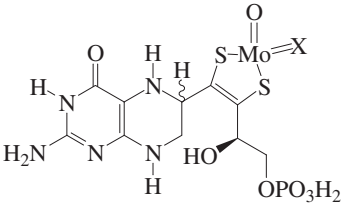
Molybdenum cofactor M-681

Molybdoenzyme molybdenum cofactor, 9CI. Molybdopterin. MOCO



Molybdenum cofactor can be released from molybdoenzymes by treatment with denaturing reagents. Catalyses oxidative hydroxylation or reductive dehydroxylation at C,N, or S atoms. During these redox reactions Mo undergoes changes between oxidn. states of Mo^{VI} and Mo^{IV}, possibly linked to changes in the pyrazine ring oxidn. level. Molybdenum cofactor functions as a prosthetic metal in the 12 or so Mo-containing enzymes discovered, except nitrogenase which has its own FebMo cofactor. Air-sensitive ($t_{½}$ 15 min, 3.5°). Oxidative degradation involves labilisation of the metal and oxidn. of the reduced pterin. Stable under anaerobic conditions in presence of stabilising agents, e.g. sodium dithionite, or in DMSO (activity loss 3%/24 h at 20-25°).

Dioxomolybdate-*form* [104676-61-1]
[73508-07-3]

X = O. Isol. from purified milk xanthine oxidase. Molybdenum cofactor functions as a prosthetic metal in the 12 or so Mo-containing enzymes discovered, except nitrogenase which has its own FebMo cofactor.
Stable at pH 5.9 under anaerobic conditions.
