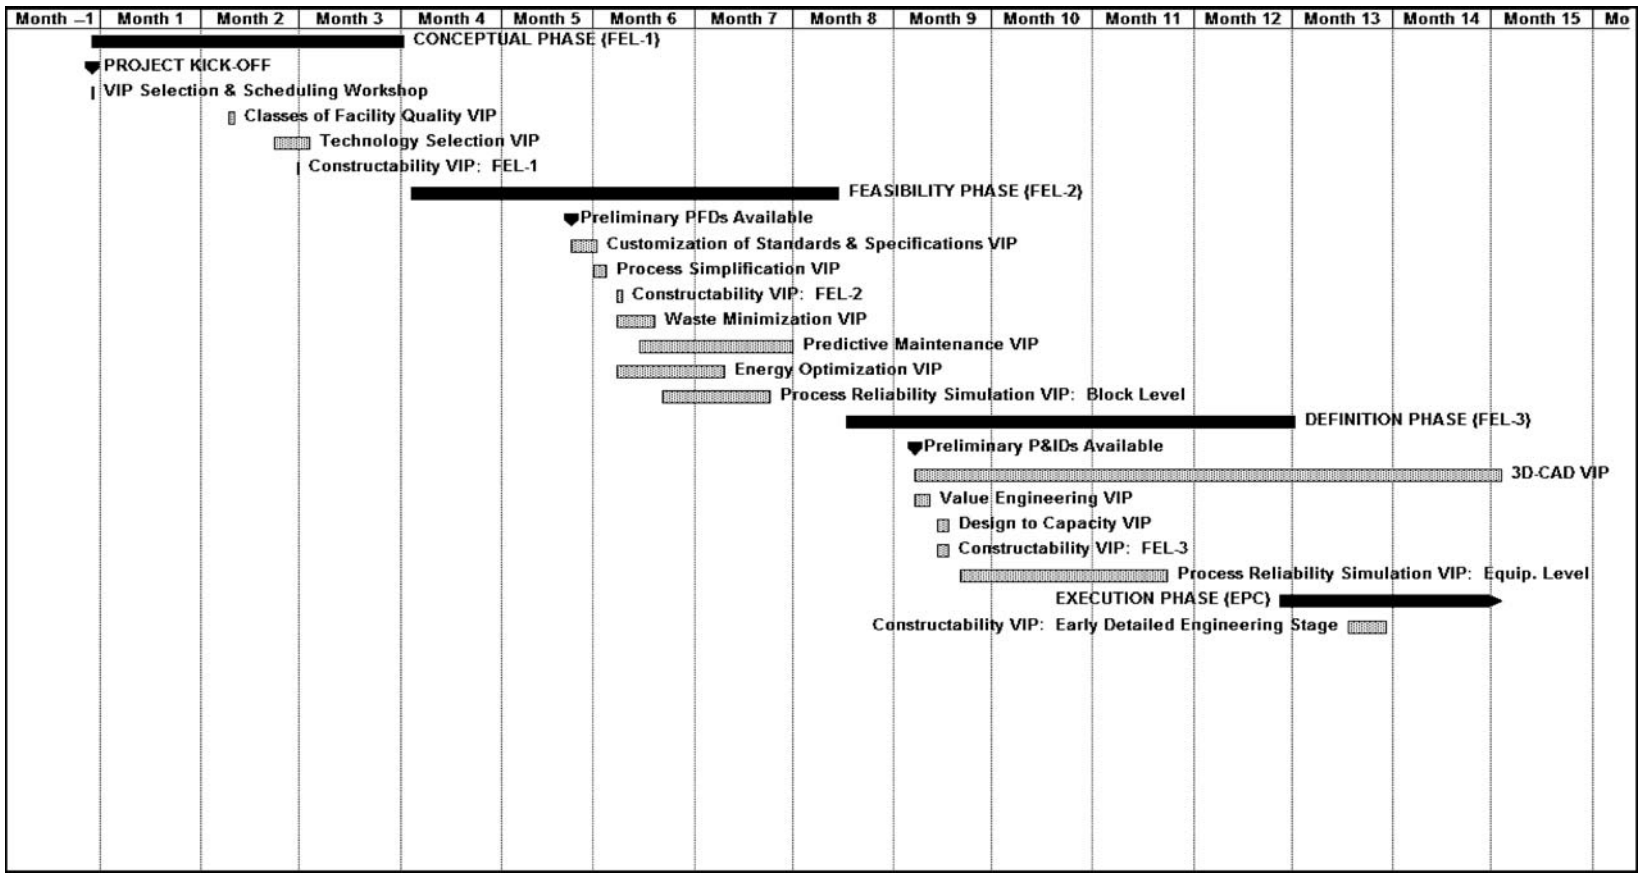

**FIG. 9-34** Typical VIP implementation relationship.

unique duration for FEL with each phase dictated by the owner organization. The best times to conduct the VIP workshops should be considered at the project outset. Key anchor points for VIPs are the first appearance of the process flow diagrams (PFDs). The second anchor point for VIPs is the issue of preliminary piping and instrumentation diagrams (P&IDs).

When capital projects are benchmarked by third-party organizations such as IPA or through CII's Project Definition Rating Index (PDRI: Project Definition Rating Index—Industrial Projects, Construction Industry Institute), the implementation of applicable VIPs to the project is a part of their analysis. All the VIPs, when properly implemented, focus on producing better project definition and resultant economic improvements. The level of project definition achieved during FEL phases of the project is the focus of such benchmarking efforts.

VIPs as a group of practices are often described by their characteristics:

- Out-of-the-ordinary practices are used to improve cost, schedule, and/or reliability of capital projects.
- They are used primarily during FEL project phases.
- Formal and documented practices involve repeatable work processes.
- All involve a formal facilitated workshop to confirm the value gained to the project and to formally approve VIP team recommendations.
- All involve stated explicit support from the owner's corporate executive team.
- VIPs must be performed by a trained experienced VIP facilitator—someone who is not a member of the project team
- VIPs are characterized by statistical links between the use of the practice and better project performance which are demonstrated, systematic, repeatable, and proven correlations

VIPs are also further clarified by what they are not, as below.

- Just "good engineering"
- Simple brainstorming or strategy sessions
- Business as usual
- A special look at some aspect of the project
- Cost reduction or scope reduction exercises
- PFD or P&ID reviews
- Safety reviews
- Audits
- Project readiness reviews

**VIP Descriptions**

***Classes of Facility Quality VIP*** The class of facility quality VIP determines the appropriate classes of facility quality that would produce the highest value or profitability in terms of

- Capital investment (CAPEX)
- Planned facility life
- Expandability
- Level of automation
- Equipment selection,
- Operating expense (OPEX)
- Environmental controls
- Capacity
- Technology

This VIP individually confirms the best overall design philosophy for the project team, for each of the parameters listed above. Here, the designer first learns how aggressive the owner organization wants the facility design and operation to be in terms of overall risk. For example, if the plant is to have the lowest possible OPEX, then the designer will incorporate greater levels of automation, instrumentation, and robustness of mechanical design in the overall facility.

The results of this VIP are used by the project management team to update its project execution plan for each FEL phase. The class of facility quality VIP provides the best results when conducted prior to executing any other VIP effort in the conceptual phase (FEL-1) of the project.

***Technology Selection VIP*** The technology selection VIP is the application of evaluation criteria aligned with the project's business objectives to identify manufacturing and processing technology that may be superior to that currently used. The goal is to ensure that the technology suite finally selected is the most competitive available. This requires a systematic search, both inside and outside the operating company's organization, to identify emerging technology alternatives. This formal facilitated process is also meant to ensure due diligence for all parties involved and that all emerging and near-commercial alternative technologies for accomplishing a particular processing function are objectively considered. This VIP is most commonly applied at the unit operation level, although it has also been successfully applied down to the major equipment level (KBR Value Improving Practices Program, 2000 through 2005). This VIP is particularly effective for combating the NIH syndrome ("not-invented-here").

The goals of this VIP are to document which technology evaluation criteria are applicable and then to conduct a formal technology screening and evaluation assessment. The result is a prioritized listing of technology options for each selected application for the project. The preferred time to execute this VIP is the midpoint in the conceptual phase (FEL-1).

***Process Simplification VIP*** The process simplification VIP uses the value methodology and is a formal, rigorous process to search for opportunities to eliminate or combine process and utility system steps or equipment, ultimately resulting in the reduction of investment and operating costs. The focus is the reduction of installed costs and critical path schedule while balancing these value improvements with expected facility operability, flexibility, and overall life cycle costs.

The process simplification VIP does far more than just evaluate and simplify processing steps. This very productive VIP ensures that low- or zero-value functions or equipment included in the project scope are challenged by experienced world-class experts and eliminated, if possible. This VIP tries to systematically differentiate "wants" from "needs" and remove the "wants." It can be especially effective for providing a neutral professional environment for identifying and challenging "sacred cows" and then removing them. Removal of these low- or zero-value functions yields significant profitability improvements to the overall project. Process simplification results in

- Reduced capital costs (CAPEX)
- Improved critical path schedule
- Reduced process inventory
- Increased yields
- Reduced operating and maintenance costs (OPEX)
- Increased productivity
- Incremental capacity gains
- Reduced utility and support systems requirements
- Reduced waste generation

Process simplification is executed in a formal workshop with a trained experienced facilitator. This VIP should always include key participants from each of the project owner's organizations, the engineering contractor organization, key third-party technology licensors, and equipment or systems vendors, where possible. One or more "cold eyes" reviewers or subject matter experts, who have extensive experience, should be included to provide an objective and unbiased perspective.

This VIP also provides a means for integrating overall plantwide systems. The process simplification VIP is typically performed during the feasibility phase (FEL-2) after the preliminary PFDs and heat and material balances become available. However, for very large and complex projects, considerable value has been gained by also performing this VIP at the midpoint or later in the conceptual phase (FEL-1).

***Constructability VIP*** The constructability VIP is the systematic implementation of the latest engineering, procurement and construction concepts and lessons learned, which are consistent with the facility's operations and maintenance requirements. The goal is to enhance construction safety, scope, cost, schedule, and quality.

Since the constructability VIP has seen widespread implementation in industry for capital projects over the last 20 years, in order for this VIP to remain consistent with the definition of a VIP (i.e., above what project teams can do on their own), at least one large engineering and construction company has enhanced this VIP to include a formal facilitated workshop that seeks profitability improvements above those already identified by the project team in the course of its normal work (KBR Value Improving Practices Program, 2001 through 2005). Both work processes described below are mutually additive, flexible, and compatible.

The traditional constructability work process includes the following characteristics:

- Starts at the FEL-1 phase and continues through facility start-up
- Is an ongoing structured program

- Optimizes the combined use of operations, maintenance, engineering, procurement, key vendors, and construction knowledge and experience
- Enhances the achievement of project objectives
- Has construction experts working with the engineering and procurement process that results in construction safety, cost, schedule, and quality savings
- Uses on-project and off-project expertise

The enhanced constructability VIP adds the following to the traditional approach:

- Includes a formal facilitated workshop
- Is held in every engineering phase of the project with a focus on the pertinent aspects of that phase
- Identifies value improvements and their benefits above those already being considered by the traditional constructability work process
- Focuses on the systematic implementation of the latest engineering, procurement, construction concepts, and lessons learned
- Involves a detail review of planning, design, procurement, fabrication, and installation functions to achieve the best overall project safety performance, lowest CAPEX, and the shortest reasonable schedule
- Applies operations and maintenance requirements and expertise
- Includes considerations for operability and maintainability
- Enhances construction safety, scope, cost, schedule, and quality

A formal constructability VIP workshop conducted in the conceptual phase (FEL-1) should focus on the overall project construction strategies regarding site layout, construction and turnaround laydown areas, access to the site for large equipment and modules, modularization, sequencing of heavy lifts, limitations regarding procurement, limitations regarding fabrication and transport, area labor limitations, and coordination with any existing or nearby structures or facilities.

A formal constructability VIP workshop conducted in the feasibility phase (FEL-2) should focus on more specific topics of layout optimization, using a preliminary plot plan and equipment layout for the project. Considerations should include optimum site layout in terms of construction laydown areas; optimum equipment arrangement to reduce piping and steel for structures and piperack; specific sizes and weights for modules; which components will be included in each module; crane locations for heavy lifts; equipment requiring early purchase to allow project schedule to be achieved; further analysis of limitations regarding procurement, fabrication, and area labor availability; and precommissioning, commissioning, and start-up considerations.

A formal constructability VIP workshop conducted in the definition phase (FEL-3) focuses on even greater detail for what was discussed above. In the detailed engineering stage (EPC phase), considerable detail will be reviewed to evaluate how the project can best construct what will be needed. Here, significant application of detailed lessons learned is reviewed and considered.

Constructability VIP workshops should be formal facilitated workshops drawing on personnel from operations, maintenance, and construction in addition to project and owner organization representation.

***Customization of Standards and Specifications VIP*** The customization of standards and specifications VIP is a direct and systematic method to improve project value by selecting the most appropriate codes, standards, and specifications for the project. The goal is to make helpful changes to meet the actual project requirements, ensuring that the codes, standards, and specifications selected do not exceed those required for the project, and maximizing the use of specifications from equipment vendors to obtain the best overall value. This VIP is beyond typical good engineering practices and should not be confused with ongoing systematic improvements in corporate standards and specifications, or with required identification of applicable procurement specifications to be used for the project. This formal VIP takes a combination of project owner and engineering contractor corporate specifications and aggressively seeks profitability improvements consistent with the project's goals and limitations. This VIP maximizes the procurement of off-the-shelf equipment over equipment customized for the project.

Industry experience indicates that project-specific "Fit for Purpose" standards and specifications on the average cost less than the general application of traditional standards. This VIP is best performed early in the feasibility phase (FEL-2), and should include project team members involved from both the project owner and engineering contractor, as well as appropriate suppliers of major packaged subsystems, modularized equipment, etc.

***Energy Optimization VIP*** The energy optimization VIP is the systematic process for the evaluation of the thermal efficiency of a process (or multiple subunits within a larger process or facility). The goal is to improve the economic utilization of energy. This optimization starts by using the "pinch" technology branch of process energy integration (energy pinch) to identify better process energy exchange options.

Energy pinch (usually just called *pinch*) is a methodology for the conceptual design of process heating, utility, and power systems. Pinch allows the maximization of energy utilization within a process, while minimizing the use of plant utilities. Such minimization is achieved by reusing energy, via process stream–to–process stream heat exchange. A pinch analysis is performed by analyzing the tradeoff between the energy which can be recovered and the additional capital costs which must be added to do so. It includes the project's design and thermodynamic constraints (performance targets) available during this preliminary design phase.

The benefits of pinch technology include lower operating costs, occasionally reduced capital cost, improved operability/flexibility, increased throughput, and site-specific process optimization and reduced emissions. Pinch technology can be applied for both grass-roots and retrofit applications. Typical applications include process heat integration as well as sitewide heat and power integration. However, this methodology is profitably applied to the optimization of high-value complex mass flow problems, such as refinery hydrogen network optimization (hydrogen pinch) and wastewater minimization (water pinch).

Once the minimum theoretical energy requirements and applicable process options have been determined, a formal facilitated workshop follows to modify the process or facility to bring the design closer to the thermodynamic optimum within project economic constraints.

The energy optimization VIP is most beneficial for processes where energy and related capital expense are a relatively large fraction of the total operating cost. The benefits result in reduced energy requirements and environmental emissions in balance with project economics. This VIP should be implemented in the feasibility phase (FEL-2) when preliminary PFDs and heat and material balances are available.

***Predictive Maintenance VIP*** The predictive maintenance VIP is the proactive use of sensors and associated controls to monitor the machinery mechanical "health," using both current state and historical trends, to optimize effective planning of all shutdowns and maintenance, thereby detecting equipment abnormalities and diagnosing potential problems before they cause permanent equipment damage. Examples include real-time corrosion monitoring and equipment vibration monitoring. This additional instrumentation is generally economically justified in the case of critical equipment items and key operations. Predictive maintenance reduces maintenance costs, improves the confidence of extending time between turnarounds, improves reliability, and provides a more predictable maintenance schedule for key process equipment. It also minimizes the amount of remaining equipment life that is lost through using only preventive maintenance practices. Preventive maintenance is an older practice which is limited to periodic inspections and repairs to avoid unplanned equipment breakdowns.

For the predictive maintenance VIP to be effective, maintenance personnel from the project owner's organization must be involved in determining key predictive maintenance requirements. Suppliers of critical equipment items (i.e., compressors) are also important participants in this process.

The predictive maintenance VIP is considered by some operating companies and engineering contractors to have become standard practice. For those where it is not already standard practice, this VIP should be initiated in the feasibility phase (FEL-2) and concluded with a formal facilitated workshop and report of recommendations to the project management team.

***Waste Minimization VIP*** The waste minimization VIP involves a formal process stream-by-stream analysis to identify ways to eliminate or reduce the generation of wastes or nonuseful streams within the chemical process itself. For those streams not eliminated or converted to salable by-products, it provides the method for managing the resulting wastes. This VIP incorporates environmental requirements into the facility design and combines life cycle environmental

benefits and positive economic returns through energy reductions, reduced end-of-pipe treatment requirements, and improved raw material yields. The waste reduction hierarchy is to

- Eliminate or minimize the generation of waste through source reduction
- Recycle by use, reuse, or reclamation those potential waste materials that cannot be eliminated or minimized
- Treat all waste that is nevertheless generated to reduce volume, toxicity, or mobility prior to storage or disposal

This VIP is considered by some engineering contractors to have become standard practice. For those where it is not standard practice, the waste minimization VIP should be executed in a formal workshop with an experienced facilitator with project owner and engineering contractor representatives always involved. A "cold eyes" reviewer with extensive experience should also be included to add a nonbiased perspective. The waste minimization VIP should be implemented at the feasibility phase (FEL-2) when preliminary PFDs and heat and material balances are available.

***Process Reliability Simulation VIP*** The process reliability simulation VIP is the use of reliability, availability, and maintainability (RAM) computer simulation modeling of the process and the mechanical reliability of the facility. A principal goal is to optimize the engineering design in terms of life cycle cost, thereby maximizing the project's potential profitability. The objective is to determine the optimum relationships between maximum production rates and design and operational factors. Process reliability simulation is also applied for safety purposes, since it considers the consequences of specific equipment failures and failure modes.

This VIP is typically led by an engineer experienced in plant operations and the use of the RAM simulation modeling software. The VIP should also directly involve the project owner since that organization would most often supply the historical operating and maintenance information required for the development of the simulation model. This process provides the project team with a more effective means of assessing, early in the design, the cost/benefit impact of changes in design, identification of bottlenecks in the system, simulation of key operating scenarios, determination of equipment-sparing needs, training and maintenance requirements of a facility.

The process reliability simulation VIP should be initiated in the feasibility phase (FEL-2) to produce a block-level RAM model. Based on the results of that model, a more detailed equipment-level RAM model should be developed starting in the definition phase (FEL-3).

***Value Engineering VIP*** The value engineering VIP is a flexible, organized, multidisciplinary team effort directed at analyzing the functions, issues, and essential characteristics of a project, process, technology, or system. The goal is to satisfy those functions, issues, and essential characteristics at the lowest life cycle cost. The value engineering VIP rigorously examines what is needed to meet the business objectives of a project and the elimination of non-value-adding investment. An open-minded attitude by participants is required to effectively remove unneeded scope and in doing so reduce the installed costs of the project. This VIP tries to systematically differentiate "wants" from "needs" and remove the "wants." Tests for non-income-producing investments include redundancy, overdesign, manufacturing add-ons, upgraded materials of construction, and customized design versus vendor standards.

The value engineering VIP also ensures that low- or zero-value functions or equipment included in the project scope are challenged to be the highest value possible for the project. Removal of these low- or zero-value functions from the project scope, if possible, will most likely yield significant profitability improvements to the overall project. These can encompass the following:

- Misalignment of unit or system capacity or operations capability with respect to the overall facility
- Overly conservative assumptions of the basic design data
- Overly conservative interpretation of how the facilities will be used during peak, seasonal, or upset conditions
- Preinvestment included in the project scope that may not be value added
- Overdesign of equipment or systems to provide uneconomic added flexibility

The value engineering VIP is executed in a formal workshop with a trained experienced technical workshop facilitator. Both the project owner and the engineering contractor are always involved. Third-party licensors and equipment/system vendors should be included where applicable. One (or more) cold-eyes reviewer with extensive experience should also be included to provide an unbiased perspective.

This VIP leverages the growing accumulation of more detailed project knowledge to test the value of earlier, more generalized scope assumptions. It also tests the presumed added value of different stakeholder requirements, which have influenced the evolution of the project scope. This highly adaptable VIP results in reduced capital costs (CAPEX), improved critical path schedule, reduced process inventory, increased yields, reduced operating and maintenance costs (OPEX), increased productivity, incremental capacity gains, reduced utility and support systems requirements, and reduced waste generation.

The value engineering VIP should be conducted in the definition phase (FEL-3) when the first issue of P&IDs is available.

***Design to Capacity VIP*** The design to capacity VIP systematically evaluates the maximum capacity of major equipment, ancillary piping, valving, instrumentation, and associated engineering calculations and guidelines. The goal is to improve life cycle costs (profitability) by eliminating preinvestment and overdesign. This VIP requires the systematic and formal evaluation of the maximum capacity of each piece of equipment instead of the traditional practice of designing with an extra safety factor or margin to allow for additional catch-up capacity or some future production increase. The goal is also to eliminate overdesign in both calculations and engineering guidelines. This VIP is conducted as a facilitated workshop with both project owner and engineering contractor representation.

This VIP reduces capital investment by confirming minimum required capacities and flexibility necessary only to meet current project business objectives. The workshop drills down to each specific system and subsystem and finally scrutinizes the design of each equipment item. This workshop is often combined with the value engineering VIP, which overlaps significantly. The design to capacity VIP should be conducted in the definition phase (FEL-3) when the first issue of P&IDs is available.

***3D-CAD VIP*** The 3D-CAD VIP is the creation of a detailed three-dimensional (3D) computer model depicting the proposed process and associated equipment along with the optimized plant layout and specific equipment arrangements and orientations. The 3D model can then be used to generate computerized interference checks of bulk material configurations and equipment and extraction of error-free fabrication drawings and material quantities. The goals of this VIP are to reduce engineering and construction rework, improve operability and maintainability, and confirm the incorporation into the design of advantageous human factors (a.k.a. ergonomics) focused on ease of operation and maintenance.

A number of industry-accepted state-of-the-art 3D computer-aided design (CAD) systems have been used for this purpose. The specification-driven 3D-CAD system allows a computer model to be built to allow extraction of drawings from the model for fabrication and erection. The extracted drawings are enhanced in their accuracy by the computer interference detection system which greatly reduces field rework.

The principal benefit of utilizing 3D-CAD is the ability to produce an electronic model that accurately resembles the completed facility. This enables project teams, clients, and constructors to review and agree on the plant design before construction starts. The model can then be used to generate interference checks of bulk material configurations and equipment, as well as the extraction of error-free fabrication drawings and material quantities. The system also utilizes its design review capabilities to confirm proposed designs and obtain approvals from key project stakeholders and owners.

This VIP is considered by most major engineering contractors to have become standard practice. The 3D-CAD VIP model development should be initiated in the feasibility phase (FEL-2) after the plot plan has been finalized and the first issue of P&IDs is available.

**VIP Planning and Implementation** Each VIP has a unique character, and it should be performed at a certain time and in a certain way to produce the best results for the project. Part of the power of VIPs is that they can be used to improve the overall economics of the project without the need for inordinate additional time or expense. Ironically, the return on investment (ROI) for the cost of implementing each VIP is usually much greater than that ROI for the overall proposed project. For one engineering contractor, *the typical ROI for*

*implementing VIPs is at least one order of magnitude higher* (KBR Value Improving Practices Program, 2000 through 2005).

It is important to reiterate that the benefits of VIPs cannot be realized by just executing "good engineering." The application and implementation of VIPs to any project must have the explicit commitment of the owner's corporation executives. VIP execution must be deliberately and carefully planned in the initial phase of the project. For all projects, this VIP planning meeting should take place immediately following project kickoff. The project management team and the selected VIP facilitator should

- Confirm which VIPs should be applied to the project and when
- Incorporate the planned VIPs into the project scope of work and schedule
- Determine the required workshop resources and best combination of engineering, operations, maintenance, construction, and other expertise for each selected VIP workshop team

**VIPs That Apply the Value Methodology** Nearly all VIPs are conducted only once in a project at a "sweet spot" where maximum benefit is found. For example, the process simplification VIP is anchored at the first appearance of the preliminary PFDs, while the value engineering VIP and the design to capacity VIP are anchored at the first issue of the P&IDs. Both of these apply the value methodology [Society of American Value Engineers International (SAVE)] that has produced excellent results in industry for more than 55 years. The typical approach and steps for these three unique VIPs are presented below.

***Preparation and Planning*** Before the VIP is begun, the goals, objectives, and scheduled time for the formal workshop must be agreed upon by the integrated project management team. The workshop facilitator must ensure that all the information required for the workshop is available and that the workshop team members have been fully briefed on the VIP's objectives, methodology, and expectations.

***The Formal Workshop*** The formal workshop is always structured to make maximum use of the multi-disciplinary team's time and effort. Such workshops typically require no less than 2 days and as many as 5 days depending on the size and complexity of the project. The required workshop length should be determined by the VIP facilitator. A typical process simplification VIP, value engineering VIP, and design to capacity VIP workshop includes the following phases of a typical "job plan" that are supported by the Society of American Value Engineers International.

*The information phase* In this phase, team members review important background materials and confirm their understanding of the basis for the design of the project, the constraints, and the sensitivity of the relevant capital and operating costs. Here, incorporating important unresolved project issues into the workshop produces more meaningful financial and technical results. Discussion of the issues' validity and basis are determined during the first day of the workshop. These issues very often become some of the best brainstorming targets for cost and schedule reduction ideas.

A very specific and structured methodology is used which is known as the *Function Analysis System Technique (FAST)*. This function analysis diagramming illustrates the logical or functional relationships and dependencies between different process systems and project activities. These diagrams are then reviewed and critiqued together with the associated costs of selected groups of process functions or project functions. The function analysis can be performed at this stage, but often time can be saved by preparing a draft of these FAST diagrams prior to the workshop with a small group of the workshop team members.

*The speculation phase* Once the pertinent information and issues have been reviewed and the important functions of each process and project step identified, the team is encouraged to speculate on alternative methods to perform each function and to solve each major project issue. Brainstorming sessions within a creative environment encourage the team to strive for new and innovative ideas.

*The conceptual phase* The team then reviews the ideas against relevant project criteria such as potential impact on long-term project economics, impact on operations and maintenance costs, effect on the capital cost for the project, validity to the project scope of work, technical risks associated with implementation of the new concept, impact on project schedule, and cost required to implement the improvement. Each study has specific criteria against which proposed alternatives are judged. The ideas are weighted, sorted, grouped, linked, and ranked so that the best of the technically viable ideas are efficiently identified for further detailed study.

*The feasibility phase* The ideas with the most merit are developed into preliminary two-page written proposals with potential benefits approximated as part of the workshop. Performing this important activity following the formal workshop has been shown to often result in significant loss of potential for implementation. The VIP team expands the ideas ranked highest to obtain additional technical and economic insights and information to support the idea. The proposals are then presented internally, to the assembled VIP workshop team, and discussed to determine whether the ideas retain sufficient technical and economic merit to be recommended by the VIP team to a separate steering committee or project management team.

Experience indicates that having the VIP team perform this stage within the formal workshop produces the best results.

*The presentation phase* The VIP team formally presents the profitability recommendations consistent with the objectives and constraints of the workshop and their implementation plans to the steering committee or the project management team. The steering committee then approves those recommendations that pass muster and authorizes the project team to begin the implementation effort. Often, this approval is conditional on early validation by subject matter experts within the project owner's organization, but not present within the workshop. This external feasibility check is meant to provide support to the project team for any additional resources and schedule time needed to fully incorporate the improvements into the project scope of work.

*Report and follow-up* After completing the intensive VIP workshop, the workshop facilitator completes the written VIP final report for the project record. During this time, the project management team assigns each approved recommendation to a member of the project team, estimates the engineering time and resources required to incorporate the improvement into the project scope of work, and communicates the results of the VIP within the integrated project team. This follow-up action plan creates a very positive and cost-conscious attitude within the project team that leads to further improvements in project value.

**Sources of Expertise** VIP workshops should be planned and led by a trained experienced facilitator who has significant experience in effectively conducting such VIP workshops. Technical expertise for VIP workshops should be a combination of senior project team members and subject matter experts from the operating company's organization, the engineering contractor's organization, licensed technology providers, and any key fabrication or installation subcontractors to be used. Figure 9-35 illustrates the best balance of expertise for VIP workshops (KBR Value Improving Practices Program, 1995 through 2005).

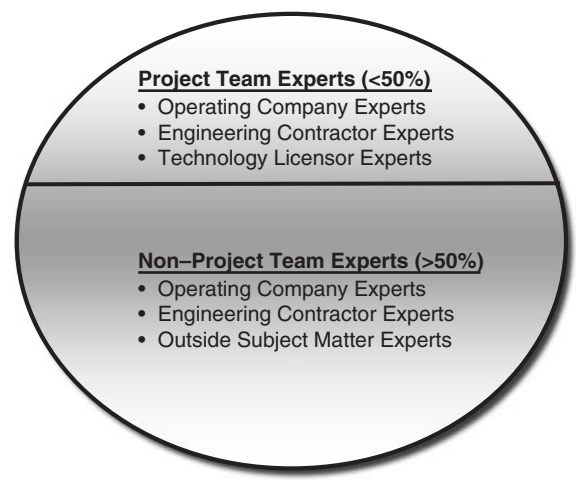

**FIG. 9-35** The ideal VIP team makeup.

## GLOSSARY

***Accounts payable*** The value of purchased goods and services that are being used but have not been paid.

***Accounts receivable*** Credit extended to customers, usually on a 30-day basis. Cash is set aside to take care of the probability that some customers may not pay their bills.

***Accrual basis*** The accounting method that recognizes revenues and disbursement of funds by receipt of bills or orders and not by cash flow, distinguished from *cash basis*.

***Administrative expense*** An overhead expense due to the general direction of a company beyond the plant level. It includes administrative and office salaries, rent, auditing, accounting, legal, central purchasing and engineering, etc., expenses.

***Allocation of expenses*** A procedure whereby overhead expenses and other indirect charges are assigned back to processing units or to products on what is expected to be an equitable basis. All allocations are somewhat arbitrary.

***Amortization*** Often used interchangeably with *depreciation*, but there is a slight difference depending on whether the life of an asset is known. If the period of time is known to be usually more than a year, this annual expense is *amortization*; however, if the life is estimated, then it is *depreciation.*

***Annual net sales*** Pounds of product sold times the net selling price. *Net* means that any allowances have been subtracted from the gross selling price.

***Annual report*** Management's report to the stockholders and other interested parties at the end of a year of operation showing the status of the company, its activities, funds, income, profits, expenses, and other information.

***Appurtenances*** The auxiliaries to either process or nonprocess equipment: piping, electrical, insulation, instrumentation, etc.

***Assets*** The list of money on hand, marketable securities, monies due, investments, plants, properties, intellectual property, inventory, etc., at cost or market value, whichever is smaller. The assets are what a company (or person) owns.

***Balance sheet*** This is an accounting, historical tabulation of assets, liabilities, and stockholders' equity for a company. The assets must equal the liabilities plus the stockholders' equity.

***Battery limit*** A geographic boundary defining the coverage of a specific project. Usually it takes in the manufacturing area of a proposed plant, including all process equipment but excluding provision for storage, site preparation, utilities, administrative buildings, or auxiliary facilities.

***Bonds*** When one purchases a bond, the company (or person) acquires an interest in debt and becomes a creditor of the company. The purchaser receives the right to receive regular interest payments and the subsequent repayment of the principal.

***Book value*** Current investment value on the company books as the original installed cost less depreciation accruals.

***Book value of common stock*** Net worth of a firm divided by the number of shares of common stock issued at the time of a report.

***Break-even chart*** An economic production chart depicting total revenue and total expenses as functions of operation of a processing facility.

***Break-even point*** The percentage of capacity at which income equals all fixed and variable expenses at that level of operation.

***By-product*** A product made as a consequence of the production of a main product. The by-product may have a market value or a value as a raw material.

***Capacity*** The estimated maximum level of production on a sustained basis.

***Capital ratio*** Ratio of capital investment to sales dollars; the reciprocal of capital turnover.

***Capital recovery*** The process by which original investment in a project is recovered over its life.

***Capital turnover*** The ratio of sales dollars to capital investment; the reciprocal of capital ratio.

***Cash*** Money that is on hand to pay for operating expenses, e.g., wages, salaries, raw materials, supplies, etc., to maintain a liquid financial position.

***Cash basis*** The accounting basis whereby revenue and expense are recorded when cash is received and paid, distinguished from accrual basis.

***Cash flow*** Net income after taxes plus depreciation (and depletion) flowing into the company treasury.

***Code of accounts*** A system in which items of expense or fixed capital such as equipment and material are identified with numerical figures to facilitate accounting and cost control.

***Common stock*** Money paid into a corporation for the purchase of shares of common stock that becomes the permanent capital of the firm. Common stockholders have the right to transfer ownership and may sell the stock to individuals or firms. Common stockholders have the right to vote at annual meetings on company business or may do so by proxy.

***Compound interest*** The interest charges under the condition that interest is charged on previous interest plus principal.

***Contingencies*** An allowance for unforeseeable elements of cost in fixed investment estimates that previous experience has shown to exist.

***Continuous compounding*** A mathematical procedure for evaluating compound interest based upon continuous interest function rather than discrete interest periods.

***Conversion expense*** The expense of converting raw materials to finished product.

***Corporation*** In 1819, defined by Chief Justice Marshall of the Supreme Court as "an artificial being, invisible, intangible and existing only in contemplation of law." It exists by the grace of a state, and the laws of a state govern the procedure for its formation.

***Cost of capital*** The cost of borrowing money from all sources, namely, loans, bonds, and preferred and common stock. It is expressed as an interest rate.

***Cost center*** For accounting purposes, a grouping of equipment and facilities comprising a product manufacturing system.

***Cost of sales*** The sum of the fixed and variable (direct and indirect) expenses for manufacturing a product and delivering it to a customer.

***Decision or decision making*** A program of action undertaken as a result of (1) an established policy or (2) an analysis of variables that can be altered to influence a final result.

***Depletion*** A provision in the tax regulations that allows a business to charge as current expense a noncash expense representing the portion of limited natural resources consumed in the conduct of business.

***Depreciation*** A reasonable allowance by the Internal Revenue Service for the exhaustion, wear and tear, and normal obsolescence of equipment used in a trade or business. The property must have a useful life of more than 1 year. Depreciation is a noncash expense deductible from income for tax purposes.

***Design to cost*** A management technique to achieve system designs that meet cost parameters. Cost as a design parameter is considered on a continuous basis as part of a system's development and production processes.

***Direct expense*** An expense directly associated with the production of a product such as utilities, labor, and maintenance.

***Direct labor expense*** The expense of labor involved in the manufacture of a product or in the production of a service.

***Direct material expense*** The expense associated with materials consumed in the manufacture of a product or the production of a service.

***Distribution expense*** Expense including advertising, preparation of samples, travel, entertainment, freight, warehousing, etc., to distribute a sample or product.

***Dollar volume*** Dollar worth of a product manufactured per unit of time.

***Earnings*** The difference between income and operating expenses.

***Economic life*** The period of commercial use of a product or facility. It may be limited by obsolescence, physical life of equipment, or changing economic conditions.

***Economic value added*** The period dollar profit above the cost of capital. It is a means to measure an organization's value and a way to determine how management's decisions contribute to the value of a company.

***Effective interest*** The true value of interest computed by equations for the compound interest rate for a period of 1 year.

***Equity*** The owner's actual capital held by a company for its operations.

***Escalation*** A provision in actual or estimated cost for an increase in equipment cost, material, labor, expenses, etc., over those specified in an original estimate or contract due to inflation.

***External funds*** Capital obtained by selling stocks or bonds or by borrowing.

***FEL (front-end loading)*** The process by which a company develops a detailed definition of the scope of a capital project that meets corporate business objectives.

***FIFO (first in, first out)*** The valuation of raw material and supplies inventory, meaning first into the company or process is the first used or out.

***Financial expense*** The charges for use of borrowed funds.

***Fixed assets*** The real or material facilities that represent part of the capital in an economic venture.

***Fixed capital*** Item including the equipment and buildings.

***Fixed expense*** An expense that is independent of the rate of output, e.g., depreciation and plant indirect expenses.

***Fringe benefits*** Employee welfare benefits; expenses of employment over and above compensation for actual time worked, such as holidays, vacations, sick leave, insurance.

***Full cost accounting*** Method of pricing goods and services to reflect their true costs, including production, use recycling, and disposal.

***Future worth*** The expected value of capital in the future according to some predetermined method of computation.

***Goods manufactured, cost of*** Total expense (direct and indirect expenses) including overhead charges.

***Goods-in-process inventory*** The holdup of product in a partially finished state.

***Goods sold, cost of*** The total of all expenses before income taxes that is deducted from income (revenue).

***Grass-roots plant*** A complete plant erected on new site including land, site preparation, battery-limits facilities, and auxiliary facilities.

***Gross domestic product*** An indicator of a country's economic activity. It is the sum of all goods and services produced by a nation within its borders.

***Gross margin (profit)*** Total revenue minus cost of goods manufactured.

***Gross national product*** An economic indicator of a country's economic activity. It is the sum of all the goods and services produced by a nation both within and outside its borders.

***Income*** Profit before income taxes or gross income from sales before deduction of expenses.

***Income statement*** The statement of earnings of a firm as approximated by accounting practices, usually covering a 1-year period.

***Income tax*** The tax imposed on corporate profits by the federal and/or state governments.

***Indirect expenses*** Part of the manufacturing expense of a product not directly related to the amount of product manufactured, e.g., depreciation, local taxes, and insurance.

***Internal funds*** Capital available from depreciation and accumulated retained earnings.

***Inventory*** The quantity of raw materials and/or supplies held in a process or in storage.

***Last in, first out (LIFO)*** The valuation of raw materials and supplies, meaning the last material into a process or storage is the first used or out.

***Leverage*** The influence of debt on the earning rate of a company.

***Liabilities*** An accounting term for capital owed by a company.

***Life cycle cost*** Cost of development, acquisition, support, and disposal of a system over its full life.

***Manufacturing expense*** The sum of the raw material, labor, utilities, maintenance, depreciation, local taxes, etc., expenses. It is the sum of the direct and indirect (fixed and variable) manufacturing expenses.

***Marginal cost*** The incremental cost of making one additional unit without additional investment in facilities

***Market capitalization*** The product of the number of shares of common stock outstanding and the share price.

***Market value added*** A certain future economic value added for a company. It is the present value of the future economic value (EVA) generated by a company. It is a measure of how much value a firm has created.

***Minimum acceptable rate of return (MARR)*** The level of return on investment, at or above the cost of capital, chosen as acceptable for discounting or cutoff purposes.

***Net sales price*** Gross sales price minus freight adjustments.

***Net worth*** The sum of the stockholders' investment plus surplus, or total assets minus total liabilities.

***Nominal interest*** The number applied loosely to describe the annual interest rate.

***Obsolescence*** The occurrence of decreasing value of physical assets due to technological changes rather than physical deterioration.

***Operating expense*** The sum of the manufacturing expense for a product and the general, administrative, and selling expenses.

***Operating margin*** The gross margin minus the general, administrative, and selling expenses.

***Opportunity cost*** The estimate of values that are forgone by undertaking one alternative instead of another one.

***Payout time (payback period)*** The time to recover the fixed capital investment from profit plus depreciation. It is usually after taxes but not always.

***Preferred stock*** Stock having claims that it commands over common stock, with the preference related to dividends. The holders of such stock receive dividends before any distribution is made to common stockholders. Preferred stockholders usually do not have voting rights as common stockholders do.

***Present worth*** The value at some datum time (present time) of expenditures, costs, profits, etc., according to a predetermined method of computation. It is the current value of cash flow obtained by discounting.

***Production rate*** The amount of product manufactured in a given time period.

***Profitability*** A term generally applied in a broad sense to the economic feasibility of a proposed venture or an ongoing operation. It is generally considered to be related to return on investment.

***Rate of return on investment*** The efficiency ratio relating profit or cash flow to investment.

***Replacement*** A new facility that takes the place of an older facility with no increase in capacity.

***Revenue*** The net sales received from the sale of a product or a service to a customer.

***Sales, administration, research, and engineering expenses (SARE)*** Overhead expenses incurred as a result of maintaining sales offices and administrative offices and the expense of maintaining research and engineering departments. This item is usually expressed as a percentage of annual net sales.

***Sales volume*** The amount of sales expressed in pounds, gallons, tons, cubic feet, etc., per unit of time.

***Salvage value*** The value that can be realized from equipment or other facilities when taken out of service and sold.

***Selling expense*** Salaries and commissions paid to sales personnel.

***Simple interest*** The interest charges in any time period that is only charged on the principal.

***Sinking fund*** An accounting procedure computed according to a specified procedure to provide capital to replace an asset.

***Surplus*** The excess of earnings over expenses that is not distributed to stockholders.

***Tax credit*** The amount available to a firm as part of its annual return because of deductible expenses for tax purposes. Examples have been research and development expenses, energy tax credit, etc.

***Taxes*** In a manufacturing cost statement, usually property taxes. In an income statement, usually federal and state income taxes.

***Time value of money*** The expected interest rate that capital should or would earn. Money has value with respect to time.

***Total operating investment*** The fixed capital investment, backup capital, auxiliary capital, utilities and services capital, and working capital.

***Utilities and services capital*** Electrical substations, plant sewers, water distribution facilities, and occasionally the steam plant.

***Value added*** The difference between the raw material expense and the selling price of that product.

***Value-improving practices (VIPs)*** Formal structured practices applied to capital projects to improve profitability ("or value") above that which is attained through the application of proven good engineering and project management practices.

***Variable expense*** Any expense that varies directly with production output.

***Working capital*** In the accounting sense, the current assets minus the current liabilities. It consists of the total amount of money invested in raw materials, supplies, goods in process, product inventories, accounts receivable, and cash minus those liabilities due within 1 year.

### Nomenclature and Units

In this listing, symbols used in the section are defined in a general way and appropriate SI and U.S. customary units are given. Specific definitions, as denoted by subscripts, are stated at the place of application in the section. Some specialized symbols used in the section are defined only at the place of application.

| Symbol | Definition | SI units | U.S. customary units |
|---|---|---|---|
| $A$ | Area | $m^2$ | $ft^2$ |
| $A$ | Factor for determining minimum value of $R_1$ | | |
| $A_\infty$ | Free-stream speed of sound | | |
| $a$ | Area | $m^2$ | $ft^2$ |
| $a$ | Duct or channel width | m | ft |
| $a$ | Coefficient, general | | |
| $B$ | Height | m | ft |
| $b$ | Duct or channel height | m | ft |
| $b$ | Coefficient, general | | |
| $C$ | Coefficient, general | | |
| $C$ | Conductance | $m^3/s$ | $ft^3/s$ |
| $C$ | Sum of mechanical allowances (thread or groove depth) plus corrosion or erosion allowances | mm | in |
| $C$ | Cold-spring factor | | |
| $C$ | Constant | | |
| $C_a$ | Capillary number | Dimensionless | Dimensionless |
| $C_1$ | Estimated self-spring or relaxation factor | | |
| $c_p$ | Constant-pressure specific heat | J/(kg·K) | Btu/(lb·°R) |
| $c_v$ | Constant-volume specific heat | J/(kg·K) | Btu/(lb·°R) |
| $D$ | Diameter | m | ft |
| $D$, $D_0$ | Outside diameter of pipe | mm | in |
| $d$ | Diameter | m | ft |
| $E$ | Modulus of elasticity | $N/m^2$ | $lbf/ft^2$ |
| $E$ | Quality factor | | |
| $E_a$ | As-installed Young's modulus | MPa | $kip/in^2$ (ksi) |
| $E_c$ | Casting quality factor | | |
| $E_j$ | Joint quality factor | | |
| $E_m$ | Minimum value of Young's modulus | MPa | $kip/in^2$ (ksi) |
| $F$ | Force | N | lbf |
| $F$ | Friction loss | (N·m)/kg | (ft·lbf)/lb |
| $F$ | Correction factor | Dimensionless | Dimensionless |
| $f$ | Frequency | Hz | l/s |
| $f$ | Friction factor | Dimensionless | Dimensionless |
| $f$ | Stress-range reduction factor | | |
| $G$ | Mass velocity | $kg/(s·m^2)$ | $lb/(s·ft^2)$ |
| $g$ | Local acceleration due to gravity | $m/s^2$ | $ft/s^2$ |
| $g_c$ | Dimensional constant | 1.0 (kg·m)/(N·$s^2$) | 32.2 (lb·ft)/(lbf·$s^2$) |
| $H$ | Depth of liquid | m | ft |
| $H$, $h$ | Head of fluid, height | m | ft |
| $H_{ad}$ | Adiabatic head | N·m/kg | lbf·ft/lbm |
| $h$ | Flexibility characteristic | | |
| $h$ | Height of truncated cone; depth of head | m | in |
| $i$ | Specific enthalpy | J/kg | Btu/lb |
| $i$ | Stress-intensification factor | | |
| $i_i$ | In-plane stress-intensification factor | | |
| $i_o$ | Out-plane stress intensification factor | | |
| $I$ | Electric current | A | A |
| $J$ | Mechanical equivalent of heat | 1.0 (N·m)/J | 778 (ft·lbf)/Btu |
| $K$ | Index, constant or flow parameter | | |
| $K$ | Fluid bulk modulus of elasticity | $N/m^2$ | $lbf/ft^2$ |
| $K_1$ | Constant in empirical flexibility equation | | |
| $k$ | Ratio of specific heats | Dimensionless | Dimensionless |
| $k$ | Flexibility factor | | |
| $k$ | Adiabatic exponent $c_p/c_v$ | | |
| $L$ | Length | m | ft |
| $L$ | Developed length of piping between anchors | m | ft |
| $L$ | Dish radius | m | in |
| $M$ | Molecular weight | kg/mol | lb/mol |
| $M_i$, $m_i$ | In-plane bending moment | N·mm | in·lbf |
| $M_o$ | Out-plane bending moment | N·mm | in·lbf |
| $M_t$ | Torsional moment | N·mm | in·lbf |
| $M_\infty$ | Free stream Mach number | | |
| $m$ | Mass | kg | lb |
| $m$ | Thickness | m | ft |
| $N$ | Number of data points or items | Dimensionless | Dimensionless |
| $N$ | Frictional resistance | Dimensionless | Dimensionless |
| $N$ | Equivalent full temperature cycles | | |
| $N_S$ | Strouhal number | Dimensionless | Dimensionless |
| $N_{De}$ | Dean number | Dimensionless | Dimensionless |
| $N_{Fr}$ | Froude number | Dimensionless | Dimensionless |
| $N_{Re}$ | Reynolds number | Dimensionless | Dimensionless |
| $N_{We}$ | Weber number | Dimensionless | Dimensionless |
| NPSH | Net positive suction head | m | ft |
| $n$ | Polytropic exponent | | |
| $n$ | Pulsation frequency | Hz | 1/s |
| $n$ | Constant, general | | |
| $n$ | Number of items | Dimensionless | Dimensionless |
| $P$ | Design gauge pressure | kPa | $lbf/in^2$ |
| $P_{ad}$ | Adiabatic power | kW | hp |
| $p$ | Pressure | Pa | $lbf/ft^2$ |
| $p$ | Power | kW | hp |
| $Q$ | Heat | J | Btu |
| $Q$ | Volume | $m^3$ | $ft^3$ |
| $Q$ | Volume rate of flow (liquids) | $m^3/h$ | gal/min |
| $Q$ | Volume rate of flow (gases) | $m^3/h$ | $ft^3$/min (cfm) |
| $q$ | Volume flow rate | $m^3/s$ | $ft^3/s$ |
| $R$ | Gas constant | 8314 J/(K·mol) | 1545 (ft·lbf)/(mol·°R) |
| $R$ | Radius | m | ft |
| $R$ | Electrical resistance | Ω | Ω |
| $R$ | Head reading | m | ft |
| $R$ | Range of reaction forces or moments in flexibility analysis | N or N·mm | lbf or in·lbf |
| $R$ | Cylinder radius | m | ft |
| $R$ | Universal gas constant | J/(kg·K) | (ft·lbf)/(lbm·°R) |
| $R_a$ | Estimated instantaneous reaction force or moment at installation temperature | N or N·mm | lbf or in·lbf |
| $R_m$ | Estimated instantaneous maximum reaction force or moment at maximum or minimum metal temperature | N or N·mm | lbf or in·lbf |
| $R_1$ | Effective radius of miter bend | mm | in |

**Nomenclature and Units** (*Concluded*)

| Symbol | Definition | SI units | U.S. customary units |
|---|---|---|---|
| $r$ | Radius | m | ft |
| $r$ | Pressure ratio | Dimensionless | Dimensionless |
| $r_c$ | Critical pressure ratio | | |
| $r_k$ | Knuckle radius | m | in |
| $r_2$ | Mean radius of pipe using nominal wall thickness $\overline{T}$ | mm | in |
| $S$ | Specific surface area | $m^2/m^3$ | $ft^2/ft^3$ |
| $S$ | Fluid head loss | Dimensionless | Dimensionless |
| $S$ | Specific energy loss | $m/s^2$ | lbf/lb |
| $S$ | Speed | $m^3/s$ | $ft^3/s$ |
| $S$ | Basic allowable stress for metals, excluding factor $E$, or bolt design stress | MPa | $kip/in^2$ (ksi) |
| $S_A$ | Allowable stress range for displacement stress | MPa | $kip/in^2$ (ksi) |
| $S_E$ | Computed displacement-stress range | MPa | $kip/in^2$ (ksi) |
| $S_L$ | Sum of longitudinal stresses | MPa | $kip/in^2$ (ksi) |
| $S_T$ | Allowable stress at test temperature | MPa | $kip/in^2$ (ksi) |
| $S_b$ | Resultant bending stress | MPa | $kip/in^2$ (ksi) |
| $S_c$ | Basic allowable stress at minimum metal temperature expected | MPa | $kip/in^2$ (ksi) |
| $S_h$ | Basic allowable stress at maximum metal temperature expected | MPa | $kip/in^2$ (ksi) |
| $S_t$ | Torsional stress | MPa | $kip/in^2$ (ksi) |
| $s$ | Specific gravity | | |
| $s$ | Specific entropy | J/(kg·K) | Btu/(lb·°R) |
| $T$ | Temperature | K (°C) | °R (°F) |
| $T_s$ | Effective branch-wall thickness | mm | in |
| $\overline{T}$ | Nominal wall thickness of pipe | mm | in |
| $\overline{T}_b$ | Nominal branch-pipe wall thickness | mm | in |
| $\overline{T}_h$ | Nominal header-pipe wall thickness | mm | in |
| $t$ | Head or shell radius | mm | in |
| $t$ | Pressure design thickness | mm | in |
| $t$ | Time | s | s |
| $t_m$ | Minimum required thickness, including mechanical, corrosion, and erosion allowances | mm | in |
| $t_r$ | Pad or saddle thickness | mm | in |
| $U$ | Straight-line distance between anchors | m | ft |
| $u$ | Specific internal energy | J/kg | Btu/lb |
| $u$ | Velocity | m/s | ft/s |
| $V$ | Velocity | m/s | ft/s |
| $V$ | Volume | $m^3$ | $ft^3$ |
| $v$ | Specific volume | $m^3/kg$ | $ft^3/lb$ |
| $W$ | Work | N·m | lbf·ft |
| $W$ | Weight | kg | lb |
| $w$ | Weight flow rate | kg/s | lb/s |
| $x$ | Weight fraction | Dimensionless | Dimensionless |
| $x$ | Distance or length | m | ft |
| $x$ | Value of expression $[(p_2/p_1)^{(k-1/k)} - 1]$ | | |
| $Y$ | Expansion factor | Dimensionless | Dimensionless |
| $y$ | Distance or length | m | ft |
| $y$ | Resultant of total displacement strains | mm | in |
| $Z$ | Section modulus of pipe | $mm^3$ | $in^3$ |
| $Z$ | Vertical distance | m | ft |
| $Z_e$ | Effective section modulus for branch | $mm^3$ | $in^3$ |
| $Z$ | Gas-compressibility factor | Dimensionless | Dimensionless |
| $z$ | Vertical distance | m | ft |
| | Greek symbols | | |
| $\alpha$ | Viscous-resistance coefficient | $1/m^2$ | $1/ft^2$ |
| $\alpha$ | Angle | ° | ° |
| $\sigma$ | Half-included angle | ° | ° |
| $\alpha, \beta, \theta$ | Angles | ° | ° |
| $\beta$ | Inertial-resistance coefficient | 1/m | 1/ft |
| $\beta$ | Ratio of diameters | Dimensionless | Dimensionless |
| $\Gamma$ | Liquid loading | kg/(s·m) | lb/(s·ft) |
| $\Gamma$ | Pulsation intensity | Dimensionless | Dimensionless |
| $\delta$ | Thickness | m | ft |
| $\varepsilon$ | Wall roughness | m | ft |
| $\varepsilon$ | Voidage—fractional free volume | Dimensionless | Dimensionless |
| $\eta$ | Viscosity, nonnewtonian fluids | Pa·s | lb/(ft·s) |
| $\eta_{ad}$ | Adiabatic efficiency | | |
| $\eta_p$ | Polytropic efficiency | | |
| $\theta$ | Angle | ° | ° |
| $\lambda$ | Molecular mean free-path length | m | ft |
| $\mu$ | Viscosity | Pa·s | lb/(ft·s) |
| $\nu$ | Kinematic viscosity | $m^2/s$ | $ft^2/s$ |
| $\rho$ | Density | $kg/m^3$ | $lb/ft^3$ |
| $\sigma$ | Surface tension | N/m | lbf/ft |
| $\sigma_c$ | Cavitation number | Dimensionless | Dimensionless |
| $\tau$ | Shear stress | $N/m^2$ | $lbf/ft^2$ |
| $\phi$ | Shape factor | Dimensionless | Dimensionless |
| $\phi$ | Angle | ° | ° |
| $\phi$ | Flow coefficient | | |
| $\psi$ | Pressure coefficient | | |
| $\psi$ | Sphericity | Dimensionless | Dimensionless |

## INTRODUCTION

The flow rate of fluids is a critical variable in most chemical engineering applications, ranging from flows in the process industries to environmental flows and to flows within the human body. *Flow* is defined as mass flow or volume flow per unit of time at specified temperature and pressure conditions for a given fluid. This subsection deals with the techniques of measuring pressure, temperature, velocities, and flow rates of flowing fluids. For more detailed discussion of these variables, consult Sec. 8. Section 8 introduces methods of measuring flow rate, temperature, and pressure. This subsection builds on the coverage in Sec. 8 with emphasis on measurement of the flow of fluids.

## PROPERTIES AND BEHAVIOR OF FLUIDS

Transportation and the storage of fluids (gases and liquids) involves the understanding of the properties and behavior of fluids. The study of fluid dynamics is the study of fluids and their motion in a force field.

Flows can be classified into two major categories: (a) incompressible and (b) compressible flow. Most liquids fall into the incompressible-flow category, while most gases are compressible in nature. A perfect fluid can be defined as a fluid that is nonviscous and nonconducting. Fluid flow, compressible or incompressible, can be classified by the ratio of the inertial forces to the viscous forces. This ratio is represented by the Reynolds number ($N_{Re}$). At a low Reynolds number, the flow is considered to be laminar, and at high Reynolds numbers, the flow is considered to be turbulent. The limiting types of flow are the inertialess flow, sometimes called Stokes flow, and the inviscid flow that occurs at an infinitely large Reynolds number. Reynolds numbers (dimensionless) for flow in a pipe is given as:

$$N_{Re} = \frac{\rho V D}{\mu} \tag{10-1}$$

where $\rho$ is the density of the fluid, $V$ the velocity, $D$ the diameter, and $\mu$ the viscosity of the fluid. In fluid motion where the frictional forces interact with the inertia forces, it is important to consider the ratio of the viscosity $\mu$ to the density $\rho$. This ratio is known as the kinematic viscosity ($\nu$). Tables 10-1 and 10-2 give the kinematic viscosity for several fluids. A flow is considered to be *adiabatic* when there is no transfer of heat between the fluid and its surroundings. An isentropic flow is one in which the entropy of each fluid element remains constant.

To fully understand the mechanics of flow, the following definitions explain the behavior of various types of fluids in both their static and flowing states.

A perfect fluid is a nonviscous, nonconducting fluid. An example of this type of fluid would be a fluid that has a very small viscosity and conductivity and is at a high Reynolds number. An ideal gas is one that obeys the equation of state:

$$\frac{P}{\rho} = RT \tag{10-2}$$

where $P$ = pressure, $\rho$ = density, $R$ is the gas constant per unit mass, and $T$ = temperature.

A flowing fluid is acted upon by many forces that result in changes in pressure, temperature, stress, and strain. A fluid is said to be isotropic when the relations between the components of stress and those of the rate of strain are the same in all directions. The fluid is said to be Newtonian when this relationship is linear. These pressures and temperatures must be fully understood so that the entire flow picture can be described.

The *static pressure* in a fluid has the same value in all directions and can be considered as a scalar point function. It is the pressure of a flowing fluid. It is normal to the surface on which it acts and at any given point has the same magnitude irrespective of the orientation of the surface. The static pressure arises because of the random motion in the fluid of the molecules that make up the fluid. In a diffuser or nozzle, there is an increase or decrease in the static pressure due to the change in velocity of the moving fluid.

**Total pressure** is the pressure that would occur if the fluid were brought to rest in a reversible adiabatic process. Many texts and engineers use the words *total* and *stagnation* to describe the flow characteristics interchangeably. To be accurate, the stagnation pressure

**TABLE 10-1 Density, Viscosity, and Kinematic Viscosity of Water and Air in Terms of Temperature**

| Temperature | | Water | | | Air at a pressure of 760 mm Hg (14.696 lbf/in²) | | |

| Lubricating oil | 40 | 104 | 1076 |
| Lubricating oil | 60 | 140 | 323 |

is the pressure that would occur if the fluid were brought to rest adiabatically or diabatically.

Total pressure will only change in a fluid if shaft work or work of extraneous forces are introduced. Therefore, total pressure would increase in the impeller of a compressor or pump; it would remain constant in the diffuser. Similarly, total pressure would decrease in the turbine impeller but would remain constant in the nozzles.

Static temperature is the temperature of the flowing fluid. Like static pressure, it arises because of the random motion of the fluid molecules. Static temperature is in most practical installations impossible to measure since it can be measured only by a thermometer or thermocouple at rest relative to the flowing fluid that is moving with the fluid. Static temperature will increase in a diffuser and decrease in a nozzle.

Total temperature is the temperature that would occur when the fluid is brought to rest in a reversible adiabatic manner. Just like its counterpart *total pressure, total* and *stagnation temperatures* are used interchangeably by many test engineers.

Dynamic temperature and pressure are the difference between the total and static conditions.

$$P_d = P_T - P_s \tag{10-3}$$

$$T_d = T_T - T_s \tag{10-4}$$

where subscript $d$ refers to dynamic, $T$ to total, and $s$ to static.

Another helpful formula is:

$$P_K = \frac{1}{2}\rho V^2 \tag{10-5}$$

For incompressible fluids, $P_K = P_d$.

## TOTAL TEMPERATURE

For most points requiring temperature monitoring, either thermocouples or resistive thermal detectors (RTDs) can be used. Each type of temperature transducer has its own advantages and disadvantages, and both should be considered when temperature is to be measured. Since there is considerable confusion in this area, a short discussion of the two types of transducers is necessary.

**Thermocouples** The various types of thermocouples provide transducers suitable for measuring temperatures from –330 to 5000°F (–201 to 2760°C). Thermocouples function by producing a voltage proportional to the temperature differences between two junctions of dissimilar metals. By measuring this voltage, the temperature difference can be determined. It is assumed that the temperature is known at one of the junctions; therefore, the temperature at the other junction can be determined. Since the thermocouples produce a voltage, no external power supply is required to the test junction; however, for accurate measurement, a reference junction is required. For a temperature monitoring system, reference junctions must be placed at each thermocouple or similar thermocouple wire installed from the thermocouple to the monitor where there is a reference junction. Properly designed thermocouple systems can be accurate to approximately ±2°F (±1°C).

**Resistive Thermal Detectors (RTDs)** RTDs determine temperature by measuring the change in resistance of an element due to temperature. Platinum is generally utilized in RTDs because it remains mechanically and electrically stable, resists contaminations, and can be highly refined. The useful range of platinum RTDs is –454–1832°F (–270–1000°C). Since the temperature is determined by the resistance in the element, any type of electrical conductor can be utilized to connect the RTD to the indicator; however, an electrical current must be provided to the RTD. A properly designed temperature monitoring system utilizing RTDs can be accurate ±0.02°F (±0.01°C).

## STATIC TEMPERATURE

Since this temperature requires the thermometer or thermocouple to be at rest relative to the flowing fluid, it is impractical to measure. It can be, however, calculated from the measurement of total temperature and total and static pressure.

$$T_S = \frac{T_O}{\left(\frac{P_O}{P_S}\right)^{(k-1)/k}} \tag{10-6}$$

## DRY- AND WET-BULB TEMPERATURES

The moisture content or humidity of air has an important effect on the properties of the gaseous mixture. Steam in air at any relative humidity less than 100 percent must exist in a superheated condition. The saturation temperature corresponding to the actual partial pressure of the steam in air is called the dew point. This term arose from the fact that when air at less than 100 percent relative humidity is cooled to the temperature at which it becomes saturated, the air has reached the minimum temperature to which it can be cooled without precipitation of the moisture (dew). Dew point can also be defined as that temperature at which the weight of steam associated with a certain weight of dry air is adequate to saturate that weight of air.

The dry-bulb temperature of air is the temperature that is indicated by an ordinary thermometer. When an air temperature is stated without any modifying term, it is always taken to be the dry-bulb temperature. In contrast to dry-bulb, or air, temperature, the term *wet-bulb temperature of the air*, or simply *wet-bulb temperature*, is employed. When a thermometer, with its bulb covered by a wick wetted with water, is moved through air unsaturated with water vapor, the water evaporates in proportion to the capacity of the air to absorb the evaporated moisture, and the temperature indicated by the thermometer drops below the dry-bulb, or air, temperature. The equilibrium temperature finally reached by the thermometer is known as the wet-bulb temperature. The purpose in measuring both the dry-bulb and wet-bulb temperature of the air is to find the exact humidity characteristics of the air from the readings obtained, either by calculation or by use of a psychrometric chart. Instruments for measuring wet-bulb and dry-bulb temperatures are known as psychrometers. A sling psychrometer consists of two thermometers mounted side by side on a holder, with provision for whirling the whole device through the air. The dry-bulb thermometer is bare, and the wet bulb is covered by a wick which is kept wetted with clean water. After being whirled a sufficient amount of time, the wet-bulb thermometer reaches its equilibrium point, and both the wet-bulb and dry-bulb thermometers are then quickly read. Rapid relative movement of the air past the wet-bulb thermometer is necessary to get dependable readings.

For other methods of measuring the moisture content of gases, see Sec. 8.

## PRESSURE MEASUREMENTS

*Pressure* is defined as the force per unit area. Pressure devices measure with respect to the ambient atmospheric pressure: The absolute pressure $P_a$ is the pressure of the fluid (gauge pressure) plus the atmospheric pressure.

Process pressure-measuring devices may be divided into three groups:

1. Those that are based on the height of a liquid column (manometers)
2. Those that are based on the measurement of the distortion of an elastic pressure chamber (mechanical pressure gauges such as Bourdon-tube gauges and diaphragm gauges)

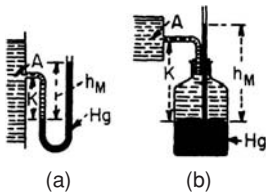

**FIG. 10-1** Open manometers.

3. Electric sensing devices (strain gauges, piezoresistive transducers, and piezoelectric transducers)

This subsection contains an expanded discussion of manometric methods. See Sec. 8 for other methods.

**Liquid-Column Manometers** The **height,** or **head,** $p_n = \rho hg/g_c$ to which a fluid rises in an open vertical tube attached to an apparatus containing a liquid is a direct measure of the pressure at the point of attachment and is frequently used to show the level of liquids in tanks and vessels. This same principle can be applied with U-tube gauges (Fig. 10-1*a*) and equivalent devices (such as that shown in Fig. 10-1*b*) to measure pressure in terms of the head of a fluid other than the one under test. Most of these gauges may be used either as **open** or as **differential manometers.** The manometric fluid that constitutes the measured liquid column of these gauges may be any liquid immiscible with the fluid under pressure. For high vacuums or for high pressures and large pressure differences, the gauge liquid is a high-density liquid, generally mercury; for low pressures and small pressure differences, a low-density liquid (e.g., alcohol, water, or carbon tetrachloride) is used.

The **open U tube** (Fig. 10-1*a*) and the **open gauge** (Fig. 10-1*b*) each show a reading $h_M$ m (ft) of manometric fluid. If the interface of the manometric fluid and the fluid of which the pressure is wanted is $K$ m (ft) below the point of attachment, $A$, $\rho_A$ is the density of the latter fluid at $A$, and $\rho_M$ is that of the manometric fluid, then gauge pressure $p_A$ (lbf/ft$^2$) at $A$ is

$$p_A = (h_M\rho_M - K\rho_A)(g/g_c) \qquad (10\text{-}7)^*$$

where $g$ = local acceleration due to gravity and $g_c$ = dimensional constant. The head $H_A$ at $A$ as meters (feet) of the fluid at that point is

$$h_A = h_M(\rho_M/\rho_A) - K \qquad (10\text{-}8)^*$$

When a gas pressure is measured, unless it is very high, $\rho_A$ is so much smaller than $\rho_M$ that the terms involving $K$ in these formulas are negligible.

The **differential U tube** (Fig. 10-2) shows the pressure difference between taps $A$ and $B$ to be

$$p_A - p_B = [h_M(\rho_M - \rho_A) + K_A\rho_A - K_B\rho_B](g/g_c) \qquad (10\text{-}9)^*$$

where $h_M$ is the difference in height of the manometric fluid in the U tube; $K_A$ and $K_B$ are the vertical distances of the upper surface of the manometric fluid above $A$ and $B$, respectively; $\rho_A$ and $\rho_B$ are the densities of the fluids at $A$ and $B$, respectively; and $\rho_M$ is the density of the manometric fluid. If either pressure tap is above the higher level of manometric fluid, the corresponding $K$ is taken to be negative. Valve $D$, which is kept closed when the gauge is in use, is used to vent off gas which may accumulate at these high points.

*The line leading from the pressure tap to the gauge is assumed to be filled with fluid of the same density as that in the apparatus at the location of the pressure tap; if this is not the case, $\rho_A$ is the density of the fluid actually filling the gauge line, and the value given for $h_A$ must be multiplied by $\rho_A/\rho$ where $\rho$ is the density of the fluid whose head is being measured.

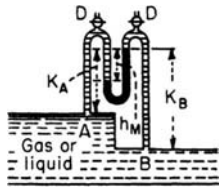

**FIG. 10-2** Differential U tube.

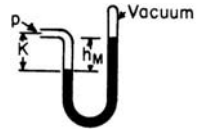

**FIG. 10-3** Closed U tube.

The **inverted differential U tube,** in which the manometric fluid may be a gas or a light liquid, can be used to measure liquid pressure differentials, especially for the flow of slurries where solids tend to settle out.

**Closed U tubes** (Fig. 10-3) using mercury as the manometric fluid serve to measure directly the absolute pressure $p$ of a fluid, provided that the space between the closed end and the mercury is substantially a perfect vacuum.

The **mercury barometer** (Fig. 10-4) indicates directly the absolute pressure of the atmosphere in terms of height of the mercury column. Normal (standard) barometric pressure is 101.325 kPa by definition. Equivalents of this pressure in other units are 760 mm mercury (at 0°C), 29.921 inHg (at 0°C), 14.696 lbf/in$^2$, and 1 atm. For cases in which barometer readings, when expressed by the height of a mercury column, must be corrected to standard temperature (usually 0°C), appropriate temperature correction factors are given in ASME PTC, op. cit., pp. 23–26; and Weast, *Handbook of Chemistry and Physics,* 62d ed., Chemical Rubber, Cleveland, 1984, pp. E36–E37.

**Tube Size for Manometers** To avoid capillary error, tube diameter should be sufficiently large and the manometric fluids of such densities that the effect of capillarity is negligible in comparison with the gauge reading. The effect of capillarity is practically negligible for tubes with inside diameters 12.7 mm (½ in) or larger (see ASME PTC, op. cit., p. 15). Small diameters are generally permissible for U tubes because the capillary displacement in one leg tends to cancel that in the other.

The capillary rise in a small vertical open tube of circular cross section dipping into a pool of liquid is given by

$$h = \frac{4\sigma g_c \cos\theta}{gD(\rho_1 - \rho_2)} \qquad (10\text{-}10)$$

Here $\sigma$ = surface tension, $D$ = inside diameter, $\rho_1$ and $\rho_2$ are the densities of the liquid and gas (or light liquid) respectively, $g$ = local acceleration due to gravity, $g_c$ = dimensional constant, and $\theta$ is the contact angle subtended by the heavier fluid. For most organic liquids and water, the contact angle $\theta$ is zero against glass, provided the glass is wet with a film of the liquid; for mercury against glass, $\theta = 140°$ (*International Critical Tables,* vol. IV, McGraw-Hill, New York, 1928, pp. 434–435). For further discussion of capillarity, see Schwartz, *Ind. Eng. Chem.,* **61**(1), 10–21 (1969).

**Multiplying Gauges** To attain the requisite precision in measurement of small pressure differences by liquid-column manometers,

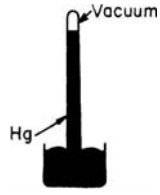

**FIG. 10-4** Mercury barometer.

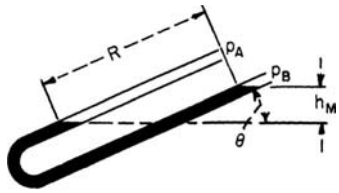

**FIG. 10-5** Inclined U tube.

means must often be devised to magnify the readings. Of the schemes that follow, the second and third may give tenfold multiplication; the fourth, as much as thirtyfold. In general, the greater the multiplication, the more elaborate must be the precautions in the use of the gauge if the gain in precision is not to be illusory.

1. *Change of manometric fluid.* In open manometers, choose a fluid of lower density. In differential manometers, choose a fluid such that the difference between its density and that of the fluid being measured is as small as possible.

2. *Inclined U tube* (*Fig. 10-5*). If the reading $R$ m (ft) is taken as shown and $R_0$ m (ft) is the zero reading, by making the substitution $h_M = (R - R_0) \sin \theta$, the formulas of preceding paragraphs give $(p_A - p_B)$ when the corresponding upright U tube is replaced by one inclined. For precise work, the gauge should be calibrated because of possible variations in tube diameter and slope.

3. *The draft gauge* (*Fig. 10-6*). Commonly used for low gas heads, this gauge has for one leg of the U a reservoir of much larger bore than the tubing that forms the inclined leg. Hence variations of level in the inclined tube produce little change in level in the reservoir. Although $h_M$ may be readily computed in terms of reading $R$ and the dimensions of the tube, calibration of the gauge is preferable; often the changes of level in the reservoir are not negligible, and also variations in tube diameter may introduce serious error into the computation. Commercial gauges are often provided with a scale giving $h_M$ directly in height of water column, provided a particular liquid (often not water) fills the tube; failure to appreciate that the scale is incorrect unless the gauge is filled with the specified liquid is a frequent source of error. If the scale reads correctly when the density of the gauge liquid is $\rho_0$, then the reading must be multiplied by $\rho/\rho_0$ if the density of the fluid actually in use is $\rho$.

4. *Two-fluid U tube* (*Fig. 10-7*). This is a highly sensitive device for measuring small gas heads. Let $A$ be the cross-sectional area of each of the reservoirs and $a$ that of the tube forming the U; let $\rho_1$ be the density of the lighter fluid and $\rho_2$ that of the heavier fluid; and if $R$ is the reading and $R_0$ its value with zero pressure difference, then the pressure difference is

$$p_A - p_B = (R - R_0)\left(\rho_2 - \rho_1 + \frac{a}{A}\rho_1\right)\frac{g}{g_c} \qquad (10\text{-}11)$$

where $g$ = local acceleration due to gravity and $g_c$ = dimensional constant.

When $A/a$ is sufficiently large, the term $(a/A)\ \rho_1$ in Eq. (10-11) becomes negligible in comparison with the difference $(\rho_2 - \rho_1)$. However, this term should not be omitted without due consideration. In applying Eq. (10-11), the densities of the gauge liquids may not be taken from tables without the possibility of introducing serious error, for each liquid may dissolve appreciable quantities of the other. Before the gauge is filled, the liquids should be shaken together, and the actual densities of the two layers should be measured for the temperature at which the gauge is to be used. When high magnification is being sought, the U tube may have to be enclosed in a constant-temperature bath so that $(\rho_2 - \rho_1)$ may be accurately known. In general, if highest accuracy is desired, the gauge should be calibrated.

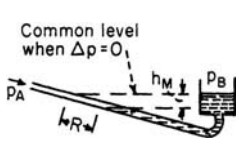

**FIG. 10-6** Draft gauge.

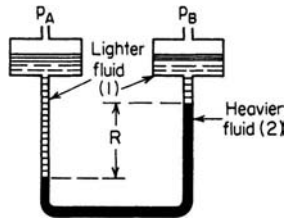

**FIG. 10-7** Two-fluid U tube.

Several **micromanometers,** based on the liquid-column principle and possessing extreme precision and sensitivity, have been developed for measuring minute gas-pressure differences and for calibrating low-range gauges. Some of these micromanometers are available commercially. These micromanometers are free from errors due to capillarity and, aside from checking the micrometer scale, require no calibration.

**Mechanical Pressure Gauges** The **Bourdon-tube gauge** indicates pressure by the amount of flection under internal pressure of an oval tube bent in an arc of a circle and closed at one end. These gauges are commercially available for all pressures below atmospheric and for pressures up to 700 MPa (about 100,000 lbf/in$^2$) above atmospheric. Details on Bourdon-type gauges are given by Harland [*Mach. Des.*, **40**(22), 69–74 (Sept. 19, 1968)].

A **diaphragm gauge** depends for its indication on the deflection of a diaphragm, usually metallic, when subjected to a difference of pressure between the two faces. These gauges are available for the same general purposes as Bourdon gauges but are not usually employed for high pressures. The aneroid barometer is a type of diaphragm gauge.

Small **pressure transducers with flush-mounted diaphragms** are commercially available for the measurement of either steady or fluctuating pressures up to 100 MPa (about 15,000 lbf/in$^2$). The metallic diaphragms are as small as 4.8 mm ($^3/_{16}$ in) in diameter. The transducer is mounted on the apparatus containing the fluid whose pressure is to be measured so that the diaphragm is flush with the inner surface of the apparatus. Deflection of the diaphragm is measured by unbonded strain gauges and recorded electrically.

With nonnewtonian fluids the pressure measured at the wall with non-flush-mounted pressure gauges may be in error (see subsection "Static Pressure").

Bourdon and diaphragm gauges that show both pressure and vacuum indications on the same dial are called **compound gauges.**

**Conditions of Use** Bourdon tubes should not be exposed to temperatures over about 65°C (about 150°F) unless the tubes are specifically designed for such operation. When the pressure of a hotter fluid is to be measured, some type of liquid seal should be used to keep the hot fluid from the tube. In using either a Bourdon or a diaphragm gauge to measure gas pressure, if the gauge is below the pressure tap of the apparatus so that liquid can collect in the lead, the gauge reading will be too high by an amount equal to the hydrostatic head of the accumulated liquid.

For measuring pressures of corrosive fluids, slurries, and similar process fluids which may foul Bourdon tubes, a **chemical gauge,** consisting of a Bourdon gauge equipped with an appropriate flexible diaphragm to seal off the process fluid, may be used. The combined volume of the tube and the connection between the diaphragm and the tube is filled with an inert liquid. These gauges are available commercially.

Further details on pressure-measuring devices are found in Sec. 8.

**Calibration of Gauges** Simple **liquid-column manometers** do not require calibration if they are so constructed as to minimize errors due to capillarity (see subsection "Liquid-Column Manometers"). If the scales used to measure the readings have been checked against a standard, the accuracy of the gauges depends solely upon the precision of determining the position of the liquid surfaces. Hence liquid-column manometers are primary standards used to calibrate other gauges.

For **high pressures** and, with commercial mechanical gauges, even for quite moderate pressures, a deadweight gauge (see ASME PTC, op. cit., pp. 36–41) is commonly used as the primary standard because it is safer and more convenient than use of manometers. When manometers are used as high-pressure standards, an extremely high mercury column may be avoided by connecting a number of the usual U tubes in series. Multiplying gauges are standardized by comparing

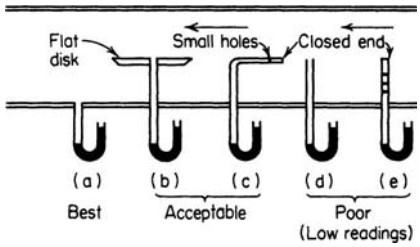

**FIG. 10-8** Measurement of static pressure.

them with a micromanometer. Procedure in the calibration of a gauge consists merely of connecting it, in parallel with a standard gauge, to a reservoir wherein constant pressure may be maintained. Readings of the unknown gauge are then made for various reservoir pressures as determined by the standard.

Calibration of **high-vacuum gauges** is described by Sellenger [*Vacuum*, **18**(12), 645–650 (1968)].

## STATIC PRESSURE

**Local Static Pressure** In a moving fluid, the local static pressure is equal to the pressure on a surface which moves with the fluid or to the normal pressure (for newtonian fluids) on a stationary surface which parallels the flow. The pressure on such a surface is measured by making a small hole perpendicular to the surface and connecting the opening to a pressure-sensing element (Fig. 10-8*a*). The hole is known as a piezometer opening or pressure tap.

Measurement of local static pressure is frequently difficult or impractical. If the channel is so small that introduction of any solid object disturbs the flow pattern and increases the velocity, there will be a reduction and redistribution of the static pressure. If the flow is in straight parallel lines, aside from the fluctuations of normal turbulence, the flat disk (Fig. 10-8*b*) and the bent tube (Fig. 10-8*c*) give satisfactory results when properly aligned with the stream. Slight misalignments can cause serious errors. Diameter of the disk should be 20 times its thickness and 40 times the static opening; the face must be flat and smooth, with the knife edges made by beveling the underside. The piezometer tube, such as that in Fig. 10-8*c*, should have openings with size and spacing as specified for a pitot-static tube (Fig. 10-12).

Readings given by open straight tubes (Fig. 10-8*d* and 10-8*e* are too low due to flow separation. Readings of closed tubes oriented perpendicularly to the axis of the stream and provided with side openings (Fig. 10-8*e*) may be low by as much as two velocity heads.

**Average Static Pressure** In most cases, the object of a static-pressure measurement is to obtain a suitable average value for substitution in Bernoulli's theorem or in an equivalent flow formula. This can be done simply only when the flow is in straight lines parallel to the confining walls, such as in straight ducts at sufficient distance downstream from bends (2 diameters) or other disturbances. For such streams, the sum of static head and gravitational potential head is the same at all points in a cross section taken perpendicularly to the axis of flow. Thus the exact location of a piezometer opening about the periphery of such a cross section is immaterial provided its elevation is known. However, in stating the static pressure, the custom is to give the value at the elevation corresponding to the centerline of the stream.

With flow in curved passages or with swirling flow, determination of a true average static pressure is, in general, impractical. In metering, straightening vanes are often placed upstream of the pressure tap to eliminate swirl. Figure 10-9 shows various flow equalizers and straighteners.

**Specifications for Piezometer Taps** The size of a static opening should be small compared with the diameter of the pipe and yet large compared with the scale of surface irregularities. For reliable results, it is essential that (1) the surface in which the hole is made be substantially smooth and parallel to the flow for some distance on either side of the opening, and (2) the opening be flush with the surface and possess no "burr" or other irregularity around its edge. Rounding of the edge is often employed to ensure absence of a burr. Pressure readings will be high if the tap is inclined upstream, is rounded excessively on the upstream side, has a burr on the downstream side, or has an excessive countersink or recess. Pressure readings will be low if the tap is inclined downstream, is rounded excessively on the downstream side, has a burr on the upstream side, or protrudes into the flow stream. Errors resulting from these faults can be large.

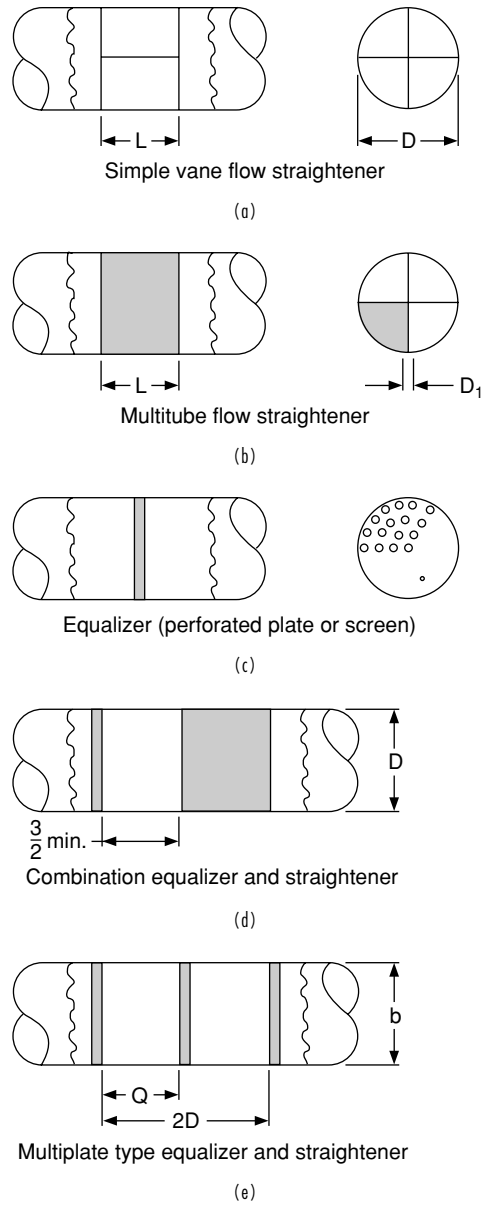

**FIG. 10-9** Flow equalizers and straighteners [*Power Test Code 10, Compressors and Exhausters, Amer. Soc. of Mechanical Engineers, 1997*].

Recommendations for **pressure-tap dimensions** are summarized in Table 10-3. Data from several references were used in arriving at these composite values. The length of a pressure-tap opening prior to any enlargement in the tap channel should be at least two tap diameters, preferably three or more.

**TABLE 10-3 Pressure-Tap Holes**

| Nominal inside pipe diameter, in | Maximum diameter of pressure tap, mm (in) | Radius of hole-edge rounding, mm (in) |
|---|---|---|
| 1 | 3.18 (⅛) | <0.40 (1/64) |
| 2 | 6.35 (¼) | 0.40 (1/64) |
| 3 | 9.53 (⅜) | 0.40–0.79 (1/64–1/32) |
| 4 | 12.7 (½) | 0.79 (1/32) |
| 8 | 12.7 (½) | 0.79–1.59 (1/32–1/16) |
| 16 | 19.1 (¾) | 0.79–1.59 (1/32–1/16) |

A **piezometer ring** is a toroidal manifold into which are connected several sidewall static taps located around the perimeter of a common cross section. Its intent is to give an average pressure if differences in pressure other than those due to static head exist around the perimeter. However, there is generally no assurance that a true average is provided thereby. The principal advantage of the ring is that use of several holes in place of a single hole reduces the possibility of completely plugging the static openings.

For information on prediction of static-hole error, see Shaw, *J. Fluid Mech.,* **7,** 550–564 (1960); Livesey, Jackson, and Southern, *Aircr. Eng.,* **34,** 43–47 (February 1962).

For nonnewtonian fluids, pressure readings with taps may also be low because of fluid-elasticity effects. This error can be largely eliminated by using flush-mounted diaphragms.

For information on the pressure-hole error for nonnewtonian fluids, see Han and Kim, *Trans. Soc. Rheol.,* **17,** 151–174 (1973); Novotny and Eckert, *Trans. Soc. Rheol.,* **17,** 227–241 (1973); and Higashitani and Lodge, *Trans. Soc. Rheol.,* **19,** 307–336 (1975).

## VELOCITY MEASUREMENTS

Measurement of flow can be based on the measurement of velocity in ducts or pipes by using devices such as pitot tubes and hot wire anemometers. The local velocity is measured at various sections of a conduit and then averaged for the area under consideration.

$$\frac{w}{\rho} = A \times V = Q \tag{10-12}$$

where $w$ = mass flow rate, $lb_m/s$, kg/s
$\rho$ = density, $lb_m/ft^3$, $kg/m^3$
$A$ = area, ft/s, m/s
$V$ = velocity, ft/s, m/s
$Q$ = volumetric flow rate, $ft^3/s$, $m^3/s$

Equation (10-12) shows that the fluid density directly affects the relationship between mass flow rate and both velocity and volumetric flow rate. Liquid temperature affects liquid density and hence volumetric flow rate at a constant mass flow rate. Liquid density is relatively insensitive to pressure. Both temperature and pressure affect gas density and thus volumetric flow rate.

**Variables Affecting Measurement** Flow measurement methods may sense local fluid velocity, volumetric flow rate, total or cumulative volumetric flow (the integral of volumetric flow rate with respect to elapsed time), mass flow rate, and total mass flow.

**Velocity Profile Effects** Many variables can influence the accuracy of specific flow measurement methods. For example, the velocity profile in a closed conduit affects many types of flow-measuring devices. The velocity of a fluid varies from zero at the wall and at other stationary solid objects in the flow channel to a maximum at a distance from the wall. In the entry region of a conduit, the velocity field may approach plug flow and a constant velocity across the conduit, dropping to zero only at the wall. As a newtonian fluid progresses down a pipe, a velocity profile develops that is parabolic for laminar flow [Eq. (6-41)] and that approaches plug flow for highly turbulent flow. Once a steady flow profile has developed, the flow is said to be fully developed; the length of conduit necessary to achieve fully developed flow is called the entrance region. For long cylindrical, horizontal pipe ($L < 40D$, where $D$ is the inside diameter of the pipe and $L$ is the upstream length of pipe), the velocity profile becomes fully developed. Velocity profiles in flowing fluids are discussed in greater detail in Sec. 6 (p. 6-11).

For steady-state, isothermal, single-phase, uniform, fully developed newtonian flow in straight pipes, the velocity is greatest at the center of the channel and symmetric about the axis of the pipe. Of those flowmeters that are dependent on the velocity profile, they are usually calibrated for this type of flow. Thus any disturbances in flow conditions can affect flowmeter readings.

Upstream and downstream disturbances in the flow field are caused by valves, elbows, and other types of fittings. Two upstream elbows in two perpendicular planes will impart swirl in the fluid downstream. Swirl, similar to atypical velocity profiles, can lead to erroneous flow measurements. Although the effect is not as great as in upstream flow disturbances, downstream flow disturbances can also lead to erroneous flow measurements.

**Other Flow Disturbances** Other examples of deviations from fully developed, single-phase newtonian flow include nonnewtonian flow, pulsating flow, cavitation, multiphase flow, boundary layer flows, and nonisothermal flows. See Sec. 6.

**Pitot Tubes** The combination of pitot tubes in conjunction with sidewall static taps measures local or point velocities by measuring the difference between the total pressure and the static pressure. The pitot tube shown in Fig. 10-10 consists of an impact tube whose opening faces directly into the stream to measure impact pressure, plus one or more sidewall taps to measure local static pressure.

Dynamic pressure may be measured by use of a pitot tube that is a simple impact tube. These tubes measure the pressure at a point where the velocity of the fluid is brought to zero. Pitot tubes must be parallel to the flow. The pitot tube is sensitive to yaw or angle attack. In general angles of attack over 10° should be avoided. In cases where the flow direction is unknown, it is recommended to use a Kiel probe. Figure 10-11 shows a Kiel probe. This probe will read accurately to an angle of about 22° with the flow.

The combined pitot-static tube shown in Fig. 10-12 consists of a jacketed impact tube with one or more rows of holes, 0.51 to 1.02 mm (0.02 to 0.04 in) in diameter, in the jacket to measure the static pressure. Velocity $V_0$ m/s (ft/s) at the point where the tip is located is given by

$$V_0 = C\sqrt{2g_c\Delta h} = C\sqrt{2g_c(P_T - P_S)/\rho_0} \tag{10-13}$$

where $C$ = coefficient, dimensionless; $g_c$ = dimensional constant; $\Delta h$ = dynamic pressure ($\Delta h_s g/g_c$), expressed in (N·m)/kg[(ft·lbf)/lb or ft of fluid flowing]; $\Delta h_s$ = differential height of static liquid column corresponding to $\Delta h$; $g$ = local acceleration due to gravity; $g_c$ = dimensional constant; $p_i$ = impact pressure; $p_0$ = local static pressure; and $\rho_0$ = fluid density measured at pressure $p_0$ and the local temperature. With gases at velocities above 60 m/s (about 200 ft/s), compressibility becomes important, and the following equation should be used:

$$V_0 = C\sqrt{\frac{2g_c k}{k-1}\left(\frac{p_0}{\rho_0}\right)\left[\left(\frac{p_i}{p_0}\right)^{(k-1)/k} - 1\right]} \tag{10-14}$$

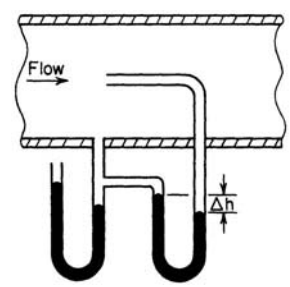

**FIG. 10-10** Pitot tube with sidewall static tap.

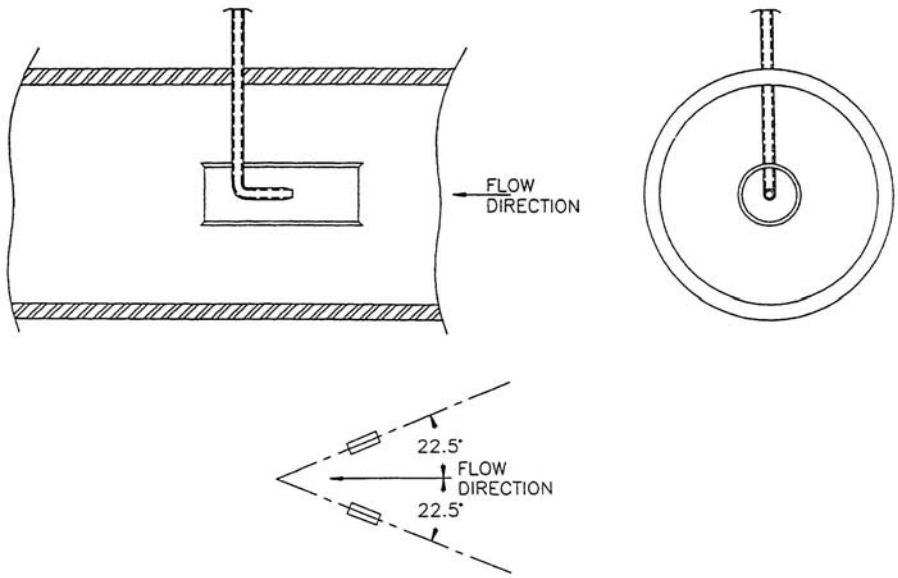

**FIG. 10-11** Kiel probe. Accurate measurements can be made at angles up to 22.5° with the flow stream.

where $k$ is the ratio of specific heat at constant pressure to that at constant volume. (See ASME Research Committee on Fluid Meters Report, op. cit., p. 105.) Coefficient $C$ is usually close to 1.00 (±0.01) for simple pitot tubes (Fig. 10-10) and generally ranges between 0.98 and 1.00 for pitot-static tubes (Fig. 10-12).

There are certain limitations on the range of usefulness of pitot tubes. With gases, the differential is very small at low velocities; e.g., at 4.6 m/s (15.1 ft/s) the differential is only about 1.30 mm (0.051 in) of water (20°C) for air at 1 atm (20°C), which represents a lower limit for 1 percent error even when one uses a micromanometer with a precision of 0.0254 mm (0.001 in) of water. Equation does not apply for Mach numbers greater than 0.7 because of the interference of shock waves. For supersonic flow, local Mach numbers can be calculated from a knowledge of the dynamic and true static pressures. The free stream Mach number ($M_\infty$) is defined as the ratio of the speed of the stream ($V_\infty$) to the speed of sound in the free stream:

$$A_\infty = \sqrt{\left(\frac{\partial P}{\partial \rho}\right)_{s=c}} \tag{10-15}$$

$$M_\infty = \frac{V_\infty}{\sqrt{\left(\frac{\partial P}{\partial \rho}\right)_{s=c}}} \tag{10-16}$$

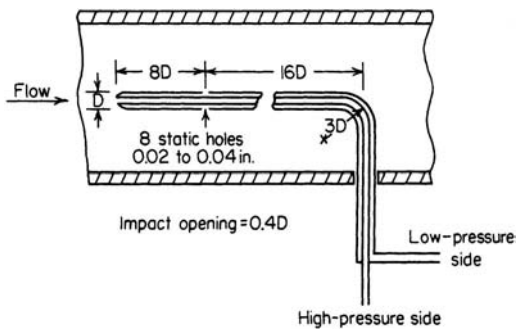

**FIG. 10-12** Pitot-static tube.

where $S$ is the entropy. For isentropic flow, this relationship and pressure can be written as:

$$M_\infty = \frac{V_\infty}{\sqrt{kRT_s}} \tag{10-17}$$

The relationships between total and static temperature and pressure are given by the following relationship:

$$\frac{T_T}{T_S} = 1 + \frac{k-1}{2} M^2 \tag{10-18}$$

$$\frac{P_T}{P_S} = \left(1 + \frac{k-1}{2} M^2\right)^{(k-1)/k} \tag{10-19}$$

With **liquids** at low velocities, the effect of the Reynolds number upon the coefficient is important. The coefficients are appreciably less than unity for Reynolds numbers less than 500 for pitot tubes and for Reynolds numbers less than 2300 for pitot-static tubes [see Folsom, *Trans. Am. Soc. Mech. Eng.*, **78,** 1447–1460 (1956)]. Reynolds numbers here are based on the probe outside diameter. Operation at low Reynolds numbers requires prior calibration of the probe.

The pitot-static tube is also sensitive to **yaw** or **angle of attack** than is the simple pitot tube because of the sensitivity of the static taps to orientation. The error involved is strongly dependent upon the exact probe dimensions. In general, angles greater than 10° should be avoided if the velocity error is to be 1 percent or less.

**Disturbances** upstream of the probe can cause large errors, in part because of the turbulence generated and its effect on the static-pressure measurement. A calming section of at least 50 pipe diameters is desirable. If this is not possible, the use of straightening vanes or a honeycomb is advisable.

The effect of **pulsating flow** on pitot-tube accuracy is treated by Ower et al., op. cit., pp. 310–312. For sinusoidal velocity fluctuations, the ratio of indicated velocity to actual mean velocity is given by the factor $\sqrt{1 + \lambda^2/2}$, where $\lambda$ is the velocity excursion as a fraction of the mean velocity. Thus, the indicated velocity would be about 6 percent high for velocity fluctuations of ±50 percent, and pulsations greater than ±20 percent should be damped to avoid errors greater than 1 percent. The error increases as the frequency of flow oscillations approaches the natural frequency of the pitot tube and the density of

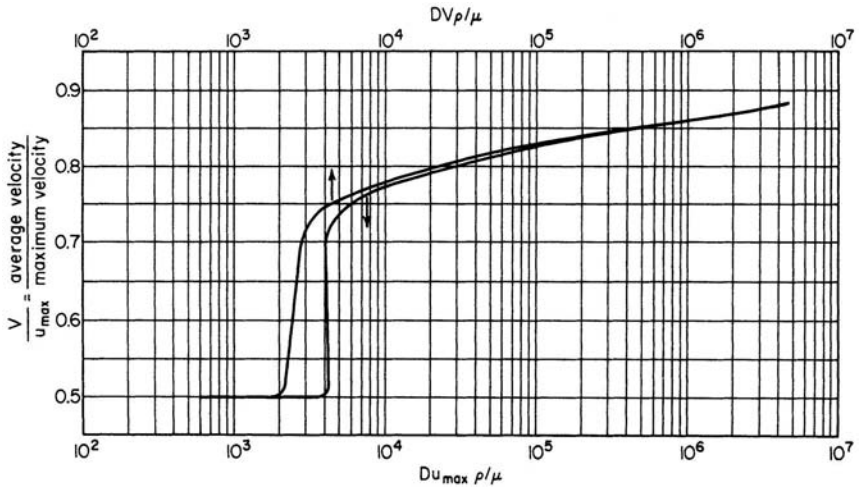

**FIG. 10-13** Velocity ration versus Reynolds number for smooth circular pipes. [*Based on data from Rothfus, Archer, Klimas, and Śikchi,* Am. Inst. Chem. Eng. J., *3, 208 (1957).*]

the measuring fluid approaches the density of the process fluid [see Horlock and Daneshyar, *J. Mech. Eng. Sci.,* **15,** 144–152 (1973)].

Pressures substantially lower than true impact pressures are obtained with pitot tubes in turbulent flow of dilute polymer solutions [see Halliwell and Lewkowicz, *Phys. Fluids,* **18,** 1617–1625 (1975)].

**Special Tubes** A variety of special forms of the pitot tube have been evolved. Folsom (loc. cit.) gives a description of many of these special types together with a comprehensive bibliography. Included are the impact tube for **boundary-layer** measurements and **shielded total-pressure tubes.** The latter are insensitive to angle of attack up to 40°.

Chue [*Prog. Aerosp. Sci.,* **16,** 147–223 (1975)] reviews the use of the pitot tube and allied pressure probes for impact pressure, static pressure, dynamic pressure, flow direction and local velocity, skin friction, and flow measurements.

A reversed pitot tube, also known as a **pitometer,** has one pressure opening facing upstream and the other facing downstream. Coefficient $C$ for this type is on the order of 0.85. This gives about a 40 percent increase in pressure differential as compared with standard pitot tubes and is an advantage at low velocities. There are commercially available very compact types of pitometers which require relatively small openings for their insertion into a duct.

The **pitot-venturi** flow element is capable of developing a pressure differential 5 to 10 times that of a standard pitot tube. This is accomplished by employing a pair of concentric venturi elements in place of the pitot probe. The low-pressure tap is connected to the throat of the inner venturi, which in turn discharges into the throat of the outer venturi. For a discussion of performance and application of this flow element, see Stoll, *Trans. Am. Soc. Mech. Eng.,* **73,** 963–969 (1951).

**Traversing for Mean Velocity** Mean velocity in a duct can be obtained by dividing the cross section into a number of equal areas, finding the local velocity at a representative point in each, and averaging the results. In the case of **rectangular passages,** the cross section is usually divided into small squares or rectangles and the velocity is found at the center of each. In circular pipes, the cross section is divided into several equal annular areas as shown in Fig. 10-13. Readings of velocity are made at the intersections of a diameter and the set of circles which bisect the annuli and the central circle.

For an $N$-point traverse on a circular cross section, make readings on each side of the cross section at

$$100 \times \sqrt{(2n-1)/N} \text{ percent} \quad (n = 1, 2, 3 \text{ to } N/2)$$

of the pipe radius from the center. Traversing several diameters spaced at equal angles about the pipe is required if the velocity distribution is unsymmetrical. With a normal velocity distribution in a circular pipe, a 10-point traverse theoretically gives a mean velocity 0.3 percent high; a 20-point traverse, 0.1 percent high.

For normal velocity distribution in straight circular pipes at locations preceded by runs of at least 50 diameters without pipe fittings or other obstructions, the graph in Fig. 10-13 shows the ratio of mean velocity $V$ to velocity at the center $u_{max}$ plotted against the Reynolds number, where $D$ = inside pipe diameter, $\rho$ = fluid density, and $\mu$ = fluid viscosity, all in consistent units. Mean velocity is readily determined from this graph and a pitot reading at the center of the pipe if the quantity $Du_{max}\rho/\mu$ is less than 2000 or greater than 5000. The method is unreliable at intermediate values of the Reynolds number.

Methods for determining mean flow rate from probe measurements under nonideal conditions are described by Mandersloot, Hicks, and Langejan [*Chem. Eng.* (*London*), no. 232, CE370-CE380 (1969)].

The **hot-wire anemometer** consists essentially of an electrically heated fine wire (generally platinum) exposed to the gas stream whose velocity is being measured. An increase in fluid velocity, other things being equal, increases the rate of heat flow from the wire to the gas, thereby tending to cool the wire and alter its electrical resistance. In a constant-current anemometer, gas velocity is determined by measuring the resulting wire resistance; in the constant-resistance type, gas velocity is determined from the current required to maintain the wire temperature, and thus the resistance, constant. The difference in the two types is primarily in the electric circuits and instruments employed.

The hot-wire anemometer can, with suitable calibration, accurately measure velocities from about 0.15 m/s (0.5 ft/s) to supersonic velocities and detect velocity fluctuations with frequencies up to 200,000 Hz. Fairly rugged, inexpensive units can be built for the measurement of mean velocities in the range of 0.15 to 30 m/s (about 0.5 to 100 ft/s). More elaborate, compensated units are commercially available for use in unsteady flow and turbulence measurements. In calibrating a hot-wire anemometer, it is preferable to use the same gas, temperature, and pressure as will be encountered in the intended application. In this case the quantity $I^2R_w/\Delta t$ can be plotted against $\sqrt{V}$, where $I$ = hot-wire current, $R_w$ = hot-wire resistance, $\Delta t$ = difference between the wire temperature and the gas bulk temperature, and $V$ = mean local velocity. A procedure is given by Wasan and Baid [*Am. Inst. Chem. Eng. J.,* **17,** 729–731 (1971)] for use when it is impractical to calibrate with the same gas composition or conditions of temperature and pressure. Andrews, Bradley, and Hundy [*Int. J. Heat Mass Transfer,* **15,** 1765–1786 (1972)] give a calibration correlation for measurement

of small gas velocities. The hot-wire anemometer is treated in considerable detail in Dean, op. cit., chap. VI; in Ladenburg et al., op. cit., art. F-2; by Grant and Kronauer, *Symposium on Measurement in Unsteady Flow,* American Society of Mechanical Engineers, New York, 1962, pp. 44–53; ASME Research Committee on Fluid Meters Report, op. cit., pp. 105–107; and by Compte-Bellot, *Ann. Rev. Fluid Mech.,* **8,** pp. 209–231 (1976).

The hot-wire anemometer can be modified for liquid measurements, although difficulties are encountered because of bubbles and dirt adhering to the wire. See Stevens, Borden, and Strausser, David Taylor Model Basin Rep. 953, December 1956; Middlebrook and Piret, *Ind. Eng. Chem.,* **42,** 1511–1513 (1950); and Piret et al., *Ind. Eng. Chem.,* **39,** 1098–1103 (1947).

The **hot-film anemometer** has been developed for applications in which use of the hot-wire anemometer presents problems. It consists of a platinum-film sensing element deposited on a glass substrate. Various geometries can be used. The most common involves a wedge with a 30° included angle at the end of a tapered rod. The wedge is commonly 1 mm (0.039 in) long and 0.2 mm (0.0079 in) wide on each face. Compared with the hot wire, it is less susceptible to fouling by bubbles or dirt when used in liquids, has greater mechanical strength when used with gases at high velocities and high temperatures, and can give a higher signal-to-noise ratio. For additional information see Ling and Hubbard, *J. Aeronaut. Sci.,* **23,** 890–891 (1956); and Ling, *J. Basic Eng.,* **82,** 629–634 (1960).

The **heated-thermocouple anemometer** measures gas velocity from the cooling effect of the gas stream flowing across the hot junctions of a thermopile supplied with constant electrical power input. Alternate junctions are maintained at ambient temperature, thus compensating for the effect of ambient temperature. For details see Bunker, *Proc. Instrum. Soc. Am.,* **9,** pap. 54-43-2 (1954).

A glass-coated bead **thermistor anemometer** can be used for the measurement of low fluid velocities, down to 0.001 m/s (0.003 ft/s) in air and 0.0002 m/s (0.0007 ft/s) in water [see Murphy and Sparks, *Ind. Eng. Chem. Fundam.,* **7,** 642–645 (1968)].

The **laser-Doppler anemometer** measures local fluid velocity from the change in frequency of radiation, between a stationary source and a receiver, due to scattering by particles along the wave path. A laser is commonly used as the source of incident illumination. The measurements are essentially independent of local temperature and pressure. This technique can be used in many different flow systems with transparent fluids containing particles whose velocity is actually measured. For a brief review of the laser-Doppler technique see Goldstein, *Appl. Mech. Rev.,* **27,** 753–760 (1974). For additional details see Durst, Melling, and Whitelaw, *Principles and Practice of Laser-Doppler Anemometry,* Academic, New York, 1976.

## FLOWMETERS

In the process industries, flow measurement devices are the largest market in the process instrumentation field. Two web sites for process equipment and instrumentation, www.globalspec.com, and www.thomasnet.com, both list more than 800 companies that offer flow measurement products. There are more than one hundred types of flowmeters commercially available. The aforementioned web sites not only facilitate selection and specification of commercial flowmeters, but also provide electronic access to manufacturers' technical literature.

Devices that measure flow can be categorized in two areas as follows:

1. All types of measuring devices in which the material passes without being divided into isolated quantities. Movement of the material is usually sensed by a primary measuring element which activates a secondary device. The flow rate is then inferred from the response of the secondary device by means of known physical laws or from empirical relationships.

2. A positive-displacement meter, which applies to a device in which the flow is divided into isolated measured volumes. The number of fillings of these known volumes are measured with respect to time.

The most common application of flow measurement in process plants is flow in pipes, ducts, and tubing. Table 10-4 lists widely used flowmeters for these closed conduits as well as the two major classes of open-channel flowmeters. Table 10-4 also lists many other types of flowmeters that are discussed later in this subsection.

This subsection summarizes selection and installation of flowmeters, including the measurement of pressure and velocities of fluids when the flow measurement technique requires it.

## INDUSTRY GUIDELINES AND STANDARDS

Because flow measurement is important, many engineering societies and trade organizations have developed flow-related guidelines, standards, and other publications (Table 10-5). The reader should consult the appropriate standards when specifying, installing, and calibrating flow measurement systems.

There are also numerous articles in scholarly journals, trade magazines, and manufacturers' literature related to flow measurement.

Different types of flowmeters differ markedly in their degrees of sensitivity to flow disturbances. In the most extreme cases, obtaining highly accurate flow measurements with certain types of flowmeters may require 60*D* upstream straight pipe and 20*D* downstream. Valves can be particularly problematic because their effects on a flowmeter vary with valve position. Numerous types of flow straighteners or conditioners, as shown in Fig. 10-9, can significantly reduce the required run of straight pipe upstream of a given flowmeter.

## CLASSIFICATION OF FLOWMETERS

Table 10-4 lists the major classes of flowmeters, along with common examples of each. Brief descriptions are provided in this subsection, followed by more details in subsequent subsections.

**Differential Pressure Meters** Differential pressure meters or head meters measure the change in pressure across a special flow element. The differential pressure increases with increasing flow rate. The pitot tubes described previously work on this principle. Other examples include orifices [see also Eqs. (6-111) and (8-102), and Fig. 10-14], nozzles (Fig. 10-19), targets, venturis (see also Sec. 8 and Fig. 10-17), and elbow meters. Averaging pitot tubes produce a pressure differential that is based on multiple measuring points across the flow path.

Differential pressure meters are widely used. Temperature, pressure, and density affect gas density and readings of differential pressure meters. For that reason, many commercial flowmeters that are based on measurement of differential pressure often have integral temperature and absolute pressure measurements in addition to differential pressure. They also frequently have automatic temperature and pressure compensation.

**Velocity Meters** Velocity meters measure fluid velocity. Examples include electromagnetic, propeller, turbine, ultrasonic Doppler, ultrasonic transit time, and vortex meters. Section 8 describes the principles of operation of electromagnetic, turbine, ultrasonic, and vortex flowmeters.

**Mass Meters** Mass flowmeters measure the rate of mass flow through a conduit. Examples include Coriolis flowmeters and thermal mass flowmeters. Coriolis flowmeters can measure fluid density simultaneously with mass flow rate. This permits calculation of volumetric flow rate as well. Section 8 includes brief descriptions of Coriolis and thermal mass flowmeters.

**Volumetric Meters** Volumetric meters (also called positive-displacement flowmeters) are devices that mechanically divide a fluid stream into discrete, known volumes and count the number of volumes that pass through the device. See Spitzer (2005, op. cit.).

**Variable-Area Meters** Variable-area meters, which are also called rotameters, offer popular and inexpensive flow measurement devices. These meters employ a float inside a tube that has an internal cross-sectional area that increases with distance upward in the flow path through the tube. As the flow rate increases, the float rises in the tube to provide a larger area for the flowing fluid to pass.

**Open-Channel Flow Measurement** Open-channel flow measurements are usually based on measurement of liquid level in a flow channel constructed of a specified geometry. The two most common flow channels used are weirs and flumes. See Spitzer (2005, op. cit.).

**TABLE 10-4 Comparison of Flowmeter Technologies**

| Flowmeter technology | Accuracy* (+/–) | Turndown | Fluids† | Pipe sizes,‡ in | Maximum pressure,‡ psig | Temperature range,‡ °F | Pipe run | Relative pressure loss |
|---|---|---|---|---|---|---|---|---|
| Differential Pressure Meters | | | | | | | | |
| Pitot | | 8:1 | L, G | 1 to 96 | 2.76E-4 to 200 | –200 to 750 | | L |
| Averaging pitot | 1% R | 8:1 | L, G, S | 0.25 to 72 | 8800 | –20 to 2370 | | L |
| Orifice | | | | | | | Long | |
| Square-edged | 0.5 to 1.5% R | 4:1 | L, G, S | 0.5 to 40 | 8800 | –4 to 2300 | | M |
| Eccentric | 2% R | 4:1 | L, G, S | 0.5 to 40 | 8800 | –4 to 2300 | | M |
| Segmental | 2% R | 4:1 | L, G, S, SL | 0.5 to 40 | 8800 | –4 to 2300 | | M |
| Orifice and multi-variable flow transmitter | 0.5 to 1% R | 10:1 | L, G, S | > 0.5 | 4000 | 1000 | | M |
| Venturi | 0.5 to 1.5% R | 10:1 | L, G, S, SL | 1 to 120 | 8800 | –4 to 2300 | | L |
| Flow nozzle | 0.5 to 2% R | 8:1 | L, G, S | 2 to 80 | >1000 | <1000 | | M |
| V cone | 0.5% F | 10:1 | L, G, S, SL | 0.25 to 120 | 6000 | To 400 | | M |
| Wedge | 0.5 to 5% R | 10:1 | L, G, S, SL | 0.5 to 24 | >600 | ‡ | | M |
| Velocity Meters | | | | | | | | |
| Correlation | 0.5% R | 10:1 | L, G, SL | 1 to 60 | Piping limits | To 600 | Long | L |
| Electromagnetic | 0.2 to 2% R | 10:1 | L | 0.15 to 60 | 5000 | –40 to 350 | Short | L |
| Propeller | 2% R | 15:1 | L | 2 to 12 | 230 | 0 to 300 | | M |
| Turbine | 0.15 to 1% R | 10:1 | L, G | 0.5 to 30 | 6000 | –450 to 600 | Short | M |
| Ultrasonic Doppler | 1 to 30% R | 50:1 | L, G, SL | 0.5 to 200 | 6000 | –40 to 250 | Long | L |
| Ultrasonic transit time | 0.5 to 5% R | Down to zero flow | L, G | 1 to 540 | 6000 | –40 to 650 | Long | L |
| Vortex | 0.5 to 2% R | 20:1 | L, G, S | 0.5 to 16 | 1500 | –330 to 800 | Short | M |
| Mass Meters | | | | | | | | |
| Coriolis | 0.1 to 0.3% R | 10:1 to 80:1 | L, G | 0.06 to 12 | 5700 | –400 to 800 | None | L, M |
| Thermal (for gases) | 1% F | 50:1 | G | 0.125 to 8 | 4500 | 32 to 572 | Short | L |
| Thermal (for liquids) | 0.5% F | 50:1 | L | 0.06 to 0.25 | 4500 | 40 to 165 | Short | L |
| Volumetric | 0.15 to 2% R | 10:1 | L | 0.25 to 16 | 2000 | –40 to 600 | None | M to H |
| Variable area | 1 to 5% F | 10:1 | L, G | 0.125 to 6 | 6000 | <1000 | None | M |
| Open-Channel Flowmeters | | | | | | | | |
| Weirs | 2 to 5% R | 25:1 | L | Wide range | NA | NA | | L |
| Flumes | 3 to 10% R | 40:1 | L | Wide range | NA | NA | | L |

*F = full scale, R = rate. †L = liquid, G = gas, S = steam, SL = slurry.

‡Dependent on the material selection and application. Readers should consult manufacturers for current capabilities.

## DIFFERENTIAL PRESSURE FLOWMETERS

**General Principles** If a constriction is placed in a closed channel carrying a stream of fluid, there will be an increase in velocity, and hence an increase in kinetic energy, at the point of constriction. From an energy balance, as given by Bernoulli's theorem [see Sec. 6, subsection "Energy Balance," Eq. (6-16)], there must be a corresponding reduction in pressure. Rate of discharge from the constriction can be calculated by knowing this pressure reduction, the area available for flow at the constriction, the density of the fluid, and the coefficient of discharge *C*. The last-named is defined as the ratio of actual flow to the theoretical flow and makes allowance for stream contraction and frictional effects. The metering characteristics of commonly used differential pressure meters are reviewed and grouped by Halmi [*J. Fluids Eng.*, **95,** 127–141 (1973)].

The term **static head** generally denotes the pressure in a fluid due to the head of fluid above the point in question. Its magnitude is given by the application of Newton's law (force = mass × acceleration). In the case of **liquids** (constant density), the static head $p_h$ Pa (lbf/ft$^2$) is given by

$$p_h = h\rho g/g_c \tag{10-20}$$

where $h$ = head of liquid above the point, m (ft); $\rho$ = liquid density; $g$ = local acceleration due to gravity; and $g_c$ = dimensional constant.

The head developed in a compressor or pump is the energy force per unit mass. In the measuring systems it is often misnamed as (ft) while the units are really ft-lb/lbm or kilojoules.

For a compressor or turbine, it is represented by the following relationship:

$$E = U_1V_{\theta 1} - U_2V_{\theta 2} \tag{10-21}$$

where $U$ is the blade speed and $V_\theta$ is the tangential velocity component of absolute velocity. This equation is known as the Euler equation.

**Orifice Meters** A **square-edged** or **sharp-edged** orifice, as shown in Fig. 10-14, is a clean-cut square-edged hole with straight walls perpendicular to the flat upstream face of a thin plate placed crosswise of the channel. The stream issuing from such an orifice attains its minimum cross section (vena contracta) at a distance downstream of the orifice which varies with the ratio β of orifice to pipe diameter (see Fig. 10-15).

For a centered circular orifice in a pipe, the pressure differential is customarily measured between one of the following pressure-tap pairs. Except in the case of flange taps, all measurements of distance from the orifice are made from the upstream face of the plate.

1. *Corner taps.* Static holes drilled one in the upstream and one in the downstream flange, with the openings as close as possible to the orifice plate.
2. *Radius taps.* Static holes located one pipe diameter upstream and one-half pipe diameter downstream from the plate.
3. *Pipe taps.* Static holes located 2½ pipe diameters upstream and eight pipe diameters downstream from the plate.

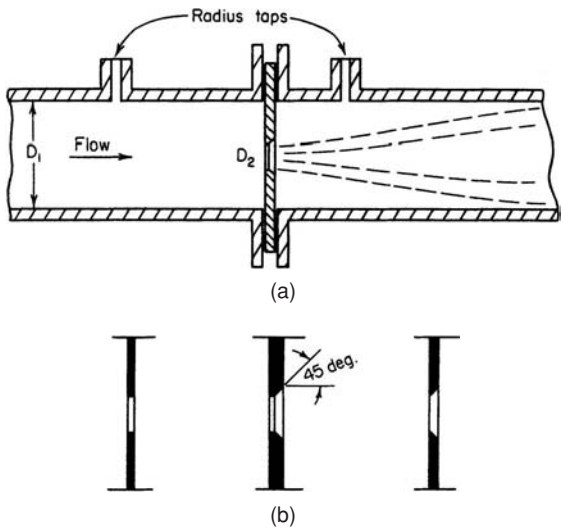

**FIG. 10-14** Square-edged or sharp-edged orifices. The plate at the orifice opening must not be thicker than one-thirtieth of the pipe diameter, one-eighth of the orifice diameter, or one-fourth of the distance from the pipe wall to the edge of the opening. (*a*) Pipe-line orifice. (*b*) Types of plates.

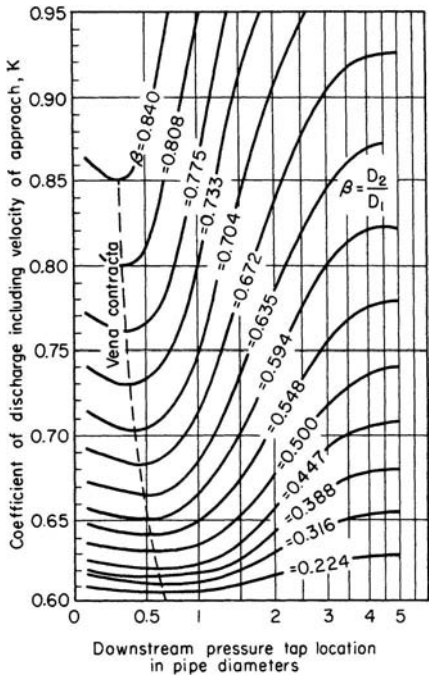

**FIG. 10-15** Coefficient of discharge for square-edged circular orifices for $N_{Re}$ > 30,000 with the upstream tap located between one and two pipe diameters from the orifice plate. [*Spitzglass,* Trans. Am. Soc. Mech. Eng., ***44,*** *919 (1922).*]

4. *Flange taps.* Static holes located 25.4 mm (1 in) upstream and 25.4 mm (1 in) downstream from the plate.
5. *Vena-contracta taps.* The upstream static hole is one-half to two pipe diameters from the plate. The downstream tap is located at the position of minimum pressure (see Fig. 10-15).

Radius taps are best from a practical standpoint; the downstream pressure tap is located at about the mean position of the vena contracta, and the upstream tap is sufficiently far upstream to be unaffected by distortion of the flow in the immediate vicinity of the orifice (in practice, the upstream tap can be as much as two pipe diameters from the plate without affecting the results). Vena-contracta taps give the largest differential head for a given rate of flow but are inconvenient if the orifice size is changed from time to time. Corner taps offer the sometimes great advantage that the pressure taps can be built into the plate carrying the orifice. Thus the entire apparatus can be quickly inserted in a pipe line at any convenient flanged joint without having to drill holes in the pipe. Flange taps are similarly convenient, since by merely replacing standard flanges with special orifice flanges, suitable pressure taps are made available. Pipe taps give the lowest differential pressure, the value obtained being close to the permanent pressure loss.

The practical working equation for weight rate of discharge, adopted by the ASME Research Committee on Fluid Meters for use with either gases or liquids, is

$$w = q_1\rho_1 = CYA_2\sqrt{\frac{2g_c(p_1 - p_2)\rho_1}{1-\beta^4}}$$

$$= KYA_2\sqrt{2g_c(p_1 - p_2)\rho_1} \qquad (10\text{-}22)$$

where $A_2$ = cross-sectional area of throat; $C$ = coefficient of discharge, dimensionless; $g_c$ = dimensional constant; $K = C/\sqrt{1-\beta^4}$, dimensionless; $p_1$, $p_2$ = pressure at upstream and downstream static pressure taps respectively; $q_1$ = volumetric rate of discharge measured at upstream pressure and temperature; $w$ = weight rate of discharge; $Y$ = expansion factor, dimensionless; β = ratio of throat diameter to

pipe diameter, dimensionless; and $\rho_1$ = density at upstream pressure and temperature.

For the case of subsonic flow of a gas ($r_c < r < 1.0$), the expansion factor $Y$ for orifices is approximated by

$$Y = 1 - [(1 - r)/k](0.41 + 0.35\beta^4) \qquad (10\text{-}23)$$

where $r$ = ratio of downstream to upstream static pressure ($p_2/p_1$), $k$ = ratio of specific heats ($c_p/c_v$), and $\beta$ = diameter ratio. (See also Fig. 10-18.) Values of $Y$ for supercritical flow of a gas ($r < r_c$) through orifices are given by Benedict [*J. Basic Eng.*, **93,** 121–137 (1971)]. For the case of **liquids,** expansion factor $Y$ is unity, and Eq. (10-27) should be used, since it allows for any difference in elevation between the upstream and downstream taps.

**Coefficient of discharge** $C$ for a given orifice type is a function of the Reynolds number $N_{Re}$ (based on orifice diameter and velocity) and diameter ratio $\beta$. At Reynolds numbers greater than about 30,000, the coefficients are substantially constant. For square-edged or sharp-edged concentric circular orifices, the value will fall between 0.595 and 0.620 for vena-contracta or radius taps for $\beta$ up to 0.8 and for flange taps for $\beta$ up to 0.5. Figure 10-15 gives the coefficient of discharge $K$, including the velocity-of-approach factor ($1/\sqrt{1 - \beta^4}$), as a function of $\beta$ and the location of the downstream tap. Precise values of $K$ are given in *ASME PTC,* op. cit., pp. 20–39, for flange taps, radius taps, vena-contracta taps, and corner taps. Precise values of $C$ are given in the ASME Research Committee on Fluid Meters Report, op. cit., pp. 202–207, for the first three types of taps.

The discharge coefficient of sharp-edged orifices was shown by Benedict, Wyler, and Brandt [*J. Eng. Power,* **97,** 576–582 (1975)] to increase with edge roundness. Typical as-purchased orifice plates may exhibit deviations on the order of 1 to 2 percent from ASME values of the discharge coefficient.

In the transition region ($N_{Re}$ between 50 and 30,000), the coefficients are generally higher than the above values. Although calibration is generally advisable in this region, the curves given in Fig. 10-16 for corner and vena-contracta taps can be used as a guide. In the laminar-flow region ($N_{Re} < 50$), the coefficient $C$ is proportional to $\sqrt{N_{Re}}$. For $1 < N_{Re} < 100$, Johansen [*Proc. R. Soc.* (*London*), **A121,** 231–245 (1930)] presents discharge-coefficient data for sharp-edged orifices with corner taps. For $N_{Re} < 1$, Miller and Nemecek [ASME Paper 58-A-106 (1958)] present correlations giving coefficients for sharp-edged orifices and short-pipe orifices ($L/D$ from 2 to 10). For short-pipe orifices ($L/D$ from 1 to 4), Dickerson and Rice [*J. Basic Eng.*, **91,** 546–548 (1969)] give coefficients for the intermediate range ($27 < N_{Re} < 7000$). See also subsection "Contraction and Entrance Losses."

**Permanent pressure loss** across a concentric circular orifice with radius or vena-contracta taps can be approximated for turbulent flow by

$$(p_1 - p_4)/(p_1 - p_2) = 1 - \beta^2 \qquad (10\text{-}24)$$

where $p_1$, $p_2$ = upstream and downstream pressure-tap readings respectively, $p_4$ = fully recovered pressure (four to eight pipe diameters downstream of the orifice), and $\beta$ = diameter ratio. See *ASME PTC,* op. cit., Fig. 5.

See Benedict, *J. Fluids Eng.*, **99,** 245–248 (1977), for a general equation for pressure loss for orifices installed in pipes or with plenum inlets. Orifices show higher loss than nozzles or venturis. Permanent pressure loss for laminar flow depends on the Reynolds number in addition to $\beta$. See Alvi, Sridharan, and Lakshmana Rao, loc. cit., for details.

For the case of **critical flow** through a square- or sharp-edged concentric circular orifice (where $r \le r_c$, as discussed earlier in this subsection), use Eqs. (10-31), (10-32), and (10-33) as given for critical-flow nozzles. However, unlike nozzles, the flow through a sharp-edged orifice continues to increase as the downstream pressure drops below that

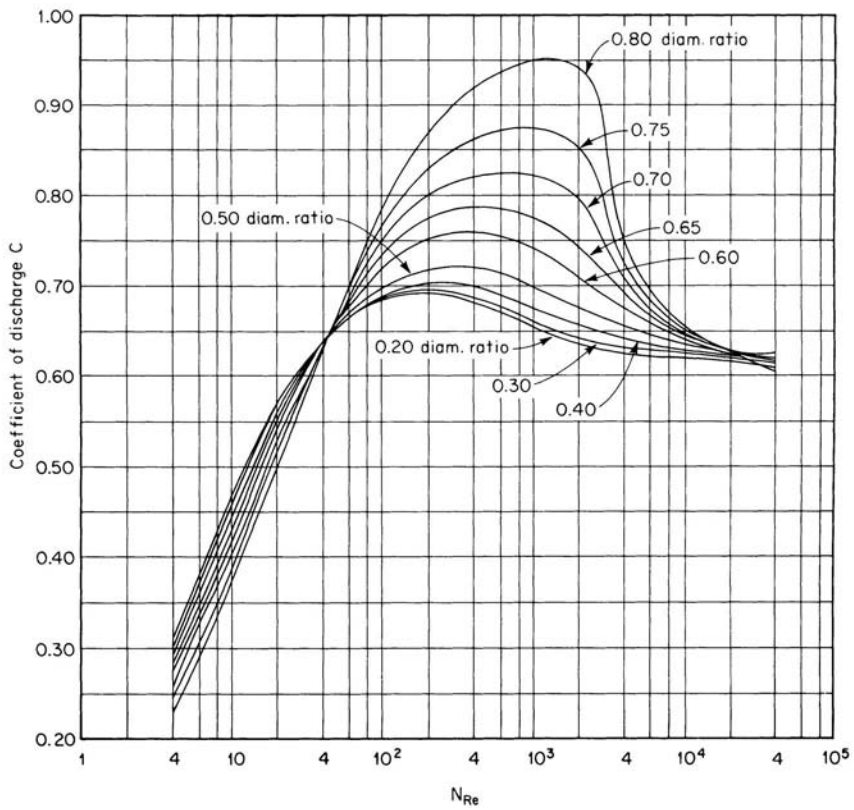

**FIG. 10-16** Coefficient of discharge for square-edged circular orifices with corner taps. [*Tuve and Sprenkle,* Instruments, ***6,*** *201 (1933).*]

corresponding to the critical pressure ratio $r_c$. This is due to an increase in the cross section of the vena contracta as the downstream pressure is reduced, giving a corresponding increase in the coefficient of discharge. At $r = r_c$, $C$ is about 0.75, while at $r \cong 0$, $C$ has increased to about 0.84. See Grace and Lapple, loc. cit.; and Benedict, *J. Basic Eng.*, **93,** 99–120 (1971).

Measurements by Harris and Magnall [*Trans. Inst. Chem. Eng.* (*London*), **50,** 61–68 (1972)] with a venturi ($\beta = 0.62$) and orifices with radius taps ($\beta = 0.60 - 0.75$) indicate that the discharge coefficient for **nonnewtonian fluids,** in the range $N'_{Re}$ (generalized Reynolds number) 3500 to 100,000, is approximately the same as for newtonian fluids at the same Reynolds number.

**Quadrant-edge orifices** have holes with rounded edges on the upstream side of the plate. The quadrant-edge radius is equal to the thickness of the plate at the orifice location. The advantages claimed for this type versus the square- or sharp-edged orifice are constant-discharge coefficients extending to lower Reynolds numbers and less possibility of significant changes in coefficient because of erosion or other damage to the inlet shape.

Values of discharge coefficient $C$ and Reynolds numbers limit for constant $C$ are presented in Table 10-6, based on Ramamoorthy and Seetharamiah [*J. Basic Eng.*, **88,** 9–13 (1966)] and Bogema and Monkmeyer (*J. Basic Eng.*, **82,** 729–734 (1960)]. At Reynolds numbers above those listed for the upper limits, the coefficients rise abruptly. As Reynolds numbers decrease below those listed for the lower limits, the coefficients pass through a hump and then drop off. According to Bogema, Spring, and Ramamoorthy [*J. Basic Eng.*, **84,** 415–418 (1962)], the hump can be eliminated by placing a fine-mesh screen about three pipe diameters upstream of the orifice. This reduces the lower $N_{Re}$ limit to about 500.

Permanent pressure loss across quadrant-edge orifices for turbulent flow is somewhat lower than given by Eq. (10-24). See Alvi, Sridharan, and Lakshmana Rao, loc. cit., for values of discharge coefficient and permanent pressure loss in laminar flow.

**Slotted orifices** offer significant advantages over a standard square-edged orifice with an identical open area for homogeneous gases or liquids [G. L. Morrison and K. R. Hall, *Hydrocarbon Processing* **79,** 12, 65–72 (2000)]. The slotted orifice flowmeter only requires compact header configurations with very short upstream pipe lengths and maintains accuracy in the range of 0.25 percent with no flow conditioner. Permanent head loss is less than or equal to that of a standard orifice that has the same $\beta$ ratio. Discharge coefficients for the slotted orifice are much less sensitive to swirl or to axial velocity profiles. A slotted orifice plate can be a "drop in" replacement for a standard orifice plate.

**Segmental** and **eccentric orifices** are frequently used for gas metering when there is a possibility that entrained liquids or solids would otherwise accumulate in front of a concentric circular orifice. This can be avoided if the opening is placed on the lower side of the pipe. For liquid flow with entrained gas, the opening is placed on the upper side. The pressure taps should be located on the opposite side of the pipe from the opening.

Coefficient $C$ for a square-edged eccentric circular orifice (with opening tangent to pipe wall) varies from about 0.61 to 0.63 for $\beta$'s from 0.3 to 0.5, respectively, and pipe Reynolds numbers > 10,000 for either vena-contracta or flange taps (where $\beta$ = diameter ratio). For square-edged segmental orifices, the coefficient $C$ falls generally between 0.63 and 0.64 for $0.3 \le \beta \le 0.5$ and pipe Reynolds numbers > 10,000, for vena-contracta or flange taps, where $\beta$ = diameter ratio for an equivalent circular orifice = $\sqrt{\alpha}$ ($\alpha$ = ratio of orifice to pipe cross-sectional areas). Values of expansion factor $Y$ are slightly higher than for concentric circular orifices, and the location of the vena contracta is moved farther downstream as compared with concentric circular orifices. For further details, see ASME Research Committee on Fluid Meters Report, op. cit., pp. 210–213.

**TABLE 10-6 Discharge Coefficients for Quadrant-Edge Orifices**

| | | | Limiting $N^*_{Re}$ for constant coefficient† | |
|---|---|---|---|---|
| $\beta$ | $C$‡ | $K$‡ | Lower | Upper |
| 0.225 | 0.770 | 0.771 | 5,000 | 60,000 |
| 0.400 | 0.780 | 0.790 | 5,000 | 150,000 |
| 0.500 | 0.824 | 0.851 | 4,000 | 200,000 |
| 0.600 | 0.856 | 0.918 | 3,000 | 120,000 |
| 0.630 | 0.885 | 0.964 | 3,000 | 105,000 |

*Based on pipe diameter and velocity.
†For a precision of about ±0.5 percent.
‡Can be used with corner taps, flange taps, or radius taps.

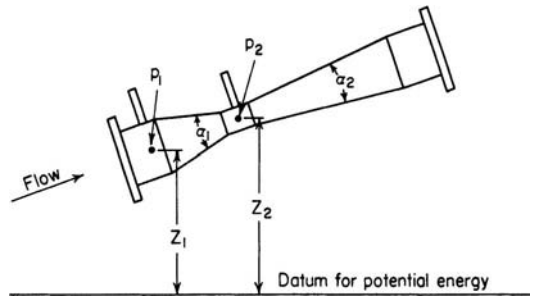

**FIG. 10-17** Herschel-type venturi tube.

For permanent pressure loss with segmental and eccentric orifices with laminar pipe flow see Lakshmana Rao and Sridharan, *Proc. Am. Soc. Civ. Eng., J. Hydraul. Div.*, **98** (HY 11), 2015–2034 (1972).

**Annular orifices** can also be used to advantage for gas metering when there is a possibility of entrained liquids or solids and for liquid metering with entrained gas present in small concentrations. Coefficient $K$ was found by Bell and Bergelin [*Trans. Am. Soc. Mech. Eng.*, **79,** 593–601 (1957)] to range from about 0.63 to 0.67 for annulus Reynolds numbers in the range of 100 to 20,000 respectively for values of $2L/(D - d)$ less than 1 where $L$ = thickness of orifice at outer edge, $D$ = inside pipe diameter, and $d$ = diameter of orifice disk. The annulus Reynolds number is defined as

$$N_{Re} = (D - d)(G/\mu) \tag{10-25}$$

where $G$ = mass velocity $pV$ through orifice opening and $\mu$ = fluid viscosity. The above coefficients were determined for $\beta$'s (= $d/D$) in the range of 0.95 to 0.996 and with pressure taps located 19 mm (¾ in) upstream of the disk and 230 mm (9 in) downstream in a 5.25-in-diameter pipe.

**Venturi Meters** The standard Herschel-type venturi meter consists of a short length of straight tubing connected at either end to the pipe line by conical sections (see Fig. 10-17). Recommended proportions (*ASME PTC*, op. cit., p. 17) are entrance cone angle $\alpha_1 = 21 \pm 2°$, exit cone angle $\alpha_2 = 5$ to 15°, throat length = one throat diameter, and upstream tap located 0.25 to 0.5 pipe diameter upstream of the entrance cone. The straight and conical sections should be joined by smooth curved surfaces for best results. **Rate of discharge** of either gases or liquids through a venturi meter is given by Eq. (10-22).

For the flow of **gases,** expansion factor $Y$, which allows for the change in gas density as it expands adiabatically from $p_1$ to $p_2$, is given by

$$Y = \sqrt{r^{2/k}\left(\frac{k}{k-1}\right)\left(\frac{1 - r^{(k-1)/k}}{1 - r}\right)\left(\frac{1 - \beta^4}{1 - \beta^4 r^{2/k}}\right)} \tag{10-26}$$

for venturi meters and flow nozzles, where $r = p_2/p_1$ and $k$ = specific heat ratio $c_p/c_v$. Values of $Y$ computed from Eq. (10-26) are given in Fig. 10-18 as a function of $r$, $k$, and $\beta$.

For the flow of **liquids,** expansion factor $Y$ is unity. The change in potential energy in the case of an inclined or vertical venturi meter must be allowed for. Equation (10-22) is accordingly modified to give

$$w = q_1\rho = CA_2\sqrt{\frac{[2g_c(p_1 - p_2) + 2g\rho(Z_1 - Z_2)]\rho}{1 - \beta^4}} \tag{10-27}$$

where $g$ = local acceleration due to gravity and $Z_1$, $Z_2$ = vertical heights above an arbitrary datum plane corresponding to the centerline pressure-reading locations for $p_1$ and $p_2$ respectively.

Value of the **discharge coefficient** $C$ for a **Herschel-type venturi meter** depends upon the Reynolds number and to a minor extent upon the size of the venturi, increasing with diameter. A plot of $C$ versus pipe Reynolds number is given in *ASME PTC,* op. cit., p. 19. A value of 0.984 can be used for pipe Reynolds numbers larger than 200,000.

**Permanent pressure loss** for a Herschel-type venturi tube depends upon diameter ratio $\beta$ and discharge cone angle $\alpha_2$. It ranges from 10 to 15 percent of the pressure differential $(p_1 - p_2)$ for small angles (5 to 7°) and from 10 to 30 percent for large angles (15°), with the larger losses occurring at low values of $\beta$ (see *ASME PTC,* op. cit., p. 12). See Benedict, *J. Fluids Eng.,* **99,** 245–248 (1977), for a general equation for pressure loss for venturis installed in pipes or with plenum inlets.

For flow measurement of **steam and water mixtures** with a Herschel-type venturi in 2½-in- and 3-in-diameter pipes, see Collins and Gacesa, *J. Basic Eng.,* **93,** 11–21 (1971).

A variety of **short-tube** venturi meters are available commercially. They require less space for installation and are generally (although not always) characterized by a greater pressure loss than the corresponding Herschel-type venturi meter. Discharge coefficients vary widely for different types, and individual calibration is recommended if the manufacturer's calibration is not available. Results of tests on the Dall flow tube are given by Miner [*Trans. Am. Soc. Mech. Eng.,* **78,** 475–479 (1956)] and Dowdell [*Instrum. Control Syst.,* **33,** 1006–1009 (1960)]; and on the Gentile flow tube (also called Beth flow tube or Foster flow tube) by Hooper [*Trans. Am. Soc. Mech. Eng.,* **72,** 1099–1110 (1950)].

The use of a **multiventuri system** (in which an inner venturi discharges into the throat of an outer venturi) to increase both the differential pressure for a given flow rate and the signal-to-loss ratio is described by Klomp and Sovran [*J. Basic Eng.,* **94,** 39–45 (1972)].

**Flow Nozzles** A simple form of flow nozzle is shown in Fig. 10-19. It consists essentially of a short cylinder with a flared approach section. The approach cross section is preferably elliptical in shape but may be conical. Recommended contours for long-radius flow nozzles are given in *ASME PTC,* op. cit., p. 13. In general, the length of the straight portion of the throat is about one-half throat diameter, the upstream pressure tap is located about one pipe diameter from the nozzle inlet face, and the downstream pressure tap about one-half pipe diameter from the inlet face. For subsonic flow, the pressures at points 2 and 3 will be practically identical. If a conical inlet is preferred, the inlet and throat geometry specified for a Herschel-type venturi meter can be used, omitting the expansion section.

**Rate of discharge** through a flow nozzle for subcritical flow can be determined by the equations given for venturi meters, Eq. (10-22) for gases and Eq. (10-27) for liquids. The expansion factor $Y$ for nozzles is the same as that for venturi meters [Eq. (10-26), Fig. 10-18]. The value of the discharge coefficient $C$ depends primarily upon the pipe Reynolds number and to a lesser extent upon the diameter ratio $\beta$. Curves of recommended coefficients for long-radius flow nozzles with pressure taps located one pipe diameter upstream and one-half pipe diameter downstream of the inlet face of the nozzle are given in *ASME PTC,* op. cit., p. 15. In general, coefficients range from 0.95 at a pipe Reynolds number of 10,000 to 0.99 at 1,000,000.

The performance characteristics of pipe-wall-tap nozzles (Fig. 10-19) and throat-tap nozzles are reviewed by Wyler and Benedict [*J. Eng. Power,* **97,** 569–575 (1975)].

**Permanent pressure loss** across a subsonic flow nozzle is approximated by

$$p_1 - p_4 = \frac{1 - \beta^2}{1 + \beta^2}(p_1 - p_2) \tag{10-28}$$

where $p_1$, $p_2$, $p_4$ = static pressures measured at the locations shown in Fig. 10-19; and $\beta$ = ratio of nozzle throat diameter to pipe diameter, dimensionless. Equation (10-28) is based on a momentum balance assuming constant fluid density (see Lapple et al., *Fluid and Particle Mechanics,* University of Delaware, Newark, 1951, p. 13).

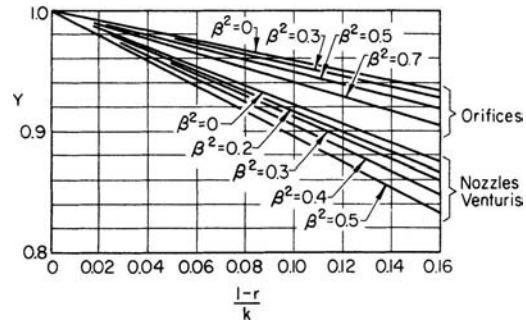

**FIG. 10-18** Values of expansion factor $Y$ for orifices, nozzles, and venturis.

See Benedict, loc. cit., for a general equation for pressure loss for nozzles installed in pipes or with plenum inlets. Nozzles show higher loss than venturis. Permanent pressure loss for laminar flow depends on the Reynolds number in addition to $\beta$. For details, see Alvi, Sridharan, and Lakshamana Rao, *J. Fluids Eng.,* **100,** 299–307 (1978).

**Critical Flow Nozzle** For a given set of upstream conditions, the rate of discharge of a gas from a nozzle will increase for a decrease in the absolute pressure ratio $p_2/p_1$ until the linear velocity in the throat reaches that of sound in the gas at that location. The value of $p_2/p_1$ for which the acoustic velocity is just attained is called the critical pressure ratio $r_c$. The actual pressure in the throat will not fall below $p_1 r_c$ even if a much lower pressure exists downstream.

The **critical pressure ratio** $r_c$ can be obtained from the following theoretical equation, which assumes a perfect gas and a frictionless nozzle:

$$r_c^{(1-k)/k} + \left(\frac{k-1}{2}\right)\beta^4 r_c^{2/k} = \frac{k+1}{2} \tag{10-29}$$

This reduces, for $\beta \le 0.2$, to

$$r_c = \left(\frac{2}{k+1}\right)^{k/(k-1)} \tag{10-30}$$

where $k$ = ratio of specific heats $c_p/c_v$ and $\beta$ = diameter ratio. A table of values of $r_c$ as a function of $k$ and $\beta$ is given in the ASME Research Committee on Fluid Meters Report, op. cit., p. 68. For small values of $\beta$, $r_c = 0.487$ for $k = 1.667$, 0.528 for $k = 1.40$, 0.546 for $k = 1.30$, and 0.574 for $k = 1.15$.

Under **critical flow conditions,** only the upstream conditions $p_1$, $v_1$, and $T_1$ need be known to determine flow rate, which, for $\beta \le 0.2$, is given by

$$w_{max} = CA_2\sqrt{g_c k\left(\frac{p_1}{v_1}\right)\left(\frac{2}{k+1}\right)^{(k+1)/(k-1)}} \tag{10-31}$$

For a **perfect gas,** this corresponds to

$$w_{max} = CA_2 p_1\sqrt{g_c k\left(\frac{M}{RT_1}\right)\left(\frac{2}{k+1}\right)^{(k+1)/(k-1)}} \tag{10-32}$$

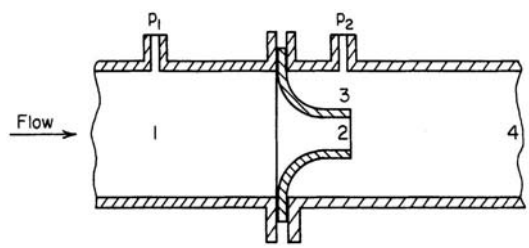

**FIG. 10-19** Flow-nozzle assembly.

For air, Eq. (10-31) reduces to

$$w_{max} = C_1 C A_2 p_1 / \sqrt{T_1} \qquad (10\text{-}33)$$

where $A_2$ = cross-sectional area of throat; $C$ = coefficient of discharge, dimensionless; $g_c$ = dimensional constant; $k$ = ratio of specific heats, $c_p/c_v$; $M$ = molecular weight; $p_1$ = pressure on upstream side of nozzle; $R$ = gas constant; $T_1$ = absolute temperature on upstream side of nozzle; $v_1$ = specific volume on upstream side of nozzle; $C_1$ = dimensional constant, 0.0405 SI units (0.533 U.S. customary units); and $w_{max}$ = maximum-weight flow rate.

Discharge coefficients for critical flow nozzles are, in general, the same as those for subsonic nozzles. See Grace and Lapple, *Trans. Am. Soc. Mech. Eng.,* **73,** 639–647 (1951); and Szaniszlo, *J. Eng. Power,* **97,** 521–526 (1975). Arnberg, Britton, and Seidl [*J. Fluids Eng.,* **96,** 111–123 (1974)] present discharge-coefficient correlations for circular-arc venturi meters at critical flow. For the calculation of the flow of natural gas through nozzles under critical-flow conditions, see Johnson, *J. Basic Eng.,* **92,** 580–589 (1970).

**Elbow Meters** A pipe elbow can be used as a flowmeter for liquids if the differential centrifugal head generated between the inner and outer radii of the bend is measured by means of pressure taps located midway around the bend. Equation (10-27) can be used, except that the pressure-difference term $(p_1 - p_2)$ is now taken to be the differential centrifugal pressure and $\beta$ is taken as zero if one assumes no change in cross section between the pipe and the bend. The discharge coefficient should preferably be determined by calibration, but as a guide it can be estimated within ±6 percent for circular pipe for Reynolds numbers greater than $10^5$ from $C = 0.98\sqrt{R_c/2D}$, where $R_c$ = radius of curvature of the centerline and $D$ = inside pipe diameter in consistent units. See Murdock, Foltz, and Gregory, *J. Basic Eng.,* **86,** 498–506 (1964); or the ASME Research Committee on Fluid Meters Report, op. cit., pp. 75–77.

**Accuracy** Square-edged orifices and venturi tubes have been so extensively studied and standardized that reproducibilities within 1 to 2 percent can be expected between standard meters when new and clean. This is therefore the order of reliability to be had, if one assumes (1) accurate measurement of meter differential, (2) selection of the coefficient of discharge from recommended published literature, (3) accurate knowledge of fluid density, (4) accurate measurement of critical meter dimensions, (5) smooth upstream face of orifice, and (6) proper location of the meter with respect to other flow-disturbing elements in the system. Care must also be taken to avoid even slight corrosion or fouling during use.

Presence of **swirling flow** or an **abnormal velocity distribution** upstream of the metering element can cause serious metering error unless calibration in place is employed or sufficient straight pipe is inserted between the meter and the source of disturbance. Table 10-7 gives the minimum lengths of straight pipe required to avoid appreciable error due to the presence of certain fittings and valves either upstream or downstream of an orifice or nozzle. These values were extracted from plots presented by Sprenkle [*Trans. Am. Soc. Mech. Eng.,* **67,** 345–360 (1945)]. Table 10-7 also shows the reduction in spacing made possible by the use of straightening vanes between the fittings and the meter. Entirely adequate straightening vanes can be provided by fitting a bundle of thin-wall tubes within the pipe. The center-to-center distance between tubes should not exceed one-fourth of the pipe diameter, and the bundle length should be at least 8 times this distance.

The distances specified in Table 10-7 will be conservative if applied to venturi meters. For specific information on requirements for venturi meters, see a discussion by Pardoe appended to Sprenkle (op. cit.). Extensive data on the effect of installation on the coefficients of venturi meters are given elsewhere by Pardoe [*Trans. Am. Soc. Mech. Eng.,* **65,** 337–349 (1943)].

In the presence of **flow pulsations,** the indications of head meters such as orifices, nozzles, and venturis will often be undependable for several reasons. First, the measured pressure differential will tend to be high, since the pressure differential is proportional to the square of flow rate for a head meter, and the square root of the mean differential pressure is always greater than the mean of the square roots of the differential pressures. Second, there is a phase shift as the wave passes through the metering restriction which can affect the differential. Third, pulsations can be set up in the manometer leads themselves. Frequency of the pulsation also plays a part. At low frequencies, the meter reading can generally faithfully follow the flow pulsations, but at high frequencies it cannot. This is due to inertia of the fluid in the manometer leads or of the manometric fluid, whereupon the meter would give a reading intermediate between the maximum and minimum flows but having no readily predictable relation to the mean flow. Pressure transducers with flush-mounted diaphragms can be used together with high-speed recording equipment to provide accurate records of the pressure profiles at the upstream and downstream pressure taps, which can then be analyzed and translated into a mean flow rate.

The rather general practice of producing a steady differential reading by placing restrictions in the manometer leads can result in a reading which, under a fixed set of conditions, may be useful in control of an operation but which has no readily predictable relation to the actual average flow. If calibration is employed to compensate for the presence of pulsations, complete reproduction of operating conditions, including source of pulsations and waveform, is necessary to ensure reasonable accuracy.

According to Head [*Trans. Am. Soc. Mech. Eng.,* **78,** 1471–1479 (1956)], a pulsation-intensity limit of $\Gamma = 0.1$ is recommended as a practical pulsation threshold below which the performance of all types of flowmeters will differ negligibly from steady-flow performance (an error of less than 1 percent in flow due to pulsation). $\Gamma$ is the peak-to-trough flow variation expressed as a fraction of the average flow rate. According to the ASME Research Committee on Fluid Meters Report (op. cit., pp. 34–35), the fractional metering error $E$ for **liquid flow** through a head meter is given by

$$(1 + E)^2 = 1 + \Gamma^2/8 \qquad (10\text{-}34)$$

When the pulsation amplitude is such as to result in a greater-than-permissible metering error, consideration should be given to installation of a pulsation damper between the source of pulsations and the

flowmeter. References to methods of pulsation-damper design are given in the subsection "Unsteady-State Behavior."

Pulsations are most likely to be encountered in discharge lines from reciprocating pumps or compressors and in lines supplying steam to reciprocating machinery. For **gas flow,** a combination involving a surge chamber and a constriction in the line can be used to damp out the pulsations to an acceptable level. The surge chamber is generally located as close to the pulsation source as possible, with the constriction between the surge chamber and the metering element. This arrangement can be used for either a suction or a discharge line. For such an arrangement, the metering error has been found to be a function of the Hodgson number $N_H$, which is defined as

$$N_H = Qn\,\Delta p_s/qp_s \qquad (10\text{-}35)$$

where $Q$ = volume of surge chamber and pipe between metering element and pulsation source; $n$ = pulsation frequency; $\Delta p_s$ = permanent pressure drop between metering element and surge chamber; $q$ = average volume flow rate, based on gas density in the surge chamber; and $p_s$ = pressure in surge chamber.

Herning and Schmid [*Z. Ver. Dtsch. Ing.,* **82,** 1107–1114 (1938)] presented charts for a simplex double-acting compressor for the prediction of metering error as a function of the Hodgson number and $s$, the ratio of piston discharge time to total time per stroke. Table 10-8*a* gives the minimum Hodgson numbers required to reduce the metering error to 1 percent as given by the charts (for specific heat ratios between 1.28 and 1.37). Schmid [*Z. Ver. Dtsch. Ing.,* **84,** 596–598 (1940)] presented similar charts for a duplex double-acting compressor and a triplex double-acting compressor for a specific heat ratio of 1.37. Table 10-8*b* gives the minimum Hodgson numbers corresponding to a 1 percent metering error for these cases. The value of $Q\,\Delta p_s$ can be calculated from the appropriate Hodgson number, and appropriate values of $Q$ and $\Delta p_s$ selected so as to satisfy this minimum requirement.

## VELOCITY METERS

**Anemometers** An anemometer may be any instrument for measurement of gas velocity, e.g., a pitot tube, but usually the term refers to one of the following types.

The vane **anemometer** is a delicate revolution counter with jeweled bearings, actuated by a small windmill, usually 75 to 100 mm (about 3 to 4 in) in diameter, constructed of flat or slightly curved radially disposed vanes. Gas velocity is determined by using a stopwatch to find the time interval required to pass a given number of meters (feet) of gas as indicated by the counter. The velocity so obtained is inversely proportional to gas density. If the original calibration was carried out in a gas of density $\rho_0$ and the density of the gas stream being metered is $\rho_1$, the true gas velocity can be found as follows: From the calibration curve for the instrument, find $V_{t,0}$ corresponding to the quantity $V_m\sqrt{\rho_1/\rho_0}$, where $V_m$ = measured velocity. Then the actual velocity $V_{t,1}$ is equal to $V_{t,0}\sqrt{\rho_0/\rho_1}$. In general, when working with air, the effects of atmospheric-density changes can be neglected for all velocities above 1.5 m/s (about 5 ft/s). In all cases, care must be taken to hold the anemometer well away from one's body or from any object not normally present in the stream.

Vane anemometers can be used for gas-velocity measurements in the range of 0.3 to 45 m/s (about 1 to 150 ft/s), although a given instrument generally has about a twentyfold velocity range. Bearing friction has to be minimized in instruments designed for accuracy at the low end of the range, while ample rotor and vane rigidity must be provided for measurements at the higher velocities. Vane anemometers are sensitive to shock and cannot be used in corrosive atmospheres. Therefore, accuracy is questionable unless a recent calibration has been made and the history of the instrument subsequent to calibration is known. For additional information, see Ower et al., op. cit., chap. VIII.

**Turbine Flowmeters** They consist of a straight flow tube containing a turbine which is free to rotate on a shaft supported by one or more bearings and located on the centerline of the tube. Means are provided for magnetic detection of the rotational speed, which is proportional to the volumetric flow rate. Its use is generally restricted to clean, noncorrosive fluids. Additional information on construction, operation, range, and accuracy can be obtained from Baker, pp. 215–252, 2000; Miller, op. cit.; and Spitzer, pp. 303–317, 2005.

The **current meter** is generally used for measuring velocities in open channels such as rivers and irrigation channels. There are two types, the cup meter and the propeller meter. The former is more widely used. It consists of six conical cups mounted on a vertical axis pivoted at the ends and free to rotate between the rigid arms of a U-shaped clevis to which a vaned tailpiece is attached. The wheel rotates because of the difference in drag for the two sides of the cup, and a signal proportional to the revolutions of the wheel is generated. The velocity is determined from the count over a period of time. The current meter is generally useful in the range of 0.15 to 4.5 m/s (about 0.5 to 15 ft/s) with an accuracy of ±2 percent. For additional information see Creager and Justin, *Hydroelectric Handbook,* 2d ed., Wiley, New York, 1950, pp. 42–46.

Other important classes of velocity meters include electromagnetic flowmeters and ultrasonic flowmeters. Both are described in Sec. 8.

## MASS FLOWMETERS

**General Principles** There are two main types of mass flowmeters: (1) the so-called true mass flowmeter, which responds directly to mass flow rate, and (2) the inferential mass flowmeter, which commonly measures volume flow rate and fluid density separately. A variety of types of true mass flowmeters have been developed, including the following: (*a*) the Magnus-effect mass flowmeter, (*b*) the axial-flow, transverse-momentum mass flowmeter, (*c*) the radial-flow, transverse-momentum mass flowmeter, (*d*) the gyroscopic transverse-momentum mass flowmeter, and (*e*) the thermal mass flowmeter. Type *b* is the basis for several commercial mass flowmeters, one version of which is briefly described here.

**Axial-Flow Transverse-Momentum Mass Flowmeter** This type is also referred to as an angular-momentum mass flowmeter. One embodiment of its principle involves the use of axial flow through a driven impeller and a turbine in series. The impeller imparts angular momentum to the fluid, which in turn causes a torque to be imparted to the turbine, which is restrained from rotating by a spring. The torque, which can be measured, is proportional to the rotational speed of the impeller and the mass flow rate.

**Inferential Mass Flowmeter** There are several types in this category, including the following:

1. *Head meters with density compensation.* Head meters such as orifices, venturis, or nozzles can be used with one of a variety of densitometers [e.g., based on (*a*) buoyant force on a float, (*b*) hydraulic coupling, (*c*) voltage output from a piezoelectric crystal, or (*d*) radiation absorption]. The signal from the head meter, which is proportional to $\rho V^2$ (where $\rho$ = fluid density and $V$ = fluid velocity), is multiplied by $\rho$ given by the densitometer. The square root of the product is proportional to the mass flow rate.

2. *Head meters with velocity compensation.* The signal from the head meter, which is proportional to $\rho V^2$, is divided by the signal from a velocity meter to give a signal proportional to the mass flow rate.

3. *Velocity meters with density compensation.* The signal from the velocity meter (e.g., turbine meter, electromagnetic meter, or sonic velocity meter) is multiplied by the signal from a densitometer to give a signal proportional to the mass flow rate.

**Coriolis Mass Flowmeter** This type, described in Sec. 8, offers simultaneous direct measurement of both mass flow rate and fluid density. The coriolis flowmeter is insensitive to upstream and downstream flow disturbances, but its performance is adversely affected by the presence of even a few percent of a gas when measuring a liquid flow.

## VARIABLE-AREA METERS

**General Principles** The underlying principle of an ideal area meter is the same as that of a head meter of the orifice type (see subsection "Orifice Meters"). The stream to be measured is throttled by a constriction, but instead of observing the variation with flow of the differential head across an orifice of fixed size, the constriction of an area meter is so arranged that its size is varied to accommodate the flow while the differential head is held constant.

A simple example of an area meter is a gate valve of the rising-stem type provided with static-pressure taps before and after the gate and a means for measuring the stem position. In most common types of area meters, the variation of the opening is automatically brought about by the motion of a weighted piston or float supported by the fluid. Two different cylinder- and piston-type area meters are described in the ASME Research Committee on Fluid Meters Report, op. cit., pp. 82–83.

**Rotameters** The rotameter, an example of which is shown in Fig. 10-20, has become one of the most popular flowmeters in the chemical-process industries. It consists essentially of a plummet, or "float," which is free to move up or down in a vertical, slightly tapered tube having its small end down. The fluid enters the lower end of the tube and causes the float to rise until the annular area between the float and the wall of the tube is such that the pressure drop across this constriction is just sufficient to support the float. Typically, the tapered tube is of glass and carries etched upon it a nearly linear scale on which the position of the float may be visually noted as an indication of the flow.

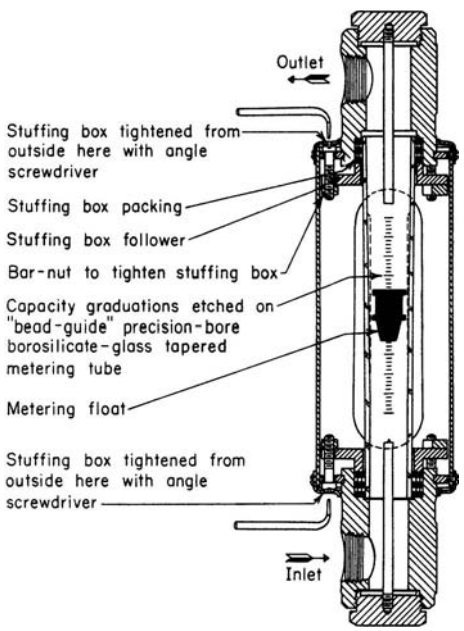

**FIG. 10-20** Rotameter.

Interchangeable precision-bore glass tubes and metal metering tubes are available. Rotameters have proved satisfactory both for gases and for liquids at high and at low pressures. A single instrument can readily cover a tenfold range of flow, and by providing floats of different densities a two-hundredfold range is practicable. Rotameters are available with pneumatic, electric, and electronic transmitters for actuating remote recorders, integrators, and automatic flow controllers (see Considine, op. cit., pp. 4-35–4-36, and Sec. 8 of this *Handbook*).

Rotameters require no straight runs of pipe before or after the point of installation. Pressure losses are substantially constant over the whole flow range. In experimental work, for greatest precision, a rotameter should be calibrated with the fluid which is to be metered. However, most modern rotameters are precision-made so that their performance closely corresponds to a master calibration plot for the type in question. Such a plot is supplied with the meter upon purchase.

According to Head [*Trans. Am. Soc. Mech. Eng.,* **76,** 851–862 (1954)], flow rate through a rotameter can be obtained from

$$w = q\rho = KD_f \sqrt{\frac{W_f(\rho_f - \rho)\rho}{\rho_f}} \tag{10-36}$$

and

$$K = \phi \left[ \frac{D_t}{D_f}, \frac{\mu}{\sqrt{\dfrac{W_f(\rho_f - \rho)\rho}{\rho_f}}} \right] \tag{10-37}$$

where $w$ = weight flow rate; $q$ = volume flow rate; $\rho$ = fluid density; $K$ = flow parameter, $m^{1/2}/s$ ($ft^{1/2}/s$); $D_f$ = float diameter at constriction; $W_f$ = float weight; $\rho_f$ = float density; $D_t$ = tube diameter at point of constriction; and $\mu$ = fluid viscosity. The appropriate value of $K$ is obtained from a composite correlation of $K$ versus the parameters shown in Eq. (10-37) corresponding to the float shape being used. The relation of $D_t$ to the rotameter reading is also required for the tube taper and size being used.

The ratio of flow rates for two different fluids $A$ and $B$ at the same rotameter reading is given by

$$\frac{w_A}{w_B} = \frac{K_A}{K_B} \sqrt{\frac{(\rho_f - \rho_A)\rho_A}{(\rho_f - \rho_B)\rho_B}} \tag{10-38}$$

A measure of self-compensation, with respect to weight rate of flow, for fluid-density changes can be introduced through the use of a float with a density twice that of the fluid being metered, in which case an increase of 10 percent in $\rho$ will produce a decrease of only 0.5 percent in $w$ for the same reading. The extent of immunity to changes in fluid viscosity depends upon the shape of the float.

According to Baird and Cheema [*Can. J. Chem. Eng.,* **47,** 226–232 (1969)], the presence of square-wave pulsations can cause a rotameter to overread by as much as 100 percent. The higher the pulsation frequency, the less the float oscillation, although the error can still be appreciable even when the frequency is high enough so that the float is virtually stationary. Use of a damping chamber between the pulsation source and the rotameter will reduce the error.

Additional information on rotameter theory is presented by Fischer [*Chem. Eng.,* **59**(6), 180–184 (1952)], Coleman [*Trans. Inst. Chem. Eng.,* **34,** 339–350 (1956)], and McCabe, Smith, and Harriott (*Unit Operations of Chemical Engineering,* 4th ed., McGraw-Hill, New York, 1985, pp. 202–205).

## TWO-PHASE SYSTEMS

It is generally preferable to meter each of the individual components of a two-phase mixture separately prior to mixing, since it is difficult to meter such mixtures accurately. Problems arise because of fluctuations in composition with time and variations in composition over the cross section of the channel. Information on metering of such mixtures can be obtained from the following sources.

**Gas-Solid Mixtures** Carlson, Frazier, and Engdahl [*Trans. Am. Soc. Mech. Eng.,* **70,** 65–79 (1948)] describe the use of a **flow nozzle** and a **square-edged orifice** in series for the measurement of both the gas rate and the solids rate in the flow of a finely divided solid-in-gas mixture. The nozzle differential is sensitive to the flow of both phases, whereas the orifice differential is not influenced by the solids flow.

Farbar [*Trans. Am. Soc. Mech. Eng.,* **75,** 943–951 (1953)] describes how a **venturi meter** can be used to measure solids flow rate in a gas-solids mixture when the gas rate is held constant. Separate calibration curves (solids flow versus differential) are required for each gas rate of interest.

Cheng, Tung, and Soo [*J. Eng. Power,* **92,** 135–149 (1970)] describe the use of an **electrostatic probe** for measurement of solids flow in a gas-solids mixture.

Goldberg and Boothroyd [*Br. Chem. Eng.,* **14,** 1705–1708 (1969)] describe several types of solids-in-gas flowmeters and give an extensive bibliography.

**Gas-Liquid Mixtures** An empirical equation was developed by Murdock [*J. Basic Eng.,* **84,** 419–433 (1962)] for the measurement of gas-liquid mixtures using **sharp-edged orifice** plates with either radius, flange, or pipe taps.

An equation for use with **venturi meters** was given by Chisholm [*Br. Chem. Eng.,* **12,** 454–457 (1967)]. A procedure for determining steam quality via pressure-drop measurement with upflow through either venturi meters or sharp-edged orifice plates was given by Collins and Gacesa [*J. Basic Eng.,* **93,** 11–21 (1971)].

**Liquid-Solid Mixtures** Liptak [*Chem. Eng.,* **74**(4), 151–158 (1967)] discusses a variety of techniques that can be used for the measurement of solids-in-liquid suspensions or slurries. These include metering pumps, weigh tanks, magnetic flowmeter, ultrasonic flowmeter, gyroscope flowmeter, etc.

Shirato, Gotoh, Osasa, and Usami [*J. Chem. Eng. Japan,* **1,** 164–167 (January 1968)] present a method for determining the mass flow rate of suspended solids in a liquid stream wherein the liquid velocity is measured by an electromagnetic flowmeter and the flow of solids is calculated from the pressure drops across each of two vertical sections of pipe of different diameter through which the suspension flows in series.

## FLOWMETER SELECTION

Web sites for process equipment and instrumentation, such as www.globalspec.com and www.thomasnet.com, are valuable tools when selecting a flowmeter. These search engines can scan the flowmeters manufactured by more than 800 companies for specific products that meet the user's specifications. Table 10-4 was based in part on information from these web sites. Note that the accuracies claimed are achieved only under ideal conditions when the flowmeters are properly installed and calibrated for the application.

The purpose of this subsection is to summarize the preferred applications as well as the advantages and disadvantages of some of the common flowmeter technologies.

Table 10-9 divides flowmeters into four classes. Flowmeters in class I depend on wetted moving parts that can wear, plug, or break. The potential for catastrophic failure is a disadvantage. However, in clean fluids, class I flowmeters have often proved reliable and stable when properly installed, calibrated, and maintained.

**TABLE 10-9 Flowmeter Classes**

| Class I: Flowmeters with wetted moving parts | Class II: Flowmeters with no wetted moving parts |
|---|---|
| Positive displacement<br>Turbine<br>Variable-area | Differential pressure<br>Vortex<br>Target<br>Thermal |
| **Class III: Obstructionless flowmeters** | **Class IV: Flowmeters with sensors mounted external to the pipe** |
| Coriolis mass<br>Electromagnetic<br>Ultrasonic | Clamp-on ultrasonic<br>Correlation |

Adapted from Spitzer, op. cit., 2005.

Class II flowmeters have no wetted moving parts to break and are thus not subject to catastrophic failure. However, the flow surfaces such as orifice plates may wear, eventually biasing flow measurements. Other disadvantages of some flowmeters in this class include high pressure drop and susceptibility to plugging. Very dirty and abrasive fluids should be avoided.

Because class III flowmeters have neither moving parts nor obstructions to flow, they are suitable for dirty and abrasive fluids provided that appropriate materials of construction are available.

Class IV flowmeters have sensors mounted external to the pipe, and would thus seem to be ideal, but problems of accuracy and sensitivity have been encountered in early devices. These comparatively new technologies are under development, and these problems may be overcome in the future.

Section 8 outlines the following criteria for selection of measurement devices: measurement span, performance, reliability, materials of construction, prior use, potential for releasing process materials to the environment, electrical classification, physical access, invasive or noninvasive, and life-cycle cost.

Spitzer, op. cit., 2005, cites four intended end uses of the flowmeter: rate indication, control, totalization, and alarm. Thus high accuracy may be important for rate indication, while control may just need good repeatability. Volumetric flow or mass flow indication is another choice.

Baker, op. cit., 2003, identifies the type of fluid (liquid or gas, slurry, multiphase), special fluid constraints (clean or dirty, hygienic, corrosive, abrasive, high flammability, low lubricity, fluids causing scaling). He lists the following flowmeter constraints: accuracy or measurement uncertainty, diameter range, temperature range, pressure range, viscosity range, flow range, pressure loss caused by the flowmeter, sensitivity to installation, sensitivity to pipework supports, sensitivity to pulsation, whether the flowmeter has a clear bore, whether a clamp-on version is available, response time, and ambient conditions. Finally, Baker identifies these environmental considerations: ambient temperature, humidity, exposure to weather, level of electromagnetic radiation, vibration, tamperproof for domestic use, and classification of area requiring explosionproof, intrinsic safety, etc.

Note that the accuracies cited in Table 10-4 can be achieved by those flowmeters only under ideal conditions of application, installation, and calibration. This subsection has only given an introduction to issues to consider in the choice of a flowmeter for a given application. See Baker, op. cit., 2003; Miller, op. cit., 1996; and Spitzer, op. cit., 2005, for further guidance and to obtain application-specific data from flowmeter vendors.

## WEIRS

Liquid flow in an open channel may be metered by means of a weir, which consists of a dam over which, or through a notch in which, the liquid flows. The terms "rectangular weir," "triangular weir," etc., generally refer to the shape of the notch in a notched weir. All weirs considered here have flat upstream faces that are perpendicular to the bed and walls of the channel.

**Sharp-edged weirs** have edges like those of square or sharp-edged orifices (see subsection "Orifice Meters"). Notched weirs are ordinarily sharp-edged. Weirs not in the sharp-edged class are, for the most part, those described as **broad-crested weirs.**

The head $h_0$ on a weir is the liquid-level height above the crest or base of the notch. The head must be measured sufficiently far upstream to avoid the drop in level occasioned by the overfall which begins at a distance about $2h_0$ upstream from the weir. Surface-level measurements should be made a distance of $3h_0$ or more upstream, preferably by using a stilling box equipped with a high-precision level gauge, e.g., a hook gauge or float gauge.

With sharp-edged weirs, the sheet of discharging liquid, called the "nappe," contracts as it leaves the opening and free discharge occurs. Rounding the upstream edge will reduce the contraction and increase the flow rate for a given head. A clinging nappe may result

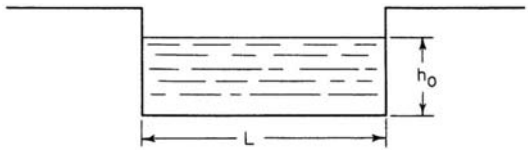

**FIG. 10-21** Rectangular weir.

if the head is very small, if the edge is well rounded, or if air cannot flow in beneath the nappe. This, in turn, results in an increase in the discharge rate for a given head as compared with that for a free nappe. For further information on the effect of the nappe, see Gibson, *Hydraulics and Its Applications*, 5th ed., Constable, London, 1952; and Chow, *Open-Channel Hydraulics*, McGraw-Hill, New York, 1959.

Flow through a **rectangular weir** (Fig. 10-21) is given by

$$q = 0.415(L - 0.2h_0)h_0^{1.5}\sqrt{2g} \tag{10-39}$$

where $q$ = volume flow rate, $L$ = crest length, $h_0$ = weir head, and $g$ = local acceleration due to gravity. This is known as the modified Francis formula for a rectangular sharp-edged weir with two end corrections; it applies when the velocity-of-approach correction is small. The Francis formula agrees with experiments within 3 percent if (1) $L$ is greater than $2h_0$, (2) velocity of approach is 0.6 m/s (2 ft/s) or less, (3) height of crest above bottom of channel is at least $3h_0$, and (4) $h_0$ is not less than 0.09 m (0.3 ft).

**Narrow rectangular notches** ($h_0 > L$) have been found to give about 93 percent of the discharge predicted by the Francis formula. Thus

$$q = 0.386Lh_0^{1.5}\sqrt{2g} \tag{10-40}$$

In this case, no end corrections are applied even though the formula applies only for sharp-edged weirs. See Schoder and Dawson, *Hydraulics*, McGraw-Hill, New York, 1934, p. 175, for further details.

The **triangular-notch weir** has the advantage that a single notch can accommodate a wide range of flow rates, although this in turn reduces its accuracy. The discharge for sharp- or square-edged weirs is given by

$$q = (0.31h_0^{2.5}\sqrt{2g})/\tan\phi \tag{10-41}$$

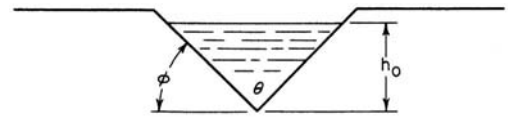

**FIG. 10-22** Triangular weir.

See Eq. (10-39) for nomenclature. Angle $\phi$ is illustrated in Fig. 10-22. Equations (10-39), (10-40), and (10-41) are applicable only to the flow of water. However, for the case of triangular-notch weirs Lenz [*Trans. Am. Soc. Civ. Eng.*, **108,** 759–802 (1943)] has presented correlations predicting the effect of viscosity over the range of 0.001 to 0.15 Pa·s (1 to 150 cP) and surface tension over the range of 0.03 to 0.07 N/m (30 to 70 dyn/cm). His equation predicts about an 8 percent increase in flow for a liquid of 0.1-Pa·s (100-cP) viscosity compared with water at 0.001 Pa·s (1 cP) and about a 1 percent increase for a liquid with one-half of the surface tension of water. For fluids of moderate viscosity, Ranga Raju and Asawa [*Proc. Am. Soc. Civ. Eng., J. Hydraul. Div.*, **103** (HY 10), 1227–1231 (1977)] find that the effect of viscosity and surface tension on the discharge flow rate for rectangular and triangular-notch ($\phi = 45°$) weirs can be neglected when

$$(N_{Re})^{0.2}(N_{We})^{0.6} > 900 \tag{10-42}$$

where $N_{Re}$ (Reynolds number) $= \sqrt{gh_0^3}/\nu$, $g$ = local acceleration due to gravity, $h_0$ = weir head, $\nu$ = kinematic viscosity; $N_{We}$ (Weber number) $= \rho g h_0^2/g_c\sigma$, $\rho$ = density, $g_c$ = dimensional constant, and $\sigma$ = surface tension.

For the flow of high-viscosity liquids over rectangular weirs, see Slocum, *Can. J. Chem. Eng.*, **42,** 196–200 (1964). His correlation is based on data for liquids with viscosities in the range of 2.5 to 500 Pa·s (25 to 5000 cP), in which range the discharge decreases markedly for a given head as viscosity is increased.

Information on other types of weirs can be obtained from Addison, op. cit.; Gibson, *Hydraulics and Its Applications*, 5th ed., Constable, London, 1952; Henderson, *Open Channel Flow*, Macmillan, New York, 1966; Linford, *Flow Measurement and Meters*, Spon, London, 1949; Lakshmana Rao, "Theory of Weirs," in *Advances in Hydroscience*, vol. 10, Academic, New York, 1975; and Merritt, *Standard Handbook for Civil Engineers*, 2d ed., McGraw-Hill, New York, 1976.

# PUMPS AND COMPRESSORS

## INTRODUCTION

The following subsections deal with pumps and compressors. A pump or compressor is a physical contrivance that is used to deliver fluids from one location to another through conduits. The term *pump* is used when the fluid is a liquid, while the term *compressor* is used when the fluid is a gas. The basic requirements to define the application are suction and delivery pressures, pressure loss in transmission, and flow rate. Special requirements may exist in food, pharmaceutical, nuclear, and other industries that impose material selection requirements of the pump.

The primary means of transfer of energy to the fluid that causes flow are gravity, displacement, centrifugal force, electromagnetic force, transfer of momentum, mechanical impulse, and a combination of these energy-transfer mechanisms. Displacement and centrifugal force are the most common energy-transfer mechanisms in use.

Pumps and compressors are designed per technical specifications and standards developed over years of operating and maintenance experience. Table 10-10 lists some of these standards for pumps and compressors and for related equipment such as lubrication systems and gearboxes which, if not properly specified, could lead to many operational and maintenance problems with the pumps and compressors. These standards specify design, construction, maintenance, and testing details such as terminology, material selection, shop inspection and tests, drawings, clearances, construction procedures, and so on.

There are four (4) major types of pumps: (1) positive displacement, (2) dynamic (kinetic), (3) lift, and (4) electromagnetic. Piston pumps are positive displacement pumps. The most common centrifugal

pumps are of dynamic type; ancient bucket-type pumps are lift pumps; and electromagnetic pumps use electromagnetic force and are common in modern reactors. Canned pumps are also becoming popular in the petrochemical industry because of the drive to minimize fugitive emissions. Figure 10-23 shows pump classification:

## TERMINOLOGY

**Displacement** Discharge of a fluid from a vessel by partially or completely displacing its internal volume with a second fluid or by mechanical means is the principle upon which a great many fluid-transport devices operate. Included in this group are reciprocating-piston and diaphragm machines, rotary-vane and gear types, fluid piston compressors, acid eggs, and air lifts.

The large variety of displacement-type fluid-transport devices makes it difficult to list characteristics common to each. However, for most types it is correct to state that (1) they are adaptable to high-pressure operation, (2) the flow rate through the pump is variable (auxiliary damping systems may be employed to reduce the magnitude of pressure pulsation and flow variation), (3) mechanical considerations limit maximum throughputs, and (4) the devices are capable of efficient performance at extremely low-volume throughput rates.

**Centrifugal Force** Centrifugal force is applied by means of the centrifugal pump or compressor. Though the physical appearance of the many types of centrifugal pumps and compressors varies greatly, the basic function of each is the same, i.e., to produce kinetic energy by the action of centrifugal force and then to convert this energy into pressure by efficiently reducing the velocity of the flowing fluid.

In general, centrifugal fluid-transport devices have these characteristics: (1) discharge is relatively free of pulsation; (2) mechanical design lends itself to high throughputs, capacity limitations are rarely a problem; (3) the devices are capable of efficient performance over a wide range of pressures and capacities even at constant-speed operation; (4) discharge pressure is a function of fluid density; and (5) these are relatively small high-speed devices and less costly.

A device which combines the use of centrifugal force with mechanical impulse to produce an increase in pressure is the axial-flow compressor or pump. In this device the fluid travels roughly parallel to the shaft through a series of alternately rotating and stationary radial blades having airfoil cross sections. The fluid is accelerated in the axial direction by mechanical impulses from the rotating blades; concurrently, a positive-pressure gradient in the radial direction is established in each stage by centrifugal force. The net pressure rise per stage results from both effects.

**Electromagnetic Force** When the fluid is an electrical conductor, as is the case with molten metals, it is possible to impress an electromagnetic field around the fluid conduit in such a way that a driving force that will cause flow is created. Such pumps have been developed for the handling of heat-transfer liquids, especially for nuclear reactors.

**Transfer of Momentum** Deceleration of one fluid (motivating fluid) in order to transfer its momentum to a second fluid (pumped fluid) is a principle commonly used in the handling of corrosive materials, in pumping from inaccessible depths, or for evacuation. Jets and eductors are in this category.

Absence of moving parts and simplicity of construction have frequently justified the use of jets and eductors. However, they are relatively inefficient devices. When air or steam is the motivating fluid, operating costs may be several times the cost of alternative types of fluid-transport equipment. In addition, environmental considerations in today's chemical plants often inhibit their use.

**Mechanical Impulse** The principle of mechanical impulse when applied to fluids is usually combined with one of the other means of imparting motion. As mentioned earlier, this is the case in axial-flow compressors and pumps. The turbine or regenerative-type pump is another device which functions partially by mechanical impulse.

**Measurement of Performance** The amount of useful work that any fluid-transport device performs is the product of (1) the mass rate of fluid flow through it and (2) the total pressure differential measured immediately before and after the device, usually expressed in the height of column of fluid equivalent under adiabatic conditions. The first of these quantities is normally referred to as **capacity,** and the second is known as **head.**

**Capacity** This quantity is expressed in the following units. In SI units capacity is expressed in cubic meters per hour ($m^3/h$) for both liquids and gases. In U.S. customary units it is expressed in U.S. gallons per minute (gal/min) for liquids and in cubic feet per minute ($ft^3/min$) for gases. Since all these are volume units, the density or specific gravity must be used for conversion to mass rate of flow. When gases are being handled, capacity must be related to a pressure and a temperature, usually the conditions prevailing at the machine inlet. It is important to note that all heads and other terms in the following equations are expressed in height of column of liquid.

**Total Dynamic Head** The total dynamic head $H$ of a pump is the total discharge head $h_d$ minus the total suction head $h_s$.

**Total Suction Head** This is the reading $h_{gs}$ of a gauge at the suction flange of a pump (corrected to the pump centerline*), plus the barometer reading and the velocity head $h_{vs}$ at the point of gauge attachment:

$$h_s = h_{gs} + \text{atm} + h_{vs} \tag{10-43}$$

If the gauge pressure at the suction flange is less than atmospheric, requiring use of a vacuum gauge, this reading is used for $h_{gs}$ in Eq. (10-43) with a negative sign.

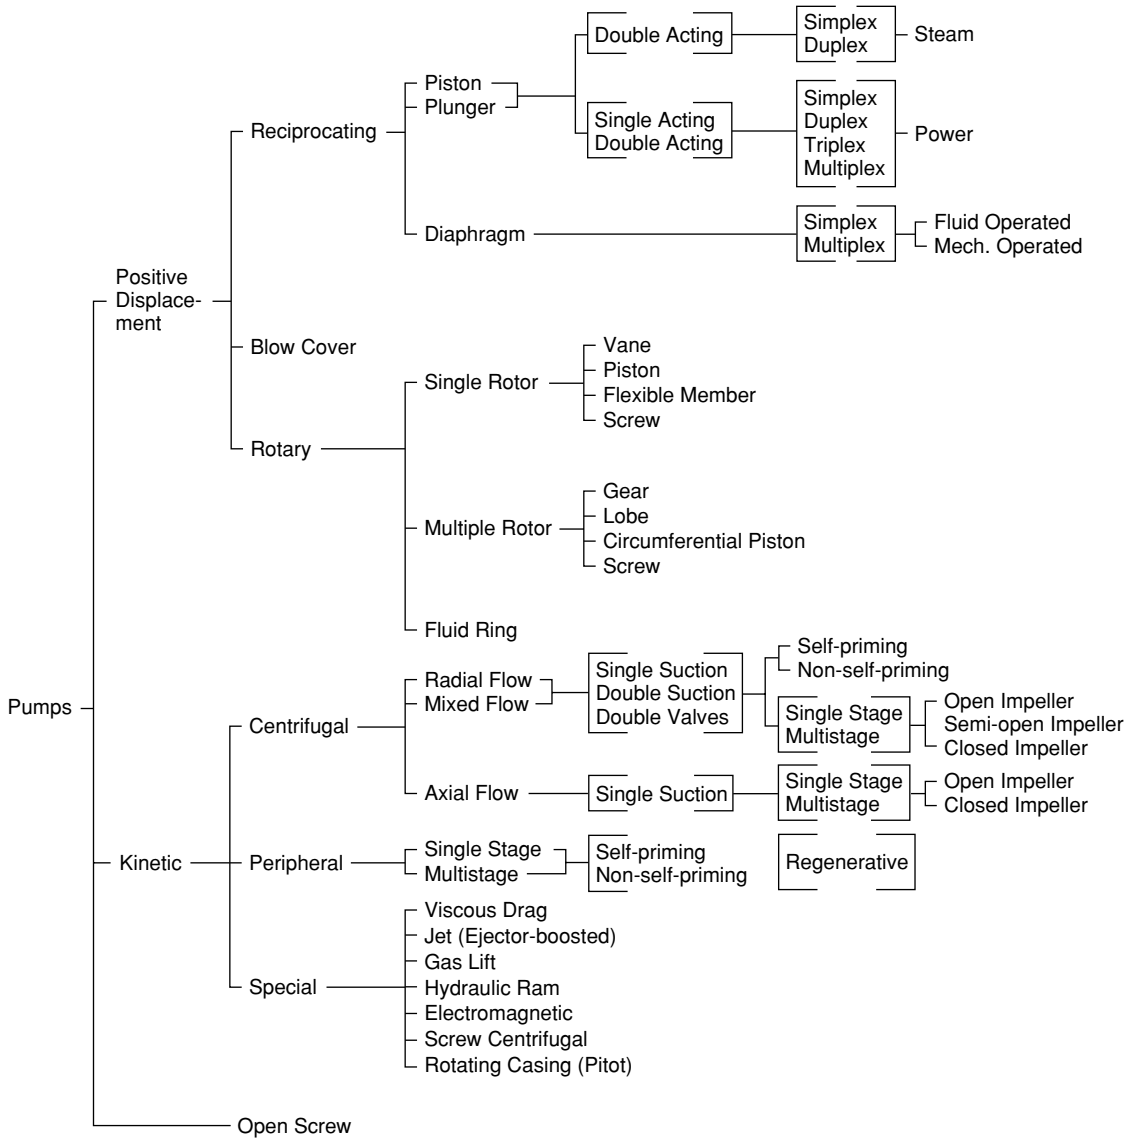

**FIG. 10-23** Classification of pumps. (*Courtesty of Hydraulic Institute.*)

Before installation it is possible to estimate the total suction head as follows:

$$h_s = h_{ss} - h_{fs} \tag{10-44}$$

where $h_{ss}$ = static suction head and $h_{fs}$ = suction friction head.

**Static Suction Head** The static suction head $h_{ss}$ is the vertical distance measured from the free surface of the liquid source to the pump centerline plus the absolute pressure at the liquid surface.

**Total Discharge Head** The total discharge head $h_d$ is the reading $h_{gd}$ of a gauge at the discharge flange of a pump (corrected to the pump centerline*), plus the barometer reading and the velocity head $h_{vd}$ at the point of gauge attachment:

$$h_d = h_{gd} + \text{atm} + h_{vd} \tag{10-45}$$

Again, if the discharge gauge pressure is below atmospheric, the vacuum-gauge reading is used for $h_{gd}$ in Eq. (10-45) with a negative sign.

Before installation it is possible to estimate the total discharge head from the static discharge head $h_{sd}$ and the discharge friction head $h_{fd}$ as follows:

$$h_d = h_{sd} + h_{fd} \tag{10-46}$$

**Static Discharge Head** The static discharge head $h_{sd}$ is the vertical distance measured from the free surface of the liquid in the receiver to the pump centerline,* plus the absolute pressure at the liquid surface. **Total static head** $h_{ts}$ is the difference between discharge and suction static heads.

*On vertical pumps, the correction should be made to the eye of the suction impeller.

**Velocity** Since most liquids are practically incompressible, the relation between the quantity flowing past a given point in a given time and the velocity of flow is expressed as follows:

$$Q = Av \tag{10-47}$$

This relationship in SI units is as follows:

$$v \text{ (for circular conduits)} = 3.54\ Q/d^2 \tag{10-48}$$

where $v$ = average velocity of flow, m/s; $Q$ = quantity of flow, $m^3/h$; and $d$ = inside diameter of conduit, cm.

This same relationship in U.S. customary units is

$$v \text{ (for circular conduits)} = 0.409\ Q/d^2 \tag{10-49}$$

where $v$ = average velocity of flow, ft/s; $Q$ = quantity of flow, gal/min; and $d$ = inside diameter of conduit, in.

**Velocity Head** This is the vertical distance by which a body must fall to acquire the velocity $v$.

$$h_v = v^2/2g \tag{10-50}$$

**Viscosity** (See Sec. 6 for further information.) In flowing liquids the existence of internal friction or the internal resistance to relative motion of the fluid particles must be considered. This resistance is called viscosity. The viscosity of liquids usually decreases with rising temperature. Viscous liquids tend to increase the power required by a pump, to reduce pump efficiency, head, and capacity, and to increase friction in pipe lines.

**Friction Head** This is the pressure required to overcome the resistance to flow in pipe and fittings. It is dealt with in detail in Sec. 6.

**Work Performed in Pumping** To cause liquid to flow, work must be expended. A pump may raise the liquid to a higher elevation, force it into a vessel at higher pressure, provide the head to overcome pipe friction, or perform any combination of these. Regardless of the service required of a pump, all energy imparted to the liquid in performing this service must be accounted for; consistent units for all quantities must be employed in arriving at the work or power performed.

When arriving at the performance of a pump, it is customary to calculate its **power output,** which is the product of (1) the total dynamic head and (2) the mass of liquid pumped in a given time. In SI units power is expressed in kilowatts; horsepower is the conventional unit used in the United States.

In SI units,

$$\text{kW} = HQ\rho/3.670 \times 10^5 \tag{10-51}$$

where kW is the pump power output, kW; $H$ = total dynamic head, N·m/kg (column of liquid); $Q$ = capacity, $m^3/h$; and $\rho$ = liquid density, $kg/m^3$.

When the total dynamic head $H$ is expressed in pascals, then

$$\text{kW} = HQ/3.599 \times 10^6 \tag{10-52}$$

In U.S. customary units,

$$\text{hp} = HQs/3.960 \times 10^3 \tag{10-53}$$

where hp is the pump-power output, hp; $H$ = total dynamic head, lbf·ft/lbm (column of liquid); $Q$ = capacity, U.S. gal/min; and $s$ = liquid specific gravity.

When the total dynamic head $H$ is expressed in pounds-force per square inch, then

$$\text{hp} = HQ/1.714 \times 10^3 \tag{10-54}$$

The **power input** to a pump is greater than the **power output** because of internal losses resulting from friction, leakage, etc. The efficiency of a pump is therefore defined as

$$\text{Pump efficiency} = (\text{power output})/(\text{power input}) \tag{10-55}$$

## PUMP SELECTION

When selecting pumps for any service, it is necessary to know the liquid to be handled, the total dynamic head, the suction and discharge heads, and, in most cases, the temperature, viscosity, vapor pressure, and specific gravity. In the chemical industry, the task of pump selection is frequently further complicated by the presence of solids in the liquid and liquid corrosion characteristics requiring special materials of construction. Solids may accelerate erosion and corrosion, have a tendency to agglomerate, or require delicate handling to prevent undesirable degradation.

**Range of Operation** Because of the wide variety of pump types and the number of factors which determine the selection of any one type for a specific installation, the designer must first eliminate all but those types of reasonable possibility. Since range of operation is always an important consideration, Fig. 10-24 should be of assistance. The boundaries shown for each pump type are at best approximate. In most cases, following Fig. 10-24 will select the pump that is best suited for a given application. Low-capacity pumps with high discharge head requirements are best served by positive-displacement pumps. Reciprocating pumps and rotary pumps such as gear and roots rotor-type pumps are examples of positive-displacement pumps. Displacement pumps provide high heads at low capacities which are beyond the capability of centrifugal pumps. Displacement pumps achieve high pressure with low velocities and are thus suited for high-viscosity service and slurry.

The centrifugal pump operates over a very wide range of flows and pressures. For low heads but high flows the axial pump is best suited. Both the centrifugal and axial flow pumps impart energy to the fluid by the rotational speed of the impeller and the velocity it imparts to the fluid.

## NET POSITIVE SUCTION HEAD

Net positive suction head available $(NPSH)_A$ is the difference between the total absolute suction pressure at the pump suction nozzle when the pump is running and the vapor pressure at the flowing liquid temperature. All pumps require the system to provide adequate $(NPSH)_A$. In a positive-displacement pump the $(NPSH)_A$ should be large enough to open the suction valve, to overcome the friction losses within the pump liquid end, and to overcome the liquid acceleration head.

**Suction Limitations of a Pump** Whenever the pressure in a liquid drops below the vapor pressure corresponding to its temperature, the liquid will vaporize. When this happens within an operating pump, the vapor bubbles will be carried along to a point of higher pressure, where they suddenly collapse. This phenomenon is known as **cavitation.** Cavitation in a pump should be avoided, as it is accompanied by metal removal, vibration, reduced flow, loss in efficiency, and noise. When the absolute suction pressure is low, cavitation may occur in the pump inlet and damage result in the pump suction and on the impeller vanes near the inlet edges. To avoid this phenomenon, it is necessary to maintain a **required net positive suction head**

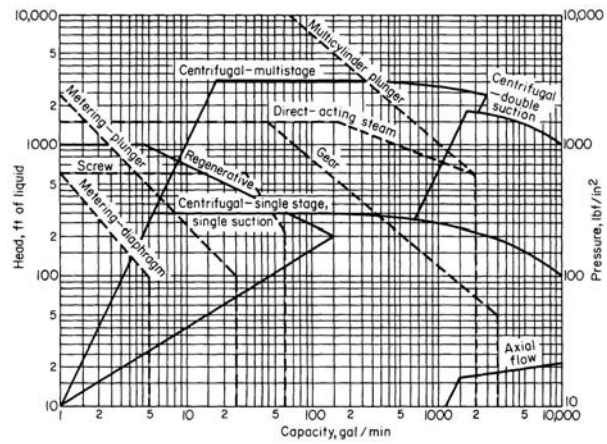

**FIG. 10-24** Pump coverage chart based on normal ranges of operation of commercially available types. Solid lines: use left ordinate, head scale. Broken lines: use right ordinate, pressure scale. To convert gallons per minute to cubic meters per hour, multiply by 0.2271; to convert feet to meters, multiply by 0.3048; and to convert pounds-force per square inch to kilopascals, multiply by 6.895.
