DEDICATION

The past years have seen the loss of two staunch champions for the both of us — the late Athel L.J. Beckwith FAA, FRS from the Research School of Chemistry, ANU (scientist extraordinaire, mentor and friend) as well as Mrs Joan E. Smith, Research School of Chemistry ANU (a dedicated and amazing librarian, and a strong supporter of this book and its previous editions. In her eyes, we could do no wrong). The world is a little less bright in their absence. We dedicate this book to their memories.

Preface to the Seventh Edition

THE SALES of the sixth edition, which appeared in April 2009, were high by about October 2009, and one of us (WLFA) was approached by Ms Melanie Benson, Editorial Project Manager of Elsevier Science & Technology Books (who was mainly responsible for the production of the 6th edition), about writing a 7th edition within 2–3 years. In the past, 6–9 years were allowed to lapse between editions. However, the attraction this time, was that we were allowed to increase the size of the work by up to 249 pages. This has given us the opportunity to update all the previous chapters in the light of current thinking on safety (personal and environmental), and to introduce two new chapters. The award of five Nobel Prizes in the past ten years or so in Chemistry and one in Physics, of which three were awarded for work on *Catalysis* and *the catalytic process* (2001, 2005 and 2010), and two for work on *Nanomaterials and Nanotechnology* (1996, 2010) have prompted us to write a new chapter on *Catalysts* and a new chapter on *Nanomaterials and Nanotechnology*. Chemical suppliers have now made commercially available a large number of catalysts as well as many nanomaterials of various sorts. Since the number of commercially available catalysts are currently considerably larger than that of nanomaterials, the chapter on Catalysts is larger than that on Nanomaterials and Nanotechnology, and had to be divided into two parts. The availability, preparation and purification of a large range of these, are presented in these chapters. The other chapters have been updated and expanded, also in keeping with the purpose of all previous editions which is to provide information for the purification of commercially available laboratory materials. Of course, the General Subjects Index and the Chemical Abstracts Registry Numbers (CASRNs) Index increased in size accordingly. Much of the cross-referencing is done *via* CASRNs and a page of how to use this book through these is included before Chapter 1 to assist the reader, not only to locate the pages where the required CASRNs are to be found, but also to let the reader know whether a particular substance is included in this work. CASRNs can be readily obtained from chemical catalogues or from SciFinder.

We would like to acknowledge Professor Martin Banwell FAA (Director, Research School of Chemistry, ANU) for his generosity in allowing the use of IT services, and to Dr Emil Mittag (Research School of Chemistry, ANU) for editing and updating the *Macro* program used for making the CASRNs Index.

We are greatly indebted to many people who have made valuable and constructive comments, and indicated errors, in previous editions. The continued help from Joe Papa of BS MS (EXAXOL in Clearwater, Florida, USA) with the preparation and purification of several inorganic compounds, particularly beryllium and cerium, is appreciated and gratefully acknowledged.

One of us (W.L.F.A) owes a debt of gratitude to Professor Jill E. Gready (John Curtin School of Medical Research, ANU) for her continued encouragement and for strongly supporting a Visiting Fellowship over a period of many years.

We thank Dr Pauline M. Armarego for assistance in the painstaking task of proofreading and correcting typographical errors as well as checking the General Index and the CASRNs Index.

We thank the ANU library and its staff, both on campus and at the ANU Print Repository, for their prompt and unfailing assistance.

W.L.F. Armarego & C.L.L. Chai

May 2012

Preface to the First Edition

WE BELIEVE that a need exists for a book to help the chemist or biochemist who wishes to purify the reagents she or he uses. This need is emphasised by the previous lack of any satisfactory central source of references dealing with individual substances. Such a lack must undoubtedly have been a great deterrent to many busy research workers who have been left to decide whether to purify at all, to improvise possible methods, or to take a chance on finding, somewhere in the chemical literature, methods used by some previous investigators.

Although commercially available laboratory chemicals are usually satisfactory, as supplied, for most purposes in scientific and technological work, it is also true that for many applications further purification is essential.

With this thought in mind, the present volume sets out, first, to tabulate methods, taken from the literature, for purifying some thousands of individual commercially available chemicals. To help in applying this information, two chapters describe the more common processes currently used for purification in chemical laboratories and give fuller details of new methods which appear likely to find increasing application for the same purpose. Finally, for dealing with substances not separately listed, a chapter is included setting out the usual methods for purifying specific classes of compounds.

To keep this book to a convenient size, and bearing in mind that its most likely users will be laboratory-trained, we have omitted manipulative details with which they can be assumed to be familiar, and also detailed theoretical discussion. Both are readily available elsewhere, for example in Vogel's very useful book **Practical Organic Chemistry** (Longmans, London, 3rd ed., 1956), or Fieser's **Experiments in Organic Chemistry** (Heath, Boston, 3rd ed., 1957).

For the same reason, only limited mention is made of the kinds of impurities likely to be present, and of the tests for detecting them. In many cases, this information can be obtained readily from existing monographs.

By its nature, the present treatment is not exhaustive, nor do we claim that any of the methods taken from the literature are the best possible. Nevertheless, we feel that the information contained in this book is likely to be helpful to a wide range of laboratory workers, including physical and inorganic chemists, research students, biochemists, and biologists. We hope that it will also be of use, although perhaps to only a limited extent, to experienced organic chemists.

We are grateful to Professor A. Albert and Dr D.J. Brown for helpful comments on the manuscript.

D.D.P., W.L.F.A. & D.R.P.
1966

Preface to the Second Edition

SINCE the publication of the first edition of this book, there have been major advances in purification procedures. Sensitive methods have been developed for the detection and elimination of progressively lower levels of impurities. Increasingly stringent requirements for reagent purity have gone hand-in-hand with developments in semiconductor technology, in the preparation of special alloys and in the isolation of highly biologically active substances. The need to eliminate trace impurities at the micro- and nanogram levels has placed greater emphasis on ultrapurification technique. To meet these demands the range of purities of laboratory chemicals has become correspondingly extended. Purification of individual chemicals thus depends more and more critically on the answers to two questions-Purification from what, and to what permissible level of contamination. Where these questions can be specifically answered, suitable methods of purification can usually be devised.

Several periodicals devoted to ultrapurification and separations have been started. These include "Progress in Separation and Purification" (vol. 1) Ed. E.S. Perry, Wiley-Interscience, New York, vols. 1-4, 1968-1971, and **Separation and Purification Methods**, Ed. E.S.Perry and C.J.van Oss, Marcel Dekker, New York, vol. 1, 1973. Nevertheless, there still remains a broad area in which a general improvement in the level of purity of many compounds can be achieved by applying more or less conventional procedures. The need for a convenient source of information on methods of purifying available laboratory chemicals was indicated by the continuing demand for copies of this book even though it had been out of print for several years.

We have sought to revise and update this volume, deleting sections that have become more familiar or less important, and incorporating more topical material. The number of compounds in Chapters 3 and 4 have been increased appreciably. Also, further details in purification and physical constants are given for many compounds that were listed in the first edition.
We take this opportunity to thank users of the first edition who pointed out errors and omissions, or otherwise suggested improvements or additional material that should be included. We are indebted to Mrs S.Schenk who emerged from retirement to type this manuscript.

1980

Preface to the Third Edition

THE CONTINUING demand for this monograph and the publisher's request that we prepare a new edition are an indication that **Purification of Laboratory Chemicals** fills a gap in many chemists' reference libraries and laboratory shelves. The present volume is an updated edition that contains significantly more detail than the previous editions, as well as an increase in the number of individual entries and a new chapter.

Additions have been made to Chapters 1 and 2 in order to include more recent developments in techniques (e.g. Schlenk-type, *cf* p. 10), and chromatographic methods and materials. Chapter 3 still remains the core of the book, and lists in alphabetical order relevant information on *ca* 4000 organic compounds. Chapter 4 gives a smaller listing of *ca* 750 inorganic and metal-organic substances, and makes a total increase of ca 13% of individual entries in these two chapters. Some additions have also been made to Chapter 5.
We are currently witnessing a major development in the use of physical methods for purifying large molecules and macromolecules, especially of biological origin. Considerable developments in molecular biology are apparent in techniques for the isolation and purification of key biochemicals and substances of high molecular weight. In many cases something approaching homogeneity has been achieved, as evidenced by electrophoresis, immunological and other independent criteria. We have consequently included a new section, Chapter 6, where we list upwards of 100 biological substances to illustrate their current methods of purification. In this chapter the details have been kept to a minimum, but the relevant references have been included.

The lists of individual entries in Chapters 3 and 4 range in length from single-line entries to *ca* one page or more for solvents such as acetonitrile, benzene, ethanol and methanol. Some entries include information such as likely contaminants and storage conditions. More data referring to physical properties have been inserted for most entries [i.e. melting and boiling points, refractive indexes, densities, specific optical rotations (where applicable) and UV absorption data]. Inclusion of molecular weights should be useful when deciding on the quantities of reagents needed to carry out relevant synthetic reactions, or preparing analytical solutions. The Chemical Abstracts registry numbers have also been inserted for almost all entries and should assist in the precise identification of the substances.

In the past ten years laboratory workers have become increasingly conscious of safety in the laboratory environment. We have therefore in three places in Chapter 1 (pp. 3 and 33, and bibliography p. 52) stressed more strongly the importance of safety in the laboratory. Also, where possible, in Chapters 3 and 4 we draw attention to the dangers involved with the manipulation of some hazardous substances.

The worldwide facilities for retrieving chemical information provided by the Chemical Abstract Service (CAS on-line) have made it a relatively easy matter to obtain CAS registry numbers of substances, and most of the numbers in this monograph were obtained *via* CAS on-line. We should point out that two other available useful files are CSCHEM and CSCORP, which provide, respectively, information on chemicals (and chemical products) and addresses and telephone numbers of the main branch offices of chemical suppliers.

The present edition has been produced on an IBM PC and a Laser Jet printer using the **Microsoft Word (4.0)** word-processing program with a set stylesheet. This has allowed the use of a variety of fonts and font sizes which has made the presentation more attractive than in the previous edition. Also, by altering the format and increasing slightly the sizes of the pages, the length of the monograph has been reduced from 568 to 391 pages. The reduction in the number of pages has been achieved in spite of the increase of *ca* 15% of total text.

We extend our gratitude to the readers whose suggestions have helped to improve the monograph, and to those who have told us of their experiences with some of the purifications stated in the previous editions, and in particular with the hazards that they have encountered. We are deeply indebted to Dr M.D. Fenn for the several hours that he has spent on the terminal to provide us with a large number of CAS registry numbers.

This monograph could not have been produced without the expert assistance of Mr David Clarke who has spent many hours loading the necessary fonts in the computer, and for advising one of the authors (W.L.F.A.) on how to use them together with the idiosyncrasies of Microsoft Word.

D.D.P. & W.L.F.A.
1988

Preface to the Fourth Edition

THE AIMS of the first three editions, to provide purification procedures of commercially available chemicals and biochemicals from published literature data, are continued in this fourth edition. Since the third edition in 1988 the number of new chemicals and biochemicals that have been added to most chemical and biochemical catalogues have increased enormously. Accordingly there is a need to increase the number of entries with more recent useful reagents and chemical and biochemical intermediates. With this in mind, together with the need to reorganise and update general purification procedures, particularly in the area of biological macromolecules, as well as the time lapse since the previous publication, this fourth edition of **Purification of Laboratory Chemicals** has been produced. Chapter 1 has been reorganised with some updating, and by using a smaller font it was kept to a reasonable number of pages. Chapters 2 and 5 were similarly altered and have been combined into one chapter. Eight hundred and three hundred and fifty entries have been added to Chapters 3 (25% increase) and 4 (44% increase), respectively, and four hundred entries (310% increase) were added to Chapter 5 (Chapter 6 in the Third Edition), making a total of 5700 entries-all resulting in an increase from 391 to 529 pages, i.e., by *ca* 35%.

Many references to the original literature have been included remembering that some of the best references happened to be in the older literature. Every effort has been made to provide the best references, but this may not have been achieved in all cases. Standard abbreviations, listed on page 1, have been used throughout this edition to optimise space, except where no space advantage was achieved, in which cases the complete words have been written down to improve the flow of the sentences.

With the increasing facilities for information exchange, chemical, biochemical and equipment suppliers are making their catalogue information available on the Internet; e.g., Aldrich-Fluka-Sigma catalogue information is available on the World Wide Web by using the address http://www.sigma.sial.com and GIBCO BRL catalogue information from http://www.lifetech.com as well as on CD-ROMS which are regularly

updated. Facility for enquiring about, ordering and paying for items is available *via* the Internet. CAS on-line can be accessed on the Internet, and CAS data is available now on CD-ROM. Also biosafety bill boards can similarly be obtained by sending SUBSCRIBE SAFETY John Doe at the address "listserv@uvmvm.uvm.edu", SUBSCRIBE BIOSAFETY at the address "listserv@mitvma.mit.edu", and SUBSCRIBE RADSAF at the address "listserv@romulus.ehs.uiuc.edu"; and the Occupational, Health and Safety information (Australia) is available at the address "http://www. safework.gov.au/". Sigma-Aldrich provided Material Safety data sheets on CD-ROMs.

It is with much sadness that Dr Douglas D. Perrin was unable to participate in the preparation of the present edition due to illness. His contributions towards the previous editions have been substantial, and his drive and tenacity have been greatly missed.

The Third Edition was prepared on an IBM-PC, and the previous IBM files were converted into Macintosh files. These have now been reformatted on a Macintosh LC575 computer, and all further data to complete the Fourth Edition were added to these files. The text was printed with a Hewlett-Packard 4MV -600dpi Laser Jet printer, which gives a clearer resolution.

I thank my wife Dr Pauline M. Armarego, also an organic chemist, for the arduous and painstaking task of entering the new data into the respective files, and for the numerous hours of proofreading as well as the corrections of typographic errors in the files. I should be grateful to my readers for any comments, suggestions, amendments and criticisms which could, perhaps, be inserted in the second printing of this edition.

W.L.F. Armarego, 30 June 1996

Preface to the Fifth Edition

THE DEMAND for **Purification of Laboratory Chemicals** has not abated since the publication of the fourth edition as evidenced by the number of printings and the sales. The request by the Editor for a fifth edition offered an opportunity to increase the usefulness of this book for laboratory purposes. It is with deep regret that mention should be made that Dr Douglas D. Perrin had passed away soon after the fourth edition was published. His input in the first three editions was considerable, and his presence has been greatly missed. A fresh, new and young outlook was required in order to increase the utility of this book, and it is with great pleasure that Dr Christina L.L. Chai, a Reader in Chemistry and leader of a research group in organic and bio-organic chemistry, has agreed to coauthor this edition. The new features of the fifth edition have been detailed below.

Chapters 1 and 2 have been reorganised and updated in line with recent developments. A new chapter on the Future of Purification has been added. It outlines developments in syntheses on solid supports, combinatorial chemistry as well as the use of ionic liquids for chemical reactions and reactions in fluorous media. These technologies are becoming increasingly useful and popular, so much so that many future commercially available substances will most probably be prepared using these procedures. Consequently, knowledge of their basic principles will be helpful in many purification methods of the future.

Chapters 4, 5 and 6 (3, 4 and 5 in the 4th ed.) form the bulk of the book. The number of entries has been increased to include the purification of many recent commercially available reagents that have become more and more popular in the syntheses of organic, inorganic and bio-organic compounds. Several purification procedures for commonly used liquids, e.g., solvents, had been entered with excessive thoroughness, but in many cases the laboratory worker only requires a simple, rapid but effective purification procedure for immediate use. In such cases a **rapid purification** procedure has been inserted at the end of the respective entry, and should be satisfactory for most purposes. With the increased use of solid phase synthesis, even for small molecules, and the use of reagents on solid support (e.g., on polystyrene) for reactions in liquid media, compounds on solid support have become increasingly commercially available. These have been inserted at the end of the respective entry and have been listed in the General Index together with the above rapid purification entries.

A large number of substances are ionisable in aqueous solutions, and knowledge of their ionisation constants, stated as pK (pKa) values, can be of importance not only in their purification but also in their reactivity. Literature values of the pK's have been inserted for ionisable substances, and where values could not be found they were estimated (pK_{Est}). The estimates are usually so close to the true values as not to affect the purification process or the reactivity seriously. The book will thus be a good compilation of pK values for ionisable substances.

Almost all the entries in Chapters 4, 5 and 6 have CAS (Chemical Abstract Service) Registry Numbers to identify them, and these have been entered for each substance. Unlike chemical names which may have more than one synonymous name, there is only one CAS Registry Number for each substance (with only a few exceptions, e.g., where a substance may have another number before purification, or before determination of absolute configuration). To simplify the method for locating the purification of a substance, a CAS Registry Number Index with the respective page numbers has been included after the General Index at the end of the book. This will also provide the reader with a rapid way to see if the purification of a particular substance has been reported in the book. The brief General Index includes page references to procedures and equipment, page references to abbreviations of compounds, e.g., TRIS, as well as the names of substances for which a Registry Number was not found.

Website references for distributors of substances or/and of equipment have been included in the text. However, since these may be changed in the future we must rely on the suppliers to inform users of their change in website references.

We wish to thank readers who have provided advice, constructive criticism and new information for inclusion in this book. We should be grateful to our readers for any further comments, suggestions, amendments and criticisms which could, perhaps, be inserted in a second printing of this edition. In particular, we thank Professor Ken-chi Sugiura (Graduate School of Science, Tokyo Metropolitan University, Japan) who has

provided us with information on the purification of several organic compounds from his own experiences, and Joe Papa BS MS (EXAXOL in Clearwater, Florida, USA) who has provided us not only with his experiences in the purification of many inorganic substances in this book, but also gave us his analytical results on the amounts of other metal impurities at various stages of purification of several salts. We thank them graciously for permission to include their reports in this work. We express our gratitude to Dr William B. Cowden for his generous advice on computer hardware and software over many years and for providing an Apple LaserWriter (16/600PS) which we used to produce the master copy of this book. We also extend our sincere thanks to Dr Bart Eschler for advice on computer hardware and software and for assistance in setting up the computers (iMac and eMac) used to produce this book.

We thank Dr Pauline M. Armarego for assistance in the painstaking task of entering data into respective files, for many hours of proofreading, correcting typographical errors and checking CAS Registry Numbers against their respective entries.

One of us (W.L.F.A) owes a debt of gratitude to Dr Desmond (Des) J. Brown of the Research School of Chemistry, ANU, for unfailing support and advice over several decades and for providing data that was difficult to acquire not only for this edition but also for the previous four editions of this book.

One of us (C.L.L.C) would especially like to thank her many research students (past and present) for their unwavering support, friendship and loyalty, which enabled her to achieve what she now has. She wishes also to thank her family for their love, and would particularly like to dedicate her contribution towards this book to the memory of her brother Andrew who had said that he should have been a scientist.

We thank Mrs. Joan Smith, librarian of the Research School of Chemistry, ANU, for her generous help in many library matters, which has made the tedious task of checking references more enduring.

W.L.F. Armarego & C.L.L. Chai
November 2002

Preface to the Sixth Edition

THERE IS a continuing demand for the **Purification of Laboratory Chemicals** book, to the extent that the 5th edition which was published in early 2003 was carefully translated into Chinese (ISBN 978-7-5025-94367) by Ying-Jie Lin, Wei Liu, Hui-Ping Wang, Xiao-Bo Sun, Qing-Shan Li and Jun-Gang Cao from Jilin University (People's Republic of China) in 2007. In response to the demand, it was timely to update the 5th edition to include the more recently developed purification procedures, as well as add to the list of compounds for purification. The latter comprise some commercially available compounds that have gained usefulness and popularity in the past few years.

The first two chapters have been updated, sections of current interest have been expanded and new sections added. Chapter 3 has been rewritten so that areas of work that have lost popularity have been reduced in size or deleted and sections on recent, and now commonly adopted, technologies have been inserted. Chapters 4, 5 and 6 are now completely reorganized, and each is subdivided into several sections which will make it easier for the reader to locate compounds of similar classification. Chapter 4 is subdivided into aliphatic, alicyclic, aromatic and heterocyclic compounds, Chapter 5 has been subdivided into inorganic and metal-organic compounds, and Chapter 6 has been subdivided into amino acids and peptides, proteins, enzymes, DNA and RNA, carotenoids, carbohydrates, steroids and a miscellaneous section which includes small biologically active substances such as antibiotics, coenzymes, co-factors, lipids, phospholipids, polynucleotides and vitamins. Some useful compounds that have been added recently to commercial catalogues have been included in these three chapters. A large number of derivatives of previous entries with their physical properties and purifications have been inserted together with extensive referencing to the original literature including *Beilstein* references. This resulted in an increase in size of the 5th edition, in text and number of compounds, by over 20%. The purifications of some 7400 substances are described. As in the 5th edition, substance entries are in alphabetical order within subsections and each substance is defined by its Chemical Abstracts Service (CAS) Registry Number. An index of these numbers with their respective page numbers at the end of the book will make it possible to locate the purification of a desired substance readily and to check if the substance is contained in the book. For this purpose we thank Rodney Armarego for setting up a *Macro* on the MacBook Pro computer used for collating the CAS Registry Numbers for the index. There is also a General Index of Contents.

Website references of distributors of substances and/or of equipment have been included in the text. However, since these may change in the future, users should check for current websites of suppliers. The bibliographies have been updated, and websites of a few publishers and book suppliers have been included. Several texts with publication dates older than fifteen years have been deleted except for a few very useful textbooks which are out of print and where recent editions have not been produced. In these cases it is usually possible to obtain used copies from good suppliers of old books, for which there are several websites, e.g. visit Google under "old books suppliers"; also visit websites such as <http//www.abebooks.com>, <http//www.betterworld.com/usedbooks>, <http//www.booksandcollectibles.com.au/index>, <http//www.ebay.com.au/>. Further information for almost every entry in Chapters 4, 5 and 6 of the 6th edition can be obtained from the references to the original literature, which are cited under each entry together with their respective *Beilstein* reference(s).

We thank readers who have provided advice, constructive criticism and new information. We are grateful for any further comments, suggestions, amendments and criticisms which could, perhaps, be inserted in a second printing of this edition. We thank Joe Papa BS MS (EXAXOL in Clearwater, Florida, USA) in particular for sharing his experiences on the purification of several inorganic substances in this and previous editions, and also for allowing us to use his analytical results on the amounts of metal impurities at various stages of purification of several salts.

We thank Dr Pauline M. Armarego for assistance in the painstaking task of entering data into respective files, for many hours of proofreading, correcting typographical errors and checking CAS Registry Numbers against their respective entries.

One of us (W.L.F.A) owes a debt of gratitude to Dr Desmond (Des) J. Brown of the Research School of Chemistry, ANU, for unfailing support and advice over several decades and for providing data that was difficult to acquire not only for this edition but also for the previous five editions of this book.

One of us (C.L.L.C) would like to acknowledge the support and friendship of her many research staff and students (past and present at ANU and A*STAR). She especially thanks Drs Paul Huleatt, Paul Bernardo, Felicity Moore and Brendan Burkett for their unfailing faith in her, through chemical and personal journeys both in Singapore and Australia. The legacy of this book is for Kimberley and Victoria Tse because it is cool to be a scientist!

We thank Mrs Joan Smith, librarian of the Research School of Chemistry, ANU, for her generous help in many library matters which made the tedious task of checking references more enduring.

W.L.F. Armarego & C.L.L. Chai

November 2008

HOW THIS BOOK SHOULD BE USED

Substances have been entered under their respective chapters, sections and subsections. In these sections compounds have been entered in alphabetical order according to the more commonly used name. However, because compounds can be named differently (some of these other names have been included in brackets after their entries) and may be difficult to find, it is advisable to obtain the page number of the entry from the Chemical Abstracts Registry Numbers (CASRNs) Index at the end of the book. CASRNs of substances are readily obtained from "SciFinder", or better, from any commercial catalogue that sells these compounds, as almost all of these have CASRNs inserted after the names of their products. Also, in this book we could not insert some substances that can be formally included in more than one section without repeating the entry. In such cases the compounds are entered in a preferred section and are cross-referenced by inserting "see [CASRN]" or just "[CASRN]". Thus the cross-reference is its CASRN. The CASRNs Index provides the page numbers in bold/italic type. If the CASRN of a desired substance is not in the CASRN Index, or its full or abbreviated name is not in the General Index, then it will not be present in this book.

CASRNs are unique for each chemical substance and are such that they are internally consistent. They are set up according to a specific formula. Refer to the first page of the CASRNs Index to calculate the formula in order to check whether the number is a valid number or not.

W.L.F.A. & C.L.L.C.

ABOUT THE AUTHORS

Wilfred L.F. Armarego

Division of Molecular Bioscience, The John Curtin School of Medical Research, Australian National University, Canberra

Wilfred L.F. Armarego graduated BSc (Hons) in 1953 and PhD from the University of London in 1956 and came to Australia in that year. After two years at the Central Research Laboratories (ICIANZ) in Melbourne, where he worked on plant growth substances, and one year on potentially carcinogenic polycyclic aromatic hydrocarbons at the University of Melbourne as Senior Demonstrator in Organic Chemistry, he joined the Department of Medical Chemistry as a Research Fellow in 1960. He became a Fellow in 1963 and was awarded a DSc degree (London) in 1968. He was promoted to Senior Fellow in 1967 and began research work on the biochemistry and molecular biology of pteridine-requiring enzymes related to the inherited metabolic disease phenylketonuria and its variants. He was head of the Protein Biochemistry Group and Pteridine Biochemistry Laboratory and is now a visiting fellow at the John Curtin School of Medical Research, and member of the editorial boards of 'Medicinal Research Reviews' and 'Pteridines' journals. He is a Chartered Chemist, a Fellow of the Royal Society of Chemistry and a Fellow of the Royal Australian Chemical Institute.

Christina L.L. Chai

Department of Pharmacy, National University of Singapore and Institute of Chemical and Engineering Sciences, Agency for Science Technology and Research, Singapore.

Christina Li Lin Chai obtained her BSc (Hons) from the University of Canterbury, Christchurch, New Zealand and her PhD in synthetic organic chemistry from the Research School of Chemistry, Australian National University, Canberra, Australia. Upon completion of her PhD, she was awarded a Samuel-Glasstone Research Fellowship tenable at the Dyson Perrins Laboratory, University of Oxford, UK. Her first faculty position was at the Department of Chemistry, Victoria University of Wellington in 1991–1993, followed by a second faculty position at the Australian National University (1994–2004) where she was an Associate Professor. She moved to the Institute of Chemical and Engineering Sciences, Agency for Science Technology and Research (A*STAR), Singapore as a Principal Scientist and Programme Manager in Dec 2004 and held various co-appointments as Director of Graduate Affairs at the Science and Engineering Council (SERC), A*STAR as well as an honorary adjunct appointment at Nanyang Technological University, Singapore. Since August 2011, Dr Chai holds a joint appointment as Associate Professor in the Department of Pharmacy, National University of Singapore and as Principal Scientist in the Institute of Chemical and Engineering Sciences.

CHAPTER 1

COMMON PHYSICAL TECHNIQUES USED IN PURIFICATION

INTRODUCTION

Purity is a matter of degree. Other than contaminants such as dust, paper fibres, wax, cork, etc., that may have been inadvertently introduced into the sample during manufacture, all commercially available chemical substances are in some measure impure. Any amounts of unreacted starting material, intermediates, by-products, isomers and related compounds may be present depending on the synthetic or isolation procedures used for preparing the substances. Inorganic reagents may deteriorate because of defective packaging (glued liners affected by sulfuric acid, zinc extracted from white rubber stoppers by ammonia), corrosion or prolonged storage. Organic molecules may undergo changes on storage. In extreme cases the container may be incorrectly labelled or, where compositions are given, they may be misleading or inaccurate for the proposed use. Where any doubt exists, it is usual to check for impurities by appropriate spot tests, or by recourse to tables of physical or spectral properties such as the extensive infrared and NMR libraries published by the Sigma-Aldrich Chemical Co.

The important question, then, is not whether a substance is pure but whether a given sample is sufficiently pure for some intended purpose. That is, are the contaminants likely to interfere in the process or measurement that is to be studied? By suitable manipulation it is often possible to reduce levels of impurities to acceptable limits, but absolute purity is an ideal which, no matter how closely approached, can never be attained. A *negative* physical or chemical test indicates only that the amount of an impurity in a substance lies below a certain sensitivity level; no test can demonstrate that a likely impurity is entirely absent.

When setting out to purify a laboratory chemical, it is desirable that the starting material is of the best grade commercially available. Particularly among organic solvents there is a range of qualities varying from *laboratory chemical* to *spectroscopic* and *chromatographic* grades. Many of these are suitable for use as received. With the more common reagents it is usually possible to obtain from the current literature some indications of likely impurities, their probable concentrations and methods for detecting them. However, in many cases complete analyses are not given so that significant concentrations of unspecified impurities may be present.

THE QUESTION OF PURITY

Solvents and substances that are specified as *pure* for a particular purpose may, in fact, be quite impure for other uses. Absolute ethanol may contain traces of benzene, which makes it unsuitable for ultraviolet spectroscopy, or plasticizers which make it unsuitable for use in solvent extraction. See also the section on “Criteria of Purity” in Chapter 2.

Irrespective of the grade of material to be purified, it is essential that some criteria exist for assessing the degree of purity of the final product. The more common of these include:

1. Examination of physical properties such as:
   (a) Melting point, freezing point, boiling point, and the freezing curve (i.e. the variation, with time, in the freezing point of a substance that is being slowly and continuously frozen).
   (b) Density.

Purification of Laboratory Chemicals. http://dx.doi.org/10.1016/B978-0-12-382161-4.00001-7

(c) Refractive index at a specified temperature and wavelength. The sodium D line at 589.26 nm (weighted mean of the D_1 and D_2 lines) is the usual wavelength used but the refractive index values at other wavelengths can often be interpolated from a plot of refractive index versus $1/(\text{wavelength})^2$.
(d) Specific conductivity (This can be used to detect, for example, water, salts, inorganic and organic acids and bases, in non-electrolytes).
(e) Optical rotation, optical rotatory dispersion and circular dichroism.

2. Empirical analysis, for C, H, N, ash, etc.

3. Chemical tests for particular types of impurities, e.g. for peroxides in aliphatic ethers (with acidified KI), or for water in solvents (quantitatively by the Karl Fischer method, see Fieser and Fieser, *Reagents for Organic Synthesis*, J. Wiley & Sons, NY, Vol 1 pp. 353, 528 *1967*, Library of Congress Catalog Card No 66-27894, also see Karl Fischer titrant or Hydranal® –Titrant type 5E [64-17-5] and other types in Fluka and Sigma-Aldrich Catalogue.

4. Physical tests for particular types of impurities:
Emission and atomic absorption spectroscopy for detecting organic impurities and determining metal ions.
Chromatography, including paper, thin layer, liquid (high, medium and normal pressure), flash and vapour phase.
Electron spin resonance for detecting free radicals.
Other spectroscopic methods (see 5 below).

5. Examination of spectroscopic properties
Nuclear Magnetic Resonance (^{1}H, ^{13}C, ^{31}P, ^{19}F, ^{11}B NMR, etc.)
Infrared spectroscopy (IR and Fourier Transform IR)
Ultraviolet (UV), visible and fluorescence spectroscopy
X-ray photoelectron spectroscopy (XPS)
Atomic absorption spectroscopy (AAA)
Mass spectroscopy [electron ionisation (EI), chemical ionisation (CI), electrospray ionisation (ESI), fast atom bombardment (FAB), matrix-associated laser desorption ionisation (MALDI), inductively coupled plasma-mass spectrometry (ICP-MS)

6. Electrochemical methods (see Chapter 6 for macromolecules).

7. Nuclear methods which include a variety of radioactive elements as in organic reagents, complexes or salts.

A substance is usually taken to be of an acceptable purity when the measured property is unchanged by further treatment (especially if it agrees with a recorded value). In general, at least two different methods, such as recrystallisation and distillation, should be used in order to ensure maximum purity. Crystallisation may be repeated (from the same solvent or better from different solvents) until the substance has a constant melting point, and until it distils repeatedly within a narrow specified temperature range. The purified product should have spectroscopic properties which indicate that the traces of impurities left in the sample are of acceptable levels for the intended purpose.

With liquids, the refractive index at a specified temperature and wavelength is a sensitive test of purity. Note however that this is sensitive to dissolved gases such as O_2, N_2 or CO_2. Under favourable conditions, freezing curve studies are sensitive to impurity levels of as little as 0.001 moles percent. Analogous fusion curves or heat capacity measurements can be up to ten times as sensitive as this. With these exceptions, most of the above methods are rather insensitive, especially if the impurities and the substances in which they occur are chemically similar. In some cases, even an impurity comprising many parts per million of a sample may escape detection.

The common methods of purification, discussed below, comprise distillation (including fractional distillation, distillation under reduced pressure, sublimation and steam distillation), crystallisation, extraction, chromatographic, electrophoresis and other methods. In some cases, volatile and other impurities can be removed simply by heating. Impurities can also sometimes be eliminated by the formation of derivatives from which the purified material is regenerated (see Chapter 2).

Common techniques used for determining the purity of a specimen and for following the purification procedure are described below (p. 33).

SOURCES OF IMPURITIES

Some of the more obvious sources of contamination of solvents arise from storage in metal drums and plastic containers, and from contact with grease and screw caps. Many solvents contain water. Others have traces of acidic materials such as hydrochloric acid in chloroform. In both cases this leads to corrosion of the drum and contamination of the solvent by traces of metal ions, especially Fe^{3+}. Grease, for example on stopcocks of separating funnels and other apparatus, e.g. greased ground joints, is also likely to contaminate solvents during extractions and chemical manipulation. Oxygen from the air is also a source of contamination by virtue of its ability to produce small or large amounts of oxidation products (see section on the *Solubilities of gases in liquids* below).

A much more general source of contamination that has not received the consideration it merits comes from the use of plastics for tubing and containers. Plasticisers can readily be extracted by organic solvents from PVC and other plastics, so that most solvents, irrespective of their grade (including spectrograde and ultrapure), have been reported to contain 0.1 to 5ppm of plasticiser [de Zeeuw, Jonkman and van Mansvelt *Anal Biochem* **67** 339 *1975*]. Where large quantities of solvent are used for extraction followed by evaporation, this can introduce significant amounts of impurity, even exceeding the weight of the genuine extract and giving rise to spurious peaks in gas chromatography, for example of fatty acid methyl esters [Pascaud, *Anal Biochem* **18** 570 *1967*]. Likely contaminants are di(2-ethylhexyl)phthalate and dibutyl phthalate, but upwards of 20 different phthalate esters are listed as plasticisers as well as adipates, azelates, phosphates, epoxides, polyesters and various heterocyclic compounds. These plasticisers would enter the solvent during passage through plastic tubing or from storage in containers or from plastic coatings used in cap liners for bottles. Such contamination could arise at any point in the manufacture or distribution of a solvent. The problem with cap liners is avoidable by using corks wrapped in aluminium foil, although even in this case care should be taken because aluminium foil can dissolve in some liquids, e.g. benzylamine and propionic acid. Polycarbonate containers invariably leach out the 'estrogenic chemical' **Bisphenol A** (see Chapter 4, Aromatic Compounds) into the liquid in the container [Fiona Case *Chemistry World* **5** (No. 4) 12 *2008*, Rebecca Trager *Chemistry World* **5** (No. 5) 8 *2008*].

Solutions in contact with polyvinyl chloride can become contaminated with trace amounts of lead, titanium, tin, zinc, iron, magnesium or cadmium from additives used in the manufacture and moulding of PVC.

N-Phenyl-2-naphthylamine is a contaminant of solvents and biological materials that have been in contact with black rubber or neoprene (in which it is used as an antioxidant). Although this naphthylamine was only an artifact of the isolation procedures, it was at first thought to be a genuine component of vitamin K preparations, extracts of plant lipids, algae, butter, animal livers, eye tissue and kidney tissue [Brown *Chem Br* **3** 524 *1967*].

Most of the above impurities can be removed by prior distillation of the solvent, and care should be taken to avoid further contact with plastic or black rubber materials.

PRACTICES TO AVOID IMPURITIES

Cleaning practices

Laboratory glassware and Teflon equipment can be cleaned satisfactorily for most purposes by careful immersion into a solution of sodium dichromate in concentrated sulfuric acid, followed by draining, and rinsing copiously with distilled water. This is an exothermic reaction and should be carried out **very** cautiously in an efficient fume cupboard. [To prepare the chromic acid bath, dissolve 5 g of sodium dichromate (CARE: cancer suspect agent) in 5 ml of water. The dichromate solution is then cooled and stirred while 100 ml of concentrated sulfuric acid is added slowly. Store it in a glass bottle.] Where traces of chromium (adsorbed on the glass) must be avoided, a 1:1 mixture of concentrated sulfuric and nitric acid is a useful alternative. (*Use in a fumehood to remove vapour and with adequate face protection.*) Acid washing is also suitable for polyethylene ware, but prolonged contact (some weeks) leads to severe deterioration of the plastic. Alternatively an alcoholic solution of sodium hydroxide (alkaline base bath) can be used. This strongly corrosive solution (CAUTION: alkali causes serious burns) can be made by dissolving 120 g of NaOH in 120 ml of water, followed by dilution to 1 L with 95% ethanol.

This solution is conveniently stored in suitable alkali-resistant containers (e.g. Nalgene heavy duty rectangular tanks) with lids. Glassware can be soaked overnight in the base bath and rinsed thoroughly after soaking. For much glassware, washing with hot detergent solution, using tap water, followed by rinsing well with distilled water and acetone, and heating to 200–300° overnight, is adequate. (Volumetric apparatus should not be heated: after washing it is rinsed with acetone, then pure diethyl ether, and air-dried. Prior to use, equipment can be rinsed with acetone, then with petroleum ether or pure diethyl ether, to remove the last traces of contaminants.)
Teflon equipment should be soaked, first in acetone, then in petroleum ether or pure diethyl ether for ten minutes, then dried in a vacuum or flushed with dry nitrogen prior to use.
For trace metal analyses, prolonged soaking of equipment in 1M nitric acid may be needed to remove adsorbed metal ions.
Soxhlet thimbles and filter papers may contain traces of lipid-like materials. For manipulations with highly pure materials, as in trace-pesticide analysis, thimbles and filter papers should be thoroughly extracted with pure diethyl ether before use.
Trace impurities in silica gel for TLC can be removed by heating at 300° for 16 hours or by Soxhlet extraction for 3 hours with distilled chloroform, followed by 4 hours extraction with distilled pure diethyl ether and drying in a vacuum.

Silylation of glassware and plasticware

Silylation of apparatus makes it repellant to water and hydrophilic materials. It minimises loss of solute by adsorption onto the walls of the container. The glassware is placed in a desiccator containing dichloromethyl silane (1ml) in a small beaker and evacuated for 5 minutes. The vacuum is turned off and air is introduced into the desiccator, which allows the silylating agent to coat the glassware uniformly. The desiccator is then evacuated, closed and set aside for 2 hours. The glassware is removed from the desiccator and baked at 180° for 2 hours before use.

Fluka supplies a variety of silylating mixtures including (a) Silanization solution I (Fluka gel repel I: ~5% dimethyldichlorosilane in hexane, (b) Silanization solution II (Fluka gel repel II: ~2% dimethyldichlorosilane in 1,1,1-trichloroethane) for silanizing micro electrode, (c) Silanization solution III (Selectophore: 10% hexamethyldisilazane and 6% trimethylchlorosilane in 1-chloronaphthalene), (d) Silanization solution IV (Selectophore: ~4% trimethylchlorosilane in *o*-xylene, (e) Silanization solution V (Selectophore: ~5% dimethyldichlorosilane in *o*-xylene, and (f) Silanization solution VI (Selectophore: ~3% tributylchlorosilane in 1-chloronaphthalene for silanizing micropipette electrodes by the dip-and-bake method. Most powerful general silylating mixtures among many others are also available from Fluka (see catalogue).

Plasticware is treated similarly except that it is rinsed well with water before use instead of baking. Note that dichloromethyl silane is highly **TOXIC** and **VOLATILE**, and the whole operation should be carried out in an efficient fume cupboard.
An alternative procedure used for large apparatus is to rinse the apparatus with a 5% solution of dichloromethyl silane in chloroform, followed by several rinses with water before baking the apparatus at 180°/2 hours (for glass) or drying in air (for plasticware).
A solution of 2% w/v of dichloromethyl silane in octamethyl cyclooctasilane or octmethylcyclotetrasiloxane is used to inhibit the sticking of polyacrylamide gels, agarose gels and nucleic acids to glass surfaces and these chemicals are available commercially [from Fluka (Riedel-deHaën)].

SAFETY PRECAUTIONS ASSOCIATED WITH THE PURIFICATION OF LABORATORY CHEMICALS

Although most of the manipulations involved in purifying laboratory chemicals are inherently safe, care is necessary if hazards are to be avoided in the chemical laboratory. In particular there are dangers inherent in the inhalation of vapours and absorption of liquids and low melting solids through the skin. In addition to the toxicity of solvents there is also the risk of their flammability and the possibility of eye damage. Chemicals, particularly in admixture, may be explosive. Compounds may be carcinogenic or otherwise deleterious to health. Present-day chemical catalogues specifically indicate the particular dangerous properties of the individual chemicals they list, and these should be consulted whenever the use of commercially available chemicals is contemplated. Radioisotopic labeled compounds pose special problems of human exposure and of disposal of laboratory waste.

Hazardous purchased chemicals are accompanied by detailed MSDS (Material Safety Data Sheets), which contain information regarding their toxicity, safety handling procedures and the necessary precautions to be taken. These should be read carefully and filed for future reference. In addition, chemical management systems such as Chem-ChemWatch, which include information on hazards, handling and storage, are commercially available. There are a number of websites which provide selected safety information: these include the Sigma-Aldrich website <www.sigmaaldrich.com> and other chemical websites, e.g. <www.ilpi.com/msds>.

The most common hazards are:

(1) Explosions due to the presence of peroxides formed by aerial oxidation of ethers and tetrahydrofuran, decahydronaphthalene, acrylonitrile, styrene and related compounds.
(2) Compounds with low flash points (below room temperature). Examples are acetaldehyde, acetone, acetonitrile, benzene, carbon disulfide, cyclohexane, diethyl ether, ethyl acetate and *n*-hexane.
(3) Contact of oxidising agents ($KMnO_4$, $HClO_4$, chromic acid) with organic liquids.
(4) Toxic reactions with tissues (Me_2SO_4).

The laboratory should at least be well-ventilated and safety glasses should be worn, particularly during distillations and manipulations carried out under reduced pressure or elevated temperatures. With this in mind we have endeavoured to warn users of this book whenever greater than usual care is needed in handling chemicals. As a general rule, however, **all chemicals which users are unfamiliar with should be treated with extreme care and assumed to be highly flammable and toxic.** The safety of others in a laboratory should always be foremost in mind, with ample warning whenever a potentially hazardous operation is in progress. Also, unwanted solutions or solvents should never be disposed of *via* the laboratory sink. The operator should be aware of the usual means for disposal of chemicals in her/his laboratories, and she/he should remove unwanted chemicals accordingly. **Organic liquids for disposal should be temporarily stored, as is practically possible, in respective containers. Avoid placing all organic liquids in the same container particularly if they contain small amounts of reagents which could react with each other. Halogenated waste solvents should be kept separate from other organic liquids.**
Laboratory coats, disposable aprons, caps, sleeves, dust/mist respirators and foot protection, hearing protection as well as a variety of safety glasses, goggles, face and body shields should be used when the demand arises and are available commercially (see e.g. the Sigma-Aldrich Labware catalogue).

SOME HAZARDS OF CHEMICAL MANIPULATION IN PURIFICATION AND RECOVERY OF RESIDUES

Performing chemical manipulations calls for some practical knowledge if danger is to be avoided. However, with care, hazards can be kept to an acceptable minimum. A good general approach is to consider every operation as potentially perilous and then to adjust one's attitude as the operation proceeds. A few of the most common dangers are set out below. For a larger coverage of the following sections, and of the literature, the bibliography at the end of this chapter should be consulted.

Perchlorates and perchloric acid. At 160° perchloric acid is an exceedingly strong oxidising acid and a strong dehydrating agent. Organic perchlorates, such as methyl and ethyl perchlorates, are unstable and are violently explosive compounds. A number of heavy-metal perchlorates are extremely prone to explode. The use of anhydrous magnesium perchlorate, *Anhydrone*, *Dehydrite*, as a drying agent for organic vapours is **not** recommended. Desiccators which contain this drying agent should be adequately shielded at all times and kept in a cool place, i.e. **never** on a window sill where sunlight can fall on it.
No attempt should be made to purify perchlorates, except for ammonium, alkali metal and alkaline earth salts which, in water or aqueous alcoholic solutions are insensitive to heat or shock. Note that perchlorates react relatively slowly in aqueous organic solvents, but as the water is removed there is an increased possibility of an explosion. Perchlorates, often used in non-aqueous solvents, are explosive in the presence of even small amounts of organic compounds when heated. Hence stringent care should be taken when purifying perchlorates, and direct flame and infrared lamps should be avoided. Tetra-alkylammonium perchlorates should be dried below 50° under vacuum (and protection). Only very small amounts of such materials should be prepared, and stored, at any one time.

Peroxides. These are formed by aerial oxidation or by autoxidation of a wide range of organic compounds, including diethyl ether, allyl ethyl ether, allyl phenyl ether, dibenzyl ether, benzyl butyl ether, *n*-butyl ether, *iso*-butyl ether, *t*-butyl ether, dioxane, tetrahydrofuran, olefins, and aromatic and saturated aliphatic hydrocarbons. They accumulate during distillation and can detonate violently on evaporation or distillation when their concentration becomes high. If peroxides are likely to be present materials should be tested for peroxides before distillation (for tests see entry under "Ethers", in Chapter 2). Also, distillation should be discontinued when at least one quarter of the residue is left in the distilling flask.

Heavy-metal-containing explosives. Ammoniacal silver nitrate, on storage or treatment, will eventually deposit the highly explosive silver nitride *fulminating silver*. Silver nitrate and ethanol may give silver fulminate (see Chapter 5), and in contact with azides or hydrazine and hydrazides may form silver azide. Mercury can also form such compounds. Similarly, ammonia or ammonium ions can react with gold salts to form *"fulminating gold"*. Metal fulminates of cadmium, copper, mercury and thallium are powerfully explosive, and some are detonators [Luchs, *Photog Sci Eng* **10** 334 *1966*]. Heavy-metal-containing solutions, particularly when organic material is present, should be treated with great respect and precautions towards possible explosion should be taken.

Strong acids. In addition to perchloric acid (see above), extra care should be taken when using strong mineral acids. Although the effects of concentrated sulfuric acid are well known, these cannot be stressed strongly enough. Contact with tissues will leave irreparable damage. **Always dilute the concentrated acid by carefully adding the acid down the side of the flask which contains the water, and the process should be carried out under cooling. This solution is not safe to handle until the acid has been thoroughly mixed (care) with the water. Protective face, and body coverage should be used at all times.** Fuming sulfuric acid and chlorosulfonic acid are even more dangerous than concentrated sulfuric acid, and adequate precautions should be taken. Chromic acid cleaning mixture contains strong sulfuric acid and should be treated in the same way; and in addition the mixture is potentially ***carcinogenic.***
Concentrated and fuming nitric acids are also dangerous because of their severe deleterious effects on tissues.

Picric acid. This acid and related nitro compounds, e.g. styphnic acid, are explosive and should **not** be kept dry. The acid is generally stored wet by covering the crystals with water. Solutions in ethanol and benzene are used occasionally. They should be stored in the cold (to minimise evaporation), and a rubber or plastic stopper (**not a ground glass stopper**) should be used. **Note** that picric acid and picrates stain skin protein with a yellow colour that is not readily washed off. This can be avoided by wearing rubber gloves.

Reactive halides and anhydrides. Substances like acid chlorides, low-molecular-weight anhydrides and some inorganic halides (e.g. PCl_3) can be **highly toxic and lachrymatory, affecting mucous membranes and lung tissues. Utmost care should be taken when working with these materials. Work should be carried out in a very efficient fume cupboard.**

Salts and organic esters of some inorganic acids. In addition to the dangers of perchlorate salts, other salts such as nitrates, azides, diazo salts, organic nitrates, organic azides and picrates (see above) can be hazardous, and due care should be taken when these are dried. Large quantities should never be prepared or stored for long periods.

Solvents. The flammability of low-boiling organic liquids cannot be emphasised strongly enough. These invariably have very low flash points and can ignite spontaneously. Special precautions against explosive flammability should be taken when recovering such liquids. Care should be taken with small volumes (*ca* 250ml) as well as large volumes (> 1L), and the location of all the fire extinguishers, and fire blankets, in the immediate vicinity of the apparatus should be checked. The fire extinguisher should be operational. The following flammable liquids (in alphabetical order) are common fire hazards in the laboratory: acetaldehyde, acetone, acrylonitrile, acetonitrile, benzene, carbon disulfide, cyclohexane, diethyl ether, ethyl acetate, hexane, low-boiling petroleum ether, tetrahydrofuran and toluene. Toluene should always be used in place of benzene wherever possible due to the potential *carcinogenic* effects of the liquid and vapour of the latter.
The drying of flammable solvents with sodium or potassium metal and metal hydrides poses serious potential fire hazards, and adequate precautions should be stressed.

SAFETY DISCLAIMER

Experimental chemistry is a very dangerous occupation, and extreme care and adequate safety precautions should be taken at all times. Although we have stated the safety measures that have to be taken under specific entries, these are by no means exhaustive and some may have been unknowingly or accidentally omitted. The experimenter without prior knowledge or experience must seek further safety advice on reagents and procedures from experts in the field before undertaking the purification of any material. *We take no responsibility whatsoever if any mishaps occur when using any of the procedures described in this book.*

METHODS OF PURIFICATION OF REAGENTS AND SOLVENTS

Many methods exist for the purification of reagents and solvents. A number of these methods are routinely used in synthetic as well as analytical chemistry and biochemistry. These techniques, outlined below, will be discussed in greater detail in the respective sections in this chapter. It is important to note that more than one method of purification may need to be implemented in order to obtain compounds of highest purity.
Common methods of purification are:

Solvent Extraction and Distribution
Distillation
Recrystallisation
Sublimation
Electrophoresis
Chromatography

For substances contaminated with water or solvents, drying with appropriate absorbents and desiccants may be sufficient.

SOLVENT EXTRACTION AND DISTRIBUTION

Extraction of a substance from suspension or solution into another solvent can sometimes be used as a purification process. Thus, organic substances can often be separated from inorganic impurities by shaking an aqueous solution or suspension with suitable immiscible solvents such as benzene, carbon tetrachloride, chloroform, diethyl ether, diisopropyl ether or petroleum ether. After several such extractions, the combined organic phase is dried and the solvent is evaporated. Grease from the glass taps of conventional separating funnels is invariably soluble in the solvents used. Contamination with grease can be very troublesome particularly when the amounts of material to be extracted are very small. Instead, the glass taps should be lubricated with the extraction solvent; or better, the taps of the extraction funnels should be made of the more expensive material *Teflon*. Immiscible solvents suitable for extractions are given in Table 1. Addition of electrolytes (such as ammonium sulfate, calcium chloride or sodium chloride) to the aqueous phase helps to ensure that the organic layer separates cleanly and also decreases the extent of extraction into the latter. Emulsions can also be broken up by filtration (with suction) through Celite, or by adding a little diethyl ether, octyl alcohol or some other paraffinic alcohol. The main factor in selecting a suitable immiscible solvent is to find one in which the material to be extracted is readily soluble, whereas the substance from which it is being extracted is not. The same considerations apply irrespective of whether it is the substance being purified, or one of its contaminants, that is taken into the new phase. (The second of these processes is described as washing.)

Common examples of washing with aqueous solutions include the following:

Removal of acids from water-immiscible solvents by washing with aqueous alkali, sodium carbonate or sodium bicarbonate.
Removal of phenols from similar solutions by washing with aqueous alkali.
Removal of organic bases by washing with dilute hydrochloric or sulfuric acids.
Removal of unsaturated hydrocarbons, of alcohols and of ethers from saturated hydrocarbons or alkyl halides by washing with cold concentrated sulfuric acid.

This process can also be applied to purification of the substance if it is an acid, a phenol or a base, by extracting into the appropriate aqueous solution to form the salt which, after washing with pure solvent, is again converted to the free species and re-extracted. Paraffin hydrocarbons can be purified by extracting them with phenol (in which aromatic hydrocarbons are highly soluble) prior to fractional distillation.

For extraction of solid materials with a solvent, a *Soxhlet* extractor is commonly used. This technique is applied, for example, in the alcohol extraction of dyes to free them from insoluble contaminants such as sodium chloride or sodium sulfate.
Acids, bases and amphoteric substances can be purified by taking advantage of their ionisation constants (see below).
The recovery of some fifty more commonly used solvents from water, other solvents, residues etc. have been discussed, together with information on their behaviour before and after use, by I.M. Smallwood in the *Solvent Recovery Handbook*, Blackwood Science Publ Ltd, *2001*, ISBN 9780632056477.

DISTILLATION

One of the most widely applicable and most commonly used methods of purification of liquids or low melting solids (especially of organic chemicals) is fractional distillation at atmospheric, or some lower, pressure. Almost without exception, this method can be assumed to be suitable for all organic liquids and most of the low-melting organic solids. For this reason it has been possible, e.g. in Chapter 4, to omit many procedures for purification of organic chemicals when only a simple fractional distillation is involved-the suitability of such a procedure is implied from the boiling point.
The boiling point of a liquid varies with the 'atmospheric' pressure to which it is exposed. A liquid boils when its vapour pressure is the same as the external pressure on its surface, its normal boiling point being the temperature at which its vapour pressure is equal to that of a standard atmosphere (760 mmHg). Lowering the external pressure lowers the boiling point. For most substances, boiling point and vapour pressure are related by an equation of the form,

$$\log p = A + B/(t + 273),$$

where p is the pressure in mmHg, t is in ^{o}C, and A and B are constants. Hence, if the boiling points at two different pressures are known, the boiling point at another pressure can be calculated from a simple plot of $\log p$ *versus* $1/(t + 273)$. For organic molecules that are not strongly associated, this equation can be written in the form,

$$\log p = 8.586 - 5.703\ (T + 273)/(t + 273)$$

where T is the boiling point in ^{o}C at 760 mmHg. Tables 2A and 2B give computed boiling points over a range of pressures. Some examples illustrate its application. Ethyl acetoacetate, **b** 180^{o} (with decomposition) at 760 mmHg has a predicted **b** of 79^{o} at 16 mm; the experimental value is 78^{o}. Similarly 2,4-diaminotoluene, **b** 292^{o} at 760mm, has a predicted **b** of 147^{o} at 8mm; the experimental value is 148–150^{o}. For self-associated molecules the predicted **b** are lower than the experimental values. Thus, glycerol, **b** 290^{o} at 760mm, has a predicted **b** of 146^{o} at 8mm: the experimental value is 182^{o}.

Similarly an estimate of the boiling points of liquids at reduced pressure can be obtained using a nomogram (see Fig. 1).

For pressures near 760mm, the change in boiling point is given approximately by

$$\delta t = a(760 - p)(t + 273)$$

where a = 0.00012 for most substances, but a = 0.00010 for water, alcohols, carboxylic acids and other associated liquids, and a = 0.00014 for very low-boiling substances such as nitrogen or ammonia [Crafts *Chem Ber* **20** 709 *1887*]. When all the impurities are non-volatile, simple distillation is adequate purification. The observed boiling point remains almost constant and approximately equal to that of the pure material. Usually, however, some of the impurities are appreciably volatile, so that the boiling point progressively rises during the distillation because of the progressive enrichment of the higher-boiling components in the distillation flask. In such cases, separation is effected by fractional distillation using an efficient column. [For further reading see section on "Variation of Boiling Points with Pressure" on pp. 15–26 in *CRC—Handbook of Chemistry and Physics 88th Edition*, David R Lide (Editor–in-Chief) CRC Press, Boca Raton, Florida *2007–2008*, ISBN 0849304881.]

Techniques

The distillation apparatus consists basically of a distillation flask, usually fitted with a vertical fractionating column (which may be empty, or packed with suitable materials such as glass helices or stainless-steel wool) to which is attached a condenser leading to a receiving flask. The bulb of a thermometer projects into the vapour phase just below the region where the condenser joins the column. The distilling flask is heated so that its contents are steadily vaporised by boiling. The vapour passes up into the column where, initially, it condenses and runs back into the flask. The resulting heat transfer gradually warms the column so that there is a progressive movement of the vapour phase-liquid boundary up the column, with increasing enrichment of the more volatile component. Because of this fractionation, the vapour finally passing into the condenser (where it condenses and flows into the receiver) is commonly that of the lowest-boiling components in the system. The conditions apply until all of the low-boiling material has been distilled, whereupon distillation ceases until the column temperature is high enough to permit the next component to distil. This usually results in a temporary fall in the temperature indicated by the thermometer.

Distillation of liquid mixtures

The principles involved in fractional distillation of liquid mixtures are complex but can be seen by considering a system which approximately obeys *Raoult's law*. (This law states that the vapour pressure of a solution at any given temperature is the sum of the vapour pressures of each component multiplied by its mole fraction in the solution.) If two substances, A and B, having vapour pressures of 600 mmHg and 360 mmHg, respectively, were mixed in a molar ratio of 2:1 (i.e. 0.666:0.333 mole ratio), the mixture would have (ideally) a vapour pressure of 520 mmHg (i.e. 600 x 0.666 + 360 x 0.333, or 399.6 + 119.88 mmHg) and the vapour phase would contain 77% (399.6 x 100/520) of A and 23% (119.88 x 100/520) of B. If this phase was now condensed, the new liquid phase would, therefore, be richer in the volatile component A. Similarly, the vapour in equilibrium with this phase is still further enriched in A. Each such liquid-vapour equilibrium constitutes a "theoretical plate". The efficiency of a fractionating column is commonly expressed as the number of such plates to which it corresponds in operation. Alternatively, this information may be given in the form of the height equivalent to a theoretical plate, or HETP. The number of theoretical plates and equilibria between liquids and vapours are affected by the factors listed to achieve maximum separation by fractional distillation in the section below on techniques.

In most cases, systems deviate to a greater or lesser extent from Raoult's law, and vapour pressures may be greater or less than the values calculated. In extreme cases (e.g. azeotropes), vapour pressure-composition curves pass through maxima or minima, so that attempts at fractional distillation lead finally to the separation of a constant-boiling (azeotropic) mixture and one (but not both) of the pure species if either of the latter is present in excess.

Elevation of the boiling point by dissolved solids. Organic substances dissolved in organic solvents cause a rise in boiling point which is proportional to the concentration of the substance, and the extent of rise in temperature is characteristic of the solvent. The following equation applies for dilute solutions and non-associating substances:

$$\frac{M\,\Delta t}{c} = K$$

where M is the molecular weight of the solute, Δt is the elevation of boiling point in ^{o}C, c is the concentration of solute in grams for 1000 gm of solvent, and K is the *Ebullioscopic Constant* (molecular elevation of the boiling point) for the solvent. K is a fixed property (constant) for the particular solvent. This has been very useful for the determination of the molecular weights of organic substances in solution.

The efficiency of a distillation apparatus used for purification of liquids depends on the difference in boiling points of the pure material and its impurities. For example, if two components of an ideal mixture have vapour pressures in the ratio 2:1, it would be necessary to have a still with an efficiency of at least seven plates (giving an enrichment of $2^7 = 128$) if the concentration of the higher-boiling component in the distillate was to be reduced to less than 1% of its initial value. For a vapour pressure ratio of 5:1, three plates would achieve as much separation.

In a fractional distillation, it is usual to reject the initial and final fractions, which are likely to be richer in the lower-boiling and higher-boiling impurities respectively. The centre fraction can be further purified by repeated fractional distillation.

To achieve maximum separation by fractional distillation:

1. The column must be flooded initially to wet the packing. For this reason it is customary to operate a still at reflux for some time before beginning the distillation.

2. The reflux ratio should be high (i.e. the ratio of drops of liquid which return to the distilling flask and the drops which distil over), so that the distillation proceeds slowly and with minimum disturbance of the equilibria in the column.

3. The hold-up of the column should not exceed one-tenth of the volume of any one component to be separated.

4. Heat loss from the column should be prevented but if the column is heated to offset this, its temperature must not exceed that of the distillate in the column.

5. Heat input to the still-pot should remain constant.

6. For distillation under reduced pressure there must be careful control of the pressure to avoid flooding or cessation of reflux.

Types of distillation

The distilling flask. To minimise superheating of the liquid (due to the absence of minute air bubbles or other suitable nuclei for forming bubbles of vapour), and to prevent bumping, one or more of the following precautions should be taken:

(a) The flask is heated uniformly over a large part of its surface, either by using an electrical heating mantle or, by partial immersion in a bath above the boiling point of the liquid to be distilled (Table 3).

(b) Before heating begins, small pieces of unglazed fireclay or porcelain (porous pot, boiling chips), pumice, diatomaceous earth, or platinum wire are added to the flask. These act as sources of air bubbles.

(c) The flask may contain glass siphons or boiling tubes. The former are inverted J-shaped tubes, the end of the shorter arm being just above the surface of the liquid. The latter comprise long capillary tubes sealed above the lower end.

(d) A steady slow stream of inert gas (e.g. N_2, Ar or He) is passed through the liquid.

(e) The liquid in the flask is stirred mechanically. This is especially necessary when suspended insoluble material is present.

For simple distillations a Claisen flask is often used. This flask is, essentially, a round-bottomed flask to the neck of which is joined another neck carrying a side arm. This second neck is sometimes extended so as to form a Vigreux column [a glass tube in which have been made a number of pairs of indentations which almost touch each other and which slope slightly downwards. The pairs of indentations are arranged to form a spiral of glass inside the tube].

For heating baths, see Table 3. For distillation apparatus on a macro, semi-micro or micro scale see Aldrich and other glassware catalogues. Alternatively, visit some useful websites for suppliers of laboratory glassware, e.g. <www.wheatonsci.com>; <www.sigmaaldrich.com> and <www.kimble-kontes.com>.

Types of columns and packings. A slow distillation rate is necessary to ensure that equilibrium conditions operate and also that the vapour does not become superheated so that the temperature rises above the boiling point. Efficiency is improved if the column is heat insulated (either by vacuum jacketing or by lagging) and, if necessary, heated to just below the boiling point of the most volatile component. Efficiency of separation also improves with increase in the heat of vaporisation of the liquids concerned (because fractionation depends on heat equilibration at multiple liquid-gas boundaries). Water and alcohols are more easily purified by distillation for this reason.

Columns used in distillation vary in their shapes and types of packing. Packed columns are intended to give efficient separation by maintaining a large surface of contact between liquid and vapour. Efficiency of separation is further increased by operation under conditions approaching total reflux, i.e. under a high reflux ratio. However, great care must be taken to avoid flooding of the column during distillation. The minimum number of theoretical plates for satisfactory separation of two liquids differing in boiling point by δt is approximately $(273 + t)/3\delta t$, where t is the average boiling point in ^{o}C.

Some of the commonly used *columns* are:

Bruun column. A type of all-glass bubble-cap column.

Bubble-cap column. A type of plate column in which inverted cups (bubble caps) deflect ascending vapour through reflux liquid lying on each plate. Excess liquid from any plate overflows to the plate lying below it and ultimately returns to the flask. (For further details, see Bruun & Faulconer *Ind Eng Chem (Anal Ed)* **9** 247 *1937*). Like most plate columns, it has a high through-put, but a relatively low number of theoretical plates for a given height.

Dufton column. A plain tube, into which fits closely (preferably ground to fit) a solid glass spiral wound round a central rod. It tends to choke at temperatures above 100^{o} unless it is lagged (Dufton *J Soc Chem Ind* (London) **38** 45T *1919*).

Hempel column. A plain tube (fitted near the top with a side arm) which is almost filled with a suitable packing, which may be of rings or helices.

Oldershaw column. An all-glass perforated-plate column. The plates are sealed into a tube, each plate being equipped with a baffle to direct the flow of reflux liquid, and a raised outlet which maintains a definite liquid level on the plate and also serves as a drain on to the next lower plate [see Oldershaw *Ind Eng Chem (Anal Ed)* **11** 265 *1941*].

Podbielniak column. A plain tube containing "Heli-Grid" Nichrome or Inconel wire packing. This packing provides a number of passage-ways for the reflux liquid, while the capillary spaces ensure very even spreading of the liquid, so that there is a very large area of contact between liquid and vapour while, at the same time, channelling and flooding are minimised. A column 1m high has been stated to have an efficiency of 200-400 theoretical plates (for further details, see Podbielniak *Ind Eng Chem (Anal Ed)* **13** 639 *1941*; Mitchell & O'Gorman *Anal Chem* **20** 315 *1948*).

Stedman column. A plain tube containing a series of wire-gauze discs stamped into flat, truncated cones and welded together, alternatively base-to-base and edge-to-edge, with a flat disc across each base. Each cone has a hole, alternately arranged, near its base, vapour and liquid being brought into intimate contact on the gauze surfaces (Stedman *Can J Research B* **15** 383 *1937*).

Todd column. A column (which may be a Dufton type, fitted with a Monel metal rod and spiral, or a Hempel type, fitted with glass helices) which is surrounded by an open heating jacket so that the temperature can be adjusted to be close to the distillation temperature (Todd *Ind Eng Chem (Anal Ed)* **17** 175 *1945*).

Vigreux column. A glass tube in which have been made a number of pairs of indentations which almost touch each other and which slope slightly downwards. The pairs of indentations are arranged to form a spiral of glass inside the tube.

Widmer column. A Dufton column, modified by enclosing within two concentric tubes the portion containing the glass spiral. Vapour passes up the outer tube and down the inner tube before entering the centre portion. Thus flooding of the column, especially at high temperatures, is greatly reduced (Widmer *Helv Chim Acta* **7** 59 *1924*).

The packing of a column greatly increases the surface of liquid films in contact with the vapour phase, thereby increasing the efficiency of the column, but reducing its capacity (the quantities of vapour and liquid able to flow in opposite directions in a column without causing flooding). Material for packing should be of uniform size, symmetrical shape, and have a unit diameter less than one-eighth that of the column. (Rectification efficiency increases sharply as the size of the packing is reduced but so, also, does the hold-up in the column.) It should also be capable of uniform, reproducible packing.

The usual ***packings*** are:

(a) **Rings.** These may be hollow glass or porcelain (Raschig rings), of stainless steel gauze (Dixon rings), or hollow rings with a central partition (Lessing rings) which may be of porcelain, aluminium, copper or nickel.

(b) **Helices.** These may be of metal or glass (Fenske rings), the latter being used where resistance to chemical attack is important (e.g. in distilling acids, organic halides, some sulphur compounds, and phenols). Metal single-turn helices are available in aluminium, nickel or stainless steel. Glass helices are less efficient, because they cannot be tamped to ensure uniform packing.

(c) **Balls.** These are usually glass.

(d) **Wire packing.** For use of "Heli-Grid" and "Heli-Pak" packings, see references given for Podbielniak column. For Stedman packing, see entry under Stedman column.

Types of condensers:

Air condenser. A glass tube such as the inner part of a Liebig condenser. Used for liquids with boiling points above 90^{o}. Can be of any length.

Allihn condenser. The inner tube of a Liebig condenser is modified by having a series of bulbs to increase the condensing surface. Further modifications of the bubble shapes give the Julian and Allihn-Kronbitter condensers.

Bailey-Walker condenser. A type of all-metal condenser fitting into the neck of extraction apparatus and being supported by the rim. Used for high-boiling liquids.

Coil condenser. An open tube, into which is sealed a glass coil or spiral through which water circulates. The tube is sometimes also surrounded by an outer cooling jacket.

Double surface condenser. A tube in which the vapour is condensed between an outer and inner water-cooled jacket after impinging on the latter. Very useful for liquids boiling below 40°.

Friedrichs condenser. A "cold-finger" type of condenser sealed into a glass jacket open at the bottom and near the top. The cold finger is formed into glass screw threads.

Graham condenser. A type of coil condenser.

Hopkins condenser. A cold-finger type of condenser resembling that of Friedrichs.

Liebig condenser. An inner glass tube surrounded by a glass jacket through which water is circulated.

Othmer condenser. A large-capacity condenser which has two coils of relatively large bore glass tubing inside it, through which the water flows. The two coils join at their top and bottom.

West condenser. A Liebig condenser with a light-walled inner tube and a heavy-walled outer tube, with only a narrow space between them.

Wiley condenser. A condenser resembling the Bailey-Walker type.

Vacuum distillation. This expression is commonly used to denote a distillation under reduced pressure lower than that of the normal atmosphere. As the boiling point of a substance depends on the pressure, it is often possible to distil materials at a temperature low enough to avoid partial or complete decomposition by lowering the pressure, even if they are unstable when boiled at atmospheric pressure.

Sensitive or high-boiling liquids should invariably be distilled or fractionally distilled under reduced pressure. The apparatus is essentially as described for distillation except that ground joints connecting the different parts of the apparatus should be air tight by using grease, or better Teflon sleeves. For low, moderately high, and very high temperatures Apiezon L, M and T greases, respectively, are very satisfactory. Alternatively, it is often preferable to avoid grease and to use thin Teflon sleeves in the joints. The distilling flask, must be supplied with a capillary bleed (which allows a fine stream of air, nitrogen or argon into the flask), and the receiver should be of the fraction collector type. When distilling under vacuum it is very important to place a loose packing of glass wool above the liquid to buffer sudden boiling of the liquid. The flask should be not more than two-thirds full of liquid. The vacuum must have attained a steady state, i.e. the liquid has been completely degassed, before the heat source is applied, and the temperature of the heat source must be raised *very slowly* until boiling is achieved.

If the pump is a filter pump off a high-pressure water supply, its performance will be limited by the temperature of the water because the vapour pressure of water at 10°, 15°, 20° and 25° is 9.2, 12.8, 17.5 and 23.8 mmHg, respectively. The pressure can be measured with an ordinary manometer. For vacuums in the range 10^{-2} mmHg to 10 mmHg, rotary mechanical pumps (oil pumps) are used and the pressure can be measured with a Vacustat McLeod-type gauge. If still higher vacuums are required, for example for high vacuum sublimations, a mercury diffusion pump is suitable. Such a pump can provide a vacuum up to 10^{-6} mmHg. For better efficiencies, the diffusion pump can be backed up by a mechanical pump. In all cases, the mercury pump is connected to the distillation apparatus through several traps to remove mercury vapours. These traps may operate by chemical action, for example the use of sodium hydroxide pellets to react with acids, or by condensation, in which case empty tubes cooled in solid carbon dioxide-ethanol or liquid nitrogen (contained in wide-mouthed Dewar flasks) are used.

Special oil or mercury traps are available commercially, and a liquid-nitrogen (**b** –209.9°C) trap is the most satisfactory one to use between these and the apparatus. It has an advantage over liquid air or oxygen in that it is non-explosive if it becomes contaminated with organic matter. Air should not be sucked through the apparatus before starting a distillation because this will cause liquid oxygen (**b** –183°C) to condense in the liquid nitrogen trap, and this is potentially explosive (especially in mixtures with organic materials). Due to the potential lethal consequences of liquid oxygen/organic material mixtures, care must be exercised when handling liquid nitrogen. Hence, it is advisable to degas the system for a short period before the trap is immersed into the liquid nitrogen (which is kept in a Dewar flask).

Spinning-band distillation. Factors which limit the performance of distillation columns include the tendency to flood (which occurs when the returning liquid blocks the pathway taken by the vapour through the column) and the increased hold-up (which decreases the attainable efficiency) in the column that should, theoretically, be highly efficient. To overcome these difficulties, especially for distillation under high vacuum of heat sensitive or high-boiling highly viscous fluids, spinning band columns are commercially available. In such units, the distillation columns contain a rapidly rotating, motor-driven, spiral band, which may be of polymer-coated metal, stainless steel or platinum. The rapid rotation of the band in contact with the walls of the still gives intimate mixing of descending liquid with ascending vapour while the screw-like motion

of the band drives the liquid towards the still-pot, helping to reduce hold-up. There is very little pressure drop in such a system, and very high throughputs are possible, with high efficiency. For example, a 765-mm long 10-mm diameter commercial spinning-band column is reported to have an efficiency of 28 plates and a pressure drop of 0.2 mmHg for a throughput of 330ml/hour. The columns may be either vacuum jacketed or heated externally. The stills can be operated down to 10^{-5} mmHg. The principle, which was first used commercially in the Podbielniak Centrifugal Superfractionator, has also been embodied in descending-film molecular distillation apparatus.

Steam distillation. When two immmiscible liquids distil, the sum of their (independent) partial pressures is equal to the atmospheric pressure. Hence in steam distillation, the distillate has the composition

$$\frac{\text{Moles of substance}}{\text{Moles of water}} = \frac{P_{substance}}{P_{water}} = \frac{760 - P_{water}}{P_{water}}$$

where the *P*'s are vapour pressures (in mmHg) in the boiling mixture.

The customary technique consists of heating the substance and water in a flask (to boiling), usually with the passage of steam, followed by condensation and separation of the aqueous and non-aqueous phases in the distillate. Its advantages are those of selectivity (because only some water-insoluble substances, such as naphthalene, nitrobenzene, phenol and aniline are volatile in steam) and of ability to distil certain high-boiling substances well below their boiling point. It also facilitates the recovery of a non-steam-volatile solid at a relatively low temperature from a high-boiling solvent such as nitrobenzene. The efficiency of steam distillation is increased if superheated steam is used (because the vapour pressure of the organic component is increased relative to water). In this case the flask containing the material is heated (without water) in an oil bath and the steam passing through it is superheated by prior passage through a suitable heating device (such as a copper coil heated electrically or an oil bath).

Azeotropic distillation. In some cases two or more liquids form constant-boiling mixtures, or azeotropes. Azeotropic mixtures are most likely to be found with components which readily form hydrogen bonds or are otherwise highly associated, especially when the components are dissimilar, for example an alcohol and an aromatic hydrocarbon, but have similar boiling points.

Examples where the boiling point of the distillate is a minimum (less than either pure component) include:
Water with ethanol, *n*-propanol and isopropanol, *tert*-butanol, propionic acid, butyric acid, pyridine,
methanol with methyl iodide, methyl acetate, chloroform,
ethanol with ethyl iodide, ethyl acetate, chloroform, benzene, toluene, methyl ethyl ketone,
benzene with cyclohexane,
acetic acid with toluene.
Although less common, azeotropic mixtures are known which have higher boiling points than their components. These include water with most of the mineral acids (hydrofluoric, hydrochloric, hydrobromic, perchloric, nitric and sulfuric) and formic acid. Other examples are acetic acid-pyridine, acetone-chloroform, aniline-phenol, and chloroform-methyl acetate.

The following azeotropes are important commercially for drying ethanol:

ethanol 95.5% (by weight) - water 4.5%	**b** 78.1°
ethanol 32.4% - benzene 67.6%	**b** 68.2°
ethanol 18.5% - benzene 74.1% - water 7.4%	**b** 64.9°

Materials are sometimes added to form an azeotropic mixture with the substance to be purified. Because the azeotrope boils at a different temperature, this facilitates separation from substances distilling in the same range as the pure material. (Conversely, the impurity might form the azeotrope and be removed in this way.) This method is often convenient, especially where the impurities are isomers or are otherwise closely related to the desired substance. Formation of low-boiling azeotropes also facilitates distillation.

One or more of the following methods can generally be used for separating the components of an azeotropic mixture:

1. By using a chemical method to remove most of one species prior to distillation. (For example, water can be removed by suitable drying agents; aromatic and unsaturated hydrocarbons can be removed by sulfonation).
2. By redistillation with an additional substance which can form a ternary azeotropic mixture (as in the ethanol-water-benzene example given above).
3. By selective adsorption of one of the components. (For example, of water on to silica gel or molecular sieves, or of unsaturated hydrocarbons onto alumina).
4. By fractional crystallisation of the mixture, either by direct freezing or by dissolving in a suitable solvent.

Kügelrohr distillation. The Aldrich Kügelrohr Distillation Apparatus (see Aldrich-Sigma Labware catalogue) is made up of small glass bulbs (*ca* 4–5cm diameter) which are joined together *via* Quickfit joints at each pole of the bulbs. The liquid (or low melting solid) to be purified is placed in the first bulb of a series of bulbs joined end to end, and the system can be evacuated. The first bulb is heated in a furnace (e.g. Büchi Kügelrohr micro distillation oven from Sigma-Aldrich Labware catalogue) at a high temperature whereby most of the material distils into the second bulb (which is outside of the furnace). The second bulb is then moved into the furnace and the furnace temperature is reduced by *ca* 5º whereby the liquid in the second bulb distils into the third bulb (at this stage the first bulb is now out at the back of the furnace, and the third and subsequent bulbs are outside the front of the furnace). The furnace temperature is lowered by a further *ca* 5º, and the third bulb is moved into the furnace. The lower boiling material will distil into the fourth bulb. The process is continued until no more material distils into the subsequent bulb. The vacuum (if applied) and the furnace are removed, the bulbs are separated and the various fractions of distillates are collected from the individual bulbs. For volatile liquids, it may be necessary to cool the receiving bulb with solid CO_2 held in a suitable container (a Kügelrohr distillation apparatus with an integrated cooling system is available). This procedure is used for preliminary purification and the distillates are then redistilled or recrystallised.

Isopiestic or isothermal distillation. This technique can be useful for the preparation of metal-free solutions of volatile acids and bases for use in trace metal studies. The procedure involves placing two beakers, one of distilled water and the other of a solution of the material to be purified, in a desiccator. The desiccator is sealed and left to stand at room temperature for several days. The volatile components distribute themselves between the two beakers whereas the non-volatile contaminants remain in the original beaker. This technique has afforded metal-free pure solutions of ammonia, hydrochloric acid and hydrogen fluoride.

RECRYSTALLISATION

Techniques

The most commonly used procedure for the purification of a solid material by recrystallisation from a solution involves the following steps:

(a) The impure material is dissolved in a suitable solvent, by shaking or vigorous stirring, at or near the boiling point, to form a near-saturated solution.
(b) The hot solution is filtered to remove any insoluble particles. To prevent crystallisation during this filtration, a heated filter funnel can be used, or the solution can be diluted with more of the solvent.
(c) The solution is then allowed to cool so that the dissolved substance crystallises out.
(d) The crystals are separated from the mother liquor, either by centrifuging or by filtering, under suction, through a sintered glass, a Hirsch or a Büchner, funnel. Usually, centrifugation is preferred because of the greater ease and efficiency of separating crystals and mother liquor, and also because of the saving of time and effort, particularly when very small crystals are formed or when there is entrainment of solvent.
(e) The crystals are washed free from mother liquor with a little fresh cold solvent, then dried.

If the solution contains extraneous coloured material likely to contaminate the crystals, this can often be removed by adding some activated charcoal (decolorising carbon) to the hot, but not boiling, solution which is then shaken frequently for several minutes before being filtered. (The large active surface of the carbon makes it a good adsorbent for this purpose.) In general, the cooling and crystallisation steps should be rapid so

as to give small crystals which occlude less of the mother liquor. This is usually satisfactory with inorganic material, so that commonly the filtrate is cooled in an ice-water bath while being vigorously stirred. In many cases, however, organic molecules crystallise much more slowly, so that the filtrate must be set aside to cool to room temperature or left in the refrigerator. It is often desirable to subject material that is very impure to preliminary purification, such as steam distillation, Soxhlet extraction, or sublimation, before recrystallising it. A greater degree of purity is also to be expected if the crystallisation process is repeated several times, especially if different solvents are used. The advantage of several crystallisations from different solvents lies in the fact that the material sought, and its impurities, are unlikely to have similar solubilities as solvents and temperatures are varied.

For the final separation of solid material, sintered-glass discs are preferable to filter paper. Sintered glass is unaffected by strongly acidic solutions or by oxidising agents. Also, with filter paper, cellulose fibres are likely to become included in the sample. The sintered-glass discs or funnels can be readily cleaned by washing in freshly prepared *chromic acid cleaning mixture*. This mixture is made by adding 100ml of concentrated sulfuric acid slowly with stirring to a solution of 5g of sodium dichromate (CARE: cancer suspect) in 5ml of water. (The mixture warms to about 70°, and sulfuric acid becomes hot when water is added to it; see p 3).

For materials with very low melting points it is sometimes convenient to use dilute solutions in acetone, methanol, pentane, diethyl ether or $CHCl_3/CCl_4$. The solutions are cooled to –78° in a dry-ice/acetone bath, to give a slurry which is filtered off through a precooled Büchner funnel. Experimental details, as applied to the purification of nitromethane, are given by Parrett and Sun [*J Chem Educ* **54** 448 *1977*].

Where substances vary little in solubility with temperature, *isothermal crystallisation* may sometimes be employed. This usually takes the form of a partial evaporation of a saturated solution at room temperature by leaving it under reduced pressure in a desiccator.

However, in rare cases, crystallisation is not a satisfactory method of purification, especially if the impurity forms crystals that are isomorphous with the material being purified. In fact, the impurity content may even be greater in such recrystallised material. For this reason, it still remains necessary to test for impurities and to remove or adequately lower their concentrations by suitable chemical manipulation prior to recrystallisation.

Filtration. Filtration removes particulate impurities rapidly from liquids and is also used to collect insoluble or crystalline solids which separate or crystallise from solution. The usual technique is to pass the solution, cold or hot, through a fluted filter paper in a conical glass funnel.

If a solution is hot and needs to be filtered rapidly, a Büchner funnel and flask are used and filtration is performed under a slight vacuum (water pump), the filter medium being a circular cellulose filter paper wet with solvent. If filtration is slow, even under high vacuum, a pile of about twenty filter papers, wet as before, are placed in the Büchner funnel and, as the flow of solution slows down, the upper layers of the filter paper are progressively removed. Alternatively, a filter aid, e.g. Celite, Florisil or Hyflo-supercel, is placed on top of a filter paper in the funnel. When the flow of the solution (under suction) slows down, the upper surface of the filter aid is scratched gently. Filter papers with various pore sizes are available covering a range of filtration rates. Hardened filter papers are slow filtering, but they can withstand acidic and alkaline solutions without appreciable hydrolysis of the cellulose (see Table 4). When using strong acids it is preferable to use glass micro fibre filters, which are commercially available (see Tables 4 and 5).

Freeing a solution from extremely small particles [e.g. for optical rotatory dispersion (ORD) or circular dichroism (CD) measurements] requires filters with very small pore size. Commercially available (Millipore, Gelman, Nucleopore) filters other than cellulose or glass include nylon, Teflon, and polyvinyl chloride, and the pore diameter may be as small as 0.01 micron (see Table 9). Special containers are used to hold the filters, through which the solution is pressed by applying pressure, e.g. from a syringe. Some of these filters can be used to clear strong sulfuric acid solutions.

As an alternative to the Büchner funnel for collecting crystalline solids, a funnel with a sintered glass-plate under suction may be used. Sintered-glass funnels with various porosities are commercially available and can be easily cleaned with warm chromic or nitric acid (see above).

When the solid particles are too fine to be collected on a filter funnel because filtration is extremely slow, separation by **centrifugation** should be used. Bench-type centrifuges are most convenient for this purpose. The solid is placed in the centrifuge tube, the tubes containing the solutions on opposite sides of the rotor should be balanced accurately (at least within 0.05 to 0.1g), and the solutions are spun at maximum speed for as long as it takes to settle the solid (usually *ca* 3–5 minutes). The solid is washed (by shaking) with cold solvent by centrifugation, and finally twice with a pure volatile solvent in which the solid is insoluble,also by centrifugation.

After decanting the supernatant, the residue is dried in a vacuum, at elevated temperatures if necessary. In order to avoid "spitting" and contamination with dust while the solid in the centrifuge tube is dried, the mouth of the tube is covered with aluminium foil and held fast with a tight rubber band near the lip. The flat surface of the aluminium foil is then perforated in several places with a pin, and the tube and contents are dried in a vacuum desiccator over a desiccant.

Solvents

Choice of solvents. The best solvents for recrystallisation have the following properties:

(a) The material is much more soluble at higher temperatures than it is at room temperature or below.
(b) Well-formed (but not large) crystals are produced.
(c) Impurities are either very soluble or only sparingly soluble.
(d) The solvent must be readily removed from the purified material.
(e) There must be no reaction between the solvent and the substance being purified.
(f) The solvent must not be inconveniently volatile or too highly flammable. (These are reasons why diethyl ether and carbon disulfide are not commonly used in this way.)

The following generalisations provide a rough guide to the selection of a suitable solvent:

(a) Substances usually dissolve best in solvents to which they are most closely related in chemical and physical characteristics. Thus, hydroxylic compounds are likely to be most soluble in water, methanol, ethanol, acetic acid or acetone. Similarly, petroleum ether might be used with water-insoluble substances. However, if the resemblance is too close, solubilities may become excessive.
(b) Higher members of homologous series approximate more and more closely to their parent hydrocarbon.
(c) Polar substances are more soluble in polar than in non-polar solvents.

Although Chapters 4, 5 and 7 provide details of the solvents used for recrystallising a large portion of commercially available laboratory chemicals, they cannot hope to be exhaustive, nor need they necessarily be the best choice, but they are the solvents reported in the literature. In other cases where it is desirable to use this process, it is necessary to establish whether a given solvent is suitable. This is usually done by taking only a small amount of material in a small test-tube and adding enough solvent to cover it. If it dissolves readily in the cold or on gentle warming, the solvent is unsuitable. Conversely, if it remains insoluble when the solvent is heated to boiling (adding more solvent if necessary), the solvent is again unsuitable. If the material dissolves in the hot solvent but does not crystallise readily within several minutes of cooling in an ice-salt mixture, another solvent should be tried.

Water

The properties and purification of water are described in the “Inorganic Compounds” section of Chapter 5. Fluka (Riedel-de Haën) supply purified water prepared specifically for a variety of uses, e.g. LC-MS, HPLC, gradient elution, for cell biology which is freed from enterotoxins by ultrafiltration and autoclaving, for organic and for inorganic trace analysis, for residue analysis and other analytical purposes. Some of these have been prepared by reverse osmosis, or ultrafiltration, under clean room conditions and filtered through 0.2 μm membranes into bottles of high purity glass under inert gas. They have a limited shelf life once opened most probably because O_2 from the air dissolves readily in the water. The solubility of O_2 in 100 ml of water is ~1.02 ml (0.455 mM) at 0°, 0.68 ml (0.282 mM) at 20°, 0.63 ml (0.258 mM) at 25°, 0.63 ml (0.237 mM) at 30°, and 0.12 ml (0.033 mM) at 100°, all at ~760 mmHg in equilibrium with air (see Tables 20–23). This is in comparison with the concentration of O_2 of 0.23 mM in 0.1M Tris HCl buffer at pH 7.2 and 25° in equilibrium with air at 760 mmHg. Routinely, water is best purified by redistilling it twice in an all glass apparatus, storing it under N_2 or He in stoppered glass containers and, if necessary, preferably subjected to ultrafiltration through a single or multistage 0.2 μm membrane system or reverse osmosis (visit <www.millipore.com>). If oxygen-free water is required, N_2 or argon should be bubbled through a sintered glass frit in the highly purified water for 2–3 hours, and stoppered immediately. It is best to use a glass container from which the water can be withdrawn without it coming into contact with air. Note that boiling and distilling water, and condensing it in an inert atmosphere should de-gas it.

Petroleum ethers are commercially available fractions of refined petroleum and are sold in fractions of about 20° boiling ranges. This ensures that little of the hydrocarbon ingredients boiling below the range is lost during standing or boiling when recrystallising a substance. Petroleum ethers with boiling ranges (at 760 mm pressure) of 35–60°, 40–60°, 60–80°, 80–100°, and 100–120° are generally free from unsaturated and aromatic hydrocarbons. The lowest boiling petroleum ether commercially available has **b** 30–40°/760 mm and is mostly *n*-pentane. The purer spectroscopic grades are almost completely free from olefinic and aromatic hydrocarbons. ***Petroleum spirit*** (which is sometimes used synonymously with petroleum ether or light petroleum) is usually less refined petroleum, and ***ligroin*** is used for fractions boiling above 100°. The lower boiling fractions consist of mixtures of *n*-pentane (**b** 36°), *n*-hexane (**b** 68.5°) and *n*-heptane (**b** 98°), and some of their isomers in varying proportions. For purification see petroleum ether b 35–60° in "Aliphatic Compounds", chapter 4, which is typical.

Solvents commonly used for recrystallisation, and their boiling points, are given in Table 6.
For comments on the toxicity and use of **benzene** see the "Introduction" pages of Chapters 4, 5 and 6.

Mixed Solvents. Where a substance is too soluble in one solvent and too insoluble in another, for either to be used for recrystallisation, it is often possible (provided the solvents are miscible) to use them as a mixed solvent system. (In general, however, it is preferable to use a single solvent if this is practicable.) Table 7 contains many of the common pairs of miscible solvents.
Several procedures with mixed solvents have been used successfully for crystallisation. These include the following:
(a) The material is dissolved in the solvent in which it is more soluble at room temperature, then the second solvent (heated to near boiling) is added cautiously to the cold solution until a slight turbidity persists or crystallisation begins. The turbidity is cleared by warming or by adding several drops of the first solvent, and the clear solution is allowed to cool slowly for crystallisation to occur. The supernatant is decanted off carefully (do not disturb the crystals unduly) and more of the second solvent is added to the clear decanted supernatant until turbidity begins again, and is set aside for further crystals to form. The procedure is repeated until no more crystals separate.
(b) A variation of the procedure in (a) is simply to precipitate the material in a microcrystalline form from solution in one solvent at room temperature, by adding a little more of the second solvent also at room temperature, filtering off the crystals, adding a little more of the second solvent and repeating the process. This ensures, at least in the first or last precipitation, a material which contains as little as possible of the impurities, which may also be precipitated in this way. With inorganic salts or metal salts of organic acids, the first solvent is commonly water, and the second solvent is alcohol or acetone. With salts of organic bases and inorganic acids, e.g. hydrochloride, or salts of organic acids and organic bases, the first solvent is usually an alcohol or acetone, in which the salt is very soluble and the second solvent is dry diethyl ether.
(c) A very concentrated solution of the compound in the first solvent in one beaker, and a second beaker containing the second solvent in which the compound is insoluble are placed in a desiccator. As the vapours of the two solvents equilibrate in the desiccator, and crystals separate in the first beaker that contains the compound.
(d) This procedure is best carried out in a cold room (at *ca* 4°). A strong solution of the solid in the solvent in which it is very soluble is *layered* carefully with the second solvent. As the second solvent diffuses and dissolves into the solution, crystals begin to form at the 'interface'. When separation of crystals is complete and the solvent mixture is homogeneous, another layer of the second solvent is applied and the process is repeated.
Seeding is well known to initiate the crystallisation process. A good way to procure seed crystals is to dissolve the crystals in the minimum amount of solvent, place the solution in a watch glass, then blow a fine stream of dry N_2 or argon gently over the surface of the solution until seed crystals are formed. Alternatively, the inert gas is allowed to evaporate all the solvent, and the residual crystals or fine powder are used for seeding. The seeds are applied in the above procedures at the appropriate time, e.g. when first turbidity appears, or placed onto the tip of a glass rod which is then rubbed against the sides of the container of the solution until crystallisation begins.

Recrystallisation from the melt

A crystalline solid melts when its temperature is raised sufficiently for the thermal agitation of its molecules or ions to overcome the restraints imposed by the crystal lattice. Usually, impurities weaken crystal structures, and hence lower the melting points of solids (or the freezing points of liquids). If an impure material is melted and cooled slowly (with the addition, if necessary, of a trace of solid material near the freezing point to avoid supercooling), the first crystals that form will usually contain less of the impurity, so that fractional solidification by partial freezing can be used as a purification process for solids with melting points lying in a convenient temperature range (or for more readily frozen liquids). Some examples of cooling baths that are

useful in recrystallisation are summarised in Table 8. In some cases, impurities form higher melting eutectics with substances to be purified, so that the first material to solidify is less pure than the melt. For this reason, it is often desirable to discard the first crystals and also the final portions of the melt. Substances having similar boiling points often differ much more in melting points, so that fractional solidification can offer real advantages, especially where ultrapurity is sought. For further information on this method of recrystallisation, consult the earlier editions of this book as well as references by Schwab and Wichers (*J Res Nat Bur Stand* **25** 747 *1940*). This method works best if the material is already nearly pure, and hence tends to be a final purification step.

Zone refining. Zone refining (or zone melting) is a particular development for fractional solidification and is applicable to all crystalline substances that show differences in the concentrations of impurities in liquid and solid states at solidification. The apparatus used in this technique consists essentially of a device in which the crystalline solid to be purified is placed in a glass tube (set vertically) which is made mechanically to move slowly upwards while it passes through a fixed coil (one or two turns) of heated wire. A narrow zone of molten crystals is formed when the tube is close to the heated coil. As the zone moves away from the coil the liquid crystallises, and a fresh molten zone is formed below it at the coil position. The machine can be set to recycle repeatedly. At its advancing side, the zone has a melting interface with the impure material whereas on the upper surface of the zone there is a constantly growing face of higher-melting, resolidified purer material. This leads to a progressive increase in impurity in the liquid phase which, at the end of the run, is discarded from the bottom of the tube. Also, because of the progressive increase in impurity in the liquid phase, the resolidified material contains correspondingly less of the impurites. For this reason, it is usually necessary to make several zone-melting runs before a sample is satisfactorily purified. This is also why the method works most successfully if the material is already fairly pure. In all these operations the zone must travel slowly enough to enable impurities to diffuse or be convected away from the area where resolidification is occurring.
The technique finds commercial application in the production of metals of extremely high purity (tubes other than glass are used in these cases, and impurities are reduced down to 10^{-9} ppm), in purifying refractory oxides, and in purifying organic compounds, using commercially available equipment. Criteria for indicating that definite purification is achieved include elevation of melting point, removal of colour, fluorescence or smell, and a lowering of electrical conductivity. Difficulties likely to be found with organic compounds, especially those of low melting points and low rates of crystallisation, are supercooling and, because of surface tension and contraction, the tendency of the molten zone to seep back into the recrystallised areas. The method is likely to be useful in cases where fractional distillation is not practicable, either because of unfavourable vapour pressures or ease of decomposition, or where super-pure materials are required. The method has been used for the latter purpose for purifying anthracene, benzoic acid, chrysene, morphine, 1,8-naphthyridine and pyrene to name a few. [See E.F.G. Herington, *Zone Melting of Organic Compound*s, Wiley & Sons, NY, 1963; W. Pfann, *Zone Melting*, 2nd edn, Wiley, NY, 1966; H. Schildknecht, *Zonenschmelzen*, Verlag Chemie, Weinheim, 1964; W.R. Wilcox, R.Friedenberg et al. *Chem Rev* **64** 187 *1964*; M. Zief and W.R. Wilcox (Eds), *Fractional Solidification*, Vol I, M Dekker Inc. NY, 1967.]

SUBLIMATION

Sublimation differs from ordinary distillation because the vapour condenses to a solid instead of a liquid. Usually, the pressure in the heated system is diminished by pumping, and the vapour is condensed (after travelling a relatively short distance) onto a cold finger or some other cooled surface. This technique, which is applicable to many organic solids, can also be used with inorganic solids such as aluminium chloride, ammonium chloride, arsenious oxide and iodine to name a few. In some cases, passage of a stream of inert gas over the heated substance secures adequate vaporisation and reduces oxidation. This procedure has the added advantage of removing occluded solvent used for recrystallising the solid.

CHROMATOGRAPHY

Chromatography is often used with advantage for the purification of small, and large, amounts of complex organic mixtures. Chromatography techniques all rely on the differential distribution of the various components in the solution, between the mobile phase and the stationary phase. The mobile phase can either be a gas or a liquid, whereas the stationary phase can either be a solid or a non-volatile liquid adsorbed on a solid surface.

The major chromatographic techniques can also be categorised according to the nature of the mobile phase used – vapour phase chromatography for when a gas is the mobile phase and liquid chromatography for when a liquid is the mobile phase.
The suppliers of chromatography equipment for every need are too numerous to list here but can be viewed on the internet under "Chromatography products". Details and orders can be obtained from the respective websites listed at the end of the section on HPLC below.

Vapour phase chromatography (GC or gas-liquid chromatography)

The mobile phase in vapour phase chromatography is a gas (e.g. hydrogen, helium, nitrogen or argon), and the stationary phase is a non-volatile liquid impregnated onto a porous material. The mixture to be purified is injected into a heated inlet whereby it is vaporised and taken into the column by the carrier gas. It is separated into its components by partition between the liquid on the porous support and the gas. For this reason vapour-phase chromatography is sometimes referred to as gas-liquid chromatography (g.l.c). Vapour phase chromatography is very useful for the resolution of a mixture of volatile compounds. This type of chromatography uses either packed or capillary columns. Packed columns have internal diameters of 3–5 mm with lengths of 2–6 metres. These columns can be packed with a range of materials including firebrick derived materials (chromasorb P, for separation of non-polar hydrocarbons) or diatomaceous earth (chromasorb W, for separation of more polar molecules such as acids, amines). Capillary columns have stationary phase bonded to the walls of long capillary tubes. The diameters of capillary columns are less than 0.5 mm, and the lengths of these columns can go up to 50 metres! These columns have much superior separating powers than the packed columns. Elution times for equivalent resolutions with packed columns can be up to ten times shorter. It is believed that almost any mixture of compounds can be separated using one of the four stationary phases, OV-101, SE-30, OV-17 and Carbowax-20M. Capillary columns for analysis in gas chromatography are now routinely used. An extensive range of packed and capillary columns is available from chromatographic specialists such as Supelco, Alltech, Hewlett-Packard, Phenomenex (for stainless steel capillary columns see <phenomenex.com>, etc. (see above and at the end of the section on HPLC below).
Table 9 shows some typical liquids used for stationary phases in gas chromatography.
Although gas chromatography is routinely used for the analysis of mixtures, this form of chromatography can also be used for separation/purification of substances. This is known as preparative GC. In preparative GC, suitably packed columns are used, and as substances emerge from the column, they are collected by condensing the vapour of these separated substances in suitable traps. The carrier gas blows the vapour through these traps; hence these traps have to be very efficient. Improved collection of the effluent vaporised fractions in preparative work is attained by strong cooling, increasing the surface of the traps by packing them with glass wool, and/or by applying an electrical potential which neutralises the charged vapour and causes it to condense.
When the gas chromatograph is attached to a mass spectrometer, a very powerful analytical tool (*gas chromatography-mass spectrometry*; **GC-MS**) is produced. Gas chromatography allows the separation of mixtures but does not allow the definitive identification of unknown substances, whereas mass spectrometry is good for the identification of individual compounds of the mixtures of compounds. This means that with GC-MS, both separation *and* identification of substances in mixtures can be achieved. The spectrometer can be connected to a computer that has a library from which the mass peaks can be compared and is a very powerful analytical tool. Because of the relatively small amounts of material required for mass spectrometry, a splitting system is inserted between the column and the mass spectrometer. This enables only a small fraction of the effluent to enter the spectrometer; the rest of the effluent is usually collected or vented to the air.
For more detail on apparatus and chromatographic columns see http://www.sigmaaldrich.com/analytical-chromatography/gas-chromatography.html and websites at the end of the section on HPLC below.

Liquid chromatography

In contrast to vapour phase chromatography, the mobile phase in liquid chromatography is a liquid. In general, there are four main types of liquid chromatography: *adsorption*, *partition*, *ion-chromatography*, and *gel filtration*.

Adsorption chromatography is based on the difference in the extent to which substances in solution are adsorbed onto a suitable surface. The main techniques in adsorption chromatography are TLC (thin layer chromatography), paper and column chromatography.

Thin layer chromatography **(TLC)**. In thin layer chromatography, the mobile phase, i.e. the solvent, creeps up the stationary phase (the absorbent) by capillary action. The adsorbent (e.g. silica, alumina, cellulose) is spread on a rectangular glass plate (or solid inert plastic sheet or aluminium foil). Some adsorbents (e.g. silica) are mixed with a setting material (e.g. $CaSO_4$) by the manufacturers which causes the film to set hard on drying. The adsorbent can be activated by heating at 100–110° for a few hours. Other adsorbents (e.g. celluloses) adhere on glass plates without a setting agent. Thus some grades of absorbents have prefixes; e.g. prefix G means that the absorbent can cling to a glass plate and is used for TLC (e.g. silica gel GF_{254} is for TLC plates which have a dye that fluoresces under 254nm UV light). Those lacking this binder have the letter H after any coding and is suitable for column chromatography e.g. silica gel 60H. The materials to be purified or separated are spotted in a solvent close to the lower end of the plate and allowed to dry. The spots will need to be placed at such a distance so as to ensure that when the lower end of the plate is immersed in the solvent, the spots are a few mm above the eluting solvent. The plate is placed upright in a tank containing the eluting solvent. Elution is carried out in a closed tank to ensure equilibrium. Good separations can be achieved with square plates if a second elution is performed at right angles to the first using a second solvent system. For rapid work, plates of the size of microscopic slides or even smaller are used which can decrease the elution time and cost without loss of resolution. The advantage of plastic backed and aluminium foil backed plates is that the size of the plate can be made as required by cutting the sheet with scissors or a sharp guillotine. Visualisation of substances on TLC can be carried out using UV light if they are UV absorbing or fluorescing substances or by spraying or dipping the plate with a reagent that gives coloured products with the substance (e.g. iodine solution or vapour gives brown colours with amines), or with dilute sulfuric acid (organic compounds become coloured or black when the plates are heated at 100° if the plates are of alumina or silica, but not cellulose). (See Table 10 for some methods of visualisation.) Some alumina and silica powders are available with fluorescent materials in them, in which case the whole plate fluoresces under UV light. Non-fluorescing spots are thus clearly visible, and fluorescent spots invariably fluoresce with a different colour. The colour of the spots can be different under UV light at 254 nm and at 365 nm. Another useful way of showing up non-UV absorbing spots is to spray the plate with a 1–2% solution of Rhodamine 6G in acetone. Under UV light the dye fluoresces and reveals the non-fluorescing spots. For preparative work, if the material in the spot or fraction is soluble in ether or petroleum ether, the desired substance can be extracted from the absorbent with these solvents which leave the water soluble dye behind.

TLC can be used as an analytical technique, or as a guide to establishing conditions for column chromatography or as a preparative technique in its own right.

The thickness of the absorbent on the TLC plates could be between 0.2 mm to 2 mm or more. In preparative work, the thicker plates are used and hundreds of milligrams of mixtures can be purified conveniently and quickly. The spots or areas are easily scraped off the plates and the desired substances extracted from the absorbent with the required solvent. For preparative TLC, non-destructive methods for visualising spots and fractions are required. As such, the use of UV light is very useful. If substances are not UV active, then a small section of the plate (usually the right or left edge of the plate) is sprayed with a visualising agent while the remainder of the plate is kept covered.

Thin layer chromatography has been used successfully with ion-exchange celluloses as stationary phases and various aqueous buffers as mobile phases. Also, gels (e.g. Sephadex G-50 to G-200 superfine) have been adsorbed on glass plates and are good for fractionating substances of high molecular weights (1500 to 250,000). With this technique, which is called *thin layer gel filtration* (**TLG**), molecular weights of proteins can be determined when suitable markers of known molecular weights are run alongside (see Chapter 6).

Commercially available pre-coated plates with a variety of adsorbents are generally very good for quantitative work because they are of a standard quality. Plates of a standardised silica gel 60 (as medium porosity silica gel with a mean porosity of 6 mm) released by Merck have a specific surface of 500 m^2/g and a specific pore volume of 0.75 ml/g. They are so efficient that they have been called *high performance thin layer chromatography* (**HPTLC**) plates (Ropphahn & Halpap *J Chromatogr* **112** 81 *1975*). In another variant of thin layer chromatography the adsorbent is coated with an oil as in gas chromatography thus producing *reverse-phase thin layer chromatography*. Reversed-phase TLC plates e.g. silica gel RP-18 are available from Fluka and Merck.

A very efficient form of chromatography makes use of a circular glass plate (rotor) coated with an adsorbent (silica, alumina or cellulose). As binding to a rotor is needed, the sorbents used may be of a special quality and/or binders are added to the sorbent mixtures. For example when silica gel is required as the absorbent, silica gel 60 PF-254 with calcium sulfate (Merck catalog 7749) is used. The thickness of the absorbent (1, 2 or 4mm) can vary depending on the amount of material to be separated. The apparatus used is called a **Chromatotron** (available from Harrison Research, USA). The glass plate is rotated by a motor, and the sample followed by the eluting solvent is allowed to drip onto a central position on the plate. As the plate rotates the solvent elutes the

mixture, centrifugally, while separating the components in the form of circular bands radiating from the central point. The separated bands are usually visualised conveniently by UV and as the bands approach the edge of the plate, the eluent is collected. The plate with the adsorbent can be re-used many times if care is employed in the usage, and hence this form of chromatography utilises less absorbents as well as solvents.
Recipes and instructions for coating the rotors are available from the Harrison website <http://www.harrisonresearch.com/chromatotron/>. In addition, information on how to regenerate the sorbents and binders is also included.

Paper chromatography. This is the technique from which thin layer chromatography was developed. It uses cellulose paper (filter paper) instead of the TLC adsorbent and does not require a backing like the plastic sheet in TLC. It is used in the **ascending procedure** (like in TLC) whereby a sheet of paper is hung in a jar, and the materials to be separated are spotted (after dissolving in a suitable solvent and drying) near the bottom of the sheet which dips into the eluting solvent just below the spots. As the solvent rises up the paper the spots are separated according to their adsorption properties. A variety of solvents can be used, the sheet is then dried in air (fume cupboard), and can then be run again with the solvent running at right angles to the first run to give a two-dimensional separation. The spots can then be visualised as in TLC or can be cut out and analysed as required. A **descending procedure** had also been developed where the material to be separated is spotted near the top of the paper and the top end is made to dip into a tray containing the eluting solvent. The whole paper is placed in a glass jar, and the solvent then runs down the paper causing the materials in the spots to separate also according to their adsorption properties and to the eluting ability of the solvent. This technique is much cheaper than TLC and is still used (albeit with thicker cellulose paper) with considerable success for the separation of protein hydrolysates for sequencing analysis and/or protein identification. However, modern and more efficient technologies are available for analysing proteins and their hydrolysates although the equipment is expensive. (Whatman papers for chromatography and electrophoresis are available also from Sigma-Aldrich Labware.)

Column Chromatography. The substances to be purified are usually placed on the top of the column and the solvent is run down the column. Fractions are collected and checked for compounds using TLC (UV and/or other means of visualisation). The adsorbent for chromatography can be packed dry and solvents to be used for chromatography are used to equilibrate the adsorbent by flushing the column several times until equilibration is achieved. Alternatively, the column containing the adsorbent is packed wet (slurry method), and pressure is applied at the top of the column until the column is well packed (i.e. the adsorbent is settled).

Graded Adsorbents and Solvents. Some materials used in columns for adsorption chromatography are grouped in Table 11 in an approximate order of effectiveness. Other adsorbents sometimes used include barium carbonate, calcium sulfate, calcium phosphate, charcoal (usually mixed with Kieselguhr or other form of diatomaceous earth, for example, the filter aid Celite) and cellulose. The alumina can be prepared in several grades of activity (see below).
In most cases, adsorption takes place most readily from non-polar solvents such as petroleum ether and least readily from polar solvents such as alcohols, esters, and acetic acid. Common solvents, arranged in approximate order of increasing eluting ability are also given in Table 11. Eluting power roughly parallels the dielectric constants of solvents. The series also reflects the extent to which the solvent binds to the column material, thereby displacing the substances that are already adsorbed. This preference of alumina and silica gel for polar molecules explains, for example, the use of percolation through a column of silica gel for the following purposes-drying of ethylbenzene, removal of aromatics from 2,4-dimethylpentane and of ultraviolet absorbing substances from cyclohexane.
Mixed solvents are intermediate in strength, and so provide a finely graded series. In choosing a solvent for use as an eluent it is necessary to consider the solubility of the substance in it and the ease with which it can subsequently be removed.

Preparation and Standardisation of Alumina. The activity of alumina depends inversely on its water content, and a sample of poorly active material can be rendered more active by leaving for some time in a round bottomed flask heated up to about 200^{o} in an oil bath or a heating mantle while a slow stream of a dry inert gas is passed through it. *Alternatively*, it is heated to red heat (380–400^{o}) in an open vessel for 4–6 hours with occasional stirring and then cooled in a vacuum desiccator: this material is then of grade I activity. Conversely, alumina can be rendered less active by adding small amounts of water and thoroughly mixing for several hours. Addition of about 3% (w/w) of water converts grade I alumina to grade II.

Used alumina can be regenerated by repeated extraction, first with boiling methanol, then with boiling water, followed by drying and heating. The degree of activity of the material can be expressed conveniently in terms of the scale due to Brockmann and Schodder (*Chem Ber* B **74** 73 *1941*).

Alumina is normally slightly alkaline. A (less strongly adsorbing) neutral alumina can be prepared by making a slurry in water and adding 2M hydrochloric acid until the solution is acid to Congo red. The alumina is then filtered off, washed with distilled water until the wash water gives only a weak violet colour with Congo red paper, and dried.
Alumina used in TLC can be recovered by washing in ethanol for 48 hours with occasional stirring, to remove binder material and then washed with successive portions of ethyl acetate, acetone and finally with distilled water. Fine particles are removed by siphoning. The alumina is first suspended in 0.04M acetic acid, then in distilled water, siphoning off 30 minutes after each wash. The process is repeated 7–8 times. It is then dried and activated at 200° [Vogh & Thomson *Anal Chem* **53** 1365 *1981*].

Preparation of other adsorbents

Silica gel can be prepared from commercial water-glass by diluting it with water to a density of 1.19 and, while keeping it cooled to 5°, adding concentrated hydrochloric acid with stirring until the solution is acid to thymol blue. After standing for 3 hours, the precipitate is filtered off, washed on a Büchner funnel with distilled water, then suspended in 0.2M hydrochloric acid. The suspension is set aside for 2–3 days, with occasional stirring, then filtered, washed well with water and dried at 110°. It can be activated by heating up to about 200° as described for alumina.
Powdered commercial silica gel can be purified by suspending and standing overnight in concentrated hydrochloric acid (6 ml/g), decanting the supernatant and repeating with fresh acid until the latter remains colourless. After filtering with suction on a sintered-glass funnel, the residue is suspended in water and washed by decantation until free of chloride ions. It is then filtered, suspended in 95% ethanol, filtered again and washed on the filter with 95% ethanol. The process is repeated with anhydrous diethyl ether before the gel is heated for 24 hours at 100° and stored for another 24 hours in a vacuum desiccator over phosphorus pentoxide.
To buffer silica gel for flash chromatography (see later), 200g of silica is stirred in 1L of 0.2M NaH_2PO_4 for 30 minutes. The slurry is then filtered with suction using a sintered glass funnel. The silica gel is then activated at 110°C for 16 hours. The pH of the resulting silica gel is ~4. Similar procedures can be utilised to buffer the pH of the silica gel at various pHs (up to pH ~8: pH higher than this causes degradation of silica) using appropriate phosphate buffers.
Commercial silica gel has also been purified by suspension of 200g in 2L of 0.04M ammonia, and stood for 5minutes before siphoning off the supernatant. The procedure was repeated 3–4 times, before rinsing with distilled water and drying, and activating the silica gel in an oven at 110° [Vogh & Thomson, *Anal Chem* **53** 1345 *1981*].
Although silica gel is not routinely recycled after use (due to fear of contamination as well as the possibility of reduced activity), the costs of using new silica gel for purification may be prohibitive. In these cases, recycling may be achieved by stirring the used silica gel (1 kg) in a mixture of methanol and water (2L MeOH/4L water) for 30–40 minutes. The silica gel is filtered (as described above) and reactivated at 110°C for 16 hours.

Diatomaceous earth (Celite 535 or 545, Hyflo Super-cel, Dicalite, Kieselguhr) is purified before use by washing with 3M hydrochloric acid, then water, or it is made into a slurry with hot water, filtered at the pump and washed with water at 50° until the filtrate is no longer alkaline to litmus. Organic materials can be removed by repeated extraction at 50° with methanol or chloroform, followed by washing with methanol, filtering and drying at 90-100°.

Charcoal is generally satisfactorily activated by heating gently to red heat in a crucible or quartz beaker in a muffle furnace, finally allowing to cool under an inert atmosphere in a desiccator. Good commercial activated charcoal is made from wood, e.g. *Norit* (from Birch wood), *Darco* and *Nuchar*. If the cost is important, then the cheaper *animal charcoal* (bone charcoal) can be used. However, this charcoal contains calcium phosphate and other calcium salts and cannot be used with acidic materials. In this case the charcoal is boiled with dilute hydrochloric acid (1:1 by volume) for 2–3 hours, diluted with distilled water and filtered through a fine grade paper on a Büchner flask, washed with distilled water until the filtrate is almost neutral, and dried first in air, then in a vacuum, and activated as above. To improve the porosity, charcoal columns are usually prepared in admixture with diatomaceous earth.

Cellulose for chromatography is purified by sequential washing with chloroform, ethanol, water, ethanol, chloroform and acetone. More extensive purification uses aqueous ammonia, water, hydrochloric acid, water, acetone and diethyl ether, followed by drying in a vacuum. Trace metals can be removed from filter papers by washing for several hours with 0.1M oxalic, citric acid, or 0.1M EDTA solution, followed by repeated washing with distilled water.

Supelco supply a variety of "solvent desorption tubes", which are cartridges that remove specific impurities (e.g. LpDNPH cartridges which contain a high purity silica adsorbent coated with 2,4-dinitrophenylhydrazine and remove carbonyl compounds; ozone scrubbers which eliminate ozone). Other cartridges such as the "ORBO charcoal" cartridges contain various beds such as *activated coconut charcoal, activated petroleum charcoal, HBr on petroleum charcoal or 4-tert-butyl catechol on charcoal* and are used for specific or for general purposes. Other ORBO cartridges contain activated silica gel and coated silica gel, Florisil, Carboxen, Carbosieve and carbon-coated traps, as well as a variety of ORBO porous polymers, polyurethane, and glass fibre coated with 1-(2-pyridyl)piperazine (which is specific for sampling diisocyanates). They also supply filter cartridges for trapping aerosols and particulate forms of semivolatiles.

Flash Chromatography (FC and HPFC)

A faster method of separating components of a mixture is *flash chromatography* (see Still et al. *J Org Chem* **43** 2923 *1978*). Flash chromatography has become an extremely useful and popular means of purification of small as well as large quantities of compounds. In flash chromatography the eluent flows through the column under a pressure of *ca* 1 to 4 atmospheres. The lower end of the chromatographic column has a relatively long taper closed with a tap. The upper end of the column is connected through a ball joint to a tap. Alternatively a specially designed chromatographic column with a solvent reservoir can also be used (for an example, see the Aldrich Chemical Catalog-glassware section). The tapered portion is plugged with cotton, or quartz, wool and *ca* 1 cm length of fine washed sand (the latter is optional). The adsorbent is then placed in the column as a dry powder or as a slurry in a solvent and allowed to fill to about one-third of the column. A fine grade of adsorbent is required in order to slow the flow rate at the higher pressure, e.g. Silica 60, 230 to 400 mesh with particle size 0.040-0.063mm (e.g. from Merck). The top of the adsorbent is layered with *ca* 1 cm length of fine washed sand. The mixture in the smallest volume of solvent is applied at the top of the column and allowed to flow into the adsorbent under gravity by opening the lower tap momentarily. The top of the column is filled with eluent, the upper tap is connected by a tube to a nitrogen supply from a cylinder, or to compressed air, and turned on to the desired pressure (monitor with a gauge). The lower tap is turned on and fractions are collected rapidly until the level of eluent has reached the top of the adsorbent (do not allow the column to run dry). If further elution is desired then both taps are turned off, the column is filled with more eluting solvent and the process repeated. The top of the column can be modified so that gradient elution can be performed. Alternatively, an apparatus for producing the gradient is connected to the upper tap by a long tube and placed high above the column in order to produce the required hydrostatic pressure. Much better resolution is obtained by dry loading the sample for purification rather than loading the sample as a solution. Flash chromatography is more efficient and gives higher resolution than conventional chromatography at atmospheric pressure and is completed in a relatively shorter time. A successful separation of components of a mixture by TLC using the same adsorbent is a good indication that flash chromatography will give the desired separation on a larger scale.

Very elaborate equipment is now available for FC and HPFC (high-performance flash chromatography), which may include a pump, facility for gradient elution, UV detection and fraction collection of effluent. A large variety of columns (disposable cartridges) with packings such as silicate, carbon, reverse phases for a wide range of applications are commercially available. In addition a plethora of cartridges are available for preliminary purification, prior to FC or HPFC, packed with adsorbents which can remove specific impurities, e.g. unwanted reaction products such as aldehydes or ketone which may be suspected by-products and/or starting materials See

Biotage: *Synthesis and Purification* Catalogue and the *Analytical Sample Preparation* Catalogue contain details on available FC and HPFC equipment, accessories and consumables, as well as means of optimising purification, see <www.biotage.com>.

Paired-ion Chromatography (PIC)

Mixtures containing ionic compounds (e.g. acids and/or bases), non-ionisable compounds, and zwitterions can be separated successfully by paired-ion chromatography (PIC). It utilises the "reverse-phase" technique (Eksberg & Schill *Anal Chem* **45** 2092 *1973*). The stationary phase is lipophilic, such as μ-BONDAPAK C_{18} or any other adsorbent that is compatible with water. The mobile phase is water or aqueous methanol containing the acidic or basic counter ion. Thus the mobile phase consists of dilute solutions of strong acids (e.g. 5mM

1-heptanesulfonic acid) or strong bases (e.g. 5 mM tetrabutylammonium phosphate) that are completely ionised at the operating pH values which are usually between 2 and 8. An equilibrium is set up between the neutral species of a mixture in the stationary phase and the respective ionised (anion or cation) species which dissolve in the mobile phase containing the counter ions. The extent of the equilibrium will depend on the ionisation constants of the respective components of the mixture, and the solubility of the unionised species in the stationary phase. Since the ionisation constants and the solubility in the stationary phase will vary with the water-methanol ratio of the mobile phase, the separation may be improved by altering this ratio gradually (gradient elution) or stepwise. If the compounds are eluted too rapidly, the water content of the mobile phase should be increased, e.g. by steps of 10%. Conversely, if components do not move, or move slowly, the methanol content of the mobile phase should be increased by steps of 10%.

The application of pressure to the liquid phase in liquid chromatography generally increases the separation (see HPLC). In PIC also, improved efficiency of the column is observed if pressure is applied to the mobile phase (Wittmer et al. *Anal Chem* **47** 1422 *1975*). [See the Fluka (Riedel-deHaën) catalogue and Supelco catalogue, <http://sigma-aldrich.dirxion.com/WebProject.asp?BookCode=chr09flx#> for IPC reagents for the separation of cations and anions,]

Ion-exchange Chromatography

Ion-exchange chromatography involves an electrostatic process which depends on the relative affinities of various types of ions for an immobilised assembly of ions of opposite charge. The mobile phase is an aqueous buffer with a fixed pH or an aqueous mixture of buffers in which the pH is continuously increased or decreased as the separation may require. This form of liquid chromatography can also be performed at high inlet pressures of liquid with increased column performances.

Ion-exchange Resins. An ion-exchange resin is made up of particles of an insoluble elastic hydrocarbon network to which is attached a large number of ionisable groups. Materials commonly used comprise synthetic ion-exchange resins made, for example, by crosslinking polystyrene to which has been attached non-diffusible ionised or ionisable groups. Resins with relatively high crosslinkage (8–12%) are suitable for the chromatography of small ions, whereas those with low cross linkage (2–4%) are suitable for larger molecules. Applications to hydrophobic systems are possible using aqueous gels with phenyl groups bound to the rigid matrix (Phenyl-Superose/Sepharose, Pharmacia-Amersham Biosciences) or neopentyl chains (Alkyl-Superose, Pharmacia-Amersham Biosciences). (Superose is a cross-linked agarose-based medium with an almost uniform bead size.) These groups are further distinguishable as strong [$-SO_2OH$, $-NR_3^+$] or weak [$-OH$, $-CO_2H$, $-PO(OH)_2$, $-NH_2$]. Their charges are counterbalanced by diffusible ions, and the operation of a column depends on its ability and selectivity to replace these ions. The exchange that takes place is primarily an electrostatic process but adsorptive forces and hydrogen bonding can also be important. A typical sequence for the relative affinities of some common anions (and hence the inverse order in which they pass through such a column) is the following, obtained using a quaternary ammonium (strong base) anion-exchange column:

Fluoride < acetate < bicarbonate < hydroxide < formate < chloride < bromate < nitrite < cyanide < bromide < chromate < nitrate < iodide < thiocyanate < oxalate < sulfate < citrate.

For an amine (weak base) anion-exchange column in its chloride form, the following order has been observed:

Fluoride < chloride < bromide = iodide = acetate < molybdate < phosphate < arsenate < nitrate < tartrate < citrate < chromate < sulfate < hydroxide.

With strong cation-exchangers (e.g. with SO_3H groups), the usual sequence is that polyvalent ions bind more firmly than mono- or di- valent ones, a typical series being as follows:

$Th^{4+} > Fe^{3+} > Al^{3+} > Ba^{2+} > Pb^{2+} > Sr^{2+} > Ca^{2+} > Co^{2+} > Ni^{2+} = Cu^{2+} > Zn^{2+} = Mg^{2+} > UO_2^{+} = Mn^{2+} > Ag^{+} > Tl^{+} > Cs^{+} > Rb^{+} > NH_4^{+} = K^{+} > Na^{+} > H^{+} > Li^{+}$.

Thus, if an aqueous solution of a sodium salt contaminated with heavy metals is passed through the sodium form of such a column, the heavy metal ions will be removed from the solution and will be replaced by sodium ions from the column. This effect is greatest in dilute solution. Passage of sufficiently strong solutions of alkali metal salts or mineral acids readily displaces all other cations from ion-exchange columns. (The regeneration of columns depends on this property.) However, when the cations lie well to the left in the above series it is often advantageous to use a complex-forming species to facilitate removal. For example, iron can be displaced from ion-exchange columns by passage of sodium citrate or sodium ethylenediaminetetraacetate.

Some of the more common commercially available resins are listed in Table 12.
Ion-exchange resins swell in water to an extent which depends on the amount of crosslinking in the polymer, so that columns should be prepared from the wet material by adding it as a suspension in water to a tube already partially filled with water. (This also avoids trapping air bubbles.) The exchange capacity of a resin is commonly expressed as mg equiv/ml of wet resin. This quantity is pH-dependent for weak-acid or weak-base resins but is constant at about 0.6–2 for most strong-acid or strong-base types.
Apart from their obvious applications to inorganic species, sulfonic acid resins have been used in purifying amino acids, aminosugars, organic acids, peptides, purines, pyrimidines, nucleosides, nucleotides and polynucleotides. Thus, organic bases can be applied to the H^+ form of such resins by adsorbing them from neutral solution and, after washing with water, they are eluted sequentially with suitable buffer solutions or dilute acids. Alternatively, by passing alkali solution through the column, the bases will be displaced in an order that is governed by their pK values. Similarly, strong-base anion exchangers have been used for aldehydes and ketones (as bisulfite addition compounds), carbohydrates (as their borate complexes), nucleosides, nucleotides, organic acids, phosphate esters and uronic acids. Weakly acidic and weakly basic exchange resins have also found extensive applications, mainly in resolving weakly basic and acidic species. For demineralisation of solutions without large changes in pH, mixed-bed resins can be prepared by mixing a cation-exchange resin in its H^+ form with an anion-exchange resin in its OH– form. Commercial examples include Amberlite MB-1 (IR-120 + IRA-400) and Bio-Deminrolit (Zeo-Karb 225 and Zerolit FF). The latter is also available in a self-indicating form.

Ion-exchange Celluloses and Sephadex. A different type of ion-exchange column that finds extensive application in biochemistry for the purification of proteins, nucleic acids and acidic polysaccharides derives from cellulose by incorporating acidic and basic groups to give ion-exchangers of controlled acid and basic strengths. Commercially available cellulose-type resins are listed in Tables 13 and 14. AG 501 x 8 (Bio-Rad) is a mixed-bed resin containing equivalents of AG 50W-x8 H^+ form and AG 1-x8 HO^- form, and Bio-Rex MSZ 501 resin. A dye marker indicates when the resin is exhausted. Removal of unwanted cations, particularly of the transition metals, from amino acids and buffer can be achieved by passage of the solution through a column of Chelex 20 or Chelex 100. The metal-chelating abilities of the resin reside in the bonded iminodiacetate groups. Chelex can be regenerated by washing in two bed volumes of 1M HCl, two bed volumes of 1M NaOH and five bed volumes of water.
Ion-exchange celluloses are available in different particle sizes. It is important that the amounts of ‘fines’ are kept to a minimum otherwise the flow of liquid through the column can be extremely slow to the point of no liquid flow. Celluloses with a large range of particle sizes should be freed from 'fines' before use. This is done by suspending the powder in the required buffer and allowing it to settle for one hour and then decanting the ‘fines’. This separation appears to be wasteful, but it is necessary for reasonable flow rates without applying high pressures at the top of the column. Good flow rates can be obtained if the cellulose column is packed dry whereby the ‘fines’ are evenly distributed throughout the column. Wet packing causes the ‘fines’ to rise to the top of the column, which thus becomes clogged.
Several ion-exchange celluloses require recycling before use, a process which must be applied for recovered celluloses. Recycling is done by stirring the cellulose with 0.1M aqueous sodium hydroxide, washing with water until neutral, then suspending in 0.1M hydrochloric acid and finally washing with water until neutral. When regenerating a column it is advisable to wash with a salt solution (containing the required counter ions) of increasing ionic strength up to 2M. The cellulose is then washed with water and recycled if necessary. Recycling can be carried out more than once if there are doubts about the purity of the cellulose and when the cellulose had been used previously for a different purification procedure than the one to be used. The basic matrix of these ion-exchangers is cellulose and it is important not to subject them to strong acid (> 1M) and strongly basic (> 1M) solutions.
When storing ion-exchange celluloses, or during prolonged usage, it is important to avoid growth of microorganisms or moulds which slowly destroy the cellulose. Good inhibitors of microorganisms are phenyl mercuric salts (0.001%, effective in weakly alkaline solutions), chlorohexidine (Hibitane at 0.002% for anion exchangers), 0.02% aqueous sodium azide or 0.005% of ethyl mercuric thiosalicylate (Merthiolate); these are most effective in weakly acidic solutions for cation exchangers. Trichlorobutanol (Chloretone, at 0.05% is only effective in weakly acidic solutions) can be used for both anion and cation exchangers. Most organic solvents (e.g. methanol) are effective antimicrobial agents but only at high concentrations. These inhibitors must be

removed by washing the columns thoroughly before use because they may have adverse effects on the material to be purified (e.g. inactivation of enzymes or other active preparations).

Sephadex. Other carbohydrate matrices such as *Sephadex* are a bead form of cross-linked gels (based on dextran) which have more uniform particle sizes. Their advantages over the celluloses include faster and more reproducible flow rates and they can be used directly without removal of 'fines'. *Sephadex*, which can also be obtained in a variety of ion-exchange forms (see Table 14) consists of beads of a cross-linked dextran gel which swells in water and aqueous salt solutions. The smaller the bead size, the higher the resolution that is possible but the slower the flow rate. Typical applications of Sephadex gels are the fractionation of mixtures of polypeptides, proteins, nucleic acids, polysaccharides and for desalting solutions.
Sephadex ion-exchangers, unlike celluloses, are available in narrow ranges of particle sizes. These are of two medium types**,** the G-25 and G-50, and their dry bead diameter sizes are *ca* 50 to 150 microns. They are available as cation and anion exchange Sephadex. One of the disadvantages of using Sephadex ion-exchangers is that the bed volume can change considerably with alteration of pH. *Ultragels* also suffer from this disadvantage to a varying extent, but ion-exchangers of the bead type have been developed e.g. *Fractogels, Toyopearl*, which do not suffer from this disadvantage.

Sepharose (e.g. *Sepharose CL and Bio-Gel A*) is a bead form of agarose gel which is useful for the fractionation of high molecular weight substances, for molecular weight determinations of large molecules (molecular weight > 5000), and for the immobilisation of enzymes, antibodies, hormones and receptors usually for affinity chromatography applications.

In preparing any of the above for use in columns, the dry powder is evacuated, then mixed under reduced pressure with water or the appropriate buffer solution. Alternatively it is stirred gently with the solution until all air bubbles are removed. Because some of the wet powders change volumes reversibly with alteration of pH or ionic strength (see above), it is imperative to make allowances when packing columns (see above) in order to avoid overflowing of packing when the pH or salt concentrations are altered.

Cellex CM ion-exchange cellulose can be purified by treatment of 30–40g (dry weight) with 500ml of 1mM cysteine hydrochloride. It is then filtered through a Büchner funnel and the filter cake is suspended in 500ml of 0.05M NaCl/0.5M NaOH. This is filtered and the filter cake is resuspended in 500ml of distilled water and filtered again. The process is repeated until the washings are free from chloride ions. The filter cake is again suspended in 500ml of 0.01M buffer at the desired pH for chromatography, filtered, and the last step repeated several times.

Cellex D and other anionic celluloses are washed with 0.25M NaCl/0.25M NaOH solution, then twice with deionised water. This is followed with 0.25M NaCl and then washed with water until chloride-free. The *Cellex* is then equilibrated with the desired buffer as above.

Crystalline Hydroxylapatite is a structurally organised, highly polar material which, in aqueous solution (in buffers) strongly adsorbs macromolecules such as proteins and nucleic acids, permitting their separation by virtue of the interaction with charged phosphate groups and calcium ions, as well by physical adsorption. The procedure therefore is not entirely ion-exchange in nature. Chromatographic separations of singly and doubly stranded DNA are readily achievable, whereas there is negligible adsorption of low-molecular-weight species.

Gel Filtration

The gel-like, bead nature of wet Sephadex enables small molecules such as inorganic salts to diffuse freely into it while, at the same time, protein molecules are unable to do so. Hence, passage through a Sephadex column can be used for complete removal of salts from protein solutions. Polysaccharides can be freed from monosaccharides and other small molecules because of their differential retardation. Similarly, amino acids can be separated from proteins and large peptides.
Gel filtration using Sephadex G-types (50 to 200) is essentially useful for fractionation of large molecules with molecular weights above 1000. For Superose, the range is given as 5000 to 5 x 10^6. Fractionation of lower molecular weight solutes (e,g, ethylene glycols, benzyl alcohols) can now be achieved with Sephadex G-10 (up to Mol.Wt 700) and G-25 (up to Mol.Wt 1500). These dextrans are used only in aqueous solutions. In contrast, Sephadex LH-20 and LH-60 (prepared by hydroxypropylation of Sephadex) are used for the separation of small molecules (Mol.Wt less than 500) using most of the common organic solvents as well as water.
Sephasorb HP (ultrafine, prepared by hydroxypropylation of crossed-linked dextran) can also be used for the separation of small molecules in organic solvents and water, and in addition it can withstand pressures up to

1400 psi making it useful in HPLC. These gels are best operated at pH values between 2 and 12, because solutions with high and low pH values slowly decompose them (see further in Chapter 7).
Supelco (see catalogue) supply a variety of SUPELCOGEL columns (for small molecule separations), TSK-GEL columns (for large molecules separation) and guard columns for gel permeation chromatography. They have columns of the latter type (e.g. TSL-GEL column G4000SW) which can separate globular proteins of 20–10,000 x 10^3 Daltons in molecular weight. They also supply "Ascentis HPLC Applications CDs" containing a comprehensive library of their columns and possible applications.

High Performance Liquid Chromatography (HPLC)

When pressure is applied at the inlet of a liquid chromatographic column the performance of the column can be increased by several orders of magnitude. This is partly because of the increased speed at which the liquid flows through the column and partly because fine column packings which have larger surface areas can be used. Because of the improved efficiency of the columns, this technique has been referred to as high performance, high pressure, or high speed liquid chromatography and has found great importance in chemistry and biochemistry.

The equipment consists of a hydraulic system to provide the pressure at the inlet of the column, a column, a detector, data storage and output, usually in the form of a computer. The pressures used in HPLC vary from a few psi to 4000–5000 psi. The most convenient pressures are, however, between 500 and 1800psi. The plumbing is made of stainless steel or non-corrosive metal tubing to withstand high pressures. Plastic tubing and connectors are used for low pressures, e.g. up to ~500psi. Increase of temperature has a very small effect on the performance of a column in liquid chromatography. Small variations in temperatures, however, do upset the equilibrium of the column, hence it is advisable to place the column in an oven at ambient temperature in order to achieve reproducibility. The packing (stationary phase) is specially prepared for withstanding high pressures. It may be an adsorbent (for adsorption or solid-liquid HPLC), a material impregnated with a high boiling liquid (e.g. octadecyl sulfate, in *reverse-phase* or *liquid-liquid or paired-ion* HPLC), an ion-exchange material (in *ion-exchange* HPLC), or a highly porous non-ionic gel (for high performance *gel filtration* or *permeation*). The mobile phase is water, aqueous buffers, salt solutions, organic solvents or mixtures of these.

Detectors

The more commonly used detectors for column chromatography in general have UV, visible, diode array or fluorescence monitoring for light absorbing substances in the effluent, and refractive index monitoring and evaporative light scattering for transparent compounds in the effluent. UV detection is not useful when molecules do not have UV absorbing chromophores, and solvents for elution should be carefully selected when UV monitoring is used so as to ensure the lack of background interference in detection. The sensitivity of the refractive index monitoring is usually lower than the light absorbing monitoring by a factor of ten or more. It is also difficult to use a refractive index monitoring system with gradient elution of solvents. When substances have readily oxidised and reduced forms, e.g. phenols, nitro compounds, heterocyclic compounds etc. then electrochemical detectors are useful. These detectors oxidise and/or reduce these substances and make use of this process to provide a peak on the recorder.
The cells of the monitoring devices are very small (*ca* 5 µl) and the detection is very good. The volumes of the analytical columns are quite small (*ca* 2ml for a 1 metre column); hence the result of an analysis is achieved very quickly. Larger columns have been used for preparative work and can be used with the same equipment. Most machines have solvent mixing chambers for solvent gradient or ion gradient elution. The solvent gradient (for two solvents) or pH or ion gradient can be adjusted in a linear, increasing or decreasing exponential manner. Splitters can be used, whereby very small volumes of the effluent are directed through the detectors so that the whole effluent does not pass through the detector.

Columns for HPLC

In general two different types of HPLC columns are available. Prepacked columns are those with metal casings with threads at both ends onto which capillary connections are attached. The cartridge HPLC columns are cheaper and are used with cartridge holders. As the cartridge is fitted with a groove for the holding device, no threads are necessary and the connection pieces can be reused.
A large range of HPLC columns (including guard columns, i.e. small pre-columns) are available from Supelco < http://sigma-aldrich.dirxion.com/WebProject.asp?BookCode=chr09flx# >, Waters <www.waters.com>, Agilent Technologies <www.chem.agilent.com>, Phenomenex <www.phenomenex.com>, YMC <www.ymc.co.jp/en/>, Merck <www.merck.de>, SGE <www.sge.com>, GE Healthcare

<www.gehealthcare.com>, and other leading companies. It is not possible to list the range of columns here that are commercially available because the numbers are too large and include prepared columns for the type of chromatography described below in the *Other Types of Liquid Chromatography* such as Monolithic Chromatography and UPLC (see below). Also, in this range of columns are columns with chiral bonded phases capable of separating enantiomeric mixtures. The number of these, on the other hand, is relatively smaller and some *chiral* columns are listed in Table 15.

Other Types of Liquid Chromatography

New stationary phases for specific purposes in chromatographic separation are being continually developed. *Charge transfer adsorption chromatography* makes use of a stationary phase which contains immobilised aromatic compounds and permits the separation of aromatic compounds by virtue of the ability to form charge transfer complexes (sometimes coloured) with the stationary phase. The separation is caused by the differences in stability of these complexes (Porath and Dahlgren-Caldwell *J Chromatogr* **133** 180 *1977*).

In *metal chelate adsorption chromatography* a metal is immobilised by partial chelation on a column which contains bi- or tri- dentate ligands. Its application is in the separation of substances which can complex with the bound metals and depends on the stability constants of the various ligands (Porath et al. *Nature* **258** 598 *1975*; Loennerdal et al. *FEBS Lett* **75** 89 *1977*).

An application of chromatography which has found extensive use in biochemistry and has brought a new dimension in the purification of enzymes is *affinity chromatography*. A specific enzyme inhibitor is attached by covalent bonding to a stationary phase (e.g. AH-Sepharose 4B for acidic inhibitors and CH-Sepharose 4B for basic inhibitors, Phenyl-Sepharose for hydrophobic proteins), and will strongly bind only the specific enzyme which is inhibited or preferentially bound, allowing all other proteins to flow through the column. The enzyme is then eluted with a solution of high ionic strength (e.g. 1M sodium chloride) or a solution containing a substrate or reversible inhibitor of the specific enzyme. (The ionic medium can be removed by gel filtration using a mixed-bed gel.) Similarly, an immobilised lectin may interact with the carbohydrate moiety of a glycoprotein. The most frequently used matrixes are cross-linked (4-6%) agarose and polyacrylamide gel. Many adsorbents are commercially available for nucleotides, coenzymes and vitamins, amino acids, peptides, lectins and related macromolecules and immunoglobulins. Considerable purification can be achieved by one passage through the column and the column can be reused several times.

The affinity method may be *biospecific*, for example as an antibody-antigen interaction, or chemical as in the chelation of boronate by *cis*-diols, or of unknown origin as in the binding of certain dyes to albumin and other proteins.

Hydrophobic adsorption chromatography takes advantage of the hydrophobic properties of substances to be separated and has also found use in biochemistry (Hoftsee *Biochem Biophys Res Commun* **50** 751 *1973*; Jennissen & Heilmayer Jr *Biochemistry* **14** 754 *1975*). Specific covalent binding with the stationary phase, a procedure that was called *covalent chromatography*, has been used for the separation of compounds and for immobilising enzymes on a support: the column was then used to carry out specific bioorganic reactions (Mosbach *Method Enzymol* **44** 1976; A. Rosevear et al. *Immobilised Enzymes and Cells: A Laboratory Manual*, Adam Hilger, Bristol, 1987, ISBN 085274515X). See Bibliography for further literature.

More recently ***Monolithic Chromatography*** has been introduced which is a new type of high-performance liquid chromatography in which the columns are a 'one-piece porous solid', or *monolith*, instead of particles. These columns take a variety of forms for use in adsorption, ion exchange (weak and strong, cation and anion), reverse phase, and are for use in the separation of small and large molecules. The mobile phase in these columns flows through the whole of the stationary phase. [P. Wang ed., *Monolithic Chromatography and its Modern Applications* ILM Publications, pp 648 *2010*, ISBN 9781906799038, 1906799032; and for columns see BIA Separations <www.biaseparations.com>.

Ultra performance Liquid chromatography **(UPLC)** affords a considerable improvement by bringing high performance liquid chromatography to a new level. Great improvements in analysis and purification of amino acids, peptides, proteins, oligonucleotides and glycans can be accomplished. This has been achieved by packing columns with smaller sized particles (1.7–1.8μm) and applying pressures of ~15,000psi (~1030 bar) to the mobile phase. NanoACQUITY UPLC trapping and nanoflow columns have been specifically designed for use on Waters nanoACQUITY systems that can be integrated with MS components [see www.waters.com].

Automated column chromatography

Most of the above methods of column chromatography have been, or can be, automated. Devices are available for the automated injection of samples to columns which are useful for analytical evaluation of samples, for

repeated analyses, or for repeated separations to obtain larger amounts of material. The specific fractions of the effluent can be collected. Equipment for these purposes can be obtained from several of the suppliers listed at the end of the HPLC section above with the corresponding websites. GC systems coupled with mass spectrometers (GC-MS) and HPLC systems coupled to mass spectrometers (LC-MS) are extremely important methods for the separation and identification of substances. These are invariably linked to a computer with internal libraries which can identify the peaks, and the libraries can be continually updated (see above). With more elaborate equipment LC-MS-MS where the peaks from the first spectrometer are further analysed by a second mass spectrometer provide a wealth of information. If not for the costs involved in GC-MS, GC-MS-MS, LC-MS and LC-MS-MS equipment, these systems would be more commonly found in analytical and research laboratories. [For further reading see Bibliography.]

ELECTROPHORESIS

Ionisable substances such as organic and inorganic acids, bases and salts migrate to their respective electrodes (anode or cathode) if a voltage is applied. When they are placed onto a matrix, e.g. paper or gel, then their rate of migration to the electrodes will vary with the charge, nature and structure of the substance. This phenomenon is known as electrophoresis and is very useful for separating and purifying substances. Capillary techniques have been adapted to electrophoresis and "capillary electrophoresis", and "capillary zone electrophoresis" are finding wide use for identification, separation and isolation of ionisable substances (see text in the Bibliography under "electrophoresis" and the "Introduction" in Chapter 7). The method is used extensively for biological substances, e.g. proteins, polypeptides, DNA, RNA, (see Introduction in Chapter 7) but has been used to a limited extent for identifying and purifying small molecules. Elaborate equipment is available commercially which contains essentially an electrolytic cell and a power supply which provides variable voltage for the process. The use of paper (Whatman of various thicknesses) as the matrix on a flat bed or in a vertical descending mode has been completely superseded with polyacrylamide or agarose flat bed gels. These are routinely used mainly for the separation of proteins and nucleic acids. Also capillary electrophoresis (CE) is now widely used for the analysis and detection of biological substances. It is used for the separation and purification of carbohydrates, nucleic acids, proteins and peptides and for chiral analysis and separations [see Bibliography].

DRYING

Removal of Solvents

Where substances are sufficiently stable, removal of solvent from recrystallised materials presents no problems. The crystals, after filtering at the pump (and perhaps air-drying by suction), are heated in an oven above the boiling point of the solvent (but below the melting point of the crystals), followed by cooling in a desiccator. Where this treatment is inadvisable, it is still often possible to heat to a lower temperature under reduced pressure, for example in an Abderhalden pistol. This device consists of a small chamber which is heated externally by the vapour of a boiling solvent. Inside this chamber, which can be evacuated (pump) is placed a small boat containing the sample to be dried and also a receptacle with a suitable drying agent. Convenient liquids for use as boiling liquids in an Abderhalden pistol, and their boiling temperatures, are given in Table 16. Alternatively an electrically heated drying pistol can also be used. In cases where heating above room temperature cannot be used, drying must be carried out in a vacuum desiccator containing suitable absorbents. For example, hydrocarbons, such as cyclohexane and petroleum ether, can be removed by using shredded paraffin wax, and acetic acid and other acids can be absorbed by pellets of sodium or potassium hydroxide. However, in general, solvent removal is less of a problem than ensuring that the water content of solids and liquids is reduced below an acceptable level.

Removal of Water

Methods for removing water from solids depend on the thermal stability of the solids or the time available. The safest way is to dry in a vacuum desiccator over concentrated sulfuric acid, phosphorus pentoxide, silica gel, calcium chloride, or some other desiccant. Where substances are stable in air and melt above 100^{o}, drying in an air oven may be adequate. In other cases, use of an Abderhalden pistol may be satisfactory.

Often, in drying inorganic salts, the final material that is required is a hydrate. In such cases, the purified substance is left in a desiccator to equilibrate above an aqueous solution having a suitable water-vapour pressure. A convenient range of solutions used in this way is given in Table 17.

The choice of desiccants for drying liquids is more restricted because of the need to avoid all substances likely to react with the liquids themselves. In some cases, direct distillation of an organic liquid is a suitable method

for drying both solids and liquids, especially if low-boiling azeotropes are formed. Examples include acetone, aniline, benzene, chloroform, carbon tetrachloride, heptane, hexane, methanol, nitrobenzene, petroleum ether, toluene and xylene. Addition of benzene can be used for drying ethanol by distillation. In carrying out distillations intended to yield anhydrous products, the apparatus should be fitted with guard-tubes containing calcium chloride or silica gel to prevent entry of moist air into the system. (Many anhydrous organic liquids are appreciably hygroscopic.)

Traces of water can be removed from solvents such as benzene, 1,2-dimethoxyethane, diethyl ether, pentane, toluene and tetrahydrofuran by refluxing under nitrogen a solution containing sodium wire and benzophenone, and fractionally distilling. Drying with, and distilling from CaH_2 is applicable to a number of solvents including aniline, benzene, *tert*-butylamine, *tert*-butanol, 2,4,6-collidine, diisopropylamine, dimethylformamide, hexamethyl-phosphoramide, dichloromethane, ethyl acetate, pyridine, tetramethylethylene diamine, toluene, triethylamine.

Removal of water from gases may be by physical or chemical means, and is commonly by adsorption on to a drying agent in a low-temperature trap. The effectiveness of drying agents depends on the vapour pressure of the hydrated compound - the lower the vapour pressure the less the remaining moisture in the gas.

The most usually applicable of the specific methods for detecting and determining water in organic liquids is due to Karl Fischer. (See J. Mitchell & D.M. Smith, *Aquametry*, 2nd Ed, J Wiley & Sons, New York, *1977–1984*, ISBN 0471022640; Fieser & Fieser, *Reagents for Organic Synthesis*, J.Wiley & Sons, NY, Vol 1, 528 *1967*, ISBN 0271616X), also see Karl Fischer titrant or Hydranal® –Titrant Type 5E [64-17-5] and other types in the Fluka and <http://www.sigmaaldrich.com/analytical-chromatography/titration/hydranal.html>.

Other techniques include electrical conductivity measurements and observation of the temperature at which the first cloudiness appears as the liquid is cooled (applicable to liquids in which water is only slightly soluble). Addition of anhydrous cobalt (II) iodide (blue) provides a convenient method (colour change to pink on hydration) for detecting water in alcohols, ketones, nitriles and some esters. Infrared absorption measurements of the broad band for water near 3500 cm^{-1} can also sometimes be used for detecting water in non-hydroxylic substances.

Cartridges for the removal not only water from solvents or solutions but other specific impurities, e.g. acids, amines , aldehydes, are now commercially available [see supplies listed at the end of the HPLC section together with their respective websites].

For further useful information on mineral adsorbents and drying agents, go to the SigmaAldrich website <sigmaaldrich.com>, under technical library (Aldrich) for technical bulletin AL-143.

Intensity and Capacity of Common Desiccants

Drying agents are conveniently grouped into three classes, depending on whether they combine with water reversibly, they react chemically (irreversibly) with water, or they are molecular sieves. The first group varies in their drying intensity with the temperature at which they are used, depending on the vapour pressure of the hydrate that is formed. This is why, for example, drying agents such as anhydrous sodium sulfate, magnesium sulfate or calcium chloride should be filtered off from the liquids before the latter are heated. The intensities of drying agents belonging to this group fall in the sequence:

P_2O_5 >> BaO > $Mg(ClO_4)_2$, CaO, MgO, KOH (fused), conc H_2SO_4, $CaSO_4$, Al_2O_3 > KOH (pellets), silica gel, $Mg(ClO_4)_2.3H_2O$ > NaOH (fused), 95% H_2SO_4, $CaBr_2$, $CaCl_2$ (fused) > NaOH (pellets), $Ba(ClO_4)_2$, $ZnCl_2$, $ZnBr_2$ > $CaCl_2$ (technical) > $CuSO_4$ > Na_2SO_4, K_2CO_3.

Where large amounts of water are to be removed, a preliminary drying of liquids is often possible by shaking with concentrated solutions of sodium sulfate or potassium carbonate, or by adding sodium chloride to salt out the organic phase (for example, in the drying of lower alcohols), as long as the drying agent does not react (e.g. $CaCl_2$ with alcohols and amines, see below).

Drying agents that combine irreversibly with water include the alkali metals, the metal hydrides (discussed in Chapter 2), and calcium carbide.

Suitability of Individual Desiccants

Alumina. (Preheated to 175^{o} for about 7 hours). Mainly as a drying agent in a desiccator or as a column through which liquid is percolated.

Aluminium amalgam. Mainly used for removing traces of water from alcohols *via* refluxing followed by distillation.

Barium oxide. Suitable for drying organic bases.

Barium perchlorate. Expensive. Used in desiccators (*covered with a metal guard*). Unsuitable for drying solvents or organic material where contact is necessary, because of the danger of **EXPLOSION.**

Boric anhydride. (Prepared by melting boric acid in an air oven at a high temperature, cooling in a desiccator, and powdering.) Mainly used for drying formic acid.

Calcium chloride (anhydrous). Cheap. Large capacity for absorption of water, giving the hexahydrate below 30^{o}, but is fairly slow in action and not very efficient. Its main use is for preliminary drying of alkyl and aryl halides, most esters, saturated and aromatic hydrocarbons and ethers. Unsuitable for drying alcohols and amines (which form addition compounds), fatty acids, amides, amino acids, ketones, phenols, or some aldehydes and esters. Calcium chloride is suitable for drying the following gases: hydrogen, hydrogen chloride, carbon monoxide, carbon dioxide, sulfur dioxide, nitrogen, methane, oxygen, also paraffins, ethers, olefins and alkyl chlorides.

Calcium hydride. See Chapter 2.

Calcium oxide. (Preheated to 700–900^{o} before use.) Suitable for alcohols and amines (but does not dry them completely). Need not be removed before distillation, but in that case the head of the distillation column should be packed with glass wool to trap any calcium oxide powder that might be carried over. Unsuitable for acidic compounds and esters. Suitable for drying gaseous amines and ammonia.

Calcium sulfate (anhydrous). (Prepared by heating the dihydrate or the hemihydrate in an oven at 235^{o} for 2–3 hours; it can be regenerated.) Available commercially as *Drierite*. It forms the hemihydrate, $2CaSO_4.H_2O$, so that its capacity is fairly low (6.6% of its weight of water), and hence is best used on partially dried substances. It is very efficient (being comparable with phosphorus pentoxide and concentrated sulfuric acid). Suitable for most organic compounds. Solvents boiling below 100^{o} can be dried by direct distillation from calcium sulfate.

Copper (II) sulfate (anhydrous). Suitable for esters and alcohols. Preferable to sodium sulfate in cases where solvents are sparingly soluble in water (for example, benzene or toluene). The colourless to fawn coloured powder turns blue as it absorbs water

Lithium aluminium hydride. See Chapter 2.

Magnesium amalgam. Mainly used for removing traces of water from alcohols by refluxing the alcohol in the presence of the Mg amalgam followed by distillation.

Magnesium perchlorate (anhydrous). (Available commercially as *Dehydrite*. Expensive.) Used in desiccators. Unsuitable for drying solvents or any organic material where contact is necessary, because of the danger of **EXPLOSION**.

Magnesium sulfate (anhydrous). (Prepared from the heptahydrate by drying at 300^{o} under reduced pressure.) More rapid and effective than sodium sulfate but is slightly acidic. It has a large capacity, forming $MgSO_4.7H_2O$ below 48^{o}. Suitable for the preliminary drying of most organic compounds.

Molecular sieves. See below.

Phosphorus pentoxide. Very rapid and efficient, but difficult to handle and should only be used after the organic material has been partially dried, for example with magnesium sulfate. Suitable for anhydrides, alkyl and aryl halides, ethers, esters, hydrocarbons and nitriles, and for use in desiccators. Not suitable with acids, alcohols, amines or ketones, or with organic molecules from which a molecule of water can be eliminated. Suitable for drying the following gases: hydrogen, oxygen, carbon dioxide, carbon monoxide, sulfur dioxide, nitrogen, methane, ethene and paraffins. It is available on a solid support with an indicator under the name *Sicapent* (from Merck). The colour changes in Sicapent depend on the percentage of water present (e.g. in the absence of water, Sicapent is colourless but becomes green with 20% water and blue with 33% w/w water). When the quantity of water in the desiccator is high, a crust of phosphoric acid forms a layer over the phosphorus pentoxide powder and decreases its efficiency. The crust can be removed with a spatula to expose the dry powder and restore the desiccant property.

Potassium (metal). Properties and applications are similar to those for sodium but as the reactivity is greater than that of sodium, the hazards are greater than those of sodium. **Handle with extreme care**.

Potassium carbonate (anhydrous). Has a moderate efficiency and capacity, forming the dihydrate. Suitable for an initial drying of alcohols, bases, esters, ketones and nitriles by shaking with them, then filtering off. Also suitable for salting out water-soluble alcohols, amines and ketones. Unsuitable for acids, phenols, thiols and other acidic substances.

Potassium carbonate. Solid potassium hydroxide is very rapid and efficient. Its use is limited almost entirely to the initial drying of organic bases. Alternatively, sometimes the base is shaken first with a concentrated solution of potassium hydroxide to remove most of the water present. Unsuitable for acids, aldehydes, ketones, phenols, thiols, amides and esters. Also used for drying gaseous amines and ammonia.

Silica gel. Granulated silica gel is a commercially available drying agent for use with gases, in desiccators, and (because of its chemical inertness) in physical instruments (pH meters, spectrometers, balances). Its drying action depends on physical adsorption, so that silica gel must be used at room temperature or below. By incorporating cobalt chloride into the material it can be made self indicating (blue when dry, pink when wet), re-drying in an oven at 110^{o} being necessary when the colour changes from blue to pink.

Sodium (metal). Used as a fine wire or as chips, for more completely drying ethers, saturated hydrocarbons and aromatic hydrocarbons which have been partially dried (for example with calcium chloride or magnesium sulfate). Unsuitable for acids, alcohols, alkyl halides, aldehydes, ketones, amines and esters. Reacts violently if water is present and can cause a fire with highly flammable liquids.

Sodium hydroxide. Properties and applications are similar to those for potassium hydroxide.

Sodium-potassium alloy. Used as lumps. Lower melting than sodium, so that its surface is readily renewed by shaking. Properties and applications are similar to those for sodium.

Sodium sulfate (anhydrous). Has a large capacity for absorption of water, forming the decahydrate below 33°, but drying is slow and inefficient, especially for solvents that are sparingly soluble in water. It is suitable for the preliminary drying of most types of organic compounds.

Sulfuric acid (concentrated). Widely used in desiccators. Suitable for drying bromine, saturated hydrocarbons, alkyl and aryl halides. Also suitable for drying the following gases: hydrogen, nitrogen, carbon dioxide, carbon monoxide, chlorine, methane and paraffins. Unsuitable for alcohols, bases, ketones or phenols. Also available on a solid support with an indicator under the name *Sicacide* (from Merck) for desiccators. The colour changes in Sicacide depends on the percentage of water present (e.g. when dry Sicacide is red-violet but becomes pale violet with 27% water and pale yellow to colourless with 33% w/w water).

For convenience, many of the above drying agents are listed in Table 18 under the classes of organic compounds for which they are commonly used.

Molecular sieves

Molecular sieves are types of adsorbents composed of crystalline zeolites (sodium and calcium aluminosilicates). By heating them, water of hydration is removed, leaving holes of molecular dimensions in the crystal lattices. These holes are of uniform size and allow the passage into the crystals of small molecules, but not of large ones.

This *sieving* action explains their use as very efficient drying agents for gases and liquids. The pore size of these sieves can be modified (within limits) by varying the cations built into the lattices. The four types of molecular sieves currently available are:

Type 3A sieves. A crystalline potassium aluminosilicate with a pore size of about 3 Angstroms. This type of molecular sieves is suitable for drying liquids such as acetone, acetonitrile, methanol, ethanol and 2-propanol, and drying gases such as acetylene, carbon dioxide, ammonia, propylene and butadiene. The material is supplied as beads or pellets.

Type 4A sieves. A crystalline sodium aluminosilicate with a pore size of about 4 Angstroms, so that, besides water, ethane molecules (but not butane) can be adsorbed. This type of molecular sieves is suitable for drying chloroform, dichloromethane, diethyl ether, dimethylformamide, ethyl acetate, cyclohexane, benzene, toluene, xylene, pyridine and diisopropyl ether. It is also useful for low pressure air drying. The material is supplied as beads, pellets or powder.

Type 5A sieves. A crystalline calcium aluminosilicate with a pore size of about 5 Angstroms, these sieves adsorb larger molecules than type 4A. For example, as well as the substances listed above, propane, butane, hexane, butene, higher *n*-olefins, *n*-butyl alcohol and higher *n*-alcohols, and cyclopropane can be adsorbed, but not branched-chain C_6 hydrocarbons, cyclic hydrocarbons such as benzene and cyclohexane, or secondary and tertiary alcohols, carbon tetrachloride or boron trifluoride. This is the type generally used for drying gases, though organic liquids such as THF and dioxane can be dried with this type of molecular sieves.

Type 13X sieves. A crystalline sodium aluminosilicate with a pore size of about 10 Angstroms which enables many branched-chain and cyclic compounds to be adsorbed, in addition to all the substances removed by type 5A sieves.

They are unsuitable for use with strong acids but are stable over the pH range 5–11.

Because of their selectivity, molecular sieves offer advantages over silica gel, alumina or activated charcoal, especially in their very high affinity for water, polar molecules and unsaturated organic compounds. Their relative efficiency is greatest when the impurity to be removed is present at low concentrations. Thus, at 25° and a relative humidity of 2%, type 5A molecular sieves adsorb 18% by weight of water, whereas for silica gel and alumina the figures are 3.5 and 2.5% respectively. Even at 100° and a relative humidity of 1.3%, molecular sieves adsorb about 15% by weight of water.

The greater preference of molecular sieves for combining with water molecules explains why this material can be used for drying ethanol and why molecular sieves are probably the most universally useful and efficient drying agents. Percolation of ethanol with an initial water content of 0.5% through a 144 cm long column of type 4A molecular sieves reduced the water content to 10ppm. Similar results have been obtained with pyridine.

The main applications of molecular sieves to purification comprise:

1. Drying of gases and liquids containing traces of water.
2. Drying of gases at elevated temperatures.
3. Selective removal of impurities (including water) from gas streams.

(For example, carbon dioxide from air or ethene; nitrogen oxides from nitrogen; methanol from diethyl ether. In general, carbon dioxide, carbon monoxide, ammonia, hydrogen sulfide, mercaptans, ethane, ethene, acetylene (ethyne), propane and propylene are readily removed at 25°. In mixtures of gases, the more polar ones are preferentially adsorbed).

The following applications include the removal of straight-chain from branched-chain or cyclic molecules. For example, type 5A sieves will adsorb *n*-butyl alcohol but not its branched-chain isomers. Similarly, it separates *n*-tetradecane from benzene, or *n*-heptane from methylcyclohexane.
The following liquids have been dried with molecular sieves: acetone, acetonitrile, acrylonitrile, allyl chloride, amyl acetate, benzene, butadiene, *n*-butane, butene, butyl acetate, *n*-butylamine, *n*-butyl chloride, carbon tetrachloride, chloroethane, 1-chloro-2-ethylhexane, cyclohexane, dichloromethane, dichloroethane, 1,2-dichloropropane, 1,1-dimethoxyethane, dimethyl ether, 2-ethylhexanol, 2-ethylhexylamine, *n*-heptane, *n*-hexane, isoprene, isopropyl alcohol, diisopropyl ether, methanol, methyl ethyl ketone, oxygen, *n*-pentane, phenol, propane, *n*-propyl alcohol, propylene, pyridine, styrene, tetrachloroethylene, toluene, trichloroethylene and xylene. In addition, the following gases have been dried: acetylene, air, argon, carbon dioxide, chlorine, ethene, helium, hydrogen, hydrogen chloride, hydrogen sulfide, nitrogen, oxygen and sulfur hexafluoride.
After use, molecular sieves can be regenerated by heating at between 300–350° for several hours, preferably in a stream of dry inert gas such as nitrogen or preferably under vacuum, then cooling in a desiccator. Special precautions must be taken before regeneration of molecular sieves used in the drying of flammable solvents.
However, care must be exercised in using molecular sieves for drying organic liquids. Appreciable amounts of impurities were *formed* when samples of acetone, 1,1,1-trichloroethane and methyl-*t*-butyl ether were dried in the liquid phase by contact with molecular sieves 4A (Connett *Lab Pract* **21** 545 *1972*). Other, less reactive types of sieves may be more suitable but, in general, it seems desirable to make a preliminary test to establish that no unwanted reaction takes place. Useful comparative data for Type 4A and 5A sieves are in Table 19.
With the advent of nanotechnology, nanoparticles are finding use as porous materials for a variety of purposes [see J.A. Schwartz & C. Contescu (Eds), *Surfaces of Nanoparticles & Porous Materials*, Marcel Dekker Inc, *1999*. ISBN 9780824719333].

PROPERTIES USEFUL IN PURIFICATION

Spectroscopic

Spectroscopic instruments of one sort or another are generally available in laboratories and useful for providing some idea of the purity of the specimen in question. Among these are IR, UV-VIS, fluorescence, NMR and mass spectrometers.
Infrared spectra [IR or FT(Fourier Transformed)-IR with frequency range of ν from ~ 600 to 3400 cm^{-1}], generally of the solid grounded in a large excess of KBr, or in a mull by grinding into an oil, e.g. Nujol, or in solution, e.g. $CHCl_3$, provide a 'fingerprint' of the substance. The KBr spectrum, or the spectrum of a film between NaCl plates if the substance is a liquid, are more useful as they give detailed information without interfering signals from Nujol or solvent which may mask important signals. Since the IR spectra consist of several signals many of which are sharp, impurities show up clearly. However, if the impurities are less than say 10% it may be difficult to say how impure the sample is, or what impurities are present in it. On the other hand, if the sample is very pure then its spectrum will be superimposable on that of the pure authentic sample.
Ultraviolet Spectra (with wavelength range of λ form ~ 200 to 400 mμ) are measured in dilute solution and are generally broad bands. Although the broadness of the bands make it difficult to identify impurities, the values of the molecular absorption extinction coefficients ε ($M^{-1}cm^{-1}$) at all wavelengths, but usually measured at the peaks or troughs, are characteristics of the substance in the particular solvent used, and would be different if the sample was impure. Glass cuvettes cannot be used as they are not transparent to UV radiation, and quartz cells should be used. However, quartz cells need only be on the two opposite faces of the four sided cuvette through which the light passes; the other two faces being made of glass. Similarly in the *visible* spectra (wavelength range of λ form ~ 400 to 800 mμ) the ε values are characteristics of the substance in the solvent used. In this case the cheaper glass cuvettes may be used as they are transparent to visible light.
Fluorescence Spectra are measured in the wavelength range similar to the *visible* range, but from light that is scattered at right angles to the incident excitation (UV) wavelength. Thus at a set excitation wavelength λ_{ex}, the fluorescence spectrum is scanned and the peak maximum λ_{em} and its ε_{em} are recorded. In this case the cuvettes generally have quartz faces on all four sides, as the UV light has to go through adjacent sides of the cell. This spectroscopy is useful as sometimes impurities in a sample may fluoresce at a particular wavelength. Generally, dyes have fluorescent properties and are identified in this way. Substances with strongly fluorescing properties have found considerable use in biology. Here they have been tagged to biological molecules and their movement into particular tissues and cells has been traced through their fluorescence. Table 20 lists a number

of *Fluorochromes* which have found many applications in analytical chemistry (by tagging to non-fluorescent compounds) and in biology. By selecting a mixture of two fluorochromes it is possible to obtain a desired emission wavelength. In this case the emitted fluorescence energy from the excitation of the first fluorochrome is transferred to the second fluorochrome to provide the desired fluorescence.
For other than macromolecules it is important that *at least* the ^{1}H NMR spectrum and/or the mass spectrum of the substance should be measured routinely. These measurements require no more than one to three milligrams of material and provide a considerable amount of information about the substance. The ^{1}H NMR and ^{13}C NMR spectra are measured to assess the purity of hydrogen and carbon containing samples. The use of very high magnetic field NMR spectrometers is especially useful for detecting impurities in such samples. The signals and their relative heights can provide valuable information not only about the extent of the impurities, but also some indications about the nature of the impurities. A variety of NMR solvents are available for dissolving the samples, and the hydrogen atoms of the solvents are replaced by deuterium which does not interfere with the ^{1}H or ^{13}C spectra. However, deuteration is generally just under 100% and signals from residual H in the solvent may appear in the spectrum and need to be identified. Similarly ^{13}C signals from solvents also should be identified. Common solvents and reagents that contain trace impurities will also show minor signals in the NMR spectra. The ^{1}H NMR signals of trace impurities in some common organic solvents (including water) and some reagents are presented in Tables 21 and 22. Similarly presented in Table 23 are the ^{13}C NMR signals of some common solvents and reagents. In some instances these minor signals have been very useful as internal standards for reporting the chemical shifts of substances, thus avoiding contamination from other added standards, particularly if the samples need to be used for further studies. The NMR spectra of other nuclei such as ^{11}B and ^{31}P are currently also measured routinely for boron and phosphorus containing compounds. Since the compounds invariably have only a small number of these atoms in their molecules, boron or phosphorus containing impurities are readily identified in the ^{11}B or ^{31}P NMR spectra.

References in the bibliography at the end of this chapter to the Aldrich-Sigma catalogues of NMR, IR and mass spectral data for a large number of the compounds are listed. These collections of spectra are extremely useful for identifying compounds and impurities. If the material appears to have several impurities, these spectra should be valuable for identifying the impurities as much as possible. Preliminary chromatographic (e.g. TLC) and spot tests could be devised to monitor the material and its impurities. Purification methods can then be devised to remove these impurities, and a monitoring method will have already been established.

Ionisation Constants — pK

When substances ionize, their neutral species produce positive and negative species. The ionisation constants are those constant values (equilibrium constants) for the equilibria between the charged species and the neutral species, or species with a larger number of charges (e.g. between mono and dications). These ionisation constants are given as **pK** values where **pK = -log K**, and **K** is the dissociation constant for the equilibrium between the species [Albert and Serjeant, *The Determination of Ionisation Constants*, A Laboratory Manual, 3rd Edition, Chapman & Hall, New York, London, 1984, ISBN 0412242907].

The advantage of using pK values (instead of K values) is that theory (and practice) states that the pK values of ionisable substances are numerically equal to the pH of the solution at which the concentrations of ionised and neutral species are equal. For example acetic acid has a pK^{25} value of 4.76 at 25^{o} in H_2O; then at pH 4.76 the aqueous solution contains equal amounts of acetic acid [AcOH] and acetate anion [AcO^{-}], i.e. [AcOH]/[AcO^{-}] of 50/50. At pH 5.76 (pK + 1) the solution contains [AcOH]/[AcO^{-}] of 10/90, at pH 6.76 (pK + 2) the solution contains [AcOH]/[AcO^{-}] of 1/99 etc; conversely at pH 3.76 (pK – 1) the solution contains [AcOH]/[AcO^{-}] of 90/10, and at pH 2.76 (pK – 2) the solution contains [AcOH]/[AcO^{-}] of 99/1.

One can readily appreciate the usefulness of pK value in purification procedures, e.g. as when purifying acetic acid. If acetic acid is placed in aqueous solution and the pH adjusted to 7.76 {[AcOH]/[AcO^{-}] with a ratio of 0.1/99.9}, and extracted with say diethyl ether, neutral impurities will be extracted into diethyl ether leaving almost all the acetic acid in the form of AcO^{-} in the aqueous solution. If then the pH of the solution is adjusted to 1.67 where the acid is almost all in the form AcOH, almost all of it will be extracted into diethyl ether.

Aniline will be used as a second example. It has a pK^{25} of 4.60 at 25° in H_2O. If it is placed in aqueous solution at pH 1.60 it will exist almost completely (99.9%) as the anilinium cation. This solution can then be extracted with solvents e.g. diethyl ether to remove neutral impurities. The pH of the solution is then adjusted to 7.60 whereby aniline will exist as the free base (99.9%) and can be extracted into diethyl ether in order to give purer aniline.

See Table 24 for the pH values of selected buffers.

A knowledge of the pK allows the adjustment of the pH without the need of large excesses of acids or base. In the case of inorganic compounds, knowledge of the pK is useful for adjusting the ionic species for making metal complexes which could be masked or extracted into organic solvents [Perrin and Dempsey, *Buffers for pH and Metal ion Control*, Chapman & Hall, New York, London, 1974, ISBN 0412117002], or for obtaining specific anionic species in solution e.g. $H_2PO_4^-$, HPO_4^{2-} or PO_4^{3-}.

The **pK** values that have been entered in Chapters 4, 5 and 6 have been collected directly from the literature or from compilations of literature values for organic bases [Perrin, *Dissociation Constants of Organic Bases in Aqueous Solution*, Butterworths, London, 1965, Supplement 1972, ISBN 040870408X; Albert and Serjeant, *The Determination of Ionisation Constants*, A Laboratory Manual, 3rd Edition, Chapman & Hall, London, New York, 1984, ISBN 0412242907]; organic acids [Kortum, Vogel and Andrussow, *Dissociation Constants of Organic Acids in Aqueous Solution,* Butterworth, London, 1961; Serjeant and Dempsey, *Dissociation Constants of Organic Acids in Aqueous Solution,* Pergamon Press, Oxford, New York, 1979, ISBN 0080223397; and inorganic acids and bases [Perrin, *Ionisation Constants of Inorganic Acids and Bases in Aqueous Solution*, Second Edition, Pergamon Press, Oxford, New York, 1982, ISBN 0080292143]. Where literature values were not available, values have been predicted and assigned $\mathbf{pK_{Est}}$ ~. Most predictions should be so close to true values as to make very small difference for the purposes intended in this book. The success of the predictions, i.e. how close to the true value, depends on the availability of pK values for closely related compounds because the effect of substituents or changes in structures are generally additive [Perrin, Dempsey and Serjeant, *pKa Prediction for Organic Acids and Bases*, Chapman & Hall, London, New York, 1981, ISBN 041222190X].

All the pK values in this book are pKa values, the acidic pK, i.e. dissociation of H^+ from an acid (AH) or from a conjugate base (BH^+). Occasionally pKb values are reported in the literature but these can be converted using the equation **pKa + pKb = 14**. For strong acids e.g. sulfuric acid, and strong bases, e.g. sodium hydroxide, the pK values lie beyond the 1 to 11 pH scale and have to be measured in strong acidic and basic media. In these cases appropriate scales e.g. the H_o (for acids) and H_- (for bases) have been used [see Katritzky & Waring, *J Chem Soc* 1540 *1962*]. These values will be less than 1 (and negative) for acids and >11 for bases. They are rough guides to the strengths of acids and bases. Errors in the stated pK and pK_{Est} ~ values can be judged from the numerical values given. Thus pK values of 4.55, 4.5 and 4 mean that the respective errors are better than ± 0.05, ± 0.3 and ± 0.5. Values taken from the literature are written as **pK**, and all the values that were estimated because they were not found in the literature are written as $\mathbf{pK_{Est}}$.

pK and Temperature

The temperatures at which the literature measurements were made are given as superscripts, e.g. pK^{25}. Where no temperature is given, it is assumed that the measurements were carried out at room temperature, e.g. 15–25°. No temperature is given for estimated values ($\mathbf{pK_{Est}}$ ~), and these have been calculated from data at room temperature. The variation of pK with temperature is given by the equation:

$$- \delta(pK)/ \delta T = (pK + 0.052\Delta S^o)/T$$

where T is in degrees Kelvin and ΔS^o is in Joules deg^{-1} mol^{-1}. The $\delta(pK)/dT$ in the range of temperatures between 5 to 70° is generally small (e.g. between ~0.0024 and ~0.04), and for chemical purification purposes is not a seriously deterring factor. It does, however, vary with the compound under study because ΔS^o varies from compound to compound. The following are examples of the effect of temperature on pK values: for imidazole the pK values are 7.57 (0°), 7.33 (10°), 7.10 (20°), 6.99 (25°), 6.89 (30°), 6.58 (40°) and 6.49 (50°), and for 3,5-di-nitrobenzoic acid they are 2.60 (10°), 2.73 (20°), 2.85 (30°), 2.96 (40°) and 3.07 (40°), and for *N*-acetyl-β-

alanine they are 4.4788 (5°), 4.4652 (10°), 4.4564 (15°), 4.4488 (20°), 4.4452 (25°), 4.4444 (30°), 4.4434 (35°) and 4.4412 (40°).

pK and solvent

All stated pK values in this book are for data in dilute aqueous solutions unless otherwise stated, although the dielectric constants, ionic strengths of the solutions and the method of measurement, e.g. potentiometric, spectrophotometric etc., are not given. Estimated values are also for dilute aqueous solutions whether or not the material is soluble enough in water. Generally the more dilute the solution the closer is the pK to the real thermodynamic value. The pK in mixed aqueous solvents can vary considerably with the relative concentrations and with the nature of the solvents. For example the pK^{25} values for *N*-benzylpenicillin are 2.76 and 4.84 in H_2O and H_2O/EtOH (20:80) respectively; the pK^{25} values for (–)-ephedrine are 9.58 and 8.84 in H_2O and $H_2O/MeOCH_2CH_2OH$ (20:80), respectively; and for cyclopentylamine the pK^{25} values are 10.65 and 4.05 in H_2O and H_2O/EtOH (50:50) respectively. pK values in acetic acid or aqueous acetic acid are generally lower than in H_2O.

The dielectric constant of the medium affects the equilibria where charges are generated in the dissociations e.g. $AH \leftrightarrows A^- + H^+$ and therefore affects the pK values. However, its effect on dissociations where there are no changes in total charge such as $BH^+ \leftrightarrows B + H^+$ is considerably less, with a slight decrease in pK with decreasing dielectric constant.

Solubilities of Gases in Liquids

There are two ways to define the solubilites of gases in water.

The first is the *Bunsen coefficient* (β), which is the ratio of the volume of gas corrected to STP (0°C and 1atm, i.e. 760 mmHg) that dissolves in unit volume of solvent at the temperature of the experiment in equilibrium with the gas at 1atm. The second is the *Ostwald coefficient* (*l*) which is the ratio of the volume of gas that dissolves in unit volume of solvent at the temperature of the experiment in equilibrium with the gas at 1atm.

The latter is a more convenient ratio to use because no correction for volume is required. Note that the volume of an ideal gas occupied by one molecular weight in grams of element or compound is ~22.4L at STP (e.g. 32g of oxygen occupy 22.4L at STP). The discussion will be limited to the solubilites of oxygen, nitrogen and air (which behave almost as ideal gases) in water, water containing salts, and in some organic solvents. Generally the solubility of these three gases in water decreases with increase of temperature and can be "boiled out" of the liquid. Their solubilities in organic liquids, on the other hand, generally increase with increase of temperature. The presence of salts in water tends to decrease the solubilities of these gases, i.e. a salting out effect, and increase in pressure increases their solubilities. These properties have to be noted in liquid chromatography at atmospheric and at high pressures. They become important when purifying small amounts of compounds by crystallisation or chromatography when large amounts of solvents are used. One must be wary of the presence of oxygen in solution, particularly in the presence of organic matter. Also the formation of reactive oxygen species e.g. "singlet" oxygen, superoxide and hydroxyl radicals, especially in the presence of trace metals such as iron, and/or of ultraviolet light can result in the formation of impurities.

The composition of air is: 78.08% of N_2, 20.95% of O_2, 0.03% of CO_2, 0.93% of Ar and less than 0.01% of other gases. Although the partial pressure of O_2 in air at 1atm is ~0.20, it has a higher solubility in H_2O than N_2. At STP the solubility of O_2 by volume in H_2O is 34.9% when in equilibrium with excess of air. Thus by successively dissolving air in H_2O, expelling it, and redissolving the expelled air six to seven times it is possible to increase the concentration of oxygen by volume in the expelled air to 90%. The (β) values for O_2 and N_2 in H_2O at STP are 0.028 and 0.014 respectively. There are 55.5 moles of H_2O in 1L of H_2O, so the molar ratios of O_2 to H_2O can be calculated. Note that the concentration of O_2 in liquids is higher when the liquids are in equilibrium with excess O_2 than when they are with excess of air.

The solubility coefficients (β) and/or (*l*) of some gases in liquids are give in Tables 25–28. Tables of the solubilities of HCl and NH_3 (g/100g of solution) at 760 mm (Table 29) and the boiling points of some useful gases at 760 mm (Table 30) are included.

MISCELLANEOUS TECHNIQUES

Freeze-pump-thaw and purging

Volatile contaminants, e.g. traces of low boiling solvent residue or oxygen, in liquid samples or solutions can be very deleterious to the samples on storage. These contaminants can be removed by repeated freeze-pump-thaw cycles. This involves freezing the liquid material under high vacuum in an appropriate vessel (which should be large enough to avoid contaminating the vacuum line with liquid that has bumped) connected to the vacuum line *via* efficient liquid nitrogen traps. The frozen sample is then thawed until it liquefies, kept in this form for some time (*ca* 10–15 minutes), refreezing the sample and the cycle repeated several times without interrupting the vacuum. This procedure applies equally well to solutions, as well as purified liquids, e.g. as a means of removing oxygen from solutions for NMR and other measurements. If the presence of nitrogen, helium or argon, is not a serious contaminant then solutions can be freed from gases, e.g. oxygen, carbon dioxide, and volatile impurities by purging with N_2, He or Ar at room, or slightly elevated, temperature. The gases used for purging are then removed by freeze-pump-thaw cycles or simply by keeping in a vacuum for several hours. Special NMR tubes with a screw cap thread and a PTFE valve (Wilmad) are convenient for freeze thawing of NMR samples. Alternatively NMR tubes with "J Young" valves (Wilmad) can also be used.

Vacuum lines, Schlenk and glovebox techniques

Manipulations involving materials sensitive to air or water vapour can be carried out by these procedures. Vacuum line methods make use of quantitative transfers, and **P**(pressure)-**V**(volume)-**T**(temperature) measurements, of gases, and trap-to-trap separations of volatile substances.

It is usually more convenient to work under an inert-gas atmosphere using **Schlenk** type apparatus. The *principle* of Schlenk methods involve all-glass tubes, flasks or vessels which have standard ground-glass joints with one or more side-arms, one of which may have a tap. The system can be purged by evacuating and flushing with an inert gas (usually dry nitrogen, or in some cases, argon or helium), repeating the process until the contaminants, e.g. O_2, H_2O or CO_2 in the vapour phases have been diminished to acceptable limits. Many of the reactions using Schlenk equipment require anhydrous conditions and in this case the equipment should be heated in an oven slightly above 100^o for 1 to 2 hours (preferably with dry N_2, He or argon flushing), and allowed to cool to room temperature in the presence of a desiccant. A large range of Schlenk glassware is commercially available. Schlenk equipment in which refluxing of liquids is possible without contact with the atmosphere outside of the apparatus is available commercially. With these, and tailor-made pieces of glassware, inert atmospheres can be maintained during transfer of material, crystallisation, reflux, filtration, and sublimation. Where addition of a solid sample should be made, an L-tube, or a small bulb with a bent neck, with a glass joint is used in which the solid is placed, and can be transferred to the main reaction vessel by simply rotating the tube or bulb. In the case of a liquid, a separating funnel with an equalising tube can be used to allow equilibration of pressure. Also, liquids can be injected, *via* a syringe through "Sure/Seal" caps which can be stretched over, or insert nicely into, the ground joint necks of the main reaction container.

Syringe techniques have been developed for small volumes, while for large volumes or where much manipulation is required, dryboxes (*glove boxes*) or dry chambers should be used. Disposable glove bags (e.g. Atmosbags see Sigma-Aldrich Labware of various dimensions) with two or four hands which can be sealed, purged and inflated with an inert gas are available and are relatively cheap and disposable. They are useful not only for handling moisture-sensitive substances, but also for toxic materials.

CHEMICAL AND BIOCHEMICAL SOURCES

Apart from wishing to obtain a pure substance there are many reasons for wanting to purify a substance. For example the substance may have been in the store for too long and has deteriorated to a smaller or larger extent and needs to be used. Large quantities may be required, so bulk amounts, less pure but of cheaper grade could serve the purpose if they can be purified readily and cheaply. The cost consideration is very important. Substances that are available commercially can be of varying grades of purity and the purer the grade the higher the price. Biological substances may be only available in crude form, e.g. acetone powders for enzymes. There are a large number of suppliers of substances for chemical, biochemical and for biological requirements and they are continually improving quality, increasing their range and introducing recently developed substances. The following is a website list of the more commonly used suppliers from which almost all the substances and equipment described in this book can be purchased. The list also contains suppliers of laboratory ware as well as of scientific instruments. The list is not exhaustive.

For high purity inorganic compounds, NIST Traceable inorganic reference standards/calibrants and aqueous standard solutions for ICP, ICP-MS, AA, GFAA and IC visit <www.exaxol.com>. Note that all the trace metal analyses in the "Inorganic Compounds" section of Chapter 5 are by courtesy of Joe Papa (EXAXOL see Preface).

TABLES

TABLE 1. SOME COMMON IMMISCIBLE OR SLIGHTLY MISCIBLE PAIRS OF SOLVENTS AT AMBIENT TEMPERATURES

Acetonitrile with hexane, heptane, iso-octane, cyclohexane.

Benzene with water, brine and aqueous solutions generally.

Butanol with water, brine and aqueous solutions generally.

Carbon tetrachloride with ethanolamine, ethylene glycol, formamide, water or brine.

Chloroform with glycerol, ethylene glycol, water, aqueous solutions generally

Cyclohexane with alohols, dimethyl formamide, dimethyl sulfoxide, glycerol, pyridine.

Cyclopropyl methyl ether same as ethyl ether but less so.

Dimethyl formamide or **dimethyl acetamide** with cyclohexane, pentane, petroleum ether, xylene.

Dimethyl sulfoxide with ethyl ether, pentane, petroleum ethers, cyclohexane, xylene.

Ethyl acetate with aqueous solutions generally or petroleum ethers.

Ethyl ether with ethanolamine, dimethyl sulfoxide, ethylene glycol, glycerol, water or aqueous solutions generally.

Ethanol with carbon disulfide, petroleum ethers, cyclohexanes.

Glyerol with benzene, ether, chloroform, carbon tetrachloride, carbon disulfide, petroleum ethers, oils.

Iso-octane with acetonitrile, dimethyl formamide, dimethyl sulfoxide, methanol, water.

Methanol with carbon disulfide, hexane, heptane, cyclohexane or petroleum ethers.

***N*-Methylpyrrolidone** with petroleum ethers, cyclohexanes.

Petroleum ether(s) with aniline, benzyl alcohol, dimethyl formamide, dimethyl sulfoxide, formamide, phenol or water and aqeuous solutions generally.

Phenol with petroleum ethers, cyclohexanes.

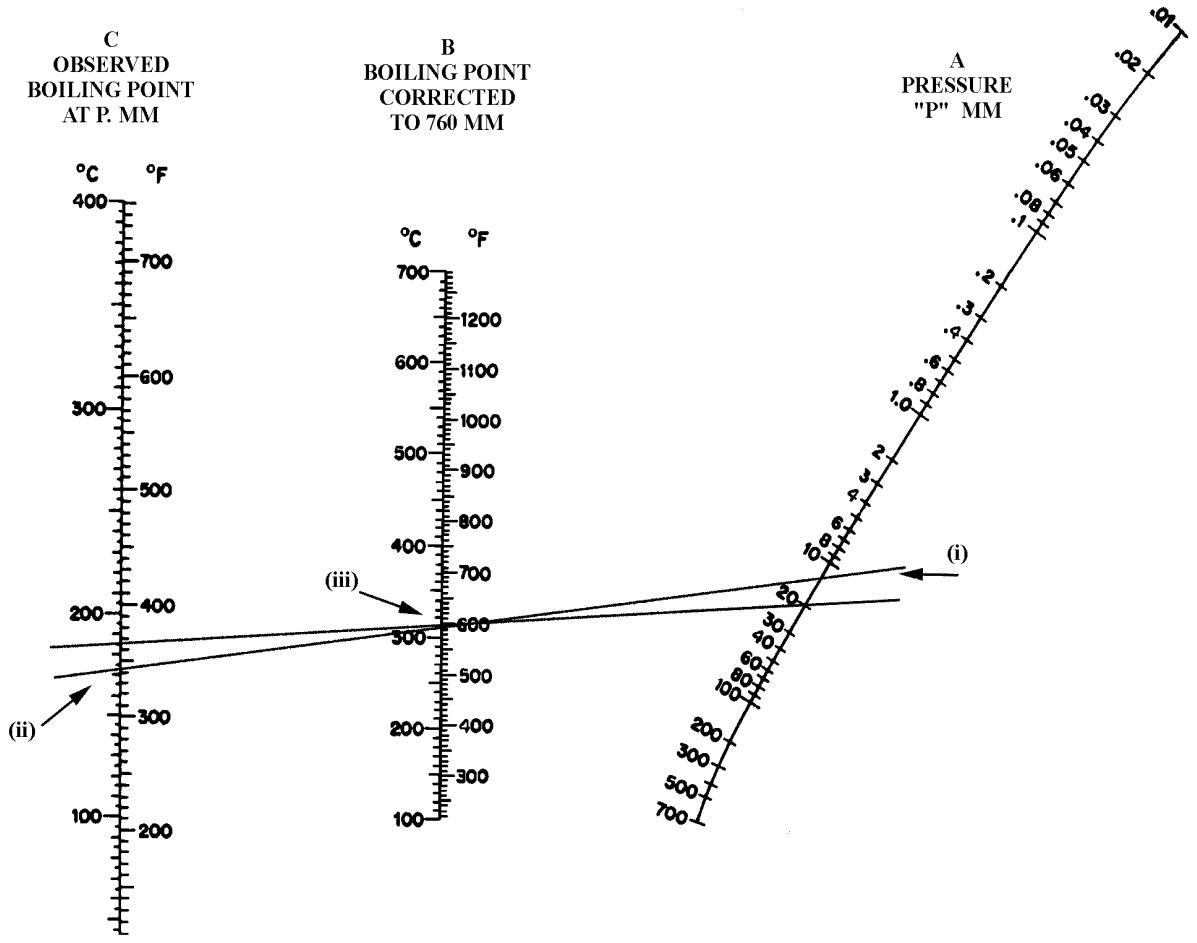
Pyridine with petroleum ethers, hexanes.

Toluene with water, brine, aqueous solutions generally, glycerol but less so than benzene.

Water with aniline, benzene, benzyl alcohol, carbon disulfide, carbon tetrachloride, chloroform, cyclohexane, cyclohexanol, cyclohexanone, diethyl ether, ethyl acetate, isoamyl alcohol, methyl ethyl ketone, nitromethane, tributyl phosphate or toluene.

Xylene with water, brine, aqueous solutions generally, glycerol, dimethyl formamide, dimethyl sulfoxide.

FIGURE 1: NOMOGRAM



How to use Figure 1:

You can use a nomogram to estimate the boiling points of a substance at a particular pressure. For example, the boiling point of 4-methoxybenzenesulfonyl chloride is 173°C/14mm. Thus to find out what the boiling point of this compound will be at 760 mm (atmospheric), draw a point on curve A (pressure) at 14mm (this is shown in (i). Then draw a point on curve C (observed boiling point) corresponding to 173° (or as close as possible). This is shown in (ii). Using a ruler, find the point of intersection on curve B, drawing a line between points (i) and (ii). This is the point (iii) and is the boiling point of 4-methoxybenzenesulfonyl chloride (i.e. approx. 310°C) at atmospheric pressure. If you want to distil 4-methoxybenzenesulfonyl chloride at 20 mm, then you will need to draw a point on curve A (at 20 mm). Using a ruler, find the point of intersection on curve C drawing through the line intersecting (iii, curve B, i.e. 310°C) and the point in curve A corresponding to 20 mm. You should have a value of 185°C; that is, the boiling point of 4-methoxybenzenesulfonyl chloride is estimated to be at 185°C at 20 mm.

TABLE 2A. PREDICTED EFFECT OF PRESSURE ON BOILING POINT*

	Temperature in degrees Centigrade

* *How to use the Table*: Take as an example a liquid with a boiling point of 80°C at 760 mmHg. The Table gives values of the boiling points of this liquid at pressures from 0.1 to 800 mmHg. Thus at 50 mmHg this liquid has a boiling point of 19°C, and at 2 mmHg its boiling point would be –30°C.

TABLE 2B. PREDICTED EFFECT OF PRESSURE ON BOILING POINT*

	Temperature in degrees Centigrade

200.0	156	174	193	211	229	247	265	283	302	320	338
300.0	169	187	206	225	243	262	281	299	318	337	355
400.0	178	197	216	235	254	273	292	311	330	350	369
500.0	185	205	224	244	263	282	302	321	340	360	379
600.0	192	211	231	251	270	290	310	329	349	368	388
700.0	197	217	237	257	277	296	316	336	356	376	396
750.0	200	220	239	259	279	299	319	339	359	279	399
770.0	200	220	241	261	281	301	321	341	361	381	401
800.0	202	222	242	262	282	302	322	342	262	382	403

**How to use the Table*: Taking as an example a liquid with a boiling point of 340°C at 760 mmHg, the column headed 340°C gives values of the boiling points of this liquid at each value of pressures from 0.1 to 800 mmHg. Thus, at 100 mmHg its boiling point is 258°C, and at 0.8mm Hg its boiling point will be 130°C.

TABLE 3. HEATING BATHS

Up to 100°	Water baths
20 to 200°	Glycerol or di-*n*-butyl phthalate
Up to about 200°	Medicinal paraffin
Up to about 250°	Hard hydrogenated cotton-seed oil (**m** 40–60°) or a 1:1 mixture of cotton-seed oil and castor oil containing about 1% of hydroquinone.
40 to 250° (to 400° under N_2)	D.C. 550 silicone fluid
Up to about 260°	A mixture of 85% orthophosphoric acid (4 parts) and metaphosphoric acid (1 part)
Up to 340°	A mixture of 85% orthophosphoric acid (2 parts) and metaphosphoric acid (1 part)
60 to 500°	Fisher bath wax (highly unsaturated)
73 to 350°	Wood's Metal*
250 to 800°	Solder*
350 to 800°	Lead*

* In using metal baths, the container (usually a metal crucible) should be removed while the metal is still molten.

Carbon tetrachloride (77°)	Formamide (110°/10mm)	Trimethylene glycol (59°/11mm)
Chlorobenzene (132°)	Glycerol (126°/11mm)	Water (100°)
Chloroform (61°)	Isoamyl alcohol (131°)	Xylenes (*o* 143-145°, *m* 138-139°, *p* 138°)

***Highly flammable, should be heated or evaporated on steam or electrically heated water baths only (preferably under nitrogen). None of these solvents should be heated over a naked flame.**

TABLE 7. PAIRS OF MISCIBLE SOLVENTS

Acetic acid: with chloroform, ethanol, ethyl acetate, acetonitrile, petroleum ether, or water.
Acetone: with benzene, butyl acetate, butyl alcohol, carbon tetrachloride, chloroform, cyclohexane, ethanol, ethyl acetate, methyl acetate, acetonitrile, petroleum ether or water.
Ammonia: with ethanol, methanol, pyridine.
Aniline: with acetone, benzene, carbon tetrachloride, ethyl ether, *n*-heptane, methanol, acetonitrile or nitrobenzene.
Benzene: with acetone, butyl alcohol, carbon tetrachloride, chloroform, cyclohexane, ethanol, acetonitrile, petroleum ether or pyridine.
Butyl alcohol: with acetone or ethyl acetate.
Carbon disulfide: with petroleum ether.
Carbon tetrachloride: with cyclohexane.
Chloroform: with acetic acid, acetone, benzene, ethanol, ethyl acetate, hexane, methanol or pyridine.
Cyclohexane: with acetone, benzene, carbon tetrachloride, ethanol or diethyl ether.
Diethyl ether: with acetone, cyclohexane, ethanol, methanol, methylal (dimethoxymethane), acetonitrile, pentane or petroleum ether.
Dimethyl formamide: with benzene, ethanol or ether.
Dimethyl sulfoxide: with acetone, benzene, chloroform, ethanol, diethyl ether or water.
Dioxane: with benzene, carbon tetrachloride, chloroform, ethanol, diethyl ether, petroleum ether, pyridine or water**.**
Ethanol: with acetic acid, acetone, benzene, chloroform, cyclohexane, dioxane, ethyl ether, pentane, toluene, water or xylene.
Ethyl acetate: with acetic acid, acetone, butyl alcohol, chloroform, or methanol.
Glycerol: with ethanol, methanol or water.
Hexane: with benzene, chloroform or ethanol.
Methanol: with chloroform, diethyl ether, glycerol or water.
Methylal: with diethyl ether.
Methyl ethyl ketone: with acetic acid, benzene, ethanol or methanol.
Nitrobenzene: with aniline, methanol or acetonitrile.
Pentane: with ethanol or diethyl ether.
Petroleum ether: with acetic acid, acetone, benzene, carbon disulfide or diethyl ether.
Phenol: with carbon tetrachloride, ethanol, diethyl ether or xylene.
Pyridine: with acetone, ammonia, benzene, chloroform, dioxane, petroleum ether, toluene or water.
Toluene: with ethanol, diethyl ether or pyridine.
Water: with acetic acid, acetone, ethanol, methanol, or pyridine.
Xylene: with ethanol or phenol.

TABLE 8. MATERIALS FOR COOLING BATHS

Temp. (°)	Composition	Temp. (°)	Composition
0	Crushed ice	–72	Solid CO_2 with ethanol
–5 to –20	Ice-salt mixtures	–77	Solid CO_2 with chloroform or acetone
Up to –20	Ice-MeOH mixtures	–78	Solid CO_2 (powdered; CO_2 snow)
–33	Liquid ammonia	–100	Solid CO_2 with diethyl ether
–40 to –50	Ice (3.5–4 parts) - $CaCl_2 \cdot 6H_2O$ (5 parts)	–196	liquid nitrogen (see footnote*)

Alternatively, the following liquids can be used, partially frozen, as cryostats, by adding solid CO_2 from time to time to the material in a Dewar-type container and stirring to make a slush:

13	*p*-Xylene	–55	Diacetone
12	Dioxane	–56	*n*-Octane
6	Cyclohexane	–60	Di-isopropyl ether
5	Benzene	–73	Trichloroethylene or isopropyl acetate
2	Formamide	–74	*o*-Cymene or *p*-cymene
–8.6	Methyl salicylate	–77	Butyl acetate
–9	Hexane-2,5-dione	–79	Isoamyl acetate
–10.5	Ethylene glycol	–83	Propylamine
–11.9	*tert*-Amyl alcohol	–83.6	Ethyl acetate
–12	Cycloheptane or methyl benzoate	–86	Methyl ethyl ketone
–15	Benzyl alcohol	–89	*n*-Butanol
–16.3	*n*-Octanol	–90	Nitroethane
–18	1,2-Dichlorobenzene	–91	Heptane
–22	Tetrachloroethylene	–92	*n*-Propyl acetate
–22.4	Butyl benzoate	–93	2-Nitropropane or cyclopentane
–22.8	Carbon tetrachloride	–94	Ethyl benzene or hexane
–24.5	Diethyl sulfate	–94.6	Acetone
–25	1,3-Dichlorobenzene	–95.1	Toluene
–29	*o*-Xylene or pentachloroethane	–97	Cumene
–30	Bromobenzene	–98	Methanol or methyl acetate
–32	*m*-Toluidine	–99	Isobutyl acetate
–32.6	Dipropyl ketone	–104	Cyclohexene
–38	Thiophene	–107	Isooctane
–41	Acetonitrile	–108	1-Nitropropane
–42	Pyridine or diethyl ketone	–116	Ethanol or diethyl ether
–44	Cyclohexyl chloride	–117	Isoamyl alcohol
–45	Chlorobenzene	–126	Methylcyclohexane
–47	*m*-Xylene	–131	*n*-Pentane
–50	Ethyl malonate or *n*-butylamine	–160	Isopentane
–52	Benzyl acetate or diethylcarbitol		

For other organic materials used in low temperature slush-baths with liquid nitrogen see R.E.Rondeau [*J Chem Eng Data* **11** 124 *1966*]. ***NOTE**: Use high quality pure nitrogen; do not use liquid air or liquid nitrogen that has been in contact with air for a long period (due to the dissolution of oxygen in it) as this could EXPLODE in contact with organic matter.

TABLE 9. LIQUIDS FOR STATIONARY PHASES IN GAS CHROMATOGRAPHY*

Material	Temp. (°)	Retards
Dimethylsulfolane	0–40	Olefins and aromatic hydrocarbons
Di-*n*-butyl phthalate	0–40	General purposes
Squalane	0–150	Volatile hydrocarbons and polar molecules
Silicone oil or grease	0–250	General purposes
Diglycerol	20–120	Water, alcohols, amines, esters, and aromatic hydrocarbons
Dinonyl phthalate	20–130	General purposes
Polydiethylene glycol succinate	50–200	Aromatic hydrocarbons, alcohols, ketones, esters
Polyethylene glycol	50–200	Water, alcohols, amines, esters and aromatic hydrocarbons
Apiezon grease	50–200	Volatile hydrocarbons and polar molecules
Tricresyl phosphate	50–250	General purposes

* See Suppliers at the end of section on HPLC and E.F. Barry and R.L. Grob, *Columns for Gas Chromatography*, J. Wiley and Sons NY, *2007*, ISBN 9780471740438.

TABLE 10. METHODS OF VISUALISATION OF TLC SPOTS

Reagent	Compound	Preparation	Observations
Iodine	General	Iodine crystals in a closed chamber or spray 1% methanol solution of Iodine	Brown spots which may disappear upon standing
H_2SO_4	General	50% solution, followed by heating to 150°C	Black or coloured spots
Molybdate	General	5% $(NH_4)_6Mo_7O_{24}$ + 0.2% $Ce(SO_4)_2$ in 5% H_2SO_4, followed by heating to 150°C	Deep blue spots
Vanillin	General	0.5g vanillin, 0.5 ml H_2SO_4, 9 ml ethanol	various coloured spots
Ammonia	phenols	Ammonia vapour in a closed chamber	various coloured spots
$FeCl_3$	phenols, enols	1% aqueous $FeCl_3$	various coloured spots
2,4-DNP	aldehydes, ketones	0.5% 2,4-dinitrophenylhydrazine/2M HCl	red to yellow spots
HCl	aromatic acids and amines	HCl vapour in a closed chamber	various coloured spots
Ninhydrin	amino acids, and amines	0.3% ninhydrin in *n*-BuOH with 3% AcOH, followed by heating to 125°C/10 min	blue spots
$PdCl_2$	S and Se compds	0.5% aq. $PdCl_2$ + few drops of conc. HCl	red and yellow spots
Anisaldehyde	carbohydrates	0.5 ml anisaldehyde in 0.5 ml conc H_2SO_4 + 95% EtOH + a few drops of AcOH Heat at 100–110°C for 20–30 minutes	various blue spots

TABLE 11. GRADED ADSORBENTS AND SOLVENTS FOR CHROMATOGRAPHY

Adsorbents (decreasing effectiveness)	**Solvents** (increasing eluting ability)
Fuller's earth (hydrated aluminosilicate)	Petroleum ether, b. 40–60°.
Magnesium oxide	Petroleum ether, b. 60–80°.
Charcoal	Carbon tetrachloride
Alumina	Cyclohexane
Magnesium trisilicate	Benzene
Silica gel	Diethyl ether
Calcium hydroxide	Chloroform
Magnesium carbonate	Ethyl acetate
Calcium phosphate	Acetone
Calcium carbonate	Ethanol
Sodium carbonate	Methanol
Talc	Pyridine
Inulin	Acetic acid
Sucrose = starch	

TABLE 12. REPRESENTATIVE ION-EXCHANGE RESINS USED IN CHROMATOGRAPHY

Sulfonated polystyrene	**Aliphatic amine-type**
Strong-acid cation exchanger	**weak base anion exchangers**
AG 50W-x8	Amberlites IR-45 and IRA-67
Amberlite IR-120	Dowex 3-x4A
Dowex 50W-x8	Permutit E
Duolite 225	Permutit A 240A
Permutit RS	
Permutite C50D	
Carboxylic acid-type	**Strong Base, anion exchangers**
Weak acid cation exchangers	AG 2x8
Amberlite IRC-50	Amberlite IRA-400
Bio-Rex 70	Dowex 2-x8
Chelex 100	Duolite 113
Duolite 436	Permutit ESB
Permutit C	Permutite 330D
Permutits H and H-70	

TABLE 13. MODIFIED FIBROUS CELLULOSES FOR ION-EXCHANGE CHROMATOGRAPHY

Cation exchange	**Anion exchange**
CM cellulose (carboxymethyl)	DEAE cellulose (diethylaminoethyl)
CM 22, 23 cellulose	DE 22, 23 cellulose
P cellulose (phosphate)	PAB cellulose (*p*-aminobenzyl)
SE cellulose (sulfoethyl)	TEAE cellulose (triethylaminoethyl)
SM cellulose (sulfomethyl)	ECTEOLA cellulose

SE and SM are much stronger acids than CM, whereas P has two ionisable groups (pK 2–3, 6–7)*, one of which is stronger, the other weaker, than for CM* (3.5–4.5). For basic strengths, the sequence is: TEAE » DEAE (pK 8-95) > ECTEOLA (pK 5.5-7) > PAB. **Their exchange capacities lie in the range 0.3 to 1.0 mg equiv/g.**

TABLE 14. BEAD FORM ION-EXCHANGE PACKAGINGS FOR CHROMATOGRAPHY[1]

Cation exchange	Capacity (meq/g)	Anion exchange	Capacity (meq/g)
CM-Sephadex C-25, C-50.[2](weak acid)	4.5±0.5	DEAE-Sephadex A-25, A-50.[7] (weak base)	3.5±0.5
SP-Sephadex C-25, C-50.[3](strong acid)	2.3±0.3	QAE-Sephadex A-25, A-50.[8] (strong base)	3.0±0.4
CM-Sepharose CL-6B.[4]	0.12±0.02	DEAE-Sepharose CL-6B.[4]	0.13±0.02
		DEAE-Sephacel.[9]	1.4±0.1
Fractogel EMD,CO_2^- ($pK \sim 4.5$), SO_3^{2-} ($pK \sim < 1$).[5]		Fractogel EMD, DMAE (pK ~9), DEAE (pK ~10.8), TMAE (pK >13).[5]	
CM-32 Cellulose.		DE-32 Cellulose.	
CM-52 Cellulose.[6]		DE-52 Cellulose	

[1]May be sterilised by autoclaving at pH 7 and below 120°. [2]Carboxymethyl. [3]Sulfopropyl. [4]Crosslinked agarose gel, no pre-cycling required, pH range 3-10. [5]Hydrophilic methacrylate polymer with very little volume change on change of pH (equivalent to *Toyopearl,* Sigma), available in superfine 650S, and medium 650M particle sizes. [6]Microgranular, pre-swollen, no pre-cycling required. [7]Diethylaminoethyl. [8]Diethyl(2-hydroxy-propyl)aminoethyl. [9]Bead form cellulose, pH range 2–12, no pre-cycling required. Sephadex and Sepharose from GE Healthcare, Fractogel from Merck, Cellulose from Whatman.

TABLE 15 SELECTED CHIRAL COLUMNS FOR CHROMATOGRAPHY*

Column name	Chiral ligand	Attributes	Manufacture
CHIRA-chrom-1 CHIRA-chrom-2	*R*- or *S*- phenylglycine *S*-leucine dinitrophenyl tartramide	High capacity & efficiency	HICHROM
CHIRAL-AGP CHIRAL-CBH CHIRAL-HAS	α 1-acid glycoprotein cellobiohydrolase human serum albumin	Used in wide pH range	CHROM TECH
CHIRALCEL OD/OJ CHIRALPAK AD/AS/H CHIRALPAK 1A CHIRALPAK 1B CROWNPAK	cellulose derivative amylose derivative immobilised amylose immobilised cellulose 18-crown 6 type ether	Particular separations versatile broad range broad range for amino acids and primary amines	DIACEL
CHIROSIL	(18-crown 6)$(CO_2H)_4$	for amino acids and primary amines	RStech

(continued)

TABLE 15 (Continued) SELECTED CHIRAL COLUMNS FOR CHROMATOGRAPHY*

Column name	Chiral ligand	Attributes	Manufacture
CHIROBIOTIC R	Ristocetin A	Broad selectivity	
CHIROBIOTIC T	Teicoplanin	Broad selectivity	Astech 1
CHIROBIOTIC V	Vancomycin	Broad selectivity	
CYCLOBOND I	β-cyclodextrin	form chiral	Astech 1
CYCLOBOND II	γ-cyclodextrin	inclusion complexes	
KROMASIL DMB	Acetylated *N*,*N'*-diallyl	stable, high capacity	Eka Chemicals
KROMASIL TBB	*S*-tartardiamide	for large prep work	
NUCLEODEX β-OH	β-cyclodextrin	reverse phase work	
NUCLEODEX α-, β-	permethylated α-, β- and	reverse phase work	Macherey–
and γ-PM	γ-cyclodextrins	reverse phase work	Nagel
NUCLEOSIL Chiral-1	*S*-hydroxyproline-Cu^{2+} complex	ligand exchange, e.g. α-amino acids	
RESOLVOSIL BSA-7PX	bovine serum albumen	various applications	
ULTRON ES-OVM	ovomucoid protein	stable phase	Shinwa Chem
ULTRON ES-Pepsin	pepsin protein	stable phase	Industries
DACH-DNB	3,5-dinitrobenzoyl derivs	π-electron acceptor/	
ULMO	3,5-dinitrobenzoyl derivs	donor — widely used	
α-Burke 2	3,5-dinitrobenzoyl derivs	π-electron acceptor	
β-GEM 1	3,5-dinitrobenzoyl derivs	π-electron acceptor	
Leucine	3,5-dinitrobenzoyl derivs	π-electron acceptor	REGIS
Phenyglycine	β-lactamase chiral selector	π-electron acceptor	
PIRKLE-1J	*S*-naphthylleucine	π-electron donor	
Naphthylleucine	ligand exchange	good for underivatised	
DAVAKOV	ligand exchange	amino acids

TABLE 18. DRYING AGENTS FOR CLASSES OF COMPOUNDS

Class	Dried with
Acetals	Potassium carbonate.
Acids (organic)	Calcium sulfate, magnesium sulfate, sodium sulfate.
Acyl halides	Magnesium sulfate, sodium sulfate.
Alcohols	Calcium oxide, calcium sulfate, magnesium sulfate, potassium carbonate, followed by magnesium and iodine.
Aldehydes	Calcium sulfate, magnesium sulfate, sodium sulfate.
Alkyl halides	Calcium chloride, calcium sulfate, magnesium sulfate. phosphorus pentoxide, sodium sulfate.
Amines	Barium oxide, calcium oxide, potassium hydroxide, sodium carbonate, sodium hydroxide.
Aryl halides	Calcium chloride, calcium sulfate, magnesium sulfate, phosphorus pentoxide, sodium sulfate.
Esters	Magnesium sulfate, potassium carbonate, sodium sulfate.
Ethers	Calcium chloride, calcium sulfate, magnesium sulfate, sodium, lithium aluminium hydride.
Heterocyclic bases	Magnesium sulfate, potassium carbonate, sodium hydroxide.
Hydrocarbons	Calcium chloride, calcium sulfate, magnesium sulfate, phosphorus pentoxide, sodium (not for olefins).
Ketones	Calcium sulfate, magnesium sulfate, potassium carbonate, sodium sulfate.
Mercaptans	Magnesium sulfate, sodium sulfate.
Nitro compounds and Nitriles	Calcium chloride, magnesium sulfate, sodium sulfate.
Sulfides	Calcium chloride, calcium sulfate.

TABLE 19. STATIC DRYING FOR SELECTED LIQUIDS (25°C)

Liquid	Water	Linde Type 4 A	Linde Type 5 A	Activated Alumina	Silicic Acid Gel
MeOH	Residual H_2O % Wt % absorbed	0.54 2.50	0.55 1.50	— —	0.60 —

TABLE 20 FLUOROCHROMES*

	CAS registry No	λ_{ex} (nm) #	λ_{em} (nm)#	Applications
Acriflavin	[8048-52-0]	463	490	Stains many compounds
Allophycocyanin (APC)		604 (650)	650 (660)	Polypeptide with exceptional Fluorescence for cytometry
3-Aminocoumarin	[1635-31-0]	350	445	Forms fluorescent derivatives *via* reaction with the 3-NH_2 group
Auramine O (basic yellow 2)	[2465-27-2]	440	530	Fluorescent stain for bacteria and probe for certain enzymes, e.g. alcohol dehydrogenases
4-Bromomethyl-7-methoxycoumarin	[35231-44-8]	360 (340)	410 (421)	Forms fluorescent probes with various compds for TLC/HPLC
Chromomycin A_3	[7059-24-7]	445	575	Stains DNA
Ethidium bromide	[1239-45-8]	493	620	Stains DNA
Fluorescamine	[38183-12-9]			Reacts with various R-NH_2 to form fluorescent compds
Fluorescein	[2321-07-5]	490	514	Fluorescent nucleus for staining a Variety of compounds
Fluorescein-Isothiocyanate (FITC)	[3326-32-7]	492	518	Microsequencing of peptides & proteins, makes fluorescent Amino acids
Hoechst H 2495 (benzoxanthene yellow)	[72845-94-4]			Fluorochrome for various compds
Hoechst H33342 (bisBenzimide 3HCl)	[23491-52-3]	346	640	Intercalates DNA for cytometry and fluorescence microscopy
R-Phycoerythrin	[11016-17-4]	488	572	Forms fluorescent probes with proteins
PKH 2 and 72 (green)		490	504	A Protein Kinase polypeptide that links to cells causing fluorescence
PKH 26 (red)		557	567	Used for labeling cells. (cf PKH 2 or 72)
Tetramethyl rhodamine Isothiocyanate (TRITC)	[95197-95-8]	529 (492)	596 (518)	Protein fluorochrome, used for immunofluorescence

** Of the many fluorochromes reported in this book only a very small selection is tabulated here. # These wavelengths may vary somewhat depending on the solvent used, and on the pH if measured in aqueous solutions.

TABLE 21. RESIDUAL SOLVENT SIGNALS OF COMMON NMR SOLVENTS
(Adapted from Gottieb et al. *J Org Chem* **62** 7512 *1997*, Fulmer et al. *Organometallics* **29**, 2176 *2010.*)

Solvents	**^{1}H NMR**	**^{13}C NMR**
Deuterated chloroform , $CDCl_3$	7.26	77.16
Deuterated dichloromethane CD_2Cl_2	5.32	53.84
Deuterated benzene, C_6D_6	7.16	128.06
Deuterated acetone, $(CD_3)_2CO$	2.05	29.84; 206.26
Deuterated dimethylsulfoxide, $(CD_3)_2SO$	2.50	35.52
Deuterated acetonitrile, CD_3CN	1.94	1.32; 118.26
Deuterated methanol, CD_3OD	3.31	49.00
Deuterated water, D_2O	4.79	–

Shaded region denotes residual undeuterated solvent. Multiplicities are singlet unless denoted otherwise (s=singlet, t=triplet, m=multiplet).
. The multiplicities of trace impurities maybe different for methanol and ethanol if coupling with the OH proton is observed.

TABLE 24. AQUEOUS BUFFERS

Approx. pH	Composition
0	2N sulfuric acid or N hydrochloric acid
1	0.1N hydrochloric acid or 0.18N sulfuric acid
2	**Either** 0.01N hydrochloric acid or 0.013N sulfuric acid **Or** 50 ml of 0.1M glycine (also 0.1M NaCl) + 50 ml of 0.1N hydrochloric acid
3	**Either** 20 ml of the 0.2M Na_2HPO_4 + 80 ml of 0.1M citric acid **Or** 50 ml of 0.1M glycine + 22.8 ml of 0.1N hydrochloric acid in 100 ml
4	**Either** 38.5 ml of 0.2M Na_2HPO_4 + 61.5 ml of 0.1M citric acid **Or** 18 ml of 0.2M NaOAc + 82 ml of 0.2M acetic acid
5	**Either** 70 ml of 0.2M NaOAc + 30 ml of 0.2M acetic acid **Or** 51.5 ml of 0.2M Na_2HPO_4 + 48.5 ml of 0.1M citric acid
6	63 ml of 0.2M Na_2HPO_4 + 37 ml of 0.1M citric acid
7	82 ml of M Na_2HPO_4 + 18 ml of 0.1M citric acid
8	**Either** 50 ml of 0.1M Tris buffer + 29 ml of 0.1N hydrochloric acid, in 100 ml **Or** 30 ml of 0.05M borax + 70 ml of 0.2M boric acid
9	80 ml of 0.05M borax + 20 ml of 0.2M boric acid
10	**Either** 25 ml of 0.05M borax + 43 ml of 0.1N NaOH, in 100 ml **Or** 50 ml of 0.1M glycine + 32 ml of 0.1N NaOH, in 100 ml
11	50 ml of 0.15M Na_2HPO_4 + 15 ml of 0.1N NaOH
12	50 mL of 0.15M Na_2HPO_4 + 75 ml of 0.1N NaOH
13	0.1N NaOH or KOH
14	N NaOH or KOH

These buffers are suitable for use in obtaining ultraviolet spectra. Alternatively, for a set of accurate buffers of low, but constant, ionic strength (I = 0.01) *covering a pH range 2.2 to 11.6 at 20*°, *see* Perrin *Aust J Chem* **16** 572 *1963.* "In 100 ml" means that the solution is made up to 100 ml with pure water.

TABLE 25. SOLUBILITY COEFFICIENTS OF AIR AT 1atm IN WATER

T °C	$(\beta)_{air}$	$(l)_{air}$	% O_2 (by vol)	$(l)_{O_2}$	Conc of O_2 in H_2O
0	0.0292	0.0292	34.91	0.0102	0.455mM
20	0.0187	0.0199	34.03	0.0068	0.282mM
25	0.0171	0.0187	33.82	0.0063	0.258mM
30	0.0156	0.0173	33.62	0.0060	0.237mM

(β) is the Bunsen coeff. in ml gas/ml H_2O at STP. (*l*) is the Ostwald coeff. in ml gas/ml H_2O at stated temp.

CHAPTER 2

CHEMICAL METHODS USED IN PURIFICATION

GENERAL REMARKS

Greater selectivity in purification can often be achieved by making use of differences in chemical properties between the substance to be purified and the contaminants. Unwanted metal ions may be removed by precipitation in the presence of a *collector* (see below). Sodium borohydride and other metal hydrides transform organic peroxides and carbonyl-containing impurities such as aldehydes and ketones in alcohols and ethers. Many classes of organic chemicals can be purified by conversion into suitable derivatives, followed by regeneration. This chapter describes relevant procedures.

REMOVAL OF TRACES OF METALS FROM REAGENTS

METAL IMPURITIES

The presence of metal contaminants in reagents may sometimes affect the chemical or biochemical outcomes of an experiment. In these cases, it is necessary to purify the reagents used. Metal (and other) impurities can be determined qualitatively and quantitatively by atomic absorption spectroscopy (AAA), x-ray photoelectron spectroscopy (XPS), various mass spectrometric methods and/or inductively coupled plasma mass spectrometry (ICP-MS) (see Chapter 1, Question of Purity) and the required purification procedures can be formulated. Metal impurities in organic compounds are usually in the form of ionic salts or complexes with organic compounds and very rarely in the form of free metal. If they are present in the latter form then they can be removed by crystallising the organic compound (whereby the insoluble metal can be removed by filtration), or by distillation in which case the metal remains behind with the residue in the distilling flask. If the impurities are in the ionic or complex forms, then extraction of the organic compound in a suitable organic solvent with aqueous acidic or alkaline solutions will reduce their concentration to acceptable levels.

When the metal impurities are present in inorganic compounds as in metals or metal salts, then advantage of the differences in chemical properties should be taken. Properties of the impurities like the solubility, the solubility product (product of the metal ion and the counter-ion concentrations), the stability constants of the metal complexes with organic complexing agents and their solubilities in organic solvents should be considered. Alternatively the impurities can be masked by the addition of complexing agents which could lower the concentration of the metal ion impurities to such low levels that they would not interfere with the main compound (see **complexation** below). Specific procedures and examples are provided below.

DISTILLATION

Reagents such as water, ammonia, hydrochloric acid, nitric acid, perchloric acid, and sulfuric acid can be purified *via* distillation (preferably under reduced pressure and particularly with perchloric acid) using an all-glass still. Isothermal distillation is convenient for ammonia: a beaker containing concentrated ammonia is placed alongside a beaker of distilled water for several days in an empty desiccator so that some of the ammonia distils over into the water. The redistilled ammonia should be kept in polyethylene or paraffin-waxed bottles. Hydrochloric acid can be purified in the same way. To ensure the absence of metal contaminants from some salts (e.g. ammonium acetate), it may be more expedient to synthesise the salts using distilled components rather than to attempt to purify the salts themselves.

Purification of Laboratory Chemicals. http://dx.doi.org/10.1016/B978-0-12-382161-4.00002-9

SCAVENGER RESINS AND OTHER SUPPORTS

There is now an extensive range of supported reactants that use resins, silica, carbons etc, to clean up reactions prior to final purification which is gaining favour in the laboratory. [See section on "Scavenger Resins" in Chapter 3, at the end of the sections on "*Preparation of other adsorbents"*, "FPLC" and "HPLC".]

USE OF ION-EXCHANGE RESINS

Application of ion-exchange columns has greatly facilitated the removal of heavy metal ions such as Cu^{2+}, Zn^{2+} and Pb^{2+} from aqueous solutions of many reagents. Thus, sodium salts and sodium hydroxide can be purified by passage through a column of a cation-exchange resin in its sodium form, prepared by washing the resin with 0.1M aqueous NaOH then washing with water until the pH of the effluent is ~7. Similarly, for acids, a resin in its H^+ form [prepared by washing the column with 0.1M aqueous mineral acid (HCl, H_2SO_4) followed by thorough washing with water until the effluent has pH ~7 is used]. In some cases, where metals form anionic complexes, they can be removed by passage through an anion-exchange resin. Iron in hydrochloric acid solution can be removed in this way.

Ion-exchange resins are also useful for demineralising biochemical preparations such as proteins. Removal of metal ions from protein solutions using polystyrene-based resins, however, may lead to protein denaturation. This difficulty may be avoided by using a weakly acidic cation exchanger such as Bio-Rex 70.

Heavy metal contamination of pH buffers can be removed by passage of the solutions through a Chelex X-100 column. For example when a solution of 0.02M HEPES [4-(2-Hydroxyethyl)piperazine-1-ethanesulfonic acid] containing 0.2M KCl (1L, pH 7.5) alone or with calmodulin, is passed through a column of Chelex X-100 (~60g) in the K^+ form, the level of Ca^{2+} ions falls to less than 2×10^{-7} M as shown by atomic absorption spectroscopy. Such solutions should be stored in polyethylene containers that have been washed with boiling deionised water (5 minutes) and rinsed several times with deionised water. TES [*N*,*N*,*N*′,*N*′-Tetraethylsulfamide] and TRIS [Tris-(hydroxymethyl)aminomethane] have been similarly decontaminated from metal ions.

Water, with very low concentrations of ionic impurities (and approaching conductivity standards), is very readily obtained by percolation through alternate columns of cation- and anion-exchange resins, or through a mixed-bed resin, and many commercial devices are available for this purpose. For some applications, this method is unsatisfactory because the final deionised water may contain traces of organic material after passage through the columns. However, organic matter can be removed by using yet another special column in series for this purpose (see Water Purification Systems-Pure and Ultrapure in <www.millipore.com>).

PRECIPITATION

In removing traces of impurities by precipitation, it is necessary to include a material to act as a *collector* of the precipitated substance so as to facilitate its removal by filtration or decantation. The following are a few examples.

Removal of lead contaminants

Aqueous hydrofluoric acid can be freed from lead by adding 1ml of 10% strontium chloride per 100ml of acid, lead being co-precipitated as lead fluoride with the strontium fluoride. If the hydrofluoric acid is decanted from the precipitate and the process repeated, the final lead content in the acid is less than 0.003ppm. Similarly, lead can be precipitated from a nearly saturated sodium carbonate solution by adding 10% strontium chloride dropwise (1–2ml per 100ml) followed by filtration. (If the sodium carbonate is required as a solid, the solution can be evaporated to dryness in a platinum dish.) Removal of lead from potassium chloride uses precipitation as lead sulfide by bubbling H_2S, followed, after filtration, by evaporation and recrystallisation of the potassium chloride.

Removal of iron contaminants

Iron contaminants have been removed from potassium thiocyanate solutions by adding a slight excess of an aluminium salt, then precipitating aluminum and iron as their hydroxides by adding a few drops of ammonia. Iron is also carried down on the hydrated manganese dioxide precipitate formed in cadmium chloride or cadmium sulfate solutions by adding 0.5% aqueous potassium permanganate (0.5ml per 100ml of solution), sufficient ammonia to give a slight precipitate, and 1ml of ethanol. The solution is heated to boiling to coagulate the precipitate, then filtered. Ferrous ion can be removed from copper solutions by adding some hydrogen peroxide to the solution to oxidise the iron, followed by precipitation of ferric hydroxide by adding a small amount of sodium hydroxide.

Removal of other metal contaminants

Traces of calcium can be removed from solutions of sodium salts by precipitation at pH 9.5–10 as the 8-hydroxyquinolinate. The excess 8-hydroxyquinoline acts as a *collector* and is extracted out with an organic solvent.

EXTRACTION

In some cases, a simple solvent extraction is sufficient to remove a particular impurity. For example, traces of gallium can be removed from titanous chloride in hydrochloric acid by extraction with diisopropyl ether. Similarly, ferric chloride can be removed from aluminium chloride solutions containing hydrochloric acid by extraction with diethyl ether. Usually, however, it is necessary to extract an undesired metal with an organic solvent in the presence of a suitable complexing agent such as dithizone (diphenylthiocarbazone) or sodium diethyl dithiocarbamate. When the former is used, weakly alkaline solutions of the substance containing the metal impurity are extracted with dithizone in chloroform (at about 25mg/L of chloroform) or carbon tetrachloride until the colour of some fresh dithizone solution remains unchanged after shaking. Dithizone complexes metals more strongly in weakly alkaline solutions. Excess dithizone in the aqueous medium is removed by extracting with the pure solvent (chloroform or carbon tetrachloride), the last traces of which, in turn, are removed by aeration. This method has been used to remove metal impurities from aqueous solutions of ammonium hydrogen citrate, potassium bromide, potassium cyanide, sodium acetate and sodium citrate. The advantage of dithizone for such a purpose lies in the wide range of metals with which it combines under these conditions. 8-Hydroxyquinoline (oxine) can also be used in this way. Sodium diethyl dithiocarbamate has been used to remove metals from aqueous hydroxylamine hydrochloride (made just alkaline to thymol blue by adding ammonia) from copper and other heavy metals by repeated extraction with chloroform until no more diethyl dithiocarbamate remained in the solution (which was then acidified to thymol blue by adding hydrochloric acid).

COMPLEXATION

Although not strictly a removal of an impurity, addition of a suitable complexing agent such as ethylenediaminetetraacetic acid often overcomes the undesirable effects of contaminating metal ions by reducing the concentrations of the free metal species to very low levels, i.e. sequestering metal ions by complexation. For a detailed discussion of this *masking*, see *Masking and Demasking of Chemical Reactions*, D.D.Perrin, Wiley-Interscience, New York, 1970.

USE OF METAL HYDRIDES

This group of reagents is commercially available in large quantities; some of its members-notably lithium aluminium hydride ($LiAlH_4$), calcium hydride (CaH_2), sodium borohydride ($NaBH_4$) and potassium borohydride (KBH_4)-have found widespread use in the purification of chemicals.

LITHIUM ALUMINIUM HYDRIDE

This solid is stable at room temperature and is soluble in ether-type solvents. It reacts violently with water, liberating hydrogen, and is a powerful drying and reducing agent for organic compounds. It reduces aldehydes, ketones, esters, carboxylic acids, peroxides, acid anhydrides and acid chlorides to the corresponding alcohols. Similarly, amides, nitriles, aldimines and aliphatic nitro compounds yield amines, while aromatic nitro compounds are converted to azo compounds. For this reason it finds extensive application in purifying organic chemical substances by the removal of water and carbonyl containing impurities as well as peroxides formed by autoxidation. Reactions can generally be carried out at room temperature, or in refluxing diethyl ether, at atmospheric pressure. *When drying organic liquids with this reagent it is important that the concentration of water in the liquid is below 0.1% - otherwise a violent reaction or* **EXPLOSION** *may occur. $LiAlH_4$ should be added cautiously to a cooled solution of organic liquid in a flask equipped with a reflux condenser.*

CALCIUM HYDRIDE

This powerful drying agent is suitable for use with hydrogen, argon, helium, nitrogen, hydrocarbons, chlorinated hydrocarbons, esters and higher alcohols.

SODIUM BOROHYDRIDE

This solid, which is stable in dry air up to 300°, is a less powerful reducing agent than lithium aluminium hydride, from which it differs also by being soluble in hydroxylic solvents and to a lesser extent in ether-type solvents. Sodium borohydride forms a dihydrate melting at 36–37°, and its aqueous solutions decompose slowly unless stabilised to above pH 9 by alkali. (For example, a useful sodium borohydride solution is one that is nearly saturated at 30–40° and containing 0.2% sodium hydroxide.) Its solubility in water is 25, 55 and 88g per 100ml of water at 0, 25 and 60°, respectively. Boiling or acidification rapidly decomposes aqueous sodium borohydride solutions. The reagent, available either as a hygroscopic solid or as an aqueous sodium hydroxide solution, is useful as a water soluble reducing agent for aldehydes, ketones and organic peroxides. This explains its use for the removal of carbonyl-containing impurities and peroxides from alcohols, polyols, esters, polyesters, amino alcohols, olefins, chlorinated hydrocarbons, ethers, polyethers, amines (including aniline), polyamines and aliphatic sulfonates.

Purifications using sodium borohydride can be carried out conveniently using alkaline aqueous or methanolic solutions of sodium borohydride, allowing the reaction mixture to stand at room temperature for several hours. Other solvents that can be used with this reagent include isopropyl alcohol (without alkali), amines (including liquid ammonia, in which its solubility is 104g per 100g of ammonia at 25°, and ethylene diamine), diglyme, formamide, dimethylformamide and tetrahydrofurfuryl alcohol. Alternatively, the material to be purified can be percolated through a column of the borohydride. In the absence of water, sodium borohydride solutions in organic solvents such as dioxane or amines decompose only very slowly at room temperature. Treatment of ethers with sodium borohydride appears to inhibit peroxide formation.

POTASSIUM BOROHYDRIDE

Potassium borohydride is similar in properties and reactions to sodium borohydride, and can similarly be used as a reducing agent for removing aldehydes, ketones and organic peroxides. It is non-hygroscopic and can be used in water, ethanol, methanol or water-alcohol mixtures, provided some alkali is added to minimise decomposition, but it is somewhat less soluble than sodium borohydride in most solvents. For example, the solubility of potassium borohydride in water at 25° is 19g per 100ml of water (as compared to 55g of sodium borohydride).

PURIFICATION *via* DERIVATIVES

Relatively few derivatives of organic substances are suitable for use as aids to purification. This is because of the difficulty in regenerating the starting material. For this reason, we list below the common methods of preparation of derivatives that can be used in this way.

Whether or not any of these derivatives is likely to be satisfactory for the use of any particular case will depend on the degree of difference in properties, such as solubility, volatility or melting point, between the starting material, its derivative and likely impurities, as well as on the ease with which the substance can be recovered. Purification *via* a derivative is likely to be of most use when the quantity of pure material that is required is not too large. Where large quantities (for example, more than 50g) are available, it is usually more economical to purify the material directly (for example, in distillations and recrystallisations).

The most generally useful purifications *via* derivatives are as follows.

ALCOHOLS

Aliphatic or aromatic alcohols are converted to solid esters. *p*-Nitrobenzoates are examples of convenient esters to form because of their sharp melting points, and the ease with which they can be recrystallised as well as the ease with which the parent alcohol can be recovered. The *p*-nitrobenzoyl chloride used in the esterification is prepared by refluxing dry *p*-nitrobenzoic acid with a 3 molar excess of thionyl chloride for 30minutes on a steam bath (*in a fume cupboard*). The solution is cooled slightly and the excess thionyl chloride is distilled off under vacuum, keeping the temperature below 40°. Dry toluene is added to the residue in the flask, then distilled off under vacuum, the process being repeated two or three times to ensure complete removal of thionyl chloride, hydrogen chloride and sulfur dioxide. (This freshly prepared *p*-nitrobenzoyl chloride cannot be stored without decomposition; it should be used directly.) A solution of the acid chloride (1mol) in dry toluene or alcohol-free chloroform (distilled from P_2O_5 or by passage through an activated Al_2O_3 column) under a reflux condense is cooled in an ice bath while the alcohol (1mol), with or without a solvent (preferably miscible

with toluene or alcohol-free chloroform), is added dropwise to it. When addition is over and the reaction subsides, the mixture is refluxed for 30minutes and the solvent is removed under reduced pressure. The solid ester is then recrystallised to constant melting point from toluene, acetone, low boiling point petroleum ether or mixtures of these, but not from alcohols (due to unwanted trans-esterifiction).
Hydrolysis of the ester is achieved by refluxing in aqueous N or 2N NaOH solution until the insoluble ester dissolves. The solution is then cooled, and the alcohol is extracted into a suitable solvent, e.g. ether, toluene or alcohol-free chloroform. The extract is dried ($CaSO_4$, $MgSO_4$) and distilled, then fractionally distilled if liquid or recrystallised if solid. (The *p*-nitrobenzoic acid can be recovered by acidification of the aqueous layer.) In most cases where the alcohol to be purified can be readily extracted from ethanol, the hydrolysis of the ester is best achieved with N or 2N ethanolic NaOH or 85% aqueous ethanolic N NaOH. The former is prepared by dissolving the necessary alkali in a minimum volume of water and diluting with absolute alcohol. The ethanolic solution is refluxed for one to two hours and hydrolysis is complete when an aliquot gives a clear solution on dilution with four or five times its volume of water. The bulk of the ethanol is distilled off and the residue is extracted as above. Alternatively, use can be made of ester formation with benzoic acid, toluic acid or 3,5-dinitrobenzoic acid, by the above method.
Other derivatives can be prepared by reaction of the alcohol with an acid anhydride. For example, phthalic or 3-nitrophthalic anhydride (1 mol) and the alcohol (1mol) are refluxed for half to one hour in a non-hydroxylic solvent, e.g. toluene or alcohol-free chloroform, and then cooled. The phthalate ester crystallises out, is precipitated by the addition of low boiling petroleum ether or is isolated by evaporation of the solvent. It is recrystallised from water, 50% aqueous ethanol, toluene or low boiling petroleum ether. Such an ester has a characteristic melting point and the alcohol can be recovered by acid or alkaline hydrolysis.

ALDEHYDES

The best derivative from which an aldehyde can be recovered readily is its bisulfite addition compound, the main disadvantage being the lack of a sharp melting point. The aldehyde (sometimes in ethanol) is shaken with a cold saturated solution of sodium bisulfite until no more solid adduct separates. The adduct is filtered off, washed with a little water, followed by alcohol. A better reagent to use is a freshly prepared saturated aqueous sodium bisulfite solution to which 75% ethanol is added to near-saturation. (Water may have to be added dropwise to render this solution clear.) With this reagent the aldehyde need not be dissolved separately in alcohol and the adduct is finally washed with alcohol. The aldehyde is recovered by dissolving the adduct in the least volume of water and adding an equivalent quantity of sodium carbonate (not sodium hydroxide) or concentrated hydrochloric acid to react with the bisulfite, followed by steam distillation or solvent extraction.
Other derivatives that can be prepared are the Schiff bases and semicarbazones. Condensation of the aldehyde with an equivalent of primary aromatic amine yields the Schiff base, for example aniline at 100° for 10–30minutes.
Semicarbazones are prepared by dissolving semicarbazide hydrochloride (*ca* 1g) and sodium acetate (*ca* 1.5g) in water (8–10ml) and adding the aldehyde or ketone (0.5–1g) with stirring. The semicarbazone crystallises out and is recrystallised from ethanol or aqueous ethanol. These are hydrolysed by steam distillation in the presence of oxalic acid or better by exchange with pyruvic acid (Hershberg *J Org Chem* **13** 542 *1948*) [see entry under Ketones].

AMINES

Picrates

The most versatile derivative from which the free base can be readily recovered is the picrate. This is very satisfactory for primary and secondary aliphatic amines and aromatic amines and is particularly so for heterocyclic bases. The amine, dissolved in water or alcohol, is treated with excess of a saturated solution of picric acid in water or alcohol, respectively, until separation of the picrate is complete. If separation does not occur, the solution is stirred vigorously and warmed for a few minutes, or diluted with a solvent in which the picrate is insoluble. Thus, a solution of the amine and picric acid in ethanol can be treated with petroleum ether to precipitate the picrate. Alternatively, the amine can be dissolved in alcohol and aqueous picric acid added. The picrate is filtered off, washed with water or ethanol and recrystallised from boiling water, ethanol, methanol, aqueous ethanol, methanol or chloroform. The solubility of picric acid in water and ethanol is 1.4 and 6.23% respectively at 20°.
It is not advisable to store large quantities of picrates for long periods, *particularly when they are dry due to their potential* **EXPLOSIVE** *nature*. Also this method is not advised when large quantities of amines (e.g. >25g) are to be purified. The free base should be recovered as soon as possible. The picrate is suspended in an

excess of 2N aqueous NaOH and warmed a little. Because of the limited solubility of sodium picrate, excess hot water must be added. Alternatively, because of the greater solubility of lithium picrate, aqueous 10% lithium hydroxide solution can be used. The solution is cooled, the amine is extracted with a suitable solvent such as diethyl ether or toluene, washed with 5N NaOH until the alkaline solution remains colourless, then with water, and the extract is dried with anhydrous sodium carbonate. The solvent is distilled off and the amine is fractionally distilled (under reduced pressure if necessary) or recrystallised.
If the amines are required as their hydrochlorides, picrates can often be decomposed by suspending them in acetone and adding two equivalents of 10N HCl. The hydrochloride of the base is filtered off, leaving the picric acid in the acetone. Dowex No 1 anion-exchange resin in the chloride form is useful for changing solutions of the more soluble picrates (for example, of adenosine) into solutions of their hydrochlorides, from which sodium hydroxide precipitates the free base.

Salts

Amines can also be purified *via* their salts, e.g. hydrochlorides. A solution of the amine in dry toluene, diethyl ether, dichloromethane or chloroform is saturated with dry hydrogen chloride (generated by addition of concentrated sulfuric acid to dry sodium chloride, or to concentrated HCl followed by drying the gas through sulfuric acid, or the HCl gas is obtained from a hydrogen chloride cylinder) and the insoluble hydrochloride is filtered off and dissolved in water. The solution is made alkaline and the amine is extracted, as above. Hydrochlorides can also be prepared by dissolving the amine in ethanolic HCl and adding diethyl ether. Where hydrochlorides are too hygroscopic or too soluble for satisfactory isolation, other salts, e.g. nitrate, sulfate, bisulfate or oxalate, can be used.

Double salts

The amine (1mol) is added to a solution of anhydrous zinc chloride (1mol) in concentrated HCl (42ml) in ethanol (200ml, or less depending on the solubility of the double salt). The solution is stirred for 1 hour and the precipitated salt is filtered off and recrystallised from ethanol. The free base is recovered by adding excess of 5-10N NaOH (to dissolve the zinc hydroxide that separates) and is steam distilled. Mercuric chloride (highly poisonous) in hot water can be used instead of zinc chloride and the salt is crystallised from 1% hydrochloric acid. Other double salts have been used, e.g. cuprous salts, but are not as convenient as the above salts.

***N*-Acetyl derivatives**

Purification as their *N*-acetyl derivatives is satisfactory for primary, and to a limited extent, secondary amines. Tertiary amines are not acetylated. The base is refluxed with slightly more than one equivalent of acetic anhydride for half to one hour, cooled and poured into ice-cold water. The insoluble derivative is filtered off, dried, and recrystallised from water, ethanol, aqueous ethanol or benzene (CAUTION **toxic**!). The derivative can be hydrolysed to the parent amine by refluxing with 70% sulfuric acid for a half to one hour. The solution is cooled, poured onto ice, and made alkaline. The amine is steam distilled or extracted as above. Alkaline hydrolysis is very slow.

***N*-Tosyl derivatives**

Primary and secondary amines are converted into their tosyl derivatives by mixing equimolar amounts of amine and *p*-toluenesulfonyl chloride in dry pyridine (*ca* 5–10mols) and allowing to stand at room temperature overnight. The solution is poured into ice-water and the pH adjusted to 2 with HCl. The solid derivative is filtered off, washed with water, dried (vacuum desiccator) and recrystallised from an alcohol or aqueous alcohol solution to a sharp melting point. The derivative is decomposed by dissolving in liquid ammonia (*fume cupboard*) and adding sodium metal (in small pieces with stirring) until the blue colour persists for 10–15 minutes. Ammonia is allowed to evaporate (*fume cupboard*), the residue treated with water and the solution checked that the pH is above 10. If the pH is below 10, then the solution has to be basified with 2N NaOH. The mixture is extracted with diethyl ether or toluene, the extract is dried (K_2CO_3), evaporated and the residual amine recrystallised if solid or distilled if liquid.

AROMATIC HYDROCARBONS

Adducts

Aromatic hydrocarbons can be purified as their picrates using the procedures described for amines. Instead of picric acid, 1,3,5-trinitrobenzene or 2,4,7-trinitrofluorenone can also be used. In all these cases, following recrystallisation, the hydrocarbon can be isolated either as described for amines or by passing a solution of the adduct through an activated alumina column and eluting with toluene or petroleum ether. The picric acid and nitro compounds are more strongly adsorbed on the column.

Sulfonation

Naphthalene, xylenes and alkyl benzenes can be purified by sulfonation with concentrated sulfuric acid and crystallisation of the sodium sulfonates. The hydrocarbon is distilled out of the mixture with superheated steam.

CARBOXYLIC ACIDS

4-Bromophenacyl esters

A solution of the sodium salt of the acid is prepared. If the salt is not available, the acid is dissolved in an equivalent of aqueous NaOH and the pH adjusted to 8–9 with this base. A solution of one equivalent of 4-bromophenacyl bromide (for a monobasic acid, two equivalents for a dibasic acid, etc) in ten times its volume of ethanol is then added. The mixture is heated to boiling, and, if necessary, enough ethanol is added to clarify the solution which is then refluxed for half an hour to three hours depending on the number of carboxylic groups that have to be esterified. (One hour is generally sufficient for monocarboxylic acids.) On cooling, the ester should crystallise out. If it does not, then the solution is heated to boiling, and enough water is added to produce a slight turbidity. The solution is again cooled. The ester is collected, and recrystallised or fractionally distilled.

The ester is hydrolysed by refluxing for 1–2 hours with 1–5% of barium carbonate suspended in water or with aqueous sodium carbonate solution. The solution is cooled and extracted with diethyl ether, toluene or chloroform. It is then acidified and the acid is collected by filtration or extraction, and recrystallised or fractionally distilled. 4-Bromophenylphenacyl esters are used similarly.

p-Nitrobenzyl esters can be prepared in an analogous manner using the sodium salt of the acid and *p*-nitrobenzyl bromide. They are readily hydrolysed.

Alkyl esters

Of the alkyl esters, methyl esters are the most useful because of their rapid hydrolysis. The acid is refluxed with one or two equivalents of methanol in excess alcohol-free chloroform (or dichloromethane) containing about 0.1g of *p*-toluenesulfonic acid (as catalyst), using a Dean-Stark apparatus. (The water formed by the esterification is carried away into the trap.) When the theoretical amount of water is collected in the trap, esterification is complete. The chloroform solution in the flask is washed with 5% aqueous sodium carbonate solution, then water, and dried over anhydrous sodium sulfate or magnesium sulfate. The chloroform is distilled off and the ester is fractionally distilled through an efficient column, or recrystallised if it is a solid. The ester is hydrolysed by refluxing with 5–10% aqueous NaOH solution until the insoluble ester has completely dissolved. The aqueous solution is concentrated a little by distillation to remove almost all of the methanol. It is then cooled and acidified. The acid is either extracted with diethyl ether, toluene or chloroform, or filtered off and isolated as above. Other methods for preparing esters are available, e.g. addition of an ethereal solution of diazomethane (yellow in colour, poisonous, use a fume cupboard. CARE: Use diazomethane with extreme care as the reagent is POISONOUS and HIGHLY explosive; special precautions MUST be used; see *Fieser and Fieser's Reagents for Organic Synthesis* **1** pp. 191–195 *1967*) to the acid which dissolves as the acid is esterified, liberating N_2 and the yellow colour. The methyl ester so produced is obtained by evaporating the ethereal solution.

Salts

The most useful salt derivatives for carboxylic acids are the isothiouronium salts. These are prepared by mixing almost saturated solutions containing the acid (carefully neutralised with N NaOH using phenolphthalein indicator) then adding two drops of N HCl and an equimolar amount of *S*-benzylisothiouronium chloride in ethanol and filtering off the salt that crystallises out. After recrystallisation from water, alcohol or aqueous alcohol the salt is decomposed by suspending or dissolving in 2N HCl and extracting the carboxylic acid from aqueous solution into diethyl ether, chloroform or toluene.

HYDROPEROXIDES

These can be converted to their sodium salts by precipitation below 30º with aqueous 25% NaOH. The salt is then decomposed by addition of solid (powdered) carbon dioxide and extracted with low-boiling petroleum ether. The solvent should be removed under reduced pressure below 20º. **The manipulation should be adequately shielded at all times to guard against EXPLOSIONS for the safety of the operator.**

KETONES

Bisulfite adduct

The adduct can be prepared and decomposed as described for aldehydes. Alternatively, because no Cannizzaro reaction is possible, it can also be decomposed with 0.5N NaOH.

Semicarbazones

A powdered mixture of semicarbazide hydrochloride (1mol) and anhydrous sodium acetate (1.3mol) is dissolved in water by gentle warming. A solution of the ketone (1mol) in the minimum volume of ethanol needed to dissolve it is then added. The mixture is warmed on a water bath until separation of the semicarbazone is complete. The solution is cooled, and the solid filtered off. After washing with a little ethanol followed by water, it is recrystallised from ethanol or dilute aqueous ethanol. The derivative should have a characteristic melting point. The semicarbazone is decomposed by refluxing with excess of oxalic acid or with

aqueous sodium carbonate solution. The ketone (which steam distils) is distilled off. It is extracted or separated from the distillate (after saturating with NaCl), dried with $CaSO_4$ or $MgSO_4$ and fractionally distilled using an efficient column (under vacuum if necessary). [See entry under Aldehydes.]

PHENOLS

The most satisfactory derivatives for phenols that are of low molecular weight or monohydric are the benzoate esters. (Their acetate esters are generally liquids or low-melting solids.) Acetates are more useful for high molecular weight and polyhydric phenols.

Benzoates

The phenol (1mol) in 5% aqueous NaOH is treated (while cooling) with benzoyl chloride (1mol) and the mixture is stirred in an ice bath until separation of the solid benzoyl derivative is complete. The derivative is filtered off, washed with alkali, then water, and dried (in a vacuum desiccator over NaOH). It is recrystallised from ethanol or dilute aqueous ethanol. The benzoylation can also be carried out in dry pyridine at low temperature (*ca* 0°) instead of in NaOH solution, finally pouring the mixture into water and collecting the solid as above. The ester is hydrolysed by refluxing in an alcohol (for example, ethanol, *n*-butanol) containing two or three equivalents of the alkoxide of the corresponding alcohol (for example, sodium ethoxide or sodium *n*-butoxide) and a few (*ca* 5–10) millilitres of water, for half an hour to three hours. When hydrolysis is complete, an aliquot will remain clear on dilution with four to five times its volume of water. Most of the solvent is distilled off. The residue is diluted with cold water and acidified, and the phenol is steam distilled. The latter is collected from the distillate, dried and either fractionally distilled or recrystallised. It can also be isolated by extraction from a slightly acidified (pH ~3) aqueous solution with diethyl ether.

Acetates

These can be prepared as for the benzoates using either acetic anhydride with 3N NaOH or acetyl chloride in pyridine. They are hydrolysed as described for the benzoates. This hydrolysis can also be carried out with aqueous 10% NaOH solution, completion of hydrolysis being indicated by the complete dissolution of the acetate in the aqueous alkaline solution. On steam distillation, acetic acid also distils off, but in these cases the phenols (see above) are invariably solids which can be filtered off and recrystallised.

PHOSPHATE AND PHOSPHONATE ESTERS

These can be converted to their uranyl nitrate addition compounds. The crude or partially purified ester is saturated with uranyl nitrate solution and the adduct is filtered off. It is recrystallised from *n*-hexane, toluene or ethanol. For the more soluble members crystallisation from hexane using low temperatures (–40°) has been successful. The adduct is decomposed by shaking with sodium carbonate solution and water, the solvent is steam distilled (if hexane or toluene is used) and the ester is collected by filtration. Alternatively, after decomposition, the organic layer is separated, dried with $CaCl_2$ or BaO, filtered, and fractionally distilled under high vacuum.

MISCELLANEOUS

Impurities can sometimes be removed by conversion to derivatives under conditions where the major component does not react or reacts much more slowly. For example, normal (straight-chain) paraffins can be freed from unsaturated and branched-chain components by taking advantage of the greater reactivity of the latter with chlorosulfonic acid or bromine. Similarly, the preferential nitration of aromatic hydrocarbons can be used to remove e.g. benzene or toluene from cyclohexane by shaking for several hours with a mixture of concentrated nitric acid (25%), sulfuric acid (58%), and water (17%).

GENERAL METHODS FOR THE PURIFICATION OF CLASSES OF COMPOUNDS

Chapters 4, 5 and 6 list a large number of individual compounds, with a brief statement of how each one may be purified. For substances that are not included in these chapters the following procedures may prove helpful.

PROCEDURES

If the laboratory worker does not know of a reference to the preparation of a commercially available substance, he/she may be able to make a reasonable guess at the synthetic methods used from published laboratory syntheses.

This information, in turn, can simplify the necessary purification steps by suggesting probable contaminants.
Physical methods of purification depend largely on the melting and boiling points of the materials. For gases and low-boiling liquids use is commonly made of the *freeze-pump-thaw* procedure. Gas chromatography is also useful, especially for low-boiling point liquids. Liquids are usually purified by refluxing with drying agents, acids or bases, reducing agents, charcoal, etc., followed by fractional distillation under reduced pressure. For solids, general methods include fractional freezing of the melted material, taking the middle fraction. Another procedure is sublimation of the solid under reduced pressure. The other commonly used method for purifying solids is by recrystallisation from a solution in a suitable solvent, by cooling with or without the prior addition of a solvent in which the solute is not very soluble (see Chapter 1).

The nature of the procedure will depend to a large extent on the quantity of purified material that is required. For example, for small quantities (50–250mg) of a pure volatile liquid, preparative gas chromatography is probably the best method. Two passes through a suitable column may well be sufficient. Similarly, for smaller amounts (100–500 mg) of an organic solid, column chromatography is likely to be satisfactory, the eluate being collected as a number of separate fractions (*ca* 5–10 ml) which are examined by FT-IR, NMR or UV spectroscopy, TLC or by some other appropriate analytical technique. (For information on suitable adsorbents and eluents the texts referred to in the bibliography at the end of Chapters 1 and 2 should be consulted.) Preparative thin layer chromatography or HPLC, FC and HPFC can also be used successfully for purifying up to 500 mg of solid. The latter chromatographic techniques (see Chapter 1) are more and more commonly used procedures for the purification of small molecules as well as large molecules such as polypeptides and DNA.

Where larger quantities (upwards of 1g) are required, most of the impurities should be removed by preliminary treatments, such as solvent extraction, liquid-liquid partition, or conversion to a derivative (*vide supra*) which can be purified by crystallisation or fractional distillation before being reconverted to the starting material. The substance is then crystallised or distilled. If the final amounts must be in excess of 25 g, preparation of a derivative is sometimes omitted because of the cost involved. In all of the above cases, purification is likely to be more laborious if the impurity is an isomer or a derivative with closely similar physical properties.

CRITERIA OF PURITY

Purification becomes meaningful only insofar as adequate tests of purity are applied: the higher the degree of purity that is sought, the more stringent these tests must be. For this, the experimenter has to resort, in the first place, to preliminary physical methods such as melting and boiling points, chromatographic and spectroscopic procedures which are described in detail in Chapter 1. If the material is an organic solid, its melting point should first be taken and compared with the recorded value. *Note that the melting points of most salts, organic or inorganic, are generally decomposition points and are not reliable criteria of purity.* As part of the preliminary examination, the sample might be examined by thin layer chromatography in several different solvent systems and in high enough concentrations to facilitate the detection of minor components. On the other hand, if the substance is a liquid, its boiling point should be measured. If, further, the boiling point of the liquid is too high, or it decomposes on heating, then its purity should be assessed by high pressure liquid chromatography. Liquids, especially volatile ones, can be studied very satisfactorily by gas chromatography, preferably using at least two different stationary and/or mobile phases. Spectroscopic methods, if facilities are available, such as atomic absorption spectroscopy (AAA), and inductively coupled plasma mass spectrometry (ICP-MS) are useful and sensitive methods for detecting metal impurities and the concentrations of metals and metal salts or complexes.
Application of these tests at successive steps will give a good indication of whether or not the purification is satisfactory and will also show when adequate purification has been achieved. Finally elemental analyses, e.g. of carbon, hydrogen, nitrogen, sulfur, metals etc., are very sensitive to impurities (other than with isomers), and are good criteria of purity.
There are certain requirements for purity of new compounds in most journals. This is especially so for samples which are shown to have biological activity. See instructions to authors for ACS journals especially in *J. Med. Chem* (see "Guidelines for Authors under *Purity Criteria of Tested Compounds* <http://pubs.acs.org/journal/jmcmar>.)

GENERAL PROCEDURES FOR THE PURIFICATION OF SOME CLASSES OF ORGANIC COMPOUNDS

In the general methods of purification described below, it is assumed that the impurities belong essentially to a class of compounds different from the one being purified. They are suggested for use in cases where substances are not listed in Chapters 4, 5 and the low-molecular-weight compounds in Chapter 6. In such cases, the experimenter is advised to employ them in conjunction with information given in these chapters for the purification of suitable analogues. Also, for a wider range of drying agents and the use of cartridges (e.g. Na_2SO_4 for removal of H_2O, or Celite for removal of tar), solvents for extraction and solvents for recrystallisation, the reader is referred to Chapter 1. A common method of purification of organic compounds is to convert them to a suitable derivative which is purified (with the assumption that the impurity does not form a similar derivative, or if it does its properties are different), and then regenerate the original compound and purify it further. Various derivatives are described for different classes of compounds below, but many more can be considered, and the reader is referred to texts on "Protecting Groups" which describe ways of selectively protecting functional groups and facile means of deprotecting them, i.e. regenerating the unprotected group [P.J. Kocienski *Protecting Groups* Thieme International Publisher, 2005, ISBN 9783131356031; J.R. Hanson *Protecting Groups in Organic Synthesis* Sheffield Academic Press, 1999, ISBN 9781850759577, or J. Wiley & Sons Inc, 1999, ISBN 980632045068]. See Chapter 6 for general purification procedures used for macromolecules.

ACETALS

These are generally diethyl or dimethyl acetal derivatives of aldehydes. They are more stable to alkali than to acids. Their common impurities are the corresponding alcohol, aldehyde and water. Drying with sodium wire removes alcohols and water, and polymerizes aldehydes so that, after decantation, the acetal can be fractionally distilled. In cases where the use of sodium is too drastic, aldehydes can be removed by shaking with alkaline hydrogen peroxide solution and the acetal is dried with sodium carbonate or potassium carbonate. Residual water and alcohols (up to *n*-propyl) can be removed with Linde type 4A molecular sieves. The acetal is then filtered and fractionally distilled. Solid acetals (i.e. acetals of high-molecular-weight aldehydes) are generally low-melting and can be recrystallised from low-boiling petroleum ether, toluene or a mixture of both.

ACIDS

Carboxylic acids

Liquid carboxylic acids are first freed from neutral and basic impurities by dissolving them in aqueous alkali and extracting with diethyl ether. (The pH of the solution should be at least three units above the pK_a of the acid, see pK in Chapter 1). The aqueous phase is then acidified to a pH at least three units below the pK_a of the acid and again extracted with ether. It is quite unnecessary to add large excesses of mineral acid (e.g. HCl) to liberate the organic acid, as mineral acids dissolve appreciably in organic solvents such as diethyl ether. The extract is dried with magnesium sulfate or sodium sulfate and the ether is distilled off. The acid is fractionally distilled through an efficient column. It can be further purified by conversion to its methyl or ethyl ester (*vide supra*) which is then fractionally distilled. Hydrolysis yields the original acid which is again purified as above.
Acids that are solids can be purified in this way, except that distillation is replaced by repeated crystallisation (preferable from at least two different solvents such as water, alcohol or aqueous alcohol, toluene, toluene/petroleum ether or acetic acid.) Water-insoluble acids can be partially purified by dissolution in N sodium hydroxide solution and precipitation with dilute mineral acid. If the acid is required to be free from sodium ions, then it is better to dissolve the acid in hot N ammonia, heat to *ca* 80°, adding slightly more than an equal volume of N formic acid and allowing to cool slowly for crystallisation. Any ammonia, formic acid or ammonium formate that adhere to the acid are removed when the acid is dried in a vacuum — these are volatile.
Cartridges and columns are available (e.g. the Isolute SCX-2 made of polysulfonic acid bonded to silica as an ion exchange column developed by Biotage Inc (<www.biotage.com>), particularly for the purification of acids using flash chromatography.
The separation and purification of naturally occurring fatty acids, based on distillation, salt solubility and low temperature crystallisation, are described by K.S. Markley (Ed.), *Fatty Acids*, 2nd Edn, part 3, Chap. 20, Interscience, New York, 1964, see also N. Reavley *Essential Fatty Acids* Book Media Publ, 2002, ISBN 9780958157643; G. Grati and K. Sato (Eds) *Crystallisation and Polymorphism of Fats and Fatty Acids* Marcel Dekker, 1988, ISBN 9780824778750.
Aromatic carboxylic acids can be purified by conversion to their sodium salts, recrystallisation from hot water, and reconversion to the free acids.

Sulfonic acids

The low solubility of sulfonic acids in organic solvents and their high solubility in water makes necessary a treatment different from that for carboxylic acids. Sulfonic acids are strong acids, they have the tendency to hydrate, and many of them contain water of crystallisation. The lower-melting and liquid acids can generally be purified with only slight decomposition by fractional distillation, preferably under reduced pressure. A common impurity is sulfuric acid, but this can be removed by recrystallisation from concentrated aqueous solutions. The wet acid can be dried by azeotropic removal of water with toluene, followed by distillation. The higher-melting acids, or acids that melt with decomposition, can be recrystallised from water or, occasionally, from ethanol. For a typical purification of aromatic sulfonic acids using their barium salts refer to benzenesulfonic acid in the "Aromatic Compounds" section in Chapter 4.

Sulfinic acids

These acids are less stable, less soluble and less acidic than the corresponding sulfonic acids. The common impurities are the respective sulfonyl chlorides from which they have been prepared, and the thiolsulfonates (neutral) and sulfonic acids into which they decompose. The first two of these can be removed by solvent extraction from an alkaline solution of the acid. On acidification of an alkaline solution, the sulfinic acid crystallises out leaving the sulfonic acid behind. The lower molecular weight members are isolated as their metal (e.g. ferric) salts, but the higher members can be crystallised from water (made slightly acidic), or alcohol.

ACID CHLORIDES

The corresponding acid and hydrogen chloride are the most likely impurities. Usually these can be removed by efficient fractional distillation. Where acid chlorides are not readily hydrolysed (e.g. aryl sulfonyl chlorides) the compound can be freed from contaminants by dissolving in a suitable solvent such as alcohol-free chloroform, dry toluene or petroleum ether and shaking with dilute sodium bicarbonate solution. The organic phase is then washed with water, dried with anhydrous sodium sulfate or magnesium sulfate, and distilled or recrystallised. This procedure is *hazardous* with readily hydrolysable *carboxylic* acid chlorides such as acetyl chloride and benzoyl chloride. Solid acid chlorides should be thoroughly dried *in vacuo* over strong drying agents and are satisfactorily recrystallised from toluene, toluene-petroleum ether, petroleum ethers, alcohol-free chloroform/toluene, and, occasionally, from dry diethyl ether. Hydroxylic or basic solvents should be strictly avoided. *All operations should be carried out in a fume cupboard because of the* ***irritant*** *nature of these compounds which also attack the skin.*

ALCOHOLS

Monohydric alcohols

The common impurities in alcohols are aldehydes or ketones, and water. [*Ethanol* in Chapter 4 is typical.] Aldehydes and ketones can be removed by adding a small amount of sodium metal and refluxing for 2 hours, followed by distillation. Water can be removed in a similar way but it is preferable to use magnesium metal instead of sodium because it forms a more insoluble hydroxide, thereby shifting the equilibrium more completely from metal alkoxide to metal hydroxide. The magnesium should be activated with iodine (or a small amount of methyl iodide), and the water content should be low, otherwise the magnesium will be deactivated. If the amount of water is large, it should be removed by azeotropic distillation (see below), or by drying over anhydrous $MgSO_4$ (not $CaCl_2$ which combines with alcohols). Acidic materials can be removed by treatment with anhydrous Na_2CO_3, followed by a suitable drying agent, such as calcium hydride, and fractional distillation, using gas chromatography to establish the purity of the product (Ballinger & Long, *J Am Chem Soc* **82** 795 *1960*). Alternatively, the alcohol can be refluxed with freshly ignited CaO for 4hours and then fractionally distilled (McCurdy & Laidler, *Can J Chem* **41** 1867 *1963*).

With higher-boiling alcohols it is advantageous to add some freshly prepared magnesium ethoxide solution (only slightly more than required to remove the water), followed by fractional distillation. Alternatively, in such cases, water can be removed by azeotropic distillation with toluene. Higher-melting alcohols can be purified by crystallisation from methanol or ethanol, toluene/petroleum ether or petroleum ether. Sublimation in vacuum, molecular distillation and gas and liquid chromatographic methods are also useful means of purification. For purification *via* derivatives, *vide supra*.

Polyhydric alcohols

These alcohols are more soluble in water than are monohydric alcohols. Liquids can be freed from water by shaking with type 4A Linde molecular sieves and can safely be distilled only under high vacuum. Carbohydrate alcohols can be crystallised from strong aqueous solution or, preferably, from mixed solvents such as ethanol/petroleum ether or dimethyl formamide/toluene. Crystallisation usually requires seeding and is extremely slow. Further purification can be effected by conversion to the acetyl or benzoyl derivatives which are much less soluble in water and which can readily be recrystallised, e.g. from ethanol. Hydrolysis of the acetyl derivatives, followed by removal of acetate or benzoate and metal ions by ion-exchange chromatography, gives the purified material. On no account should solutions of carbohydrates be concentrated above 40° because of darkening and formation of *caramel*. Ion exchange, charcoal or cellulose column chromatography has been used for the purification and separation of carbohydrates.

ALDEHYDES

Common impurities found in aldehydes are the corresponding alcohols, aldols and water from self-condensation, and the corresponding acids formed by autoxidation. Acids can be removed by shaking with aqueous 10% sodium bicarbonate solution. The organic liquid is then washed with water. It is dried with anhydrous sodium sulfate or magnesium sulfate and then fractionally distilled. Water soluble aldehydes must be dissolved in a suitable solvent such as diethyl ether before being washed in this way. Further purification can be effected *via* the bisulfite derivative (see above) or the Schiff base formed with aniline or benzidine. Solid aldehydes can be dissolved in diethyl ether and purified as above. Alternatively, they can be steam distilled, then sublimed and crystallised from toluene or petroleum ether.

AMIDES

Amides are stable compounds. The lower-melting members (such as acetamide) can be readily purified by fractional distillation. Most amides are solids which have low solubilities in water. They can be recrystallised from large quantities of water, ethanol, ethanol/ether, aqueous ethanol, chloroform/toluene, chloroform or acetic acid. The likely impurities are the parent acids or the alkyl esters from which they have been made. The former can be removed by thorough washing with aqueous ammonia followed by recrystallisation, whereas elimination of the latter is by trituration or recrystallisation from an organic solvent. Amides can be freed from solvent or water by drying below their melting points. These purifications can also be used for sulfonamides and acid hydrazides.

AMINES

The common impurities found in amines are nitro compounds (if prepared by reduction), the corresponding halides (if prepared from them) and the corresponding carbamate salts. Amines are dissolved in aqueous acid, the pH of the solution being at least three units below the pK_a value of the base to ensure almost complete formation of the cation. They are extracted with diethyl ether to remove neutral impurities and to decompose the carbamate salts. The solution is then made strongly alkaline and the amines that separate are extracted into a suitable solvent (ether or toluene) or steam distilled. The latter process removes coloured impurities. Note that chloroform cannot be used as a solvent for primary amines because, in the presence of alkali, poisonous carbylamines (isocyanides) are formed. However, chloroform is a useful solvent for the extraction of heterocyclic bases. In this case it has the added advantage that while the extract is being freed from the chloroform most of the moisture is removed with the solvent.

Alternatively, the amine may be dissolved in a suitable solvent (e.g. toluene), and dry HCl gas is passed through the solution to precipitate the amine hydrochloride. This is purified by recrystallisation from a suitable solvent mixture (e.g. ethanol/diethyl ether). The free amine can be regenerated by adding sodium hydroxide and isolated as above. Cartridges and columns are available (e.g. KP-NH silica column with slightly nitrogenous alkaline chemistry developed by Biotage Inc (<www.biotage.com>) for the purification of amines using flash chromatography.

Liquid amines can be further purified *via* their acetyl or benzoyl derivatives (*vide supra*). Solid amines can be recrystallised from water, alcohol, toluene or toluene-petroleum ether. *Care should be taken in handling large quantities of amines because their vapours are* ***harmful (possibly carcinogenic)*** *and they are readily absorbed through the skin.*

AMINO ACIDS

Because of their zwitterionic nature, amino acids are generally soluble in water. Their solubility in organic solvents rises as the fat-soluble portion of the molecule increases. The likeliest impurities are traces of salts, heavy metal ions, proteins and other amino acids. Purification of these is usually easy, by recrystallisation from water or ethanol/water mixtures. The amino acid is dissolved in the boiling solvent, decolourised if necessary by boiling with 1g of acid-washed charcoal/100g amino acid, then filtered hot, chilled, and set aside for several hours to crystallise. The crystals are filtered off, washed with ethanol, then ether, and dried.

Amino acids have high melting or decomposition points and are best examined for purity by paper or thin layer chromatography. The spots are developed with ninhydrin. Customary methods for the purification of small quantities of amino acids obtained from natural sources (i.e. 1–5g) are ion-exchange chromatography (see Chapter 1). For general treatment of amino acids see Greenstein and Winitz [*The Amino Acids*, Vols 1–3, J.Wiley & Sons, New York 1961] and individual amino acids in Chapters 4 and 7.

A useful source of details such as likely impurities, stability and tests for homogeneity of amino acids is *Specifications and Criteria for Biochemical Compounds*, 3rd edn, National Academy of Sciences, USA, 1972.

ANHYDRIDES

The corresponding acids, resulting from hydrolysis, are the most likely impurities. Distillation from phosphorus pentoxide, followed by fractional distillation, is usually satisfactory. With high boiling or solid anhydrides, another method involves boiling under reflux for 0.5–1 hours with acetic anhydride, followed by fractional distillation. Acetic acid distils first, then acetic anhydride and finally the desired anhydride. Where the anhydride is a solid, removal of acetic acid and acetic anhydride at atmospheric pressure is followed by heating under vacuum. The solid anhydride is then either crystallised as for acid chlorides or (in some cases) sublimed in a vacuum. A preliminary purification when large quantities of acid are present in a solid anhydride (such as phthalic anhydride) is by preferential solvent extraction of the (usually) more soluble anhydride from the acid (e.g. with $CHCl_3$ in the case of phthalic anhydride). *All operations with liquid anhydrides should be carried out in a fume cupboard because of their* **LACHRYMATORY** *properties. Almost all anhydrides attack skin.*

CAROTENOIDS

These usually are decomposed by light, air and solvents, so that degradation products are probable impurities. Chromatography and adsorption spectra permit the ready detection of coloured impurities, and separations are possible using solvent distribution, chromatography or crystallisation. Thus, in partition between immiscible solvents, xanthophyll remains in 90% methanol while carotenes pass into the petroleum ether phase. For small amounts of material, thin-layer or paper chromatography may be used, while column chromatography is suitable for larger amounts. Colourless impurities may be detected by IR, NMR or mass spectrometry. The more common separation procedures are described by P. Karrer and E. Jucker in *Carotenoids*, E.A. Braude (translator), Elsevier, NY, 1950.

Purity can be checked by chromatography (on thin-layer plates, Kieselguhr, paper or columns), by UV or NMR procedures. See "Carotenoids" in Chapter 7.

ESTERS

The most common impurities are the corresponding acid and hydroxy compound (i.e. alcohol or phenol), and water. A liquid ester from a carboxylic acid is washed with 2N sodium carbonate or sodium hydroxide to remove acid material, then shaken with calcium chloride to remove ethyl or methyl alcohols (if it is a methyl or ethyl ester). It is dried with potassium carbonate or magnesium sulfate, and distilled. Fractional distillation then removes residual traces of hydroxy compounds. This method does not apply to esters of inorganic acids (e.g. dimethyl sulfate) which are more readily hydrolysed in aqueous solution when heat is generated in the neutralisation of the excess acid. In such cases, several fractional distillations, preferably under vacuum, are usually sufficient.

Solid esters are easily crystallisable materials. It is important to note that esters of alcohols must be recrystallised either from non-hydroxylic solvents (e.g. toluene) or from the alcohol from which the ester is derived. Thus methyl esters should be crystallised from methanol or methanol/toluene, but not from ethanol, *n*-butanol or other alcohols, in order to avoid alcohol exchange and contamination of the ester with a second ester. Useful solvents for crystallisation are the corresponding alcohols or aqueous alcohols, toluene, toluene/petroleum ether, and chloroform (ethanol-free)/toluene. Esters of carboxylic acids derived from phenols are more difficult to hydrolyse and exchange, hence any alcoholic solvent can be used freely. Sulfonic acid esters of phenols are even more resistant to hydrolysis: they can safely be crystallised not only from the above solvents but also from acetic acid, aqueous acetic acid or boiling *n*-butanol. Note that sulfonic esters of lower alcohols, e.g. methanol, are good alkylating agents.

Fully esterified phosphoric acid and phosphonic acids differ only in detail from the above mentioned esters. Their major contaminants are alcohols or phenols, phosphoric or phosphonic acids (from hydrolysis), and (occasionally) basic material, such as pyridine, which is used in their preparation. Water-insoluble esters are washed thoroughly and successively with dilute acid (e.g. 0.2N sulfuric acid), water, 0.2N sodium hydroxide and water. After drying with calcium chloride they are fractionally distilled. Water-soluble esters should first be dissolved in a suitable organic solvent and, in the washing process, water should be replaced by saturated aqueous sodium chloride. Some esters (e.g. phosphate and phosphonate esters) can be further purified through their uranyl adducts (*vide supra*). Traces of water or hydroxy compounds can be removed by percolation through, or shaking with, activated alumina (about 100g/L of liquid solution), followed by filtration and fractional distillation in a vacuum. For high molecular weight esters (which cannot be distilled without some decomposition) it is advisable to carry out distillation at as low a pressure as possible. Solid esters can be crystallised from toluene or petroleum ether. Alcohols can be used for recrystallising phosphoric or phosphonic esters of phenols.

ETHERS

The purification of diethyl ether (see Chapter 4) is typical of liquid ethers. The most common contaminants are the alcohols or hydroxy compounds from which the ethers are prepared, their oxidation products (e.g. aldehydes), peroxides and water. Dialkyl ethers form peroxides much more readily than other ethers, e.g. ethyl phenyl ethers, on standing in air. Peroxides, aldehydes and alcohols can be removed by shaking with alkaline potassium permanganate solution for several hours, followed by washing with water, concentrated sulfuric acid [CARE], then water. After drying with calcium chloride, the ether is distilled. It is then dried with sodium or with lithium aluminium hydride, redistilled and given a final fractional distillation. The drying process is repeated if necessary.

Alternatively, methods for removing peroxides include leaving the ether to stand in contact with iron filings or copper powder, shaking with a solution of ferrous sulfate acidified with N sulfuric acid, shaking with a copper-zinc couple, passage through a column of activated alumina, and refluxing with phenothiazine. Cerium(III) hydroxide has also been used.

A simple test for ether peroxides is to add 10ml of the ether to a stoppered cylinder containing 1ml of freshly prepared 10% solution of potassium iodide containing a drop of starch indicator. No colour should develop during one minute if free from peroxides. Alternatively, a 1% solution of ferrous ammonium sulfate, 0.1M in sulfuric acid and 0.01M in potassium thiocyanate should not increase appreciably in red colour when shaken with two volumes of the ether. Merck-Chemicals supply peroxide test kits (Perex Test) which use a colorimetric method with test strips which can be used to estimate the amount of hydrogen peroxide, from as low a concentration as 0.2mg/L to as high as1000mg/L. They are very convenient as they can give an indication of the concentration of peroxide rapidly <see http://www.merck-chemicals.com>. As a safety precaution against **EXPLOSION** in case purification from peroxides has been insufficiently thorough, at least a quarter of the total volume of liquid ether should remain in the distilling flask when the distillation is discontinued, as the peroxides are generally higher boiling than the corresponding ethers. To minimise peroxide formation, ethers should be stored in dark bottles and, if they are liquids, they should be left in contact with type 4A Linde molecular sieves, in a cold place, over sodium amalgam. The rate of formation of peroxides depends on storage conditions and is accelerated by metal impurities, heat, light, air and moisture. Always be vigilant and test for peroxides. The formation of peroxides is inhibited in the presence of diphenylamine, di-*tert*-butylphenol, or other antioxidants which can be used as stabilisers.

Ethers that are solids (e.g. phenyl ethers) can be steam distilled from an alkaline solution which will hold back any phenolic impurity. After the distillate is made alkaline with sodium carbonate, the insoluble ether is collected either by extraction (e.g. with chloroform, diethyl ether or toluene) or by filtration. It is then crystallised from alcohols, alcohol/petroleum ether, petroleum ether, toluene or mixtures of these solvents, sublimed in a vacuum and recrystallised if necessary.

HALIDES

Aliphatic halides are likely to be contaminated with halogen acids and the alcohols from which they have been prepared, whereas in aromatic halides the impurities are usually aromatic hydrocarbons, amines or phenols. In both groups the halogen is less reactive than it is in acid halides. Purification is by shaking with concentrated hydrochloric acid, followed by washing successively with water, 5% sodium carbonate or bicarbonate, and water. After drying with calcium chloride, the halide is distilled and then fractionally distilled using an efficient column. For a solid halide the above purification is carried out by dissolving it in a suitable solvent such as toluene. Solid halides can also be purified by chromatography using an alumina column and eluting with toluene or petroleum ether.

They can be crystallised from toluene, petroleum ethers, toluene/petroleum ether or toluene/chloroform/petroleum ether. Care should be taken when handling organic halogen compounds because of their HIGH **TOXICITY**. It should be noted that methyl iodide is a cancer suspect.
Liquid aliphatic halides are obtained alcohol-free by distillation from phosphorus pentoxide. They are stored in dark bottles to prevent oxidation and, in some cases, the formation of phosgene.
A general method for purifying *chlorohydrocarbons* uses repeated shaking with concentrated sulfuric acid [CARE] until no further colour develops in the acid, then washing with water followed by a solution of sodium bicarbonate, then with water again. After drying with calcium chloride, the chlorohydrocarbon is fractionally redistilled to constant boiling point or recrystallised.

HYDROCARBONS

Gaseous hydrocarbons are best freed from water and gaseous impurities by passage through suitable adsorbents and (if olefinic material is to be removed) oxidants such as alkaline potassium permanganate solution, followed by fractional cooling (see Chapter 1 for cooling baths) and fractional distillation at low temperature. To effect these purifications and also to store the gaseous sample, a vacuum line is necessary.
Impurities in hydrocarbons can be characterised and evaluated by gas chromatography and mass spectrometry. The total amount of impurities present can be estimated from the thermometric freezing curve.
Liquid aliphatic hydrocarbons are freed from aromatic impurities by shaking with concentrated sulfuric acid [CARE] whereby the aromatic compounds are sulfonated. Shaking is carried out until the sulfuric acid layer remains colourless for several hours. The hydrocarbon is then freed from the sulfuric acid and the sulfonic acids by separating the two phases and washing the organic layer successively with water, 2N sodium hydroxide, and water. It is dried with $CaCl_2$ or Na_2SO_4, and then distilled. The distillate is dried with sodium wire, P_2O_5, or metallic hydrides, or passage through a dry silica gel column, or preferably, and more safely, with molecular sieves (see Chapter 1) before being finally fractionally distilled through an efficient column. If the hydrocarbon is contaminated with olefinic impurities, shaking with aqueous alkaline permanganate is necessary prior to the above purification. Alicyclic and paraffinic hydrocarbons can be freed from water, non-hydrocarbon and aromatic impurities by passage through a silica gel column before the final fractional distillation. This may also remove isomers. (For the use of chromatographic methods to separate mixtures of aromatic, paraffinic and alicyclic hydrocarbons see references in the bibliography in Chapter 1 under *Liquid and Flash Chromatography, Gas Chromatography and High Performance Liquid and Flash Chromatography*).
Another method of removing branched-chain and unsaturated hydrocarbons from straight-chain hydrocarbons depends on the much faster reaction of the former with chlorosulfonic acid.
Isomeric materials which have closely similar physical properties can be serious contaminants in hydrocarbons. With aromatic hydrocarbons, e.g. xylenes and alkyl benzenes, advantage is taken of differences in ease of sulfonation. If the required compound is sulfonated more readily, the sulfonic acid is isolated, crystallised (e.g. from water), and decomposed by passing superheated steam through the flask containing the acid. The sulfonic acid undergoes hydrolysis, and the liberated hydrocarbon distils with the steam. It is separated from the distillate, dried, distilled and then fractionally distilled. For small quantities (10–100mg), vapour phase chromatography is the most satisfactory method for obtaining a pure sample (for column materials for packings see Chapter 1).
Azeotropic distillation with methanol or 2-ethoxyethanol (cellosolve) has been used to obtain highly purified saturated hydrocarbons and aromatic hydrocarbons such as xylenes and isopropylbenzenes.
Carbonyl-containing impurities can be removed from hydrocarbons (and other oxygen-lacking solvents such as $CHCl_3$ and CCl_4) by passage through a column of Celite 545 (100g) mixed with concentrated sulfuric acid (60ml). After first adding some solvent and about 10g of granular Na_2SO_4, the column is packed with the mixture and a final 7-8cm of Na_2SO_4 is added at the top [Hornstein & Crowe, *Anal Chem* **34** 1037 *1962*]. Alternatively, Celite impregnated with 2,4-dinitrophenylhydrazine can be used.
With solid hydrocarbons such as naphthalene and polycyclic hydrocarbons, preliminary purification by sublimation in vacuum (or high vacuum if the substance is high melting) is followed by zone refining and finally by chromatography (e.g. on alumina) using low-boiling liquid hydrocarbon eluents. These solids can be recrystallised from alcohols, alcohol/petroleum ether or from liquid hydrocarbons (e.g. toluene) and dried below their melting points. Aromatic hydrocarbons that have been purified by zone melting include anthracene, biphenyl, fluoranthrene, naphthalene, perylene, phenanthrene, pyrene and terphenyl, among others. Some polycyclic hydrocarbons, e.g. benzopyrene, are CARCINOGENIC.
Olefinic hydrocarbons have a very strong tendency to polymerise, and commercially available materials are generally stabilised, e.g. with hydroquinone. When distilling compounds such as vinylpyridine or styrene, the stabiliser remains behind and the purified olefinic material is more prone to polymerisation. The most common impurities are higher-boiling dimeric or polymeric compounds. Vacuum distillation in a nitrogen

atmosphere not only separates monomeric from polymeric materials but in some cases also depolymerises the impurities. The distillation flask should be charged with a polymerisation inhibitor, and the purified material should be used immediately or stored in the dark and mixed with a small amount of stabiliser (e.g. 0.1% of hydroquinone or di-*tert*-butylcatechol). It is also advisable to add to the flask a small amount (*ca* 5-10% by volume of liquid in the flask) of a ground mixture of Kieselguhr and NaCl which will provide nuclei for facilitating boiling and finally for cleaning the flask from insoluble polymeric residue (due to the presence of the water soluble NaCl).

IMIDES

Imides (e.g. phthalimide) can be purified by conversion to their potassium salts by reaction in ethanol with ethanolic potassium hydroxide. The imides are regenerated when the salts are hydrolysed with water or dilute acid. Like amides, imides readily crystallise from alcohols and, in some cases (e.g. quinolinic imide), from glacial acetic acid.

IMINO COMPOUNDS

These substances contain the -C=NH group and, because they are strong, unstable bases, they are kept as their more stable salts, such as the hydrochlorides. (The free base usually hydrolyses to the corresponding oxo compound and ammonia.) Like amine hydrochlorides, the salts are purified by solution in alcohol containing a few drops of hydrochloric acid. After treatment with charcoal, and filtering, dry diethyl ether (or petroleum ether if ethanol is used) is added until crystallisation sets in. The salts are dried and kept in a vacuum desiccator.

KETONES

Ketones are more stable to oxidation than aldehydes and can be purified from oxidisable impurities by refluxing with potassium permanganate until the colour persists, followed by shaking with sodium carbonate (to remove acidic impurities) and distilling. Traces of water can be removed with type 4A Linde molecular sieves. Ketones which are solids can be purified by crystallisation from alcohol, toluene, or petroleum ether, and are usually sufficiently volatile for sublimation in vacuum. Ketones can be further purified *via* their bisulfite, semicarbazone or oxime derivatives (*vide supra*). The bisulfite addition compounds are formed only by aldehydes and methyl ketones but they are readily hydrolysed in dilute acid or alkali.

MACROMOLECULES See Chapter 7.

NITRILES

All purifications should be carried out in an efficient fume cupboard because of the **TOXIC** *nature of these compounds*.

Nitriles are usually prepared either by reacting the corresponding halide or diazonium salts with a cyanide salt or by dehydrating an amide. Hence, possible contaminants are the respective halide or alcohol (from hydrolysis), phenolic compounds, amines or amides. Small quantities of phenols can be removed by chromatography on alumina. More commonly, purification of liquid nitriles or solutions of solid nitriles in a solvent such as diethyl ether is by shaking with dilute aqueous sodium hydroxide, followed by washing successively with water, dilute acid and water. After drying with sodium sulfate, the solvent is distilled off. Liquid nitriles are best distilled from a small amount of P_2O_5 which, besides removing water, dehydrates any amide impurity to the nitrile. About one-fifth of the nitrile should remain in the distilling flask at the end of the distillation (*the residue may contain some inorganic cyanide*). This purification also removes alcohols and phenols. Solid nitriles can be recrystallised from ethanol, toluene or petroleum ether, or a mixture of these solvents. They can also be sublimed under vacuum. Preliminary purification by steam distillation is usually possible.

Strong alkali or heating with dilute acids may lead to hydrolysis of the nitrile and should be avoided.

NITRO COMPOUNDS

Aliphatic nitro compounds are generally acidic. They are freed from alcohols or alkyl halides by standing for a day with concentrated sulfuric acid, then washed with water, dried with magnesium sulfate followed by calcium sulfate and distilled. The principal impurities are isomeric or homologous nitro compounds. In cases where the nitro compound was originally prepared by vapour phase nitration of the aliphatic hydrocarbon, fractional distillation should separate the nitro compound from the corresponding hydrocarbon. Fractional crystallisation is more effective than fractional distillation if the melting point of the compound is not too low.

The impurities present in aromatic nitro compounds depend on the aromatic portion of the molecule. Thus, benzene, phenols or anilines are probable impurities in nitrobenzene, nitrophenols and nitroanilines, respectively.

Purification should be carried out accordingly. Isomeric compounds are likely to remain as impurities after the preliminary purifications to remove basic and acidic contaminants. For example, *o*-nitrophenol may be found in samples of *p*-nitrophenol. Usually, the *o*-nitro compounds are more steam volatile than the *p*-nitro isomers and can be separated in this way. Polynitro impurities in mononitro compounds can be readily removed because of their relatively lower solubilities in solvents. With acidic or basic nitro compounds which cannot be separated in the above manner, advantage may be taken of their differences in pK values (see Chapter 1). The compounds can thus be purified by preliminary extractions with several sets of aqueous buffers of known pH (see for example Table 24, Chapter 1) from a solution of the substance in a suitable solvent such as diethyl ether. This method is more satisfactory and less laborious the larger the difference between the pK value of the impurity and the desired compound. Heterocyclic nitro compounds require similar treatment to the nitroanilines. Neutral nitro compounds can be steam distilled.

NUCLEIC ACIDS See Chapter 7.

PHENOLS

Because phenols are weak acids, they can be freed from neutral impurities by dissolution in aqueous N sodium hydroxide (cf pK) and extraction with a solvent such as diethyl ether, or by steam distillation to remove the non-acidic material. The phenol is recovered by acidification of the aqueous phase with 2N sulfuric acid, and either extracted with ether or steam distilled. In the second case the phenol is extracted from the steam distillate after saturating it with sodium chloride (salting out). A solvent is necessary when large quantities of liquid phenols are purified. The phenol is fractionated by distillation under reduced pressure, preferably in an atmosphere of nitrogen to minimise oxidation. Solid phenols can be crystallised from toluene, petroleum ether or a mixture of these solvents, and can be sublimed under vacuum. Purification can also be effected by fractional crystallisation or zone refining. For further purification of phenols *via* their acetyl or benzoyl derivatives *vide supra*.

POLYPEPTIDES AND PROTEINS See Chapter 7.

QUINONES

These are neutral compounds which are usually coloured. They can be separated from acidic or basic impurities by extraction of their solutions in organic solvents with aqueous basic or acidic solutions, respectively. Their colour is a useful property in their purification by chromatography through an alumina column with, e.g. toluene, as eluent. They are volatile enough for vacuum sublimation, although with high-melting quinones a very high vacuum is necessary. *p*-Quinones are stable compounds and can be recrystallised from water, ethanol, aqueous ethanol, toluene, petroleum ether or glacial acetic acid. *o*-Quinones, on the other hand, are readily oxidised. They should be handled in an inert atmosphere, preferably in the absence of light.

SALTS

With metal ions

Water-soluble salts are best purified by preparing a concentrated aqueous solution to which, after decolourising with charcoal and filtering, ethanol or acetone is added so that the salts crystallise. They are collected, washed with aqueous ethanol or aqueous acetone, and dried. In some cases, water-soluble salts can be recrystallised satisfactorily from alcohols. With very water-soluble salts, pure crystals are best obtained by dissolving them in water and allowing the solution to evaporate slowly in a desiccator over a suitable desiccant in a cold room. When crystals are formed they are removed, e.g. by centrifugation, washed with a little ice-cold water and dried in a vacuum. Water-insoluble salts are purified by Soxhlet extraction, first with organic solvents and then with water, to remove soluble contaminants. The purified salt is recovered from the thimble.

With organic cations

Organic salts (e.g. trimethylammonium benzoate) are usually purified by recrystallisation from polar solvents (e.g. water, ethanol or dimethyl formamide). If the salt is too soluble in a polar solvent, its concentrated solution should be treated dropwise with a miscible non-polar, or less polar, solvent (see Table 8, Chapter 1) until crystallisation begins.

With sodium alkane sulfonates

These are purified from sulfites by boiling with aqueous HBr. They are purified from sulfates by adding $BaBr_2$. Sodium alkane disulfonates are finally precipitated by addition of MeOH (Pethybridge & Taba *J Chem Soc Faraday Trans 1* **78** 1331 *1982*).

SULFUR COMPOUNDS

Disulfides

These can be purified by extracting acidic and basic impurities with dilute aqueous base or acid, respectively. However, they are somewhat sensitive to strong alkali which slowly cleaves the disulfide bond. The lower-melting members can be fractionally distilled under vacuum. The high members can be recrystallised from alcohol, toluene or glacial acetic acid.

Sulfones

Sulfones are neutral and very stable compounds that can be distilled without decomposition. They are freed from acidic and basic impurities in the same way as disulfides. The low-molecular-weight members are quite soluble in water, but the higher members can be recrystallised from water, ethanol, aqueous ethanol or glacial acetic acid.

Sulfoxides

These are odourless, rather unstable compounds because they oxidise to sulfones, and should be distilled under vacuum in an inert atmosphere. They are generally water-soluble but can be extracted from aqueous solution with a solvent such as diethyl ether.

Thioethers (sulfides)

Thioethers are neutral stable compounds that can be freed from acidic and basic impurities as described for disulfides. They can be recrystallised from organic solvents and distilled without decomposition. They have sulfurous odours.

Thiols

Thiols, or mercaptans, are stronger acids than the corresponding aliphatic hydroxy or phenolic compounds, but can be purified in a similar manner. However, care must be exercised in handling thiols to avoid their oxidation to disulfides. For this reason, purification is best carried out in an inert atmosphere in the absence of oxidising agents. Similarly, thiols should be stored out of contact with air. They can be distilled without change, and the higher-melting thiols (which are usually more stable) can be crystallised, e.g. from water or dilute alcohol. They oxidise readily in alkaline solution but can be separated from the disulfide which is insoluble in this medium. They should be stored in the dark below 0^o. *All operations with thiols should be carried out in an efficient fume cupboard because of their very unpleasant odour and their* **TOXICITY**.

Thiolsulfonates (disulfoxides)

Thiolsulfonates are neutral and are somewhat light-sensitive compounds. Their most common impurities are sulfonyl chlorides (neutral) or the sulfinic acid or disulfide from which they are usually derived. The first can be removed by partial freezing or crystallisation, the second by shaking with dilute alkali, and the third by recrystallisation because of the higher solubility of the disulfide in solvents. Thiolsulfonates decompose slowly in dilute, or rapidly in strong, alkali to form disulfides and sulfonic acids. Thiolsulfonates also decompose on distillation but they can be steam distilled. The solid members can be recrystallised from water, alcohols or glacial acetic acid.

PURIFICATION *via* FLUOROCHROMES

If the purification procedure is proving difficult then by tagging the desired molecule in a mixture with a fluorochrome (see Table 20, Chapter 1) can provide a means of following the substance through the purification process. The fluorochrome should have a group which can react with the desired compound, and it should be possible to remove the fluorochromic group after purification. Such groups are present for example in fluorescein-isothiocyanate (FITC), where the SCN group can react with an RNH_2 compound to form fluorescent thioureas; 4-bromomethyl-7-methoxycoumarin, which can react with R-OH or R-COONa compounds to form fluorescent ether or ester links with the desired compound; or 3-aminocoumarin, which reacts through its NH_2 group to form fluorescent amides. The fluorescent products can then be readily identified by their fluorescence, separated from impurities, and it should be possible to recover the purified compound after chemically separating it from the fluorescent tag. Such procedures can also be used as analytical tools for detecting specific substances (see *fluorescence spectra* in Chapter 1 and Table 20).

CHAPTER 3

THE FUTURE OF PURIFICATION

INTRODUCTION

The essence of research is to seek answers wherever there are questions. Regardless of what the answers are, the experiments to be conducted must be carried out with utmost care. For this, one must ensure that the quality of the reactants used and the products obtained are of the highest possible purity. In general terms, one can broadly categorise experimental chemistry and biological chemistry into the following areas:

> Isolation and identification of substances (natural products from nature, protein purification and characterisation, etc).
> Synthesis of substances (organic, or inorganic in nature; these substances may be known substances or new compounds).
> Analysis of substances (this is a key process in the identification of new or known chemical and biological substances. Methods of analysis include spectroscopic methods, derivatisation and sequencing methods).
> Measurements of particular properties of a compound or substance (enzyme kinetics, reaction kinetics, FACS, fluorescence-activated cell sorting, assay).

Impressive and sophisticated strategies, in the form of new reagents, catalysts and chemical transformations, are currently available for the synthesis of molecules. In recent years there has been a deviation in focus from developing new synthetic routes and reactions to improving methods for carrying out reactions. In particular, traditional reactions are carried out in new ways such that the efficiencies of reactions are greatly improved. Emphasis on "Green Technologies" and "Green Chemistry" is continually being stressed to the experimenter and will be for many years to come. Included in this is the movement towards the development of "greener" technologies. Although there is continual debate over the definition of "green" technologies, for our intent and purpose we consider these to include methodologies that are developed to reduce waste and energy, improve on atom economy and are environmentally benign. [Anastas & Kirchhoff *Acc Chem Res* **35** 686 *2002*; *Benign by Design*; American Chemical Society: Washington, DC, *1994*; Constable et al, *Green Chem* **9** 411 *2007*; Li & Trost *PNAS* **105** 13197 *2008*; Anastas & Eghbali, *Chem Soc. Rev*. **39** 301 *2010*]. This may mean that there will be a new world order for carrying out synthesis, which in turn will change the way that one approaches purification. Hence the future of purification very much depends on future methods and trends in synthesis. In the previous edition of this book, some improved methods of synthesis which seek to minimise purification steps were outlined. These included the use of solid phase synthesis, fluorous chemistry as well as ionic liquids. Although some of these methods are still important in some areas of research, other trends have emerged. In this chapter, a brief survey of the emerging trends is presented.

Safety is another issue that goes hand in hand with "Green Science", and cannot be emphasised enough. It should be the first consideration when planning a scientific operation. Safety issues have already been discussed in Chapter 1, and should never be considered a *nuisance*, or an aspect which hampers procedures. This is no longer a *local* or a *regional* issue, but is becoming more and more a *global* problem. It is true that it means more effort should be put in planning an operation, but this is something that the worker should get used to. It is totally *unacceptable* today, and certainly will be in the future, not to take safety very seriously. Questions to be addressed include: Could this procedure be carried out in a safer way with respect not only to the operator but also to those around him or her? How does it affect the immediate as well as the extended environment around the operation? Could the operation be performed in an alternative way that can better satisfy these criteria? Safety now goes well beyond the laboratory and all should be consciously aware of the consequences of a potentially unsafe situation.

Purification of Laboratory Chemicals. http://dx.doi.org/10.1016/B978-0-12-382161-4.00003-0

ATOM ECONOMY

Atom economic chemistry seeks to maximise the incorporation of starting materials into the final product of any given reaction and thus reduce side products or waste formed in a chemical transformation. [Trost *Angew Chem, Int Ed* **34** 259 *2005*.] Thus in an ideal atom economic reaction, all the atoms present in the starting materials are present in the product. Ways to achieve atom economy or efficient reactions include the use of catalysts to enable transformations that will otherwise utilise multiple steps or are impossible to perform. Cross coupling reactions to form C-N, C-O, C-C bonds can now be achieved with relative ease. Despite the progress in the area of catalysis, there are continual challenges to reduce the number of steps needed to achieve the desired transformations. For example, direct methods for C-H functionalisation in a selective and predictable fashion can dramatically alter the way organic molecules are assembled, negating multi-step chemical processes and rendering functional group interconversion steps obsolete. To date, there are numerous reported protocols, with new catalyst systems and designs, for the direct transformation of C-H bond to C-C or C-heteroatom bonds [for a sample of articles on C-H functionalisation, see the special issue on C-H functionalisation in organic synthesis themed issue, Eds. Davies, Du Bois & Yu, in *Chem Soc Rev* Issue 4, *2011*]. This field is an emerging, highly competitive area of research and a comprehensive review of C-H functionalisation is beyond the scope of this book.

Even a seemingly 'simple' transformation such as amide bond formation warrants investigation of new atom economic methods. This is because 'traditional' methods for amide formation suffer from the drawback of producing a stoichiometric amount of waste. Advances in this area are metal catalysed approaches to amide bond formation that includes oxidative amidation of alcohols [for examples, see Taylor et al. *Synlett* 1293 *2002*; Owston et al. *Org. Lett*. **9** 73 *2007*; Zweifel et al. *Angew Chem, Int Ed* **48** 559 *2009*] and amines [e.g. Kim et al. *Angew Chem, Int Ed* **47** 9249 *2008*], aminocarbonylation of aryl halides, [for example, Ueda et al. *J Am Chem Soc* **122** 10722 *2000*; Schnyder, et al. *J Org Chem* **66** 4311 *2001*; Wu et al. *Chem Asian J* **5** 2168 *2010*], rearrangement of aldoximes [e.g. Shie & Fang *J Org Chem* **68** 1158 *2003*; Owston et al. *Org Lett* **9** 3599 *2007*], and direct amidation of aldehydes [e.g. Ali & Punniyamurthy *Adv Synth Catal* **352** 288 *2010*; Shie & Fang *J Org Chem* **68** 1158 *2003*; Yoo & Li *J Am Chem Soc* **128** 13064 *2006*].

Improved atom efficiency can also be achieved if it was possible to carry out synthesis without the use of protecting groups. The protection-deprotection sequence of functional groups increases the number of steps in the synthesis of target compounds. As such, novel chemistry is needed to overcome this. In elegant work reported by Baran et al. [*Nature* **446** 404 *2007*], a total synthesis of a natural product was achieved without any protecting groups.

ORGANOCATALYSIS

One of the major areas of chemical research is in the development of efficient catalysts for carrying out organic transformations. Traditionally this field is dominated by metal mediated catalysis, although increasingly biocatalysis and organocatalysis are gaining prominence. Organocatalysts are defined as catalysts (usually small organic molecules) with low molecular weights (<1000g/mol) where a metal is not part of the active principle. The potential advantages that organocatalysts can offer over metal catalysts include the ease of handling, good stability, low costs and the environmentally benign nature of the former. A major disadvantage of organocatalysis is the limited substrate scope for a particular organocatalyst in a particular transformation. It should be added that the field of organocatalysis was in its relative infancy and stunning progress has been made in the last ten years or so. For example, readily available organic compounds have been found to be capable of catalysing a range of reactions. These include carbon-carbon bond forming reactions (Aldol, Mannich, Diels-Alder, alkylations, cyclopropanations, etc), epoxidation reactions, desymmetrisation reactions and so on [for an excellent book, see Berkessel and Gröger, in the bibliography]. Classes of compounds that have demonstrated applications as organocatalysts include α-amino acids [Jarvo & Miller *Tetrahedron* **58** 2481 *2002*], *N*-heterocyclic carbenes [Marion et al. *Angew Chem, Int Ed* **46** 2988 *2007*], thioureas [Connon *Chemistry-A Eur J* **12** 5419 *2006*], cinchona alkaloids [Dalaigh *Syn Lett* 875 *2005*] and so on. One of the earliest practical demonstrations of the use of organocatalysts is exemplified by the Hajos-Parrish-Eder-Sauer-Wiechert reaction which was patented as early as 1971 [Eder, Sauer & Wiechert DE 2014757 1971, Eder, Sauer & Wiechert *Angew Chem, Int Ed* **10** 496 *1971*, Hajos & Parrish DE 2102623 1971, Hajos & Parrish *J Org Chem* **39** 1612 *1974*]. The Robinson aldol annulation reaction utilised the humble proline molecule as the organocatalyst, and is the *first* example of a highly enantioselective carbon-carbon bond forming reaction. Recently, advances in organocatalysis have progressed to the level of sophistication that has enabled the synthesis of relatively complex organic molecules with multiple stereocentres in high chemical and optical yields. There are many excellent reviews and monographs on organocatalysis, and some of these are listed in the bibliography. Also see ChemFiles, Vol 6, no 4 from Sigma-Aldrich for a compilation of some commercially

available organocatalysts. Another class of organocatalysts are the Phase Transfer Catalysts (PTCs) which have been used for quite some time, and chiral PTCs have more recently been used to catalyse reactions stereospecifically. Sections on "Organocatalysts" and "Phase Transfer Catalysts" are presented in Chapter 6, Part 1 and Part 2, respectively.

MICROWAVE TECHNOLOGIES

The first reports of the use of microwave technologies to accelerate organic reactions were published in 1986 [Gedye et al. *Tetrahedron Lett* **27** 279 *1986,* Giguere et al. *Tetrahedron Lett.* **27** 4945 *1986*]. These days, dedicated microwave instrumentation for carrying out organic synthesis is an almost indispensable piece of equipment in chemical laboratories. Microwave assisted organic synthesis have several advantages over conventional heating methods in that the reaction times are greatly reduced, yields are increased, side reactions are decreased and reactions have greater reproducibility. Microwave irradiation produces efficient internal heating due to the direct coupling of the microwave energy with the reactants and solvents. Inverted temperature gradients in microwave *versus* traditional oil-bath heating have been demonstrated. Although there is still some controversy regarding the "special" effects of microwave assisted technologies, it is generally accepted that microwave technologies provide "specific microwave effects" – that resulting due to thermal effects. The microwave thermal effect may be different to thermal effects from conventional heating methods in view of the inverted temperature gradient leading to direct "in-core" heating, or superheating effects of solvents at atmospheric pressure, or selective heating by strongly absorbing components of some of the reactants. Microwave-assisted organic synthesis has been demonstrated in a number of reactions: from transition metal catalysed reactions to solid phase synthesis to polymerisation reactions. For online resources on microwave chemistry, go to http://www.milestonesci.com (and follow the links to the resource library). Some excellent reviews and books on this topic are listed in the bibliography. It should be noted that microwave technologies have been touted as an important development towards "green" technologies in terms of reduction in energy and waste as well as improved efficiencies. In many instances, solventless reactions under microwave conditions have also been developed and reported [see e.g. Varma *Green Chem* **1** 43 *1999*].

There are a number of commercial microwaves for carrying out synthesis. Mono-mode (single mode) reactors direct electromagnetic irradiation onto a reaction vessel which is mounted at a fixed position. In these reactors, only one vessel can be used at any one time. In contrast, a multi-mode reactor can accommodate several reaction vessels which can be irradiated simultaneously. The choice of solvent for microwave reactions is dependent on the loss factor "tan δ". A reaction medium with a high "tan δ" is required for efficient absorption of electromagnetic energy from the microwave and hence leads to rapid heating. High microwave absorbing solvents include ethanol, DMSO, methanol, 1-butanol ("tan δ" >0.5), while medium solvent absorbers ("tan δ" between 0.1–0.5) include water and DMF. Poor absorbers are solvents like hexane, dichloromethane, chloroform, THF, acetone and ethyl acetate. Common solvents without a permanent dipole, e.g. carbon tetrachloride and *benzene are more or less microwave transparent. Solvents with low "tan δ" values can still be used in microwave reactions as the other components present are likely to be polar and can allow enough heating by microwaves. Alternatively, practices such as doping the reaction with solvents with high "tan δ" values have also been successful. Of note, ionic liquids (which have high "tan δ" values) have been used successfully [see Leadbeater, Torenius & Tye *Comb Chem High Throughput Screening* **7** 511 *2004*, for a review].

FLOW CHEMISTRY

The traditional way of carrying out synthesis utilises batch chemistry, with chemistry occurring inside flasks or reaction vessels. Although there are limitations with batch chemistry, especially in the scale-up of reactions, this has been the mainstay of organic synthesis. In recent years, continuous flow chemistry, an old process concept, has gained increasing attention as an alternative technology to batch chemistry. This will clearly have an impact on the way we carry out synthesis or think about synthesis. The advantages of continuous flow chemistry are improved safety and process reliability, reproducibility and facile automation. Continuous flow chemistry can be carried out on different scales, from using microfluidics (miniaturisation) to large continuous reactors found in chemical plants. In a research laboratory setting, there are advantages and disadvantages in using microfluidics *versus* minifluidic reactors as is summarised by Kirschning et al. [*Chem Commun* **47** 4583 *2011*]. There are a number of vendors that offer flow chemistry equipment, with varying capabilities and price ranges [e.g. http://www.vapourtec.co.uk/; http://www.syrris.com/.] One of the hurdles to the ready adoption of flow chemistry in a research laboratory setting is the need to consider physical chemistry and engineering principles such as mixing times, residence time, flow rates, etc. when designing an experiment. This can initially be a daunting task to a traditional organic chemist. One of the early pioneers of flow chemistry in organic

synthesis is S.V. Ley, University of Cambridge, UK. The reader is advised to refer to his numerous, elegant work in this area – from the development of solid supported reagents and scavengers to applications to complex natural product synthesis. Many types of reactions can be carried out using flow chemistry, and flow chemistry has particular advantage when carrying out "dangerous" reactions such as oxidations. Also see Aldrich Chem Files, Vol 5, no 7 for enabling technologies: Microreactor Technology.

SOLID PHASE SYNTHESIS

The promise of cleaner, more rapid and efficient chemistries *via* solid phase synthesis (SPS) was the driving force behind the huge body of research that emerged. The ease of work-up and purification procedures in solid phase as compared to solution phase chemistry, as well as the scope for combinatorial chemistry provided impetus for further development in this field. The earliest studies on solid phase chemistry were focused on solid phase peptide synthesis (SPPS). The concept of carrying out reactions on a polymer support as distinct to reactants in solution, was conceived by R.B. Merrifield who received the Nobel Prize in Chemistry in 1984 for his pioneering work. However, since the mid-1990s, advances in solid phase chemistry have moved beyond the routine (often robotic) synthesis of small to medium sized peptides and oligonucleotides. SPOS (solid phase organic synthesis) gained much prominence due to the wealth of compounds (combinatorial libraries) that can be synthesised rapidly. This is especially important for pharmaceutical companies screening for compounds with certain biological profiles, or for chemical companies screening for new catalysts or reagents. However, the lack of generality of reactions carried out on solid support as well as the difficulties in monitoring reactions on solid phase has limited the synthetic applications of SPOS. The legacy from solid phase synthesis that is more widely adopted in recent times is the use of solid supported reactants and reagents for carrying out synthesis and for scavenging and purification purposes. The more common methods of SPS are outlined here. For a more complete treatise, readers are encouraged to consult the 5th and 6th editions of this book.

SOLID PHASE PEPTIDE SYNTHESIS (SPPS)

Extensive studies on the synthesis of peptides on solid phase have been carried out, so much so that the technique of SPPS can be reliably and routinely used for the synthesis of short peptides by novices in the field. A large number of resins and reagents have been developed specifically for this purpose, and much is known about problems and avoidance of racemisation, difficult couplings, compatibility of reagents and solvents. Methods for monitoring the success of coupling reactions are available. Automated synthesisers are available commercially (e.g. from Protein Technologies, Rainin Inst Inc, Tuscon AZ; See Google) which can carry out as many as a dozen polypeptide syntheses simultaneously. A more recent advance is in the use of microwave energy to carry out the reactions (e.g. Liberty™ Microwave Peptide Synthesis, cf http://www.cem.com). By using different solid supports, protected amino acids and slightly different chemistry but the same equipment, peptide synthesis can be accomplished from the carboxy or the amino terminal with equal success [refer to CEM Corporation catalogues]. The most satisfactory chemistry currently used is FMOC (9-fluorenylmethoxycarbonyl) chemistry whereby the amino group of the individual amino acid residues is protected as the FMOC. A large number of Fmoc-amino acids are commercially available as well as polymer resins to which the specific Fmoc-amino acid (which will eventually become the carboxy terminal residue of the peptide) is attached. With automated synthesisers, the solvent used is *N*-methylpyrrolidone and washings are carried out with dimethylformamide. A cycle for one residue varies with the residue but can take an hour or more. This means that 70–80 mer polypeptides could take more than a week to prepare. This is not a serious drawback because several different polypeptides can be synthesised simultaneously. The success of the synthesis is dependent on the amino acid sequence since there are some twenty or more different amino acids and the facility of forming a peptide bond varies with the pair of residues involved. However, generally 70 to 80 mers are routinely prepared, and if the sequence is favourable, up to 120-mer polypeptides can be synthesised. After deprotection, the polypeptide is usually purified by HPLC using a C18 column with reverse phase chromatography. A new paradigm in solid phase peptide synthesis developed by A.G. Livingston and co-workers [So et al. *Organic Process Research and Development* **14** 1313 *2010*] is the use of solvent resistant nano filters (SRNFs) which adopt the newly emerging technology of organic solvent nanofiltration (OSN). Thus after the activation and coupling reactions, reagents and unreacted compounds are removed by nanofiltration, and then again after deprotection, reaction products other than the support-bound peptide are removed by SRNF (see SRNFs in Chapter 8). There are many commercial firms that will supply custom-made polypeptides at a price depending on the degree of purity required.

SOLID PHASE DEOXYRIBONUCLEOTIDE SYNTHESIS

The need for oligodeoxyribonucleotides mainly as primers for the preparation of deoxyribonucleic acids (DNA) and for DNA sequencing has resulted in considerable developments in oligo-deoxyribonucleotide synthesis. The solid phase procedure is the method commonly used. Automated synthesisers are commercially available, but with the increase in the number of firms that will provide custom-made oligo-deoxyribonucleotides, it is often not economical to purchase a synthesiser to make one's own oligo-deoxyribonucleotides. Unlike in polypeptide synthesis where there are some twenty different residues to "string" together, in DNA synthesis there are only four deoxyribonucleotides. Consequently there is usually little difficulty in synthesising 100-mers in quantities from 10 μg to 10 milligrams of material. The deprotected deoxyribonucleic acid which is separated from the solid support is purified on an anion exchange column followed by reverse phase HPLC using C8 to C18 columns for desalting. As for the polypeptides, the cost of DNA will depend on the purification level required.

POLYMER SUPPORTED REACTANTS

These have become of increasing importance in synthesis, and a broad classification of polymer supported reactants is as follows: Polymer bound bases (e.g. dimethylaminopyridine, morpholine, piperidine); Polymer supported catalysts (e.g. Grubbs catalyst for metathesis reactions, palladium for hydrogenation reactions, tributylmethylammonium chloride for phase transfer reactions); Polymer supported condensation reagents {e.g. DEAD (diethyl azodicarboxylate) for Mitsonobu reactions, DEC [1-(3-dimethylamino-propyl)-3-ethyl-carbodiimide hydrochloride] {or EDCI [1-ethyl-3-(3-di-methylaminopropyl) carbodiimide HCl]} for peptide synthesis, HOBt (1-hydroxybenzotriazole) for peptide synthesis; Polymer supported oxidising agents (e.g. osmium tetroxide, perruthenate, pyridinium chlorochromate); Polymer supported reducing agents (e.g. borohydride, tributyltin fluoride); Polymer-supported phosphines (for miscellaneous applications depending on the structure) and so on. Commercially available polymer supported catalysts and reagents can be purchased from a number of companies including Sigma-Aldrich (see Chem Files, Vol 5, issue 11 as well as the main catalog), Biotage, Alfa-Aesar, TCI.

SCAVENGER RESINS

The use of resins to clean up reactions has gained much importance over the years. The type of commercially available scavenger resins are electrophilic scavenger resins (e.g. benzaldehyde derivatised resins to scavenge amines; isocyanate resins to scavenge amines, anilines and hydrazines; tosyl chloride resins to scavenge nucleophiles) and nucleophilic scavenger resins (e.g. diethylenetriamine resins to scavenge acids, acid chlorides, anhydrides; sulfonyl amide resins to scavenge acids, acid chlorides, aldehydes, isocyanates and chloroformates) [e.g. see Bhattacharyya *Comb Chem High Throughput Screening* **3** 65 *2000*, Bhattacharyya *Curr Opin Drug Disc Dev* **7** 752 *2004*].

Specific scavengers that use purified silica support (e.g. LpDNPH cartridges which contain a high purity silica adsorbent coated with 2,4-dinitrophenylhydrazine to remove carbonyl compounds), charcoal in various forms and Florisil etc. for particular purposes are available commercially (see Biotage: the *Synthesis and Purification* Catalogue and the *Analytical Sample Preparation* Catalogue and <www.biotage.com> which contain details of such resins, and Supelco: *the Chromatographic Products for Analysis & Purification* Catalogue <www.sigmaaldrich.com/supelco/analytical> for various supports). General types of scavenger resins are also available from a number of companies including Sigma-Aldrich and Biotage.

COMBINATORIAL CHEMISTRY

The major impetus for the development of solid phase synthesis centers on applications in combinatorial chemistry. The notion that new drug leads and catalysts can be discovered in a high throughput fashion has been demonstrated many times over as is evidenced from the number of publications that have arisen (see references at the end of this chapter). A number of approaches to combinatorial chemistry exist. These include the split-mix method, serial techniques and parallel methods to generate libraries of compounds. The advances in combinatorial chemistry are also accompanied by sophisticated methods in deconvolution and identification of compounds from libraries. In a number of cases, innovative hardware and software have been developed for these purposes.

Depending on the size of the combinatorial library to be generated as well as the scale of the reactions to be carried out, a wide range of specialised glassware and equipment is commercially available. For example, in order to carry out parallel combinatorial synthesis, reaction stations equipped with temperature and stirring control are available from a number of sources (e.g. www.fisher.co.uk; www.radleys.com). These reaction stations are readily adapted, using appropriate modules, for conditions under reflux or under inert atmosphere. For automated synthesis of large libraries of compounds, reactions can be carried out using reaction blocks on microtiter plates.

ALTERNATIVE SOLVENTS

The bulk of a reaction medium usually comprises the solvent for reaction. It has been estimated that generally solvents account for 80–90% of the mass utilisation in a typical batch reaction. In view of this, one of the greatest challenges to the 'greening' of chemistry is to consider the 'greening' of solvents. In this regard, issues such as environmental toxicities, waste minimisation, recyclability or the use of renewable solvents are considered in the greening of solvents. A number of publications have provided a framework for the environmental assessment of solvents [Capello et al. *Green Chem* **8** 927 *2007*, Alfonsi et al. *Green Chem* **10** 31 *2008*]. Some approaches to the replacement of conventional solvents include the use of supercritical fluids, e.g. carbon dioxide, ionic liquids, perfluorohydrocarbons. The use of water as an environmentally friendly reaction media has also been the focus of study by several groups [Dallinger & Kappe *Chem Rev* **107** 2563 *2007*, Hailes *Org Proc Res Dev* **11** 114 *2007*, Li & Chen *Chem Soc Rev* **35** 68 *2006*, Leadbeater *J Chem Soc, Chem Commun* 2881 *2005*] as is the study of solvent-less reactions [Polshettiwar & Varma *Pure Appl Chem* **80** 777 *2008*].

SUPERCRITICAL FLUIDS

Supercritical fluids (SCF) are defined as substances that are above their critical temperatures and pressures such that at this critical point, this is the highest temperature and pressure at which the substance can exist as a vapour and liquid in equilibrium. The commonly used SCF in chemistry is that of supercritical carbon dioxide ($scCO_2$), which has a critical point at 31.1°C and a pressure of 73.8 Bar. The density of CO_2 at this critical point is approximately 0.4g/mL. CO_2 is potentially an ideal green solvent–it is non-toxic to the environment and at atmospheric pressure, CO_2 is a gas and hence does not require any waste treatment. It has a high gas-dissolving ability, a low solvation ability, good mass transfer properties and high diffusion rates. CO_2 is inexpensive, non-flammable, environmentally benign and can be removed completely from products. Although CO_2 is a greenhouse gas, CO_2 is naturally occurring as well as obtained as a byproduct of many processes, and the use of CO_2 as solvent is to use a "renewable" resource. In this respect, CO_2 is easily recovered either by cooling (condensing) or absorption by aqueous alkaline solutions and re-used. The disadvantages of using $scCO_2$ are the specialised and expensive equipment needed to achieve the critical conditions, the low dielectric constant and low dissolving abilities. In addition, $scCO_2$ cannot be used in reactions with strong nucleophiles. Applications with $scCO_2$ as solvent has been demonstrated, in extractions (e.g. of caffeine), dry-cleaning, polymerisation reactions, pharmaceutical processing. The use of $scCO_2$ in organic synthesis has also been demonstrated in a number of reactions including hydrogenation reactions, Diels-Alder chemistry, free radical reactions, Friedel Crafts reactions and so on [S. Hadlington *Chem Br* **39** 21 *2003*, Liu & Xiao, *J Mol Cat A: Chem* **270** 1 *2007*]. The solvent properties of $scCO_2$ can be tuned by adjusting the temperature and pressure. Liquids and solid solutes are surprisingly soluble in $scCO_2$ though it is generally true that the solubility of non-polar substances is higher than the polar ones because CO_2 is a non-polar molecule. The solubility can be tuned by changing the bulk densities of CO_2 or by adding a co-solvent or modifying the solute. Other fluids that have been used in this way are ammonia and SO_2, although they do not have the many advantages of CO_2, especially those pertaining to its low reactivity under "normal" reaction conditions.

IONIC LIQUIDS

Ionic liquids (ILs) are organic or inorganic salts that are liquids at room or reaction temperatures. Although ionic liquids are themselves not new discoveries (e.g. the ionic liquid $[EtNH_3]$ $[NO_3]$ was described in 1914), the use of ionic liquids in synthesis is relatively recent. In particular, the potential applications of ionic liquids as solvents in synthesis and in catalysis have been achieved. They have high mechanical, thermal and electrochemical stability. Their physical properties make them unique solvents for synthesis, and are 'green' alternatives to volatile organic solvents, though there has been some debate on whether ionic liquids can be considered as 'green' solvents. [R. Sanghi & M.M. Srivasatava, *Green Chemistry: Environment Friendly Alternatives*, Alpha Science International, *2003*, ISBN 9781842651735; C. Alfonso, A.M. Crespo & P.S.G. Joao, *Green Separation Processes: Fundamentals and Applications*, VCH-Wiley Publishing, *2005*, ISBN 978357309856; J. Clark & J. Hardy, *Green Chemistry in Undergraduate Practical Classes (with CD-ROM)*, Royal Society of Chemistry, *2006*, ISBN 978054042784]. The impact of ILs on health and environment is not known. In addition to this, many ILs are difficult to prepare and can be expensive if bulk, high purity ILs are needed. Ionic liquids are good solvents for both organic and inorganic substances and hence can be used to bring reagents into the same phase for reaction. Ionic liquids are also immiscible with a number of organic solvents and thus provide a non-aqueous, polar alternative for two-phase extraction systems. As ionic liquids are non-flammable and non-volatile (with hardly any measurable vapour pressure), they can be used in high vacuum systems without the possibility of loss or contaminants. In addition, this also facilitates the isolation of products as products can be distilled from the ionic liquid or alternatively extracted with an organic solvent that is immiscible with the ionic liquid. Although ionic liquids are frequently composed of poorly coordinating ions,

they are highly polar which are important characteristics in the activation of catalysts. For example the 1-butyl-3-methylimidazolinium salt with $AlCl_3$ is a very good catalyst for the Friedel-Crafts reaction, and varying the ratio of salt to $AlCl_3$ produces a more or less acidic medium. ILs are used successfully in organic reactions which are mediated by microwaves. ILs have found uses in phase-separation processes, in electrochemical processes, as heat storage media, lubricants and additives.

A large variety of ILs of high purity with water content below 100ppm and halide content below 10ppm are now available commercially. These include numerous *N*-alkylpyridinium, *N,N'*-dialkylimidazolium, alkylammonium and alkylphosphonium salts, covalent hydrophobic ILs (e.g. 1,2-dimethyl-3-propylimidazolium bis(trifluoromethylsulfonyl)imide, task-specific ILs, Brønsted acidic ILs (e.g. 3-[triphenylphosphonio]propane-1-sulfonic acid tosylate), nitrile-functionalised ILs, perfluorinated ILs (e.g. tetrabutylammonium nonafluorobutane sulfonate, BASF Basionics (e.g. 1,2,3-trimethylimidazolium methyl sulfate), and TOMATS for heavy metal extraction (e.g. methyltrioctylammonium thiosalicylate)

A number of reactions have been carried out in ionic liquids; for examples see Dell'Anna et al. *J Chem Soc, Chem Commun* 434 *2002*, Nara et al. *Tetrahedron Lett* **43** 1127 *2002*, Semeril et al. *J Chem Soc, Chem Commun* 146 *2002*, Buijsman et al. *Org Lett* **3** 3785 *2001*. These include Diels-Alder reactions, Friedel-Crafts (above), transition-metal mediated catalysis, e.g. Heck and Suzuki coupling reactions, and olefin metathesis reactions. An example of ionic liquid acceleration of reactions carried out on solid phase is given by Revell & Ganesan [*Org Lett* **4** 3071 *2002*]. [See also Fluka, Riedel-deHaën, Catalogue 2007–2008, and <www.sigmaaldrich.com/ionicliquids>, with or without Basionics™ and Cytec (Cytos®); Chem Files (Sigma-Aldrich) Vol 6, No 9 *2006*, Ghassemi et al. Application Note 48 in Synthesis and Purification Catalog 2007, <www.Biotage.com>.]

FLUOROUS CHEMISTRY

Fluorous chemistry is defined as chemistry that is related to highly fluorinated sp^3-hybridised carbon containing compounds. The seminal work by Horvath and Rabai (*Science* **266** 72 *1994*) described the applications of fluorous biphasic catalysis and applied it to Rh catalysed hydroformylation reactions. To date the scope of fluorous chemistry has expanded to include applications in organic synthesis and material science, separation, extraction and chromatography. For example, fluorous phase labels can be attached to substrates such that the subsequent fluorinated products can be extracted into the fluorous phase. This has applications in liquid-liquid extractions (typical work-up procedures) where a three-phase extraction is now possible (organic, fluorous and aqueous phases). As organic and inorganic compounds have little or no tendency to dissolve in highly fluorinated solvents and compounds, phase labelling a compound as fluorous will enable successful extraction into the fluorous phase. However, in order to carry out homogenous reactions with these fluorinated compounds, organic solvents with a good dissolving power for fluorous compounds or miscible organic and fluorous solvents can be used. Alternatively organic solvents with a few fluorine atoms, e.g. trifluoroethanol, benzotrifluoride ("hybrid solvents") will dissolve both organic and fluorous compounds. A number of synthetic applications utilising fluorous chemistry have been reported in the literature. [For examples, see Schneider & Bannwarth *Helv Chim Acta* **84** 735 *2001*, Galante et al. *Tetrahedron Lett* **42** 5425 *2001*, Studer & Curran *Tetrahedron* **53** 6681 *1997*, Studer et al. *J Org Chem* **62** 2917 *1997*, Crich & Neelamkavil *Tetrahedron* **58** 3865 *2002*.] For some fluorous compounds for synthesis and separation, see Chem Files from Sigma-Aldrich, Supplement II, 2008. One potential limitation of fluorous solvents is their cost.

BIOMASS DERIVED ORGANIC SOLVENTS

Biomass derived organic solvents are solvents that are obtained from renewable resources, which is in contrast to the traditional petrochemical based solvents that are limited in resource. These solvents are gaining traction as green solvents, though the scope of the reaction transformations and other solvent replacement applications have not been fully studied. Examples of such biomass derived solvents are 2-methyltetrahydrofuran [96-47-9], glycerol [56-81-5], glycerol ethers, ethyl lactate and cyclopentylmethyl ethers. 2-Methyltetrahydrofuran is an aprotic ether which has polarity and Lewis base strengths between that for diethyl ether and THF [Aycock *Org Proc Res Dev* **11** 156 *2007*; Ripin & Vetelino *Syn Lett* 2353 *2003*]. It had been used as a replacement solvent for THF [109-99-9] in organometallic reactions (e.g. Grignard, lithiation, hydride reduction, coupling reactions) with the advantage that MeTHF is only partially water miscible and hence can be conveniently used to recover reaction products [Comanita & Aul *Chimica Oggi* **25** 26 *2007*; Pace et al. *Tetrahedron* **67** 2670 *2011*]. Cyclopentylmethyl ether has been used as an alternative to ethereal solvents such as THF [109-99-0], 1,4-dioxane [123-91-1], 1,2-dimethoxyethane [110-71-4] [Watanabe et al. *Org Proc Res Dev* **11** 251 *2007*]. The formation of peroxides is suppressed in cyclopentylmethyl ether [5614-37-9] and this solvent has a narrow explosion range and can be easily dried. The use of cyclopentylmethyl ether as solvent has also been demonstrated in a number of reactions including organometallic reactions, oxidation and reduction reactions

and reactions with transition metal catalysts. Interestingly, a promising new sustainable solvent is glycerol. Glycerol is an organic waste product from biodiesel production and hence is cheap, readily available and is renewable. Glycerol is a non-toxic polar solvent that is able to dissolve inorganic salts, acids, bases, transition metal complexes as well as organic compounds that are poorly miscible in water [Diaz-Alvarez *Chem Commun* **47** 6208 *2011*; Gu & Jerome *Green Chem* **12** 1127 *2010*]. The disadvantages of using glycerol as solvent are the high viscosity as well as the possible reactivity of the hydroxyl groups in chemical transformations. Nevertheless, the use of glycerol as solvent in a variety of organic transformations has been demonstrated. In some cases, glycerol as solvent has a beneficial effect on reaction rates and selectivity. Due to glycerol's immiscibility with non-polar solvents, the use of glycerol facilitates isolation of reaction products and has been used in separation processes.

CHAPTER 4

PURIFICATION OF ORGANIC CHEMICALS

INTRODUCTION

The general principles, techniques and methods of purification in Chapters 1 and 2 are applicable to this chapter. Most organic liquids and a number of solids can readily be purified by fractional distillation, usually at atmospheric pressure. Sometimes, particularly with high boiling or sensitive liquids, or when in doubt about stability, distillation or fractionation under as low a pressure as possible should be carried out. To save space, the present chapter omits many substances for which the published purification methods involve simple distillation. Where boiling points are given, purification by distillation is another means of removing impurities. Literature references, and in particular Beilstein references, are included for most entries which refer the reader directly or indirectly to the original sources. Substances are listed alphabetically in each section, usually with some criteria of purity, giving brief details of how they can be purified. Also noted are the molecular weights (to the first decimal place), melting points and/or boiling points together with the respective densities and refractive indexes for liquids, and optical rotations for chiral compounds. All temperatures are in centigrade unless stated otherwise. When temperatures and/or wavelengths are not given for the last three named properties, then they should be assumed to be 20°C and the average of the wavelengths of the sodium D lines respectively; and most densities are relative to water at 4°C.

Ionisation constants of ionisable compounds are given as **pK** values (published in the literature) and refer to the **pKa** values at room temperature (~15°C to 25°C). Values at other temperatures are given as superscripts, e.g. $\mathbf{pK^{30}}$ for 30°C. Estimated values are entered as $\mathbf{pK_{Est}}$ (see Chapter 1**,** pp 34–36).

The present chapter includes commercially available organic chemicals. Most of the inorganic, metal-organic, organo- bismuth, boron, phosphorus, selenium, silicon and alkali metal compounds and metal ion salts of organic acids are in Chapter 5. Naturally occurring commercially available organic compounds for use in biochemistry, molecular biology and biology are in Chapter 6. Commercially available polymer supported reagents are indicated with **§** under the appropriate reagent.

Rapid purification procedures are included for commonly used solvents and reagents which make them suitable for general use in synthetic chemistry.

Abbreviations of titles of periodicals are defined as in the Chemical Abstracts Service Source Index (CASSI) except that punctuation is deleted. Other abbreviations are self evident.

As a good general rule, all low boiling (<100°) organic liquids should be treated as highly flammable and toxic (because they can be inhaled in large quantities) and the necessary precautions should be taken (see Safety precautions associated with the purification of laboratory chemicals in Chapter 1, p 4).

Benzene has been used as a solvent successfully and extensively in the past for reactions and purification by chromatography and crystallisation but is now considered a **very dangerous substance**. It should be used with extreme care. We emphasise that an alternative solvent to benzene (e.g. toluene, toluene-petroleum ether, or a petroleum ether to name a few) should be used first. However, if no other solvent system can be found, then all operations involving benzene (and storage) have to be performed in an efficiently running fumehood, and precautions must be taken to avoid inhalation and contact with skin and eyes. An asterisk has been inserted in the text, e.g. $^{*}C_6H_6$ or *benzene, to remind the user that special precautions should be adopted.

This chapter consists of five sections *viz*: **Aliphatic Compounds, Alicyclic Compounds, Aromatic Compounds, Heterocyclic Compounds** and **Miscellaneous As, B, P, Si, S, Se, and Te Compounds.**

Purification of Laboratory Chemicals. http://dx.doi.org/10.1016/B978-0-12-382161-4.00004-2

ALIPHATIC COMPOUNDS

Acetal (acetaldehyde diethylacetal) *[105-57-7]* **M 118.2, b 103.7-104°, d $_4^{20}$ 0.831, n $_D^{25}$ 1.38054, n^{25} 1.3682.** Dry acetal over Na to remove alcohols and H_2O, and to polymerise aldehydes, then fractionally distil. Or, treat it with alkaline H_2O_2 at 40-45° to remove aldehydes, then saturate with NaCl, separate, dry with K_2CO_3 and distil it from Na [Vogel *J Chem Soc* 616 *1948*]. [*Beilstein* **1** IV 3103.]

Acetaldehyde *[75-07-0]* **M 44.1, b 20.2°, d $_4^{20}$ 0.788, n $_D^{25}$ 1.33113, pK^{25} 13.57 (hydrate).** Acetaldehyde is usually purified by fractional distillation in a glass helices-packed column under dry N_2, discarding the first portion of distillate. Or, it is shaken for 30 minutes with $NaHCO_3$, dried with $CaSO_4$ and fractionally distilled at 760mm through a 70cm Vigreux column. The middle fraction is collected and further purified by standing for 2 hours at 0° with a small amount of hydroquinone (free radical inhibitor), followed by distillation [Longfield & Walters *J Am Chem Soc* **77** 810 *1955*]. [*Beilstein* **1** IV 3094.]

Acetaldehyde dimethyl acetal (1,1-dimethoxyethane) *[534-15-6]* **M 90.1, b 63-65°, d $_4^{20}$ 0.852, n $_D^{25}$ 1.36678.** Distil the dimethyl acetal through a fractionating column and fraction boiling at 63.8°/751mm is collected. It forms an azeotrope with MeOH. *Alternatively*, purify it as for *acetal* above. It has been purified by GLC. [*Beilstein* **1** IV 3103.]

Acetamide *[60-35-5]* **M 59.1, m 81°, pK $_1^{25}$ -1.4, pK $_2^{25}$ +0.37.** Acetamide is crystallised by dissolving in hot MeOH (0.8ml/g), diluting with Et_2O and allowing to stand [Wagner *J Chem Edu* **7** 1135 *1930*]. Alternate crystallisation solvents are acetone, *benzene, chloroform, dioxane, methyl acetate or *benzene/ethyl acetate mixtures (3:1 and 1:1). It has also been recrystallised from hot water after treating with HCl-washed activated charcoal (which had been repeatedly washed with water until free from chloride ions), then crystallised again from hot 50% aqueous EtOH and finally twice from hot 95% EtOH [Christoffers & Kegeles *J Am Chem Soc* **85** 2562 *1963*]. Finally it is dried in a vacuum desiccator over P_2O_5. Acetamide is also purified by distillation (**b** 221-223°) or by sublimation *in vacuo*. It has also been purified by two recrystallisations from cyclohexane containing 5% (v/v) of *benzene. Needle-like crystals separate and are filtered, washed with a small volume of distilled H_2O and dried with a flow of dry N_2. [Slebocka-Tilk et al. *J Am Chem Soc* **109** *4620 1987*, *Beilstein* **2** H 175, **2** I 80, **2** II 177, **2** III 384, **2** IV 399.]

Acetamidine hydrochloride *[124-42-5]* **M 94.5, m 164-166°, 165-170°(dec), 174°, pK^{25} 12.40.** The hydrochloride can be recrystallised from small volumes of EtOH. *Alternatively*, it is dissolved in EtOH, filtered, Et_2O is added; filter the crystalline salt off under N_2 and dry it in a vacuum desiccator over H_2SO_4. The salt is deliquescent and should be stored in a tightly stoppered container. Its solubility in H_2O is 10% at room temperature and it is soluble in Me_2CO. The *free base* reacts strongly alkaline in H_2O. It has λ_{max} 224nm (ε 4000) in H_2O. The *picrate* has **m** 252° (sintering at ~245°). [Dox *Org Synth* Coll Vol **I** 5 *1941*, Davies & Parsons *Chem Ind (London)* 628 *1958*, Barnes et al. *J Am Chem Soc* **62** 1286 *1940* give **m** 177-178°, *Beilstein* **2** H 185, **2** I 85, **2** II 183, **2** III 416, **2** IV 428.]

***N*-(2-Acetamido)-2-aminoethanesulfonic acid (ACES)** *[7365-82-4]* **M 182.2, m > 220°(dec), pK$_{Est}$ ~1.5, pK$_2$ 6.9.** Recrystallise ACES from hot aqueous EtOH. [Perrin & Dempsey *Buffers for pH and Metal Ion Control* Chapman & Hall, London *1974*, *Beilstein* **4** III 1707.]

***N*-(2-Acetamido)iminodiacetic acid (ADA)** *[26239-55-4]* **M 190.2, m 219°(dec), pK$_1$ ~2.3, pK$_2$ 6.6.** Dissolve ADA in water, add one equivalent of NaOH solution (to final pH of 8-9), then acidify with HCl to precipitate the free acid. This is filtered off, washed with water and dried *in vacuo*. [*Beilstein* **4** IV 2441.]

Acetamidomethanol *[625-51-4]* **M 89.1, m 47-50°, 54-56°, 55°.** Recrystallise it from freshly distilled Me_2CO, wash the crystals with dry Et_2O and dry them in a vacuum desiccator over P_2O_5. R_F 0.4 on paper chromatography with $CHCl_3$/EtOH (2:8) as solvent and developed with ammoniacal $AgNO_3$. It also crystallises in needles from EtOAc containing a few drops of Me_2CO. It is *hygroscopic* and should be stored under dry conditions. [Bachmann et al. *J Am Chem Soc* **73** 2775 *1951*, Walter et al. *Chem Ber* **99** 3204 *1966*, Einhorn &

Ladisch *Justus Liebigs Ann Chem* **343** 265 *1905*, *Beilstein* **2** IV 405.]

Acetic acid (glacial) *[64-19-7]* **M 60.1, m 16.6°, b 118°, d $_4^{20}$ 1.049, n $_D^{25}$ 1.37171, n^{25} 1.36995, pK^{25} 4.76.** Usual impurities are traces of acetaldehyde and other oxidisable substances and water. (Glacial acetic acid is very *hygroscopic*. The presence of 0.1% water lowers its **m** by 0.2°.) Purify it by adding some acetic anhydride to react with water present, heat it for 1 hour to just below boiling in the presence of 2g CrO_3 per 100ml and then fractionally distil it [Orton & Bradfield *J Chem Soc* 960 *1924*, Orton & Bradfield *J Chem Soc* 983 *1927*]. Instead of CrO_3, use 2-5% (w/w) of $KMnO_4$, and boil under reflux for 2-6 hours. Traces of water have been removed by refluxing with tetraacetyl diborate (prepared by warming 1 part of boric acid with 5 parts (w/w) of acetic anhydride at 60°, cooling, and filtering off, followed by distillation [Eichelberger & La Mer *J Am Chem Soc* **55** 3633 *1933*].
Refluxing with acetic anhydride in the presence of 0.2g % of 2-naphthalenesulfonic acid as catalyst has also been used [Orton & Bradfield *J Chem Soc* 983 *1927*]. Other suitable drying agents include anhydrous $CuSO_4$ and chromium triacetate: P_2O_5 converts some acetic acid to the anhydride. Azeotropic removal of water by distillation with thiophene-free *benzene or with butyl acetate has been used [Birdwhistell & Griswold *J Am Chem Soc* **77** 873 *1955*]. An alternative purification uses fractional freezing. [*Beilstein* **2** H 96, **2** IV 94.]
Rapid procedure: Add 5% acetic anhydride, and 2% of CrO_3. Reflux and fractionally distil.

Acetic anhydride *[108-24-7]* **M 102.1, b 138°, d $_4^{20}$ 1.082, n $_D^{25}$ 1.3904.** Adequate purification can usually be achieved by fractional distillation through an efficient column. Acetic acid can be removed by prior refluxing with CaC_2 or with coarse Mg filings at 80-90° for 5 days, or by distillation from a large excess of quinoline (1% AcOH in quinoline) at 75mm pressure. Acetic anhydride can also be dried by standing with Na wire for up to a week, removing the Na and distilling it under vacuum. (Na reacts vigorously with acetic anhydride at 65-70°). Dippy & Evans [*J Org Chem* **15** 451 *1950*] let the anhydride (500g) stand over P_2O_5 (50g) for 3 hours, then decanted it and stood it with ignited K_2CO_3 for a further 3 hours. The supernatant liquid was distilled and the fraction **b** 136-138° was further dried with P_2O_5 for 12 hours, followed by shaking with ignited K_2CO_3, before two further distillations through a five-section Young and Thomas fractionating column. The final material distilled at 137.8-138.0°. It can also be purified by azeotropic distillation with toluene: the azeotrope boils at 100.6°. After removal of the remaining toluene, the anhydride is distilled [sample had a specific conductivity of 5×10^{-9} ohm^{-1}cm^{-1}]. [*Beilstein* **2** H 96, **2** I 39, **2** II 91, **2** III 134, **2** IV 94.]
Rapid procedure: Shake with P_2O_5, separate, shake with dry K_2CO_3 and fractionally distil.

Acetic hydrazide *[1068-57-1]* **M 74.1, m 67°, b 127°/18mm.** Acetic hydrazide crystallises as needles from EtOH. It reduces $NH_3/AgNO_3$. [*Beilstein* **2** H 191, **2** IV 435.]

Acetoacetamide *[5977-14-0]* **M 101.1, m 54-55°, 54-56°**. Recrystallise the amide from $CHCl_3$, or Me_2CO/petroleum ether. It also crystallises from pyridine with 4mols of solvent. It is slightly soluble in H_2O, EtOH and AcOH but is insoluble in Et_2O. The *phenylhydrazone* has **m** 128°. [Kato *Chem Pharm Bull Jpn* **15** 921 923 *1967*, Claisen & Meyer *Chem Ber* **35** 583 *1902*, *Beilstein* **3** H 659, **3** I 231, **3** III 1204, **3** IV 1545.]

Acetone *[67-64-1]* **M 58.1, b 56.2°, d $_4^{20}$ 0.791, n $_D^{25}$ 1.35880, pK $_1^{25}$ –6.1 (basic, mono-protonated), pK $_2^{25}$ 20.0 (acidic)** The commercial preparation of acetone by catalytic dehydrogenation of isopropyl alcohol gives relatively pure material. Analytical reagent quality generally contains less than 1% of organic impurities but may have up to about 1% of H_2O. Dry acetone is appreciably *hygroscopic*. The main organic impurity in acetone is mesityl oxide, formed by aldol condensation. It can be dried with anhydrous $CaSO_4$, K_2CO_3 or type 4A Linde molecular sieves, and then distilled. Silica gel and alumina, or mildly acidic or basic desiccants cause acetone to undergo the aldol condensation, so that its water content is increased by passage through these reagents. This also occurs to some extent when P_2O_5 or sodium amalgam is used. Anhydrous $MgSO_4$ is an inefficient drying agent, and $CaCl_2$ forms an addition compound. Drierite (anhydrous $CaSO_4$) offers minimum acid and base catalysis for aldol formation and is the recommended drying agent for this solvent [Coetzee & Siao *Inorg Chem* **14** 2 *1987*, Riddick & Bunger *Organic Solvents* Wiley-Interscience, N.Y., 3rd edn, *1970*]. Acetone can be shaken with Drierite (25g/L) for several hours before it is decanted and distilled from fresh Drierite (10g/L) through an efficient column, maintaining atmospheric contact through a Drierite drying tube.

The equilibrium water content is about 10^{-2}M. Anhydrous $Mg(ClO_4)_2$ **should not be used as drying agent as there is a high risk of EXPLOSION with acetone vapour.**
Organic impurities have been removed from acetone by adding 4g of $AgNO_3$ in 30ml of water to 1L of acetone, followed by 10ml of M NaOH, shaking for 10 minutes, filtering, drying with anhydrous $CaSO_4$ and distilling [Werner *Analyst (London)* **58** 335 *1933*]. *Alternatively*, successive small portions of $KMnO_4$ have been added to acetone at reflux, until the violet colour persists, followed by drying and distilling. Refluxing with chromium trioxide (CrO_3) has also been used. Methanol has been removed from acetone by azeotropic distillation (at 35°) with methyl bromide, and treatment with acetyl chloride.
Small amounts of acetone can be purified as the NaI addition compound, by dissolving 100g of finely powdered NaI in 400g of boiling acetone, then cooling in ice and salt to –8°. Crystals of $NaI.3Me_2CO$ are filtered off and, on warming in a flask, acetone distils off readily. [This method is more convenient than the one using the bisulfite addition compound.] It has also been purified by gas chromatography on a 20% free fatty acid phthalate (on Chromosorb P) column at 100°.
For efficiency of desiccants in drying acetone see Burfield and Smithers [*J Org Chem* **43** 3966 *1978*]. The water content of acetone can be determined by a modified Karl Fischer titration [Koupparis & Malmstadt *Anal Chem* **54** 1914 *1982*]. [*Beilstein* **1** IV 3180.]
Rapid procedure: Dry over anhydrous $CaSO_4$ and distil.

Acetone cyanohydrin *[75-86-5]* **M 85.1, b 48°/2.5mm, 68-70°/11mm, 78-82°/15mm, d_4^{20} 0.93.** Dry the cyanohydrin with Na_2SO_4, and distil it as rapidly as possible under vacuum to avoid decomposition. Discard fractions boiling below 78-82°/15mm. Store it in the dark. **USE AN EFFICIENT FUME HOOD as HCN (POISONOUS) is always present.** [Cox & Stormont *Org Synth* Coll.Vol. **II** 7 *1940*, *Beilstein* **3** H 316, **3** IV 785.]

Acetonedicarboxylic acid (3-oxoglutaric acid) *[542-05-2]* **M 146.1, m 138°(dec), pK^{25} 3.10.** Crystallise it from ethyl acetate and store it over P_2O_5. It decarboxylates in hot water. [*Beilstein* **3** IV 1816.]

Acetone semicarbazone *[110-20-3]* **M 115.1, m 187°, pK^{25} 1.33.** Acetone semicarbazone crystallises from water or from aqueous EtOH. [*Beilstein* **3** H 101, **3** I 48, **3** II 81, **3** III 189, **3** IV 179.]

Acetonitrile (methyl cyanide) *[75-05-8]* **M 41.1, b 81.6°, d^{25} 0.77683, n_D^{20} 1.3441, n^{25} 1.34163.** Commercial acetonitrile is a by-product of the reaction of propylene and ammonia to acrylonitrile. The following procedure that significantly reduces the levels of acrylonitrile, allyl alcohol, acetone and *benzene was used by Kiesel [*Anal Chem* **52** 2230 *1988*]. Methanol (300ml) is added to 3L of acetonitrile fractionated at high reflux ratio until the boiling temperature rises from 64° to 80°, and the distillate becomes optically clear down to λ = 240nm. Add sodium hydride (1g) free from paraffin, to the liquid, reflux for 10 minutes, and then distil rapidly until about 100ml of residue remains. Immediately pass the distillate through a column of acidic alumina, discarding the first 150ml of percolate. Add 5g of CaH_2 and distil the first 50ml at a high reflux ratio. Discard this fraction, and collect the following main fraction. The best way of detecting impurities is by gas chromatography.
Usual contaminants in commercial acetonitrile include H_2O, acetamide, NH_4OAc and NH_3. Anhydrous $CaSO_4$ and $CaCl_2$ are inefficient drying agents. Preliminary treatment of acetonitrile with cold, saturated aqueous KOH is undesirable because of base-catalysed hydrolysis and the introduction of water. Drying by shaking with silica gel or Linde 4A molecular sieves removes most of the water in acetonitrile. Subsequent stirring with CaH_2 until no further hydrogen is evolved leaves only traces of water and removes acetic acid. The acetonitrile is then fractionally distilled at high reflux, taking precaution to exclude moisture by refluxing over CaH_2 [Coetzee *Pure Appl Chem* **13** 429 *1966*]. *Alternatively*, 0.5-1% (w/v) P_2O_5 is often added to the distilling flask to remove most of the remaining water. Excess P_2O_5 should be avoided because it leads to the formation of an orange polymer. Traces of P_2O_5 can be removed by distilling from anhydrous K_2CO_3.
Kolthoff, Bruckenstein and Chantooni [*J Am Chem Soc* **83** 3297 *1961*] removed acetic acid from 3L of acetonitrile by shaking for 24 hours with 200g of freshly activated alumina (which had been reactivated by heating at 250° for 4 hours). The decanted solvent was again shaken with activated alumina, followed by five batches of 100-150g of anhydrous $CaCl_2$. (Water content of the solvent was then less than 0.2%.) It was shaken for 1 hour with 10g of P_2O_5, twice; and distilled in a 1m×2cm column, packed with stainless steel wool and

protected from moisture by $CaCl_2$ tubes. The middle fraction had a water content from 0.7 to 2mM. Traces of unsaturated nitriles can be removed by initially refluxing with a small amount of aqueous KOH (1ml of 1% solution per L). Acetonitrile can be dried by azeotropic distillation with dichloromethane, *benzene or trichloroethylene. Isonitrile impurities can be removed by treatment with conc HCl until the odour of isonitrile has gone, followed by drying with K_2CO_3 and distilling.
Acetonitrile is refluxed with, and distilled from alkaline $KMnO_4$ and $KHSO_4$, followed by fractional distillation from CaH_2. (This is better than fractionation from molecular sieves or passage through a type H activated alumina column, or refluxing with KBH_4 for 24 hours and fractional distillation) [Bell et al. *J Chem Soc, Faraday Trans 1* **73** 315 *1977*, Moore et al. *J Am Chem Soc* **108** 2257 *1986*].
Material suitable for polarography is obtained by refluxing over anhydrous $AlCl_3$ (15g/L) for 1 hour, distilling, refluxing over Li_2CO_3 (10g/L) for 1 hour and redistilling. It is then refluxed over CaH_2 (2g/L) for 1 hour and fractionally distilled, retaining the middle portion. The product is not suitable for UV spectroscopy use. A better purification procedure uses refluxing over anhydrous $AlCl_3$ (15g/L) for 1 hour, distilling, refluxing over alkaline $KMnO_4$ (10g $KMnO_4$, 10g Li_2CO_3/L) for 15 minutes, and distilling. A further reflux for 1 hour over $KHSO_4$ (15g/L), then distillation, is followed by refluxing over CaH_2 (2g/L) for 1 hour, and fractional distillation. The product is protected from atmospheric moisture and stored under nitrogen [Walter & Ramalay *Anal Chem* **45** 165 *1973*]. Purificaton of "General Purity Reagent" for this purpose is not usually satisfactory because very large losses occur at the $KMnO_4/LiCO_3$ step. For electrochemical work involving high oxidation fluorides, further reflux over P_2O_5 (1g/ml for 0.5 hours) and distilling (discarding 3% of first and last fractions) and repeating this step is necessary. The distillate is kept over molecular sieves *in vacuo* after degassing, for 24 hours and distilling in a vacuum onto freshly activated 3A molecular sieves. The MeCN should have absorption at 200nm of <0.05 (H_2O reference) and UV cutoff at *ca* 175nm. Also the working potential range of purified $Et_4N^+ BF_4^-$ (0.1mol.dcm^{-3} in the MeCN) should be +3.0 to –2.7V *vs* Ag^+/Ag^o. If these criteria are not realised then further impurities can be removed by treatment with activated neutral alumina (60 mesh) *in vacuo* before final molecular sieves treatment [Winfield *J Fluorine Chem* **25** 91 *1984*].
Acetonitrile has been distilled from $AgNO_3$, Payecting the middle fraction over freshly activated Al_2O_3. After standing for two days, the liquid is distilled from the activated Al_2O_3. The specific conductivity should be 0.8-1.0 × 10^{-8} mhos [Harkness & Daggett *Can J Chem* **43** 1215 *1965*]. *Acetonitrile* ^{14}C is best purified by gas chromatography and is water free, and distils at 81°. [*Beilstein* **2** H 183, **2** IV 419.]
Rapid procedure: Dry over anhydrous K_2CO_3 for 24 hours, followed by further drying for 24 hours over 3A molecular sieves or boric anhydride, followed by distillation. *Alternatively*, stir over P_2O_5 (5% w/v) for 24 hours then distil. However, this last method is not suitable for reactions with very acid sensitive compounds.

Acetonylacetone (2,5-hexanedione) *[110-13-4]* **M 114.2, m –9°, b 76-78°/13mm, 88°/25mm, 137°/150mm, 188°/atm, d $_4^{20}$ 0.9440, n $_D^{20}$ 1.423, pK^{25} 18.7.** Purify it by dissolving in Et_2O, stiring with K_2CO_3 (a quarter of the weight of dione), filtering, drying over anhydrous Na_2SO_4 (**not $CaCl_2$**), filtering again, evaporating the filtrate and distilling it in a vacuum. It is then redistilled through a 30cm Vigreux column (oil bath temperature 150°). It is miscible with H_2O and EtOH. The *dioxime* has **m** 137° (plates from *C_6H_6), the *mono-oxime* has **b** 130°/11mm, and the *2,4-dinitrophenylhydrazone* has **m** 210-212° (red needles from EtOH). It forms complexes with many metals. [Werner et al. *Chem Ber* **22** 2100 *1989*, for enol content see Gero *J Org Chem* **19** 1960 *1954*, *Beilstein* **1** IV 3688.]

Acetoxime (acetone oxime) *[127-06-0]* **M 73.1**, **m 63°, b 135°/760mm, d $_4^{20}$ 0.901, pK^{40} 0.99.** It crystallises from petroleum ether (b 40-60°) and can be sublimed. [*Beilstein* **1** H 649, **1** IV 3202.]

Acetoxyacetone (acetonyl acetate, acetol acetone) *[592-20-1]* **M 116.1, b 65°/11mm, 73-75°/17mm, 174-176°/atm, d $_4^{20}$ 1.0757, n $_D^{20}$ 1.4141.** Distil it in a vacuum, then redistil it at atmospheric pressure. It is miscible with H_2O, but is slowly decomposed by it. Store it in a dry atmosphere. The *2,4-dinitrophenylhydrazone* has **m** 115-115.5° (from $CHCl_3$/hexane). [Perkin Jr *J Chem Soc* **59** 789 *1891*, Reich & Samuels *J Org Chem* **21** 68 *1956*, Nef *Justus Liebigs Ann Chem* **335** 260 *1904*, *Beilstein* **2** IV 297.]

1-Acetoxy-1,3-butadiene (1,3-butadienyl acetate) ***cis-trans*** mixture *[1515-76-0]* **M 112.1, b 42-43°/16mm, 51-52°/20mm, 60-61°/40mm, d $_4^{20}$ 0.9466, n $_D^{20}$ 1.4622.** The commercial sample is stabilised with 0.1% of *p*-

tert-butylcatechol. If the material contains crotonaldehyde (by IR, used in its synthesis), it should be dissolved in Et_2O, shaken with 40% aqueous sodium bisulfite, then 5% aqueous Na_2CO_3, water, dried (Na_2SO_4) and distilled several times in a vacuum through a Widmer [*Helv Chim Acta* **7** 59 *1924*] or Vigreux column [Wicterle & Hudlicky *Col Czech Chem Commun* **12** 564 *1947*, Hagemeyer & Hull *Ind Eng Chem* **41** 2920 *1949*]. [*Beilstein* **2** III 295.]

1-Acetoxy-2-butoxyethane (2-butyloxyethyl acetate) *[112-07-2]* **M 160.2, b 61-62°/0.2mm, 75-76°/12mm, 185.5°/740mm, 188-192°/atm, d_4^{20} 0.9425, n_D^{20} 1.4121.** Shake the ester with anhydrous Na_2CO_3, filter and distil it in a vacuum. Redistillation can then be carried out at atmospheric pressure. [Dunbar & Bolstad *J Org Chem* **21** 1041 *1956*, *Beilstein* **2** IV 215.]

2-Acetoxyethanol (2-hydroxyethyl acetate) *[542-59-6]* **M 104.1, b 61°/1mm, 79-81°/12mm, 187°/761mm, d_4^{20} 1.108, n_D^{20} 1.42.** Dry the ester over K_2CO_3 (**not $CaCl_2$**), and distil it. [Davis & Ross *J Chem Soc* 3061 1950, rate of hydrolysis: Davis & Ross *J Chem Soc* 2706 *1951*, *Beilstein* **2** H 141, **2** I 66, **2** II 154, **2** III 303, **2** IV 214.]

1-Acetoxy-2-ethoxyethane *[111-15-9]* **M 132.2, b 30°/3mm, 49-50°/12mm, 156-159°, d_4^{20} 0.97, n_D^{20} 1.406.** Shake the ethoxy-ethane with anhydrous Na_2CO_3, filter and distil it in a vacuum. Redistillation can then be carried out at atmospheric pressure. [Dunbar & Bolstad *J Org Chem* **21** 1041 *1956*, *Beilstein* **2** IV 214.]

1-Acetoxy-2-methoxyethane *[110-49-6]* **M 118.1, b 30°/6mm, 40-41°/12mm, 140-144°/760mm, d_4^{20} 1.009, n_D^{20} 1.4011.** Shake the methoxy-ethane with anhydrous Na_2CO_3, filter and distil it in a vacuum. Redistillation can be then be carried out at atmospheric pressure. [Dunbar & Bolstad *J Org Chem* **21** 1041 *1956*, *Beilstein* **2** IV 214.]

***S*-(-)-2-Acetoxypropionyl chloride** *[36394-75-9]* **M 150.6, b 51-53°/11mm, d_4^{20} 1.19, n_D^{20} 1.423, $[\alpha]_D^{27}$ -33°, (c 4, $CHCl_3$), $[\alpha]_{546}^{20}$ –38° (c 4, $CHCl_3$).** It is moisture sensitive and is hydrolysed to the corresponding acid. Check the IR spectrum. If the OH band above 3000cm^{-1} is too large and broad then the mixture should be refluxed with pure acetyl chloride for 1 hour, evaporated and distilled under reduced pressure. [Julia & Sans *J Chromatographic Sci* **17** 651 *1979*, Dolittle & Heath *J Org Chem* **49** 5041 1984, *Beilstein* **3** II 189.]

***S*-Acetoxysuccinic anhydride** *[59025-03-5]* **M 158.1, m 58° (*RS* 81.5-82.5°, 86-87°), $[\alpha]_D^{20}$ –26.0° (c 19, Me_2CO), $[\alpha]_D^{20}$ –28.4° (c 13, Ac_2O).** Recrystallise it from Ac_2O and dry it in a vacuum over KOH, or by washing it with dry Et_2O due to its deliquescent nature. [Jones *J Chem Soc* 788 *1933,* Henrot et al. *Synth Commun* **16** 183 *1986*, Shiuey et al. *J Org Chem* **52** 1040 *1988*, *RS*: Cohen et al. *J Am Chem Soc* **88** 5306 *1966*.]

Acetylacetone (2,4-pentanedione, acac) *[123-54-6]* **M 100.1, m –23°, 45°/30mm, b 140.4°/atm, $d^{30.2}$ 0.9630, $n^{18.5}$ 1.45178, pK_1^{25} –5.0 (enol), –6.6 (keto), pK_2^{25} 8.95.** Small amounts of acetic acid are removed by shaking with small portions of 2M NaOH until the aqueous phase remains faintly alkaline. The sample, after washing with water, is dried with anhydrous Na_2SO_4, and distilled through a modified Vigreux column [Cartledge *J Am Chem Soc* **73** 4416 *1951*]. An additional purification step is fractional crystallisation from the liquid. *Alternatively*, there is less loss of acetylacetone if it is dissolved in four volumes of *benzene and the solution is shaken three times with an equal volume of distilled water (to extract acetic acid): the *benzene is then removed by distillation at 43-53° and 20-30mm through a helices-packed column. It is then refluxed over P_2O_5 (10g/L) and fractionally distilled under reduced pressure. The distillate (sp conductivity 4×10^{-8} $ohm^{-1}cm^{-1}$) is suitable for polarography [Fujinaga & Lee *Talanta* **24** 395 *1977*]. To recover used acetylacetone, metal ions are stripped from the solution at pH 1 (using 100ml 0.1M H_2SO_4/L of acetylacetone). The acetylacetone is then washed with (1:10) ammonia solution (100ml/L) and with distilled water (100ml/L, twice), then treated as above. It complexes with Al, Be, Ca, Cd, Ce , Cu, Fe^{2+}, Fe^{3+}, Mn, Mg, Ni, Pb and Zn. [*Beilstein* **1** H 777, **1** I 401, **1** II 831, **1** III 3113, **1** IV 3662.]

Acetyl bromide *[506-96-7]* **M 123.0, b 76-77°, d_4^{20} 1.65.** Boil acetyl bromide with PBr_3/Ac_2O for 1 hour, then distil the latter off and redistil it. Store it dry. [Burton & Degering *J Am Chem Soc* **62** 227 *1940*, *Beilstein* **2** IV

398.] **LACHRYMATORY.**

2-Acetylbutyrolactone *[517-23-7]* **M 128.1, b 105°/5mm, 120-123°/11mm, 142-143°/30mm, d_4^{20} 1.1846, n_D^{20} 1.459.** Purify the lactone by distillation, which will convert any free acid to the lactone, *alternatively* dissolve it in Et_2O, wash well with 0.5N HCl, dry the organic layer and distil it. Its solubility in H_2O is 20% v/v. The *2,4-dinitrophenylhydrazone* forms orange needles from MeOH, **m** 146°. The lactone hydrolyses in mineral acid to 2-acetyl-4-hydroxybutyric acid which can be converted to the *di-n-propylamine salt* with **m** 68-70°. The lactone is a **SKIN IRRITANT**. [Matsuhawa *Yakugaku Zasshi (J Pharm Soc Jpn)* **62** 417 *1942*, Willman & Schinz *Helv Chim Acta* **35** 2401 *1952*, *Beilstein* **17/11** V 16.]

Acetyl chloride *[75-36-5]* **M 78.5, b 52°, d_4^{20} 1.1051, n_D^{20} 1.38976.** Reflux acetyl chloride with PCl_5 for several hours to remove traces of acetic acid, then distil it. Redistil it from one-tenth its volume of dimethylaniline or quinoline to remove free HCl. A.R. quality is freed from HCl by pumping it for 1 hour at –78° and distilling it into a trap at –196°. [*Beilstein* **2** IV 395.] **LACHRYMATORY.**

Acetylene *[74-86-2]* **M 26.0, m –80.8°, b –84°, pK^{25} ~25.** If very impure, acetylene should be purified by successive passage through spiral wash bottles containing, in this order, saturated aqueous $NaHSO_4$, H_2O, 0.2M iodine in aqueous KI (two bottles), sodium thiosulfate solution (two bottles), alkaline sodium hydrosulfite with sodium anthraquinone-2-sulfonate as indicator (two bottles), and 10% aqueous KOH solution (two bottles). The gas is then passed through a Dry-Ice trap and two drying tubes, the first containing $CaCl_2$, and the second, Dehydrite [$Mg(ClO_4)_2$] [Conn et al. *J Am Chem Soc* **61** 1868 *1939*]. Acetone vapour can be removed from acetylene by passage through H_2O, then conc H_2SO_4, or by passage through two gas traps at –65° and –80°, conc H_2SO_4 and a soda lime tower, a tower of 1-mesh Al_2O_3 then through H_2SO_4 [Reichert & Nieuwland *Org Synth* Coll Vol **I** 229 *1941*, Wiley *Org Synth* Coll Vol **III** 853 *1955*, Jones & Whiting *Org Synth* Coll Vol **IV** 793 *1963*]. Sometimes it contains acetone and air. These can be removed by a series of bulb-to-bulb distillations, e.g. a train consisting of a conc H_2SO_4 trap and a cold EtOH trap (–73°), or passage through H_2O and H_2SO_4, then over KOH and $CaCl_2$. [See Brandsma *Preparative Acetylenic Chemistry,* 1st Edn Elsevier 1971 p15, for pK, ISBN 0444409475, 2nd Edn Elsevier 1988, ISBN 0444429603, and below for sodium acetylide.] It is also available commercially as 10ppm in helium, and several concentrations in N_2 for instrument calibration. [*Beilstein* **1** IV 939.]
Sodium acetylide *[1066-26-8]* M 48.0, is prepared by dissolving Na (23g) in liquid NH_3 (1L) and bubbling acetylene until the blue colour is discharged (ca 30 minutes) and evaporated to dryness [Saunders *Org Synth* Coll Vol **III** 416 *1955*], and is available commercially as a suspension in xylene/light mineral oil. [See entry in "Metal-organic Compounds", Chapter 5.]

Acetylenedicarboxamide (Aquamycin, Cellocidin) *[543-21-5]* **M 112.1, m 216-218°(dec), 219-221°(dec).** Acetylenedicarboxamide crystallises from MeOH and H_2O [**m** 190-192°(dec) as *hemihydrate*]. When prepared from the ester + NH_3 it has **m** 213°(dec). Also a melting point of 290-292°(dec) has been reported. [Saggimo *J Org Chem* **22** 1171 *1857*, Kharash et al. *J Org Chem* **10** 392 *1945*, Blomquist & Winslow *J Org Chem* **10** 156 *1945*, *Beilstein* **2** I 317, **2** III 1995, **2** IV 2295.]

Acetylenedicarboxylic acid (butynedioic acid) *[142-45-0]* **M 114.1, m 179°(anhydrous), pK_1^{19} 1.04, pK_2^{19} 2.50.** The acid is soluble in Et_2O and crystallises from Et_2O/petroleum ether (**m** 183-183.5°), or H_2O as the *dihydrate* which dehydrates in a desiccator over conc H_2SO_4 in a vacuum. The *dipicrate* crystallises from aqueous ether. For the mono K salt see entry in "Metal-organic Compounds", Chapter 5. [Abbott et al. *Org Synth* Coll Vol **II** 10 *1943*, Huntress et al. *Org Synth* Coll Vol **IV** 329 *1963*, *Beilstein* **2** H 801, **2** I 317, **2** II 670, **2** III 1991, **2** IV 2290.]

***N*-Acetylethylenediamine** *[1001-53-2]* **M 102.1, m 50-51°, 51°, b 128°/3mm, 125-130°/5mm, 133-139°/27mm, pK^{25} 9.28.** The acetyl-diamine has been fractionated under reduced pressure and fraction **b** 125-130°/5mm was refractionated, fraction **b** 132-135°/4mm was collected and solidified. It is a low melting *hygroscopic* solid which can be recrystallised from dioxane/Et_2O. It is soluble in H_2O, Et_2O and $*C_6H_6$. The *p-toluenesulfonate salt* can be recrystallised from EtOH/EtOAc (1:8), has **m** 125-126°, but the free base cannot be recovered from it by basifying and extracting with CH_2Cl_2. The *picrate* has **m** 175° (from EtOH) [Aspinall *J*

Am Chem Soc **63** 853 *1941*, Hall *J Am Chem Soc* **78** 2570 *1956*]. [*Beilstein* **4** IV 1193.]

Acetyl fluoride *[557-99-3]* **M 62.0, b 20.5°/760mm, d_4^{20} 1.032.** Purify acetyl fluoride by fractional distillation. It attacks glass and is sold in steel cylinders. [*Beilstein* **2** H 172, **2** I 79, **2** II 175, **2** III 385, **2** IV 393.] **TOXIC and LACHRYMATORY.**

Acetyl iodide *[507-02-8]* **M 170.0, b 39.5-40°/64mm, 108°/760mm.** Purify it by fractional distillation. [*Beilstein* **2** H 174, **2** I 80, **2** II 177, **2** III 393, **2** IV 399.] **TOXIC and LACHRYMATORY.**

3-(S-Acetylmercapto)isobutyric acid *[RS 33325-40-5]* **M 162.2, m 40-40.5°, b *ca* 120°/1.25mm, pK_{Est} ~4.0.** Distil the acid under high vacuum and recrystallise it from $*C_6H_6$. [Fredga & Mastersson *Chem Abstr* **38** 3616 *1944*.]

Acetyl methanesulfonate *[5539-53-7]* **M 170.2, b <120°/<0.01mm.** The main impurity is methanesulfonic acid. Reflux it with redistilled acetyl chloride for 6-10 hours, i.e. until no further HCl is absorbed in a trap, and exclude moisture. Distil off excess of AcCl and carefully distil it below 0.001mm with the bath temperature below 120° to give the anhydride as a pale yellow oil which solidifies below 0°. Below ~130° it gives the disulfonic anhydride, and above ~130° polymers are formed, and it is used for cleaving ethers [Preparation, IR, NMR: Karger & Mazur *J Org Chem* **36** 528, 532 *1971*]. [*Beilstein* **2** H 166, **2** III 349.]

3-(Acetylthio)propionic acid *[41345-70-4]* **M 148.2, m 48-52°, 52-54°, b 127-128°/3mm, pK_{Est} ~4.2.** Purify the propionic acid by distillation in a vacuum. It has λ_{max} at 231nm (ε 4200). It is a potential enzyme inhibitor [Noda et al. *J Am Chem Soc* **75** 914 *1953*, Clegg et al. *J Am Chem Soc* **121** 5319 *2004*, Clegg & Hutchinson *Angew Chem, Int Edn* **43** 3716 *2005*]. [*Beilstein* **3** III 551, **3** IV 731.]

***N*-Acetylthiourea** *[591-08-2]* **M 118.2, m 164-165°, 166-168°**. Recrystallise the thiourea from AcOH; the solid is washed with Et_2O and dried in air then at 100°. [Zahradnik *Col Czech Chem Commun* **24** 3678 *1959*, *Beilstein* **3** IV 354.]

***cis*-Aconitic acid** *[585-84-2]* **M 174.1, m 126-129°(dec).** Crystallise the *cis*-acid from water by cooling (solubility is 1g in 2ml of water at 25°). Dry it in a vacuum desiccator. [*Beilstein* **2** IV 2405.]

***trans*-Aconitic acid (1,2,3-propenetriscarboxylic acid)** *[4023-65-8]* **M 174.1, m 195°(dec), m 198-199°(dec), 204-205°(dec), pK_1^{25} 2.81, pK_2^{25} 4.46.** Purify the *trans*-acid by dissolving it in AcOH (77g/150ml), filtering and cooling. The acid separates (55g) as colourless needles. A further quantity (10g) can be obtained by reducing the volume of the filtrate. The acid is dried in air then in a vacuum desiccator over NaOH. The acid can be recrystallised from $Me_2CO/CHCl_3$. The highest melting point is obtained with the very dry acid. A melting point of 209° was obtained on a Dennis bar [Dennis & Shalton *J Am Chem Soc* **52** 3128 *1930*, Bruce *Org Synth* Coll Vol **II** 12 *1943*]. [*Beilstein* **2** IV 2405.]

cis*-Aconitic anhydride** *[6318-55-4]* **M 156.1, m 75°, 76-78°, 78-78.5°.** Reflux it in xylene (7.5 parts) for 1 hour, then evaporate and recrystallise the residue from $*C_6H_6$. *Alternatively*, reflux it in Ac_2O, evaporate and recrystallise from $*C_6H_6$. It is sensitive to moisture, store dry. [IR: Groth & Dahlén *Acta Chem Scand* ***21 291 *1967*, Malachowski & Maslowski *Chem Ber* **61** 2523 *1928*, NMR: Gawron & Mahajan *Biochemistry* **5** 2335 *1966*.] [*Beilstein* **18/8** V 530.]

Acrolein (acraldehyde, 2-propenal) *[107-02-8]* **M 56.1, fp –86.95°, b 25°/100mm, 52.69°/760mm (dt/dp 0.0355°/mm, d_4^{20} 0.839, n^{25} 1.3992**. Purify acrolein by fractional distillation, under nitrogen, drying with anhydrous $CaSO_4$ and then distilling under vacuum. Blacet, Young and Roof [*J Am Chem Soc* **59** 608 *1937*] distilled it under nitrogen through a 90cm column packed with glass rings. To avoid formation of diacryl, the vapour is passed through an ice-cooled condenser into a receiver cooled in an ice-salt mixture and containing 0.5g catechol. The acrolein is then distilled twice from anhydrous $CuSO_4$ at low pressure, catechol being placed in the distilling flask and the receiver to avoid polymerisation. [*Alternatively*, hydroquinone (1% of the final

solution) can be used.] **Respiratory irritant, work in an efficient fume cupboard.** [*Beilstein* **1** IV 3435.]

Acrolein diacetyl acetal (1,1-diacetoxy-2-propene). *[869-29-4]* **M 158.2, b 75°/10mm, 184°/atm, d $_4^{20}$ 1.08, n $_D^{20}$ 1.4203.** Check the NMR spectrum. If it is not satisfactory, then add Ac_2O and a drop of conc H_2SO_4 and heat at 50° for 10 minutes. Then add anhydrous NaOAc (*ca* 3g/100g of liquid) and fractionate. Note that it forms an azeotrope with H_2O, so do not add H_2O at any time. It is a **highly flammable and TOXIC** liquid; use protective gloves. [Smith et al. *J Am Chem Soc* **73** 5282 *1951*, *Beilstein* **2** H 154, **2** I 72, **2** III 356, **2** IV 291.]

Acrolein diethyl acetal (3,3-diethoxy-I-propene or 1,1-diethoxy2-propene) *[3054-95-3]* **M 130.2, b 120-125°/atm, n $_D^{20}$ 1.398-1.407**. Add Na_2CO_3 (*ca* 3.5%) and distil it using an efficient column, or better use a spinning band column. [Witzemann et al. *Org Synth* Coll Vol **II** 17 *1943*, *Beilstein* **1** H 727, **1** I 378, **1** III 2960, **1** IV 3437.]

Acrolein dimethyl acetal (1,1-dimethoxy-2-propene) *[6044-68-4]* **M 102.1, b 87.5-88°/750mm, 89-90°/760mm, d $_4^{20}$ 0.86, n $_D^{20}$ 1.3962.** Fractionally distil it (after adding 0.5g of hydroquinone) under reduced pressure through an all glass column (40 cm × 2.5 cm) packed with glass helices and provided with a heated jacket and a total reflux variable take-off head. Stainless steel Lessing rings (1/8 x 1/8 in) or gauze have also been used as packing. It is a **highly flammable and TOXIC** liquid; keep away from the skin. [Hall & Stern *J Chem Soc* 2657 *1955*, *Beilstein* **1** IV 3437.]

Acrolein semicarbazone *[6055-71-6]* **M 113.1, m 171°**. It crystallises from water in needles. [Auwers & Heineke *Justus Liebigs Ann Chem* **458** 202 *1927*, *Beilstein* **1** II 785.]

Acrylamide *[79-06-1]* **M 71.1, m 84°, b 125°/25mm**. Crystallise acrylamide from acetone, chloroform, ethyl acetate, methanol or *benzene/chloroform mixture, then vacuum dry and store it in the dark under vacuum. Recrystallise it from $CHCl_3$ by dissolving 200g in 1L, heating to boiling and filtering without suction in a warmed funnel through Whatman 541 filter paper; allowing to cool to room temperature and keeping at –15° overnight. The crystals are collected with suction in a cooled funnel and washed with 300ml of cold MeOH. The crystals are air-dried in a warm oven. [Dawson et al. *Data for Biochemical Research*, Oxford Press 1986 p. 449, *Beilstein* **2** IV 1471.]
CAUTION: *Acrylamide is extremely* **TOXIC (neurotoxic),** *and precautions must be taken to avoid skin contact or inhalation. Use gloves and handle in a well-ventilated fume cupboard.*

Acrylic acid *[79-10-7]* **M 72.1, m 13°, b 30°/3mm, 70°/50mm, d $_4^{20}$ 1.051, pK^{25} 4.25.** It can be purified by steam distillation, or vacuum distillation through a column packed with copper gauze to inhibit polymerisation. (This treatment also removes inhibitors such as methylene blue that may be present.) Azeotropic distillation of the water with *benzene converts aqueous acrylic acid to the anhydrous material. [*Beilstein* **2** H 397, **2** I 186, **2** II 383, **2** III 1215, **2** IV 1455.]

Acrylonitrile *[107-13-1]* **M 53.1, b 78°, d $_4^{20}$ 0.806, n^{25} 1.3886**. Wash acrylonitrile with dilute H_2SO_4 or dilute H_3PO_4, then with dilute Na_2CO_3 and water. Dry it with Na_2SO_4, $CaCl_2$ or (better) by shaking with molecular sieves. Fractionally distil it under N_2. It can be stabilised by adding 10ppm *tert*-butyl catechol. Immediately before use, the stabiliser can be removed by passage through a column of activated alumina (or by washing with 1% NaOH solution if traces of water are permissible in the final material), followed by distillation. *Alternatively*, shake it with 10% (w/v) NaOH to extract inhibitor, and then wash it in turn with 10% H_2SO_4, 20% Na_2CO_3 and distilled water. Dry for 24 hours over $CaCl_2$ and fractionally distil under N_2 taking fraction boiling at 75.0-75.5°C (at 734mm). Store it with 10ppm *tert*-butyl catechol. Acrylonitrile is distilled off when required. [Burton et al. *J Chem Soc, Faraday Trans 1* **75** 1050 *1979*, *Beilstein* **2** IV 1473.]

Acryloyl chloride *[814-68-6]* **M 90.5, b 72-74°/740mm, 74°/760mm, d $_4^{20}$ 1.1127, n $_D^{20}$ 1.4337.** Distil acryloyl chloride rapidly through an efficient 25cm column after adding 0.5g of hydroquinone/200g of chloride, and then redistil it carefully at atmospheric pressure preferably in a stream of dry N_2. [Stempel et al. *J Am Chem Soc* **72** 72 *1950*, Gresham et al. *J Am Chem Soc* **72** 2299 *1950*, *Beilstein* **2** IV 1471.] **The liquid is an irritant and is**

TOXIC.

Adipic acid *[124-04-9]* **M 146.1, m 154-154.5°, b 159.5°/0.1mm, 191°/5mm, 205.5°/10mm, 222.5°/20mm, 337.5°/760mm, pK_1^{20} 4.42, pK_2^{20} 5.41; pK_1^{25} 4.44, pK_2^{25} 5.45; pK_1^{40} 4.54, pK_2^{40} 5.59.** For use as a volumetric standard, adipic acid is crystallised once from hot water with the addition of a little animal charcoal, dried at 120° for 2 hours, then recrystallised from acetone and again dried at 120° for 2 hours. Other purification procedures include crystallisation from ethyl acetate and from acetone/petroleum ether, fusion, followed by filtration and crystallisation from the melt, and preliminary distillation under vacuum. [*Beilstein* **2** H 649, **2** I 277, **2** II 572, **2** III 1705, **2** IV 1956.]
Diethyl adipate *[141-28-6]* **M 202.3, m –20°** to **–19°, b 111°/5mm, 125°/10mm, 133°/15mm, 251°/atm, d^{25} 1.0034, n_D^{20} 1.42776**, is prepared in the usual way by boiling the acid and excess EtOH in the presence of a catalytic amount of H_2SO_4 and distilled. [*Beilstein* **2** H 652, 2 I 277, **2** II 574, **2** III 1721, **2** IV 1960.]

Adiponitrile (1,4-dicyanobutane) *[111-69-3]* **M 108.14, m 2.4°, b 123°/0.5mm, 153°/6mm, 175°/26mm, 184°/30mm, 295°/atm, d_4^{20} 0.9396, n_D^{20} 1.4371.** Reflux adiponitrile over P_2O_5 and $POCl_3$, and fractionally distil it, then fractionate it through an efficient column. **The liquid is TOXIC and is an IRRITANT.** [Braun & Rudolph *Chem Ber* **67** 1770 *1934*, Reppe et al. *Justus Liebigs Ann Chem* **596** 127 *1955*, Gagnon et al. *Can J Chem* **34** 1662 *1956*, Copley et al. *J Am Chem Soc* **62** 228 *1940*, *Beilstein* **2** IV 1947.]

Agaricic acid [1-(*n*-hexadecyl)citric acid] *[666-99-9]* **M 416.6, m 142°(dec), $[\alpha]_D$ –9.8° (in NaOH), $pK_{Est(1)}$ ~2.7, $pK_{Est(2)}$ ~4.2, $pK_{Est(3)}$ ~5.5.** Crystallise the acid from EtOH. The *trihydrazide* has **m** 170°(dec) (from EtOH). [Brandänge et al. *Acta Chem Scand B* **31** 307 *1977*, *Beilstein* **3** I 186, **3** II 372, **3** III 1109, **3** IV 1284.]

Agmatine sulfate [5-guanidinopent-1-ylamine sulfate] *[2482-00-0]* **M 228.3, m 231°, $pK_{Est(1)}$ ~9.1, $pK_{Est(2)}$ ~13.0.** Crystallise the salt from aqueous MeOH. The *free base* has **m** 101.5-103°, the *gold chloride hydrochloride* crystallises from H_2O with **m** 223°(dec), and the *picrate* has **m** 236-238°. [Odo *J Chem Soc Jpn* **67** 132 *1946*, *Beilstein* **4** I 420, **4** II 703, **4** III 575, **4** IV 1291.]

Aldol (3-hydroxybutanal) *[107-89-1]* **M 88.1, b 80-81°/20mm, d^{16} 1.109.** An ethereal solution of aldol is washed with a saturated aqueous solution of $NaHCO_3$, then with water. The non-aqueous layer is dried with anhydrous $CaCl_2$ and distilled immediately before use. The fraction, **b** 80-81°/20mm, is collected as a thick liquid which decomposes at 85°/atm. It is a sedative and a hypnotic, but is used in perfumery. [Mason et al. *J Am Chem Soc* **76** 2255 *1954*]. [*Beilstein* **1** H 824, **1** I 419, **1** II 868, **1** III 3195, **1** IV 3984.]

Aleuritic acid [*RS-erythro*-9,10,16-trihydroxyhexadecanoic acid] *[533-87-9]* **M 304.4, m 100-101°, pK_{Est} ~4.9.** Crystallise this *RS*-acid from aqueous EtOH. It is soluble in MeOH, and forms a less soluble crystalline sodium salt. The *methyl ester* **m** 72-73°, **b** 235°/0.2mm, is best prepared by reaction with diazomethane and forms fine feathery needles; it is soluble in MeOH, EtOH, $CHCl_3$, Me_2CO, slightly soluble in $*C_6H_6$ and insoluble in petroleum ether. The *ethyl ester [6003-09-4]* **m** 59°, crystallises in needles from EtOH. The *hydrazide [6003-10-7]* crystallises from EtOH and has **m** 139-140°.
The *RS-acid* has been isolated from Shellac although it has two asymmetric carbon atoms, and possibly contains the *RS-erythro* or *RS-cis form* [Gidvani *J Chem Soc* 306 *1944*, Sengupta & Bose *J Sci Ind Res* (India) **11B** 458 *1952*]. A stereoisomer have been synthesised [Hunsdieker *Chem Ber* **76** 142 *1943*, Hunsdieker *Chem Ber* **77** 185 *1944*]. [*Beilstein* **3** III 901.]

***n*-Alkylammonium chloride *n*=2,4,6**. Recrystallise them from EtOH or an EtOH/Et_2O mixture. [Hashimoto & Thomas *J Am Chem Soc* **107** 4655 *1985,* Chu & Thomas *J Am Chem Soc* **108** 6270 *1986*.]

***n*-Alkyltrimethylammonium bromide *n*=10,12,16**. Recrystallise them from an EtOH/Et_2O mixture. [Hashimoto & Thomas *J Am Chem Soc* **107** 4655 *1985*.]

Allene (propadiene) *[463-49-0]* **M 40.1, m –146°, b –32°**. Freeze allene in liquid nitrogen, evacuate, then thaw out. This cycle is repeated several times, then the allene is frozen in a methylcyclohexane/liquid nitrogen bath and pumped for some time. It has also been purified by HPLC. [Cripps & Kiefer *Org Synth* **42** 12 *1962*,

Beilstein **1** IV 966.]

***neo*-Alloocimene (allocimene B, *tc*-2,6-dimethyl-2,4,6-octatriene)** *[7216-56-0; cis/trans mixture 673-84-7; trans/trans 3016-19-1]* **M 136.2, b 80°/13mm, 196-198°/atm, d $_4^{20}$ 0.8161, n $_D^{20}$ 1.5437.** Fractionally distil allocimene through an efficient column and repeatedly distil it at 15mm through a long column of glass helices, with a final distillation from sodium under nitrogen. It should be stabilised with *ca* 0.1% of hydroquinone. Its UV has λ_{max} nm(ε $M^{-1}cm^{-1}$) at 290 (32 500), 279 (41,900) and 278 (42,870). [Alder et al. *Justus Liebigs Ann Chem* **609** 1 *1957*, O'Connor & Goldblatt *Anal Chem* **26** 1726 *1954*, *Beilstein* **1** IV 1106.]

Allyl acetate *[591-87-7]* **M 100.1, b 103°, d $_4^{20}$ 0.928, n $_D^{17}$ 1.4004, n $_D^{20}$ 1.4040.** The ester is freed from peroxides by standing with crystalline ferrous ammonium sulfate, then washed with 5% $NaHCO_3$, followed by saturated $CaCl_2$ solution. Dry it with Na_2SO_4 and fractionally distil it in an all-glass apparatus. **FLAMMABLE LIQUID.** [*Beilstein* **2** H 136, **2** IV 180.]

Allylacetic acid (pent-4-enoic acid) *[591-80-0]* **M 100.1, m –22.5°, b 83-84°/12mm, 90°/15mm, 187-189°/~760mm, d $_4^{20}$ 0.9877, n $_D^{20}$ 1.4280, pK^{25} 4.68.** Distil the acid through an efficient column (allyl alcohol has **b** 95-97°). It is characterised as the S-*benzylisothiouronium salt* **m** 155-158° (from 96% EtOH, or aqueous EtOH) [Friediger & Pedersen *Acta Chem Scand* **9** 1425 *1955*], and the *4-bromophenacyl ester* has **m** 59.5-60.5° (from 90% EtOH). Its solubility at 18° in solvents is: pyridine (57%), AcOH (7.3%), MeOH (5.4%), Me_2CO (3.2%), MeOAc (2.8%), EtOH (5.4%), H_2O (1.8%), PrOH (1.6%), isoPrOH (0.27%). [Brown & Berkowski *J Am Chem Soc* **74** 1894 *1952*, *Beilstein* **2** IV 1542.]

Allyl alcohol *[107-18-6]* **M 58.1, b 98°, d $_4^{20}$ 0.857, n $_D^{20}$ 1.4134.** It can be dried with K_2CO_3 or $CaSO_4$, or by azeotropic distillation with *benzene followed by distillation under nitrogen. It is difficult to obtain it free of peroxide. It has also been refluxed with magnesium and fractionally distilled [Hands & Norman *Ind Chem* **21** 307 *1945*]. [*Beilstein* **1** IV 2079.]

Allylamine *[107-11-9]* **M 57.1, b 52.9°, d $_4^{20}$ 0.761, n $_D^{20}$ 1.42051, pK^{25} 9.49.** Purify allylamine by fractional distillation from calcium chloride. It causes sneezing and tears. [*Beilstein* **4** IV 1057.]

Allyl bromide *[106-95-6]* **M 121, b 70°, d $_4^{20}$ 1.398, n $_D^{20}$ 1.46924.** Wash the bromide with $NaHCO_3$ solution then distilled water, dry ($CaCl_2$ or $MgSO_4$), and fractionally distil. Protect it from strong light. [*Beilstein* **1** IV 754.] **LACHRYMATORY, HIGHLY TOXIC and FLAMMABLE.**

Allyl butyl ether *[3739-64-8]* **M 114.2, b 64-65°/120mm, 117.8-118°/763mm, d $_4^{20}$ 1.4057, n $_D^{20}$ 0.7829.** Check the IR for the presence of OH str vibrations; if so then wash it well with H_2O, dry it with $CaCl_2$ and distil it through a good fractionating column. **The liquid is an irritant.** [Watanabe et al. *J Org Chem* **23** 1666 *1958*, Schueler & Hanna *J Am Chem Soc* **73** 3528 *1951*, *Beilstein* **1** IV 2084.]

Allyl chloride *[107-05-1]* **M 76.5, b 45.1°, d $_4^{20}$ 0.939, n $_D^{20}$ 1.4130.** Likely impurities include 2-chloropropene, propyl chloride, *iso*-propyl chloride, 3,3-dichloropropane, 1,2-dichloropropane and 1,3-dichloropropane. Purify it by washing with conc HCl, then with Na_2CO_3 solution, dry it with $CaCl_2$, and distil it through an efficient column [Oae & Vanderwerf *J Am Chem Soc* **75** 2724 *1953*]. [*Beilstein* **1** IV 738.] **LACHRYMATORY, TOXIC.**

Allyl chloroformate *[2937-50-0]* **M 120.5, b 56°/97mm, 109-110°/atm, d $_4^{20}$ 1.14, n $_D^{20}$ 1.4223.** Wash the chloroformate several times with cold H_2O to remove alcohol and HCl and dry it over $CaCl_2$. It is **important** to dry well before distilling *in vacuo*. Note that the receiver should be cooled in ice to avoid loss of distillate into the trap and vacuum pump. The liquid is **highly TOXIC and flammable.** [Fierz-David & Müller *J Chem Soc* **125** 26 *1924*, Strain et al. *J Am Chem Soc* **72** 1254 *1950*, *Beilstein* **3** IV 29.]

Allyl cyanide (3-butene nitrile) *[109-75-1]* **M 67.1, b –19.6°/1.0mm, 2.9°/5mm, 14.1°/5mm, 26.6°/20mm, 48.8°/60mm, 60.2°/100mm, 98°/400mm, 119°/760mm, d $_4^{20}$ 0.8341, n $_D^{20}$ 1.406.** The nitrile should be redistilled at atmospheric pressure, then distilled under a vacuum to remove the final traces of HCN from the

residue. Note that the residue from the first distillation may be difficult to remove from the flask and should be treated with conc HNO_3 then H_2O and finally hot EtOH **(CARE)**. Allyl cyanide has an onion-like odour and is stable to heat. It forms a complex with $AlCl_3$ (2:2) **m** 41°, and (3:2) **m** 120°. **All operations should be done in an efficient fume hood as the liquid is flammable, may contain cyanide and is HIGHLY TOXIC.** [Supniewski et al. *Org Synth* Coll Vol **I** 46 *1941*, *Beilstein* **2** IV 1491.]

Allyl disulfide (diallyl disulfide) *[2179-57-9]* **M 146.3, b 58-59°/5mm, 79-81°/20mm, 138-139°/atm, d_4^{20} 1.01, n_D^{20} 1.541.** Purify the disulfide by fractional distillation until the molar refractivity is in uniformly good agreement with the calculated value [Small et al. *J Am Chem Soc* **69** 1710 *1947*]. It has also been purified by gas chromatography [retention times: Carson & Wong *J Org Chem* **24** 175 *1959*, UV: Koch *J Chem Soc* 395 *1949*]. It is present in garlic. [*Beilstein* **1** IV 2098.]

Allyl iodide (3-iodopropene) *[556-56-9]* **M 167.7, b 103°/760mm, d^{12} 1.848.** Purify allyl iodide in a dark room by washing with aqueous Na_2SO_3 to remove free iodine, then dry with $MgSO_4$ and distil at 43°/90 mm or at atmospheric pressure to give a very pale yellow liquid. (This material, dissolved in hexane, can be stored in a light-protected tight container at –5° for up to three months before free iodine can be detected, by its colour in the solution.) Store it away from light. [Sibbett & Noyes *J Am Chem Soc* **75** 761 *1953*, *Beilstein* **1** H 202, **1** I 84, **1** II 172, **1** III 714, **1** IV 761.]

Allylisocyanate *[1476-23-9]* **M 83.1, b 84°/atm, 87-89°/atm, d_4^{20} 0.94, n_D^{20} 1.417.** Purify it as for allylisothiocyanate below and it is **TOXIC**. [*Beilstein* **4** IV 1081.]

Allylisothiocyanate *[57-06-7]* **M 99.2, m –80°, b 84-85°/80mm, 150°/760mm, 151°/atm, d_4^{20} 1.017, n_D^{20} 1.5268.** Fractionate the isothiocyanate using an efficient column, preferably in a vacuum. It is a yellow **pungent, irritating and TOXIC (suspected CARCINOGEN) liquid.** Store it in a sealed tube under N_2. The *N'-benzylthiourea* derivative has **m** 94.5° (from aqueous EtOH) [Weller et al. *J Am Chem Soc* **74** 1104 *1952*]. [*Beilstein* **4** IV 1081.]

***N*-Allylthiourea (thiosinamine)** *[109-57-9]* **M 116.2, m 70-73°, 78°.** Recrystallise it from H_2O. It is soluble in 30 parts of cold H_2O, and it is soluble in EtOH but insoluble in $*C_6H_6$. It has also been recrystallised from acetone, EtOH or ethyl acetate, after decolorising with charcoal. The white crystals have a bitter taste with a slight garlic odour and are **TOXIC**. An unstable crystalline form is obtained by recrystallising from the melt. [McCrone et al. *Anal Chem* **21** 421 *1949*, *Beilstein* **4** IV 1072.]

***N*-Allylurea** *[557-11-9]* **M 100.1, m 85°.** It crystallises from EtOH, EtOH/ether, EtOH/chloroform or EtOH/toluene. [*Beilstein* **4** IV 1070.]

Aminoacetaldehyde dimethyl acetal (2,2-dimethoxyethylamine) *[22483-09-6]* **M 105.1, m <–78°, b 139.5°/768mm, 137-139°/atm, d_4^{20} 0.9676 n_D^{20} 1.4144.** Dry the acetal over KOH pellets and distil it through a 30cm vacuum jacketed Vigreux column. [Lawson *J Am Chem Soc* **75** 3398 *1953*, Erickson et al. *J Am Chem Soc* **77** 6640 *1955*, *Beilstein* **4** IV 1918.]

Aminoacetonitrile bisulfate *[151-63-3]* **M 154.1, m 125°(dec), pK^{25} 5.34 (NH_2).** Recrystallise the hydrogensulfate (1:1) from EtOH/Et_2O (hygroscopic leaflets). The ***Sulfate* (2:1)** [5466-22-8] crystallises as flat prisms from H_2O/EtOH with **m** 166°(dec). [Stephen *J Chem Soc* 871 *1931*, Anslow & King *J Chem Soc* 2465 *1929*, *Beilstein* **4** III 1120.]

Aminoacetonitrile hydrochloride *[6011-14-9]* **M 92.5, m 166-167°, 172-174°, pK^{25} 5.24 (NH_2).** The salt recrystallises from dilute EtOH as *hygroscopic* leaflets. It is best to crystallise it from absolute EtOH/Et_2O (1:1) and then recrystallise it from absolute EtOH. The melting point recorded ranges from 144 to 174°. The *free base* has **b** 58°/15mm with partial decomposition. [Klages *J Prakt Chem* **[2] 65** 189 *1902*, Mange *J Am Chem Soc* **56** 2197 *1934*, Goldberg & Kelly *J Chem Soc* 1371 *1947*, *Beilstein* **4** H 344, **4** I 468, **4** II 783, **4** III 1120, **4** IV 2363.]

2-Amino-1-butanol *[RS(±) 96-20-8, R(–) 5856-63-3, S(+) 5856-62-2]* **M 89.1, m ~ -2°, b 78-80°/10mm and 179-183°/atm for (±), 172-174°/atm for (+) or (–), pK^{0} 10.353, pK^{20} 9.672, pK^{60} 8.555.** They are purified by shaking with solid NaOH, filtering and distilling through a short column. The *oxalate salt* of the racemate has **m** 176°. They are strong bases and should be stored under N_2 in the absence of CO_2. The *enantiomers* have $[\alpha]_D^{20}$ +12.5° and –12.5° (c 2, EtOH). [Johnson & Degering *J Org Chem* **8** 7 *1943*, Nagao et al. *J Org Chem* **51** 2392 *1986*, Santaniello et al. *J Chem Soc, Perkin Trans 1* 919 *1985*, *Beilstein* **4** H 291, **4** IV 1705.]

2-Aminoethanol (ethanolamine) *[141-43-5]* **M 61.1, f 10.5°, b 72-73°/12mm, 171.1°/760mm, d_4^{20} 1.012, n_D^{20} 1.14539, pK^{25} 9.51.** It decomposes slightly when distilled at atmospheric pressure, with the formation of conducting impurities. Fractional distillation at about 12mm pressure is most satisfactory. After distillation, 2-aminoethanol is further purified by repeated washing with ether and crystallising from EtOH (at low temperature). After fractional distillation in the absence of CO_2, it is twice crystallised by cooling, followed again by distillation. It is *hygroscopic*, and absorbs CO_2 from the atmosphere. [Reitmeier et al. *J Am Chem Soc* **62** 1943 *1940*.] It can be dried by azeotropic distillation with dry *benzene. [*Beilstein* **4** IV 1406.]

2-Aminoethanol hydrochloride *[2002-24-6]* **M 97.6, m 75-77°.** Recrystallise the salt from EtOH. It is deliquescent; store it dry. [*Beilstein* **4** IV 1406.]

2-Aminoethyl hydrogen sulfate (sulfuric acid mono-2-aminoethyl ester) *[926-39-6]* **M 141.1, m 285-287° (chars at 275°).** Crystallise the sulfate ester from water or dissolve it in water and add EtOH. Wash this with Et_2O and dry it *in vacuo*. [*Beilstein* **4** III 1414.]

S-(2-Aminoethyl)isothiouronium bromide hydrobromide *[56-10-0]* **M 281.0, m 194-195°**. Crystallise the salt from absolute EtOH/ethyl acetate or MeOH. Store dry as it is *hygroscopic* in a humid atmosphere. It is a radioprotective agent. When refluxed in EtOH for 16 hours or H_2O for 30 minutes, it decomposes to *2-amino-4(5H)-thiazoline hydrobromide* which on recrystallisation from isoPrOH/EtOAc has **m** 175-176° [Doherty et al. *J Am Chem Soc* **79** 5667 *1957*].

(2-Aminoethyl)trimethylammonium chloride hydrochloride (chloramine chloride hydrochloride) *[3399-67-5]* **M 175.1, m 268°(dec).** Crystallise the hydrochloride from EtOH. The material is very soluble in H_2O. [*Beilstein* **4** II 690.]

Aminomalononitrile toluene-4-sulfonate *[5098-14-6]* **M 253.4, m 168-170°, 172°(dec), pK_{Est} ~ 1.3.** It forms colourless crystals on recrystallisation from MeCN (1.8g in 100mL) using activated charcoal. Wash the crystals with dry Et_2O and dry them at 25°/1mm. Recovery is ~80%. [Ferris et al. *Org Synth* Coll Vol **V** 32 *1973*.]

(±)-2-Amino-4-methylhexane (Forthane, 1,3-dimethylpentylamine) *[105-41-9]* **M 115.2, b 131-133°/atm, 130-135°/atm, 135-136°/atm, d_4^{20} 0.760, n_D^{15} 1.4160, n_D^{24} 1.4160, pK^{25} 10.54.** This strong base is obtained by catalytic hydrogenation of 4-methylhexan-2-one oxime (57g) in EtOH (50ml) with Raney Ni (6g) in a bomb at 75-80° and 1000psi of H_2, cool, filter off the catalyst, acidify with HCl, and evaporate to dryness. Basify the residue with aqueous NaOH, extract it with Et_2O, dry the extract ($MgSO_4$), filter, evaporate, and distil to give the base in 75-80% yield. It forms a *sulfate salt* **m 215-220°(dec)**, and it readily forms a *carbonate salt*, hence it should be stored in the absence of CO_2. It is physiologically active as an opium pressor and is adrenergic. [Rohrmann & Shonle *J Am Chem Soc* **66** 1516 *1944*, Chiang *J Clin Chem Soc* **18** 65 *1951*, USP to E. Lilly 2350318 (1943) *Chem Abstr* **39** 1510 *1945*, USP 2386273 (1943) *Chem Abstr* **40** 598 *1946*, *Beilstein* **4** III 378, **4** IV 747.]

2-Amino-2-methyl-1,3-propanediol *[115-69-5]* **M 105.1, m 111°, b 151-152°/10mm, pK^{25} 8.80.** Crystallise the diol three times from MeOH, dry in a stream of dry N_2 at room temperature, then in a vacuum oven at 55°. Store it over $CaCl_2$ [Hetzer & Bates *J Phys Chem* **66** 308 *1962*]. [*Beilstein* **4** IV 1881.]

2-Amino-2-methyl-1-propanol (β-aminoisobutanol) *[124-68-5]* **M 89.4, m 24°, 31°, b 67°/10mm, 164-166°/760mm, d_4^{20} 0.935, n_D^{20} 1.45, pK^{25} 9.71.** Purify it by distilling and fractional freezing. The *hydrochloride* [3207-12-3] has **m** 204°-206°. [*Beilstein* **4** III 783, **4** IV 1740.]

***n*-Amyl acetate (*n*-pentyl acetate)** *[628-63-7]* **M 130.2, b 149.2°, d_4^{20} 0.876, n_D^{20} 1.40228.** Shake the ester with saturated $NaHCO_3$ solution until neutral, washed it with water, dry with $MgSO_4$ and distil it. The ester has also been purified by repeated fractional distillation through an efficient column or spinning band column. [Timmermann & Hennant-Roland *J Chim Phys* **52** 223 *1955*, Mumford & Phillips *J Chem Soc* 75 *1950*, ^{1}H NMR: Crawford & Foster *Can J Phys* **34** 653 *1956*, *Beilstein* **2** IV 152.]

***n*-Amyl alcohol (1-pentanol)** *[71-41-0]* **M 88.2, b 138.1°, d^{15} 0.818, n_D^{20} 1.4100.** Dry 1-pentanol with anhydrous K_2CO_3 or $CaSO_4$, filter and fractionally distil it. It has also been treated with 1-2% of sodium and heated at reflux for 15 hours to remove water and chlorides. Traces of water can be removed from the near-dry alcohol by refluxing it with a small amount of sodium in the presence of 2-3% *n*-amyl phthalate or succinate followed by distillation (see *ethanol*).
Small amounts of amyl alcohol have been purified by esterifying with *p*-hydroxybenzoic acid, recrystallising the ester from CS_2, saponifying with ethanolic-KOH, drying with $CaSO_4$ and fractionally distilling [Olivier *Rec Trav Chim Pays Bas* **55** 1027 *1936*]. [*Beilstein* **1** IV 1640.]

***tert*-Amyl alcohol (2-methyl-2-butanol)** *[75-85-4]* **M 88.2, m –12°, b 102.3°, d^{15} 0.8135, n_D^{20} 1.4058.** Reflux it with K_2CO_3, CaH_2, CaO or sodium, then fractionally distil. The near-dry alcohol is further dried by refluxing with Mg activated with iodine, as described for *ethanol*. Further purification is possible using fractional crystallisation and zone refining at <–10° or preparative gas chromatography. [*Beilstein* **1** IV 1668.]

***n*-Amylamine [1-aminopentane]** *[110-58-7]* **M 87.2, b 105°, d_4^{20} 0.752, pK^{25} 10.63.** Dry it by prolonged shaking with NaOH pellets, then distilling. Store it in a CO_2-free atmosphere. [*Beilstein* **4** IV 674.]

***n*-Amyl bromide (*n*-pentylbromide)** *[110-53-2]* **M 151.1, b 129.7°, d_4^{20} 1.218, n_D^{20} 1.445.** Wash the bromide with conc H_2SO_4, then water, 10% Na_2CO_3 solution, again with water, dry with $CaCl_2$ or K_2CO_3, and fractionally distil it just before use. [*Beilstein* **1** IV 312.]

***n*-Amyl chloride (1-chloropentane)** *[543-59-9]* **M 106.6, b 107.8°, d_4^{20} 0.882, n_D^{20} 1.41177.** Purify as for *sec*-amyl chloride. [*Beilstein* **1** IV 309.]

***sec*-Amyl chloride (1-chloro-2-methylbutane)** *[616-13-7]* **M 106.6, b 52.2°/150mm, 96-97° (100°)/760mm, d_4^{20} 0.886, n_D^{20} 1.412.** Purify the chloride by stirring vigorously with 95% H_2SO_4, replacing the acid when it becomes coloured, until the layer remains colourless after 12 hours stirring. The amyl chloride is then washed with saturated Na_2CO_3 solution, then distilled water, and dried with anhydrous $MgSO_4$, followed by filtration, and distillation through a 10-in Vigreux column. *Alternatively*, a stream of oxygen containing 5% ozone is passed through the amyl chloride for three times as long as it takes to cause the first coloration of starch iodide paper by the exit gas. The liquid is washed with $NaHCO_3$ solution to hydrolyse the ozonides and remove organic acids prior to drying and fractional distillation [Chien & Willard *J Am Chem Soc* **75** 6160 *1953*]. The *S*(+)-*enantiomer* has **b** 50-51°/140mm, 100°/760, mm, $[\alpha]_D^{20}$ +1.64° (neat) [Brown et al. *J Am Chem Soc* **62** 3437 *1940*]. [*Beilstein* **1** H 134, **1** I 46, **1** III 356, **1** IV 326.]

***tert*-Amyl chloride (2-chloro-2-methylbutane)** *[594-36-5]* **M 106.6, b 86°, d_4^{20} 0.866.** Methods of purification commonly used for other alkyl chlorides lead to decomposition. Unsaturated contaminants are removed by chlorination with a small amount of chlorine in bright light, followed by distillation [Chien & Willard *J Am Chem Soc* **75** 6160 *1953*]. [*Beilstein* **1** H 134, **1** I 46, **1** II 100, **1** III 357, **1** IV 324.]

Amylene (β-*iso*-amylene, 2-methyl-2-butene) *[513-35-9]* **M 70.1, b 37-38°/~760mm, d_4^{20} 0.663, n_D^{20} 1.387.** Distil amylene and collect the distillate at low temperature. It has also been distilled from sodium. **FLAMMABLE.** It is available in steel cylinders and has a short shelf life. [*Beilstein* **1** H 211, **1** I 87, **1** II 187, **1** III 788, **1** IV 820.]

Amyl ether (dipentyl ether) *[693-65-2]* **M 158.3, b 186.8°, d_4^{20} 0.785, n_D^{20} 1.41195.** Repeatedly reflux amyl ether over sodium and distil it. [*Beilstein* **1** IV 1643.]

Arachidic (eicosanoic C_{20}) acid *[506-30-9]* **M 312.5, m 77°, pK_{Est} ~5.0.** Crystallise the C_{20} acid from absolute EtOH. [*Beilstein* **2** IV 1276.]

Arachidic alcohol (1-eicosanol C_{20}) *[629-96-9]* **M 298.6, m 65.5° (71°), b 200°/3mm.** Crystallise the C_{20} alcohol from *benzene or *benzene/petroleum ether. [*Beilstein* **1** IV 1900.]

Azelaic acid (1,9-nonanedioic acid, heptane-1,7-dicarboxylic acid) *[123-99-9]* **M 188.2, m 105-106°, b 225°/10mm, 256°/50mm, pK_1^{25} 4.53, pK_2^{25} 5.33.** Recrystallise it from H_2O (charcoal) or thiophene-free *benzene. The acid can be dried by azeotropic distillation with toluene, the residual toluene solution is then cooled and filtered, and the precipitate is dried in a vacuum oven. It has been purified by zone refining or by sublimation onto a cold finger at 10^{-3}torr. It distils above 360° with partial formation of the anhydride. The *dimethyl ester* has **m** –3.9° and **b** 140°/8mm. [Hill & McEwen *Org Synth* Coll Vol **II** 53 *1943*, *Beilstein* **2** IV 2055.]

2,2'-Azobis(isobutyronitrile) (α,α'bis-azo-[2-methylpropionitrile], AIBN) *[78-61-1]* **M 164.2, m 102.1-103.2°, 103°, 103-104°.** Crystallise the nitrile from Et_2O, Me_2CO, $CHCl_3$, aqueous EtOH or MeOH. It has also been crystallised from absolute EtOH below 40° in subdued light. Dry it under vacuum at room temperature over P_2O_5 and store it under vacuum in the dark at <–10° until required. Also crystallise it from $CHCl_3$ solution by addition of petroleum ether (b <40°). It is a radical inhibitor. [Askham et al. *J Am Chem Soc* **107** 7423 *1985*, Ennis et al. *J Chem Soc, Dalton Trans* 2485 *1986*, Inoue & Anson *J Phys Chem* **91** 1519 *1987,* Tanner *J Org Chem* **52** 2142 *1987*.] It is prepared by the oxidation of *N,N'-bis(isobutyronitrile)hydrazine* by addition of the solid hydrazine (4.15g, 0.025mole) to a solution of HNO_3 (100%, 6.5g, 0.1mol) and Ac_2O (30ml) (0.1mole) which are previously mixed at -30°. As the temperature rises to –20° the solid begins to dissolve and the colour of the solution turns to green, and dissolution is complete at ~5°. After stirring at 25° for 0.5 hours, the solution is poured onto cracked ice and H_2O (100ml), the product separates out, is filtered off, washed free from acid with H_2O. The solid (m 95-100°) is dried *in vacuo,* recrystallised from 50% EtOH and from Et_2O to give pure *AIBN* (2.5g, 60%), m 105°. [Picard & Boivin *Can J Chem* **29** 223 *1951*.] *Alternatively*, the *hydrazine* (0.989g, 6mmol) is added to a solution of glacial acetic acid (40ml) and concentrated H_2SO_4 (3ml) at ~0°, followed by addition of $NaMnO_2.3H_2O$ (1.8g) in H_2O (25ml). MnO_2 separates immediately, excess of $NaMnO_2$ and MnO_2 are reduced with aqueous sodium bisulfite and poured into H_2O. AIBN separates, is filtered off, washed with H_2O, dried in a vacuum desiccator and recrystallised as above to give pure *azo* compound (0.61g, 63%). [Overberger & Lebovitz *J Am Chem Soc* **76** 2722 *1954*, Overberger et al. *J Am Chem Soc* **71** 2661 *1949*.] [*Beilstein* **4** H 563, **4** I 566, **4** III 1750, **4** IV 3377.]

Azomethane (dimethyldiimide) *[503-28-6]* **M 58.1, m –78°, b 1.5°, d_0^{15} 0.981, n_D^{19} 1.3933.** Purify azomethane by distillation in a vacuum line and store it in the dark at –80°. It is soluble in EtOH, Et_2O and EtOAc. It can be **EXPLOSIVE.** [*Beilstein* **4** H 562, **4** I 566, **4** II 966, **4** III 1747, **4** IV 3366.]

B.A.L. (British Anti-Lewesite) see 2,3-dimercapto-1-propanol.

Batyl alcohol (*rac*-3-[1-octadecyloxy]-1,2-propanediol) *[544-62-7]* **M 344.6, m 70.5-71°.** Batyl alcohol crystallises from aqueous Me_2CO, EtOH or petroleum ether (b 40-60°). [Taguchi & Armarego *Med Res Rev* **18** pp43-88 *1998*, *Beilstein* **1** IV 2758.]

Behenoyl chloride (docosanoyl chloride) *[21132-76-3]* **M 359.0, m 40°.** If the IR shows OH bands, then it should be dissolved in oxalyl chloride in *C_6H_6 solution and warmed at 35° for 24 hours in the absence of moisture, evaporated and distilled in a vacuum of 10^{-5}mm. It is soluble in *C_6H_6 and Et_2O. It is moisture sensitive and is **LACHRYMATORY**. [Francis et al. *J Chem Soc* 1001 *1937*, Levene & Taylor *J Biol Chem* **59** 905 *1924*, *Beilstein* **2** III 1076.]

Biacetyl (butan-2,3-dione) *[431-03-8]* **M 86.1, b 88°, d_4^{20} 0.981, $n^{18.5}$ 1.3933.** Dry biacetyl over anhydrous $CaSO_4$, $CaCl_2$ or $MgSO_4$, then distil it in a vacuum under nitrogen, taking the middle fraction and storing it at Dry-Ice temperature in the dark (to prevent polymerisation). [*Beilstein* **1** IV 3644.]

Biguanide *[56-03-1]* **M 101.1, m 130° pK_1^{25} 3.1, pK_2^{25} 12.8.** Crystallise biguanide from EtOH. It gives a red Cu derivative, and it forms salts with many metals. The *monohydrochloride* has **m** 235° [38664-03-8] and the *dihydrochloride* forms plates with **m** 248° (213-214°, also reported) [25836-74-2]. [*Beilstein* **3** H 93, **3** I 44, **3** II 76, **3** III 171, **3** IV 162.]

Bis-acrylamide (*N,N'*-methylene bisacrylamide) *[110-26-9]* **M 154.2, m >300°.** Recrystallise the amide from MeOH (100g dissolved in 500ml boiling MeOH) and filter without suction in a warmed funnel. Allow to stand at room temperature and then at –15°C overnight. The crystals are collected with suction in a cooled funnel and washed with cold MeOH. The crystals are air-dried in a warm oven. [*Beilstein* **2** IV 1472.] **VERY TOXIC (neurotoxic).**

Bis(β-chloroethyl)amine hydrochloride *[821-48-7]* **M 178.5, m 214-215°, 216-217°, pK_{Est} ~5.8 (free base).** Crystallise the salt from Me_2CO or MeOH/Et_2O. The *picrate* has **m** 112-113° (from EtOH or Me_2CO). [Mann *J Chem Soc* 464 *1934*, Ward *J Am Chem Soc* **57** 915 *1935*, *Beilstein* **4** III 238.]

Bis(β-chloroethyl) ether *[111-44-4]* **M 143.0, b 94°/33mm, 178.8°, d_4^{20} 1.220, n_D^{20} 1.45750.** Wash the ether with conc H_2SO_4, then Na_2CO_3 solution, dry with anhydrous Na_2CO_3, and finally pass it through a 50cm column of activated alumina before distillation. *Alternatively*, wash it with 10% ferrous sulfate solution to remove peroxides, then H_2O, dry with $CaSO_4$, and distil it in a vacuum. Add 0.2% of catechol to stabilise it. [*Beilstein* **1** IV 1375, Kamm & Waldo *J Am Chem Soc* **43** 2223 *1921*.] **VERY TOXIC**.

2,2'-Bis[di-(carboxymethyl)-amino]diethyl ether, $(HOOCCH_2)_2NCH_2CH_2OCH_2CH_2N-(CH_2COOH)_2$ *[923-73-9]* **M 336.3, pK_1^{20} 1.8, pK_2^{20} 2.76, pK_3^{20} 8.84, K_4^{20} 9.47.** Crystallise it from EtOH.

Bis(2-ethylhexyl) sebacate ['dioctyl' sebacate, di(2-ethylhexyl) 1,8-octanedicarboxylate] *[122-62-3]* **M 426.7, b 212°/1mm, d_4^{25} 1.914, n_D^{20} 1.4496.** If it is acidic due to hydrolysis (effervesces with $NaHCO_3$), then purify by dissolving in Et_2O, shaking with aqueous Na_2CO_3, dry (Na_2SO_4), filter, evaporate and distil the residue at a high vacuum. Note that 2-ethylhexan-1-ol has **b 184-185°/760mm** with estimated **b ~40-50°/1mm** (see Figure 1, and Table 2A, Chapter 1) and will distil at a much lower temperature than the ester. Otherwise it should be distilled through a short column under high vacuum and the higher boiling fraction is redistilled. This vacuum pump oil can be prepared by esterifying decanedioic acid with 2-ethylhexanoic acid by Fischer-Speier's method (Fiscer & Speier *Chem Ber* **28** 1150 *1895*], whereby dry HCl gas is bubbled through the alcohol until its weight is increased by ~10%, the acid is added, the mixture is heated at 100° until esterification is complete (~2-3 hours), and purified as above. [Bruno USPat 2628249 *1953*, GBPat 747260 *1956*, *Beilstein* **2** IV 2803.]

***N,N*-Bis(2-hydroxyethyl)-2-aminoethanesulfonic acid (BES)** *[10191-18-1]* **M 213.3, m 150-155°, pK^{25} 7.17.** Crystallise BES from aqueous EtOH. [*Beilstein* **4** IV 3290.]

Bis(2-hydroxyethyl)amino-*tris*-(hydroxymethyl)methane (BIS-TRIS) *[6976-37-0]* **M 209.2, m 89°, 104°, pK^{20} 6.46.** Crystallise BIS-TRIS from hot 1-butanol and dry it in a vacuum at 25°.

***N,N*-Bis(2-hydroxyethyl)glycine** (BICINE) See in "Amino Acids and Peptides", Chapter 7.

Bis(2-mercaptoethyl)sulfone (BMS) *[145626-87-5]* **M 186.3, m 57-58°, pK_1^{25} 7.9, pK_2^{25} 9.0**. BMS recrystallises from hexane as white fluffy crystals. Large amounts are best recrystallised from de-oxygenated H_2O (charcoal). It is a good alternative reducing agent to dithiothreitol. Its IR (film) has ν_{max} □□ 2995, 2657, 1306, 1248, 1124 and 729 cm^{-1}. The synthetic intermediate *thioacetate* has **m** 82-83° (white crystals from CCl_4). The *disulfide* is purified by flash chromatography on SiO_2 and elution with 50% EtOAc/hexane, recrystallised from hexane, and has **m** 137-139°. [Lamoureux & Whitesides *J Org Chem* **58** 633 *1993*, *Beilstein* **1** IV 2455.]

Bis(trichloromethyl) carbonate (triphosgene) *[32315-10-9]* **M 296.8, m 79-83°, 81-83°, b 203-206°(slight dec).** It is a good solid substitute for phosgene (using a third mol per mol). Crystallise it from petroleum ether (b 60-80°), wash it with anhydrous cold Et_2O, de-gas it at 200mm then dry at 0.1mm (over H_2SO_4). It has IR with ν_{max} at 900 and 1900 cm^{-1}. It is a **lachrymator**, is **TOXIC**, and should be handled with gloves and in an efficient fume hood. [Hales et al. *J Chem Soc* 620 *1957*, Eckert & Forster *Angew Chem, Int Ed Engl* **26** 894 *1987*, *Aldrichimica Acta* **21** 47 *1988*, *Beilstein* **3** H 17, **3** I 8, **3** II 16, **3** III 36, **3** IV 33.]

Bistrifluoroacetamide (BTFA) *[407-24-9]* **M 209.1, m 85°, b 135-136°/744mm, 141°/760mm.** A major impurity is trifluoroacetamide. Add trifluoroacetic anhydride to BTFA, reflux for 2 hours and fractionate using a Vigreux column at atmospheric pressure. [Donike *J Chromatogr* **78** 273 *1973*, *Beilstein* **2** IV 471.]

Biuret (allophanic acid amide, carbamoylurea) *[108-19-0]* **M 103.1, sinters at 218° and chars at 270°, pK_1^{25} –0.88, pK_2^{25} >4.** Crystallise biuret from EtOH. [*Beilstein* **3** IV 141.]

***N*-Bromoacetamide** *[79-15-2]* **M 138.0, m 102-105°, 107-109°, 108°(anhydrous).** A possible contaminant is CH_3CONBr_2. Recrystallise it from $CHCl_3$/hexane (1:1, seed if necessary) or water and dry over $CaCl_2$. It is a brominating agent. [Oliveto & Gerold *Org Synth* Coll Vol **IV** 104 *1963*.] *Alternatively*, dissolve it in the minimum volume of warm H_2O (60°), then cool in an ice bath, collect the crystals and dry them in an anhydrous atmosphere, dissolve in Et_2O, chill and evaporate till crystallisation. Dry the crystals *in vacuo* at 25°, then at 45° (**m** 108°). Crystallise from $CHCl_3$ (**m** 103°). Estimate the available Br iodometrically [Buckles et al. *J Org Chem* **23** 483 *1958*]. [*Beilstein* **2** H 181, **2** I 82, **2** II 180, **2** III 406, **2** IV 417.]

Bromoacetic acid *[79-08-3]* **M 138.9, m 50°, b 118°/15mm, 208°/760mm, d^{25} 1.93, pK^{25} 2.92.** Crystallise bromoacetic acid from pet ether (b 40-60°). A diethyl ether solution of it is passed through an alumina column, and the ether is evaporated at room temperature under vacuum. It is best obtained by distillation from a Claisen (flask immersed in an oil bath) fitted with an insulated Vigreux column and the fraction **b** 108-110°/30mm is collected. It is light and moisture sensitive. [Natelson & Gottfried *Org Synth* Coll Vol **III** 381 *1955*, *Beilstein* **2** IV 526.] **LACHRYMATORY and is a skin IRRITANT**.

Bromoacetone *[598-31-2]* **M 137.0, b 31.5°/8mm, 63.5-64°/50mm, 137°/atm, d^{23} 1.643.** Stand bromoacetone over anhydrous $CaCO_3$, filter, distil it under low vacuum, and store it with $CaCO_3$ in the dark at 0°. [Levene *Org Synth* Coll Vol **II** 88 *1943*.] **Violently LACHRYMATORY and skin IRRITANT.**

2-Bromobutane *[78-76-2]* **M 137.0, b 91.2°, d_4^{20} 1.255, n_D^{20} 1.4367, n^{25} 1.4341.** Wash 2-bromobutane with conc HCl, water, 10% aqueous $NaHSO_3$, and then water. Dry it with $CaCl_2$, Na_2SO_4 or anhydrous K_2CO_3, and fractionally distil it through a 1m glass helices packed column. [*Beilstein* **1** IV 261.]

Bromoform *[75-25-2]* **M 252.8, m 8.1°, 55-56°/35mm, 149.6°/760mm, d^{15} 2.9038, d^{30} 2.86460, n^{15} 1.60053, n_D^{20} 1.5988.** The storage and stability of bromoform and chloroform are similar. Ethanol, added as a stabiliser, is removed by washing with H_2O or with saturated $CaCl_2$ solution, and the $CHBr_3$, after drying with $CaCl_2$ or K_2CO_3, is fractionally distilled. Prior to distillation, $CHBr_3$ has also been washed with conc H_2SO_4 until the acid layer is no longer coloured, then dilute NaOH or $NaHCO_3$, and H_2O. A further purification step is fractional crystallisation by partial freezing. [*Beilstein* **1** IV 82.]

(±)-2-Bromohexadecanoic acid (2-bromopalmitic acid) *[18263-25-7]* **M 335.3, m 51-53°, 52.3-52.5°, 53°, pK_{Est} ~3.2.** Recrystallise the acid from petroleum ether (b 60-80°, charcoal) and finally from EtOH. The *ethyl ester* has **b** 177-178°/2mm, d_{28}^{28} 1.0484, n_D^{20} 1.4560. [IR: Sweet & Estes *J Org Chem* **21** 1426 *1956*, *Beilstein* **2** IV 1184.]

6-Bromohexanoic acid (6-bromocaproic acid) *[4224-70-8]* **M 195.1, m 32-33°, 35°, 34-36°, b 129-130°/5mm.** It has been prepared by the oxidation of 6-bromohexanol with concentrated HNO_3 (sp. gr. 1.42, one hour for addition at 25-30°, stir at ~25° for 4 hours then at 100° for 45 minutes) [Degering & Boatright *J Am Chem Soc* **72** 5137]. It is made more conveniently by oxidation of cyclohexanone (174 g) with Caro's acid (using a mixture prepared from 919g of potassium persulfate for 10-15 minutes as in Barger et al. *J Chem Soc*

718 *1937*), and the crude lactones (200g) are treated with a cooled mixture of 48% HBr (1L) and concentrated H_2SO_4 (240ml). After standing at ~25° for 2 hours, then for 4 hours at 100°, the mixture is cooled, poured into H_2O, the organic layer is separated, the aqueous layer is saturated with $(NH_4)_2SO_4$, and is extracted with Et_2O. The combined organic layers and extracts are washed with saturated $(NH_4)_2SO_4$, dried (Mg_2SO_4), evaporated and distilled in a vacuum. [See Brown & Partridge *J Am Chem Soc* **66** 839 *1944*, Degering & Boatright *J AmChem Soc* **72** 5137 *1950*]. [*Beilstein* **2** II 287, **2** III 737, **2** IV 940.] When the acid is refluxed with $SOCl_2$ in the absence of moisture until all the HCl and SO_2 have evolved, then evaporated, and the residue is distilled in a vacuum, it provides **6-bromohexanoyl chloride** *[22809-37-6]* **M 213.5, b 130°/20mm, d ^{25} 1.395, n $^{20}_{D}$ 1.486** as an almost colourless oil which is typically reactive and corrosive like most acid chlorides. [Osmond *J Chem Soc* 3469 *1951*]. *6-Bromohexanamide* has **m 107-108°**, and the *anilide* has **m 84°**. [*Beilstein* **2** IV 940.]

***S*-(+)-1-Bromo-2-methylbutane** *[534-00-9]* **M 151.1, b 38.2°/39mm, 49°/62mm, 60.8°(57-58°)/100mm, 65-65.6°/140mm, 116-122°/atm, d $^{20}_{4}$ 1.2232, n $^{20}_{D}$ 1.4453, [α] $^{20}_{D}$ +5.1° (c 5, $CHCl_3$) (neat, +5.8°).** Wash the bromobutane with ice-cold H_2O, dry by freezing, shake it twice with an equal volume of H_2SO_4 at 0°, and twice with an equal volume of H_2O at 0°. Freeze-dry and keep over freshly heated (and then cooled) K_2CO_3, and distil it through a vacuum jacketed column of broken glass. *Alternatively*, dissolve it in petroleum ether (b 40-60°), wash it with 5% NaOH, conc H_2SO_4 (at 0°), then H_2O, dry ($CaCl_2$), evaporate it and distil. [Heller *J Am Chem Soc* **74** 4858 *1952*, Foley *J Am Chem Soc* **81** 2779 *1959*, Easton & Hargreaves *J Chem Soc* 1413 *1959*, Crombie & Harper *J Chem Soc* 2685 *1950*, *Beilstein* **1** IV 327.]

2-Bromo-2-methylpropane *[507-19-7]* **M 137.0, b 71-73°, d $^{20}_{4}$ 1.218, n $^{20}_{D}$ 1.429.** Neutralise the bromomethylpropane with K_2CO_3, distil, and dry it using molecular sieves (5A), then distil it in a vacuum and degas it by the freeze-pump-thaw technique. Seal it under vacuum. [*Beilstein* **1** IV 295.]

1-Bromooctadecane *[112-89-0]* **M 333.4, m 26°, 27.3°, 28-30°, b 178-179°/2mm, 214-218°/15mm, d $^{20}_{4}$ 0.976, n $^{20}_{D}$ 1.461.** Twice recrystallise bromooctadecane from the melt, then distil it under vacuum three times taking the middle cut. *Alternatively*, wash the oil with aqueous Na_2SO_4, then conc H_2SO_4 (cool) and again with aqueous Na_2SO_4, and then fractionally distil it. [Meyer & Ried *J Am Chem Soc* **55** 1574 *1933*, Hoffmann & Smyth *J Am Chem Soc* **72** 171 *1950*, IR: LeFévre et al. *Aust J Chem* **12** 743 *1959*, IR: Brini-Fritz *Bull Soc Chim Fr* 516 *1957*, *Beilstein* **1** IV 555.]

(±)-2-Bromopentane *[107-81-3]* **M 151.1, b 117.2°/753mm, 116-117°/atm, 117.5°/740mm, d $^{20}_{4}$ 1.2190, n $^{20}_{D}$ 1.4401.** Dry it over K_2CO_3 and distil it through a short Vigreux column. [IR: Pines et al. *J Am Chem Soc* **74** 4063 *1952*, Brown & Wheeler *J Am Chem Soc* **78** 2199 *1956*, *Beilstein* **1** IV 312.]

Bromopicrin (tribromonitromethane) *[464-10-8]* **M 297.8, m 10.2-10.3°, b 85-87°/16mm, d $^{20}_{4}$ 2.788, n $^{20}_{D}$ 1.579.** Steam distil it, dry it with anhydrous Na_2SO_4 and distil it again in a vacuum. **HIGHLY TOXIC.** [*Beilstein* **1** H 77, **1** I 21, **1** II 43, **1** III 115, **1** IV 106.]

***R*-(+)-2-Bromopropionic acid** *[10009-70-8]* **M 153.0, b 78°/4mm, d $^{20}_{4}$ 1.474, [α] $^{25}_{D}$ +27.2° (neat), pK^{25} 4.07.** Dissolve it in Et_2O, dry ($CaCl_2$), evaporate and distil it through a short column. Distillation through a Podbielniak column (see *S*-(–)-2-chloropropionic acid below) led to decomposition. Store it in the dark under N_2, preferably in sealed ampoules. Even at –10° it slowly decomposes. **LACHRYMATORY.** [Fuet et al. *J Am Chem Soc* **76** 6054 *1954*, *Beilstein* **2** IV 761.]

3-Bromopropionic acid *[590-92-1]* **M 153.0, m 62.5°, 62.5-63.5°, 63-64°, pK^{25} 4.01.** The acid crystallises as plates from CCl_4. It is soluble in organic solvents and H_2O. Its *methyl ester* has **b** 65°/18mm and 80°/27mm. The *S-benzylisothiouronium salt* has **m** 136°. [Kendall & McKenzie *Org Synth* Coll Vol **I** 131 *1941*, *Beilstein* **2** IV 764.]

Bromopyruvic acid (3-bromo-2-oxopropionic acid) *[1113-59-3]* **M 167.0, m 79-82°, pK$_{Est}$ ~1.6.** Dry it by azeotropic distillation (with toluene), and then recrystallise it from dry $CHCl_3$. Dry for 48 hours at 20° (0.5 torr) over P_2O_5. Store it at 0°. [Labandiniere et al. *J Org Chem* **52** 157 *1987*, *Beilstein* **3** III 1167.]

***N*-Bromosuccinimide** *[128-08-5]* **M 178.0, m 183-184°(dec).** *N*-Bromosuccinimide (30g) is purified by dissolving rapidly in boiling water (300ml) and filtering through a fluted filter paper into a flask immersed in an ice bath, and left for 2 hours. The crystals are filtered off, washed thoroughly with of ice-cold water (*ca* 100ml) and drained on a Büchner funnel before drying under vacuun over P_2O_5 or $CaCl_2$ [Dauben & McCoy *J Am Chem Soc* **81** 4863 *1959*]. This *brominating agent* has also been recrystallised from acetic acid or water (10 parts see above), washed in water and dried *in vacuo* [Wilcox et al. *J Am Chem Soc* **108** 7693 *1986,* Shell et al. *J Am Chem Soc* **108** 121 *1986*, Phillips & Cohen *J Am Chem Soc* **108** 2013 *1986*, *Beilstein* **21/9** V 543.]

Bromotetronic acid (2-bromo-4-hydroxyacetoacetic lactone) *[21151-51-9]* **M 179.0, m 182.8°, pK^{25} 2.23.** Decolourise with Norit in EtOAc, evaporate, and crystallise from EtOAc or $*C_6H_6$. [Schuler et al. *J Phys Chem* **78** 1063 *1974*, Gillespie & Price *J Org Chem* **22** 782 *1957*, *Beilstein* **17** III/IV 5819.]

Bromotrichloromethane *[75-62-7]* **M 198.5, f –5.6°, m 21°, b 104.1°, d $_{D}^{20}$ 2.01, n $_{D}^{20}$ 1.5061.** Wash it with aqueous NaOH solution or dilute Na_2CO_3, then with H_2O, and dry with $CaCl_2$, BaO, $MgSO_4$ or P_2O_5 before distilling in diffuse light and storing in the dark. It has also been purified by treatment with charcoal and fractional crystallisation by partial freezing. It is purified also by vigorous stirring with portions of conc H_2SO_4 until the acid does not discolour during several hours stirring. Wash with Na_2CO_3 and water, dry with $CaCl_2$ and then illuminate it with a 1000W projection lamp at 15cm for 10 hours, after making it 0.01M in bromine. Pass it through a 30 × 1.5cm column of activated alumina and fractionally redistil it through a 12-in Vigreux column. [Firestone & Willard *J Am Chem Soc* **83** 3511 *1961*; see also Cadogan & Duell *J Chem Soc* 4154 *1962*, *Beilstein* **1** IV 77.]

1-Bromo-2,2,2-trifluoroethane *[421-06-7]* **M 163.0, m –94°, b 26-27°, d $_{4}^{20}$ 1.788, n $_{D}^{20}$ 1.332.** Wash it with water, dry ($CaCl_2$) and distil it. [*Beilstein* **1** III 179, **1** IV 154.]

Bromotrifluoromethane (Freon 13B1) *[75-63-8]* **M 148.9, b –59°, d $_{4}^{20}$ 1.590.** Purify the gas by passing it through a tube containing P_2O_5 on glass wool into a vacuum system where it is frozen out in a quartz tube and degassed by cycles of freezing, evacuating and thawing. [*Beilstein* **1** III 83, **1** IV 73.]

5-Bromovaleric (γ–bromopentanoic) acid *[2067-33-6]* **M 181.0, m 40°, pK$_{Est}$ ~4.6.** Crystallise the acid from petroleum ether. [*Beilstein* **2** IV 883.]

(±)-Bromural [*N*-(aminocarbonyl)-2-bromo-3-methylbutanamide, bromisovalum] *[496-67-3]* **M 223.1, m 154-155°.** Crystallise it from aqueous EtOH or toluene, and dry it in air. [*Beilstein* **3** H 63, **3** I 29, **3** II 51, **3** III 123, **3** IV 117.]

1,3-Butadiene *[106-99-0]* **M 54.1, b –2.6°.** Dry the gas by condensing it into a solution of triethylaluminium in decahydronaphthalene, then it is flash distilled. It has also been dried by passage over anhydrous $CaCl_2$ or distilled from $NaBH_4$. Also purify by passing through a column packed with molecular sieves (4A), followed by cooling in a Dry-ice/MeOH bath overnight, filtering off the ice and drying over CaH_2 at –78° then distilling in a vacuum line. [*Beilstein* **1** IV 976.]

***n*-Butane** *[106-97-8]* **M 58.1, m –135°, b –0.5°.** Dry by passing over anhydrous $Mg(ClO_4)_2$ and molecular sieves type 4A. Air is removed by prolonged and frequent degassing at –107°. [*Beilstein* **1** IV 236.]

1,4-Butanediol (tetramethylene glycol) *[110-63-4]* **M 90.1, f 20.4°, b 107-108°/4mm, 127°/20mm, d $_{4}^{20}$ 1.02, n $_{D}^{20}$ 1.4467.** Distil the glycol and store it over Linde type 4A molecular sieves, or crystallise it twice from anhydrous diethyl ether/acetone, and redistil it. It has been recrystallised from the melt and doubly distilled *in vacuo* in the presence of Na_2SO_4. [*Beilstein* **1** IV 2515.]

***erythro*-2,3-Butanediol (*meso*-2,3-butylene glycol)** *[5341-95-7]* **M 90.1, m 32-34°, 34.4°, b 89°/16mm, 181.7°/742mm, d $_{4}^{20}$ 0.9939, n $_{D}^{20}$ 1.443, n $_{D}^{25}$ 1.4324.** The *meso*-form is prepared from *trans*-2,3-epoxybutane and is recrystallised from isopropyl ether at low temperature. [Wilson & Lucas *J Am Chem Soc* **58** 2396 *1936*, *Beilstein* **1** II 546, 1 III 2178, **1** IV 2524.]

***threo*-2,3-Butanediol (*rac* ±-2,3-butylene glycol)** *[513-85-9]* **M 90.1, m 7.6°, b 86°/16mm, 172.7°/742mm, 183-184°/760mm, d_4^{25} 0.995, n_D^{20} 1.443, n_D^{25} 1.4310.** The ±-*threo*-form is prepared from *cis*-2,3-epoxybutane and is recrystallised from isopropyl ether at low temperature. [*Beilstein* **1** II 546, **1** III 2180, **1** IV 2525.]

***threo*-2,3-Butanediol** *[R,R(–) 24347-58-8, S,S(+) 19132-06-0]* **M 90.1, m 16-19°, 19.7°, b 77.5-78°/10mm, 179-180°/atm, d_4^{25} 0.987, n_D^{20} 1.443, n_D^{25} 1.4310, $[\alpha]_D^{20}$ (–) or (+) 13.1° (neat).** Purify by fractional distillation. The *bis-(p-nitrobenzoate) ester* has **m** 141-142°, and $[\alpha]_D^{20}$ (–) or (+) 52° (c 4, $CHCl_3$). [Ghirardelli & Lucas *J Am Chem Soc* **79** 734 *1957*, Rubin et al. *J Am Chem Soc* **74** 425 *1952*, Neish *Can J Res* **27** 6 *1949*, Neish & Ledingham *Can J Res* **27** 694 *1949*, *Beilstein* **1** IV 2524-2525.] When (-)-*2R,3R*-butane-2,3-diol (22g, 21ml, 244.5mmol) is added slowly to a stirred mixture of toluene-*p*-sulfonyl chloride (100g, 525mmol) in dry pyridine at 0° (ice-water bath), kept thus for 20 minutes, and the semi-solid mixture is set aside at ~25° overnight, then is shaken vigorously with crushed ice-water for 2 hours, poured rapidly with stirring into a mixture of concentrated HCl (70ml) and crushed ice, and the slurry is filtered gives solid **(+)-*2R,3R*-butane-2,3-diol bis(tosylate)** after washing thoroughly with H_2O and drying (91.0g, 93.5%). *Alternatively*, the crude dry ester is dissolved in CH_2Cl_2, dried ($MgSO_4$), evaporated *in vacuo*, and the residue is washed with petroleum ether (b 20-60°), and stored over solid KOH in a desiccator. It has **m 62-64° (65.1-65.5°), $[\alpha]_D^{20}$ +37.2° (c 2.105, $CHCl_3$)**. [Corey & Mitra *J Am Chem Soc* **84** 2938 *1962*, Lucas et al. *J Am Chem Soc* **72** 2138 *1950*, Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 *1977*.] This (+)-*2R,3R*-ditosylate provides the chiral ligand (–)-*S,S*-CHIRAPHOS [cf 64896-28-2] after reaction with 2 mols of Ph_2PLi, *via* inversion of configuration at the two chiral centres. **(+)-*2R,3R*-butane-2,3-diol bis(methanesulfonate)** has **m 123-125°, $[\alpha]_D^{22}$ +2° (c 1, $CHCl_3$)**. [*Beilstein* **1** I 250, **1** II 547, **1** III 2181-3, **1** IV 2525.]

1-Butanesulfonyl chloride *[2386-60-9]* **M 156.6, b 75-76°/7mm, 98°/13mm, 100-103°/27-28mm, d_4^{20} 1.2078, n_D^{20} 1.4559**. It has a pungent odour and is **LACHRYMATORY.** If IR shows OH bands, then dissolve in Et_2O, wash with cold saturated aqueous $NaHCO_3$ (care since CO_2 will be generated) then H_2O, dry it over solid Na_2SO_4, filter, evaporate and distil the residue twice. Characterise it by shaking a solution in Et_2O or $*C_6H_6$ with aqueous NH_3, collect the solid *1-butanesulfonamide* with **m** 48° after recrystallisation from $CHCl_3$, CCl_4 or Et_2O/petroleum ether. [Douglass & Johnson *J Am Chem Soc* **60** 1488 *1938*, Lee & Dougherty *J Org Chem* **5** 83 *1940*, *Beilstein* **4** IV 45.]

1-Butanethiol *[109-79-5]* **M 90.2, b 98.4°, d^{25} 0.837, n_D^{20} 1.443, n^{25} 1.440, pK_{Est} ~11.3.** Dry the thiol with $CaSO_4$ or Na_2SO_4, then reflux it over magnesium, or dry with, and distil it from CaO, under nitrogen [Roberts & Friend *J Am Chem Soc* **108** 7204 *1986*.] It has been separated from hydrocarbons by extractive distillation with aniline.
Dissolve it also in 20% NaOH, extract with a small amount of $*C_6H_6$, then steam distil it until clear. The distillate is then cooled and acidified slightly with 15% H_2SO_4. The thiol is distilled out, dried with $CaSO_4$ or $CaCl_2$, and fractionally distilled under N_2 [Mathias & Filho *J Phys Chem* **62** 1427 *1958*]. It has also been purified by precipitation as the lead mercaptide from alcoholic solution, then regeneration by addition of dilute HCl to the residue followed by steam distillation. *All operations should be carried out in a fume cupboard due to the* **TOXICITY** *and obnoxious odour of the thiol.* [*Beilstein* **1** IV 1555.]

2-Butanethiol *[513-53-1]* **M 90.2, b 37.4°/134mm, d^{25} 0.846, n^{25} 1.4338, pK_{Est} ~11.4.** Purify it as for 1-butanethiol. [*Beilstein* **1** IV 1584.]

***n*-Butanol** *[71-36-3]* **M 74.1, b 117.7°, d^{25} 0.80572, n_D^{20} 1.39922, n^{15} 1.40118.** Dry it with $MgSO_4$, CaO, K_2CO_3, or solid NaOH, followed by refluxing with, and distilling from, small amounts of calcium, magnesium activated with iodine, or aluminium amalgam. It can also be dried with molecular sieves, or by refluxing with *n*-butyl phthalate or succinate. (For method, see *Ethanol*.) *n*-Butanol can also be dried by efficient fractional distillation, water passing over in the first fraction as a binary azeotrope (contains about 37% water). An ultraviolet-transparent distillate has been obtained by drying with magnesium and distilling from sulfanilic acid. To remove bases, aldehydes and ketones, the alcohol is washed with dilute H_2SO_4, then $NaHSO_4$ solution; esters are removed by boiling for 1.5 hours with 10% NaOH.
It has also been purified by adding $NaBH_4$ (2g) to butanol, (1.5L) gently bubbling under argon and a reflux con-

denser for 1 day at 50°. Then add freshly cut sodium (2g, washed with butanol) and reflux 1 day. Distil, and collect the middle fraction [Jou & Freeman *J Phys Chem* **81** 909 *1977*]. [*Beilstein* **1** IV 1506.]

2-Butanone (methyl ethyl ketone, MEK) *[78-93-0]* **M 72.1, b 79.6°, d $_4^{20}$ 0.853, n $_D^{20}$ 1.37850, n^{25} 1.37612, pK^{25} –7.2 (aqueous H_2SO_4).** In general, purification methods are the same as for acetone. Aldehydes can be removed by refluxing with $KMnO_4$ + CaO, until the Schiff aldehyde test is negative, prior to distillation. Shaking with saturated K_2CO_3, or passing through a small column of activated alumina, removes cyclic impurities. The ketone can be dried by careful distillation (an azeotrope containing 11% water boils at 73.4°), or over $CaSO_4$, P_2O_5, Na_2SO_4, or K_2CO_3, followed by fractional distillation. Purification as the bisulfite addition compound is achieved by shaking with excess saturated Na_2SO_3, cooled to 0°, filtering off the precipitate, washing with a little ethyl ether and drying in air; this is followed by decomposition with a slight excess of Na_2CO_3 solution and steam distillation, the distillate being saturated with K_2CO_3 so that the ketone can be separated, dried with K_2CO_3, filtered, and distilled. Purification as the *NaI addition compound* (**m** 73-74°) is more convenient. (For details, see *Acetone*.) Small quantities of 2-butanone can be purified by conversion to the semicarbazone, recrystallisation to constant melting point, drying under vacuum over $CaCl_2$ and paraffin wax, refluxing for 30 minutes with excess oxalic acid, followed by steam distillation, salting out, drying and distilling. [Cowan et al. *J Chem Soc* 171 *1940*]. [*Beilstein* **1** IV 3243.]

***cis*-2-Butene** *[590-18-1]* **M 56.1, b 2.95-3.05°/746mm.** The gas is dried with CaH_2 and purified by gas chromatography. [*Beilstein* **1** H 205, **1** II 176, **1** III 728, **1** IV 778.] **HIGHLY FLAMMABLE.**

***trans*-2-Butene** *[624-64-6]* **M 56.1, b 0.3-0.4°/744mm.** The gas is dried with CaH_2 and purified by gas chromatography. [*Beilstein* **1** H 205, **1** II 176, **1** III 730, **1** IV 781.] **HIGHLY FLAMMABLE.**

2-Butene-1,4-dicarboxylic acid (*trans*-3-hexenedioic acid, *trans*-ß-hydromuconic acid) *[4436-74-2]* **M 144.1, m 194-197°, 195-196°, $pK_{Est(1)}$ ~4.2, $pK_{Est(2)}$ ~5.00.** Crystallise the acid from boiling water, then dry it at 50-60° in a vacuum oven. [*Beilstein* **2** IV 2237.]

2-Butoxyethanol (butyl cellosolve) *[111-76-2]* **M 118.2, b 171°/745mm, d $_4^{20}$ 0.903, n $_D^{20}$ 1.4191.** Peroxides can be removed by refluxing with anhydrous $SnCl_2$ or by passage under slight pressure through a column of activated alumina. Dry with anhydrous K_2CO_3 and $CaSO_4$, filter and distil, or reflux with, and distil from NaOH. [*Beilstein* **1** IV 2380.]

***n*-Butyl acetate** *[123-86-4]* **M 116.2, b 126.1°, d $_4^{20}$ 0.882, n $_D^{20}$ 1.394.** Distil, reflux with successive portions of $KMnO_4$ until the colour persists, dry with anhydrous $CaSO_4$, filter and redistil. [*Beilstein* **2** IV 143.]

***tert*-Butyl acetate** *[540-88-5]* **M 116.2, b 97-98°, d $_4^{20}$ 0.866, n $_D^{20}$ 1.387.** Wash the ester with 5% Na_2CO_3 solution, then saturated aqueous $CaCl_2$, dry with $CaSO_4$ and distil it. [McClosky et al. *Org Synth* Coll Vol **IV** 263 *1963,* Mangia et al. *Org Prep Proc Int* **18** 13 *1986*, *Beilstein* **2** IV 151.]

***tert*-Butyl acetoacetate** *[1694-31-1]* **M 158.2, b 71°/10mm, 85°/20mm, d $_4^{20}$ 0.954, n $_D^{20}$ 1.42.** Distil it under reduced pressure through a short column. [Lawesson et al. *Org Synth* Coll Vol **V** 155 *1973*, Lawesson et al. *Org Synth* **42** 28 *1962*, *Beilstein* **3** IV 1536.] **HARMFUL VAPOUR.**

***tert*-Butylacetyl chloride** *[7065-46-5]* **M 134.6, b 68-71°/100mm, 81°/180mm, 128-132°/atm, d $_4^{20}$ 0.964, n $_D^{20}$ 1.423.** Distil it under vacuum. If IR shows OH group, then treat with thionyl chloride or oxalyl chloride at *ca* 50° for 30 minutes, evaporate and fractionate the residue using a short column. Strongly **LACHRYMATORY**, use a good fume hood. [Berliner & Berliner *J Am Chem Soc* **72** 222 *1950*, Traynham & Battiste *J Org Chem* **22** 1551 *1957*, *Beilstein* **2** IV 956.]

Butyl acrylate *[141-32-2]* **M 128.2, b 59°/25mm, d $_4^{20}$ 0.894, n^{12} 1.4254.** Wash it repeatedly with aqueous NaOH to remove inhibitors such as hydroquinone, then with distilled water. Dry with $CaCl_2$. Fractionally distil under reduced pressure in an all-glass apparatus. The middle fraction is sealed under N_2 and stored at 0° in the dark until required or with a stabiliser [Mallik & Das *J Am Chem Soc* **82** 4269 *1960*]. [*Beilstein* **2** IV 1463.]

***tert*-Butyl acrylate** *[1663-39-4]* **M 128.2, b 30.0-30.8°/26mm, 61-63°/15mm, 117-120°/760mm, d^{25} 0.875, n_D^{20} 1.410.** Purify the ester by fractional distillation. If it contains acid (OH bands in the IR), then dissolve it in Et_2O, wash it with aqueous $NaHCO_3$, dry the organic layer (Na_2SO_4), filter it and distil it under reduced pressure. Stabilise it by adding hydroquinone monomethyl ether (~0.05%). It forms a crystalline *tert*-butyl acrylate polymer which is soluble in organic solvents [Garrett et al. *J Am Chem Soc* **81** 1007 *1959*]. [*Beilstein* **2** IV 1465.] For other alkyl acrylates see Rehberg *Org Synth Coll Vol* **3** 146 *1955*.

(±)-*sec*-Butyl alcohol (± 2-butanol) *[78-92-2; 15892-23-6]* **M 74.1, b 99.4°, d_4^{20} 0.808.** Purification methods are the same as for *n*-Butanol. These include drying with K_2CO_3 or $CaSO_4$, followed by filtration and fractional distillation, refluxing with CaO, distillation, then refluxing with magnesium and redistillation, and refluxing with, then distilling from CaH_2. Calcium carbide has also been used as a drying agent. The anhydrous alcohol is obtained by refluxing with *sec*-butyl phthalate or succinate. (For method see *Ethanol*.) Small amounts of alcohol can be purified *via* conversion to the alkyl hydrogen phthalate and recrystallisation [Hargreaves *J Chem Soc* 3679 *1956*]. For purification of optical isomers, see Timmermans and Martin [*J Chem Phys* **25** 411 *1928*]. [*Beilstein* **2** III 1566.]

***tert*-Butyl alcohol** *[75-65-0]* **M 74.1, m 23-25°, 25.7°, b 28.3°/60mm, 43.3°/123.8mm, 61.8°/315mm, 72.5°/507mm, 82.45°/760mm, d_4^{20} 0.7858, n_D^{20} 1.3878.** It is synthesised commercially by the hydration of 2-methylpropene in dilute H_2SO_4. Dry it with CaO, K_2CO_3, $CaSO_4$ or $MgSO_4$, filter and fractionally distil it. Dry further by refluxing with, and distilling from, either magnesium activated with iodine, or small amounts of calcium, sodium or potassium, under nitrogen. Passage through a column of type 4A molecular sieve is another effective method of drying; as well as refluxing with *tert*-butyl phthalate or succinate. (For method see *Ethanol*.) Other methods include refluxing with excess aluminium *tert*-butylate, or standing with CaH_2, and distilling as needed. Further purification is achieved by fractional crystallisation by partial freezing, taking care to exclude moisture. *tert*-Butyl alcohol samples containing much water can be dried by adding *benzene, so that the water distils off as a tertiary azeotrope, **b** 67.3°. Traces of isobutylene have been removed from dry *tert*-butyl alcohol by bubbling dry pre-purified nitrogen through for several hours at 40-50° before using. It forms azeotropic mixtures with a large number of compounds. It has also been purified by distillation from CaH_2 into Linde 4A molecular sieves which had been activated at 350° for 24 hours [Jaeger et al. *J Am Chem Soc* **101** 717 *1979*]. [*Beilstein* **1** IV 1609.]
Rapid purification: Dry *tert*-butanol over CaH_2 (5% w/v), distil and store it over 3A molecular sieves.

***n*-Butylamine** *[109-73-9]* **M 73.1, b 77.8°, d_4^{20} 0.740, n_D^{20} 1.4009, n^{25} 1.399, pK^{25} 10.66.** Dry it with solid KOH, K_2CO_3, $LiAlH_4$, CaH_2 or $MgSO_4$, then reflux it with, and fractionally distil it from P_2O_5, CaH_2, CaO or BaO. Further purification is by precipitation as the *hydrochloride,* **m** 213-213.5°, from ethereal solution by bubbling HCl gas into it. This is re-precipitated three times from EtOH by adding ether, followed by liberation of the free amine using excess strong base. The amine is extracted into ether, which is separated, dried with solid KOH, the ether is removed by evaporation and then the amine is distilled. It is stored in a desiccator over solid NaOH [Bunnett & Davis *J Am Chem Soc* **82** 665 *1960*, Lycan et al. *Org Synth* Coll Vol **II** 319 *1943*]. [*Beilstein* **4** IV 540.] **SKIN IRRITANT.**

R*-(-)-*sec*-Butylamine** *[13250-12-9]* **M 73.1, b 61-63°/atm, 62.5°/atm, d_4^{20} 0.731, n_D^{20} 1.393, $[\alpha]_D^{20}$ –7.5° (neat), pK^{25} 10.56.** Dry it over solid NaOH overnight and fractionate it through a short helices packed column. The L-*hydrogen tartrate salt* has **m** 139-140° (from H_2O), the *1H_2O* has **m** 96° $[\alpha]_D^{21}$ +18.1° (c 11, H_2O), the *hydrochloride* has **m** 152° $[\alpha]_D^{21}$ –1.1° (c 13, H_2O) and the *benzoyl* derivative crystallises from EtOH as needles with **m** 97°, $[\alpha]_D^{21}$–34.9° (c 11, H_2O). [Bruck et al. *J Chem Soc* 921 *1956*, Kjaer & Hansen *Acta Chem Scand* **11** 898 *1957*.] [*Beilstein* **4** H 161, **4** I 372, **4** III 308, **4** IV 617.] The ***S*-(+)-*enantiomer has has same properties except for the optical rotation which has the opposite sign.

***tert*-Butylamine** *[75-64-9]* **M 73.1, b 42°, d_4^{20} 0.696, pK^{25} 10.68.** Dry it with KOH or $LiAlH_4$, and/or distil it from CaH_2 or BaO. [*Beilstein* **4** IV 657.]

***tert*-Butylammonium bromide** *[60469-70-7]* **M 154.1, m >250°(dec).** Recrystallise the salt several times from absolute EtOH and thoroughly dry it at 105° *in vacuo*. [*Beilstein* **4** IV 657.]

***n*-Butyl bromide** *[109-65-9]* **M 137.0, b 101-102°, d^{25} 1.2678, n_D^{20} 1.4399, n^{25} 1.4374.** Wash the bromide with conc H_2SO_4, water, 10% Na_2CO_3 and again with water. Dry it over $CaCl_2$, $CaSO_4$ or K_2CO_3, and distil it. Redistil it after drying with P_2O_5, or pass it through two columns containing 5:1 silica gel/Celite mixture and store it with freshly activated alumina. [*Beilstein* **1** IV 258.]

***tert*-Butyl bromoacetate** *[5292-43-3]* **M 195.1, b 52°/10mm, 74-76°/25mm, d_4^{20} 1.324, n_D^{25} 1.4162.** Dissolve the ester in Et_2O, wash it well with ice cold 10% aqueous K_2CO_3, dry it over $CaCl_2$, filter and evaporate the Et_2O, then fractionate it through a Vigreux column in a vacuum. **LACHRYMATORY.** [Abramovitch et al. *J Am Chem Soc* **64** 2274 *1942*, Abramovitch & Hauser *J Am Chem Soc* **65** 986 *1943*, *Beilstein* **2** III 482.]

***tert*-Butyl carbazate** *[870-46-2]* **M 132.2, m 41-42°, b 64°/0.01mm, 55-57°/0.4mm.** Distil it in a Claisen flask with a water or oil bath at *ca* 80°. After a couple of drops have distilled, the carbazate is collected as an oil which solidifies to a snow white solid. It can be crystallised with 90% recovery from a 1:1 mixture of petroleum ether (b 30-60°) and petroleum ether (b 60-70°). [Carpino et al. *Org Synth* Coll Vol **V** 166 *1973*, Caprino et al. *Org Synth* **44** 20 *1964*, *Beilstein* **3** IV 175.]

***n*-Butyl chloride** *[109-69-3]* **M 92.6, b 78°, d_4^{20} 0.886, n_D^{25} 1.4021.** Shake it repeatedly with conc H_2SO_4 (until no further colour develops in the acid layer), then wash it with water, aqueous $NaHCO_3$ or Na_2CO_3, and more water. Dry it with $CaCl_2$, or $MgSO_4$ (then with P_2O_5 if desired), decant and fractionally distil it. *Alternatively*, a stream of oxygen continuing *ca* three times as long as is necessary to obtain the first coloration of starch iodide paper by the exit gas. After washing with $NaHCO_3$ solution to hydrolyse ozonides and to remove the resulting organic acid, the liquid is dried and distilled [Chien & Willard *J Am Chem Soc* **75** 6160 *1953*]. [*Beilstein* **1** IV 246.]

***tert*-Butyl chloride** *[507-20-0]* **M 92.6, f –24.6°, b 50.4°, d_4^{20} 0.851, n_D^{25} 1.38564.** Purification methods commonly used for other alkyl halides lead to decomposition. Some impurities can be removed by photochlorination with a small amount of chlorine prior to use. The liquid is washed with ice water, dried with $CaCl_2$ or $CaCl_2$ + CaO and fractionally distilled. It has been further purified by repeated fractional crystallisation by partial freezing. [*Beilstein* **1** IV 288.]

***tert*-Butyl chloroacetate** *[107-59-5]* **M 150.6, b 48-49°/11mm, 60.2°/15mm, 155°/atm (dec), d_4^{25} 1.4204, n_D^{20} 1.4259.** Check the NMR spectrum; if satisfactory then distil in a vacuum; if not then dissolve in Et_2O, wash with H_2O, 10% H_2SO_4 until the acid extract does not become cloudy when made alkaline with NaOH. Wash the organic layer again with H_2O, then saturated aqueous $NaHCO_3$, dry over Na_2SO_4, evaporate and fractionate it through a carborundum-packed column or a 6-inch Widmer column (*see tert-butyl ethyl malonate for precautions to avoid decomposition during disillation*). [Johnson et al. *J Am Chem Soc* **75** 4995 *1953*, Baker *Org Synth* Coll Vol **III** 144 *1944*, *Beilstein* **2** III 444.]

***tert*-Butyl cyanide (trimethylacetonitrile, pivalonitrile)** *[630-18-2]* **M 83.1, m 16-18°, d_4^{20} 0.765, b 104-106°.** Purify it by a two-stage vacuum distillation and de-gas by the freeze-pump-thaw technique. Store it under vacuum at 0°. **TOXIC,** use an efficient fume hood. [*Beilstein* **2** IV 875.]

***tert*-Butyl cyanoacetate** *[1116-98-9]* **M 141.2, b 40-42°/0.1mm, 54-56°/0.3mm, 90°/10mm, 107-108°/23mm, d_4^{20} 0.989, n_D^{20} 1.4198**. The IR spectrum of a film should have bands at 1742 (ester CO) and 2273 (C≡N), but no band at *ca* 3500 broad (OH) cm^{-1}. If it does not have the last-named band, then fractionally distil; otherwise dissolve in Et_2O, wash with saturated aqueous $NaHCO_3$, dry over K_2CO_3, evaporate Et_2O, and distil the residue under a vacuum (*see tert-butyl ethyl malonate for precautions to avoid decomposition during distillation*). [Beech & Piggott *J Chem Soc* 423 *1955*, Dahn & Hauth *Helv Chim Acta* **42** 1214 *1959*, *Beilstein* **2** I 255.]

***tert*-Butyl diazoacetate** *[3505950-8]* **M 142.2, b 51-53°/12mm, d_4^{25} 1.026, n_D^{20} 1.443.** It is a poisonous orange-yellow liquid which is explosive, and the necessary precautions should be strictly adhered to (i.e. efficient fume cupboard, and face and body protection; see reference below). Check the purity by TLC on Merck Kieselgel F_{254} or Eastman Kodak Silica Gel without indicator using $CHCl_3$ as eluent (R_F 0.72). If the

ester is suspect, then dissolve it in Et_2O, wash it with brine, H_2O, dry the organic layer (Na_2SO_4), and filter. Remove most of the Et_2O at 30°/water pump vacuum (rotovap), the remaing ether during distillation under lower pressure (<12mm), and the residual oil then distils as a coloured liquid using a water bath at ~50° (no higher as heat source). [Regitz et al. *Org Synth* Coll Vol **V** 179 *1972*.]

***n*-Butyl disulfide** *[629-45-8]* **M 178.4, b 110-113°/15mm, d_4^{20} 0.938, n^{22} 1.494.** Shake it with lead peroxide, filter and distil it in a vacuum under N_2. [*Beilstein* **1** IV 1560.]

***n*-Butyl ether (di-*n*-butyl ether)** *[142-96-1]* **M 130.2, b 52-53°/26mm, 142.0°/760mm, d_4^{20} 0.764, n_D^{20} 1.39925, n^{25} 1.39685, pK^{25} –5.40 (aqueous H_2SO_4).** Peroxides (detected by the liberation of iodine from weakly acid HCl solutions of 2% KI) can be removed by shaking 1L of ether with 5-10ml of a solution comprising of ferrous sulfate (6.0g) in conc H_2SO_4 (6ml) of water (110ml), with aqueous Na_2SO_3, or with acidified NaI, water, then aqueous $Na_2S_2O_3$. After washing with dilute NaOH, KOH, or Na_2CO_3, then water, the ether is dried with $CaCl_2$ and distilled. It can be further dried by distillation from CaH_2 or Na (after drying with P_2O_5), and stored in the dark with Na or NaH. The ether can also be purified by treating with CS_2 and NaOH, expelling the excess sulfide by heating. The ether is then washed with water, dried with NaOH and distilled [Kusama & Koike *J Chem Soc Jpn, Pure Chem Sect* **72** 229 *1951*]. Other purification procedures include passage through an activated alumina column to remove peroxides, or through a column of silica gel, and distillation after adding about 3% (v/v) of a 1M solution of MeMgI in *n*-butyl ether. [*Beilstein* **1** IV 1520.]

***n*-Butyl ethyl ether** *[628-81-9]* **M 102.2, b 92.7°, d_4^{20} 0.751, n_D^{20} 1.38175, n^{25} 1.3800.** Purify by drying with $CaSO_4$, by passage through a column of activated alumina (to remove peroxides), followed by prolonged refluxing with Na and then fractional distillation. [*Beilstein* **4** IV 1518.]

***tert*-Butyl ethyl ether** *[637-92-3]* **M 102.2, b 71-72°, d_4^{20} 0.741.** Dry the ether with $CaSO_4$, pass it through an alumina column, and fractionally distil it. [*Beilstein* **1** IV 1618.]

***tert*-Butyl ethyl malonate** *[32864-38-3]* **M 188.2, b 83-85°/8mm, 93-95°/17mm, 107-109°/24mm, d_4^{25} 0.994, n_D^{24} 1.4150.** A likely impurity is monoethyl malonate; check IR for OH bands at 3330 br cm^{-1}. To *ca* 50g of ester add ice cold NaOH (50g in 200ml of H_2O and 200g of ice). Swirl a few times (filter off ice if necessary), place it in a separating funnel and extract with Et_2O (2 x 75ml). Dry the extract ($MgSO_4$) (since traces of acid decompose the *t*-Bu group of the ester, the distillation flask has to be washed with aqueous NaOH, rinsed with H_2O and allowed to dry). Addition of some K_2CO_3 or MgO before distilling is recommended to inhibit decomposition. Distil it under reduced pressure through a 10cm Vigreux column. *Decomposition is evidenced by severe foaming due to autocatalytic decomposition and cannot be prevented from accelerating except by stopping the distillation and rewashing the distillation flask with alkali again.* [Breslow et al. *J Am Chem Soc* **66** 1287 *1944*, Hauser et al. *J Am Chem Soc* **64** 2714 *1942*, Strube *Org Synth* Coll Vol **IV** 417 *1963*, Stube *Org Synth* **37** 35 *1957*, *Beilstein* **2** IV 1884.]

***n*-Butyl formate** *[592-84-7]* **M 102.1, b 106.6°, d_4^{20} 0.891, n_D^{20} 1.3890.** Wash the formate with saturated $NaHCO_3$ solution in the presence of saturated NaCl, until no further reaction occurs, then with saturated NaCl solution, dry ($MgSO_4$), filter and fractionally distil the filtrate. [*Beilstein* **2** IV 28.]

Butyl glycolate *[7397-62-8]* **M 132.2, b 191-192°/755mm, 187-190°/atm, d_4^{20} 1.019, n_D^{20} 1.4263.** Dissolve the ester in $CHCl_3$ (EtOH-free), wash with 5% $KHCO_3$ until effervescence ceases (if free acid is present), dry over $CaCl_2$, filter, evaporate and distil through a short column. [Bøhme & Opfer *Z Anal Chem* **139** 255 *1953*, Filachione et al. *J Am Chem Soc* **73** 5265 *1951*, *Beilstein* **3** IV 589.]

***tert*-Butyl hydroperoxide (TBHP)** *[75-91-2]* **M 90.1, f 5.4°, m 0.5-2.0°, b 38°/18mm, d_4^{20} 0.900, n_D^{20} 1.4013, pK^{20} 12.8.** *Care should be taken when handling this peroxide because of the possibility of* **EXPLOSION. It explodes when heated over an open flame. Work in an efficient fume cupboard, behind a thick plastic transparent shield, and with eye protection.** Alcoholic and volatile impurities can be removed by prolonged refluxing at 40° under reduced pressure, or by steam distillation. For example, Bartlett, Benzing and Pincock [*J Am Chem Soc* **82** 1762 *1960*] refluxed at 30mm pressure in an apparatus for azeotropic liquid separation until the

two phases no longer separated, and then distilled at 41°/23mm. Pure material is stored under N_2, in the dark at 0°. Crude commercial material has been added to 25% NaOH below 30°, and the crystals of the sodium salt have been collected, washed twice with *benzene and dissolved in distilled water. After the pH of the solution is adjusted to 7.5 by adding solid CO_2, the peroxide is extracted into petroleum ether, from which, after drying with K_2CO_3, TBHP is recovered by distilling off the solvent under reduced pressure at room temperature [O'Brien et al. *J Am Chem Soc* **79** 6238 *1957*]. **The temperatures should be kept below 75°**. It has also been distilled through a helices packed column (*ca* 15 plates) and the material with **b 34-35°/20mm** is collected. Similarly, a solution in petroleum ether has been extracted with cold aqueous NaOH, and the hydroperoxide has been regenerated by adding at 0°, $KHSO_4$ to a pH not higher than 4.5, then extracted into diethyl ether, dried with $MgSO_4$, filtered and the ether evaporated in a rotary evaporator under reduced pressure at as low a temperature as possible [Milac & Djokic *J Am Chem Soc* **84** 3098 *1962*].
A 3M solution of TBHP in CH_2Cl_2 is prepared by swirling of commercial TBHP (85ml, 0.61mol, 70% TBHP-30% H_2O, **d** 0.935 *ca* 7.2mmol/ml) with of CH_2Cl_2 (140ml) in a separating funnel. The milky mixture is allowed to stand until the phases separate (*ca* 30 minutes). The organic (lower) layer (*ca* 200ml) containing 0.60mole of TBHP is separated from the aqueous layer (*ca* 21ml) and used without further drying. TBHP is assayed by iodometric titration. With 90% grade TBHP (w/w, d 0.90, *ca* 9.0mmole/ml) no separation of layers occurs, i.e. when TBHP (66.67ml, 0.60mole) is added to CH_2Cl_2 (140ml) the resulting solution (*ca* 200ml) should be clear. [Walling & Buckler *J Am Chem Soc* **77** 6032 *1955*, Rogers & Campbell *J Am Chem Soc* **74** 4742 *1952*, Akashi et al. *J Org Chem* **43** 2063 *1978* state the quality of available grades, handling and compatibility for reactions, *Beilstein* **1** IV 1616.]

***n*-Butyl iodide (1-iodobutane)** *[542-69-8]* **M 184.0, b 130.4°, d $_4^{20}$ 1.616, n^{25} 1.44967.** Dry the iodide with $MgSO_4$ or P_2O_5, fractionally distil it through a column packed with glass helices, taking the middle fraction and storing over calcium or mercury in the dark. *Alternatively*, purify it by prior passage through activated alumina or by shaking with conc H_2SO_4 then washing with Na_2SO_3 solution. It has also been treated carefully with sodium to remove free HI and H_2O, before distilling through a column containing copper turnings at the top. Another purification procedure consisted of treatment with bromine, followed by extraction of free halogen with $Na_2S_2O_3$, washing with H_2O, drying and fractionally distilling. [*Beilstein* **1** IV 271.]

***tert*-Butyl iodide** *[558-17-8]* **M 184.0, b 100°(dec), d $_4^{20}$ 1.544.** Vacuum distillation has been used to obtain a distillate which remained colourless for several weeks at –5°. More extensive treatment has been used by Boggs, Thompson and Crain [*J Phys Chem* **61** 625 *1957*] who washed it with aqueous $NaHSO_3$ solution to remove free iodine, dried this for 1 hour over Na_2SO_3 at 0°, and purified it by four or five successive partial freezings of the liquid to obtain colourless material, and was stored at –78° with Ag wool. [*Beilstein* **1** IV 300.]

***tert*-Butyl isocyanate** *[1609-86-5]* **M 99.1, m 10.5-11.5°, b 30.5-32°/10mm, 64°/52mm, d $_{25}^{25}$ 0.9079, n $_D^{25}$ 1.470.** It is **LACHRYMATORY** and **TOXIC**, and should have IR with 2251 (C≡N) cm^{-1} but no OH bands. The NMR should have one band at 1.37 ppm from TMS. Purify it by fractional distillation under reduced pressure. [Greene & Bergmark *J Org Chem* **36** 3056 *1971*, Curtius *J Prakt Chem* **125** 152 *1930*, *Beilstein* **4** IV 669.]

***tert*-Butyl isocyanide** *[7188-38-7]* **M 83.1, b 91-92°/730mm, 90°/758mm, d $_4^{20}$ 0.735.** Dissolve it in petroleum ether (b 40-60°), wash it with H_2O, dry (Na_2SO_4), filter, remove petroleum ether under slight vacuum, and distil it using a vacuum-jacketed Vigreux column at atmospheric pressure, its IR has a band at 2134 cm^{-1}. [Ugi & Meyr *Chem Ber* **93** 239 *1960*, *Beilstein* **4** IV 661.] It has **toxic vapours**.

***tert*-butyl isocyanoacetate** *[2769-72-4]* **M 141.2, b 50°/0.1mm, 49-50°/10mm, 63-65°/15mm, d $_4^{20}$ 0.970, n $_D^{20}$ 1.420.** If it contains some free acid (OH bands in IR), then dissolve it in Et_2O, shake with 20% Na_2CO_3, dry over anhydrous K_2CO_3, evaporate and distil it. [Ugi et al. *Chem Ber* **94** 2814 *1961*, Schhöllkopf *Angew Chem* **89** 351 1977.]

***n*-Butyl methacrylate** *[97-88-1]* **M 142.2, b 49-52°/0.1mm, 163-165°/atm, d $_4^{20}$ 0.896, n $_D^{20}$ 1.424.** Purify it as for butyl acrylate. [*Beilstein* **2** IV 1525.]

***tert*-Butyl methacrylate** *[585-07-9]* **M 142.2, f –48°, b 135-136°/760mm, d $_4^{20}$ 0.878, n$_D^{20}$ 1.415.** Purify it as for butyl acrylate. [*Beilstein* **2** IV 1582.]

***n*-Butyl methyl ether** *[628-28-4]* **M 88.2, b 70°, d $_4^{20}$ 0.744, pK^{25} –3.50 (aqueous H_2SO_4).** Dry it with $CaSO_4$, pass it through an alumina column to remove peroxides, and fractionally distil it. [*Beilstein* **1** IV 1518.]

***tert*-Butyl methyl ether** (methyl *tert*-butyl ether, MTBE) *[1634-04-4]* **M 88.2, b 56°, n 1.369.** Purify it as for *n*-butyl methyl ether. [*Beilstein* **1** IV 1615.]

***tert*-Butyl methyl ketone (3,3-dimethyl-2-butanone, pinacolone)** *[75-97-8]* **M 100.2, b 105°/746mm, 106°/760mm, d $_4^{20}$ 0.814, n$_D^{20}$ 1.401.** Reflux the ketone with a little $KMnO_4$. Dry it with $CaSO_4$ and distil it. [*Beilstein* **1** IV 3310.]

***tert*-Butyl nitrite** *[540-80-7]* **M 103.1, b 34°/250mm, 61-63°/atm, d $_4^{20}$ 0.8671, n $_D^{25}$ 1.3660.** If it is free from OH bands (IR) then distil it through a 12inch helices packed column under reduced pressure, otherwise wash with aqueous 5% $NaHCO_3$ (**effervescence**), then H_2O, dry (Na_2SO_4) and fractionate it through a 10 theoretical plates column at *ca* 10mm pressure. [Allen *J Chem Soc* 1968 *1954*, Coe & Doumani *J Am Chem Soc* **70** 1516 *1948*, UV: Ungnade & Smiley *J Org Chem* **21** 993 *1956*, IR: Terte *Bull Soc Chim Belg* **60** 240 *1951*, *Beilstein* **1** IV 1622.]

***tert*-Butyl peracetate** *[107-71-1]* **M 132.2, b 23-24°/0.5mm, n^{25} 1.4030.** Wash the ester with $NaHCO_3$ from a *benzene solution, then redistil to remove *benzene [Kochi *J Am Chem Soc* **84** 774 *1962*]. *Handle with adequate protection due to possible* **EXPLOSIVE** *nature*. [*Beilstein* **2** IV 391.]

***tert*-Butylperoxy isobutyrate** *[109-13-7]* **M 160.2, f –45.6°.** After diluting the material (90ml) with petroleum ether (120ml), the mixture is cooled to 5° and shaken twice with 5% NaOH solution (90ml portions, also at 5°). The non-aqueous layer, after washing once with cold water, is dried at 0° with a mixture of anhydrous $MgSO_4$ and $MgCO_3$ containing *ca* 40% MgO. After filtering, this material is passed, twice, through a column of silica gel at 0° (to remove *tert*-butyl hydroperoxide). The solution is then evaporated at 0°/0.5-1mm to remove the solvent, and the residue is recrystallised several times from petroleum ether at –60°, then subjected to high vacuum to remove traces of solvent [Milos & Golubovic *J Am Chem Soc* **80** 5994 *1958*]. *Handle with adequate protection due to possible* **EXPLOSIVE** *nature.*

Butyl stearate *[123-95-5]* **M 340.6, m 26.3°, d $_4^{20}$ 0.861.** Acidic impurities are removed by shaking with 0.05M NaOH or a 2% $NaHCO_3$ solution, followed by several water washes, then purified by fractional freezing of the melt and fractional crystallisation from solvents with boiling points below 100°. [*Beilstein* **2** IV 1219.]

S-*tert*-Butyl thioacetate *[999-90-6]* **M 132.2, b 31-32°/11mm, 38°/14mm, 44-45°/28mm, 67°/54mm, 135.6-135.9°/773mm, d $_4^{25}$ 0.9207, n $_D^{20}$ 1.4532.** Dissolve it in $CHCl_3$ (EtOH-free), wash with H_2O, 10% H_2SO_4, saturated aqueous $NaHCO_3$ (care CO_2 liberated), H_2O again, dry over Drierite and anhydrous K_2CO_3, and fractionate under reduced pressure. [Rylander & Tarbell *J Am Chem Soc* **72** 3021 *1950*, *Beilstein* **2** IV 546.]

***N*-*tert*-Butyl urea** *[1118-12-3]* **M 116.2, m 182°, 185°(dec).** Possible impurity is *N,N′*-di-*tert*-butyl urea which is quite insoluble in H_2O. Recrystallise it from hot H_2O, filter off insoluble material, and cool from 0° to –5° with stirring. Dry in vacuum at room temperature over KOH or H_2SO_4. If dried at higher temperatures, it sublimes slowly. It can be recrystallised from EtOH as long white needles or from 95% aqueous EtOH as plates. During melting point determination the bath temperature has to be raised rapidly as the urea sublimes slowly above 100° at 760mm. [Smith & Emerson *Org Synth* Coll Vol **III** 151 *1955*, *Beilstein* **4** IV 665.]

***n*-Butyl vinyl ether** *[111-34-2]* **M 100.2, b 93.3°, d $_4^{20}$ 0.775.** After five washings with equal volumes of water to remove alcohols (made slightly alkaline with KOH), the ether is dried with sodium and distilled under vacuum, taking the middle fraction [Coombes & Eley *J Chem Soc* 3700 *1957*]. Store it over KOH. [*Beilstein* **1** IV 2052.]

2-Butyne *[503-17-3]* **M 54.1, b 0°/253mm, d $_4^{20}$ 0.693.** Keep it over Na wire for 24 hours, then fractionally distil it under reduced pressure into a cooled receiver. [*Beilstein* **1** IV 971.]

2-Butyne-1,4-diol *[110-65-6]* **M 86.1, m 54-57°, 56-58°, b 238°.** Crystallise the diol from EtOAc. [*Beilstein* **1** IV 2687.]

Butyramide *[514-35-5]* **M 87.1, m 115°, b 230°.** Crystallise it from acetone, *benzene, CCl_4/petroleum ether, 20% EtOH or water. Dry it under vacuum over P_2O_5, $CaCl_2$ or 99% H_2SO_4. [*Beilstein* **2** H 275, **2** I 122, **2** II, 251, **2** III 616, **2** IV 804.]

***n*-Butyric acid** *[107-92-6]* **M 88.1, f –5.3°, b 163.3°, d $_4^{20}$ 0.961, n^{25} 1.396, pK^{25} 2.82.** Distil the acid, them mix it with $KMnO_4$ (20g/L), and fractionally redistil, discarding the first third of the distillate [Vogel *J Chem Soc* 1814 *1948*]. [*Beilstein* **2** IV 779.]

***n*-Butyric anhydride** *[106-31-0]* **M 158.2, b 198°, d $_4^{20}$ 0.968.** Dry the anhydride by shaking it with P_2O_5, then distilling it. [*Beilstein* **2** IV 802.]

γ-Butyrolactone *[96-48-0]* **M 86.1, b 83.8°/12mm, d $_4^{20}$ 1.124.** Dry the lactone over anhydrous $CaSO_4$, then fractionally distil it. *Handle it in a fume cupboard due to its* **TOXICITY.** [*Beilstein* **17** V 7.]

Butyronitrile *[109-74-0]* **M 69.1, b 117.9°, d $_4^{20}$ 0.793, n $_D^{20}$ 1.3846, n^{30} 1.37954.** Treat it with conc HCl until the smell of the isonitrile had gone, then dry with K_2CO_3 and fractionally distil [Turner *J Chem Soc* 1681 *1956*]. *Alternatively*, it is twice heated at 75° and stirred for several hours with a mixture of Na_2CO_3 (7.7g) and $KMnO_4$ (11.5g) per L of butyronitrile. The mixture is cooled, then distilled. The middle fraction is dried over activated alumina. [Schoeller & Wiemann *J Am Chem Soc* **108** 22 *1986*, *Beilstein* **2** IV 806.]

Butyryl chloride (butanoyl chloride) *[141-75-3]* **M 106.6, f –89°, b 101-102°/atm, d $_4^{20}$ 1.026, n$_D^{20}$ 1.412.** Check IR to see if there is a significant peak at 3000-3500 cm^{-1} (br) for OH. If OH is present then reflux it with less than one mole equivalent of $SOCl_2$ for 1 hour and distil directly. The fraction boiling between 85-100° is then refractionated at atmospheric pressure. Keep all apparatus free from moisture and store the product in sealed glass ampoules under N_2. **LACHRYMATORY**; *handle in a good fume hood***.** [Hefferich & Schaeffer *Org Synth* Coll Vol **I** 147 *1941*, *Beilstein* **2** IV 803.]

Capric acid (decanoic acid) *[334-48-5]* **M 172.3, m 31.5°, b 148°/11mm, d $_4^{20}$ 0.886, n^{25} 1.424, pK$_{Est}$ ~4.9.** The acid is best purified by conversion into its *methyl ester*, **b** 114.0°/15mm (using excess MeOH, in the presence of H_2SO_4). The H_2SO_4 and MeOH are removed, the ester is distilled *in vacuo* through a 3ft column packed with glass helices. The acid is then obtained from the ester by saponification and vacuum distillation. [Trachtman & Miller *J Am Chem Soc* **84** 4828 *1962*, *Beilstein* **2** IV 1041.]

***n*-Caproamide (*n*-hexanamide)** *[628-02-4]* **M 115.2, m 100°, 100.5°.** Recrystallise the amide from hot water. [*Beilstein* **2** H 324, **2** I 141, **2** II 286, **2** III 732.]

Caproic acid (hexanoic acid) *[142-62-1]* **M 116.2, b 205.4°, d $_4^{20}$ 0.925, n $_D^{20}$ 1.417, pK^{25} 4.85.** Dry the acid with $MgSO_4$ and fractionally distil it from $CaSO_4$. [*Beilstein* **2** IV 917.]

Capronitrile (hexanenitrile) *[628-73-9]* **M 97.2, m –80°, b 163.7°, n $_D^{20}$ 1.4069, n^{25} 1.4048.** Wash the nitrile twice with half-volumes of conc HCl, then with saturated aqueous $NaHCO_3$, dry over $MgSO_4$, filter and distil it. [*Beilstein* **2** H 324, **2** I 141, **2** II 286, **2** III 733, **2** IV 930.]

Caprylonitrile (heptylcyanide) *[124-12-9]* **M 125.2, m –45°, b 198-200°/~760mm, d $_4^{20}$ 0.812, n $_D^{20}$ 1.420.** Wash the nitrile twice with half-volumes of conc HCl, then with saturated aqueous $NaHCO_3$, dry over $MgSO_4$, filter and distil it. [*Beilstein* **2** H 349, **2** I 148, **2** II 303, **2** III 798, **2** IV 993.]

Carbon Black *[1333-86-4]* **M 12.0, d 1.887/ml, bulk d 0.056g/ml, surface area >200m^2/g, av pore diameter 64Å.** Leach the carbon for 24 hours with 1:1 HCl to remove oil contamination, then wash it repeatedly with distilled water. Dry it in air, and elute for one day each with *benzene and acetone. Again dry it in air at room temperature, then heat it in a vacuum for 24 hours at 600^o to remove adsorbed gases. [Tamamushi & Tamaki *Trans Faraday Soc* **55** 1007 *1959*.]

Carbon disulfide See entry in "Inorganic Compounds", Chapter 5.

Carbon tetrabromide *[558-13-4]* **M 331.7, m 92.5^o.** Reactive bromide is removed from CBr_4 by refluxing with dilute aqueous Na_2CO_3, then steam distilling, crystallising from EtOH, and drying in the dark under vacuum. [Sharpe & Walker *J Chem Soc* 157 *1962*.] It can be sublimed at 70^o and low pressure. **It must not be dried with sodium.** [*Beilstein* **1** IV 85.]

Carbon tetrachloride *[56-23-5]* **M 153.8, b 76.8^o, d^{25} 1.5842.** For many purposes, careful fractional distillation gives adequate purification. Carbon disulfide, if present, can be removed by shaking vigorously for several hours with saturated KOH, separating, and washing with water: this treatment is repeated. The CCl_4 is shaken with conc H_2SO_4 until there is no further coloration, then washed with water, dried with $CaCl_2$ or $MgSO_4$ and distilled (from P_2O_5 if desired). **It must not be dried with sodium.** An initial refluxing with mercury for 2 hours removes sulfides. Other purification steps include passage of dry CCl_4 through activated alumina, and distillation from $KMnO_4$. Carbonyl containing impurities can be removed by percolation through a Celite column impregnated with 2,4-dinitrophenylhydrazine (DNPH), H_3PO_4 and water. (Prepared by dissolving 0.5g DNPH in 6ml of 85% H_3PO_4 by grinding together, then mixing with 4ml of distilled water and 10g Celite.) [Schwartz & Parks *Anal Chem* **33** 1396 *1961*]. Photochlorination of CCl_4 has also been used: CCl_4 to which a small amount of chlorine has been added is illuminated in a glass bottle (e.g. for 24 hours with a 200W tungsten lamp near it), and, after washing out the excess chlorine with 0.02M Na_2SO_3, the CCl_4 is washed with distilled water and distilled from P_2O_5. It can be dried by passing through 4A molecular sieves and distilled. Another purification procedure is to wash CCl_4 with aqueous NaOH, then repeatedly with water and N_2 gas is bubbled through the liquid for several hours. After drying over $CaCl_2$ it is percolated through silica gel and distilled under dry N_2 before use [Klassen & Ross *J Phys Chem* **91** 3664 *1987*]. [*Beilstein* **1** IV 56.]
Rapid purification: Distil, discarding the first 10% of distillate or until the distillate is clear. The distilled CCl_4 is then stored over 5A molecular sieves.

Carbon tetrafluoride *[75-73-0]* **M 88.0, b –15^o.** Purify CF_4 by repeated passage over activated charcoal at solid-CO_2 temperatures. Traces of air are removed by evacuating while alternately freezing and melting. *Alternatively*, liquefy CF_4 by cooling in liquid air and then fractionally distil it under vacuum. (The chief impurity originally present is probably CF_3Cl). Use brass equipment. It is non-flammable, but is TOXIC. [*Beilstein* **1** H 59, **1** I 8, **1** II 11, **1** III 35, **1** IV 26.]

Carbon tetraiodide *[507-25-5]* **M 519.6, m 168^o(dec).** Sublime CI_4 *in vacuo*. [*Beilstein* **1** H 74, **1** IV 98.]

Carbonyl sulfide See "Inorganic Compounds"in Chapter 5.

Cerulenin (helicocerin, 2*R*,3*S*-2,3-epoxy-4-oxo-7*E*,10*E*-dodecadienamide) *[17397-89-6]* **M 223.3, m 93-94^o, 93-95^o, b 120^o/10^{-8}mm, $[\alpha]_D^{16}$ +63^o (c 2, MeOH).** It forms white needles from *C_6H_6. It has also been purified by repeated chromatography through Florisil and silica gel. It is soluble in EtOH, MeOH, *C_6H_6, slightly soluble in H_2O and petroleum ether. The *dl*-form has **m** 40–42^o (from *C_6H_6/hexane), and the 2*R*,3*S*-*tetrahydrocerulenin* has **m** 86–87^o, $[\alpha]_D^{20}$ +44.4 (c 0.25, MeOH after 24 hours). [Ohrui & Emato *Tetrahedron Lett* 2095 *1978*, Sneda et al. *Tetrahedron Lett* 2039 *1979*, Broeckman & Thomas *J Am Chem Soc* **99** 2805 *1977*, Jakubowski et al. *J Org Chem* **47** 1221 *1982*, *Beilstein* **18/2** V 201.]

Cetyl acetate *[629-70-9]* **M 284.5, m 18.3^o, b 158^o/2mm, 204^o/18mm, d_4^{20} 0.861.** Distil the ester in a vacuum twice, then recrystallise it several times from diethyl ether/MeOH. [*Beilstein* **2** H 136, **2** II 146, **2** III 265, **2** IV 171.]

Cetyl alcohol (1-hexadecanol) *[36653-82-4]* **M 242.5, m 49.3°.** Crystallise the alcohol from aqueous EtOH or from cyclohexane. *Alternatively*, purify it by zone refining. The purity can be checked by gas chromatography. [*Beilstein* **1** H 429, **1** I 219, **1** II 466, **1** III 1815, **1** IV 1876.]

Cetylamide *[629-54-9]* **M 255.4, m 104-104.5°, 106-107°, b 235-236°/12mm.** Crystallise the amide from thiophene-free *benzene and dry it under vacuum over P_2O_5. It is slightly soluble in EtOH, Me_2CO, $CHCl_3$ and toluene but insoluble in H_2O. [*Beilstein* **2** H 374, **2** II 341, **2** III 975, **2** IV 1182.]

Cetylamine (1-hexadecylamine) *[143-27-1]* **M 241.5, m 48°, b 162-165°/5.2mm, pK^{25} 10.60.** Crystallise the base from thiophene-free *benzene and dry under vacuum over P_2O_5. Store away from CO_2 [*Beilstein* **4** IV 818.]

Cetylammonium chloride *[1602-97-7]* **M 278.0, m 178°.** Crystallise the salt from MeOH. [*Beilstein* **4** IV 818.]

Cetyl bromide (1-bromohexadecane) *[112-82-3]* **M 305.4, m 15°, 16-18°, b 144.8°/1mm, 171.5-172°/5mm, 190°/11mm, 193-196°/14mm, d^{25} 0.999, n_D^{20} 1.461.** It is prepared by boiling hexadecan-1-ol with 48% aqueous HBr and 25% H_2SO_4 for several hours, distilling and purifying by shaking the bromide with H_2SO_4, washing with H_2O, drying with K_2CO_3 and fractionally distilling it *in vacuo*. [Bezzi & Lanza *Gazzetta* **80** 180 *1950*, Vogel *J Chem Soc* **146** 637 *1943*, Heston et al. *J Am Chem Soc* **72** 2071 *1950*, *Beilstein* **1** H 17, **1** I 68, **1** II 138, **1** III 559, **1** IV 542.]

Cetyl ether (dihexadecyl ether) *[4113-12-6]* **M 466.9, m 54°.** Distil the ether in a vacuum then crystallise it several times from MeOH/*benzene. [*Beilstein* **1** H 430, **1** II 467, **1** III 1820, **1** IV 1878.]

Cetyltrimethylammonium bromide (cetrimonium bromide, CTAB) *[57-09-0]* **M 364.5, m 227-235°(dec).** Crystallise it from EtOH, EtOH/*benzene or from wet acetone after extracting twice with petroleum ether. Shake it with anhydrous diethyl ether, filter and dissolve it in a little hot MeOH. After cooling in the refrigerator, the precipitate is filtered off at room temperature and re-dissolved in MeOH. Anhydrous ether is added and, after warming to obtain a clear solution, it is cooled and the crystalline material is collected and dried *in vacuo*. [Dearden & Wooley *J Phys Chem* **91** 2404 *1987*, Hakemi et al. *J Am Chem Soc* **91** 120 *1987*, *Beilstein* **4** IV 819.]

Cetyltrimethylammonium chloride *[112-02-7]* **M 320.0.** Crystallise the chloride from acetone/ether mixture, EtOH/ether, or from MeOH. [Moss et al. *J Am Chem Soc* **109** 4363 *1987*, *Beilstein* **4** IV 819.]

Charcoal *[7440-44-0]* **M 12.0, m ~3550°.** Charcoal (50g) is added to 1L of 6M HCl and boiled for 45 minutes. The supernatant is discarded, and the charcoal is boiled with two more lots of HCl, then with distilled water until the supernatant no longer gives a test for chloride ion. The charcoal (now phosphate-free) is filtered onto a sintered-glass funnel and dried in air at 120° for 24 hours. [Lippin et al. *J Am Chem Soc* **76** 2871 *1954*.] The purification can be carried out using a Soxhlet extractor (without cartridge), allowing longer extraction times. Treatment with conc H_2SO_4 instead of HCl has been used to remove reducing substances.

Chimyl alcohol (1-*O*-*n*-hexadecylglycerol) *[(±) 506-03-6, 10550-58-0 (chimyl alcohol)]* **M 316.5, m 64°.** Recrystallise it from hexane. [*Beilstein* **1** III 2322.]

Chloral (trichloroacetaldehyde) *[75-87-6, 302-17-0 (hydrate)]* **M 147.4, b 26°/35mm, 98°/760mm. pK^{25} 10.04.** Distil chloral, then dry it by distilling through a heated column of $CaSO_4$. It readily forms a *hydrate* **m 57°**, an *alcoholate* **m 47.5°** [515-83-3] and an *ammonia adduct* **m 72-74°** [507-47-1]. It is a sedative and a hypnotic. [*Beilstein* **1** H 616, **1** I 328, **1** II 467, **1** III 2663, **1** IV 3142 for anhydr, **1** IV 3143 for hydrate.]

Chloralacetone chloroform (2,2,2-trichloro-1-[2,2,2-trichloro-1,1-dimethylethoxy]ethanol) *[512-47-0]* **M 324.9, m 65°.** Crystallise it from *benzene. It sublimes on careful heating and hydrolyses in cold H_2SO_4 to chloral acetone and chloroform. [*Beilstein* **1** H 622.]

Chloroacetaldehyde dimethyl acetal *[97-97-2]* **M 124.6, m –34.4°, b 64°/23mm, 71-72°/35mm, d_4^{20} 1.0172, n_D^{20} 1.4175.** Purify the acetal by fractional distillation, preferably in a vacuum. [Melhotra *J Indian Chem Soc* **36** 4405 *1959*, *Beilstein* **1** IV 3134.]

α-Chloroacetamide *[79-07-2]* **M 93.5, m 121°, b 224-225°/743mm.** Recrystallise the amide from acetone and dry it under vacuum over P_2O_5. [*Beilstein* **2** IV 490.]

Chloroacetic acid *[79-11-8]* **M 94.5, m 62.8°, b 189°, pK^{25} 2.87.** Crystallise the acid from $CHCl_3$, CCl_4, *benzene or water. Dry it over P_2O_5 or conc H_2SO_4 in a vacuum desiccator. Further purification is by distillation from $MgSO_4$, and by fractional crystallisation from the melt. Store it under vacuum or under dry N_2. [Bernasconi et al. *J Am Chem Soc* **107** 3621 *1985*, *Beilstein* **2** IV 474.]

Chloroacetic anhydride *[541-88-8]* **M 171.0, m 46°, b 122-123°/20mm, 203°/760mm, d_4^{20} 1.5494.** Crystallise it from *benzene. [Eglinton et al. *J Chem Soc* 1860 *1954*, *Beilstein* **2** IV 487.]

Chloroacetone *[78-95-5]* **M 92.5, b 61°/50mm, 119°/763mm, d_4^{20} 1.15.** Dissolve it in water and shake it repeatedly with small amounts of diethyl ether which extracts, preferentially, 1,1-dichloroacetone present as an impurity. The chloroacetone is then extracted from the aqueous phase using a large volume of diethyl ether, and distill at slightly reduced pressure. It is dried with $CaCl_2$ and stored at Dry-ice temperature. *Alternatively*, it is kept over $CaSO_4$ for several hours, distilled and stored over $CaSO_4$. It is steam volatile. The *2,4-dinitrophenylhydrazone* forms yellow needles from EtOH with **m** 120° or 124°. [*Beilstein* **1** IV 3215.] **LACHRYMATOR with toxic vapour.**

Chloroacetonitrile *[107-14-2]* **M 75.5, b 125°.** Reflux it with P_2O_5 for one day, then distil it through a helices-packed column. Also purified by gas chromatography. [*Beilstein* **2** IV 492.] **LACHRYMATORY AND HIGHLY TOXIC.**

2-Chlorobutane *[78-86-4]* **M 92.6, b 68.5°, d_4^{20} 0.873, n^{25} 1.3945.** Purify it in the same way as *n*-butyl chloride. [*Beilstein* **1** IV 248.]

***N*-Chlorocarbonyl isocyanate** *[27738-96-1]* **M 105.5, m –68°, b 63.6°/atm, d_4^{20} 1.310.** Fractionally distil it at 760mm using a 40cm column. **TOXIC** *vapour, use a good fume hood.* Store it dry, its IR (film) has ν_{max} at 2260 (NCO), 1818 (CO) and 1420 (NCO sym) cm^{-1}. [Jäckl & Sundmeyer *Chem Ber* **106** 1752 *1975*.]

2-Chloroethanol (ethylene chlorohydrin) *[107-07-3]* **M 80.5, b 51.0°/31mm, 128.6°/760mm, d_4^{20} 1.201, n^{15} 1.444.** Dry it with, then distil it from, $CaSO_4$ in the presence of a little Na_2CO_3 to remove traces of acid. [*Beilstein* **1** IV 1372.]

2-Chloroethyl bromide (1-bromo-2-chloroethane) *[107-04-0]* **M 143.4, b 106-108°, d_4^{20} 1.723, n_D^{20} 1.490.** Wash it with conc H_2SO_4, water, 10% Na_2CO_3 solution, and again with water, then dry with $CaCl_2$ and fractionally distil before use. [*Beilstein* **1** H 89, **1** I 28, **1** II 61, **1** III 179, **1** IV 155.]

2-Chloroethyl chloroformate *[627-11-2]* **M 143.0, b 52-54°/12mm, 153°/760mm, d_4^{18} 1.3760, n_D^{20} 1.446.** Purify it by fractional distillation, preferably in a vacuum, and store it in a dry atmosphere. [Jones *J Chem Soc* 2735 *1957*, *Beilstein* **3** IV 24.]

2-Chloroethyl vinyl ether *[110-75-8]* **M 106.6, b 109°/760mm, d_4^{20} 1.048, n_D^{20} 1.437.** Wash the ether repeatedly with equal volumes of water made slightly alkaline with KOH, dry with sodium, and distil it under a vacuum. Stabilise it with ~0.01% of triethanolamine. [*Beilstein* **1** IV 2051.] **TOXIC**.

Chlorofluoroacetonitrile (ClFCHCN) *[± 92484-61-2 and 359-05-7]* **M 93.4, b 66°/atm, d_4^{20} 1.267, n_D^{25} 1.3627.** It is prepared from ethyl chlorofluoroacetate (see below) by conversion to the amide (0.5mol, b 72-77°/1mm) which is added slowly to, P_2O_5 (0.25mol), and the nitrile (3.5g) is distilled off at 50-70°/atmospheric and redistilled (30g, 66°/atmospheric). It is slowly hydrolysed by H_2O but rapidly by aqueous alkali. [Young &

Tarrant *J Am Chem Soc* **71** 2432 *1949*, *Beilstein* **2** III 454]. Theoretical studies of the molecular dynamics of the enantiomers {(+)- [85196-70-9] and (–)- [85196-71-0]} have been made although they had not been separated [Roselli et al. *J Mol Liq* **28** 1 *1984*, Evans *Phys Rev* A **30** 2062 *1984*, Craig & Elsam *Chem Phys* **73** 349 *1982*]. Samarium (II) iodide [32248-43-4] promotes the reaction of chlorofluoroacetonitrile with aldehydes to form cyanofluorohydrins in the presence of HMPA [Asano et al. *Synthesis* 1309 *2007*].

Chloroform *[67-66-3]* **M 119.4, b 61.2°, d^{15} 1.49845, d^{10} 1.47060, n^{15} 1.44858.** It reacts slowly with oxygen, or oxidising agents, when exposed to air and light, giving, mainly, phosgene, Cl_2 and HCl. Commercial $CHCl_3$ is usually stabilised with up to 1% of EtOH or of dimethylaminoazobenzene. Simplest purifications involve washing with water to remove the EtOH, drying with K_2CO_3 or $CaCl_2$, refluxing with P_2O_5, $CaCl_2$, $CaSO_4$ or Na_2SO_4, and distilling. **It must not be dried with sodium.** The distilled $CHCl_3$ should be stored in the dark to avoid photochemical formation of phosgene. In an alternative purification, $CHCl_3$ (500ml) was shaken (mechanically) with several small portions of 12% H_2SO_4 for 1 hour, washed thoroughly with water, saturated $NaHCO_3$, washed again with water, and dried over $CaCl_2$ or K_2CO_3 (100g) for 1 hour before filtering and distilling. After further drying for a short time over P_2O_5, the $CHCl_3$ was redistilled and stored over Drierite in the dark [Reynolds & Evans *J Am Chem Soc* **60** 2559 *1938*].
EtOH can be removed from $CHCl_3$ by passage through a column of activated alumina, or through a column of silica gel 4-ft long by 1.75-in diameter at a flow rate of 3ml/minute. (The alumina column, which can hold about 8% of its weight of EtOH, is regenerated by air drying and then heating at 600° for 6 hours. It is pre-purified by washing with $CHCl_3$, then EtOH, leaving in conc H_2SO_4 for about 8 hours, washing with water until the washings are neutral, then air drying, followed by activation at 600° for 6 hours. Just before use it is reheated for 2 hours at 154°.) [McLaughlin et al. *Anal Chem* **30** 1517 *1958*.]
Carbonyl-containing impurities can be removed from $CHCl_3$ by percolation through a Celite column impregnated with 2,4-dinitrophenylhydrazine (DNPH), phosphoric acid and water. (Prepared by dissolving 0.5g DNPH in 6ml of 85% H_3PO_4 by grinding together, then mixing with 4ml of distilled water and 10g of Celite.) [Schwartz & Parks *Anal Chem* **33** 1396 *1961*]. Chloroform can be dried by distillation from powdered type 4A Linde molecular sieves. For use as a solvent in IR spectroscopy, chloroform is washed with water (to remove EtOH), then dried for several hours over anhydrous $CaCl_2$ and fractionally distilled. This treatment removes material absorbing near 1600 cm^{-1}. (Percolation through activated alumina increases this absorbing impurity). [Goodspeed & Millson *Chem Ind (London)* 1594 *1967*, *Beilstein* **1** IV 42.]
Rapid purification: Pass through a column of basic alumina (Grade I, 10g/ml of $CHCl_3$), and either dry by standing over 4A molecular sieves, or *alternatively*, distil from P_2O_5 (3% w/v). Store away from light (to avoid formation of phosgene which is tested by shaking with conc NH_3 forming urea) and use as soon as possible.

Chloromethyl methyl ether (MOMCl) *[107-30-2]* **M 80.5, b 55-57°, d_4^{20} 1.060, n_D^{20} 1.396.** If suspect (check IR), shake it with saturated aqueous $CaCl_2$ solution, dry over $CaCl_2$ and fractionally distil taking the middle fraction. *Alternatively*, it can be prepared afresh. While working in a fume cupboard, a rapid stream of HCl gas ([7647-73-6] from a cylinder, or generated from concentrated H_2SO_4 on NaCl) is bubbled through a solution of MeOH (438ml, 10.9moles) and technical formalin **(**900ml, 252g, 8.4moles, [50-00-0]) which is cooled with running water. After 2 hours two layers are formed, but HCl flow is continued for 2 to 3 hours further until saturation. The MOMCl layer is separated, the aqueous phase is saturated with $CaCl_2$, and the additional MOMCl that is salted out is combined with the first lot, dried over $CaCl_2$, filtered and fractionally distilled at atmospheric pressure. The fraction that distils at 55-60° is redistilled to give pure MOMCl (586-600g, 86-89%). [Marvel & Porter *Org Synth* Coll Vol **I** 377 *1941*, *Beilstein* **1** H 580, **1** I 304, **1** II 645, **1** III 2587, **1** IV 3046.] **VERY TOXIC VAPOUR** and **CARCINOGENIC**.

1-Chloro-2-nitroethane *[625-47-8]* **M 109.5, b 37-38°/20mm, 55°/60mm, 127.5°/atm, n_D^{20} 1.4224, n^{25} 1.4235.** Dissolve it in alkali, extract with ether (discard), then the aqueous phase is acidified with hydroxylamine hydrochloride, and the nitro compound is collected and fractionally distilled under reduced pressure. [Pearson & Dillon *J Am Chem Soc* **75** 2439 *1953*, *Beilstein* **1** H 101, **1** III 202, **1** IV 173.]

Chloropicrin (trichloronitromethane) *[76-06-2]* **M 164.5, b 112°.** Dry it over $MgSO_4$ and fractionally distil. [*Beilstein* **1** IV 106.] **EXTREMELY NEUROTOXIC, use appropriate precautions.**

***RS*-2-Chloropropionic acid** *[598-78-7]* **M 108.5, b 98°/3mm, d $_4^{20}$ 1.182, n $_D^{20}$ 1.453 pK^{25} 2.89.** Dry it with P_2O_5 and fractionally distil it under vacuum. [*Beilstein* **2** IV 745.]

***S*-(–)-2-Chloropropionic acid** *[29617-66-1]* **M 108.5, b 77°/10mm, 80.7°/10mm, 185-188°/atm, d $_4^{25}$ 1.2485, n $_D^{25}$ 1.436, [α] $_D^{25}$ –14.6° (neat).** Purify the acid by fractionating twice through a 115cm Podbielniak column (calculated 50 theoretical plates at atmospheric pressure) using a take-off ratio of 1:5. The *acid chloride* is prepared by dissolving the acid in $SOCl_2$, adding a few drops of PCl_3, refluxing and then distilling through a 30cm column, **b** 53°/100mm, [α] $_D^{25}$ –4.6° (neat), d $_4^{25}$ 1.2689, n $_D^{25}$ 1.4368. [Fu et al. *J Am Chem Soc* **76** 6954 *1954*, *Beilstein* **2** IV 745.]

3-Chloropropionic acid *[107-94-8]* **M 108.5, m 41°, pK^{25} 4.08.** Crystallise the acid from petroleum ether or *benzene. [*Beilstein* **2** IV 748.]

3-Chloropropyl bromide (1-bromo-3-chloropropane) *[109-70-6]* **M 157.5, b 142-145°, n^{25} 1.4732.** Wash it with conc H_2SO_4, water, 10% Na_2CO_3 solution, water again and then dry with $CaCl_2$ and fractionally distil it just before use [Akagi et al. *J Am Chem Soc* **78** 4034 *1956*]. [*Beilstein* **1** H 109, **1** IV 212.]

2-Chloro-1,1,1-triethoxyethane *[51076-95-0]* **M 196.7, b 75-80°/5mm, 91°/25mm, 147°/atm, d $_4^{25}$ 1.024, n $_D^{20}$ 1.422.** Distil the chloroethane in a vacuum; but if it is discoloured or suspect, then it is better to prepare it anew. To $(EtO)_3CH$ (ethyl orthoformate see [122-51-0]) in CCl_4 add a slight excess of *N*-chlorosuccinimide and heat to 60° while exposing to a sun lamp. An exothermic reaction occurs during 30 minutes; filter off the succinimide formed, evaporate and distil the residue *in vacuo.* [McElvain & Nelson *J Am Chem Soc* **64** 1825 *1942*, Mylari et al. *Synth Commun* **19** 2921 *1989*, Ueno et al. *J Med Chem* **34** 2468 *1991*, *Beilstein* **2** III 442, **2** IV 482.]

2-Chlorotriethylamine hydrochloride *[869-24-9]* **M 172.1, m 208-210°, pK$_{Est}$ ~8.6 (free base).** Crystallise the salt from absolute MeOH (to remove highly coloured impurities). [*Beilstein* **4** III 240.]

Chlorotrifluoroethylene (CTFE) *[79-38-9]* **M 116.5, b –26 to –24°.** Scrub it with 10% KOH solution, then 10% H_2SO_4 solution to remove inhibitors, dry and pass it through silica gel. It is stabilised with ~1% tributylamine. Use brass equipment. [*Beilstein* **1** III 646.] **TOXIC GAS.**

Chlorotrifluoromethane *[75-72-9]* **M 104.5, m –180°, b –81.5°.** Main impurities are CO_2, O_2, and N_2. The CO_2 is removed by passage through saturated aqueous KOH, followed by concentrated H_2SO_4. The O_2 is removed using a tower packed with activated copper on Kieselguhr at 200°, and the gas is dried over P_2O_5. [Miller & Smyth *J Am Chem Soc* **79** 20 *1957*, *Beilstein* **1** III 42, **1** IV 34.] **TOXIC GAS.**

Choline acetate ([2-hydroxyethyl]trimethylammonium acetate) *[16586-35-7]* **M 163.2, m varies with amount of H_2O.** Choline acetate is a *very hygroscopic* solid and should be kept in well stoppered containers, preferably under N_2 or Ar. [Sasaki & Kobayashi *J Agric Chem Soc* **23** 456 *1949*, *Chem Abstr* **47** 2696 *1953*.] It forms a *gold complex* $[HOCH_2CH_2N^+(Me)_3][AcO^-]$ $[AuCl_3]$ with **m** 263°. *Choline Reineckate* has **m** 267-270° (from aqueous Me_2CO, **m** 226-258° was also reported). *Choline picrate* has **m** 247-247.5° (from EtOH, **m's** of 237-238° and 242-245° were also reported) [Taylor & Kraus *J Am Chem Soc* **69** 1732 *1947*] and *choline picrolonate* has **m** 186° (from EtOH). [*Beilstein* **4** IV 1444.]

Choline chloride ([2-hydroxyethyl]trimethylammonium chloride) *[67-48-1]* **M 139.6, m 302-305°(dec).** *Extremely deliquescent*. Check purity by $AgNO_3$ titration or by titration of OH-base after passage through an anion-exchange column. Crystallise it from absolute EtOH, or EtOH/Et_2O, dry it under vacuum and store it in a vacuum desiccator over P_2O_5 or $Mg(ClO_4)_2$. [*Beilstein* **4** IV 1443.]

Citraconic acid (methylmaleic acid) *[498-23-7]* **M 130.1, m 91°, pK $_1^{25}$ 2.2, pK $_2^{25}$ 5.60 (cis).** Steam distil and crystallise it from EtOH/ligroin. [*Beilstein* **2** H 768, **2** I 309, **2** II 652, **2** III 1938, **2** IV 2230.]

Citraconic anhydride (methylmaleic anhydride) *[616-02-4]* **M 112.1, m 8-9°, b 109°/30mm, 132°/74mm, 213°/760mm, d $_4^{20}$ 1.245, n $_D^{20}$ 1.472.** Possible contamination is from the acid formed by hydrolysis. If the IR

has OH bands, then reflux with Ac_2O for 30 minutes, evaporate, and distil the residue in a vacuum; otherwise distil in a vacuum. Store it in a dry atmosphere. [Vaughan & Andersen *J Am Chem Soc* **77** 6702 *1955*, Vaughan & Andersen *J Org Chem* **21** 680 *1956*, *Beilstein* **17** H 440, **17** I 234, **17** II 448, **17** III/IV 5912, **17/11** V 65.]

Citric acid (H_2O) *[5949-29-1 (monohydrate); 77-92-9 (anhydrous)]* **M 210.1, m 156-157°, 153° (anhyd), pK_1^{25} 2.96, pK_2^{25} 4.38, pK_3^{25} 5.68.** Crystallise it from hot H_2O solution (w/w solubility is 54% at 10°, 71% at 50° and 84% at 100°). The *monohydrate* (softens at ~75° and melts at ~100°) dehydrates in air or when heated gently above 40°. The *triethylester* (*[77-93-0]* **M 276.3, b 127°/1mm, 294°/atm, d_4^{20} 1.137, n_D^{20} 1.4420**) is a bitter tasting oil. [*Beilstein* **3** H 556 and 568, **3** IV 1272.]

Citronellal (3,7-dimethyloctan-6-al) *[R(+) 2385-77-5, S(–) 5949-05-3]* **M 154.3, b 67°/4mm, 89°/14mm, 104-105°/21mm, 207°/760mm, $[\alpha]_{546}^{20}$ (+) and (–) 20°, $[\alpha]_D^{20}$ (+) and (–) 16.5° (neat).** Fractionally distil it. *Alternatively*, extract it with $NaHSO_3$ solution, wash it with Et_2O, then acidify it to decompose the bisulfite adduct and extract with Et_2O, dry (Na_2SO_4), evaporate and distil. Check for purity by hydroxylamine titration. The ORD in MeOH (c 0.167) has: $[\alpha]_{700}$ +9°, $[\alpha]_{589}$ +11°, $[\alpha]_{275}$ +12° and $[\alpha]_{260}$ +12°. The *semicarbazone* has **m** 85°, and the *2,4-dinitrophenylhydrazone* has **m** 79-80°. [(–) Arigoni & Jeager *Helv Chim Acta* **37** 881 *1954*, (+) Eschenmoser & Schinz *Helv Chim Acta* **33** 171 *1950*, *Beilstein* **1** IV 1059-1060.]

β–Citronellol (3,7-dimethyloctan-6-ol) *[R-(+): 11171-61-9, S-(-): 106-22-9]* **M 156.3, b 47°/1mm, 102-104(110)°/10mm, 112-113°/12mm, 221-224°/atm, 225-226°/atm, d_4^{24} 0.8551, n_D^{24} 1.4562, $[\alpha]_{546}^{20}$ (+) and (-) 6.3°, $[\alpha]_D^{20}$ (+) and (-) 5.4° (neat).** Purify them by distillation through a cannon packed (Ni) column and the main cut collected at 84°/14mm and redistilled. Also purify *via* the benzoate. [IR: Eschenazi *J Org Chem* **26** 3072 *1961*, Naves *Bull Soc Chim Fr* 505 *1951*, *Beilstein* **1** IV 2188.]

Crotonaldehyde (2-butenal) *[123-73-9]* **M 70.1, b 104-105°, d_4^{20} 0.851, n_D^{20} 1.437.** Fractionally distil it under N_2, through a short Vigreux column. Stabilise it with 0.01% of 2,6-di-tert-butyl-*p*-cresol and store it in sealed ampoules. [*Beilstein* **1** IV 3447.]

***trans*-Crotonic acid (*trans*-2-butenoic acid)** *[107-93-7]* **M 86.1, m 72-72.5°, pK_1^{25} –6.17 (aqueous H_2SO_4), pK_2^{18} 4.71.** Distil the acid under reduced pressure and/or recrystallise it from petroleum ether (b 60-80°) or water, or by partial freezing of the melt. [*Beilstein* **2** IV 1498.]

***E*- and *Z*-Crotonitrile (mixture)** *[4786-20-3]* **M 67.1, b 120-121°, d_4^{20} 1.091, n_D^{20} 1.4595.** Separate the mixture by preparative GLC on a column using 5% FFAP on Chromosorb G. [Lewis et al. *J Am Chem Soc* **108** 2818 *1986*, *Beilstein* **2** IV 1507.]

***trans*-Crotonoyl chloride** *[625-35-4]* **M 104.5, b 42-45°/20mm, 124-125°/760mm, d_4^{20} 1.080, n_D^{20} 1.4570.** If the IR of a film has no OH bands, then fractionally distil it, taking the middle fraction and redistilling it. If OH bands are present then add excess of oxalyl chloride, reflux for 3 hours, then distil off the reagent and fractionally distil the crotonoyl chloride as before. Stabilise the distillate with 160ppm of hydroquinone. The *amide* forms needles **m** 158° from aqueous ammonia, and the *anilide* also forms needles from H_2O, but with **m** 115-118°. [*Beilstein* **2** H 411, **2** I 188, **2** II 392, **2** III 1265, **2** IV 1506.]

Crotyl bromide *[29576-14-5]* **M 135.0, b 103-105°/740mm, n^{25} 1.4792.** Dry the bromide with $MgSO_4/CaCO_3$ mixture and fractionally distil it through an all-glass Todd column. [*Beilstein* **1** IV 789.]

Cyanoacetamide *[107-91-5]* **M 84.1, m 119.4°.** Crystallise the amide from MeOH/dioxane (6:4), then water

and dry it over P_2O_5 under vacuum. [*Beilstein* **2** IV 1891.]

Cyanoacetic acid *[372-09-8]* **M 85.1, m 70.9-71.1°, pK^{25} 2.47.** Recrystallise the acid to constant melting point from *benzene/acetone (2:3), and dry it over silica gel. [*Beilstein* **2** H 583, **2** I 253, **2** II 530, **2** III 1626, **2** IV 1888.]

Cyanoacetic acid hydrazide *[140-87-4]* **M 99.1, m 114.5-115°.** Crystallise the hydrazide from EtOH. The *hydrochloride* has **m** 178-180° and the *benzylidene* derivative has **m** 178°. It is converted to *3-oxo-5-iminopyrazolidine* in hot 40% aqueous NaOH. [*Beilstein* **2** H 591, **2** I 256, **2** III 1636.] **IRRITANT.**

Cyanoguanidine (dicyanodiamide) *[461-58-5]* **M 84.1, m 209.5°, pK^{25} -0.4.** Recrystallise cyanoguanidine from water or EtOH. [*Beilstein* **3** IV 160.]

***n*-Decane** *[124-18-5]* **M 142.3, m –29.7°, b 57.6°/10mm, 174.1°, d $_4^{20}$ 0.7300, n $_D^{20}$ 1.4102, n^{25} 1.40967.** It can be purified by shaking with conc H_2SO_4, washing with water, aqueous $NaHCO_3$, and more water, then drying with $MgSO_4$, refluxing with Na and distilling. Also purify through a column of silica gel or alumina. It has been purified by azeotropic distillation with 2-butoxyethanol, the alcohol being washed out of the distillate using water, the decane is next dried and redistilled. It can be stored with NaH. Further purification can be achieved by preparative gas chromatography on a column packed with 30% SE-30 (General Electric methyl-silicone rubber) on 42/60 Chromosorb P at 150° and 40psig, using helium [Chu *J Chem Phys* **41** 226 *1964*]. It is soluble in EtOH and Et_2O. [*Beilstein* **1** IV 484.]

Decan-1,10-diol *[112-47-0]* **M 174.3, m 72.5-74°.** Crystallise the diol from dry ethylene dichloride. [*Beilstein* **1** IV 2613.]

***n*-Decanol (*n*-decyl alcohol)** *[112-30-1]* **M 158.3, f 6.0°, b 109°/8mm, 231°/atm, d $_4^{20}$ 0.823, n $_D^{20}$ 1.434.** Fractionally distil *n*-decanol in an all-glass unit at 10mm pressure (**b** 110°), then fractionally crystallise by partial freezing. Also purify by preparative GLC, and by passage through alumina before use. [*Beilstein* **1** IV 1815.]

***n*-Decyl bromide (1-bromodecane)** *[112-29-8]* **M 221.2, b 117-118°/15.5mm, d $_4^{20}$ 1.066.** Shake the it with H_2SO_4, wash with H_2O, dry with K_2CO_3, and fractionally distil it. [*Beilstein* **1** IV 470.]

Decyltrimethylammonium bromide *[2082-84-0]* **M 280.3, m 239-242°.** Crystallise the salt from 50% (v/v) EtOH/Et_2O, or from acetone and wash with ether. Dry it under vacuum at 60°. Also recrystallise it from EtOH and dry it over silica gel. [McDonnell & Kraus *J Am Chem Soc* **73** 2170 *1952*, Dearden & Wooley *J Phys Chem* **91** 2404 *1987*, *Beilstein* **4** IV 784.]

Diacetamide *[625-77-4]* **M 101.1, m 75.5-76.5°, b 222-223°.** Purify the amide by recrystallisation from MeOH [Arnett & Harrelson *J Am Chem Soc* **109** 809 *1987*]. [*Beilstein* **2** H 181.]

(+)-Di-*O*-acetyl-L-tartaric anhydride [(*R,R*)-2,3-diacetoxysuccinic anhydride] *[6283-74-5]* **M 216.2, m 129-132°, 133-134°, 135°, 137.5°, [α] $_D^{20}$ +97.2° (c 0.5, dry $CHCl_3$), [α] $_D^{20}$ +60° (c 6, Me_2CO).** If the IR is good, i.e. no OH bands, then keep it in a vacuum desiccator overnight (over P_2O_5/paraffin) before use. If OH bands are present then reflux 4g in Ac_2O (12.6ml) containing a few drops of conc H_2SO_4 for 10 minutes (use a relatively large flask), pour onto ice, collect the crystals, wash with dry *C_6H_6 (2 x 2ml), stir with 17ml of cold Et_2O, filter and dry in it a vacuum desiccator as above, or store it in dark evacuated ampoules under N_2 in small aliquots. It is not very stable in air, the melting point of the crystals drop one degree in the first four days then remains constant (132-134°). If placed in a stoppered bottle, it becomes gummy and the **m** falls 100° in three days. Recrystallisation leads to decomposition. If good quality anhydride is required it, should be prepared freshly from tartaric acid. It sublimes in a CO_2 atmosphere. [Shriner & Furrow *Org Synth* Coll Vol **IV** 242 *1963*, Bell *Aust J Chem* **34** 671 *1981*, *Beilstein* **18** III/IV 2296.]

1,3-Diaminopropan-2-ol *[616-29-5]* **M 90.1, m 38-40°, pK_1^{25} 7.94, pK_2^{25} 9.57.** Dissolve it in an equal amount of water, shake it with charcoal and distil it at 68°/0.1mm. The distillate solidifies. It is too viscous to be distilled through a packed column. [*Beilstein* **4** IV 1694.]

1,11-Diamino-3,6,9-trioxaundecane [2,2'-oxybis(ethyleneoxy)bisethylamine] *[929-75-9]* **M 192.3, b 115°/0-2mm, 138-153°/1mm, 145-150°/2mm, 135°/3mm, n_D^{20} 1.440.** Distil the diamine under vacuum, but if it is suspect then dissolve it in EtOH add 6N HCl boil for 1 hour, evaporate to dryness, and dry the residue in a vacuum. The solid di-hydrochloride residue is treated with 4N NaOH to release the free base which is extracted into CH_2Cl_2, the extract is dried over K_2CO_3, filtered, evaporated and then distilled in a vacuum. It is a hydrophilic linker in dendrimer formation or biotinylation. [Zhan et al. *J Am Chem Soc* **123** 8914 *2001*, Han et al. *Synth Commun* **21** 79 *1999*, Bogatiskii et al. *J Org Chem USSR* (English Transl) **16** 1124 *1980*, McReynolds et al. *Bioorg Med Chem* **10** 625 *2002*.]

Diazomethane [H_2CN_2] *[334-88-3]* **M 42.0, m –145°, b –23°.** Diazomethane is produced when *N*-methyl-*N*-nitroso-amides, e.g. *N*-methyl-*N*-nitrosourea, *N,N'*-dimethyl-*N,N'*-dinitrosooxamide, *bis*-(*N*-methyl-*N*-nitroso)terephthalamide or *p*-toluenesulfonyl-*N*-methyl-*N*-nitrosoamide (Diazald), are treated with strong solutions of NaOH or KOH. [Fieser and Fieser's *Reagents for Organic Synthesis* **1** 191 *1967*, see also **2** 102 *1969*.] It has been commonly prepared from Diazald as it is commercially available, although *N*-methyl-*N*-nitrosourea, which is readily prepared and stored below 5° [Arndt *Org Synth* Coll Vol **II** 461 *1943*], is also

frequently used. *Diazomethane is a sweet smelling, highly irritating yellow gas which is TOXIC when inhaled, causing severe irritation, pulmonary oedema, asthma, chest pains, headaches, weakness as well as producing hypersensitivity reactions and skin irritation. It is a carcinogen. Diazomethane and its precursors should be handled in an efficient fume cupboard; and because of its potentially explosive nature experiments should be carried out behind a safety screen with face and eye protection.*
Preparation: A distilling flask (100ml) containing KOH (5g) in H_2O (8ml) and diluted with 95% EtOH (25ml) is heated to ~65° using a water bath, and a solution of Diazald (21.4g, see [80-11-5]) in Et_2O (130ml) is added through a dropping funnel in ~25 minutes while the ether which is yellow in colour due to the diazomethane distils off, and the distillate is collected in a receivers immersed in ice. When addition of Diazald is complete, a further volume of Et_2O (20ml) is added dropwise and distillation is continued until the Et_2O distillate is colourless. The yield of diazomethane in the distillate is ~3g. [Note that if 95% EtOH is not added to the KOH solution no diazomethane is formed since the base does not dissolve into the Et_2O.] Do **NOT** redistil this ethereal solution as an explosion may result, particularly from the smaller volume left in the flask. [For alcohol-free diazomethane distillate, the distilling flask should contain diethyleneglycol monomethyl ether (35ml), Et_2O (10ml) and KOH (6g) in H_2O (10ml) to which is added the ethereal Diazald as before.] [deBoer & Backer *Org Synth* **34** 96 1954, *Org Synth* Coll Vol **VI** 943 *1963*, *Rec Trav Chim Pays Bas* **73** 229 *1954*.] By using ^{13}C, ^{14}C and/or ^{2}H or ^{3}H methyl labeled Diazald (some of these are also commercially available) appropriately labeled diazomethane can be prepared. The amount of diazomethane is determined by adding a measured volume of 0.2N pure benzoic acid in ether to an aliquot of the ethereal diazomethane solution which will discharge the yellow colour, meaning that all the diazomethane has been consumed. Water is added to this mixture and the excess of benzoic acid is then titrated with 0.1N aqueous NaOH. (See the safer Me_3SiCHN_2 [18107-18-1].)
For most purposes it is not necessary to distil the diazomethane in ether. In such cases it is better to use *N*-methyl-*N*-nitrosourea because the unwanted products of the reaction are soluble in water. To a mixture of 50% aqueous KOH (60ml) and pure Et_2O (200ml) at 0 to 5° is added solid nitrosomethylurea (20g) with shaking or stirring. The ethereal layer becomes deep yellow and is decanted or siphoned off; or separated if in a separating funnel. The aqueous layer can be extracted with Et_2O to get a further amount of diazomethane. The ethereal solutions can be dried over KOH pellets and can be used directly or kept at ~0° for 2-3 days. [Arndt *Org Synth* Coll Vol **II** 165 *1943*] Diazomethane is a very powerful methylating agent and, in so doing the yellow colour disappears and N_2 bubbles off. It is a versatile reagent in organic synthesis [Black *Aldrichim Acta* **16** 2 *1983*.]

Di-*O*-benzoyl-(*R* and *S*)-tartaric acid (H_2O) *[R-(+) 17026-42-5, S-(–) 2743-38-6 (anhydrous), 62708-56-9 (hydrate)]* **M 376.3, m 88-89° (hydrate), 173° (anhydrous), $[\alpha]_{546}^{20}$ (+) and (–) 136° (c 2, EtOH), $[\alpha]_{D}^{20}$ (+) and (–) 117° (c 5, EtOH), $pK_{Est(1)}$ ~2.9, $pK_{Est(2)}$ ~4.2.** Crystallise the acid from water (18g from 400 ml boiling H_2O) and stir vigorously while cooling in order to obtain crystals; otherwise an oil will separate which solidifies on cooling. Dry it in a vacuum desiccator over KOH/H_2SO_4 (yield 16.4g) as *monohydrate*, **m** 88-89°.
It crystallises from xylene as the *anhydrous acid*, **m** 173° (150-153°). It does not crystallise from $*C_6H_6$, toluene, $*C_6H_6$/petroleum ether (oil), or $CHCl_3$/petroleum ether. [Butler & Cretcher *J Am Chem Soc* **55** 2605 *1933*, Acs et al. *Tetrahedron* **41** 2465 *1985*, *R*(+) *Beilstein* **9** IV 557, *S*(–) *Beilstein* **9** III 870.]

***trans*-1,4-Dibromobut-2-ene** *[821-06-7]* **M 213.9, m 54°, b 85°/10mm.** Crystallise the dibromide from ligroin and/or distil it in a vacuum. [*Beilstein* **1** IV 79.]

Dibromodichloromethane *[594-18-3]* **M 242.7, m 21.8°, b 66°/81mm, d_4^{20} 2.433, n_D^{25} 1.5499.** Crystallise CBr_2Cl_2, repeatedly from its melt, after washing with aqueous $Na_2S_2O_3$ and drying with BaO. *Alternatively*, distil it in a vacuum. Store away from light. [*Beilstein* **1** H 68, **1** III 88, **1** IV 82.]

1,2-Dibromoethane *[106-93-4]* **M 187.9, f 10.0°, b 29.1°/10mm, 131.7°/760mm, d 2.179, n^{15} 1.54160.** Wash the dibromide with conc HCl or H_2SO_4, then water, aqueous $NaHCO_3$ or Na_2CO_3, more water, and dry it with $CaCl_2$. Fractionally distil it. *Alternatively*, keep in daylight with excess bromine for 2 hours, then extract with aqueous Na_2SO_3, wash with water, dry with $CaCl_2$, filter and distil. It can also be purified by fractional crystallisation by partial freezing. Store it in the dark. [*Beilstein* **1** H 90, **1** I 28, **1** II 61, **1** III 182, **1** IV 158.]

Dibromomaleic acid *[608-37-7]* **M 273.9, m 123.5°, 125°(dec), pK_1^{25} 1.45, pK_2^{25} 4.62.** It has been recrystallised from Et_2O or $Et_2O/CHCl_3$. It is soluble in AcOH, also slightly soluble in water, but insoluble in

*C_6H_6 and $CHCl_3$. [Salmony & Simonis *Chem Ber* **38** 2583 *1905*, Ruggli *Helv Chim Acta* **3** 566 *1929*, *Beilstein* **3** IV 2224.]

1,3-Dibromopropane *[109-64-8]* **M 201.9, f –34.4°, b 63-63.5°/26mm, 76-77°/40mm, 90°/80mm, 165°/atm, d_4^{20} 1.977, n 1.522.** Wash the dibromide with dilute aqueous Na_2CO_3, then water. Dry and fractionally distil it under reduced pressure. [*Beilstein* **1** IV 216.]

***meso*-2,3-Dibromosuccinic acid** *[608-36-6]* **M 275.9, m 288-290°(sealed tube, dec), pK_1^{20} 1.56, pK_2^{20} 2.71.** Crystallise the acid from distilled water, keeping the temperature below 70°. [*Beilstein* **2** IV 1930.]

1,2-Dibromotetrafluoroethane *[124-73-2]* **M 259.8, b 47.3°/760mm.** Wash it with water, then with weak alkali. Dry with $CaCl_2$ or H_2SO_4 and distil it. [Locke et al. *J Am Chem Soc* **56** 1726 *1934*.] Also purify it by gas chromatography on a silicone DC-200 column.

Di-*n*-butylamine *[111-92-2]* **M 129.3, b 159°, d_4^{20} 0.761, n_D^{20} 1.41766, pK^{25} 11.25.** Dry this strong base with $LiAlH_4$, CaH_2 or KOH pellets, filter and distil it from BaO or CaH_2. [*Beilstein* **4** IV 550.]

Di-*tert*-butylazodicarboxylate *[870-50-8]* **M 230.3, m 89-92°**, **90-92°.** The *tert*-butyl ester has the advantage over the ethyl ester (below) in being a solid and more acid labile. It crystallises from ligroin and is best purified by covering the dry solid (22g) with petroleum ether (b 30-60°, 35-40 ml) heating to boiling and adding ligroin (b 60-90°) until the solid dissolves. On cooling, large lemon yellow crystals of the ester separate (~ 20g), **m** 90.7-92°. Evaporation of the filtrate gives a further crop of crystals [Carpino & Crowley *Org Synth* **44** 18 *1964*]. This reagent is useful in the Mitsunobu reaction [Mitsunobu *Synthesis* 1 *1981*, Gennari et al. *J Am Chem Soc* **108** 6394 *1986*, Evans et al. *J Am Chem Soc* **108** 6394 *1986*, Hughes *Org React* **42** 335 *1992*, Dodge et al. *Org Synth* **73** 110 *1996*, Hughes *Org Prep Proc Int* **28** 127 *1996*, Ferguson & Marcelle *J Am Chem Soc* **128** 4576 *2006*, see also **DEAD** and **DIAD** below].

Dibutylcarbitol (di[ethyleneglycol]-dibutyl ether, bis[2-butoxethyl]-ether *[112-73-2]* **M 218.3, b 125-130°/0.1mm, d_4^{20} 0.883, n_D^{20} 1.424.** Dibutylcarbitol is freed from peroxides by slow passage through a column of activated alumina. The eluate is then shaken with Na_2CO_3 (to remove any remaining acidic impurities), washed with water, and stored with $CaCl_2$ in a dark bottle [Tuck *J Chem Soc* 3202 *1957*]. [*Beilstein* **1** IV 2395.]

Di-*tert*-butyl dicarbonate (di-*tert*-butyl pyrocarbonate, Boc anhydride) *[24424-99-5]* **M 218.3, m 23° (21-22°), b 55-56°/0.15mm, 62-65°/0.4mm, d_4^{20} 0.950, n_D^{20} 1.409.** Melt the ester by heating at ~35°, and distil it in a vacuum. If the IR and NMR (ν_{max}1810m and 1765 cm^{-1}, δ in CCl_4 1.50 singlet) suggest that it is very impure, then wash it with an equal volume of H_2O containing citric acid to make the aqueous layer slightly acidic, collect the organic layer, dry it over anhydrous $MgSO_4$ and distil it in a vacuum. Store it away from moisture at ~ 4°. If some moisture enters the container pressure may develop since it hydrolyses to *tert*-BuOH and CO_2. It is also available commercially as a 1.0 M solution in THF. It is **FLAMMABLE.** [Pope et al. *Org Synth* **57** 45 *1977*, Keller et al. *Org Synth* **63** 160 *1985*.] It is a useful reagent for easy introduction of the *N*-Boc protecting group in amines [Iwanowicz et al. *Synth Commun* **23** 1443 *1993*], amino acids, peptides and proteins [Keller et al. *Org Synth* **63** 160 *1985*], amides [Flynn et al. *J Org Chem* **48** 2424 *1983*, Grehn et al. *Angew Chem* **97** 519 *1985*], and *N*-Boc-ylation of sensitive compounds in non-aqueous media [Kemp & Carey *J Org Chem* **54** 3640 *1989*]. Boc protection of alcohols has been achieved *via* Lewis acid catalysis [Bartoli et al. *Synlett* 2104 *2006*], and Boc reacted with 4-carboxyphenylhydrazine to form the *N,N,N'-tris*-Boc protected acid which was converted to 4-Fmoc(9-fluorenylmethoxycarbonyl ester)phenyl-hydrazine which is used as a chromophoric reagent to quantify aldehydes attached to a solid-phase since the hydrazine NH_2 group forms a coloured Schiff's base with the aldehyde [Shannon & Barany *J Org Chem* **69** 4586 *2004*]. [See the many volumes of Fieser and Fieser *Reagents for Organic Synthesis*, J Wiley & Sons, for more applications.]

***N,N*-Dibutyl formamide** *[761-65-9]* **M 157.3, b 63°/0.1mm, 118-120°/15mm, 244-246°/760mm, d_4^{20} 0.878, n_D^{20} 1.445.** Purify the amide by fractional distillation [Mandel & Hill *J Am Chem Soc* **76** 3981 *1954*]. [*Beilstein* **4** IV 565.]

Di-*tert*-butyl peroxide (*tert*-butyl peroxide) *[110-05-4]* **M 146.2, d 0.794, n_D^{20} 1.389.** Wash the peroxide with aqueous $AgNO_3$ to remove olefinic impurities, water and dry ($MgSO_4$). Free it from *tert*-butyl hydroperoxide by passage through an alumina column [Jackson et al. *J Am Chem Soc* **107** 208 *1985*], and if necessary two high vacuum distillations from room temperature to a liquid-air trap [Offenbach & Tobolsky *J Am Chem Soc* **79** 278 *1957*]. 2,5-Dichlorobenzoic acid *[50-79-3]* **M 191.0, m 154°, b 301°/760mm, pK^{25} 2.47.** Recrystallise the acid from water. [*Beilstein* **9** IV 1005.]

2,3-Dichloro-1,3-butadiene *[1653-19-6]* **M 123.0, b 41-43°/85mm, 98°/760mm.** Crystallise it from pentane to constant melting point of –40°. A mixture of *meso* and *d,l* forms is separated by gas chromatography on an 8m stainless steel column (8mm i.d.) with 20% DEGS (diethyleneglycolsilyl chloride) on Chromosorb W (60-80 mesh) at 60° and 80ml He/min. Distil it under vacuum. [Su & Ache *J Phys Chem* **80** 659 *1976*.]

1,2-Dichloro-1,2-difluoroethane *[431-06-1]* **M 134.9, b 59°, n_D^{20} 1.376.** Purify it by fractional distillation [Hazeldine *J Chem Soc* 4258 *1952*]. For purification of a diastereoisomeric mixture, with resolution into *meso* and *rac* forms, see Machulla and Stocklin [*J Phys Chem* **78** 658 *1974*].

Dichlorodifluoromethane (Freon 12) *[75-71-8]* **M 120.9, m –158°, b –29.8°/atm, 42.5°/10atm.** Pass the gas through saturated aqueous KOH then conc H_2SO_4, and a tower packed with activated copper on Kielselguhr at 200° to remove CO_2 and O_2. A trap cooled to –29° removes a trace of high boiling material. It is a non-flammable propellant.

1,1-Dichloroethane (ethylidene dichloride) *[75-34-3]* **M 99.0, b 57.3°, d^{15} 1.18350, d_4^{20} 1.177, n^{15} 1.41975.** Shake it with conc H_2SO_4 or aqueous $KMnO_4$, then wash it with water, saturated aqueous $NaHCO_3$, again with water, dry with K_2CO_3 and distil it from CaH_2 or $CaSO_4$. Store it over silica gel. [*Beilstein* **1** IV 130.]

1,2-Dichloroethane *[107-06-2]* **M 99.0, b 83.4°, d_4^{20} 1.256, n^{15} 1.44759.** It is usually prepared by chlorinating ethylene, so that likely impurities include higher chloro derivatives and other chloro compounds depending on the impurities originally present in the ethylene. It forms azeotropes with water, MeOH, EtOH, trichloroethylene, CCl_4 and isopropanol. Its azeotrope with water (containing 8.9% water, has **b** 77°) can be

used to remove gross amounts of water prior to final drying. As a preliminary purification step, it can be steam distilled, and the lower layer is treated as below.
Shake it with conc H_2SO_4 (to remove alcohol added as an oxidation inhibitor), wash with water, then dilute KOH or aqueous Na_2CO_3 and again with water. After an initial drying with $CaCl_2$, $MgSO_4$ or by distillation, it is refluxed with P_2O_5, $CaSO_4$ or CaH_2 and fractionally redistilled. Carbonyl-containing impurities can be removed as described for chloroform. [*Beilstein* **1** IV 131.]

1,2-Dichloroethylene *[cis + trans 540-59-0]* **M 96.9, b 60° (*cis*), d $_4^{20}$ 1.284, b 48° (*trans*), d $_4^{20}$ 1.257.** Shake it successively with conc H_2SO_4, water, aqueous $NaHCO_3$ and water. Dry it with $MgSO_4$ and fractionally distil it through an efficient column to separate the *cis*- and *trans*-isomers. [*Beilstein* **1** IV 707-709.]

***cis*-1,2-Dichloroethylene** *[156-59-2]* **M 96.9, b 60.4°, d $_4^{20}$ 1.2830, n^{15} 1.44903, n $_D^{20}$ 1.4495.** Purify it by careful fractional distillation, followed by passage through neutral activated alumina. Also by shaking with mercury, drying with K_2CO_3 and distilling from $CaSO_4$. Stabilise it with 0.02% of 2,6-di-*tert*-butyl-*p*-cresol. [*Beilstein* **1** IV 707.]

***trans*-1,2-Dichloroethylene** *[156-60-5]* **M 96.9, b 47.7°, n^{15} 1.45189, d $_4^{20}$ 1.2551, n $_D^{20}$ 1.4462.** Dry it with $MgSO_4$, and fractionally distil it under CO_2. Fractional crystallisation at low temperatures has also been used. [*Beilstein* **1** IV 709.]

2,3-Dichloromaleic anhydride *[1122-17-4]* **M 167.0, m 105-115°, 120°, 121-121.5°.** Purify the anhydride by sublimation *in vacuo* [Katakis et al. *J Chem Soc, Dalton Trans* 1491 *1986*]. It has also been purified by Soxhlet extraction with hexane, recrystallisation from $CHCl_3$ and by sublimation. [MS, Relles *J Org Chem* **37** 3630 *1972*]. [*Beilstein* **17/11** V 63.]

Dichloromethane (methylene dichloride) *[75-09-2]* **M 84.9, b 40.0°, d $_4^{20}$ 1.325, n $_D^{20}$ 1.42456, n^{25} 1.4201.** Shake it with portions of conc H_2SO_4 until the acid layer remains colourless, then wash with water, aqueous 5% Na_2CO_3, $NaHCO_3$ or NaOH, then water again. Pre-dry with $CaCl_2$, and distil it from $CaSO_4$, CaH_2 or P_2O_5. Store it away from bright light in a brown bottle with Linde type 4A molecular sieves, in an atmosphere of dry N_2. Other purification steps include washing with aqueous $Na_2S_2O_3$, passage through a column of silica gel, and removal of carbonyl-containing impurities as described under **Chloroform**. It has also been purified by treatment with basic alumina, distillation, and stored over molecular sieves under nitrogen [Puchot et al. *J Am Chem Soc* **108** 2353 *1986*].
Dichloromethane from Japanese sources contained MeOH as stabiliser which is not removed by distillation. It can, however, be removed by standing over activated 3A Molecular Sieves (note that 4A Sieves cause the development of pressure in bottles), passed through activated Al_2O_3 and distilled [Gao et al. *J Am Chem Soc* **109** 5771 *1987*]. It has been fractionated through a platinum spinning band column, degassed, and distilled onto degassed molecular sieves Linde 4A (heated under high vacuum at over 450° until the pressure readings reached the low values of 10^{-6} mm, ~1-2 hours). Stabilise it with 0.02% of 2,6-di-*tert*-butyl-*p*-cresol [Mohammad & Kosower *J Am Chem Soc* **93** 2713 *1971*]. [*Beilstein* **1** IV 35.]
Rapid purification: Reflux over CaH_2 (5% w/v) and distil it. Store it over 4A molecular sieves.

1,2-Dichloropropane *[78-87-5]* **M 113°, b 95.9-96.2°, d $_4^{20}$ 1.158, n $_D^{20}$ 1.439.** Distil the propane from CaH_2. It has a limited shelf life. [*Beilstein* **1** IV 195.]

2,2-Dichloropropane *[594-20-7]* **M 113.0, b 69.3°, d $_4^{20}$ 1.090, n $_D^{20}$ 1.415.** Wash it with aqueous Na_2CO_3 solution, then distilled water, dry it over $CaCl_2$ and fractionally distil it. [*Beilstein* **1** IV 196.]

Di-*n*-decylamine *[1120-49-6]* **M 297.6, m 34°. b 153°/1mm, 359°/760mm, pK_{Est} ~11.0.** Dissolve the amine in *benzene and precipitate it as its bisulfate salt by shaking with 4M H_2SO_4. Filter, wash with *benzene, separate by centrifugation, then the free base is obtained by treating with NaOH [McDowell & Allen *J Phys Chem* **65** 1358 *1961*]. It is a strong base; store away from CO_2. [*Beilstein* **4** IV 780.]

Didodecylamine *[3007-31-6]* **M 353.7, m 51.8°, b 263-265°/27mm, d $_4^{25}$ 0.806, pK^{25} 11.00.** Crystallise the

amine from EtOH/*C_6H_6 under N_2, and store away from CO_2. It provides two crystalline forms: an α-form with **m** 44.4° and a β-form with **m** 51.8°. The *hydrochloride* has **m** 207-208°(dec, from isoProOH), the *hydroiodide* has **m** 23.8-234°(dec, sealed capillary), and the *nitrate* has **m** 125.4-125.2°(dec. sealed capillary) when crystallised from MeOH/Me_2CO. [Hoerr et al. *J Am Chem Soc* **65** 328 1943, Hoerr & Harwood *J Org Chem* **16** 779 *1951*, *Beilstein* **4** III 412, **4** IV 801.]

Didodecyldimethylammonium bromide *[3282-73-3]* **M 463.6, m 157-162°.** Recrystallise the salt from acetone, acetone/ether mixture, then from ethyl acetate, wash with ether and dry it in a vacuum oven at 60° [Chen et al. *J Phys Chem* **88** 1631 *1984*, Rupert et al. *J Am Chem Soc* **107** 2628 *1985*, Halpern et al. *J Am Chem Soc* **108** 3920 *1986*, Allen et al. *J Phys Chem* **91** 2320 *1987*]. [*Beilstein* **4** IV 801.]

Diethanolamine (2,2'-iminodiethanol) *[111-42-2]* **M 105.1, m 28°, b 154-155°/10mm, 270°/760mm pK^{25} 8.88.** Fractionally distil the amine twice, then fractionally crystallise it from its melt. Its solubility in H_2O is 10% at 20°. It absorbs CO_2 and HO_2 from the atmosphere. [Perrin & Dempsey *Buffers for pH and Metal Ion Control* Chapman & Hall, London *1974*, *Beilstein* **4** H 283, **4** II 729, **4** III 689, **4** IV 1514.]

***N,N*-Diethylacetamide** *[685-91-6]* **M 157.2, b 86-88°, d_4^{20} 0.994, n_D^{20} 1.474.** Dissolve the amide in cyclohexane, shake with anhydrous BaO and then filter. The procedure is repeated three times, and the cyclohexane is distilled off at atmospheric pressure. The crude amide is also fractionally distilled three times from anhydrous BaO. [*Beilstein* **4** III 349.]

Diethyl acetamidomalonate *[1068-90-2]* **M 217.2, m 96°.** Crystallise the ester from *benzene/petroleum ether. [*Beilstein* **4** III 2993.]

Diethyl acetylenedicarboxylate *[762-21-0]* **M 170.2, b 60-62°/0.3mm, 107-110°/11mm, 118-120°/20mm, d_4^{20} 1.0735, n_D^{20} 1.4428.** Dissolve the ester in *C_6H_6, wash it with $NaHCO_3$, H_2O, dry over Na_2SO_4, filter, evaporate and distil it in a vacuum [IR: Walton & Hughes *J Am Chem Soc* **79** 3985 *1957*, Truce & Kruse *J Am Chem Soc* **81** 5372 *1959*]. [*Beilstein* **2** H 803.]

Diethylamine *[109-89-7]* **M 73.1, b 55.5°, d_4^{20} 0.707, n 1.38637, pK^{15} 11.38.** Dry diethylamine with $LiAlH_4$ or KOH pellets. Reflux it with, and distil it from, BaO or KOH. Convert it to the *p*-toluenesulfonamide and crystallise it to constant melting point from dry petroleum ether (b 90-120°), then hydrolyse it with HCl; excess NaOH is added, and the amine is passed through a column of activated alumina. Redistil the amine and dry it with activated alumina before use [Swift *J Am Chem Soc* **64** 115 *1942*]. [*Beilstein* **4** III 313.]
§ A polystyrene diethylaminomethyl supported version is commercially available.

Diethylamine hydrochloride *[660-68-4]* **M 109.6, m 223.5°, 226-229°.** Crystallise salt from absolute EtOH. Also recrystallise it from dichloroethane/MeOH. *Hygroscopic.* [*Beilstein* **4** III 113.]

Diethyl azodicarboxylate (DEAD) *[1972-28-7]* **M 174.2, b 104.5°/12mm, 211-213°/atm, d_4^{20} 1.110, n_D^{20} 1.420.** Dissolve DEAD in toluene, wash it with 10% $NaHCO_3$ till neutral (may require several washes if too much hydrolysis had occurred: check IR for OH bands), then it wash with H_2O (2x), dry it over Na_2SO_4, filter, evaporate the toluene and distil it through a short Vigreux column at as high a vacuum as possible. The main portion boils at 107-111°/15mm. *Since it is likely to explode, use an oil bath for heating the still and all operations should be carried out behind an adequate shield with head protection.* [Rabjohn *Org Synth* Coll Vol **III** 375 *1955*, see Kauer *Org Synth* Coll Vol **IV** 412 *1963*]. [*Beilstein* **3** III 233.] It is commercially available as a 40% solution in toluene. This reagent is useful in the Mitsunobu reaction [Mitsunobu *Synthesis* 1 *1981*, Gennari et al. *J Am Chem Soc* **108** 6394 *1986*, Evans et al. *J Am Chem Soc* **108** 6394 *1986*, Hughes *Org React* **42** 335 *1992*, Dodge et al. *Org Synth* **73** 110 *1996*, Hughes *Org Prep Proc Int* **28** 127 *1996*, Ferguson & Marcelle *J Am Chem Soc* **128** 4576 *2006*; see also di-*tert*-butyl azodicarboxylate above and **DIAD** below].
§ A polystyrene supported DEAD version is commercially available with a loading of ~1.2mmol/g.

Diethyl bromomalonate *[685-87-0]* **M 239.1, b 116-118°/10mm, 122-123°/20mm, d_4^{20} 1.420, n_D^{20} 1.4507.** Purify the ester by fractional distillation in a vacuum. Its IR (film) has ν_{max} 1800 and 1700cm^{-1} [Abramovitch

Can J Chem **37** 1146 *1959*, Bretschneider & Karpitschka *Monatsh Chem* **84** 1091 *1053*]. [*Beilstein* **2** IV 1904.]

Diethyl *tert*-butylmalonate *[759-24-0]* **M 216.3, b 40-42°/0.03, 102-104°/11mm, 109.5-110.5°/17mm, 205-210°/760mm, d_4^{20} 0.980, n_D^{20} 1.425.** Dissolve it in Et_2O, wash with aqueous $NaHCO_3$, H_2O, dry ($MgSO_4$), filter, evaporate and distil the residue. Identify by hydrolysis to the acid and determine the neutralisation equivalent (theor: 80.0). The *acid* has **m** 155-157° effervescence [Hauser et al. *J Am Chem Soc* **64** 2715 *1942*, Bush & Beauchamp *J Am Chem Soc* **75** 2949 *1953*]. [*Beilstein* **2** IV 2027.]

Diethyl carbonate *[105-58-8]* **M 118.1, b 124-125°, 126.8°, d_4^{20} 0.975, n^{25} 1.38287.** Wash the ester (100ml) with an aqueous 10% Na_2CO_3 (20ml) solution, saturated $CaCl_2$ (20ml), then water (30ml). After drying by standing over solid $CaCl_2$ for 1 hour (note that prolonged contact should be avoided because slow combination with $CaCl_2$ occurs), it should be fractionally distilled. Also dry it over $MgSO_4$ and distil it. [*Beilstein* **3** H 5, **3** I 4, **3** II 4, **3** III 5, **3** IV 5.]

Diethyl disulfide *[110-81-6]* **M 122.3, b 86.2°/87mm, 154-155°/atm, d_4^{20} 0.993, n_D^{20} 1.506.** Dry the disulfide over silica gel or $MgSO_4$ and distil it under reduced pressure (optionally from $CaCl_2$). [*Beilstein* **1** H 347, **1** I 173, **1** II 345, **1** III 1377, **1** IV 1379.]

Diethylene glycol *[111-46-6]* **M 106.1, f -10.5°, b 244.3°, d_4^{20} 1.118, n^{15} 1.4490, n_D^{20} 1.4475.** Fractionally distil it in a vacuum (**b** 133°/14mm, 2.5cm x 1.3m heli-grid column), then recrystallise it by partial freezing. [Feldman et al. *J Am Chem Soc* **73** 4341 *1951*, *Beilstein* **1** III 2090, **1** IV 2390.]

Diethylene glycol diethyl ether *[112-36-7]* **M 162.2, b 76°/32mm, 85-86°/10mm, 188.2-188.3°/751mm, d_4^{20} 0.910, n_D^{20} 1.412.** Dry the ether with $MgSO_4$, then CaH_2 or $LiAlH_4$, under N_2. If sodium is used, the ether should be redistilled alone to remove any products which may be formed by the action of sodium on the ether. As a preliminary purification, the crude ether (2L) can be refluxed for 12 hours with 25ml of conc HCl in 200ml of water, under reduced pressure, with slow passage of N_2 to remove aldehydes and other volatile substances. After cooling, add sufficient solid KOH pellets (slowly and with shaking until no more dissolves) to give two liquid phases. The upper of these is decanted, dried with fresh KOH pellets, decanted, then refluxed over, and distilled from sodium. It can be passed through (alkaline) alumina prior to purification. [*Beilstein* **1** IV 2394.]

Diethylene glycol ditosylate *[7460-82-4]* **M 414.5, m 86-87°, 87-88°, 88-89°**. Purify the ester by recrystallisation from Me_2CO and dry it in a vacuum. [*Beilstein* **11** III 225.]

Diethylene glycol mono-*n*-butyl ether (butyl carbitol) *[112-34-5]* **M 162.2, b 69-70°/0.3mm, 230.5°/760mm, d_4^{20} 0.967, n_D^{20} 1.4286.** Dry the ether with anhydrous K_2CO_3 or $CaSO_4$, filter and fractionally distil it. Peroxides can be removed by refluxing with stannous chloride or a mixture of $FeSO_4$ and $KHSO_4$ (or, less completely, by filtration under slight pressure through a column of activated alumina). [*Beilstein* **1** IV 2394.]

Diethylene glycol monoethyl ether *[111-90-0]* **M 134.2, b 201.9°, d_4^{20} 0.999, n_D^{20} 1.4273, n^{25} 1.4254.** Ethylene glycol can be removed by extracting 250g in 750ml of *benzene with 5ml portions of water, allowing for phase separation, until successive aqueous portions show the same volume increase. Dry, and free from peroxides, as described for diethylene glycol mono-*n*-butyl ether. [*Beilstein* **1** IV 2393.]

Diethylene glycol monomethyl ether *[111-77-3]* **M 120.2, b 194°, d_4^{20} 1.010, n_D^{20} 1.423.** Purify it as for diethylene glycol mono-*n*-butyl ether. [*Beilstein* **1** IV 2392.]

Diethylenetriaminepenta-acetic acid (DTPA, DEPTAPAC) *[67-43-6]* **M 393.4, m 219-220°, pK_1^{25} 1.79, pK_2^{25} 2.56, pK_3^{25} 4.42, pK_4^{25} 8.76, pK_5^{25} 10.42.** Crystallise DTPA from water. Dry it under vacuum or at 110°. [Bielski & Thomas *J Am Chem Soc* **109** 7761 *1987*, NMR: Wenzel et al. *Anal Chem* **54** 615 *1982*, *Beilstein* **4** IV 2454.]

Diethyl ether (ethyl ether) *[60-29-7]* **M 74.1, b 34.6°/760mm, d_4^{20} 0.714, n^{15} 1.3555, n_D^{20} 1.35272.** Usual

impurities are water, EtOH, diethyl peroxide (which is explosive when concentrated), and aldehydes. Peroxides [detected by liberation of iodine from weakly acid (HCl) solutions of KI, or by the blue colour in the ether layer when 1mg of $Na_2Cr_2O_7$ and 1 drop of dilute H_2SO_4 in 1ml of water is shaken with 10ml of ether] can be removed in several different ways. The simplest method is to pass dry ether through a column of activated alumina (80g Al_2O_3/700ml of ether). More commonly, 1L of ether is shaken repeatedly with 5-10ml of a solution comprising 6.0g of ferrous sulfate and 6ml of conc H_2SO_4 in 110ml of water. Aqueous 10% Na_2SO_3 or stannous chloride can also be used. The ether is then washed with water, dried for 24 hours with $CaCl_2$, filtered and dried further by adding sodium wire until it remains bright. The ether is stored in a dark cool place, until distilled from sodium before use. Peroxides can also be removed by wetting the ether with a little water, then adding excess $LiAlH_4$ or CaH_2 and leaving to stand for several hours. (This also dried the ether.)
Werner [*Analyst* **58** 335 *1933*] removed peroxides and aldehydes by adding 8g $AgNO_3$ in 60ml of water to 1L of ether, then 100ml of 4% NaOH and shaking for 6 minutes. Fierz-David [*Chimia* **1** 246 *1947*] shook 1L of ether with 10g of a zinc-copper couple. (This reagent is prepared by suspending zinc dust in 50ml of hot water, adding 5ml of 2M HCl and decanting after 20 seconds, washing twice with water, covering with 50ml of water and 5ml of 5% cuprous sulfate with swirling. The liquid is decanted and discarded, and the residue is washed three times with 20ml of ethanol and twice with 20ml of diethyl ether).
Aldehydes can be removed from diethyl ether by distillation from hydrazine hydrogen sulfate, phenylhydrazine or thiosemicarbazide. Peroxides and oxidisable impurities have also been removed by shaking with strongly alkaline saturated-$KMnO_4$ (with which the ether was left to stand in contact for 24 hours), followed by washing with water, conc H_2SO_4, water again, then drying ($CaCl_2$) and distillation from sodium, or sodium containing benzophenone to form the ketyl. Other purification procedures include distillation from sodium triphenylmethide or butyl magnesium bromide, and drying with solid NaOH or P_2O_5. [*Beilstein* **1** IV 1314.]
Rapid purification: Same as for 1,4-dioxane.

Diethyl ethoxymethylene malonate *[87-13-8]* **M 216.2, b 014°/0.2mm, 109°/0.5mm, 279-283°/atm, d $_4^{20}$ 1.079, n $_D^{20}$ 1.4623.** Likely impurity is diethyl diethoxymethylene malonate which is difficult to separate from diethyl ethoxymethylene malonate by distillation, and it is necessary to follow the course of the distillation by the change in refractive index instead of boiling point. After a low boiling fraction is collected, there is obtained an intermediate fraction (n $_D^{20}$ 1.414—1.458), the size of which depends on the amount of the diethoxymethylene compound. This fraction is fractionated through a 5inch Vigreux column at low pressure, and avoiding interruption in heating. Fraction **b** 108-110°/0.25mm is *ca* 10° lower than the submitters' fraction (**b** 97.2°/0.25mm, n $_D^{20}$ 1.4612—1.4623) [*Org Synth* Coll Vol **III** 395 *1955*, Fuson et al. *J Org Chem* **11** 197 *1946*, Duff & Kendal *J Chem Soc* 893 *1948*]. [*Beilstein* **3** IV 1192.]

***N,N′*-Dimethylethylenediamine [1,2-bis(methylamino)ethane]** *[110-70-3]* **M 88.2, b 110-112°/750mm, 119°/760mm, d $_4^{20}$ 0.819, n $_D^{20}$ 1.431, (pK^{25} 7.01 and 9.88).** This strong base has been prepared in various ways including hydrolysis of *N,N'-di(benzylsulfonyl)-N,N'-dimethylethylenediamine* (**m 217-219°**, from AcOH) and concentrated HCl (120-130°) [Johnson & Bailey *J Am Chem Soc* **38** 2135 *1916*], the reaction of 1,2-dibromoethane with 21-33% aqueous $MeNH_2$ in EtOH (reflux for 2 hours, 50% yield) [Kermack & Wight *J Chem Soc* 1421 *1935*, Woodburn & O'Gee *J Org Chem* **17** 1235 *1952*], hydrolysis of *N,N'-di(p-toluenesulfonyl)-N,N'-dimethylethylenediamine* (1mol, **m 164°**, from AcOH) with H_2SO_4 (8.2mol) and H_2O (9mol) at 140-145°/7 hours [Boon *J Chem Soc* 307 *1947*], LAH reduction in THF of *3-benzenesulfonyloxy-5,6-dihydrouracil* (**m 175-176°**, from iso-PrOH) and isolated as the *dibenzoyl derivative* (41%, **m 177-178°**, from $*C_6H_6$) [Bauer *J Am Chem Soc* **78** 1945 *1956*], and by catalytic hydrogenation of *N-benzyl-N,N'-dimethylethylenediamine* (**b 73-74°/0.1mm**) with 10% Pd/C [Jucker & Rissi *Helv Chim Acta* **45** 2383 *1962*]. General isolation and purification procedures involve steam distillation of the product diamine, acidifying the distillate with HCl, evaporating to dryness, treating the residual salt with 10% excess of cold 32% aqueous NaOH, collecting the organic layer (**care**: very caustic solution), drying it over solid KOH, and distilling from it. Final distillation of the dry base over Na has been reported (see also [107-15-3]). The diamine is a strong base and readily absorbs CO_2 and H_2O from the atmosphere—store it in a dark stoppered bottle, wax the stopper if it should be stored for long periods. The *dihydrochloride* [5752-40-9] has **m 235-236°(dec)**, and the *picrate* has **m 160°** (from EtOH and Me_2CO in rectangular plates). It forms complexes with Cu, Ni, and Pt among other metals. Its FT-IR (neat) has ν_{max} at

3285.5, 2788.2, 1447.2, 1346.5, 1251.0, 1106.5, 1040.5, 876.9, 763.7 cm^{-1}. [For pK and metal complexes see Gastafson & Martell *J Am Chem Soc* **81** 525 *1959*, *Beilstein* **4** H 250, **4** I 415, **4** II 689, **4** III 512, **4** IV 1171.]

***N,N'*-Diethylformamide** *[617-84-5]* **M 101.2, b 29°/0.5mm, 61-63°/10mm, 178.3-178.5°/760mm, d $_4^{20}$ 0.906, n $_D^{25}$ 1.4313.** Distil it under reduced pressure, then at atmospheric pressure [Wintcler et al. *Helv Chim Acta* **37** 2370 *1954*, NMR: Hoffmann *Z Anal Chem* **170** 177 *1959*]. [*Beilstein* **4** IV 346.]

Diethyl fumarate *[623-91-6]* **M 172.2, b 218°, d 1.052, n 1.441.** Wash the fumarate with aqueous 5% Na_2CO_3, then with saturated $CaCl_2$ solution, dry with $CaCl_2$ and distil it. [*Beilstein* **2** IV 2207.] Note that **dimethyl fumarate** *[624-49-7]* **M 144.1, m 102°, b 192-193°/atm** is a solid. [*Beilstein* **2** IV 2205.]

***N,N*-Diethyl-1,1,2,3,3,3-hexafluoropropylamine (Ishikawa's Reagent, perfluoropropyldiethylamine, PPDA)** *[309-88-6]* **M 223.2, b 56-57°/58mm d $_4^{25}$ 1.230, n $_D^{20}$ 1.3460.** When this reagent is prepared from diethylamine (11g, 0.15mol) in dry Et_2O (30ml) in a glass pressure bomb cooled to –70° (Me_2CO/Dry Ice), and liquefied *F*-propene (25.5g, 0.17mol, see[116-15-4]) is added, and the temperature of the sealed bomb is allowed to rise to ~25°, and stirred at this temperature overnight, the reaction is complete. Crystalline $Et_2NH.HF$ is removed by fitration, the solvent (Et_2O) is evaporated, and the residual oil is distilled in a vacuum to give a liquid (23.7g, ~72%) which boils at **56-57°/58mm**. This liquid is shown, by its ^{19}F NMR signal intensities, to be a 3:1 mixture of PPDA and exclusively (*E*)-*N,N*-**d**iethyl-**p**entafluoro-**p**ropenyl**a**mine (*trans*-dppa) with respectively δ_F [PPDA] at -3.0 (1-CF_3), 6.0 (3-CF_A), 11.0 (3-CF_B), 131.0 (2-CF), and δ_F [*trans*-dppa] at –12.0 (1–CF_3, $^{1,3}J$ = 14Hz, $^{1,4}J$ = 23.5Hz), 41.0 (3-CF, $^{1,4}J$ = 23.5Hz, $^{1,3}J_{trans}$ = 117Hz), 122 (2-CF, $^{1.3}J$ = 14Hz, $^{1,3}J_{trans}$ = 117Hz) upfield from external CF_3CO_2H with 3:1 relative intensities. The mixture is easy to handle, and is stable on storage at room temperature without discolouration or loss of activity for at least 6 months. It reacts with a variety of CHOH groups to form the respective CHF derivatives, with carboxylic acids to form the acid fluorides [Takaoka, Iwakiri and Ishikawa *Bull Chem Soc Jpn* **11** 3377 *1979*, Watanabe, Fujita, Ushi and Kitazume *J Fluorine Chem* **31** 247 *1986*, Watanabe, Fujita, Sakamoto, Kuramochi and Kitazume *J Fluorine Chem* **36** 361 *1987*], and allylic alcohols to form α-fluoro-α-(trifluoromethyl)-γ,δ-unsaturated amide precursors [Ogu, Akazome and Ogura *Tetrahedron Lett* **39** 305 *1998*]. The crude 3:1 reaction product has been used satisfactorily without distillation. The presence of 33% of *trans*-dppa is not a drawback because HF is liberated in these reaction of PPDA with OH, and the HF that is liberated adds on to the olefinic *trans*-dppa to give PPDA; so that as long as there is at least equal amounts of these two compounds the mixture behaves as if it were completely made up of DDPA.
When the above synthesis is carried out at ~5-10° while *F*-propene is bubbled through (completely absorbed within 2 hours), then stirred at ~25° overnight, an oil is obtained (89% yield) with **51-53°/58mm** which is a 1:1 mixture (by ^{19}F NMR) of PPDA and *trans*-dppa. If *n*-Bu_2NH, or piperidine, replace Et_2NH in the reaction at –70° in sealed bombs, (*n*-$Bu)_2N$-CF_2CHFCF_3 and (*E*)-(*n*-$Bu)_2N$-CF=$CFCF_3$ (**55-57°/5mm**, 2:1, 78% yield) or $C_5H_{10}N$-CF_2CHFCF_3 only (**49-50°/7mm**, 80% yield) respectively are obtained [Takaoka, Iwakiri and Ishikawa *Bull Chem Soc Jpn* **11** 3377 *1979*].

Diethyl ketone (3-pentanone) *[96-22-0]* **M 86.1, b 102.1°, d $_4^{20}$ 0.8099, n $_D^{20}$ 1.392.** The ketone is dried with anhydrous $CaSO_4$ or $CuSO_4$, and distil from P_2O_5 under N_2 or under reduced pressure. Further purification is by conversion to the semicarbazone (recrystallise to constant **m** 139°, from EtOH) which, after drying *in vacuo* over $CaCl_2$ and paraffin wax, is refluxed for 30 minutes with excess oxalic acid, then steam distilled and salted out with K_2CO_3. Dry with Na_2SO_4 and distil [Cowan et al. *J Chem Soc* 171 *1940*]. [*Beilstein* **1** IV 3279.]

Diethyl malonate *[105-53-3]* **M 160.2, b 92°/22mm, 198-199°/760mm, d $_4^{20}$ 1.056, d^{25} 1.0507, n $_D^{20}$ 1.413.** If too impure (IR, NMR) the ester (250g) is heated on a steam bath for 36 hours with absolute EtOH (125ml) and conc H_2SO_4 (75ml), then fractionally distilled under reduced pressure. Otherwise fractionally distil it under reduced pressure and collect the steady boiling middle fraction. [*Beilstein* **2** IV 1881.]

2,2-Diethyl-1,3-propanediol *[115-76-4]* **M 132.2, m 61.4-61.8°, b 130-133°/16mm, n $_D^{20}$ 1.4574.** Crystallise the diol from petroleum ether (b 65-70°). **IRRITANT.** [McKusick *J Am Chem. Soc* **70** 1982 *1948*, *Beilstein* **1**

III 2217, **1** IV 2589.]

Diethyl pyrocarbonate (DEP) *[1609-47-8]* **M 162.1, b 38-40°/12mm, 160-163°/atm, d $_4^{20}$1.119, n $_D^{20}$ 1.398.** Dissolve the ester in Et_2O, wash it with dilute HCl, H_2O, dry over Na_2SO_4, filter, evaporate and distil the residue first *in vacuo* then at atmospheric pressure. It is soluble in alcohols, esters, ketones and hydrocarbon solvents. A 50% w/w solution is usually prepared for general use. **Treat with great CAUTION as DEP irritates the eyes, mucous membranes and skin.** [Boehm & Mehta *Chem Ber* **71** 1797 *1938*, Thoma & Rinke *Justus Liebigs Ann Chem* **624** 30 *1959*, *Beilstein* **3** IV 18.]

Diethyl succinate *[123-25-1]* **M 174.2, b 105°/15mm, 218°/atm, d $_4^{20}$ 1.047, n $_D^{20}$ 1.4199.** Dry the succinate with $MgSO_4$, and distil it at 15mm pressure. [*Beilstein* **2** IV 1914.]

Diethyl sulfate *[64-67-5]* **M 154.2, b 96°/15mm, 118°/40mm, d $_4^{20}$ 1.177, n $_D^{20}$ 1.399.** Wash the ester with aqueous 3% Na_2CO_3 (to remove acidic material), then distilled water, dry ($CaCl_2$), filter and distil it in a vacuum. *It is an ethylating agent and blisters the skin.* [*Beilstein* **1** IV 1236.]

Diethyl sulfide *[352-93-2]* **M 90.2, m 0°/15mm, b 90.1°/760mm, d $_4^{20}$ 0.837, n $_D^{20}$ 1.443.** Wash the sulfide with aqueous 5% NaOH, then water, dry with $CaCl_2$ and distil it from sodium. It can also be dried with $MgSO_4$ or silica gel. *Alternative*, purification is *via* the Hg(II) chloride complex [$(Et)_2S.2HgCl_2$] (see dimethyl sulfide). [*Beilstein* **1** IV 1394.]

Diethyl (–)-D- (from the non-natural) *[13811-71-7]* **and (+)-L- (from the natural acid)** *[89-91-2]* **tartrate M 206.2, m 17°, b 80°/0.5mm, 162°/19mm, 278-282°/atm, d $_4^{20}$ 1.204, n $_D^{20}$ 1.4476, [α] $_D^{20}$ (+) and (+) 26.5° (c 1, H_2O) and (–) and (+) 8.5° (neat), [α] $_{546}^{20}$ (+) and (+) 30° (c 1, H_2O).** Distil the esters under high vacuum and store them under vacuum or in an inert atmosphere in a desiccator in round bottomed flasks equiped with a vacuum stopcock. They have also been distilled by Kügelrohr distillation and/or by 'wiped-film' molecular distillation. They are slightly soluble in H_2O but miscible with EtOH and Et_2O. [Gao et al. *J Am Chem Soc* **109** 5770 (5771) *1987*, IR: Pristera *Anal Chem* **25** 844 *1953*, *Beilstein* **3** III 1025 for D-(–), **3** IV 1232 for L(+).]

***sym*-Diethylthiourea** *[105-55-5]* **M 132.2, m 76-77°. 77-79°.** Crystallise it from *benzene. [*Beilstein* **4** H 118, **4** I 355, **4** II 610, **4** III 220, **4** IV 375.]

Difluoroacetic acid *[381-73-7]* **M 96.0, m –0.35°, b 67-70°/20mm, 134°/760mm, d $_4^{20}$ 1.530, n $_D^{20}$ 1.3428, pK^{25} 1.28.** Purify the acid by distilling over P_2O_5. The *acid chloride* is a fuming liquid **b** 25°/atm, the *amide* has **b** 108.6°/35mm, **m** 52° (from *C_6H_6), and the *anilide* has **b** 90°/1mm, 114°/5mm, **m** 58° [Henne & Pelley *J Am Chem Soc* **74** 1426 *1952*, Coffman et al. *J Org Chem* **14** 749 *1949*, NMR: Meyer et al. *J Am Chem Soc* **75** 4567 *1953*, pK: Wegscheider *Z Phys Chem* **69** 614 1909]. [*Beilstein* **2** IV 455.]

Diglycolic acid (2-oxapentane-1,5-dioic acid) *[110-99-6]* **M 134.1, m 148° (monohydrate), pK $_1^{25}$ 2.97, pK $_2^{25}$ 4.37.** Crystallise diglycolic acid from water. [*Beilstein* **3** IV 577.]

Diglyme [bis(2-methoxyethyl) ether, diethylene glycol dimethyl ether] *[111-96-6]* **M 134.2, b 62°/17mm, 75°/35mm, 160°/760mm, d $_4^{20}$ 0.917, n $_D^{20}$ 1.4087.** Dry diglyme with NaOH pellets or CaH_2, then reflux with, and distil it (under reduced pressure) from Na, CaH_2, $LiAlH_4$, $NaBH_4$ or NaH. These operations are carried out under N_2. The amine-like odour of diglyme has been removed by shaking with a weakly acidic ion-exchange resin (Amberlite IR-120) before drying and distilling. Addition of 0.01% $NaBH_4$ to the distillate inhibits peroxidation. Purify it also as for dioxane. It has been passed through a 12-in column of molecular sieves to remove water and peroxides. [*Beilstein* **1** IV 2393.]

Dihydroxyfumaric (1,2-dihydroxybut-1-ene-1,2-dioic) acid dihydrate *[133-38-0]* **M 184.1, m 155°(dec), pK $_1^{25}$ 1.57, pK $_2^{25}$ 3.36.** Crystallise the acid from water. [*Beilstein* **3** IV 1975.]

1,2-Diiodoethane *[624-73-7]* **M 281.9, m 81-84°, d 2.134.** Dissolve it in ether, wash it with saturated aqueous $Na_2S_2O_3$, dry it over $MgSO_4$, and evaporate the ether *in vacuo* then distil it. Store it in the dark.

[Molander et al. *J Am Chem Soc* **109** 453 *1987*]. [*Beilstein* **1** IV 169.]

Diiodomethane (methylene diiodide) *[75-11-6]* **M 267.8, m 6.1°, b 66-70°/11-12mm, d_4^{20} 3.325.** Fractionally distil it under reduced pressure, then fractionally crystallise it by partial freezing, and stabilise it with silver wool if necessary. It has also been purified by drying over $CaCl_2$ and fractionally distilling from Cu powder. Store it in the dark. [*Beilstein* **1** IV 97.]

Diisopropanolamine *[110-97-4]* **M 133.2, m 41-44°, d_4^{20} 1.004, pK_{Est} ~10.7.** Crystallise the amine repeatedly from dry diethyl ether. It is a strong base, store away from CO_2 and H_2O. [*Beilstein* **4** III 761.]

Diisopropylamine *[108-18-9]* **M 101.2, b 83.5°/760mm, d_4^{20} 0.720, n_D^{20} 1.39236, pK^{25} 11.20.** Distil the amine from NaOH, or reflux it three minutes over Na wire or NaH, and distil it into a dry receiver under N_2. It is a strong base, store away from CO_2 and H_2O. [*Beilstein* **4** H 154, **4** I 369, **4** II 630, **4** III 274, **4** IV 510.]
§ A polystyrene supported version of diisopropylamine is commercially available.

Diisopropylazodicarboxylate (DIAD) *[2446-83-5]* **M 202.2, b 75°/0.2mm, d^{25} 1.420, n_D^{20} 1.420.** Purify the azo compound by distillation at as high a vacuum as possible. Since it is likely to explode, use an oil bath for heating the still, and all operations should be carried out behind an adequate shield. [Kauer *Org Synth* Coll Vol **IV** 412 *1963*, *Beilstein* **3** III 233]. This reagent is useful in the Mitsunobu reaction [Mitsunobu *Synthesis* 1 *1981*, Gennari et al. *J Am Chem Soc* **108** 6394 *1986*, Evans et al. *J Am Chem Soc* **108** 6394 *1986*, Hughes *Org React* **42** 335 *1992*, Dodge et al. *Org Synth* **73** 110 *1996*, Hughes *Org Prep Proc Int* **28** 127 *1996*, Ferguson & Marcelle *J Am Chem Soc* **128** 4576 *2006*; see also di-*tert*-butyl azodicarboxylate and **DEAD** above].

Diisopropylethylamine (Hünig's base) *[7087-68-5]* **M 129.3, b 119°/731mm, 127°/760mm, d_4^{27} 1.440, n_D^{25} 1.4376, pK_{Est} ~10.9.** Distil the amine from ninhydrin, then from KOH [Dryland & Sheppard, *J Chem Soc, Faraday Trans 1* 125 *1986*]. It is a strong base and should be stored in the absence of carbon dioxide. [Hünig & Kiessel *Chem Ber* **91** 380, 387 *1958*, Wotiz et al. *J Org Chem* **24** 1202 *1959*, *Beilstein* **4** IV 551.]

Diisopropyl ketone (2,4-dimethyl-3-pentanone) *[565-80-0]* **M 114.2, b 124°, d 0.801, n 1.400.** Dry the ketone with $CaSO_4$, shake it with chromatographic alumina and fractionally distil it from P_2O_5 under N_2. [*Beilstein* **1** IV 3334.]

Diketene See 2-methylene-oxetan-2-one in "Heterocyclic Compounds", in this Chapter, and see ketene below.

2,3-Dimercapto-1-propanol (BAL, British Anti-Lewisite) *[59-52-9]* **M 124.2, b 82-84°/0.8mm, 120°/15mm, d_4^{20} 1.239, n_D^{20} 1.5732, pK_1^{25} 8.62, pK_2^{25} 10.75.** Precipitate BAL as the Hg mercaptide [see Björberg *Chem Ber* **75** 13 *1942*], regenerate with H_2S, and distil it under a vacuum [Rosenblatt & Jean *Anal Chem* 951 *1955*]. *It is an antidote for heavy metal (As, Hg, Au, etc.) poisoning*. [*Beilstein* **1** IV 2770.]

1,3-Dimercapto-2-propanol *[584-04-3]* **M 124.2, b 68-69°/0.8mm, 82°/1.5mm, 94°/12mm, n_D^{23} 1.5696.** Purify the dithiol as for 2,3-dimercapto-1-propanol above. [Johary & Owen *J Chem Soc* 1305 *1955*, *Beilstein* **1** IV 2773 or **2** IV 1102.]

***meso*-2,3-Dimercaptosuccinic acid** *[304-55-2]* **M 182.2, m 191-192°(dec), 210°(dec), 210-211° (dec), pK_1^{25} 2.71, pK_2^{25} 3.48, pK_3^{25} 8.89, pK_4^{25} 10.75.** Purify the acid by dissolving it in NaOH and precipitating with dilute HCl, drying and recrystallising from MeOH. IR has $\nu_{\square\square\square}$ at 2544 (SH) and 1689 (CO_2H) cm^{-1}. The *bis-S-acetyl* derivative has **m** 183-185° (from EtOAc or Me_2CO), and its *Me ester* has **m** 119-120° (from petroleum ether) [Gerecke et al. *Helv Chim Acta* **44** 957 *1961*, Owen & Sultanbawa *J Chem Soc* 3112 *1949*]. [*Beilstein* **3** III 1033.]

1,2-Dimethoxyethane (DME, glycol dimethyl ether, glyme) *[110-71-4]* **M 90.1, b 84°, d_4^{20} 0.867, n 1.380.** Traces of water and acidic materials have been removed from it by refluxing with Na, K or CaH_2, decanting and distilling from Na, K, CaH_2 or $LiAlH_4$. The reaction has been speeded up by using vigorous high-speed stirring with molten potassium. For virtually complete elimination of water, 1,2-dimethoxyethane has been dried with

Na-K alloy until a characteristic blue colour is formed in the solvent at Dry-ice/cellosolve temperatures: the solvent is kept with the alloy until distilled for use [Ward *J Am Chem Soc* **83** 1296 *1961*]. *Alternatively*, glyme, refluxed with benzophenone and Na-K, is dry enough if, on distillation, it gives a blue colour of the ketyl immediately on addition to benzophenone and sodium [Ayscough & Wilson *J Chem Soc* 5412 *1963*]. It has also been purified by distillation under N_2 from sodium benzophenone ketyl (see above). [*Beilstein* **1** IV 2376.]

***N,N*-Dimethylacetamide (DMAc)** *[127-19-5]* **M 87.1, b 58.0-58.5°/11.4mm, 66-67°/15mm, 85-87°/33mm, 96°/80mm, 163-165°/760mm, d_4^{20} 0.940, n_D^{20} 1.4373.** Shake the amide with BaO for several days, reflux it over BaO for 1 hour, then fractionally distil it under reduced pressure. Store it over molecular sieves. It is a useful organic solvent for reactions, as it is soluble in many organic solvents and in H_2O. Use it in a fume hood because over-exposure causes liver damage, jaundice, lethargy and can irritate skin. [*Beilstein* **4** IV 180.]

***β,β*-Dimethylacrylic acid (senecioic acid, 3-methyl-2-butenoic acid)** *[541-47-9]* **M 100.1, m 68°, pK^{25} –5.4 (aqueous H_2SO_4).** Crystallise the acid from hot water or petroleum ether (b 60-80°). [*Beilstein* **2** IV 1555.]

Dimethyl adipate *[627-93-0]* **M 174.2, m 9-11°, b 109°/10mm, 121-123°/20mm, 235°/760mm, d_4^{20} 1.0642, n_D^{20} 1.4292.** Dissolve it in Et_2O, wash with $NaHCO_3$, H_2O, dry over $MgSO_4$, filter, evaporate and distil it several times until the IR and NMR are consistent with the structure [Lorette & Brown *J Org Chem* **24** 261 *1959*, Hoffmann & Weiss *J Am Chem Soc* **79** 4759 *1957*]. [*Beilstein* **2** IV 1959.]

Dimethyl adipimidate dihydrochloride *[14620-72-5]* **M 245.1, m 218-220°, 222-224°**. If the salt smells of HCl, then wash it with MeOH and dry Et_2O (1:3) under N_2 until the free HCl is completely removed. Recrystallise it from MeOH/Et_2O (it is very important that the solvents are super dry) [Hartman & Wold *Biochemistry* **6** 2439 *1967*, McElvain & Shroeder *J Am Chem Soc* **71** 40 *1949*].

Dimethylamine *[124-40-3]* **M 45.1, f –92.2°, b 0°/563mm, 6.9°/760mm, pK^{25} 10.73.** Dry dimethylamine by passage through a KOH-filled tower, or by standing with sodium pellets at 0° during 18 hours. It is a strong base — *do not inhale its vapours*. [*Beilstein* **4** IV 128.]
§ A dimethylaminomethyl polystyrene supported version is commercially available.

Dimethylamine hydrochloride *[506-59-2]* **M 81.6, m 171°.** Crystallise the salt from hot $CHCl_3$ or absolute EtOH. It also recrystallises from MeOH/ether solution. Dry it in a vacuum desiccator over H_2SO_4, then P_2O_5. *Hygroscopic.* [*Beilstein* **4** IV 132.]

2-Dimethylaminoethanol *[108-01-0]* **M 89.1, b 134.5-135.5°, d_4^{20} 1.430, n_D^{20} 1.4362, pK^{25} 9.23.** Dry the amine with anhydrous K_2CO_3 or KOH, and fractionally distil it. [*Beilstein* **4** IV 1424.]

1-(3-Dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (EDCI, DEC, 1-ethyl-3-(3-dimethyl aminopropyl) carbodiimide hydrochloride) *[25952-53-8]* **M 191.7, m 113.5-114.5°, 114-116°, pK_{Est} ~ 10.3.** It is an excellent H_2O-soluble peptide coupling reagent. It is purified by dissolving (*ca* 1g) in CH_2Cl_2 (10ml) at room temperature and then add dry Et_2O (~110ml) dropwise and the crystals that separate are collected, washed with dry Et_2O, recrystallised from CH_2Cl_2/Et_2O and dried in a vacuum over P_2O_5. It is important to work in a dry atmosphere or work rapidly, and then dry the solid as soon as possible. The material is moderately *hygroscopic*, but once it becomes wet it reacts slowly with H_2O. Store it away from moisture at –20° to slow down the hydrolysis process. The *free base* has **b** 47-48°/0.27mm, 53-54°/0.6mm, n_D^{25} 1.4582. The *methiodide* is recrystallised from $CHCl_3$/EtOAc, the crystals are filtered off, washed with dry Et_2O, recrystallised from $CHCl_3$/Et_2O, and dried *in vacuo* over P_2O_5, **m** 93-95°, 94-95°. [Sheehan et al. *J Am Chem Soc* **87** 2492 *1965*, Sheehan & Cruickshank *Org Synth* Coll Vol **V** 555 *1973*.]
§ A polymer bound version is commercially available.

***N,N*-Dimethylbiuret** *[7710-35-2]* **M 131.1, m 178°.** Purify it by repeated crystallisation from the melt, or from H_2O. [Bredereck & Richter *Chem Ber* **99** 2461 *1968*, Dunning & Close *J Am Chem Soc* **75** 3615 *1953*.]

2,3-Dimethyl-1,3-butadiene *[513-81-5]* **M 82.2, m –69-70°, b 68-69°/760mm, d_4^{20} 0.727, n_D^{20} 1.4385.** Distil

it from $NaBH_4$, and purify it by zone melting. [*Beilstein* **1** IV 1023.]

1,3-Dimethylbutadiene sulfone (1,3-dimethylsulfolene, 2,4-dimethyl-2,5-dihydrothiophen-1,1-dioxide) *[10033-92-8]* **M 145.2, m 40.4-41.0°.** Crystallise the sulfone from diethyl ether (three times), or from CCl_4 (**m** 39.5-40°). [Grummitt et al. *J Am Chem Soc* **72** 5768 *1950*, *Beilstein* **17/1** V 97.]

2,2-Dimethylbutane *[75-83-2]* **M 86.2, b 49.7°, d_4^{20} 0.649, n^{25} 1.36595.** Distil it azeotropically with MeOH, then wash it with water, dry (Na_2SO_4) it, and distil it. [*Beilstein* **1** IV 367.]

2,3-Dimethylbutane *[79-29-8]* **M 86.2, b 58.0°, d_4^{20} 1.375, n^{25} 1.37231.** Distil it from sodium, pass it through a column of silica gel (activated by heating in nitrogen to 350° before use) to remove unsaturated impurities, and again distil it from sodium. Also distil it azeotropically with MeOH, then wash with water, dry (Na_2SO_4), filter and redistil it. [*Beilstein* **1** IV 371.]

2,3-Dimethylbut-2-ene *[563-79-1]* **M 84.2, b 72-73°/760mm, d_4^{20} 0.708, n_D^{20} 1.41153.** Purify it by GLC on a column of 20% squalene on chromosorb P at 50° [Flowers & Rabinovitch *J Phys Chem* **89** 563 *1985*]. Also wash it with 1M NaOH solution followed by H_2O. Dry it over Na_2SO_4, distil it over powdered KOH under nitrogen and pass it through activated alumina before use. [Woon et al. *J Am Chem Soc* **108** 7990 *1986*, Wong et al. *J Am Chem Soc* **109** 3428 *1987*, *Beilstein* **1** IV 853.]

Dimethylcarbamoyl chloride *[79-44-7]* **M 107.5, m –33°, b 34°/0.1mm, d_4^{20} 1.172, n_D^{20} 1.4511.** It must be distilled under high vacuum to avoid decomposition. It is moisture sensitive. [*Beilstein* **4** IV 224.]

Dimethyl carbonate *[616-38-6]* **M 90.1, m 2-4°, 4.65°, b 89.5°/755mm, 90.2°/atm, 90-91°/atm, d_4^{20} 1.079, n_D^{20} 1.3687.** If the reagent has broad intense bands at 3300cm^{-1} and above (i.e. OH stretching), then it should be purified further. It will contain small amounts of water and/or alcohol which form azeotropes with it. Wash it successively with 10% Na_2CO_3 solution, saturated $CaCl_2$, H_2O, and dry it by shaking mechanically for 1 hour with anhydrous $CaCl_2$, and fractionate. *Alternatively*, stand it for several days in contact with Linde type 4A molecular sieves, then fractionally distil it. The middle fraction is frozen slowly at 2°, several times, retaining 80% of the liquid at each cycle. [Bowden & Butler *J Chem Soc* 78 *1939,* Vogel *J Chem Soc* 1847 *1948*, *Beilstein* **3** IV 3.]

Dimethyl dicarbonate (dimethyl pyrocarbonate) *[4525-33-1]* **M 134.1, m 15.2°, b 45-46°/5mm, d_4^{20} 1.2585, n_D^{20} 1.3950.** If the reagent has broad intense bands at 3300cm^{-1} and above (i.e. OH stretching), then it should be purified further. Dissolve it in Et_2O, shake this with a small volume of 0.1N HCl, dry the Et_2O solution (Na_2SO_4), and distil it *in vacuo* at as low pressure as possible, but below 100°, to give a clear liquid. It decomposes to CO_2 and dimethyl carbonate on heating at 123-149°. It is readily hydrolysed by H_2O and is a yeast inhibitor. It is an **IRRITANT**. [Brysov et al. *J Org Chem USSR* **10** 2551 *1974*, Boehm & Mehta *Chem Ber* **71** 1797 *1938, Beilstein* **3** IV 17.]

1,5-Dimethyl-1,5-diazaundecamethylene polymethobromide (Hexadimethrene, Polybrene) *[28728-55-4]* **M 5000—10,000 polymer.** Purify it by chromatography on Dowex 50 and/or by filtration through alumina before use [Frank *Hoppe-Seyler's Z Physiol Chemie* **360** 997 *1979*]. It is hygroscopic, and its solubility in H_2O is 10%.

***N,N'*-Dimethylethylenediamine [1,2-bis(methylamino)ethane]** *[110-70-3]* **M 88.2, b 110-112°/750mm, 119°/760mm, d_4^{20} 0.819, n_D^{20} 1.431, (pK^{25} 7.01 and 9.88).** This strong base has been prepared in various ways including hydrolysis of *N,N'-di(benzylsulfonyl)-N,N'-dimethylethylenediamine* (**m 217-219°**, from AcOH) and concentrated HCl (120-130°) [Johnson & Bailey *J Am Chem Soc* **38** 2135 *1916*], the reaction of 1,2-dibromoethane with 21-33% aqueous $MeNH_2$ in EtOH (reflux for 2 hours, 50% yield) [Kermack & Wight *J Chem Soc* 1421 *1935*, Woodburn & O'Gee *J Org Chem* **17** 1235 *1952*], hydrolysis of *N,N'-di(p-toluenesulfonyl)*

N,N'-dimethylethylenediamine (1mol, **m 164°**, from AcOH) with H_2SO_4 (8.2mol) and H_2O (9mol) at 140-145°/7 hours [Boon *J Chem Soc* 307 *1947*], LAH reduction in THF of *3-benzenesulfonyloxy-5,6-dihydrouracil* (**m 175-176°**, from iso-PrOH) and isolated as the *dibenzoyl derivative* (41%, **m 177-178°**, from *C_6H_6) [Bauer *J Am Chem Soc* **78** 1945 *1956*], and by catalytic hydrogenation of *N-benzyl-N,N'-dimethylethylenediamine* (**b 73-74°/0.1mm**) with 10% Pd/C [Jucker & Rissi *Helv Chim Acta* **45** 2383 *1962*]. General isolation and purification procedures involve steam distillation of the product diamine, acidifying the distillate with HCl, evaporating to dryness, treating the residual salt with 10% excess of cold 32% aqueous NaOH, collecting the organic layer (**care**: very caustic solution), drying it over solid KOH, and distilling from it. Final distillation of the dry base over Na has been reported (see also [107-15-3]). The diamine is a strong base and readily absorbs CO_2 and H_2O from the atmosphere—store it in a dark stoppered bottle, wax the stopper if it should be stored for long periods. The *dihydrochloride* [5752-40-9] has **m 235-236° (dec)**, and the *picrate* has **m 160°** (from EtOH and Me_2CO in rectangular plates). It forms complexes with Cu, Ni, and Pt among other metals. Its FT-IR (neat) has ν_{max} at 3285.5, 2788.2, 1447.2, 1346.5, 1251.0, 1106.5, 1040.5, 876.9, 763.7 cm^{-1}. [For pK and metal complexes see Gastafson & Martell *J Am Chem Soc* **81** 525 *1959*, *Beilstein* **4** H 250, **4** I 415, **4** II 689, **4** III 512, **4** IV 1171.]

Dimethyl disulfide *[624-92-0]* **M 94.2, f –98°, b 40°/12mm, 110°/760mm, d_4^{20} 1.0605, n 1.5260.** Pass it through neutral alumina before use. [Trost *Chem Rev* **78** 363 *1978*, *Beilstein* **1** IV 1281.]

***N,N*-Dimethylformamide (DMF)** *[68-12-2]* **M 73.1, b 40°/10mm, 61°/30mm, 88°/100mm, 153°/760mm, d_4^{20} 0.948, n^{25} 1.4269, pK^{25} –0.3.** DMF decomposes slightly at its normal boiling point to give small amounts of dimethylamine and carbon monoxide. The decomposition is catalysed by acidic or basic materials, so that even at room temperature DMF is appreciably decomposed if allowed to stand for several hours with solid KOH, NaOH or CaH_2. If these reagents are used as dehydrating agents, therefore, they should not be refluxed with the DMF. Use of $CaSO_4$, $MgSO_4$, silica gel or Linde type 4A molecular sieves is preferable, followed by distillation under reduced pressure. This procedure is adequate for most laboratory purposes. Larger amounts of water can be removed by azeotropic distillation with *benzene (10% v/v, previously dried over CaH_2), at atmospheric pressure: water and *benzene distil below 80°. The liquid remaining in the distillation flask is further dried by adding $MgSO_4$ (previously ignited overnight at 300-400°) to give 25g/L. After shaking for one day, a further quantity of $MgSO_4$ is added, and the DMF is distillied at 15-20mm pressure through a 3-ft vacuum-jacketed column packed with steel helices. However, $MgSO_4$ is an inefficient drying agent, leaving about 0.01M water in the final DMF. More efficient drying (to around 0.001-0.007M water) is achieved by standing with powdered BaO, followed by decanting before distillation, then with alumina powder (50g/L, previously heated overnight to 500-600°), and distilling from more of the alumina, or by refluxing at 120-140° for 24 hours with triphenylchlorosilane (5-10g/L), then distilling at *ca* 5mm pressure [Thomas & Rochow *J Am Chem Soc* **79** 1843 *1957*]. Free amine in DMF can be detected by the colour reaction with 1-fluoro-2,4-dinitrobenzene. It has also been purified by drying overnight over KOH pellets and then distilling from BaO through a 10 cm Vigreux column [Jasiewicz et al. *Exp Cell Res* **100** 213 *1976*]. [For efficiency of desiccants in drying dimethylformamide see Burfield & Smithers *J Org Chem* **43** 3966 *1978*, and for a review on purification, tests of purity and physical properties, see Juillard *Pure Appl Chem* **49** 885 *1977*.]
It has been purified by distilling from K_2CO_3 under high vacuum and fractionated in an all-glass apparatus. The middle fraction is collected, degassed (seven or eight freeze-thaw cycles) and redistilled under as high a vacuum as possible [Mohammad & Kosower *J Am Chem Soc* **93** 2713 *1971*]. [*Beilstein* **4** IV 171.]
Rapid purification: Stir over CaH_2 (5% w/v) overnight, filter, then distil at 20 mmHg. Store the distilled DMF over 3A or 4A molecular sieves. For solid phase synthesis, the DMF used must be of high quality and free from amines.

***d,l*-2,4-Dimethylglutaric acid** *[2121-67-7]* **M 160.2, m 144-145° $pK_{Est(1)}$~4.4, $pK_{Est(2)}$ ~5.4.** Distil the acid in steam and recrystallise it from ether/petroleum ether. [*Beilstein* **2** H 681, **2** I 284, **2** II 590, **21** III 1755, **2** IV 2022.]

3,3-Dimethylglutaric acid *[4839-46-7]* **M 160.2, m 103-104°, b 89-90°/2mm, 126-127°/4.5mm, pK_1^{25} 3.85, pK_2^{25} 6.45.** Crystallise the acid from water, *benzene or ether/petroleum ether. Dry it in a vacuum. [*Beilstein*

21 H 391, **21** I 334, **21** II 309, **21** III/IV 4601, **21/9** V 592.]

Dimethylglyoxime *[95-45-4]* **M 116.1, m 240°, pK $_1^{25}$ 10.60, pK $_2^{25}$ 11.85.** Crystallise it from EtOH (10ml/g) or aqueous EtOH. [*Beilstein* **1** III 3105.] **TOXIC.**

2,5-Dimethyl-2,4-hexadiene *[764-13-6]* **M 110.2, f 14.5°, b 132-134°, d $_4^{20}$ 0.773, n $_D^{20}$ 1.4796.** Distil it, then repeatedly fractionally crystallise it by partial freezing. Immediately before use, the diene is passed through a column containing Woelm silica gel (activity I) and Woelm alumina (neutral) in separate layers. [*Beilstein* **1** IV 1043.]

2,2-Dimethylhexane *[590-73-8]* **M 114.2, m –121.2°, b 107°, d $_4^{20}$ 0.695.** Dry the hexane over type 4A molecular sieves and distil it. [*Beilstein* **1** IV 432.]

2,5-Dimethylhexane *[592-13-2]* **M 114.2, m –91.2°, b 109°, d $_4^{20}$ 0.694.** Dry the hexane over type 4A molecular sieves and distil it. [*Beilstein* **1** IV 434.]

2,5-Dimethylhexane-2,5-diol *[110-03-2]* **M 146.2, m 88-90°.** Purify the diol by fractional crystallisation. Then the diol is dissolved in hot acetone, treated with activated charcoal, and filtered while hot. The solution is cooled and the diol is filtered off and washed well with cold acetone. The crystallisation process is repeated several times, and the crystals are dried under a vacuum in a freeze-drying apparatus [Goates et al. *J Chem Soc, Faraday Trans 1* **78** 3045 *1982*]. [*Beilstein* **1** IV 2600.]

1,1-Dimethylhydrazine *[57-14-7]* **M 60.1, b 60.1°/702mm, d $_4^{20}$ 0.790, n $_D^{20}$ 1.408 pK^{30} 7.21.** Fractionally distil the hydrazine through a 4-ft column packed with glass helices. Precipitate it as its oxalate from diethyl ether solution. After crystallising from 95% EtOH, the salt is decomposed with aqueous saturated NaOH, and the free base is distilled, dried over BaO and redistilled [McBride & Kruse *J Am Chem Soc* **79** 572 *1957*]. Distillation and storage should be under nitrogen. [*Beilstein* **4** IV 3322.]

Dimethyl itaconate *[617-52-7]* **M 158.2, m 38°, b 208°, d 1.124.** Crystallise the ester from MeOH by cooling to –78°. [*Beilstein* **2** IV 2229.]

Dimethylmaleic anhydride *[766-39-2]* **M 126.1, m 96°, b 225°/760mm.** Distil the anhydride from *benzene/ligroin and sublime in a vacuum. [*Beilstein* **17/11** V 69.]

Dimethylmalonic acid *[595-46-0]* **M 132.1, m 192-193° pK $_1^{25}$ 3.03, pK $_2^{25}$ 5.73.** Crystallise the acid from *benzene/petroleum ether. It sublimes in a vacuum with slight decomposition. [*Beilstein* **2** IV 1955.]

Dimethylnitrosamine (*N*-nitrosodimethylamine) *[62-75-9]* **M 74.0, m –28°, b 149-150°/atm, 153°/774mm, d $_4^{20}$ 1.006, n $_D^{20}$ 1.4370.** Dry the nitrosamine over anhydrous K_2CO_3 or dissolve it in Et_2O, dry it over solid KOH, filter, evaporate Et_2O and distil the yellow oily residue through a 30cm fractionating column discarding the first fraction which may contain Me_2N. Also dry over $CaCl_2$ and distil it at atmospheric pressure. All operations should be done in an efficient fume cupboard as the vapors are **TOXIC** and **CARCINOGENIC**. [Fischer *Chem Ber* **8** 1588 *1875*, Romberg *Rec Trav Chim Pays Bas* **5** 248 *1886*, Hatt *Org Synth* Coll Vol **II** 211 *1961*, Krebs & Mandt *Chem Ber* **108** 1130 *1975*.]

2,6-Dimethyl-2,4,6-octatriene see *neo*-alloocimene below.

Dimethylolurea (di-[hydroxymethyl]urea) *[140-95-4]* **M 120.1, m 137-139°.** Crystallise it from aqueous 75% EtOH. [*Beilstein* **3** IV 107.]

Dimethyl oxalate *[553-90-2]* **M 118.1, m 54°, b 163-165°, d $_4^{20}$ 1.148.** Crystallise the ester repeatedly from EtOH. De-gas it under nitrogen at high vacuum and distil it. [*Beilstein* **2** IV 1847.]

2,4-Dimethylpentane *[108-08-7]* **M 100.2, b 80.5°, d_4^{20} 0.763, n_D^{20} 1.3814, n^{25} 1.37882.** Extract it repeatedly with conc H_2SO_4, wash with water, dry and distil it. *Alternatively*, percolated it through silica gel (previously heated in nitrogen to 350°). Purify it by azeotropic distillation with EtOH, followed by washing out the EtOH with water, drying and distilling. [*Beilstein* **1** IV 406.]

4,4-Dimethyl-1-pentene *[762-62-9]* **M 98.2, b 72.5°/760mm, d_4^{20} 0.6827, n_D^{20} 1.3918.** Purify it by passing through alumina before use [Traylor et al. *J Am Chem Soc* **109** 3625 *1987*]. [*Beilstein* **1** IV 869.]

Dimethyl peroxide *[690-02-8]* **M 62.1, b 13.5°/760mm, d_4^{20} 0.8677, n_D^{20} 1.3503.** Purify dimethyl peroxide by repeated trap-to-trap fractionation until no impurities could be detected by gas IR spectroscopy [Haas & Oberhammer *J Am Chem Soc* **106** 6146 *1984*]. *All necessary precautions should be taken in case of* **EXPLOSION.**

2,2-Dimethyl-1,3-propanediol (neopentyl glycol) *[126-30-7]* **M 104.2, m 128.4-129.4°, b 208°/760mm.** Crystallise the diol from *benzene or acetone/water (1:1). [*Beilstein* **1** IV 2551.]

2,2-Dimethyl-1-propanol (*neo*-pentyl alcohol) *[75-84-3]* **M 88.2, m 52°, b 113.1°/760mm.** It is difficult to distil because it is a solid at ambient temperatures. Purify it by fractional crystallisation and sublimation. [*Beilstein* **1** IV 1690.]

***N,N*-Dimethylpropionamide** *[758-96-3]* **M 101.2, b 175-178°, d_4^{20} 0.920, n_D^{20} 1.440.** Shake the amide over BaO for 1-2 days, then distil it under reduced pressure. [*Beilstein* **4** III 126.]

***meso*-α,β-Dimethylsuccinic acid** *[608-40-2]* **M 146.1, m 211°, pK_1^{25} 3.77, pK_2^{25} 5.36.** Crystallise the *meso*-acid from EtOH/ether or EtOH/chloroform.

2,2-Dimethylsuccinic acid *[597-43-3]* **M 146.1, m 141°, pK_1^{20} 4.15, pK_2^{20} 6.40.** Crystallise the acid from EtOH/ether or EtOH/chloroform. [*Beilstein* **2** IV 1996.]

(±)-2,3-Dimethylsuccinic acid *[13545-04-5]* **M 146.1, m 129°, pK_1^{25} 3.82, pK_2^{25} 5.98.** Crystallise the *racemic* acid from water. [*Beilstein* **2** IV 1998.]

Dimethyl sulfide *[75-18-3]* **M 62.1, f –98.27°, b 0°/172mm, 37.5-38°/760mm, d^{21} 0.8458, n^{25} 1.4319.** Purify dimethyl sulfide *via* the Hg(II) chloride complex by dissolving 1 mole of $Hg(II)Cl_2$ in 1250ml of EtOH and slowly adding the boiling alcoholic solution of Me_2S to give the right ratio for $2(CH_3)_2S.3HgCl_2$. After recrystallisation of the complex to constant melting point, 500g of complex is heated with 250ml conc HCl in 750ml of water. The sulfide is separated, washed with water, and dried with $CaCl_2$ and $CaSO_4$. Finally, it is distilled under reduced pressure from sodium. Precautions should be taken (*efficient fume hood*) because of its very **UNPLEASANT ODOUR** and **TOXICITY**. [*Beilstein* **1** IV 1275.]

2,4-Dimethylsulfolane *[1003-78-7]* **M 148.2, b 128°/77mm, d^{25} 1.1314, n_D^{20} 1.474.** Distil the sulfolane in a vacuum. [*Beilstein* **17/1** IV 97.]

Dimethyl sulfone *[67-71-0]* **M 94.1, m 109°.** Crystallise the sulfone from water. Dry it over P_2O_5. [*Beilstein* **1** IV 1279.]

Dimethyl sulfoxide (DMSO) *[67-68-5]* **M 78.1, m 18.0-18.5°, b 75.6-75.8°/12mm, 190°/760mm, d_4^{20} 1.100, n_D^{20} 1.479.** This colourless, odourless, very *hygroscopic* liquid, is synthesised from dimethyl sulfide. The main impurity is water, with a trace of dimethyl sulfone. The Karl-Fischer test is applicable. It is dried with Linde types 4A or 13X molecular sieves, by prolonged contact and passage through a column of the material, then distilled under reduced pressure. Other drying agents include CaH_2, CaO, BaO and $CaSO_4$. It can also be fractionally crystallised by partial freezing. More extensive purification is achieved by standing overnight with freshly heated and cooled chromatographic grade alumina. It is then refluxed for 4 hours over CaO, dried

over CaH_2, and fractionally distilled at low pressure. For efficiency of desiccants in drying dimethyl sulfoxide see Burfield and Smithers [*J Org Chem* **43** 3966 *1978*, Sato et al. *J Chem Soc, Dalton Trans* 1949 *1986*]. [Reddy *Pure Appl Chem* **25** 459 *1969*, *Beilstein* **1** IV 1277.]
Rapid purification: Stand over freshly activated alumina, BaO or $CaSO_4$ overnight. Filter and distil it over CaH_2 under reduced pressure (~12 mmHg). Store it over 4A molecular sieves.

***N,N*-Dimethylthiocarbamoyl chloride** *[16420-13-6]* **M 123.6, m 42-43°, b 64-65°/0.1mm.** Crystallise it twice from pentane and/or distil it at low pressure. [*Beilstein* **4** III 147.]

***sym*-Dimethylurea** *[96-31-1]* **M 88.1, m 106°.** Crystallise the urea from acetone/diethyl ether by cooling in an ice bath. Also crystallise it from EtOH and dry it at 50°/5mm for 24 hours [Bloemendahl & Somsen *J Am Chem Soc* **107** 3426 *1985*]. [*Beilstein* **4** IV 207.]

2,2-Dinitropropane *[595-49-3]* **M 162.1, m 53.5°.** Crystallise it from EtOH or MeOH. Dry it over $CaCl_2$ or *in vacuo* for 1 hour just above the melting point. [*Beilstein* **2** H 117, **2** II 79, **2** III 261, **2** IV 234.]

Dioctadecyldimethylammonium bromide *[3700-67-2]* **M 630.9, m 161-163°.** Crystallise the bromide from acetone, then MeOH [Lukac *J Am Chem Soc* **106** 4387 *1984*]. Also purify it by chromatography on alumina by washing with $*C_6H_6$ and eluting with Me_2CO, evaporating and crystallising from MeCN [Swain & Kreevoy *J Am Chem Soc* **77** 1126 *1955*]. [*Beilstein* **4** IV 829.]

***N,N*-Dioctadecyl methylamine (hydrogen ionophore III)** *[4088-22-6]* **M 536.0, m 40°, 44-46°, 48-49°, b 252-259°, pK_{Est} ~10.** It can be distilled at high vacuum, but dissolving in $*C_6H_6$, filtering and evaporating give a waxy solid suitable for electrode use. It recrystallises from Me_2CO or MeCN. [Hoerr et al. *J Org Chem* **9** 201 *1944*, Wu & Yu *Talanta* **34** 577 *1987*, *Beilstein* **4** III 435.]

Dipropylene glycol (octan-4,5-diol) *[110-98-5]* **M 134.2, b 109-110°/8mm, d_4^{20} 1.022, n_D^{20} 1.441.** Fractionally distil the diol below 15mm pressure, using a packed column and taking precautions to avoid absorption of water. [*Beilstein* **1** IV 2473.]

Di-*n*-propyl ketone (4-pentanone) *[123-19-3]* **M 114.2, b 143.5°, d_4^{20} 0.8143, n_D^{20} 1.40732.** Dry 4-pentanone with $CaSO_4$, then distil it from P_2O_5 under nitrogen. [*Beilstein* **1** IV 3323.]

Di-*n*-propyl sulfide *[111-47-7]* **M 118.2, b 141-142°, d_4^{20} 0.870, n_D^{20} 1.449.** Wash the sulfide with aqueous 5% NaOH, then water. Dry it with $CaCl_2$ and distil it from Na [Dunstan & Griffiths *J Chem Soc* 1344 *1962*]. [*Beilstein* **1** IV 1452.]

***S*-1,2-Distearin (*S*-glycerol-1,2-distearate)** *[S- 1429-59-0, RS- 51063-97-9, R- 1188-58-5]* **M 625.0, m 76-77°, $[\alpha]_D^{20}$ –2.8° (c 6.3, $CHCl_3$), $[\alpha]_{546}^{20}$ +1.4° (c 10, $CHCl_3$/MeOH, 9:1).** Crystallise the glyceride from chloroform/petroleum ether. [cf p 678, *Beilstein* **2** IV 1231.]

1,4-Dithioerythritol (DTE, *erythro*-2,3-dihydroxy-1,4-dithiobutane) *[6892-68-8]* **M 154.3, m 82-84°, pK_1 9.0, pK_2 9.9.** Crystallise DTE from ether/hexane and store it in the dark at 0°. [*Beilstein* **1** III 2360.]

Dithiooxamide (rubeanic acid) *[79-40-3]* **M 120.2, m >300°.** Crystallise dithiooxamide from EtOH and sublime it at high vacuum. [*Beilstein* **2** IV 1871.]

***RS*-1,4-Dithiothreitol (DTT, Cleland's reagent)** *[27565-41-9]* **M 154.3, m 42-43°, pK_1 8.3, pK_2 9.5.** Crystallise DTT from ether and sublime it at 37°/0.005mm. It should be stored at 0°. [*Beilstein* **1** III 2360.]

***All-cis*-4,7,10,13,16,19-Docosahexaenoic acid** *[6217-54-5]* **M 328.5, m –44.1°, n_D^{20} 1.5017, pK_{Est} ~4.6.** Its solubility in $CHCl_3$ is 5%. It has been purified from fish oil by GLC using Ar as mobile phase and EGA as stationary phase with an ionisation detector [UV: Stoffel & Ahrens *J Lipid Res* **1** 139 *1959*], and *via* the ester by evaporative "molecular" distillation using a 'continuous molecular still' at 10^{-4} mm with the highest temperature

being 110° and a total contact time with the hot surface being 60 seconds [Farmer & van den Heuvel *J Chem Soc* 427 *1938*]. The *methyl ester [2566-90-7]* has **b** 208-211°/2mm, d_4^{20} 0.9398, n_D^{20} 1.5035. With Br_2 it forms a *dodecabromide* **m** *ca* 240°(dec). Also, the acid was converted to the methyl ester and purified through a three-stage molecular still [as described by Sutton *Chem Ind (London)* 11383 *1953*] at 96°, and the rate was adjusted so that one-third of the material was removed each cycle of three distillations. The distillate (numbered 4) (13g) was dissolved in EtOH (100ml containing 8g of KOH) at −70° and set aside for 4 hours at 30° with occasional shaking under a vacuum. Water (100ml) was added and the solution was extracted with pentane, washed with HCl, dried ($MgSO_4$), filtered and evaporated to give a clear oil (11.5g) **m** –44.5° to –44.1°. In the catalytic hydrogenation of the oil six mols of H_2 are absorbed and *docosanoic acid (behenic acid)* is produced with **m** 79.0-79.3° undepressed with an authentic sample (see docosanoic acid below) [Whitcutt *Biochem J* **67** 60 *1957*]. [*Beilstein* **2** IV 1812.]

Docosane (C22) *[629-97-0]* **M 310.6, m 47°, b 224°/15mm.** Crystallise docosane from EtOH or ether. [*Beilstein* **1** IV 572.]

Docosanoic acid (behenic acid) *[112-85-6]* **M 340.6, m 81-82°, pK_{Est} ~4.9.** Crystallise the acid from ligroin. [Francis & Piper *J Am Chem Soc* **61** 577 *1939*, *Beilstein* **2** IV 1290.]

1-Docosanol (behenyl alcohol) *[661-19-8]* **M 182.3, m 70.8°.** Crystallise docosanol from ether or chloroform/ether. [*Beilstein* **1** IV 1906.]

***n*-Dodecane** *[112-40-3]* **M 170.3, b 97.5-99.5°/5mm, 216°/760mm, d_4^{20} 0.748, n_D^{20} 1.42156.** Pass it through a column of Linde type 13X molecular sieves. Store it in contact with, and distil it from sodium. Pass it through a column of activated silica gel. It has been crystallised from diethyl ether at –60°. Unsaturated dry material which remained after passage through silica gel has been removed by catalytic hydrogenation (Pt_2O) at 45lb/in^2 (3.06 atmospheres), followed by fractional distillation under reduced pressure [Zook & Goldey *J Am Chem Soc* **75** 3975 *1953*]. It has also purified by partial crystallisation from the melt. [*Beilstein* **1** IV 498.]

Dodecane-1,10-dioic acid (decane-1,10-dicarboxylic acid) *[693-23-2]* **M 230.3, m 129°, b 245°/10mm, pK_{Est} ~4.8.** Crystallise the dioic acid from water, 75% or 95% EtOH (solubility is 10%), or glacial acetic acid. [*Beilstein* **2** IV 2126.]

1-Dodecanol (dodecyl alcohol) *[112-53-8]* **M 186.3, m 24°, b 91°/1mm, 135°/10mm, 167°/40mm, 213°/200mm, 259°/760mm, d^{24} 0.8309 (liquid).** Crystallise dodecanol from aqueous EtOH, and distil it through a spinning-band column under vacuum. [Ford & Marvel *Org Synth* **10** 62 *1930*, *Beilstein* **1** IV 1844.]

1-Dodecanthiol *[112-55-0]* **M 202.4, b 111-112°/3mm, 153-155°/24mm, d_4^{20} 0.844, n_D^{20} 1.458, pK_{Est} ~10.8.** Dry it with CaO for several days, then distil it from CaO. [*Beilstein* **1** IV 1851.]

Dodecylamine *[124-22-1]* **M 185.4, m 28°, 27-29°, 120-121°/2mm, 134°/15mm, 156°/33mm, pK^{25} 10.63.** Fractionally distil the amine, preferably under N_2 and in a vacuum. Store it in the absence of CO_2. It can be recrystallised from *n*-hexane at low temperature. The *hydrochloride* crystallises from Me_2CO (**m** 182-183°) or $CHCl_3$/petroleum ether (**m** 185-187°). [Magnien & Baltzly *J Org Chem* **23** 2029 *1958*, *Beilstein* **4** H 200, III 406, **4** IV 794.]

Dodecylammonium butyrate *[17615-97-3]* **M 273.4, m 39-40°, 39-41°, pK^{25} 10.63 (for free base).** Recrystallise the salt from *n*-hexane. [*Beilstein* **4** III 409, **4** IV 791.]

Dodecylammonium propionate *[17448-65-6]* **M 259.4, m 55-56°.** Recrystallise the salt from hexanol/petroleum ether (b 60-80°). [*Beilstein* **4** III 409, **4** IV 797.]

Dodecyldimethylamine oxide *[1643-20-5]* **M 229.4, m 102°.** Crystallise the oxide from acetone or ethyl

acetate. [Bunton et al. *J Org Chem* **52** 3832 *1987*, *Beilstein* **4** III 410, **4** IV 798.]

Dodecyl ether (didodecyl ether) *[4542-57-8]* **M 354.6, m 32.5-33°, 33°, b 175°/0.15mm, d^{36} 0.8127, n^{39} 1.4393.** Distil the ether in a vacuum, then crystallise it from MeOH or MeOH/*benzene. [Mannich & Nadelmann *Chem Ber* **63** 799 *1930*, Butterworth & Hey *J Chem Soc* 390 *1940*, *Beilstein* **1** III 1785, **1** IV 1846.]

Dodecyl methacrylate (lauryl methacrylate) *[142-90-5]* **M 254.4, m –7°, b 142°/4mm, d^{25} 0.8717, n_D^{25} 1.4330.** Purify the ester by fractional distillation in a high vacuum. Add 0.05% of hydroquinone monomethyl ether as stabiliser. [Rehberg & Fischer *Ind Eng Chem* **40** 1430 *1948*, *Beilstein* **2** III 1290, **2** IV 1528.]

Dodecyltrimethylammonium bromide *[1119-94-4]* **M 308.4, m 246°(dec).** Purify the salt by repeated crystallisation from acetone. Wash it with diethyl ether and dry it in a vacuum oven at 60° [Dearden & Wooley *J Phys Chem* **91** 2404 *1987*]. [*Beilstein* **4** IV 798.]

Dodecyltrimethylammonium chloride *[112-00-5]* **M 263.9, m 246°(dec).** Dissolve the chloride in MeOH, treat with active charcoal, filter and dry it *in vacuo* [Waldenburg *J Phys Chem* **88** 1655 *1984*], or recrystallise it several times from 10% EtOH in acetone. It has also been repeatedly crystallised from EtOH/ether or MeOH. [Cella et al. *J Am Chem Soc* **74** 2062 *1952*, *Beilstein* **4** IV 79.]

Eicosane (C20) *[112-95-8]* **M 282.6, m 36-37°, b 205°/15mm, $d^{36.7}$ 0.7779, n^{40} 1.43453.** Crystallise eicosane from EtOH. [*Beilstein* **1** IV 563.]

Elaidic (*trans*-oleic) acid *[112-79-8]* **M 282.5, m 44.5°, pK^{25} 4.9.** Crystallise the acid from acetic acid, then EtOH. [*Beilstein* **2** IV 1647.]

***RS*-Epichlorohydrin (± 2-chloromethyloxirane)** *[106-89-8]* **M 92.5, b 115.5°, d_4^{20} 1.180, n_D^{20} 1.438,.** Distil epichlorohydrin under atmospheric pressure, heat it on a steam bath with one-quarter its weight of CaO, then decant and fractionally distil it. [*Beilstein* **17** V 20.]

1,2-Epoxybutane *[106-88-7]* **M 72.1, b 66.4-66.6°, d_4^{20} 0.837, n_D^{20} 1.3841.** Dry it with $CaSO_4$, and fractionally distil it through a long (126cm) glass helices-packed column. The first fraction contains a water azeotrope. [*Beilstein* **17** II 17.]

Erucic acid (*cis*-13-docosenoic acid) *[112-86-7]* **M 338.6, m 33.8°, b 358°/400mm, pK_{Est} ~4.9.** Crystallise erucic acid from MeOH. [*Beilstein* **2** IV 1676.]

Ethane *[74-84-0]* **M 30.1, f –172°, b –88°, d_4^0 1.0493 (air = 1).** Ethylene can be removed by passing the gas through a sintered-glass disc into fuming H_2SO_4 then slowly through a column of charcoal saturated with bromine. Bromine and HBr are removed by passage through firebrick coated with *N,N*-dimethyl-*p*-toluidine. The ethane is also passed over KOH pellets (to remove CO_2) and dried with $Mg(ClO_4)_2$. Further purification is by several distillations of liquified ethane, using a condensing temperature of –195°. Yang and Gant [*J Phys Chem* **65** 1861 *1961*] treated ethane by standing it for 24 hours at room temperature in a steel bomb with activated charcoal treated with bromine. They then immersed the bomb in a Dry-ice/acetone bath and transferred the ethane to an activated charcoal trap cooled in liquid nitrogen. (The charcoal had previously been degassed by pumping for 24 hours at 450°.) By allowing the trap to warm slowly, the ethane distils, and only the middle third fraction is kept. Removal of methane is achieved using Linde type 13X molecular sieves (previously degassed by pumping for 24 hours at 450°) in a trap which, after cooling in Dry-ice/acetone, is saturated with ethane. After pumping for 10 minutes, the ethane is recovered by warming the trap to 25°. (The final gas contains less than 10^{-4} mole % of either ethylene or methane). [*Beilstein* **1** IV 108.]

Ethanesulfonyl chloride *[594-44-5]* **M 128.6, b 55°/9mm, 62°/12mm, 74°/19mm, 76-79°/22mm, 95-98°/50mm, 177°/760mm, d_4^{20} 1.357, n_D^{20} 1.4539.** Purify the sulfonyl chloride by repeated distillation to remove HCl formed from hydrolysis. **It is a fuming, corrosive liquid, handle in a good fumehood.** It is

hydrolysed by aqueous N NaOH at room temperature and is best stored in aliquots in sealed ampules under N_2. [Davies & Dick *J Chem Soc* 484 *1932*, Klamann & Drahowzal *Monatsh Chem* **83** 463 *1952*, Saunders et al. *Biochem J* **36** 372 *1942*, *Beilstein* **4** IV 34.]

Ethanethiol (ethyl mercaptan) *[75-08-1]* **M 62.1, b 32.9°/704mm, d^{52} 0.83147, pK^{25} 10.61.** Dissolve the thiol in aqueous 20% NaOH, extract it with a small amount of *benzene and then steam distil until clear. After cooling, the alkaline solution is acidified slightly with 15% H_2SO_4 and the thiol is distilled off, dried with $CaSO_4$, $CaCl_2$ or 4A molecular sieves, and fractionally distilled under nitrogen [Ellis & Reid *J Am Chem Soc* **54** 1674 *1932*]. It has a foul odour, work in an efficient fume cupboard. [*Beilstein* **1** IV 1390.]

Ethanol *[64-17-5]* **M 46.1, b 78.3°, d^{15} 0.79360, d^{5} 0.78506, n_D^{20} 1.36139, pK^{25} 15.93.** Usual impurities of fermentation alcohol are fusel oils (mainly higher alcohols, especially pentanols), aldehydes, esters, ketones and water. With synthetic alcohol, likely impurities are water, aldehydes, aliphatic esters, acetone and diethyl ether. Traces of *benzene are present in ethanol that has been dehydrated by azeotropic distillation with *benzene. Anhydrous ethanol is very *hygroscopic*. Water (down to 0.05%) can be detected by formation of a voluminous precipitate when aluminium ethoxide in *benzene is added to a test portion. Rectified spirit (95% ethanol) is converted to *absolute* (99.5%) ethanol by refluxing with freshly ignited CaO (250g/L) for 6 hours, standing overnight and distilling with precautions to exclude moisture.
Numerous methods are available for further drying of *absolute* ethanol for making "Super dry ethanol". Lund and Bjerrum [*Chem Ber* **64** 210 *1931*] used reaction with magnesium ethoxide, prepared by placing 5g of clean dry magnesium turnings and 0.5g of iodine (or a few drops of CCl_4), to activate the Mg, in a 2L flask, followed by 50-75 ml of *absolute* ethanol, and warming the mixture until a vigorous reaction occurs. When this subsides, heating is continued until all the magnesium is converted to magnesium ethoxide. Up to 1L of ethanol is then added and, after refluxing for an hour, it is distilled off. The water content should be below 0.05%. Walden, Ulich and Laun [*Z Phys Chem* **114** 275 *1925*] used ***amalgamated aluminium*** chips, prepared by degreasing aluminium chips (by washing with Et_2O and drying in a vacuum to remove grease from machining the Al), treating with alkali until hydrogen evolved vigorously, washing with H_2O until the washings were weakly alkaline and then stirring with 1% $HgCl_2$ solution. After 2 minutes, the chips were washed quickly with H_2O, then alcohol, then ether, and dried with filter paper. (The amalgam became warm.) These chips were added to the ethanol, which was then gently warmed for several hours until evolution of hydrogen ceased. The alcohol was distilled and aspirated for some time with pure dry air. Smith [*J Chem Soc* 1288 *1927*] reacted 1L of *absolute* ethanol in a 2L flask with 7g of clean dry sodium, and added 25g of pure ethyl succinate (27g of pure ethyl phthalate was an alternative), and refluxed the mixture for 2 hours in a system protected from moisture, and then distilled the ethanol. A modification used 40g of ethyl formate instead, so that sodium formate separated out and, during reflux the excess of ethyl formate decomposed to CO and ethanol.
Drying agents suitable for use with ethanol include Linde type 4A molecular sieves, calcium metal, and CaH_2. The calcium hydride (2g) is crushed to a powder and dissolved in 100ml of *absolute* ethanol by gently boiling. About 70ml of the ethanol are distilled off to remove any dissolved gases before the remainder is poured into 1L of *ca* 99.9% ethanol in a still, where it is boiled under reflux for 20 hours, while a slow stream of pure, dry hydrogen (better use nitrogen or Ar) is passed through. It is then distilled [Rüber *Z Elektrochem* **29** 334 *1923*]. If calcium is used for drying, about ten times the theoretical amount should be used, and traces of ammonia (from some calcium nitride in the Ca metal) would be removed by passing dry air into the vapour during reflux. Ethanol can be freed from traces of basic materials by distillation from a little 2,4,6-trinitrobenzoic acid or sulfanilic acid. *Benzene can be removed by fractional distillation after adding a little water (the *benzene/water/ethanol azeotrope distils at 64.9°), the alcohol is then re-dried using one of the methods described above. *Alternatively*, careful fractional distillation can separate *benzene as the *benzene/ethanol azeotrope (**b** 68.2°). Aldehydes can be removed from ethanol by digesting with 8-10g of dissolved KOH and 5-10g of aluminium or zinc per L, followed by distillation. Another method is to heat under reflux with KOH (20g/L) and $AgNO_3$ (10g/L) or to add 2.5-3g of lead acetate in 5ml of water to 1L of ethanol, followed (slowly and without stirring) by 5g of KOH in 25ml of ethanol: after 1 hour the flask is shaken thoroughly, then set aside overnight before filtering and distilling. The residual water can be removed by standing the distillate over activated aluminium amalgam for 1 week, then filtering and distilling. Distillation of ethanol from Raney nickel

eliminates catalyst poisons.
Other purification procedures include pre-treatment with conc H_2SO_4 (3ml/L) to eliminate amines, and with $KMnO_4$ to oxidise aldehydes, followed by refluxing with KOH to resinify aldehydes, and distilling to remove traces of H_3PO_4 and other acidic impurities after passage through silica gel, and drying over $CaSO_4$. Water can be removed by azeotropic distillation with dichloromethane (azeotrope boils at 38.1° and contains 1.8% water) or 2,2,4-trimethylpentane. [*Beilstein* **1** IV 1289.]
Rapid purification: Place degreased Mg turnings (grease from machining the turnings is removed by washing with dry EtOH then Et_2O, and drying in a vacuum) (5g) in a dry 2L round bottomed flask fitted with a reflux condenser (protect from air with a drying tube filled with $CaCl_2$ or KOH pellets) and flushed with dry N_2. Then add iodine crystals (~0.5g) and gently warm the flask until iodine vapour is formed and coats the turnings. Cool, then add EtOH (50ml) and carefully heat to reflux until the iodine disappears. Cool again, then add more EtOH (to 1L) and reflux under N_2 for several hours. Distil and store over 3A molecular sieves (pre-heated at 300°–350° for several hours and cooled under dry N_2 or argon).

Ethoxycarbonyl isocyanate *[19617-43-7]* **M 115.1, b 51-55°/13mm, 56°/18mm, 115-116°/781mm, d_4^{20} 1.15.** Distil it twice from P_2O_5 (1-2g) through a small Vigreux column and then through a 20-plate column. All fractional distillations should be under a vacuum. [Lamon *J Heterocycl Chem* **5** 837 *1968*, *Beilstein* **3** H 36, **3** I 17.]

Ethoxycarbonyl isothiocyanate *[16182-04-0]* **M 131.5, b 43°/14mm, 51-55°/13mm, 56°/18mm, d_4^{20} 1.12.** Fractionally distil it through a short column. It also distils at 83°/30mm with some decomposition liberating CO_2 and sulfurous gases, best distil below 20mm vacuum. [Capp et al. *J Chem Soc* 1340, *1948*, Lamon *J Heterocycl Chem* **5** 837 *1968*, *Beilstein* **3** H 174, **3** I 71, **3** III 279, **3** IV 323.]

2-Ethoxyethanol *[110-80-5]* **M 90.1, b 134.8°, d_4^{20} 0.931, n_D^{20} 1.40751.** Dry it with $CaSO_4$ or K_2CO_3, filter and fractionally distil it. Peroxides can be removed by refluxing with anhydrous $SnCl_2$ or by filtration under slight pressure through a column of activated alumina. [*Beilstein* **1** IV 2377.]

2-Ethoxyethyl methacrylate *[2370-63-0]* **M 158.2, b 91-93°/35mm, d_4^{20} 0.965, n_D^{20} 1.429.** Purify the ester as described under methyl methacrylate below. [*Beilstein* **2** III 1291.]

Ethyl acetate *[141-78-6]* **M 88.1, b 77.1°, d_4^{20} 0.9003, n_D^{20} 1.37239, n^{25} 1.36979, pK^{25} –6.93 (aqueous H_2SO_4).** The most common impurities in EtOAc are water, EtOH and acetic acid. These can be removed by washing with aqueous 5% Na_2CO_3, then with saturated aqueous $CaCl_2$ or NaCl, and drying with K_2CO_3, $CaSO_4$ or $MgSO_4$. More efficient drying is achieved if the solvent is further dried with P_2O_5, CaH_2 or molecular sieves before distillation. CaO has also been used. *Alternatively*, ethanol can be converted to ethyl acetate by refluxing with acetic anhydride (*ca* 1ml per 10ml of ester), the liquid is then fractionally distilled, dried with K_2CO_3 and redistilled. [*Beilstein* **2** III 127.]
Rapid purification: Distil, dry over K_2CO_3, re-distil and store over 4A molecular sieves.

Ethyl acetimidate *[1000-84-6]* **M 87.1, b 92-95°/atm, 89.7-90°/765mm, d_4^{20} 0.8671, n_D^{20} 1.4025, pK_{Est} ~5.5.** It is best to prepare it freshly from the *hydrochloride* (see below). Dissolve the hydrochloride (123.5g) by adding it slowly to an ice-cold mixture of H_2O (500ml), K_2CO_3 (276g) and Et_2O (200ml) and stirring rapidly. The Et_2O layer is separated, the aqueous layer is extracted with Et_2O (100ml), the combined Et_2O layers are dried ($MgSO_4$), evaporated and the residual oil is distilled through a glass helices packed column (70x1.2cm). The yield is 19g (22%). [Glickman & Cope *J Am Chem Soc* **67** 1020 *1945*, Chaplin & Hunter *J Chem Soc* 1118 *1937*, Hunter & Ludwig *Methods Enzymol* **25** 585 *1972*.]

Ethyl acetimidate hydrochloride *[2208-07-3]* **M 123.6, m 98-100°(dec), 110-115°(dec), 112-113°(dec), m 112-114°(dec), pK_{Est} ~5.5.** Recrystallise the hydrochloride by dissolving it in the minimum volume of super dry EtOH and adding dry Et_2O or from dry Et_2O. Dry it in a vacuum and store it in a vacuum desiccator with P_2O_5. *Alternatively*, it could be crystallised from EtOH (containing a few of drops of ethanolic HCl) and adding dry Et_2O. Filter and dry it in a vacuum desiccator over H_2SO_4 and NaOH. [Pinner *Chem Ber* **16** 1654 *1883*,

Glickman & Cope *J Am Chem Soc* **67** 1020 *1945*, Chaplin & Hunter *J Chem Soc* 1118 *1937*, McElvain & Schroeder *J Am Chem Soc* **71** 40 *1949*, McElvain & Tate *J Am Chem Soc* **73** 2233 *1951*, *Methods Enzymol* **25** 585 *1972*, *Beilstein* **2** III 418.]

Ethyl acetoacetate *[141-97-9]* **M 130.1, b 71°/12mm, 100°/80mm, d_4^{20} 1.026, n_D^{20} 1.419, pK^{25} 10.68.** Shake the ester with small amounts of saturated aqueous $NaHCO_3$ (until no further effervescence), then with water. Dry it with $MgSO_4$ or $CaCl_2$ and distil it under reduced pressure. [*Beilstein* **3** IV 1528.]

Ethyl acrylate *[140-88-5]* **M 100.1, b 20°/40mm, 99.5°/atm, d_4^{20} 0.922, n_D^{20} 1.406.** Wash the ester repeatedly with aqueous NaOH until free from inhibitors such as hydroquinone, then wash it with saturated aqueous $CaCl_2$ and distil it under reduced pressure. Hydroquinone should be added if the ethyl acrylate is to be stored for extended periods. [*Beilstein* **2** IV 1460.] **LACHRYMATORY.**

Ethylamine *[75-04-7]* **M 45.1, b 16.6°/760mm, d_4^{20} 1.3663, pK^{20} 10.79.** Condense it in an all-glass apparatus cooled by circulating ice-water, and store it with KOH pellets below 0°. [*Beilstein* **4** IV 307.]

Ethylamine hydrochloride *[557-66-4]* **M 81.5, m 109-110°.** Crystallise the hydrochloride from absolute EtOH or MeOH/$CHCl_3$, wash it with dry ether and dry it in a vacuum. [*Beilstein* **4** IV 310.]

Ethyl bromide *[74-96-4]* **M 109.0, b 0°/165mm, 38°/745mm, d_4^{20} 1.460, n_D^{20} 1.4241.** The main impurities are usually EtOH and water, both of which form azeotropes with it. Ethanol and unsaturated compounds can be removed by washing with conc H_2SO_4 until no further coloration is produced. The ethyl bromide is then washed with water, aqueous Na_2CO_3, and water again, then dried with $CaCl_2$, $MgSO_4$ or CaH_2, and distilled from P_2O_5. Olefinic impurities can also be removed by storing the ethyl bromide in daylight with elemental bromine, later removing the free bromine by extraction with dilute aqueous Na_2SO_3, drying the ethyl bromide with $CaCl_2$ and fractionally distilling it. *Alternatively*, unsaturated compounds can be removed by bubbling oxygen containing *ca* 5% ozone through the liquid for an hour, then washing with aqueous Na_2SO_3 to hydrolyse ozonides and remove hydrolysis products, followed by drying and distillation. [*Beilstein* **1** IV 150.]

Ethyl bromoacetate *[105-36-2]* **M 167.0, b 158-158.5°/758mm, d_4^{20} 1.50, n_D^{20} 1.450.** Wash the ester with saturated aqueous Na_2CO_3 (three times), 50% aqueous $CaCl_2$ (three times) and saturated aqueous NaCl (twice). Dry with $MgSO_4$, $CaCl_2$ or $CaCO_3$, and distil it. [*Beilstein* **2** IV 527.] **LACHRYMATORY.**

Ethyl 6-bromohexanoate (ethyl 6-bromocaproate) *[25542-62-5]* **M 223.1, b 120-125°/14mm, 126-127°/20-21mm, 128-130°/16mm, 127-130°/19mm, d_{23}^{23} 1.241, d^{25} 1.254, n_D^{20} 1.458, n_D^{21} 1.4566.** 6-Bromohexanoic acid (250g) is esterified by refluxing with EtOH (600ml) containing H_2SO_4 (15ml) for 8 hours, evaporating *in vacuo*, the residue is taken up in Et_2O, washed with H_2O, then 5% of aqueous Na_2CO_3 (effervescence), the Et_2O layer is dried ($CaCl_2$), filtered, evaporated, and the residual oil is distilled to give the ester (178-218g). [Brown & Partridge *J Am Chem Soc* **66** 819 *1844*.] It has also been prepared from 6-hydroxyhexanoic acid by reaction with PBr_3 in pyridine, or HBr (*d* 1.5) and H_2SO_4 and then esterifying in the same way [Barger et al. *J Chem Soc* 718 *1937*]. [*Beilstein* **2** IV 940.]

Ethyl 2-(bromomethyl)acrylate *[17435-72-2]* **M 193.1, b 38°/0.8mm, d_4^{20} 1.398, n_D^{20} 1.479.** If it contains some free acid, add H_2O, cool, and neutralise with $NaHCO_3$ until evolution of CO_2 ceases. Extract the mixture with Et_2O (3x) and dry the combined extracts (Na_2SO_4, 3 hours). Evaporate Et_2O and distil the ester collecting fraction **b** 39-40°/0.9mm, and check spectra. [Preparation and NMR: Ramarajan et al. *Org Synth* Coll Vol **VII** 211 *1990*, *Beilstein* **2** IV 1541.]

Ethyl α-bromopropionate *[535-11-5]* **M 181.0, b 69-70°/25mm, d_4^{20} 1.39, n_D^{20} 1.447.** Wash the ester with saturated aqueous Na_2CO_3 (three times), 50% aqueous $CaCl_2$ (three times) and saturated aqueous NaCl (twice). Dry with $MgSO_4$, $CaCl_2$ or $CaCO_3$, and distil it. [*Beilstein* **2** IV 762.] **LACHRYMATORY.**

Ethyl bromopyruvate *[70-23-5]* **M 195.0, b 47°/0.5mm, 71-73°/5mm, 87°/9mm, 89-104°/14mm, d_4^{20} 1.561,**

n_D^{20} 1.464. The most likely impurity is free acid (bromopyruvic or bromoacetic acids). Dissolve the ester in dry Et_2O or dry $CHCl_3$, stir with $CaCO_3$ until effervescence ceases, filter (may wash with a little H_2O rapidly), dry ($MgSO_4$) and distil it at least twice. The *2,4-dinitrophenylhydrazone* has **m** 144-145°. [Burros & Holland *J Chem Soc* 672 *1947*, Letsinger & Laco *J Org Chem* **21** 764 *1956*, Kruse et al. *J Am Chem Soc* **76** 5796 *1954*, *Beilstein* **3** IV 1519.] **LACHRYMATORY.**

2-Ethyl-1-butanol *[97-95-0]* **M 102.2, b 146.3°, n^{15} 1.4243, n^{25} 1.4205.** Dry it with $CaSO_4$ for several days, filter and fractionally distil it. [*Beilstein* **1** IV 1725.]

2-Ethylbut-1-ene *[760-21-4]* **M 84.1, b 66.6°, d_4^{20} 0.833, n_D^{20} 1.423.** Wash it with 10N aqueous NaOH, then water. Dry the organic layer with $CaCl_2$, filter and fractionally distil it. [*Beilstein* **1** IV 850.]

Ethyl *n*-butyrate *[105-54-4]* **M 116.2, b 49°/50mm, 119-120°/760mm, d_4^{20} 0.880, n_D^{20} 1.393.** Dry the ester with anhydrous $CuSO_4$ and distil it under dry nitrogen. [*Beilstein* **2** IV 787.]

Ethyl carbamate see **urethane** below.

Ethyl carbazate (*N*-ethoxycarbonyl hydrazine) *[4114-31-2]* **M 104.1, m 44-48°, 51-52°, b 95.5°/10m, 92-95°/12mm, 100-102°/11mm.** Fractionate the carbazate using a Vigreux column until the distillate crystallises [Allen & Bell *Org Synth* Coll Vol **III** 404 *1955*, *Beilstein* **3** IV 174].

Ethyl chloride *[75-00-3]* **M 64.5, b 12.4°, d_4^{20} 0.8978, n_D^{20} 1.3676.** Pass ethyl chloride through absorption towers containing, successively, conc H_2SO_4, NaOH pellets, P_2O_5 on glass wool, or soda-lime, $CaCl_2$, P_2O_5. Condense it into a flask containing CaH_2 and fractionally distil it. It has also been purified by illumination in the presence of bromine at 0° using a 1000W lamp, followed by washing, drying and distilling. [*Beilstein* **1** IV 124.]

Ethyl chloroacetate *[105-39-5]* **M 122.6, b 143-143.2°, d_4^{20} 1.150, n^{25} 1.4192.** Shake the ester with satutated aqueous Na_2CO_3 (three times), aqueous 50% $CaCl_2$ (three times) and saturated aqueous NaCl (twice). Dry it with Na_2SO_4 or $MgSO_4$ and distil it. [*Beilstein* **2** IV 481.] **LACHRYMATORY.**

Ethyl chlorofluoroacetate ($ClFCHCCO_2Et$) *[± 401-56-9]* **M 140.5, b 128°/atm, 133°/atm, d_4^{25} 1.225, n_D^{25} 1.3926.** The ester is prepared from 2-chloro-1,1,2-trifluoroethyl ether (340g, 2.09mol at < 5°) while 96% H_2SO_4 (228ml, 420g, 4.1mol) is added dropwise to it with stirring, and allowing the liberated HF (HIGHLY TOXIC vapour which etches glass) to vacate in an efficient fume cupboard, at a rate such that the temperature is maintained at 5-15° (*ca* 30-45 minutes). The mixture is stirred further at 10° for 2 hours when all the HF is released, then it is poured carefully onto crushed ice (I Kg) and H_2O (500ml). The lower white oily layer is allowed to settle, separated, washed until free of acid with saturated aqueous $NaHCO_3$ (3 x 25ml, **CARE**: CO_2 may be liberated), H_2O (4 x 25ml) and dried over Drierite (10g) [Note that thorough washing is essential to avoid decomposition on distillation]. The crude dry ester is filtered, and fractionated through an efficient helix packed column (2 x 12cm) to give pure *ethyl chlorofluoroacetate* (190-100g, 65-68%) boiling at 129-130° and atmospheric pressure.
The *free acid* has **b** 162°/atm (160.5-161°/atm has also been reported), d_4^{25} 1.532, n_D^{25} 1.4085, is obtained by hydrolysis of the *methyl ester*, **b** 116°/atm, with 10% aqueous NaOH. The ethyl ester provides *chlorofluoroacetamide*, **b** 72-77°/1mm, d_4^{25} 1.510, n_D^{25} 1.4535, by reaction with ammonia [Young & Tarrant *J Am Chem Soc* **71** 2432 *1949*, Hazeldine *J Chem Soc* 4259 *1952*]. [*Beilstein* **2** III 453, **2** IV 493, Englund *Org Synth* Coll Vol **IV** 423 *1963*, cf also Young & Terrant *J Am Chem Soc* **71** 982 *1949*.]

Ethyl chloroformate *[541-41-3]* **M 108.5, m –81°, b 94-95°, d_4^{20} 1.135, n_D^{20} 1.3974.** Wash the ester several times with water, redistil it using an efficient fractionating column at atmospheric pressure and a $CaCl_2$ guard tube to keep free from moisture [Hamilton & Sly *J Am Chem Soc* **47** 435 *1925*, Saunders et al. *J Am Chem Soc* **73** 3796 *1951*]. [*Beilstein* **3** IV 23.] **LACHRYMATORY AND TOXIC.**

Ethyl *trans*-crotonate *[623-70-1]* **M 114.2, b 137°, d_4^{20} 0.917, n_D^{20} 1.425.** Wash it with aqueous 5% Na_2CO_3,

then with saturated aqueous $CaCl_2$, dry it with $CaCl_2$ and distil it. [*Beilstein* **2** IV 1500.]

Ethyl cyanoacetate *[105-56-6]* **M 113.1, b 206.0°, d_4^{20} 1.061, n_D^{20} 1.41751.** Shake the ester several times with aqueous 10% Na_2CO_3, wash it well with water, dry with Na_2SO_4 and fractionally distil it. [*Beilstein* **2** IV 1889.]

Ethyl cyanoformate *[623-49-4]* **M 99.1, b 113-114°/740mm, 116.5-116.8°/765.5mm, d_4^{20} 1.0112, n_D^{20} 1.3818.** Dissolve the cyanoformate in Et_2O, dry it over Na_2SO_4, filter, evaporate and distil it [Malachowsky et al. *Chem Ber* **70** 1016 *1937*, Adickes et al. *J Prakt Chem* [2] **133** 313 *1932*, Grundmann et al. *Justus Liebigs Ann Chem* **577** 77 *1952*]. [*Beilstein* **2** IV 1862.]

Ethyl diazoacetate *[623-73-4]* **M 114.1, m –22°, b 42°/5mm, 45°/12mm, 85-86°/88mm, 140-141°/720mm, 140-143°/atm, $d_4^{17.6}$ 1.0852, $n_D^{17.6}$ 1.4588.** It is a very volatile yellow oil with a strong pungent odour. **EXPLOSIVE [distillation even under reduced pressure is dangerous and may result in an explosion — TAKE ALL THE NECESSARY PRECAUTIONS IF DISTILLATION IS TO BE CARRIED OUT].** It explodes in contact with conc H_2SO_4-trace acid causes rapid decomposition. It is slightly soluble in H_2O, but is miscible with EtOH, *C_6H_6, petroleum ether and Et_2O. To purify, dissolve it in Et_2O [using CH_2Cl_2 instead of Et_2O, protects the ester from acid], wash it with 10% aqueous Na_2CO_3, dry ($MgSO_4$), filter and repeat as many times as possible until the Et_2O layer loses its yellow colour, then remove the solvent below 20° (vacuum). Note that prolonged heating may lead to rapid decomposition and low yields. It can also be purified by steam distillation under reduced pressure but with considerable loss in yield. Place the residual oil in a brown bottle, keep below 10°, and use as soon as possible without distilling. For preparing esters usually the ethereal solution is used directly without purification. [Womack & Nelson *Org Synth* Coll Vol **III** 392 *1955*, UV: Miller & White *J Am Chem Soc* **79** 5974 *1957*, Fieser **1** 367 *1967*, *Beilstein* **3** IV 1495.]

Ethyl dibromoacetate *[617-33-4]* **M 245.9, b 81-82°/14.5mm, 194°/atm, d^{22} 1.9081, n^{22} 1.4973.** Wash the ester briefly with conc aqueous $NaHCO_3$, then with aqueous $CaCl_2$. Dry it with $CaSO_4$ and distil it under reduced pressure. [Hornyak & Amis *J Am Chem Soc* **79** 2079 *1957*, *Beilstein* **2** H 219, **2** I 97, **2** III 484, **2** IV 533.]

Ethyl dichloroacetate *[535-15-9]* **M 157.0, b 54-55°/11mm, 131.0-131.5°/40mm, d_4^{20} 1.28, n_D^{20} 1.438.** Shake the ester with aqueous 3% $NaHCO_3$ to remove free acid, wash with distilled water, dry for 3 days with $CaSO_4$ and distil it under reduced pressure. [*Beilstein* **2** IV 501.]

Ethyl 3,3-diethoxypropionate *[10601-80-6]* **M 190.2, b 58.5°/1.5mm, 65°/2mm, 95-96°/12mm, d_4^{20} 0.78, n_D^{25} 1.4101.** Dissolve it in dry Et_2O, and dry with solid $NaHCO_3$, filter, distil and carefully fractionate it [Dyer & Johnson *J Am Chem Soc* **56** 223 *1934*]. [*Beilstein* **3** II 411.]

Ethylene (ethene) *[74-85-1]* **M 28.0, m –169.4°, b –102°/700mm.** Purify ethylene by passage through a series of towers containing molecular sieves, or anhydrous $CaSO_4$, or cuprous ammonium solution, then conc H_2SO_4, followed by KOH pellets. *Alternatively*, it has been condensed in liquid nitrogen, with melting, freezing and pumping to remove air before passage through an activated charcoal trap, followed by a further condensation in liquid air. A sputtered sodium trap was used to remove oxygen. [*Beilstein* **1** IV 677.]

Ethylenediamine (1,2-diaminoethane) *[107-15-3]* **M 60.1, f 11.0°, b 117.0°, d_4^{20} 0.897, n_D^{20} 1.45677, n^{30} 1.4513, pK_1^{25} 6.86, pK_2^{25} 9.92.** It forms a constant-boiling (**b** 118.5°, *monohydrate*, **m** 10°) mixture with water (23w/w%). [It is *hygroscopic* and miscible with water.] Recommended purification procedure [Asthana & Mukherjee in J.F .Coetzee (ed), *Purification of Solvents,* Pergamon Press, Oxford, 1982 cf p 53]: to 1L of ethylenediamine is added 70g of type 5A Linde molecular sieves and shaken for 12 hours. The liquid is decanted and shaken for a further 12 hours with a mixture of CaO (50g) and KOH (15g). The supernatant is fractionally distilled (at 20:1 reflux ratio) in contact with freshly activated molecular sieves. The fraction distilling at 117.2° /760mm is collected. Finally it is fractionally distilled from sodium metal. All distillations and storage of ethylenediamine should be carried out under nitrogen to prevent reaction with CO_2 and water. The material containing 30% water is dried with solid NaOH (600g/L) and heated on a water bath for 10 hours.

Above 60°, separation into two phases takes place. The hot ethylenediamine layer is decanted off, refluxed with 40g of sodium for 2 hours and distilled [Putnam & Kobe *Trans Electrochem Soc* **74** 609 *1938*]. Ethylenediamine is usually distilled under nitrogen. *Alternatively*, it is dried over type 5A Linde molecular sieves (70g/L), then a mixture of 50g of CaO and 15g of KOH/L, with further dehydration of the supernatant with molecular sieves followed by distillation *from* molecular sieves and, finally, from sodium metal. A spectroscopically improved material is obtained by shaking with freshly baked alumina (20g/L) before distillation. [*Beilstein* **4** IV 1166.]

***N,N′*-Ethylenediaminediacetic acid (EDDA)** *[5657-17-0]* **M 176.2, m 222-224°(dec), pK_1^{25} 6.48, pK_2^{25} 9.57 (for NH groups).** Crystallise EDDA from H_2O. [*Beilstein* **4** IV 2446.]

Ethylenediamine dihydrochloride *[333-18-6]* **M 133.0, m >300°, pK_1^{25} 6.86, pK_2^{25} 9.92.** Crystallise the salt from H_2O or H_2O/EtOH. Wash the crystals with EtOH and dry them *in vacuo*. It sublimes on heating. [*Beilstein* **4** IV 1168.]

Ethylenediaminetetraacetic acid (EDTA) *[60-00-4]* **M 292.3, m 253°(dec), pK_1^{25} 0.26 pK_2^{25} 0.96, pK_3^{25} 2.60, pK_4^{25} 2.67, pK_5^{25} 6.16, pK_6^{25} 10.26.** Dissolve EDTA in aqueous KOH or ammonium hydroxide, and precipitate it twice with dilute HCl or HNO_3. Boil it twice with distilled water to remove mineral acid, then recrystallise it from water or dimethylformamide. Dry it at 110°. It also recrystallises from boiling 1N HCl; wash the crystals with distilled H_2O and dry them *in vacuo*. [Ma & Ray *Biochemistry* **19** 751 *1980*, *Beilstein* **4** IV 2449.]

Ethylene dimethacrylate (ethylene glycol dimethacrylate) *[97-90-5]* **M 198.2, b 98-100°/5mm, d_4^{20} 1.053, n_D^{20} 1.456.** Distil it through a short Vigreux column (p 11) at about 1mm pressure, in the presence of 3% (w/w) of phenyl-ß-naphthylamine. [*Beilstein* **2** IV 1532.]

Ethylene dimyristate [1,2-bis(myristoyloxy)ethane] *[627-84-9]* **M 482.8, m 61.7°.** Crystallise the ester from *benzene/MeOH or diethyl ether/MeOH, and dry it in a vacuum desiccator. It forms an inclusion compound with 25.9 mols of urea. [McGreer et al. *J Am Chem Soc* **74** 3441 *1952*, *Beilstein* **2** H 366, **2** II 327, **2** III 924, **2** IV 1133.]

Ethylene dipalmitate [1,2-bis(palmitoyloxy)ethane] *[624-03-3]* **M 538.9, m 69.1°, 71.2°.** Crystallise the ester from *benzene/MeOH , diethyl ether/MeOH or Me_2CO and dry it in a vacuum desiccator. It forms an inclusion compound with 28.2 mols of urea. [McGreer et al. *J Am Chem Soc* **74** 3541 *1952*, *Beilstein* **2** H 373, **2** I 166, **2** II 338, **2** III 926, **2** IV 1169.]

Ethylene distearate [1,2-bis(stearoyloxy)ethane] *[627-83-8]* **M 595.0, m 74.4-75°, 75.3°, 77°.** Crystallise the ester from *benzene/MeOH, diethyl ether/MeOH or Me_2CO and dry it in a vacuum desiccator. It forms an inclusion compound with 31 mols of urea. [McGreer et al. *J Am Chem Soc* **74** 3541 *1952*, *Beilstein* **2** H 380, **2** II 354, **2** III 1021, **2** IV 1223.]

Ethylene glycol *[107-21-1]* **M 62.1, b 68°/4mm, 197.9°/760mm, d_4^{20} 1.0986, n^{15} 1.43312, n^{25} 1.43056, pK^{25} 10.6.** It is very *hygroscopic*, and also likely to contain higher diols. Dry it with CaO, $CaSO_4$, $MgSO_4$ or NaOH and distil it under vacuum. Dry further by reaction with a small amount of sodium under nitrogen (to remove moisture), reflux for several hours and distil. The distillate is then passed through a column of Linde type 4A molecular sieves and finally distil under nitrogen, from more molecular sieves. Then fractionally distil it. [*Beilstein* **1** IV 2369.]

Ethylene glycol bis(ß-aminoethylether)-*N,N′*-tetraacetic acid (EGTA) *[67-42-5]* **M 380.4, m >245°(dec), pK_1^{20} 1.15 (2.40), pK_2^{20} 2.40 (2.50), pK_3^{20} 8.40 (8.67), pK_4^{20} 8.94 (9.22).** Dissolve EGTA in aqueous NaOH, precipitate it by adding aqueous HCl, wash it with water and dry at 100° *in vacuo*. [*Beilstein* **4** IV 217.]

Ethylene glycol diacetate *[111-55-7]* **M 146.2, b 190.1°, 79-81°/11mm, d^{25} 1.4188, n_D^{20} 1.4150.** Dry the diacetate with $CaCl_2$, filter (excluding moisture) and fractionally distil it under reduced pressure. [*Beilstein* **2** IV

1541.]

Ethylene glycol dibutyl ether *[112-48-1]* **M 174.3, b 78-80°/16mm, 200-201°/760mm, d_4^{20} 1.105, n_D^{20} 1.42.** Shake the ether with aqueous 5% Na_2CO_3, dry with $MgSO_4$ and store it with chromatographic alumina to prevent peroxide formation. [*Beilstein* **1** III 2083, **1** IV 2382.]

Ethylene glycol diethyl ether (1,2-diethoxyethane) *[629-14-1]* **M 118.2, m –74°, b 121.5°, d_4^{20} 0.842, n_D^{20} 1.392.** After refluxing for 12 hours, a mixture of the ether (2L), conc HCl (27ml) and water (200ml) is added with slow passage of nitrogen. The solution is cooled, and KOH pellets are added slowly and with shaking until no more dissolves. The organic layer is decanted, treated with some KOH pellets and again decanted. It is then refluxed with, and distilled from sodium immediately before use. *Alternatively*, after removal of peroxides by treatment with activated alumina, the ether is refluxed in the presence of the blue ketyl formed by sodium-potassium alloy with benzophenone, then distilled. [*Beilstein* **1** H 468, **1** II 519, **1** III 2078, **1** IV 2379.]

Ethyl formate *[109-94-4]* **M 74.1, b 54.2°, d_4^{20} 0.921, d^{30} 0.909, n_D^{20} 1.35994, n^{25} 1.3565.** Free acid or alcohol is removed by standing the ester over anhydrous K_2CO_3, with occasional shaking, then decanting and distilling from P_2O_5. *Alternatively*, the ester can be kept over CaH_2 for several days, then distilled from fresh CaH_2. It cannot be dried with $CaCl_2$ because it reacts rapidly with the ester to form a crystalline compound. [*Beilstein* **2** IV 23.]

Ethyl iodide (iodoethane) *[75-03-6]* **M 156.0, b 72.4°, d_4^{20} 1.933, n^{15} 1.5682, n^{25} 1.5104.** Drying the iodide with P_2O_5 is unsatisfactory, and with $CaCl_2$ it is incomplete. It is probably best to dry it with sodium wire and distil [Hammond et al. *J Am Chem Soc* **82** 704 *1960*]. Exposure of ethyl iodide to light leads to rapid decomposition, with the liberation of iodine. Free iodine can be removed by shaking with several portions of dilute aqueous $Na_2S_2O_3$ (until the colour is discharged), followed by washing with water, drying (with $CaCl_2$, then sodium), and distilling. The distilled ethyl iodide is stored, over mercury, in a dark bottle away from direct sunlight. Other purification procedures include passage through a 60cm column of silica gel, followed by distillation, and treatment with elemental bromine, extraction of free halogen with $Na_2S_2O_3$ solution, followed by washing with water, drying and distilling. Free iodine and HI have also been removed by direct distillation through a LeBel-Henninger column containing copper turnings. Purification by shaking with alkaline solutions, and storage over silver, are reported to be unsatisfactory. [*Beilstein* **1** IV 163.]

Ethyl isobutyrate *[97-62-1]* **M 116.2, b 110°, d_4^{20} 0.867, n_D^{20} 1.388.** Wash the ester with aqueous 5% Na_2CO_3, then with saturated aqueous $CaCl_2$. Dry it over $CaSO_4$ and distil. [*Beilstein* **1** IV 846.]

Ethyl isocyanate *[109-90-0]* **M 71.1, b 559.8°/759mm, 59-61°/760mm, 60-63°/~760mm, d_4^{20} 0.9031, n_D^{20} 1.3808.** Fractionate the isocyanate through an efficient column preferably in an inert atmosphere and store it in aliquots in sealed tubes [Bieber *J Am Chem Soc* **74** 4700 *1952*, Slocombe et al. *J Am Chem Soc* **72** 1888 *1950*]. [*Beilstein* **4** IV 402.]

Ethyl isovalerate *[108-64-5]* **M 130.2, b 134.7°, d_4^{20} 0.8664, n_D^{20} 1.39621, n^{25} 1.3975.** Wash the ester with aqueous 5% Na_2CO_3, then saturated aqueous $CaCl_2$. Dry it over $CaSO_4$ and distil. [*Beilstein* **2** IV 898.]

Ethyl levulinate (4-oxopentanoic acid ethyl ester) *[539-88-8]* **M 144.2, m 37.2°, b 106-108°/2mm, 138.8°/8mm, 203-205°/atm, d_4^{20} 1.012, n_D^{20} 1.423.** Stir the ester with Na_2CO_3 and charcoal, filter and distil. It is freely soluble in H_2O and EtOH [IR, NMR: Sterk *Monatsh Chem* **99** 1770 *1968*, Thomas & Schuette *J Am Chem Soc* **53** 2328 *1931*, Cox & Dodds *J Am Chem Soc* **55** 3392 *1933*]. [*Beilstein* **3** IV 1562.]

Ethyl malonate monoamide *[7597-56-0]* **M 131.1, m 47-50°, 49.5-50°, 50°, b 130-135°/2mm.** The amide crystallises from Et_2O or by slow evaporation of an aqueous solution as colourless crystals [Snyder & Elston *J Am Chem Soc* **76** 3039 *1954*, McAlvain & Schroeder *J Am Chem Soc* **71** 45 *1949*, Rising et al. *J Biol Chem* **89** 20 *1930*]. [*Beilstein* **2** IV 1887.]

Ethyl methacrylate *[97-63-2]* **M 114.2, b 59°/100mm, d_4^{20} 0.915, n_D^{20} 1.515.** Wash the ester successively

with 5% aqueous $NaNO_2$, 5% $NaHSO_3$, 5% NaOH, then water. Dry it over $MgSO_4$, add 0.2% (w/w) of phenyl-ß-naphthylamine, and distil it through a short Vigreux column [Schultz *J Am Chem Soc* **80** 1854 *1958*]. [*Beilstein* **2** IV 1523.]

Ethyl methyl ether *[540-67-0]* **M 60.1, b 7°/760mm, d^{o} 0.725, n^{4} 1.3420.** Dry the ether with $CaSO_4$, pass it through an alumina column (to remove peroxides), then fractionally distil it while collecting fractions in receivers kept below 0°. [*Beilstein* **1** H 314, **1** I 158, **1** II 311, **1** III 1288, **1** IV 1314.]

3-Ethyl-2-methyl-2-pentene *[19780-67-7]* **M 112.2, b 109°/757mm, 114.5°/760mm, d_4^{20} 0.72468, n_D^{20} 1.4124.** Purify it by preparative GLC on a column of 20% squalene on Chromosorb P at 70°. *Alternatively*, fractionate it under an inert atmosphere. It forms an azeotrope with methoxyethanol. [*Beilstein* **1** H 222, **1** III 8471, **1** IV 890.]

Ethyl nitroacetate *[626-35-7]* **M 133.1, b 42-43°/0.2mm, 71-72°/3mm, 93-96°/9mm, 194-195°/atm, d_4^{20} 1.1953, n_D^{20} 1.4260, pK^{25} 5.82.** Purify the ester by repeated distillation. IR:ν_{max} 1748 (CO_2), 1570 and 1337 (NO_2), and 800cm^{-1} [Haszeldine *J Chem Soc* 2525 *1953*]. The *hydrazine salt* crystallises from 95% EtOH or MeOH as yellow crystals **m** 104-105° [Ungnade & Kissinger *J Org Chem* **22** 1661 *1957*, Emmons & Freeman *J Am Chem Soc* **77** 4391 *1955*]. [*Beilstein* **2** IV 537.]

Ethyl propionate *[105-37-3]* **M 102.1, b 99.1°, d_4^{20} 0.891, n^{15} 1.38643, n_D^{20} 1.38394.** Treat the ester with anhydrous $CuSO_4$ and distil it under nitrogen. [*Beilstein* **2** IV 205.]

Ethyl pyruvate *[617-35-6]* **M 116.1, m –50°, b 44-45°/10mm, 56°/20mm, 69-71°/42mm, 63°/23mm, 155.5°/760mm, d_4^{20} 1.047, n_D^{20} 1.4052.** Shake the ester with 10ml portions of saturated aqueous $CaCl_2$ solution (removes ethyl acetate) and the organic layer is removed by centrifugation, decantation and filtration, and is distilled under reduced pressure. Purification of small quantities is carried out *via* the bisulfite adduct: the ester (2.2ml) is shaken with saturated $NaHSO_3$ (3.6ml), chilled in a freezing mixture when crystals separate rapidly (particularly if seeded). After 5 minutes EtOH (10ml) is added and the crystals are filtered off, washed with EtOH and Et_2O and dried. Yield *ca* 3g of *bisulfite adduct*. Then treat the adduct (16g) with saturated aqueous $MgSO_4$ (32ml) and 40% formaldehyde (5ml) and shake, whereby the ester separates as an oil which is extracted with Et_2O. The extract is dried ($MgSO_4$), filtered, evaporated and the residue is distilled (**b** 56°/20mm), and then redistilled (**b** 147.5°/750mm) to give 5.5g of pure ester. [Cornforth *Org Synth* Coll Vol **IV** 467 *1963*, *Beilstein* **3** IV 1513.]

Ethyl stearate *[111-61-5]* **M 312.5, m 33°, b 213-215°/15mm.** The solid portion is separated from the partially solid starting material, then crystallised twice from EtOH, dried by azeotropic distillation with *benzene, and fractionally distilled through a spinning-band column at low pressure [Welsh *Trans Faraday Soc* **55** 52 *1959*]. [*Beilstein* **2** IV 1218.]

Ethyl thiocyanate (ethyl rhodanide) *[542-90-5]* **M 87.1, b 144-145°, d_4^{20} 1.011, n_D^{20} 1.462.** Fractionally distil the ester at atmospheric pressure. [*Beilstein* **2** IV 1218.] **(CARE LACHRYMATOR.)**

Ethyl thioglycolate (ethyl 2-mercaptoacetate) *[623-51-8]* **M 120.2, b 50-51°/10mm, 55°/17mm, 62.5-64°/22mm, 67-68°/24mm, 155-158°/atm, d_4^{20} 1.096, n_D^{20} 1.457.** Dissolve the thioglycolate in Et_2O, wash with H_2O, dry it over Na_2SO_4, filter, evaporate and distil the residue under reduced pressure [Bredereck et al. *Chem Ber* **90** 1837 *1957*]. The *Ni complex [Ni(SCH$_2$CO$_2$Et)$_2$]*, when recrystallised twice from EtOH, gives crystals which become black when dried in a vacuum over H_2SO_4, **m** 104-105° [Dranet & Cefola *J Am Chem Soc* **76** 1975 *1954*]. [*Beilstein* **3** H 255.]

***N*-Ethyl thiourea** *[625-53-6]* **M 104.2, m 110°.** Crystallise the thiourea from EtOH, MeOH or ether. [*Beilstein* **4** IV 374.]

Ethyl trichloroacetate *[515-84-4]* **M 191.4, b 100-100.5°/30mm, d_4^{20} 1.383.** Shake the ester with saturated aqueous Na_2CO_3 (three times), aqueous 50% $CaCl_2$ (three times), saturated aqueous NaCl (twice), then distil it

over $CaCl_2$, and redistil it under reduced pressure. [*Beilstein* **2** IV 514.]

Ethyl trifluoroacetate *[383-63-1]* **M 142.1, b 61.3°/750, 60-62°/atm, 62-64°/755mm, d_4^{20} 1.191, n_D^{20} 1.30738.** It has been prepared by treating sodium trifluoroacetate with Et_2SO_4, or the acid with excess of EtOH and a small amount of H_2SO_4, distilling the azeotropic mixture of ester and EtOH, removing the latter with $CaCl_2$, filtering and fractionally distilling [Henne et al *J Am Chem Soc* **69** 1819]. Fractionate it through a long Vigreux column. IR has ν_{max} at 1800 (CO_2) and 1000 (OCO) cm^1 [Fuson et al. *J Chem Phys* **20** 1627 *1952*, Bergman *J Org Chem* **23** 476 *1958*]. [*Beilstein* **2** II 186, **2** III 427, **2** IV 463.]

Ethyl 4,4,4-trifluoroacetoacetate (ethyl 3-oxo-4,4,4-trifluorobutyrate) *[372-31-6]* **M 184.1, b 47-49°/25mm, 129-130°/atm, 131.8°/atm, d_4^{25} 1.259, n_D^{20} 1.375.** The ester was prepared by the method of Swarts [*Bull Acad Roy Belg* **13** 175 *1927*] in which ethyl trifluoroacetate (1mol) was added slowly to a stirred suspension of NaOEt (1mol) in EtOH (exothermic reaction), followed EtOAc (1mol), and refluxed overnight. An improved purification was by treatment with a concentrated aqueous solution of $NaHSO_4$ (very small molar excess), followed by addition of a clear aqueous solution of $Cu(OAc)_2$**,** and the organic layer was distilled off. The Cu derivative was filtered off and recrystallised from EtOH, washed with Et_2O to give green crystals of the *copper chelate* **m 189°** [UV has λ_{max} at 220nm (ε 11,000) and 270nm (ε 21,000), 3.0mg % in EtOH]. The dry Cu chelate was suspended in Et_2O (some dissolved) and H_2S was bubbled through until precipitation of CuS was complete. The CuS was filtered off, and the filtrate was carefully fractionation (to avoid losses) to provide the *ester* in 54% overall yield. Its UV has λ_{max} at 238nm (ε 3000) and 288nm (ε 400), in cyclohexane [Breslow et al. *J Am Chem Soc* **68** 102, *1946*, Henne et al. *J Am Chem Soc* **69** 1819 *1947*, Haszeldine et al. *J Chem Soc* 609 *1951*, *Beilstein* **3** II 425, **3** III 1206, **3** IV 1548].

Ethyl trifluoromethanesulfonate *[425-75-2]* **M 178.1, b 115°/atm, 118-120°/atm, d_4^{20} 1.378, n_D^{20} 1.336.** The ester reacts slowly with H_2O and aqueous alkali. If its IR has no OH bands (~3000 cm^{-1}) then purify it by redistillation. If OH bands are present, then dilute with dry Et_2O and shake (carefully) with aqueous $NaHCO_3$ until effervescence ceases, then wash with H_2O and dry ($MgSO_4$), filter, evaporate and distil the residue under a slight vacuum then at atmospheric pressure in a N_2 atmosphere. **It is a powerful alkylating agent, and the fumes are very toxic — perform all operations in an efficient fume cupboard.** [Gramstad & Haszeldine *J Chem Soc* 173 *1956*, Howells & McCown *Chem Rev* **77** 69 *1977*, *Beilstein* **3** IV 34.]

S-Ethyl trifluorothioacetate *[383-64-2]* **M 158.1, b 88-90°/atm, 90.5°/760mm, d_4^{20} 1.255, n_D^{20} 1.372.** If IR is free of OH bands then fractionally distil it; otherwise dilute the thio-ester with dry Et_2O, wash with 5% KOH and H_2O, dry over $MgSO_4$ and fractionate it through an efficient column [Hauptschein et al. *J Am Chem Soc* **74** 4005 *1952*]. [*Beilstein* **2** IV 567.] *Powerful obnoxious odour.*

Ethyl vinyl ether *[109-92-2]* **M 72.1, b 35.5°, d_4^{20} 0.755.** It usually contains polymerisation inhibitors (usually amines, e.g. triethanolamine) which can be removed by fractional distillation. Redistil it from sodium. [*Beilstein* **1** IV 2049.] **LACHRYMATORY.**

Fluoroacetamide *[640-19-7]* M 77.1, m 108°.

Crystallise fluoroacetamide from chloroform and dry it in a vacuum. **TOXIC** [*Beilstein* **2** IV 454.]

Formaldehyde *[50-00-0]* **M 30.0, m -92°, b -79.6°/20mm, -19.5°/760mm, d_4^{20} 0.815, pK^{25} 13.27 (hydrate).** Technical aqueous formaldehyde (***formalin***) solution commonly contains added MeOH (8-10%) to inhibit oxidation to formic acid. As a rough guide the d_4^{18} ***vs* [*concentration in g of HCHO/100ml (100g) of aqueous solution*]** is as follows: 1.0054 [2.24 (2.23)], 1.0126 [4.66 (4.60)], 1.0311 [11.08 (10.74)], 1.0410 [14.15 (13.59)], 1.0568 [19.89 (18.82)], 1.0719 [25.44 (23.73)], 1.0853 [30.17 (27.80)], 1.1057 [37.72 (34.11)] and 1.1158 [41.87 (37.53)]; values in curved brackets are from alternative determinations. [Marvel & Porter *Org Synth* Coll Vol **I** 377 1941]. If pure formaldehyde is required, add KOH solution (1 mole KOH: 100 moles HCHO) to ~37% by weight of aqueous formaldehyde solution (*formalin*), or evaporate formalin to dryness, to

give ***paraformaldehyde polymer*** {$HO(CH_2O)_nH$, [30525-89-4] **m 120-170°** depending on ***n***} as a white solid which, after washing with water, is dried in a vacuum desiccator over P_2O_5 or H_2SO_4. Formaldehyde is regenerated by heating the paraformaldehyde to 120° under vacuum, or by decomposing it with barium peroxide. The *monomer*, a colourless flammable gas, is passed through a glass-wool filter cooled to –48° in a $CaCl_2$/ice mixture to remove particles of polymer, then dried by passage over P_2O_5 and either condensed in a bulb immersed in liquid nitrogen or absorbed in ice-cold conductivity water. The gas or aqueous solutions have *pungent suffocating odours***,** are LACHRYMATORY and SUSPECTED CARCINOGEN, handle carefully. Formalin is a disinfectant and a preservative of dead animal and plant tissues. [*Beilstein* **1** IV 3017.]

Formaldehyde dimethyl acetal (dimethoxymethane, methylal, formal) *[109-87-5]* **M 76.1, m –108°, b 41-42°/736mm, 41-43°/atm, 42-46°/atm, d_4^{20} 0.8608, n_D^{20} 1.35335.** It is a volatile flammable liquid which is soluble in three parts of H_2O, and is readily hydrolysed by acids. Purify it by shaking with an equal volume of 20% aqueous NaOH, stand for 20 minutes, dry over fused $CaCl_2$, filter and fractionally distil it through an efficient column. Store it over molecular sieves. [Buchler et al. *Org Synth* Coll Vol **III** 469 *1955*, Rambaud & Besserre *Bull Soc Chim Fr* 45 *1955*, IR: Wilmshurst *Can J Chem* **36** 285 *1958*, *Beilstein* **1** IV 3026.]

Formaldehyde dimethyl mercaptal (bis-[methylthio]methane) *[1618-26-4]* **M 108.2, b 44-47°/13mm, 45.5°/18mm, 148-149°/~760mm, d_4^{20} 1.0594, n_D^{20} 1.5322. Work in an efficient fume cupboard as the substance may contain traces (or more) of methylmercaptan which has a very bad odour.** Dissolve the mercaptal in Et_2O, shake it with aqueous alkalis then dry it over anhydrous K_2CO_3, filter and distil it over K_2CO_3 under a stream of N_2. If the odour is very strong, then allow all gas efluents to bubble through 5% aqueous NaOH solution which is then treated with dilute $KMnO_4$ in order to oxidise MeSH to odourless products. Its UV has λ_{max} at 238 nm (log ε 2.73) [Fehnel & Carmack *J Am Chem Soc* **71** 90 *1949*, Fehér & Vogelbruch *Chem Ber* **91** 996 *1958*, Bøhme & Marz *Chem Ber* **74** 1672 *1941*]. Oxidation with aqueous $KMnO_4$ yields *bis-(methylsulfonyl)methane* which has **m** 142-143° [Fiecchi et al. *Tetrahedron Lett* 1681 *1967*]. [*Beilstein* **1** IV 3088.]

Formamide *[75-12-7]* **M 45.0, f 2.6°, b 103°/9mm, 210.5°/760mm(dec), d_4^{20} 1.13, n_D^{20} 1.44754, n^{25} 1.44682.** Formamide is easily hydrolysed by acids and bases. It also reacts with peroxides, acid halides, acid anhydrides, esters and (on heating) alcohols, while strong dehydrating agents convert it to a nitrile. It is very *hygroscopic*. Commercial material often contains acids and ammonium formate. Vorhoek [*J Am Chem Soc* **58** 2577 *1956*] added some bromothymol blue to formamide and then neutralise it with NaOH before heating to 80-90° under reduced pressure to distil off ammonia and water. The amide is again neutralised and the process is repeated until the liquid remained neutral on heating. Sodium formate is added, and the formamide is concentrated under reduced pressure at 80-90°. The distillate is again neutralised and redistilled. It is then fractionally crystallised in the absence of CO_2 and water by partial freezing.
Formamide (specific conductance 2 x 10^{-7} ohm^{-1} cm^{-1}) of low water content is dried by passage through a column of 3A molecular sieves, then deionised by treatment with a mixed-bed ion-exchange resin loaded with H^+ and $HCONH^-$ ions (using sodium formamide in formamide) [Notley & Spiro *J Chem Soc (B)* 362 *1966*]. [*Beilstein* **2** IV 45.]

Formamidine acetate *[3473-63-0]* **M 104.1, m 159-161°(dec), 164°(dec), pK_{Est} ~12.** Unlike the hydrochloride, the acetate salt is not hygroscopic. It is recrystallised from a small volume of acetic acid, by addition of EtOH, and the crystals are washed with EtOH then Et_2O and dried in a vacuum. [Taylor et al. *Org Synth* **46** 39 *1966*, *Beilstein* **2** IV 82.]

Formamidine sulfinic acid (thiourea-S-dioxide) *[1758-73-2]* **M 108.1, m 124-126°(dec).** Dissolve it in five parts of aqueous 1:1% $NaHSO_3$ at 60-63° (charcoal), then allow it to crystallise slowly, with agitation, at 10°. Filter and dry it immediately at 60° [Koniecki & Linch *Anal Chem* **30** 1134 *1958*]. [*Beilstein* **3** I 36, **3** IV 145.]

Formic acid *[64-18-6]* **M 46.0 (anhydrous), f 8.3°, b 25°/40mm, 100.7°/760mm, d_4^{20} 1.22, n 1.37140, n^{25} 1.36938, pK^{25} 3.74.** Anhydrous formic acid can be obtained by direct fractional distillation under reduced pressure, the receiver being cooled in ice-water. The use of P_2O_5 or $CaCl_2$ as dehydrating agents is unsatisfactory. Reagent grade 88% formic acid can be dried satisfactorily by refluxing with phthalic anhydride

for 6 hours and then distilling it. *Alternatively*, if it is left in contact with freshly prepared anhydrous $CuSO_4$ for several days about one half of the water is removed from 88% formic acid; distillation then removes the remainder. Boric anhydride (prepared by melting boric acid in an oven at a high temperature, cooling in a desiccator, and powdering) is a suitable dehydrating agent for 98% formic acid; after prolonged stirring with the anhydride the formic acid is distilled under vacuum. Formic acid can be further purified by fractional crystallisation using partial freezing. [*Beilstein* **2** IV 3.]

***N*-Formyl *tert*-butylamine (*N-tert*-butylformamide)** *[2425-74-3]* **M 101.2, m 16°, b 48°/0.2mm, 78-83°/9mm, 135-136°/107mm, 202°/760mm, d_4^{25} 0.903, n_D^{20} 1.4330.** If the IR indicates some hydrolysis, then dissolve it in Et_2O, wash it with 20% aqueous Na_2CO_3, dry it ($MgSO_4$), filter and fractionate it. Collect the fraction that solidifies on cooling and recrystallise it from Et_2O at low temperature if necessary. [Emmons *J Am Chem Soc* **79** 5753 *1957*, *Beilstein* **4** III 324, **4** IV 661.]

***N*-Formyl ethylamine (*N*-ethylformamide)** *[627-45-2]* **M 73.1, b 29°/0.5mm, 176-179°/758mm, d_4^{20} 0.950, n_D^{20} 1.4346.** If the IR is good, then distil it and collect the middle fraction and redistil if necessary; otherwise proceed as for the previous amide. [Erickson *J Org Chem* **20** 1569 *1955*, *Beilstein* **4** H 109, **4** I 352, **4** II 601, **4** III 207, **4** IV 346.]

Formyl hydrazine (formic acid hydrazide) *[624-84-0]* **M 60.1, m 54°, 54-57°, pK_{est} ~2.5.** Recrystallise it from EtOH and dry it *in vacuo*. Store below 10°; it may disproportionate on storage to 1,2-diformyl hydrazine and hydrazine. It forms a blue $[Cu(CH_4N_2O)]SO_4$ salt with $CuSO_4$. [*Beilstein* **2** H 93, **2** III 127, **2** IV 85.]

Formyloxy acetonitrile (cyanomethyl formate) *[150760-95-5]* **M 85.1, b 62-64°/12mm, 172-173°/atm, d_4^{25} 0.903, n_D^{20} 1.4330.** Purify it by fractional distillation and redistilling the middle fraction. It is useful for the formylation of alcohols and amines. The ^{13}C NMR has δ ($CDCl_3$) at 47.87, 114.47 and 159.46 ppm. [Deutsch & Niclas *Synth Commun* **23** 1561 *1993*, Duczek et al. *Synthesis* 37 *1966*.]

Fumaraldehyde bis-(dimethyl acetal) (*trans*-1,1,4,4-tetramethoxybut-2-ene) *[6068-62-8]* **M 176.2, b 100-103°/15mm, 101-103°/25mm, d_4^{20} 1.011, n_D^{20} 1.425.** Dry it over fused $CaCl_2$ and distil it *in vacuo*. The maleic (*cis*) isomer has **b** 112°/11mm, and d^{23} 0.932 and n_D^{25}1.4243. [Zeik & Heusner *Chem Ber* **90** 1869 *1957*, Clauson-Kaas et al. *Acta Chem Scand* **9** 111 *1955,* Clauson-Kaas *Acta Chem Scand* **6** 569 *1952*, *Beilstein* **1** IV 3754.]

Fumaric (*trans*-but-2-ene-1,4-dioic) acid *[110-17-8]* **M 116.1, m 289.5-291.5° (sealed tube), pK_1^{25} 3.10, pK_2^{25} 4.60 (4.38).** Crystallise it from hot M HCl or water and dry it at 100°. [*Beilstein* **2** IV 2202.]

Geraniol (*trans*-3,7-dimethyl-2,6-octadien-8-ol) *[106-24-1]* **M 154.3, b 114-115°/11-12mm, 230°, d_4^{20} 0.879, n_D^{20} 1.4766.** Purify geraniol by ascending chromatography or by thin layer chromatography on plates of kieselguhr G with acetone/water/liquid paraffin (130:70:1) as solvent system. Hexane/ethyl acetate (1:4) is also suitable. Also purify it by GLC on a silicone-treated column of Carbowax 20M (10%) on Chromosorb W (60-80 mesh). [Porter *Pure Appl Chem* **20** 499 *1969*.] Store it in full, tightly sealed containers in the cool and protect from light. It has a pleasant odour. [cf p 681, *Beilstein* **1** IV 2277.]

Glutaraldehyde *[111-30-8]* **M 100.1, b 71°/10mm, as 50% aqueous solution.** Likely impurities are oxidation products-acids, semialdehydes and polymers. It can be purified by repeated washing with activated charcoal (Norit) followed by vacuum filtration, using 15-20g charcoal/100ml of glutaraldehyde solution. Distil it at 60-65°/15mm, discarding the first 5-10%, then dilute with an equal volume of freshly distilled water at 70-75°, using magnetic stirring under nitrogen. The solution is stored at low temperature (3-4°), in a tightly stoppered container, and protected from light. Standardise by titration with hydroxylamine. [Anderson *J Histochem Cytochem* **15** 652 *1967*, *Beilstein* **1** IV 3659.]

Glutaric acid *[110-94-1]* **M 132.1, m 97.5-98°, pK_1^{25} 4.35, pK_2^{25} 5.40.** Crystallise the acid from *benzene, $CHCl_3$, distilled water or *benzene containing 10% (w/w) of diethyl ether. Dry it under vacuum. [*Beilstein* **2**

IV 1934.]

***dl*-Glyceraldehyde** *[56-82-6]* **M 90.1, m 145°.** Crystallise it from EtOH/diethyl ether. The D(+)-*enantiomer* [453-17-8] is a syrup (70 + % H_2O) with $[\alpha]_D^{25}$ +14° (c 2, H_2O) and the *dimethyl acetal* has **b** 124-127 °/14mm and $[\alpha]_D^{15}$ +21° (c 18, H_2O). [*Beilstein* **1** H 845, **1** IV 4114.]

Glycerol *[56-81-5]* **M 92.1, m 18.2°, b 182°/20mm, 290°/760mm, d_4^{20} 1.261, n_D^{25} 1.47352, pK^{25} 14.4.** Glycerol is dissolved in an equal volume of *n*-butanol (or *n*-propanol, amyl alcohol or liquid ammonia) in a water-tight container, cooled and seeded while slowly revolving in an ice-water slurry. The crystals are collected by centrifugation, then washed with cold acetone or isopropyl ether. [Hass & Patterson *Ind Eng Chem (Anal Ed)* **33** 615 *1941*.] Coloured impurities can be removed from substantially dry glycerol by extraction with 2,2,4-trimethylpentane. *Alternatively*, glycerol can be decolorised and dried by treatment with activated charcoal and alumina, followed by filtering. Glycerol can be distilled at 15mm in a stream of dry nitrogen, and stored in a desiccator over P_2O_5. Crude glycerol can be purified by digestion with concentrated H_2SO_4 and then saponification with a lime paste, re-acidification with H_2SO_4, filteration, treatment with an anion exchange resin and fractional distillation under vacuum. [*Beilstein* **1** IV 2751.]

Glycolic (α-hydroxyacetic) acid *[79-14-1]* **M 76.1, m 81°, pK^{25} 3.62.** Crystallise it from diethyl ether. [*Beilstein* **3** IV 571.]

Guanidine *[113-00-8]* **M 59.1, m 47.5-48.5°, 48-49°, ~50°, pK^{25} 13.6.** Crystallise it from water/EtOH under nitrogen. It is very deliquescent and absorbs CO_2 from the air readily. [Jones *Trans Faraday Soc* **55** 524 *1959*, *Beilstein* **3** H 82, **3** I 39, **3** II 69, **3** III 154, **3** IV 148.]

Guanidine carbonate *[593-85-1]* **M 180.2, m 197°, 230°.** Crystallise it from MeOH. [*Beilstein* **3** H 86, **3** I 41, **3** II 72, **3** III 161, **3** IV 152.]

Guanidine hydrochloride *[50-01-1]* **M 95.5, m 181-183°.** Crystallise the hydrochloride from hot methanol by chilling to about –10°, with vigorous stirring. The fine crystals are filtered through fritted glass, washed with cold (–10°) methanol, dried at 50° under vacuum for 5 hours. (The product is purer than that obtained by crystallisation at room temperature from methanol by adding large amounts of diethyl ether.) [Kolthoff et al. *J Am Chem Soc* **79** 5102 *1957*, *Beilstein* **3** H 86, **3** II 71, **3** III 160, **3** IV 150.]

Heptadecanoic acid (margaric) *[506-12-7]* **M 270.5, m 60-61°, b 227°/100mm, pK_{Est} ~4.9.** Crystallise the acid from MeOH or petroleum ether. [*Beilstein* **2** IV 1193.]

1-Heptadecanol *[1454-85-9]* **M 256.5, m 54°.** Crystallise it from acetone. [*Beilstein* **1** IV 1884.]

Heptafluoro-2-iodopropane *[677-69-0]* **M 295.9, b 39°/735mm, 41°/760mm, d_4^0 2.1306, n_D^{20} 1.3281.** Purify it by gas chromatography on a triacetin (glyceryl triacetate) column, followed by bulb-to-bulb distillation at low temperature. Store it over Cu powder to stabilise it. UV has ν_{max} at 271nm (ε 240) in petroleum ether (b 60-80°). [Haszeldine *J Chem Soc* 1767, 3761 *1953*, *Beilstein* **1** III 255, **1** IV 225.]

***n*-Heptaldehyde** *[111-71-7]* **M 114.2, b 40.5°/12mm, 152.8°/760mm, d_4^{20} 0.819, n_D^{25} 1.4130.** Dry *n*-heptaldehyde with $CaSO_4$ or Na_2SO_4 and fractionally distil it under reduced pressure. More extensive purification is by precipitation as the bisulfite compound (formed by adding the aldehyde to saturated aqueous $NaHSO_3$) which is filtered off and recrystallised from hot H_2O. The crystals, after being filtered and washed well with H_2O, are hydrolysed by adding 700ml of aqueous Na_2CO_3 (12.5% w/w of anhydrous Na_2CO_3) per 100g of aldehyde. The aldehyde is then steam distilled off, separated, dried with $CuSO_4$ and distilled under reduced pressure in a slow stream of nitrogen. [McNesby & Davis *J Am Chem Soc* **76** 2148 *1954*, *Beilstein* **1** H 695, **1** I 357, **1** II 750, **1** III 2844, **1** IV 3314.]

***n*-Heptaldoxime** *[629-31-2]* **M 129.2, m 53-55°.** Separate the *cis*(Z) and *trans*(E) oximes by liquid chromatography through a silica gel column and eluting with petroleum ether (b 40-65°)/EtOAc (50:10) at a flow rate of 2-3.4 ml/sec where the *trans-isomer* comes through first and is a liquid with n_D^{22} 1.38512, followed by the *cis-isomer* which is a solid, and crystallises from 60% aqueous EtOH with **m** 55°. They are identified by TLC on 0.2mm silica gel G by eluting with *C_6H_6/EtOAc (50/10) and visualising with I_2 vapour: the *trans-isomer* has R_F 0.6 and the *cis-isomer* has R_F 0.5 [Pejkovic-Tadic et al. *J Chromatography* **21** 239 *1966*, Emmous & Pagano *J Am Chem Soc* **77** 4557 *1955*]. [*Beilstein* **1** H 698, **1** I 358, **1** II 752, **1** III 2850.]

***n*-Heptane** *[142-18-5]* **M 100.2, b 98.4°, d_4^{20} 0.684, n_D^{20} 1.38765, n_D^{25} 1.38512.** Pass it through a silica gel column which greatly reduces the ultraviolet absorption of *n*-heptane. (The silica gel is previously heated to 350° before use.) For more extensive purification, heptane is shaken with successive small portions of conc H_2SO_4 until the lower (acid) layer remains colourless. The heptane is then washed successively with water, aqueous 10% Na_2CO_3, water (twice), and dried with $CaSO_4$, $MgSO_4$ or $CaCl_2$. It is distilled from sodium. *n*-Heptane can be distilled azeotropically with methanol, then the methanol is washed out with water and, after drying, the heptane is redistilled. Other purification procedures include passage through activated basic Al_2O_3, drying with CaH_2, storage with sodium, and stirring with 0.5*N* $KMnO_4$ in 6N H_2SO_4 for 12 hours after treatment with conc H_2SO_4. Carbonyl-containing impurities have been removed by percolation through a column of impregnated Celite made by dissolving 0.5g of 2,4-dinitrophenylhydrazine in 6ml of 85% H_3PO_4 by grinding together, then adding 4ml of distilled water and 10g Celite. [Schwartz & Parks *Anal Chem* **33** 1396 *1961*, *Beilstein* **1** IV 376.]

Hept-1-ene *[592-76-7]* **M 98.2, b 93°/771mm, d_4^{20} 0.698, n_D^{20} 1.400.** Distil hept-1-ene from sodium, then carefully fractionally distilling it using an 18-in gauze-packed column. It can also be purified by azeotropic distillation with EtOH. It usually contains the 2- and 3-isomers as impurities. These can be removed by gas chromatography using a Carbowax column at 70°. [*Beilstein* **1** IV 857.]

***n*-Heptyl alcohol (1-heptanol)** *[111-70-6]* **M 116.2, b 175.6°, d 0.825, n_D^{20} 1.425.** Shake the alcohol with successive lots of alkaline $KMnO_4$ until the colour persists for 15 minutes, then dry it with K_2CO_3 or CaO, and fractionally distil it. [*Beilstein* **1** IV 1731.]

***n*-Heptylamine** *[111-68-2]* **M 115.2, b 155°, d_4^{20} 0.775, n_D^{20} 1.434, pK^{25} 10.66.** Dry it in over KOH pellets for 24 hours, then decant it and fractionally distil it. Store away from CO_2. [*Beilstein* **4** IV 734.]

***n*-Heptyl bromide** *[629-04-9]* **M 179.1, b 70.6°/19mm, 180°/760mm, d_4^{20} 1.140, n_D^{20} 1.45.** Shake it with conc H_2SO_4, wash with water, dry it with K_2CO_3, and fractionally distil. [*Beilstein* **1** IV 391.]

Hexachloro-1,3-butadiene (perchlorobutadiene) *[87-68-3]* **M 260.8, b 144.1°/100mm, 210-212°/760mm, d_4^{20} 1.683, n_D^{20} 1.5556.** Wash the diene with four or five 1/10th volumes of MeOH (or until the yellow colour has been extracted), then stir it for 2 hours with H_2SO_4, wash it with distilled water until neutral and filter it through a column of P_2O_5. Distil it under reduced pressure through a packed column. [Rytner & Bauer *J Am Chem Soc* **82** 298 *1960*, *Beilstein* **1** IV 998.]

Hexachloroethane *[67-72-1]* **M 236.7, m 187°.** Steam distil it, then crystallise it from 95% EtOH. Dry it in the dark under vacuum. [*Beilstein* **1** IV 148.]

Hexacosane (C-26) *[630-01-3]* **M 366.7, m 56.4°, b 169°/0.05mm, 205°/1mm, 262°/15mm.** Distil hexacosane under vacuum and recrystallise it from diethyl ether. [*Beilstein* **1** IV 583.]

Hexacosanoic acid (cerotinic acid) *[506-46-7]* **M 396.7, m 86-87°, 88-89°, pK_{Est} ~4.9.** Crystallise the acid from EtOH, aqueous EtOH and petroleum ether/Me_2CO. [*Beilstein* **2** IV 1310.]

***n*-Hexadecane (Cetane)** *[544-76-3]* **M 226.5, m 18.2°, b 105°/0.1mm, d_4^{20} 0.773, n_D^{20} 1.4345, n^{25} 1.4325.** Pass cetane through a column of silica gel and distil it under vacuum in a column packed with Pyrex helices. Store it over silica gel. It also crystallises from acetone, or is fractionally crystallised by partial freezing.

[*Beilstein* **1** IV 537.]

1,14-Hexadecanedioic acid (Thaspic acid) *[505-54-4]* **M 286.4, m 126°, $pK_{Est(1)}$ ~4.5, $pK_{Est(2)}$ ~5.5.** Recrystallise thaspic acid from EtOH, ethyl acetate or $*C_6H_6$. [*Beilstein* **2** IV 2162.]

Hexadecanoic acid (palmitic acid) *[57-10-3]* **M 256.4, m 62-63°, b 215°/15mm, pK^{25} 6.46 (50% aqueous EtOH), 5.0 (H_2O).** Purify palmitic acid by slow (overnight) recrystallisation from hexane. Some samples are also crystallised from acetone, EtOH or EtOAc. The crystals are kept in air to lose solvent, or are pumped dry of solvent on a vacuum line. [Iwahashi et al. *J Chem Soc, Faraday Trans 1* **81** 973 *1985*, pK: White *J Am Chem Soc* **72** 1858 *1950*, *Beilstein* **2** IV 1157.]

1,5-Hexadiene *[592-42-7]* **M 82.2, b 59.6°, d_4^{20} 0.694, n_D^{20} 1.4039.** Distil 1,5-hexadiene from $NaBH_4$. [*Beilstein* **1** IV 1013.]

Hexafluoroacetone *[684-16-2, 34202-69-2 ($3H_2O$)]* **M 166.1, m –129°, (trihydrate m 18-21°), b -28°.** Dehydrate hexafluoroacetone by passing the vapours over P_2O_5. Ethylene is removed by passing the dried vapours through a tube containing Pyrex glass wool moistened with conc H_2SO_4. Further purification is by low temperature distillation using Warde-Le Roy stills. Store it in the dark at –78°. [Holmes & Kutschke *Trans Faraday Soc* **58** 333 *1962*, *Beilstein* **1** IV 3215.]

Hexafluoroacetylacetone (1,1,1,5,5,5-hexafluoro-2,4-pentanedione, hfacac) *[1522-22-1]* **M 208.1, b 63-65°/atm, 68°/736mm, 70-70.2°/760mm, 68-71°/atm, d_4^{20} 1.490, n_D^{20} 1.333.** Hfacac has been prepared from a mixture of Na wire (0.34mole) covered with dry Et_2O and CF_3CO_2Et (0.27mole see [383-63-1]) at 0°, to which was added trifluoroacetone (0.27mol, see [421-50-1]) at –78°. The mixture was then set aside overnight at ~25°, and any trifluoroacetone which distilled out was made to condense back into the reaction mixture which was stirred at ~25° until all the Na dissolved [Haszeldine et al. *J Chem Soc* 609 *1951*, compare with Henne et al. *J Am Chem Soc* **69** 1819 *1947*]. The reddish-brown mixture was treated with an excess of 2N H_2SO_4 and extracted with ether. The organic layer was dried (Na_2SO_4), and distilled to give *hfacac* (20g, 37%). By using NaOEt instead of Na metal, Henne and coworkers obtained a 72% yield of *hfacac*, which gave the *copper chelate* as bright grass green crystals (see below) [Henne et al. *J Am Chem Soc* **69** 1819 *1947*]. Hfacac (100g) is purified by shaking twice with 98% H_2SO_4 (300ml, *use protective clothing*) until it is completely dispersed, and set aside overnight. The anhydrous facac is separated and distilled through a glass-helices packed column with fraction b 70.2-70.5°/atm (~20g, analytically pure) being retained for metal complex studies [Buckingham et al. *Aust J Chem* **20** 281 *1967*]. The oil readily forms a solid white stable *covalent dihydrate* [CF_3-$C(OH)_2$-CH_2-$C(OH)_2$-CF_3] which is caused by the strong electron-withdrawing effect of the fluorine atoms. The dihydrate has no UV absorption spectrum; compare with λ_{max} ($CHCl_3$) 273nm (ε 7,800) for the anhydrous diketone. The dihydrate decomposes at ~90°. The hydrate (10g) can also be dehydrated by heating with anhydrous $CaSO_4$ (Drierite, 30g) and distilling; the distillate is treated with more $CaSO_4$ and redistilled (see above). When the distillate is treated with aqueous NaOH and heated, the dihydrate crystallises on cooling. The *Cu (II) complex* is more easily prepared from the anhydrous than from the hydrated diketone which needs to be dehydrated in the reaction medium, and has **m 135°** (after sublimation or crystallisation from CCl_4). Store hfacac as the dihydrate; but the anhydrous diketone should be kept in an anhydrous atmosphere. [Gilman et al. *J Am Chem Soc* **78** 2790 *1956*, Belford et al. *J Inorg Nucl Chem* **2** 11 *1956*, *Beilstein* **1** III 3123, **1** IV 3681.]

Hexafluoroethane *[76-16-4]* **M 138.0, b –79°.** Purify it for pyrolysis studies by passing through a copper vessel containing CoF_3 at *ca* 270°, and held for 3 hours in a bottle with a heated (1300°) platinum wire. It is then fractionally distilled. [Steunenberg & Cady *J Am Chem Soc* **74** 4165 *1962*, *Beilstein* **1** IV 132.]

Hexafluoropropene (hexafluoropropylene, perfluoropropene, *F*-propene) *[116-15-4]* **M 150.0, m –153°, –156.2°, b –28°/atm, –29.4°/atm, d_4^{-40} 1.583.** *F*-Propene is a gas that is available commercially in brass cylinders and is very **corrosive**, **toxic**, attacks skin and tissue membranes. It is prepared by treating $CFCl_2CFClCF_3$ with Zn in boiling EtOH (3 days), but is faster under pressure at 100°. The gas is best handled

in a vacuum line and should be scrubbed over caustic alkali in a brass tube, as any HF present in it will attack glass. [Henne & Waalkes *J Am Chem Soc* **68** 496 *1946*, Henne & Hinkamp *J Am Chem Soc* **67** 1194 *1945*, *Beilstein* **1** III 697, **1** IV 735.]

1,1,1,3,3,3-Hexafluoropropan-2-ol (HFIP) *[920-66-1]* **M 168.1, m –4°, b 57-58°/760mm, d_4^{20} 1.4563, n^{22} 1.2750, pK^{25} 9.30.** Distil it from 3A molecular sieves, retaining the middle fraction. It has been prepared by reduction of *hexafluoroacetone* in tetrahydrofuran (THF). In this case hexafluoropropanol forms a stable 1:1 THF complex which distils at 99-100°/760mm (n_D^{25} 1.3283). The complex is decomposed by mixing with 20% oleum and distilling in a vacuum; the distillate is redistilled to give pure hexafluoropropan-2-ol with **b** 59°/760mm. The ^{1}H NMR shows a doublet at 4.52ppm ($J_{H,H}$ = 2Hz). The *benzoyl* derivative, [10315-85-2] M 272.1, has **m** 53.9° after crystalllisation from pentane at –50°, and its IR has ν_{max} at 1760cm^{-1}. [Middleton & Lindsey *J Am Chem Soc* **86** 4948 *1964*, Urry et al. *J Org Chem* **32** 347 *1967*.] It has very high peptide solubilising properties, alone or with CH_2Cl_2 [use as a solvent: Narita et al. *Bull Chem Soc Jpn* **61** 281 *1988*, *Biochemistry* **29** 2639 *1990*.] It is **CORROSIVE, causes severe eye irritation.**

Hexamethylenediamine (1,6-diaminohexane) *[124-09-4]* **M 116.2, m 42°, b 46-47°/1mm, 84.9°/9mm, 100°/20mm, 204-205°/760mm, pK_1^{25} 10.24, pK_2^{25} 11.02.** Crystallise it in a stream of nitrogen. It sublimes in a vacuum. [*Beilstein* **4** IV 1320.]

Hexamethylenediamine dihydrochloride *[6055-52-3]* **M 189.2, m 248°.** Crystallise the salt from water or EtOH. [*Beilstein* **4** IV 1320.]

Hexamethylene glycol (1,6-hexanediol) *[629-11-8]* **M 118.2, m 41.6°, 43-45°, b 134°/10mm, 250°, n_D^{20} 1.458.** Fractionally crystallise it from its melt or from water. Distil it *in vacuo*. [*Beilstein* **1** IV 2556.]

***n*-Hexane** *[110-54-3]* **M 86.2, b 68.7°, d_4^{20} 0.660, n 1.37486, n^{25} 1.37226.** Purify as for *n*-heptane. Modifications include the use of chlorosulfonic acid or 35% fuming H_2SO_4 instead of conc H_2SO_4 in washing the alkane, and final drying and distilling from sodium hydride. Unsaturated impurities can be removed by shaking the hexane with nitrating acid (58% H_2SO_4, 25% conc HNO_3, 17% water, or 50% HNO_3, 50% H_2SO_4), then washing the hydrocarbon layer with conc H_2SO_4, followed by H_2O, drying, and distilling over sodium or *n*-butyl lithium. It can also be purified by distillation under nitrogen from sodium benzophenone ketyl solubilised with tetraglyme. Also purify it by passage through a silica gel column followed by distillation [Kajii et al. *J Phys Chem* **91** 2791 *1987*]. It is a FLAMMABLE liquid and a possible nerve toxin. [*Beilstein* **1** IV 338.]
Rapid purification: Distil, discarding the first forerun and stored over 4A molecular sieves.

(±)-1,2-Hexanediol *[6920-22-5]* **M 118.2, b 96-98°/1mm, 118.4-118.5°/13mm, 214-215°/760mm, d_4^{20} 0.951, n_D^{20} 1.442.** Fractionally distil it, preferably in a vacuum. *Alternatively*, dissolve it in Et_2O, dry with K_2CO_3 then Na_2SO_4, filter, evaporate and distil it in a vacuum. The *bis-4-nitrobenzoyl* derivative has **m** 101.5-102.5°. [Rudloff *Can J Chem* **36** 486 *1958*, *Beilstein* **1** I 251, **1** III 2200, **1** IV 2554.]

1-Hexene *[592-41-6]* **M 84.2, b 63°, d 0.674, n_D^{20} 1.388.** Purify it by stirring over Na/K alloy for at least 6 hours, then fractionally distil it from sodium under nitrogen. [*Beilstein* **1** IV 828.]

***cis*-2-Hexene** *[7688-21-3]* **M 84.2, b 68-70°, d_4^{20} 0.699, n_D^{20} 1.399.** Purify it as for 1-hexene above. [*Beilstein* **1** IV 833.]

***trans*-2-Hexene** *[4050-45-7]* **M 84.2, b 65-67°, n_D^{20} 1.390.** Purify it as for 1-hexene above. [*Beilstein* **1** IV 834.]

***trans*-3-Hexene** *[13269-52-8]* **M 84.2, b 67-69°, d_4^{20} 0.678, n_D^{20} 1.393.** Purify it as for 1-hexene above. [*Beilstein* **1** IV 837.]

***n*-Hexyl alcohol (1-hexanol)** *[111-27-3]* **M 102.2, b 157.5°, d_4^{20} 0.818, n^{15} 1.4198, n^{25} 1.4158.** The commer-

cial material usually contains other alcohols which are difficult to remove. A suitable method is to esterify with hydroxybenzoic acid, recrystallise the ester and saponify. [Olivier *Rec Trav Chim Pays Bas* **55** 1027 *1936*.] Drying agents include K_2CO_3 and $CaSO_4$, followed by filtration and distillation. (Some decomposition to the olefin occurs when Al amalgam is used as drying agent at room temperature, even if the amalgam is removed prior to distillation.) If the alcohol is required anhydrous, the redistilled material can be refluxed with the appropriate alkyl phthalate or succinate, as described under *Ethanol*. [*Beilstein* **1** IV 1694.]

***n*-Hexylamine** *[111-26-2]* **M 101.2, b 131°, d_4^{20} 0.765, n_D^{20} 1.419, pK^{25} 10.64.** Dry with, and fractionally distil the hexylamine from, KOH or CaH_2. Store away from CO_2. [*Beilstein* **4** IV 709.]

***n*-Hexyl bromide** *[111-25-1]* **M 165.1, b 87-88°/90mm, 155°/743mm, d_4^{20} 1.176, n_D^{20} 1.448.** Shake the bromide with H_2SO_4, wash with water, dry (K_2CO_3) and fractionally distil. [*Beilstein* **1** IV 352.]

***n*-Hexyl methacrylate** *[142-09-6]* **M 154.2, b 65-66°/4mm,88-88.5°/14mm, d_4^{20} 0.8849, n_D^{20} 1.4320.** Purify it as for *methyl methacrylate*. [IR: Hughes & Walton *J Am Chem Soc* **79** 3985 *1957*, *Beilstein* **2** III 1288, **2** IV1527.]

Hexyltrimethylammonium bromide *[2650-53-5]* **M 224.3, m 186°.** Recrystallise it from acetone. It is extremely *hygroscopic*. [McDowell and Kraus *J Am Chem Soc* **73** 2170 *1951*, *Beilstein* **4** IV 710.]

1-Hexyne *[693-02-7]* **M 82.2, b 12.5°/75mm, 71°/760mm, d_4^{20} 0.7156, n_D^{20} 1.3989.** Distil it from $NaBH_4$ to remove peroxides. Stand over sodium for 24 hours, then fractionally distil it under reduced pressure. Also dry it by repeated vacuum transfer into freshly activated 4A molecular sieves, followed by vacuum transfer onto Na/K alloy, and stirring for 1 hour before fractionally distilling. [*Beilstein* **1** IV 1006.]

2-Hexyne *[764-35-2]* **M 82.2, b 83.8°/760mm, d_4^{20} 0.73146, n_D^{20} 1.41382.** Purify as for 1-hexyne above. [*Beilstein* **1** IV 1009.]

3-Hexyne *[928-49-4]* **M 82.2, b 81°/760mm, d_4^{20} 0.7231, n_D^{20} 1.4115.** Purify as for 1-hexyne above. [*Beilstein* **1** IV 1009.]

(±)-5-Hexyn-3-ol (4-hydroxy-1-hexyne) *[19780-84-8]* **M 98.1, b 58-59°/25mm, 73-76°/60mm, d_4^{20} 0.8918, n_D^{20} 1.4437.** Purify the hexynol by fractionation in a vacuum. The *carbamoyl* derivative (prepared by reaction with $COCl_2$/toluene followed by NH_3) is crystallised by dissolving in the minimum volume of toluene and adding excess of petroleum ether (b 40-60°), and has **m** 70-71°. [Länger et al. *Helv Chim Acta* **42** 2379 *1959*, *Beilstein* **1** IV 2235.]

Hydrazine *N,N′*-dicarboxylic acid diamide *[110-21-4]* **M 116.1, m 245-246°(dec), 248°.** Crystallise the diamide from water, wash the crystals with EtOH then Et_2O and dry in vacuum over P_2O_5. It does **not** decompose on drying at 110° /48 hours. Its solubility in H_2O is 1% at 0°. [Andrieth & Mohr *Inorg Synth* **IV** 26 *1953*, *Beilstein* **3** H 116, **3** I 56, **3** III 229.]

3-Hydroxy-2-butanone (acetoin) *[513-86-0]* **M 88.1, b 144-145°, [m 100-105° dimer].** Wash acetoin with EtOH until colourless, then with diethyl ether or acetone to remove biacetyl. Dry it in air by suction and dry further in a vacuum desiccator. [*Beilstein* **1** IV 3991.]

(±)-α-Hydroxy-γ-butyrolactone *[19444-84-9,* S(–)- *733-52-4]* **M 102.1, b 84°/0.2mm, 133°/10mm, d_4^{20} 1.310, n_D^{20} 1.4656.** It has been purified by repeated fractionation and forms a colourless liquid. It has to be distilled at high vacuum; otherwise it will dehydrate. The *acetoxy* derivative has **b** 94°/0.2mm. The *S-enantiomer* has d_4^{20} 1.24, n_D^{20} 1.464, $[\alpha]_D^{25}$ –82° (c 2, MeOH). [NMR: Daremon & Rambaud *Bull Soc Chim Fr* 294 *1971*, Schmitz et al. *Chem Ber* **108** 1010 *1975*, *Beilstein* **18/1** V 5.]

12-Hydroxydodecanoic acid *[505-95-3]* **M 216.3, m 86-88°, pK_{Est} ~4.8.** Crystallise the acid from toluene

[Sadowik et al. *J Am Chem Soc* **108** 7789 *1986*]. [*Beilstein* **3** III 658.]

***N*-[2-Hydroxyethyl]ethylenediamine [2-(2-aminoethylamino)ethanol]** *[111-41-1]* **M 104.1, b 91.2°/5mm, 238-240°/752mm, d_4^{20} 1.030, n_D^{20} 1.485, pK_1^{20} 3.75, pK_2^{20} 9.15.** Distil the amine twice through a Vigreux column. Redistil it from solid NaOH, then from CaH_2. *Alternatively*, it can be converted to the dihydrochloride and recrystallised from water. It is then dried, mixed with excess of solid NaOH and the free base is distilled from the mixture. It is finally redistilled from CaH_2. [Drinkard et al. *J Am Chem Soc* **82** 2992 *1960*, *Beilstein* **4** IV 1558.]

***N*-[2-Hydroxyethyl]ethylenediaminetriacetic acid (HEDTA)** *[150-39-0]* **M 278.3, m 212-214°(dec), pK_1^{20} 2.51, pK_2^{20} 5.31, pK_3^{20} 9.86.** Crystallise HEDTA from warm H_2O, after filtering, by addition of 95% EtOH and allowing to cool. The crystals, collected on a sintered-glass funnel, are washed three times with cold absolute EtOH, then again crystallised from H_2O. After leaching with cold H_2O, the crystals are dried at 100° under vacuum. [Spedding et al. *J Am Chem Soc* **78** 34 *1956*, *Beilstein* **4** IV 2449.]

***N*-Hydroxyethyliminodiacetic acid (HIMDA)** *[93-62-9]* **M 177.2, m 181°(dec), pK_1^{25} 2.16, pK_2^{25} 8.72, pK_3^{25} 13.7 (OH).** Crystallise HIMDA from water. [*Beilstein* **4** IV 2432.]

2-Hydroxyethylimino-tris(hydroxymethyl)methane (MONO-TRIS) *[7343-51-3]* **M 165.2, m 91°, pK_{Est} ~9.8.** Crystallise it twice from EtOH. Dry it under vacuum at 25°.

2-Hydroxyethyl methacrylate *[868-77-9]* **M 130.1, b 67°/3.5mm, d_4^{20} 1.071, n_D^{20} 1.452.** Dissolve the ester in water and extract with *n*-heptane to remove ethylene glycol dimethacrylate (checked by gas-liquid chromatography and by NMR) and distil it twice under reduced pressure [Strop et al. *J Phys Chem* **80** 694 *1976*]. [*Beilstein* **2** IV 1530.]

***dl*-2-Hydroxy-2-methylbutyric acid** *[3739-30-8]* **M 118.1, m 72-73°, pK^{25} 3.73.** Crystallise the acid from *benzene, and sublime it at 90°. [*Beilstein* **3** H 324.] **IRRITANT.**

***dl*-2-Hydroxy-3-methylbutyric (α-hydroxyisovaleric) acid** *[600-37-3]* **M 118.1, m 86°, pK_{Est} ~3.9.** Crystallise the acid from ether/pentane. [*Beilstein* **3** IV 618.] **IRRITANT.**

***R*-γ-Hydroxymethyl-γ-butyrolactone** *[52813-63-5]* **M 116.1, b 101-102°/0.048mm, d_4^{20} 1.2238, n_D^{20} 1.471, $[\alpha]_{546}^{20}$ –38°, $[\alpha]_D^{20}$–33° (c 3, EtOH), $[\alpha]_D^{30}$–53.5° (c 3, EtOH).** Purify it by column chromatography on Silica gel 60 (Merck 70-230 mesh) and elute with 7% EtOH/73% $CHCl_3$. Its IR (film) has ν_{max} at 3400 (OH), 1765 (C=O) and 1180 (COC) cm^{-1}. [Eguchi & Kakuta *Bull Chem Soc Jpn* **47** 1704 *1974*, IR and NMR: Ravid et al. *Tetrahedron* **34** 1449 *1978, Beilstein* **3** III 620.]

3-Hydroxy-3-methylglutaric acid (Meglutol) *[503-49-1]* **M 162.1, m 99-102°, 108-109°, 100°, $pK_{Est(1)}$ ~4.0, $pK_{Est(2)}$ ~5.0.** Recrystallise the acid from diethyl ether/hexane and dry it under a vacuum at 60° for 1 hour. [*Beilstein* **3** IV 1166.]

4-Hydroxy-4-methyl-2-pentanone *[123-42-2]* **M 116.2, b 166°, d_4^{20} 0.932, n_D^{20} 1.4235, n_D^{25} 1.4213.** The pentanone loses water when heated. It can be dried with $CaSO_4$, then fractionally distilled under reduced pressure. [*Beilstein* **1** IV 403.]

2-Hydroxy-2-methylpropionic acid (α-hydroxyisobutyric acid, 2-methyllactic acid)) *[594-61-6]* **M 104.1, m 79°, b 114°/12mm, 212°/760mm, pK^{25} 3.78.** Distil the acid in steam, crystallise it from Et_2O or *benzene, dry it under vacuum, or sublime it at 50°. [*Beilstein* **3, 7** IV 782.]

(±)-2-Hydroxyoctanoic acid (2-hydroxycaprylic acid) *[617-73-2]* **M 160.2, m 69.5°, b 160-165°/10mm, pK_{Est} ~3.7.** Crystallise the acid from EtOH/petroleum ether or ether/ligroin. [*Beilstein* **3** IV 873.]

***N*-Hydroxysuccinimide** *[6066-82-6]* **M 115.1, m 96-98°, pK^{25} 6.0.** Recrystallise the imide from EtOH/ethyl

acetate [Manesis & Goodmen *J Org Chem* **52** 5331 *1987*]. [*Beilstein* **21/9** V 498.]

(±)-2-Hydroxytetradecanoic acid (α-hydroxymyristic acid) *[2507-55-3]* **M 244.4, m 81-82°, pK_{Est} ~3.7.** Crystallise the acid from chloroform or twice from MeOH (**m** 85.8-86.6°) [Horn & Pretorious *J Chem Soc* 1463 *1954,* Chibnall et al. *Biochem J* **30** 1034 *1963*, *Beilstein* **3** H 361, **3** I 130, **3** II 246, **3** III 660, **3** IV 921].

***R*-2-Hydroxytetradecanoic acid** *[26632-17-7]* **M 244.4, m 88-2-88.5°, $[\alpha]_D^{20}$ –3.1° ($CHCl_3$).** Crystallise the acid from chloroform or first from Me_2CO, then hexane [Horn & Pretorious *J Chem Soc* 1463 *1954,* Horn et al. *J Chem Soc* 177 *1954*, *Beilstein* **3** III 660.]

Hydroxyurea See in "Inorganic Compounds", Chapter 5.

Iminodiacetic acid

[142-73-4] **M 133.1, m 225°(dec), pK_1^{25} 2.50, pK_2^{25} 9.40.** Recrystallise iminodiacetic acid from water and dry it in a vacuum over P_2O_5. [*Beilstein* **4** IV 2428.]

Iodoacetamide *[144-48-9]* **M 185.0, m** *ca* **143°(dec).** Crystallise it from water or CCl_4. It is used for tagging proteins. [Gurd *Methods Enzymol* **25** 424 1972, *Beilstein* **2** IV 536.]

Iodoacetic acid *[64-69-7]* **M 160.6, m 78°, pK^{25} 3.19.** Crystallise it from petroleum ether (b 60-80°) or $CHCl_3/CCl_4$. [*Beilstein* **2** IV 534.]

2-Iodobutane (*sec*-butyl iodide) *[513-48-4]* **M 184.0, b 120.0, d_4^{20} 1.50, n_D^{25} 1.4973.** Purify the iodide by shaking with conc H_2SO_4, then washing it with water, aqueous Na_2SO_3 and again with water. Dry ($MgSO_4$) and distil. *Alternatively*, pass it through a column of activated alumina before distillation, or treat with bromine, followed by extraction of the free halogen with aqueous $Na_2S_2O_3$, thoroughly washing with water, drying and distilling. It is stored over silver powder and distilled before use. [*Beilstein* **1** IV 272.]

Iodoform *[75-47-8]* **M 393.7, m 119°.** Crystallise it from MeOH, EtOH or EtOH/EtOAc. It is steam volatile. It is a disinfectant. [*Beilstein* **1** IV 97.]

***N*-Iodosuccinimide** *[516-12-1]* **M 225.0, m 200-201°.** Crystallise it from dioxane/CCl_4. It iodinates arenes in triflic acid. [Olah et al *J Org Chem* **58** 3194 *1993*, *Beilstein* **21/9** V 544.]

Isoamyl acetate (1-butyl-3-methyl acetate, isopentyl acetate) *[123-92-2]* **M 130.2, b 142.0°, d_4^{20} 0.871, n_D^{20} 1.40535.** Dry the acetate with finely divided K_2CO_3 and fractionally distil it. [*Beilstein* **2** IV 157.]

Isoamyl alcohol (3-methyl-1-butanol, 1-butyl-3-methyl alcohol) *[123-51-3]* **M 88.2, b 128°/750mm, 132°/760mm, d^{15} 0.8129, n^{15} 1.4085, n_D^{20} 1.4075.** Dry the alcohol by heating with CaO and fractionally distilling, then heating with BaO and redistilling. *Alternatively*, boil it with concentrated KOH solution, wash it with dilute H_3PO_4, and dry it with K_2CO_3, then anhydrous $CuSO_4$, before fractionally distilling it. If very dry alcohol is required, the distillate is refluxed with the appropriate alkyl phthalate or succinate as described for *ethanol.* It is separated from 2-methyl-1-butanol by fractional distillation, fractional crystallisation and preparative gas chromatography. [*Beilstein* **1** IV 1677.]

Isoamyl bromide (1-butyl-3-methyl bromide) *[107-82-4]* **M 151.1, f -112°, b 119.2°/ 737mm, d_4^{20} 1.208, n 1.444.** Shake the bromide with conc H_2SO_4, wash with water, dry with K_2CO_3 and fractionally distil it. [*Beilstein* **1** IV 378.]

Isoamyl chloride (1-butyl-3-methyl chloride) *[107-84-6]* **M 106.6, b 99°/734mm, d_4^{20} 0.8704, n_D^{20} 1.4084.** Shake the chloride vigorously with 95% H_2SO_4 until the acid layer no longer becomes coloured during 12 hours, then wash it with water, saturated aqueous Na_2CO_3, and more water. Dry it with $MgSO_4$, filter and fractionally distil it. *Alternatively*, a stream of oxygen containing 5% of ozone is passed through the chloride for a time, three times longer than is necessary to cause the first coloration of starch iodide paper by the exit gas.

Subsequent washing of the liquid with aqueous $NaHCO_3$ hydrolyses the ozonides and removes organic acids. After drying and filtering, the isoamyl chloride is distilled. [Chien & Willard *J Am Chem Soc* **75** 6160 *1953*, *Beilstein* **1** IV 287.]

Isoamyl ether [diisopentyl ether, di-(1-butyl-3-methyl) ether] *[544-01-4]* **M 158.3, b 173.4°, d_4^{20} 0.778, n_D^{20} 1.40850.** This is a mixture of 2- and 3-methylbutyl ether. It is purified by refluxing with sodium for 5 hours, then it is distilled under reduced pressure, to remove alcohols. Isoamyl ether can also be dried with $CaCl_2$ and fractionally distilled from P_2O_5. [*Beilstein* **1** IV 1682.]

Isobutane (2-methylpropane) *[75-28-5]* **M 58.1, b -10.2°, d_4^{20} 0.557.** Olefins and moisture can be removed by passage at 65° through a bed of silica-alumina catalyst which has previously been evacuated at about 400°. *Alternatively*, water and CO_2 can be removed by passage through P_2O_5, then asbestos impregnated with NaOH. Treatment with anhydrous $AlBr_3$ at 0° then removes traces of olefins. Inert gases can be separated by freezing the isobutane at –195° and evacuating out the system. [*Beilstein* **1** IV 282.]

Isobutene (2-methylpropene, isobutylene) *[115-11-7]* **M 56.1, b –6.6°/760mm.** Dry isobutene by passage through anhydrous $CaSO_4$ at 0°. Purify it further by freeze-pump-thaw cycles and trap-to-trap distillation. [*Beilstein* **1** IV 796.]

Isobutyl bromide (1-bromo-2-methylpropane) *[78-77-3]* **M 137.0, b 91.2°, d_4^{20} 1.260, n_D^{20} 1.437.** Partially hydrolyse it to remove any tertiary alkyl halide, then fractionally distil it, then wash it with conc H_2SO_4, water and aqueous K_2CO_3, then redistil it from dry K_2CO_3. [Dunbar & Hammett *J Am Chem Soc* **72** 109 *1950*, *Beilstein* **1** IV 294.]

Isobutyl chloride (1-chloro-2-methylpropane) *[513-36-0]* **M 92.6, m –131°, 68.8°/760mm, d_4^{20} 0.877, n_D^{20} 1.398.** Use the same methods as described under *isoamyl chloride*. [*Beilstein* **1** IV 287.]

Isobutyl chloroformate *[543-27-1]* **M 136.6, b 123-127°/atm, 128.8°/atm, d_4^{20} 1.053, n_D^{20} 1.4070.** It can be dried over $CaCl_2$ and fractionated at atmospheric pressure while keeping moisture out. Its purity can be checked by conversion to the *phenyl urethane* derivative with PhNCO [Saunders et al. *J Am Chem Soc* **73** 3796 *1951*.] Its IR (film) has ν_{max} at 1780cm^{-1}. [Thompson & Jameson *Spectrochim Acta* **13** 236 *1959*, Röse *Justus Liebigs Ann Chem* **205** 227 *1880*]. [*Beilstein* **3** IV 26.]

Isobutyl formate *[542-55-2]* **M 102.1, b 98.4°, d_4^{20} 0.885, n_D^{20} 1.38546.** Wash the formate with saturated aqueous $NaHCO_3$, in the presence of saturated aqeous NaCl solution until no further reaction occurs, then with saturated aqueous NaCl, dry ($MgSO_4$) and fractionally distil it. [*Beilstein* **2** H 21, **2** I 18, **2** II 30, **2** III 41, **2** IV 29.]

Isobutyl iodide (1-iodo-2-methylpropane) *[513-38-2]* **M 184.0, b 83°/250mm, 120°/760mm, d_4^{20} 1.60, n_D^{20} 1.495.** Shake the iodide with conc H_2SO_4, and wash it with water, aqueous Na_2SO_3, and water, dry with $MgSO_4$ and distil it. *Alternatively*, pass it through a column of activated alumina before distillation. Store it under nitrogen with mercury in a brown bottle or in the dark. [*Beilstein* **1** IV 299.]

Isobutyl vinyl ether *[109-53-5]* **M 100.2, b 108-110°, d_4^{20} 0.768, n_D^{20} 1.398.** Wash the ether three times with equal volumes of aqueous 1% NaOH, dry it with CaH_2, reflux it with sodium for several hours, then fractionally distil it from sodium. [*Beilstein* **1** IV 2054.]

Isobutyraldehyde *[78-84-2]* **M 72.1, b 62.0°, d_4^{20} 0.789, n_D^{20} 1.377.** Dry isobutyraldehyde with $CaSO_4$ and use it immediately after distillation under nitrogen because of the great difficulty in preventing oxidation. It can be purified through its acid bisulfite derivative. [*Beilstein* **1** IV 3262.]

Isobutyramide (2-methylpropionamide) *[563-83-7]* **M 87.1, m 128-129°, b 217-221°/760mm.** Crystallise the amide from acetone, *benzene, $CHCl_3$, EtOAc or water, then dry it under vacuum over P_2O_5 or 99% at H_2SO_4, or at 70°/3 hours in a desiccator. Sublime it under vacuum. [Kent & McAlvain *Org Synth* Coll Vol **III**

491 *1955*, *Beilstein* **2** H 293, **2** I 129, **2** II 262, **2** III 654, **2** IV 852.]

Isobutyric acid (2-methylpropionic acid) *[79-31-2]* **M 88.1, b 78°/34mm, 154-154.5°/760mm, d_4^{20} 0.949, n_D^{20} 1.393, pK^{25} 4.60.** Distil the acid from $KMnO_4$, then redistil it from P_2O_5. [*Beilstein* **2** H 288, **2** I 126, **2** II 257, **2** III 637, **2** IV 843.]

Isobutyronitrile (2-methylpropionitrile, isopropyl cyanide) *[78-82-0]* **M 69.1, b 103.6°/760mm, d^{25} 0.7650, n_D^{20} 1.378.** Shake the nitrile with conc HCl (to remove isonitriles), then with water and aqueous $NaHCO_3$. After a preliminary drying with silica gel or Linde type 4A molecular sieves, it is shaken or stirred with CaH_2 until hydrogen evolution ceases, then decanted and distilled from P_2O_5 (not more than 5g/L, to minimise gel formation) or Drierite (**b** 101-103°/760mm). Finally it is refluxed with, and slowly distilled from CaH_2 (5g/L), taking precautions to exclude moisture. [*Beilstein* **2** H 294, **2** I 129, **2** II 263, **2** III 655, **2** IV 853.]

Isonitrosoacetone (*anti*-pyruvic aldehyde-1-oxime) *[31915-82-9]* **M 87.1, m 65-67°, 69°, pK^{25} 8.3.** Crystallise isonitrosoacetone from $*C_6H_6$, ether/petroleum ether or CCl_4. It sublimes at 90-100° (water bath temperature)/0.05mm [Kahovec & Kohlrausch *Chem Ber* **75** 1547 *1942*]. It forms an iron and a Cu^{2+} salt (**m** 170° dec). [*Beilstein* **1** H 763, **1** I 396, **1** II 822, **1** III 3092, **1** IV 3632.]

(±)-Isononane (3,3,4-trimethylhexane) *[34464-40-9]* **M 128.3, b 142°/760mm, 142°/760mm, d_4^{20} 0.7454, n_D^{20} 1.4178.** Isononane is passed through columns of activated silica gel and basic alumina (activity 1) and distilled under high vacuum from Na/K alloy. [*Beilstein* **1** III 517, **1** IV 462.]

Isopentyl formate *[110-45-2]* **M 116.2, b 27°/10mm, 123-123.6°/760mm, 123-124°/atm, d_4^{20} 0.8713, n_D^{20} 1.391.** The colourless liquid ester is soluble in 300 volumes of H_2O and is soluble in common organic solvents. It is purified by repeated distillation using an efficient column at atmospheric pressure. [*Beilstein* **2** H 22, **2** I 18, **2** II 31, **2** III 43, **2** IV 30.]

Isoprene (2-methyl-1,3-butadiene) *[78-79-5]* **M 68.1, b 34.5-35°/762mm, d_4^{20} 0.681, n^{25} 1.4225.** Reflux it with sodium then distil it from sodium or $NaBH_4$ under nitrogen, and pass it through a column containing KOH, $CaSO_4$ and silica gel. *tert*-Butylcatechol (0.02% w/w) is added, and the isoprene is stored in this way until redistilled before use. The inhibitor (*tert*-butylcatechol) in isoprene can be removed by several washings with dilute NaOH and water. The isoprene is then dried over CaH_2, distilled under nitrogen at atmospheric pressure, and the fraction distilling at 32° is collected. Store it under nitrogen at –15°. [*Beilstein* **1** H 252, **1** IV 1001.]

Isopropenyl acetate (1-methylvinyl acetate, 2-acetoxypropene) *[108-22-5]* **M 100.1, b 96.7°/749mm, 97.2-97.4°/757mm, d_4^{25} 0.909, n_D^{20} 1.4010.** Prepared by reacting ketene with a mixture of Me_2CO and polyphosphoric acid [Wacher US Patent 2 867 653 *1957*], fractionally distilling through a 75cm packed column, and collecting the fraction with **b** 96.7°/749mm. It forms an azeotrope with H_2O. Its equivalent weight is determined by hydrolysis in 90% EtOH containing twice the required amount of NaOH and titrating the excess of alkali; which should give an equivalent weight of ~100.1. Its heat of hydrolysis has been determined [Sunner *Acta Chem Scand* **11** 1757 *1957*]. It is a good source the $=CMe_2$ group, as in the preparation of Meldrum's acid (see [2033-24-1]), because it is the activated enol ester of acetone. Its FT-IR (neat) has ν_{max} at 1757.3, 1673.0, 1431.4, 1372.5, 1253.1, 1198.2, 1027.9, 900.0 and 871.4 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.92 (s, 3H, ester Me), 2.13 (s, 3H, isoPr-Me) and 7.00 (d, J = ~6Hz, 2H, $=CH_2$); and the ^{13}C NMR (15MHz, $CDCl_3$, TMS) has δ at 19.54, 21.05, 102.05, 152.94 and 169.04. [*Beilstein* **2** III 278, **2** IV 179.]

Isopropanol (propan-2-ol) *[67-63-0]* **M 60.1, b 82.5°, d_4^{20} 0.783, $n^{25.8}$ 1.3739, pK^{25} 17.1.** Isopropyl alcohol is prepared commercially by dissolution of propene in H_2SO_4, followed by hydrolysis of the sulfate ester. Major impurities are water, lower alcohols and oxidation products such as aldehydes and ketones. Purification of isopropanol follows substantially the same procedure as for *n*-propyl alcohol.
Isopropanol forms a constant-boiling mixture, **b** 80.3°, with water. Most of the water can be removed from this 91% isopropanol by refluxing with CaO (200g/L) for several hours, then distilling. The distillate can be dried further with CaH_2, magnesium ribbon, BaO, $CaSO_4$, calcium, anhydrous $CuSO_4$ or Linde type 5A molecular

sieves. Distillation from sulfanilic acid removes ammonia and other basic impurities. Peroxides [indicated by liberation of iodine from weakly acid (HCl) solutions of 2% KI] can be removed by refluxing with solid stannous chloride or with $NaBH_4$ then the alcohol is fractionally distilled. To obtain isopropanol containing only 0.002M of water, sodium (8g/L) is dissolved in material dried by distillation from $CaSO_4$. Isopropyl benzoate (35ml) is then added and, after refluxing for 3 hours, the alcohol is distilled through a 50-cm Vigreux column [Hine & Tanabe *J Am Chem Soc* **80** 3002 *1958*]. Other purification steps for isopropanol include refluxing with solid aluminium isopropoxide, refluxing with $NaBH_4$ for 24 hours, and removing acetone by treatment with, and distillation from 2,4-dinitrophenylhydrazine. Peroxides re-form in isopropanol if it is kept for several days in contact with air. [*Beilstein* **1** IV 1461.]

Isopropyl acetate *[108-21-4]* **M 102.1, b 88.4°, d $_4^{20}$ 0.873, n $_D^{20}$ 1.3773.** Wash the acetate with 50% aqueous K_2CO_3 (to remove acid), then with saturated aqueous $CaCl_2$ (to remove any alcohol). Dry it with $CaCl_2$ and fractionally distil it. [*Beilstein* **2** IV 141.]

Isopropyl acrylamide *[2210-25-5]* **M 113.2, m 60-63°, b 89-92°/2mm, 110-115°/15mm.** Fractionate the amide under reduced pressure, and recrystallise the solid distillate from hexane (**m** 59°), *C_6H_6 (**m** 62°) or *C_6H_6/hexane (**m** 62-63°). Store it with 0.05% of 4-*tert*-butylcatechol. It is used for making water soluble swellable hydrogels. [*Beilstein* **4** IV 517.]

Isopropyl bromide (2-bromopropane) *[75-26-3]* **M 123.0, b 0°/69.2mm, 59.4°/760mm, d $_4^{20}$ 1.31, n^{15} 1.42847, n $_D^{20}$ 1.4251.** Wash the bromide with 95% H_2SO_4 (concentrated acid partially oxidised it) until a fresh portion of acid did not become coloured after several hours, then with water, aqueous $NaHSO_3$, aqueous 10% Na_2CO_3 and again with water. (The H_2SO_4 can be replaced by conc HCl.) Prior to this treatment, isopropyl bromide has been purified by bubbling a stream of oxygen containing 5% ozone through it for 1 hour, followed by shaking with 3% hydrogen peroxide solution, neutralising with aqueous Na_2CO_3, washing with distilled water and drying. *Alternatively*, it has been treated with elemental bromine and stored for 4 weeks, then extracted with aqueous $NaHSO_3$ and dried with $MgSO_4$. After the acid treatment, isopropyl bromide can be dried with Na_2SO_4, $MgSO_4$ or CaH_2, and fractionally distilled. [*Beilstein* **1** IV 208.]

Isopropyl chloride (2-chloropropane) *[75-29-6]* **M 78.5, b 34.8°, d $_4^{20}$ 0.864, n $_D^{20}$ 1.3779, n^{25} 1.3754.** Purify the chloride with 95% H_2SO_4 as described for *isopropyl bromide*, then dry with $MgSO_4$, P_2O_5 or CaH_2, and fractionally distil it from Na_2CO_3 or CaH_2. *Alternatively*, a stream of oxygen containing *ca* 5% ozone is passed through the chloride for about three times as long as is necessary to obtain the first coloration of starch iodide paper by the exit gas, and the liquid is then washed with $NaHCO_3$ solution to hydrolyse ozonides and remove organic acids before drying and distilling. [*Beilstein* **1** IV 191.]

Isopropyl ether (diisopropyl ether) *[108-20-3]* **M 102.2, b 68.3°, d $_4^{20}$ 0.719, n $_D^{20}$ 1.3688, n^{25} 1.36618.** Common impurities are water and peroxides [detected by the liberation of iodine from weakly acid (HCl) solutions of 2% KI]. Peroxides can be removed by shaking with aqueous Na_2SO_3 or with acidified ferrous sulfate (0.6g $FeSO_4$ and 6ml conc H_2SO_4 in 110ml of water, using 5-10g of solution per L of ether), or aqueous $NaBH_4$ solution. The ether is then washed with water, dried with $CaCl_2$ and distilled. *Alternatively*, refluxing with $LiAlH_4$ or CaH_2, or drying with $CaSO_4$, then passage through an activated alumina column, can be used to remove water and peroxides. Other dehydrating agents used with isopropyl ether include P_2O_5, sodium amalgam and sodium wire. (The ether is often stored in brown bottles, or in the dark, with sodium wire.) Bonner and Goishi (*J Am Chem Soc* **83** 85 *1961*) treated isopropyl ether with dilute sodium dichromate/sulfuric acid solution, followed by repeated shaking with a 1:1 mixture of 6M NaOH and saturated $KMnO_4$. The ether is washed several times with water, dilute aqueous HCl, and water, with a final washing with, and storage over, ferrous ammonium sulfate acidified with H_2SO_4. Blaustein and Gryder (*J Am Chem Soc* **79** 540 *1957*), after washing with alkaline $KMnO_4$, then water, treated the ether with ceric nitrate in nitric acid, and again washed it with water. Hydroquinone is added before drying with $CaCl_2$ and $MgSO_4$, and refluxing with sodium amalgam (108g Hg/100g Na) for 2 hours under nitrogen. The distillate (nitrogen atmosphere) is made 2 x10^{-5}M in hydroquinone to inhibit formation of peroxides (which is negligible if the ether is stored in the dark). Catechol (pyrocatechol) and resorcinol are alternative inhibitors. [*Beilstein* **1** IV 1471.]

Isopropyl iodide (2-iodopropane) *[75-30-9]* **M 170.0, b 88.9°, d_4^{20} 1.70, n_D^{20} 1.4987.** Treat the iodide with bromine, followed by extraction of free halogen with aqueous $Na_2S_2O_3$ or $NaHSO_3$, washing with water, drying ($MgSO_4$ or $CaCl_2$) and distilling. (The treatment with bromine is optional.) Other purification methods include passage through activated alumina, or shaking with copper powder or mercury to remove iodine, drying with P_2O_5 and distilling. Washing with conc H_2SO_4 or conc HCl (to remove any alcohol), water, aqueous Na_2SO_3, water and aqueous Na_2CO_3 has also been used. Treatment with silica gel causes some liberation of iodine. Distillations should be carried out at slightly reduced pressure. Purified isopropyl iodide is stored in the dark in the presence of a little mercury. [*Beilstein* **1** IV 223.]

Isopropyl methyl ether *[598-53-8]* **M 74.1, b 32.5°/777mm, d^{15} 0.724, n_D^{20} 1.3576.** Purify the ether by drying with $CaSO_4$, passing through a column of alumina (to remove peroxides) and fractional distillation. [*Beilstein* **1** H 362, **1** II 381, **1** III 1458, **1** IV 1471.]

Isovaleric acid (3-methylbutyric acid) *[502-74-2]* **M 102.1, b 176.5°/762mm, d_4^{20} 0.927, n^{15} 1.4064, n_D^{20} 1.40331, pK^{25} 4.77.** Dry the acid (Na_2SO_4), then fractionally distil. [*Beilstein* **2** IV 895.]

Itaconic acid (2-propen-1,2-dicarboxylic acid) *[97-65-4]* **M 130.1, m 165-166°, pK_1^{25} 3.63, pK_2^{25} 5.00.** Crystallise itaconic acid from EtOH, EtOH/water or EtOH/*benzene. [*Beilstein* **2** IV 2228.]

Itaconic anhydride (2-propen-1,2-dicarboxylic anhydride) *[2170-03-8]* **M 112.1, m 66-68°, 67-68°, 68°, b 139-140°/30mm.** Crystallise the anhydride from $CHCl_3$/petroleum ether. It can be distilled under reduced pressure. Distillation at atmospheric pressure, or prolonged distillation causes rearrangement to citraconic anhydride (2-methylmaleic anhydride). If the material (as seen in the IR spectrum) contains much free acid, then heat with acetyl chloride or $SOCl_2$, evaporate and distil at as high a vacuum as possible. The crude anhydride deposits crystals of itaconic acid on standing probably due to hydrolysis by H_2O — store it in sealed ampoules under dry N_2. [Skinner et al. *Org Synth* Coll Vol **II** 368 *1943*, IR: Nagai *Bull Chem Soc Jpn* **37** 369 *1964*, Kelly & Segura *J Am Chem Soc* **56** 2497 *1934*, *Beilstein* **17/11** V 66.]

Kerosene *[8008-20-6]* **(mixture of hydrocarbons) b ~175-225°, ~190-250°, d_4^{20} 0.75-0.82, n_D^{20} 1.443.** Stir it with conc H_2SO_4 until a fresh portion of acid remains colourless, then wash with water, dry with solid KOH and distil it in a Claisen flask. For more complete drying, the kerosene can be refluxed with Na, and distilled from Na.

Ketene *[463-51-4]* **M 42.0, b –56°, –41°, d_4^{20} 1.093, n_D^{20} 1.441.** Ketene is prepared by pyrolysis of acetic anhydride. Purify it by passing through a trap at –75° and collecting in a liquid-nitrogen-cooled trap. Ethylene is removed by evacuating the ethylene in an isopentane-liquid-nitrogen slush pack at –160°. Store it at room temperature in a suitable container in the dark or better at –80°, but do not store it under pressure as it may **EXPLODE**. It is a strong **IRRITANT** when inhaled and is as **POISONOUS** as phosgene. See diketene in "Heterocyclic Compounds", in this Chapter. [Hurd *Org Synth* Coll Vol **I** 330 *1941*, Andreades & Carlson *Org Synth* Coll Vol **V** 679 *1973*.]

L(+)-Lactic acid **(*S*(+)-2-hydroxypropionic acid)** *[79-33-4]* **M 90.1, m 52.8°, b 105°/0.1mm, $[\alpha]_D^{20}$ +3.82° (H_2O), pK^{31} 3.83.** Purify lactic acid by fractional distillation at 0.1mm pressure, followed by fractional crystallisation from diethyl ether/isopropyl ether (1:1, dried with sodium). [Borsook et al. *J Biol Chem* **102** 449 *1933*.] The solvent mixture, *benzene/diethyl ether (1:1) containing 5% petroleum ether (b 60-80°) has also been used. [Brin *Biochemical Preparations* **3** 61 *1953*, *Beilstein* **3** IV 633.]

Lanthanide shift reagents A variety of these reagents are available commercially, and they are generally quite stable and should not deteriorate on long storage in a dry state and in the absence of light. [See J.R. Campbell *Aldrichimica Acta* **4** 55 *1971*, G.R. Sullivan in *Top Stereochem* (Eliel & Allinger Eds) J Wiley & Sons Vol 10 287 *1978*, T.C. Morrill Ed. *Lanthanide Shift Reagents* Deerfield Beach Florida *1986*, ISBN 0895731193.]

Lauraldehyde (1-dodecanal) *[112-54-9]* **M 184.3, b 99.5-100°/3.5mm, $n^{24.7}$ 1.4328.** Convert lauraldehyde to the bisufite addition compound by shaking with saturated aqueous $NaHSO_3$ for 1 hour. The precipitate is filtered off, washed with ice cold water, EtOH and ether, then decomposed with aqueous Na_2CO_3. The aldehyde is extracted into diethyl ether which, after drying and evaporating, gives an oil which is fractionally distilled under vacuum. [*Beilstein* **1** IV 3380.]

Lauric acid (1-dodecanoic acid) *[143-07-7]* **M 200.3, m 44.1°, b 141-142°/0.6-0.7mm, 225°/100mm, pK^{20} 5.3.** Distil the acid in a vacuum. Also crystallise it from absolute EtOH, or from acetone at –25°. *Alternatively*, purify it *via* its *methyl ester* (**b** 140.0°/15mm), as described for *capric* acid (see [334-48-5]). It has also been purified by zone melting. [cf *Beilstein* **1** III 2913.]

Lauryl peroxide (di-dodecyl peroxide) *[105-74-8]* **M 398.6, m 53-54°.** Crystallise it from *n*-hexane or *benzene and store it below 0°. Potentially **EXPLOSIVE**. [cf *Beilstein* **2** IV 1102.]

***Z*-Maleamic acid (*cis*-maleic acid monoamide)** *[557-24-4]* **M 115.1, m 172°, 172-173°(dec), 178-180°, pK_{Est} ~2.65.** Crystallise it from EtOH. [*Beilstein* **2** H 752, **2** II 646, **2** III 1927, **2** IV 1927.] **IRRITANT**.

Maleic acid *[110-16-7]* **M 116.1, m 143.5°, pK_1^{25} 1.91, pK_2^{25} 6.33.** Crystallise the acid from acetone/petroleum ether (b 60-80°) or hot water. Dry it at 100°. [*Beilstein* **2** H 748, **2** I 303, **2** II 641, **2** III 1911, **2** IV 2199.]

Maleic anhydride See furan-2,5-dione in "Heterocyclic Compounds', in this Chapter.

Maleic hydrazide *[123-33-1]* **M 112.1, m 144°(dec), pK_1^{25} 5.67, pK_2^{25} 13.3.** Crystallise the hydrazide from water. Dry it at ~100° over P_2O_5. [*Beilstein* **24** III/IV 1186.]

Maleimide See pyrrol-2,5-dione in "Heterocyclic Compounds", in this Chapter.

Maleuric acid (Z-*N*-carbamoylmaleamic acid) *[105-61-3]* **M 158.1, m 167-168°(dec).** Crystallise the acid from hot water. Dry it at ~100° over H_2SO_4. [Batt et al. *J Am Chem Soc* **76** 3663 *1954*.]

***dl*-Malic acid** *[617-48-1 and 6915-15-7]* **M 134.1, m 128-129°.** Crystallise the acid from acetone, then from acetone/CCl_4, or from ethyl acetate by adding petroleum ether (b 60-70°). Dry it at 35° under 1mm pressure to avoid formation of the anhydride. [*Beilstein* **3** IV 1124.]

L-Malic acid (*S*(–)-2-hydroxysuccinic acid) *[97-67-6]* **M 134.1, m 104.5-106°, $[\alpha]_D^{20}$ –2.3° (c 8.5, H_2O), $[\alpha]_D^{20}$ –30° (c 5.5, pyridine), pK_1^{25} 3.46, pK_2^{25} 5.10.** Crystallise *S*-malic acid (charcoal) from ethyl acetate/petroleum ether (b 55-56°), keeping the temperature below 65°. Or dissolve it by refluxing in fifteen parts of anhydrous diethyl ether, decant, concentrate to one-third volume and crystallise it at 0°, repeatedly to constant melting point. [*Beilstein* **3** IV 1123.]

Malonamide *[108-13-4]* **M 102.1, m 170°.** Crystallise the amide from water. [*Beilstein* **2** IV 1887.]

Malonic acid *[141-82-2]* **M 104.1, m 136°, pK_1^{25} 2.58, pK_2^{25} 5.69.** Crystallise malonic acid from *benzene/diethyl ether (1:1) containing 5% of petroleum ether (b 60-80°), wash with diethyl ether, then recrystallise it from H_2O or acetone. Dry it under vacuum over conc H_2SO_4. [*Beilstein* **2** IV 1874.]

Malononitrile *[109-77-3]* **M 66.1, m 32-34°, b 109°/20mm, 113-118°/25mm, 220°/760mm.** Crystallise the nitrile from water, EtOH, *benzene or chloroform. Distil it in a vacuum from, and store over, P_2O_5. [Bernasconi et al. *J Am Chem Soc* **107** 7692 *1985*, Gratenhuis *J Am Chem Soc* **109** 8044 *1987*, *Beilstein* **2** IV 1892.]

Meprobamate [2,2-di(carbamoyloxymethyl)pentane] *[57-53-4]* **M 246.3, m 104-106°.** Crystallise it from hot water, aqueous EtOH (**m** 104-105.5°) or xylene (**m** 104.1-105.3°). It can be an addictive drug. [*Beilstein* **3** IV 73.]

2-Mercaptoethanol *[60-24-2]* **M 78.1, b 44°/4mm, 53.5°/10mm, 58°/12mm, 68°/20mm, 78.5°/40mm, 96-97° (92°)/100mm, 157°/748mm, d_4^{20} 1.114, n_D^{20} 1.500, pK^{25} 9.72 (9.43).** Purify it by distilling in a vacuum. Distilling at atmospheric pressure causes some oxidation and should be done in an inert atmosphere. [Woodward *J Chem Soc* 1892 *1948*.] **It has a foul odour, is irritating to the eyes, nose and skin — should be handled in an efficient fume cupboard.** It is miscible with H_2O, EtOH, Et_2O and $*C_6H_6$ and the UV has λ_{max} at 235nm. The *2,4-dinitrophenyl thioether* has **m** 101-102° (from EtOH or aqueous MeOH) [Grogen et al. *J Org Chem* **20** 50 *1955*]. [*Beilstein* **1** IV 2428.]

Mesaconic acid (methylfumaric acid) *[498-24-8]* **M 130.1, m 204-205°, pK^{18} 4.82.** Crystallise it from H_2O or EtOH [Katakis et al. *J Chem Soc, Dalton Trans* 1491 *1986*]. [*Beilstein* **2** IV 2231.]

Mesityl oxide (4-methyl-3-penten-2-one) *[141-79-7]* **M 98.2, b 57°/55mm, 128-129°/745mm, 112°/760mm, n^{24} 1.4412, d 0.854, pK^{20} –5.36 (H_o scale, aqueous H_2SO_4).** Purify it by distillation, preferably in a vacuum or *via* the *semicarbazone* (**m** 165°) which is decomposed to pure ketone. The *2,4-dinitrophenylhydrazone* (**m** 205-206°) crystallises from EtOH. [Johnson *J Am Chem Soc* **73** 5888 *1951*, Johnson *J Am Chem Soc* **75** 2720 *1953*, Erskine & Waight *J Chem Soc* 3425 *1960*, *Beilstein* **1** H 736, **1** I 382, **1** II 793, **1** III 2995, **1** IV 3471.]

α-Methacraldehyde (methacrolein) *[78-85-3]* **M 68.1, b 68.4°, d_4^{20} 0.849, n_D^{20} 1.416.** Fractionally distil it under nitrogen through a short Vigreux column. Store it in sealed ampoules. (Slight polymerisation may occur.) [*Beilstein* **1** IV 3455.]

Methacrylamide *[79-39-0]* **M 85.1, m 111-112°.** Crystallise the amide from *benzene or ethyl acetate and dry it under vacuum at room temperature. [*Beilstein* **2** IV 1538.]

Methacrylic acid *[79-41-4]* **M 86.1, b 72°/14mm, 160°/760mm, d_4^{20} 1.015, n_D^{20} 1.431, pK^{25} 4.65.** Aqueous methacrylic acid (90%) is saturated with NaCl (to remove the bulk of the water), then the organic phase is dried with $CaCl_2$ and distilled under vacuum. Polymerisation inhibitors should be added to the distillate and include 0.25% *p*-methoxyphenol, 0.1% hydroquinone, or 0.05% *N,N′*-diphenyl-*p*-phenylenediamine. [*Beilstein* **2** IV 1518.]

Methacrylic anhydride *[760-93-0]* **M 154.2, b 65°/2mm, d_4^{20} 1.040, n_D^{20} 1.454.** Distil the anhydride at 2mm pressure, immediately before use, in the presence of hydroquinone. [*Beilstein* **2** IV 1537.]

Methacrylonitrile *[126-98-7]* **M 67.1, b 90.3°, d_4^{20} 0.800, n_D^{20} 1.4007, n^{30} 1.3954.** Wash it with saturated aqueous $NaHSO_3$ (to remove inhibitors such as *p-tert*-butylcatechol), 1% NaOH in saturated NaCl and then with saturated NaCl. Dry it with $CaCl_2$ and fractionally distil it under nitrogen to separate it from impurities such as methacrolein and acetone. [*Beilstein* **2** IV 1539.]

Methacryloyl chloride *[920-46-7]* **M 104.5, m -60°, b 95-96°/760mm, 98.4°/772mm, d^{25} 1.076, n_D^{20} 1.4432.** Purify the ester by fractional distillation. If it contains the acid (OH bands in the IR) then add redistilled $SOCl_2$ (with cooling) and cuprous chloride (ca to 2%), reflux the mixture gently for 1 hour and fractionate it through a 1 metre column packed with glass helices. Redistillation then provides the acid chloride in high purity as a colourless liquid. It is necessary to keep the apparatus moisture free (use $CaCl_2$ tubes). Stabilise it with 0.05% of 2,6-di-*tert*-butyl-4-methylphenol. [Lal & Green *J Org Chem* **20** 1032 *1955*, *Beilstein* **2** IV 1537.]

Methane *[74-82-8]* **M 16.0, m –184°, b –164°/760mm, –130°/6.7atmospheres, d_4^0 0.554 (**cf **d_4^0 1.00 for air).** Dry methane by passing over $CaCl_2$ and P_2O_5, then through a Dry-ice trap and fractionally distil it from a liquid-nitrogen trap. Oxygen can be removed by prior passage in a stream of hydrogen over reduced copper oxide at 500°, and higher hydrocarbons can be removed by chlorinating about 10% of the sample: the hydrocarbons, chlorides and HCl are readily separated from the methane by condensing the sample in the liquid nitrogen trap

and fractionally distilling it. Methane has also been washed with conc H_2SO_4, then solid NaOH and then 30% NaOH solution. It is dried with $CaCl_2$, then P_2O_5, and condensed in a trap at liquid air temperature, then transferred to another trap cooled in liquid nitrogen. CO_2, O_2, N_2 and higher hydrocarbons can be removed from methane by adsorption on charcoal. [Eiseman & Potter *J Res Nat Bur Stand* **58** 213 *1957*, *Beilstein* **1** IV 3.] **HIGHLY FLAMMABLE.**

Methanesulfonic acid *[75-75-2]* **M 96.1, m 20°, b 134.5-135°/3mm, d_4^{20} 1.483, n_D^{20} 1.432, pK^{25} –1.86 (–1.2).** Dry the acid, either by azeotropic removal of water with *benzene or toluene, or by stirring 20g of P_2O_5 with 500ml of the acid at 100° for 0.5 hours. Then distil it under vacuum and fractionally crystallise it by partial freezing. Sulfuric acid, if present, can be removed by prior addition of $Ba(OH)_2$ to a dilute solution, filtering off the $BaSO_4$ and concentrating under reduced pressure; and is sufficiently pure for most applications. [*Beilstein* **4** IV 10.]

Methanesulfonothioic acid Na salt (sodium methanethiosulfonate, sodium methylthiosulfonate) *[1950-85-2]* **M 134.1, m 265°(dec).** Recrystallise the salt from H_2O (plates as *monohydrate*) or MeOH. The *potassium salt* crystallises from H_2O, EtOH or MeOH (thick plates) with **m** 201-202° [Foss *Acta Chem Scand* **10** 868 *1956*]. The *S-benzylisothiouronium salt* has **m** 141-142° (from EtOH) [Kurzer & Powell *J Chem Soc* 3733 *1952*]. [*Beilstein* **4** IV 31.] It is used for preparing unsymmetrical disulfides [Grayson et al. *J Org Chem* **70** 9740 *2005*, Kalai et al. *Synthesis* 439 *2006*].

Methanesulfonyl chloride *[124-63-0]* **M 114.5. b 55°/11mmm, d_4^{20} 1.474, n_D^{20} 1.452.** Distil the sulfonyl chloride from P_2O_5 under vacuum. It is a strong **IRRITANT**. [*Beilstein* **4** IV 27.]

Methanol *[67-56-1]* **M 32.0, b 64.5°, d^{15} 0.79609, d^{25} 1.32663, n^{15} 1.33057, n^{25} 1.32663, pK^{25} 15.5.** Almost all methanol is now obtained synthetically. Likely impurities are water, acetone, formaldehyde, ethanol, methyl formate and traces of dimethyl ether, methylal, methyl acetate, acetaldehyde, carbon dioxide and ammonia. Most of the water (down to about 0.01%) can be removed by fractional distillation. Drying with CaO is unnecessary and wasteful. Anhydrous methanol can be obtained from "absolute" material by passage through Linde type 4A molecular sieves, or by drying with CaH_2, $CaSO_4$, or with just a little more sodium than required to react with the water present, in all cases the methanol is then distilled. Two treatments with sodium reduces the water content to about 5 x 10^{-5}%. [Friedman et al. *J Am Chem Soc* **83** 4050 *1961*.] Lund and Bjerrum [*Chem Ber* **64** 210 *1931*] warmed clean dry magnesium turnings (5g) and iodine (0.5g) with 50-75ml of "absolute" methanol in a flask until the iodine disappeared and all the magnesium was converted to the methoxide. Up to 1L of methanol was added and, after refluxing for 2-3 hours, it was distilled off, excluding moisture from the system. Redistillation from tribromobenzoic acid removes basic impurities and traces of magnesium oxides, and leaves conductivity-quality material. The method of Hartley and Raikes [*J Chem Soc* **127** 524 *1925*] gives a slightly better product. This consists of an initial fractional distillation, followed by distillation from aluminium methoxide, and then ammonia and other volatile impurities are removed by refluxing for 6 hours with freshly dehydrated $CuSO_4$ (2g/L) while dry air is passed through: the methanol is finally distilled. (The aluminium methoxide is prepared by warming with aluminium amalgam (3g/L) until all the aluminium has reacted. The amalgam is obtained by warming pieces of sheet aluminium with a solution of $HgCl_2$ in dry methanol.) This treatment also removes aldehydes.
If acetone is present in the methanol, it is usually removed prior to drying. Bates, Mullaly and Hartley [*J Chem Soc* 401 *1923*] dissolved 25g of iodine in 1L of methanol and then poured the solution, with constant stirring, into 500ml of M NaOH. Addition of 150ml of water precipitated iodoform. The solution was allowed to stand overnight, filtered, then boiled under reflux until the odour of iodoform disappeared, and fractionally distilled. (This treatment also removes formaldehyde.) Morton and Mark [*Ind Eng Chem (Anal Edn)* **6** 151 *1934*] refluxed methanol (1L) with furfural (50ml) and 10% NaOH solution (120ml) for 6-12 hours, the refluxing resin carries down with it the acetone and other carbonyl-containing impurities. The alcohol was then fractionally distilled. Evers and Knox [*J Am Chem Soc* **73** 1739 *1951*], after refluxing 4.5L of methanol for 24 hours with 50g of magnesium, distilled off 4L of it, which they then refluxed with $AgNO_3$ for 24 hours in the absence of moisture or CO_2. The methanol was again distilled, shaken for 24 hours with activated alumina before being filtered through a glass sinter and distilled under nitrogen in an all-glass still. Material suitable for conductivity

work was obtained.
Variations of the above methods have also been used. For example, a sodium hydroxide solution containing iodine has been added to methanol and, after standing for 1 day, the solution has been poured slowly into about a quarter of its volume of 10% $AgNO_3$, shaken for several hours, then distilled. Sulfanilic acid has been used instead of tribromobenzoic acid in Lund and Bjerrum's method. A solution of 15g of magnesium in 500ml of methanol has been heated under reflux, under nitrogen, with hydroquinone (30g), before degassing and distilling the methanol, which was subsequently stored with magnesium (2g) and hydroquinone (4g per 100ml). Refluxing for about 12 hours removes the bulk of the formaldehyde from methanol: further purification has been obtained by subsequent distillation, refluxing for 12 hours with dinitrophenylhydrazine (5g) and H_2SO_4 (2g/L), and again fractionally distilling. [*Beilstein* **1** IV 1227.]
Rapid purification: Methanol purification is the same as for ethanol. Another simple purification procedure consists of adding 2g of $NaBH_4$ to 1.5L methanol, gently bubbling argon through it and refluxing for a day at 30°, then adding 2g of freshly cut sodium (washed with methanol) and refluxing for 1 day before distilling. The middle fraction is taken. [Jou & Freeman *J Phys Chem* **81** 909 *1977*.]

Methoxyacetic acid *[625-45-6]* **M 90.1, b 97°/13-14mm, d_4^{20} 1.175, n_D^{20} 1.417, pK^{25} 3.57.** Fractionally crystallise the acid by repeated partial freezing, then fractionally distil it under vacuum through a vacuum-jacketed Vigreux column ~20cm long. [*Beilstein* **3** IV 574.]

Methoxyamine hydrochloride *[593-56-6]* **M 83.5, m 151-152°, pK^{25} 4.60.** Crystallise the hydrochloride from absolute EtOH or EtOH by addition of diethyl ether. [Kovach et al. *J Am Chem Soc* **107** 7360 *1985*, *Beilstein* **1** IV 1252.]

2-Methoxyethanol (methylcellosolve) *[109-86-4]* **M 76.1, b 124.4°, d_4^{20} 0.964, n_D^{20} 1.4017, pK^{25} 14.8.** Peroxides can be removed by refluxing with stannous chloride or by filtration under slight pressure through a column of activated alumina. 2-Methoxyethanol can be dried with K_2CO_3, $CaSO_4$, $MgSO_4$ or silica gel, then distilled from sodium. Aliphatic ketones (and water) can be removed by making the solvent 0.1% in 2,4-dinitrophenylhydrazine and allowing to stand overnight with silica gel before fractionally distilling. [*Beilstein* **1** IV 2375.]

2-Methoxyethoxymethylchloride (MEMCl) *[3970-21-6]* **M 124.6, b 50-52°/13mm, 140-145°(dec)/atm, d_4^{20} 1.092, n_D^{20} 1.427.** Possible impurities are methoxyethanol (**b** 124°/atm), HCHO and HCl which can be removed below the boiling point of MEMCl. Purify MEMCl by fractional distillation in a vacuum. If too impure, prepare it from methoxyethanol (152g) and *s*-trioxane (66g) by bubbling a stream of dry HCl (with stirring) until a clear mixture is obtained. Dilute with pentane (900ml), dry (3 hours over 100g $MgSO_4$, at 5°), evaporate and the residue is distilled in a vacuum. It is MOISTURE SENSITIVE and **TOXIC.** The $MEM.NEt_3^+Cl^-$ salt, prepared by reaction with 1.3 equivalents of Et_3N (16 hours/25°) and dried in a vacuum, has **m** 58-61°, and is moisture sensitive. [Corey et al. *Tetrahedron Lett* 809 *1976*, Yoshimatsu et al. *J Org Chem* **59** 1011 *1994*, Greene & Wuts *Protective Groups in Organic Synthesis* 3rd edn, J Wiley & Sons NY *1991*.] **CARCINOGEN.**

2-Methoxyethylamine *[109-85-3]* **M 75.1, b 94°, d_4^{20} 0.874, n_D^{20} 1.407, pK^{25} 9.40.** An aqueous 70% solution of the amine is dehydrated by azeotropic distillation with *benzene or methylene chloride and the amine is distilled twice from zinc dust. Store it in a tight container as it absorbs CO_2 from the atmosphere. [*Beilstein* **4** IV 1411.]

8-Methoxypsoralen See xanthotoxin in "Miscellaneous Compounds", Chapter 7.

***N*-Methylacetamide** *[79-16-3]* **M 73.1, m 30°, b 70-71°/2.5-3mm, pK_1^{25} –3.70, pK_2^{25} –0.42.** Fractionally distil it under vacuum, then fractionally crystallise it twice from its melt. Likely impurities include acetic acid, methyl amine and H_2O. For a detailed purification procedure, see Knecht and Kolthoff, *Inorg Chem* **1** 195 *1962*. Although *N*-methylacetamide is commercially available it is often extensively contaminated with acetic acid, methylamine, water and an unidentified impurity. The recommended procedure is to synthesise it in the laboratory by direct reaction. The gaseous amine is passed into hot glacial acetic acid, to give a partially

aqueous solution of methylammonium acetate which is heated to *ca* 130° to expel water. Chemical methods of purification such as extraction by petroleum ether, treatment with H_2SO_4, K_2CO_3 or CaO can be used but are more laborious.
Tests for purity include the Karl Fischer titration for water; this can be applied directly. Acetic acid and methylamine can be detected polarographically.
In addition to the above, purification of *N*-methylacetamide can be achieved by fractional freezing, including zone melting, repeated many times, or by vacuum distillation under reduced pressures. For details of zone melting techniques, see Knecht in *Recommended Methods for Purification of Solvents and Tests for Impurities*, Coetzee Ed. Pergamon Press *1982*. [*Beilstein* **4** IV 176.]

Methyl acetate *[79-20-9]* **M 74.1, b 56.7-57.2°, d $_4^{20}$ 0.934. n $_D^{20}$ 1.36193, n $_D^{25}$ 1.3538, pK^{20} –7.28 (H_o scale, aqueous H_2SO_4).** Methanol in methyl acetate can be detected by measuring its solubility in water. At 20°, the solubility of methyl acetate in water is *ca* 35g per 100ml, but 1% MeOH confers complete miscibility. Methanol can be removed by conversion to methyl acetate, by refluxing for 6 hours with acetic anhydride (85ml/L), followed by fractional distillation. Acidic impurities can be removed by shaking with anhydrous K_2CO_3 and distilling. An alternative treatment is with acetyl chloride, followed by washing with concentrated NaCl and drying with CaO or $MgSO_4$. (Solid $CaCl_2$ cannot be used because it forms a crystalline addition compound.) Distillation from copper stearate destroys peroxides. Free alcohol or acid can be eliminated from methyl acetate by shaking with strong aqueous Na_2CO_3 or K_2CO_3 (three times), then with aqueous 50% $CaCl_2$ (three times), saturated aqueous NaCl (twice), drying with K_2CO_3 and distilling it from P_2O_5. [*Beilstein* **2** IV 122.]

Methyl acetimidate hydrochloride *[14777-27-6]* **M 109.6, m 93-95°, 105°(dec), pK_{Est} ~5.5.** Crystallise the imidate from methanol by adding dry ether to a ratio of 1:1 and cooling at 0°. Filter off the crystals in a cold room, wash them with methanol/ether (1:2), then dry in a vacuum. [Hunter & Ludwig *J Am Chem Soc* **84** 3491 *1962*.] The *free base* has **b** 90-91°/765mm, d $_4^{20}$ 0.867, n $_D^{20}$ 1.403. [Hunter & Ludwig *Methods Enzymol* **25** 585 *1973*, *Beilstein* **2** IV 181.]

Methyl acrylate *[96-33-3]* **M 86.1, b 80°, d $_4^{20}$ 0.9535, n $_D^{20}$ 1.4040.** Wash the ester repeatedly with aqueous NaOH until free from inhibitors (such as hydroquinone), then wash it with distilled water, dry ($CaCl_2$) and fractionally distil it under reduced pressure in an all-glass apparatus. Seal it under nitrogen and store it at 0° in the dark. [Bamford & Han *J Chem Soc, Faraday Trans 1* **78** 855 *1982*, *Beilstein* **2** IV 1457.]

Methylamine (gas) *[74-89-5]* **M 31.1, b –7.55°/719mm, pK^{25} 10.62.** Dry the amine with sodium or BaO. It is commercially available in metal cylinders. [*Beilstein* **4** IV 118.]

Methylamine hydrochloride *[593-51-1]* **M 67.5, m 231.8-233.4°, b 225-230°/15mm, pK^{25} 10.62.** Crystallise the salt from *n*-butanol, absolute EtOH or MeOH/$CHCl_3$. Wash it with $CHCl_3$ to remove traces of dimethylamine hydrochloride. Dry it under vacuum first with H_2SO_4 then P_2O_5. It is deliquescent; store it in a desiccator over P_2O_5. [*Beilstein* **4** IV 122.]

Methyl bromide *[74-83-9]* **M 94.9, b 3.6°.** Purify it by bubbling through conc H_2SO_4, followed by passage through a tube containing glass beads coated with P_2O_5. Also purify it by distillation from $AlBr_3$ at –80°, by passage through a tower of KOH pellets and by partial condensation. [*Beilstein* **1** IV 68.]

2-Methylbutane (isopentane) *[78-78-4]* **M 72.2, b 27.9°, d $_4^{20}$ 0.621, n $_D^{20}$ 1.35373, n $_D^{25}$ 1.35088.** Stir isopentane for several hours in the cold with conc H_2SO_4 (to remove olefinic impurities), then wash it with H_2O, aqueous Na_2CO_3 and H_2O again. Dry it with $MgSO_4$ and fractionally distil it using a Todd column packed with glass helices. Material transparent down to 180nm is obtained by distilling from sodium wire, and passing through a column of silica gel which had previously been dried in place at 350° for 12 hours before use. [Potts *J Phys Chem* **20** 809 *1952*, *Beilstein* **1** IV 320.]

2-Methyl-1-butanol *[137-32-6, RS(±) 34713-94-5, S(–) 1565-80-6]* **M 88.2, b 130°(*RS*), 128.6°(*S*), [α] $_D^{25}$ –5.8° (neat), d $_4^{20}$ 0.809, n^{52} 1.4082.** Reflux the butanol with CaO, distil, reflux with magnesium and again

fractionally distil it. A small sample of highly purified material is obtained by fractional crystallisation after conversion into a suitable ester such as the trinitrophthalate or the 3-nitrophthalate. The latter is converted to the cinchonine salt in acetone and recrystallised from $CHCl_3$ by adding pentane. The salt is saponified, extracted with ether, and fractionally distilled. [Terry et al. *J Chem Eng Data* **5** 403 *1960*, *Beilstein* **1** IV 1666.]

3-Methyl-2-butanol *[598-75-4]* **M 88.2, b 111.5°, d $_4^{20}$ 0.807, n $_D^{20}$ 1.4095, n $_D^{25}$ 1.4076.** Reflux it with magnesium, then fractionally distil it. [*Beilstein* **1** IV 1675.]

3-Methyl-2-butanone (methyl isopropyl ketone) *[563-80-4]* **M 86.1, b 93-94°/752mm, d $_4^{20}$ 0.818, n 1.410, pK^{25} –7.1 (aqueous H_2SO_4).** Reflux the ketone with a little $KMnO_4$. Fractionate it through a spinning-band column, dry with $CaSO_4$ and distil it. [*Beilstein* **1** IV 3287.]

2-Methyl-2-butene see **amylene** above.

2-Methyl-3-butyn-2-amine (1,1-dimethylpropargylamine, 3-amino-3-methyl-1-butyne) *[2978-58-7]* **M 83.1, b 79-80°/760mm, d $_4^{25}$ 0.790, n $_D^{25}$ 1.4183, pK$_{Est}$ ~8.0.** Dissolve the amine in Et_2O, dry over anhydrous K_2CO_3, filter, evaporate and distil (preferably under N_2). Store it away from CO_2. The *hydrochloride* [2978-59-8] has **m** 234° (from EtOH/Et_2O). The *benzoyl* derivative has **m** 152-153° (from EtOH). [Hennion & Teach *J Am Chem Soc* **75** 1653 *1953*, Hennion & DiGiovanna *J Org Chem* **30** 2645 *1965*.]

Methyl *n*-butyrate *[623-42-7]* **M 102.1, b 102.3°/760mm, d $_4^{20}$ 0.898, n $_D^{20}$ 1.389.** Treat the ester with anhydrous $CuSO_4$, then distil it under dry nitrogen. [*Beilstein* **2** IV 786.]

***S*-(+)-2-Methylbutyric acid** *[1730-91-2]* **M 102.1, b 64°/2mm, 78°/15mm, 90-94°/23mm, 174-175°/atm, d $_4^{20}$ 0.938, n $_D^{20}$ 1.406, [α] $_{546}^{20}$ +23°, [α] $_D^{20}$ +19.8° (neat), [α] $_D^{13}$ +18.3° (c 6, EtOH), pK^{25} 4.76 (for *RS*).** Purify the acid by distilling it *in vacuo* [Sax & Bergmann *J Am Chem Soc* **77** 1910 *1955*, Doering & Aschner *J Am Chem Soc* **75** 393 *1953*]. The *methyl ester* is formed by addition of diazomethane and has **b** 112-115°/760mm, [α] $_D^{27}$ +21.1° (c 1.7, MeOH). [*Beilstein* **2** IV 888.]

Methyl carbamate *[598-55-0]* **M 75.1, m 54.4-54.8°, 56-58°, b 176-177°/~760mm.** Crystallise the carbamate from *benzene or distil it. [*Beilstein* **3** H 21.]

Methyl chloride *[74-87-3]* **M 50.5, b –24.1°.** Bubble methyl chloride through a sintered-glass disc dipped into conc H_2SO_4, then wash it with water, condense it at low temperature and fractionally distil it. It has been distilled from $AlCl_3$ at –80°. *Alternatively*, pass it through towers containing $AlCl_3$, soda-lime and P_2O_5, then condense and fractionally distil it. Store it as a gas. [*Beilstein* **1** IV 28.]

Methyl chloroacetate *[96-34-4]* **M 108.5, b 129-130°, d $_4^{20}$ 1.230, n $_D^{20}$ 1.423.** Shake the ester with saturated aqueous Na_2CO_3 (three times), aqueous 50% $CaCl_2$ (three times), saturated aqueous NaCl (twice), dry (Na_2SO_4) and fractionally distil it. **Very toxic.** [*Beilstein* **2** IV 480.]

***R*-(+) Methyl 2-chloropropionate** *[77287-29-7]* **M 122.6, b 49-50°/35mm, 78-80°/120mm, 132-134°/760mm, d $_4^{20}$ 1.152, n $_D^{20}$ 1.417, [α] $_D^{20}$ +26° (19.0°) (neat).** Purify the ester by repeated distillation [Walker *J Chem Soc* **67** 916 *1895*, Walden *Chem Ber* **28** 1293 *1985*, see also Gless *Synth Commun* **16** 633 *1986*]. [*Beilstein* **2** H 248.]

Methyl cyanoacetate *[105-34-0]* **M 99.1, f –13°, b 115°/36mm, 200.4-200.9°/761mm, d $_4^{20}$ 1.128, n $_D^{20}$ 1.420.** Purify the ester by shaking with 10% Na_2CO_3 solution, wash well with water, dry with anhydrous Na_2SO_4, and distil it. [*Beilstein* **2** H 584, **2** I 253, **2** II 530, **2** III 1628, **2** IV 1889.]

Methyl cyanoformate *[17640-15-2]* **M 85.1, b 81°/47mm, 97°/751mm, 100-101°/760mm, d $_4^{20}$ 1.072, n $_D^{20}$ 1.37378.** Purify the ester by fractionation through a 45cm glass helices packed column or a 30cm spinning band column. [Sheppard *J Org Chem* **27** 3756 *1962*.] It has been distilled through a short Vigreux column, and further purified by recrystallisation from Et_2O at –40° as white crystals which melt at room temperature.

NMR: δ 4.0 (CH_3), and the IR has ν_{max} at 2250 (CN) and 1750 (CO) cm^{-1}. [Childes & Weber *J Org Chem* **41** 3486 *1976*, *Beilstein* **2** III 1587.]

Methyl decanoate (methyl caprate) *[110-42-9]* **M 186.3, b 114°/15mm, 224°/760mm, d_4^{20} 0.874, n_D^{20} 1.426.** Pass the ester through alumina before use and distil in a vacuum. [*Beilstein* **2** IV 1044.]

***N*-Methyldiethanolamine [MDEA, *N,N*-bis(hydroxyethyl)methylamine, 2,2′-methyliminodiethanol]** *[105-59-9]* **M 119.2, b 75-77°/0.5mm, 115°/5mm, 131°/10mm, 141-142°/18mm, 246-248°/atm, d_4^{25} 1.038, n_D^{20} 1.469, pK^{25} 8.57, pK^{35} 8.31, pK^{45} 8.13, pK^{60} 7.87.** Purify MDEA by fractional distillation preferably under vacuum in a stream of N_2, and store it under N_2. The colourless distillate darkens in air and absorbs CO_2 under pressure [Goodridge *Trans Farad Soc* **51** 1703 *1955*]. It is a tertiary base, hence it does not form an *N-carbamate salt* like primary and secondary amines, but **does** form a *carbonate salt* in the presence of carbonic acid (i.e. $CO_2 + H_2O = H_2CO_3$). It is soluble in H_2O and EtOH, but slightly soluble in Et_2O. The *hydrochloride* is very hygroscopic; the *O,O′-diacetyl ester* has **b 110°/4mm**, **133°/15mm**, **b 251°/atm**, the *O,O′-bis(4-nitrobenzoyl) ester* has **m 112-113°**, the *Reineckate salt* has **m 168°**, the *picrate* crystallises from EtOAc with **m 95-96°**, and with a strong aqueous solution of $AuCl_3$/HCl the *chloroaurate salt*, **m 101-102°**, is formed which crystallises from H_2O. With $PtCl_4$/HCl, the *chloroplatinate salt* is obtained, forming orange-yellow rhombic crystals upon recrystallisation from a concentrated aqueous solution which sinter at **145°** and decompose at **148-150°**. The IR spectrum in CCl_4 has C-H str at ν_{max} (ε $mole^{-1}$ $L.cm^{-1}$) 2779 (93), 2844 (81), 2877 (99) and 2948 (107) cm^{-1}. [Hanby & Rydon *J Chem Soc* 516 *1947*, Hill & Meakin *J Chem Soc* 760 *1958*, Knorr & Matthes *Chem Ber* **31** 1071 *1898*, *Beilsten* **4** H 284, **4** II 729, **4** III 692, **4** IV 1517.]

Methyl dodecanoate (methyl laurate) *[111-82-0]* **M 214.4, m 5°, b 141°/15mm, d_4^{20} 0.870, n^{50} 1.4199.** Pass the ester through alumina before use, and distil it in a vacuum. [*Beilstein* **2** IV 1090.]

***N*-Methyleneaminoacetonitrile (MAAN)** *[109-82-0]* **M 68.1, m 129°.** Crystallise MAAN from EtOH or acetone. It crystallises nicely from H_2O but with considerable loss of material. It is an inhibitor of bone growth. [Adams & Langley *Org Synth* Coll Vol **I** 355 *1941*.]

Methyl ether (dimethyl ether) *[115-10-6]* **M 46.1, m -141°, b –63.5°/96.5mm, –24°/~760mm, d^{25} 1.918/L (at 1 atmosphere relative to air as 1).** Dry methyl ether by passing over alumina and then BaO, or over CaH_2, followed by fractional distillation at low temperatures. Its solubility is 37ml per ml of H_2O at 18°, and it is very soluble in EtOH and Et_2O. [*Beilstein* **1** IV 1245.]

***N*-Methyl ethylamine hydrochloride** *[624-60-2]* **M 95.6, m 126-130°, pK^{25} 10.9 (free base).** Crystallise the hydrochloride from absolute EtOH or diethyl ether. Dry it *in vcuo*. [*Beilstein* **4** H 94.]

***N*-Methyl formamide** *[123-39-7]* **M 59.1, m –3.5°, b 100.5°/25mm, d_4^{20} 1.005., n^{52} 1.4306** Dry it over molecular sieves for 2 days, then distil it under reduced pressure through a column packed with glass helices. Fractionally crystallise it by partial freezing and the solid portion is distilled in a vacuum. [*Beilstein* **4** IV 170.]

Methyl formate *[107-31-3]* **M 60.1, b 31.5°, 34°, d_4^{20} 0.971, n^{15} 1.34648, n_D^{20} 1.34332.** Wash the formate with strong aqueous Na_2CO_3, dry it with solid Na_2CO_3 and distil it from P_2O_5. (Procedure removes free alcohol or acid.) [*Beilstein* **2** IV 20.]

2-Methylglutaric acid *[18069-17-5]* **M 146.1, m 79°, pK_1^{25} 4.36, pK_2^{25} 5.37.** Crystallise the acid from distilled water, then dry it under vacuum over conc H_2SO_4. [*Beilstein* **2** IV 1989.]

3-Methylglutaric acid *[626-51-7]* **M 146.1, m 87°, pK_1^{25} 4.35, pK_2^{25} 5.44.** Crystallise the acid from distilled water, then dry it under vacuum over conc H_2SO_4. [*Beilstein* **2** IV 1992.]

Methylglyoxal *[78-98-8]* **M 72.1, b *ca* 72°/760mm.** Commercial 30% (w/v) aqueous solution is diluted to about 10% and distilled twice, taking the fraction boiling below 50°/20mm Hg. (This treatment does not remove lactic acid). [*Beilstein* **1** IV 3631.]

2-Methylhexane *[591-76-4]* **M 100.2, b 90.1°, d_4^{20} 0.678, n_D^{20} 1.38485, n_D^{20} 1.38227.** Purify it by azeotropic distillation with MeOH, then wash it with water (to remove the MeOH), dry it over type 4A molecular sieves and distil it. [*Beilstein* **1** IV 397.]

3-Methylhexane *[589-34-4]* **M 100.2, b 91.9°, d_4^{20} 0.687, n_D^{20} 1.38864, n_D^{20} 1.38609.** Purify it as for 2-methylhexene. [*Beilstein* **1** IV 399.]

Methyl hexanoate (methyl caproate) *[106-70-7]* **M 130.2, b 52°/15mm, 150°/760mm, d_4^{20} 0.885, n_D^{20} 1.410.** Pass it through alumina and distil it before use. [*Beilstein* **2** IV 921.]

Methylhydrazine *[60-34-4]* **M 46.1, b 87°/745mm, d_4^{20} 0.876, n_D^{20} 1.436, pK^{30} 7.87.** Dry with BaO, then distil it in a vacuum. Store it under nitrogen. [*Beilstein* **4** IV 3322.]

Methyl hydrazinocarboxylate *[6294-89-9]* **M 90.1, m 70-73°, b 108°/12mm.** To remove impurities, the material is melted and pumped under vacuum until the vapours are spectroscopically pure [Caminati et al. *J Am Chem Soc* **108** 4364 *1986*]. Distil it in a vacuum. [*Beilstein* **3** I 46.]

Methyl iodide *[74-88-4]* **M 141.9, b 42.8°, d_4^{20} 2.281, n_D^{20} 1.5315.** Methyl iodide deteriorates rapidly with liberation of iodine if exposed to light. It is usually purified by shaking it with dilute aqueous $Na_2S_2O_3$ or $NaHSO_3$ until colourless, then washing with water, dilute aqueous Na_2CO_3, and more water, drying with $CaCl_2$ and distilling. It is stored in a brown bottle away from sunlight in contact with a small amount of mercury, powdered silver or copper. (Prolonged exposure of mercury to methyl iodide forms methylmercuric iodide.) Methyl iodide can be dried further using $CaSO_4$ or P_2O_5. An alternative purification is by percolation through a column of silica gel or activated alumina, then distillation. The solution can be degassed by using repeated freeze-pump-thaw cycles. [*Beilstein* **1** IV 87.]

***O*-Methylisourea hydrogen sulfate (2-methylpseudourea sulfate)** *[29427-58-5]* **M 172.2, m 114-118°, 119°.** Recrystallise the salt from MeOH/Et_2O (327g of salt dissolved in 1L of MeOH and 2.5L of Et_2O is added) [Fearing & Fox *J Am Chem Soc* **76** 4382 *1954*]. The *picrate* has **m** 192° [Odo et al. *J Org Chem* **23** 1319 *1958*]. [*Beilstein* **3** IV 143.]

***N*-Methyl maleimide** *[930-88-1]* **M 111.1, m 94-96°.** Crystallise the imide three times from diethyl ether. Dry it *in vacuo*. [*Beilstein* **21/10** V 5.]

Methylmalonic acid *[516-05-2]* **M 118.1, m 135°(dec), pK_1^{25} 3.05, pK_2^{25} 5.76.** The acid crystallises as the *hydrate* from water. [*Beilstein* **2** IV 1932.]

Methyl methacrylate *[80-62-6]* **M 100.1, f –50°, b 46°/100mm, 100°/~760mm, d_4^{20} 0.937, n_D^{20} 1.4144.** Wash the ester twice with aqueous 5% NaOH (to remove inhibitors such as hydroquinone) and twice with water. Dry it with $CaCl_2$, Na_2CO_3, Na_2SO_4 or $MgSO_4$, then with CaH_2 under nitrogen under reduced pressure. The distillate is stored at low temperatures and redistilled before use. Prior to distilling, inhibitors such as hydroquinone (0.004%), ß-naphthylamine (0.2%) or di-β-naphthol are sometimes added. Also purify it by boiling with aqueous H_3PO_4 solution and finally with saturated NaCl solution. It is dried for 24 hours over anhydrous $CaSO_4$, distilled at 0.1mm Hg at room temperature and stored at –30° [Albeck et al. *J Chem Soc, Faraday Trans 1* **1** 1488 *1978*]. [*Beilstein* **2** II 398, **2** III 1279, **2** IV 1519.]

Methyl methanesulfonate *[66-27-3]* **M 110.3, b 59°/0.6mm, 96-98°/19mm, d_4^{20} 1.300, n_D^{20} 1.4140.** Purify the ester by careful fractionation and collecting the middle fraction. Suspected **CARCINOGEN.** Note that $MeSO_3H$ has **b** 167-167.5°/10mm and methanesulfonic anhydride has **b** 138°/10mm) — both are possible impurities. [*Beilstein* **4** IV 11.]

Methyl methanethiolsulfonate *[2949-92-0]* **M 126.2, b 69-71°/0.4mm, 96-97°/4.5mm, 104-105°/10mm, 119°/16mm, d_4^{20} 1.226, n_D^{20} 1.515.** Purify it by fractional distillation under reduced pressure, the IR has ν_{max} at 1350, 750 cm^{-1}. [Applegate et al. *J Org Chem* **38** 943 *1973*, *Beilstein* **4** IV 31.]

Methyl nitrate *[598-58-3]* **M 77.0, b 5°/50mm, 65°/760mm, d^5 1.2322, d^{15} 1.2167, d^{25} 1.2032.** Wash $MeONO_2$ once with H_2O then again with H_2O containing a few drops of concentrated NaOH to keep it slightly alkaline (litmus). Dry the ester over anhydrous $CaCl_2$, decant it and use it directly. It is possible to distil it under a vacuum with slow and gentle heating, as a sudden rise in temperature can cause decomposition with copious release of nitrous fumes (use extreme precautions and protection). The middle fraction can then be subjected to several freeze-pump-thaw cycles. [Black & Bakers *Org Synth* Col Vol **II** 412 *1943*.] [*Beilstein* **1** H 284, **1** I 141, **1** II 273, **1** III 1201, **1** IV 1254.] The **VAPOUR CAN EXPLODE ON HEATING.**

Methyl nitrite *[624-91-9]* **M 61.0, b –18°, –17°, d^{15} (liquid) 0.991.** Condense MeONO in a liquid nitrogen trap. Distil the greenish liquid under vacuum (preferably in a vacuum line), into the first trap containing dry Na_2CO_3 to free it from acid impurities then into further Na_2CO_3 and fused $CaCl_2$ traps before collection at –78°. It has been distilled through columns that are surrounded by Et_2O/Dri-ice cooled to –30°. [Leermakers & Ramsperger *J Am Chem Soc* **54** 1838 *1932*, Thompson & Purkis *Trans Farad Soc* **32** 675 *1936*, *Beilstein* **1** H 284, **1** I 141, **1** II 273, **1** III 1201, **1** IV 1253.] **CARCINOGEN.**

2-Methyl-2-nitro-1,3-propanediol *[77-49-6]* **M 135.1, m 145°, 147-148°, 149-150°.** Crystallise it from *n*-butanol or Me_2CO (**m** 150.6°). It decomposes on attempted distillation at 10mm. Its solubility in H_2O is 80g/100ml at 20°. [*Beilstein* **1** H 489, **1** II 547, **1** III 2190, **1** IV 2537.]

2-Methyl-2-nitro-1-propanol *[76-39-1]* **M 119.1, m 87-88°, b 94-95°/10mm.** Distil it under vacuum and/or crystallise it from petroleum ether or MeOH. [Astle & Abbott *J Org Chem* **21** 1229 *1956*, Kambe & Yasuda *Bull Soc Chem Jpn* **41** 1444 *1968*, *Beilstein* **1** H 378, **1** III 1546, **1** IV 1604.]

***RS*(±)-2-Methyl-2,4-pentanediol (MPD, pinecon, hexylene glycol)** *[107-41-5]* **M 118.2, m -40°, b 97°/10mm, 107.5-108.5°/25mm, 135-136°/40mm, 197°/760mm, d_4^{20} 0.922, n_D^{25} 1.4265.** Dry the diol with Na_2SO_4, then CaH_2, and fractionally distil it under reduced pressure through a helices packed column, taking precautions to avoid absorption of water. It is soluble in H_2O, EtOH, Et_2O, pentane and hexane. The *diacetate* is a liquid with **b 95°/15mm. It has very harmful vapours; use efficient fume cupboard** as it irritates eyes, skin throat and lungs, causing headaches and nausea and is a CNS depressant. [*Beilstein* **1** IV 2565.]

3-Methyloctane *[2216-33-3]* **M 128.3, b 142-144°/760mm, d_4^{20} 0.719, n_D^{20} 1.407.** Take it through a silica gel column and distil it. [Klassen & Ross *J Phys Chem* **91** 3668 *1987*, *Beilstein* **1** IV 455]

Methyl octanoate (methyl caprylate) *[111-11-5]* **M 158.2, b 83°/15mm, 193-194°/760mm, d_4^{20} 0.877, n_D^{20} 1.419.** Pass the ester through alumina and distil it before use. [*Beilstein* **2** IV 986.]

Methyl oleate (methyl *cis*-9-octadecenoate) *[112-62-9]* **M 296.5, f –19.9°, b 217°/16mm, d_4^{20} 0.874, n_D^{20} 1.4522.** Purify the oleate by fractional distillation under reduced pressure, and by low temperature crystallisation from acetone. Store it in the dark under N_2. [*Beilstein* **2** IV 1649.]

Methylpentane (mixture of isomers). Pass the mixture through a long column of activated silica gel (or alumina) and collect material that is transparent down to 200nm in the UV.

2-Methylpentane *[107-83-5]* **M 86.2, b 60.3°, d_4^{20} 0.655, n_D^{20} 1.37145, n_D^{25} 1.36873.** Purify it by azeotropic distillation with MeOH, followed by washing out the MeOH with water, drying ($CaCl_2$, then sodium), and distilling it. [Forziati et al. *J Res Nat Bur Stand* **36** 129 *1946*.]

3-Methylpentane *[96-14-0]* **M 86.2, b 63.3°, d_4^{20} 0.664, n_D^{20} 1.37652, n_D^{25} 1.37384.** Purify it by azeotropic distillation with MeOH, as for 2-methylpentane. Purify it for ultraviolet spectroscopy by passing it through

columns of silica gel or alumina activated by heating for 8 hours at 210° under a stream of nitrogen. *Alternatively*, treat it with conc (or fuming) H_2SO_4, then wash it with water, aqueous 5% NaOH, water again, then dry ($CaCl_2$, then sodium), and distil it through a long, glass helices-packed, column. [*Beilstein* **1** IV 363.]

2-Methyl-2,4-pentanediol *[107-41-5]* **M 118.2, b 107.5-108.5°/25mm, d_4^{20} 0.922, n_D^{25} 1.4265.** Dry the diol with Na_2SO_4, then CaH_2 and fractionally distil it under reduced pressure through a packed column, taking precautions to avoid absorption of water. [*Beilstein* **1** IV 2565.]

2-Methyl-1-pentanol *[105-30-6]* **M 102.2, b 65-66°/60mm, 146-147°/760mm, d_4^{20} 0.827, n_D^{20} 1.420.** Dry the 1-pentanol with Na_2SO_4 and distil it. [*Beilstein* **1** IV 1713.]

4-Methyl-2-pentanol *[108-11-2]* **M 102.2, b 131-132°, d_4^{20} 0.810, n_D^{20} 1.413.** Wash the 2-pentanol with aqueous $NaHCO_3$, dry and distil it. Purify it further by converting it to the phthalate ester by adding 120ml of dry pyridine and 67g of phthalic anhydride per mole of alcohol, purifying the ester and steam distilling it in the presence of NaOH. The distillate is extracted with ether, and the extract is dried and fractionally distilled. [Levine & Walti *J Biol Chem* **94** 367 *1931*, *Beilstein* **1** IV 1717.]

3-Methyl-3-pentanol carbamate (Emylcamate) *[78-28-4]* **M 145.2, m 56-58.5°.** Crystallise the carbamate from 30% aqueous EtOH. [*Beilstein* **1** IV 1773.]

4-Methyl-2-pentanone (methyl isobutyl ketone) *[108-10-1]* **M 100.2, b 115.7°/~760mm d_4^{20} 0.801, n_D^{20} 1.3958, n_D^{25} 1.3938.** Reflux the ketone with a little $KMnO_4$, wash it with aqueous $NaHCO_3$, dry with $CaSO_4$ and distil it. Acidic impurities are removed by passage through a small column of activated alumina. [*Beilstein* **1** IV 3305.]

2-Methyl-1-pentene *[763-29-1]* **M 84.2, b 61.5-62°, d_4^{20} 0.680, n_D^{20} 1.395.** Water is removed, and formation of peroxides is prevented by several vacuum distillations of 2-methyl-1-pentene from sodium. It is stored with sodium-potassium alloy. [*Beilstein* **1** IV 841.]

***cis*-4-Methyl-2-pentene** *[691-38-3]* **M 84.2, m –134.4°, b 57.7-58.5°, d_4^{20} 0.672, n_D^{20} 1.388.** Dry the *cis*-pentene with CaH_2, and distil it. [*Beilstein* **1** IV 841.]

***trans*-4-Methyl-2-pentene** *[674-76-0]* **M 84.2, m –140.8°, b 58.5°, d_4^{20} 0.669, n_D^{20} 1.389.** Dry the *trans*-isomer with CaH_2, and distil it. [*Beilstein* **1** IV 844.]

2-Methylpropane-1,2-diamine (1,2-diamino-2-methylpropane) *[811-93-8]* **M 88.2, b 47-48°/17mm, pK_1^{25} 6.25 (6.18), pK_2^{25} 9.82 (9.42).** Dry the diamine with sodium for 2 days, then distil it from sodium under reduced pressure. [*Beilstein* **4** IV 1306.]

2-Methylpropane-1-thiol (isobutylmercaptan) *[513-44-0]* **M 90.2, b 41.2°/142mm, 88.5°/760mm, n_D^{25} 1.43582, pK_{Est} ~10.8.** Dissolve the thiol in EtOH, and add to 0.25M $Pb(OAc)_2$ in 50% aqueous EtOH. The precipitated lead mercaptide is filtered off, washed with a little EtOH, and impurities are removed from the molten salt by steam distillation. After cooling, dilute HCl is added dropwise to the residue, and the mercaptan is distilled directly from the flask. Water is separated from the distillate, and the mercaptan is dried (Na_2CO_3) and distilled under nitrogen. [Mathias *J Am Chem Soc* **72** 1897 *1950*, *Beilstein* **1** H 378, **1** I 191, **1** II 412, **1** III 1565, **1** IV 1605.]

2-Methylpropane-2-thiol (*tert*-butylmercaptan) *[75-66-1]* **M 90.2, b 61.6°/701mm, 66°/760mm, d_4^{25} 0.79426, n_D^{25} 1.41984, pK^{25} 11.22.** Dry the thiol for several days over CaO, then distil it from CaO. Purify it as for *2-methylpropane-1-thiol* above. [*Beilstein* **1** H 383, **1** II 416, **1** III 1589, **1** IV 1634.]

2-Methyl-1-propanol (isobutanol) *[78-83-1]* **M 74.1, b 107.9°760mm, d_4^{20} 0.804, n^{15} 1.39768, n_D^{25} 1.3939.** Isobutanol is dried by refluxing with CaO and BaO for several hours, followed by treatment with calcium or aluminium amalgam, then fractional distilling it from sulfanilic or tartaric acids. More exhaustive purifications

involve formation of phthalate or borate esters. Heating it with phthalic anhydride gives the *acid phthalate* which, after crystallisation to constant melting point (**m** 65°) from petroleum ether, is hydrolysed with aqueous 15% KOH. The alcohol is distilled off as the water azeotrope and dried (K_2CO_3, then anhydrous $CuSO_4$), and finally magnesium turnings, followed by fractional distillation. [Hückel & Ackermann *J Prakt Chem* **136** 15 *1933*.] The borate ester is formed by heating the dried alcohol for 6 hours in an autoclave at 160-175° with a quarter of its weight of boric acid. After fractional distillation under vacuum, the ester is hydrolysed by heating for a short time with aqueous alkali and the alcohol is dried with CaO and distilled. [Michael et al. *J Am Chem Soc* **38** 653 *1916*.] *Alternatively*, dry the alcohol with K_2CO_3, $CaSO_4$ or $CaCl_2$, filter and fractionally distil it. For further drying, the redistilled alcohol can be refluxed with the appropriate alkyl phthalate or succinate as described under *ethanol*. [*Beilstein* **1** IV 1588.]

Methyl propiolate *[922-67-8]* **M 84.1, b 100°/atm, 102°/atm, 103-105°/atm, d_4^{20} 0.945, n_D^{20} 1.4080.** Purify the propiolate by fractional distillation and collecting the middle fraction, note that propiolic acid has a higher boiling point [144°(dec)/760mm]. [*Beilstein* **2** IV 1688.] **LACHRYMATORY**.

***N*-Methylpropionamide** *[1187-58-2]* **M 87.1, f –30.9°, b 103°/12-13mm, d_4^{20} 0.934, n_D^{25} 1.4356.** The amide is a colourless, odourless, neutral liquid at room temperature with a high dielectric constant. The amount of water present can be determined directly by Karl Fischer titration, GLC and NMR have been used to detect unreacted propionic acid. Commercial material of high quality is available, probably from the condensation of anhydrous methylamine with 50% excess of propionic acid. Rapid heating to 120-140° with stirring favours the reaction by removing water either directly or as the ternary xylene azeotrope. The quality of the distillate improves during the distillation.
N-Methylpropionamide can be dried over CaO. Water and unreacted propionic acid are removed as their xylene azeotropes. It is then distilled in a vacuum. Material used as an electrolyte solvent (specific conductance less than 10^{-6} ohm^{-1} cm^{-1}) is obtained by fractional distillation under reduced pressure, and storage over BaO or molecular sieves because it readily absorbs moisture from the atmosphere on prolonged storage. [Hoover *Pure Appl Chem* **37** 581 *1974*, *Recommended Methods for Purification of Solvents and Tests for Impurities,* Coetzee Ed., Pergamon Press, *1982*, *Beilstein* **4** IV 183.]

Methyl propionate *[554-12-1]* **M 88.1, b 79.7°.** Wash the ester with saturated aqueous NaCl, then dry it with Na_2CO_3 and distil it from P_2O_5. (This removes any free acid and alcohol.) It has also been dried with anhydrous $CuSO_4$. [*Beilstein* **2** IV 104.]

Methyl *n*-propyl ether *[557-17-5]* **M 74.1, b 39°/743mm d_4^{20} 0.736, n^{14} 1.3602, pK^{25} –3.79 (aqueous H_2SO_4).** Dry it with $CaSO_4$, then pass the ether through a column of alumina (to remove peroxides) and fractionally distil it. [*Beilstein* **1** H 354, **1** I 178, **1** II 367, **1** III 1413, **1** IV 1421.]

Methyl *n*-propyl ketone (pentan-2-one) *[107-87-9]* **M 86.1, b 102.4°, d_4^{20} 0.807, n_D^{20} 1.3903.** Purify the ketone by refluxing it with a little $KMnO_4$, dry it with $CaSO_4$ and distil it. It can be converted to its bisulfite addition compound by shaking with excess saturated aqueous $NaHSO_3$ at room temperature, cooling to 0°, filtering, washing with diethyl ether and drying. Steam distillation of the adduct gives a distillate from which the ketone is recovered, washed with aqueous $NaHCO_3$ and distilled water, dried (K_2CO_3) and fractionally distilled. [Waring & Garik *J Am Chem Soc* **78** 5198 *1956*, *Beilstein* **1** IV 3271.]

(±)-3-Methyl-1-propyn-3-ol carbamate (Meparfynol carbamate) *[302-66-9]* **M 141.2, m 55.8-57°, 56-58°, 120-121°/16mm.** Crystallise it from $*C_6H_6$, hexane, ether/petroleum ether or cyclohexane. [*Beilstein* **1** IV 65.] It is a sedative.

Methyl stearate *[122-61-8]* **M 298.5, m 41-43°, b 181-182°/4mm.** Crystallise the ester from petroleum ether or distil it in a vacuum. [*Beilstein* **2** IV 1216.]

Methylsuccinic acid *[498-21-5]* **M 132.1, m 115.0°, pK_1^{25} 3.88, pK_2^{25} 5.35.** Crystallise the acid from water. [*Beilstein* **2** IV 1948.]

***N*-Methylthioacetamide** *[5310-10-1]* **M 89.1, m 59°.** Recrystallise the amide from *benzene or EtOH. [Todd et al. *Chem Ber* **69** 220 *1936*, *Beilstein* **4** I 329, **4** III 124.]

Methyl trifluoromethanesulfonate (methyl triflate) *[333-27-7]* **M 164.1, b 97-97.5°/736mm, 99°/~760mm, 100-102°/~760mm, d_4^{20} 1.496, n_D^{25} 1.3238.** It is a strong methylating agent but is corrosive and **POISONOUS**. Fractionate it carefully and collecting the middle fraction (use an efficient fume cupboard) and keep away from moisture. It is a **POWERFUL ALKYLATING AGENT** and a strong **IRRITANT.** [IR: Gramstad & Haszeldine *J Chem Soc* 173 *1956*, *J Chem Soc* 4069 *1957*.] *Trifluoromethanesulfonic acid* (triflic acid) *[1493-13-6]* **M** 151.1, boils higher (**b** 162°/atm), has a **pKa** of 3.10, and is **TOXIC** and hygroscopic. [Hansen *J Org Chem* **30** 4322 *1965*, Kurz & El-Nasr *J Am Chem Soc* **104** 5823 *1982*, *Beilstein* **3** IV 34.]

Methyl vinyl ketone (3-buten-2-one) *[78-94-4]* **M 70.1, b 62-68°/400mm, 79-80°/760mm, d_4^{20} 0.845, n_D^{20} 1.413.** It forms an 85% azeotrope with water. After drying with K_2CO_3 and $CaCl_2$ (with cooling), the ketone is distilled at low pressures. [*Beilstein* **1** IV 3444.]

Methyl vinyl sulfone *[3680-02-2]* **M 106.1, b 116-118°/20mm, d_4^{20} 1.215, n_D^{20} 1.461.** Pass the sulfone through a column of alumina, then de-gas, distil it in a vacuum line and store it at –190° until required. [*Beilstein* **1** III 1866.]

***N*-Monobutyl urea** *[592-31-4]* **M 116.2, m 96-98°, pK_{Est} ~0.2.** Crystallise the urea from EtOH/water, then dry it under vacuum at room temperature. [*Beilstein* **4** I 371, **4** IV 578.]

***N*-Monoethyl urea** *[625-52-5]* **M 88.1, m 92-95°, pK_{Est} ~0.2.** Crystallise the urea from EtOH/water, then dry it under vacuum at room temperature. [*Beilstein* **4** IV 369.]

***N*-Monomethyl urea** *[598-50-5]* **M 74.1, m 93-95°, pK_{Est} ~0.2.** Crystallise the urea from EtOH/water, then dry it under vacuum at room temperature. [*Beilstein* **4** IV 205.]

***N*-Monopropyl urea** *[627-06-5]* **M 102.1, m 107°, 110°, pK_{Est} ~0.2.** Crystallise the urea from EtOH or EtOH/Et_2O. [Biovin & Biovin *Can J Chem* **29** 479 *1951*, IR: Biovin & Biovin *Can J Chem* **32** 563 *1954*, *Beilstein* **4** H 142, **4** III 261, **4** IV 482.]

Mucochloric acid (2,3-dichloro-4-oxo-2-butenoic acid) *[87-56-9]* **M 169.0, m 124-126°, pK^{25} 4.20.** Crystallise the acid twice from water (charcoal). [*Beilstein* **3** IV 1720.]

***trans, trans*-Muconic acid (hexa-2,4-dienedioic acid)** *[3588-17-8]* **M 142.1, m 300°, pK^{25} 4.51, for *cis,cis* pK^{25} 4.49.** Crystallise the diacid from H_2O. [*Beilstein* **2** IV 2298.]

Myristic acid (tetradecanoic acid) *[544-63-8]* **M 228.4, m 58°, pK^{20} 6.3 (50% aqueous EtOH), pK_{Est} ~4.9 (H_2O).** Purify the acid *via* the *methyl ester* (**b** 153-154°/10mm, n^{25} 1.4350), as for capric acid. [Trachtman & Miller *J Am Chem Soc* **84** 4828 *1962*.] Also purify it by zone melting. It crystallises from petroleum ether, and is dried in a vacuum desiccator containing shredded wax. [*Beilstein* **2** IV 1126.]

Neopentane (2,2-dimethylpropane) *[463-82-1]* **M 72.2, flash point 79.3°, m –19.8°, b 9.5°/760mm, d_4^{20} 0.6737, n_D^{20} 1.38273.** It is freed from isobutene by passage over conc H_2SO_4 or P_2O_5, and through silica gel. [*Beilstein* **1** H 141, **1** I 50, **1** II 104, **1** 369, **1** IV 333.]

Nerolidol (3,7,11-trimethyl-1,6,10-dodecatrien-3-ol) M 222.4 *[cis/trans 7212-44-4]* **b 122°/3mm, d_4^{20} 0.73, n_D^{20} 1.477,** *[cis 3790-78-1]* **b 70°/0.1mm,** *[trans 40716-66-3]* **b 78°/0.2mm, 145-146°/2mm.** Purify it by TLC on plates of Kieselguhr G [McSweeney *J Chromatogr* **17** 183 *1965*] or silica gel impregnated with $AgNO_3$, using 1,2-CH_2Cl_2/$CHCl_3$/EtOAc/PrOH (10:10:1:1) as solvent system. Also by GLC on butanediol succinate (20%) on Chromosorb W. Stored it under N_2 at ~5° in the dark. [*Beilstein* **1** IV 2336.]

Nitrilotriacetic acid [tris(carboxymethyl)amine, NTA, Complexone 1] *[139-13-9]* **M 191.1, m 247°(dec), pK_1 0.8, pK_2 1.71, pK_3 2.47, pK_4 9.71.** Crystallise it from water and dry it at 110°. [*Beilstein* **4** IV 2441.]

Nitroethane *[79-24-3]* **M 75.1, b 115°, d_4^{20} 1.049, n_D^{20} 1.3920, n_D^{25} 1.39015, pK^{25} 8.60 (8.46, pH equilibrium requires *ca* 5 minutes).** Purify it as described for *nitromethane* below. A spectroscopic impurity can be removed by shaking it with activated alumina, decanting and distilling it rapidly. [*Beilstein* **1** IV 170.]

Nitroguanidine *[556-88-7]* **M 104.1, m 246-246.5°(dec), 257°, pK_1^{25} -0.55, pK_2^{25} 12.20.** Crystallise it from water (20ml/g). The *nitrate* has **m** 147°(dec)(prisms, H_2O). [*Beilstein* **3** H 126, **3** III 236.]

Nitromethane *[75-52-5]* **M 61.0, f –28.5°, b 101.3°, d_4^{20} 1.13749, d^{30} 1.12398, n_D^{20} 1.3819, n^{30} 1.37730, pK^{25} 10.21.** Nitromethane is generally manufactured by gas-phase nitration of methane. The usual impurities include aldehydes, nitroethane, water and small amounts of alcohols. Most of these can be removed by drying with $CaCl_2$ or by distillation to remove the water/nitromethane azeotrope, followed by drying with $CaSO_4$. Phosphorus pentoxide is not suitable as a drying agent. [Wright et al. *J Chem Soc* 199 *1936*.] The purified material should be stored by dark bottles, away from strong light, in a cool place. Purifications using extraction are commonly used. For example, Van Looy and Hammett [*J Am Chem Soc* **81** 3872 *1959*] mixed about 150ml of conc H_2SO_4 with 1L of nitromethane and allowed it to stand for 1 or 2 days. The solvent was washed with water, aqueous Na_2CO_3, and again with water, then dried for several days with $MgSO_4$, filtered again with $CaSO_4$. It was fractionally distilled before use. Smith, Fainberg and Winstein [*J Am Chem Soc* **83** 618 *1961*] washed it successively with aqueous $NaHCO_3$, aqueous $NaHSO_3$, water, 5% H_2SO_4, water and dilute $NaHCO_3$. The solvent was dried with $CaSO_4$, then percolated through a column of Linde type 4A molecular sieves, followed by distillation from some of this material (in powdered form). Buffagni and Dunn [*J Chem Soc* 5105 *1961*] refluxed it for 24 hours with activated charcoal while bubbling a stream of nitrogen through the liquid. The suspension was filtered, dried (Na_2SO_4) and distilled, then passed through an alumina column and re-distilled. It has also been refluxed over CaH_2, distilled and kept under argon over 4A molecular sieves.
It has been purified by zone melting at low temperature, or by distillation under vacuum at 0°, subjecting the middle fraction to several freeze-pump-thaw cycles. An impure sample containing higher nitroalkanes and traces of cyanoalkanes was purified (on the basis of its NMR spectrum) by crystallisation from diethyl ether at –60° (cooling in Dry-ice) [Parrett & Sun *J Chem Educ* **54** 448 *1977*].
Fractional crystallisation is more effective than fractional distillation from Drierite in purifying nitromethane for conductivity measurements. [Coetzee & Cunningham *J Am Chem Soc* **87** 2529 *1965*.] Specific conductivities around 5 x 10^{-9} $ohm^{-1}cm^{-1}$ were obtained. [*Beilstein* **1** IV 100.]

1-Nitropropane *[108-03-2]* **M 89.1, b 131.4°, d_4^{20} 1.004, n_D^{20} 1.40161, n_D^{25} 1.39936, pK^{25} 8.98.** Purify it as for *nitromethane.* [*Beilstein* **1** IV 229.]

2-Nitropropane *[79-46-9]* **M 89.1, b 120.3°, d_4^{20} 0.989, n_D^{20} 1.3949, n_D^{25} 1.39206, pK^{25} 7.68.** Purify it as for *nitromethane.* [*Beilstein* **1** IV 230.]

***N*-Nitrosodiethanolamine (NDELA)** *[1116-54-7]* **M 134.4, b 100°/2.6x10^{-5}mm, 125°/0.01mm, n_D^{20} 1.4849.** Purify NDELA by dissolving the amine (0.5g) in 1-propanol (10ml) and 5g of anhydrous Na_2SO_4 added with stirring. After standing for 1-2 hours, it is filtered and passed through a chromatographic column packed with 10ml of AG 50W x 8 (H^+form 50-100mesh, a strongly acidic cation exchanger). The eluent and washings (50 ml EtOH) are combined and evaporated to dryness at 35°. It has also been extracted with EtOH from the nitrosation mixture of ethanolamine, filtered and distilled under high vacuum. [Fukuda et al. *Anal Chem* **53** 2000 *1981*, Jones & Wilson *J Chem Soc* 550, *1949*, *Beilstein* **1** III 721, see Spiegelhalder et al. *N-Nitroso Compounds*: *Occurrence Biological Effects and Relevance in Human Cancer* (eds. O'Neill et al. IARC Scientific Publications No 57; IARC Lyon p943 *1984*.] *Possible* **CARCINOGEN.**

Nitrourea *[556-89-8]* **M 105.1, m 158.4-158.8°(dec).** Crystallise it from EtOH/petroleum ether. Dry it *in vacuo* ~50°. [Ingersoll & Arenendt *Org Synth* Coll Vol **I** 417 *1941*.]

***n*-Nonane** *[111-84-2]* **M 126.3, b 150.8°, d_4^{20} 0.719, n_D^{20} 1.40542, n_D^{25} 1.40311.** Fractionally distil *n*-nonane,

then stir it with successive volumes of conc H_2SO_4 for 12 hours each until no further coloration is observed in the acid layer. Then wash it with water, dry with $MgSO_4$ and fractionally distil it. *Alternatively*, it is purified by azeotropic distillation with 2-ethoxyethanol, followed by washing out the alcohol with water, drying and distilling it. [Forziati et al. *J Res Nat Bur Stand* **36** 129 *1946*, *Beilstein* **1** IV 447.]

Nylon powder. Pellets are purified by dissolving them in ethylene glycol under reflux, then precipitating nylon as a white powder by adding EtOH at 25°. This is washed with EtOH and dried at 100° under vacuum.

***n*-Octacosane** *[630-02-4]* **M 394.8, m 62.5°.** Purify it by forming its adduct with urea, washing it and crystallising it from acetone/water. [McCubbin *Trans Faraday Soc* **58** 2307 *1962*.] Crystallise it then from hot filtered isopropyl ether solution (10ml/g). [*Beilstein* **1** IV 588.]

***n*-Octacosanol (octacosyl alcohol)** *[557-61-9]* **M 410.8, m 83.4°, 84°.** Recrystallise it from large volumes of Me_2CO. Sublime it at 200-250°/1mm instead of distilling it. [*Beilstein* **2** IV 1318.]

***n*-Octadecane** *[593-45-3]* **M 254.5, m 28.1°, b 173.5°/10mm, 316.1°/760mm, d_4^{20} 0.7768, n_D^{20} 1.4390.** Crystallise it from acetone and distil it from sodium in a vacuum. [*Beilstein* **1** IV 553.]

Octadecyl acetate *[822-23-1]* **M 312.5, m 32.6°, b 166-168°/1mm, 172-174°/1.5mm.** Distil the ester under high vacuum, then crystallise it from Et_2O/MeOH, EtOH (**m** 32.8°) or Me_2CO (**m** 32.4°). Also recorded are **m** 30.2°; and 35.3° for an α form as well as 38-39° for a β form. [Phillips & Mumford *J Chem Soc* 1663 *1934*, *Beilstein* **2** H 136, **2** II 147, **2** III 266, **2** IV 171.]

***n*-Octadecyl alcohol (stearyl alcohol, octadecanol)** *[112-92-5]* **M 270.5, m 61°, b 153-154°/0.3mm.** Crystallise octadecanol from MeOH, or dry Et_2O and $*C_6H_6$, then fractionally distil it *in vacuo*. Also purify it by column chromatography. Free it from cetyl alcohol by zone refining. [*Beilstein* **1** IV 1888.]

***n*-Octadecylamine (1-aminooctadecane, stearylamine, ODA)** *[124-30-1]* **M 269.5, m 49-52°, 50-52°, 52-54°, b 183.0-183.1°/5mm, 232°/32mm, pK^{25} 10.60.** *n*-Octadecylamine can be prepared from nonadecanoic acid (*n*-nonadecylic acid, [646-30-0]) by Schmidt's hydrazoic acid method whereby the carboxylic acid (15.8g, 53mmol) in $*C_6H_6$ (500ml) is treated carefully with concentrated H_2SO_4 (30ml), stirred vigorously at 40° and hydrazoic acid (52ml of a 5.3% solution in $*C_6H_6$, 1.2 equivalents, i.e. 63.3mmol; see [7782-79-8], **POISONOUS** use efficient fumehood] is added slowly. After evolution of N_2 and CO_2 have ceased (~2 hours) the acid layer is poured into cold H_2O whereby octadecylamine sulfate precipitates (~96% yield decomposing at ~200°). [see Briggs et al *J Chem Soc* 61 *1942*.] The free base is obtained by shaking with 10% KOH solution, extracting into Et_2O, drying (K_2CO_3), evaporating and distilling the residue in a vacuum. Its FT-IR (film) has ν_{max} at 2923.9, 1466.3, 792.4, 720.9 cm^{-1}; its ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 0.89 (t, J = 7 Hz, 3H, CH_3), 1.01 (s), 1.25 (s, 10H), 1.43 (m, 2H), 2.67 (t, J = ~7 Hz, 2H, CH_2-N); and the ^{13}C NMR (75MHz, $CDCl_3$, $CHCl_3$ standard) has δ at 42.35, 33.99, 31.95, 29.72, 29.56, 29.39, 26.94, 22.71, 14.11. It has also been prepared by the Gabriel Synthesis whereby octadecanol is converted to octadecyl iodide, m 29-32° (by reaction with P_2O_5/KI), then with potassium phthalimide in DMF, to the *N*-*n*-octdecylphthalimide, m 80-81°, followed by hydrazinolysis with 85% $NH_2NH_2.H_2O$, and isolation as the *hydrochloride* [1838-08-0] **m 162-163°** after crystallisation from EtOH/Et_2O [Wood *J Chem Soc* 3327 *1953*]. Another method of prepartion include reduction of stearic amide with LAH in ~60% yield using a Soxhlet extractor with the amide in the thimble and LAH/Et_2O in the boiling flask [Murr & Lester *J Am Chem Soc* **77** 1684 *1955*]. The *N-acetyl derivative* has **m 84-85°** (EtOH/Et_2O), and the *N-methyl derivative* [2439-55-6] has **m 42-46°**, **b 155°/0.5mm**. [*Beilstein* **4** II 661, **4** III 431, **4** IV 825.] The base and its derivatives are **skin and eye irritants**, and release histamine.

Octadecyl ether (dioctadecyl ether) *[6297-03-6]* **M 523.0, m 59.4°, n_D^{60} 1.440.** Distil the ether in a vacuum, then crystallise it from MeOH/$*C_6H_6$, MeOH (**m** 58.5-59.5°) or Me_2CO (**m** 59.5°). It has an α form **m** 57.8° and a β form **m** 40°. [*Beilstein* **1** IV 1891.]

Octafluoropropane (profluorane) *[76-19-7]* **M 188.0, m –183°, b –38°.** Purify it for pyrolysis studies by passage through a copper vessel containing CoF_3 at about 270°, then fractionally distil it. [Steunenberg & Cady *J Am Chem Soc* **74** 4165 *1952*.] Also purify it by several trap-to-trap distillations at low temperatures [Simons & Block *J Am Chem Soc* **59** 1407 *1937*].

***n*-Octane** *[111-65-9]* **M 114.2, m –56.8°, b 19.2°/10mm, 125.6°/760mm, d_4^{20} 0.704, n_D^{20} 1.39743, n_D^{25} 1.39505.** Extract the octane repeatedly with conc H_2SO_4 or chlorosulfonic acid, then wash it with water, dry and distil it. *Alternatively*, purify it by azeotropic distillation with EtOH, followed by washing with water to remove the EtOH, drying and distilling it. For further details, see n-*heptane*. It is also purified by zone melting at low temperature. [*Beilstein* **1** H 159, **1** I 60, **1** II 122, **1** III 457, **1** IV 412.]

***RS*-(±)-Octane-1,2-diol** *[1117-86-8]* **M 146.2, m 30-30.5°, 36°, b 103-105°/0.5mm, 131-132°/10mm.** Distil the diol *in vacuo* and/or recrystallise it from petroleum ether. The *α-naphthylurethane* has **m** 112-114°. [*Beilstein* **1**III 2217, **1** IV 2590.] *S*-(–)-*Octane-1,2-diol* [87720-91-0] also crystallises from petroleum ether with **m** 35-37° and $[\alpha]_D^{17}$ –4.7° (c 35, EtOH) [Späth et al. *Chem Ber* **66** 598 *1933*]; *R*-(+)-*octane-1,2-diol* [87720-90-9] has similar properties but with a positive optical rotation.

Octane-1,8-diol (octamethylene glycol) *[629-41-4]* **M 146.2, m 59-61°, b 172°/20mm.** Recrystallise the diol from EtOH and distil it in a vacuum. [*Beilstein* **1** IV 2592.]

1-Octanethiol *[111-88-6]* **M 146.3, b 86°/15mm, 197-200°/760mm, d_4^{20} 0.8433, n_D^{20} 1.4540, pK^{25} 10.72(dilute *t*-BuOH).** Pass the thiol through a column of alumina and work under N_2, or Ar. Distil it under N_2 and a vacuum. Store it under N_2, or Ar in the dark. [Battacharyya et al. *J Chem Soc, Faraday Trans 1* **82** 135 *1986,* Fletcher *J Am Chem Soc* **68** 2727 *1946*]. [*Beilstein* **1** III 1710, **1** IV 1767.]

1-Octene *[111-66-0]* **M 112.2, b 121°/742mm, d_4^{20} 0.716, n_D^{20} 1.4087.** Distil 1-octene under nitrogen from sodium which removes water and peroxides. Peroxides can also be removed by percolation through dried, acid washed, alumina. Store it under N_2, or Ar in the dark. [Strukul & Michelin *J Am Chem Soc* **107** 7563 *1985*, *Beilstein* **1** H 221, **1** II 199, **1** IV 874.]

***trans*-2-Octene** *[13389-42-9]* **M 112.2, b 124-124.5°/760mm, d_4^{20} 0.722, n_D^{20} 1.4132.** Purify it as for 1-octene above. [*Beilstein* **1** IV 879.]

***n*-Octyl alcohol** *[111-87-5]* **M 130.2, b 98°/19mm, 195.3°/760mm, d_4^{20} 0.828, n_D^{20} 1.43018.** Fractionally distil it under reduced pressure. Dry it with sodium and again fractionally distil or reflux with boric anhydride and re-distilled (**b** 195-205°/5mm), the distillate being neutralised with NaOH and again fractionally distilled. Also purify it by distillation from Raney nickel and by preparative GLC. [*Beilstein* **1** IV 1756.]

***n*-Octylamine (1-aminooctane, caprylamine)** *[111-86-4]* **M 129.2, m –5-1°, b 62-64°/11mm 175-177°/745mm, 185-187°/atm, d_4^{20} 0.7819, d_4^{25} 0.728, n_D^{20} 1.4292, pK^{25} 10.57.** *n*-Octylamine has been prepared from nonanoic acid (pelargonic acid, see [112-05-0]) by Schmidt's hydrazoic acid method as described for octadecylamine above. [Adamson & Kenner *J Chem Soc* 383 *1943*.] The syntheses decribed below for octadecyl amine can be used for preparing octylamine. A more recent preparation involves formation of tri-*n*-octylborane from 1-octene and BH_3.THF *in situ*, then reaction with NaN_3/HCl to give a 79% yield of octylamine [Kabalka et al. *Organometallics* **6** 1369 *1987*]. The free base can be isolated from its salts or the picrate by treatment with strong aqueous alkaline solution, extraction into Et_2O or CH_2Cl_2, drying (K_2CO_3), evaporating and distilling the residue preferably in a vacuum. Solubility in H_2O is ~2%. It is a strong base which readily absorbs CO_2 in moist air and should be stored under N_2. Its FT-IR (film) has ν_{max} at 3371.9, 2924.6, 1617.3, 1467.0, 1378.3, 1072.7, 822.1, 722.9 cm^{-1}; its ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 0.89 (t, J = ~7 Hz, 3H, CH_3), 1.15 (s), 1.29 (s, $6CH_2$), 1.42 (t, J = ~7 Hz, NH_2), 2.69 (t, J = ~7 Hz, 2H, CH_2-N) ppm; and the ^{13}C NMR (300MHz, $CDCl_3$, $CHCl_3$ standard) has δ at 42.32, 33.96, 31.88, 29.51, 29.34, 26.94, 22.69, 14,10 ppm. The *picrate* [78498-55-2] crystallises as plates with **m 111.5-112.5°**, the *N-acetyl derivative* [7462-62-6] has **b 148-149°/3mm**, and the *N-methyl derivative* [2439-54-5] has **b 60-65°/3mm**, **75-78°/13mm**. [*Beilstein* **4** H 196, **4** I 386, **4** II 655, **4** III 379, **4** IV 751.] *n*-Octylamine is quite a strong primary base capable of forming a carbamate

salt of the type $RNHCO_2^-$ RNH_3^+ in the presence of CO_2 and H_2O (see storage above). The free base and its derivatives are **skin and eye irritants**.

***n*-Octylammonium hexadecanoate** *[88020-97-7]* **M 385.7, m 52-53°.** Purify it by several recrystallisations from *n*-hexane or ethyl acetate. The solid is then washed with cold anhydrous diethyl ether, and dried *in vacuo* over P_2O_5. [*Beilstein* **4** IV 751 for octylamine.]

***n*-Octylammonium octadecanoate** *[32580-92-0]* **M 413.7, m 56-57°.** Purify it as for the *hexadecanoate* above.

***n*-Octylammonium tetradecanoate** *[17463-35-3]* **M 358.6, m 46-48°.** Purify it as the *hexadecanoate* above.

***n*-Octyl bromide** *[111-83-1]* **M 193.1, b 201.5°, d_4^{20} 1.118, n^{25} 1.4503.** Shake the bromide with H_2SO_4, wash it with water, dry with K_2CO_3 and fractionally distil it. [*Beilstein* **1** IV 422.]

1-Octyne *[629-05-0]* **M 110.2, b 76-77°/150mm, 126.2°/760mm, d_4^{20} 0.717, n^{25} 1.4159.** Distil I-octyne from $NaBH_4$ to remove peroxides. Fractionate it through a 10inch Widmer column at 125-126°/759mm [Sletzinger & Dawson *J Org Chem* **14** 853 *1949*.] [*Beilstein* **1** III 1005, **1** IV 1034.]

Oleic acid (*cis*-9-octadecenoic acid, olainic acid) *[112-80-1]* **M 282.5, m 16°, b 145°/0.1mm, 194-195°/1.2mm, 228-229°/15mm, 360°(dec), d_4^{20} 0.891, n^{30} 1.4571, pK^{25} 6.42 (50% aqueous EtOH), pK_{Est} ~4.8 (H_2O).** Purify the acid by fractional crystallisation from its melt, followed by molecular distillation at 10^{-3}mm, or by conversion to its methyl ester, the free acid can be crystallised from acetone at –40° to –45° (12ml/g). For purification by the use of lead and lithium salts see Keffler and McLean [*J Soc Chem Ind (London)* **54** 176T *1935*]. Purification based on direct crystallisation from acetone is described by Brown and Shinowara [*J Am Chem Soc* **59** 6 *1937,* pK White *J Am Chem Soc* **72** 1857 *1950*]. [*Beilstein* **2** H 463, **2** I 198, **2** II 429, **2** III 1387, **2** IV 1641.]

Oleyl alcohol *[143-28-2]* **M 268.5, b 182-184°/1.5mm, d_4^{20} 0.847, $n^{27.5}$ 1.4582.** Purify it by fractional crystallisation at –40° from acetone, then distil it under vacuum. [*Beilstein* **2** IV 2204.]

Oxalic acid ($2H_2O$) *[6153-56-6]* **M 90.0, m 101.5°,** *[anhydrous 144-62-7]* **m 189.5°, pK_1^{25} 1.08 (1.37), pK_2^{25} 3.55 (3.80).** Crystallise oxalic acid from distilled water. Dry it in a vacuum over H_2SO_4. The anhydrous acid can be obtained by drying at 100° overnight. [*Beilstein* **2** IV 1819.]

Oxaloacetic acid *[328-42-7]* **M 132.1, m 160°(decarboxylates), pK_1^{25} 2.22, pK_2^{25} 3.89, pK_3^{25} 13.0.** Crystallise it from boiling EtOAc, or from hot Me_2CO/hot $*C_6H_6$. [*Beilstein* **3** IV 1808.]

2-Oxoglutaric acid (2-oxopentane-1,5-dioic, α-ketoglutaric acid) *[328-50-7]* **M 146.1, m 114°, 115-117°, (pK_{Est} see oxaloacetic acid above).** Crystallise the keto-acid repeatedly from Me_2CO/*benzene, EtOAc or ethyl propionate. Dry it *in vacuo*. [*Beilstein* **3** IV 1813.]

Oxamide *[471-46-5]* **M 88.1, m >320°(dec).** Crystallise oxamide from water, grind it and dry it in an oven at 150°. [*Beilstein* **2** IV 1860.]

Palmitic acid anhydride (hexadecanoic anhydride) *[623-65-4]* **M 494.9, m 63-64°, 64°, d^{82} 0.838, n^{68} 1.436.** It is moisture sensitive and hydrolyses in water. Purify it by refluxing with acetic anhydride for 1 hour, evaporating and freeing the residue of acetic acid and anhydride by drying the residue at high vacuum and recrystallising from petroleum ether at low temperature. [*Beilstein* **2** IV 1181.]

Paraffin (oil) *[8012-95-1]* **d_4^{20} 0.880, n_D^{20} 1.482.** Treat the oil with fuming H_2SO_4 (care), then wash it with water and dilute aqueous NaOH, then percolate it through activated silica gel.

Paraffin Wax. Melt the wax in the presence of NaOH, wash it with water until all of the base had been removed. The paraffin is allowed to solidify after each wash. Finally, 5g of paraffin is melted by heating it on a water-bath, then shaken for 20-30 minutes with 100ml of boiling water and and dry the melt under vacuum.

Pelargonic acid (nonanoic acid) *[112-05-0]* **M 158, m 15°, b 98.9°/1mm, 225°/760mm, pK^{25} 4.96.** Esterify the acid with ethylene glycol and distil the ester. (This removes dibasic acids as undistillable residues.) The acid is regenerated by hydrolysing the ester in the usual way and is distilled *in vacuo*. [*Beilstein* **2** IV 1018.]

Pelargononitrile (octyl cyanide) *[2243-27-8]* **M 139.2, m –34°, b 92°/10mm, 224°, d_4^{20} 0.818, n_D^{20} 1.4255.** Stir the nitrile with P_2O_5 (~5%), distil it from P_2O_5 and redistil it under a vacuum. IR should have CN but no OH bands. [*Beilstein* **2** IV 1204.]

Pelargonyl chloride (nonanoyl chloride) *[764-85-2]* **M 176.7, b 88°/12mm, d_4^{20} 0.941, n_D^{20} 1.436.** Reflux it with acetyl chloride (~ 3 volumes) for 1 hour, then distil off AcCl followed by the nonanoyl chloride at ~12mm. It is moisture sensitive and should be stored in sealed ampoules. [*Beilstein* **2** IV 1023.]

Pentabromoacetone *[79-49-2]* **M 452.6, m 76°, pK^{25} 8.0 (MeOH), pK_{Est} ~4.6 (H_2O).** Crystallise it from Et_2O, EtOH or aqueous EtOH (**m** 73.2°) and sublime it. Its solubility in H_2O is 0.01mg/100ml. [*Beilstein* **1** H 659, **1** I 345, **1** III 2753, **1** IV 3226.]

Pentachloroethane (pentalin) *[76-01-7]* **M 202.3, b 69°/37mm, 152.2°/64mm, 162.0°/~760mm, d_4^{20} 1.678, n^{15} 1.50542.** Usual impurities include trichloroethylene. It partially decomposes if it is distilled at atmospheric pressure. Drying it with CaO, KOH or sodium is unsatisfactory because of the elimination of the elements of HCl. It can be purified by steam distillation, or by washing with conc H_2SO_4, water, and then aqueous K_2CO_3, drying with solid K_2CO_3 or $CaSO_4$, and fractionally distilling under reduced pressure. [*Beilstein* **2** IV 147.]

Pentadecafluoro octanoic acid (perfluorocaprylic acid) *[335-67-1]* **M 414.1, m 54.9-55.6°, b 189°/736mm, pK_{Est} <0.** Crystallise the acid from CCl_4 and toluene, and distil it. It forms micelles in H_2O and the solubility is 1% in H_2O. The *acid chloride* has **b** 129-130°/744mm. The *amide* has **m** 138°. [Bernett & Zisman *J Phys Chem* **63** 1911 *1959*, Bro & Sperati *J Polym Sci* **38** 289 *1959*, *Beilstein* **2** IV 994.]

Pentadecanoic acid *[1002-84-2]* **M 242.4, m 51-53°, 80°, b 158°/1mm, 257°/760mm, d_4^{80} 0.8424, pK_{Est} ~5.0.** Crystallise the acid from Et_2O and distil it *in vacuo*. It is very hygroscopic. See the purification of palmitic acid. [*Beilstein* **2** IV 1147.]

Pentadecanolide (1-oxacyclohexadecan-2-one, pentadecanoic-ω-lactone, 15-hydroxypentadecanoic lactone, exaltolide, Tibetolide) *[106-02-5]* **M 240.4, m 34-36°, 37-37.5°, 37-38°, b 102-103°/0.03mm, 112-114°/0.2mm, 137°/2mm, 169°/10-11mm, d_4^{40} 0.9401.** It has been recrystallised from MeOH (4 parts) at –15°, and distilled under high vacuum. [Hundiecker & Erlbach *Chem Ber* **80** 135 *1947*, Galli & Mandolini *Org Synth* **58** 100 *1978*, Demole & Enggist *Helv Chim Acta* **11** 2318 *1978*, *Beilstein* **17/9** V 106.]

Penta-1,3-diene *[cis: 1574-41-0, trans: 2004-70-8]* **M 68.1, b 42°, d_4^{20} 0.680, n_D^{20} 1.4316.** Distil the diene from $NaBH_4$. Purify it also by preparative gas chromatography. [Reimann et al. *J Am Chem Soc* **108** 5527 *1986*, *Beilstein* **1** IV 994.]

Penta-1,4-diene *[591-93-5]* **M 68.1, b 25.8-26.2°/756mm, d_4^{20} 0.645, n_D^{20} 1.3890.** Distil it from $NaBH_4$. Purify it by preparative gas chromatography or distillation and stabilise it with 0.1% of 2,6-di-*tert*-butyl-*p*-cresol. [Reimann et al. *J Am Chem Soc* **108** 5527 *1986*, *Beilstein* **1** IV 998.]

Pentaethylenehexamine *[4067-16-7]* **M 232.4, d_4^{20} 0.950, n_D^{20} 1.510, pK_1 1.2, pK_2 2.7, pK_3 4.3, pK_4 7.8, pK_5 9.1, pK_6 9.9 (all estimated).** Fractionally distil it twice at 10-20mm, the fraction boiling at 220-250° being collected. It can be further purified *via* the *hydrochloride*. Its solution in MeOH (40ml of base in 250ml) is cooled in an ice-bath and conc HCl (~50ml) is added dropwise with stirring. The precipitated *hydrochloride* is

filtered off, washed with Me_2CO, and Et_2O, then dried in a vacuum desiccator. The free base is then obtained by basification, extraction into Et_2O, drying (NaOH), filtering, evaporating and distilling the residue as before. It forms a Cu complex $[Cu(C_{10}H_{28}N_6)]^{2+}$. [Jonassen et al. *J Am Chem Soc* **79** 4279 *1957*, *Beilstein* **4** IV 1245.]

2,2,3,3,3-Pentafluoropropan-1-ol *[422-05-9]* **M 150.1, b 80°/~760mm, d_4^{20} 1.507, n_D^{20} 1.288, pK^{25} 12.74.** Shake the alcohol with alumina for 24 hours, dry with anhydrous K_2CO_3, and distil it, collect the middle fraction (**b** 80-81°) and redistil it. [*Beilstein* **1** IV 1438.]

***n*-Pentane** *[109-66-0]* **M 72.2, b 36.1°, d_4^{20} 0.626, n_D^{25} 1.35472.** Stir the pentane with successive portions of conc H_2SO_4 until there is no further coloration during 12 hours, then with 0.5N $KMnO_4$ in 3M H_2SO_4 for 12 hours, wash with water and aqueous $NaHCO_3$. Dry it with $MgSO_4$ or Na_2SO_4, then P_2O_5 and fractionally distil it through a column packed with glass helices. It is also purified by passage through a column of silica gel, followed by distillation and storage with sodium hydride. An alternative purification is by azeotropic distillation with MeOH, which is subsequently washed out from the distillate (using water), followed by drying and re-distilling. For removal of carbonyl-containing impurities, see n-*heptane.* Also purify it by fractional freezing (*ca* 40%) on a copper coil through which cold air is passed, then wash with conc H_2SO_4 and fractionally distil it. [*Beilstein* **1** IV 303.]

Pentane-1-thiol *[110-66-7]* **M 104.2, m –76°, b 122.9°/697.5mm, d^{25} 0.8375, pK_{Est} ~10.1.** Dissolve the thiol in aqueous 20% NaOH, then extract with a small amount of diethyl ether. The aqueous solution is acidified slightly with 15% H_2SO_4, and the thiol is distilled out, dried with $CaSO_4$ or $CaCl_2$, and fractionally distilled under nitrogen. [Ellis & Reid *J Am Chem Soc* **54** 1674 *1932*, *Beilstein* **1** IV 1453.]

(±)-Pentan-2-ol *[6032-29-7]* **M 88.2, b 119.9°/~760mm, d_4^{20} 0.810, n_D^{20}1.41787, n_D^{25} 1.4052.** Reflux it with CaO, distil it, then reflux it with magnesium and again fractionally distil it. [*Beilstein* **1** IV 1655.]

Pentan-3-ol *[584-02-1]* **M 88.2, b 116.2°, d_4^{20} 0.819, n_D^{25} 1.4072.** Reflux the alcohol with CaO, distil, then reflux it with magnesium and again fractionally distil it. [*Beilstein* **1** IV 1662.]

Pentan-3-one see **diethyl ketone** above.

Pent-2-ene (mixed isomers) *[109-68-2]* **M 70.1, b 36.4°, d_4^{20} 0.650, n_D^{20} 1.38003, n_D^{25} 1.3839.** Reflux the mixture with sodium wire, then fractionally distil it twice through a Fenske (glass helices packing) column. [*Beilstein* **1** IV 815.]

***cis*-Pent-2-ene** *[627-20-3]* **M 70.1, b 37.1°, d_4^{20} 0.657, n_D^{25} 1.3798.** Dry it with sodium wire and fractionally distil it, or purify it by azeotropic distillation with MeOH, followed by washing out the MeOH with water, drying and distilling. Also purify it by chromatography through silica gel and alumina [Klassen & Ross *J Phys Chem* **91** 3668 *1987*]. [*Beilstein* **1** IV 814.]

***trans*-Pent-2-ene** *[646-04-8]* **M 70.1, b 36.5°, d_4^{20} 0.6482, n_D^{20} 1.3793.** It is treated as above and washed with water, dried over anhydrous Na_2CO_3, and fractionally distilled. The middle cut is purified by two passes of fractional melting. [*Beilstein* **1** IV 814.]

Pent-2-yne *[627-21-4]* **M 68.1, b 26°/2.4mm, 56.1°/760mm, d_4^{20} 0.710, n_D^{25} 1.4005.** It is stood with, then distilled at low pressure from sodium or $NaBH_4$. [*Beilstein* **1** III 958, **1** IV 992.]

Perfluorobutyric acid (heptafluorobutyric acid) *[375-22-4]* **M 214.0, m -17.5°, b 120°/735mm, d_4^{20} 1.651, n_D^{16} 1.295, pK^{25} -0.17.** Fractionally distil the acid twice in an Oldershaw column with an automatic vapour-dividing head, the first distillation being in the presence of conc H_2SO_4 as a drying agent. (Take care with the hot acid.) [*Beilstein* **2** IV 810.]

Perfluoroheptane (hexadecafluoroheptane) *[335-57-9]* **M 388.1, b 99-101°, d_4^{25} 1.7200.** Purify it as for *perfluorodimethylhexane*. Other procedures include shaking with H_2SO_4, washing with water, and drying with

P_2O_5 for 48 hours then fractionally distilling. *Alternatively*, it has been refluxed for 24 hours with saturated acid $KMnO_4$ (to oxidise and remove hydrocarbons), then neutralised, steam distilled, dried with P_2O_5, and passed slowly through a column of dry silica gel. It has been purified by fractional crystallisation using partial freezing. [*Beilstein* **1** IV 388.]

Perfluoro-*n*-hexane (tetradecafluorohexane) *[355-42-0]* **M 338.1, m –4°, b 58-60°, d_4^{20} 1.684.** Purify the fluorohexane by fractional freezing. The methods described for *perfluoroheptane* should be applicable here. [*Beilstein* **1** IV 348.]

Perfluorononane (eicosafluorononane) *[375-96-2]* **M 488.1, b 126-127°, d_4^{20} 1.80, n_D^{20} 1.275.** Purify as for *perfluorodimethylcyclohexane.* [*Beilstein* **1** III 505.]

Perfluoropropyl iodide (heptafluoro-1-iodopropane) *[754-34-7]* **M 295.9, b 41°, d_4^{20} 2.13, n_D^{20} 1.339.** Purify the fluoro-iodide by fractional distillation. Store it over Cu as stabiliser. [*Beilstein* **1** IV 225.]

Perfluorotributylamine (heptacosafluorotributylamine) *[311-89-7]* **M 671.1, b 177.6°/760mm, d_4^{20} 1.881, n_D^{20} 1.291, pK_{Est} ~5.0.** Purify it as for perfluorodimethylcyclohexane (see [335-27-3]); see also perfluorotripropylamine below [Haszeldine *J Chem Soc* 102 *1951*]. [*Beilstein* **2** IV 819.]

Perfluorotripropylamine (heneicosafluorotripropylamine) *[338-83-0]* **M 521.1, b 130°/atm, 129.5-130.5°/atm, d_4^{20} 1.822, n_D^{20} 1.279, pK_{Est} ~5.6.** Purify it as for *perfluorodimethylcyclohexane* (see [335-27-3]) [Haszeldine *J Chem Soc* 102 *1951,* for azeotropes see Simons & Linevsky *J Am Chem Soc* **74** 4750 *1972*.] **IRRITANT.**

Petroleum ether *[8032-32-4]* **b 35-60°, d_4^{20} 0.640, n_D^{20} 1.363.** Shake it several times with conc H_2SO_4, then 10% H_2SO_4 and concentrated $KMnO_4$ (to remove unsaturated, including aromatic, hydrocarbons) until the permanganate colour persists. Wash it with water, aqueous Na_2CO_3 and again with water. Dry it with $CaCl_2$ or Na_2SO_4, and distil it. It can be dried further using CaH_2 or sodium wire. Passage through a column of activated alumina, or treatment with CaH_2 or sodium, removes peroxides. For the elimination of carbonyl-containing impurities without using permanganate, see *n-heptane*. These procedures could be used for all fractions of petroleum ethers. See **skellysolve** below, p. 201.
Rapid purification: Pass it through an alumina column and fractionally distilling, collecting the desired boiling fraction.

Phorone (2,6-dimethylhepta-2,5-dien-4-one) *[504-20-1]* **M 138.2, m 28°, b 197°/743mm.** Crystallise phorone repeatedly from EtOH. [*Beilstein* **1** IV 3564.]

Pimelic acid (heptane-1,7-dioic acid) *[111-16-0]* **M 160.2, m 105-106°, pK_1^{25} 4.46, pK_2^{25} 5.58.** Crystallise the acid from water or from *benzene containing 5% diethyl ether. [*Beilstein* **1** IV 2003.]

Pinacol (hexahydrate) *[6091-58-3 ($6H_2O$), 76-09-5 (anhydrous)]* **M 194.3, m 46.5°, b 59°/4mm.** Distil pinacol, then crystallise it repeatedly from water. (See also below.) [*Beilstein* **1** IV 2575.]

Pinacol (anhydrous) *[76-09-5]* **M 118.1, m 41.1°, b 172°.** The hydrate is rendered anhydrous by azeotropic distillation of water with *benzene. Recrystallise it from *benzene or toluene/petroleum ether, absolute EtOH or dry diethyl ether. It recrystallises from water to give the *hexahydrate*. [*Beilstein* **1** IV 2575.]

Pinacolone see ***tert*-butyl methyl ketone.**

Pinacolone oxime *[2475-93-6]* **M 115.2, m 75.5-76°, 78°, 78.5-79.5°, 171.6°/748mm.** Crystallise the oxime from aqueous EtOH, EtOH (small needles) or petroleum ether (plates). [Markownikoff *Chem Ber* **32** 1448 *1899*, Smith & Atkins *J Am Chem Soc* **60** 660 *1938*, Whitmore et al. *J Am Chem Soc* **61** 684 *1939*, *Beilstein* **1** H 694, **1** II 750, **1** III 2842, **1** IV 3310.]

Pivalic acid (trimethylacetic acid) *[75-98-9]* **M 102.1, m 35.4°, b 71-73°/0.1mm, pK^{25} 5.03.** Fractionally distil the acid under reduced pressure, then fractionally crystallise it from its melt. Recrystallise it from *benzene. [*Beilstein* **2** IV 908.]

Pivaloyl chloride (trimethylacetyl chloride) *[3282-30-2]* **M 120.6, b 57.6°/150mm, 70.5-71/250mm, 104°/754mm, 104-105°/atm, 105-108°/atm, d $_4^{20}$ 1.003, n $_D^{20}$ 1.4142.** First check the IR to see if OH bands are present. If absent, or present in small amounts, then redistil it under a moderate vacuum. If present in large amounts then treat it with oxalyl chloride or thionyl chloride and reflux for 2-3 hours, evaporate and distil the residue. **Strongly LACHRYMATORY – work in a fume cupboard.** Store it in sealed ampoules under N_2. [Traynham & Battiste *J Org Chem* **22** 1551 *1957*, Grignard reactions: Whitmore et al. *J Am Chem Soc* **63** 647 *1941*, *Beilstein* **2** IV 912.]

Polyacrylonitrile *[25014-41-9]***.** Precipitate it from dimethylformamide by addition of MeOH.

Poly(diallyldimethylammonium) chloride *[26062-79-3]***.** Precipitate it from water with acetone, and dry the salt in a vacuum for 24 hours. [Hardy & Shriner *J Am Chem Soc* **107** 3822 *1985*.]

Polyethylene *[9002-88-4]*. Crystallise it from thiophen-free *benzene and dry it over P_2O_5 under vacuum.

Polymethyl acrylate *[9003-21-8]*. Precipitate it from a 2% solution in acetone by addition of water.

Polyvinyl acetate *[9003-20-7]*. Precipitate it from acetone by addition of *n*-hexane.

Polyvinyl chloride *[9002-81-2]*. Precipitate it from cyclohexanone by addition of MeOH.

Propane *[74-98-6]* **M 44.1, m -189.7, b -42.1°/760mm, d $_4^{20}$ 0.5005, n $_D^{20}$ 1.2898.** Purify propane by bromination of the olefinic contaminants. Propane is treated with bromine for 30 minutes at 0°. Unreacted bromine is quenched, and the propane is distilled through two -78° traps and collected at -196° [Skell et al. *J Am Chem Soc* **108** 6300 *1986*]. It autoignites at 450° and the flash point is -104°. It is highly **FLAMMABLE** and is available in metal cylinders. [*Beilstein* **1** H 103, **1** I 33, **1** II 71, **1** III 204, **1** IV 175.]

Propane-1,2-diamine (propylenediamine) *[78-90-0]* **M 74.1, b 120.5°/~760mm, d $_4^{20}$ 0.868, n $_D^{20}$ 1.446, pK $_1^{25}$ 6.61, pK $_2^{25}$ 9.82.** Purify the diamine by azeotropic distillation with toluene. Then distil it. Store it in a CO_2 free atmosphere. [Horton et al. *Anal Chem* **27** 269 *1955*, *Beilstein* **4** IV 1255.]

(±)-Propane-1,2-diol (propyleneglycol) *[57-55-6]* **M 76.1, m -60°, b 45.5°/1.0mm, 70.8°/5.0mm, 83.2°/10mm, 96.4°/20mm, 104°/32mm, 111.2°/40mm, 119.9°/60mm, 132.0°/100mm, 149.7°/200mm, 168.1°/400mm, 188.2°/atm, d $_4^{20}$ 1.040, n $_D^{20}$ 1.433.** Dry the diol over Na_2SO_4, decant and distil it under reduced pressure. It is soluble in H_2O, Me_2CO, $CHCl_3$, many oils, is used as an antifreeze in dairies and breweries; and is a substitute for glycerol or ethylene glycol. [*Beilstein* **1** IV 2468.]

***R*-(–)- and *S*-(+)- Propane-1,2-diol (*R*- and *S*- propylene glycol)** *[R(–) 4254-14-2: S(+) 4254-15-3]* **M 76.1, b 78.5°/10mm, 94-96°/14mm, 186-188°/765mm, d $_4^{20}$ 1.036, n $_D^{20}$ 1.432, [α] $_D^{25}$ (–) or (+) 17.5° (neat).** The laevo *R-enantiomer* can be obtained from reduction of hydroxyacetone by yeast [Levene & Walti *Org Synth* Coll Vol **II** 545 *1943*], and the dextro *S-enantiomer* is obtained by reduction of *S*-(+)-lactic acid. Thus (+)-lactic acid (33.4g, 370mmol) in dry THF (200ml) is added dropwise to a suspension of LAH (32.1g, 850mmol) in dry THF (500ml) at 0° during 2 hours, allowed to warm to 25°, refluxed for 2 hours, cooled, then quenched by careful addition of ice-cold H_2O (32ml), followed by 4N NaOH (32ml) and again H_2O (96ml). The white precipitate is coagulated by refluxing the mixture for 0.5 hours, filtered, washed with THF, the white cake is slurred with hot THF (4 x ~100ml), the combined THF layers are evaporated *in vacuo* (~40°), and the residual oil is distilled through a vacuum jacketed Vigreux column under vacuum to give the *S*-diol as a colourless liquid (23,9g, 85%). [Fryzuk & Bosnich *J Am Chem Soc* **100** 5491 *1978*.]

Propane-1,3-diol *[504-63-2]* **M 76.1, b 110-122°/12mm, d $_4^{20}$ 1.053, n$^{18.5}$ 1.4398.** Dry this diol with K_2CO_3

and distil it under reduced pressure. More extensive purification involves conversion with benzaldehyde to *2-phenyl-1,3-dioxane* (**m** 47-48°) which is subsequently decomposed by shaking with 0.5M HCl (3ml/g) for 15 minutes and standing overnight at room temperature. After neutralisation with K_2CO_3, the benzaldehyde is removed by steam distillation and the diol is recovered from the remaining aqueous solution by continuous extraction with $CHCl_3$ for 1 day. The extract is dried with K_2CO_3, the $CHCl_3$ is evaporated and the diol is distilled. [Foster et al. *Tetrahedron* **6** 177 *1961*, *Beilstein* **1** IV 2493.]

***S*-(-)-Propane-1,2-diol bis(*p*-toluenesulfonate)** *[60434-71-1]* **M 384.5, m 68-70° (62°), $[\alpha]_D^{20}$ –20° (c 1, $CHCl_3$)**, is prepared in much the same way as for *S,S*-butane-2,3-diol bis-tosylate (see above) from *S*-(+)-propane-1,2-diol (310mmol) in dry pyridine (30ml) and toluene-*p*-sulfonyl chloride (700mmol, recrystallised from hexane) in dry pyridine (135ml) at 0° during 0.5 hours, then at 25° for 17 hours. The crude ester is purified by dissolving in CH_2Cl_2 and cyclohexane is added to cloud point at 40°, then allowed to crystallise at 25° when more cyclohexane is added and set aside (5°/12 hours) to give the *bis-tosylate* as white feathery crystals which are dried over $CaCl_2$ *in vacuo* (114g, 95%). [Fryzuk & Bosnich *J Am Chem Soc* **100** 5491 *1978*.] This *S*-(–)-2,3-ditosylate provides the chiral ligand *R*-(+)- [cf 15629-92-2], which involves inversion of configuration at the chiral centre.

Propane-1-thiol *[107-03-9]* **M 76.1, b 65.3°/702mm, d_4^{25} 0.83598, n_D^{25} 1.43511, pK^{20} 10.82.** Purify the thiol by dissolving it in aqueous 20% NaOH, extracting with a small amount of *benzene and steam distilling until clear. After cooling, the solution is acidified slightly with 15% H_2SO_4, and the thiol is distilled out, dried with anhydrous $CaSO_4$ or $CaCl_2$, and fractionally distilled under nitrogen. [Mathias & Filho *J Phys Chem* **62** 1427 *1958*.] Also purify it by liberating the mercaptan by adding dilute HCl to the residue remaining after steam distilling. After direct distillation from the flask, and separation of the water, the mercaptan is dried (Na_2SO_4) and distilled under nitrogen. [*Beilstein* **1** IV 1449.]

Propane-2-thiol (Isopropyl mercaptan) *[75-33-2]* **M 76.1, b 49.8°/696mm, d_4^{25} 0.80895, n_D^{25} 1.42154, pK^{25} 10.86.** Purify it as for propane-1-thiol above. [*Beilstein* **1** IV 1498.]

Propargyl alcohol (2-propyn-1-ol) *[107-19-7]* **M 56.1, b 54°/57mm, 113.6°/760mm, d_4^{20} 0.947, n_D^{20} 1.432.** The commercial material contains a stabiliser. An aqueous solution of propargyl alcohol can be concentrated by azeotropic distillation with butanol or butyl acetate. Dry it with K_2CO_3 and distil it under reduced pressure, in the presence of about 1% succinic acid, through a glass helices-packed column. [*Beilstein* **1** IV 2214.]

Propargyl chloride (3-chloropropyne) *[624-65-7]* **M 74.5, b 58°/760mm, 65°/760mm, d_4^{20} 1.03, n_D^{20} 1.435.** Purify the chloride by fractional distillation at atmospheric pressure. Note that a possible impurity is propargyl alcohol which has **b** 114-115°/~760mm (see above). [Henry *Chem Ber* **8** 398 *1875*.] **HIGHLY TOXIC** and **FLAMMABLE**. [*Beilstein* **1** IV 960.]

Propene (propylene) *[115-07-1]* **M 42.1, m -185.2°, b -47.8°/750mm, d_4^{20} 0.519, n^{-71} 1.357.** Purify it by freeze-pump-thaw cycles and trap-to-trap distillation. [*Beilstein* **1** IV 725.]

β-Propiolactone see oxetan-2-one in "Heterocyclic Compounds", in this Chapter.

Propionaldehyde *[123-38-6]* **M 58.1, b 48.5-48.7°, d_4^{20} 0.804, n_D^{20} 1.3733, n_D^{25} 1.37115.** Dry the aldehyde with $CaSO_4$ or $CaCl_2$, and fractionally distil it under nitrogen or in the presence of a trace of hydroquinone (to retard oxidation). Blacet and Pitts [*J Am Chem Soc* **74** 3382 *1952*] repeatedly distilled the middle fraction in a vacuum until it no longer gave a solid polymer when cooled to -80°. It is stored with $CaSO_4$. [*Beilstein* **1** IV 3165.]

Propionamide *[79-05-0]* **M 73.1, m 79.8-80.8°, pK^{24} –0.9 (H_o scale, aqueous H_2SO_4).** Crystallise it from acetone, *benzene, $CHCl_3$, water or acetone/water, then dry it in a vacuum desiccator over P_2O_5 or conc H_2SO_4. [*Beilstein* **2** H 243, **2** I 108, **2** II 223, **2** III 542, **2** IV 725.]

Propionic acid *[79-09-4]* **M 74.1, b 141°, d_4^{20} 0.992, n_D^{20} 1.3865, n_D^{25} 1.3843, pK_1^{25} –6.8 (H_o scale, aqueous H_2SO_4), pK_2^{25} 4.88.** Dry the acid with Na_2SO_4 or by fractional distillation, then redistil after refluxing with a few crystals of $KMnO_4$. An alternative purification uses conversion to the ethyl ester, fractional distillation and hydrolysis. [Bradbury *J Am Chem Soc* **74** 2709 *1952*.] Propionic acid can also be heated for 0.5 hour with an amount of benzoic anhydride equivalent to the amount of water present (in the presence of CrO_3 as catalyst), followed by fractional distillation. [Cham & Israel *J Chem Soc* 196 *1960*, *Beilstein* **2** IV 695.]

Propionic anhydride *[123-62-6]* **M 130.2, b 67°/18mm, 168°/780mm, d_4^{20} 1.407, n_D^{20} 1.012.** Shake the anhydride with P_2O_5 for several minutes, then distil. [*Beilstein* **2** IV 722.]

Propionitrile *[107-12-0]* **M 55.1, b 97.2°, d_4^{20} 1.407, n^{15} 1.36812, n^{30} 1.36132.** Shake the nitrile with dilute HCl (20%), or with concentrated HCl until the odour of isonitrile has gone, then wash with water, and aqueous K_2CO_3. After a preliminary drying with silica gel or Linde type 4A molecular sieves, it is stirred with CaH_2 until hydrogen evolution ceases, then decant and distil from P_2O_5 (not more than 5g/L, to minimise gel formation). Finally, it is refluxed with, and slowly distilled from CaH_2 (5g/L), taking precautions to exclude moisture. [*Beilstein* **2** IV 728.]

***n*-Propyl acetate** *[109-60-4]* **M 102.1, b 101.5°, d_4^{20} 0.887, n_D^{20} 1.38442, pK^{25} –7.18 (H_o scale, aqueous H_2SO_4).** Wash the ester with saturated aqueous $NaHCO_3$ until neutral, then with saturated aqueous NaCl. Dry it with $MgSO_4$ and fractionally distil it. [*Beilstein* **2** IV 138.]

***n*-Propyl alcohol (1-propanol)** *[71-23-8]* **M 60.1, b 97.2°, d_4^{25} 0.79995, n_D^{20} 1.385, pK^{25} 16.1.** The main impurities in *n*-propyl alcohol are usually water and 2-propen-1-ol, reflecting the commercial production by hydration of propene. Water can be removed by azeotropic distillation either directly (azeotrope contains 28% water) or by using a ternary system, e.g. by also adding *benzene. *Alternatively*, for removal of gross amounts of water, reflux over CaO for several hours is desirable, followed by distillation and a further drying. To obtain more nearly anhydrous alcohol, suitable drying agents are firstly NaOH, $CaSO_4$ or K_2CO_3, then CaH_2, aluminium amalgam, magnesium activated with iodine, or a small amount of sodium. *Alternatively*, the alcohol can be refluxed with *n*-propylsuccinate or phthalate in a method similar to the one described under EtOH. Allyl alcohol is removed by adding bromine (15ml/L), and then fractionally distilling from a small amount of K_2CO_3. Propionaldehyde, also formed in the bromination, is removed as the 2,4-dinitrophenylhydrazone. *n*-Propyl alcohol can be dried down to 20 ppm of water by passage through a column of pre-dried molecular sieves (type 3 or 4A, heated for 3 hours at 300°) in a current of nitrogen. Distillation from sulfanilic or tartaric acids removes impurities.
Albrecht [*J Am Chem Soc* **82** 3813 *1960*] obtained spectroscopically pure material by heating with charcoal to 50-60°, filtering and adding 2,4-dinitrophenylhydrazine and a few drops of conc H_2SO_4. After standing for several hours, the mixture is cooled to 0°, filtered and distilled in a vacuum. Gold and Satchell [*J Chem Soc* 1938 *1963*] heated *n*-propyl alcohol with 3-nitrophthalic anhydride at 76-110° for 15 hours, then recrystallised the resulting ester from H_2O, *benzene/petroleum ether (b 100-120°)(3:1), and *benzene. The ester was hydrolysed under reflux with aqueous 7.5M NaOH for 45 minutes under nitrogen, followed by distillation (also under nitrogen). The fraction with **b** 87-92° is dried with K_2CO_3 and stirred under reduced pressure in the dark over 2,4-dinitrophenylhydrazine, then freshly distilled. Also purify it by adding 2g $NaBH_4$ to 1.5L of alcohol, gently flushing with argon and refluxing for 1 day at 50°. Then 2g of freshly cut sodium (washed with propanol) is added and refluxed for one day, and finally distilled, taking the middle fraction [Jou & Freeman *J Phys Chem* **81** 909 *1977*]. [*Beilstein* **1** IV 1413.]

***n*-Propylamine** *[107-10-8]* **M 59.1, b 48.5°, d_4^{20} 0.716, n_D^{20} 1.38815, pK^{25} 10.69.** Distil the amine from zinc dust, under reduced pressure, in an atmosphere of nitrogen. [*Beilstein* **4** IV 464.]

***n*-Propyl bromide.** *[106-94-5]* **M 123.0, b 71.0°, d_4^{20} 1.354, n^{15} 1.43695, n_D^{25} 1.43123.** Likely contaminants include *n*-propyl alcohol and isopropyl bromide. The simplest purification procedure uses drying with $MgSO_4$ or $CaCl_2$ (with or without a preliminary wash of the bromide with aqueous $NaHCO_3$, then water), followed by fractional distillation away from bright light. Chien and Willard [*J Am Chem Soc* **79** 4872 *1957*] bubbled a stream of oxygen containing 5% ozone through *n*-propyl bromide for 1 hour, then stirred it with 3% hydrogen

peroxide solution, neutralised it with aqueous Na_2CO_3, washed it with distilled water and dried it. This was followed by vigorous stirring with 95% H_2SO_4 until fresh acid did not discolour within 12 hours. The propyl bromide was separated, neutralised, washed, dried with $MgSO_4$ and fractionally distilled. The centre cut was stored in the dark. Instead of ozone, Schuler and McCauley [*J Am Chem Soc* **79** 821 *1957*] added bromine and stored it for 4 weeks, the bromine then being extracted with aqueous $NaHSO_3$ before the sulfuric acid treatment was applied and finally distilled. Further purification is by preparative gas chromatography on a column packed with 30% SE-30 (General Electric ethylsilicone rubber) on 42/60 Chromosorb P at 150° and 40psi, using helium as carrier gas. [Chu *J Phys Chem* **41** 226 *1964*, *Beilstein* **1** IV 205.]

***n*-Propyl chloride** *[540-54-5]* **M 78.5, b 46.6°, d_4^{20} 0.890, n_D^{20} 1.3880.** Dry the chloride with $MgSO_4$ and fractionally distil. It can be more extensively purified using extraction with H_2SO_4 as for *n*-propyl bromide. *Alternatively*, Chien and Willard [*J Am Chem Soc* **75** 6160 *1953*] passed a stream of oxygen containing about 5% ozone through the *n*-propyl chloride for three times as long as was needed to cause the first coloration of starch iodide paper by the exit gas. After washing with aqueous $NaHCO_3$ to hydrolyse ozonides and remove organic acids, the chloride was dried with $MgSO_4$ and fractionally distilled. [*Beilstein* **1** IV 189.]

Propylene glycol diacetate (1,2-diacetoxypropane, propylene diacetate) *[623-84-7]* **M 160.2, b 84-85°/12mm, 191°/760mm, d_4^{25} 1.050, n_D^{20} 1.414.** Wash the ester with aqueous $NaHCO_3$ in the presence of solid NaCl, dry it with $MgSO_4$ and fractionally distil it. [*Beilstein* **2** H 142, **2** II 156, **2** III 312, **2** IV 220.]

Propylene glycol 1-methylether (1-methoxy-2-propanol) *[RS(±) 107-98-2, R(+) 4984-22-9, S(–) 26550-55-0]* **M 90.1, b 119-120°/atm for *RS*, 131-132°/atm for *R* or *S*, d_4^{25} 0.922, n_D^{20} 1.403.** Wash the ethers with aqueous $NaHCO_3$ in the presence of solid NaCl, dry them with $MgSO_4$ and fractionally distil them. The *RS-acetate* [108-65-6] **M** 132.2 has **b** 145-146°/atm. The *R(+)* and *S(–) enantiomers* have $[\alpha]_D^{20}$ ±20.5° (c 10, H_2O). [*Beilstein* **1** II 536, **1** III 2146, **1** IV 2471.]

***n*-Propyl ether (dipropyl ether)** *[111-43-3]* **M 102.2, b 90.1°, d_4^{20} 0.740, n^{15} 1.38296, n_D^{20} 1.3803, pK^{25} –4.40 (aqueous H_2SO_4).** Purify the ether by drying with $CaSO_4$, by passage through an alumina column (to remove peroxides), and by fractional distillation. [*Beilstein* **1** III 2146, **1** IV 1422.]

Propyl formate *[110-74-7]* **M 88.1, b 81.3°, d_4^{20} 0.9058, n_D^{20} 1.3779.** Distil the formate, then wash it with saturated aqueous NaCl, and with saturated aqueous $NaHCO_3$ in the presence of solid NaCl, dry it with $MgSO_4$ and fractionally distil it. [*Beilstein* **2** IV 26.]

***n*-Propyl iodide (1-iodopropane)** *[107-08-4]* **M 170.0, b 38°/80mm, 102.5°/atm, d_4^{20} 1.745, n_D^{20} 1.5041.** It should be distilled first under reduced pressure to avoid decomposition. Dry the iodide with $MgSO_4$ or silica gel and fractionally distil it. Store it under nitrogen with mercury in a brown bottle. Prior to distillation, free iodine can be removed by shaking with copper powder or by washing with aqueous $Na_2S_2O_3$ and drying. *Alternatively*, the *n*-propyl iodide can be treated with bromine, then washed with aqueous $Na_2S_2O_3$, dried and distilled. See also *n-butyl iodide*. [*Beilstein* **1** IV 222.]

2-Propylpentanoic acid (Valproic acid, VPA, di-*n*-propylacetic acid) *[99-66-1]* **M 144.2, b 120-121°/14mm, 219.5°/760mm, 220°/atm, d_4^{20} 0.91, n_D^{25} 1.425, pK^{25} 4.61.** Purify it in the same way as for propionic acid using $KMnO_4$ (see [79-09-4]). It distils as a colourless oil with a characteristic smell and is soluble in most organic solvents. Its solubility in H_2O is 1.3mg/ml at room temperature. Its FT-IR (film) has ν_{max} at 3572.9, 2969.9, 2885.0, 1771.8, 1465.6, 1388.2, 1102.6, 738.5, 586.5 cm^{-1}; its ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 0.92 (t, *J* = 7Hz, 2 CH_3), 1.40 (m, 6H), 1.60 (m, 2H), 2.29 (m, 1H), 12.2 (brs, OH); and the ^{13}C NMR (75MHz, $CDCl_3$, $CHCl_3$ standard) has δ at 183.41, 45.20, 34.37, 20.59, 13.99. The ***ethyl ester*** [17022-31-0] M 172.2 has **b 183°/760mm**. It forms a ***1:1 Na salt (sodium valproate, Depakin among other trade names)*** [1069-66-5] M 166.2 as a white, crystalline, odourless, hygroscopic solid with the following solubilities in g/ml: 2.5 in H_2O, 0.66 in EtOH, 0.2 in MeOH, and is insoluble in organic solvents. It also forms a ***2:1 Na salt* [*sodium hydrogen bis(2-propylpentanoate), valproate semisodium*]** [76584-70-8] M 310.4, a ***Magnesium salt (Depamag)***, and the pro-drug amide, ***Valpromide (Depramide)*** [2430-27-5] M 143.2, **m 123°, 122-124°, 125-126°**, obtained as needles by heating the acid with NH_3 at 180°, is a bitter, crystalline white

powder [*Beilstein* **2** IV 695]. These are all commercially available drugs for the treatment of epilepsy, dipolar disorders and migraine. They are **toxic** at high concentrations. [Wiemann et al. *Bull Soc Chim Fr* 189 *1958*, Nau et al. *Pharmacol Toxicol* **69** 310 *1991*, Lscher *Prog Neurobiol* **58** 31 *1999*, *Beilstein* **2** H 350.]

***n*-Propyl propionate** *[106-36-5]* **M 120.2, b 122°, d $_4^{20}$ 0.881, n 1.393.** Treat the ester with anhydrous $CuSO_4$, then distil it under nitrogen. [*Beilstein* **2** IV 707.]

Propyne *[74-99-7]* **M 40.1, m -101.5°, b –23.2°/760mm, d^{-50} 0.7062, n^{-40} 1.3863.** Purify it by preparative gas chromatography. [*Beilstein* **1** H 246.]

Pyruvic acid *[127-17-3]* **M 88.1, m 13°, b 65°/10mm, pK^{25} 2.39 (2.60).** Distil it twice, then fractionally crystallise it by partial freezing. [*Beilstein* **3** IV 1505.]

Ricinoleic acid (*dl* 12-hydroxyoleic acid) *[141-22-0]* **M 298.5, m 7-8° (α-form), 5.0° (γ-form), n $_D^{20}$1.4717, pK$_{Est}$ ~4.5.** Purify it as the methyl acetylricinoleate [Rider *J Am Chem Soc* **53** 4130 *1931*], fractionally distilling it at 180-185°/0.3mm, then 87g of this ester is hydrolysed by refluxing with KOH (56g), water (25ml), and MeOH (250ml) for 10 minutes. The free acid is separated on acidification and extracted into Et_2O, dried (Na_2SO_4), filtered, evaporated and the residue is crystallised from acetone at –50°, and distilled in small batches, **b** 180°/0.005mm. The *R-enantiomer* has **m** +5.5°, **b** 245°/10mm and $[\alpha]_D^{26}$ +7.2° (c 5, Me_2CO). [Bailey et al. *J Chem Soc* 3027 *1957*, *Beilstein* **3** IV 1026, 1207.]

Sebacic acid (1,10-decanedioic acid) *[111-20-6]* **M 202.3, m 134.5°, pK$_1^{25}$ 4.58, pK$_2^{25}$ 5.54.** Purify sebacic acid *via* the disodium salt which, after crystallisation from boiling water (charcoal), is then converted to the free acid. The free acid is crystallised repeatedly from hot distilled water or from Me_2CO/petroleum ether and dried under vacuum. [*Beilstein* **2** IV 2078.]

Sebacic acid monomethyl ester *[818-88-2]* **M 216.3, m 42-43°, b 169-171°/4mm.** Recrystallise the ester from Me_2CO/petroleum ether or petroleum ether at low temperature and distil it in a vacuum. [*Beilstein* **2** IV 608.]

Sebaconitrile (decanedinitrile) *[1871-96-1]* **M 164.3, m 8°, b 199-200°.** Mix the nitrile with P_2O_5 (10% by wt) distil the dinitrile from it, then redistil it. [*Beilstein* **2** IV 2089.]

Semicarbazide hydrochloride (hydrazine carboxamide hydrochloride) *[563-41-7]* **M 111.5, m 173°(dec), 175°(dec), pK^{24} 3.66.** Crystallise the salt from aqueous 75% EtOH and dry it under vacuum over $CaSO_4$. *Alternatively*, crystallise it from a mixture of 3.6 mole % MeOH and 6.4 mole % of water. [Kovach et al. *J Am Chem Soc* **107** 7360 *1985*.] It IR has ν_{max} at 700, 3500 cm^{-1} [Ingersoll et al. *Org Synth* Coll Vol **I** 485 *1941*, Davison & Christie *J Chem Soc* 3389 *1955*, Thiele & Stange *Chem Ber* **27** 33 *1894*, pK: Bartlett *J Am Chem Soc* **54** 2853 *1923*]. The ***free base*** crystallises as prisms from absolute EtOH, **m** 96°. [Curtius & Heidenreich *Chem Ber* **27** 55 1894, *Beilstein* **3** IV 177.] **TOXIC ORALLY**, possible **CARCINOGEN** and **TERATOGEN**.

Senecialdehyde (3,3-dimethylacraldehyde, 3-methyl-2-butenal) *[107-86-8]* **M 84.1, b 78-80°/70mm, 133-135°/atm, d $_4^{20}$ 0.911, n $_D^{20}$ 1.428.** This flammable oil oxidises readily and should be fractionated under N_2. It should be stored under N_2 and/or vacuum. The UV has λ_{max} at 235.5nm. The *semicarbazone* has **m** 221-222° (from MeOH) and the *2,4-dinitrophenylhydrazone* has **m** 184-185° (from MeOH). [Forbes & Skilton *J Org Chem* **24** 436 *1959*, *Beilstein* **1** III 2990, **1** IV 3464.]

Skellysolve A is essentially *n*-pentane, **b** 28-30°,
Skellysolve B is essentially *n*-hexane, **b** 60-68°,
Skellysolve C is essentially *n*-heptane, **b** 90-100°,
Skellysolve D is mixed heptanes, **b** 75-115°,
Skellysolve E is mixed octanes, **b** 100-140°,

Skellysolve F is petroleum ether, **b** 30-60°,
Skellysolve G is petroleum ether, **b** 40-75°,
Skellysolve H is hexanes and heptanes, **b** 69-96°,
Skellysolve L is essentially octanes, **b** 95-127°. For methods of purification, see **petroleum ether**.

Solanone [*S*(+)-*trans*-2-methyl-5-isopropyl-1,3-nonan-8-one] *[1937-54-8]* **M 194.3, b 60°/1mm, n_D^{20}1.4755, $[\alpha]_D^{20}$ +14° (neat).** Purify solanone by high vacuum distillation and store it in sealed ampules [Kohda & Sato *J Chem Soc, Chem Commun* 951 *1981*]. It has UV (hexane) at λ_{max} 230nm (ε 11,800). The *semicarbazone* crystallises from aqueous EtOH or toluene with **m** 160.5-161.5°. [Johnson et al. *J Org Chem* **30** 2918 *1965*.]

Sorbic acid (2,4-hexadienoic acid) *[110-44-1]* **M 112.1, m 134°, pK^{25} 4.76.** Crystallise the acid from water. Dry it air or in a desiccator over P_2O_5. [*Beilstein* **2** IV 1701.]

Spermidine [*N*-(3-aminopropyl)-1,4-diaminobutane] *[124-20-9]* **M 145.3, m 23-25°, b 128-131°/15mm, d_4^{20} 0.918, n_D^{20} 1.482, pK_1^{25} 8.25, pK_2^{25} 9.64, pK_3^{25} 10.43.** It is a strong base with an alkylamine odour and absorbs CO_2 from the atmosphere. It is purified by shaking with solid K_2CO_3 or NaOH, decanting and distilling from K_2CO_3 in a vacuum. Store it in the dark under N_2. [*Beilstein* **4** IV 1300.]

Spermidine trihydrochloride *[334-50-9]* **M 245.3, m ~250°(dec), 256-258°, for pKa see *free base* above.** Recrystallise the salt from dry 3% HCl in ethanol and adding dry Et_2O if necessary. Filter it off rapidly and dry it in a vacuum desiccator. *Alternatively*, centrifuge the crystals off, wash them with dry Et_2O and dry them in a vacuum. [*Beilstein* **4** IV 1300.]

Spermine 4HCl (*N,N*-bis(3-aminopropyl)-1,4-butanediamine 4HCl) *[306-67-2]* **M 348.2, m 313-315°.** Its pK values are similar to those of spermidine above. Purify it as for spermidine trihydrochloride above. [*Beilstein* **4** IV 1301.]

Stearic acid (octadecanoic acid) *[57-11-4]* **M 284.5, m 71.4°, 72°, b 144-145°/27mm, 383°/760mm, d_4^{20} 0.911, n_D^{20} 1.428, pK_{Est} ~5.0.** Crystallise stearic acid from acetone, acetonitrile, EtOH (5 times), aqueous MeOH, ethyl methyl ketone or petroleum ether (b 60-90°), or by fractional precipitation by dissolving in hot 95% EtOH and pouring into distilled water, with stirring. The precipitate, after washing with distilled water, is dried under vacuum over P_2O_5. It has also been purified by zone melting and partial freezing. [Tamai et al. *J Phys Chem* **91** 541 *1987*, *Beilstein* **2** IV 1206.]

Suberic acid (hexane-1,6-dicarboxylic acid) *[505-48-6]* **M 174.2, m 141-142°, pK_1^{25} 4.12, pK_2^{25} 5.40.** Crystallise it from acetone. It sublimes at 300° without decomposition. [*Beilstein* **2** IV 2028.]

Succinamic acid (succinic acid amide) *[638-32-4]* **M 117.1, m 155°, 156-157°, pK^{25} 4.54.** Crystallise the amide from Me_2CO or H_2O and dry it in a vacuum. It is not very soluble in MeOH. It is converted to succinimide above 200°. [*Beilstein* **2** H 614.]

Succinamide *[110-14-5]* **M 116.1, m 262-265°(dec).** Crystallise it from water. [*Beilstein* **2** H 614.]

Succinic acid *[110-15-6]* **M 118.1, m 185-185.5°, pK_1^{25} 4.21, pK_2^{25} 5.72.** Wash it with diethyl ether. Crystallise it from acetone, distilled water, or *tert*-butanol. Dry it under vacuum over P_2O_5 or conc H_2SO_4. Also purify it by conversion to the disodium salt which, after crystallisation from boiling water (charcoal), is treated with mineral acid to regenerate the succinic acid. The acid is then recrystallised and dried in a vacuum. [*Beilstein* **2** H 606, **2** IV 1908.]

Succinic anhydride *[108-30-5]* **M 100.1, m 119-120°.** Crystallise the anhydride from redistilled acetic anhydride or $CHCl_3$, then filter, wash with diethyl ether and dry it in a vacuum. [*Beilstein* **17** H 606, **17** V 6.]

Succinimide *[123-56-8]* **M 99.1, m 124-125°, pK^{25} 9.62.** Crystallise the imide from EtOH (1ml/g) or water. [*Beilstein* **21** H 369, **21/9** V 438.]

Succinonitrile *[110-61-2]* **M 80.1, m 57.9°, b 108°/1mm, 267°/760mm.** Purify the nitrile by vacuum sublimation, and/or crystallisation from acetone. [*Beilstein* **2** H 615, **2** IV 1923.]

***D*(–)-Tartaric acid** *[147-71-7]* **M 150.1, m 169.5-170° (2*S*,3*S*-form, natural) [α] $^{20}_{546}$ –15° (c 10, H_2O), m 208° (2*RS*,3*RS*-form), pK $^{25}_{1}$ 3.03, pK $^{25}_{2}$ 4.46, pK $^{25}_{3}$ 14.4.** Crystallise the acid from distilled H_2O or *benzene/diethyl ether containing 5% of petroleum ether (b 60-80°) (1:1). Soxhlet extraction with diethyl ether has been used to remove an impurity absorbing at 265nm. It has also been crystallised from absolute EtOH/hexane and dried in a vacuum for 18 hours [Kornblum & Wade *J Org Chem* **52** 5301 *1987*]. [*Beilstein* **3** IV 1229.]

***meso*-Tartaric acid** *[147-73-9]* **M 150.1, m 139-141°, pK $^{25}_{1}$ 3.17, pK $^{25}_{2}$ 4.91.** Crystallise it from water, wash it with cold MeOH and dry it at 60° under vacuum. [*Beilstein* **3** IV 1218.]

Tetra-*n*-amylammonium bromide (tetra-*n*-pentylammonium bromide) *[866-97-7]* **M 378.5, m 100-101°.** Crystallise it from petroleum ether, *benzene or acetone/ether mixtures and dry in vacuum at 40-50° for 2 days. It is used in ion-paired chromatography (Sagara et al. *J Chromatogr* **328** 289 *1985*). [*Beilstein* **4** IV 677.]

Tetra-*n*-amylammonium iodide *[2498-20-6]* **M 425.5, m 135-137°.** Crystallise the iodide from EtOH and dry it at 35° under a vacuum. It has also been purified by dissolving in acetone and precipitating by adding diethyl ether, and drying at 50° for 2 days. [*Beilstein* **4** IV 677.]

1,1,2,2,-Tetrabromoethane *[79-27-6]* **M 345.7, f 0.0°, b 119°/15mm, 243.5°/atm, d $^{20}_{4}$ 2.965, n $^{20}_{D}$ 1.63533.** Wash it successively with conc H_2SO_4 (three times) and H_2O (three times), dry it with K_2CO_3 and $CaSO_4$ and distil it in a vacuum or at ~760mm. [*Beilstein* **1** IV 162.]

Tetra-*n*-butylammonium bromide *[1643-19-2]* **M 322.4, m 119.6°.** Recrystallise the salt from *benzene (5ml/g) at 80° by adding hot *n*-hexane (three volumes) and allowing to cool. Dry it over P_2O_5 or $Mg(ClO_4)_2$, under vacuum. The salt is *very* ***hygroscopic*.** It can also be crystallised from ethyl acetate or dry acetone by adding diethyl ether and dried *in vacuo* at 60° for 2 days. It has been crystallised from acetone by addition of diethyl ether. It is so *hygroscopic* that all manipulations should be carried out in a dry-box. It has been purified by precipitation from a saturated solution in dry CCl_4 on addition of cyclohexane or by recrystallisation from ethyl acetate, then heating in vacuum to 75° in the presence of P_2O_5. [Symons et al. *J Chem Soc, Faraday Trans 1* **76** 2251 *1908*.] It also recrystallises from CH_2Cl_2/diethyl ether and is dried in a vacuum desiccator over P_2O_5. [Blau & Espenson *J Am Chem Soc* **108** 1962 *1986*, *Beilstein* **4** IV 657.]

Tetra-*n*-butylammonium chloride *[1112-67-0]* **M 277.9, m 15.7°.** Crystallise the chloride from acetone by addition of diethyl ether. It is very **hygroscopic** and forms crystals with $34H_2O$. It is used in ion-paired chromatography (Sagara et al. *J Chromatogr* **328** 289 *1985*). [*Beilstein* **4** IV 557.]

Tetra-*n*-butylammonium hexafluorophosphate *[3109-63-5]* **M 387.5, m 239-241°.** Recrystallise it from saturated EtOH/water and dry it for 10 hours in a vacuum at 70°. Also recrystallise it three times from absolute EtOH and dry it for 2 days in a drying pistol under a vacuum at boiling toluene temperature [Bedard & Dahl *J Am Chem Soc* **108** 5933 *1986*]. It is a stable supporting electrolyte in organic solvents [Baiser in *Organic Electrochemistry* M. Dekker NY p228 *1973*.]

Tetra-*n*-butylammonium hydrogen sulfate *[32503-27-8]* **M 339.5, m 171-172°.** The sulfate crystallises from acetone. It has been used as a phase transfer catalyst.

Tetra-*n*-butylammonium iodide *[311-28-4]* **M 369.4, m 146°.** Crystallise the iodide from toluene/petroleum ether (see entry for the corresponding bromide), acetone, ethyl acetate, EtOH/diethyl ether, nitromethane, aqueous EtOH or water. Dry it at room temperature under a vacuum. It has also been dissolved in MeOH/acetone (1:3, 10ml/g), filtered and allowed to stand at room temperature to evaporate to *ca* half its original volume. Distilled water (1ml/g) is then added, and the precipitate is filtered off and dried. It can also

be dissolved in acetone, precipitated by adding ether and dried in a vacuum at 90° for 2 days. It has also been recrystallised from CH_2Cl_2/petroleum ether or hexane, or anhydrous methanol and stored in a vacuum desiccator over H_2SO_4. [Chau & Espenson *J Am Chem Soc* **108** 1962 *1986*, *Beilstein* **4** IV 558.]

Tetra-*n*-butylammonium nitrate *[1941-27-1]* **M 304.5, m 119°.** Crystallise it from *benzene (7ml/g), EtOH or EtOAc (**m** 121-122°); dry it in a vacuum over P_2O_5 at 60° for 2 days. [*Beilstein* **4** IV 558.]

Tetra-*n*-butylammonium perchlorate *[1923-70-2]* **M 341.9°, m 210°(dec).** Crystallise the perchlorate from EtOH, ethyl acetate, *n*-hexane or diethyl ether/acetone mixture, or hot CH_2Cl_2. Dry it in a vacuum at room temperature over P_2O_5 for 24 hours. [Anson et al. *J Am Chem Soc* **106** 4460 *1984*, Ohst & Kochi *J Am Chem Soc* **108** 2877 *1986,* Collman et al. *J Am Chem Soc* **108** 2916 *1986*, Blau & Espenson *J Am Chem Soc* **108** 1962 *1986*, Gustowski et al. *J Am Chem Soc* **108** *1986*, Ikezawa & Kutal *J Org Chem* **52** 3299 *1987*, *Beilstein* **4** IV 557.]

Tetra-*n*-butylammonium picrate *[914-45-4]* **M 490.6, m 106.5-107°.** Crystallise the picrate from EtOH. Dry it in a vacuum desiccator over P_2O_5. [*Beilstein* **6** II 271, **4** III 292.]

Tetra-*n*-butylammonium tetrabutylborate (Bu_4N^+ Bu_4B^-) *[23231-91-6]* **M 481.7, m 155°, 161.8°**. Dissolve it in MeOH or acetone, and crystallise by adding distilled water. It also crystallises from EtOH or EtOAc. Dry it in a vacuum at 70°. It has also been successively recrystallised from isopropyl ether, isopropyl ether/acetone (50:1) and isopropyl ether/EtOH (50:1) for 10 hours, then isopropyl ether/acetone for 1 hour, and dried at 65° under reduced pressure for 1 week. [Kondo et al. *J Chem Soc, Faraday Trans 1* **76** 812 *1980*, *Beilstein* **4** III 293, **4** III 558.]

Tetra-*n*-butylammonium tetrafluoroborate *[429-42-5]* **M 329.3, m 161.8°, 161-163°, pK^{25} –4.9 (for HBF_4)**. Recrystallise it from H_2O, aqueous EtOH or from EtOAc by cooling in Dry-ice. Also recrystallise it from ethyl acetate/pentane or dry acetonitrile. Dry it at 80° under vacuum. [Detty & Jones *J Am Chem Soc* **109** 5666 *1987*, Hartley & Faulkner *J Am Chem Soc* **107** 3436 *1985*.] The *acetate* has **m** 118±2° (from BuCl), the *bromide* has **m** 118° (from EtOAc), and the *nitrate* has **m** 120° (from $*C_6H_6$). [Witschonka & Kraus *J Am Chem Soc* **69** 2472 *1947*, Wheeler & Sandstedt *J Am Chem Soc* **77** 2024 *1955*, *Beilstein* **4** IV 558.]

1,1,2,2-Tetrachloro-1,2-difluoroethane *[72-12-0]* **M 203.8, f 26.0°, b 92.8°/760mm, d_4^{25} 1.6252, n_D^{25} 1.4130.** Purify it as for trichlorotrifluoroethane. [*Beilstein* **1** III 165, **1** III 146.]

***sym*-Tetrachloroethane** *[79-34-5]* **M 167.9, b 62°/100mm, 146.2°/atm, d_4^{20} 1.588, n_D^{15} 1.49678.** Stir the ethane, on a steam-bath, with conc H_2SO_4 until a fresh portion of acid remains colourless. The organic phase is then separated, distilled in steam, dried ($CaCl_2$ or K_2CO_3), and fractionally distilled in a vacuum. [*Beilstein* **1** IV 144.]

Tetrachloroethylene *[127-18-4]* **M 165.8, b 62°/80mm, 121.2°, d_4^{15} 1.63109, d_4^{20} 1.623, n_D^{15} 1.50759, n_D^{20} 1.50566.** It decomposes under similar conditions to $CHCl_3$, to give phosgene and trichloroacetic acid. Inhibitors of this reaction include EtOH, diethyl ether and thymol (effective at 2-5 ppm). Tetrachloroethylene should be distilled under a vacuum (to avoid formation of phosgene) and stored in the dark out of contact with air. It can be purified by washing with 2M HCl until the aqueous phase no longer becomes coloured, then with water, drying with Na_2CO_3, Na_2SO_4, $CaCl_2$ or P_2O_5, and fractionally distilling just before use. 1,1,2-Trichloroethane and 1,1,1,2-tetrachloroethane can be removed by counter-current extraction with EtOH/water. [*Beilstein* **1** IV 715.]

Tetracosane (C24) *[646-31-1]* **M 338.7, m 54°, b 243-244°/15mm.** Crystallise it from diethyl ether and/or distil it under high vacuum. [*Beilstein* **1** IV 578.]

Tetracosanoic (lignoceric) acid *[557-59-5]* **M 368.7, m 84°, 87.5-88°, pK_{Est} ~5.0.** Crystallise the acid from acetic acid, Me_2CO, toluene, petroleum ether/Me_2CO or$*C_6H_6$/Me_2CO. [*Beilstein* **2** IV 1301.]

Tetracyanoethylene *[670-54-2]* **M 128.1, m 199-200°(sealed tube).** Rerystallise it from chlorobenzene, dichloroethane, or dichloromethane [Hall et al. *J Org Chem* **52** 5528 *1987*]. Store it at 0° in a desiccator over NaOH pellets. (It slowly evolves HCN on exposure to moist air **CARE**.) It can also be sublimed at 120° under vacuum. Also purify it by repeated sublimation at 120-130°/0.5mm. [Frey et al. *J Am Chem Soc* **107** 748 *1985*, Traylor & Miksztal *J Am Chem Soc* **109** 2778 *1987*, Fatiadi *Synthesis* 249 *1986*, *Synthesis* 749 *1967*, *Beilstein* **2** IV 1245.]

Tetradecane (C14) *[629-59-4]* **M 198.4, m 6°, b 122°/10mm, 252-254°, d_4^{20} 0.763, n_D^{20} 1.429.** Wash it successively with 4M H_2SO_4 and water. Dry it over $MgSO_4$ and distil it several times under reduced pressure [Poë et al. *J Am Chem Soc* **108** 5459 *1986*]. It is used as a standard in gas chromatography. [*Beilstein* **1** H 171, **1** IV 520.]

1-Tetradecanol *[112-72-1]* **M 214.4, m 39-39.5°, b 160°/10mm, 170-173°/20mm.** Crystallise the alcohol from aqueous EtOH. It has also been purified by zone melting. [*Beilstein* **1** IV 1864.]

Tetradecyl ether (di-tetradecyl ether) *[5412-98-6]* **M 410.7, m 43.5°, d_4^{43} 0.8117.** Distil the ether under a vacuum and then crystallise it repeatedly from MeOH/*benzene. It also crystallises from MeOH alone (**m** 31.2°, 33°, and 44.4° also reported), or Me_2CO (**m** 43.5°). [Di Giacomo & Smyth *J Am Chem Soc* **78** 2027 *1956*, *Beilstein* **1** IV 1865.]

Tetradecyltrimethylammonium bromide (myristyl trimethylammonium bromide) *[1119-97-7]* **M 336.4, m 244-245°, 244-249°.** Crystallise the bromide from Me_2CO or a mixture of Me_2CO and >5% MeOH or Me_2CO and EtOH. Wash it with diethyl ether and dry it in a vacuum oven at 60°. It is a cationic detergent. Its solubility is 1g/5g H_2O. [Dearden & Wooley *J Phys Chem* **91** 2404 *1987*, Shelton et al. *J Am Chem Soc* **68** 754 *1946*, *Beilstein* **4** III 419, **4** IV 813.]

Tetraethoxymethane See tetraethyl orthocarbonate below.

Tetraethylammonium bromide *[71-91-0]* **M 210.2, m 269°(dec), 284°(dec).** Recrystallise the bromide from EtOH, $CHCl_3$ or diethyl ether, or, recrystallise it from acetonitrile and dry it over P_2O_5 under reduced pressure for several days. It also recrystallises from EtOH/diethyl ether (1:2), EtOAc, water or boiling MeOH/acetone (1:3) or by adding an equal volume of acetone and allowing to cool. Dry it at 100° *in vacuo* for 12 days, and store over P_2O_5. [*Beilstein* **4** IV 332.]

Tetraethylammonium chloride hydrate *[68696-18-4 (H_2O), 56-34-8 (anhydrous)]* **M 165.7, m dec >200°.** Crystallise the chloride from EtOH by adding diethyl ether, from warm water by adding EtOH and diethyl ether, from dimethylacetamide or from CH_2Cl_2 by addition of diethyl ether. Dry it over P_2O_5 in vacuum for several days. It also crystallises from acetone/CH_2Cl_2/hexane (2:2:1) [Blau & Espenson *J Am Chem Soc* **108** 1962 *1986*, White & Murray *J Am Chem Soc* **109** 2576 *1987*]. [*Beilstein* **4** IV 332.]

Tetraethylammonium hexafluorophosphate *[429-07-2]* **M 275.2, m >300°, 331°(dec), pK_1^{25} ~0.5, pK_2^{25} 5.12 (for fluorophosphoric acid H_2PO_3F).** Dissolve the salt (0.8g) in hot H_2O (3.3ml) and cool to crystallise. Yield of prisms is 0.5g. Its solubility in H_2O is 8.1g/L at 19° [Lange & Müller *Chem Ber* **63** 1067 *1930*]. [*Beilstein* **4** III 199.]

Tetraethylammonium iodide *[68-05-3]* **M 257.2, m 302°, >300°(dec).** Crystallise the iodide from acetone/MeOH, EtOH/water, dimethylacetamide or ethyl acetate/EtOH (19:1). Dry it under a vacuum at 50° and store it over P_2O_5. [*Beilstein* **4** IV 332.]

Tetraethylammonium perchlorate *[2567-83-1]* **M 229.7, m 345°(dec).** Crystallise the perchlorate repeatedly from water, aqueous MeOH, acetonitrile or acetone, and dry it at 70° under a vacuum for 24 hours. [Cox et al. *J Am Chem Soc* **106** 5965 *1984*, Liu et al. *J Am Chem Soc* **108** 1740 *1986*, White & Murray *J Am Chem Soc* **109** 2576 *1987*.] It has also been crystallised twice from ethyl acetate/95% EtOH (2:1) [Lexa et al. *J Am Chem Soc*

109 6464 *1987*]. [*Beilstein* **4** IV 332.]

Tetraethylammonium picrate *[741-03-7]* **M 342.1, m >300°(dec).** Purify it by successive crystallisations from water or 95% EtOH followed by drying in vacuum at 70°. [*Beilstein* **4** IV 332.]

Tetraethylammonium tetrafluoroborate *[429-06-1]* **M 217.1, m 235°, 356-367°, 275-277°, 289-291°, pK^{25} –4.9 (for HBF_4)**. Dissolve the salt in hot MeOH, filter and add Et_2O. It is soluble in ethylene chloride [Thompson & Kraus *J Am Chem Soc* **69** 1016 *1947*, Wheeler & Sandstadt **77** 2025 *1955*]. It has also been recrystallised three times from a mixture of ethyl acetate/hexane (5:1) or MeOH/petroleum ether, then stored at 95° for 48 hours under vacuum [Henry & Faulkner *J Am Chem Soc* **107 3436** *1985*, Huang et al. *Anal Chem* **58** 2889 *1986*]. It is used as a supporting electrolyte. [*Beilstein* **4** IV 333.]

Tetraethylammonium tetraphenylborate *[12099-10-4]* **M 449.4.** Recrystallise the borate from aqueous acetone. Dry it in a vacuum oven at 60° for several days. *Similarly for the propyl and butyl homologues.* [*Beilstein* **4** IV 333.]

Tetraethylene glycol dimethyl ether *[143-24-8]* **M 222.3, b 105°/1mm, d_4^{20} 1.010, n_D^{20} 1.435.** Stand the ether over CaH_2, $LiAlH_4$ or sodium, and distil it when required. [*Beilstein* **1** IV 2404.]

Tetraethylenepentamine *[112-57-2]* **M 189.3, b 169-171°/0.05mm, d_4^{20} 0.999, n_D^{20} 1.506, pK_1^{25} 2.98, pK_2^{25} 4.72, pK_3^{25} 8.08, pK_4^{25} 9.10, pK_5^{25} 9.68.** Distil the amine under vacuum. Also purify *via* its penta hydrochloride, nitrate or sulfate. Jonassen, Frey and Schaafsma [*J Phys Chem* **61** 504 *1957*] cooled a solution of 150g of the base in 300ml of 95% EtOH, and added dropwise 180ml of conc HCl, keeping the temperature below 20°. The white precipitate was filtered off, crystallised three times from EtOH/water, then washed with diethyl ether and dried by suction. Reilley & Holloway [*J Am Chem Soc* **80** 2917 *1958*], starting with a similar solution cooled to 0°, added slowly (keeping the temperature below 10°) a solution of 4.5g-moles of HNO_3 in 600ml of aqueous 50% EtOH (also cooled to 0°). The precipitate was filtered by suction, recrystallised five times from aqueous 5% HNO_3, then washed with acetone and absolute EtOH and dried at 50°. [For purification *via* the sulfate see Reilley and Vavoulis (*Anal Chem* **31** 243 *1959*), and for an additional purification step using the Schiff base with benzaldehyde see Jonassen et al. *J Am Chem Soc* **79** 4279 *1957*]. [*Beilstein* **4** IV 1244.]

Tetraethyl 1,1,2,2-ethanetetracarboxylate *[632-56-4]* **M 318.3, m 73-74°.** Recrystallise the ester twice from EtOH by cooling to 0°. [Mochizuki et al. *Bull Chem Soc Jpn* **64** 1750 *1991*, Weinges et al. *Angew Chem* **93** 1008 *1981*, *Beilstein* **2** IV 2415.]

Tetraethyl orthocarbonate (ethyl orthocarbonate, tetraethoxy ethane) *[78-09-1]* **M 192.3, b 59.6-60°/14mm, 158°/atm, 159°/atm, 160-161°/atm, d_4^{20} 0.9186, n_D^{20} 1.3932.** Likely impurities are hydrolysis products. Shake the orthocarbonate with brine (saturated NaCl, dilute with a little Et_2O if amount of material is small) and dry ($MgSO_4$). The organic layer is filtered off and evaporated, and the residue is distilled through a helices packed fractionating column with a total reflux partial take-off head. All distillations can be done at atmospheric pressure in an inert atmosphere (e.g. N_2). [Roberts & McMahon *Org Synth* Coll Vol **IV** 457 *1963*, Connolly & Dyson *J Chem Soc* 828 *1937*, Tieckelmann & Post *J Org Chem* **13** 266 *1948*, for review see Kantlehner et al. *Justus Liebigs Ann Chem* **507** 207 *1982*, *Beilstein* **3** IV 6.]

2,2,3,3-Tetrafluoropropan-1-ol *[76-37-9]* **M 132.1, b 106-106.5°/~760mm, pK^{25} 12.74.** Tetrafluoro-1-propanol (450ml) is added to a solution of $NaHSO_3$ (2.25g) in water (90ml), shaken vigorously and set aside for 24 hours. The fraction distilling at or above 99° is refluxed for 4 hours with 5-6g of KOH and rapidly distilled, followed by a final fractional distillation. [Kosower & Wu *J Am Chem Soc* **83** 3142 *1961*.] *Alternatively*, shake the alcohol with alumina for 24 hours, dry it overnight with anhydrous K_2CO_3 and distil it, taking the middle fraction (**b** 107-108°). [*Beilstein* **1** IV 2438.]

Tetra-*n*-heptylammonium bromide *[4368-51-8]* **M 490.7, m 88.9-89.1°.** Crystallise the bromide from *n*-hexane, then dry it in a vacuum oven at 70°. [Goodrich et al. *J Am Chem Soc* **72** 4412 *1950*, *Beilstein* **4** IV 736.]

Tetra-*n*-heptylammonium iodide *[3535-83-9]* **M 537.7, m 102-103°.** Recrystallise the iodide from EtOH or aqueous EtOH. [Eriksen et al. *J Org Chem* **25** 849 *1960*, *Beilstein* **4** IV 736 for triheptylamine.]

Tetra-*n*-hexylammonium bromide *[4328-13-6]* **M 434.6, m 99-100°.** Wash the bromide with ether, and dry it in a vacuum at room temperature for 3 days.

Tetra-*n*-hexylammonium chloride *[5922-92-9]* **M 390.1.** Crystallise the chloride from EtOH.

Tetra-*n*-hexylammonium iodide *[2138-24-1]* **M 481.6, m 99-101°, 102-103°.** Wash the iodide with diethyl ether and dry it at room temperature *in vacuo* for 3 days. It is soluble in CH_2Cl_2. [Eriksen et al. *J Org Chem* **25** 849 *1960*, *Beilstein* **4** IV 711 for trihexylamine.]

Tetrahexylammonium perchlorate *[4656-81-9]* **M 454.1, m 104-106°.** Crystallise the salt from acetone and dry it *in vacuo* at 80° for 24 hours.

Tetrakis(dimethylamino)ethylene *[996-70-3]* **M 300.2, b 60°/1mm, d_4^{20} 0.861, n_D^{20}1.4817, $pK_{Est(1)}$<0, $pK_{Est(2)}$<0, $pK_{Est(3)}$~1.5, $pK_{Est(4)}$ ~5.1.** Impurities include tetramethylurea, dimethylamine, tetramethylethane-diamine and tetramethyloxamide. It is washed with water while being flushed with nitrogen to remove dimethylamine, dried over molecular sieves, then passed through a silica gel column (previously activated at 400°) under nitrogen. De-gas it in a vacuum line by distillation from a trap at 50° to one at –70°. Finally, it is stirred over sodium-potassium alloy for several days. [Holroyd et al. *J Phys Chem* **89** 4244 *1985*, Wiberg *Angew Chem Int Ed Engl* **7** 766 *1968*, *Beilstein* **4** IV 167.]

Tetramethylammonium bromide *[64-20-0]* **M 154.1, sublimes with dec >230°.** Crystallise the bromide from EtOH, EtOH/diethyl ether, MeOH/acetone, water or from acetone/MeOH (4:1) by adding an equal volume of acetone. It is dried at 110° under reduced pressure or at 140° for 24 hours. [*Beilstein* **4** IV 145.]

Tetramethylammonium chloride *[75-57-0]* **M 109.6, m >230°(dec).** Crystallise the chloride from EtOH, EtOH/$CHCl_3$, EtOH/diethyl ether, acetone/EtOH (1:1), isopropanol or water. Traces of the free amine can be removed by washing with $CHCl_3$. [*Beilstein* **4** IV 145.]

Tetramethylammonium hydroxide ($5H_2O$) *[10424-65-4 ($5H_2O$), 75-59-2 (aqueous solution)]* **M 181.2, m 63°, 65-68°.** It is freed from chloride ions by passage through an ion-exchange column (e.g. Amberlite IRA-400, prepared in its OH^- form by passing 2M NaOH until the effluent is free from chloride ions, then washed with distilled H_2O until neutral). A modification, to obtain carbonate-free hydroxide, uses the method of Davies and Nancollas [*Nature* **165** 237 *1950*]. [*Beilstein* **4** IV 145.]

Tetramethylammonium hexafluorophosphate *[558-32-7]* **M 219.1, m >300°, d_4^{25} 1.617, pK_1^{25} ~0.5, pK_2^{25} 5.12 (for fluorophosphoric acid H_2PO_3F).** The salt (0.63g) is recrystallised from boiling H_2O (76ml), yielding pure (0.45) $Me_4N.PF_6$ after drying at 100°. It is a good supporting electrolyte. [Lange & Müller *Chem Ber* **63** 1067 *1930*, *Beilstein* **4** III 110.]

Tetramethylammonium iodide *[75-58-1]* **M 201.1, m >230°(dec).** Crystallise the iodide from water or 50% EtOH, EtOH/diethyl ether, ethyl acetate, or from acetone/MeOH (4:1) by adding an equal volume of acetone. Dry it in a vacuum desiccator. [*Beilstein* **4** IV 145.]

Tetramethylammonium nitrate *[1941-24-8]* **M 136.2, m >300°, 410°.** Recrystallise the nitrate from EtOH and dry at 110° in an air oven. [Coats & Taylor *J Chem Soc* 1498 *1936, Beilstein* **4** III 113, **4** IV 147.]

Tetramethylammonium perchlorate *[2537-36-2]* **M 123.6, m>300°, pK^{25} –2.4 to –3.1 (for $HClO_4$)**. Crystallise it twice from H_2O and dry it at 110° in an air oven. It is insoluble in most organic solvents. [Mead et al. *J Chem Soc* 1210 *1933*, Coats & Taylor *J Chem Soc* 1498 *1936*.]

Tetramethylammonium tetraphenylborate *[15525-13-0]* **M 393.3.** Recrystallise it from acetone, acetone/CCl_4 and from acetone/1,2-dichloroethane. Dry it over P_2O_5 in a vacuum, or in a vacuum oven at 60° for several days. [*Beilstein* **4** IV 145.]

***N,N,N′,N′*-Tetramethylethylenediamine (TMEDA, TMED)** *[110-18-9]* **M 116.2, m –55°, b 122°, d $_4^{20}$ 1.175, n $_D^{25}$ 1.4153, pK $_1^{25}$ 5.90, pK $_2^{25}$ 9.14.** Dry TMEDA partially with molecular sieves (Linde type 4A), then distil it in a vacuum from butyl lithium. This treatment removes all traces of primary and secondary amines and water. [Hay et al. *J Chem Soc, Faraday Trans 1* **68** 1 *1972*.] Or dry it with KOH pellets, reflux for 2 hours with one-sixth its weight of *n*-butyric anhydride (to remove primary and secondary amines) and fractionally distil it. Reflux it with fresh KOH, and distil it under nitrogen. [Cram & Wilson *J Am Chem Soc* **85** 1245 *1963*.] It was also distilled from Na. Store it sealed under N_2. The *dipicrate* has **m** 263°(dec). [*Beilstein* **4** H 250, **4** I 415, **4** II 690, **4** III 512, **4** IV 1172.]

Tetramethylethylenediamine dihydrochloride *[7677-21-8]* **M 198.2, m ~300°.** Crystallise the salt from 98% EtOH/conc HCl. It is *hygroscopic*. [Knorr *Chem Ber* **37** 3510 *1904*, *Beilstein* **4** IV 1172.]

1,1,3,3-Tetramethylguanidine *[80-70-6]* **M 115.2, b 159-160°, d $_4^{20}$ 0.917 n $_D^{20}$ 1.470, pK^{25} 13.6.** Reflux it over granulated BaO, then fractionally distil it. Protect it from CO_2. [*Beilstein* **4** IV 227.]

Tetramethyl orthocarbonate (methyl orthocarbonate, tetramethoxy methane) *[1850-14-2]* **M 136.2, m –5.6°, –5°, –2°, b 113.5°/760mm, 113.5-114°/755mm, 112-114°/atm, d $_4^{20}$ 1.0202, n $_D^{20}$ 1.3860.** Purify it in the same way as for tetraethyl orthocarbonate. [Smith *Acta Chem Scand* **10** 1006 *1956*, Tiekelmann & Post *J Org Chem* **13** 266 *1948*, Kantlehner et al. *Synthesis* 73 *1977*, *Beilstein* **3** IV 4.]

2,6,10,14-Tetramethylpentadecane (pristane, norphytane) *[1921-70-6]* **M 268.5, b 68° (bath temp)/0.004mm, 158°/10mm, 296°/atm, d $_4^{20}$ 0.7827, n $_D^{20}$ 1.4385.** Purify pristane by shaking it with conc H_2SO_4 (**care**, if amount of pristane is too small then it should be diluted with petroleum ether *not* Et_2O which is quite soluble in H_2SO_4), then H_2O (**care,** as it may heat up in contact with conc H_2SO_4), dry ($MgSO_4$), evaporate and distil it over Na. [Sörensen & Sörensen *Acta Chem Scand* **3** 939 *1949*, *Beilstein* **1** III 570.]

Tetramethylthiuram disulfide [bis-(dimethylthiocarbamyl)disulfide, Thiram] *[137-26-8]* **M 240.4, m 146-148°, 155-156°.** Crystallise thiram (three times) from boiling $CHCl_3$, then recrystallise it from boiling $CHCl_3$ by adding EtOH dropwise to initiate crystallisation, and allow it to cool. Finally, it is precipitated from cold $CHCl_3$ by adding EtOH (which retains the monosulfide in solution). [Ferington & Tobolsky *J Am Chem Soc* **77** 4510 *1955*, *Beilstein* **4** IV 242.]

1,1,3,3-Tetramethyl urea *[632-22-4]* **M 116.2, f –1.2°, b 175.2°/760mm, d $_4^{20}$ 0.969, n $_D^{20}$ 1.453.** Dry it over BaO and distil it under nitrogen. It denatures proteins in H_2O. [Elbaum & Herskovits *Biochemistry **13** 1268* 1974*,* Kane *Anal Biochem* **53** 350 *1973*, *Beilstein* **4** IV 225.]

Tetranitromethane *[509-14-8]* **M 196.0, m 14.2°, b 46°/36mm, 21-23°/23mm, 126°/760mm, d $_4^{20}$ 1.640, n $_D^{20}$ 1.438.** Shake tetranitromethane with dilute NaOH, wash (H_2O), steam distil, dry with Na_2SO_4 and fractionally crystallise it by partial freezing. The melted crystals are dried with $MgSO_4$ and fractionally distilled under reduced pressure. *Alternatively*, shake it with a large volume of dilute NaOH until no absorption attributable to the *aci*-nitro anion (from mono- di- and tri- nitromethanes) is observable in the water. Then wash it with distilled water, and distil it at room temperature by passing a stream of air or nitrogen through the liquid and condensing it in a trap at –80°. It can be dried with $MgSO_4$ or Na_2SO_4, fractionally crystallised from the melt, and fractionally distilled under reduced pressure. [Liang *Org Synth* Coll Vol **III** 803 *1955*, *Beilstein* **4** H 80, **4** I 21, **4** II 45, **4** III 116, **4** IV 107.] **Potentially explosive (when impure e.g. with toluene), toxic, carcinogenic.**

Tetra-*n*-propylammonium bromide *[1941-30-6]* **M 266.3, m >280°(dec).** Crystallise it from ethyl acetate/EtOH (9:1), acetone or MeOH. Dry it at 110° under reduced pressure. [*Beilstein* **4** IV 471.]

Tetra-*n*-propylammonium iodide *[631-40-3]* **M 313.3, m >280°(dec).** Purify the iodide by crystallising it from EtOH, EtOH/diethyl ether (1:1), EtOH/water or aqueous acetone. Dry it at 50° under a vacuum and store it over P_2O_5 in a vacuum desiccator. Keep it away from light. [*Beilstein* **4** IV 472.]

Tetra-*n*-propylammonium perchlorate *[15780-02-6]* **M 285.8, m 238-240°, 239-241°, pK^{25} –2.4 to –3.1 (for $HClO_4$).** Purify it by recrystallisation from H_2O or MeCN/H_2O (1:4.v/v), and dry it in an oven at 60° for several days, or in a vacuum over P_2O_5 at 100°. [Walden & Hilgert *Z Phys Chem* **165** 245 *1933*, Walden & Birr *Z Phys Chem* **144** 281 *1929*, Walden & Busch *Z Phys Chem* **140** 97 *1929*, *Beilstein* **4** II 628.]

Thioacetamide *[62-55-5]* **M 75.1, m 112-113°, pK^{25} 13.4.** Crystallise the amide from absolute diethyl ether or *benzene. Dry it at 70° in a vacuum and store it over P_2O_5 at 0° under nitrogen. (*It develops an obnoxious odour on storage*, and the absorption at 269nm decreases, hence it should be freshly recrystallised before use). [*Beilstein* **2** IV 565.]

Thiodiglycollic acid (2,2′-dithioacetic acid) *[123-93-3]* **M 150.2, m 129°, pK$_1^{25}$ 3.15 (3.24), pK$_2^{25}$ 4.13 (4.56).** Crystallise the acid from water. [*Beilstein* **3** IV 612.]

3,3'-Thiodipropionic acid (bis[2-carboxyethyl]sulfide) *[111-17-1]* **M 178.2, m 134°, pK$_1^{25}$ 3.84, pK$_2^{25}$ 4.66.** Crystallise the sulfide from water (very soluble at 100°, but 3.7% at 26°). Antioxidant. [*Beilstein* **3** IV 735.]

Thioformamide *[115-08-2]* **M 61.0, m 29°, 32.0-33.8°, pK$_{Est}$ ~12.4.** Crystallise thioformamide from EtOAc, Et_2O or ether/petroleum ether. The *monohydrate* is a yellow oil soluble in many organic solvents. Its UV has λ_{max} at 263nm (ε 2500) in MeOH. [Erlenmyer & Menzi *Helv Chim Acta* **31** 2071 *1948*.] *Alternatively*, dissolve it in Et_2O to separate it from any formanide and/or polymers, filter, evaporate and recrystallise the residue from EtOAc at Dry-ice temperature [Londergan et al. *J Am Chem Soc* **75** 4456 *1953*]. Store it in Et_2O solution over P_2O_5. [Cousineau & Secrist *J Org Chem* **44** 4351 *1979*, *Beilstein* **2** H 95, **2** I 39, **2** III 128, **2** IV 92.]

Thioglycollic acid *[68-11-1]* **M 92.1, b 95-96°/8mm, d$_4^{20}$ 1.326, n$_D^{20}$ 1.505, pK$_1^{25}$ 3.42, pK$_2^{25}$ 10.20.** Mix the acid with an equal volume of *benzene; the *benzene is then distilled off to dehydrate the acid. After heating to 100° to remove most of the *benzene, the residue is distilled under vacuum and stored in sealed ampoules at 3°. [Eshelman et al. *Anal Chem* **22** 844 *1960*, *Beilstein* **3** IV 1130.]

(±)-Thiomalic (mercaptosuccinic) acid *[70-49-5]* **M 150.2, m 153-154°, pK$_1^{25}$ 3.64 (3.17), pK$_2^{25}$ 4.64 (4.67), pK$_3^{25}$ 10.37 (10.52).** Dissolve the acid in water and extract it several times with diethyl ether to remove imprities. The aqueous solution gave the acid on freeze-drying. [*Beilstein* **3** IV 472.]

Thiosemicarbazide *[79-19-6]* **M 91.1, m 181-183°, pK$_1^{25}$ 1.88, pK$_2^{25}$ 12.81.** Crystallise thiosemicarbazide from H_2O (solubility is 20.3% w/w at 80°). The *hydrochloride* has **m** 190-191°(dec, 184° also reported). It forms salts with heavy metals. [*Beilstein* **3** H 195, **3** I 79, **3** II 134, **3** III 315, **3** IV 374.]

Thiourea *[62-56-6]* **M 76.1, m 179°, pK^{20} –1.19 (aqueous H_2SO_4).** Crystallise thiourea from absolute EtOH, MeOH, acetonitrile or water. Dry it under vacuum over H_2SO_4 at room temperature. [*Beilstein* **3** IV 342.]

Tiglic acid (*trans*-2,3-dimethylacrylic acid) *[80-59-1]* **M 100.1, m 63.5-64°, b 198.5°, 95°/11mm, pK^{18} 4.96**. Crystallise it from water. It is steam volatile and is soluble in organic solvents. [*Beilstein* **2** IV 1552.]

***trans*-Traumatic acid (2-dodecene-1,12-dioic acid)** *[6402-36-4]* **M 228.3, m 165-166°, 150-160°/0.001mm, pK$_{Est(1)}$~4.2, pK$_{Est(2)}$~4.6.** Crystallise the acid from EtOH, acetone or glyme. The *bis-4-phenylphenacyl ester* has **m** 144-145° (from EtOH). [*Beilstein* **2** III 1978, **2** IV 2279.]

1,2,3-Triaminopropane trihydrochloride ***[free base** 21291-99-6]* **M 198.7, m 250° (sintering at 100°), pK$_1^{20}$ 3.72, pK$_2^{20}$ 7.95, pK$_3^{20}$ 9.59.** Crystallise the trihydrochloride from EtOH or H_2O. The *free base*

decomposes at 190°/760mm, but has **b 92-93°/9mm** without decomposition. [*Beilstein* **4** H 274, **4** III 630.]

Tribromochloromethane *[594-15-0]* **M 287.2, m 55°, b 158-159.5°/~760mm, 160°/~760mm.** Melt it, wash it with aqueous $Na_2S_2O_3$, dry it with BaO and fractionally crystallise from its melt. It also crystallises from EtOH and distils at atmospheric pressure. [*Beilstein* **1** H 68, **1** II 35, **1** III 91, **1** IV 85.]

Tri-*n*-butylamine (TBA) *[102-82-9]* **M 185.4, b 68°/3mm, 120°/44mm, d_4^{20} 0.7788, n_D^{20} 1.4294, pK^{25} 9.93.** Purify the amine by fractional distillation from sodium under reduced pressure. Pegolotti and Young [*J Am Chem Soc* **83** 3251 *1961*] heated the amine overnight with an equal volume of acetic anhydride, in a steam bath. The amine layer was separated and heated with water for 2 hours on the steam bath (to hydrolyse any remaining acetic anhydride). The solution was cooled, solid K_2CO_3 was added to neutralise any acetic acid that had been formed, and the amine was separated, dried (K_2CO_3) and distilled at 44mm pressure. Davis and Nakshbendi [*J Am Chem Soc* **84** 2085 *1926*] treated the amine with one-eighth of its weight of benzenesulfonyl chloride in aqueous 15% NaOH at 0-5°. The mixture was shaken intermittently and allowed to warm to room temperature. After a day, the amine layer was washed with aqueous NaOH, then water and dried with KOH. (This treatment removes primary and secondary amines.) It was further dried with CaH_2 and distilled under vacuum. [*Beilstein* **4** IV 554.]

Tri-*n*-butylammonium hydrobromide *[37026-85-0]* **M 308.3, m 75.2-75.9°.** Crystallise the hydrobromide from ethyl acetate. [*Beilstein* **4** H 157, **4** III 292, **4** IV 555.]

Tri-*n*-butylammonium nitrate *[33850-87-2]* **M 304.5.** Crystallise the nitrate from mixtures of *n*-hexane and acetone (95:5). Dry it over P_2O_5 in a vacuum. [*Beilstein* **2** IV 554.]

Tri-*n*-butylammonium perchlorate *[14999-66-7]* **M 285.5.** Recrystallise the perchlorate from *n*-hexane. (Potentially explosive.) [*Beilstein* **2** IV 554.]

Tricarballylic acid (propane-1,2,3-tricarboxylic acid) *[99-14-9]* **M 176.1, m 166°, pK_1^{25} 3.47, pK_2^{25} 4.54, pK_3^{25} 5.89.** Crystallise the acid from diethyl ether. [*Beilstein* **2** IV 2366.]

Trichloroacetamide *[594-65-0]* **M 162.4, m 139-141°, b 238-240°.** Its solution in xylene is dried with P_2O_5, then fractionally distilled. [*Beilstein* **2** IV 520.]

Trichloroacetic acid *[76-03-9]* **M 163.4, m 59.4-59.8°, pK^{25} 0.51.** Purify this strong acid (care) by fractional crystallisation from its melt, then crystallise it repeatedly from dry *benzene and store it over conc H_2SO_4 in a vacuum desiccator. It can also be crystallised from $CHCl_3$ or cyclohexane, and dried over P_2O_5 or $Mg(ClO_4)_2$ in a vacuum desiccator. Trichloroacetic acid can be fractionally distilled under reduced pressure from $MgSO_4$. Layne, Jaffé and Zimmer [*J Am Chem Soc* **85** 435 *1963*] dried trichloroacetic acid in *benzene by distilling off the *benzene-water azeotrope, then crystallised the acid from the remaining *benzene solution. Manipulations should be carried out under N_2. [*Toxic vapours, use a well ventilated fume cupboard*.] [*Beilstein* **2** IV 508.]

Trichloroacetonitrile *[545-06-2]* **M 144.4, m –42°, –44°, b 84.6°/741mm, 85.8-86°/764mm, 85.7°/760mm, d_4^{20} 1.441, n_D^{25} 1.4409.** It is prepared by mixing trichloroacetamide (150g, obtained from ethyl trichloroacetate and ammonia) with an equal weight of P_2O_5 and heating at ~200° in an oil bath, and a further amount of P_2O_5 is added before distilling the nitrile off. The distillate is then carefully fractionated, and the fraction **b** 85.8-86°/764mm is collected (yield 70-75%), and should contain <0.02% of amide: *cf* IR (film) has a nitrile band at 2250 cm^{-1}, and is almost free from bands at ~1735 (CO) and >2502 (NH) cm^{-1}. The liquid shows no signs of change after several months, even with traces of moisture, provided that it is kept in away from light. [Davies & Jenkins *J Chem Soc* 2374 *1954*, and references therein, Carpenter *J Org Chem* **27** 2085 *1962*, *Beilstein* **2** H 212, **2** I 95, **2** II 201, **2** III 477, **2** IV 524]. **It is lachrymatory, a skin and eye irritant, and has been used as a fumigant.**
It is a useful reagent for selectively esterifying phosphoric acid, e.g. with benzyl alcohol in the presence of Et_2N it gives monobenzylphosphate with H_2PO_4 [Cramer & Baldauf *Chem Ber* **92**, 370 *1959*], and converts a monophosphoric ester into a symmetrical pyrophosphate in the presence of pyridine [Cramer et al. *Justus*

Liebigs Ann Chem **654** 180 *1962*]. It is readily converted into its trichloroacetimidate esters by reaction with allylic alcohols in CH_2Cl_2, in the presence of DBU at ~0° to ambient temperatures [Anderson & Overman *J Am Chem Soc* **125** 12412 *2003*, Kirsch et al. *Org Lett* **9** 911 *2007*]; similarly prepared trichloroacetimidates of allylic alcohols were shown to undergo ether-directed Pd(II)-catalysed aza-Claisen rearrangements [Jamieson & Sutherland *Tetrahedron* **63** 2132 *2007*], and bis-trichloroacetimidates from 2-aminopropane-1,3-diols yielded dihydrooxazines through an acid catalysed cyclisation [Rondot et al. *Org Lett* **9** 247 *2007*].

1,1,1-Trichloroethane *[71-55-6]* **M 133.4, f -32.7°, b 74.0°, d $_4^{20}$ 1.337, n $_D^{20}$ 1.4385.** Wash it successively with conc HCl (or conc H_2SO_4), aqueous 10% K_2CO_3 (Na_2CO_3), aqueous 10% NaCl, dry it with $CaCl_2$ or Na_2SO_4, and fractionally distil it. It can contain up to 3% dioxane as preservative. This is removed by washing successively with 10% aqueous HCl, 10% aqueous $NaHCO_3$ and 10% aqueous NaCl, and distilling over $CaCl_2$ before use. [*Beilstein* **1** IV 138.]

1,1,2-Trichloroethane *[79-00-5]* **M 133.4, f -36.3°, b 113.6°, d $_4^{20}$ 1.435, n $_D^{20}$ 1.472.** Purify the chloroethane as for 1,1,1-trichloroethane above. [*Beilstein* **1** IV 139.]

Trichloroethylene *[79-01-6]* **M 131.4, f -88°, b 87.2°, d $_4^{20}$ 1.463, n $_D^{21}$ 1.4767.** Tricloroethylene undergoes decomposition in a similar way as $CHCl_3$, giving HCl, CO, $COCl_2$ and organic products. It reacts with KOH, NaOH and 90% H_2SO_4, and forms azeotropes with water, MeOH, EtOH, and acetic acid. It is purified by washing successively with 2M HCl, water and 2M K_2CO_3, then dried with K_2CO_3 and $CaCl_2$, then fractionally distilled before use. It has also been steam distilled from 10% $Ca(OH)_2$ slurry, most of the water being removed from the distillate by cooling to –30 to –50° and filtering off the ice through chamois skin: the trichloroethylene is then fractionally distilled at 250mm pressure and collected in a blackened container. [Carlisle & Levine *Ind Eng Chem (Anal Ed)* **24** 1164 *1932*, *Beilstein* **1** IV 712.]

1,1,2-Trichloro-1,2,2-trifluoroethane *[76-13-1]* **M 187.4, b 47.6°/760mm, d $_4^{20}$ 1.576, n $_D^{20}$ 1.360.** Wash it with water, then with weak alkali. Dry it with $CaCl_2$ or H_2SO_4 and distil it. [Locke et al. *J Am Chem Soc* **56** 1726 *1934*, *Beilstein* **1** III 157, **1** IV 142.]

Tridecanoic acid *[638-53-9]* **M 214.4, m 41.8°, 44.5-45.5° (several forms), b 199-200°/24mm, pK$_{Est}$ ~5.0.** Recrystallise the acid from acetone. [*Beilstein* **2** IV 1117.]

7-Tridecanone (dihexyl ketone) *[462-18-0]* **M 198.4, m 33°, b 255°/766mm.** Crystallise the ketone from EtOH. [*Beilstein* **1** H 715.]

Tri-*n*-dodecylamine (Hydrogen ionophore I) *[102-87-4]* **M 522.0, m 15.7°, b 220-228°/0.03mm, d $_4^{20}$ 0.833, n $_D^{20}$ 1.4577, pK$_{Est}$ ~11.0.** Distil tridodecylamine under high vacuum and N_2, and store it in the absence of CO_2. It can be recrystallised from 95%EtOH/*C_6H_6 at low temperature under vacuum. The *hydrochloride* has **m 78-79°**. [Ra et al. *J Org Chem* **9** 259 *1944*, *Beilstein* **4** III 413, **4** IV 801.]

Tri-*n*-dodecylammonium nitrate *[2305-34-2]* **M 585.0.** Crystallise the salt from *n*-hexane/acetone (95:5) and keep it in a desiccator over P_2O_5 under vacuum. [*Beilstein* **4** IV 801 for tridodecylamine.]

Tri-*n*-dodecylammonium perchlorate *[5838-82-4]* **M 622.4.** Recrystallise the salt from *n*-hexane or acetone and keep it in a desiccator over P_2O_5. (**Potentially explosive.**)

Triethanolamine *[102-71-6]* **M 149.2, m 20-22°, b 190-103°/5mm, 206-207°/15mm, 335.4°/760mm, d $_4^{20}$ 1.124, n $_D^{20}$ 1.485, pK^{25} 7.92.** Shake the amine gently with Linde type 4A molecular sieves for 24 hours, filter and fractionate it under a vacuum, and preferably in the presence of N_2. Store it in dark stoppered bottles under N_2 as it is *hygroscopic*, and turns brown in air and light. It has a strong ammoniacal odour (like diethanolamine). It is miscible with H_2O, MeOH and Me_2CO and its solubilities at 25° in *n*-heptane, Et_2O and *C_6H_6 are 0.4%, 1.6% and 4.2%, respectively. [See **diethanolamine** above, *Beilstein* **4** IV 1524.]

Triethanolamine hydrochloride *[637-39-8]* **M 185.7, m 177°, pK^{25} 7.92 (free base).** Crystallise the salt

from EtOH. Dry it at 80°. [*Beilstein* **4** IV 1525.]

1,1,2-Triethoxyethane *[4819-77-6]* **M 162.2, b 74°/28mm, 164°/~760mm, 167.2°/760mm, d_4^{20} 0.897, n_D^{20} 1.401.** Dry it with Na_2SO_4, and distil it. [McElvain & Walters *J Am Chem Soc* **64** 1964 *1942*, *Beilstein* **1** H 818, **1** I 418, **1** III 3184, **1** IV 3958.]

Triethylamine *[121-44-8]* **M 101.2, b 89.4°, d_4^{20} 0.7280, n_D^{20} 1.4005, pK^{25} 10.82.** Dry triethylamine with $CaSO_4$, $LiAlH_4$, Linde type 4A molecular sieves, CaH_2, KOH, or K_2CO_3, then distil it, either alone or from BaO, sodium, P_2O_5 or CaH_2. It has also been distilled from zinc dust, under nitrogen. To remove traces of primary and secondary amines, triethylamine has been refluxed with acetic anhydride, benzoic anhydride, phthalic anhydride, then distilled, refluxed with CaH_2 (ammonia-free) or KOH (or dried with activated alumina), and again distilled. Another purification method involved refluxing for 2 hours with *p*-toluenesulfonyl chloride, then distilling. Grovenstein and Williams [*J Am Chem Soc* **83** 412 1961] treated triethylamine (500ml) with benzoyl chloride (30ml), filtered off the precipitate, and refluxed the liquid for 1 hour with a further volume of benzoyl chloride (30ml). After cooling, the liquid was filtered, distilled, and allowed to stand for several hours with KOH pellets. It was then refluxed with, and distilled from, stirred molten potassium. Triethylamine has been converted to its *hydrochloride* (see below), crystallised from EtOH (to **m** 254°), then liberated with storng aqueous NaOH, dried with solid KOH and distilled from sodium under N_2. It is a strong base and should not be inhaled. [*Beilstein* **4** H 99, **4** I 348, **4** II 593, **4** III 194, **4** IV 322.]

Triethylammonium hydrobromide *[636-70-4]* **M 229.1, m 248°.** Equimolar portions of triethylamine and aqueous solutions of HBr in acetone are mixed with cooling. The precipitated salt is washed with anhydrous acetone and dried in a vacuum for 1-2 hours. [Odinekov et al. *J Chem Soc, Faraday Trans 2* **80** 899 *1984*.] Recrystallise it from $CHCl_3$ or EtOH. [*Beilstein* **4** IV 322.]

Triethylammonium hydrochloride *[554-68-7]* **M 137.7, m 257-260°(dec).** Purify it like the bromide above. [*Beilstein* **4** IV 327.]

Triethylammonium hydroiodide *[4636-73-1]* **M 229.1, m 181°.** Purify it as for triethylammonium bromide, except the solution for precipitation should be precooled acetone at –10°, and the precipitate is twice recrystallised from a cooled acetone/hexane mixture at –10°. Store it in the dark. [*Beilstein* **4** IV 327.]

Triethylammonium trichloroacetate *[4113-06-8]* **M 263.6.** Equimolar solutions of triethylamine and trichloroacetic acid in *n*-hexane are mixed at 10°. The solid so obtained is recrystallised from $CHCl_3$/*benzene. [Hoigbné & Gäumann *Helv Chim Acta* **42** 444 *1959*, *Beilstein* **4** IV 330.]

Triethylammonium trifluoroacetate *[454-49-9]* **M 196.2.** Purify as for the corresponding trichloroacetate but in Et_2O. Evaporation of the Et_2O gives the salt as a colourless viscous liquid at ambient temperature. [Emmons et al. *J Am Chem Soc* **76** 3472 *1954*, *Beilstein* **4** IV 330.]

Triethylene glycol *[112-27-6]* **M 150.2, b 115-117°/0.1mm, 278°/760mm, d_4^{15} 1.1274, n_D^{15} 1.4578.** Dry the glycol with $CaSO_4$ for 1 week, then it is repeatedly and very slowly fractionally distilled under a vacuum. Store it in a vacuum desiccator over P_2O_5. It is very *hygroscopic*. [*Beilstein* **1** IV 2400.]

Triethylene glycol dimethyl ether (triglyme) *[112-49-2]* **M 178.2, b 225°, d_4^{20} 0.987, n_D^{20} 1.425.** Reflux it with, and distil it from sodium hydride or $LiAlH_4$. [*Beilstein* **1** IV 2401.]

Triethylenetetramine (TRIEN, TETA, trientine, $H_2NCH_2CH_2NHCH_2CH_2NHCH_2CH_2NHCH_2CH_2NH_2$) *[112-24-3]* **M 146.2, m 12°, b 157°/20mm, d_4^{20} 0.971, n_D^{20} 1.497, pK_1^{25} 3.32, pK_2^{25} 6.67, pK_3^{25} 9.20, pK_4^{25} 9.92.** Dry the amine with sodium, then distil it under a vacuum. Further purification has been *via* the nitrate or the chloride salts. For example, Jonassen and Strickland [*J Am Chem Soc* **80** 312 *1958*] separated TRIEN from admixture with TREN (38%) by solution in EtOH, cooling to approximately 5° in an ice-bath and adding conc HCl dropwise from a burette, keeping the temperature below 10°, until all of the white crystalline precipitate of TREN.HCl (see p 216) had formed and was removed. Further addition of HCl then precipitated thick, creamy

white TRIEN.HCl (see below) which was crystallised several times from hot water by adding an excess of cold EtOH. The crystals were finally washed with Me_2CO, then Et_2O and dried in a vacuum desiccator. [*Beilstein* **4** H 255, **4** II 695, **4** III 542, **4** IV 1242.]

Triethylenetetramine tetrahydrochloride (TRIEN HCl) *[4961-10-4]* **M 292.1, m 266-270°.** Crystallise the salt repeatedly from hot water by precipitation with cold EtOH or EtOH/HCl. Wash it with acetone and absolute EtOH and dry it in a vacuum oven at 80° (see TRIEN above). The *tetrabenzoyl* derivative has **m** 230° after recrystallisation from boiling EtOH. [Peacock *J Chem Soc* 1519 *1936*, *Beilstein* **4** H 255, **4** II 695, **4** III 543.]

Triethyl orthoformate (ethyl orthoformate, 1,1,1-triethoxymethane) *[122-51-0]* **M 148.2, m 30°, b 60°/30mm, 144-146°/760mm, d_4^{20} 0.891, n_D^{20} 1.392.** Fractionate it first at atmospheric pressure, then in a vacuum. If impure, then shake it with aqueous 2% NaOH, dry it with solid KOH and distil it from sodium through a 20cm Vigreux column. *Alternatively*, wash it with H_2O, dry it over anhydrous K_2CO_3, filter and fractionate it through a Widmer column. [Sah & Ma *J Am Chem Soc* **54** 2964 *1932*, Ohme & Schmitz *Justus Liebigs Ann Chem* **716** 207 *1968*, *Beilstein* **2** IV 25.] **IRRITANT** and **FLAMMABLE**.

Triethyloxonium fluoroborate *[368-39-8]* **M 190.0, m 92-93°(dec).** Crystallise it from diethyl ether. It is *very hygroscopic*, and must be handled in a dry box and stored at 0°. [Meerwein *Org Synth* Coll Vol **V** 1096 *1973*.] Pure material should give a clear and colourless solution in dichloromethane (1 in 50, w/v). [*Beilstein* **1** IV 1322.]

Trifluoroacetic acid *[76-05-1]* **M 114.0, f -15.5°, b 72.4°, d_4^{20} 1.494, n_D^{20} 1.2850, pK^{25} 0.52.** Although an improved preparation of the acid (in 87% yield) involving the oxidation of 2,3-dichloro-1,1,1,4,4,4-hexafluorobut-2-ene (b 65-66°/745mm, [303-04-8], steam volatile, **d_4^{25} 1.605, n_D^{20} 1.3458)** *via* oxidation with $KMnO_4$/KOH/95°/8-10 hours has been reported [Henne & Trott *J Am Chem Soc* **69** 1820 *1947*], the next purification procedure should be avoided. The purification of trifluoroacetic acid, reported in earlier editions of this work, by refluxing over $KMnO_4$ for 24 hours and slowly distilling has resulted in very **SERIOUS EXPLOSIONS** on various occasions, but not always. This apparently depends on the source and/or age of the acid. The method is **NOT RECOMMENDED**. It form an azeotropic mixture of acid and H_2O (80:20) which boils at 103-105°/745mm. Water can be removed by adding trifluoroacetic anhydride (0.05%, to diminish water content) and distilling. [Conway & Novak *J Phys Chem* **81** 1459 *1977*]. It can be refluxed and distilled from P_2O_5, but do not use an excess of P_2O_5 as it produces the anhydride (see below and Schmidt & Staub *Chem Ber* **87** 388 *1954*) which can be separated by fractional distillation because the anhydride distils about 30° lower at atmospheric pressure. It is further purified by fractional crystallisation by partial freezing and again distilled. It is a strong acid and attacks skin (wear gloves) and eyes (wear safety glasses). **Highly TOXIC vapour — do not inhale it. Work in an efficient fume hood.** [*Beilstein* **2** II 186, **2** III 426, **2** IV 458.]

Trifluoroacetic anhydride *[407-25-0]* **M 210.0, b 38-40°/760mm, d_4^{20} 1.508.** Purification by distilling over $KMnO_4$, as for the acid above, is **EXTREMELY DANGEROUS** due to the possiblility of **EXPLOSION** (see preceding acid). It is best purified by distilling from P_2O_5 slowly, and collecting the fraction boiling at 39.5°. Store it in a dry atmosphere. **Highly TOXIC vapour and attacks skin, work in an efficient fume hood — see previous entry. [**Tedder *Chem Rev* **55** 787, *Beilstein* **2** II 186, **2** III 427, **2** IV 469.]

1,1,1-Trifluoroacetone *[421-50-1]* **M 112.1, b 21°/atm, 22°/atm, d_4^{25} 1.252, n_D^{20} 1.3.** The ketone was obtained by refluxing ethyl 4,4,4-trifluoroacetoacetate (see [372-31-6]) for 2 hours with 10% aqueous H_2SO_4 and collecting the distillate into a receiver containing P_2O_5, and redistilling it from P_2O_5. The *2,4-dinitrophentlhydrazone* has **m 139°** [Henne et al. *J Am Chem Soc* **69** 1819 *1947*]. *Alternatively*, ethyl 4,4,4-trifluoro-sodio-acetoacetate, prepared from the ester with one equivalent of NaOEt was heated with hot (80-90°) dilute H_2SO_4 in an all-glass apparatus to give trifluoroacetone which was condensed in dry Et_2O at –78°. The ethereal solution was dried ($MgSO_4$ or $CaCl_2$), distilled, and the desired product condensed at –78° [Haszeldine et al. *J Chem Soc* 609 *1951*]. The vapours are very **TOXIC (work in an efficient fume cupboard)**. The *semicarbazone* has, **m 129-130°**, and the *2,4-dinitrophenylhydrazone* has **m 141-142°**. [McBee et al. *J Am Chem*

Soc **75** 4090 *1953*, *Beilstein* **1** II 717, **1** III 2745, **1** IV 3214.] Trifluoroacetone has been used to prepare trifluoromethylimines of chiral amines in order to prepare *R* or *S* enantiopure α-trifluoromethyl alanines, diamines and amino alcohols *via* a Strecker-type synthesis in a few steps [Huguenot & Brigaud *J Org Chem* **71** 7075 *2006*]. It has also been used to synthesise 2-trifluoromethyl-7-azaindoles from 2,6-dihalopyridines [Schirok et al. *Synthesis* 251 *2007*].

2,2,2-Trifluoroethanol *[75-89-8]* **M 100.0, m –44°, b 72.4°/738mm, 77-80°/atm, n_D^{20} 1.30, d_4^{20} 1.400, pK^{25} 12.8.** Dry it with $CaSO_4$ and a little $NaHCO_3$ (to remove traces of acid) and distil it. It is used as a calibration standard for NMR spectroscopy. **Highly TOXIC vapour.** [*Beilstein* **1** IV 1370.]

Trifluoromethanesulfonic anhydride (triflic anhydride) *[358-23-6]* **M 282.1, b 82-85°, 84°, d_4^{20} 1.71, n_D^{20} 1.322.** Distil it through a short Vigreux column. It can be freshly prepared from the anhydrous acid (11.5g) and P_2O_5 (11.5g, or half this weight) by setting aside at room temperature for 1 hour, distilling off volatile products then distil it through a short Vigreux column. It is readily hydrolysed by H_2O and decomposes appreciably after a few days to liberate SO_2 and produce a viscous liquid. Store it dry at low temperatures. [Burdon et al. *J Chem Soc* 2574 *1957*, Beard et al. *J Org Chem* **38** 373 *1973*, *Beilstein* **3** IV 35.] **Highly TOXIC vapour.**

1,1,1-Trifluoro-2,4-pentanedione (α,α,α-trifluoroacetlyacetone, tfacac or facac) *[367-57-7]* **M 154.1, b 105-107°/atm, 107°/760mm, d_4^{25} 1.27, n_D^{20} 1.3890.** The diketone was prepared from ethyl trifluoroacetate (74.5g) and Na wire (10g, or an equivalent of NaOEt) in Et_2O (5ml) at 0°, by adding Me_2CO (80ml) at a rate to maintain a steady reaction, kept at 0° for 2 hours, and then allowed to warm to room temperature. Ice-water (5ml) was added, the aqueous layer was acidified with AcOH, and the Cu complex was precipitated with a warm saturated solution of $Cu(OAc)_2$. The *copper trifluoroacetylacetone* crystallised in long blue needles from EtOH and had **m 189°**; its UV has λ_{max} at 240nm (ε 19,500) and 294nm (ε 31,000) in EtOH, and the effect of fluorine substitution on the complexing properties has been studied in detail by Calvin and coworkers [Belford et al. *J Inorg Nucl Chem* **2** 11 *1956*]. An ethereal mixture of the complex (partly dissolved) was shaken with 2N H_2SO_4, then H_2O, the organic layer was separated, dried (Na_2SO_4), filtered and distilled to give a 62% yield of *trifluoroacetylacetone*. *Alternatively*, the metal can be removed by bubbling H_2S through the ethereal mixture, the CuS was filtered off and the filtrate was distilled. [Reid & Calvin *J Am Chem Soc* **72** 2948 *1950*, Henne et al. *J Am Chem Soc* **69** 1819 *1947*, Haszeldine et al. *J Chem Soc* 609 *1951*, Belford et al. *J Inorg Nucl Chem* **2** 11 *1956*]. Its UV has λ_{max} at 284nm (ε 10,500) in $CHCl_3$; the FT-IR (film) has ν_{max} at 1604.7, 1422.3, 1369.5, 1282.2, 1154.7, 887.4, 857.4, 795.2, 726.4 cm^{-1}; and the ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 2.36 (s), 4.60 (s, 3H, CH_3), 8.30 (s, CH); and the ^{13}C NMR (75MHz, $CDCl_3$, TMS) has δ at 193.47, 176.71, 176.22, 175.74, 175.25, 127.75, 119.00, 115.25, 111.50, 96.37, 96.35, 24.83. It enolises in aqueous solution, and rates of enolisation were determined by Ried and Calvin (*vide infra*) in H_2O, 0.1N and 0.5N HCl, and in aqueous EtOH of varying concentrations; and are temperature dependent. Thus at equilibrium, at 0.08-0.09M solution of *tfacac* and 25°, 16% aqueous EtOH contains 2.5% of enol+enolate, whereas at 95% it contains 20.7% of enol+enolate. This enolisation should be taken into account when measuring spectra and other physical parameters. Complexation with Cu, Fe and Al can be used to extract the metals from aqueous medium (acetate buffered) by a 0.10M of the diketone in $CHCl_3$ [Scribner et al. *Anal Chem* **37** 1136 *1965*], and Be into organic solvents [Scribner et al. *Anal Chem* **38** 1779 1966]. The *oxime*, **m 86-87°**, crystallises from H_2O or aqueous EtOH. [*Beilstein* **1** III 3123, **1** IV 3680.]

Trimethylamine *[75-50-3]* **M 59.1, b 3.5°, pK^{25} 9.80.** Dry triethylamine by passing the gas through a tower filled with solid KOH. Water and impurities containing labile hydrogen were removed by treatment with freshly sublimed, ground, P_2O_5. It has been refluxed with acetic anhydride, and then distilled through a tube packed with HgO and BaO. [Comyns *J Chem Soc* 1557 *1955*.] For more extensive purification, trimethylamine is converted to the hydrochloride, crystallised (see below), and regenerated by treating the hydrochloride with excess aqueous 50% KOH; the gas is passed through a $CaSO_4$ column into a steel cylinder containing sodium ribbon. After 1-2 days, the cylinder is cooled to –78° and hydrogen and air are removed by pumping. [Day & Felsing *J Am Chem Soc* **72** 1698 *1950*.] Me_3N has been distilled from trap-to-trap methods and degassed by freeze-pump-thaw [Halpern et al. *J Am Chem Soc* **108** 3907 *1986*]. It is commercially available under pressure

in tin cylinders. [*Beilstein* **4** H 43, **4** I 322, **4** II 553, **4** III 99, **4** IV 134.]

Trimethylamine hydrochloride *[593-81-7]* **M 95.7, m >280°(dec).** The salt crystallises from $CHCl_3$, EtOH or *n*-propanol, and is dried under vacuum. It also crystallises from *benzene/MeOH, MeOH/diethyl ether and is dried under vacuum over paraffin wax and H_2SO_4. It is kept over P_2O_5 as it is *hygroscopic*. [*Beilstein* **4** H 262, **4** I 419, **4** IV 138.]

Trimethylamine hydroiodide *[20230-89-1]* **M 186.0, m 263°.** It crystallises from MeOH.

Trimethylolpropane (1,1,1-tris-hydroxymethylpropane, 2-ethyl-2-hydroxymethyl-1,3-propanediol) *[77-99-6]* **M 134.2, m 57-59°, 60-62°, b 159-161°/2mm.** Crystallise it from acetone and ether, and it distils at high vacuum. [*Beilstein* **1** III 2349.]

2,2,3-Trimethylpentane *[564-02-3]* **M 114.2, b 109.8°, d_4^{20} 0.7161, n_D^{20} 1.40295, n_D^{25} 1.40064.** Purify it by azeotropic distillation with 2-methoxyethanol, which is subsequently washed out with water. The trimethylpentane is then dried and fractionally distilled. [Forziati et al. *J Res Nat Bur Stand* **36** 129 *1946*, *Beilstein* **1** IV 439.]

2,2,4-Trimethylpentane (isooctane) *[540-84-1]* **M 114.2, m -107°, b 99.2°, d_4^{20} 0.693, n_D^{20} 1.39145, n_D^{25} 1.38898.** Distil isooctane from sodium, pass it through a column of silica gel or activated alumina (to remove traces of olefins), and again distilled from sodium. Extract it repeatedly with conc H_2SO_4, then agitate it with aqueous $KMnO_4$, wash it with water, dry ($CaSO_4$) and distil it. Purify it also by azeotropic distillation with EtOH, which is subsequently washed out with water, and the trimethylpentane is dried and fractionally distilled. [Forziati et al. *J Res Nat Bur Stand* **36** 126 *1946*.] [*Beilstein* **1** IV 439.]

2,4,4-Trimethylpent-2-ene (β-diisobutylene) *[107-40-4]* **M 112.2, m -106°, b 104°, d_4^{20} 0.720, n_D^{20}1.4160.** Fractionate it under N_2 as it is highly flammable. [*Beilstein* **1** III 848, **1** IV 891.]

Trimethylsulfonium iodide *[2181-42-2]* **M 204.1, m 211-212.5°(dec), 215-220°(dec).** Crystallise the iodide from EtOH. [Emeleus & Heal *J Chem Soc* 1126 *1946*, Swain & Kaiser *J Am Chem Soc* **80** 4089 *1958*, Borredon et al. *J Org Chem* **55** 501 *1990*, Bouda et al. *Synth Commun* **17** 503 *1987*.]

Trimyristin *[555-45-3]* **M 723.2, m 56.5°.** Crystallise it from diethyl ether. [*Beilstein* **2** IV 1135.]

Tri-*n*-octylamine *[1116-76-3]* **M 353.7, b 164-168°/0.7mm, 365-367°/760mm, d_4^{20} 0.813, n_D^{20} 1.450, pK^{25} 10.65.** It is converted to the amine hydrochloride etherate which is recrystallised four times from diethyl ether at –30° (see below). Neutralisation of this salt regenerates the free amine which distil under high vacuum. [Wilson & Wogman *J Phys Chem* **66** 1552 *1962*.] Distil the strong base amine at <1-2mm pressure. [*Beilstein* **4** H 196, **4** III 382, **4** IV 754.]

Tri-*n*-octylammonium chloride *[1188-95-0]* **M 384.2, m 78-79°, pK^{25} 8.35 (in 70% aqueous EtOH).** Crystallise it from Et_2O, then *n*-hexane (see above). [Burrows et al. *J Chem Soc* 200 *1947*, *Beilstein* **4** H 196.]

Tri-*n*-octylammonium perchlorate *[2861-99-6]* **M 454.2, m >300°(dec).** Crystallise the perchlorate from *n*-hexane. (Possibly explosive.) [*Beilstein* **4** IV 754.]

Tripalmitin *[555-44-2]* **M 807.4, m 66.4°.** Crystallise it from acetone, diethyl ether or EtOH. It exists in an α-form (**m** 56.0°), a β'-form (**m** 63.5°) and a β-form (**m** 65.5°). [*Beilstein* **2** H 373, **2** I 167, **2** II 340, **2** III 971.]

Tri-*n*-propylamine *[102-69-2]* **M 143.3, b 156.5°, d_4^{20} 0.757, n_D^{20} 1.419, pK^{25} 10.66.** Dry the amine with KOH and fractionally distil it. Also reflux it with toluene-*p*-sulfonyl chloride and with KOH, then fractionally distil it. The distillate, after additon of 2% phenyl isocyanate, was redistilled and the residue fractionally distilled from sodium. It is a strong base. [Takahashi et al. *J Org Chem* **52** 2666 *1987*, *Beilstein* **4** IV 470.]

Tris(2-aminoethyl)amine (TREN) *[4097-89-6]* **M 146.2, b 114°/15mm, 263°/744mm, d_4^{20} 0.977, n_D^{20} 1.498, pK_1^{25} 8.42, pK_2^{25} 9.44, pK_3^{25} 10.13.** For a separation from a mixture containing 62% TRIEN, see entry under triethylenetetramine [112-24-3] above. Also purify it by conversion to the hydrochloride (see below), recrystallise it and regenerate the free base [Xie & Hendrickson *J Am Chem Soc* **109** 6981 *1987*]. [*Beilstein* **4** H 256, **4** II 695, **4** III 545, **4** IV 1250.]

Tris(2-aminoethyl)amine trihydrochloride (TREN.HCl) *[14350-52-8]* **M 255.7, m 300°(dec).** Crystallise the salt several times by dissolving it in the minimum of hot water and precipitating it with excess of cold EtOH. The precipitate is washed with acetone, then diethyl ether and dried in a vacuum desiccator. [*Beilstein* **4** H 256, **4** II 695, **4** III 545, **4** IV 1250.]

Tris(dimethylamino)methane (*N,N,N′,N′,N″,N″*-hexamethylmethanetriamine) *[5762-56-1]* **M 145.3, b 42-43°/12mm, n_D^{20} 1.4349, pK_{Est} ~10.** Dry it over KOH and distil it through a Vigreux column at water pump vacuum. Store it in the absence of CO_2. [Bredereck et al. *Chem Ber* **101** 1885 *1968* and *Angew Chem, Int Ed Engl* **5** 132 *1966*.]

Tris(hydroxymethyl)methylamine (TRIS) *[77-86-1]* **M 121.1, m 172°, pK^{25} 8.07.** TRIS can ordinarily be obtained in highly pure form suitable sources for use as an acidimetric standard. If only impure material is available, it should be crystallised from 20% EtOH, aqueous MeOH (**m** 171.1°) or isopropanol (**m** 172-173°). Dry it in a vacuum desiccator over P_2O_5 or $CaCl_2$. *Alternatively*, it is dissolved in twice its weight of water at 55-60°, filtered, concentrated to half its volume and poured slowly, with stirring, into about twice its volume of EtOH. The crystals which separate on cooling to 3-4° are filtered off, washed with a little MeOH, air dried by suction, then finally ground and dried in a vacuum desiccator over P_2O_5. It has also been recrystallised from water, MeOH or aqueous MeOH, and vacuum dried at 80° for 2 days. [*Beilstein* **4** H 303, **4** III 857, **4** IV 1903.]

Tris(hydroxymethyl)methylammonium hydrochloride (TRIS-HCl) *[1185-53-1]* **M 157.6, m 149-150°(dec).** Crystallise the salt from 50% EtOH, then from 70% EtOH. TRIS-hydrochloride is also available commercially in a highly pure state. Otherwise, recrystallise it from 50% EtOH, then 70% EtOH, and dry it below 40° to avoid risk of decomposition. [*Beilstein* **4** H 304.]

1,1,1-Tris(hydroxymethyl)ethane (2-hydroxymethyl-2-methyl-1,3-propanediol) *[77-85-0]* **M 120.2, m 200°.** Dissolve it in hot tetrahydrofuran, filter and precipitate it with hexane. It has also been crystallised from acetone/water (1:1). Dry it in a vacuum. [*Beilstein* **1** H 520, **1** IV 2780.]

***N*-Tris(hydroxymethyl)methyl-2-aminomethanesulfonic acid (TES)** *[7365-44-8]* **M 229.3, m 224-226°(dec), pK^{20} 7.50.** Crystallise the acid from hot EtOH containing a little water.

Tris(hydroxymethyl)nitromethane [2-(hydroxymethyl)-2-nitro-1,3-propanediol] *[126-11-4]* **M 151.1, m 174-175°(dec, tech. grade), 214°(pure).** Crystallise it from $CHCl_3$/ethyl acetate or ethyl acetate/*benzene. It is an acid and a 0.1M solution in H_2O has pH 4.5. **IRRITANT.** [*Beilstein* **1** H 520.]

Tris[2-(methylamino)ethyl]amine *[65604-89-9]* **M 188.3, b 77-78°/0.1mm, d_4^{20} 0.896, $pK_{Est(1)}$ ~8.8, $pK_{Est(2)}$ ~9.4, $pK_{Est(3)}$ ~10.4.** If this strong base contains carbonate (check IR) it should be shaken with solid KOH, decanted and distilled at high vaccum to give a colourless oil with a strong amine odour. Store it in the dark under N_2 as it absorbs CO_2 in moist air. It is synthesised in two steps. Ethyl chloroformate (33.4g, 310mmol, lachrymatory, see [541-41-3] above) is added dropwise to a mixture of TREN (29.2g, 200mmol, see [4097-89-6] above) in $*C_6H_6$ (225ml) and H_2O (100ml), and cooled to 5°. Then a solution of KOH (36.4g, 650mmol) in H_2O (35ml) is added simultaneously with more ethyl chloroformate (33.4g, 310mmol), with stirring, while keeping the reaction mixture below 5° for 2 hours followed, still with stirring, by 8 hours at ~25°. The $*C_6H_6$ layer is separated, the aqueous layer is extracted with $CHCl_3$ (3 x 100ml), the combined organic layers are dried ($MgSO_4$), filtered and the filtrate is evaporated to leave *tris[2-(ethoxycarbonylamino)ethyl]amine* (~85%) as a thick oil which is used directly in the subsequent step. [The crude tri-ester has IR (film) bands with ν_{max} at

3300, 1720, 1530, and 1250 cm^{-1}; and the ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 1.27 (t, 9H, $^3J_{HH}$ = 7.1Hz), 2.60 (t, 6H, $^3J_{HH}$ = 5.7 Hz), 3.23 (br s, 6H), 4.10 (q, 6H, $^3J_{HH}$ = 7.1 Hz) and 5.50 (br s, 3H)].
In the second step the preceding crude tri-ester (61.3g, 170mmol) in THF (250ml) is added dropwise to a suspension of $LiAlH_4$ (30.0g, 790mmol) in THF (700ml), and the reaction mixture is refluxed overnight. Water (50ml), followed by a solution of KOH (50g) in H_2O (50ml) are very carefully added to it (cool if necessary), the solvent is decanted from the inorganic gel, evaporated *in vacuo*, and the residual yellow oil is fractionated in a vacuum to give the desired *amine* in 88% yield. It has ^1H NMR (300MHz, $CDCl_3$, TMS) with δ at 1.30 (br s, 3H, NH), 2.39 (s, 9H, CH_3), 2.48 (m, 6H, $^3J_{HH}$ = 6.1 Hz, $3CH_2$) and 2.52 (m, 6H, $^3J_{HH}$ = 6.1 Hz, $3CH_2$); the ^{13}C NMR (75MHz, $CDCl_3$, TMS) has δ at 54.1 (CH_2), 49.6 (CH_2) and 36.3 (CH_3); and HRMS has *m/z* 189.2082 (calc for M + H is 189.20793). [Schmidt et al. *Z Anorg Allg Chem* **578** 75 *1989*.]

Triuret (1,3-dicarbamoylurea) *[556-99-0]* **M 146.1, m 233°(dec).** It crystallises from aqueous ammonia or H_2O (plates **m** 232-234°). It gives mono and dipotassium salts. [*Beilstein* **3** H 72, **3** I 35, **3** II 60, **3** III 142.]

Undecan-1-ol *[112-42-5]* **M 172.3, m 16.5°, 146°/30mm, d^{25} 0.830, n_D^{20} 1.440.** Purify the alcohol by repeated fractional crystallisation from its melt or by distillation in a vacuum. [*Beilstein* **1** H 427, **1** IV 1835.]

Undecanoic acid (C11, undecylic acid)) *[112-78-8]* **M 186.3, m 28.5°, b 164°/18mm, 228°/160mm, 248-250°/~760mm, d_4^{20} 0.8907, n_D^{25} 1.4294, pK_{Est} ~5.0.** Purify the acid by repeated fractional crystallisation from its melt or by distillation in a vacuum. [*Beilstein* **2** H 358, **2** IV 1068.]

Undec-10-enoic acid *[112-38-9]* **M 184.3, m 25-25.5°, b 131°/1mm, 168°/15mm, d_4^{20} 0.912, n_D^{25} 1.447, pK_{Est} ~5.0.** Purify the acid by repeated fractional crystallisation from its melt or by distillation, preferably in a high vacuum. [*Beilstein* **2** IV 1612.]

Urea *[57-13-6]* **M 60.1, m 132.7-132.9°, pK^{25} 0.12.** Crystallise urea twice from conductivity water using centrifugal drainage and keeping the temperature below 60°. The crystals are dried under vacuum at 55° for 6 hours. Levy and Margouls [*J Am Chem Soc* **84** 1345 *1962*] prepared a 9M solution in conductivity water (keeping the temperature below 25°) and, after filtering through a medium-porosity glass sinter, added an equal volume of absolute EtOH. The mixture was set aside at –27° for 2-3 days and filtered cold. The precipitate was washed with a small amount of EtOH and dried in air. Crystallisation from 70% EtOH between 40° and –9° has also been used. Ionic impurities such as ammonium isocyanate have been removed by treating the concentrated aqueous solution at 50° with Amberlite MB-1 cation- and anion-exchange resin, and allowing it to crystallise on evaporation. [Benesch et al. *J Biol Chem* **216** 663 *1955*.] It can also be crystallised from MeOH or EtOH, and is dried under vacuum at room temperature. [*Beilstein* **3** H 42, **3** I 19, **3** II 35, **3** III 80.]

Urea nitrate *[124-47-0]* **M 123.1, m 152°(dec), 157-158°, 163°.** Crystallise it from dilute HNO_3 or EtOH (**m** 157-158°), and dry it in a vacuum over P_2O_5. [*Beilstein* **3** H 54, **3** I 25, **3** II 45, **3** III 105, **3** IV 94.]

Urethane (ethyl carbamate, ethyl urethane) *[51-79-6]* **M 89.1, m 48-50°, b 182-184°/~760mm, d_4^{20} 0.986, n_D^{25} 1.4144.** Urethane is best purified by fractional distillation, but it can be sublimed at ~103°/~50mm. It has also been recrystallised from *benzene. Its solubilitiy at room temperature is 2g/ml in H_2O, 1.25g/ml in EtOH, 1.1g/ml in $CHCl_3$, 0.67g/ml in Et_2O and 0.03g/ml in olive oil. It is a suspected **human carcinogen**. [*Beilstein* **3** H 22, **3** IV 40.]

***cis*-Vaccenic acid (octadec-11-enoic acid)** *[506-17-2]* **M 282.5, m 14-15°, b 158-163°/0.4mm, d_4^{20} 0.880, n_D^{25} 1.4598, pK_{Est} ~ 4.9.** Purify the acid by fractional distillation under high vacuum or crystallisation form its melt in an inert atmosphere away from light. [*Beilstein* **2** I 198, **2** III 1384, **2** IV 1639.]

***trans*-Vaccenic acid (octadec-11-enoic acid)** *[693-72-1]* **M 282.5, m 43-44°, n_D^{50} 1.4472, pK_{Est} ~ 4.9.** Crystallise the acid from acetone (**m** 45-45.5°) or aqueous MeOH (**m** 43.5-43.7°). The *methyl ester* has **b** 174-

175°/5mm. [Böeseken & Hoagland *Rec Trav Chim Pays Bas* **46** 632 *1927*, Ahmad et al. *J Am Chem Soc* **70** 3391 *1948*, IR: Rao & Daubert *J Am Chem Soc* **70** 1102 *1948*.]

***n*-Valeraldehyde (pentanal)** *[110-62-3]* **M 86.1, m –92°, b 103°, d $_4^{20}$ 0.811, n $_D^{25}$ 1.40233.** Purify pentanal *via* the bisulfite derivative (see **2-butanone** above for the preparation and decomposition of the bisulfite derivative). [Birrell & Trotman-Dickinson *J Chem Soc* 2059 *1960*, *Beilstein* **1** H 676, **1** IV 3268.] The *2,4-dinitrophenylhydrazone* [2057-84-3] **M** 266.3 has **m** 103-105° (from EtOH). [*Beilstein* **15** III/IV 429.]

***n*-Valeramide (pentanamide)** *[626-97-1]* **M 101.1, m 115-116°.** Crystallise the amide from EtOH. It sublimes at 80°. [Philbrook *J Org Chem* **19** 624 *1954*, *Beilstein* **2** H 301, 2 I 131, **2** II 266, **2** III 674, **2** IV 874.]

Valeric acid (*n*-pentanoic acid) *[109-52-4]* **M 102.1, b 95°/22mm, 186.4°/~760mm, d $_4^{20}$ 0.938, n $_D^{20}$ 1.4080, pK^{25} 4.81.** Water is removed from the acid by distillation using a Vigreux column, until the boiling point reaches 183°. A few crystals of $KMnO_4$ are added, and after refluxing, the distillation is continued. [Andrews & Keefer *J Am Chem Soc* **83** 3708 *1961*, *Beilstein* **2** H 299, 2 I 130, **2** II 263, **2** III 663, **2** IV 868.]

Valeronitrile *[110-59-8]* **M 83.1, b 142.3°/~760mm, d $_4^{20}$ 0.799, n $_D^{15}$ 1.39913, n $_D^{30}$ 1.39037.** Wash the nitrile with half its volume of concentrated HCl (twice), then with saturated aqueous $NaHCO_3$, dry it with $MgSO_4$ and fractionally distil it from P_2O_5. [*Beilstein* **2** H 301, **2** I 131, **2** II 267, **2** III 675, **2** IV 875.]

Vinyl acetate *[108-05-4]* **M 86.1, b 72.3°, d $_4^{20}$ 0.938, n $_D^{20}$ 1.396.** Inhibitors such as hydroquinone and other impurities are removed by drying with $CaCl_2$ and fractionally distilling under nitrogen, then refluxing briefly with a small amount of benzoyl peroxide and redistilling it under nitrogen. Store it in the dark at 0°. Add inhibitor (~0.004%) for storage. [*Beilstein* **2** IV 176.]

Vinyl butoxyethyl ether (ethylene glycol butyl vinyl ether) *[4223-11-4]* **M 144.2, b 70-72°/20mm, d $_4^{20}$ 0.866, n $_D^{20}$ 1.4220.** Wash the ether with aqueous 1% NaOH, dry with CaH_2, then reflux with, and distil it from sodium. Stabilise it with 0.5% of 2,6-di-*tert*-butyl-*p*-cresol for storage. [*Beilstein* **1** IV 2387.] **IRRITANT.**

Vinyl chloroformate *[5130-24-5]* **M 106.5, b 46.5°/80mm, 67-69°/atm, 109-110°/760mm, d $_4^{20}$ 1.136, n $_D^{21}$ 1.420**. It has been fractionated through a Todd column (Model A with ~60 plates) under atmospheric pressure and the purity can be checked by gas chromatography. Stabilise it with 0.5% of 2,6-di-*tert*-butyl-*p*-cresol. It has IR with ν_{max} at 3100 + 2870 (CH_2), 1780 (C=O), 1640 (C=C) and 940 (CH_2 out-of-plane) and 910 (CH_2 wagging) cm^{-1}. [IR: Lee *J Org Chem* **30** 3943 *1965*, Levaillant *Ann Chim (Paris)* **6** 504 *1936*.] It is used for protecting NH_2 groups in peptide synthesis [Olofson et al. *Tetrahedron Lett* 1563 *1977*]. [*Beilstein* **3** III 28.]

Vinyl stearate *[111-63-7]* **M 310.5, m 35°, b 166°/1.5mm, 187-188°/4.3mm, d $_4^{40}$ 0.8517, n $_D^{40}$ 1.4423.** Distil the ester in a vacuum under nitrogen, then crystallise it from acetone (3ml/g) or ethyl acetate at 0°. Store it under nitrogen in the dark. [Swern & Jordan *J Am Chem Soc* **70** 2338 *1948*, Swern & Jordan *Org Synth* **30** 108 *1950*, *Beilstein* **2** III 1019.]

ALICYCLIC COMPOUNDS

Abietic acid *[514-10-3]* **M 302.5**, **m 172-175°**, **$[\alpha]_D^{25}$ –116° (–106°)(c 1, EtOH), pK^{25} 5.27.** Crystallise it by dissolving 100g of acid in 95% EtOH (700ml), adding to H_2O (600ml) and cooling. Filter, dry it in a vacuum (over KOH or $CaSO_4$) and store it in an O_2-free atmosphere. It can also be purified *via* the anhydride, tritylabietate and the potassium, piperidine and brucine salts. λ_{max} : nm(log ε): 2343(4.3), 241(4.4), 2505(4.2), 235(4.34) and 240(4.36) in EtOH. [Harris & Sanderson *Org Synth* Coll Vol **IV** 1 *1963*, *J Am Chem Soc* **35** 3736 *1949*, Lambard & Frey *Bull Soc Chim Fr* 1194 *1948*, Buchbauer et al. *Monatsh Chem* **116** 1345 *1985*.] [*Beilstein* **9** IV 2175.]

***S*-Abscisic acid (Dormin)** *[21293-29-8]* **M 264.3, m 160-161°, 161-163° (sublimation), $[\alpha]_{287}$ +24,000°, $[\alpha]_{245}$ –69,000° (c 1-50µg/ml in acidified MeOH or EtOH), pK_{Est} ~3.9.** Crystallise the acid from CCl_4/petroleum ether, EtOH/hexane and sublime it at 120°. Also purify it by dissolving ~30g in 30ml of EtOAc, adding 100ml of hexane and allow to crystallise overnight (yield 8.4g), **m** 156-158°, 161-163°, $[\alpha]_D^{20}$ +426° (c 0.005M H_2SO_4 in MeOH). [Cornforth et al. *Nature (London)* **206** 715 *1965*, Soukemp et al. *Helv Chim Acta* **72** 361 *1989*.] The *RS-isomer* was purified on a Kieselgel F_{254} plate with toluene/EtOAc/AcOH (50:50:3) and has **m** 188-190° [Cornforth et al. *Aust J Chem* **45** 179 *1992*]. [*Beilstein* **17/3** V 13.]

Acetylcyclohexane (cyclohexyl methylketone) *[823-76-7]* **M 126.2, b 64°/11mm, 76.2-77°/25mm, d_4^{20} 0.9178, n_D^{20} 1.4519.** Dissolve acetylcyclohexane in Et_2O, shake it with H_2O, dry, evaporate and fractionate it under reduced pressure. [UV: Mariella & Raube *J Am Chem Soc* **74** 518 *1952*, enol content: Gero *J Org Chem* **19** 1960 *1954*.] The *semicarbazone* has **m** 174° and the *2,4-dinitrophenylhydrazone* has **m** 139-140° [Theus & Schinz *Helv Chim Acta* **39** 1290 *1956*].

2-Acetylcyclohexanone *[874-23-7]* **M 140.2, m –11°, b 62-64°/2.5mm, 95-98°/10mm, 111-112°/18mm, d_4^{20} 1.08, n_D^{20} 1.51.** Dissolve it in ligroin (b 30-60°), wash it with saturated aqueous $NaHCO_3$, dry over Drierite and fractionate in a vacuum. [Perfetti & Levine *J Am Chem Soc* **75** 626 *1953*, Manyik et al. *J Am Chem Soc* **75** 5030 *1953*, Eistert & Reiss *Chem Ber* **87** 108 *1954*.] It forms a *Cu salt* which crystallises in green leaflets from EtOH, **m** 162-163° [UV: McEntee & Pinder *J Chem Soc* 4419 *1957*].

2-Acetylcyclopentanone *[1670-46-8]* **M 126.2, b. 72-75°/8mm, 82-86°/12mm, 88°/18mm, d_4^{20} 1.043, n_D^{20} 1.490.** Dissolve the ketone in petroleum ether (b 30-60°), wash it with saturated aqueous $NaHCO_3$, dry over Drierite and fractionate in a vacuum. It gives a violet colour with ethanolic $FeCl_3$ and is only slowly hydrolysed by 10% aqueous KOH but rapidly on boiling to yield 6-oxoheptanoic acid. [Manyik et al. *J Am Chem Soc* **75** 5030 *1953*, Acheson *J Chem Soc* 4232 *1956*, UV: Martin & Frenelius *J Am Chem Soc* **81** 2342 *1959*.] It gives a gray green *Cu salt* from Et_2O/pentane, **m** 237-238° [House & Wasson *J Am Chem Soc* **79** 1488 *1957*].

2-Acetyl-5,5-dimethylcyclohexane-1,3-dione (2-acetyldimedone) *[1755-15-3]* **M 182.2, m 36°**, **36-40°**, **b 132-133°/20mm, 138°/23mm, pK ~4.5.** It can be purified by fractional distillation. *Alternatively*, convert it into the insoluble Cu salt in H_2O and recrystallise it from EtOH, **m ~260°**. The Cu salt is decomposed with N H_2SO_4, extracted into Et_2O, dried (Na_2SO_4), evaporated and distilled in a vacuum. The residual oil, which solidifies on cooling can be recrystallised from AcOH. It gives a red colour with Fe^{3+} ions. The *oxime* has **m 115°**(dec, from EtOH), and with concentrated NH_3 it forms the *mono-imide* which crystallises from H_2O in needles with **m 133°**. Its UV in EtOH has $\lambda_{max}(\varepsilon)$ 231(10,620) and 273(10,800)nm. It is used as a protecting group for primary amines. [Dieckmann & Stein *Chem Ber* **37** 3379 *1904*, Birch *J Chem Soc* 3026 *1951*, Crossley & Renouf *J Chem Soc* **101** 1529 *1912,* Nash et al. *Tetrahedron Lett* **37** 2625 *1996*, Kellam et al. *Tetrahedron Lett* **38** 4849 *1997*, *Beilstein* **7** H 860, **7** I 471, **7** IV 2756.]

4-Acetyl-1-methyl-1-cyclohexene *[6090-09-1]* **M 138.2, b 73-75°/7.5mm, 85-86°/13mm, 94-94.7°/20mm, 204.5-206°/747mm, d_4^{20} 1.0238, n_D^{20} 1.469.** Purify it by fractionation under reduced pressure *in vacuo*, and if it is almost pure it can be fractionated at atmospheric pressure, preferably in an inert atmosphere. It forms two *semicarbazones* one of which is more soluble in $*C_6H_6$, and both can be recrystallised from EtOH; the more

soluble has **m** 149º(151º), and the less soluble has **m** 172-175º(191º). The *4-nitrophenylhydrazone* has **m** 166-167º and the *2,4-dinitrophenylhydrazone* has **m** 114-115º. [Pfau & Plattner *Helv Chim Acta* **17** 129, 142 *1934*, Adler & Vogt *Justus Liebigs Ann Chem* **564** 109 *1949*.]

2-Acetyl-1-methyl-3,5-dioxo-1-methylcyclohexanecarboxylic acid (ADCC-linker) *[181486-37-3]* **M 212.2, m 95-99º**, **pK_{est} ~4.5.** It is prepared from 3,5-dioxo-1-methylcyclohexane-1-carboxylic acid methyl ester (obtained from 3,5-dimethoxybenzoic acid [119-52-8] *via* Birch reduction, methylation with MeI and treatment with aqueous HCl) by acetylation to 3-acetoxy-5-oxo-1-methylcyclohex-3,4-ene-1-carboxylic acid methyl ester, rearrangement (heating with DMAP) to 4-acetyl-3,5-dioxo-1-methylcyclohexane carboxylic acid methyl ester (93% yield) followed by hydrolysis (LiOH/THF/MeOH/H_2O) and H^+ ion-exchange purification to give the ADCC-linker as a crystalline solid. It should be stored at ~5º. After attaching to a solid support through the carboxy function (e.g. to amino-modified polystyrene beads), it is used for linking to primary amines (including α-amino-acid esters) *via* enamine formation of the 4-acetyl group for combinatorial synthesis. The linker is stable to acids such as CF_3CO_2H, bases such as piperidine or BTU, and uronium type coupling agents; and by treatment with 2% hydrazine in DMF, the primary amine is released quantitatively from the support. Its ^1H NMR (250MHz, Me_2SO) has δ at 1.25 (s, Me-C1(1)), 2.50 (s, MeCO-C(4)), 2.50-3.00 (m, 2H-C(3), 2H-C(5)), 17.80 (2H, enol OH and COOH). [Bannwarth et al. *Bioorg Med Chem Lett* **6** 1525 *1966*.]

Adamantane (tricyclo[3.3.1.$1^{3,7}$]-decane) *[281-23-2]* **M 136.2, m 269.6-270.8º (sublimes).** Crystallise adamantane from acetone or cyclohexane, and sublime it in a vacuum below its melting point [Butler et al. *J Chem Soc, Faraday Trans I* **82** 535 *1986*]. Adamantane is also purified by dissolving it in *n*-heptane (*ca* 10ml/g of adamantane) on a hot plate, adding activated charcoal (2g/100g of adamantane), and boiling for 30 minutes, filtering the hot solution through a filter paper, concentrating the filtrate until crystallisation just starts, adding one quarter of the original volume of *n*-heptane, and allowing to cool slowly over a period of hours. The supernatant is decanted off and the crystals are dried *in vacuo* at 25º. [Prelog & Seiwerth *Chem Ber* **74** 1769 *1941*, Schleyer et al. *Org Synth* Coll Vol **V** 16 *1973*, Walter et al. *J Am Chem Soc* **107** 793 *1985*.] [*Beilstein* **5** III 393, **5** IV 469.]

1-Adamantane acetic acid *[4942-47-6]* **M 194.3, m 136º, pK_{Est} ~4.8.** Dissolve the acid in hot N NaOH, treat with charcoal, filter and acidify. Collect the solid, wash it with H_2O, dry and recrystallise it from MeOH. [Stetter et al. *Chem Ber* **92** 1629 *1959*.] The *acid chloride* [2094-72-6] has **M** 168.7, **m** 51-54º, and **b** 135-136º/1mm. **LACHRYMATORY.**

1-Adamantane carboxylic acid *[828-51-3]* **M 180.3, m 175-176.5º, 177º, pK_{Est} ~4.9.** Possible impurities are trimethylacetic acid and C9 and C13 acids. Dissolve 15g of the acid in CCl_4 (300ml) and shake with 110ml of 15N aqueous NH_3 whereby the ammonium salt separates and is collected. Acid impurities form soluble ammonium salts. The salt is washed with cold Me_2CO (20ml) and suspended in H_2O (250mL). This is treated with 12N HCl and extracted with $CHCl_3$ (100ml). The dried (Na_2SO_4) extract is evaporated and the residue is recrystallised from a mixture of MeOH (30ml) and H_2O (*ca* 10ml) to give the pure acid (10-11g). [Koch & Haaf *Org Synth* Coll Vol **V** 20 *1973*.] It was also recrystallised from absolute EtOH and dried under vacuum at 100º.
Alternatively, the acid (5g) is refluxed for 2 hours with 15ml of MeOH and 2ml of 98% H_2SO_4 (cool when mixing this solution). Pour into 10 volumes of H_2O and extract with the minimum volume of $CHCl_3$ to give clear separation of phases. The extract is washed with H_2O, dried ($CaCl_2$) and distilled. The *methyl ester* is collected at 77-79º/1mm, **m** 38-39º. The ester is hydrolysed with the calculated amount of N KOH and refluxed until clear. Acidification with HCl provides the pure acid with 90% recovery. The *amide* crystallises from cyclohexane, **m** 189º. [Stetter et al. *Chem Ber* **92** 1629 *1959*.] [*Beilstein* **9** IV 253.]

1,3-Adamantane diamine dihydrochloride *[26562-81-2]* **M 239.2, m >310º, $pK_{Est(1)}$ ~8.1, $pK_{Est(2)}$ ~10.1.** Dissolve it in boiling conc HCl (400mg in 15ml) and evaporate to dryness. Dissolve it in absolute EtOH and add dry Et_2O to crystallise the *dihydrochloride*. [Stetter & Wulff *Chem Ber* **93** 1366 *1960*, *Beilstein* **13** III 27,]

1,3-Adamantane dicarboxylic acid *[39269-10-8]* **M 224.3, m 276º, 276-278º, 279º, $pK_{Est(1)}$ ~4.9. $pK_{Est(2)}$ 5.9.** Dissolve the acid in aqueous NaOH, treat with charcoal, filter and acidify with dilute HCl. It crystallises

from MeOH. [Stetter & Wulff *Chem Ber* **93** 1366 *1960*, *Beilstein* **9** III 4066, **9** IV 2997.]

1-Adamantane methylamine *[17768-41-1]* **M 165.3, b 83-85°/0.3mm, d $_4^{20}$ 0.93, pK$_{Est}$ ~10.2.** Dissolve the amine in Et_2O, dry over KOH and distil it. The *N-Tosyl* derivative has **m** 134-135° (from EtOH). [Stetter & Goebel *Chem Ber* **96** 550 *1963*.]

1-Adamantanol (1-hydroxyadamantane) *[768-95-6]* **M 152.4, m 288.5-290°.** If 2-adamantanol is a suspected impurity, then dissolve the substance (10g) in acetone (100ml) and add Jones's reagent [CrO_3 (10.3g) in H_2O (30ml)], then conc H_2SO_4 (8.7ml) is added dropwise (turns green in colour) until excess reagent is present (slight red colour). Stir overnight, decant the acetone solution from the Cr salts and adamantan-2-one, dry (Na_2SO_4) and evaporate to dryness. The residue (*ca* 7g) is chromatographed through Al_2O_3 (250g) and washed with 50% *benzene/petroleum ether (b 40-60°), then 100% Et_2O (to remove any adamantan-2-one present) and the 1-adamantanol is then eluted with 5% MeOH in Et_2O. The eluate is evaporated, and the residue is recrystallised from petroleum ether (b 30-60°) at –70°, **m** 287.2-288.5°. It also crystallises from MeOH and can be sublimed *in vacuo*. It has characteristic IR, with ν_{max} *at* 3640, 1114, 1086, 982 and 930 cm^{-1}. [Schleyer & Nicholas *J Am Chem Soc* **83** 182 *1961*.] [*Beilstein* **6** IV 391.]
Alternatively, if free from the 2-isomer, dissolve it in tetrahydrofuran, and dilute with H_2O to precipitate the alcohol. Collect, dry and sublime it in a vacuum at 130°. [Stetter et al. *Chem Ber* **92** 1629 *1959*.]

2-Adamantanol (2-hydroxyadamantane) *[700-57-2]* **M 152.4, m 296.2-297.7°.** It can be purified by chromatography as for the 1-isomer. It crystallises from cyclohexane and has characteristic IR with ν_{max} at 3600, 1053, 1029 and 992 cm^{-1} [Schleyer & Nicholas *J Am Chem Soc* **83** 182 *1961*].

2-Adamantanone *[700-58-3]* **M 150.2, m 256-258°(sublimes).** Purify 2-admantanone by repeated sublimation *in vacuo.* [Butler et al. *J Chem Soc, Faraday Trans II* **82** 535 *1986*.]

***N*-(1-Adamantyl)acetamide** *[880-52-4]* **M 193.3, m 149°.** Wash the amide well with H_2O, dry and recrystallise it from cyclohexane. *It is an* **irritant.** [Stetter et al. *Chem Ber* **92** 1629 *1959*.]

1-Adamantylamine (1-adamantanamine) *[768-94-5]* **M 151.2, m 160-190° (sealed tube), 180-192°, 208-210°, pK^{25} 10.58.** Dissolve the amine in Et_2O, dry it over KOH, evaporate and sublime it *in vacuo*. [Stetter et al. *Chem Ber* **93** 226 *1960*.]

1-Adamantylamine hydrochloride (Amantadine hydrochloride, Amazolone, Mantadan, Mantadix, Virofral) *[665-66-7]* **M 187.7, m >360° (dec), pK^{25} 10.58.** Dissolve the salt in dry EtOH, add a few drops of dry EtOH saturated with HCl gas, followed by dry Et_2O to crystallise the hydrochloride out. Dry the salt in a vacuum. Its solubility in H_2O is >5%; and it is soluble in EtOH but insoluble Et_2O. [Stetter et al. *Chem Ber* **93** 226 *1960*.] It is antiviral and anti-Parkinsonian agent [Kornhuber et al. *J Neural Transm* **46** (Suppl) 399 *1995*].

2-Adamantylamine hydrochloride *[10523-68-9]* **M 187.7, m >300°, pK$_{Est}$ ~10.4.** The *free amine* in Et_2O, liberated by the action of alkali in H_2O, is dried over KOH, filtered, evaporated and sublimed at 110°/12torr, **m** 230-236°. The base is dissolved in EtOH, sufficient ethanolic HCl is added dropwise and crystallised by the addition of Et_2O. Dry it *in vacuo*. [Stetter et al. *Justus Liebigs Ann Chem* **658** 151 *1962*].

1-Adamantyl bromide *[768-90-1]* **M 215.1, m 117-119°, 118°, 119.5-120°.** If coloured, dissolve it in CCl_4, wash with H_2O, treat with charcoal, dry ($CaCl_2$), filter and evaporate to dryness. Dissolve the residue in a small volume of MeOH and cool in a CO_2/trichloroethylene bath and collect the crystals. Sublime it at 90-100°/water pump vacuum. [Stetter et al. *Chem Ber* **92** 1629 *1959*, Schleyer & Nicholas *J Am Chem Soc* **83** 2700 *1961*, *Beilstein* **5** III 469.]

1-Adamantyl bromomethylketone *[5122-82-7]* **M 257.2, m 76-79°, 78-79°.** Dissolve the ketone in Et_2O, wash it with H_2O, dry ($MgSO_4$), evaporate and crystallise the residue from small volumes of MeOH. **LACHRYMATORY.** [Stetter & Rauscher *Chem Ber* **93** 2054 *1960*.]

1-Adamantyl chloride *[935-56-8]* **M 170.7, m 164.3-165.6°.** Crystallise the chloride from aqueous MeOH and sublime it at 100°/12torr. It also crystallises from MeOH at –70°. Do not keep in contact with MeOH for too long. [Stetter et al. *Chem Ber* **92** 1629 *1959*, Schleyer & Nicholas *J Am Chem Soc* **83** 2700 *1961*, *Beilstein* **5** IV 469.]

1-Adamantyl chloroformate *[5854-52-4]* **M 214.6, m 46-47°.** Crystallise it from petroleum ether (b 30-60°) at –20°. Also purify it as for 1-adamantyl fluoroformate below. Its IR has ν_{max} at 4.2, 5.6 and 8.4μ (2380, 1786 and 1190 cm^{-1}). [Haas et al. *J Am Chem Soc* **88** 1988 *1966*, *cf* Moroder et al. *Hoppe-Seyler's Z Physiol Chem* **357** 1647 *1976*.]

1-(1-Adamantyl)ethylamine hydrochloride (Rimantadine hydrochloride, Flumadine, Roflual) *[1501-84-4]* **M 215.8, m >300° , 373-375°(sealed tube), pK_{Est} ~10.4.** It is prepared by adding the oxime of 1-adamantyl methyl ketone (6 parts, see [1660-04-4] below) in dry THF (200 parts) to a cold suspension of excess of $LiAlH_4$ in Et_2O, refluxing for 1 hour, decomposing with cold brine, making strongly alkaline and extracting thoroughly with Et_2O. The dried (Na_2CO_3) extract, is filtered, concentrated, and saturated with dry HCl. The hydrochloride (~5.25 parts) is collected, dried and recrystallised as for 2-adamantylamine hydrochloride above. [US patent to du Pont de Nemours 1069563 (1969, Brit amended), *Chem Abstr* **75** 140372w *1971*.] It is an antiviral agent [Burkinskaya et al. *J Gen Virol* **60** 49 *1982*].

1-Adamantyl fluoride (1-fluoroadamantane) *[768-92-3]* **M 154.2, m 210-212°(dec, sealed tube), 259-260°(dec).** Dissolve it in Et_2O, dry over Na_2SO_4, evaporate to dryness and sublime the residue at 90-100°/12mm. Recrystallise the sublimate from MeOH, **m** 259-260°. To remove 1-hydroxyadamantane impurity, dissolve it in cyclohexane, cool for many hours, filter off the hydroxyadamantane, and evaporate to dryness, or by passage through an Al_2O_5 column in dry cyclohexane. Recrystallise the residue from petroleum ether at –77° and sublime it in vacuum, **m** 210-212°dec (sealed tube). [Bhandari & Pinock *Synthesis* 655 *1974*, NMR: Fort et al. *J Org Chem* **30** 789 *1965*.]

1-Adamantyl fluoroformate *[62087-82-5]* **M 198.2, m 31-32°.** Dissolve it in *n*-hexane (*ca* 10g in 150 ml) and keep at 0° for 24 hours. Any 1-adamantanol present will separate. Filter and evaporate to dryness. The crystalline residue has **m** 31-32° and is recrystallised from *n*-hexane (90g/500ml), (IR (KBr): ν_{max} 1242, 1824 and 2340 cm^{-1}). There should be no OH str band above 2500 cm^{-1}. [Moroder et al. *Hoppe-Seyler's Z Physiol Chem* **357** 1647 *1976*, *cf* Haas et al. *J Am Chem Soc* **88** 1988 *1966*.]

1-Adamantyl iodide (1-iodoadamantane) *[768-93-4]* **M 262.1, m 75.3-76.4°.** Dissolve the iodide in Et_2O, shake with aqueous $NaHSO_3$, aqueous K_2CO_3, and H_2O, dry (Na_2SO_4), evaporate and recrystallise it from MeOH at –70° (to avoid alcoholysis) to give white crystals. [Schleyer & Nicholas *J Am Chem Soc* **83** 2700 *1961*, lit **m** of 151-152.5° is incorrect.] Also purify by recrystallisation from petroleum ether (40-60°C) followed by rigorous drying and repeated sublimation. [*Beilstein* **5** IV 470.]

1-Adamantyl isocyanate *[4411-25-0]* **M 177.3, m 144-145°.** Recrystallise the isocyanate from *n*-hexane and sublime it. **Irritant.** [Stetter & Wulff *Chem Ber* **95** 2302 *1962*.]

1-Adamantyl isothiocyanate *[4411-26-1]* **M 193.3, m 168-169°.** Dissolve it in Et_2O, wash with H_2O, dry (Na_2SO_4), evaporate and sublime the residue in a vacuum at 140°, then recrystallise it from MeOH. **Irritant.** [Stetter & Wulff *Chem Ber* **95** 2302 *1962*.]

1-Adamantyl methyl ketone *[1660-04-4]* **M 178.3, m 53-55°, 54-55°.** The ketone is prepared by bubbling acetylene through a vigorously stirred solution of 1-adamantylbromide (1g, see [769-90-1]) in 96% H_2SO_4 (40ml) at 5° for 5 hours with evolution of HBr. The mixture is poured onto ice, extracted with Et_2O, the extract is dried (Na_2SO_4), filtered and evaporated to give an ~80% yield of ketone. This was purified *via* the *2,4-dinitrophenyl hydrazine derivative* (by passage of a solution through silica gel/*C_6H_6) which gave orange needles from AcOH/EtOH or EtOH with **m 221° (219-222°** and **220-222°** also reported). The *ketone* has an IR (KBr) peak at ν_{max} 1690 cm^{-1} (C=O); its ^{1}HNMR has τ at 7.96 (s, 3H), 7.90 and 8.30 (15H); and its MS has *m/z* at 178 (M^+). [Kell & McQuillin *J Chem Soc Perk I* 2100 *1972*, Sasaki et al. *Chem Commun* 780 *1968*.]

Alternatively, 1-(ethoxycarbonylmethylcarbonyl)adamantane [1-(EtOCOCH$_2$CO)-Ad), b 108-115°/0.06mm, prepared from 1-adamantylcarbonyl chloride and diethyl malonate] (~25g) was hydrolysed and decarboxylated by boiling in AcOH (50ml), H_2O (30ml) and concentrated H_2SO_4 (5.5ml) until evolution of CO_2 ceased, poured into ice-water (~300ml), the oily *ketone* solidified (94-96% yield), and was recrystallised from MeOH or aqueous MeOH. It sublimes at 40°/0.1mm. ***1-Adamantyl methyl ketone oxime***, **m 182-184°** (used for the preparation of *Rimantadine hydrochloride* see [1501-84-4] above) is obtained by shaking hydroxylamine hydrochloride (2.5g) and recrystallised NaOAc (4g) in H_2O (10ml) in a glass test tube, then warming to 40° and adding the *ketone* (2.5g), replacing the stopper and shaking vigorously for a few minutes. The crystalline oxime that soon separates is filtered off, washed with H_2O, and gives colourless plates in high yield upon recrystallising from aqueous dioxane. [Stetter & Rauscher *Chem Ber* **93** 2054 *1960*, see also Hála & Landa *Col Czech Chem Comm* **25** 2692 *1960*.]

***N*-(1-Adamantyl)urea** *[13072-69-0]* **M 194.2, m >250°(dec), 268-272°(dec).** Wash the urea with H_2O and dioxane and recrystallise it from EtOH. [Stetter & Wulff *Chem Ber* **95** 2302 *1962*.]

(–)-Alloaromadendrene *[25246-27-9]* **M 204.4, b 96°/2mm, 265-267°/atm, $[\alpha]_D^{25}$–22° (neat), d_4^{20} 0.923, n_D^{23} 1.501.** Fractionally distil it from Na. It has IR bands at 6.06 and 11.27μ due to C=CH$_2$. [Birch *J Chem Soc* 715 *1953*, *cf* Büchi et al. *J Am Chem Soc* **91** 6473 *1969*.]

***Cis*-(±)-(1-*RS*,2-*SR*-)-6-Amino-3-cyclohexene-1-carboxylic acid (*cis*-(±)-1,2,3,6-tetrahydroanthranilic acid)** *[54162-90-2]* **M 141.5, m 216-218°, $pK_{Est(1)}$ ~3.5, $pK_{Est(2)}$ ~10.2.** Purify the free amino-acid by dissolving it in H_2O and passing it through a Dowex 50W (acid form) column and eluting with 1M aqueous NH_4OH. The eluate is evaporated (*in vacuo*) and the residue is dissolved in H_2O. Me_2CO is added to turbidity, cooled at 0° and the colourless crystals of the amino-acid are collected and dried *in vacuo* [Bernáth et al. *Tetrahedron* **41** 1315 *1958*, *cf* Mazza & Crapetta *Gazzetta* **57** 297 *1927*]. In earlier work, it was recrystallised from aqueous EtOH and had reported melting points of 265-265° [Kricheldorf *Justus Liebigs Ann Chem* 1378 *1975*] and 269-271° [Marconi & Mazzochi *J Org Chem* **31** 1372 *1966*]. The *hydrochloride* [57266-56-5] M 177.6 has **m** 210-213° and the *methyl ester hydrochloride* [52766-61-2] has **m** 85-87° (from Et_2O). The *trans*-(±)-(1*RS*,2*RS*)-*amino-acid* [97945-19-2] crystallises from aqueous Me_2CO with **m** 267-269°. [*Beilstein* **14** II 203.]

α-Amyrin *[638-95-9]* **M 426.7, m 186°, 244°/0.8mm, $[\alpha]_D^{25}$ +85° (c 2, $CHCl_3$).** Purify it by acetylation to the acetate followed by hydrolysis and recrystallisation from aqueous MeOH or from EtOH. The *acetate* when crystallised from petroleum ether, *n*-heptane or $CHCl_3$/MeOH, and sublimed *in vacuo* has **m** 227° (225-226°) and $[\alpha]_D^{20}$ +76.4° (c 0.6, $CHCl_3$). [Bently et al. *J Chem Soc* 3672 *1953*, IR: Cole & Thornton *J Chem Soc* 1332 *1957*, Corey & Cantrall *J Am Chem Soc* **81** 1745 *1958*, *Beilstein* **6** III 2889, **6** IV 4191.]

ß-Amyrin *[508-04-3]* **M 426.7, m 197-197.5°, 204-205°, 260°/0.8mm, $[\alpha]_D^{23}$ +91° (c 0.9, $CHCl_3$).** Purify it through an Al_2O_3 column and elute with petroleum ether (40-60°) then Et_2O and recrystallise from petroleum ether or EtOH. The *acetate* crystallises from Ac_2O or petroleum ether and has **m** 242-143° and $[\alpha]_D^{20}$ +82.8° (c 0.81, $CHCl_3$) [Crow & Michael *Aust J Chem* **8** 133 *1955*, Barton et al. *J Chem Soc (C)* 1031 *1968*, *Beilstein* **6** III 1894, **6** IV 4195.]

1,1'-Azobis(cyclohexane carbonitrile) *[2094-98-6]* **M 244.3, m 114-114.5°, 114-115°, ε_{350nm} 16.0.** Purify the nitrile by dissolving it in boiling 95%EOH as rapidly as possible, cool overnight at 0°, filter, wash with a little EtOH and dry it in a vacuum desiccator over $CaCl_2$. Note that prolonged heating >80° causes decomposition. Recrystallise it from EtOH. It should be regarded as **potentially explosive**. It is a radical initiator. [Overberger et al. *Org Synth* Coll Vol **IV** 66 *1963*, *J Am Chem Soc* **71** 2661 *1949*, *Beilstein* **16** II 97.]

Bicyclohexyl *[92-51-3]* **M 166.3, b 238° (*cis-cis*), 217-219° (*trans-trans*).** Shake bicyclohexyl repeatedly with aqueous $KMnO_4$ and with conc H_2SO_4, wash it with water, dry, first with $CaCl_2$ then with sodium, and distil it. [Mackenzie *J Am Chem Soc* **77** 2214 *1955*, *Beilstein* **5** IV 334.]

Bicyclo[3.2.1]octane *[6221-55-2]* **M 110.2, m 141°.** Purify it by zone melting. It has been sublimed under N_2

at 70° and atmospheric pressure (closed vessel), and resublimed over P_2O_5 to give an analytically pure sample **m** 137.5-139.5°. [Von E Doering & Farber *J Am Chem Soc* **71** 1514 *1949*, Cope et al. *J Am Chem Soc* **82** 4299 *1960*, NMR: Stothers et al. *Can J Chem* **55** 841 *1977*.]

***1R*-2-*endo*-Borneol** *[464-43-7]* **M 154.3, m 204.5-205.5°, 208°, 212°/atm, $[\alpha]_D^{20}$ +37° (c 5, EtOH).** It can be steam distilled, the distillate is extracted into Et_2O, the extract dried with Drierite, filtered and evaporated. The residue is then recrystallised from boiling EtOH (charcoal) or petroleum ether. [Clark & Read *J Chem Soc* 1773 *1934*, *Beilstein* **6** III 295, **6** IV 281.]

(±)-Borneol *[6627-72-1]* **M 154.3, m 206-207°, 210-215°.** Crystallise borneol from petroleum ether (b 60-80°) and sublime it *in vacuo*. [*Beilstein* **6** II 81, **6** IV 281.]

3-Bromoadamantane-1-carboxylic acid *[21816-08-0]* **M 259.1, m 145-146°, 146.5°, 147-150°, pK^{25} 6.28 (50% aqueous EtOH).** Purify the acid by recrystallising it from cyclohexane and/or subliming at 130°/10mm. It can be converted to the *methyl ester* (diazomethane) with **m** 32° (from petroleum ether at –10°). [Stetter & Mayer *Chem Ber* **95** 667 *1962*, Stetter & Wulff *Chem Ber* **93** 1366 *1960*, Bayal & Lantvoev *J Org Chem USSR (Engl Trans)* **9** 291 *1973*.]

(+)-3-Bromocamphor-8-sulfonic acid *[5344-58-1]* **M 311.2, m 195-196°(anhydrous), $[\alpha]_D^{20}$ +88.3° (c 1, H_2O), pK ~0.** Crystallise the acid from water. The *ammonium salt* has **m** 268-207°, $[\alpha]_D^{20}$ +81.9° (c 2.2, H_2O). [Kauffman *J Prakt Chem* **33** 95 *1966*.]

***1R(endo, anti)*-3-Bromocamphor-8-sulfonic acid ammonium salt,** see entry [55870-50-3] on p. 504.

(+)-3-Bromocamphor-10-sulfonic acid hydrate *[67999-30-8]* **M 329.2, m 119-121°, $[\alpha]_D^{20}$ +98.3° (c 1, H_2O), pK ~0.** Crystallise the acid from water. [Boyle *Quart Rev Chem Soc* **25** 323 *1971*, UV: Lowry & Owen *J Chem Soc* 609 1926, *Beilstein* **11** II 181, **11** III 592.]

4-*tert*-Butyl-1-cyclohexanone *[98-53-3]* **M 154.3, m 49-50°, 52-52.5, b 90-92°/9mm.** Purify it *via* the *semicarbazone* (crystallised from EtOH with **m** 203-205°), hydrolyse this with dilute HCl and steam distil it. The distillate is extracted into Et_2O, dried, evaporated and the residue is recrystallised from pentane, aqueous EtOH or EtOH [Houlihan *J Org Chem* **27** 3860 *1962*]. The *oxime* recrystallises from 1,2-dichloropropane and has **m** 137.5-138.5°. [Harvill et al. *J Org Chem* **15** 58 1950, *Beilstein* **7** IV 82.]

(+)-Calarene [(+)-β-gurjunen, 1,3,3,11-tetramethyltricyclo[5.4.0.$0^{2,4}$]undecan-7-ene, (1a*R*)-1,1,7c,7ac-tetramethyl-1a,2,3,5,6,7,7a,7b-octahydro-1*H*-cyclopropa[α]naphthalene, new name 1(10)aristolene)] *[17334-55-3]* **M 204.35, b 45-47°/0.008-0.01mm, 255-258°/atm, d_4^{20} 0.9340, n_D^{20} 1.55051, $[\alpha]_D^{20}$ +73° (c 2, EtOH), +81.8° (neat).** Purify the sesquiterpene Calarene by gas chromatography (7% propylene glycol adipate on unglazed tile particles of size 0.2-0.3mm, 400 cm column length and 0.6 cm diameter, at 184°, with N_2 carrier gas at a flow rate of 0.54 ml/sec using a thermal detector). Also purify it by chromatography on alumina (200 times the weight of calarene) and elute with petroleum ether. Its UV has λ_{max} at 200 and 210 nm (ε 9560, 5480) in EtOH. [IR: Sorm *Col Czech Chem Comm* **18** 512 *1953*, **29** 795 *1964*, Buchi et al. *Tetrahedron Lett* **3** 827 *1962*, Vrkoc *Tetrahedron Lett* **4** 225 *1963*, *Beilstein* **5** III 1093.]

1*R*,4*S*-(–)-Camphanic acid *[13429-83-9]* **M 198.2, m 190-192°, 198-200°, $[\alpha]_{548}^{20}$ –22.5° (c 1, dioxane), -4.4° (c 8, EtOH), pK_{Est} ~3.8.** Dissolve it in CH_2Cl_2, dry ($MgSO_4$), filter, evaporate and the residue is sublimed at 120°/0.5mm or 140°/1mm. [Gerlach *Helv Chim Acta* **61** 2773 *1978*, *Beilstein* **18/8** V 101.]

1*R*,4*S*-(–)-Camphanic acid chloride *[39637-74-6]* **M 216.7, m 65-66.5°, 70.5-71°, $[\alpha]_{548}$ –23° (c 2, CCl_4), $[\alpha]_{364}^{20}$ –29.2°, $[\alpha]_{405}^{20}$ –18.0°, $[\alpha]_{436}^{20}$ –13.5°, $[\alpha]_{546}^{20}$ –7.8°, $[\alpha]_{578}^{20}$ –6.0°, (c 0.67, *C_6H_6).** It is soluble in toluene (50g/100ml at 0°) and crystallises from petroleum ether (b 40-60°). It sublimes at 70°/5mm. Store it dry at 0°, IR (CCl_4) has ν_{max} at 1805s and 1780m cm^{-1}. [Armarego et al. *J Chem Soc, Perkin Trans I* 2229 *1976*, Gerlach *Helv Chim Acta* **51** 1587 *1968*, Gerlach *Helv Chim Acta* **68** 1815 *1985*, *Beilstein* **18/8** V 101.]

***RS*-Camphene** *[565-00-4]* **M 136.2, m 51-52°, b 40-70°/10mm.** Crystallised it twice from EtOH, then repeatedly melted and frozen at 30mm pressure. [Williams & Smyth *J Am Chem Soc* **84** 1808 *1962*.] *Alternatively*, it is dissolved in Et_2O, dried over $CaCl_2$ and Na, filtered, evaporated and the residue is sublimed in a vacuum [NMR: Hana & Koch *Chem Ber* **111** 2527 *1978*].

(–)-Camphene (1*S*-2,2-dimethyl-3-methylene norbornane) *[5794-04-7]* **M 136.2, m 49.2-49.6°, 49-50°, b 79-80°/58mm, 91.5°/100mm, d_4^{54} 0.8412, n_D^{54} 1.4564, $[\alpha]_D^{21}$ -119.1° (c 2.3, *C_6H_6), -117.5° (c 19, toluene), –113.5° (c 9.7, Et_2O).** Purify the norbornane by fractionation through a Stedman column (see p. 11) at 100mm in a N_2 atmosphere, crystallise it from EtOH and sublime it in a vacuum below its melting point. It is characterised by its *camphenilone semicarbazone*, **m** 217-218.5°, or *camphor semicarbazone*, **m** 236-238°. [NMR: Hana & Koch *Chem Ber* **111** 2527 *1978*, Bartlett et al. *Justus Liebigs Ann Chem* **623** 217 *1959*, Bain et al. *J Am Chem Soc* **72** 3124 *1950*, *Beilstein* **5** IV 461.]

Camphor (1*R*-bornan-2-one) *[R-(+)- 464-49-3, S-(–)- 464-48-2]* **M 136.2, m 178.8°, 179.97° (open capillary), b 204°/atm, $[\alpha]_{546}^{35}$ (+) and (–) 59.6° (in EtOH), $[\alpha]_D^{20}$ (+) and (–) 44.3° (c 10, EtOH), $[\alpha]_{579}^{179}$ (+) and (–) 70.85°(melt).** Crystallise it from EtOH, 50% EtOH/water, MeOH, or petroleum ether or from glacial acetic acid by addition of water. It can be sublimed (50°/14mm) and also fractionally crystallised from its own melt. It is steam volatile. It should be stored in tight containers as it is appreciably volatile at room temperature. The solubility is 0.1% (H_2O), 100% (EtOH), 173% (Et_2O) and 300% ($CHCl_3$). The *R-oxime* (from Et_2O, $CHCl_3$, or aqueous EtOH) has **m** 119° $[\alpha]_D^{20}$ –42.4° (c 3, EtOH), the ± *oxime* has **m** 118-119°. It has a characteristic odour. [Asahina & Ishidate *Chem Ber* **67** 1432 *1934*, Allan & Rodgers *J Chem Soc (B)* 632 *1971*, UV, NMR: Fairley et al. *J Chem Soc, Perkin Trans 1* 2109 *1973*, White & Bishop *J Am Chem Soc* **62** 8 *1940*, *Beilstein* **7** IV 213.]

Camphoric acid (1,2,2-trimethylcyclopentan-1*r*,3*c*-dicarboxylic acid) *[1R,2S)-(+)- 124-83-4, 1S,2R)-(–)- 560-09-8]* **M 200.2, m 186-188°, 187°, 186.5-189°, $[\alpha]_{546}^{20}$ (+) and (–) 57° (c 1, EtOH), $[\alpha]_D^{20}$ (+) and (–) 47.7° (c 4, EtOH) , pK_1^{25} 4.71, pK_2^{25} 5.83 (for + isomer).** Purify the acid by re-precipitation from an alkaline solution by HCl, filter it off, and recrystallise it from water several times, rejecting the first crop. It forms leaflets from EtOH, Me_2CO and H_2O, and is insoluble in $CHCl_3$. Its solubility in H_2O is 0.8% at 25° and 10% at 100°, 50% in EtOH and 5% in ethylene glycol. The *(±)-acid* has **m** 202-203°. The *(+)-1-methyl ester* has **m** 86° (from petroleum ether) $[\alpha]_D^{20}$ +45° (c 4, EtOH), and the *(+)-3-methyl ester* has **m** 77° (from petroleum ether) $[\alpha]_D^{17.5}$ +53.9° (c 3, EtOH). [Rupe & Thommen *Helv Chim Acta* **30** 933 *1947*, Tiovonan et al. *Acta Chem Scand* **2** 597 *1948*, Howell & Fisher *J Am Chem Soc* **80** 6316 *1958*, *Beilstein* **9** IV 2851.]

(±)-Camphoric anhydride *[595-30-2, 76-32-4]* **M 182.2, transition temp. 135°, m 223.5°.** Crystallise the anhydride from EtOH. If it contains too much of the acid (check the IR), then reflux it in Ac_2O, concentrate and collect the crystals, wash them with petroleum ether and dry them *in vacuo*. [Bunton et al *J Chem Soc* 2918 *1963*, NMR: Baker & Davis *Tetrahedron* **24** 1663 *1968*, *Beilstein* **18** H 400, 401.]

Camphorquinone (borna-2,3-dione) *[1R-(–)- 10334-26-6, 1S-(+)- 2767-84-2]* **M 166.2, m 198.7°, 198-199°, 197-201°, $[\alpha]_D^{25}$ (–) and (+) 101.1° (c 2, EtOH).** It can be purified by steam distillation, recrystallisation (yellow prisms) from EtOH, *C_6H_6 or Et_2O/petoleum ether and it can be sublimed in a vacuum. The *(±)-quinone* forms needles from EtOH, **m** 197-198°, 203°. [Buxtorf & Flatt *Helv Chim Acta* **13** 1026 *1930*, Asahena et al. *Chem Ber* **67** 1432 *1934*, *Beiltein* **7** I 325.]

***RS*-Camphorquinone** *[10373-78-1]* **M 166.2, m 199-202°.** Purification is the same as for above enantiomers. [Huckel & Fichtig *Justus Liebigs Ann Chem* **628** 81 *1962*, Evans et al. *J Chem Soc* 137 *1939*, *Beilstein* **7** I 325.]

(*1R*)-(–)Camphor-10-sulfonic acid *[35963-20-3]* **M 232.3, m 197.4-198°(dec), 197-198°, $[\alpha]_D^{20}$ –20.7° (c 5.4, H_2O), pK_{Est} ~ –1.** It forms prisms from AcOH or EtOAc, and is deliquescent in moist air. Store it in tightly stoppered bottles. The *NH_4 salt* forms needles from H_2O $[\alpha]_D^{16}$ ±20.5° (c 5, H_2O)**.** [Burgess & Lowry *J Chem Soc* **127** 279 *1925*, Marsi et al. *J Am Chem Soc* **78** 3063 *1956*.] The *RS-acid* recrystallises from AcOH. [60g of (±)-acid in 60ml of AcOH at 105° gave 40g of crystals has **m** 202-203°]. [Bartlett & Knox *Org Synth* **45** 12 *1965*, *Beilstein* **11** IV 642.]

(*1S*)-(+)Camphor-10-sulfonic acid *[3144-16-9]* **M 232.3, m 193°(dec), 197-198°, $[\alpha]_{546}^{20}$ +27.5° (c 10, H_2O), $[\alpha]_D^{20}$ +43.5° (c 4.3, EtOH), pK_{Est} ~ –1.** Crystallise the acid from ethyl acetate and dry it under vacuum (deliquescent). [Loudon *J Chem Soc* 823 *1933*, Komppa *J Prakt Chem* **162** 19 *1943*, *Beilstein* **11** IV 642.] See above for *RS*-isomer.

Camphor-10-sulfonyl chloride *[1S-(+)- 21286-54-4, 1R-(–)- 39262-22-1]* **M 250.7, m 67-68°, 70°, $[\alpha]_D^{20}$ (+) and (–) 32.2° (c 3, $CHCl_3$).** If free from OH bands in the IR, then recrystallise it from Et_2O or petroleum ether; otherwise treat it with $SOCl_2$ at 50° for 30 minutes, evaporate, dry the residue over KOH in a vacuum and recrystallise it. The *(±)-acid chloride* has **m** 85° [Bartlett & Knox *Org Synth* **45** 14 *1965*]. It is characterised as the *amide* (prisms from EtOH) **m** 132°, $[\alpha]_D^{17}$ (+) and (–) 1.5° (EtOH). On repeated recrystallisation from EtOH the *anilide* has **m** 120.5-121°, $[\alpha]_D^{25}$ +76° (c 1, $CHCl_3$). [Read & Storey *J Chem Soc* 2761 *1930*, Sutherland & Shriner *J Am Chem Soc* **58** 62 *1936*, Halterman et al. *J Am Chem Soc* **109** 8105 *1987*, Bartlett & Knox *Org Synth* **45** 55 *1945*, *Beilstein* **11** IV 650.]

2,10-Camphorsultam *[1R-(+)- 108448-77-7, 1S-(–)- 94594-90-8]* **M 215.3, m 181-183°, 183-184 185-187°, $[\alpha]_D^{20}$ (+) and (–) 32° (c 5, $CHCl_3$).** The (–)-enantiomer is recrystallised from 95% EtOH and dried in a vacuum desiccator. It dissolves in dilute aqueous NaOH and can be precipitated without hydrolysis by acidifying. It forms the *N*-Na salt in EtOH (by addition of Na to the EtOH solution), and the salt can be methylated with MeI to give the (–)-*N-Me lactam* with **m** 80° after recrystallisation from hot H_2O, and has $[\alpha]_D^{25}$ –59.6° (c 5, $CHCl_3$) [Shriner et al. *J Am Chem Soc* **60** 2794 *1938*]. 4-Carboethoxy-3-methyl-2-cyclohexen-1-one (Hagemann's ester) *[487-51-4]* **M 182, b 79-80°/0.2mm, 121-123°/4mm, 142-144°/15mm, n_D^{20} 1.488, d_4^{20} 1.038.** Dissolve the ester in ether, shake with solid K_2CO_3, aqueous saturated $NaHCO_3$, brine, dry ($MgSO_4$) and distil it. The *semicarbazone* has **m** 165-167° (169°). [Smith & Rouault *J Am Chem Soc* **65** 631 *1943*, *Beilstein* **10** H 631, **10** I 300, **10** III 2899, **10** IV 2666.]

(–)-Caryophyllene oxide (1-*S*-5*c*-6*t*-epoxy-6*c*,10,10-trimethyl-2-methylene-1*r*,9*t*-bicyclo[7.2.0]undecane) *[1139-30-6]* **M 220.4, m 62-63°, 63.5-64°, 64°, b 114-117°/1.8mm, 141-142°/11mm, d_4^{20} 0.967, n_D^{20} 1.4956, $[\alpha]_D^{20}$ –79° (c 2, $CHCl_3$), $[\alpha]_D^{20}$ –68° (supercooled melt).** Purify the oxide by TLC on silica gel with EtOAc/petroleum ether (b 60-80°) (15:85), and recrystallise it from MeOH or $*C_6H_6$. [NMR: Warnhoff *Can J Chem* **42** 1664 *1964*, Ramage & Whitehead *J Chem Soc* 4336 *1954*, *Beilstein* **17** IV 392.]

(+)-Cedrol [octahydro-3,6,8,8-tetramethyl-1-3a,7-methanoazulen-6-ol, 8a*S*-6*c*-hydroxy-3*c*,6*t*,8,8-tetramethyl(8a*r*-*H*)-octahydro-3*H*,3a*t*,7*t*-methanoazulene], *[77-53-2]* **m 82-86°, 86-87°, $[\alpha]_D^{28}$ +10.5° (c 5, $CHCl_3$), $[\alpha]_D^{18}$ +13.1° (c 5.5, EtOH), $[\alpha]_D^{18}$ +14.3° (c 10, dioxane).** Purify cedrol by recrystallisation from aqueous MeOH. It is estimated colorimetrically with H_3PO_4 in EtOH followed by vanillin and HCl [Hayward & Seymour *Anal Chem* **20** 572 *1948*]. The *3,5-dinitrobenzoyl* derivative has **m** 92-93°. [Stork & Clarke *J Am Chem Soc* **83** 3114 *1961, Beilstein* **6** III 424.]

Chaulmoogric acid [(13-cyclopent-2-enylyl)tridecanoic acid] *[29106-32-9]* **M 280.4, m 68.5°, b 247-248°/20mm, $[\alpha]_D^{20}$ +60° (c 4, $CHCl_3$), pK_{Est} ~5.0.** Crystallise the acid from petroleum ether or EtOH. The *Me ester [24828-59-9]* has **m** 22°, **b** 227°/20mm and $[\alpha]_D^{15}$ +50° (c 5, $CHCl_3$). [Mislow & Steinberg *J Am Chem Soc* **77** 3807 *1955*.]

Chlorendic anhydride (1,4,5,6,7,7-hexachloro-5-norbornene-2,3-dicarboxylic anhydride) *[115-27-5]* **M 370.9, m 234-236°. 235-237°, 238°.** Steam distil the anhydride or recrystallise it from H_2O to yield pure diacid. The pure diacid yields the anhydride with Ac_2O. [Prill *J Am Chem Soc* **69** 62 *1947*.]

Chlorocyclohexane (cyclohexyl chloride) *[542-18-7]* **M 118.6, b 46-48°/26mm, 142.5°/atm, d_4^{20} 1.00, n_D^{25} 1.46265.** It has been prepared using the general procedure of Norris and coworkers by refluxing the alcohol with 5 volumes of "constant boiling HCl" for 2-4 hours [Norris et al. *J Am Chem Soc* **38** 1071 (1077) *1916*]. It has also been prepared in 76% yield by the "$CaCl_2$" procedure described for chlorocyclopentane (see below

[930-28-9]). Wash the chlorocyclohexane several times with dilute $NaHCO_3$, then repeatedly with distilled water. Dry it with $CaCl_2$ and fractionally distil it slowly at atmospheric pressure or better under vacuum. [Perlman et al. *J Org Chem* **1** 288 (294) *1936*, IR: Roberts & Chambers *J Am Chem Soc* **73** 5031 1951, *Beilstein* **5** H 21, **5** I 8, **5** II 11, **5** III 37, **5** IV 48.]

2-Chlorocyclohexanone *[822-87-7]* **M 132.6, m 23°, b 82-83°/10mm, 98-99°/14-15mm, d^{25} 1.161, n_D^{20} 1.484.** The chlorocyclohexanone is prepared in a well ventilated fume cupboard by bubbling chlorine (215g, ~3moles, use mercury traps) rapidly through a mixture of cyclohexanone (284g, 3moles) and H_2O (900ml) while being stirred in an ice bath at a reaction temperature between 20° and 50°. After about 45 minutes all the chlorocyclohexanone separates as a heavy oil which is combined with the Et_2O (3 x 150ml) extract of the upper aqueous layer, washed with H_2O (150ml), saturated aqueous NaCl (200ml), filtered (by gravity) through anhydrous Na_2SO_4, the solvent is evaporated, the residue is distilled in a Claisen flask, and the fraction boiling below 110° (300-340g, b 110°/13mm, 92°/4mm) is collected. This is then carefully fractionated through a heated 42-inch Vigreux column with a variable take-off head to give pure *2-chlorocyclohexanone* (240-265g, 61-66%, **b 90-91°/14-15mm**) with 5-13% recovery of cyclohexanone b 52°/14-15mm. [Newman et al. *Org Synth* Coll Vol **3** 188 *1855*, *Beilstein* **7** H 10, **7** I 8, **7** II 11, **7** III 36, **7** IV 32.]

Chlorocyclopentane (cyclopentyl chloride) *[930-28-9]* **M 104.6, b 113-115°/atm, 114°/atm, d_4^{20} 1.005, n_D^{20} 1.4512.** It is prepared by mixing cyclopentanol (43g) with concentrated HCl (125ml) and anhydrous $CaCl_2$ (50g), and stirring under reflux on a steam bath for 10 hours. [As HCl gas evolves continuously, the reaction should be carried out in an sufficient fume cupboard.] After cooling, the upper layer is collected, washed wih brine, saturated aqueous $NaHCO_3$ (CARE, as evolution of CO_2 will occur), brine again and dried over anhydrous $CaCl_2$ for at least 24 hours. Filter off the solid and fractionate through an efficient column at atmospheric pressure to obtain a ~ 58% yield of *cyclopentyl chloride* (30g). Bubbling dry HCl gas through the reaction mixture does not appear to increase the yield. See preparation and purification of chlorocyclohexane above. [*Beilstein* **5** IV 18.]

(–)-α-Copaene (*1R,2S,6S,7S,8S*-8-isopropyl-1,3-dimethyltricyclo[4.4.0.$0^{2,7}$]dec-3-ene) *[3856-25-5]* **M 204.4, b 119-120°/10mm, 246-251°, d_4^{20} 0.908, n_D^{20} 1.489, $[\alpha]_D^{20}$ –6.3° (c 1.2, $CHCl_3$).** Purify it by distillation, preferably under vacuum. [Heathcock *J Am Chem Soc* **88** 4110 *1966*, Heathcock et al. *J Am Chem Soc* **89** 4133 *1967*, Corey & Watt *J Am Chem Soc* **95** 2303 *1973*, *Beilstein* **5** IV 1189.]

Cyclobutane *[287-23-0]* **M 56.1, m -50°, –80°, b 13°/740mm, 12°/atm, d_4^{20} 0.721, n_D^{20} 1.426.** This easily liquefiable gas is dried over Na at melting ice temperature for 4 days and distilled at low temperature through a Podbielniak precision still. A dry sample has been prepared by passage through P_2O_5 and distilled repeatedly until all fractions had similar vapour pressures at 0°. [Cansson & Wat *J Org Chem* **14** 31 *1949*, Heisig *J Am Chem Soc* **63** 1698 *1941*, Stodola & Heisig *Org Synth* Coll Vol **III** 213 *1955*.]

Cyclobutane carboxylic acid *[3721-95-7]* **M 100.1, m 3-4°, –5.4°, b 84-84.5°/10mm, 110°/25mm, 135-138°/110mm, 194°/760mm, d_4^{20} 1.061, n_D^{20} 1.453, pK^{25} 4.79.** Dissolve the acid in aqueous HCO_3^- then acidify with HCl and extract it into Et_2O, wash with H_2O, dry (Na_2SO_4), concentrate to a small volume, then distil it through a glass helices packed column. The S-*benzylisothiuronium salt* has **m** 176° (from EtOH), the *anilide* has **m** 112.5-113°, and the *p-toluide* has **m** 123°. and the *p-bromodiphenacyl ester* has **m** 153° (from EtOH/Me_2CO). [Vogel *Justus Liebigs Ann Chem* **615** 13 *1958*, Reed *J Chem Soc* 685 *1951*, Fison et al. *J Am Chem Soc* **56** 1774 *1934*, pK: Bode *Chem Ber* **67** 332 *1934*, *Beilstein* **9** IV 2788.]

Cyclobutanone *[1191-95-3]* **M 70.1, b 96-97°, 99-100°/atm, d_4^{20} 0.931, n_D^{20} 1.4210, n_D^{52} 1.4189.** Treat cyclobutanone with dilute aqueous $KMnO_4$, dry it with molecular sieves and fractionally distil it. Purify it *via* the semicarbazone, then regenerate the ketone, dry it ($CaSO_4$), and distil it in a stainless steel spinning-band (or Vigreux column. *Alternatively*, purify it by preparative gas chromatography using a Carbowax 20-M column at 80°. (This treatment also removes acetone). It has FT-IR (NaCl) with ν_{max} at 3543.3, 2970.3 (CH), 1783.2 (C=O), 1392.5 (OH enol ?), 1208.9, 1136.4, 1080.8, 724.9, and 461.4 cm^{-1}; ^1H NMR (60MHz, $CDCl_3$, TMS) with δ at 2.01 (q, 2H, C-3 methylene), 3.09 (t, 4H, C-2 and C-4 methylenes); ^{13}C NMR (15MHz, $CDCl_3$, TMS) with δ at 9.74 (C-3), 47.73 (C-2,4) and 208.90 (C-1). The *oxime* has **m** 84-85° (from petroleum ether) and the *semicarbazone* has **m** 212-212-5° (220-221° from MeOH or H_2O, Buchanan et al. *J Am Chem Soc* **64** 2701 *1942*). [Salaun *Org Synth* **57** 36 *1977*, Fitzer & Quabeck *Synthesis* 299 1987, *Beilstein* **7** IV 3.]

Cyclobutylamine *[2516-34-9]* **M 71.1, b 82-83°/atm, 83.2-84.2°/760mm, d_4^{20} 0.839, n_D^{20} 1.437, pK^{25} 10.04 (9.34 in 50% aqueous EtOH).** It has been purified by steam distillation. The aqueous distillate (e.g. 2L) is acidified with 3N HCl (90ml) and evaporated to dryness in a vacuum. The *hydrochloride* is treated with a few ml of H_2O, cooled in ice and a slush of KOH pellets ground in a little H_2O is added slowly in portions and keeping the solution very cold. The amine separates as an oil from the strongly alkaline solution. The oil is collected, dried over solid KOH and distilled using a vacuum jacketed Vigreux column and protected from CO_2 using a soda lime tube. The fraction boiling at 79-83° is collected, dried over solid KOH for 2 days and redistilled over a few pellets of KOH (**b** 80.5-81.5°). Best distil in a dry N_2 atmosphere. The purity can be checked by GLC using a polyethylene glycol on Teflon column at 72°, 15 psi, flow rate of 102 ml/min of He. The sample can appear homogeneous but because of tailing it is not possible to tell if H_2O is present. The NMR in CCl_4 should show no signals less than 1 ppm from TMS. The *hydrochloride* has a multiplet at *ca* 1.5-2.6ppm (H 2,2,4,3,3,4,4), a quintet at 3.8 ppm (H 1) and a singlet at 4.75 for NH_2 [Roberts & Chambers *J Am Chem Soc* **73** 2509 *1951*]. The *benzenesulfonamide* has **m** 85-86° (from aqueous MeOH) and the *benzoyl* derivative has **m** 120.6-121.6°. [Roberts & Mazur *J Am Chem Soc* **73** 2509 *1951*, Iffland et al. *J Am Chem Soc* **75** 4044 *1953*, Werner & Casanova Jr *Org* Synth Coll Vol **V** 273 *1973*, *Beilstein* **12** IV 3.]

Cyclodecanone *[1502-06-3]* **M 154.2, m 21-24°, b 100-102°/12mm.** Purify the ketone *via* the *semicarbazone* (**m** 205-207°, from EtOH) and distil it through an efficient column. It sublimes in a vacuum. The *oxime* has **m** 80°, from MeOH or by sublimation in a high vacuum. [Cope et al. *Org Synth* Coll Vol **IV** 218 *1963*, Prelog et al. *Helv Chim Acta* **30** 1746 *1947*, Ruzicka et al. *Helv Chim Acta* **11** 675 1930, *Beilstein* **7** III 134, **7** IV 76.]

Cycloheptylamine *[5452-35-7]* **M 113.2, b 50-52°/11mm, 60°/18mm, d_4^{20} 0.887, n_D^{20} 1.472, pK_{Est} ~10.5 (H_2O), pK^{24} 9.99 (in 50% aqueous methyl cellosolve).** It can be purified by conversion to the *hydrochloride* **m** 242-246°, and the free base is distilled under dry N_2 in a vacuum [Cope et al. *J Am Chem Soc* **75** 3212 *1953*, Prelog et al. *Helv Chim Acta* **33** 365 *1950*]. [*Beilstein* **12** IV 115.]

1,3-Cyclohexadiene *[592-57-4]* **M 80.1, m -89°, b 83-84°/atm, d_4^{20} 0.840, n_D^{20} 1.471.** Distil the diene from $NaBH_4$ or Na under N_2 and collect it in a trap cooled in Dry Ice. It is highly flammable. [Marvel & Martell, *J Am Chem Soc* **81** 450 *1959*, *Beilstein* **5** IV 382.]

1,4-Cyclohexadiene *[628-41-1]* **M 80.1, b 83-86°/714mm, 88.3°/741mm, 86-88°/atm, 88.7-89°/760mm, d_4^{20} 0.8573, n_D^{20} 1.4725.** Dry the diene over $CaCl_2$ and distil it in a vacuum under N_2. [Hückel & Wörffel *Chem Ber* **88** 338 *1955*, Giovannini & Wegmüller *Helv Chim Acta* **42** 1142 *1959*.] [*Beilstein* **5** IV 385.]

Cyclohexane *[110-82-7]* **M 84.2, f 6.6°, b 80.7°, d_4^{24} 0.77410, n_D^{20} 1.42623, n_D^{25} 1.42354.** It is best to purify it by washing with conc H_2SO_4 until the washings are colourless, followed by water, aqueous Na_2CO_3 or 5% NaOH, and again water until neutral. It is then dried with P_2O_5, Linde type 4A molecular sieves, $CaCl_2$, or $MgSO_4$, then Na and distilled. Cyclohexane has been refluxed with, and distilled from Na, CaH_2, $LiAlH_4$ (which also removes peroxides), sodium/potassium alloy, or P_2O_5. Traces of *benzene can be removed by passage through a column of silica gel that has been freshly heated: this gives material suitable for ultraviolet and infrared spectroscopy. If there is much *benzene in the cyclohexane, most of it can be removed by a preliminary treatment with nitrating acid (a cold mixture of 30ml conc HNO_3 and 70ml of conc H_2SO_4) which converts *benzene into nitrobenzene. The impure cyclohexane and the nitrating acid are placed in an ice bath and stirred vigorously for 15 minutes, after which the mixture is allowed to warm to 25° during 1 hour. The cyclohexane is decanted, washed several times with 25% NaOH, then water, dried with $CaCl_2$, and distilled from sodium. Carbonyl-containing impurities can be removed as described for chloroform. Other purification procedures include passage through columns of activated alumina and repeated crystallisation by partial freezing. Small quantities may be purified by chromatography on a Dowex 710-Chromosorb W gas-liquid chromatographic column. **Flammable liquid.** [Sabatier *Ind Eng* Chem **18** 1005 *1926*, Schefland & Jacobs *TheHandbook of Organic Solvents* (Van Nostrand) p592 *1953, Beilstein* **5** IV 27.]
Rapid purification: Distil, discarding the forerun. Stand distillate over Grade I alumina (5% w/v) or 4A molecular sieves.

Cyclohexane butyric acid *[4441-63-8]* **M 170.3, m 31°, 26.5-28.5°, b 136-139°/4mm. 169°/20mm,**

188.8°/46mm, pK^{25} 4.95. Distil the acid through a Vigreux column, and the crystalline distillate is recrystallised from petroleum ether at low temperatures. The S-*benzylisothiuronium salt* has **m** 154-155° (from EtOH) [Friediger & Pedersen *Acta Chem Scand* **9** 1425 *1955*, English & Dayan *J Am Chem Soc* **72** 4187 *1950*]. [*Beilstein* **9** II 15.]

Cyclohexane carboxylic acid (hexahydrobenzoic acid) *[98-89-5]* **M 172.2, m 31-32°, b 63-67°/~0.1mm, 110°/8mm, 232-233°/atm, d^{15} 1.480, n^{20} 1.460, pK^{25} 4.90.** Crystallise the acid from hot H_2O (solubility is 0.2% w/w at 15°), it is soluble in organic solvents. Also distil it at as high a vacuum as possible and warm the condenser as it solidifies on cooling. The *acid chloride [2719-27-9]* **M 146.6,** has **b 184°/atm, d^{25} 1.096**, the *methyl ester* has **b** 183°/atm, and the *S-benzylisothiuronium salt* has **m** 165-166° (from EtOH). [*Beilstein* **9** H 7, **9** I 5, **9** II 6, **9** III15, **9** IV 16.]

Cyclohexane-1,2-diaminetetraacetic acid H_2O, (CDTA) *[H_2O: 12333-90-4; xH_2O: 13291-61-7]* **M 364.4, m >210°(dec), pK_1 1.34, pK_2 3.20, pK_3 5.75 (6.12), pK_4 9.26 (12.35).** Dissolve CDTA in aqueous NaOH as its disodium salt, then precipitate it by adding HCl. The free acid is filtered off and boiled with distilled water to remove traces of HCl [Bond & Jones *Trans Faraday Soc* **55** 1310 *1959*]. Recrystallise it from water and dry it *in vacuo*. [*Beilstein* **13** III 10.]

***cis*-Cyclohexane-1,2-dicarboxylic acid (*cis*-hexahydrophthalic acid)** *[610-09-3]* **M 172.2, m 191-192°, 191-194°, pK_1^{25} 4.25, pK_2^{25} 6.74.** It is purified by recrystallisation from EtOH or H_2O. [Smith & Byrne *J Am Chem Soc* **72** 4406 *1950*, Abell *J Org Chem* **22** 769 *1957*, *Beilstein* **9** III 3812, **9** IV 2801.]

It is formed by hydrolysing the anhydride with water. The *dimethyl ester* has **m** 95-96° (from $*C_6H_6$/petroleum ether). [Abell *J Org Chem* **22** 769 *1957*, Smith & Byrne *J Am Chem Soc* **72** 4406 *1950*, Linstead et al. *J Am Chem Soc* **64** 2093 *1942*, *Beilstein* **9** III 3812, **9** IV 2801.] The *1R,2R-(-)-trans-cyclohexane-1,2-acid* [46022-05-3] has **m** 171-182° and $[\alpha]_D^{20}$ -20° (c 1, Me_2CO).

***cis*-Cyclohexane-1,2-dicarboxylic anhydride (*cis*-hexahydrophthalic anhydride)** *[85-42-7, 13149-00-3]* **M 154.2, m 32-34°, b 158°/17mm.** It has been obtained by heating the *trans-acid* or *anhydride* at 200°. Crystallise it from $*C_6H_6/Et_2O$ or distil it. [Kohler & Jansen *J Am Chem Soc* **60** 2145 *1938*, Abell *J Org Chem* **22** 769 *1957*, *Beilstein* **17** II 452, **17** III/IV 5931.]

***trans*-Cyclohexane-1,2-dicarboxylic anhydride (*trans*-hexahydrophthalic anhydride)** *[14166-21-3]* **M 154.2, m 140-142°, 145-146°.** Crystallise the anhydride from $*C_6H_6/Et_2O$. It has been obtained by heating the *cis- acid* or *anhydride* with HCl at 180° for 3 hours. It is formed from the acid by heating in Ac_2O. It sublimes at 125-135°/0.02mm. [Kohler & Jansen *J Am Chem Soc* **60** 2145 *1938*, Fichter & Simon *Helv Chim Acta* **17** 1218 *1934*, *Beilstein* **9** IV 2802.]

(±)-*trans*-1,2-Cyclohexanediol *[1460-57-7]* **M 116.2, m 104°, 105°, 120°/14mm**. Crystallise the diol from Me_2CO and dry it at 50° for several days. It can also be recrystallised from CCl_4 or EtOAc and it can be distilled. The *2,4-dinitrobenzoyl* derivative has **m** 179°. [Winstein & Buckles *J Am Chem Soc* **64** 2780 *1942*.] [*Beilstein* **6** IV 5194.]

***trans*-1,2-Cyclohexanediol** *[1R,2R-(–)- 1072-86-2, 1S,2S-(+)- 57794-08-8]* **M 116.2, m 107-109°, 109-110.5°, 111-112°, 113-114°, $[\alpha]_D^{22}$ (–) and (+) 46.5° (c 1, H_2O).** The enantiomers have been recrystallised from $*C_6H_6$ or EtOAc. The (±) diol has been resolved *via* the distrychnine salt of the hemisulfate [Hayward et al. *J Chem Soc Perkin Trans 1* 2413 *1976*], or the *1-menthoxy acetates.* {*l-trans*- diastereoisomeric salt has **m** 64°, $[\alpha]_D$ –91.7° (c 1.4, EtOH) from petroleum ether or aqueous EtOH and yields the (–)-*trans*-diol} and {*d-trans*-diastereoisomeric salt has **m 126-127°**, $[\alpha]_D$ -32.7° (c 0.8, EtOH) from petroleum ether or aqueous EtOH and yields the (+)-*trans* diol}. The bis-*4-nitrobenzoate* has **m 126.5°** $[\alpha]_D$ (–) and (+) 25.5° (c 1.1, $CHCl_3$), and the bis-*3,5-dinitrobenzoate* has **m 160°** $[\alpha]_D$ (–) and (+) 83.0° (c 1.8, $CHCl_3$) [Wilson & Read *J Chem Soc* 1269 *1935*].[*Beilstein* **6** III 4060.]

***cis*-1,3-Cyclohexanediol** *[823-18-7]* **M 116.2, m 86°, 87°, 137°/13mm.** Crystallise the *cis*-diol from ethyl acetate and acetone or distil it in a vacuum . The *dibenzoyl* derivative has **m** 65.5° (from MeOH or petroleum ether). [Rigby *J Chem Soc* 1586 *1949*, Furberg & Hassell *Acta Chem Scand* **4** 518 *1950*, *Beilstein* **6** III 4077, **6** IV 5208.]

***trans*-1,3-Cyclohexanediol** *[5515-64-0]* **M 116.2, m 117°, 118-118.5°, 135°/13mm.** Crystallise the *trans*-diol from ethyl acetate or Me_2CO. The *dibenzoyl* derivative has **m** 123.5° (from EtOH or petroleum ether). [Rigby *J Chem Soc* 1586 *1949*, *Beilstein* **6** III 4077, **6** IV 5208.]

***cis*-1,4-Cyclohexanediol** *[931-71-5]* **M 116.2, m 102.5°, 113-114°.** Crystallise the *cis*-diol from acetone (charcoal), then dry and sublime it under vacuum. It also crystallises from Me_2CO or $Me_2CO/*C_6H_6$. The *diacetate* has **m** 40.6-41.1° (from petroleum ether or 34-36° from EtOH). [Grob & Baumann *Helv Chim* Acta **38** 604 *1955*, Owen & Robins *J Chem* Soc 320 *1949*, *Beilstein* **6** III 4080, **6** IV 5209.]

***trans*-1,4-Cyclohexanediol** *[6995-79-5]* **M 116.2, m 142.6-143.1°.** Crystallise the *trans*-diol from MeOH or Me_2CO. The *diacetate* has **m** 104.5-105° (from petroleum ether or 102-103° from EtOH). [Grob & Baumann *Helv Chim Acta* **38** 604 *1955*, Owen & Robins *J Chem* Soc 320 *1949*, *Beilstein* **6** III 4080, **6** IV 5209.]

Cyclohexane-1,3-dione *[504-02-9]* **M 112.1, m 107-108°, pK_1^{25} 5.25.** Crystallise the dione from *benzene. Dissolve ~50g of the diol in 140ml of $*C_6H_6$ under N_2, cool, collect the solid and dry it in a vacuum desiccator overnight. It is unstable and should be stored under N_2 or Ar at ~0°. [Thompson *Org Synth* Coll Vol **III** 278 *1955*, *Beilstein* **7** IV 1985.]

Cyclohexane-1,4-dione *[637-88-7]* **M 112.1, m 76-77°, 78°, 79.5°, 79-80°, b 130-133°/20mm, d_4^{91} 1.0861, n_D^{102} 1.4576.** Crystallise the dione from water, then *benzene. It can also be recrystallised from $CHCl_3$/petroleum ether or Et_2O. It has been purified by distillation in a vacuum, and the pale yellow distillate which solidified is then recrystallised from CCl_4 (14.3 g/100 ml) and has **m** 77-79°. The *di-semicarbazone* has **m** 231°, the *dioxime HCl* has **m** 150° (from $MeOH/*C_6H_6$) and the *bis-2,4-dinitrophenylhydrazone* has **m** 240° (from $PhNO_2$). [Nielsen & Carpenter *Org Synth* Coll Vol **V** 288 *1973*, IR: LeFevre & LeFevre *J Chem Soc* 3549 *1956*.] [*Beilstein* **7** IV 1986.]

Cyclohexane-1,2-dione dioxime (Nioxime) *[492-99-9]* **M 142.2, m 189-190°, pK_1^{25} 10.68, pK_2^{25} 11.92.** Crystallise Nioxime from alcohol/water and dry it in a vacuum at 40°. Also 2.5g of oxime have been recrystallised from 550ml of H_2O using Fe free Norit. It forms complexes with Ni and Pd. [Hach et al. *Org Synth* **32** 35 *1952*.] [*Beilstein* **7** IV 1982.]

1,4-Cyclohexanedione monoethylene acetal (1,4-dioxa-spiro[4.5]decan-8-one) *[4746-97-8]* **M 156.2, m 70-73°, 73.5-74.5°.** Recrystallise it from petroleum ether. It sublimes slowly on attempted distillation. Also purify it by dissolving it in Et_2O and adding petroleum ether (b 60-80°) until turbid, and cooling. [Gardner et al. *J Am Chem Soc* **22** 1206 *1957*, Britten & Lockwood *J Chem Soc Perkin Trans 1* 1824 *1974*.] [*Beilstein* **19/4** V 93.]

***cis,cis*-1,3,5-Cyclohexane tricarboxylic acid** *[16526-68-4]* **M 216.2, m 216-218°, $pK_{Est(1)}$ ~4.1, $pK_{Est(2)}$ ~5.4, $pK_{Est(3)}$ ~6.8.** Purify the acid by recrystallisation from toluene/EtOH or H_2O. It forms a *1.5 hydrate* with **m** 216-218°, and a *dihydrate* **m** 110°. Purify it also by conversion to the *triethyl ester* **b** 217-218°/10mm, 151°/1mm, the distillate solidifies on cooling, **m** 36-37°, which is hydrolysed by boiling in aqueous HCl. The *trimethyl ester* can be distilled and recrystallised from Et_2O, **m** 48-49°. [Newman & Lawrie *J Am Chem Soc* **76** 4598 *1954*, Lukes &S Galik *Col Czech Chem Comm* **19** 712 *1954*, *Beilstein* **9** III 4749.]

Cyclohexanol *[108-93-0]* **M 100.2, m 25.2°, b 161.1°, d 0.946, n_D^{20} 1.466, n_D^{25} 1.437, n_D^{30} 1.462.** Reflux it with freshly ignited CaO, or dry it with Na_2CO_3, then fractionally distil it. Redistil it from a very small amount of sodium, about 0.5-2% depending on the amount of H_2O estimated to be present. It is further purified by fractional crystallisation from the melt in dry air. Peroxides and aldehydes can be removed by prior washing with ferrous sulfate and water, followed by distillation under nitrogen from 2,4-dinitrophenylhydrazine, using a short fractionating column: water distils as the azeotrope. Dry cyclohexanol is *very hygroscopic*, store in a dry

atmosphere. The *3,4-dinitrobenzoate* has **m** 111-112° (EtOH or aqueous EtOH). It has **TOXIC** vapours. [*Beilstein* **6** III 10, **6** IV 20.]

Cyclohexanone *[108-94-1]* **M 98.2, f -16.4°, b 155.7°, d_4^{20} 0.947, n_D^{15} 1.452. n_D^{20} 1.451, pK^{25} –6.8 (aqueous H_2SO_4), pK^{25} 11.3 (enol), 16.6 (keto).** Dry cyclohexanone over $MgSO_4$, $CaSO_4$, Na_2SO_4 or Linde type 13X molecular sieves, then distil it. Cyclohexanol and other oxidisable impurities can be removed by treatment with chromic acid or dilute $KMnO_4$. More thorough purification is possible by conversion to the bisulfite addition compound, or the semicarbazone, followed by decomposition with Na_2CO_3 and steam distillation. [For example, equal weights of the bisulfite adduct (crystallised from water) and Na_2CO_3 are dissolved in hot water and, after steam distillation, the distillate is saturated with NaCl and extracted with Et_2O which is then dried (anhydrous $MgSO_4$ or Na_2SO_4), filtered, and the solvent evaporated prior to further distillation.] **FLAMMABLE.** The *semicarbazone* has **m 167°**, the *4-nitrophenylhydrazone* has **m 147°**, the *2,4-dinitrophenylhydrazone* has **m 162°**, and the *benzal derivative* has **m 118°**. [*Beilstein* **7** III 14, **7** IV 15.]

Cyclohexanone-2-carboxylic acid (2-oxocyclohexane carboxylic acid) *[18709-01-8]* **M 142.1, decarboxylates at 81-82°.** A preparation which is reproducible on a large scale involves adding cyclohexanone (49g, 52ml, 0.5mole) to a stirred suspension of $NaNH_2$ in Et_2O [obtained by dissolving Na (14g, 0.61g atom) in liquid NH_3 (500ml), and then replacing the NH_3 by Et_2O (500ml) carefully]. The mixture is boiled for 30 minutes, kept at ~35° while dry CO_2 is bubbled through for 3 hours, then poured into a slurry of ice and excess of 2M aqueous HCl, extracted with Et_2O (5 x 300ml), and the Et_2O is extracted with excess of saturated aqueous Na_2CO_3. The ice cold Na_2CO_3 solution is acidified with 2M aqueous HCl and again extracted with Et_2O (5 x 300ml). The combined extracts are dried ($MgSO_4$), filtered and evaporated *in vacuo* to give the carboxylic acid (29g, 41%) which can be recrystallised from Et_2O to form colourless needles. [Christie & Reid *J Chem Soc, Perkin Trans I* 880 *1976*, Gardner et al. *J Chem Soc* 1910 *1764*, cf Chiba et al. *Chem Lett* 1387 *1978*.]

Cyclohexanone oxime *[100-64-1]* **M 113.2, m 91°, b 100-105°/10-12mm, 206-210°/atm.** Crystallise the oxime from water or petroleum ether (b 60-80°). [Bousquet *Org Synth* Coll Vol **II** 313 *1943*, *Beilstein* **7** III 32, **7** IV 21.]

Cyclohexanone phenylhydrazone *[946-82-7]* **M 173.3, m 77°, 81°.** Crystallise it from EtOH.

Cyclohexene *[110-83-8]* **M 82.2, M –104°, b 83°, d_4^{20} 0.810, n_D^{20} 1.4464, n_D^{25} 1.4437.** Free cyclohexene from peroxides by washing with successive portions of dilute acidified ferrous sulfate, or with $NaHSO_3$ solution, then with distilled water, drying with $CaCl_2$ or $CaSO_4$, and distilling under N_2. Alternative methods for removing peroxides include passage through a column of alumina, refluxing with sodium wire or cupric stearate (then distilling from sodium). The diene is removed by refluxing with maleic anhydride before distilling under vacuum. Treatment with 0.1moles of MeMgI in 40ml of diethyl ether removes traces of oxygenated impurities. Other purification procedures include washing with aqueous NaOH, drying and distilling under N_2 through a spinning band column, redistilling from CaH_2, storing under sodium wire, and passing through a column of alumina, under N_2, immediately before use. Store it at <0° under argon. [Coleman & Johnstone *Org Synth* Coll Vol **I** 83 *1955*, Carson & Ipatieff *Org Synth* Coll Vol **II** 152 *1943*, Woon et al. *J Am Chem Soc* **108** 7990 *1986*, Wong et al. *J Am Chem Soc* **109** 3428 *1987*.] [*Beilstein* **5** IV 218.]

(±)-2-Cyclohexen-1-ol (3-hydroxycyclohex-1-ene) *[822-67-3]* **M 242.2, b 63-65°/12mm, 65-66°/13mm, 67°/15mm, 74°/25mm, 85°/35mm, 166°/atm, d_4^{20} 0.9865, n_D^{20} 1.4720.** Purify 2-cyclohexen-1-ol by distillation through a short Vigreux column. The *2,4-dinitrobenzoyl* derivative has **m** 120.5°, and the *phenylurethane* has **m** 107°. [Pedersen et al. *Org Synth* **48** 18 *1968*, Cook *J Chem Soc* 1774 *1938*, Deiding & Hartman *J Am Chem Soc* **75** 3725 *1953*, *Beilstein* **6** IV 196.]

Cyclohexene oxide (7-oxabicyclo[4.1.0]heptane] *[286-20-4]* **M 98.2, b 131-133°/atm, d_4^{20} 0.971, n_D^{20} 1.452.**

Fractionate the oxide through an efficient column. The main impurity is probably H_2O. Dry the oxide over $MgSO_4$, filter it, and redistil it several times (**b 129-134°/760mm**). The residue can be hard to remove from the distilling flask. To avoid this difficulty, add a small amount of a mixture of ground NaCl and Celite (1:1) to help break up the residue particularly if hot H_2O is added. [Osterberg *Org Synth* Coll Vol **I** 185 *1948*, *Beilstein* **17** H 21, **17/1** V 203.]

Cycloheximide (actidione) *[68-81-9]* **M 281.4, m 119.5-121°, $[\alpha]_{546}^{20}$ +9.5° (c 2, H_2O), pK 11.2.** Crystallise it from water/MeOH (4:1), amyl acetate, isopropyl acetate/isopropyl ether or water. The *acetate* has **m** 150-152° (from aqueous EtOH), the *p-nitrobenzoate* has **m** 215-220°(dec) (from aqueous dioxane) and the *oxime* has **m** 203-204° (from MeOH). [Kornfeld et al. *J Am Chem Soc* **71** 155 *1949*, *Beilstein* **21** IV 6632.]

Cyclohexylamine *[108-91-8]* **M 99.2, b 134.5°, d_4^{20} 0.866, d_4^{25} 0.863, n_D^{20} 1.4593, n_D^{25} 1.456, pK^{25} 10.63.** Dry the amine with $CaCl_2$ or $LiAlH_4$, then distil it from BaO, KOH or Na, under N_2. Also purify it by conversion to the hydrochloride (which is crystallised several times from water), then liberation of the amine with alkali and fractional distillation under N_2. The *hydrochloride* has **m** 205-207° (dioxane/EtOH). [Lycan et al. *Org Synth* Coll Vol **II** 319 *1943*, *Beilstein* **12** III 10, **12** IV 8.]

Cyclohexyl bromide *[108-85-0]* **M 156.3, b 72°/29mm, d_4^{20} 0.902, n_D^{25} 1.4935.** Shake the bromide with 60% aqueous HBr to remove the free alcohol. After removing excess HBr, the sample is dried and fractionally distilled. [IR: Roberts & Chambers *J Am Chem Soc* **73** 5031 *1951*, *Beilstein* **5** III 48, **5** IV 67.]

1-Cyclohexylethylamine *[S-(+)- 17430-98-7, R-(–)- 5913-13-3]* **M 127.2, b 177-178°/atm, d_4^{20}0.866, n_D^{20} 1.446, $[\alpha]_D^{15}$ (–) and (+) 3.2° (neat), pK_{Est} ~10.6.** Purify it by conversion to the *bitartrate salt* (**m** 172°), then decomposing with strong alkali and extracting into Et_2O, drying (KOH), filtering, evaporating and distilling. The *hydrochloride salt* has **m** 242° (from EtOH/Et_2O), $[\alpha]_D^{15}$ –5.0° (c 10 H_2O, from (+) amine). The *oxalate salt* has **m** 132° (from H_2O). The *(±)-base* has **b** 176-178°/760mm, and its *hydrochloride* has **m** 237-238°. [Reihlen et al. *Justus Liebigs Ann Chem* **532** 247 *1938*, Leithe *Chem Ber* **65** 660 *1932*, *Beilstein* **12** III 95.]

Cyclohexylidene fulvene (6,6-pentamethylene fulvene) *[3141-04-6]* **M 134.2.** Purify the fulvene by column chromatography and eluting with *n*-hexane [Abboud et al. *J Am Chem Soc* **109** 1334 *1987*].

Cyclohexyl mercaptan (cyclohexane thiol) *[1569-69-3]* **M 116.2, b 38-39°/12mm, 57°/23mm, 90°/100mm, 157°/763mm, d_4^{20} 0.949, n_D^{20} 1.493, pK_{Est} ~10.8.** Possible impurities are the sulfide and the disulfide. Purify the thiol by conversion to the Na salt by dissolving it in 10% aqueous NaOH, extract the sulfide and disulfide with Et_2O, and then acidify the aqueous solution (with cooling and under N_2) with HCl, extract with Et_2O, dry over $MgSO_4$, evaporate and distil it in a vacuum (**b** 41°/12mm). The *sulfide* has **b** 74°/0.2mm, $n_D^{18.5}$ 1.5162 and the *disulfide* has **b** 110-112°/0.2mm, $n_D^{18.5}$ 1.5557. The *Hg-mercaptide* has **m** 77-78° (needles from EtOH). [Naylor *J Chem Soc* 1532 *1947*, *Beilstein* **6** H 8, **6** I 6, **6** II 14, **6** III 46, **6** IV 72.]

Cyclohexyl methacrylate *[101-43-9]* **M 168.2, b 81-86°/0.1mm, d_4^{20} 0.964, n_D^{20} 1.458.** Purify it as for methyl methacrylate (see [80-62-6]). [Tong & Kenyon *J Am Chem Soc* **68** 1355 *1946*, *Beilstein* **6** III 25, **6** IV 39.]

Cyclononanone *[3350-30-9]* **M 140.2, m 142.0-142.8°, b 220-222°, 100-101.5°/15mm.** Purify it *via* the *semicarbazone* (**m** 179.5-180.5° from 90% MeOH) and regenerate it by steam distilling a mixture of 13.1g of semicarbazone, 22g of phthalic anhydride and 45ml of H_2O. After collecting 300ml of distillate, the latter is extracted with Et_2O. The dried extract ($MgSO_4$) gives on evaporation 8.4g of ketone **b** 100-101.5°/15mm. The *oxime* has **m** 76.5-77.5° (79° from MeOH) and the *iso-oxime* has **m** 138-139°. [Ruzicka et al. *Helv Chim Acta* **32** 548 *1949*.] It has also been repeatedly sublimed at 0.05-0.1mm pressure. [Blomquist et al. *J Am Chem Soc* **74** 3639, 3645 *1952*, *Beilstein* **7** III 110, **7** IV 62.]

***cis,cis*-1,3-Cyclooctadiene** *[3806-59-5]* **M 108.2, m –5°, –49°, b 55°/34mm, 142-144°/760mm, d_4^{20} 0.8690, n_D^{20} 1.48921.** Purify the diene by GLC. Fractional distillation through a Widmer column gives a mobile liquid, and redistil it with a Claisen flask or through a semi-micro column [Gould, et al. *Anal Chem* **20** 361 *1948*]. **NB:** It has a strong characteristic disagreeable odour detectable at low concentrations and causes headaches on

prolonged exposure. *Do not breath it internally*. [IR: Cope & Estes *J Am Chem Soc* **72** 1128 *1950*, UV: Cope & Baumgardner *J Am Chem Soc* **78** 2812 *1956*.] [*Beilstein* **5** IV 401.]

***cis-cis*-1,5-cyclooctadiene (COD)** *[111-78-4, 1552-12-1]* **M 108.2, m –69.5°, –70°, b 51-52°/25mm, 97°/144mm, 150.8°/757mm, d_4^{20} 0.880, n_D^{20} 1.4935.** Purify it by GLC. It has been purified *via* the $AgNO_3$ salt. This is prepared by shaking with a solution of 50% aqueous $AgNO_3$ w/w several times (e.g. 3 x 50 ml and 4 x 50 ml) at 70° for *ca* 20 minutes to get a good separation of layers. The upper layers are combined and further extracted with $AgNO_3$ at 40° (2 x 20 ml). The upper layer (19 ml) of original hydrocarbon mixture gives colourless needles of the $AgNO_3$ complex on cooling. The adduct is recrystallised from MeOH (and cooling to 0°). The hydrocarbon is recovered by steam distilling the salt. The distillate is extracted with Et_2O, dried ($MgSO_4$), filtered, evaporated and distilled. [Jones *J Chem Soc* 312 *1954*, [*Beilstein* **5** H 116, **5** IV 403.]

Cyclooctanone *[502-49-8]* **M 126.2, m 42°, 43.8°, b 115-115.5°/60mm.** Purify the ketone by sublimation after drying an ethereal solution over Linde type 13X molecular sieves, filtering and evaporating. The *semicarbazone* has **m** 168-169° (from dioxane) [Kohler et al. *J Am Chem Soc* **61** 1060 *1939*]. The *oxime* has **m** 36-37° after subliming at high vacuum, or distillation, and has **b** 128-129° /14mm. The *iso-oxime* has **m** 72-73° [Ruzicka et al. *Helv Chim Acta* **32** 548 *1949*]. [*Beilstein* **7** III 77, **7** IV 49.]

1,3,5,7-Cyclooctatetraene *[629-20-9]* **M 104.2, m –5° to –3°, b 141-141.5°, d_4^{20} 1.537, n_D^{25} 1.5350.** Purify the triene by shaking 3ml with 20ml of 10% aqueous $AgNO_3$ for 15 minutes, then filtering off the $AgNO_3$ complex which precipitates. The precipitate is dissolved in water and added to cold concentrated ammonia to regenerate the cyclooctatetraene which is fractionally distilled under vacuum onto molecular sieves and stored at 0°. It is passed through a dry alumina column before use [Broadley et al. *J Chem Soc, Dalton Trans* 373 *1986*]. [*Beilstein* **5** I 228, **5** IV 1331.]

***cis*-Cyclooctene** *[931-87-3; 931-88-4]* **M 110.2, b 32-34°/12mm, 66.5-67°/60mm, 88°/141mm, 140°/170mm, 143°/760mm, d_4^{20} 0.84843, n_D^{20} 1.4702.** The *cis*-isomer is freed from the *trans*-isomer by fractional distillation through a spinning-band column, followed by preparative gas chromatography on a Dowex 710-Chromosorb W GLC column. It is passed through a short alumina column immediately before use [Collman et al. *J Am Chem Soc* **108** 2588 *1986*]. It has also been distilled in a dry N_2 glove box from powdered fused NaOH through a Vigreux column, then passed through activated neutral alumina before use [Wong et al. *J Am Chem Soc* **109** 4328 *1987*]. *Alternatively*, it can be purified *via* the $AgNO_3$ salt. This salt is obtained from crude cyclooctene (40 ml) by shaking at 70-80° with 50% w/w $AgNO_3$ (2 x 15 ml) to remove cyclooctadienes (aqueous layer). Extraction is repeated at 40° (4 x 20 ml, of 50% $AgNO_3$). Three layers are formed each time. The middle layer contains the $AgNO_3$ adduct of cyclooctene which crystallises on cooling the layer to room temperature. The adduct (complex 2:1) is highly soluble in MeOH (at least 1g/ml) from which it crystallises in large flat needles when cooled at 0°. It is dried under slight vacuum for 1 week in the presence of $CaCl_2$ and paraffin wax soaked in cyclooctene. It has **m** 51° and loses hydrocarbon on exposure to air. *cis*-Cyclooctene can be recovered by steam distillation of the salt, collected, dried ($CaCl_2$) and distilled in a vacuum. [Braude et al. *J Chem Soc* 4711 *1957*, $AgNO_3$: Jones *J Chem Soc* 1808 *1954*, Cope & Estes *J Am Chem Soc* **72** 1128 *1950*, *Beilstein* **5** I 35, **5** IV 263.] **FLAMMABLE LIQUID.**

***cis*-Cyclooctene oxide {(1r, 8c)-9-oxabicyclo[6.1.0]nonane}** *[286-62-4]* **M 126.7, m 56-57°, 57.5-57.8°, 50-60°, b 85-88°/17mm, 82.5°/22mm, 90-93°/37mm, 189-190°/atm.** It can be distilled in a vacuum, and the solidified distillate can be sublimed in a vacuum below 50°. It has a characteristic odour. [IR: Cope et al. *J Am Chem Soc* **74** 5884 *1952*, *cf trans-isomer*: Cope et al. *J Am Chem Soc* **79** 3905 *1957*, Reppe et al. *Justus Liebigs Ann Chem* **560** 1 *1948*].

Cyclopentadecanone (Exaltone) *[502-72-7]* **M 224.4, m 63°, 65°, 65-66°, b 155-157°/5mm.** Subliming Exaltone is better than crystallising it from aqueous EtOH for purification. The *semicarbazone* has **m** 186-187°. [Stevens & Erickson *J Am Chem Soc* **64** 146 1942, Mathur et al. *J Chem Soc* 3505 *1963*, Biens & Hess *Helv Chim Acta* **71** 1704 *1988*, *Beilstein* **7** III 203, **7** IV 118.]

Cyclopentadiene *[542-92-7]* **M 66.1, b 41-42°, pK^{25} 15.** Dry the diene with $Mg(ClO_4)_2$ and distil it rapidly

as it dimerises readily at room temperature. It should be used immediately or stored in a Dry Ice or an ice-salt bath. **HIGHLY FLAMMABLE.** [Moffett *Org Synth* Coll Vol **IV** 238 *1963*.] *Cyclopentadiene Dimer (4,7-methano-3a,4,7,7a-tetrahydroindene)* has [77-73-6], **M** 132.3, **m** 33°, **b** 170°/atm, and $\mathbf{d^{25}}$ 0.986; add ~0.05% of 2,6-di-*tert*-butyl-4-methylphenol as stabiliser. Cyclopentadiene is prepared when required by de-polymerising the technical grade dimer by heating (and distilling) it carefully under a fractionating column [Wilkinson *Org Synth* Coll Vol **IV** 467 *1963*], as described by Moffett (above reference), or by adding the dimer at a steady rate onto mineral oil heated at 240-270° when it distils off. [Korach et al. *Org Synth* **42** 50 *1962*]. [*Beilstein* **5** II 391.]

Cyclopentane *[287-92-3]* **M 70.1, b 49.3°, $\mathbf{d_4^{20}}$ 0.745, $\mathbf{n_D^{20}}$ 1.40645, $\mathbf{n_D^{25}}$ 1.4340.** Free it from cyclopentene by two passages through a column of dried and degassed activated silica gel. It occurs in petroleum and is **HIGHLY FLAMMABLE.** [NMR: Christl *Chem Ber* **108** 2781 *1975*, Whitesides et al. **41** 2882 *1976*, *Beilstein* **5** III 10, **5** IV 4.]

Cyclopentane carbonitrile *[4254-02-8]* **M 95.2, m -75.2°, -76°, b 43-44°/7mm, 50-62°/10mm, 67-68°/14mm, 74.5-75°/30mm, $\mathbf{d_4^{20}}$ 0.912, $\mathbf{n_D^{20}}$ 1.441.** Dissolve the nitrile in Et_2O, wash it thoroughly with saturated aqueous K_2CO_3, dry ($MgSO_4$) and distil it through a 10 cm Vigreux column. [McElvain & Stern *J Am Chem Soc* **77** 457 *1955*, Bailey & Daly *J Am Chem Soc* **81** 5397 *1959*, *Beilstein* **9** IV 14.]

Cyclopentanecarboxaldehyde *[872-53-7]* **M 98.1, b 36°/12mm, 74-78°/100mm, 140-141°/atm, $\mathbf{d^{25}}$ 0.919, $\mathbf{n_D^{20}}$ 1.4420-1.4428.** Several preparations of this aldehyde have been described but only two will be briefly mentioned here, and both start from cyclohexene. The ***first*** requires decomposition of the mercuric sulfate complex where, under N_2, concentrated H_2SO_4 (43.5ml, 80.0g, 0.82mole) in H_2O (3L) and $HgSO_4$ (740.0g, 2.49moles, CARE **POISONOUS**) are stirred to form the deep-yellow basic salt. To this stirred mixture, under N_2 at 55°, is added all at once cyclohexene (101ml, 82.0g, 1mole, freshly distilled b 82-84°/atm [110-83-8]), and the temperature kept at 55-65° for 1 hour (optimal conditions for decomposition of complex). The colour of the mixture turns from deep-yellow to cream. The equipment is altered for distillation at the end of the hour, and the temperature is raised, stirring and the N_2 flow are continued as the crude *aldehyde* and H_2O distil during *ca* 2 hours. The layers are separated, the H_2O layer is extracted with Et_2O (3 x 50ml) which is combined with the product, dried (Na_2SO_4), filtered, and distilled rapidly (b 74-78°/100mm) to give the *aldehyde* (46-52g, 46-53%), which if not used immediately should be stored in a brown bottle at 0° for under N_2, after 0.1g of hydroquinone is added as stabiliser. The *aldehyde* readily forms a *trimer*, and does so on prolonged storage. [Grummit et al. *Org Synth* Coll Vol **5** 320 *1973*, English et al. *J Am Chem Soc* **73** 615 *1951*.] When the distillation residue is cooled a solid may be formed which can be distilled above 78°/100mm to give a clear liquid that solidifies, and can be recrystallised from 95% EtOH to give a white solid **m 122-124°**, identical with ***cyclopentanecarboxaldehyde trimer*** obtained from the *aldehyde* and 85% H_3PO_4 [Brook & Wright *Can J Chem* **29** 308 *1951*].
In the ***second*** procedure, $Tl(III)(NO_3)_3\ 3H_2O$ (4.4g, 10mmol, TTN [13453-38-8]) is dissolved in MeOH (50ml), cyclohexene (10mmol) is added, and the mixture is stirred at room temperature or heated until a starch-iodide paper indicates complete reduction of Tl(III) to Tl(I) (usually within a few minutes). The mixture is filtered, and an alcoholic solution containing 10mmol of 2,4-dinitrophenylhydrazine is added. This is evaporated to 1/3 its volume and after addition of H_2O (10ml) the mixture is heated on a steam bath for 10 minutes. On cooling to 0°, the ***2,4-dinitrophenylhydrazone*** *[20956-07-4]* crystallises out and is recrystallised from EtOH to **m 195.5-196°** (85% yield). Hydrolysis of the hydrazone in the usual way provides the free *aldehyde*. On a preparative scale the precipitated $Tl(I)(NO_3)$ salt is filtered off, the filtrate is evaporated to a small volume, the mixture of aldehyde and its methyl acetal formed is heated on a steam bath with excess of 5% H_2SO_4 for 30 minutes, and *cyclopentanecarboxaldehyde* is isolated by ether extraction followed by distillation as in the first preparation above. [Taylor et al. *J Am Chem Soc* **95** 3635 *1973*.] It should be stabilised with 0.1% of hydroquinone as before.

Cyclopentane carboxylic acid *[3400-45-1]* **M 114.1, m 3-5°, b 87-89°/2-3mm, 106.5-107°/10mm, 120-123°/27mm, 216°/atm, $\mathbf{d^{25}}$ 1.053, $\mathbf{n_D^{20}}$ 1.4530, $\mathbf{n_D^{25}}$ 1.4522, $\mathbf{pK^{25}}$ 4.98.** If it is discoloured, shake it with saturated aqueous NaCl, extract it with Et_2O, dry the extract ($MgSO_4$), filter, evaporate and distil the residue preferably under a vacuum. The **lachrymatory** *acid chloride [4524-93-0]* has **M** 132.6, **m** 4° and **b** 161-162°/

atm, **d** $_4^{20}$ 1.091, **n** $_D^{20}$ 1.4622. [*Beilstein* **9** H 6, **9** IV 11.] The *amide [3217-94-5]* has **m** 179°. Like the methyl ester below, the acid can also be prepared *via* a Favorskii reaction, but by using a little over 2 moles of alkoxide (1mol provides the ester). Thus, to sodium (83g, 3.61mol) in absolute EtOH (2.3L) is added dropwise 2-chlorocyclohexanone (240.5g, 1.82mol, [822-87-7]) during several hours, left overnight, the EtOH is distilled off, replaced by an equal volume of H_2O, acidified to pH 3, and the oily acid that separates is extracted with Et_2O. The extract is washed with H_2O, dried (Na_2SO_4), filtered, and distilled to give the pure *acid* (110g, 53%). [Jackman et al. *J Am Chem Soc* **70** 497 *1948*, Mourisson et al. *Bull Soc Chim Fr* 767 *1952*.] [*Beilstein* **6** H 6, **6** I 4, **6** II 6, **6** III 11, **6** IV 9.]

Methyl cyclopentanecarboxylate, *[4630-80-2]* **M 128.1, b 70-73°/48mm, 38-39°/7mm, 158.2°/760mm, n** $_D^{25}$ **1.4341**, can be obtained by reacting the acid chloride with MeOH and distilling; but it can also be obtained in ~55% yield directly from 2-chlorocyclohexanone and NaOMe (1mol) in dry Et_2O, *via* a Favorskii reaction, and purified by fractional distillation, using a Podbielniak column filled with tantalium wire spirals and a partial reflux head, under reduced pressure [Goheen & Vaughan *Org Synth* Coll Vol **4** 594 *1963*]. The *methyl ester* has also been prepared in 98% yield by direct esterification of cyclopentane carboxylic acid with MeOH in CH_2Cl_2 in the presence of H_2SO_4. The acid has FTIR (CCl_4) with ν_{max} at 2952(s), 2873 (m), 1734 (s), 1436 (w), 1165 (s) and 1140 (s) cm^{-1}; ^1H NMR (75MHz, $CDCl_3$, TMS) with δ at 1.5-2.0 (m, 8H, 4-methylenes), 2.7 (pentet, 1H, *J* = 9.0Hz), 3.7 (s, 3H, Me); ^{13}C NMR (300MHz, $CDCl_3$, TMS) with δ at 25.7, 29.9, 43.6, 51.5, 177.2, and the GCMS has *m/z* at 128 (M^+) [Davis et al. *J Org Chem* **58** 6843 *1993*].

1,1-Cyclopentanediacetic acid (3.3-tetramethyleneglutaric acid) *[16713-66-9]* **M 186.2, m 176-177°, 180-181°, pK** $_1^{25}$ **3.80, pK** $_2^{25}$ **6.77.** Purify it by recrystallisation from H_2O and dry it in air, *in vacuo* or over $CaCl_2$. However, if it is suspect it is better to convert the acid to the anhydride (8-oxaspiro[4.5]decane-7,8-dione, [5662-95-3], **m 64-66° (68°** also reported), **b 186°/15mm**) by refluxing it for 7 hours in excess of Ac_2O, evaporating to dryness, and distilling the residue in a vacuum or recrystallising it from light petroleum. [Kon & Thorpe *J Chem Soc* **115** 701 *1919*.] The anhydride (e.g. 30g) is then hydrolysed by refluxing it for 2.5 hours (i.e. until it dissolves) in aqueous KOH (35g, 3mols in 55ml of H_2O), then acidified with concentrated HCl, extracted with Et_2O (3 x 50ml) after saturating the aqueous solution with $(NH_4)_2SO_4$, drying the extract (Na_2SO_4), filtering, evaporating the Et_2O and recrystallising the *diacid* from hot H_2O. [Vogel *J Chem Soc* 1761 *1934*.] The *dimethyl ester [70179-60-3]* has **b 141°/17mm** [Vogel *J Chem Soc* 1761 *1934*, Dickins et al. *J Chem Soc* 1503 *1922*], and the *diethyl ester* has **b 153°/14mm** [Kon *J Chem Soc* 525 *1922*]. [*Beilstein* **9** I 319, and anhydride *Beilstein* **17/11** V 80.]

Cyclopentane-1,1-dicarboxylic acid *[5802-65-3]* **M 158.1, m 183°, 184°, (176-178°), pK$_1$ 3.23, pK$_2$ 4.08.** The dicarboxylic acid can be prepared in 71% yield by using the nickel(0) catalyst *2-{2-[2-(dicyclohexyl-phosphino)ethyl]pyridine}-4-oxo-2-nickela-3-oxa-cis-bicyclo[3.3.0]octane* which promotes the di-carbonylation of cyclopentene (1.16g, 2.44mmol) in THF (30ml)/pyridine (30ml), in the presence of BeCl (0.2g, 2.50mmol), by CO_2 (10 bar pressure) in an autoclave, and stirring at 60° for 24 hours. The solvent is evaporated off *in vacuo*, the residue is treated with Et_2O/HCl and the solid is collected, dried and recrystallised from pentane/Et_2O (10:1), or H_2O. The pure *dicarboxylic acid* melts at 183° with decarboxylation to *cyclopentanecarboxylic acid* (see preceding acid), and has FTIR (KBr) with ν_{max} at 3200-2500 (CO**OH**) and 1700 (C=O) cm^{-1}; ^1H NMR (200MHz, THF-d_8/TMS) with δ at 1.6 (m, 4H, 2-methylenes), 2.1 (m, 4H, 2-methylenes), 9.6 (br, 2H, 2-COO***H***) ppm; ^{13}C NMR (50MHz, THF-d_8/TMS) with δ at 26.3 (t), 35.2 (t), 60.6 (s), 174.2 ppm; and the MS (70 eV) has *m/z* at 158 (M^+). [Hoberg et al. *Synthesis* 395 *1991*]. ***Dimethyl 1,1-cyclopentanedicarboxylate*** *[74090-15-6]* **M 186.2, b 102°/10mm,** can be prepared in 76% yield from the preceding *methyl cyclopentanecarboxylate* (40mmol, [*4630-80-2*]) in THF (60ml), with (^{i}Pr)$_2$NH (60mmol) and *n*-BuLi (60mmol) followed by MeOCOCl (60mmol), and finally distilling. The *dimethyl ester* has FTIR (CCl_4) with ν_{max} at 2953(s), 2928 (w), 2876 (w), 1736 (s), 1434 (w), 1266 (s), 1165 (s) and 1159 (m) cm^{-1}; ^1H NMR (300MHz, $CDCl_3$, TMS) with δ at 1.7 (m, 4H, 2-methylenes), 2.1 (m, 4H, 2-methylenes), 3.7 (s, 6H, 2-Me) ppm; ^{13}C NMR (75MHz, $CDCl_3$, TMS) with δ at 25.3, 34.5, 52.4, 60.2, 173.0 ppm, and the GCMS has *m/z* at 187 (M^++1) [Davis et al. *J Org Chem* **58** 6843 *1993*].

***1RS,2SR*-(meso)-*cis*-1,2-Cyclopentanedicarboxylic acid** *[1461-96-7]* **M 158.2, m 139°, 140°, 141°, pK** $_1^{20}$ **4.42, p K** $_2^{20}$ **6.57.** The *cis*-acid has been prepared by hydrogenation of cyclopent-1-ene-1,2-dicarboxylic acid with Pt as catalyst [Peters *J Chem Soc* 1757 *1959*], heating diethyl 1-cyanocyclopentane-1,2-dicarboxylate (b

135-136°/3.5mm) with aqueous HCl and isolating the anhydride [Fuson & Cole *J Am Chem Soc* **60** 1237 *1938*, Dutta *J Indian Chem Soc* **17** 611, 617 *1940*], but is best prepared by boiling the *trans*-acid with excess of acetic anhydride for at least 2 hours (which provides the *cis-anhydride*), dissolving this in boiling H_2O or aqueous KOH with cooling (**care**, may be exothermic), and acidifying to pH ~2 in order to precipitate the *cis*-acid. The *cis*-acid crystallises from hot H_2O as colourless needles melting at 140°, and is rapidly converted to the *cis-anhydride* at 150-160°. The *cis*-acid is also obtained from the *trans*-acid by heating at 300 ° [Perkin Jnr *J Chem Soc* **51** 247 *1887*, Perkin Jnr *J Chem Soc* **65** 527 *1894*]. It is more soluble in H_2O than the (±)-*trans*-acid. It had not been possible to prepare *trans*-cyclopentane-1,2-dicarboxylic anhydride because all attempts gave the ***cis-anhydride*** (*cis*-**tetrahydro-*1H*-cyclopent[*c*]furan-1,3(*3aH*)-dione**, **m 73.5-74°, b 100-102°/1.5mm,** *[5763-49-5]*). [Perkin Jnr *J Chem Soc* **65** 588 *1894*, cf Fuson & Cole *J Am Chem Soc* **60** 1237 *1938*, Goldsworthy & Perkin Jnr *J Chem Soc* **105** 2639 *1914*.]. The nickel(0) catalyst *2-{2-[2-(dicyclohexylphosphino)ethyl]pyridine}-4-oxo-2-nickela-3-oxa-cis-bicyclo[3.3.0]octane* promotes the carbonylation of cyclopentene in THF by CO at 1bar pressure and –40°, then at ~25°/10 hours followed by treatment with 2N H_2SO_4 and recrystallisation from pentane/Et_2O (10:1), which provides cyclopentane-1,2-dicarboxylic acid (78% yield) presumed to be mainly the *cis-isomer*. However, its melting point of 124-125° suggests that it must be contaminated with some of the *trans*-isomer [Hoberg et al. *Synthesis* 395 *1991*]. Its FT-IR (KBr) has ν_{max} at 3300-2500 (CO**OH**) and 1710 (C=O) cm^{-1}; its ^1H NMR (200MHz, THF-*d*8/TMS) has δ_H at 10.4 (br s, 2H, OH), 2.9 (m, 2H, 2CH), 1.51-2.1 (m, 6H, $3CH_2$), 1.69 (m, 4H); its ^{13}C NMR (200MHz, THF-*d*8/TMS) has δ_C at 176.10 (s, carboxylic C), 47.5 (d, C1 and C2), 29.4 (t, C-3 and C-5) and 24.4 (t, C-4); and its MS (70 eV) has *m/z* = 158 (M^+), see GC-MS [below, Lu et al. *J Org Chem* **55** 2503, 2507 *1990*]. **Dimethyl *cis-cyclopentane-1,2-dicarboxylate*, b 129°/20mm, n_D^{21} 1.4528,** *[4841-91-2]*, is obtained by treating the acid with diazomethane in Et_2O, evaporating and distilling the residue [Owen & Peto *J Chem Soc* 2383, 2386 *1955*]. The ***cis-imide*** (*cis*-**tetrahydrocyclopent[*c*]pyrrole-1,3(*2H*,*3aH*)-dione**, *[5763-44-0]*) has **m 85-87° (**also **90°** reported**)** after recrystallisation from H_2O or petroleum ether (b 40-60°) [Menon & Simonsen *J Chem Soc* 302 *1929*, Rice et al. *J Org Chem* **24** 7 *1959*], and *cis-**cyclopentane-1,2-dicarboxylic acid dihydrazide***, prepared from the dimethyl ester and NH_2NH_2. H_2O in EtOH and recrsystallised from MeOH/Et_2O, has **m 125-126°** [Müller et al. *J Am Chem Soc* **73** 2489 *1951*]. [*Beilstein* **9** H 728, **9** III 3807, **9** IV 3793.]

1RS,2RS*-(±)-*trans*-1,2-Cyclopentanedicarboxylic acid** *[1461-97-8]* **M 158.2, m 160-161°, 161.5°, 162°, 162-163°, 163°, 163-165°, 164-165°, pK_1^{20} 4.14, pK_2^{20} 5.99.** Several syntheses of the (±)-*trans*-acid have been described. The first preparation involved tetraethyl cyclopentane-1,2,3,4-tetracarboxylate [b 185-190°/1mm, from trimethylene-1,3-dibromide (96g), Na (22g) and diethyl malonate (150g) in absolute EtOH (300ml)] which was refluxed with 2-3 volumes of AcOH, 1 volume of concentrated H_2SO_4 and 1 volume of H_2O for 2 days, and the AcOH and H_2O were distilled off to give *trans*-cyclopentane-1,2-dicarboxylic acid [Perkin Jnr *J Chem Soc* **65** 587 *1894*, Perkin Jnr *J Chem Soc* **51** 224 *1887*, Wassermann *Helv Chim Acta* **13** 207 *1930*, Perkin Jnr & Prentice *J Chem Soc* **59** 828 *1891*]. Other preparations include heating the *cis*-acid with concentrated HCl at 180° [Perkin Jnr *J Chem Soc* **65** 577, 590 *1894*], refluxing diethyl 1-cyanocyclopentane-1,2-dicarboxylate with concentrated aqueous HCl for 4 days which provided a 92% yield of the *trans*-acid [Fuson et al. *J Org Chem* **10** 121, 126 *1945*, Fuson & Cole *J Am Chem Soc* **60** 1237 *1938*], and electrochemical coupling between 1,3-dibromopropane and dimethyl maleate which gave a 10/1 ratio of *trans*/*cis* dimethyl esters in 42% yield [Lu et al. *J Org Chem* **55** 2503, 2507 *1990*]. Invariably the crude *trans*-diesters formed are contaminated with some *cis*-isomer and it was found that hydrolysing the ester mixture by refluxing the acidic solution for 4 to 5 days provided only the *trans*-acid in ~95% yields. The *trans*-acid crystallises (charcoal) from hot H_2O, and it is easily soluble in AcOH, and EtOH, but very soluble in Et_2O, $CHCl_3$, $*C_6H_6$ and petroleum ether. Its FT-IR (Nujol)) has ν_{max} at 3008.3, 2653.8, 1692.6, 1419.2, 1311.1, 1253.5, 1199.3, 935.7 and 689.4 cm^{-1}; its ^1H NMR (60MHz, $CDCl_3$) has δ_H at 12.2 (br s, 2H, OH), 2.96 (m, 2H, C1 and C2 methines), 1.99 (m, 2H,), 1.69 (m, 4H); its ^{13}C NMR (75MHz, $CDCl_3$) has δ_C at 176.10 (s, carboxylic C), 46.77 (s, C1 and C2), 30.03 (s, C3 and C5) and 25.01 (s, C-4); and its GC-MS has *m/z* (relative intensity) *trans*-isomer: 157(37, M^+ -2), 155(15), 126(67), 113(29), and 67(100), and *cis*-isomer: 157(6, M^+-2), 155(40), 126(32), 113(56), and 67(100) [Lu et al. *J Org Chem* **55** 2503, 2507 *1990*]. ***Dimethyl** trans-**cyclopentane-1,2-dicarboxylate*, b 118.5-119°/17mm, n_D^{20} 1.4491,** *[941-75-3]*, is obtained by treating the acid with diazomethane in Et_2O, evaporating and distilling the residue [Owen & Peto *J Chem Soc* 2383, 2386 *1955*]. *trans-**cyclopentane-1,2-dicarbonyl dichloride, has **b 98-100°/2mm** [Aspinall & Baker *J Chem Soc* 743, 747 *1950*], and *trans-**cyclopentane-1,2-dicarboxylic acid***

dihydrazide, prepared from the dimethyl ester and NH_2NH_2. H_2O in EtOH, and recrystallised from EtOH, has **m 224-225°** [Müller et al. *J Am Chem Soc* **73** 2489 *1951*]. [*Beilstein* **9** H 728, **9** I 316, **9** III 3807, **9** IV 2793.]

1S,2S*-(+)-*trans*-1,2-Cyclopentanedicarboxylic acid** *[21917-20-4]* **M 158.2, m 181°, $[\alpha]_D$ +87.6° (c 0.88, H_2O)** and ***1R,2R*-(–)-*trans*-1,2-cyclopentanedicarboxylic acid** *[17224-73-6]* **m 180-181°, $[\alpha]_D$ –85.9° (c 1.2, H_2O).** Optical resolution of the (±)-acid (above) is readily achieved *via* separation of the diastereoisomeric brucine salts (the base being *l*-brucine). Thus pure (±)-acid (15g, ~0.1mole) is dissolved in hot H_2O, and while stirring, the finely powdered brucine tetrahydrate (90g, 0.2 moles, [5892-11-5], care **POISONOUS**) that is added gradually dissolves. At the end of the addition, the mixture is stirred for ~10 minutes and filtered hot from a small amount of undissolved brucine. The brucine is washed well with hot H_2O, and the combined filtrate and washings are concentrated on a boiling water bath until crystals commence to form on the surface. When the liquid is cooled and vigorously stirred, copious crystals of the *d*-acid (*l*-base)$_2$ separate, and the whole mixture sets into a mass of crystals. These are filtered off and recrystallised from hot H_2O to constant specific rotation. An analytical sample of the *d*-acid (*l*-base)$_2$ is obtained by dissolving it in hot H_2O and allowing it to crystallise slowly in a desiccator over concentrated H_2SO_4. The decahydrate is obtained on drying the crystalline plates in air but they effloresce in a vacuum desiccator or on heating at 125° for 1 hour to give *anhydrous* ***d*-acid (*l*-base)$_2$** that has **$[\alpha]_D$ –19.9° (c 1.3, H_2O).** The *d*-acid (*l*-base)$_2$ is then decomposed by dissolving it in hot H_2O, adding aqueous ammonia, filtering off the solid brucine, washing it well with aqueous ammonia, and the combined hot filtrate and washings are cooled and acidified with hydrochloric acid. On cooling the **(+)-*acid (m 178-180°) separates and recrystallises from hot H_2O as plates with m 180°. ***Diethyl 1S,2S-(+)-trans-1,2-cyclopentanedicarboxylate*** **b 170°/100mm, $[\alpha]_D$ +70.3° (c 1.3, Me_2CO)**, is prepared by boiling the (+)-acid with 5 times its weight of 10% ethanolic H_2SO_4 for 6 hours, cooling, adding H_2O, the ester is extracted into Et_2O which is washed with dilute Na_2CO_3, dried (Na_2SO_4), filtered, evaporated and the residue is distilled in a vacuum. The ***1S,2S-(+)-trans-dianilide*****, m 245-247°, $[\alpha]_D$ +110.1° (c 0.85, Me_2CO)** is prepared by heating the (+)-acid with $SOCl_2$ in a sealed tube at 100° for 1 hour, evaporating, the di-acid chloride formed is then dissolved in $*C_6H_6$, treated with excess of aniline, evaporated again, the residue is stirred with dilute aqueous HCl, the precipitate is collected and recrystallised twice from large volumes of MeOH.
1R,2R-(–)-trans-1,2-cyclopentanedicarboxylic acid is obtained by concentrating the mother liquors from the first crystallisation of the *d*-acid (*l*-base)$_2$ above, which provides copious crystals of the more soluble ***diastereoisomeric l*-acid (*l*-base)$_2$**. Treatment of this salt with aqueous ammonia as above followed by recrystallisation from H_2O gives the pure ***(–)-acid*** with m 180-181°. ***Diethyl 1R,2R-(-)-trans-1,2-cyclopentanedicarboxylate*****,** prepared in the same way as its enantiomer above has similar properties except for the optical rotation which is **$[\alpha]_D$ -69.8° (c 1.7, Me_2CO)**. [Goldsworthy & Perkin Jnr *J Chem Soc* **105** 2639 *1914*]. [*Beilstein* **9** I 316] The absolute configuration of the ***(-)-acid*** was determined as ***1R,2R*** by comparing the ORD spectra of the respective 1,2-bis(N-methylthionamide) [1,2-(CSNHMe)$_2$] with those of the corresponding 1,2-disubstituted cyclopropane, cyclobutane and cyclohexane homologues [Inoue et al. *Tetrahedron* **23** 3237 *1967*]. [*Beilstein* **9** III 3807.]

***1RS,2SR-cis*-1,2-Cyclopentanediol (*meso-cis*-cyclopentane-1,2-diol)** *[5057-98-7]* **M 102.1, m 24-28°, 30°, b 88-92°/2mm, 108-109°/20mm, 123.5°/29mm, n_D^{21} 1.4770.** The *cis*-diol can be obtained by treating cyclopentene (21.8g, [142-29-0]) in EtOH (600ml) at –40° with a solution of $KMnO_4$ (40g) and anhydrous $MgSO_4$ (30g) in H_2O (800ml) dropwise, with vigorous stirring, during 2 hours. The MnO_2 is filtered off, washed with hot H_2O, the combined aqueous filtrates are evaporated *in vacuo* to 100ml and continuously extracted with Et_2O (liquid-liquid extractor) for 48 hours. The dried ($MgSO_4$) Et_2O extract is evaporated and the residual oil is distilled to give the *cis*-diol (11.1g, 34%). The cis-*di-p-nitrobenzoate* has **m 117° (117-118°)** (from EtOH) the cis-*di-methanesulfonate* has **m 82°** (needles from MeOH), and the cis-*di-toluene-p-sulfonate* has **m 92°** (prisms from EtOH) are obtained in the usual way in pyridine. The *cis-monoacetate* has **b 104-106°/20mm, n_D^{17} 1.4576**, the *cis-monoacetate-mono-p-nitrobenzoate* has **m 93-94°** (nodules from EtOH), and the *cis-diacetate* has **m –5°, b 80°/2mm**. The *cis-dibenzoate* has **m 47°**. [Owen & Smith *J Chem Soc* 4026 *1952*, *Beilstein* **6** I 369, **6** II 742, **6** III 4053, **6** IV 5187.]

***1RS,2RS*-(±)-*trans*-1,2-Cyclopentanediol [*trans*-(±)-cyclopentane-1,2-diol]** *[5057-99-8, (±) 86703-52-8]* **M 102.1, m 50°, 55°, b 93°/2mm, 122°/10mm, 136°/22mm.** The *cis*-diol can been prepared in a seven step synthesis from *racemic* diethyl tartrate [Cunningham & Kündig *J Org Chem* **53** 1823 *1988*], from *trans*-2-tri-

methylsilylcyclopentan-1-ol and MeOH [Kono & Ngai *Org Prep Proced Int* **6** 19 *1974*], and by performate oxidation of cyclopentene which is described herein. A mixture of 30% aqueous H_2O_2 (13g) and formic acid (105g) is added to cyclopentene (6.6g, b 44-45°/atm [142-29-0]) under a reflux condenser, when much heat is generated, the temperature is allowed to fall to 40° and is so maintained for 4 hours. The solvent is removed *in vacuo*, the residue is dissolved in 10% aqueous NaOH (50ml), boiled under reflux for 45 minutes, the solvent is distilled off, and the residue is twice distilled under reduced pressure to give pure *trans*-pentane-1,2-diol (6g, 60%) which solidified in the distillate. The *trans-dibenzoate* has **m 63°**, and the *trans-(±)-di-p-nitrobenzoate* **(m 145°**, from EtOH), the *trans-(±)-di-methanesulfonate* **(m 82°,** small needles from EtOH), and the *trans-(±)-di-p-toluenesulfonate* **(m 109°**, colourless plates from MeOH) are prepared in the usual way in pyridine. [Owen & Smith *J Chem Soc* 4026 *1952*, Englund *J Prakt Chem* **129** 1, 10 *1931*, *Beilstein* **6** H 739, **6** I 369, **6** II 743, **6** III 4053, **6** IV 5187.]

1R,2R*-(–)-*trans*-1,2-Cyclopentanediol [*trans-(-)*-cyclopentane-1,2-diol]** *[(–) 930-46-1, (-)86703-52-8]* **M 102.1, m 48-48.5°, $[\alpha]_D^{20}$ –24.88° (c 6, EtOH)** and ***1S,2S-trans*-1,2-cyclopentanediol [*trans*-(+)-cyclopentane-1,2-diol]** *[(+)107492-82-0], m 47-48°, $[\alpha]_D^{20}$ +24.54° (c 5.4, EtOH).** The *1R,2R-enantiomer* is obtained optically pure in a seven step synthesis from diethyl D(-)tartrate by benzylation (TlOEt/$PhCH_2Br$, 81%), reduction (LAH/Et_2O, 94%) to *2R,3R-(–)-2,3-bis(benzyloxy)-1,4-butanediol*, ditosylation (TsCl/py, 87%), dibromination (with LiBr/DMSO, 94%) to *2R,3R-(–)-2,3-bis(benzyloxy)-1,4-butanedibromide*, formation of the cyclopentane ring ($PhSO_2CH_2SO_2Ph/K_2CO_3$/DMF, 92%) to give *1R,2R-(–)-1,2-bis(benzyloxy)-4,4-bis(phenylsulfonyl)cyclopentane*. Removal of the bis-sulfonyl groups (Mg/MeOH, 82%) provide *1R,2R-(–)-1,2-bis(benzyloxy)cyclopentane*, and finally debenzylation (H_2/10% Pd/C, 99%) provides pure 1*R*,2*R*-(-)-cyclopentane-1,2-diol in 47% overall yield. The final step only is detailed here. The mixture of *trans-(–)*-1,2-bisbenzyloxycyclopentane (5.11g, 18.1mmol) in EtOH (35ml) containing 10% Pd/C (1.35g) is degassed three times, H_2 gas is introduced into the flask at a pressure of 6 atmospheres for 5 hours, the catalyst is filtered off, and the filtrate is evaporated to provide the 1*R*,2*R*-*trans*-(–)-diol (8.2g, 99%) as a white hygroscopic solid m 47-48° which should be stored under dry N_2 in a sealed vessel. The enantiomeric 1*S*,2*S*-*trans*-(–)-diol can be prepared in 40% overall yield from diethyl L(+)-tartrate *via* the same high yielding steps. Its IR (CH_2Cl_2) has ν_{max} at 3600, 3390br, 2920, 1450, 1280, 1075, 1040 and 970 cm^{-1}; and its ^1H NMR (200MHz, $CDCl_3$, TMS) with δ at 3.93-4.06 (m, 2H), 2.24 (s, 2H, exchanges with D_2O), 1.86-2.12 (m, 2H), 1.63-1.80 (m, 2H) and 1.42-1.62 (m, 2H). The enantiomers are >96% enantiomerically pure. The **1*R*,2*R*-*(–) [113350-86-0]*** and **1*S*,2*S*-*(+) [113303-27-8]* 1,2-bis(dimethoxyphosphinoxy)cyclopentane** derivatives, prepared from the respective diols ($2NEt_3/2(MeO)_2PCl$, in 80% and 73% yields respectively), are yellow oils with **b 120°/0.1mm** and **$[\alpha]_D^{20}$ –41.39°** and **+41.78° (c 4.8, CH_2Cl_2)**. The **1*R*,2*R*-*(–) [113303-35-8]*** and **1*S*,2*S*-*(+) [113303-28-9]* 1,2-bis(difluorophosphinoxy)cyclopentane** derivatives, prepared from the respective diols (PCl_3 in CH_2Cl_2/SbF_3 in pentane, 49% and 48% respectively) are mobile oils with **b 58°/80mm** and **$[\alpha]_D^{20}$ –12.22°** and **+12.96° (c 4.8, CH_2Cl_2)**. [Cunningham & Kündig *J Org Chem* **53** 1823 *1988*].

1,2-Cyclopentanedione *[3008-40-0]* **M 98.1, m 55-56°, 56°, b 67-69°/1.4mm, 87-88°/16mm, 97°/20mm, 105°/20mm, pK^{20} 9.14 (H_2O).** The dione has a weak amine-like odour and is soluble in H_2O, EtOH, and Et_2O, but poorly soluble in petroleum ether and CS_2, and is steam volatile. It has been prepared by various routes from cyclopentanone *via* oxidation by SeO_2 (23%) [Goto et al. *Bull Chem Soc, Jpn* **52** 2589 *1952*], conversion to the α-methylthio ether then oxidation with $CuCl_2$/CuO (42%) [Gregoire et al. *J Org Chem* 51 1419 1986], and autooxidation with O_2/*t*-BuOK/DME-*t*-BuOH (35.7%). Only the first is described because of its simplicity. *The following procedure should be carried out in a well-ventilated fume cupboard as selenium compounds have foul odours.* To cyclopentanone (1.5L) warmed at 30° is added dropwise, with stirring, a solution of selenium dioxide (361g, 3.25ml) in dioxane (420ml) and H_2O (155ml) during 24 hours, and stirring is continued for a further 18 hours at 35°. The red selenium that is formed is filtered off (Buchner) and extracted with EtOH (500ml) by boiling for 3 hours. The liquids are combined and distilled through a 60cm Vigreaux column at 20mm, the lower boiling portion (b 35-90°) is removed, and the remainder is distilled at 10mm until a thick brown residue is left in the distilling flask. This distillate is redistilled, and the fraction with b 86-88°/16mm is collected to give pure *1,2-dione* (74g, 23% based on SeO_2 used) which solidifies (m 56-58°). It should be stored at –30° under N_2, in the dark. Cyclopentane-1,2-dione has IR (NaCl) with ν_{max} at 1650 (C=C), 1700 (C=O), 3300 (OH enol) cm^{-1}; ^1H NMR (400MHz, CCl_4, TMS) with δ at 2.20-2.67 (m, 4H, 2-methylenes), 6.47-6.62 (m, 1H, C=C*H*), 6.93-7.36 (m, 1H, C=CO*H*); ^{13}C NMR (100MHz, $CDCl_3$, TMS) with δ 22.01, 32.58, 131.36, 153.62, 187.53.

In ethanolic solution the '*dione*' is almost entirely in the ***mono-enol***-form which slowly tautomerises to a mixture containing ~9% of the ***diketo-***form after 36 hours at 50°. The UV in hexane has λ_{max} (log ε) at 246nm (4.003) and 300nm (1.900) due mostly to the ***diketo***–form, whereas in 0.05N aqueous NaOH it has λ_{max} (log ε) at 288nm (3.383) due to the ***enol***-form [Hesse & Krebbiel *Justus Liebigs Ann Chem* **563** 35 *1934*].
Cyclopentane-1,2-dione dioxime (see above [6635-29-6]) decomposes at ~210° after recrystallisation from H_2O, and a 0.01M aqueous solution of it is used for the gravimetric determination of Ni. [Voter et al. *Anal Chem* **21** 1320 *1949*.] The *bis-phenylhydrazone* has **m 146°**.

1,3-Cyclopentanedione *[3859-41-4]* **M 98.1, m 149-150°, 151-152.5°, 151-154°, 151-153°, pKa 4.5.** Purify the dione by Soxhlet extraction with $CHCl_3$. The $CHCl_3$ is evaporated and the residue is recrystallised from EtOAc and/or sublimed at 120°/4mm. [IR: Boothe et al. *J Am Chem Soc* **75** 1732 *1953*, DePuy & Zaweski *J Am Chem Soc* **81** 4920 *1959*, *Beilstein* **7** IV 1981.]

Cyclopentanol *[96-41-3]* **M 86.1, m –20°, –19.5°, b 53°/10mm, 56.9-57.4°/34mm, 139.5°/752mm, 140.85°/760mm, d_4^{20} 0.9478, n_D^{20} 1.4531.** Cyclopentanol has been prepared by hydration of cyclopentene, or from cyclopentanone (see next entry) by catalytic reduction with H_2 (Ni/MeOH, Ra-Ni/EtOH, PtO_2, Pt-black in EtOH or AcOH, Cu-chromite), $Al(isoPrO)_3$/NaOH, LAH/Et_2O or $NaBH_4$ in MeOH or H_2O. The last named has many advantages in ease of use and efficiency. Thus cyclohexanone in H_2O (solubility is 15% at 10°, 8.7% at 20°, 5% 30°) is stirred with excess of $NaBH_4$ (theoretically 0.25 mol/mol ketone) at room temperature until the reaction is complete (addition of a drop of dilute HCl causes effervescence). The pH of the solution is adjusted to ~3-4, NaCl is added to almost saturation and the alcohol is extracted several times with Et_2O, dried (K_2CO_3), filtered, and the filtrate is distilled to give cyclopentanol in ~90% yield. [Chaikin & Brown *J Am Chem Soc* **71** 122 *1949*]. Its FT-IR (neat) has ν_{max} at 3334.9 (br OH), 2959.6 (CH), 1437.2 (OH ?), 1341.3, 1282.9, 1174.3, 1073.7, 994.3, and 837.1 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.55 (m, 4H, C-3 and C-4 -methylenes), 1.75 (m, 4H, C-2 and C-5 -methylenes), 2.30 (s, 1H, H-1) and 4.30 (brs, 1H, OH); and its ^{13}C NMR (15MHz, $CDCl_3$, TMS) has δ at 23.32 (C-3,4), 35.51 (C-2,5) and 73.86 (C-1). At atmospheric pressure cyclopentanol forms azeotropes with H_2O (96.3°, 42%), tetrachloroethylene (118.8°, 8%), chlorobenzene, *m*-xylene (132.8°, 40%), *p*-xylene (132.8°, 38%), *n*-Bu_2O (139.0°, 75%), among other solvents. It can be characterised as the *4-nitrobenzoate* (**m 56°**), *3,5-dinitrobenzoate* (**m 123°**), and *phenylcarbamate* (**m 137-138°**). [*Beilstein* **6** H 5, **6** I 3, **6** II 3, **6** III 4, **6** IV 5.]

Cyclopentanone (dumasine, adipic ketone) *[keto-form 120-92-3, enol-form 59557-02-7]* **M 84.1, m –58°, b 130°/atm, d_4^{20} 0.947, n_D^{20} 1.4366, n_D^{25} 1.4340. pK^{25} 16.7.** This is a flammable liquid (flash point 26-31°) with a pleasant odour, but which is a strong **SKIN** and **EYE IRRITANT**, and should be used in a well ventilated fume cupboard. It is sparingly soluble in H_2O, and forms explosive mixtures with HNO_3 and H_2O_2. It is volatile with Et_2O and care should be taken that careful fractionation is require when it is extracted with Et_2O. It is prepared by heating, in a distilling flask, a powdered mixture of adipic acid (200g, 1.34moles) and ground $Ba(OH)_2$ (10g) in a metal bath (e.g. Wood's metal) to 285-295° during 1-1.5 hours. [The temperature is best controlled with the thermometer within 5mm above the bottom of the flask and the temperature held as near as 290° as possible to minimising the amount of adipic acid which distils off.] During the heating period, the *cyclopentanone* distils slowly with small quantities of adipic acid, and after a further 2 hours of heating a very small amount of dry residue remains in the flask. The distillate is separated from some H_2O and adipic acid by salting out with K_2CO_3, washed with H_2O, dried over $CaCl_2$ or anhydrous K_2CO_3, filtered and fractionated through an efficient column; fraction with b 128-131°/atm of the pure *ketone* (86-92g, 75-80%) is collected. [Thorpe & Kon *Org Synth* Coll Vol **1** 192 *1932*.] If cyclopentanone has been standing for a while, it can be purified by shaking it with aqueous $KMnO_4$ to remove materials absorbing around 230 to 240nm. Dry it over Linde-type 13X molecular sieves and fractionally distil it. It has also been purified by conversion to the $NaHSO_3$ adduct which, after crystallising four times from EtOH/water (4:1), is decomposed by adding to an equal weight of Na_2CO_3 in hot H_2O. The free cyclopentanone is steam distilled from the solution. The distillate is saturated with NaCl and extracted with *benzene (do not use H_2O, see above) which is then dried (anhydrous K_2CO_3), filtered and evaporated. The residue is then distilled [Allen, et al. *J Chem Soc* 1909 *1960*]. Its FT-IR (NaCl) has ν_{max} at 2966 (CH), 1746.4 (C=O), 1407.6 (OH enol ?), 1278.2, 1153.0, 959.2, 834.2,

582.2 and 471.7 cm^{-1}; the ^1H NMR (15MHz, $CDCl_3$, TMS) has δ at 1.97 (t, 4H, C-3 and C-4 -methylenes), 2.17 (t, 4H, C-2 and C-5 -methylenes); and its ^{13}C NMR (60MHz, $CDCl_3$, TMS) has δ at 23.24 (C-3,4), 38.30 (C-2,5) and 220.16 (C-1).
The *oxime* [1192-28-5] forms prisms with **m 56.5°, b 120-121°/45mm**, **196°/atm**, the *semicarbazone* [5459-00-7] has **m 224°**, the *2,4-dinitrophenylhydrazone* [2057-87-6] has **m 145.5, 146.5°**, and the *ethylene ketal (1,4-dioxaspiro[4.4]nonane* [176-32-9] has **m 153°**. The ***enol***-form is present to the extent of 2.5 x 10^{-7}% in the gas phase.

Cyclopentyl methyl ether (CPME) *[5614-37-9]* **M 100.2, fp –134.8°, b 105.44°/760mm 105-106.5°/760mm 106°/760mm, d_4^{20} 0.8627, n_D^{20} 1.4206.** This ether has the advantage of having a high resistance to hydroperoxide formation. It is an "environmentally friendly" solvent and is an alternative to ether solvents like THF, Et_2O and methyl *tert*-butyl ether. Two methods after Williamson's synthesis have been reported. In the *first* Na (370g, 16g. atoms) is dissolved in MeOH (2370g, 74moles) and excess of MeOH is distilled off until NaOMe starts to separate. The solution is cooled to 60° and cyclopentyl chloride (1254g, 12moles, b 114°/atm [930-28-9]) is added slowly and kept at 60° for 100 hours. The mixture is then fractionated to give recovered cyclopentyl chloride (21%), cyclopentyl methyl ether (278g, 29% based on reacted cyclopentyl chloride) and cyclopentene (31% which distils as an azeotrope with MeOH (b 37-38°/atm). [Olson et al. *J Am Chem Soc* **69** 2451 *1947*.] In the *second*, Na (15g) is dispersed under hot xylene, cooled, the xylene is replaced with anhydrous Et_2O (150ml), and a solution of cyclopentanol (57g, b 141-142°/769mm, see [96-41-3]) in dry Et_2O (~100ml) is added with stirring during 3 hours and allowed to stand for 12 hours. Methyl iodide (103g) is then added during 2 hours to the preceding sodio compound as the Et_2O boils gently, allowed to stand overnight, the Et_2O is distilled off, the crude CPME is then distilled out and redistilled under N_2 at 105°/763mm to give pure *cyclopentyl methyl ether* (21g, 32%). It can be stabilised with 50ppm of BHT. [Vogel *J Chem Soc* 1809 *1948*, *Beilstein* **6** III 5, **6** IV 6.]

Cyclotetradecane *[295-17-0]* **M 192.3, m 56°.** Recrystallise it twice from aqueous EtOH, then sublime it *in vacuo* [Dretloff et al. *J Am Chem Soc* **109** 7797 *1987*].

Cyclotetradecanone *[3603-99-4]* **M 206.3, m 25°, b 145°/10mm, d_4^{20} 0.926, n_D^{20} 1.480.** It is converted to the semicarbazone which is recrystallised from EtOH and re-converted to the free cyclotetradecanone by hydrolysis [Dretloff et al. *J Am Chem Soc* **109** 7797 *1987*]. Fractionate it in a vacuum.

Decahydronaphthalene (decalin, mixed isomers) *[91-17-8]* **M 138.2, b 191.7°/760mm, d_4^{20} 0.886, n_D^{20} 1.476.** Stir decalin with conc H_2SO_4 for several hours. Then the organic phase is separated, washed with water, saturated aqueous Na_2CO_3, again with water, dried with $CaSO_4$ or CaH_2 (and perhaps dried further with Na), filtered and distilled under reduced pressure (**b** 63-70°/10mm). It has also been purified by repeated passage through long columns of silica gel previously activated at 200-250°, followed by distillation from $LiAlH_4$ and storage under N_2. Type 4A molecular sieves can be used as drying agent. Storage over silica gel removes water and other polar substances. [For the separation of *cis* and *trans* isomers see Seyer & Walker *J Am Chem Soc* **60** 2125 *1938*, and Baker & Schuetz *J Am Chem Soc* **69** 1250 *1949*.]

***cis*-Decahydronaphthalene** *[493-01-6]* **M 138.2, f –43.2°, b 195.7°, 81-83°/19mm, d_4^{20} 0.897, n_D^{20} 1.48113.** Purification methods described for the mixed isomers are applicable here. The individual isomers can be separated by very efficient fractional distillation, followed by fractional crystallisation by partial freezing. The *cis*-isomer reacts preferentially with $AlCl_3$ and can be removed from the *trans*-isomer by stirring the mixture with a limited amount of $AlCl_3$ for 48 hours at room temperature, filtering and distilling. [Seyer & Walker *J Am Chem Soc* **60** 2125 *1938*, Baker & Schuetz *J Am Chem Soc* **69** 1250 *1949*.] A very pure authentic sample is best obtained by synthesis from *cis*-1,2-bis-chloroethylcyclohexane [Whitesides & Gutowski *J Org Chem* **41** 2882 *1976*, *Beilstein* **5** IV 310.]

***trans*-Decahydronaphthalene** *[493-02-7]* **M 138.2, f –30.6°, b 187.3°, d_4^{20} 0.870, n_D^{20} 1.46968.** See purification of *cis*-isomer above. [Seyer & Walker *J Am Chem Soc* **60** 2125 *1938*, Baker & Schuetz *J Am Chem Soc* **69** 1250 *1949*, *Beilstein* **5** IV 311.]

(+)-Dehydroabietylamine (abieta-8,11,13-triene-18-ylamine) *[1446-61-3]* **M 285.5, m 41°, 42.5-45°, b 192-193°/1mm, 250°/12mm, n_D^{40} 1.546, $[\alpha]_{546}^{20}$ +51° (c 1, EtOH), pK_{Est} ~10.3.** The crude base is purified by converting 2g of base in toluene (3.3ml) into the *acetate salt* by heating at 65-70° with 0.46g of AcOH, and the crystals are collected and dried (0.96g from two crops, **m** 141-143°). The acetate salt is then dissolved in warm H_2O, basified with aqueous NaOH and extracted with $*C_6H_6$. The dried extract ($MgSO_4$) is evaporated in vacuum leaving a viscous oil which crystallises and can be distilled. [Gottstein & Cheney *J Org Chem* **30** 2072 *1965*.] The *picrate* has **m** 234-236° (from aqueous MeOH), and the *formate* has **m** 147-148° (from heptane). [*Beilstein* **12** IV 3005.]

Diamantane (congressane) *[2292-79-7]* **M 188.3, m 234-235°, 243-245°.** Purify diamantane by repeated crystallisation from MeOH or pentane. *Alternatively*, purify it by dissolving it in CH_2Cl_2, washing with 5% aqueous NaOH and water, and drying ($MgSO_4$). The solution is filtered, concentrated to a small volume, an equal weight of alumina is added, and the solvent evaporated. The residue is placed on an activated alumina column (*ca* 4 x weight of diamantane) and eluted with petroleum ether (b 40-60°). Eight sublimations and twenty zone refining experiments gave material **m** 251° of 99.99% purity by differential analysis [Gund et al. *Tetrahedron Lett* 3877 *1970*, Courtney et al. *J Chem Soc Perkin Trans I* 2691 *1972*]. [For spectra see Cupas et al. *J Am Chem Soc* **87** 919 *1965*.]

1.3-Diaminoadamantane *[10303-95-4]* **M 164.3, m 52°, $pK_{Est(1)}$ ~8.6, $pK_{Est(2)}$ ~10.6.** Purify it by zone refining. The *dibenzoyl* derivative has **m** 248°, and the *dihydrochloride salt* has **m** 310° (360°) after recrystallisation from aqueous EtOH or EtOH/Et_2O. [Prelog & Seiwerth *Chem Ber* **74** 1769 *1941*, Stetter & Wulff *Chem Ber* **93** 1366 *1960*.]

cis*-1,2-Diaminocyclohexane (*meso*-chxn)** *[1436-59-5]* **M 114.2, b 92-93°/8mm, 170°/atm, d_4^{25} 0.952, n_D^{20}1.493, pK_1^{20} 6.13 (6.41), pK_2^{20} 9.93(9.91).** It is prepared by reduction of the cis-1,2-dioxime with boiling Na/EtOH, or from *cis*-1,2-dihydrazinocarbonylcyclohexane with $NaNO_2$/HCl [Jaeger & Blumendal *Z Anorg Chem* **175** 165 *1928*]. Dry the diamine over solid KOH and distil it in a vacuum. It is a strong base, keep it away from CO_2, and store it in the dark under N_2. The *dihydrochloride* has **m 307-310°**, and the *dipicrate* **(**from H_2O) has **m 260°(dec)**. This cis-diamine is a ***meso form because its mirror image is identical to it, and is superimposable over it (see below) [*Beilstein* **13** II 3, **13** IV 5.]

(±)-*trans*-1,2-Diaminocyclohexane [(±)-chxn)] *[1121-22-8]* **M 114.2, m 14-15°, b 78-81°/15mm, 85-88°/25mm, d_4^{25} 0.951, n_D^{20} 1.489, pK_1^{20} 6.47(6.72), pK_2^{20} 9.94(9.86).** Purify this ***racemic base***, and store it as for the *cis*-isomer above since it is a strong base, and becomes yellow on storage. [*Beilstein* **13** H 1, **13** III 8, **13** IV 5.]

***cis/trans*-1,2-Diaminocyclohexane *resolution.* [*Note that the* trans- *isomer is a racemic mixture, whereas the* cis- *isomer has a* meso *configuration and its mirror image is identical and superimposable over it.*]** A solution of L(+)-tartaric acid (150g, 0.99mol) in distilled H_2O (400ml) in a 1L beaker is stirred until clear, and a mixture of *cis*- and *trans*- 1,2-diaminocylohexane (240ml, 1.94mol, of ~60/40 *trans*/*cis* mixture which is commercially available and is cheaper than the pure *trans* compound for which the same procedure applies) is added at a rate whereby the temperature rises to 70°. Glacial acetic acid (100ml, 1.75mol) is then added at such a rate that the temperature rises to 90°. A white precipitate immediately separates as the acid is added, and the slurry is stirred vigorously until the temperature cools slowly to 25°(~2 hours), and then is cooled further to ~5° in an ice bath for 2 hours, and is collected by filtration. The filter cake is washed with H_2O (100ml at ~5°), then EtOH (5 x 100ml), and dried by sucking air through it for 1 hour and analysed for enantiomeric purity *via* the bis-*m*-toluoyl amide*. The salt is then dried *in vacuo* at ~40° to give *R,R*-1,2-diamoniumcyclohexane mono-(+)-tartrate as a white solid (160g, 99%) in ≥99% enantiomeric excess (ee). If the optical purity is not as expected then recrystallise the salt in two crops from Me_2CO (1:20 w/v with ~60-70% recovery). The *S,S*-diastereomeric tartrate salt is obtained by using D(–)-tartaric acid. If the 'ee' is <99%, or if the difference between the top and the bottom of the cake is >0.2%, then the cake should be washed with more MeOH. If product of ≥99% 'ee' is required then recrystallisation of the tartrate salt by dissolving it in H_2O (≈ 1:10 w/v) with heating to 90°, followed by cooling to 5° overnight, gives ~60-70% recovery.

* The diammonium salt (25mg) is mixed with 4N NaOH (0.5ml), CH_2Cl_2 (1.5ml) and *m*-toluoyl chloride (50µl)

with vigorous mixing. The lower (organic layer) is diluted with 10µl of *iso*-propanol, and 10µl of this is analysed by HPLC using *iso*-propanol/hexane (1:9) mixture at 1ml/minute flow rate. [Larrow et al. *J Org Chem* **59** 1939 *1994*, Gasbøl et al. *Acad Chem Scand* **26** 3605 *1972*.]

***1R,2R*(–)-*trans*-1,2-Diaminocyclohexane [(–)-chxn)]** *[20439-47-8]* **M 114.2, m 41-45°, [α] $^{20}_{D}$ –25.5° (c 5 M HCl). m 14-15°.** Distil or recrystallise the diamine from petroleum ether under N_2 or Ar. It has a plain-negative ORD curve [Gillard *Tetrahedron* **21** 503 *1965*, O'Brien & Toole *J Am Chem Soc* **77** 1368 *1955*]. Store it as above. The *1R,2R-base L-tartrate salt* has *[39961-95-0]*, **M 264.3, m 273°** and **[α] $^{25}_{D}$ +12.5° (c 4, H_2O)**, and can be used to purify and/or optically enrich the free base. [*Beilstein* **13** III 6, and references below.]

***1S,2S*(+)-*trans*-1,2-Diaminocyclohexane [(+)-chxn)]** *[21436-03-3]* **M 114.2, m 42-45°, b 104-110°/40mm, [α] $^{20}_{D}$ +25.5° (c 5 M HCl).** Distil or recrystallise the diamine from petroleum ether under N_2 or Ar. Store it as above. It has a plain-positive ORD curve [Gillard *Tetrahedron* **21** 503 *1965*, O'Brien & Toole *J Am Chem Soc* **77** 1368 *1955*]. The *1S,2S-base D-tartrate salt* has *[67333-70-4]*, **M 264.3, m 180-184°(dec)** and **[α] $^{25}_{D}$ –12.5° (c 4, H_2O)** from which the free base can be purified or optically enriched. It is a useful chiral synthon. [Fjii et al. *J Chem Soc, Chem Commun* 45 *1985,* Takahashi et al. *Tetrahedron Lett* **30** 7095 *1989*, Hanassian et al. *J Org Chem* **58** 1991 *1993*, for absolute configuration see Gillard *Tetrahedron* **21** 503 *1965*, *Beilstein* **13** III 7.]

***trans*-1,4-Diaminocyclohexane** *[2615-25-0]* **M 114.2, m 69-72°, b 197°/760mm, $pK_{est(1)}$ ~9.4, $pK_{est(2)}$ 10.8.** Recrystallise the diamine from petroleum ether under N_2 or Ar as it should be an even stronger base than the above 1,2-diamine isomers. It distils under N_2. Store it in the dark under N_2. [*Beistein* **13** I 3, **13** III 11.]

(1*RS*,2S*R*)-*cis*-1,2-Diaminocyclopentane (1*RS*,2S*R*-*cis*-1,2-cyclopentanediamine, *meso*-1,2-cyclo-pentane-diamine, (*meso*)-cptn) *[40535-45-3; no configuration 41330-23-8]* **M 100.1, b 62-65°/13.5mm, 99°/60mm.** Whereas reduction of ***anti***-*cyclopentane-1,2-dione dioxime* (see below, and from reaction of cyclopentane-1,2-dione and NH_2OH) with Na/EtOH yields predominantly *trans-(±)-diamine,* the reaction of *cyclopentane-1,2-dione monooxime* [31597-37-0] with NH_2OH gives a 2:1 mixture of *anti*- and *amphi*- dioximes which provide the less water soluble red bis-*anti*-dioximatoNi(II) complex and the more water soluble yellow-brown bis-*amphi*-dioximatoNi(II) complex respectively. When this mixture of Ni(II) complexes, or the *amphi*-complex, is reduced with KBH_4 in "diglyme", the base finally isolated is pure *cis-1,2-cyclopentanediamine*.
Thus, ***bis(amphi-cyclopentane-1,2-dione dioximato)nickel(II)*** (79g, 90.5mol, dried over H_2SO_4 *in vacuo*) is added to a solution of KBH_4 (30g) dissolved in dry diglyme [600ml, bis(2-methoxyethyl) ether, [111-96-6]) in 2L flask. N_2 is bubbled through the solution, then during 1 hour anhydrous $AlCl_3$ (25g) in dry diglyme (100ml) is added dropwise carefully as vigorous evolution of H_2 ensues; the temperature being kept below 35° by cooling in ice-water. When evolution of H_2 ceases, the mixture is heated at 70° for 18 hours. Then a solution of KOH (100g) in H_2O (150ml) is added carefully, and the ***cis-diamine*** is steam distilled off; 6L of distillate are collected, acidified with 12M HCl (to pH 3), and the dry ***cis-1,2-cyclopentanediamine dihydrochloride*** (23g, 27% based on the Ni complex) is isolated as for the *trans-(±)-isomer* below. The free base, ***cis-1,2-cyclopentanediamine*** **b 62-65°/13.5mm (**83%, based on the dihydrochloride) is stored under N_2 at –20°. [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*]. This *cis-diamine* has been fractionated through a vacuum-jacketed distillation column as described by Ray et al. *Rev Sci Instr* **28** 200 *1957*, and the fraction with **b 99°/60mm** contained pure *cis*-isomer [Phillips & Royer *Inorg Chem* **4** 616 *1965*].
The ^1H NMR in D_2O (TMS as external standard) can be used to distinguish between *trans-(±)-1,2-diamine* and and the preceding *cis-(meso)-1,2-diamine* because the triplets from carbon atoms 1 + 2 occur at δ 2.72 and δ 2.77 respectively [Phillips & Royer *Inorg Chem* **4** 616 *1965*].
Distinct bis- and tris- *cis*-cptn complexes such as $[Ni(cis\text{-cptn})_2](ClO_4)_2.6H_2O$, $[Ni(cis\text{-cptn})_3](ClO_4)_2$ and $[Co(cis\text{-cptn})_3]Br_2.3H_2O$ are readily formed [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*]. [*Beilstein* **4** II 3.]

(1*RS*,2*RS*)-(±)-*trans*-1,2-Diaminocyclopentane [(1*RS*,2*RS*)-*trans*-1,2-cyclopentanediamine, (±)-*trans*-1,2-cyclopentanediamine, (±)-cptn] *[3145-88-8]* **M 100.1, b 65-67°/13.5mm, 103°/60mm, 170°/atm, $pK_{Est\ 1}$ ~7.0 , $pK_{Est\ 2}$ ~10.0.** This diamine is a strong base and is best kept as its salts which are not greatly affected by moisture and CO_2. It is prepared by reduction of anti-*cyclopentan-1,2-dione dioxime [6635-29-6]* **M 128.1, m 210° (215° dec; 210-225° dec, darkening at 192-205°** also reported for an analytically pure sample) which is

obtained by adding *2-ethoxycarbonylcyclopentanone* (31.2g, b 102-104°/12mm, [611-10-9]) to a solution of NaOH (8.8g) in H_2O (160ml) whereby a heavy white precipitate separates. A solution of $NaNO_2$ (13.8g) in H_2O (32ml) is then added to it and the mixture, under N_2, is shaken mechanically for 44 hours at ~25°. The resulting clear yellow solution is cooled to 0°, and at this temperature 6N H_2SO_4 is added carefully while CO_2, and oxides of nitrogen evolve. The solution is extracted with Et_2O (in a continuous liquid-liquid extractor) for 5.5 hours, the extract is evaporated under N_2 and reduced pressure to a small volume of ~20ml. This suspension of crude cyclopentane-1,2-dione monooximes is treated with a solution of hydroxylamine hydrochloride (13.9g) and NaOH (8.0g) in H_2O (50ml) when heat is evolved and a precipitate separates immediately. The mixture is allowed to stand overnight at 5°, the light tan crude ***anti**-cyclopentane-1,2-dione dioxime* (16.8g, 66%, decomposes at 230-240°) is filtered off and is dried *in vacuo*, leaving the more soluble ***amphi**-cyclopentane-1,2-dione dioxime* in the filtrate. The analytically pure *anti-dioxime* (dec at 210-225° without melting, 83% recovery, [6635-29-6]) can be obtained by dissolving the crude material (1g) in 2% aqueous NaOH (25ml) at ~25° (slightly turbid), stirring with Norit, filtering, neutralising the filtrate with 1 N HCl (to phenolphthalein), filtering off the solid, washing it twice with H_2O, once with Me_2CO and it drying *in vacuo*. [Cope et al. *J Am Chem Soc* **73** 1199 *1951*, Lloyd & Marshall *J Chem Soc* 2597 *1956*.]

Alternatively, to a stirred mixture of granulated Na (38g) and *C_6H_6 (900ml, dried over Na) is added diethyl adipate (225ml, 1.11mole, [141-28-6]) rapidly followed by absolute EtOH (5ml), and is boiled under reflux with stirring for 18 hours then cooled to 0°. The white solid that separated is filtered off, washed with a little *C_6H_6 and dried *in vacuo* over shredded paraffin wax to give ***sodium cyclopentanone-2-carboxylate*** (180g**)**. This salt (1mol) is partly dissolved in ice-water (600ml), N_2 is bubbled through for 15 minutes to remove O_2; and a mixture of a solution of NaOH (4g, 0.1mol) and $NaNO_2$ (70g, 1.03mol) in H_2O (160ml) is added dropwise to it. The mixture is then heated under N_2 with vigorous stirring at 40° for 30 hours. After cooling to 0°, 6M H_2SO_4 (200ml, 1.2mol) is added in one hour; and when evolution of CO_2 has ceased the solution is neutralised with 12M ammonia. A solution of NH_2OH HCl (70g, 1.0mol) in H_2O (160ml), neutralised with K_2CO_3 (70g, 0.5mol), is immediately added. After 1 hour, the precipitation of crude *anti-**cyclopentane-1,2-dione dioxime*** as light tanned needle-like crystals is complete; it is filtered off, washed with a little H_2O and dried *in vacuo* over H_2SO_4 for 48 hours (yield 90g, 62% calculated on diethyl adipate used). The filtrate contains the ***amphi-cyclopentane-1,2-dione dioxime*** which is isolated as the yellow-brown ***bis(**amphi**-cyclopentane-1,2-dione dioximato)nickel(II) complex*** (30g) by slowly adding Ni(II)SO_4 7H_2O (20g) in H_2O (60ml) to this filtrate, and washing the complex with H_2O and drying in air. [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*.]

Bis(**amphi**-cyclopentane-1,2-dione dioximato)nickel(II) complex is obtained analytically pure, as a red precipitate in 70% yield, from ***anti-**cyclopentane-1,2-dione dioxime* (12.8g, 0.1mol) in 4M ammonia (15ml), by adding slowly Ni(II)Cl_2 6H_2O (12g, 0.05mol) in H_2O (40ml) to it, filtering off the solid, washing it with H_2O and drying it in air. [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*.]

Reduction to (±)-diamine*:** The ***anti**-cyclopentane-1,2-dione dioxime* (10g) in absolute EtOH (2L) is reduced by addition of freshly cut small pieces of Na metal (180g) over a period of several hours. The solution is refluxed until all the metal has dissolved. The EtOH is distilled off *in vacuo*, the residue is basified strongly with 10N NaOH, and the base is steam distilled. The distillate is made strongly alkaline with aqueous NaOH, extracted with trichloroethylene, the solvent is evaporated and ***trans-1,2-cyclopenanediamine then distils at **65°/13.5mm, n_D^{25} 1.4850-1.4858** in 29% yield. When the fractional distillation is carried out using a column (90 x 1 cm) packed with glass helices and the reflux ratio is kept at >40:1, the first 25% of distillate contains a significant amount of lower boiling *cis-diamine*, **99°/60mm**; the remaining 75% of material then boils at a constant temperature, **103°/60mm**, and is the ***trans-(±)-diamine***. *Alternatively*, the steam distillate is acidified with concentrated HCl, the solution is evaporated to dryness *in vacuo*, and the residue is recrystallised from EtOH/Et_2O to provide ***trans-(±)-1,2-cyclopentanediamine dihydrochloride*** in 77% yield, which **decomposes at 287-290°** (darkening gradually >230°), and forms a ***dihydrate*** on exposure to air. The ***trans-(±)-dipicrate*** has **m 233-233.5° (dec)** after recrystallisation from aqueous EtOH or H_2O, and the ***trans-(±)-diacetyl derivative*** has **m 226.5-227.5° (dec)** after recrystallisation from EtOH by addition of Et_2O. [Cope et al. *J Am Chem Soc* **73** 1199 *1951*, Phillips & Royer *Inorg Chem* **4** 616 *1965*, Lloyd & Marshall *J Chem Soc* 2599 *1956*, Jaeger & Blumendal *Z Anorg Allgem Chem* **175** 161 *1928*.]

***Alternative reduction to (±)-diamine*:** The ***anti**-cyclopentane-1,2-dione dioxime* (20g, 156mmol) in absolute EtOH (1.5L) is reduced by heating to 40° (internal temperature), and stirring under a reflux condenser, with Mg powder (8g) and Hg(II)Cl_2 (0.1g) while Na metal (150g, 6.5mol, in 5g pieces) is added *via* the top of the condenser and keeping the temperature below 50° (internal temperature). The mixture is finally heated to boil-

ing in order to dissolve all the Na. The *(±)-diamine* is isolated by steam distillation (external heating being necessary so as to maintain a small volume in the flask) until the pH of the distillate is below 8 (*ca* 4L). This is acidified (pH 3) with 12M HCl, evaporated almost to dryness *in vacuo* (at ~25°), excess HCl is removed by washing with EtOH/Et_2O (2:1v/v, 20ml), and the hygroscopic salt is dried over KOH in a desiccator to give the ***(±)-diamine dihydrochloride*** (5g, 18% based on dioxime). The free base is obtained by adding the dihydrochloride (5g, 29mmol) in small portions with stirring to a 1:1v/v mixture of MeOH/Et_2O (50ml) into which is dissolved Na (1.7g, 74mmol, cooling). After stirring for 1 hour, the precipitated NaCl is filtered off, extracted with MeOH/Et_2O (1:1v/v, 5ml), the combined extract and filtrate are evaporated to ~3ml and this residue is distilled in a N_2 atmosphere to give **(±)-*trans*-cyclopentane-1,2-diamine**, **b 65-67°/13.5mm** (2.5g, 89%, based on the dihydrochloride) which is stored under N_2 at –20°. Distinct *trans*-(±)-cptn complexes of Ni, Co, Rh and Pt have been prepared; some are enantiomorphic and others are structural isomers [Phillips & Royer *Inorg Chem* **4** 616 *1965*, Jaeger & Blumendal *Z Anorg Allgem Chem* **175** 161 *1928*, Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*].
The ^1H NMR in D_2O (TMS as external standard) can be used to distinguish between *trans-(±)-1,2-diamine* and and the preceding *cis-(meso)-1,2-diamine* because the triplets from carbon atoms 1 + 2 occur at δ 2.72 and δ 2.77 respectively [Phillips & Royer *Inorg Chem* **4** 616 *1965*].

(1*R*,2*R*)-(–)-*trans*-1,2-Diaminocyclopentane dihydrochloride [(–)-cptn HCl] *[1030390-38-5]* **M 173.1, m dec, $[\alpha]_D^{25}$ –23.5° (c 2, 1M HCl)** and **(1*S*,2*S*)-(+)-*trans*-1,2-Diaminocyclopentane dihydrochloride [(+)-cptn HCl]** *[477873-22-6]* **M 173.1, m dec, $[\alpha]_D^{25}$ +23° (c 2, 1M HCl).** ***Optical resolution*:** (±)-Cptn (2g, 20mmol) is resolved by adding it to a solution of D-(+)-tartaric acid (7g, 47mmol) in MeOH (1ml) and H_2O (7ml), and at 40° MeOH (12ml) is added dropwise. The mixture is then kept at 3° for 18 hours, the crystalline solid is filtered off, washed with MeOH (10ml) to give the less soluble hydrogen tartrate salt [5.2g, 65% based on (±)-cptn]. After two recrystallisations, the **(–)-cptn-(+)-tartrate salt** [2.5g, 31.4% based on (±)–cptn] has **m 134-135°** (143-144° also reported), **$[\alpha]_D^{25}$ +10.1° (c 2,** H_2O**)**. When this salt (2.4g, 6mmol) in H_2O (8ml) is treated with a solution of KCl (0.9g, 12mmol) in H_2O (4ml), the highly insoluble potassium hydrogen tartrate separates and is filtered off after standing for 1 hour. Addition of solid KOH (8g, with cooling) allowed solid (–)-cptn hydrate to separate, but the mixture is extracted thoroughly with Et_2O (5 x 10ml), the extract is dried (KOH or $MgSO_4$), filtered, and evaporated to give **(–)-*trans*-cptn** (0.55g, 92% based on tartrate salt). When carried out on a larger scale the ***(–)-base*** can be distilled, **b 166°/atm, d^{25} 0.9463**, and has **$[\alpha]_D$ -54.7° (neat)**, **$[\alpha]_D$ -42° (*C_6H_6)**, **$[\alpha]_D$ –39° (H_2O)**, and a plain-negative ORD curve. **(–)-*trans*-Cptn sulfate** has **$[\alpha]_D$ -12° (H_2O)**. [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*, Jaeger & Blumendal *Z Anorg Allgem Chem* **175** 161 *1928*, Phillips & Royer *Inorg Chem* **4** 616 *1965*]. **(+)-Cptn-(+)-tartrate** can be obtained from the mother liquors of the above resolution in order to isolate the (+)-base; but it is advisable to collect all the mother liquors, liberate the free base with KOH, isolate it and repeat the process using L-(–)-tartaric acid to form the less soluble diasterioisomeric **(+)-cptn-(–)-tartrate salt.** Pure **(+)-*trans*-cptn** can then be isolated as above and will have the same physical properties except for the optical rotations that will be of opposite sign and has a plain-positive ORD curve [Dunlop et al. *J Chem Soc* 3160 *1964*, Gillard *Tetrahedron* **21** 503 *1965*, O'Brien & Toole *J Am Chem Soc* **77** 1368 *1955*]. [*Beilstein* **4** II 3, **4** III 5]
Complexes of optically active cptn with Rh, Co, Ni and Pt have been prepared, and in some cases enantiomeric and geometrical isomers have been identified. One has been used to obtain pure enantiomeric diamine, for example, the complex **$[Co_2(\pm\text{-cptn})_7\ (H_2O)_2]^{6+}$** has been resolved into three bands on Amberlite CG-50 carboxylic acid resin 400-400 by elution with aqueous HCl (pH 2, flow rate 5ml/hour) and collecting 40ml fractions. Bands I, II and III are probably geometrical isomers because when the isolated complexes are decomposed with concentrated aqueous NaOH, extracted with *C_6H_6, the extract dried and evaporated, the free base ***(+)-cptn*** with **$[\alpha]_D$ –42° ±1° (*C_6H_6)** is obtained (compare with above) [Phillips & Royer *Inorg Chem* **4** 616 *1965*].
The optical properties (ORD, CD) of several cptn-transition metal complexes have been thoroughly investigated and used to determine and confirm the absolute configuration of cptn [Dunlop et al. *J Chem Soc* 3160 *1964*, Gillard *Tetrahedron* **21** 503 *1965*]. The crystal structure of **$(-)_{587}$-$[Co(+trans\text{-cptn})_3]Cl_3.4H_2O$** confirms the *1S,2S-configuration* for the dextro-enantiomer [Ito et al. *Acta Cryst* **B 27** 2187 *1971*].

trans*-1,2-Dibromocyclopentane** ***[*10230-26-9]* **M 227.9, b 72.5°/15mm, 74°/17mm, d_4^{20} 1.857, n_D^{25} 1.5460.** It is prepared by addition of bromine to cyclopentene at –20° followed by fractional distillation. The ^1H NMR

(60MHz, CCl_4) has a complex multiplet centered at ~2.5 ppm (3 x CH_2), and two triplets centered at 4.58ppm (J = 7.4Hz, for 2 x CHBr) from TMS. [Altona et al. *Rec Trav Chim, Pays Bas* **85** 983 *1966*, cf Abell et al. *J Am Chem Soc* **82** 3610 *1960*.]

***cis*-3,4-Dichlorocyclobutene** *[2957-95-1]* **M 123.0, b 70-71°/55mm, 74-76°/55mm, d $_4^{20}$ 1.297, n $_D^{20}$ 1.499.** Distil the cyclobutene at 55mm through a 36-in platinum spinning band column, a fore-run b 58-62°/55mm is mainly 1,4-dichlorobutadiene. When the temperature reaches 70° the reflux ratio is reduced to 10:1 and the product is collected quickly. It is usually necessary to apply heat frequently with a sun lamp to prevent any dichlorobutadiene from clogging the exit in the early part of the distillation [Pettit & Henery *Org Synth* **50** 36 *1970*].

Dicyclohexylamine (Cy_2NH_2) *[101-83-7]* **M 181.3, m 20°, b 83°/1mm, 99.3°/4mm, 113.5°/9mm, 117-120°/10mm, 135.4°/30mm, 154.3°/50mm, 199°/200mm, 255.8°/atm, d $_4^{20}$ 0.912, n $_D^{20}$ 1.4845, pK^{25} 11.25.** It is a strong base, has a fishy odour, is soluble in H_2O, and organic solvents and forms adducts with some of them. It can be purified by fractional distillation at atmospheric pressure, but if the distillate is coloured (e.g. green) then distillation under reduced pressure gives a clear colourless liquid [Vogel *J Chem Soc* 1828 *1928*]. The *hydrochloride [4693-92-9]* crystallises from H_2O or EtOH and has **m 334-335°** (sealed tube), and the *acetyl derivative [1563-91-3]* has **m 103°** (from Et_2O). [Diwoky & Adkins *J Am Chem Soc* **53** 1870 *1931*, *Beilstein* **12** H 6, **12** I 114, **12** II 7, **12** III 19, **12** IV 22.] **SKIN and EYE IRRITANT**.

1,3-Dicyclohexylcarbodimide (DCC) *[538-75-0]* **M 206.3, m 34-35°, b 95-97°/0.2mm, 120-121°/0.6mm, 155°/11mm.** It is sampled as a liquid after melting in warm H_2O. It is sensitive to air, and *it is a potent* ***skin irritant.*** It can be distilled in a vacuum, and is best stored in a tightly stoppered bottle in a freezer. It dissolves readily in CH_2Cl_2 and pyridine where the reaction product with H_2O, after condensation, is dicyclohexyl urea which is insoluble and can be filtered off. *Alternatively*, dissolve it in CH_2Cl_2, add powdered anhydrous $MgSO_4$, shake for 4 hours, filter, evaporate and distil the residue at 0.6mm pressure and oil bath temperature of 145°. [Bodansky et al. *Biochemical Preparations* **10**, 122 *1963*, Schmidt & Seefelder *Justus Liebigs Ann Chem* **571** 83 *1951*, Schmidt et al. *Justus Liebigs Ann Chem* **612** 11 *1958*, *Beilstein* **12** IV 72.]

***N,N*-Dicyclohexylmethylamine (Cy_2NMe, *N*-methyldicyclohexylamine)** *[7560-83-0]* **M 195.3, b 131-133°/13mm, 135-137°/15mm, 150°/50mm, 265°/atm, d $_4^{25}$ 0.912, n $_D^{25}$ 1.4900, pK 8.2.** When dicyclohexylamine (90.5g, 0.5mol, see 101-83-7) and 55% aqueous formic acid (121.1ml, 2.5mol) are heated at ~100° and 35% aqueous formaldehyde (97.5g, 11.25mol) is added dropwise over an hour, CO_2 evolution occurs. After gas evolution is complete, ~15 hours, concentrated HCl (1mol) is added and the mixture is evaporated *in vacuo*. The free base is liberated from the residue with strong aqueous NaOH and the oil is extracted with Et_2O, dried (solid KOH), filtered, the filtrate is evaporated *in vacuo* and the residue is fractionally distilled to give Cy_2NMe in 51% yield. It was also obtained by alkylating Cy_2NH with dimethylsulfate. [Hünig & Kiessel *J Prakt Chem* **5** 224 *1958*.] The *hydrochloride* has **m 154-154°** (from EtOAc), and the *methiodide* has m **228-229°** (from EtOH/Et_2O). [*Beilstein* **12** I 115, **12** II 8, **12** III 21, **12** IV 23.]

3,4-Diethoxy-3-cyclobutene-1,2-dione (diethyl squarate) *[5321-87-8]* **M 170.2, b 89-91°/0.4mm, 88-92°/0.4mm, d $_4^{20}$ 1.162, n $_D^{25}$ 1.5000.** Dissolve the ester in Et_2O, wash it with Na_2CO_3, H_2O and dry (Na_2SO_4) it, filter, evaporate and distil it using a Kügelrohr, or purify it by chromatography. Use a Kieselgel column and elute with 20% Et_2O/petroleum ether (b 40-60°), then with Et_2O/petroleum ether (1:1), evaporate and distil the residue *in vacuo*. [Dehmlow & Schell *Chem Ber* **113** 1 *1980*, Perri & Moore *J Am Chem Soc* **112** 1897 *1990*, IR: Cohen & Cohen *J Am Chem Soc* **88** 1533 *1966*] **It can cause severe dermatitis.** [Foland et al. *J Am Chem Soc* **111** 975 *1989*, Perri et al. *Org Synth* **69** 220 *1990*].

Ethyl cyclohexanecarboxylate *[3289-28-9]* **M 156.2, b 76-77°/10mm, 92-93°/34mm, 196-196.2°/760mm, d_4^{20} 0.955, n_D^{20} 1.441.** Wash the ester with N sodium hydroxide solution, then water, dry with Na_2SO_4 and distil it. The *amide* has **m** 185-186°. [Adkins & Cramer *J Am Chem Soc* **52** 4355 *1930*, Newman & Walborsky *J Am Chem Soc* **72** 4296 *1950*, *Beilstein* **9** III 17, **9** IV 18.]

Ethyl 2-oxocyclohexanecarboxylate (2-ethoxycarbonylcyclohexanone, 2-carbethoxycyclohexanone, ethyl 2-ketohexahydrobenzoate) *[1655-07-8]* **M 170.2, b 86-88°/3.2mm, 106°/11mm, d^{25} 1.064, n_D^{20} 1.47940, pK^{25} 10.94 (12.87).** The ester is obtained by the decarbonylation of *ethyl 2-ketocyclohexylglyoxalate* (which in turn is prepared from cyclohexanone and diethyl oxalate in the presence of NaOEt). The *ethyl glyoxalate* (~250-265g, boiling at 105° to 165°/10-15mm) is mixed with Fe powder (1-3mg) and finely ground soft glass 0.5-1.0g) in a Claisen flask (~500ml), and heated in a 40mm vacuum (bath temperature at 165-175°, not higher, to avoid unreacted ester from distilling) while CO [TOXIC] evolves and decarbonylated ester distils between 125-140°, requiring 1.5 to 2 hours for pyrolysis. The desired ester obtained (200-210g, 85.8%) has n_D^{25} 1.476 to 1.479. [Snyder et al. *Org Synth* Coll Vol **II** 531 *1943*.]
The ester has FT-IR (neat) with ν_{max} at 2939.5 (CH), 1716.2 (C=O), 1658.3 (C=O ester), 1442.5 (OH enol ?), 1365.2, 1299.3, 1219.0, 1082.9 and 832.9 cm^{-1}; ^1H NMR (60MHz, $CDCl_2$, TMS) with δ at 1.30 (t, 3H, ester C*H*$_3$), 1.65 (m, ~4H, 2-methylenes), 2.25 (m, 4H 2-methylenes), 3.35 (t, 1H, partly enolised), 4.20 (q, 2H, ester C*H*$_2$) and ~12.0 (s, enolic O*H*); and ^{13}C NMR (15MHz, $CDCl_3$, TMS) with δ at 14.17, 14.33, 21.97, 22.42, 23.31, 27.13, 29.10, 29.98, 41.55, 57.22, 60.12, 61.04, 97.72, 169.93, 171.93, 172.71, 206.19. [*Beilstein* **10** IV 2606.]
The *enol* content of *ethyl 2-oxocyclohexanecarboxylate* is higher than that of the *ethyl 2-oxocyclopentanecarboxylate* below ([611-10-9]) and varies with polarity of solvent, *viz*: 67% aqueous MeOH (22.2%), MeOH (45.1%), EtOH (61.7%), $CHCl_3$ (54.5%), $*C_6H_6$ (74.8%) [Kabachnik et al. *Tetrahedron* **1** 317

1957, Gero *J Org Chem* **19** 1960 *1954*, see also Schreck *J Am Chem Soc* **71** 1881 *1949*, Buu-Hoi & Cagniant *Bull Soc Chim Fr* **10 [5]** 251 *1943*, Lewin *Izv Akad S.S.S.R Ser fiz* **11** 413 *1947*, *Chem Abstr* **42** 3261 *1948*]. [*Beilstein* **10** H 601, **10** II 420, **10** III 2813, **10** IV 2606.]

Ethyl 2-oxocyclopentanecarboxylate (2-ethoxycarbonylcyclopentanone, 2-carbethoxycyclopentanone, Dieckmann Ester) *[611-10-9, ± 53229-92-8]* **M 156.1, b 79-81°/3mm**, **86-87°/6mm**, **102°/11mm, 108-111°/15mm**. The ester is prepared in a dry N_2 atmosphere by adding ethyl adipate (202g, 1mole), during 2 hours, to a stirred (important to use a Hershberg stirrer, Hershberg *Ind Eng Chem, Anal Ed* **8** 313 *1936*) suspension of Na metal (23g, 1g.atom) in dry toluene (250ml). The reaction starts immediately and the temperature is maintained at 100-115° (oil bath) during the 2 hours and for 5 hours longer, while dry toluene is added (~750ml to 1L) so as to keep the mixture fluid and efficiently stirred, and to avoid 'caking'. The mixture is cooled to 0° and slowly added with stirring to 10% aqueous KOH (below 1°), cold H_2O being added to keep the potassium salt in solution; the toluene layer is separated, washed with cold H_2O (2 x 150ml), cold 10% aqueous KOH (adding cold H_2O to dissolve separated potassium salt), the yellow toluene solution is finally washed with cold H_2O (2 x 150ml). The combined aqueous layers, after extraction with Et_2O (250ml), are run slowly, with stirring at 0°, into cold 10% AcOH. The oily ester which separates is extracted into Et_2O (400ml), the aqueous layer is extracted with Et_2O (4 x 250ml). The combined Et_2O extracts are washed with 7% aqueous Na_2CO_3, dried (Na_2SO_4), filtered, evaporated and the residue is distilled (**b 79-81°/4mm**) to give the *keto-ester* (100-115g, 64-74%) free from ethyl adipate. An alternative synthesis in $*C_6H_6$ with slight modification provided 79-82% yield of ester. [Pinkney *Org Synth* Coll Vol **II** 116 *1943*, Cornubert & Borrel *Bull Soc Chim Fr* **47** 301 *1930*.]

The *enol* content of *ethyl 2-oxocyclopentanecarboxylate* is low and varies little with polarity of solvent, *viz*: MeOH (4.0%), EtOH (3.9%), $CHCl_3$ (3.7%), $*C_6H_6$ (8.2%) [Kabachnik et al. *Tetrahedron* **1** 317 *1957*, Lewin *Izv Akad S.S.S.R Ser fiz* **11** 413 *1947*, *Chem Abstr* **42** 3261 *1948*]. The ester has FT-IR (neat) with ν_{max} at 2979.9 (CH), 1725.6 (C=O), 1678.8 (C=O ester), 1454.5 (OH enol ?), 1370.0, 1255.0, 1190.7, 1111.9 and 1026.3 cm^{-1}; ^1H NMR (60MHz, $CDCl_3$, TMS) with δ at 1.29 (t, J = ~7Hz, 3H, ester Me), 1.89 (m, 1H, C-3 H_{eq}), 2.24 (m, 1H, C-3 H_{ax}), 2.31 (m, 4H, C-4,5 methylenes), 3.15 (t, 1H, J = ~8Hz, C-1 H), 4.20 (q, J = ~7Hz, ester CH_2); ^{13}C NMR (15MHz, $CDCl_3$, TMS) with δ at 14.18, 20.98, 27.43, 38.04, 54.77, 61.26, 169.37 and 212.25.

N-Phenyl 2-oxocyclopentanecarboxamide *[4874-65-1]* **M 203.2, m 104°** is obtained by boiling aniline (25mmol) with ethyl 2-oxocyclopentanecarboxylate (100mmol) and pyridine (0.5ml) for 2 minutes, cooling and the solid that separates is filtered off, washed with cold EtOH, then with 4% aqueous NaOH to free it from any anil formed. The solution is filtered and acidified with dilute AcOH, the precipitate is filtered off, dried and the *anilide* is recrystallised from EtOH. [Barany & Pianka *J Chem Soc* 1420 *1947*.] It is soluble hot EtOH and in Me_2CO. A 0.3% solution of the anilide in EtOH is used for the gravimetric determination of Be, Hg V and U [Chaudhuri & Das *Anal Chim Acta* **57** 193 *1971*].

1-Ethynyl-1-cyclohexanol *[78-27-3]* **M 124.2, m 30-33°, 32-33°, b 74°/12mm, 76-78°/17mm, 171-172°/694mm, 180°/atm, d_4^{25} 0.9734, n_D^{25} 1.4801.** Dissolve it in Et_2O, wash it with H_2O, dilute $NaHCO_3$, H_2O again, dry (Na_2SO_4), filter, evaporate and distil the residue. The IR (CCl_4) has ν_{max} at 3448 (OH), 2941 (CH), 1449-1123 and 956 cm^{-1}, and the ^1H NMR (CCl_4) has δ at 3.2 (OH), 2.5 (≡ CH), 1.70 (m 10H, CH_2) [Hasbrouck & Kiessling *J Org Chem* **38** 2103 *1972*]. [*Beilstein* **6** II 100.] **TOXIC.**

Eucaliptol (1,8-cineol, 1,8-epoxy-*p*-menthane, 1,3,3-trimethyl-2-oxabicyclo[2.2.2]-octane) *[470-82-6]* **M 154.2, m 1.3°, 1.5°, b 39-39.3°/4mm, 176-176.4°/760mm, d_4^{20} 0.9232, n_D^{20} 1.4575.** Purify 1,8-cineol by dilution with an equal volume of petroleum ether, then saturate it with dry HBr. The precipitate is filtered off, washed with small volumes of petroleum ether, then cineole is regenerated by stirring the crystals with H_2O. It can also be purified *via* its *o*-cresol or resorcinol addition compounds. Store it over Na until required. Purify it also by fractional distillation. It is insoluble in H_2O but soluble in organic solvents. [IR: Kome et al. *Nippon Kagaku Zasshi* [*J Chem Soc Japan* (Pure Chem Sect)] **80** 66 *1959*, *Chem Abstr* 603 *1961*, *Beilstein* **17** II 32, **17/1** V 273.]

(+)-α-Fenchol (1*R*-1,3,3-trimethylnorbornan-2-ol) *[1632-73-1]* **M 154.3, m 40-43°, 47-47.5°, b 201-**

202°, $[\alpha]_D^{20}$ +12.5° (c 10, EtOH). It is prepared by reduction of (–)-fenchone and is purified by recrystallisation from $*C_6H_6$/petroleum ether, or distillation, or both. The *2-carboxybenzoyl (monophthalate) derivative* has **m** 146.5-147.5° $[\alpha]_D^{20}$ -20.4° (EtOH), and the *2-phenylurethane* has **m** 81°. [Beckmann & Metzger *Chem Ber* **89** 2738 *1956*]. [*Beilstein* **6** III 288, **6** IV 278.]

Hexahydromandelic acid *[R-(-)- 53585-93-6, S-(+)- 61475-31-8]* **M 158.2, m 127-129°, 128-129°, 129.7°, $[\alpha]_D^{20}$ (–) and (+) 25.5° (c 1, AcOH) and $[\alpha]_D^{20}$ (–) and (+) 13.6° (c 7.6, EtOH).** It forms hexagonal clusters on recrystallisation from CCl_4 or Et_2O. [Wood & Comley *J Chem Soc* 2638 *1924*, Lettré et al. *Chem Ber* **69** 1594 *1936*]. The *racemate* has **m** 137.2-137.6° (134-135°) [Smith et al. *J Am Chem Soc* **71** 3772 *1949*]. [*Beilstein R-* **10** II 5; *S-* **10** II 6.]

Hexamethyl(Dewar)benzene (HMDB, 1,2,3,4,5,6-hexamethyl-bicyclo[2.2.0]hexa-2,5-diene) *[7641-77-2]* **M 162.3, m 7.5°, b 60°/20mm, ~152°/760mm, d_4^{20} 0.8125, n_D^{20} 1.4480.** HMDB is obtained in ~80% yield when 2-butyne (dimethylacetylene, flammable gas b 27°/atm, [503-17-3]) in $*C_6H_6$ or CH_2Cl_2 containing anhydrous $AlCl_3$ is stirred at 35° for 5-7 hours. The brown reaction mixture is poured onto crushed ice, washed with dilute aqueous NaOH, and HMDB is isolated from the organic phase by fractional vacuum distillation. Hexamethylbenzene (m 165-166°, [87-85-4]) is a by-product (~12-18%) together with a mixture (~2%) of *syn-* (m 127°) and *anti-* (m 196°) octamethyltricyclo[4.2.0.$0^{2,5}$]octa-3,7-diene, and octamethylcyclooctatetraene (m 113°). Although longer reaction times increase the conversion of 2-butyne, they lower the yields of HMDB in favour of the other by-products. It is fairly thermally stable with half-life time conversions to hexamethylbenzene with 105 hours/120°, 5.5 hours/140°, and 2.1 hours/150°. It is best to store it at low temperature and away from light as radiation from a low pressure UV lamp converts it mainly to hexamethylbenzene with ~20-25% of the valence isomer hexamethylprismane (m 91°). The UV spectrum

exhibits tail end absorption from 220 to 250nm; the FT-IR (neat) has ν_{max} at 2950.0, 1683.5, 1439.5, 1368.8, 1275.4, 1222.2, 1064.8, 736.2 and 490.7 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.08 (s, 6H, 1,4-$(CH_3)_2$) and 1.69 (s, 12H, 2,3,5,6-$(CH_3)_4$), and the ^{13}C NMR (15MHz, $CDCl_3$, TMS) has δ at 10.06 (1,4-Me carbons) and 11.22 (2,3,5,6-Me carbons), 55.68 (2 saturated carbons) and 144.09 (4 olefinic carbons). [Schäfer & Hellmann *Angew Chem Internat Edn* **6** 518 *1967*.] Purify it also by passing it neat through alumina or in $*C_6H_6$ or CH_2Cl_2 solution. [Traylor & Miksztal *J Am Chem Soc* **109** 2770 *1987*].

Humulon *[26472-41-3]* **M 362.5, m 65-66.5°, $[\alpha]_D^{26}$ –212° (95% EtOH).** Crystallise humulon from Et_2O. It dissolves slightly in hot H_2O but precipitates on cooling. It has λ_{max} nm (ε) at 237 (13,760) and 282 (8,330) in EtOH. [Wollmer *Chem Ber* **49** 780 *1916*, Carson *J Am Chem Soc* **73** 4652 *1951*, *Beilstein* **8** II 537, **8** III 4034, **8** IV 3410.]

1-Hydroxymethyladamantane *[770-71-8]* **M 166.3, m 115°.** Dissolve the adamantane in Et_2O, wash it with aqueous 0.1N NaOH and H_2O, dry over $CaCl_2$, evaporate and recrystallise the residue from aqueous MeOH. [Stetter et al. *Chem Ber* **92** 1629 *1959*, *Beilstein* **6** IV 400.]

***N*-Hydroxy-5-norbornene-2,3-dicarboxylic acid imide** *[21715-90-2]* **M 179.2, m 165-166°, 166-169°, pK_{Est}~6**. Dissolve the imide in $CHCl_3$, filter, evaporate and recrystallise from EtOAc. The IR (nujol) has ν_{max} 1695, 1710 and 1770 (C=O), and 3100 (OH) cm^{-1}. The *O-acetyl* derivative has **m** 113-114° (from EtOH) with IR bands at ν_{max} 1730, 1770 and 1815 cm^{-1} only, and the *O-benzoyl* derivative has **m** 143-144° (from propan-2-ol or $*C_6H_6$). [Bauer & Miarka *J Org Chem* **24** 1293 *1959*, Fujino et al. *Chem Pharm Bull Jpn* **22** 1857 *1974*]. [*Beilstein* **21/10** V 188.]

Lupulon (β-lupulic acid, bitter acid) *[468-28-0]* **M 414.6, m 92-94°, $pK_{Est(1)}$ ~4.2, $pK_{Est(2)}$ ~9.7.** Recrystallise Lupulon from 90% MeOH, hexane or petroleum ether at low temperature. It has been purified by chromatography through Kieselgel. [Wieland et al. *Chem Ber* **102** 2012 *1925*, Riedl *Chem Ber* **85** 692 *1952*, *Beilstein* **7** II 856, **7** III 4752, **7** IV 2866.]

***l*-(–)-Menthone (2*S*,5*R*-2-isopropyl-5-methylcyclohexan-1-one)** *[14073-97-3]* **M 154.3, b 98-100°/14mm, 205-208°/atm, 207-210°/760mm, d^{25} 0.8930, n $^{20}_{D}$ 1.4505, [α] $^{20}_{D}$ –28° (neat).** It is obtained by adding pure *l*-(–)-menthol (4.5g, see [2216-51-5]) in four portions to chromic acid [prepared from $Na_2Cr_2O_7$. $2H_2O$ (60g, CARE CARCINOGENIC) in H_2O (300ml) and concentrated H_2SO_4 (27ml) with cooling) when the temperature rises, but should be kept at 55° (warm if necessary). A black spongy mass is first formed which becomes soft and melts to a dark brown oil on the surface as the temperature rises. The temperature drops when the oxidation is complete, the mixture is cooled and extracted with Et_2O (100ml), the extract is separated, washed with 5% aqueous NaOH (100ml, CARE) several times (~ x 3) until the colour is light yellow, then H_2O and dried (Na_2SO_4 or Mg_2SO_4). The ethereal solution is evaporated and the residual oil is redistilled at

atmospheric pressure or in a vacuum through a short column to give pure *l-menthone* (38g, 91%). [Brown & Garg *J Am Chem Soc* **83** 2952 *1961*, Hussey & Baker *J Org Chem* **25** 1434 *1960*.] This menthone is the most frequently naturally occurring of the four optically active isomers. It has been used for the optical resolution of diols *via* acetalisation [Harada & Oku *Synlett* 95 *1994*], and the menthone spirocylic 1,3-dioxane-4,6-diones have been used for asymmetric [2 + 2]cycloaddition and Diels-Alder reactions [Sato et al. *Tetrahedron* **47** 7271 *1991*]. The *oxime* has **m 59°** (from petroleum ether), the *semicarbazone* has **m 189-191°** (from MeOH, EtOH or aqueous EtOH), the *phenylhydrazone* has **m 53°** (from aqueous EtOH), and the *2,4-dinitrophenylhydrazone* has **m 146°** (from EtOH, aqueous EtOH or EtOH/EtOAc). [*Beilstein* **7** H 38, **7** I 34, **7** II 39, **7** III 152, **7** IV 87.] It is used in flavourings and perfume.

1*R*-(−)-Menthyl chloride (1*S*,2*R*,4*R*-2-chloro-1-isopropyl-4-methylcyclohexane) *[16052-42-9]* **M 174.7, m −20.1° to −16.5°, b 88.5°/12.5mm, 101-105°/21mm, d_4^{20} 0.936, n_D^{20} 1.463, $[\alpha]_D^{20}$ −52.4° (neat).** Dissolve menthyl chloride in petroleum ether (b 40-60°), wash it with H_2O, conc H_2SO_4 until no discoloration of the organic layer occurs (care with conc H_2SO_4 during shaking in a separating funnel), again with H_2O and dry it ($MgSO_4$). Evaporate, and distil the residual oil through a Claisen head with a Vigreux neck of *ca* 40 cm length. [Smith & Wright *J Org Chem* **17** 1116 *1952*, Barton et al. *J Chem Soc* 453 *1952*, *Beilstein* **5** III 134, **5** IV 152.]

1-Methyladamantane *[768-91-2]* **M 150.2, m 103°, 104°.** Purify it by zone melting, chromatography through an Al_2O_3 column and eluting with pentane, and sublime it repeatedly at 90-95°/12mm. [Stetter et al. *Chem Ber* **92** 1629 *1959*, Schleyer & Nicholas *Tetrahedron Lett* **9** 305 *1961*, *Beilstein* **5** IV 479.]

2-Methyladamantane *[700-56-1]* **M 150.2, 144-146°.** Purify it by zone melting, chromatography through an Al_2O_3 column and eluting with pentane. Recrystallise it from EtOH and sublime it repeatedly at 90-95°/12mm. [Schleyer & Nicholas *J Am Chem Soc* **83** 182 *1961*, Molle et al. *Can J Chem* **65** 2428 *1987*.]

Methylcyclohexane *[108-87-2]* **M 98.2, b 100.9°, d_4^{25} 0.7650, n_D^{20} 1.4231, n_D^{25} 1.42058.** Passage through a column of activated silica gel gives material transparent down to 220nm. It can also be purified by passage through a column of activated basic alumina, or by azeotropic distillation with MeOH, followed by washing out the MeOH with H_2O, drying and distilling. Methylcyclohexane can be dried with $CaSO_4$, CaH_2 or sodium. It has also been purified by shaking with a mixture of conc H_2SO_4 and HNO_3 in the cold, washing with H_2O, drying with $CaSO_4$ and fractionally distilling it from potassium. Percolation through a column of Celite impregnated with 2,4-dinitrophenylhydrazine (DNPH), phosphoric acid and H_2O (prepared by grinding 0.5g DNPH with 6ml 85% H_3PO_4, then mixing with 4ml of distilled H_2O and 10g of Celite) removes carbonyl-containing impurities. [Cowan et al. *J Chem Soc* 1865 *1939, Beilstein* **5** III 65, **5** IV 94.]

[Wildman & Hemminger *J Org Chem* **17** 1641 *1952*, Wood & Roberts *J Org Chem* **23** 1124 *1957*, Bixter & Niemann *J Org Chem* **23** 742 *1958, Beilstein* **7** III 243, **7** IV 139.]

1,2,3,4,5-Pentamethylcyclopentadiene (Cp') *[4045-44-7]* **M 136.2, b 55-60°/13mm, 58°/13mm, 58.3°/13.5mm**, **d^{25} 0.870, n_D^{20} 1.4740.** Of the many syntheses of this useful ligand, the following is the most economical on materials and can be scaled up. Strictly anhydrous and anaerobic conditions should be used and reagents should be dried appropriately, degassed, and precaution against fire should be exercised. Three steps are involved:
Step 1: Under argon, lithium (58g, 8.36moles, with 0.02%Na, of ~3.2mm diameter cut into the flask in ~5mm lengths) is covered with Et_2O (1600ml, freshly distilled from ~3:1w/w K/Na benzophenone), and 2-bromo-2-butene (120g, 0.88mole, 90.4ml of a molecular sieves 4Å dried commercial *cis*- and *trans*- mixture or prepared according to Bordwell & Landis *J Am Chem Soc* **79** 1593 *1957*) is added slowly with stirring (10ml aliquots slowly at first until the reaction begins; with evolution of bubbles and cloudiness due to separation of LiBr), and

at such a rate as to maintain gentle reflux of the Et_2O.
Step 2: After addition is complete (~1.5 hours), still under argon, a mixture of ethyl acetate (166g, 1.88mole, 184ml, dried over molecular sieves 4Å) and 2-bromo-2-butene (430g, 3.18mole, 324ml as above) are then added dropwise with stirring, while carefully maintaining gentle reflux over a period of 4-5 hours. When this addition is completed, a further volume of dry EtOAc (50g, 55.4ml) and a further portion of 2-bromo-2-butene (~10-20g, 7.5-15ml) are added, while stirring is continued, until refluxing of Et_2O ceases. The mixture is allowed to cool over 4 hours, saturated aqueous NH_4Cl solution is added dropwise to hydrolyse unreacted Li, the Et_2O layer is collected, the aqueous layer is extracted with Et_2O (3 x 200ml), and the combined Et_2O solutions are evaporated to ~350ml.
Step 3: The Et_2O concentrate is added, with stirring, to a slurry of *p*-toluenesulfonic acid monohydrate (26g) in Et_2O (500ml) under a reflux condenser, at such a rate the the solvent refluxes gently. The mixture is then stirred for 5 minutes after refluxing ceases, and poured into saturated aqueous $NaHCO_3$ (1200ml) containing Na_2CO_3 (19g). The yellow aqueous phase is removed, extracted with Et_2O (3 x 200ml), and the combined Et_2O solutions are dried (Na_2SO_4), filtered, evaporated to 250-300ml (rotavap), then trap-to-trap distilled *in vacuo* (bath temperature at 35-40°) to give a yellow liquid (85% pure by GC) which is fractionally distilled in a vacuum under N_2 using a 50cm vigreux column. The fraction with b 65-70°/20mm collected (142g, 53% yield based on EtOAc used) as pale-yellow liquid is *1,2,3,4,5-pentamethylcyclopentadiene* (92% pure by GC). An additional fraction (15g, 5%) with b 70-75°/20mm is 85% pure by GC. The liquids are colourless to pale-yellow in colour with a sweet olefinic odour, and are pure enough for use as ligands. They should be stored in a freezer under N_2 or argon. In comparison with the unsubstituted *cyclopentadiene* it is a stronger donor of electron density, exerting considerably enhanced thermal stability, and the metal complexes that it forms are generally more soluble and easier to crystallise.
The *pentamethylpentadiene* has FT-IR (neat) with ν_{max} at 2960 (vs), 2915 (vs), 2855 (vs), 2735 (w), 1660 (m), 1640 (w), 1390 (s), 1355 (m), 1150 (w), 1105 (mw), 1048 (w), 840 (mw) and 668 (w) cm^{-1}; ^1H NMR (60MHz, CCl_4, TMS) with δ at 2.4 (m, 1H), 1.75 (br s, 13H, 2,3,4,5-Me), 0.95 (d, $^3J_{H\text{-}H}$ = 8Hz, 3H, 1-Me); ^{13}C NMR (15MHz, $CDCl_3$, TMS) with δ at 14.18, 20.98, 27.43, 38.04, 54.77, 61.26, 169.37 and 212.25. [Manriquez et al. *Inorg Synth* **XXI** 181 *1982*, Feilter et al. *Inorg Chem* **15** 466 *1976*, Threlkel et al. *Org Synth* **65** 42 *1987*.]

Perfluorocyclobutane (octafluorocyclobutane) *[115-25-3]* **M 200.0, m −40°, b −5°, d^{-20} 1.654, d^{o} 1.72.** Purify octafluorocyclobutane by trap-to-trap distillation, retaining the middle portion. [Danus *Ind Eng Chem* **47** 144 *1955*, Claasen *J Chem Phys* **18** 543 *1950*, *Beilstein* **5** III 8, **5** IV 8.]

Perfluorocyclohexane (dodecafluorocyclohexane) *[355-68-0]* **M 300.1, m 51° (sublimes), sublimes on melting at 52°, m 58.2° (sealed tube), d_4^{25} 1.720, n_D^{30} 1.269.** Extract it repeatedly with MeOH, then pass it through a column of silica gel (previously activated by heating at 250°). [Haszeldine & Smith *J Chem Soc* 2691 *1950*, IR: Thompson & Temple *J Chem Soc* 1432 *1948*, *Beilstein* **5** III 37, **5** IV 48.]

Perfluoro-1,3-dimethylcyclohexane *[335-27-3]* **M 400.1, b 101°, d_4^{20} 1.829, n_D^{20} 1.300.** Fractionally distil it, then 35ml are sealed with about 7g KOH pellets in a borosilicate glass ampoule and heated at 135° for 48 hours. The ampoule is cooled, opened, and the liquid is resealed with fresh KOH in another ampoule and heated as before. This process is repeated until no further decomposition is observed. The substance is then washed with distilled water, dried ($CaSO_4$) and distilled. [Grafstein *Anal Chem* **26** 523 *1954*, *Beilstein* **5** III 378.] **IRRITANT.**

Perfluoro(methylcyclohexane) *[355-02-2]* **M 350.1, b 76.3°, d^{25} 1.7878.** Reflux it for 24 hours with saturated acid $KMnO_4$ (to oxidise and remove hydrocarbons), then neutralise, steam distil, dry with P_2O_5 and pass slowly through a column of dry silica gel. [Glew & Reeves *J Phys Chem* **60** 615 *1956*.] It can also be purified by percolation through a 1 metre neutral activated alumina column, and the impurities are checked by ^1H NMR. [*Beilstein* **5** IV 102.] **IRRITANT.**

***R*(−)-α-Phellandrene (*p*-menta-1,5-diene)** *[4221-98-1]* **M 136.2, b 61°/11mm, 175-176°/760mm, d_4^{20} 0.838, n_D^{20} 1.471, $[\alpha]_D^{20}$ −230° (c 10, Et_2O), −153° to −183° (neat).** Purify it by gas chromatography with an Apiezon column. Also purify it by steam distillation (with 0.5% hydroquinone), then re-distil it through a 50

plate bubble cap column and collecting the fraction with **b** 72-72.5°/22mm [Pines & Eschinazi *J Am Chem Soc* **77** 6318 *1955*]. UV: λ_{max} 263nm (ε 3,345) in octane. [Read & Storey *J Chem Soc* 2770 1930, *Beilstein* **5** III 341, **5** IV 436.]

Picrotoxin (cocculin) *[124-87-8]* **M 602.6, m 203°, $[\alpha]_{546}^{20}$ −40° (c 1, EtOH), $[\alpha]_{D}^{16}$ −29.3° (c 4, EtOH).** It is the toxic principle in the seeds of *Anamirta cocculus*. Crystallise picrotoxin from H_2O or Me_2CO/H_2O. The *monoacetate* has **m** 244-245° (*C_6H_6). [Meyer & Bruger *Chem Ber* **31** 2958 *1898*, Johns et al. *J Chem Soc* 4717 *1956*, *Beilstein* **19** III/IV 5245.] HIGHLY TOXIC, stimulates the CNS and respiration.

***1R,5S*-α-Pinene** *[7785-70-8]* **M 136.2, b 61°/30mm, 156.2°/760mm, d_4^{20} 0.858, n_D^{15} 1.4634, n_D^{20} 1.4658, $[\alpha]_D^{20}$ +51° (neat).** It is isomerised by heat, acids and certain solvents. It should be distilled under reduced pressure under N_2 and stored in the dark. It has been purified *via* the nitrosochloride [Waterman et al. *Recl Trav Chim, Pays Bas* **48** 1191 *1929*]. For purification of optically active forms see Lynn [*J Am Chem Soc* **91** 361 *1919*].
Small quantities (0.5ml) have been purified by GLC using helium as carrier gas and a column at 90° packed with 20 wt% of polypropylene sebacate on a Chromosorb support. Larger quantities are fractionally distilled under reduced pressure through a column packed with stainless steel gauze spirals. The material can be dried over CaH_2 or sodium, and stored in a refrigerator: $CaSO_4$ and silica gel are not satisfactory because they induce spontaneous isomerisation. [Bates et al. *J Chem Soc* 1521 *1962*, *Beilstein* **5** III 366, **5** IV 452.]

***1S,5S*–α-Pinene** *[7785-26-4]* **M 136.2, b 155-156°/760mm, d_4^{20} 0.858, n_D^{20} 1.4634, $[\alpha]_D^{20}$ −47.2°.** Purify as for *1R,5S*-α-Pinene above. [*Beilstein* **5** III 366, **5** IV 455.]

***R*(+)-Pulegone** *[89-82-7]* **M 152.2, b 69.5°/5mm, d_4^{20} 0.936, n_D^{20} 1.4866, $[\alpha]_{546}^{20}$ +23.5°(neat), $[\alpha]_D^{20}$ +24.2°(neat).** Purify pulegone *via* the *semicarbazone* which has **m** 174° (from MeOH) and $[\alpha]_D^{20}$ +68.2° (c 1, $CHCl_3$). Fractionally distil it *in vacuo*. [Short & Read *J Chem Soc* 1309 *1939*]. [Erskine & Waight *J Chem Soc* 3425 *1960*, *cf* Ort *Org Synth* **65** 203 *1987*, *Beilstein* **7** III 334, **7** IV 188.]

1*R*,3*R*,4*R*,5*R*-Quinic acid (1,3,4,5-tetrahydroxycyclohexane carboxylic acid) *[77-95-2]* **M 192.3, m 172°(dec), $[\alpha]_{546}^{20}$ −51° (c 20, H_2O), $[\alpha]_D^{23}$ −45° (c 5, H_2O), pK^{25} 3.58.** Quinic acid crystallises from H_2O with **m** 174°, and from EtOH with **m** 168-169°. [McComsey & Maryanoff *J Am Chem Soc* **59** 2652 *1994*, pK: Timberlake *J Chem Soc* 2795 *1959*, Anet & Reynolds *Aust J Chem* **8** 282 *1955*, *Beilstein* **10** III 2407, **10** IV 2257.]

Reductic acid (1,2-dihydroxycyclopent-1,2-en-3-one) *[80-72-8]* **M 114.1, m 213°, pK_1^{20} 4.80, pK_2^{20} 12.9**. Crystallise reductic acid from EtOH, EtOAc (**m** 213-213.5°) or EtOH/EtOAc. It has been sublimed at 0.5mm. The *osazone* has **m** 245°(dec) (from BuOH). [Hess et al. *Justus Liebigs Ann Chem* **563** 31 *1939*, **592** 137 *1955*, **736** 134 *1970*, *Beilstein* **8** III 1942, **8** IV 1714.]

Squaric acid (3,4-dihydroxy-3-cyclobutene-1,2-dione) *[2892-51-5]* **M 114.1, m 293°(dec), 294°(dec), >300°, pK_1^{20} 1.50, pK_2^{20} 2.93**. Purify squaric acid by recrystallisation from H_2O — this is quite simple because the acid is ~7% soluble in boiling H_2O and only 2% at room temperature. It is not soluble in Me_2CO or Et_2O; hence it can be rinsed with these solvents and dried in air or a vacuum. It is not hygroscopic and gives an intense purple colour with $FeCl_3$. It has IR with ν_{max} at 1820 (C=O) and 1640 (C=C) cm^{-1}, and UV with λ_{max} at 269.5nm (ε 37K $M^{-1}cm^{-1}$). [Cohn et al. *J Am Chem Soc* **81** 3480 *1959*, Park et al. *J Am Chem Soc* **84** 2919 *1962*.] See also **pKa** values of 0.59 ±0.09 and 3.48 ±0.023 [Scwartz & Howard *J Phys Chem* **74** 4374 *1970*]. [Schmidt & Reid *Synthesis* 869 *1978*, *Beilstein* **8** IV 2701.]

Terpin hydrate *[2451-01-6 cis-hydrate, 565-50-4 and 565-48-0 stereoisomers]* **M 190.3, m 105.5° (*cis anhydrous*), 116-117° (*cis hydrate*), 156-158°, 157.5°(*trans*).** Crystallise terpin from H_2O or EtOH. The

anhydrous *cis-isomer* distils at 258°/760mm, but hydrates on exposure to moist air. *Anhydrous* terpin is also obtained by recrystallisation from absolute EtOH. [Sword *J Chem Soc* **127** 1632 *1925*, Lombard & Ambrose *Bull Soc Chim Fr* 230 *1961*, *Beilstein* **5** IV 435.]

1,1,2,2-Tetrafluorocyclobutane *[374-12-9]* **M 128.1, b 50-50.7°, d_4^{20} 1.275, n_D^{20} 1.3046.** Purify 1,1,2,2-tetrafluorocyclobutane by distillation or by preparative gas chromatography using a 2m x 6mm(i.d.) column packed with ß,ß'-oxydipropionitrile on Chromosorb P at 33°. [Conlin & Fey *J Chem Soc, Faraday Trans 1* **76** 322 *1980*, Coffmann et al. *J Am Chem Soc* **71** 490 *1949*, *Beilstein* **5** III 8, **5** IV 8.]

2,2,4,4-Tetramethylcyclobutan-1,3-dione *[933-52-8]* **M 140.2, m 114.5-114.9°.** Crystallise the dione from $*C_6H_6$ and dry it *in vacuo* over P_2O_5 in an Abderhalden pistol. [*Beilstein* **7** III 3234, **7** IV 2004.]

3,3,5,5-Tetramethylcyclohexanone *[14376-79-5]* **M 154.3, m 11-12°, 13.2°, b 59-61°/5mm, 80-82°/13mm, 196°/760mm, 203.8-204.8°/760mm, d_4^{20} 0.8954, n_D^{20} 1.4515.** Purify the ketone first through a 24 inch column packed with Raschig rings, then a 40cm Vigreux column under reduced pressure (**b** 69-69.3°/7mm). The *oxime* has **m** 144-145° (from 60% EtOH), and the *semicarbazone* has **m** 196-197°, 197-198° (214.5°, 217-218°) [Karasch & Tawney *J Am Chem Soc* **63** 2308 *1941*, UV: Sandris & Ourisson *Bull Soc Chim Fr* 958 *1956*]. [*Beilstein* **7** III 163, **7** IV 89.]

(1*R*)-(−)-Thiocamphor (1*R*-bornane-2-thione, 1*R*-(−)-1,7,7-trimethylbicyclo[2.2.1]heptane-2-thione) *[53402-10-1]* **M 168.3, m 136-138°, 146°, $[\alpha]_D^{22}$ −22° (c 3, EtOAc).** It forms red prisms from EtOH and sublimes under vacuum. It possesses a sulfurous odour and is volatile like camphor. [Sen *J Indian Chem Soc* **12** 647 *1935*, Sen *J Indian Chem Soc* **18** 76 *1941*.] The *racemate* crystallises from $*C_6H_6$ and has **m** 145° [138.6-139°, White & Bishop *J Am Chem Soc* **62** 10 *1940*]. [*Beilstein* **7** III 419.]

1*r*,2*t*,4*t*-Trimethylcyclohexane *[2234-75-7]* **M 126.2, b 145.7-146.7°/760mm, d_4^{20} 0.786, n_D^{20} 1.4330.** Wash the trimethylcyclohexane with conc H_2SO_4 (removes aromatic hydrocarbons), then with H_2O, dry it (type 4A molecular sieves), and fractionally distil it through a glass helices packed column with partial take-off and reflux ratio between 50 and 75. **Flammable liquid.** [cf. Henne et al. *J Am Chem Soc* **63** 3475 *1941*, Rossini *Anal Chem* **20** 112 *1948*, *Beilstein* **5** H 42, **5** I 17, **5** II 24, **5** III 121.]

***R*-(−)-2,2,6-Trimethyl-1,4-cyclohexanedione** *[60046-49-3]* **M 154.2, m 88-90°, 91-92°, $[\alpha]_D^{20}$ −270° (c 0.4%, MeOH), $[\alpha]_D^{20}$ −275° (c 1, $CHCl_3$).** It is obtained from fermentation and is purified by recrystallisation from diisopropyl ether. [ORD: Leuenberger et al. *Helv Chim Acta* **59** 1832 *1976*.] The *racemate* has **m** 65-67°, and the *4-(4-phenyl)semicarbazone* has **m 218-220°** (from CH_2Cl_2/MeOH) [Isler et al. *Helv Chim Acta* **39** 2041 *1956*, *Beilstein* **7** IV 2032.]

***cis,cis*-1α,3α,5α-Trimethylcyclohexane-1,3,5-tricarboxylic acid (Kemp's acid)** *[79410-20-1]* **M 258.3, m 241-243°, pK_1 3.30, pK_2 5.85, pK_3 7.3 (H_2O); pK_1 4.7, pK_2 7.6, pK_3 8.8 (50% H_2O/MeOH).** Recrystallise the tricarboxylic acid from Me_2CO after re-precipitating it several times with mineral acid from aqueous alkaline soltion. The *trimethyl ester* has **m 78-81°**. [See Kemp *J Org Chem* **46** 5140 *1981*, Jeong et al. *J AmChem Soc* **113** 201 *1991*, Stack et al. *J Am Chem Soc* **114** 7007 *1992*.]

(±)-2,2,6-Trimethylcyclohexanone *[2408-37-9]* **M 140.2, b 69-71.5°/20mm, 177-178.5°/758mm d_4^{20} 0.904, n_D^{20} 1.4470.** Purify it *via* the *semicarbazone* (**m 218°**, from MeOH or EtOH), decompose this in the usual way (cf p 75 and 77, or MEK, p 123) and fractionally distil the liquid ketone through a Vigreux column at ~760mm. [Chakravarti *J Chem Soc* 1567 *1947*, Milas et al. *J Am Chem Soc* **70** 1831 *1948*, *Beilstein* **7** I 24, **7** II 32, **7** III 7.]

Xanthatin (3-methylene-7-methyl-6-[3-oxo-1-buten-1-yl]cyclohept-5-ene-[10,11-*b*]furan-2-one, (−)-2-[(*1R*)-7*t*-hydroxy-5*c*-methyl-4-(3-oxobut-1-en-ξ-yl)cyclohept-3-en-*r*-yl)-acrylic acid lactone *[26791-73-1]* **M 246.3, m 114.5-115°, $[\alpha]_D^{20}$ −20° (c 2, $CHCl_3$).** Crystallise xanthatin from MeOH, aqueous MeOH, EtOH

or aqueous EtOH. Its UV has $\lambda_{max}(\varepsilon)$ at 213 (22800) and 275nm (7300). The *2,4-dinitrophenylhydrazone* has **m** 240°(dec) (twice recrystallise from $CHCl_3$/MeOH). [Geissman et al. *J Am Chem Soc* **76** 685 *1954*, Deuel & Geissman *J Am Chem Soc* **79** 3778 *1957*, *Beilstein* **17** III/IV 6221, **17/1** V 305.]

AROMATIC COMPOUNDS

Acenaphthene *[83-32-9]* **M 154.2, m 94.0°.** Crystallise acenaphthene from EtOH. It has also been purified by chromatography from CCl_4 on alumina with *benzene as eluent [McLaughlin & Zainal *J Chem Soc* 2485 *1960*]. [*Beilstein* **5** IV 1834.]

Acenaphthenequinone *[82-86-0]* **M 182.2, m 260-261°.** Extract it with, then recrystallise it twice from *C_6H_6. Dry it *in vacuo.* [LeFevre et al. *J Chem Soc* 974 *1963*, *Beilstein* **7** IV 2498.]

RS*-Acenaphthenol** *[6306-07-6]* **M 170.2, m 144.5-145.5°, 146°, 148°**. If highly coloured (yellow), dissolve it in boiling *benzene (14g in 200ml), add charcoal (0.5g), filter it through a heated funnel, concentrate to 100ml and cool to give almost colourless needles. **Benzene vapour is* **TOXIC**; *use an efficient fume cupboard.* The *acetate* has **b** 166-168°/5mm (bath temperature 180-185°). [Cason *Org Synth* Coll Vol **III** 3 *1955*.] It can also be recrystallised from *C_6H_6 or EtOH [Fieser & Cason *J Am Chem Soc* **62** 432 *1940*]. It forms a brick-red crystalline ***complex with 2,4,5,7-tetranitrofluoren-9-one which is recrystallised from AcOH and is dried in a vacuum over KOH and P_2O_5 at room temperature, **m** 170-172° [Newman & Lutz *J Am Chem Soc* **78** 2469 *1956*]. [*Beilstein* **6** IV 4623.]

Acenaphthylene *[208-96-8]* **M 152.2, m 92-93°, b 280°/~760mm.** Dissolve acenaphthylene in warm redistilled MeOH, filter through a sintered glass funnel and cool to –78° to precipitate the material as yellow plates [Dainton et al. *Trans Faraday Soc* **56** 1784 *1960*]. *Alternatively* it can be sublimed *in vacuo*. [*Beilstein* **5** H 625, **5** IV 2138.]

4-Acetamidobenzaldehyde *[122-85-0]* **M 163.2, m 155°, 156°, 160°.** Recrystallise it from water. The *4-nitrophenylhydrazone*, **m** 264-265°, crystallises as orange needles from EtOH [Hodgson & Beard *J Chem Soc* 21 *1927, Beilstein* **14** H 38, **14** II 25, **14** III 75, **14** IV 71.]

***p*-Acetamidobenzenesulfonyl chloride (*N*-acetylsulfanilyl chloride)** *[121-60-8]* **M 233.7, m 149°(dec).** Crystallise the chloride from toluene, $CHCl_3$, or ethylene dichloride. [*Beilstein* **14** IV 2703.]

α-Acetamidocinnamic acid *[5469-45-4]* **M 205.2, m 185-186° ($2H_2O$), 190-191°(anhydrous), 193-195°, pK_{Est} ~3.2.** It crystallises from H_2O as the *dihydrate,* and on drying at 100° it forms the *anhydrous* compound which is *hygroscopic*. Alkaline hydrolysis yields NH_3 and phenylpyruvic acid. [Erlenmeyer & Früstück *Justus Liebigs Ann Chem* **284** 47 *1895*, *Beilstein* **14** IV 1769.]

2-Acetamidofluorene (*N*-[2-fluorenyl)acetamide) *[53-96-3]* **M 223.3, m 194°, 196-198°**. Recrystallise it from toluene (1.3mg in 100ml). Its solubility in H_2O is 1.3mg/l at 25°, its UV has λ_{max} at nm(log ε) : 288(4.43), 313(4.13). [Sawicki *J Org Chem* **21** 271 *1956*.] It can also be recrystallised from 50% AcOH. [Diels et al. *Chem Ber* **35** 3285 *1902*]. 9-^{14}C and ω-^{14}C 2-acetamidofluorene were recrystallised from aqueous EtOH and had **m** 194-195° and 194° respectively. *Potent* **CARCINOGEN.** [Miller et al. *Cancer Res* **9** 504 *1949*, **10** 616 *1950*, Sadin et al. *J Am Chem Soc* **74** 5073 *1952*, *Beilstein* **12** H 3287, **12** IV 3373.]

2-Acetamidophenol *[614-80-2]* **M 151.2, m. 209°, pK_{Est} ~9.4.** Recrystallise it from water, EtOH or aqueous EtOH. [*Beilstein* **13** H 370, **13** I 113, **13** II 171, **13** III 778.]

3-Acetamidophenol (Metacetamol) *[621-42-1]* **M 151.2, m 148-149°, pK^{25} ~9.59.** Recrystallise the phenol from water. The *3,5-dinitrobenzamide complex* gives orange-yellow crystals from hot H_2O and has **m** 212°. [*Beilstein* **13** H 415, **13** I 132, **13** II 213, **13** III 950, **13** IV 977.]

4-Acetamidophenol (Paracetamol, acetaminophen, 4'-hydroxyacetanilide) *[103-90-2]* **M 151.2, m 169-170.5°, pK_{Est} ~10.0.** Recrystallise Paracetamol from water or EtOH. The *3,5-dinitrobenzamide complex* gives orange crystals from hot H_2O and has **m** 171.5°. [*Beilstein* **13** H 460, **13** I 159, **13** II 243, **13** III 1056, **13** IV

1091.]

***p*-Acetamidophenylacetic acid (Actarit)** *[18699-02-0]* **M 193.2, m 167°, 168-170°, 174-175°, pK^{25} 3.49.** Crystallise the acid from MeOH/Me_2CO, aqueous EtOH or H_2O. The *amide* has **m** 231° (from 50% aqueous EtOH). [Gabriel *Chem Ber* **15** 841 *1882*, Cerecedo et al. *J Biol Chem* **42** 238 *1924*, Tramontano et al. *J Am Chem Soc* **110** 2282 *1988*, *Beilstein* **14** II 281.]

Acetanilide *[103-84-4]* **M 135.2, m 114°, pK^{25} 0.5.** Recrystallise acetanilide from water, aqueous EtOH, *benzene or toluene. [*Beilstein* **12** IV 373.]

Acetoacetanilide *[102-01-2]* **M 177.2, m 86°, pK^{25} 10.68.** Crystallise the anilide from H_2O, aqueous EtOH or petroleum ether (b 60-80°). [Williams & Krynitsky *Org Synth* Coll Vol **III** 10 *1955*.]

4-Acetophenetidide (phenacetin, *p*-methoxyacetanilide) *[62-44-2]* **M 179.2, m 136°.** Crystallise it from H_2O or EtOH, and its solubility in H_2O is 0.08% (at ~10°) and 1.2% (at ~100°), and in EtOH it is 6.7% (at ~10°) and 36% (at ~100°). *Alternatively*, it can be purified by solution in cold dilute alkali and re-precipitating by addition of acid to neutralisation point. Dry it in air. [*Beilstein* **13** H 461, **13** IV 1092.]

Acetophenone *[98-86-2]* **M 120.2, m 19.6°, b 54°/2.5mm, 202°/760mm, d_4^{25} 1.0238, n_D^{25} 1.5322, pK^{26} –7.6(basic), pK^{25} 19.2(acidic).** Dry it by fractional distillation or by standing with anhydrous $CaSO_4$ or $CaCl_2$ for several days, followed by fractional distillation under reduced pressure (from P_2O_5, optional), and careful, slow and repeated partial crystallisations from the liquid at 0° excluding light and moisture. It can also be crystallised at low temperatures from isopentane. Distillation can be followed by purification using gas-liquid chromatography [Earls & Jones *J Chem Soc, Faraday Trans 1* **71** 2186 *1975*.] [*Beilstein* **7** H 271, **7** I 146, **7** II 208, **7** III 936, **7** IV 619.]
§ A commercial polystyrene supported version is available — scavenger resin (for diol substrates).

Aceto-*o*-toluidide (2-methylacetanilide) *[120-66-1]* **M 149.2, m 110°, 112°, b 176°/14mm, 296°/760mm.** Crystallise the toluidide from hot H_2O (solubility 1g/210ml), EtOH or aqueous EtOH. Its UV has λ_{max} at 230 and 280nm (EtOH). [*Beilstein* **12** H 792, **12** I 376, **12** II 439, **12** III 1853, **12** IV 1755.]

Aceto-*m*-toluidide (3-methylacetanilide) *[537-92-8]* **M 149.2, m 65.5°, b 182-183°/14mm, 303°/760mm.** Crystallise the toluidide from H_2O, EtOH, aqueous EtOH or Et_2O/petroleum ether (**m** 66°). Its UV has λ_{max} at 245nm (EtOH). [*Beilstein* **12** H 860, **12** I 400, **12** II 468, **12** III 1962, **12** IV 1823.]

Aceto-*p*-toluidide (4-methylacetanilide) *[103-89-9]* **M 149.2, m 146°, b 307°/760mm.** Crystallise it from aqueous EtOH. [*Beilstein* **12** H 920, **12** I 420, **12** II 501, **12** III 2051, **12** IV 1902.]

***R*-(–)-α-Acetoxyphenylacetic (acetyl mandelic) acid** *[51019-43-3]* **M 194.2, m 96-98°, $[\alpha]_D^{20}$ -153.7° (c 2.06, Me_2CO), $[\alpha]_{546}^{20}$ -194° (c 2.4, Me_2CO), pK_{Est} ~2.9.** It crystallises from H_2O with 1mol of solvent which is removed on drying, or from other solvents as for the *S*-isomer below. [Angus & Owen *J Chem Soc* 227 *1943*, Parker *Chem Rev* **91** 1441 *1991*, *Beilstein* **10** III 453.]

***S*-(+)-α-Acetoxyphenylacetic (acetyl mandelic) acid** *[7322-88-5]* **M 194.2, m 80-81°, 95-97.5°, $[\alpha]_D^{27}$ +158° (c 1.78, Me_2CO), $[\alpha]_{546}^{20}$ +186° (c 2, Me_2CO).** Recrystallise it from *benzene/hexane or toluene, and it has characteristic NMR and IR spectra. [Pracejus *Justus Liebigs Ann Chem* **622** 10 *1959*, Breitholle & Stammer *J Org Chem* **39** 1311 *1974*, *Beilstein* **10** IV 567.]

9-Acetylanthracene *[784-04-3]* **M 220.3, m 75-76°.** Crystallise 9-acetylanthracene from EtOH. [Masnori et al. *J Am Chem Soc* **108** 1126 *1986*, *Beilstein* **7** II 450.]

***N*-Acetylanthranilic acid** *[89-52-1]* **M 179.1, m 182-184°, 185-186°, 190°(dec), pK^{20} 3.61.** Wash the acid with distilled H_2O and recrystallise it from aqueous AcOH, dry it and recrystallise again from EtOAc. Also recrystallise it from water or EtOH. Its UV has λ_{max} at 221, 252 and 305nm (EtOH). The *amide* crystallises

from aqueous EtOH and has **m** 186-187° and λ_{max} 218, 252 and 301nm. [Chattaway *J Chem Soc* 2495 *1931*, Walker *J Am Chem Soc* **77** 6698 *1955*, *Beilstein* **14** H 337, **14** I 540, **14** II 219, **14** III 922.]

2-Acetylbenzoic acid *[577-56-0]* **M 164.2, m 115-116°, 116-118°**, **pK^{20} 4.14, pK^{25} 4.10.** It crystallises from *C_6H_6 and H_2O (15g/100ml). The *oxime* has **m** 156-157°, and the *2,4-dinitrophenylhydrazone* has **m** 185-186°(needles from EtOH). [Yale *J Am Chem Soc* **69** 1547 *1947*, Panetta & Miller *Synthesis* 43 *1977*, *Beilstein* **10** H 690, **10** I 330, **10** II 479, **10** III 3025, **10** IV2766.]

4-Acetylbenzoic acid *[586-89-0]* **M 164.2, m 207.5-209.5°, 208.6-209.4°, pK^{25} 3.70, 5.21, 5.10 (EtOH).** Dissolve the acid in 5% aqueous NaOH, extract it with Et_2O, and acidify the aqueous solution. Collect the precipitate, and recrystallise it from boiling H_2O (100 parts) using decolorising charcoal [Pearson et al. *J Org Chem* **24** 504 *1959*, Pearson et al. *J Chem Soc* 265 *1957*, Detweiler & Amstutz *J Am Chem Soc* **72** 2882 *1950*, Bordwell & Cooper *J Am Chem Soc* **74** 1058 *1952*]. [*Beilstein* **10** IV 2769.]

4-Acetylbenzonitrile *[1443-80-7]* **M 145.2, m 57-58°.** Recrystallise the nitrile from EtOH [Wagner et al. *J Am Chem Soc* **108** 7727 *1986*]. [*Beilstein* **10** H 695, **10** III 3030.]

Acetyl-5-bromosalicylic acid *[1503-53-3]* **M 259.1, m (156°), 168°, 168-169°, pK_{Est} ~3.0.** Crystallise the acid from EtOH. [Robertson *J Chem Soc* **81** 1482 *1902*, *Beilstein* **10** H 108, **10** II 64.]

2-Acetylfluorene *[781-73-7]* **M 208.3, m 130-131°, 132°.** Crystallise acetylfluorene from EtOH (solubility is 60g/800ml) or Me_2CO (solubility is 60g/400ml). The *oxime* [110827-07-1] has **m** 192-193.5° and the *2,4-dinitrophenylhydrazone* [109682-26-0] has **m** 261-262°. [Ray & Rieveschl *Org Synth* Coll Vol **III** 23 *1973*.]

5(3)-Acetyl-2(6)-methoxybenzaldehyde *[531-99-7]* **M 166.2, m 144°.** Extract a solution of the aldehyde in *C_6H_6 with 20% aqueous sodium bisulfite, and the bisulfite adduct in the aqueous solution is decomposed by acidifying and heating whereby the aldehyde separates. It is collected, washed with H_2O, dried in a vacuum. It is recrystallised from EtOH (**m** 140-141°) and then from Et_2O (**m** 143-144°). [Gray & Bonner *J Am Chem Soc* **70** *1249 1948, Angyal* et al. *J Chem Soc* 2142 *1950*, *Beilstein* **8** IV 1984.]

4-Acetyl-*N*-methylaniline ([4-methylamino]acetophenone) *[17687-47-7]* **M 149.2, m 102-106°, 103-107°.** This herbicide crystallises from H_2O. The *4-acetyl-N,N-dimethylaniline* derivative forms colourless plates also from H_2O with **m** 58-59°. [Klingel *Chem Ber* **18** 2694 *1885*, Staudinger & Kon *Justus Liebigs Ann Chem* **384** 111 *1911*, *Beilstein* **14** H 47, **14** I 366.]

1-Acetylnaphthalene (1-acetonaphthenone) *[941-98-0]* **M 170.1, m 10.5°, b 93-95°/0.1mm, 167°/12mm, 302°/760mm, d_4^{20} 1.12, pK^{25} –6.22 (H_o scale, aqueous H_2SO_4).** If the NMR spectrum indicates the presence of impurities, probably 2-acetylnaphthalene, convert the substance to its *picrate* by dissolving in *benzene or EtOH and adding excess of saturated picric acid in these solvents until separation of picrates is complete. Recrystallise the picrate till the melting point is 118°. Decompose the picrate with dilute NaOH and extract with Et_2O. Dry the extract (Na_2SO_4), filter, evaporate and distil the residue. The *2,4-dinitrophenylhydrazone* crystallises from EtOH and has **m** 259°. [Stobbe & Lenzer *Justus Liebigs Ann Chem* **380** 95 *1911*, Williams & Osborne *J Am Chem Soc* **61** 3438 *1939*, *Beilstein* **7** IV 1292.]

2-Acetylnaphthalene (2-acetonaphthenone, ß-acetonaphthone, 2-acetonaphthalene, methyl-2-naphthylketone) *[93-08-3]* **M 170.2, m 52-53°, 55°, 55.8°, b 164-166°/8mm, 171-173°/17mm, 301-303°/760mm, pK^{25} -6.16 (H_o scale, aqueous H_2SO_4).** Separate it from the 1-isomer by fractional crystallisation of the *picrate* in EtOH (see entry for the 1-isomer above) to **m** 82°. Decomposition of the picrate with dilute NaOH and extraction with Et_2O, then evaporation, give purer 2-acetylnaphthalene. If this residue solidifies, it can be recrystallised from petroleum ether, EtOH or acetic acid; otherwise it should be distilled in a vacuum and the solid distillate is recrystallised [Gorman & Rodgers *J Am Chem Soc* **108** 5074 *1986*, Levanon et al. *J Phys Chem* **91** 14 *1987*]. Purity should be checked by high field NMR spectroscopy. Its *oxime* has **m** 145°(dec), and the *semicarbazone* has **m** 235°. [Stobbe & Lenzer *Justus Liebigs Ann Chem* **380** 95 *1911*, Raffauf *J Am Chem Soc* **72** 753 *1950,* Hunsberger *J Am Chem Soc* **72** 5626 *1950*, Immediata & Day *J Org Chem* **5** 512 *1940*,

Beilstein **7** IV 1294.]

1-Acetyl-2-phenylhydrazine *[114-83-0]* **M 150.2, m 128.5°, pK^{25} 1.3.** Crystallise the hydrazine from aqueous EtOH. [*Beilstein* **15** H 241.]

Acetylsalicylic acid (Aspirin) *[50-78-2]* **M 180.2, m 133.5-135° (and various), pK^{25} 3.38, (pK^{17} 3.56).** Crystallise aspirin twice from toluene, wash it with cyclohexane and dry it at 60° under vacuum for several hours [Davis & Hetzer *J Res Nat Bur Stand* **60** 569 *1958*]. It has been recrystallised from isopropanol and from diethyl ether/petroleum ether (b 40-60°). It crystallises from EtOH (**m** 143-144°), *C_6H_6 (**m** 143°), hexane (**m** 115° and 128°), octane (**m** 121°), and has **m** 110° after sublimation. It has pK^{26} 3.69(H_2O), 4.15(20% aqueous EtOH), 4.47(30% aqueous EtOH) and 4.94(40% aqueous EtOH). It is an analgesic. [*Beilstein* **10** H 67, **10** II 41, **10** III 102, **10** IV 138.]

***O*-Acetylsalicyloyl chloride** *[5538-51-2]* **M 198.6, m 45°, 46-49°, 48-52°, b 107-110°/0.1mm, 115°/5mm, 135°/12mm, n_D^{20} 1.536.** Check first the IR to see if an OH frequency is present. If so, some free acid is present. Then reflux with acetyl chloride for 2-3 hours and fractionate at high vacuum. The distillate should crystallise. It can be recrystallised from hexane or *C_6H_6 (**m** 60°, sintering at 52°). [Riegel & Wittcoff *J Am Chem Soc* **64** 486 *1942*, *Beilstein* **10** H 86, **10** I 43, **10** II 55, **10** III 151, **10** IV 169.]

***O*-Acetylsalicylsalicylic acid (Salsalate acetate)** *[530-75-6]* **M 300.3, m 159°.** Crystallise the analgesic from dilute AcOH or EtOH (**m** 161-162°), MeOH (**m** 165-168°), and *C_6H_6/EtOH (**m** 163-165°). Its solubilities in boiling Et_2O, *C_6H_6 and EtOH are 1.4%, 2.2% and 33%, respectively. [Baker et al. *J Chem Soc* 201 *1951*, Garrett et al. *J Am Pharm Soc* **48** 684 *1959*, *Beilstein* **10** I 41, **10** II 54, **10** IV 165.]

***N*-(4)-Acetylsulfanilamide (sulfacetamide)** *[144-80-9]* **M 214.2, m 216°.** Crystallise the amide from aqueous EtOH. [*Beilstein* **14** IV 2662.]

Acetyl *p*-toluenesulfonate *[26908-82-7]* **M 214.2, m 54-56°, b 186-188°/20mm.** The most likely impurity is *p*-toluenesulfonic acid (could be up to 10%). This can be removed by dissolving it in dry Et_2O and cooling until the anhydride crystallises out. It decomposes on heating; below ~130° it gives the disulfonic anhydride and above ~130° polymers are formed, but it can be distilled in a vacuum if it is free of acid. It is used for cleaving ethers [Prep, IR, NMR: Karger & Mazur *J Org Chem* **36** 528, Karger & Mazur *J Org Chem* **36** 532 *1971*]. [*Beilstein* **11** III 255.]

Allyl phenyl sulfide *[5296-64-0]* **M 150.2, b 59-60°/1.5mm, 79-80°/3mm, 114-114.3°/23.5mm, 225-226°/740mm, 215-218°/750mm, d_4^{20} 1.0275, n_D^{20} 1.5760.** Dissolve the sulfide in Et_2O, wash with alkali, H_2O, dry over $CaCl_2$, evaporate and fractionally distil it, preferably under vacuum. It should not give a precipitate with an alcoholic solution of $Pb(OAc)_2$. [Hurd & Greengard *J Am Chem Soc* **52** 3356 *1930*, Tarbell & McCall *J Am Chem Soc* **74** 48 *1952*, *Beilstein* **6** IV 1479.]

Amberlite IRA-904 Anion exchange resin (Rohm and Haas) *[9050-98-0]***.** Wash with 1M HCl, CH_3OH (1:10) and then rinse it with distilled water until the washings are neutral to litmus paper. Finally extract successively for 24 hours in a Soxhlet apparatus with MeOH, *benzene and cyclohexane [Shue & Yan *Anal Chem* **53** 2081 *1981*]. It is a strong basic resin also used for base catalysis [Fieser & Fieser *Reagents for Org Synth* **1** 511, Wiley *1967*].

***p*-Aminoacetanilide** *[122-80-5]* **M 150.2, m 162-163°, 163°, 165-167°, 166-167°, pK^{15} 4.46, pK^{40} 3.94.** Crystallise the anilide from water. It has an unstable crystalline form with **m** 141°. It has IR has ν_{max} (CCl_4) at 1681cm^{-1}. [*Beilstein* **13** H 94, **13** I 28, **13** II 50, **13** III 166, **13** IV 137.]

ω-Aminoacetophenone hydrochloride (phenacylamine hydrochloride, 2-aminoacetophenone HCl) *[5468-37-1]* **M 171.6, m 188°(dec), 194°(dec), pK^{25} 5.34.** Crystallise the salt from Me_2CO /EtOH, EtOH/ Et_2O, 2-propanol or 2-propanol and a little HCl (slowly after a few days). The *oxime* of the free base has **m** 140°, and

the *picrate* of the free base has **m** 182° (from EtOH). [Castro *J Am Chem Soc* **108** 4179 *1986*, Baumgarten & Petersen *Org Synth* Coll Vol **V** 909 *1973*, cf *Beilstein* **14** H 49, **14** III 105.]

***m*-Aminoacetophenone** *[99-03-6]* **M 135.2, m 98-99°, b 189-290°/760mm, pK^{25} 3.56.** Recrystallise it from EtOH or aqueous EtOH (**m** 99.5°). The *thiosemicarbazone* has **m** 202-204° (from EtOH). [*Beilstein* **14** H 45, **14** IV 96.]

***p*-Aminoacetophenone** *[99-92-3]* **M 135.2, m 104-106°, 105-107°, b 293°/atm, pK^{25} 2.19.** Recrystallise it from $CHCl_3$, *C_6H_6 or H_2O. It is soluble in hot H_2O. Its UV (EtOH) has λ_{max} at 403nm (log ε 4.42) [Johnson *J Am Chem Soc* **75** 2720 *1953*]. [Vandenbelt *Anal Chem* **26** 726 *1954*.] The *2,4-dinitrophenylhydrazone* has **m** 266-267° (from $CHCl_3$ or EtOH) with λ_{max} at 403nm (logε 4.42), and the *semicarbazone* has **m** 193-194°(dec)(from MeOH). The *hydrochloride* has **m** 98°(dec)(from H_2O). [*Beilstein* **14** IV 100.]

1-Aminoanthraquinone-2-carboxylic acid *[82-24-6]* **M 276.2, m 295-296°.** Crystallise the acid from nitrobenzene. It is used for the detection of Al, Mg Cd, Zn, Mn, Cu, Hg, Fe, Co, Ni and Pb. The *methyl ester* gives red needles from AcOH, **m** 228°. The *ethyl ester*, **m** 198°, crystallises also as red needles from AcOH. [Locher & Fietz *Helv Chim Acta* **10** 667 *1927*, *Beilstein* **14** II 419, **14** III 168.]

***p*-Aminoazobenzene (*p*-phenylazoaniline)** *[60-09-3]* **M 197.2, CI 11000, m 126°, pK^{25} ~2.82.** Crystallise this dye from EtOH, CCl_4, petroleum ether/*C_6H_6, or a MeOH/H_2O mixture. [*Beilstein* **16** IV 445.]

***o*-Aminoazotoluene (Fast Garnet GBC base, 4'-amino-2,3'dimethylazobenzene, Solvent yellow 3)** *[97-56-3]* **M 225.3, m 101.4-102.6°, CI 11160, pK^{26} 2.29 (50% aqueous EtOH).** Recrystallise the dye twice from EtOH, once from *benzene, then dry it in an Abderhalden drying apparatus. [Cilento *J Am Chem Soc* **74** 968 *1952*, Sawicki *J Org Chem* **21** 605 *1956*, *Beilstein* **16** H 334, **16** I 322, **16** II 178, **16** III 386, **16** IV 525.] **CARCINOGENIC**.

2-Aminobenzaldehyde *[529-23-7]* **M 121.1, m 39-40°, 80-82°/2mm, pK^{20} 1.36.** Distil it in steam and recrystallise it from H_2O or EtOH/ Et_2O. The *semicarbazone* has **m** 247°. [*Beilstein* **14** H 21, **14** I 356, **14** II 14, **14** III 47, **14** IV 42.]

2-Aminobenzaldehyde phenylhydrazone (Nitrin) *[63363-93-9]* **M 211.3, m 227-229°.** Crystallise it from acetone. [Knöpfer *Monatsh Chem* **31** 97 *1910*, *Beilstein* **14** H 21, **14** II 14, **14** III 47.]

3-Aminobenzaldehyde *[29159-23-7]* **M 121.1, m 28-30°, pK_{Est} ~2.0.** The aldehyde crystallises as light yellow plates from ethyl acetate. The UV has λ_{max} at 227 and 327.5nm in cyclohexane. The *acetyl* derivative has **m** 122° (from EtOH) and the *oxime* has **m** 195° (yellow-brown plates from EtOH). [*Beilstein* **14** H 28, **14** I 359, **14** II 21, **14** III 53, **14** IV 46.]

4-Aminobenzamide hydrochloride *[59855-11-7]* **M 199.6, m 284-285°, pK_{Est} ~1.7.** Recrystallise the salt from EtOH. The *free base* [2835-68-9] **M** 136.2, has **m** 182.9° and crystallises with $0.25H_2O$ (**m** 178-179°). [Rupe & Vogler *Helv Chim Acta* **8** 835 *1925*, *Beilstein* **14** H 425, **14** III 1061.]

***p*-Aminobenzeneazodimethylaniline** *[539-17-3]* **M 240.3, m 182-183°.** Crystallise the azo-dye from aqueous EtOH. [*Beilstein* **14** IV 1004.]

***o*-Aminobenzoic acid (anthranilic acid)** *[118-92-3]* **M 137.1, m 145°, pK_1^{25} 2.94, pK_2^{25} 4.72.** Crystallise anthranilic acid from water (charcoal). It has also been recrystallised from 50% aqueous acetic acid. It sublimes in a vacuum. [*Beilstein* **14** IV 1004.]

***m*-Aminobenzoic acid** *[99-05-8]* **M 137.1, m 174°, pK_1^{25} 3.29, pK_2^{25} 5.10.** Crystallise the acid from water. [*Beilstein* **14** IV 1092.]

***p*-Aminobenzoic acid** *[150-13-0]* **M 137.1, m 187-188°, pK_1^{25} 2.45, pK_2^{25} 4.85.** Purify *p*-aminobenzoic acid

by dissolving it in 4-5% aqueous HCl at 50-60°, decolorising with charcoal and carefully precipitating it with 30% Na_2CO_3 to pH 3.5-4 in the presence of ascorbic acid. It can be recrystallised from water, EtOH or EtOH/water mixtures. [*Beilstein* **14** IV 1126.]

p-**Aminobenzonitrile (*p*-cyanoaniline)** *[873-74-5]* **M 118.1, m 86-86.5°, 85-87°, pK^{25} 1.74.** It crystallises from water, 5% aqueous EtOH or EtOH and is dried over P_2O_5, or dried *in vacuo* for 6 hours at 40°. [Moore et al. *J Am Chem Soc* **108** 2257 *1986*, Edidin et al. *J Am Chem Soc* **109** 3945 *1987*, *Beilstein* **14** IV 1158.]

4-Aminobenzophenone *[1137-41-3]* **M 197.2, m 123-124°, pK^{25} 2.17.** Dissolve it in aqueous acetic acid, filter and precipitate it with ammonia. This process is repeated several times, then the amine is recrystallised from aqueous EtOH. [*Beilstein* **14** IV 248.]

2-Aminobiphenyl (*o*-**aminobiphenyl)** *[90-41-5]* **M 169.2, m 47-48°, 49°, 49.3°, 47-50°, b 114°/2mm, 135°/5.5mm, 160°/11mm, 166-168°/16mm, 182°/30mm, 299.0°/atm, pK^{18} 3.85, pK^{20} 3.39, pK^{20} 3.03, 3.34 (50% aqueous EtOH).** It is prepared by reduction of 2-nitrobiphenyl [see 86-00-0] with Fe/HCl [Morgan and Walls *J Soc Chem Ind* **49** 15T *1930*], or catalytically in batches of 150g by H_2 at 75 atmospheres pressure in the presence of Raney Ni, which begins at ~80° and is not allowed to rise above 100°, in 90% yield [Cookson & Mann *J Chem Soc* 2891 *1949*]. It crystallises from aqueous EtOH (charcoal). The *picrate* has **m 164-165°** (from EtOH or H_2O), the *N-acetyl derivative* has **m 118°** (from EtOH), the *N-phenylsulfonate dervative* has **m 292°** (from MeOH), and the *N-tosylate* has **m 194.1-195.6°** (from MeOH). [*Beilstein* **12** H 1317, **12** I 546, **12** II 747, **12** III 3124, **12** IV 3223.]

p-**Aminobiphenyl** *[92-67-1]* **M 169.2, m 53°, b 191°/16mm, pK^{18} 4.38.** Crystallise it from water or EtOH. [*Beilstein* **12** IV 3241.] **CARCINOGENIC.**

5-Amino-2-bromobenzoic acid *[2840-02-0]* **M 216.0, m 178°, 180°, pK$_{Est(1)}$ ~1.7, pK$_{Est(2)}$ ~4.4.** Crystallise the acid from H_2O or *C_6H_6 (**m** 128°). The *acetyl* derivative crystallises from H_2O (as *monohydrate*) or absolute EtOH with **m** 196-197° (*anhydrous*). [Koopal *Rec Trav Chim Pays Bas* **34** 148 *1915*, Bamberger *Chem Ber* **57** 2090 *1924*, *Beilstein* **14** H 413, **14** II 245.]

2-Amino-5-bromotoluene (4-bromo-2-methylaniline) *[583-75-5]* **M 186.1, m 59°, 59.5°, 240°/760mm, pK^{25} 3.58.** Steam distil the aniline and recrystallise it from EtOH. It has UV with λ_{max} at 292.5nm (H_2O). [*Beilstein* **12** H 838, **12** I 389, **12** II 456, **12** IV 1804.]

2-Amino-5-chlorobenzoic acid *[635-21-1]* **M 171.6, m 100°, pK$_1^{25}$ 1.69, pK$_2^{25}$ 4.35.** Crystallise the acid from water, EtOH or chloroform. [*Beilstein* **14** IV 1075.]

3-Amino-4-chlorobenzoic acid *[2840-28-0]* **M 171.6, m 216-217°, pK$_{Est(1)}$ ~2.7, pK$_{Est(2)}$ ~2.9.** Crystallise the acid from water. [*Beilstein* **14** IV 1115.]

4-Amino-4'-chlorobiphenyl *[135-68-2]* **M 203.5, m 132-133°, 134°, pK$_{Est}$ ~4.0.** Crystallise the amine from petroleum ether, EtOH or aqueous EtOH. The *acetyl* derivative has **m** 245° from EtOH. [Dewar & James *J Chem Soc* 4270 *1958*, Gelmo *Chem Ber* **39** 4176 *1906, Beilstein* **12** H 1319, **12** II 757, **12** IV 3269.]

2-Amino-4,6-dichlorophenol *[527-62-8]* **M 175.0, m 95-96°, pK$_{Est(1)}$ ~3.1, pK$_{Est(2)}$ ~6.8.** Crystallise the phenol from CS_2 or *benzene. It sublimes at 0.06mm. The *hydrochloride* has **m** 280-285° from EtOH. [Meyer *Helv Chim Acta* **41** 1890 *1958*, *Beilstein* **13** II 185, **13** III 856, **13** IV 889.]

4-Amino-*N,N*-diethylaniline hydrochloride *[16713-15-8]* **M 200.7, m 233.5°, pK^{22} 6.61.** Crystallise the salt from EtOH. The *free base* [93-05-0] M **164.2** distils at **260-262°/~760mm**. [*Beilstein* **14** IV 109.]

4-Amino-3,5-diiodobenzoic acid *[2122-61-4]* **M 388.9, m ~350°, pK$_{Est(1)}$ 0.4, pK$_{Est(2)}$ ~1.6.** Purify the iodo-acid by dissolving it in dilute NaOH and precipitating with dilute HCl. *Alternatively*, dissolve it in aqueous NH_3 and acidify it with AcOH. Dry it in air. The solubility of the *Na salt* in H_2O is 2.56% at 25°. [Klemme &

Hunter *J Org Chem* **5** 510 *1940*, *Beilstein* **14** H 439, **14** III 1161, **14** IV 1284.]

2-Aminodiphenylamine *[534-85-0]* **M 184.2, m 79-80°, $pK_{Est(1)}$ ~3.8 (NH_2), $pK_{Est(2)}$ <~0.** Crystallise the amine from H_2O. [*Beilstein* **13** IV 43.]

4-Aminodiphenylamine *[101-54-2]* **M 184.2, b 155°/0.026mm, pK^{25} 5.20.** It crystallises from EtOH with **m** 66°, and from ligroin with **m** 75°. It can be distilled at high vacuum. [*Beilstein* **13** IV 113.]

2-Amino-1,2-diphenylethanol *[530-36-9]* **M 213.3, m 165°, $pK_{Est(1)}$ ~7.5.** Recrystallise the ethanol from EtOH. The *1R,2S-(–)-* [23190-16-1] and the *1S,2R(+)- enantiomers* also crystallise from EtOH and have **m 142-145°, $[\alpha]_D^{20}$ (+) and (–) 7° (c 0.6, EtOH)**. [Masters et al. *J Org Chem* **56** 5666 1991, Masters & Hegedus *J Org Chem* **58** 4547 *1993*, *Beilstein* **13** IV 2150.]

2-Aminodiphenylmethane (2-benzylaniline) *[28059-64-5]* **M 183.3, m 52°, 51-54°, b 172°/12mm and 190°/22mm, $pK_{Est(1)}$ ~4.2.** Crystallise 2-benzylaniline from ether and distil it in a vacuum. [*Beilstein* **12** IV 3279.]

2-Aminofluorene (2-fluorenamine) *[153-78-6]* **M 181.2, m 127.8-128.8°, 132-133°, pK^{25} 4.64.** Wash the amine well with H_2O and recrystallise it from Et_2O or 50% aqueous EtOH (25g with 400ml), and dry it in a vacuum. Store it in the dark. [Bavin *Org Synth* Coll Vol **V** 30 *1973*, *Beilstein* **12** H 1331, **12** IV 337.]

9-Aminofluorene (9-fluorenamine) *[525-03-1]* **M 181.2, m 64-65°, pK_{Est} ~3.5.** Purify it by converting it to the hydrochloride with HCl, then basify it with NH_3 and recrystallise it from petroleum ether (**m** 62-63°) or from hexane. The *hydrochloride* [5978-75-6] **M** 217.7, has **m** ~255°(dec, from EtOH). [Ingold et al. *J Chem Soc* 1493 *1933*, Mathieu *Bull Soc Chim Fr* 1526 *1971*, *Beilstein* **12** H 1331, **12** I 553, **12** II 780, **12** III 3297, **12** IV 3390.]

1-Amino-4-hydroxyanthraquinone *[116-85-8]* **M 293.2, m 207-208°, $pK_{Est(1)}$ ~2.6 (NH_2), $pK_{Est(2)}$ ~9.0 (OH).** Purify it by TLC on SiO_2 gel plates (0.75mm thick) using toluene/acetone (9:1) as eluent. The main band is scraped off and extracted with MeOH. The solvent is evaporated, and the dye is dried in a drying pistol [Land et al. *J Chem Soc, Faraday Trans 1* **72** 2091 *1976*]. It has also been recrystallised from aqueous EtOH. [*Beilstein* **14** H 268, **14** I 503, **14** II 168, **14** III 652, **14** IV 891.]

3-Amino-4-hydroxytoluene (2-amino-*p*-cresol) *[95-84-1]* **M 123.2, m 135°, 137-138°, $pK_{Est(1)}$ ~4.7(NH_2), $pK_{Est(2)}$ ~9.6 (OH).** Recrystallise the cresol from H_2O, Et_2O or toluene. It sublimes *in vacuo* as plates or needles. The *hydrochloride* has **m** 222-224° (dec, from aqueous EtOH). [*Beilstein* **13** H 601, **13** I 227, **13** II 338, **13** III 1576.]

4-Amino-3(5)-hydroxytoluene (2-amino-*m*-cresol) *[2835-98-5]* **M 123.2, m 159°, 159-162°, $pK_{Est(1)}$ ~5.4 (NH_2), $pK_{Est(2)}$ ~10.2 (OH).** Crystallise it from H_2O, 50% EtOH, or toluene. [*Beilstein* **13** H 590, **13** III 1552.]

2-Amino-5-hydroxytoluene *[2835-99-6]* **M 123.2, m 162°(dec), 177-179°(dec), $pK_{Est(1)}$ ~5.4 (NH_2), $pK_{Est(2)}$ ~10.4 (OH).** Crystallise it from 50% EtOH. [*Beilstein* **13** H 593, **13** IV 1698.]

5-Aminoindane *[24425-40-9]* **M 133.2, m 37-38°, b 131°/15mm, 146-147°/25mm, 247-249°/745mm, pK^{16} 5.31.** Distil the indane, and then crystallise it from petroleum ether. [*Beilstein* **12** I 511, **12** III 2798.]

1*RS*,2*SR*-(±)-*cis*-1-Amino-2-hydroxyindane (*cis*-1-amino-2-indanol) *[7480-35-5]* **M 149.2, m 132-133°, 134-135°, pK_{Est} ~8.5.** It is obtained by hydrolysis of (±)-*cis*-indano[1,2-*d*]-2-oxazolidone [in turn formed by solvolysis of ethyl *N*-(*trans*-2-iodo-1-indan)carbamate, m 159.5-160° in 87% yield by refluxing in dry diglyme for 14 hours]. The *cis*-2-oxazolidone (360mg) is dissolved in 0.85N methanolic KOH (20ml), diluted with H_2O (5ml) and refluxed under N_2 for 18 hours, evaporated to dryness *in vacuo*, the residue is extracted with Et_2O, filtered, dried (Mg_2SO_4), concentrated to a small volume and cooled to –12°, and the *2-indanol* is collected as white plates (2 crops, m 134-135° and 133-134°) in 79% yield. [Hassner et al. *J Org Chem* **32** 540 *1967*.]

Similarly hydrolysis of *2-phenyl-3a,8a-dihydro-8H-indeno[1,2-d]oxazole* with diluted H_2SO_4 (16 hours reflux), cool, basify with 10N NaOH, extract with $CHCl_3$, dry (Mg_2SO_4), and evaporation gives an 88% yield of the *(±)-amino-alcohol* (m 132-133°). It can also be prepared from (±)-hydrindan-1,2-epoxide as described in the following entry. Its ^{1}HNMR (400MHz, $CDCl_3$, TMS) has δ at 2.0-2.5 (br s, 3H), 2.95 (dd, *J* = 3 and 15Hz, 1H), 3.1 (dd, *J* = 7 and 15Hz, 1H), 4.28 (d, *J* = 7Hz, 1H), 4.4 (m, 1H), 7.2-7.35 (m, 4H). [Thompson et al. *J Med Chem* **35** 1685 *1992*.] Large scale preparations of the (±)-*cis*-1-amino-2-indanol from indene *via* the (±)*trans*-acylamido-indanol by hydrolysis with strong acids (HCl, H_2SO_4 or $MeSO_3H$) which invert the OH stereochemistry have been patented [Gao et al. USP appl 5,599,985 *1997*; *Chem Abstr* **123** 55421b *1995*, Gao et al. USP 5,616,808 *1997*, *Chem Abstr* **126** 250997h *1997*]. [*Beilstein* **13** II 398a, 399d, **13** III 1841, **13** IV 2033.]

1*S*,2*R*-(–)-*cis*-1-Amino-2-hydroxyindane [(-)-*cis*-1-amino-2-indanol)] *[126456-43-7]* **M 149.2, m 117-117.5°, 118-121°, $[\alpha]_D^{20}$ -61° (c 0.5, $CHCl_3$), $[\alpha]_D^{25}$ -62° (c 1.0, MeOH).** This enantiomer has been prepared in several ways in high state of optical purity. Oxidation of indene [95-13-6] using Jaconsen's salen catalyst *R,R*-MnCl/NaOCl/CH_2Cl_2 gave *1R,2S-indane-1,2-epoxide* in 84%ee, which on treatment with NH_3/MeOH then PhCOCl/NaOH followed by 80% H_2SO_4 provided *2-phenyl-3aS,8aR-dihydro-8H-indeno[1,2-d]oxazole* [see (±) above] by a C-1 chirality transfer process which gave the desired 1*S*,2*R*-(–)-aminoindanol on hydrolysis. *Alternatively*, oxidation of indene using Jacobsen's salen catalyst *S,S*-MnCl/PhCl/NaOCl and P_3NO (see [34122-28-6]) gave the enantiomeric 1*S,*2*R*-indane-1,2-epoxide which was reacted with Oleum/MeCN then hydrolysed with H_2O (by C-2 chirality transfer *via* a Ritter reaction) to give the same desired 1*S*,2*R*-(–)-aminoindanol 78-80% yield with high optical purity. [Senanayake *Aldrichimica Acta* **31** 3 *1998*, Senanayake et al. *Tetrahedron Lett* **36** 3993 *1995*, Senanayake et al. *Tetrahedron Lett* **37** 3271 *1996*.] In a different approach *N*-(L-phenylalanyl)-(±)-amino-2-indanol was prepared [84% yield, from (±)-aminoindanol and BOC-L-phenylalanine *via* the 1-hydroxybenzotriazole/dimethyl 3-{3-(dimethylamino)-propyl}carbodiimide procedure], and the diastereoisomeric mixture was separated by low pressure chromatography on silica gel, eluting with 8% MeOH in $CHCl_3$ to give the faster moving L-Phe—1*S,*2*R*-1-aminoindan-2-ol diastereoisomer (40% yield). A mixture of this diastereomer (30g, 0.1mol), EtOH (1L)and 20% aqueous NaOH (265ml) was refluxed for 16 hours, concentrated to remove EtOH, diluted with H_2O (100ml) and brine (100ml), extracted with $CHCl_3$ (3 x 600ml), the combined extracts were dried (Mg_2SO_4), filtered and evaporated to give 1*S,*2*R*-1-aminoindan-2-ol (14g, 93%) as a white solid m 114-115°. Recrystallisation from Et_2O/hexanes gave analytically pure white rods m 117-117.5°, with little loss of material, and with $[\alpha]_D^{25}$ -62° (c 1.0, MeOH), with ^{1}HNMR (400MHz, $CDCl_3$, TMS) which had δ at 2.0-2.5 (br s, 3H), 2.95 (dd, *J* = 3 and 15Hz, 1H), 3.1 (dd, *J* = 7 and 15Hz, 1H), 4.28 (d, *J* = 7Hz, 1H), 4.4 (m, 1H), 7.2-7.35 (m, 4H), same as the racemate. [Thompson et al. *J Med Chem* **35** 1685 *1992*.] Both enantiomers of this *cis*-aminoalcohol have also been obtained *via* enzymatic transfomations [Didier et al. *Tetrahedron* **47** 4941 *1991*]. The oxazolines, oxazolidin-2-ones and the 2-*N*-tosylamides derived from the two enantiomers have been explored extensively as *chiral auxiliaries* [Senanayake *Aldrichimica Acta* **31** 3 *1998*]. For the preparation of CBS-oxazaboroline catalysis (**C**orey-**B**akshi-**S**hibata) see Chapter 6, Catalysis-Part 1. **NOTE:** Both enantiomers are commercially available from Sepracore in gram to hundred kilogram quantities [Hong et al. *Tetrahedron Lett* **35** 6631 *1994*, see also Stinson *Chemical and Engineering News* May 16 p.6 *1994*.] [*Beilstein* **13** II 398a, 399d, **13** III 1841, **13** IV 2033.]

1*R*,2*S*-(+)-*cis*-1-Amino-2-hydroxyindane [(+)-*cis*-1-amino-2-indanol)] *[136030-00-7]* **M 149.2, m 118-121°, $[\alpha]_D^{20}$ +63° (c 0.2, $CHCl_3$).** This compound was prepared using the same syntheses as for its enantiomer (preceding entry) and purified in the same way. It can be also obtained from the slower moving chromatographic band of the L-phenylalaninyl diastereoisomer (see preceding entry).

2-Amino-5-iodotoluene *[13194-68-8]* **M 233.0, m 87°, pK_{Est} ~3.6.** Crystallise it from 50% EtOH. [*Beilstein* **12** IV 1807.]

1-Amino-4-methylaminoanthraquinone *[1220-94-6]* **M 252.3, $pK_{Est(1)}$ ~1, $pK_{Est(2)}$ <~4.** Purify the quinone by TLC on silica gel plates using toluene/acetone (3:1) as eluent. The main band is scraped off and extracted with MeOH. The solvent is evaporated, and the residue is dried in a drying pistol [Land et al. *J Chem Soc, Faraday Trans 1* **72** 2091 *1976*]. [*Beilstein* **14** H 198, **14** I 462, **14** III 440, **14** IV 458.]

4-Aminomethylbenzenesulfonamide hydrochloride (Mafenide HCl) *[138-37-4]* **M 222.3, m 265-267°, pK_1^{20}**

8.18 (NH_2), pK_2^{20} 10.23 ($SONH_2$). Crystallise the salt from dilute HCl or 95% EtOH and dry it in a vacuum at 100°. It is an antibacterial. [Miller et al. *J Am Chem Soc* **62** 2099 *1940*, Bergeim & Barker *J Am Chem Soc* **66** 1459 *1944*.] The *sulfate salt* has **m** 254-255° (from aqueous EtOH). [*Beilstein* **14** III 2223, **14** IV 2799.]

4-Amino-2-methyl-1-naphthol See **Vitamin K_5** in "Miscellaneous Compounds", Chapter 7.

3-Amino-2-naphthoic acid *[5959-52-4]* **M 187.2, m 214°(dec), $pK_{Est(1)}$ ~1.5 $pK_{Est(2)}$ ~4.0.** Crystallise the naphthoic acid from aqueous EtOH. [*Beilstein* **14** III 1341.]

4-Amino-5-naphthol-2,7-disulfonic acid *[90-20-0]* **M 320.3, pK_1^{20} 3.54, pK_2^{20} 8.55; pK_1^{25} 3.63, pK_2^{25} 8.83.** A slightly alkaline solution of Na_2CO_3 (*ca* 22g) in water (litmus) is added to a solution of 100g of the dry acid in 750ml of hot distilled water, followed by 5g of activated charcoal and 5g of Celite. The suspension is stirred for 10 minutes and filtered by suction. The acid is then precipitated by adding *ca* 40ml of conc HCl (solution is blue to Congo Red), then filter it by suction through a shark skin filter circular sheet (or hardened filter paper) and wash it with 100ml of distilled water. The purification process is repeated. The acid is dried overnight in an oven at 60° and stored in a dark bottle The *diethylamine salt* has **m** 306-307°(dec, from aqueous EtOH). [Post & Moore *Anal Chem* **31** 1872 *1959*]. [*Beilstein* **14** H 840, **14** I 758, **14** II 502, **14** III 2292, **14** IV 2824.]

1-Amino-2-naphthol hydrochloride *[1198-27-2]* **M 195.7, m 250°(dec), $pK_{Est(1)}$ ~3.7 (NH_2), $pK_{Est(2)}$ ~9.9 (OH).** Crystallise the salt from the minimum volume of hot water containing a few drops of stannous chloride in an equal weight of hydrochloric acid (to reduce atmospheric oxidation). Filter the solution and add half its volume of conc HCl and set aside. The salt crystallises almost quantitatively. Dry it in a vacuum in the dark (**m** 260°). The salt is more stable than the *free base* which has **m** 150° (darkening at 130°) and its *O-methyl ether* has **m** 49° and **b** 159-159°/9mm. [Desai et al. *J Chem Soc* 324 *1938, Beilstein* **13** H 666, **13** I 268, **13** II 408, **13** III 1875, **13** IV 2080.]

1-Amino-2-naphthol-4-sulfonic acid *[116-63-2]* **M 239.3, m 295°(dec), $pK_{Est(1)}$ <0 , $pK_{Est(2)}$ ~2.8 (NH_2), $pK_{Est(2)}$ ~8.8.** Purify it by warming 15g of the acid, 150g of $NaHSO_3$ and 5g of Na_2SO_3 (anhydrous) with 1L of water to *ca* 90°, shaking until most of the solid had dissolved, then filtering hot. The precipitate obtained by adding 10ml of conc HCl to the cooled filtrate is collected, washed with 95% EtOH until the washings are colourless, and is dried under vacuum over $CaCl_2$. It is stored in a dark-coloured bottle, in the cold [Chanley et al. *J Am Chem Soc* **74** 4347 *1952*]. [*Beilstein* **14** IV 2825.]

2-Amino-4-nitrobenzoic acid (4-nitroanthranilic acid) *[619-17-0]* **M 182.1, m 269°(dec), pK_1^{25} 0.65, pK_2^{25} 3.70.** Crystallise the acid from water, EtOH (**m** 271°) or aqueous EtOH (**m** 269°). The *acetyl* derivative has **m** 217° (from EtOH), **m** 222° (from aqueous EtOH). [Chapman & Stephen *J Chem Soc* 1796 *1925*, *Beilstein* **14** II 234, **14** III 975, **14** IV 1087.]

5-Amino-2-nitrobenzoic acid *[13280-60-9]* **M 182.1, m 235°(dec), $pK_{Est(1)}$ ~1.1, $pK_{Est(2)}$ ~1.2.** Crystallise the acid from water. [*Beilstein* **14** III 1021.]

1-Amino-4-nitronaphthalene *[776-34-1]* **M 188.2, m 195°, 196-197°, pK^{20} 0.54.** It crystallises from EtOH, ethyl acetate or aqueous NH_3 as light yellow crystals. The *acetyl* derivative also forms yellow crystals, **m** 192.5-193.5°, from Me_2CO. [*Beilstein* **12** H 1259, **12** I 530, **12** II 704, **12** III 2971, **12** IV 3114.]

2-Amino-4-nitrophenol *[99-57-0]* **M 154.1, m 80-90° (hydrate), 142-143° (anhydrous), $pK_{Est(1)}$ ~3.9 (NH_2), $pK_{Est(2)}$ ~9.2.** Crystallise the phenol from water. [*Beilstein* **13** IV 896.]

2-Amino-5-nitrophenol *[121-88-0]* **M 154.1, m 207-208°, $pK_{Est(1)}$ ~3.8, $pK_{Est(2)}$ ~9.3.** Crystallise the phenol from water. [*Beilstein* **13** IV 803.]

***RS*-(±)-3-Amino-3-(4-nitrophenyl)propionic acid** *[35005-61-9]* **M 210.2, m 220-226°(dec), 226°(dec, browning at 215°), $pK_{Est(1)}$ ~3.0, $pK_{Est(2)}$ ~9.5.** The acid crystallises from 50% aqueous EtOH. The *hydrochloride* has **m** 218-220°(dec). The *N-benzoyl derivative* has **m** 204-205° (from MeOH) and the *N-*

benzoyl-hydrazide has **m** 226-227° (from MeOH or EtOH). [Posner *Justus Liebigs Ann Chem* **389** 44 *1912*, *Beilstein* **14** I 603, **14** IV 1548.]

2-Aminophenol *[95-55-6]* **M 109.1, m 175-176°, pK_1^{25} 4.65, pK_2^{25} 9.75.** Purify it by dissolving it in hot water, decolorising with activated charcoal, filtering and cooling to induce crystallisation. Maintain an atmosphere of N_2 over the hot phenol solution to prevent its oxidation [Charles & Freiser *J Am Chem Soc* **74** 1385 *1952*]. It can also be crystallised from EtOH using the same precautions. [*Beilstein* **13** IV 805.]

3-Aminophenol *[591-27-5]* **M 109.1, m 122-123°, pK_1^{25} 4.25, pK_2^{25} 9.90.** Crystallise it from hot water or toluene. [*Beilstein* **13** IV 952.]

4-Aminophenol *[123-30-8]* **M 109.1, m 190° (under N_2), pK_1^{25} 5.38, pK_2^{25} 10.4.** Crystallise it from EtOH, then water, excluding oxygen. It sublimes at 110°/0.3mm. It has been purified by chromatography on alumina with a 1:4 (v/v) mixture of absolute EtOH/*benzene as eluent. [*Beilstein* **13** IV 1014.]

4-Aminophenol hydrochloride *[51-78-5]* **M 145.6, m 306°(dec).** Purify the salt by treating an aqueous solution with saturated $Na_2S_2O_3$, filtering under N_2, then recrystallising it from 50% EtOH twice and once from absolute EtOH [Livingston & Ke *J Am Chem Soc* **72** 909 *1950*]. [*Beilstein* **13** III 993.]

4-Aminophenylacetic acid *[1197-55-3]* **M 151.2, m 199-200°(dec), pK_1^{20} 3.60, pK_2^{20} 5.26.** Crystallise the acid from hot water (60-70ml/g). [*Beilstein* **14** III 1182.]

***1RS,2RS-2*-Amino-1-phenylbutan-1-ol [α-(α-aminopropyl)benzyl alcohol]** *[(±)-threo 5897-76-7]* **M 165.1, m 79-80°, pK_{Est} ~9.7.** Crystallise the *free base* of the *threo* isomer from *benzene/petroleum ether which has **m** 79-80°. The *threo-hydrochloride*, **m** 204-205°, crystallised from EtOH [Abrams & Kipping *J Chem Soc* 1480 *1936*, Rebstock et al. *J Am Chem Soc* **73** 3666 *1951*]. The *1RS,2RS-erythro* isomer has **m** 80.5-81° and its *hydrochloride* has **m** 242° [Harturg et al. *J Am Chem Soc* **52** 3317 *1930*. [*Beilstein* **13** II 390, **13** III 1791, **13** IV 1952.]

***N*-Aminophthalimide** *[1875-48-5]* **M 162.2, m 200-202°, pK_{Est} ~0.** The imide has been recrystallised from 96% EtOH (solubility is ~2% at boiling temperature) to form a yellow solution. It sublimes *in vacuo* at *ca* 150°. It solidifies after melting, and remelts at 338-341° (see phthalhydrazide "Heterocyclic Compounds" in this Chapter). [*Beilstein* **22/11** V 122.]

4-Aminopropiophenone *[70-69-9]* **M 163.1, m 140°, b 180°/10mm, pK_{Est} ~2.2.** Crystallise it from water or aqueous EtOH. The *hydrochloride* has **m** 188-189° (aqueous EtOH/HCl drops), and the *semicarbazone* has **m** 139-140° (from EtOH/H_2O). [Derrick & Bornemann *J Am chem. Soc* **35** 1283 *1913*, *Beilstein* **14** H 59, **14** I 375, **14** III 146, **14** IV 139.]

4-(2-Aminopropyl)phenol (hydroxyamphetamine) *[103-86-6]* **M 151.2, m 125-126°, $pK_{Est(1)}$ ~9.4 (OH), $pK_{Est(2)}$ ~9.7(NH_2), pK^{25} 9.31.** Crystallise the phenol from *benzene. The *R-(–)-enantiomer* crystallises from EtOH or *C_6H_6 with **m** 110.5-111.5° and $[\alpha]_D^{17}$ -52.0° (c 1, EtOH). The *(±)-hydrochloride* has **m** 171-172° (EtOH/Et_2O), and the *2,4-dinitrophenylhydrazone* has **m** 190-192° (EtOH). [*Beilstein* **13** I 251, **13** III 1709, **13** IV 1871.]

1-Aminopyrene *[1606-67-3]* **M 217.3, m 117-118°, pK_1^{25} 2.91 (50% aqueous EtOH), pK_2^{25} 2.77 (50% aqueous EtOH).** Crystallise it from hexane. [*Beilstein* **12** IV 3460.]

4-Aminosalicylic acid *[65-49-6]* **M 153.1, m 150-151°(dec), pK_1^{25} 1.78 (CO_2H), pK_2^{25} 3.63 (NH_2), pK^{25} 13.74 (OH).** Crystallise the acid from EtOH. [*Beilstein* **14** IV 1967.]

5-Aminosalicylic acid (5-amino-2-hydroxybenzoic acid) *[89-57-6]* **M 153.1, m 276-280°, 283°(dec), pK_1^{25} 2.74 (CO_2H), pK_2^{25} 5.84 (NH_2).** It crystallises as needles from H_2O containing a little $NaHSO_3$ to avoid aerial oxidation to the quinone-imine. The *Me ester* gives needles from *C_6H_6, **m** 96°, and the *hydrazide* has **m** 180-

182° (from H_2O). [Fallab et al. *Helv Chim Acta* **34** 26 *1951*, Shavel *J Amer Pharm Assoc* **42** 402 *1953*, *Beilstein* **14** IV 2058.]

2-Amino-5-sulfanilylthiazole (thiazolsulfone) *[473-30-3]* **M 238.3, m 219-221°(dec), pK_{Est} ~4.5 (OH).** Crystallise the thiazole from EtOH. It is antibacterial. [Bambas *J Am Chem soc* **67** 671 *1945*.]

4-Amino-2-sulfobenzoic acid *[527-76-4]* **M 217.1.** Crystallise the sulfobenzoic acid from H_2O (solubility is 0.3% at 25°. [KasHe *J Am Chem Soc* **44** *490 1910*, *Beilstein* **19** I 356, **19** III/IV 1641 for 4-NO_2.]

9-Aminotriptycene *[793-41-9]* **M 269.3, m 223.5-224.5°.** Recrystallise aminotriptycene from ligroin [Imashiro et al. *J Am Chem Soc* **109** 729 *1987*].

***p-tert*-Amylphenol (*p*-2,2-dimethylpropylphenol)** *[80-46-6]* **M 146.3, m 93.5-94.2°, 94-96°, b 138°/15mm, 262°/760mm, pK_{Est} ~10.2.** Purify *via* its benzoate, as for phenol. After evaporating the solvent from its solution in ether, the material is recrystallised (from the melt) to a constant melting point. The *benzoyl* derivative has **m** 60° (from EtOH). [Berliner et al. *J Am Chem Soc* **76** 507 *1954*, Huston et al. *J Am Chem Soc* **67** 899 *1945*, *Beilstein* **6** H 548, **6** I 269, **6** II 506, **6** III 1965, **6** IV 3383.]

Aniline *[62-53-3]* **M 93.1, f -6.0°, b 68.3/10mm, 184.4°/760mm, d_4^{20} 1.0220, n_D^{20} 1.585, n_D^{25} 1.5832, pK^{25} 4.60.** Aniline is *hygroscopic*. It can be dried with KOH or CaH_2, and distilled under reduced pressure. Treatment with stannous chloride removes sulfur-containing impurities, reducing the tendency to become coloured by aerial oxidation. It can be crystallised from Et_2O at low temperatures. More extensive purifications involve preparation of derivatives, such as the double salt of aniline hydrochloride and cuprous chloride or zinc chloride, or *N*-acetylaniline (**m** 114°) which can be recrystallised from water.
Redistilled aniline is dropped slowly into a strong aqueous solution of recrystallised oxalic acid. Aniline oxalate (**m** 174-175°) is filtered off, washed several times with water and recrystallised three times from 95% EtOH. Treatment with saturated Na_2CO_3 solution regenerated aniline which was distilled from the solution, dried and redistilled under reduced pressure [Knowles *Ind Eng Chem* **12** 881 *1920*].
After refluxing with 10% acetone for 10 hours, aniline is acidified with HCl (Congo Red as indicator) and extracted with Et_2O until colourless. The hydrochloride is purified by repeated crystallisation before aniline is liberated by addition of alkali, then dried with solid KOH, and distilled. The product is sulfur-free and remains colourless in air [Hantzsch & Freese *Chem Ber* **27** 2529, 2966 *1894*].
Non-basic materials, including nitro compounds, are removed from aniline in 40% H_2SO_4 by passing steam through the solution for 1 hour. Pellets of KOH are then added to liberate the aniline which is steam distilled, dried with KOH, distilled twice from zinc dust at 20mm, dried with freshly prepared BaO, and finally distilled from BaO in an all-glass apparatus [Few & Smith *J Chem Soc* 753 *1949*]. Aniline is absorbed through skin and is **TOXIC**. [*Beilstein* **12** IV 223.]

Aniline hydrobromide *[542-11-0]* **M 174.0, m 286°.** Crystallise the hydrobromide from water or EtOH and dry it at 5mm over P_2O_5. Also recrystallise it four times from MeOH containing a few drops of conc HBr by addition of petroleum ether (b 60-70°), then dry it to constant weight over paraffin chips *in vacuo* [Gutbezahl & Grunwald *J Am Chem Soc* **75** 559 *1953*]. It precipitates from EtOH solution on addition of Et_2O, and the filtered solid is recrystallised from EtOH and dried *in vacuo*. [Buchanan et al. *J Am Chem Soc* **108** 1537 *1986*, *Beilstein* **12** III 232.]

Aniline hydrochloride *[142-04-1]* **M 129.6, m 200.5-201°.** Purification is as for aniline HBr above. [*Beilstein* **12** IV 232.]

Aniline hydroiodide *[45497-73-2]* **M 220.0, it decomposes on heating.** Purification is as for aniline HBr; store it in the dark. [*Beilstein* **12** III 232.]

***m*-Anisaldehyde (3-methoxybenzaldehyde)** *[591-31-1]* **M 136.2, b 143°/50mm, d_4^{20} 1.119.** Wash it with saturated aqueous $NaHCO_3$, then H_2O, dry it with anhydrous $MgSO_4$ and distil it under reduced pressure under N_2. Store it under N_2 in sealed glass ampoules. [*Beilstein* **8** IV 241.]

***p*-Anisaldehyde (4-methoxybenzaldehyde)** *[123-11-5]* **M 136.2, m -1°, b 249°/atm, 89-90°/2mm, d_4^{20} 1.119, n_D^{20} 1.576.** Wash the aldehyde with saturated aqueous $NaHCO_3$, then H_2O, steam distil, extract the distillate with Et_2O, dry ($MgSO_4$) the extract, filter and distil this under a vacuum and N_2. Store it in glass ampules under N_2 in the dark. [*Beilstein* **8** IV 252.]

***o*-Anisidine (2-methoxyaniline)** *[90-04-0]* **M 123.2, m ~5°, b 109°/17mm, 119°/21mm, 225°/atm, d_4^{20} 1.096, n_D^{20} 1.575, pK^{25} 4.52.** It is separated from the *m*- and *p*- isomers by steam distillation. It is also separated from its usual synthetic precursor *o*-nitroanisole by dissolving it in dilute HCl (pH <2.0) extracting the nitro impurity with Et_2O, adjusting the pH to ~8.0 with NaOH, extracting the amine into Et_2O or steam distilling. Extract the distillate with Et_2O, dry the extract (Na_2SO_4), filter, evaporate and fractionate the residual oil. Protect the almost colourless oil from light which turns it yellow in color. [Biggs & Robinson *J Chem Soc* 388*1961*, Nodzu et al. *Yakugaku Zasshi (J Pharm Soc Japan)* **71** 713, 715 *1951*, *Beilstein* **13** IV 806.]

***m*-Anisidine (3-methoxyaniline)** *[536-90-3]* **M 123.2, m ~5°, b 79°/1mm, 128°/17mm, 251°/atm, d_4^{20} 1.101, n_D^{20} 1.583, pK^{25} 4.20.** *o*-Isomer impurity can be removed by steam distillation. Another possible impurity is the precursor 3-nitroanisole which can be removed as for the preceding *o*-isomer and fractionating using an efficient column. It is a yellow liquid. [Gilman & Kyle *J Am Chem Soc* **74** 3027 *1952*, Bryson *J Am Chem Soc* **82** 4858 *1960*, Kadaba & Massie *J Org Chem* **22** 333 *1957*, *Beilstein* **13** IV 953.]

***p*-Anisidine (4-methoxyaniline])** *[104-94-9]* **M 123.2, m 57°, pK^{25} 5.31.** Crystallise *p*-anisidine from H_2O or aqueous EtOH. Dry it in a vacuum oven at 35° for 6 hours and store it in a dry box. [More et al. *J Am Chem Soc* **108** 2257 *1986*.] Purify it also by vacuum sublimation [Guarr et al. *J Am Chem Soc* **107** 5104 *1985*]. [*Beilstein* **13** IV 1015.]

Anisole *[100-66-3]* **M 108.1, f -37.5°, b 43°/11mm, 153.8°/760mm, d^{15} 0.9988, n_D^{20} 1.5143, pK^0 -6.61 (aqueous H_2SO_4).** Shake anisole with half its volume of 2M NaOH, and the emulsion is allowed to separate. Repeat three times, then wash twice with water, dry over $CaCl_2$, filter, dry over sodium wire and finally distil it from fresh sodium under N_2 using a Dean-Stark trap (samples in the trap being rejected until free from turbidity) [Caldin et al. *J Chem Soc, Faraday Trans 1* **72** 1856 *1976*]. *Alternatively*, dry it with $CaSO_4$ or $CaCl_2$, or by refluxing with sodium or BaO with crystalline $FeSO_4$ or by passage through an alumina column. Traces of phenols are removed by prior shaking with 2M NaOH, followed by washing with water. It has been be purified by zone refining. [*Beilstein* **6** IV 548.]

2-*p*-Anisyl-1,3-indanone (anisindione) *[117-37-3]* **M 252.3, m 156-157°, pK^{20} 4.09.** Crystallise anisidinone from acetic acid or EtOH. [Horeau & Jacqius *Bull Soc Chim Fr* 53 *1948*, Koelsch *J Am Chem. Soc* **58** 1331 *1936, Beilstein* **8** III 2931.]

Anthracene *[120-12-7]* **M 178.2, m 215-216°, 218°, b 342°/760mm, pK^{25} -7.4 (aqueous H_2SO_4).** Likely impurities are anthraquinone, anthrone, carbazole, fluorene, 9,10-dihydroanthracene, tetracene and bianthryl. Carbazole is removed by continuous-adsorption chromatography [see Sangster & Irvine *J Phys Chem* **24** 670 *1956*] using a neutral alumina column and eluting with *n*-hexane. [Sherwood in *Purification of Inorganic and Organic Materials*, Zief (ed), Marcel Dekker, New York, 1969.] The solvent is evaporated, and anthracene is sublimed under vacuum, then purified by zone refining, under N_2 in darkness or non-actinic light.
It has also been purified by co-distillation with ethylene glycol (boils at 197.5°), from which it can be recovered by addition of water, followed by crystallisation from 95% EtOH, *benzene, toluene, a mixture of *benzene/xylene (4:1), or Et_2O. It has also been chromatographed on alumina with petroleum ether in a dark room (to avoid photo-oxidation of adsorbed anthracene to anthraquinone). Other purification methods include sublimation in a N_2 atmosphere (in some cases after refluxing with sodium), and recrystallisation from toluene [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*].
Anthracene has been crystallised from EtOH, chromatographed through alumina in hot *benzene (*fume hood)* and then sublimed in a vacuum in a pyrex tube that has been cleaned and baked at 100°. (For further details see Craig & Rajikan *J Chem Soc, Faraday Trans 1* **74** 292 *1978*, and Williams & Zboinski *J Chem Soc, Faraday Trans 1* **74** 611 *1978*.) It has been chromatographed on alumina, recrystallised from *n*-hexane and sublimed under reduced pressure. [Saltiel *J Am Chem Soc* **108** 2674 *1986*, Masnori et al. *J Am Chem Soc* **108** 1126 *1986*.]

Alternatively, recrystallise it from cyclohexane, chromatograph it on alumina with *n*-hexane as eluent, and recrystallise two more times [Saltiel et al. *J Am Chem Soc* **109** 1209 *1987*]. Anthracene is fluorescent and forms a *picrate complex*, **m** 139°, on mixing the components in $CHCl_3$ or $*C_6H_6$, but decomposes on attempted crystallisation. [*Beilstein* **5** IV 228.]

Anthracene-9-carboxylic acid (anthroic acid) *[723-62-6]* **M 222.2, m 214°(dec), pK^{20} 3.65.** Crystallise the acid from EtOH. It is fluorescent in EtOH. [*Beilstein* **9** IV 2671.]

9-Anthraldehyde *[642-31-9]* **M 206.2, m 104-105°.** Crystallise the aldehyde from acetic acid or EtOH. [Masnori et al. *J Am Chem Soc* **108** 1126 *1986*, *Beilstein* **7** IV 1738.]

Anthranol (enol tautomer of anthone, see below) *[529-86-2]* **M 196.2, m 120°(rapid heating), 160-170°(dec. but sainters >100°), pK^{25} -5.5 (aqueous H_2SO_4).** Crystallise anthrol from glacial acetic acid or aqueous EtOH. It is the less stable of two tautomers and is obtained by heating anthrone in aqueous NaOH (but not in cold NaOH) whereby it dissolves to form the sodium salt of anthrol. On cautious acidification anthrol precipitates as a yellowish-brown solid. It changes into anthrone on keeping, as it does on melting (120° in a preheated bath). The melting point depends on the initial bath temperature, and recrystallisation may cause it to tautomerise to *anthrone* (see below). The *acetate* (**m** 134°) crystallises from petroleum ether (**m** 134°) or EtOH (**m** 135.5-137°). [Meyer *Justus Liebigs Ann Chem* **379** 56 *1911*, Barnett et al. *J Chem Soc* 885 *1928*, for tautomerism see Almdal et al. *Acta Chem Scand* Series B **40** 230 *1986*.]

Anthranthrone *[641-13-4]* **M 306.3, m 300°, 415°, pK^{25} -7.9 (aqueous H_2SO_4).** Crystallise it from chlorobenzene, nitrobenzene or $CHCl_3$ (**m** 340°). [*Beilstein* **7** I 451, **7** II 783, **7** III 4406, **7** IV 2694.]

Anthraquinone *[84-65-1]* **M 208.2, m 286°, pK^{25} -8.27 (aqueous H_2SO_4).** Crystallise anthraquinone from $CHCl_3$ (38ml/g), *benzene, or boiling acetic acid, wash it with a little EtOH and dry it under vacuum over P_2O_5. [*Beilstein* **7** IV 2556.]

Anthrarufin (1,5-dihydroxy-9,10-anthraquinone) *[117-12-4]* **M 240.1, m 280°(dec), pK_1^{25} 9.90, pK_2^{25} 11.05.** Purify anthrarufin by column chromatography on silica gel with $CHCl_3/Et_2O$ as eluent, followed by recrystallisation from acetone. *Alternatively*, recrystallise it from glacial acetic acid [Flom & Barbara *J Phys Chem* **89** 4489 *1985*]. [*Beilstein* **7** III 2359, **8** IV 3268.]

1,8,9-Anthratriol *[480-22-8]* **M 226.2, m 176-181°, pK_{Est} ~9.5.** Crystallise it from petroleum ether and dry it *in vacuo*. [*Beilstein* **6** IV 7602.]

Anthrimide (1,1'-imino-bis-anthraquinone) *[82-22-4]* **M 429.4, m >250°(dec).** Crystallise anthrimide from chlorobenzene (red needles) or nitrobenzene (red rhombs). It is poorly soluble in organic solvents. [Eckert & Steiner *Monatsh Chem* **35** 1129 *1914*.]

Anthrone *[90-44-8]* **M 194.2, m 155°, pK^{25} -5.5 (aqueous H_2SO_4).** This stable keto tautomer of 9-anthranol (above) provides yellow crystals from a 3:1 mixture of $*C_6H_6$/petroleum ether (b 60-80°) (10-12ml/g), or successively from $*C_6H_6$ then EtOH. Dry it *in vacuo*. [Meyer *Org Synth* Coll Vol **I** 60 *1941*, *Beilstein* **6** IV 4930.]

(±)-Atrolactic acid ($0.5H_2O$) (2-hydroxy-2-phenylpropionic acid) *[515-30-0]* **M 166.2, m 94.5-95°(anhydrous), 88-91° ($0.5H_2O$), pK^{18} 3.53.** Crystallise the acid from water (4g/20ml boiling H_2O with charcoal, filter and cool overnight at 0-5°) and dry it at 55°/0.5mm [Eliel & Freeman *Org Synth* Coll Vol **IV** 58 *1963*]. The *(±)-ethyl ester* [76496-51-0] has **b 250°/~760mm, 129-130°/13mm**, and the *(±)-amide* [5908-94-1] has **m 101-102°**. [*Beilstein* **10** H 259, **10** I 113, **10** II 157, **10** III 560, **10** IV 467.]

***R*-(-) and *S*-(+) Atrolactic acid** *[R 3966-30-1 and S 13113-71-8]* **M 166.2, m 115-116°, 116-117°, *R* $[\alpha]_D^{14.6}$ -37.7° (c 3.3 EtOH) and $[\alpha]_D^{14.6}$ –51.1° (c 2.2, H_2O], *S* $[\alpha]_D^{14.6}$ +37.7° (c 3.5 EtOH).** Recrystallise them from $*C_6H_6$ or $*C_6H_6$/petroleum ether and dry them in a vacuum. [McKenzie & Clough *J Chem Soc* 1019 *1910*,

Meyers & Slade *Synth Commun* **6** 601*1972*, *Beilstein* **10** II 157, **10** III 560, **10** IV 657.]

Auramine O (4,4'-bis-dimethylaminobenzophenone imine hydrochloride) *[2465-27-2]* **M 321.9, m >250°(dec), pK^{25} 10.71 (free base), 9.78 (carbinolamine).** It crystallises from EtOH as the hydrochloride and is very slightly soluble in $CHCl_3$, its UV has λ_{max} at 434nm (ε 370). The *free base* (carbinolamine) has **m** 136° (from *C_6H_6). [Goldacre & Phillips *J Chem Soc* 1724 *1949*, Conrad et al. *Biochemistry* **9** 1540 *1970*, *Beilstein* **14** IV 256.]

Aurin tricarboxylic acid *[4431-00-9]* **M 422.4, m 300°.** The acid is dissolved in aqueous NaOH, $NaHSO_3$ solution is added until the colour is discharged and then the tricarboxylic acid is precipitated with HCl. [Heisig & Lauer *Org Synth* Coll Vol **I** 54 *1941*, *Beilstein* **10** IV 4161]. Do not extract the acid with hot water because it softens, forming a viscous mass. Make a solution in aqueous NH_3. **Aluminon** is the NH_4 salt.

Azobenzene *[103-33-3]* **M 182.2, m 68°, b 293°/atm, pK^{25} 2.48.** Ordinary azobenzene is nearly all in the *trans*-form. It is partly converted into the *cis*-form on exposure to light [for isolation see Hartley *J Chem Soc* 633 *1938*, and for spectra of *cis*- and *trans*-azobenzenes, see Winkel & Siebert *Chem Ber* **74B** 670*1941*]. *trans*-Azobenzene is obtained by chromatography on alumina using 1:4 *C_6H_6/heptane or petroleum ether, and it crystallises from EtOH (after refluxing for several hours) or hexane. All operations should be carried out in diffuse red light or in the dark. [*Beilstein* **16** IV 8.]

4-Azidoaniline hydrochloride *[91159-79-4]* **M 170.6, m 165°(dec).** Purify it in EtOAc with dry HCl gas followed by cold dry Et_2O. The *free base* has **m** 66°(dec) (MeOH) and the *picrate* has **m** 64-65°(dec) (MeOH). The IR has ν_{max} at (Nujol) at 2110cm^{-1} (N_3). [Escher et al. *Helv Chim Acta* **62** 1217 *1979*, Maffei & Rivolta *Gazetta Chim Ital* **84** 750 *1954*, *Beilstein* **12** H 772, **12** IV 1741.]

Azolitmin B *[1395-18-2]* **M ~3300, m >250°(dec)**. It crystallises from water as dark violet scales, or as a red powder on precipitation from H_2O by addtition of EtOH. It is an indicator which is red at pH 4.5 and blue at pH 8.3. [cf Kolthopff & Rosenblum *Acid-Base Indicators*, Macmillan, NY pp160-162, 365-366 *1937*.]

p,p'-**Azoxyanisole (4,4'-dimethoxyazoxybenzene)** *[1562-94-3]* **M 258.3, transition temperatures: 118.1-118.8°, 135.6-136.0°, pK^{25} -5.23 (20% aqueous EtOH + 80% aqueous H_2SO_4).** Crystallise the dye from absolute or 95% EtOH, or acetone, and dry it by heating under vacuum or sublime it in a vacuum onto a cold finger. [*Beilstein* **16** II 326.]

Azoxybenzene (Fenazox) *[495-48-7]* **M 198.2, m 36°, pK^{25} -6.16 (20% aqueous EtOH + 80% aqueous H_2SO_4).** Crystallise azobenzene from EtOH or MeOH, and dry it for 4 hours at 25°/10^{-3}mm. Sublime it before use. [Bigelow & Palm *Org Synth* Coll Vol **II** 57 *1943*, *Beilstein* **16** II 326.]

p,p-**Azoxyphenetole** *[4792-83-0]* **M 286.3, m 137-138° (turbid liquid clarifies at 167°).** Crystallise the dye from toluene or EtOH. [*Beilstein* **16** II 326.]

Azulene *[275-51-4]* **M 128.2, m 98.5-99°, pK^{25} -1.65 (aqueous H_2SO_4).** Crystallise azulene from EtOH. It has UV with λ_{max} at 270nm (logε 4.72) in hexane. [Platner & Magyar *Helv Chim Acta* **25** 581 *1942*, *Beilstein* **5** IV 1636.]

Benzalacetone (*trans*-**4-phenyl-3-buten-2-one)** *[122-57-6]* **M 146.2, m 42°.** Crystallise it from petroleum ether (b 40-60°), or distil it (**b** 137-142° /16mm). [*Beilstein* **7** IV 1003.]

Benzalacetophenone (Chalcone) *[94-41-7]* **M 208.3, m 56-58°, b 208°/25mm, pK^{25} -5.73 (aqueous H_2SO_4).** Crystallise it from EtOH by warming to 50° (about 5ml/g), iso-octane, or toluene/petroleum ether, or recrystallise it from MeOH, and then twice from hexane. SKIN IRRITANT. [*Beilstein* **7** IV 1658.]

Benzaldehyde *[100-52-7]* **M 106.1, f -26°, b 62° 58°/10mm, 179.0°/760mm, d_4^{20} 1.044, n_D^{20} 1.5455, pK^{25} -7.1**

(aqueous H_2SO_4). To diminish its rate of oxidation, benzaldehyde usually contains additives such as hydroquinone or catechol. It can be purified *via* its bisulfite addition compound but usually distillation (under nitrogen at reduced pressure) is sufficient. Prior to distillation it is washed with NaOH or 10% Na_2CO_3 (until no more CO_2 is evolved), then with saturated Na_2SO_3 and H_2O, followed by drying with $CaSO_4$, $MgSO_4$ or $CaCl_2$. [*Beilstein* **7** IV 505.]

***anti*-Benzaldoxime** *[932-90-1]* **M 121.1, m 33-34°.** Crystallise the oxime from diethyl ether by adding petroleum ether (b 60-80°). The *syn*-isomer [622-32-2] has **b** 121-124°/12mm, **m** 34-36°. [*Beilstein* **7** H 218, **7** IV 527.]

Benzamide *[55-21-0]* **M 121.1, m 129.5°, pK^{25} -2.16 (aqueous H_2SO_4).** Crystallise it from hot water (about 5ml/g), EtOH or 1,2-dichloroethane, and dry it in air. It has also been crystallised from dilute aqueous NH_3, H_2O, Me_2CO, then *C_6H_6 using a Soxhlet extractor. Dry it in an oven at 110° for 8 hours and store in a desiccator over 99% H_2SO_4. [Bates & Hobbs *J Am Chem Soc* **73** 2151 *1951*, *Beilstein* **9** IV 725.]

Benzamidine *[618-39-3]* **M 120.2, m 64-66°, pK^{20} 11.6.** It is liberated from its hydrochloride chloride (below) by treatment with 5M NaOH, extracted into diethyl ether, dried (Na_2SO_4) and sublimed *in vacuo*. [*Beilstein* 9 H 280, 9 I 123, 9 II 199, **9** 1264, 9 IV 898.]

Benzamidine hydrochloride hydrate *[206752-36-5]* **M 156.6 (anhydrous), m 86-88°, pK^{20} 11.6 (see free base above).** Recrystallise it from dilute HCl (crystals contain xH_2O) or EtOH/few drops HCl; dry it in a vacuum. It is a proteolytic inhibitor [Jeffcoate & White *J Clin Endocrinol Metab* **38** 155 *1974*, *Beilstein* **9** IV 898.]

Benzanilide *[93-98-1]* **M 197.2, m 164°, pK^{55} 1.26.** Crystallise benzanilide from petroleum ether (b 70-90°) using a Soxhlet extractor, and dry it overnight at 120°. Also crystallise it from EtOH. [*Beilstein* **12** IV 417.]

Benz[a]anthracene (1,2-benzanthracene, tetraphene) *[56-55-3]* **M 228.3, m 159-160°.** Crystallise 1,2-benzanthracene from MeOH, EtOH or *benzene (charcoal), then chromatograph it on alumina from sodium-dried *benzene (twice), using vacuum distillation to remove *benzene. Final purification is by vacuum sublimation. [*Beilstein* **5** IV 2549.]

Benz[a]anthracene-7,12-dione *[2498-66-0]* **M 258.3, m 169.5-170.5°**, **169-171°**. Crystallise the dione from MeOH (charcoal). toluene, toluene/hexane, Me_2CO, or AcOH. *Alternatively* purify it by sublimation *in vacuo*, or by zone refining. [*Beilstein* **7** H 826, **7** I 440, **7** II 760, **7** III 4278, **7** IV 2644.]

Benzanthrone *[82-05-3]* **M 230.3, m 170°, pK^{25} -3.2 (aqueous H_2SO_4).** Crystallise benzanthrone from EtOH or xylene. [*Beilstein* **7** IV 1819.]

***Benzene** *[71-43-2]* **M 78.1, f 5.5°, b 80.1°, d_4^{20} 0.874, n_D^{20} 1.50110, n_D^{25} 1.49790.** For most purposes, *benzene can be purified sufficiently by shaking with conc H_2SO_4 until free from thiophene, then with H_2O, dilute NaOH and water, followed by drying (with P_2O_5, sodium, $LiAlH_4$, CaH_2, 4X Linde molecular sieve, or $CaSO_4$, or by passage through a column of silica gel, and for a preliminary drying, $CaCl_2$ is suitable), and distillation. A further purification step to remove thiophene, acetic acid and propionic acid, is crystallisation by partial freezing. The usual contaminants in dry thiophene-free *benzene are non-benzenoid hydrocarbons such as cyclohexane, methylcyclohexane, and heptanes, together with naphthenic hydrocarbons and traces of toluene. Carbonyl-containing impurities can be removed by percolation through a *Celite column impregnated with 2,4-dinitrophenylhydrazine, phosphoric acid and H_2O*. (Prepared by dissolving 0.5g DNPH in 6ml of 85% H_3PO_4 by grinding together, then adding and mixing 4ml of distilled H_2O and 10g Celite.) [Schwartz & Parker *Anal Chem* **33** 1396 *1961*.] *Benzene has been freed from thiophene by refluxing with 10% (w/v) of Raney nickel for 15 minutes, after which the nickel is removed by filtration or centrifugation.
Dry *benzene is obtained by doubly distilling high purity *benzene from a solution containing the blue ketyl formed by the reaction of sodium-potassium alloy with a small amount of benzophenone.
Thiophene has been removed from *benzene (absence of a bluish-green coloration when 3ml of *benzene is

shaken with a solution of 10mg of isatin in 10ml of conc H_2SO_4) by refluxing the *benzene (1.25L) for several hours with 40g HgO (freshly precipitated) dissolved in 40ml glacial acetic acid and 300ml of water. The precipitate is filtered off, the aqueous phase is removed and the *benzene is washed twice with H_2O, dried and distilled. *Alternatively*, *benzene dried with $CaCl_2$ has been shaken vigorously for 0.5 hour with anhydrous $AlCl_3$ (12g/L) at 25-35°, then decanted, washed with 10% NaOH, and water, dried and distilled. The process is repeated, giving thiophene-free *benzene. [Holmes & Beeman *Ind Eng Chem* **26** 172 *1934*.]
After shaking successively for about an hour with conc H_2SO_4, distilled water (twice), 6M NaOH, and distilled water (twice), *benzene is distilled through a 3-ft glass column to remove most of the water. Absolute EtOH is added and the *benzene-alcohol azeotrope is distilled. (This low-boiling distillation leaves any non-azeotrope-forming impurities behind.) The middle fraction is shaken with distilled water to remove EtOH, and again redistilled. Final slow and very careful fractional distillation from sodium, then $LiAlH_4$ under N_2, removed traces of water and peroxides. [Peebles et al. *J Am Chem Soc* **82** 2780 *1960*.] ***Benzene liquid and vapour are very* TOXIC, CARCINOGENIC** *and* **HIGHLY FLAMMABLE**, *and all operations should be carried out in an efficient fume cupboard and in the absence of naked flames in the vicinity.* [*Beilstein* **5** H 175, **5** I 95, **5** II 119, **5** III 469.]
Rapid purification: To dry benzene, alumina, CaH_2 or 4A molecular sieves (3% w/v) may be used (dry for 6 hours). Then benzene is distilled, discarding the first 5% of distillate, and stored over molecular sieves (3A, 4A) or Na wire.

[$^2H_6$]*Benzene (benzene-d_6*) *[1076-43-3]* M 84.2, b 80°/773.6mm, 70°/562mm, 60°/399mm, 40°/186.3mm, 20°/77.1mm, 10°/49.9mm, 0°/27.5mm, d_4^{20} 0.9488, d_4^{40} 0.9257, n_D^{20} 1.4991, n^{40} 1.4865.** Hexadeuteriobenzene of 99.5% purity is refluxed over and distilled from CaH_2 onto Linde type 5A sieves under N_2. [*Beilstein* **5** III 518, **5** IV 630.]

Benzeneazodiphenylamine (4-phenylazodiphenylamine) *[28110-26-1; 101-75-7]* **M 273.3, m 82°, 86°, 87-91°, pK^{22} 0.48.** Purify the dye by chromatography on neutral alumina using dry *C_6H_6 with 1% of dry MeOH. The major component, which gave a stationary band, is cut out and eluted with EtOH or MeOH. [Högfeldt & Bigeleisen *J Am Chem Soc* **82** 15 *1960*.] It crystallises from petroleum ether, EtOH or aqueous EtOH, and has λ_{max} at 420nm (ε 28,000) (aqueous EtOH) and 540nm (aqueous EtOH/H_2SO_4) [Badger et al. *J Chem Soc* 1888 *1954*, *Beilstein* **16** H 314, **16** III 343, **16** IV 457.]

1-Benzeneazo-2-naphthol (Sudan I) *[842-07-9]* **M 248.3, m 106°, 120,5°, 132° (polymorphism) 134°, 135°, pK_{Est} ~9.5 (OH).** Crystallise the dye from EtOH. It forms Cu and Ni salts. [*Beilstein* **16** H 162, **16** I 254, **16** II 70, **16** III 129, **16** IV 228.]

1-Benzeneazo-2-naphthylamine (1-phenylazo-2-naphthylamine, Yellow AB) *[85-84-7]* **M 247.3, m 102-104°, 103-104°, pK_{Est} ~4.1.** Crystallise the dye from glacial acetic acid, acetic acid/water or ethanol. It forms Cu, Co and Ni salts. [*Beilstein* **16** H 369, **16** I 328, **16** II 193, **16** III 417, **16** IV 551.]

1,2-Benzenedimethanol (1,2-bishydroxymethylbenzene, phthalyl alcohol) *[612-14-6]* **M 138.2, m 61-64°, 63-64°, 64-65°, 65-66.5°, b 145°/3mm.** Recrystallise it from *C_6H_6, H_2O, petroleum ether or pentane. It has been extracted in a Soxhlet with Et_2O, evaporated and recrystallised from hot petroleum ether. It is also purified by dissolving in Et_2O, allowing to evaporate till crystals are formed, filtering off and washing the colourless crystals with warm petroleum ether or pentane. The *diacetate* has **m** 35°, 35-36°. [Nystrom & Brown *J Am Chem Soc* **69** 1197 *1947*, IR and UV: Entel et al. *J Am Chem Soc* **74** 441 *1952*, *Beilstein* **6** IV 5953.]

***m*-Benzenedisulfonic acid** *[98-48-6]* **M 238.2, pK_{Est} <0.** Free it from H_2SO_4 by conversion to the calcium or barium salts (using $Ca(OH)_2$ or $Ba(OH)_2$, and filtering). The calcium salt is then converted to the potassium salt, using K_2CO_3. Both the potassium and the barium salts are recrystallised from H_2O, and the acid is regenerated by passing through the H^+ form of a strong cation exchange resin. The acid is recrystallised twice from conductivity water and dried over $CaCl_2$ at 25°. [Atkinson et al. *J Am Chem Soc* **83** 1570 *1961*.] It has also been crystallised from Et_2O and dried in a vacuum oven. The *S-benzylisothiuronium salt* has **m** 214.3° (from EtOH/H_2O). [*Beilstein* **11** IV 553.] It is best kept as the *disodium salt* [831-59-4] which decomposes on heating [*Beilstein* **11** H 199, **11** I 48, **11** II 213, **11** III 453.]

***m*-Benzenedisulfonyl chloride** *[585-47-7]* **M 275.1, m 63°.** Crystallise it from $CHCl_3$ (EtOH free, by passing through an alumina column) or $*C_6H_6$/petroleum ether and dry it at 20mm pressure. [*Beilstein* **11** IV 553.]

Benzene-1,2-dithiol *[17534-15-5]* **M 142.2, m 24-25°, 27-28°, b 110-112°, $pK_{Est(1)}$ ~6.0, $pK_{Est(2)}$ ~9.4.** Likely impurities are the oxidation products, the disulfides which could be polymeric. Dissolve it in aqueous NaOH until the solution is alkaline. Extract with Et_2O and discard the extract. Acidify with cold HCl (diluted 1:1 by volume with H_2O) to Congo Red paper under N_2 and extract it three times with Et_2O. Dry the Et_2O with Na_2SO_4, filter, evaporate and distil the residue under reduced pressure in an atmosphere of N_2. The distillate solidifies on cooling. [UV: Dewar et al. *J Chem Soc* 3076 *1958*, Grunwald & Berkowitz *J Am Chem Soc* **81** 4939 *1951*, Ferretti *Org Synth* Coll Vol **V** 419 *1973*, *Beilstein* **6 IV** 5651.]

Benzenesulfinic acid *[618-41-7]* **M 142.2, m 84°, pK^{25} 2.16(2.74).** The acid is purified by dissolving the Na salt in H_2O, acidifying to Congo Red paper with HCl and adding a concentrated solution of $FeCl_3$ whereby Fe sulfinate precipitates. Collect the salt, wash it with a little H_2O, drain, suspend it in H_2O and add a slight excess of 1.5M aqueous NaOH. The $Fe(OH)_3$ precipitates, it is filtered off, the sulfinic acid in the aqueous solution is extracted with Et_2O, the extract is dried (Na_2SO_4) and evaporated to give colourless crystals of benzenesulfinic acid **m** 84° which are stored under N_2 in the dark, as it slowly oxidises in air to the sulfonic acid. [*Beilstein* **11** H 2, **11** I 3, **11** II 3, **11** III 3, **11** IV 3.]

Benzenesulfonic acid *[98-11-3]* **M 158.2, m 43-44°, 50-55°(anhydrous), 65-66°, pK^{25} -2.7, 0.70, (2.53?)** Purify benzenesulfonic acid by dissolving it in a small volume of distilled H_2O and stirring with slightly less than the theoretical amount of $BaCO_3$. When effervescence is complete and the solution is still acidic, filter off the insoluble barium benzenesulfonate. The salt is collected and dried to constant weight *in vacuo*, then suspended in H_2O and stirred with a little less than the equivalent (half mol.) of sulfuric acid. The insoluble $BaSO_4$ (containing a little barium benzenesulfonate) is filtered off and the filtrate containing the free acid is evaporated in a high vacuum. The oily residue will eventually crystallise when completely anhydrous. A 32% commercial acid is allowed to fractionally crystallise at room temperature over P_2O_5 in a vacuum desiccator giving finally colourless deliquescent plates **m** 52.5°. The anhydrous crystalline acid is deliquescent and should be stored over anhydrous Na_2SO_4 in the dark, and should be used in subdued sunlight as it darkens under sunlight. The main impurity is Fe which readily separates as the Fe salt in the early fractions [Taylor & Vincent *J Chem Soc* 3218 *1952*]. The *S-benzylisothiuronium salt* has **m** 148° (from EtOH/H_2O). It is a strong acid, and an IRRITANT to the skin and eyes. [See Adams & Marvel *Org Synth* Coll Vol **I** 84 *1941*, Michael & Adair *Chem Ber* **10** 585 *1877*, *Beilstein* **11** IV 27.]

Benzenesulfonic anhydride *[512-35-6]* **M 298.3, m 88-91°.** Crystallise the anhydride from Et_2O **(m** 88.5-91.5°), $CHCl_3$ or chlorobenzene **(m** 90-92°). Store it dry. [Field *J Am Chem Soc* **74** 394 *1952*, *Beilstein* **11** H 3, **11** I 11, **11** II 23, **11** III 50, **11** IV 50.]

Benzenesulfonyl chloride *[98-09-9]* **M 176.6, m 14.5°, b 120°/10mm, 251.2°/760mm(dec), d_4^{20} 1.384.** Distil the sulfonyl chloride, preferably under a vacuum, then treat it with 3mole % each of toluene and $AlCl_3$, and allow it to stand overnight. The sulfonyl chloride is distilled off at 1mm pressure and then carefully fractionally distilled at 10mm in an all-glass column. [Adams & Marvel *Org Synth* Coll Vol **I** 84 *1941*, Jensen & Brown *J Am Chem Soc* **80** 4042 *1958*, *Beilstein* **11** IV 49.] It is **TOXIC.**

Benzene-1,2,4,5-tetracarboxylic (pyromellitic acid) *[89-05-4]* **M 254.2, m 276°, 281-284°, pK_1^{25} 1.87, pK_2^{25} 2.72, pK_3^{25} 4.30, pK_4^{25} 5.52.** Dissolve it in 5.7 parts of hot dimethylformamide, decolorise, filter and cool. The precipitate is collected and dried in air. The solvent is removed by heating in an oven at 150-170° for several hours. It also crystallises from water. [*Beilstein* **9** H 997, **9** IV 3804.]

Benzene-1,2,4,5-tetracarboxylic dianhydride (pyromellitic dianhydride) *[89-32-7]* **M 218.1, m 286°, b 397-400°/760mm.** Crystallise the dianhydride from ethyl methyl ketone or dioxane. Dry, and sublime it *in vacuo*. [*Beilstein* **19** H 196, **19/5** V 407.]

Benzene-1,2,3-tricarboxylic (hemimellitic) acid (H_2O) *[36362-97-7]* **M 210.1, m 190°(dec), pK_1^{25} 2.62, pK_2^{25}**

3.82, pK_3^{25} 5.51. Crystallise the acid from water. [*Beilstein* **9** H 976, **9** IV 3745.]

Benzene-1,3,5-tricarboxylic (trimesic or trimellitic) acid *[554-95-0]* **M 210.1, m 360°(dec), pK_1^{25} 2.64, pK_2^{25} 3.71, pK_3^{25} 5.01.** Crystallise the acid from water. The *trimethyl ester* has **m** 144° (from MeOH or MeOH/H_2O). [*Beilstein* **9** H 978, **9** IV 3747.]

1,2,4-Benzenetriol *[533-73-3]* **M 126.1, m 140.5-141°(sintering at 139°), pK_1^{20} 9.08, pK_2^{20} 11.82.** Crystallise the triol from Et_2O or Et_2O/EtOH, and dry it in a vacuum. The *picrate* forms orange-red needles **m** 96°. [*Beilstein* **6** H 1087, **6** I 541, **6** II 1071, **6** III 6276.]

Benzethonium chloride (Hyamine 1622, [diisobutylphenoxyethoxyethyl]dimethylbenzyl-ammonium chloride, (*N,N*-dimethyl-*N*-[2-[2-[4-(1,1,3,3-tetramethylbutyl)phenoxy]-ethoxy]-ethyl]-benzenemethan-ammonium chloride) *[121-54-0]* **M 448.1, m 164-166° (sinters at 120°, monohydrate).** Crystallise it from boiling acetone after filtering or from $CHCl_3$/petroleum ether. The precipitate is filtered off, washed with diethyl ether and dried for 24 hours in a vacuum desiccator. It is a cationic antiseptic surfactant which forms crystals also from a 1:9 MeOH/Et_2O mixture. It foams in water. [*Beilstein* **12** IV 2187.]

Benzhydrol (diphenylmethanol) *[91-01-0]* **M 184.2, m 69°, b 297°/748mm, 180°/20mm.** Crystallise benzhydrol from hot H_2O or petroleum ether (b 60-70°), petroleum ether containing a little *benzene, from CCl_4, or EtOH (1ml/g). An additional purification step includes passage of a *benzene solution through an activated alumina column. It sublimes in a vacuum. Also recrystallise it three times from MeOH/H_2O [Naguib *J Am Chem Soc* **108** 128 *1986*]. [*Beilstein* **6** IV 4648.]
§ A commercial polystyrene supported version is available.

Benzidine (4,4'-diaminobiphenyl) *[92-87-5]* **M 184.2, m 128-129°, pK_1^{20} 3.85, pK_2^{20} 4.95.** Its solution in *benzene is decolorised by percolating through two 2-cm columns of activated alumina, then concentrated until benzidine crystallises on cooling. Recrystallise alternately from EtOH and *benzene to constant absorption spectrum [Carlin et al. *J Am Chem Soc* **73** 1002 *1951*]. It has also been crystallised from hot water (charcoal) and from diethyl ether. Dry it under vacuum in an Abderhalden pistol. Store it in the dark in a stoppered container. **CARCINOGENIC. [***Beilstein* **13** IV 364.]

Benzidine dihydrochloride *[531-85-1]* **M 257.2, m >250°(dec).** Crystallise the salt by dissolving in hot H_2O, and adding conc HCl to the slightly cooled solution. **CARCINOGENIC**. [*Beilstein* **13** IV 365.]

Benzil *[134-81-6]* **M 210.2, m 96-96.5°.** Crystallise benzil from *benzene after washing with alkali. (Crystallisation from EtOH did not free benzil from material reacting with alkali.) [Hine & Howarth *J Am Chem Soc* **80** 2274 *1958*.] It has also been crystallised from CCl_4, diethyl ether or EtOH [Inoue et al. *J Chem Soc, Faraday Trans 1* **82** 523 *1986*]. [*Beilstein* **7** IV 2502.]

Benzilic acid (diphenylglycollic acid) *[76-93-7]* **M 228.3, m 150°, pK^{18} 3.06.** Crystallise benzilic acid from *benzene (*ca* 6ml/g), or hot H_2O. [*Beilstein* **10** IV 1256.]

Benzil monohydrazone *[5433-88-7]* **M 224.3, m 151°(dec).** Crystallise it from EtOH. The *monoacetyl hydrazone* has **m** 91° (from EtOH). [Metze & Meyer *Chem Ber* **90** 483 *1959*, *Beilstein* **7** I 394.]

α-Benzil monoxime *[14090-77-8]*, *[E 574-15-2]*, *[Z 574-16-3]* **M 105.1, m 140°.** The *trans-isomer* crystallises from *C_6H_6 (must not use animal charcoal) and has **m** 140°. The *cis-isomer* also crystallises from *C_6H_6 but crystals have 0.5*C_6H_6 (**m** 62-63°), and the solvent free compound has **m** 112°. [*Beilstein* **7** III 3812, **7** IV 2504.]

Benzo[*a*]biphenylene *[252-47-1]* **M 202.2, m 72-73° (compare with β-isomer).** It forms yellow needles from MeOH and sublimes *in vacuo* (**m** 72.0-72.8°). The *2,4,7-trinitrofluorenone complex* crystallises as black needles **m** 201.5-202.5°. [Cava & Stucker *J Am Chem Soc* **77** 6022 *1955*, Barton et al. *J Chem Soc(C)* 1276

1967, *Beilstein* **5** IV 2462.]

Benzo[*b*]biphenylene *[259-56-3]* **M 202.2, 242.6-243.6°.** It forms yellow crystals from *C_6H_6/cyclohexane **m** 234-245° (sublimation). The *2,4,7-trinitrofluorenone complex* crystallises as red needles from *C_6H_6/MeOH **m** 214-216°. It has been sublimed *in vacuo*. [Jensen & Coleman *Tetrahedron Lett* **No 20** 7 *1959*, Barton et al. *J Chem Soc Perkin Trans 1* 967 *1986*, *Beilstein* **5** IV 2462.]

Benzoic acid *[65-85-0]* **M 122.1, m 122.6-123.1°, pK^{25} 4.12.** For use as a volumetric standard, analytical reagent grade benzoic acid should be carefully fused to *ca* 130° (to dry it) in a platinum crucible, and then powdered in an agate mortar. Benzoic acid has been crystallised from boiling water (charcoal), aqueous acetic acid, glacial acetic acid, *C_6H_6, aqueous EtOH, petroleum ether (b 60-80°), and from EtOH solution by adding water. It is readily purified by fractional crystallisation from its melt and by sublimation in a vacuum at 80°. The *S-benzylisothiuronium salt* has **m** 167° (from EtOH/H_2O). [*Beilstein* **9** IV 273.]

Benzoic anhydride *[93-97-0]* **M 226.2, m 42°.** Free it from benzoic acid by washing with $NaHCO_3$, then water, and drying. Crystallise it from *benzene (0.5ml/g) by adding just enough petroleum ether (b 40-60°) to cause cloudiness, then cool in ice. It can be distilled at 210-220°/20mm. [*Beilstein* **19** IV 550.]

(±)-Benzoin (2-hydroxy-2-phenylacetophenone) *[119-53-9]* **M 212.3, m 137°.** Crystallise benzoin from CCl_4, hot EtOH (8ml/g), or 50% acetic acid. Also crystallise it from high purity *benzene, then twice from high purity MeOH, to remove fluorescent impurities [Elliott & Radley *Anal Chem* **33** 1623 *1961*]. It can be sublimed. [*Beilstein* **8** IV 1279.]

(±)-α-Benzoinoxime *[441-38-3]* **M 227.3, m 151°.** Crystallise the oxime from diethyl ether. It is used for the spectroscopic determination of Cu^{2+}, Pd^{2+}, Pt^{4+}, Rh^{3+} and V^{5+} [Singh et al. *Talanta* **26** 425 *1979*, *Beilstein* **8** IV 1282.]

Benzonitrile *[100-47-0]* **M 103.1, f -12.9°, b 191.1°, d_4^{20} 1.010, n_D^{20} 1.528.** Dry benzonitrile with $CaSO_4$, $CaCl_2$, $MgSO_4$ or K_2CO_3, and distil it from P_2O_5 in an all-glass apparatus, under reduced pressure (**b** 69°/10mm), collecting the middle fraction. Distillation from CaH_2 causes some decomposition of benzonitrile. Isonitriles can be removed by preliminary treatment with conc HCl until the odour of isonitrile (carbylamine) has gone, followed by preliminary drying with K_2CO_3. (This treatment also removes amines.) Steam distil (to remove small quantities of carbylamine). The distillate is extracted into ether, washed with dilute Na_2CO_3, dried overnight with $CaCl_2$, and the ether is removed by evaporation. The residue is distilled at 40mm (**b** 96°) [Kice et al. *J Am Chem Soc* **82** 834 *1960*].
Conductivity grade benzonitrile (specific conductance 2 x 10^{-8} mho) is obtained by treatment with anhydrous $AlCl_3$, followed by rapid distillation at 40-50° under vacuum. After washing with alkali and drying with $CaCl_2$, the distillate is redistilled in a vacuum several times at 35° before fractionally crystallising several times by partial freezing. It is dried over finely divided activated alumina from which it is withdrawn when required [Van Dyke & Harrison *J Am Chem Soc* **73** 402 *1951*]. [*Beilstein* **9** IV 892.]

Benzo[ghi]perylene (1,12-benzoperylene) *[191-24-2]* **M 276.3, m 273°, 277-278.5°, 278-280°.** It forms light green crystals on recrystallisation from *C_6H_6 or xylene and sublimes at 320-340°/0.05mm [UV: Hopff & Schweizer *Helv Chim Acta* **42** 2315 *1959*, Clar *Chem Ber* **65** 846 *1932*, Fluoresc. Spectrum: Bowen & Brocklehurst *J Chem Soc* 3875 *1954*]. It also recrystallises from propan-1-ol [Altman & Ginsburg *J Chem Soc* 466 *1959*]. The *1,3,5-trinitrobenzene complex* has **m** 310-313° (deep red crystals from *C_6H_6), the *picrate* has **m** 267-270° (dark red crystals from *C_6H_6), and the *styphnate (2,4,6-trinitroresorcinol complex)* has **m** 234° (wine red crystals from *C_6H_6). [*Beilstein* **5** IV 2766.]

3,4-Benzophenanthrene (benzo[c]phenanthrene) *[195-19-7]* **M 228.3, m 68°.** Crystallise benzo[c]phenanthrene from EtOH, petroleum ether, or EtOH/Me_2CO. [*Beilstein* **5** III 2378, **5** IV 2552.]

Benzophenone *[119-61-9]* **M 182.2, m 48.5-49°, pK^{25} -6.0(-8.4) (aqueous H_2SO_4).** Crystallise it from MeOH, EtOH, cyclohexane, *benzene or petroleum ether, then dry in a current of warm air and store it over BaO

or P_2O_5. It is also purified by zone melting and by sublimation [Itoh *J Phys Chem* **89** 3949 *1985*, Naguib et al. *J Am Chem Soc* **108** 128 *1986*, Gorman & Rodgers *J Am Chem Soc* **108** 5074 *1986*, Ohamoto & Teranishi *J Am Chem Soc* **108** 6378 *1986*, Naguib et al. *J Phys Chem* **91** 3033 *1987*]. [*Beilstein* **7** III 2048, **7** IV 1357.]

Benzophenone oxime *[574-66-3]* **M 197.2, m 142°, 143-144°, pK^{25} 11.18.** Crystallise the oxime from MeOH (4ml/g). [*Beilstein* **7** II 355, **7** III 2063 1370.]

Benzophenone-3,3',4,4'-tetracarboxylic dianhydride (BTDA) *[2421-28-5]* **M 322.2, m 218.5-219.5°, 225.5°.** The main impurity is the free acid formed by hydrolysis (check for OH bands in the IR). This can be converted to the dianhydride by treating with Ac_2O (molar ratio of 4 to 1 of acid), heating at 110-120° for 1.5 to 2 hours, cooling to 0—5° and collecting the dianhydride. This is then dissolved in hot dioxane or Me_2CO, filtered and cooled to 10—15°. The moisture sensitive solid is collected and dried at 120—130° *in vacuo*. It has been sublimed at high vacuum. [Faberov et al. *J Org Chem USSR* **4** 153 (English translation) *1968*.]

Benzopinacol *[464-72-2]* **M 366.5, m 170-180° (depends on heating rate), 171-173°.** Crystallise benzopinacol from EtOH. [*Beilstein* **6** IV 7053.]

Benzo[a]pyrene (3,4-benzpyrene, benzo[dcf]chrysene) *[50-32-8]* **M 252.3, m 177.5-178°, 179.0-179.5°.** A solution of 250mg of benzo[a]pyrene in 100ml of *benzene is diluted with an equal volume of hexane, then passed through a column of alumina, $Ca(OH)_2$ and Celite (3:1:1). The adsorbed material is developed with a 2:3 *benzene/hexane mixture. (It showed as an intensely fluorescent zone.) The main zone is eluted with 3:1 acetone/EtOH, and is transferred into 1:1 *benzene-hexane by adding H_2O. The solution is washed, dried with Na_2SO_4, evaporated and crystallised from *benzene by the addition of MeOH [Lijinsky & Zechmeister *J Am Chem Soc* **75** 5495 *1953*]. *Alternatively*, it can be chromatographed on activated alumina, eluted with a cyclohexane/*benzene mixture containing up to 8% *benzene, and the solvent is evaporated under reduced pressure [Cahnmann *Anal Chem* **27** 1235 *1955*], and crystallised from EtOH [Nithipatikom & McGown *Anal Chem* **58** 3145 *1986*]. [*Beilstein* **5** III 2517, **5** IV 2687.] **CARCINOGENIC.**

Benzo[e]pyrene (1,2-benzpyrene) *[192-97-2]* **M 252.3, m 178-179°, 178-180°.** Purify it by passage through an Al_2O_3 column (Woelm, basic, activity I) and elute with $*C_6H_6$ and recrystallise from 2 volumes of EtOH/$*C_6H_6$ (4:1). It forms colourless or light yellow prisms or needles. [Campbell *J Chem Soc* 3659 *1954*, Buchta & Kröger *Justus Liebigs Ann Chem* **705** 190 *1967*.] The *1,3,5-trinitrobenzene complex* has **m** 253-254° (orange needles from EtOH), the *picrate* prepared by mixing 20mg in 1ml of $*C_6H_6$ with 20mg of picric acid in 2ml $*C_6H_6$, collecting the deep red crystals, and recrystallising from $*C_6H_6$ has **m** 228-229° [NMR: Cobb & Memory *J Chem Phys* **47** 2020 *1967*]. [*Beilstein* **5** III 2520, **5** IV 2689.] **CARCINOGEN.**

***p*-Benzoquinone** *[106-51-4]* **M 108.1, m 115.7°.** Purify *p*-benzoquinone in one or more of the following ways: steam distillation followed by filtration and drying (e.g. in a desiccator over $CaCl_2$), crystallisation from petroleum ether (b 80-100°), *benzene (with, then without, charcoal), water or 95% EtOH, sublimation under vacuum (e.g. from room temperature to liquid N_2). It slowly decomposes and should be stored, refrigerated, in an evacuated or sealed glass vessel in the dark. It should be resublimed before use. [Wolfenden et al. *J Am Chem Soc* **109** 463 *1987*, *Beilstein* **7** IV 2065.]

1-Benzosuberone (6,7,8,9-tetrahydrobenzocyclohepten-5-one) *[826-73-3]* **M 160.2, b 80-85°/0.5mm, 90-93°/1mm, 138-139°/12mm, 154°/15mm, 175-175°/40mm, d_4^{20} 1.086, n_D^{20} 1.5638.** Purify it by dissolving in toluene, washing with aqueous 5% NaOH, then brine, drying ($MgSO_4$), and distilling. The *2,4-dinitrophenylhydrazone* has **m** 210.5°, 207-208° (from $CHCl_3$/MeOH). The *Z-O-picryloxime* has **m** 156-157° (from Me_2CO/MeOH), the *E-O-picryloxime* has **m** 107°. The *oxime* has **m** 106.5-107.5°. [UV: Gilmore & Horton *J Am Chem Soc* **73** 1411 *1951*, Hedden & Brown *J Am Chem Soc* **75** 3744 *1953*, Huisgen et al. *Chem Ber* **90** 1844 *1957*, *Beilstein* **7** IV 1029.]

Benzoylacetone (1-phenyl-1,3-butanedione) *[93-91-4]* **M 162.2, m 58.5-59.0°.** Crystallise benzoylacetone from Et_2O or MeOH and dry it under vacuum at 40°. [*Beilstein* **7** IV 2151.]

2-Benzoylbenzoic acid *[85-52-9]* **M 226.2, m 126-129°, 129.2, 130°, pK^{25} 3.54.** Recrystallise the acid from *C_6H_6 or cyclohexane, but it is best recrystallised by dissolving in a small volume of hot toluene and then adding just enough petroleum ether to cause turbidity, and cool. Dry it in a low vacuum at 80°. It can be sublimed at 230-240°/0.3mm [Bray et al. *J Chem Soc* 265 *1957*]. The *S-benzylisothiuronium salt* has **m** 177-178° (from EtOH). [Lewenz & Serijan *J Am Chem Soc* **75** 4087 *1953*, *Beilstein* **10** H 747, **10** IV 2977.]

3-Benzoylbenzoic acid *[579-18-0]* **M 226.2, m 164-166°, 165°, pK$_{Est}$~3.5.** Crystallise the acid from EtOH and sublime it at 160°/1mm. [*Beilstein* **10** H 752, **10** III 3304, **10** IV 2982.]

4-Benzoylbenzoic acid *[611-95-0]* **M 226.2, m 196.5-198°**, **197-200°, pK$_{Est}$ ~3.7.** Dissolve the acid in hot H_2O by adding enough aqueous KOH solution till distinctly alkaline, filter and then acidify with drops of conc HCl. Filter off, wash the solid with cold H_2O, dry it at 100°, and recrystallise it from EtOH. [Wertheim *J Am Chem Soc* **55** 2540 *1933*, *Beilstein* **10** H 753, **10** IV 3305.]

Benzoyl chloride *[98-88-4]* **M 140.6, b 56°/4mm, 196.8°/745mm, d$_4^{20}$ 1.2120, n$_D^{10}$ 1.5537.** A solution of benzoyl chloride (300ml) in *C_6H_6 (200ml) is washed with two 100ml portions of cold 5% $NaHCO_3$ solution, separated, dried with $CaCl_2$ and distilled [Oakwood & Weisgerber *Org Synth* **III** 113 *1955*]. Repeated fractional distillation at 4mm Hg through a glass helices-packed column (avoiding porous porcelain or silicon-carbide boiling chips, and hydrocarbon or silicon greases on the ground joints) gave benzoyl chloride that did not darken on addition of $AlCl_3$. Further purification is achieved by adding 3 mole% each of $AlCl_3$ and toluene, standing overnight, and distilling off the benzoyl chloride at 1-2mm [Brown & Jenzen *J Am Chem Soc* **80** 2291 *1958*]. Refluxing for 2 hours with an equal weight of thionyl chloride before distillation has also been used. [*Beilstein* **9** IV 721.] *Strong* **IRRITANT**. *Use in a fume cupboard.*

Benzoyl disulfide (dibenzoyl disulfide) *[644-32-6]* **M 174.4, m 131.2-132.3°.** About 300ml of solvent is blown off from a filtered solution of dibenzoyl disulfide (25g) in acetone (350ml). The remaining acetone is decanted from the solid which is recrystallised first from 300ml of 1:1 (v/v) EtOH/ethyl acetate, then from 300ml of EtOH, and finally from 240ml of 1:1 (v/v) EtOH/ethyl acetate. The yield is about 40% [Pryor & Pickering *J Am Chem Soc* **84** 2705 *1962*]. [*Beilstein* **9** H 424, **9** II 289, **9** III 1977.] *Handle in a fume cupboard because of* **TOXICITY** *and obnoxious odour.*

Benzoylformic acid (phenylglyoxylic acid) *[611-73-4]* **M 150.14, m 62-65°, 64.5-65.5°, 67°, b 84°/0.1mm, 163-167°/15mm, pK^{25} 1.39 (1.79).** If the sample is oily, then it may contain H_2O. In this case dry it in a vacuum desiccator over P_2O_5 or KOH until crisp. For further purification dissolve 5.5g in hot CCl_4 (750ml), add charcoal (2g, this is necessary otherwise the acid may separate as an oil), filter, cool in ice-water until crystallisation is complete. Filter the acid off, and the solvent on the crystals is removed by keeping the acid (4.5g) in a vacuum desiccator for 2 days. Slightly yellow crystals are obtained. It can be recrystallised also from *C_6H_6/petroleum ether, and can be distilled in a vacuum. The acid is estimated by titration with standard NaOH. The *phenylhydrazone* is recrystallised from EtOH, **m** 163-164°, and the *semicarbazone acid* has **m** 259°(dec) (from EtOH). The *methyl ester* distils at **137°/14mm, 110-111°/2mm, n$_D^{20}$ 1.5850**. [Baert & Kates *J Am Chem Soc* **67** 1482 *1945*, Schaffer & Corey *J Org Chem* **24** 1825 *1959*, *Beilstein* **10** H 654, **10** IV 2737.]

Benzoyl isothiocyanate *[532-55-8]* **M 163.2, m 25.5-26°**, **b 72.5-73°/6mm, 88-91°/20mm, 94-96°/21mm, 202.5-204°/724mm, 250-255°/atm, d$_4^{20}$ 1.213, n$_D^{20}$ 1.637.** Distil the isothiocyanate over a small amount of P_2O_5, whereby the distillate crystallises in prisms. It is readily hydrolysed by H_2O to give benzamide and benzoylurea, but with NH_3 it gives *benzoylurea* **m** 210° which can be recrystallised from EtOH. [Hill & Degnan *J Am Chem Soc* **62** 1595 *1940,* Terss & McEwen *J Am Chem Soc* **76** 580 *1954*, Frank & Smith *Org Synth* Coll Vol **III** 735 *1955*, *Beilstein* **9** IV 777.]

Benzoyl peroxide *[94-36-0]* **M 242.2, m 95°(dec).** Dissolve benzoyl peroxide in $CHCl_3$ at room temperature and precipitate it by adding an equal volume of MeOH or petroleum ether. Similarly, it is precipitated from acetone by adding two volumes of distilled water. It has also been crystallised from 50% MeOH and from diethyl ether. Dry it under vacuum at room temperature for 24 hours. Store it in a desiccator in the dark at 0°. When purifying in the absence of water it can be **EXPLOSIVE**, and operations should be done on a very small

scale with adequate protection. Large amounts should be kept moist with water and stored in a refrigerator. [Kim et al. *J Org Chem* **52** 3691 *1987*, *Beilstein* **9** IV 777.]

***p*-Benzoylphenol (4-hydroxybenzophenone)** *[1137-42-4]* **M 198.2, m 133.4-134.8°, pK^{25} 7.95.** Dissolve *p*-benzoylphenol in hot EtOH (charcoal), filter and cool. *Alternatively*, crystallise it once from EtOH/H_2O and twice from *benzene [Grunwald *J Am Chem Soc* **73** 4934 *1951*, Dryland & Sheppard *J Chem Soc Perkin Trans 1* 125 *1986*]. [*Beilstein* **8** IV 1263.]

***N*-Benzoyl-*N*-phenylhydroxylamine** *[304-88-1]* **M 213.2, m 121-122°.** Recrystallise it from hot water, *benzene Et_2O/hexane or acetic acid. It complexes with metals. [*Beilstein* **15** III 8, **15** IV 7.]

***N*-Benzoyl-*o*-tolylhydroxylamine** *[1143-74-4]* **M 227.3, m 104°.** Recrystallise the hydroxylamine from aqueous EtOH. [*Beilstein* **15** III 8, **15** IV 7.]

Benzyl acetate *[140-11-4]* **M 150.2, m -51°, b 92-93°/10mm, 134°/102mm, 214.9°/760mm, d $^{20}_{4}$ 1.0562, n $^{25}_{D}$ 1.4994.** Purify the acetate by fractional distillation, preferably in a good vacuum. Values of n^{25} of 1.5232-1.5242 are too high and should be nearer to 1.4994. [Merker & Scott *J Org Chem* **26** 5180 *1961*, *Beilstein* **6** IV 2262.]

Benzyl acetoacetate *[5396-89-4]* **M 192.2, b 130°/2mm, 156-157°/10mm, 162-167°/15mm, 275-277°/atm, d $^{20}_{4}$ 1.114, n $^{20}_{D}$ 1.514.** Fractionate the ester and collect fractions with the expected physical properties. Otherwise add *ca* 10% by weight of benzyl alcohol and heat in an oil bath (160-170°, open vessel) for 30 minutes during which time excess of benzyl alcohol will have distilled off, then fractionate. [Baker et al. *J Org Chem* **17** 77 *1952*, *Beilstein* **6** IV 2480.]

4'-Benzylacetophenone *[782-92-3]* **M 210.3, m 37°, 38°, 39°, b 197-198°/9mm, 209-210°/15mm.** Distil it in a vacuum, then recrystallise it from EtOH (*ca* 1ml/g). The *oxime* has **m** 99.5° (from 60% aqueous EtOH). [*Beilstein* **7** H 449, **7** III 2176.]

Benzyl alcohol *[100-51-6]* **M 108.1, f -15.3°, b 205.5°, 93°/10mm, 205.5°/atm, d $^{20}_{4}$ 0.981, n $^{20}_{D}$ 1.54033, pK^{25} 15.4.** It is usually purified by careful fractional distillation under reduced pressure in the absence of air. Benzaldehyde, if present, can be detected by UV absorption at 283nm. It has also been purified by shaking with aqueous KOH and extracting with peroxide-free diethyl ether. After washing with water, the extract is treated with saturated NaHS solution, filtered, washed, dried with CaO and distilled under reduced pressure [Mathews *J Am Chem Soc* **48** 562 *1926*]. Peroxy compounds can be removed by shaking with a solution of Fe^{2+} followed by washing the alcohol layer with distilled water and fractionally distilling it. [*Beilstein* **6** IV 2222.]

Benzylamine *[100-46-9]* **M 107.2, b 178°/742mm, 185°/768mm, d $^{20}_{4}$ 0.981, n $^{20}_{D}$ 1.5392, pK^{25} 9.33.** Dry it with NaOH or KOH, then distil it under N_2, through a column packed with glass helices, taking the middle fraction. Also distil it from zinc dust under reduced pressure. The *picrate* has **m** 196° (from EtOH), and the *p-toluenesulfonamide* has **m** 116° (from MeOH). [*Beilstein* **12** IV 2155.]

Benzylamine hydrochloride *[3287-99-8]* **M 143.6, m 248° (rapid heating).** Crystallise the salt from water. [*Beilstein* **12** IV 2155.]

***N*-Benzylaniline (*N*-phenylbenzylamine)** *[103-32-2]* **M 183.4, m 36°, b 306-307°, d $^{20}_{4}$ 1.061, pK^{25} 4.04.** Crystallise the amine from petroleum ether (b 60-80°) (*ca* 0.5ml/g). The *picrate* has **m** 113° (from Et_2O). [*Beilstein* **12** H 1023, **12** I 449, **12** II 548, **12** III 2215, **12** IV 2172.]

Benzyl bromide *[100-39-0]* **M 171.0, m -4°, b 85°/12mm, 192°/760mm, d $^{20}_{4}$ 1.438, n $^{20}_{D}$ 1.575.** Wash benzyl chloride with conc H_2SO_4 (CARE), water, 10% Na_2CO_3 or $NaHCO_3$ solution, and again with water. Dry it with $CaCl_2$, Na_2CO_3 or $MgSO_4$ and fractionally distil it in the dark, under reduced pressure. It has also been thoroughly degassed at 10^{-6} mm and redistilled in the dark. This gives material with λ_{max} at (MeCN): 226nm (ε 8200) [Mohammed & Kosower *J Am Chem Soc* **93** 2709 *1971*]. [*Beilstein* **5** IV 829.] *Handle in a fume cup-*

board, extremely **LACHRYMATORY.**

Benzyl bromoacetate *[5437-45-6]* **M 229.1, b 96-98°/0.1mm, 146°/12mm, 166-170°/22mm, d_4^{20} 1.444, n_D^{25} 1.5412.** Dilute the ester with Et_2O, wash it with 10% aqueous $NaHCO_3$, H_2O, dry ($MgSO_4$) and fractionate it using a Fenske (glass helices packing) column. [Bergmann & Szinai *J Chem Soc* 1521 *1956*, *Beilstein* **6** IV 2265.] **LACHRYMATORY.**

***N*-Benzyl-*tert*-butylamine (*N-tert*-butylbenzylamine)** *[3378-72-1]* **M 163.3, b 91°/12mm, 109-110°/25mm, 218-220°/atm, d_4^{20} 0.899, n_D^{25} 1.4942, pK^{25} 10.19.** Dissolve the amine in Et_2O, dry it over KOH pellets, filter and fractionate it in a N_2 atmosphere to avoid reaction with CO_2 from the air. The *hydrochloride* has **m** 245-246°(dec) (from MeOH/Me_2CO) and the *perchlorate* has **m** 200-201°. [Freidfelder et al. *J Am Chem Soc* **80** 4320 *1958*, *Beilstein* **12** IV 2166.]

Benzyl carbamate *[621-84-1]* **M 151.2, m 86°, 86-88°, 90-91°.** If it smells of NH_3, then dry it in a vacuum desiccator and recrystallise it from 2 volumes of toluene and dry it in a vacuum desiccator again. It forms glistening plates from toluene, and can be recrystallised from H_2O [Martell & Herbst *J Org Chem* **6** 878 *1941*, Carter et al. *Org Synth* Coll Vol **III** 168 *1955*]. [*Beilstein* **6** IV 2278.]

Benzyl chloride *[100-44-7]* **M 126.6, m 139°, b 63°/8mm, d_4^{20} 1.100, n_4^{20} 1.538.** Dry it with $MgSO_4$ or $CaSO_4$, or reflux it with fresh Ca turnings, then fractionally distil it under reduced pressure, collecting the middle fraction and storing it over CaH_2 or P_2O_5. It has also been purified by passage through a column of alumina. *Alternatively*, it is dried over $MgSO_4$ and distilled in a vacuum. The middle fraction is degassed by several freeze-thaw cycles and then fractionated in an 'isolated fractionating column' (which has been evacuated and sealed off at ~10^{-6} mm) over a steam bath. The middle fraction is retained. The final samples are distilled in a vacuum from this sample and again retaining the middle fraction. The purity is >99.9% (no other peaks are visible by GLC, and the NMR spectrum is consistent with the structure. [Mohammed & Kosower *J Am Chem Soc* **93** 1709 *1971*, *Beilstein* **5** IV 809.] **IRRITANT** and s*trongly* **LACHRYMATORY.**

***N*-Benzyl-ß-chloropropionamide** *[24752-66-7]* **M 197.7, m 94°, 96°.** Crystallise the amide from MeOH. [**12** III 2257, **12** IV 2234.]

Benzyl cinnamate *[103-41-3]* **M 238.3, m 34-35°, 39°, b 154-157°/0.5mm, 228-230°/22mm.** Recrystallise the ester to a constant melting point from 95% EtOH. It has the odour of balsam. *Alternatively*, dissolve it in Et_2O, wash it with 10% aqueous Na_2CO_3, H_2O, dry (Na_2SO_4), evaporate and fractionate it under reduced pressure using a short Vigreux column. It decomposes when boiled at atmospheric pressure. [Eliel & Anderson *J Am Chem Soc* **74** 547 *1952*, Bender & Zerner *J Am Chem Soc* **84** 2550 *1962*, *Beilstein* **9** IV 2012.]

Benzyl cyanide *[140-29-4]* **M 117.1, b 100°/8mm, 233.5°/760mm, d_4^{20} 1.015, n_4^{20} 1.523.** Any benzyl isocyanide impurity can be removed by shaking vigorously with an equal volume of 50% H_2SO_4 at 60°, washing with saturated aqueous $NaHCO_3$, then half-saturated NaCl solution, drying and fractionally distilling under reduced pressure. Distillation from CaH_2 causes some decomposition of this compound: it is better to use P_2O_5. Other purification procedures include passage through a column of highly activated alumina, and distillation from Raney nickel. *Precautions should be taken because of possible formation of free* **TOXIC** *cyanide, use an efficient fume cupboard*. [*Beilstein* **9** IV 1663.]

***N*-Benzyl dimethylamine** *[103-83-3]* **M 135.2, b 66-67°/15mm, 83-84°/30mm, 98-99°/24mm, 181°/760mm, d_4^{20} 0.898, n_D^{20} 1.516, pK^{25} 8.91.** Dry the amine over KOH pellets and fractionate it over Zn dust in a CO_2—free atmosphere. It has a pKa^{25} of 8.25 in 45% aqueous EtOH. Store it under N_2 or in a vacuum. The *picrate* has **m** 94-95°, and the *picrolonate* has **m** 151° (from EtOH). [Skita & Keil *Chem Ber* **63** 34 *1930*, Coleman *J Am Chem Soc* **55** 3001 *1933*, Devereux et al. *J Chem Soc* 2845 *1957*.] The *tetraphenyl borate salt* has **m** 182-185°. [Crane *Anal Chem* **28** 1794 *1956*, *Beilstein* **12** IV 2161.]

Benzyldimethyloctadecylammonium chloride *[122-19-0]* **M 442.2, m 150-158° (sinters at 120°.** Crystallise the salt from acetone, EtOAc or EtOAc/ Et_2O. [Sumiki et al. *J Agric Chem Soc Jpn* **26** 325 *1952*,

Chem Abstr 3505 *1953*, *Beilstein* **12** III 2212, **12** IV 2168.]

Benzyl ether (dibenzyl ether) *[103-50-4]* **M 198.3, b 298°, 158-160°/0.1mm, d_4^{20} 1.043, n_4^{20} 1.54057.** Reflux the ether over sodium, then distil it under reduced pressure. It been purified by fractional freezing. [*Beilstein* **6** IV 2240.]

***N*-Benzyl-*N*-ethylaniline** *[92-59-1]* **M 221.3, b 212-222°/54mm, 285-286°/710mm, 312-313°/atm (dec), d_4^{20} 1.029, n_4^{20} 1.595, pK_{Est} ~4.6.** Dry the amine over KOH pellets and fractionate it. The *picrate* crystallises from *C_6H_6 as lemon yellow crystals **m** 126-128° (softening at 120°). [Forrest et al. *J Chem Soc* 303 *1951*, IR: Hill & Meakins *J Chem Soc* 760 *1958*, *Beilstein* **12** H 1026, **12** IV 2176.]

Benzyl ethyl ether *[539-30-0]* **M 136.2, b 186°, 65°/10mm, d_4^{20} 0.949, n_D^{20} 14955.** Dry the ether with $CaCl_2$ or NaOH, then fractionally distil it. [Letzinger & Pollart *J Am Chem Soc* **78** 6079 *1956*, *Beilstein* **6** III 1454, **6** IV 2229.]

Benzyl ethyl ketone (1-phenylbutan-2-one) *[1007-32-5]* **M 148.2, b 49-49.5°/0.01mm, 66-69°/1mm, 83-85°/5mm, 101-102°/10mm, 229-233°/atm, d_4^{20} 0.989, n_D^{25} 1.5015.** Purify the ketone by fractionation using an efficient column. It can be converted into the *oxime* which is distilled, **b** 117-118°/2mm, 145-146°/15mm, d_{25}^{25} 1.036, n_D^{25} 1.5363; decompose the oxime, and the ketone is redistilled. It can also be purified *via* the *semicarbazone* which has **m** 154-155°. [Meyers et al. *J Am Chem Soc* **77** 5655 *1955*, Hass et al. *J Org Chem* **15** 8 *1950*, *Beilstein* **7** IV 712.]

***O*-Benzylhydroxylamine hydrochloride** *[2687-43-6]* **M 159.6, m 234-238°(sublimes), pK_{Est} ~5.9.** Recrystallise the hydrochloride from H_2O or EtOH. [*Beilstein* **6** IV 2562.]

***N*-Benzylideneaniline** *[538-51-2]* **M 181.2, m 48° (54°), 56°, b 310°/760mm.** It is steam volatile and crystallises from *benzene or 85% EtOH. The *picrate* has **m** 159°. [*Beilstein* **12** H 195, **12** I 169, **12** II 113, **12** III 319, **12** IV 311.]

Benzylidene malononitrile *[2700-22-3]* **M 154.2, m 83-84°, 87°.** Recrystallise the nitrile from EtOH [Bernasconi et al. *J Am Chem Soc* **107** 3612 *1985*]. It has λ_{max} at 307nm (EtOH). [*Beilstein* **9** H 895, **9** II 640, **9** III 4380, **9** IV 3462.]

Benzyl isocyanate *[3173-56-6]* **M 133.2, b 82-84°/10mm, 87°/14mm, 95°/17mm, 101-104°/33mm, d_4^{20} 1.08, n_D^{20} 1.524.** Purify the isocyanate by fractionation through a two-plate column. It is a viscous liquid and is **TOXIC**. [Howarth et al. *J Chem Soc* 182 *1947*, Ferstandig & Scherrer *J Am Chem Soc* **81** 4838 *1959*, IR: Derkosch et al. *Monatsh Chem* **88** 35 *1957*, *Beilstein* **12** IV 2276.]

Benzyl isothiocyanate *[622-78-6]* **M 149.2, b 123-124°/1mm, 138-140°/20mm, 255-260°/atm, d_4^{20} 1.1234, n_D^{20} 1.6039.** Dissolve benzyl isothiocyanate in Et_2O, filter, if there is any solid, and distil it through an efficient column at 11mm with a bath temperature at *ca* 150°. Characterise it by reacting (0.5ml) in EtOH (1ml) with 50% $NH_2NH_2.H_2O$ (2 ml) to give *4-benzylthiosemicarbazide* as colourless needles which are recrystallised from EtOH, **m** 130°. [Hoggarth & Young *J Chem Soc* 1582 *1950*, Schmidt et al. *Justus Liebigs Ann Chem* **612** 11 *1958*, IR and UV: Svátek et al. *Acta Chem Scand* **13** 442 *1959*, *Beilstein* **12** IV 2276.]

S-Benzylisothiuronium chloride *[538-28-3]* **M 202.7, two forms, m 150° and 175°, pK_{Est} ~9.8 (free base).** Crystallise the chloride from 0.2M HCl (2ml/g) or EtOH and it dry in air. [*Beilstein* **6** III 1600.]

Benzylmalonic acid *[616-75-1]* **M 194.2, m 121°, pK_1^{25} 2.91, pK_2^{25} 5.87.** Crystallise the acid from *C_6H_6. [*Beilstein* **9** IV 3357.]

Benzyl mercaptan *[100-53-8]* **M 124.2, b 70.5-70.7°/9.5mm, d_4^{20} 1.058, n_D^{20} 1.5761, pK^{25} 9.43.** Purify benzyl mercaptan *via* the mercury salt [see Kern *J Am Chem Soc* **75** 1865 *1953*], which crystallises from *benzene as needles (**m** 121°), and then dissolve it in $CHCl_3$. Pass H_2S gas through the solution to regenerate

the mercaptan. The HgS that precipitates is filtered off and washed thoroughly with $CHCl_3$. The filtrate and washings are evaporated to remove $CHCl_3$; then the residue is fractionally distilled under reduced pressure [Mackle & McClean, *Trans Faraday Soc* **58** 895 *1962*]. [*Beilstein* **6** IV 2632.]

(-)-*N*-Benzyl-*N*-methylephedrinium bromide [benzyl(2-hydroxy-1-methyl-2-phenethyl) dimethyl-ammonium bromide] *[58648-09-2]* **M 350.3, m 209-211°, 212-214°, $[\alpha]_D^{25}$ -3.8° (c 1.45, MeOH), $[\alpha]_D^{20}$ -5.3° (c 1.45, MeOH).** Recrystallise the bromide from MeOH/Et_2O. [Horner & Brich *Justus Liebigs Ann Chem* 710 *1978*.] The *chloride* is recrystallised from EtOAc/*n*-hexane, **m** 198-199° $[\alpha]_D^{25}$ -8.67° (c 1.45, MeOH). [Julia et al. *J Chem Soc, Perkin Trans 1* 574 *1981*, *Beilstein* **13** IV 1890.]

Benzyl 4-nitrophenyl carbonate *[13795-24-9]* **M 273.2, m 78-80°.** Dissolve the carbonate in Et_2O, wash with H_2O (3x) and saturated aqueous NaCl, dry ($MgSO_4$), evaporate this in a vacuum and recrystallise the residue from a small volume of MeOH, **m** 78-79°. *Alternatively*, dissolve it in Et_2O, wash it with N HCl (2x), 0.5N $NaHCO_3$ (4x) then H_2O, dry (Na_2SO_4), evaporate the Et_2O and recrystallise the residue from *C_6H_6/petroleum ether, **m** 79-80°. The *2-nitro-isomer* has **m** 27-28°, **b** 151°/11mm. [Khosla et al. *Indian J Chem* **5** 279 *1967*, Wolman et al. *J Chem Soc (C)* 596 *1976*, *Beilstein* **6** IV 2277.]

Benzyloxyacetyl chloride *[19810-31-2]* **M 184.6, b 81°/0.2mm, 84-87°/0.4mm, 105-107°/5mm, d_4^{20} 1.19, n_D^{20} 1.523.** Check the IR to see if there are OH bands. If so, then it may be contaminated with free acid formed by hydrolysis. Add oxalyl chloride (amount depends on contamination and needs to be judged, *ca* 3mols), heat at 50° in the absence of moisture for 1 hour and fractionate twice, **b** 81°/0.2mm (with bath temperature at 81°). Excessive heating results in decomposition to give benzyl chloride. The *anilide* is formed by adding aniline in $CHCl_3$ solution and has **m** 49°. [Fischer & Gohlke *Helv Chim Acta* **16** 1130 *1933*, *Beilstein* **6** IV 2470.]

3-Benzyloxybenzoic acid *[69026-14-8]* **M 228.2, m 133-137°, 135.5-136°, pK_{Est} ~4.1.** Recrystallise the acid from acetic acid (**m** 137-138°) [Kipping & Wren *J Chem Soc* 3246 *1957*, *Beilstein* **10** III 247, **10** IV 316.]

Benzyloxybutan-2-one *[6278-91-7]* **M 178.2, b 90-92°/0.1mm, 88-91°/0.5mm, 121-126°/5mm, d_4^{20} 1.0275, n_D^{20} 1.5040.** Dissolve the ketone in $CHCl_3$, wash with H_2O, aqueous saturated $NaHCO_3$, H_2O, dry ($MgSO_4$), evaporate the $CHCl_3$, and fractionate it. [Hoffman et al. *J Am Chem Soc* **79** 2316 *1957*, *Beilstein* **6** IV 2255.]

Benzyloxycarbonyl chloride (Cbz-Cl, BOC-Cl, benzyl chloroformate) *[501-53-1]* **M 170.6, b 103°/20mm, d_4^{20} 1.195, n_D^{20} 1.5190.** The commercial material is usually better than 95% pure and may contain some toluene, benzyl alcohol, benzyl chloride and HCl. After long storage, e.g. two years at 4°, Greenstein and Winitz [*The Chemistry of the Amino Acids* **Vol 2** p. 890, J Wiley and Sons NY, *1961*] recommended that the liquid should be flushed with a stream of dry air, filtered and stored over sodium sulfate to remove CO_2 and HCl which are formed by decomposition. It may further be distilled from an oil bath at a temperature below 85° because Thiel and Dent [*Annalen* **301** 257 *1898*] stated that benzyloxycarbonyl chloride decarboxylates to benzyl chloride slowly at 100° and vigorously at 155°. Redistillation at higher vacuum below 85° yields material which shows no other peaks than those of benzyloxycarbonyl chloride by NMR spectroscopy. [*Beilstein* **6** IV 2278.] **LACHRYMATORY** and **TOXIC**.

***p*-(Benzyloxy)phenol** *[103-16-2]* **M 200.2, m 122.5°, pK_{Est} ~10.1.** Crystallise it from EtOH or H_2O, and dry (P_2O_5) under vacuum. [Walter et al. *J Am Chem Soc* **108** 5210 *1986*, *Beilstein* **6** IV 5778.]

***S*-(-)-3-Benzyloxypropan-1,2-diol** *[17325-85-8]* **M 182.2, m 24-26°, b 117-118°/10^{-4}mm, 115-116°/0.02mm, 121-123°/0.2mm, d_4^{20} 1.1437, n_D^{22} 1.5295, $[\alpha]_D^{25}$ -5.9° (neat).** Purify the diol by repeated fractional distillation. [Baer et al. *J Biol Chem* **230** 447 *1958*, Gigg & Gigg *J Chem Soc C* 1865 *1967*, *Beilstein* **6** IV 2247.]

2-Benzylphenol *[28994-41-4]* **M 184.2, m 54.5°, b 312°/760mm, 175°/18mm, pK_{Est} ~10.0.** Distil 2-benzylphenol in a vacuum and recrystallise it from EtOH. It has a stable form with **m** ~52° and an unstable form with **m** 21°. [*Beilstein* **6** H 675, **6** IV 4628.]

4-Benzylphenol (α-phenyl-*p*-cresol) *[101-53-1]* **M 184.2, m 84°, pK_{Est} ~10.2.** Crystallise 4-benzylphenol

from water. [*Beilstein* **6** H 675, **6** IV 4628.]

4-*N*-Benzylsulfanilamide (Septazen) *[1709-54-2]* **M 262.3, m 175°, 178°.** Crystallise Septazen from dioxane/H_2O, EtOH/H_2O or Me_2CO (**m** 174.5-175.8°). Its solubility in H_2O at 37° is 0.03-0.43mg/100ml. [*Beilstein* **14** III 2026.]

Benzylthiocyanate *[3012-37-1]* **M 149.2, m 43°, b 256°(dec).** Crystallise the thiocyanate from EtOH or aqueous EtOH. [*Beilstein* **6** H 460, **6** IV 2680.]

Benzyl toluene-*p*-sulfonate *[1024-41-5]* **M 162.3, m 58°, 58.5-58.8°.** Crystallise the ester from petroleum ether (b 40-60°), $CHCl_3$/hexane or Et_2O/*C_6H_6. Dry it *in vacuo* but NOT in a desiccator over $CaCl_2$ as it causes hydrolysis of the ester. [Emmons & Ferris *J Am Chem Soc* **75** 2257 *1953*, *Beilstein* **11** II 48, **11** III 207, **11** IV 273.]

Benzyltributylammonium bromide *[25316-59-0]* **M 356.4, m 169-171°, 174-175°.** Recrystallise the bromide from EtOAc/EtOH and EtOH/Et_2O. [Kantor & Hauser *J Am Chem Soc* **73** 4122 *1951*, Petersen et al. *J Am Chem Soc* **81** 3264 *1959*, *Beilstein* **12** IV 2166.]

Benzyl 2,2,2-trichloroacetimidate *[81927-55-1]* **M 252.5, b 106°/0.5mm, m 3°, d_4^{20} 1.349, n_D^{20} 1.545.** Purify the imidate by distillation to remove up to 1% of $PhCH_2OH$ as stabiliser. A solution in hexane can be stored for up to 2 months without decomposition. It is *hygroscopic* and has to be stored dry. [Wessel et al. *J Chem Soc, Perkin Trans 1* 2247 *1985*, *Beilstein* **6** IV 2265.]

Benzyltrimethylammonium chloride *[56-93-9]* **M 185.7, m 238-239°(dec).** A 60% aqueous solution of the salt is evaporated to dryness under a vacuum on a steam bath, and then left in a vacuum desiccator containing a suitable drying agent. The solid residue is dissolved in a small volume of boiling absolute EtOH and precipitated by adding an equal volume of diethyl ether with cooling. After washing, the precipitate is dried under a vacuum [Karusch *J Am Chem Soc* **73** 1246 *1951*]. [*Beilstein* **12** IV 2162.]

Benzyltrimethylammonium hydroxide (Triton B) *[100-85-6]* **M 167.3, d 0.91.** A 38% solution (as supplied) is decolorised (charcoal), then evaporated under reduced pressure to a syrup, with final drying at 75°/1mm pressure. The *anhydrous* base is obtained by prolonged drying over P_2O_5 in a vacuum desiccator. [*Beilstein* **12** IV 2162.]

Bibenzyl (1,2-diphenylethane, dibenzyl) *[103-29-7]* **M 182.3, m 50-53°, 52.0-52.5°, 52.5-53.5°.** Crystallise bibenzyl from hexane, MeOH, or 95% EtOH. It has also been sublimed under vacuum, and further purified by percolation through columns of silica gel and activated alumina. It is prepared by reduction of benzoin or benzyl [Clemmensen *Chem Ber* **47** 688 *1914*], but is best obtained by catalytic reduction of stilbene. Thus a mixture of stilbene (5g, see [103-30-0]) in dioxane (200ml) and Raney Ni (22g) is refluxed with strring for 24 hours. The catalyst is filtered off, the filtrate is evaporated *in vacuo*, and the residue is recrystallised from MeOH to give an 80% yield of bibenzyl m 52.0-52.5°. Its FT-IR (melt) has ν_{max} at 3062.6, 1601.7, 1494.9, 1030.2, 906.0, 752.1, 696.9, 580.2 and 519.3 cm^{-1}; its ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 7.27 (t, 4H, arom-H), 7.18 (t, 6H, arom-H) and 2.90 (s, 4H, benzylic-H); and its ^{13}C NMR (15MHz, $CDCl_3$, $CDCl_3$ as internal standard with δ at ~77.0) has δ at 141.7, 128.36, 128.24, 125.83 and 37.89. [Kleiderer & Kornfeld *J Org Chem* **13** 455 *1948*.] [*Beilstein* **5** IV 1868.]

(±)-1,1'-Bi-(2-naphthol) [1,1'-di-(2-naphthol), BINOL] *[602-09-5, 41024-90-2]* **M 286.3, m 215-217°, 218°, $pK_{Est(1)}$ ~7.1, $pK_{Est(2)}$ ~11.2.** Crystallise the binaphthol from toluene or *benzene (10ml/g). When crystallised from chlorobenzene it has **m** 238°. Its solubility in dioxane is 5%. [*Beilstein* **6** IV 7020.]

1,1'-Bi-(2-naphthol) [1,1'-di-(2-naphthol)] *[R-(+)- 18531-94-7], [S-(–)- 18531-99-2]* **M 286.3, m 207.5-208.5°, 209-211°, $[\alpha]_D^{20}$ (+) and (-) 37.4.0° (c 0.5, THF), $[\alpha]_{546}^{25}$ (+) and (-) 51° (c 0.1, THF), pK as above.** Dissolve it in cold 2.5N NaOH, extract with CH_2Cl_2, and acidify with 5% HCl. Collect the white precipitate and

recrystallise it from aqueous EtOH and dry it in a vacuum [Akimoto & Yamada *Tetrahedron* **27** 5999 *1971*]. It is optically stable in dioxane-water (100°/24 hours). *Racemisation*: 72% in 1.2N HCl at 100°/24 hours and 68% in 0.67M KOH in BuOH at 118°/23 hours [Kyba et al. *J Am Chem Soc* **95** 2693 *1973*]. It has also been crystallised from $*C_6H_6$ (solubility is 1%) using Norite or aqueous EtOH after chromatography through silica gel, eluting with $Me_2CO/*C_6H_6$. [Kyba et al. *J Org Chem* **42** 4173 *1977*; see also Brussee & Jansen *Tetrahedron Lett* **24** 3261 *1983*, Akimoto & Yamada *Tetrahedron* **27** 5999 *1971*, *Beilstein* **6** IV 7020.]

1,1'-Binaphthyl *[(±)- 32507-32-7* and *604-53-5*, *R(–)- 24161-30-6*, *S(+)- 734-77-0]* **M 254.3, m 145°, 159°, b ~240°/13mm, (±, 2 forms), 153-154°, 154°, (+ and -), $[\alpha]_D^{20}$ (-) and (+) ~220° ($*C_6H_6$).** Purify 1,1'-binaphthyl through a silica gel column with $Me_2CO/*C_6H_6$ [or Al_2O_3 with 10% $*C_6H_6$/petroleum ether (b 30-60°)] and recrystallise it from EtOH, pentane, or slow evaporation of $*C_6H_6$, Me_2CO or Et_2O solutions. Half life ~10 hours at 25° in various solvents. [Wilson & Pincock *J Am Chem Soc* ***97*** 1474 *1975*, Akimoto & Yamada *Tetrahedron* **27** 5999 *1971*, *Beilstein* **5** I 358, **5** II 642, **5** III 2465, **5** IV 2634.]

2,2'-Binaphthyl (β, β'-binaphthyl) *[61-78-2]* **M 254.3, m 188°.** Crystallise the 2,2'-binaphthyl from $*C_6H_6$, or $Et_2O/*C_6H_6$ (**m** 187-189°). The *2,4,7-trinitrofluorenone complex* forms orange-red needles from $EtOH/*C_6H_6$ (**m** 170.6-171°). [*Beilstein* **5** H 727, **5** I 359, **5** II 643, **5** III 2467, **5** IV 2636.]

Biphenyl *[92-52-4]* **M 154.2, m 68-75°, 70-71°, b 112°/7mm, 255°/760mm, d_4^{20} 0.992.** Crystallise biphenyl from EtOH, MeOH, aqueous MeOH, petroleum ether (b 40-60°) or glacial acetic acid. Free it from polar impurities by passage through an alumina column in *benzene, followed by evaporation. The residue has been purified by distillation in a vacuum and by zone refining. Treatment with maleic anhydride removes anthracene-like impurities. It has been recrystallised from EtOH followed by repeated vacuum sublimation and passage through a zone refiner. [Taliani & Bree *J Phys Chem* **88** 2351 *1984*, *Beilstein* **5** H 576, 5 I 271, **5** II 479, **5** III 1726, **5** IV 1807.]

4-Biphenylcarbonyl chloride *[14002-51-8]* **M 216.7, m 114-115°.** Dissolve the carbonyl chloride in a large volume of petroleum ether (10 x, b 50-70°), filter it through a short column of neutral alumina, evaporate to dryness *in vacuo* and recrystallise it from petroleum ether (b 60-80°). [*Beilstein* **9** IV 2480.] **LACHRYMATORY.**

Biphenyl-2-carboxylic (2-phenylbenzoic) acid *[947-84-2]* **M 198.2, m 114°, b 343-344°, pK^{25} 3.46.** Crystallise the acid from $*C_6H_6$/petroleum ether or aqueous EtOH. [*Beilstein* **9** IV 2472.]

Biphenyl-4-carboxylic (4-phenylbenzoic) acid *[92-92-2]* **M 198.2, m 228°, pK^{25} 5.66 (in 50% 2-butoxyethanol)**. Crystallise the acid from $*C_6H_6$/petroleum ether or aqueous EtOH. [*Beilstein* **9** IV 2479.]

2,4'-Biphenyldiamine *[492-17-1]* **M 184.2, m 45°, b 363°/760mm, $pK_{Est(1)}$ ~4.8, $pK_{Est(2)}$ ~3.9.** Crystallise the diamine from aqueous EtOH or petroleum ether (**m** 54-54.5°). [*Beilstein* **9** III 416, **9** IV 360.]

Biphenyl-4,4'-dicarboxylic acid *[787-70-2]* **M 242.2, m >300°, $pK_{Est(1)}$ ~3.5, $pK_{Est(2)}$ ~4.3.** The dicarboxylic acid is a white amorphous or microcrystalline substance which does not melt or sublime. It is best purified by precipitation of an aqueous alkaline solution with mineral acid, washing well with H_2O and drying *in vacuo* at 100°. It is characterised by conversion to *diphenyl-4,4'-dicarbonyl chloride* (with PCl_5) [Work *J Chem Soc* 1317 1940], or by phase transfer catalysis with $SOCl_2$ + $BuEt_3N^+Cl^-$ in 1,2-dichloroethane [Burdett *Synthesis* 441 *1991*]) which crystallises from $*C_6H_6$ with **m** 184°. The di-acid chloride gives the *dimethyl ester* with MeOH, and has **m** 215-217° (plates from MeOH, **m's** of 214° and 224° were also reported)**.** The *diethyl ester* is similarly prepared with EtOH and has **m** 122° (from EtOH). [*Beilstein* **9** II 665, **9** III 4519, **9** IV 3563.]

Biphenylene *[259-79-0]* **M 152.2, m 111°.** Biphenylene forms yellow crystals from cyclohexane, MeOH (**m** 110-111°) or EtOH (**m** 111-112°). It sublimes *in vacuo*. The *2,4,7-trinitrofluorenone complex* has **m** 154° and the *picrate* gives red needles **m** 122° from EtOH. [*Beilstein* **5** I 298, **5** II 530, **5** III 1935, **5** IV 2137.]

(±)–α-(4-Biphenylyl)butyric acid *[959-10-4]* **M 240.3, m 124-125°, pK_{Est} ~4.5.** Crystallise the acid from

MeOH, petroleum ether or AcOH (**m** 123-125°). [*Beilstein* **9** III 3370, **9** IV 2558.]

γ-(4-Biphenylyl)butyric acid *[6057-60-9]* **M 240.3, m 118°, 120-121°, pK_{Est} ~4.8.** Crystallise the acid from MeOH (**m** 118°) or *C_6H_6 (**m** 118-119°). [*Beilstein* **9** I 290, **9** III 3370, **9** IV 2558.]

Bis-(*p*-bromophenyl) ether *[53563-56-7]* **M 328.0, m 60.1-61.7°.** Crystallise the ether twice from EtOH, petroleum ether, once from *benzene and dry it *in vacuo* [Purcell & Smith *J Am Chem Soc* **83** 1063 *1961*]. [*Beilstein* **6** III 745, **9** IV 1048.]

2*R*,3*R*-(+)-1,4-Bis-(4-chlorobenzyloxy)-2,3-butanediol *[85362-86-3]* **and 2*S*,3*S*-(-)-1,4-Bis-(4-chlorobenzyloxy)-2,3-butanediol** *[85362-85-2]* **M 371.3, m 76-77°, $[\alpha]_D^{20}$ (+) and (-) 6.4° (c 3.11 $CHCl_3$).** Recrystallise the diol from toluene-hexane. [Tamoto & Sugimori *Tetrahedron Lett* **23** 4107 1982, Tamoto *Tetrahedron* **40** 4617 *1984*.]

***N*,*N*-Bis-(2-chloroethyl) 2-naphthylamine (chlornaphthazine)** *[494-03-1]* **M 268.3, m 54-56°, b 210°/5mm, pK_{Est} ~5.3.** Crystallise it from petroleum ether. At 15° it is soluble in EtOH (3.2%), Et_2O (50%), Me_2CO (84%) and *C_6H_6 (80%). [*Beilstein* **12** III 2996, **12** IV 3126.] **CARCINOGENIC.**

1,4-Bis-(chloromethyl)durene (1,4-bischloromethyl-2,3,5,6-tetramethylbenzene) *[3022-16-0]* **M 231.2, m 197-198°.** Crystallise it three times from *C_6H_6 (**m** 193-194°) or petroleum ether (**m** 195-196°), then dry it *in vacuo* in a drying pistol. [Fuson et al. *J Am Chem Soc* **75** 5952 *1953*, *Beilstein* **5** IV 1140.]

2,2-Bis-(*p*-chlorophenyl)-1,1-dichloroethane (*p,p'*-DDD) *[72-54-8]* **M 320.1, m 109-111°, 111-112°.** Crystallise DDD from EtOH and dry it *in vacuo*. The purity is checked by TLC. [*Beilstein* **5** III 1830.] **TOXIC INSECTICIDE.**

2,2-Bis-(*p*-chlorophenyl)-1,1-dichloroethylene (*p,p'*-DDE) *[72-55-9]* **M 318.0, m 89-91°.** Crystallise DDE from MeOH or EtOH and dry it *in vacuo*. The purity is checked by TLC. [Gätzi & Stammbach *Helv Chim Acta* **28** 569 *1946, Beilstein* **5** H 639, **5** III1891.] **POSSIBLE CARCINOGEN.**

2,2-Bis-(4-chlorophenyl)-1,1,1-trichloroethane (*p,p'*-DDT, 1,1,1-trichloro-2,2-bis(*p*-chlorophenyl)ethane) *[50-29-3]* **M 354.5, m 108.5-109°, 108°.** Crystallise DDT from *n*-propyl alcohol (5ml/g), then dry it in air or an air oven at 50-60°. *Alternatively*, crystallise it from 95% EtOH, and the purity is checked by TLC. [*Beilstein* **5** III 1833.] **TOXIC INSECTICIDE.**

4,4'-Bis-(diethylamino)benzophenone *[90-93-7]* **M 324.5, m 93-95°, 95-96°, b ~300°/10mm, $pK_{Est(1)}$ ~1.8, $pK_{Est(2)}$ ~3.3.** Crystallise the phenone from EtOH (25ml/g) and dry it under vacuum. Its *picrate* forms yellow needles from EtOH with **m** 178.5°. [*Beilstein* **14** II 59.]

Bis-(4-dimethylaminobenzylidene)benzidine *[6001-51-0]* **M 454.5, m 318°, pK_{Est} ~0.** Crystallise the benzidine from nitrobenzene. [*Beilstein* **14** H 35.]

Bis-(4-fluoro-3-nitrophenyl) sulfone *[312-30-1]* **M 344.3, m 193-194°.** Recrystallise the sulfone from Me_2CO and H_2O (5:1). It should give a yellow colour in aqueous base. [Zahn & Zuber *Chem Ber* **86** 172 *1953*, *Beilstein* **6** IV 172.]

3,4-Bis-(4-hydroxyphenyl)hexane (Hexesterol) *[5635-50-7 (no configuration), 84-16-2 (meso-3RS,4-SR)]* **M 270.4, m 185-186°, 187°.** Free it from diethylstilboestrol by zone refining. Crystallise *meso*-Hexesterol from *benzene or aqueous EtOH (**m 185-188°**). The *meso-dibenzoyl* derivative has **m 236-237°.** The ***3RS,4RS(±)-racemate*** [5776-72-7] crystallises from petroleum ether, *C_6H_6/petroleum ether, Et_2O/petroleum ether, or MeOH/H_2O and has **m 128-129°**. The *(±)-dibenzoyl* derivative has **m 123-124°**. The ***3R,4R(+)-isomer*** [26614-21-1] and ***3S,4S(–)-isomer*** [26614-22-2] crystallise from Et_2O/petroleum ether with **m 80-80.5°** and have $[\alpha]_D^{17}$ (+) and (–) 17.7° (c 5, EtOH). Their *dibenzoyl* derivatives have **m 116.5°**. [*Beilstein* **6** III 5503, **6** IV 6761.] They have estrogenic activity where optically active forms are more potent, and they have antineoplastic activity.

[Aboul-Enein et al. *Anal Profiles Drug Subst* **11** 347 *1982, J Am Chem Soc* **65** 491*1941*.]

4,4-Bis(4-hydroxyphenyl)valeric acid [diphenolic acid] *[126-00-1]* **M 286.3, m 168-171°, 171-172°, $pK_{Est(1)}$~ 4.8 (CO_2H), $pK_{Est(2)}$~ 7.55 (OH), $pK_{Est(3)}$~9.0 (OH)**. When recrystallised from *C_6H_6, the crystals have 0.5 mol of *C_6H_6 (**m** 120-122°), and when recrystallised from toluene, the crystals have 0.5 mol of toluene. Purify the acid by recrystallisation from hot H_2O. It is soluble in Me_2CO, AcOH, EtOH, propan-2-ol, methyl ethyl ketone. It can also be recrystallised from AcOH, heptane/Et_2O or Me_2CO/*C_6H_6. It has λ_{max} at 225 and 279nm in EtOH. The *methyl ester* has **m** 87-89° (aqueous MeOH to give the *trihydrate*). [Bader & Kantowicz *J Am Chem Soc* **76** 4465 *1954*, *Beilstein* **10** IV 1890.]

1,4-Bismethylaminoanthraquinone (Disperse Blue 14) *[2475-44-7]* **M 266.3, m 220-222°, C.I. 61500, λmax 640 (594)nm.** Purify the anthraquinone by thin-layer chromatography on silica gel plates, using toluene/acetone (3:1) as eluent. The main band is scraped off and extracted with MeOH. The solvent is evaporated and the dye is dried in a drying pistol [Land et al. *J Chem Soc, Faraday Trans 1* **72** 2091 *1976*]. It crystallises from *n*-butanol with **m** 221-222° and has λ_{max} at 539 and 644nm (EtOH). [*Beilstein* **14** H 198, **14** III 440, **14** IV 459.]

Bis-(1-naphthylmethyl)amine *[5798-49-2]* **M 329.4, m 62°, 63-64°, pK_{Est} ~8.4.** Crystallise the amine from petroleum ether, Et_2O (**m** 73-74°) or *C_6H_6 (**m** 62°). The *hydrochloride* crystallises from H_2O as needles **m** 239°, and the picrate has **m** 206°(202°). [*Beilstein* **12** II 741, **12** IV 3195.]

Bis-(4-nitrophenyl) carbonate *[5070-13-3]* **M 304.3, m 142-143°**. Dissolve the carbonate in $CHCl_3$, wash it with 2N NaOH (3 x) and once with conc HCl, dry (Na_2SO_4), evaporate and crystallise the residue from toluene (authors say prisms from 15 volumes of *benzene). [Glatthard & Matter *Helv Chim Acta* **46** 795 *1963*, *Beilstein* **6** III 820.]

Bis-(2-nitrophenyl) disulfide *[1155-00-6]* **M 308.3, m 192-195°, 195°, 194-197°, 198-199°.** Purify the disulfide by recrystallisation from glacial AcOH or from *C_6H_6 and the yellow needles are dried in an oven at 100° until the odour of the solvent is absent. It is sparingly soluble in EtOH and Me_2CO. [Bogert & Stull *Org Synth* Coll Vol **I** 220 *1941*, Bauer & Cymerman *J Chem Soc* 3434 *1949*, *Beilstein* **6** IV 1672.]

Bis-(4-nitrophenyl) ether *[101-63-3]* **M 260.2, m 142-143°, 144.4-144.7°, 147-148°.** Crystallise the ether twice from *C_6H_6 or petroleum ether and dry it *in vacuo*. [*Beilstein* **6** II 822, **6** IV 1290.]

Bis-(4-nitrophenyl) methane *[1817-74-9]* **M 258.2, m 183°, 184°, 187°.** Crystallise the methane twice from *C_6H_6, petroleum ether or AcOH (**m** 188.6-189.6°), and dry it *in vacuo*. [*Beilstein* **5** III 1797, **5** IV 1853.]

Bis-(trifluoroacetoxy)iodobenzene (BTI) *[2712-78-9]* **M 430.0, m 112-114°(dec), 120-121°, 124-126°.** Crystallise the iodo compound from warm trifluoroacetic acid and dry it over NaOH pellets. Recrystallise it also from Me_2CO/petroleum ether. Its melting point depends on the heating rate. [Spyroudis & Varvoglis *Synthesis* 445 *1975*, application: Almond et al. *Org Synth* **66** 132 *1988*.]

***N*-BOC-1,2-phenylenediamine ([2-aminophenyl]carbamic acid, *tert*-butyl ester)** *[146651-75-4]* **M 208.3, m 109-114°.** Purify the ester by crystallisation from $CHCl_3$/hexane (1:1, v/v) and dry it *in vacuo*. [Seto et al. *J Am Chem Soc* **115** 1321 *1993*, Seto et al. *J Am Chem Soc* **127** 11442 *2005*.]

Brilliant Green (4-dimethylaminotriphenyl carbinol) *[633-03-4]* **M 482.7, m 209-211°(dec), pK^{25} 4.75.** Purify the dye by precipitating the *perchlorate* from aqueous solution (0.3%) after filtering, heating to 75° and adjusting to pH 1-2. Recrystallise it from EtOH/water (1:4) [Kerr & Gregory *Analyst (London)* **94** 1036 *1969*]. [*Beilstein* **13** IV 2281.]

4-Bromoacetanilide *[103-88-8]* **M 214.1, m 167°.** Crystallise the anilide from aqueous MeOH or EtOH. Purify it by zone refining. [*Beilstein* **12** IV 1504.]

4-Bromoacetophenone *[99-90-1]* **M 199.1, m 54°.** Crystallise it from EtOH, MeOH or from petroleum ether (b 80-100°). [Tanner *J Org Chem* **52** 2142 *1987*, *Beilstein* **7** IV 647.]

ω–Bromoacetophenone (phenacyl bromide) *[70-11-1]* **M 199.1, m 57-58°.** Crystallise the bromide from EtOH, MeOH or petroleum ether (b 80-100°). [Tanner *J Org Chem* **52** 2142 *1987*, *Beilstein* **7** IV 649.]

4-Bromoaniline *[106-40-1]* **M 172.0, m 66°, pK^{25} 3.86.** Crystallise the aniline (with appreciable loss) from aqueous EtOH. The *benzoyl* derivative has **m** 204° (from EtOH). [*Beilstein* **12** IV 1497.]

2-Bromoanisole *[578-57-4]* **M 187.0, f 2.5°, b 124°/40mm, d$_4^{20}$ 1.513, n$_D^{25}$ 1.5717.** Crystallise the anisole by repeated partial freezing, then distil it under reduced pressure. [*Beilstein* **6** IV 1037.]

4-Bromoanisole *[104-92-7]* **M 187.0, f 13.4°, b 99-100°/18mm, 124°/40mm, d$_4^{20}$ 1.495, n$_D^{25}$ 1.5617.** Crystallise the anisole by repeated partial freezing, then distil it under reduced pressure. [*Beilstein* **6** III 741, **6** IV 1044.]

9-Bromoanthracene *[1564-64-3]* **M 257.1, m 98-100°.** Crystallise 9-bromoanthracene from MeOH or EtOH followed by sublimation *in vacuo*. [Masnori et al. *J Am Chem Soc* **108** 126 *1986*, *Beilstein* **5** IV 2295.]

4-Bromobenzal diacetate *[55605-27-1]* **M 287.1, m 95°.** Crystallise the diacetate from hot EtOH (3ml/g). [Liebermann & Connor *Org Synth* Coll Vol **II** 442 *1948*, *Beilstein* **7** II 182, **7** IV 579.]

Bromobenzene *[108-86-1]* **M 157.0, b 155.9°, d$_4^{20}$ 1.495, n$_D^{20}$ 1.5588, n$_D^{15}$ 1.56252.** Wash bromobenzene vigorously with conc H_2SO_4, then 10% NaOH or $NaHCO_3$ solutions, and H_2O. Dry it with $CaCl_2$ or Na_2SO_4, or pass it through activated alumina, before refluxing with, and distilling from, CaH_2, using a glass helix-packed column. [*Beilstein* **5** IV 670.]

4-Bromobenzene diazonium tetrafluoroborate *[673-40-5]* **M 270.8, m 133°(dec), 135-140° (dec), 135°(dec).** Wash the salt with Et_2O until the wash is colourless and allow it to dry by blowing N_2 over it. Store it at 0-4° in the dark. [Schiemann & Pillarsky *Chem Ber* **64** 1340 *1931*, *Beilstein* **16** III 517.]

4-Bromobenzenesulfonyl chloride *[98-58-8]* **M 255.5, m 73-75°, 74.3-75.1, 75-76°, 77°, b 153°/15mm, 150.6°/13mm**. Wash the sulfonyl chloride with cold water, dry and recrystallise it from petroleum ether, or from ethyl ether cooled in powdered Dry-ice after the ether solution had been washed with 10% NaOH until colourless, then dry it with anhydrous Na_2SO_4. *Alternatively*, dissolve it in $CHCl_3$, wash it with H_2O, dry (Na_2SO_4), evaporate and recrystallise it. [Huntress & Carten *J Am Chem Soc* **62** 511 *1940*.] Test for the SO_2Cl group by dissolving it in EtOH and boiling with NH_4CNS whereby a yellow amorphous precipitate forms on cooling. [*Beilstein* **11** IV 162.]

2-Bromobenzonitrile *[2042-37-7]* **M 182.0, m 52-54°, 55.8°, 56°, 53-57°, b 251-253°/754mm.** The nitrile is prepared from 2-bromobenzoic acid by treatment with $SOCl_2$ (23 hours boiling) and distilling to give *2-bromobenzoyl chloride*, **b 120-126°/15mm, n$_D^{20}$ 1.5925,** which on treatment with 12 equivalents of NH_3 gives a 98% yield of *2-bromobenzamide* **m 159.5-161.5°** [4001-73-4]. By boiling this amide with excess of $SOCl_2$ for 17 hours followed by evaporation and steam distillation gives an 84% yield of the nitrile that forms needles when crystallised from H_2O. [Lutz et al. *J Org Chem* **12** 666 *1947*.] It has also been prepared by the method of Miller [*Org Synth* Coll Vol **3** 646, 648 *1955*] in which the amide is treated with a large excess of $POCl_3$ in the presence of sodium metabisulfite ($Na_2S_2O_5$) to give the nitrile (**m 55-55.5°)** [Herbst & Wilson *J Org Chem* **22** 1142 *1957*]. [*Beilstein* **9** H 348, **9** II 232, **9** III 1387, **9** IV 1013.]

2-Bromobenzoic acid (*o*-bromobenzoic acid) *[88-65-3]* **M 201.0, m 148.9°, 150°, pK^{20} 2.88.** Crystallise the acid from *C_6H_6 or MeOH. The *anilide* has **m** 141° (from EtOH/H_2O). [*Beilstein* **9** IV 1011.]

3-Bromobenzoic acid (*m*-bromobenzoic acid) *[585-76-2]* **M 201.0, m 155°, pK^{25} 3.81.** Crystallise the acid from acetone/water, MeOH or acetic acid. The *anilide* has **m** 137° (from EtOH/H_2O). [*Beilstein* **9** IV 1013.]

4-Bromobenzoic acid (*p*-bromobenzoic acid) *[586-76-5]* **M 201.0, m 251-252°, 254-256°, 257-258°, pK^{25} 3.96.** Crystallise the acid from MeOH, or MeOH/water mixture, 90% EtOH and Et_2O. The *methyl ester* has **m** 81° from Et_2O or dilute MeOH. The *anilide* has **m** 197° (from EtOH). [Male & Thorp *J Am Chem Soc* **35** 269 *1913*, Lamneck *J Am Chem Soc* **76** 406 *1954*, Vandenbelt et al. *Anal Chem* **26** 926 *1954*, *Beilstein* **9** IV 1017.]

p-**Bromobenzophenone** *[90-90-4]* **M 261.1, m 81°, 81-82°.** Crystallise the phenone from EtOH. The *2,4-dinitrophenylhydrazone* forms orange-red leaflets from dioxane/EtOH with **m** 207-209°. [Allen & Van Allan *J Am Chem Soc* **66** 7 *1944*, *Beilstein* **7** H 422, **7** III 2079, **7** IV 1378.]

4-Bromobenzoyl acetonitrile *[4592-94-3]* **M 224.1, m 160-164°, 162.4-163.4°.** The nitrile is purified by dissolving in slightly alkaline H_2O (charcoal), filtering and acidifying with HCl to give colourless needles (**m** 162-163°). It recrystallises from EtOH. With Me_2SO_4/KOH at 130° it gives *4-bromo–β-methoxy-cinnamylnitrile* **m** 58.5-59.5° (from high boiling petroleum ether) [Fuson & Wolf *J Am Chem Soc* **61** 1940 *1939*, Grathaus & Dains *J Am Chem Soc* **58** 1334 *1936*]. [*Beilstein* **10** III 2998.]

p-**Bromobenzoyl chloride** *[586-75-4]* **M 219.5, m 36-39°, 39.8°, 41°, b 62°/0.1mm, 104.5°/6mm, 126.4-127.2°/14mm.** Check IR of a film to see if OH bands are present. If absent then recrystallise from petroleum ether and dry it *in vacuo*. If OH bands are weak, then distil it *in vacuo* and recrystallise if necessary. If OH bands are very strong, then treat with an equal volume of redistilled $SOCl_2$ reflux for 2 hours, then evaporate excess of $SOCl_2$ and distil the residual oil or low melting solid. Store it in the dark away from moisture. **LACHRYMATORY**. [Martin & Partington *J Chem Soc* 1175 *1936*, *Beilstein* **9** IV 1023.]

p-**Bromobenzyl bromide** *[589-15-1]* **M 249.9, m 60-61°.** Crystallise the bromide from EtOH. [*Beilstein* **5** IV 836.] **LACHRYMATORY.**

p-**Bromobenzyl chloride** *[589-17-3]* **M 205.5, m 40-41°, b 105-115°/12mm.** Crystallise the chloride from EtOH and distil it in a vacuum. [*Beilstein* **5** IV 832.] **LACHRYMATORY.**

2-Bromobiphenyl *[2052-07-5]* **M 233.1, m 1.5-2.0°, b 140°/11mm, 148-150°/10mm, 297-298°/atm, d$_4^{25}$ 1.352, n$_D^{20}$ 1.6248.** 2-Bromobiphenyl is prepared from 2-aminobiphenyl (12g) in hot constant-boiling aqueous HBr (21g, 3-equivalents) by diazotisation at 5° with a solution of $NaNO_2$ (6g) in H_2O (10ml), then excess of HNO_2 is removed at the end of the reaction by addition of urea with stirring for 20 minutes. This solution is added dropwise into a solution of CuBr (from 15g of $CuSO_4$) in constant-boiling aqueous HBr (20ml) with stirring, set aside for 20 minutes, after which the brown complex is decomposed by heating on a steam bath for 2 hours. The dark oil is extracted into Et_2O, the extract is filtered through glass wool, washed with H_2O, dilute NaOH, H_2O again, dried ($CaCl_2$), filtered, evaporated and the residual oil is distilled to give a pale yellow oil (7g, b 146-152°/12mm). Further purification can be achieved by it dissolving in $*C_6H_6$, passing through an alumina column and eluting with $*C_6H_6$, evaporating to dryness and distilling the residual oil (b 148-150°/10mm) to yield pure colourless 2-bromobiphenyl. This has been recrystallised from pentane at -40° to give a liquid with a freezing point of 1.5-2.0°. [de la Mare & Hassan *J Chem Soc* 3004 *1957*, Augood et al. *J Chem Soc* 3412 *1953*, NMR: Brownstein *J Am Chem Soc* **80** 2300 *1958*, *Beilstein* **5** H 580, **5** II 485, **5** III 1742, **5** IV 1818.] It is used for the preparation of John-Phos and related catalytic ligands (see Chapter 7, Catalysis—Part 2).

3-Bromobiphenyl *[2113-57-7]* **M 233.1, b 103-104°/0.2mm, 110°/1mm, 158-167°/11mm, 169-173°/17mm, d$_4^{25}$ 1.3976, n$_D^{20}$ 1.6380.** 3-Bromobiphenyl can be prepared by bromination of 2-acetamidobiphenyl (m 118-119° from aqueous AcOH) with one molecular equivalent of Br_2 in AcOH; the monobromo derivative (m 127-127.5° from EtOH) is hydrolysed with 95% EtOH/conc HCl (1.4:1, 4 hours reflux) poured into excess of H_2O, basified and filtered off to give 2-amino-5-bromobiphenyl (m 53-56°). The base is subsequently diazotised and the diazonium salt is deaminated by warming with Cu bronze or with hypophosphorous acid [*cf* Kornblum in *Organic Reactions* J. Wiley & Sons NY, **II** 294 *1944*] to yield crude 3-bromobiphenyl which is isolated by steam distillation, extraction of the distillate with $*C_6H_6$, washing the extract successively with, dilute NaOH,

H_2O, conc H_2SO_4, H_2O, drying (K_2CO_3), evaporating and distilling. This can be purified further by passing a solution of it in *C_6H_6 through an Al_2O_3 column, eluting with *C_6H_6, and the combined eluates are distilled. The distillate is dissolved in petroleum ether (b 40-60°), washed several times with concentrated H_2SO_4, H_2O again, aqueous $NaHCO_3$, H_2O again, dried ($CaCl_2$), filtered, the solvent is evaporated off and the residue is fractionally distilled to give pure *3-bromobiphenyl*. [de la Mare & Hassan *J Chem Soc* 3004 1957, Lichtin & Leftin *J Am Chem Soc* **74** 4207 *1952*, Huber et al. *J Am Chem Soc* **46** 1111 *1946*]. It has also been prepared in low yield (13%) from diazotized *m*-bromoaniline and *C_6H_6 according to Gomberg and purified as above [Marvel et al. *J Am Chem Soc* **61** 77 *1939*, also see 4-bromobiphenyl below]. [*Beilstein* **5** II 485, **5** III 1742, **5** IV 1818.]

4-Bromobiphenyl *[92-66-0]* **M 233.1, m 82-86°, 88.8-89.2°, 89.5°, 90°, b 170-175°/8mm, 310°/atm.** This biphenyl is prepared by the method of Gomberg & Bachmann [*Org Synth* **1** 113 *1944*] from diazotised 4-bromoaniline and benzene, then extract into Et_2O, wash with base, acid, brine, dry (Na_2SO_4), filter, evaporate and recrystallise to constant melting point from absolute EtOH (89.7°, after drying *in vacuo*). [Hey et al. *J Chem Soc* 1284 *1940*; Augood et al. *J Chem Soc* 3412 *1953*, *Beilstein* **5** H 580, **5 I 275, 5** II 485, **5** III 1742, **5** IV 1819.]

1-Bromo-2-chlorobenzene *[694-80-4]* **M 191.5, m -12°, b 79-82°/14mm, 200-202°/atm, 204°/atm, d_4^{25} 1.638, n_D^{20} 1.582.** *o*-Chlorobromobenzene has been prepared in at least three different ways. It is obtained in 54% yield by carrying out a Sandmeyer reaction from *o*-chloroaniline *via* diazotisation (using $NaNO_2$/HBr) and decomposing it with CuBr in 48% aqueous HBr. Steam distil off the product, basify the distillate with 20% aqueous NaOH (extract it into Et_2O if quantities are small), dry the organic layer (Na_2SO_4), filter and distil [Fry & Grote *J Am Chem Soc* **48** 710, *1926*]. The second procedure involves adding Br (32g) in CCl_4 (50ml) during 20 minutes to refluxing silver 2-chlorobenzoate in CCl_4 (250ml), boil for a further 30 minutes to complete the decarboxylation, filter off the AgBr, wash the filtrate with aqueous Na_2SO_3 (until red colour of Br is discharged), aqueous 0.5M Na_2CO_3 (2 x 25ml), evaporate the solvent and distil bromochlorobenzene (38-48% yield) [Dauben & Tilles *J Am Chem Soc* **72** 3185 *1950*, Barnes & Prochaska *J Am Chem Soc* **72** 3188 *1950*]. The third procedure involves a phase transfer catalytic radical bromination. *o*-Chlorobenzene free radical is generated from the corresponding *o*-benzenediazonium tetrafluoroborate with KOAc in tetrahydrofuran and a catalytic amount of 18-crown-6 using $CBrCl_3$ as brominating agent to produce *o*-bromochlorobenzene in 70% yield, a great improvement on the Sandmeyer method [Korzeniowski & Gokel *Tetrahedron Lett* 3519 *1977*]. [*Beilstein* **5** H 209, **5** I 115, **5** II 161, **5** III 562, **5** IV 680.]

4-Bromo-4'-chlorobenzophenone *[27428-57-5]* **M 295.6, m 150°.** Crystallise the phenone from EtOH or *C_6H_6 and further purify it by zone refining (100 passes) [Grove & Turner *J Chem Soc* 509 *1929*, Lin & Hanson *J Phys Chem* **91** 2279 *1987*]. [*Beilstein* **7** II 360, **7** III 2081.]

Bromocresol Green (3',3",5',5"-tetrabromo-*m*-cresolsulfonephthalein) *[76-60-8]* **M 698.0, m 218-219°(dec), 225°(dec), pK^{25} 4.51.** Crystallise the dye from glacial acetic acid or dissolve it in aqueous 5% $NaHCO_3$ solution and precipitate it from the hot solution by dropwise addition of aqueous HCl. Repeat this until the UV/VIS-extinction did not increase at λ_{max} 423nm. It is an indicator: at pH 3.81 (yellow) and pH 5.4 (blue-green). [*Beilstein* **19/3** V 460.]

Bromocresol Purple (5',5"-dibromo-*o*-cresolsulfonephthalein) *[115-40-2]* **M 540.2, m 241-242°(dec), pK_1 -2.15, pK_2 6.3.** Dissolve the dye in aqueous 5% $NaHCO_3$ solution and precipitate it from a hot solution by dropwise addition of aqueous HCl. Repeat this until the UV/VIS-extinction did not increase at λ_{max} 419nm. It can also be recrystallised from *benzene. It is an indicator: at pH 5.2 (yellow) and pH 6.8 (purple). [*Beilstein* **19/3** V 460.]

2'-Bromo-2,6-dimethoxybiphenyl *[755017-61-9]* **M 293.2, m 141-142°, 143-146°.** This intermediate, which is used for the preparation of the ligand S-Phos, is synthesised by adding *n*-BuLi (9.60ml, 1.6M solution in hexanes, 15.4mmol, 1.2 equivalents) *via* a syringe over 5 minutes to a cold (0°) solution of 1,3-dimethoxybenzene (2.00ml, 15.3mmol, 1.2 equivalents, [151-10-0]) in dry THF (30ml), allowing the tempera-

ture to rise to ~25°, then it is stirred for 5 hours. The mixture is re-cooled (0°) and 2-bromochlorobenzene (1.50ml, 12.8mmol, 1.0 equivalents, [694-80-4]) is added dropwise *via* a syringe over 15 minutes while stirring vigorously; and the burgundy coloured solution is stirred for a further 15 minutes at 0°. MeOH (0.25ml) is added *via* syringe to decompose excess BuLi, the whole is evaporated to dryness *in vacuo*, the residue is then stirred with Et_2O (50ml) and H_2O (50ml), the layers are separated, the aqueous phase is extracted with Et_2O (2 x 25ml), the combined Et_2O solutions are dried ($MgSO_4$), filtered and evaporated *in vacuo*. The yellow residue is recrystallised from MeOH to provide the analytically pure biphenyl (3.03g, 81%) as pale yellow crystals. The IR (film) has ν_{max} at 2964, 1584, 1472, 1432, 1248, 1108, 1025, 783 cm^{-1}; the ^1H NMR [100MHz, $CDCl_3$] has δ at 7.69 (dd, *J* = 6.9, 1.1Hz, 1H), 7.34-7.40 (m, 2H), 7.20-7.28 (m, 2H), 6.68 (d, *J* = 8.5Hz, 2H), 3.76 (s, 6H) from TMS; the ^{13}C NMR [75MHz, ^1H decoupled, $CDCl_3$] has δ at 157.8, 136.25, 132.52, 132.47, 129.6, 128.8, 127.1, 125.4, 119.0, 104.2, 56.2 from TMS. [Barder et al. *J Am Chem Soc* **127** 4685 *2005*.]

***p*-Bromo-*N*,*N*-dimethylaniline** *[586-77-6]* **M 200.1, m 55°, b 264°, pK 19.2 (acidic), pK^{25} 4.23.** Reflux the aniline for 3 hours with two equivalents of acetic anhydride, then fractionally distil it under reduced pressure. [*Beilstein* **12** IV 1499.]

1-Bromo-2,4-dinitrobenzene *[584-48-5]* **M 247.0, m 72.5-73°, 75°.** Crystallise it from ethyl ether, isopropyl ether, 80% EtOH or absolute EtOH. [*Beilstein* **5** III 640, **5** IV 749.]

***N*-(2-Bromoethyl)phthalimide** *[574-98-1]* **M 254.1, m 81-83°, 82.5-83.5°.** The following is to be carried out in an efficient **FUME HOOD**. Dissolve the compound (180g) in CS_2 (500 ml) by refluxing for 15 minutes (to cause the separation of the most likely impurity, 1,2-diphthalimidoethane), filter and evaporate under reduced pressure. The product forms light tan crystals (**m** 78-80°). Recrystallise it from EtOH (charcoal) [the compound (50g) is dissolved in hot 75% EtOH (200ml), boiled for *ca* 10 minutes, carbon is added (5g, Norite), filter and cool to 0°], to give white crystals (40g) which can be recrystallised (**m** 80-81°); and further recrystallisation gives **m** 82-83°. [Salzberg & Supniewski *Org Synth* Coll Vol **I** 119 *1932*, Landini & Rolla *Synthesis* 389 *1976*, *Beilstein* **21/10** V 275.]

3-Bromo-5-hydroxybenzoic acid *[140472-69-1]* **M 217.0, m 233.5°, 237-241°, $pK_{Est(1)}$ ~2.3, $pK_{Est(2)}$ ~13.0.** The acid crystallises from H_2O (**m** 238-239°), and with Me_2SO_4 it yields the *3-methoxy* derivative with **m** 190-191° (from EtOH). [Baddar et al. *J Chem Soc* 469 *1955*, *Beilstein* **10** IV 333.]

2-Bromomethylanthraquinone *[7598-10-9]* **M 301.1, m 200-202°.** Recrystallise the quinone from AcOH, wash the crystals with a little Et_2O, dry it in air and then in a vacuum at 100°. It is prepared by bromination of 2-methylanthraquinone with Br_2/$PhNO_2$ at 145-150°, or *N*-bromosuccinimide in CCl_4 containing a trace of $(PhCOO)_2$. [*Beilstein* **7** IV 2576.]

2-(Bromomethyl)benzonitrile *[22115-41-9]* **M 195.1, m 72-73°, 79°, b 152-155°/15mm.** Purify the nitrile by steam distillation. Extract the distillate with Et_2O, dry the extract (Na_2SO_4), evaporate and distil the residue. The solidified distillate can be recrystallised from petroleum ether or cyclohexane. ^1H NMR ($CDCl_3$) with δ at 7.8-7.2 (m 4H), 4.62 (s, 2H); the IR has ν 2238 cm^{-1}. [Drory *Chem Ber* **24** 2570 *1891*, Borsche et al. *Chem Ber* **74** 685 *1934*, Buckley et al. *Aust J Chem* **22** 594 *1969*, *Beilstein* **9** III 2312.] **LACHRYMATORY.**

4-Bromo-α-methylbenzyl alcohol *[(±) 5391-88-8, 25675-29-0, R-(+) 76155-78-7, S-(–) 100760-04-1]* **M 201.1.** The (±)-racemate is purified by distillation in a vacuum (**b** 90°/1mm, 119-121°/7mm, **d** 1.46) and it solidifies on cooling (**m** 36-37°) [Overberger et al. *Org Synth* Coll Vol **III** 200 *1955*]. The *(±)-tosyl* derivative [114200-15-6] has **m** 56-57°. The *R-(+)-enantiomer* is also purified by distillation in a vacuum (**b** 110°/3mm, d_4^{25} 1.322, n_D^{20} 1.569) and has $[\alpha]_D^{20}$ +39° (c 1, $CHCl_3$), +32.9° (c 1.39, MeOH). The *S-(–)-enantiomer* is similarly purified. [Stein et al. *Can J Chem* **63** 3442 *1985*, Crevinka et al. *Col Czech Chem Commun* **51** 401 *1986*, *Beilstein* **6** II 447.]

2-(Bromomethyl)-naphthalene *[939-26-4]* **M 221.1, m 52-54°, 56°, 56-57°, b 133-136°/0.8mm, 214°/100mm.** Dissolve the bromo compound in toluene, wash it with saturated aqueous $NaHCO_3$, dry (Mg

SO_4), evaporate, fractionally distil the residue and recrystallise the solidified distillate from EtOH. [Chapman & Williams *J Chem Soc* 5044, *1952*, Bergmann & Szmuszkovicz *Bull Soc Chim Fr* **20** 566 *1953*, *Beilstein* **5** IV 1698.]

1-Bromonaphthalene *[90-11-9]* **M 207.1, b 118°/6mm, d_D^{20} 1.489.** Purify 1-bromonaphthalene by passage through activated alumina, and three vacuum distillations. [*Beilstein* **5** H 547, **5** IV 1665.]

2-Bromonaphthalene *[580-13-2]* **M 207.1, m 59°.** Purify 2-bromonaphthalene by fractional elution from a chromatographic column of activated alumina. Crystallise it from EtOH. [*Beilstein* **5** IV 1667.]

1-Bromo-2-naphthol *[573-97-7]* **M 223.1, m 76-78°, 83°, 84°, pK_{Est} ~8.0.** Distil the naphthol at 10mm then recrystallise it from *C_6H_6/petroleum ether (b 30-60°) **m** 80-81°. The *benzoyl* derivative has **m** 98.5-99.5° (from MeOH). [Hazlet *J Am Cherm Soc* **62** 2156 *1940*, *Beilstein* **6** H 650, **6** II 604, **6** III 2994.]

6-Bromo-2-naphthol *[15231-91-1]* **M 223.1, m 122-126°, pK_{Est} ~9.1.** Crystallise the naphthol from EtOH or *C_6H_6/petroleum ether (**m** 128°). The *benzoyl* derivative has **m** 122°, (from EtOH). [Ruggli & Michels *Helv Chim Acta* **14** 779 *1931*, *Beilstein* **6** H 651, **6** II 605, **6** III 2996.]

ω-Bromo-4-nitroacetophenone *[99-81-0]* **M 244.1, m 98°.** Crystallise it from *C_6H_6/petroleum ether. [*Beilstein* **7** IV 661.]

o-**Bromonitrobenzene (2-bromo-1-nitrobenzene)** *[577-19-5]* **M 202.1, m 43°.** Crystallise it twice from petroleum ether, using charcoal before the first crystallisation. [*Beilstein* **5** III 618, **5** IV 728.]

m-**Bromonitrobenzene (3-bromo-1-nitrobenzene)** *[585-79-5]* **M 202.1, m 55-56°.** Crystallise it twice from petroleum ether, using charcoal before the first crystallisation. [*Beilstein* **5** III 618, **5** IV 729.]

p-**Bromonitrobenzene (4-bromo-1-nitrobenzene)** *[586-78-7]* **M 202.1, m 127°.** Crystallise it twice from petroleum ether, using charcoal before the first crystallisation. [*Beilstein* **5** III 619, **5** IV 729.]

p-**Bromophenacyl bromide** *[99-73-0]* **M 277.9, m 110-111°.** Crystallise the bromide from EtOH (*ca* 8ml/g). [*Beilstein* **7** IV 652.]

o-**Bromophenol** *[95-56-7]* **M 173.0, b 194°, d_D^{20} 1.490, pK^{25} 8.45.** Purify the phenol by at least two passes through a chromatographic column and distil it. [*Beilstein* **6** IV 1037.]

p-**Bromophenol** *[106-41-2]* **M 173.0, m 64°, pK^{25} 9.36.** Crystallise the phenol from $CHCl_3$, CCl_4, petroleum ether (b 40-60°), or water and dry it at 70° under vacuum for 2 hours. [*Beilstein* **6** IV 1043.]

Bromophenol Blue (3,3',5,5'-tetrabromophenolsulfonephthalein) *[115-39-9]* **M 670.0, m 270-271°(dec), 273°(dec), λ_{max} 422nm, pK^{25} 3.62 (acidic).** Crystallise the dye from *C_6H_6 or Me_2CO/AcOH, and dry it in air. It is an indicator: at pH 3.0 it is yellow and it is purple at pH 4.6. [*Beilstein* **19/3** V 458.]

(4-Bromophenoxy)acetic acid *[1878-91-7]* **M 231.1, m 157°, 158°, pK^{25} 3.13.** Crystallise the acid from EtOH or H_2O (**m** 161.4-161.8°). [Hayes & Branch *J Am Chem Soc* **65** 1555 *1943*, *Beilstein* **6** III 747, **6** IV 1052.]

3-(4-Bromophenoxy)propionic acid *[93670-18-9]* **M 247.1, m 146°, pK_{Est} ~4.2.** Crystallise the acid from EtOH, MeOH or *C_6H_6/hexane (**m** 144-145°). [*Beilstein* **6** III 748, **6** IV 1052.]

4-Bromophenylacetic acid *[1878-68-8]* **M 215.1, m 112-113°, 113-115°, 114°, pK^{25} 4.19.** The acid crystallises from H_2O as needles. The *acid chloride* has **b** 238°/760mm, **m** 50°, and the *anilide* has **m** 174-175°. [Dippy & Williams *J Chem Soc* 161 *1934,* 1251 *1948*, Schwenk & Pala *J Org Chem* **11** 798 *1946*, *Beilstein* **9** III 2275.]

4-Bromophenylhydrazine *[589-21-9]* **M 187.1, m 108-109°, pK^{20} -5.6 (aqueous H_2SO_4), pK^{25} 5.05.** Crystallise the hydrazine from H_2O. The *hydrochloride* crystallises from EtOH/H_2O with **m** 213-214°, and the *tosylate* has **m** 212° (from EtOH). [*Beilstein* **15** H 434, **15** I 117, **15** II 160, **15** III 289, **15** IV 282.]

4-Bromophenyl isocyanate *[2492-02-9]* **M 189.0, m 41-42°, b 158°/14mm.** Crystallise the isocyanate from petroleum ether (b 30-40°). It has a pungent odour. [*Beilstein* **12** H 647, **12** I 321.]

4-Bromophenyl isothiocyanate *[1985-12-2]* **M 214.1, m 56-58°.** Recrystallise the isothiocyanate from boiling *n*-hexane. Any insoluble material is most probably the corresponding urea. It is also purified by steam distillation, cool the receiver, add NaCl and extract in Et_2O, wash the extract with N H_2SO_4, dry ($MgSO_4$), evaporate and recrystallise the residual solid. [Cymerman-Craig et al. *Org Synth* Coll Vol **IV** 700 *1963*, cf Dains et al. *Org Synth* Coll Vol **I** 447 *1941*, *Beilstein* **6** IV 1051, **12** II 354, **12** III 1463p, **12** IV 1519.]

***N*-(3-Bromopropyl)phthalimide** *[5460-29-7]* **M 268.1, m 72-74°, 74°.** Place it in a Soxhlet and extract it with Et_2O, whereby the bis-phthalimido impurity is not extracted. Evaporate the Et_2O and recrystallise the residue from EtOH, aqueous EtOH or petroleum ether. [Gabriel & Weiner *Chem Ber* **21** 2669 1888, Gaudry *Can J Chem* **31** 1060 *1953*, *Beilstein* **21/10** V 1277.]

Bromopyrogallol Red (5,5'-dibromopyrogallolsulfonephthalein) *[16574-43-9]* **M 576.2, m 300°, λ_{max} 538nm (ε 54,500 H_2O pH 5.6-7.5), pK_1 2.9, pK_2 4.39, pK_3 9.15, pK_4 11.72.** Crystallise the dye from 50% EtOH, or aqueous alkaline solution followed by acidification. It is a metal chromic indicator. [Suk *Col Czech Chem Commun* **31** 3127 *1966*, *Beilstein* **19/10** V 226].

5-Bromosalicyl hydroxamic acid *[5798-94-7]* **M 210.1, m 232°(dec), $pK_{Est(1)}$~ 1.5, $pK_{Est(2)}$~ 7.0, $pK_{Est(3)}$~ 8.7.** Crystallise the hydroxamic acid from H_2O (**m** 249°) or from EtOH (**m** 232° dec). It sublimes at **m** 235°. It complexes with metals. [*Beilstein* **10** IV 221.]

4-Bromostyrene *[2039-82-9]* **M 183.1, b 49.5-50°/2.5mm, 87-88°/12mm, 102-104°/20mm, d_4^{20} 1.3984, n_D^{20} 1.5925**. It polymerises above 75° in the presence of benzoyl peroxide. To purify, if it has not gone to a solid resin, dissolve it in Et_2O, dry ($MgSO_4$) and add *ca* 0.1g of 4-*tert*butylcatechol (polymerisation inhibitor) per 100g of bromostyrene. Filter, evaporate this under reduced pressure (use as high a vacuum as possible) and distil the residue. Store it in dark bottles in the presence of the inhibitor (at above concentration). [Overberger & Saunders *Org Synth* Coll Vol **III** 204 *1955*, *Beilstein* **5** IV 1349.]

Bromothymol Blue (3',3''-dibromothymolsulfonephthalein) *[76-59-5]* **M 624.4, m 201-203°, pK_1 -0.66, pK_2 6.99.** Dissolved the dye in aqueous 5% $NaHCO_3$ solution and precipitate it from the hot solution by dropwise addition of aqueous HCl. Repeat this until the extinction at λ_{max} 420 nm does not increase. It is an indicator: aqueous solutions are yellow at pH 6.0, and blue at pH 7.6. [*Beilstein* **19/3** V 461.]

***o*-Bromotoluene** *[95-46-5]* **M 171.0, m -27°, b 58-60°/10mm, 74°/19mm, 181.7°/760mm, d_4^{20} 1.422, n_D^{20} 1.556.** Fractionally distil it through an efficient column. It can be separated from its isomers by gas chromatography on a column of "Sil-o-cel" firebrick (30-40mesh, 80 parts) coated with 5% (20 parts) of ICI E301 con rubber with N_2 carrier gas at 170°/atm and 100ml/minute and using a conductivity cell detector. [Cowley et al. *J Chem Soc* 1801 *1959*, *Beilstein* **5** H 304, **5** I 153, **5** II 234 **5** III 704, **5** IV 825.]

***p*-Bromotoluene** *[106-38-7]* **M 171.0, m 28°, b 184°, d_4^{20} 1.390.** Crystallise it from EtOH [Taylor & Stewart *J Am Chem Soc* **108** 6977 *1986*]. [*Beilstein* **5** IV 827.]

α-Bromo-4-toluic acid *[6232-88-8]* **M 215.1, m 229-230°, pK_{Est} ~3.2.** Crystallise the acid from Me_2CO. [*Beilstein* **9** IV 1745.]

α-Bromo-*p*-xylene (*p*-methylbenzyl bromide) *[104-81-4]* **M 185.1, m 35°, b 218-220°/740mm.** Crystallise the bromide from EtOH or pentane. [*Beilstein* **5** H 385, **5** IV 969.]

2-*tert*-Butoxycarbonyloxyimino-2-phenylacetonitrile (BOC-ON) *[58632-95-4]* **M 246.3, m 87-89°.** Triturate the solid with 90% aqueous MeOH, filter, wash with 90% aqueous MeOH and dry it in a vacuum. Recrystallise it from MeOH (needles or plates), but use warm MeOH and cool to crystallise; *do not boil as it decomposes slowly.* Its IR has ν_{max} at 1785 (C=O) cm^{-1} and NMR ($CDCl_3$) usually shows two *tert*-butyl singlets for *syn* and *anti* isomers. Store it in a brown bottle (fridge). It evolves CO_2 at room temperature (stoppered bottle can explode!), but can be stored over silica gel which may extend its useful life to more than a year. [Itoh et al. *Org Synth* **59** 95 *1980*.]

4-Butoxyphenylacetic acid *[4547-57-3]* **M 208.3, m 86-87°, 88.5°, pK_{Est} ~4.4.** Recrystallise it from petroleum ether (b 40-60°). [McElvain & Carney *J Am Chem Soc* **68** 2592 *1946*, *Beilstein* **10** IV 545.]

***n*-Butyl *p*-aminobenzoate (Butamben)** *[94-25-7]* **M 193.2, m 57-59°, b 174°/8mm, pK_{Est} ~2.5.** Crystallise Butamben from EtOH. [*Beilstein* **14** IV 1130.]

***tert*-Butylammonium bromide** *[60469-70-7]* **M 154.1, m >250°(dec).** Recrystallise the salt several times from absolute EtOH or by dissolving in absolute EtOH and adding Et_2O slowly to crystallise the salt. Dry it thoroughly at 105°. [IR: Chenon & Sandorfy *Can J Chem* **36** 1181 *1958*, *Beilstein* **4** IV 659.]

2-*tert*-Butylanthracene *[13719-97-6]* **M 234.3, m 148-149°.** Recrystallise the anthracene from EtOH and finally purify it by TLC. [*Beilstein* **5** IV 2364.]

***n*-Butylbenzene** *[104-51-8]* **M 134.2, b 183.3°, d_4^{20} 0.860, n_D^{20} 1.4897, n_D^{25} 1.487.** Distil butylbenzene from sodium. Wash it with small portions of conc H_2SO_4 until the acid is no longer coloured, then with water and aqueous Na_2CO_3. Dry it ($MgSO_4$), and distil it twice from Na, collecting the middle fraction [Vogel *J Chem Soc* 607 *1948*]. [*Beilstein* **5** IV 1033.]

***tert*-Butylbenzene** *[98-06-6]* **M 134.2, b 169.1°, d_4^{20} 0.867, n_D^{20} 1.493, n_D^{25} 1.490.** Wash it with cold conc H_2SO_4 until a fresh portion of acid is no longer coloured, then with 10% aqueous NaOH (care-effervescence), followed by distilled water until neutral. Dry it ($CaSO_4$), and distil it in a glass helices-packed column, taking the middle fraction. [*Beilstein* **5** IV 1045.]

4-*tert*-Butyl benzoyl chloride *[1710-98-1]* **M 196.7, b 135°/10mm, 149.9-150.5°/14mm, 266-268°(dec), d_4^{20} 1.082, n_D^{20} 1.536.** Distil it in a vacuum. If IR shows OH group, then treat it with thionyl chloride or oxalyl chloride at *ca* 50° for 30 minutes, evaporate and fractionate it in a vacuum using a short column. Strongly **LACHRYMATORY**; use a good fume hood. [Fuson & Turnbull *J Am Chem Soc* **71** 2544 *1949*, Tsuno et al. *Bull Chem Soc Jpn* **32** 960 *1959*, Swain et al. *J Am Chem Soc* **72** 5433 *1950*, *Beilstein* **9** III 2526.]

4-*tert*-Butylcatechol *[98-29-3]* **M 166.22, m 47-48°, 55-56°, 75°, b 265°/atm, $pK_{Est(1)}$ ~9.5, $pK_{Est(2)}$ ~13.0.** Distil it in a vacuum, then recrystallise it from pentane or petroleum ether (or $*C_6H_6$). [*Beilstein* **6** IV 6014.]

6-*tert*-Butyl-1-chloro-2-naphthol *[525-27-9]* **M 232.7, m 76°, b 185°/15mm, pK_{Est} ~8.0.** Recrystallise the naphthol from petroleum ether. Its *methyl ether* has **m** 115° (from EtOH/petroleum ether). [Buu-Hoi et al. *J Org Chem* **15** 1064 *1950*, *Beilstein* **6** IV 4367.]

2-*tert*-Butyl-4,5-dimethylphenol *[1445-23-4]* **M 178.3, b 144-150°/20mm**, **pK_{Est} ~11.8.** It is obtained by placing 3,4-dimethylphenol (170g, 1.39mol, m ~65°, see [95-65-8]), concentrated H_2SO_4 (1.5ml) and a magnetic stirrer bar in a medium pressure vessel, then purging the closed vessel with isobutylene while heating and stiring vigorously at 70° (which keeps the phenol in a moten state) under an isobutylene pressure of 20 psi. The reaction is complete when the liquid stops expanding. The mixture is cooled, Et_2O is added and the mixture is washed with saturated aqueous $NaHCO_3$ (3 x 150ml), the combined organic layers are dried ($MgSO_4$), filtered, the solvent is evaporated and the residual oil is distilled to give *2-tert-butyl-4,5-dimethylphenol*, with and the ^1H NMR (400MHz, $CDCl_3$, TMS) has δ at 7.02 (s, 1H, aromatic C*H*), 6.49 (s, 1H, aromatic C*H*), 2.19 (s, 3H, CH_3), 2.17 (s, 3H, CH_3), 1.40 (s, 9H, $C(CH_3)_3$). *Note tert-butyl 3,4-dimethylphenyl ether is formed instead when lower*

temperatures and very small amounts of acid are used [Stevens *J Am Chem Soc* **20** 1232 *1955*.] [Alexander et al. *J Am Chem Soc* **120** 4041 *1998*, Albert *J Am Chem Soc* **76** 1983 *1954*; for *acetyl derivative* see Fischer & Teo *Can J Chem* **56** 258 *1978*.]

2-*tert*-Butyl hydroquinone *[1948-33-0]* **M 166.2, m 125-127°, 127-128°, 129°, $pK_{Est(1)}$ ~10.5. $pK_{Est(2)}$ ~11.6.** Recrystallise the hydroquinone from H_2O or MeOH and dry it in a vacuum at 70°. Store it in a dark container. [Stroh et al. *Angew Chem* **69** 699 *1957*, *Beilstein* **6** IV 6013.]

2-*tert*-Butyl-4-methoxyphenol (2-*tert*-butyl-4-hydroxyanisole) *[121-00-6]* **M 180.3, m 64.1°, pK_{Est} ~10.8.** Fractionally distil the phenol *in vacuo*, then pass it as a solution in $CHCl_3$ through alumina, and evaporate the eluate. Recrystallise the residue from petroleum ether. [*Beilstein* **6** IV 6013.]

p-***tert*-Butylnitrobenzene** *[3282-56-2]* **M 179.2, m 28.4°, b 135°/10mm, 140-142°/15mm, n_D^{20} 1.5230.** Recrystallise it three times by partially freezing a mixture of the mono-nitro isomers, then recrystallise it twice from MeOH and dry it *in vacuo* [Brown *J Am Chem Soc* **81** 3232 *1959*]. [*Beilstein* **5** H 418, **5** I 203, **5** II 321, **5** III 943, **5** IV 1052.]

***tert*-Butyl perphthalic acid (monoperoxyphthalic acid 1-*tert*-butyl ester)** *[15042-77-0]* **M 238.2, m 104-104.5° (dec), pK_{Est} ~6.2.** Crystallise the per acid-ester from Et_2O or Et_2O/petroleum ether and dry it over H_2SO_4. The ester was prepared from *tert*-butylhydroperoxide and phthalic anhydride [Davies et al. *J Chem Soc* 1545 *1953*]. *Possibly* **EXPLOSIVE**. [*Beilstein* **9** IV 3260.]

p-***tert*-Butylphenol** *[98-54-4]* **M 150.2, m 99°, pK^{25} 10.39.** Crystallise the phenol to constant melting point from petroleum ether (b 60-80°). It sublimes *in vacuo*. Also purify it *via* the benzoate, as for phenol. The *salicylate ester* [87-18-30] has **m** 63-64° (from aqueous EtOH, or EtOH). [*Beilstein* **6** IV 3296.]

p-***tert*-Butylphenoxyacetic acid** *[1798-04-5]* **M 208.3, m 86.5°, 88-89°, 94°, 96.5°, pK_{Est} ~2.9.** Crystallise the acid from petroleum ether or petroleum ether/*C_6H_6 mixture. [*Beilstein* **6** H 524, **6** III 1869.]

***tert*-Butyl phenyl carbonate** *[6627-89-0]* **M 194.2, b 74-78°/0.5mm, 83°/0.6mm, d_4^{20} 1.05, n_D^{20} 1.480.** If IR is free from OH, then purify it by redistillation; otherwise dissolve it in Et_2O, wash it with 5% HCl, then H_2O, dry it ($MgSO_4$), evaporate and distil it through a Claisen head under vacuum. Care should be taken as distillation of large quantities can lead to decomposition with liberation of CO_2 and isobutylene; **take the necessary precautions.** [Carpino *J Am Chem Soc* **79** 98 *1957*, *Beilstein* **6** IV 629.]

***n*-Butyl phenyl ether** *[1126-79-0]* **M 150.2, b 95°/17mm, 210.20°/760mm, d_4^{20} 0.935, n_D^{20} 1.4969.** Dissolve it in diethyl ether, washed first with 10% aqueous NaOH to remove traces of phenol, then repeatedly with distilled water, followed by evaporation of the solvent and distillation under reduced pressure [Arnett & Wu *J Am Chem Soc* **82** 5660 *1960*]. [*Beilstein* **6** H 143, **6** I 82, **6** II 145, **6** III 550, **6** IV 558.]

***N*-*tert*-Butyl α-phenyl nitrone (PBN)** *[3376-24-7]* **M 177.2, m 73-74°.** Crystallise PBN from hexane. It is a free radical trap. [*cf* Janzen *Methods Enzymology* **105** 188 *1984*, *Beilstein* **7** IV 519.]

p-***tert*-Butyltoluene** *[98-51-1]* **M 148.3, f -53.2°, b 91°/28mm, 189-192°/atm, d_4^{20} 0.854, n_D^{20} 1.4920.** A sample containing 5% of the *meta*-isomer is purified by selective mercuration. Fractional distillation of the solid arylmercuric acetate, after removal from the residual hydrocarbon, gives pure *p-tert*-butyltoluene [Stock & Brown *J Am Chem Soc* **81** 5615 *1959*]. [*Beilstein* **5** H 439, **5** III 1003, **5** IV 1079.]

***tert*-Butyl 2,4,5-trichlorophenyl carbonate** *[16965-08-5]* **M 297.6, m 64-66°, 67-68.5°.** Crystallise the carbonate from a mixture of MeOH (90ml) and water (6ml) using charcoal [Broadbent et al. *J Chem Soc (C)* 2632 *1967*, Fieser & Fieser *Reagents for Organic Synthesis* **2** 55 *1969*].

Caffeic acid (3,4-dihydroxycinnamic acid) *[331-39-5]* **M 180.2, m 195°, 223-225°, pK_1^{25} 4.62, pK_2^{25} 9.07.**

Recrystallise this antioxidant from water. [*Beilstein* **10** IV 1776.]

Calcon carboxylic acid [3-hydroxy-4-(2-hydroxy-4-sulfo-1-naphthylazo)naphthalene-2-carboxylic acid] *[3737-95-9]* **M 428.4, m 300°, λ_{max} 560nm, pK_1 1.2, pK_2 3.8, pK_3 9.26, pK_4 13.14.** Purify it *via* its *p*-toluidinium salt, *viz*: dissolve the dye in warm 20% aqueous MeOH, treat with an equivalent of *p*-toluidine and cool to precipitate the salt. Finally recrystallise the acid from hot water. [Itoh & Ueno *Analyst (London)* **95** 583 *1970*.] It is an indicator and complexes with Ca^{2+} in presence of Mg^{2+} and other metal ions [Patton & Reeder *Anal Chem* **28** 1026 *1956*, Prentoe & Prentoe *Analyst* **106** 227 *1981*].

Calmagite [1-(1-hydroxy-4-methyl-2-phenylazo)-2-hydroxynaphthalene-4-sulfonic acid] *[3147-14-6]* **M 358.4, m 300°, pK_1 8.1, pK_2 12.4.** A crude dye is extracted with anhydrous diethyl ether and forms red crystals from Me_2CO. It gives a red colour in H_2O at pH 7—9 and a blue colour at pH 9—11 which turns red on addition of Ca^{2+} or Mg^{2+} ions. [Lindstrom & Diehl *Anal Chem* **32** 1123 *1960*]. Complexes with Ca, Mg and Th.

Capsaicin (*E*-*N*-[(4-hydroxy-3-methoxyphenyl)-methyl]-8-methyl-6-nonenamide) *[404-86-4]* **M 305.4, m 64-66°, 65°, 66.1°, b 210-220°/0.01mm, ε 7000 (281nm, EtOH).** Recrystallise capcaicin from petroleum ether (b 40-60°), or petroleum ether/Et_2O (9:1). Also purify it by chromatography on neutral Al_2O_3 (grade V) and elute successively with *C_6H_6, *C_6H_6/EtOAc (17:3) then *C_6H_6/EtOAc (7:3), and distil it at 120°/10^{-5}mm, then repeatedly recrystallise the needles from isopropanol (charcoal). [Crombie et al. *J Chem Soc* 11025 *1955*, Bennett & Kirby *J Chem Soc(C)* 442 *1968*.] It **causes pain** and is **neurotoxic** [Bevan & Szolcsanyi *Trends in Pharmacol Sci* **11** 330 *1990*, *Beilstein* **13** IV 2588].

4-(Carbamoylmethoxy)acetanilide *[14260-41-4]* **M 208.2, m 208°.** Crystallise the anilide from water.

***N*-Carboethoxyphthalimide (*N*-ethoxycarbonylphthalimide)** *[22509-74-6]* **M 219.2, m 87-89°, 90-92°.** Crystallise the imide from toluene/petroleum ether (or *benzene/petroleum ether). It is partly soluble in Et_2O, *benzene and $CHCl_3$. [Heller & Jacobsohn *Chem Ber* **54** 1112 *1921*, *Beilstein* **21/10** V 428.]

3-Carboxybenzaldehyde (3-formylbenzoic acid, isophthalaldehydic acid) *[619-21-6]* **M 150.1, m 173°, 173-175°, pK^{25} 3.84.** The acid was prepared in several ways including the following two. *m*-Bromomethylbenzoic acid (3g) is allowed to react with hexamine (3.9g) in $CHCl_3$ (30ml) by refluxing for 3 hours, cooled, the hexamine quaternary salt (4.7g) is collected, dried *in vacuo*, and decomposed by boiling in 50% aqueous acetic acid for 2 hours. The solution is cooled, diluted with an equal volume of H_2O and chilled to give a crop of the desired acid as needles, which are washed with aqueous $NaHCO_3$ and dried. A further crop can be obtained by extracting the acidic filtrate with Et_2O to give total yield of 48%. [Dyer et al. *J Chem Soc* 4778, 4781 *1952*]. *Alternatively*, *m*-carboxycinnamic acid (m 268-270°, 8.6g) in 1N Na_2CO_3 (50ml) and H_2O (400ml) is treated slowly at 4-5° with 5% of aqueous $KMnO_4$ (80ml) with vigorous stirring. MnO_2 is removed by filtration, the filtrate is concentrated to 150ml, acidified with 5N HCl and the mixture of acids that separated, together with the solution, are extracted thoroughly with Et_2O, which on evaporation give 3-formylbenzoic acid (3.6g) which is purified by recrystallisation from H_2O. [Berner *Acta Chim Scand* **10** 1208 *1956*].
The *acid chloride* [75650-38-3] has **b 130°/20mm**, the *methyl ester* [52178-50-4] has **m 53°**, the *ethyl ester* [33745-47-0] has **d^{18} 1.093** and **b 278°/atm**, the *amide* has **m 190°(dec)**, the *oxime* has **m 188°**, the *semicarbazone* has **m 275°(dec)** (from aqueous EtOH), the *bis(2-hydroxyethyl)amine salt* has **m 167°** (yellow crystals from aqueous EtOH), and the *phenylhydrazone* has **m 164°**. [Irreverre et al. *J Biol Chem* **236** 1093 *1961*, Davies et al. *J Chem Soc* 2202 *1922*, Simonis *Chem Ber* **45** 1584 *1912*, *Beilstein* **10** H 671, **10** I 317, **10** II 465, **10** III 2990, **10** IV 2750.]

4-Carboxybenzaldehyde (4-formylbenzoic acid, terephthalaldehydic acid) *[619-66-9]* **M 150.1, m 247°, 248°(dec), ~250°, 248-250°, 256°, pK^{25} 3.77.** Of the many syntheses of this acid, the more convenient one is by refluxing a solution of the commercially available 4-bromomethylbenzoic acid (21.0g, 6232-88-8) with 10% $Cu(NO_2)_2$ (300ml) for 6 hours, cooling, filtering off the solid and recrystallising it from glacial AcOH (100ml)

to give fine plates, which on further recrystallisation from H_2O, provide pure *4-formylbenzoic acid* as fine needles (2.2g 56%). The *phenylhydrazone* has **m 221-222°** [Stewart & Walker *Can J Chem* **35** 1561 *1957*], the *2,4-dinitrophenylhydrazone* has **m 319.5-320.5°**, after crystallisation from pyridine then $PhNO_2$ [Bowen & Wilkinson *J Chem Soc* 750 *1950*], the *oxime* has **m 216-217°** [Wheeler et al. *J Org Chem* **22** 547 *1957*]. The acid is also obtained by hydrolysis of the *methyl ester*, **m 61-61°** (from petroleum ether), **b 135°/12mm**, by aqueous H_2SO_4; the ester having been prepared from methyl 4-cyanobenzoate by reaction with $ZnCl_2$/HCl [Slotta & Kethur *Chem Ber* **71** 335 *1938*]. The UV in hexane of the *formyl acid* has λ_{max} (ε) at 249 (17,500), 257 (15,500) [*B*-band], and 279 (1,650), 288 (1,950), 298 (1,600) [*C-band*] nm [Dearden & Forbes *Can J Chem* **36** 1362 *1958*]. [for pK see Humffray et al. *JCS, Chem Comm* 610 *1965*; *Beilstein* **10** H 671, **10** I 317, **10** II 465, **10** III 2989, **10** IV 2752.]

4-**Carboxyphenylacetonitrile** *[6627-91-4]* **M 161.2, m 114-115°.** Crystallise the nitrile (with considerable loss) from *benzene, glacial acetic acid or H_2O. The *methyl ester* has **m** 47-48° (from $*C_6H_6$). [Price & Rogers *Org Synth* Coll Vol **III** 174 *1955*, *Beilstein* **9** H 859, **9** II 618, **9** III 4267.]

Catechol (1,2-dihydroxybenzene, pyrocatechol) *[120-80-9]* **M 110.1, m 105°, pK_1^{25} 9.45, pK_2^{25} 12.8.** Crystallise catechol from *benzene or toluene and sublime it *in vacuo*. [Rozo et al. *Anal Chem* **58** 2988 *1986*, *Beilstein* **6** IV 5557.]

Cation exchange resin. The resin should be conditioned before use by successive washing with water, EtOH and water, and taken through two H^+-Na^+-H^+ cycles by successive treatment with M NaOH, water and M HCl then washed with water until neutral.

***p*-Chloranil (2,3,5,6-tetrachloro-1,4-benzoquinone)** *[118-75-2]* **M 245.9, m 290°, 294.2-294.6°(sealed tube).** Crystallise *p*-chloranil from acetic acid, acetone, *benzene, EtOH or toluene, dry it in a vacuum over P_2O_5, or from acetic acid and drying over NaOH in a vacuum desiccator. It can be sublimed under vacuum at 290°. A sample may contain significant amounts of the *o*-chloranil isomer as impurity. Purify it by triple sublimation under vacuum and recrystallise before use. **It is a skin and mucous membrane irritant**. [UV: Pummerer et al. *Chem Ber* **85** 545 *1952*, Brook *J Chem Soc* 5040 *1952*, *Beilstein* **7** IV 2083.]

Chloranilic acid (2,5-dichloro-3,6-dihydroxy-1,4-benzoquinone) *[87-88-7]* **M 209.0, m 283-284° pK_1^{25} 1.22, pK_2^{25} 3.01.** A solution of 8g of quinone in 1L of boiling water is filtered while hot, then extracted twice at about 50° with 200ml portions of *benzene. The aqueous phase is cooled in ice-water. The crystals are filtered off, washed with three 10ml portions of water, and dried at 115°. It can be sublimed *in* vacuo. [Weissbart & Rysselberghe *J Phys Chem* **61** 765 *1957*.] The *diacetate* has **m** 182-185° [Conant & Fieser *J Am Chem Soc* **46** 1866 *1924*, Thamer & Voight *J Phys Chem* **56** 225 *1952*]. [*Beilstein* **8** IV 2707.]

p-**Chloroacetanilide** *[539-03-7]* **M 169.6, m 179°.** Crystallise the anilide from EtOH or aqueous EtOH. [*Beilstein* **12** IV 1178.]

2-Chloroacetophenone *[532-27-4]* **M 154.6, m 54-56°.** Crystallise it from MeOH [Tanner *J Org Chem* **52** 2142 *1987*]. [*Beilstein* **7** IV 641.]

o-**Chloroaniline** *[95-51-2]* **M 127.6, m -1.9°, b 84.5°/10mm, 108.4°/30mm, 208.8°/760mm, d_4^{20} 1.213, n_D^{20} 1.588, pK^{25} 2.66.** Free it from small amounts of the *p*-isomer by dissolving in one equivalent of H_2SO_4 and steam distilling. The *p*-isomer remains behind as the sulfate. [Sidgwick & Rubie *J Chem Soc* 1013 *1921*.] An alternative method is to dissolve it in warm 10% HCl (11ml/g of amine) and on cooling, *o-chloroaniline hydrochloride* separates out. The latter can be recrystallised until the acetyl derivative has a constant melting point (**m** 90°). (In this way, yields are better than *via* the recrystallisation of the *picrate* from EtOH or of the acetyl derivative from petroleum ether.) [King & Orton *J Chem Soc* 1377 *1911*]. [*Beilstein* **12** III 1281, **12** IV 1115.]

p-**Chloroaniline** *[106-47-8]* **M 127.6, m 70-71°, b 106.8-107.3-.5°/12mm, 116°/17mm, d_4^{20} 1.175, pK^{25} 3.98.**

Crystallise the aniline from MeOH, petroleum ether (b 30-60°), or 50% aqueous EtOH, then *benzene/petroleum ether (b 60-70°), and then dry it in a vacuum desiccator. It can be distilled under vacuum (**b** 75-77°/3mm). It sublimes in a very high vacuum. The *acetate* crystallises from aqueous MeOH (**m** 178°, 180°) or EtOH or AcOH (**m** 173-174°) and has **b** 331.3°/760mm. [*Beilstein* **12** III 1325, **12** IV 1116.]

***p*-Chloroanisole** *[623-12-1]* **M 142.6, b 79°/11.5mm, 196.6°/760mm, d_4^{20} 1.164, $n_D^{25.5}$ 1.5326.** Wash the anisole with 10% (by volume) aqueous H_2SO_4 (three times), 10% aqueous KOH (three times), and then with water until neutral. Dry it ($MgSO_4$), and fractionally distil it from CaH_2 through a glass helices-packed column under reduced pressure. [*Beilstein* **16** IV 822.]

9-Chloroanthracene *[716-53-0]* **M 212.9, m 104-106°, 105-107°.** 9-Chloroanthracene crystallises from EtOH or petroleum ether (**b** 60-80°) as yellow needles. [Nonhebel *Org Synth* Coll Vol **V** 206 *1973*, Masnori *J Am Chem Soc* **108** 1126 *1986*, *Beilstein* **5** H 663, **5** III 2133, **5** IV 2292.]

10-Chloro-9-anthraldehyde *[10527-16-9]* **M 240.7, m 218°, 217-219°.** The aldehyde crystallises as yellow needles from EtOH, AcOH or toluene. [*Beilstein* **7** III 2529.]

2-Chlorobenzaldehyde *[89-98-5]* **M 140.6, m 11°, b 213-214°, d_4^{20} 1.248, n_D^{20} 1.566.** Wash it with 10% Na_2CO_3 solution, then fractionally distil it in the presence of a small amount of catechol as stabiliser. [*Beilstein* **7** H 233, **7** IV 561.]

3-Chlorobenzaldehyde *[587-04-2]* **M 140.6, m 18°, b 213-214°, d_4^{20} 1.241, n_D^{20} 1.564.** Purify it by low temperature crystallisation from petroleum ether (b 40-60°) and distillation. [*Beilstein* **7** H 234, **7** IV 566.]

4-Chlorobenzaldehyde *[104-88-1]* **M 140.6, m 47°.** Crystallise it from EtOH/water (3:1), then sublime it twice at ~50°/2mm. [*Beilstein* **7** H 235, **7** IV 568.]

Chlorobenzene *[108-90-7]* **M 112.6, b 131.7°, d_4^{20} 1.107, n_D^{20} 1.52480.** The main impurities are likely to be chlorinated impurities originally present in the *benzene used in the synthesis of chlorobenzene, and also unchlorinated hydrocarbons. A common purification procedure is to wash it several times with conc H_2SO_4 then with aqueous $NaHCO_3$ or Na_2CO_3, and water, followed by drying with $CaCl_2$, K_2CO_3 or $CaSO_4$, then with P_2O_5, and distilling. It can also be dried with Linde 4A molecular sieve. Passage through, and storage over, activated alumina has been used to obtain low conductance material. [Flaherty & Stern *J Am Chem Soc* **80** 1034 *1958*, *Beilstein* **5** H 199, **5** IV 640.]

4-Chlorobenzenesulfonyl chloride *[98-60-2]* **M 211.1, m 53°, b 141°/15mm.** Crystallise it from ether in powdered Dry-ice, after the solution has been washed with 10% NaOH until colourless and dried (Na_2SO_4). Distil it *in vacuo* and store it in the absence of H_2O. [*Beilstein* **11** IV 114.]

4-Chlorobenzhydrazide *[536-40-3]* **M 170.6, m 164°.** Crystallise it from H_2O. [*Beilstein* **9** III 1368.]

2-Chlorobenzoic acid *[118-91-2]* **M 156.6, m 139-140°, pK^{25} 2.91.** Crystallise the acid successively from glacial acetic acid, aqueous EtOH, and petroleum ether (b 60-80°). Other solvents include hot water or toluene (*ca* 4ml/g). The crude material can be initially purified by dissolving 30g in 100ml of hot water containing 10g of Na_2CO_3, boiling with 5g of charcoal for 15 minutes, then filtering and adding 31ml of 1:1 aqueous HCl. The precipitate is washed with a little water and dried at 100°. [*Beilstein* **9** IV 956.]

3-Chlorobenzoic acid *[535-80-8]* **M 156.6, m 154-156°, 158°, d_4^{25} 1.496, pK^{25} 3.82 (5.25 in 50% dimethylacetamide).** Crystallise the acid successively from glacial acetic acid, aqueous EtOH and petroleum ether (b 60-80°). It also recrystallises from *C_6H_6 or Et_2O/hexane, and sublimes at 55° in a vacuum. [*Anal Chem* **26** 726 *1954*] The *methyl ester* has **m** 21°, **b** 231°/760mm. The *S-benzylisothiouronium salt* has **m** 164-165° (from EtOH) [Friediger & Pedersen *Acta Chem Scand* **9** 1425 *1955*, Samuel *J Chem Soc* 1318 *1960*]. [*Beilstein* **9** IV 969.]

4-Chlorobenzoic acid *[74-11-3]* **M 156.6, m 238-239°, pK^{25} 3.99.** Purify it as for *m*-chlorobenzoic acid. It has also been crystallised from hot water, and from EtOH. [*Beilstein* **9** IV 973.]

2-Chlorobenzonitrile *[873-32-5]* **M 137.6, m 45-46°.** Crystallise the nitrile to a constant melting point from *benzene/petroleum ether (b 40-60°). [*Beilstein* **9** IV 965.]

4-Chlorobenzophenone *[134-85-0]* **M 216.7, m 75-76°.** Recrystallise it from EtOH. [Wagner et al. *J Am Chem Soc* **108** 7727 *1986*, *Beilstein* **7** H 419, **7** I 227, **7** II 359, **7** III 2072, **7** IV 1375.]

***o*-Chlorobenzotrifluoride (*o*-chlorotrifluoromethylbenene)** *[88-16-4]* **M 180.6, m –6.37°, b 19.6°/3mm, 152.3°/760mm, d$_4^{25}$ 1.364, n$_D^{25}$ 1.4533.** Dry the trifluoride over $CaSO_4$, and distil it at high reflux ratio through a silvered vacuum-jacketed glass column packed with one-eight inch glass helices [Potter & Saylor *J Am Chem Soc* **73** 90 *1951*]. [*Beilstein* **5** H 302, **5** III 692, **5** IV 814.]

***m*-Chlorobenzotrifluoride** *[98-15-7]* **M 180.6, m –56.49°, b 50°/31mm, 137.6°/760mm, d$_4^{20}$ 1.3345, n$_D^{20}$ 1.4432.** Purify it as for *o*-chlorobenzotrifluoride above. [*Beilstein* **5** III 692, **5** IV 814.]

***p*-Chlorobenzotrifluoride** *[98-56-6]* **M 180.6, m –33.18°, b 19.3°/5mm, 138.6°/760mm, d$_4^{30}$ 1.3278, n$_D^{30}$ 1.4430.** Purify it as for *o*-chlorobenzotrifluoride above. [*Beilstein* **5** IV 815.]

***p*-Chlorobenzyl chloride** *[104-83-6]* **M 161.0, m 28-29°, b 96°/15mm.** Dry it over $CaSO_4$, then fractionally distil it under reduced pressure. Crystallise it from heptane or dry diethyl ether at low temperature. [*Beilstein* **5** IV 816.] **LACHRYMATORY.**

***p*-Chlorobenzylisothiuronium chloride** *[544-47-8]* **M 237.1, m 177-178°, and 197°, 201-203°, pK$_{Est}$ ~9.6 (free base).** Crystallise the salt from conc HCl by addition of water. Dry it in a vacuum over P_2O_5. Also crystallise it from EtOH, wash the crystals with EtOH, then Et_2O to give the lower melting form **m** 177-178°. By evaporating the filtrate and washings to a quarter of the volume and adding an equal volume of Et_2O the higher melting form **m** 201-203° is obtained. [Harvey & Jensen *J Org Chem* **28** 470 *1963*, *Beilstein* **6** III 1639, **6** IV 2778.]

***trans*-4-Chlorocinnamic acid** *[1615-02-7]* **M 182.6, m 243°, 248-250°, 249-251°, pK^{25} 4.41.** Recrystallise the acid from EtOH or aqueous EtOH (charcoal). Its UV has λ_{max} at 275nm (EtOH). [Walling & Wolfstirn *J Am Chem Soc* **69** 852 *1947*, *Beilstein* **9** H 596, **9** II 395, **9** III 2727, **9** IV 2033.]

4-Chloro-3,5-dimethylphenol *[88-04-0]* **M 156.6, m 115.5°, pK^{25} 9.70.** Crystallise the phenol from *benzene or toluene. [*Beilstein* **6** IV 3152.]

1-Chloro-2,4-dinitrobenzene *[97-00-7]* **M 202.6, m 48-50°, 51°, 52-54°, 54°, b 315°/atm, d$_4^{22}$ 1.697.** Usually it is recrystallised from EtOH or MeOH. It has also been crystallised from Et_2O, *C_6H_6, *C_6H_6/petroleum ether or isopropyl alcohol. A preliminary purification step is to pass its solution in *benzene through an alumina column. It has also been purified by zone refining. It exists in three forms: one stable and two unstable. The stable form crystallises as yellow needles from Et_2O, **m** 51°, **b** 315°/760mm with some decomposition, and is soluble in EtOH. A labile form also crystallises from Et_2O, **m** 43°, and is more soluble in organic solvents. The second labile form has **m** 27°. [Hoffman & Dame, *J Am Chem Soc* **41** 1015 *1919*, Welsh *J Am Chem Soc* **63** 3276 *1941*, *J Chem Soc* 2476 *1957*, *Beilstein* **5** IV 744.]

4-Chloro-3,5-dinitrobenzoic acid *[118-97-8]* **M 246.6, m 159-161°, 163°, pK$_{Est}$ ~2.5.** Crystallise the acid from EtOH/H_2O, EtOH or *C_6H_6. The 1:1 *naphthalene complex* (by fusing various ratios of ingredients and recrystallising from EtOH) has **m** 122°. [*Beilstein* **9** H 416, **9** III 1953, **9** IV 1360.]

Chlorogenic [1-(3,4-dihydroxycinnamoyloxy)-D-quinic] acid *[327-97-9]* **M 354.3, m 208°, [α]$_D^{25}$ -36° (c 1, H_2O), pK$_1^{25}$ 3.59, pK$_2^{25}$ 8.59.** Crystallise the acid from water and dry it at 110°. [*Beilstein* **10** H 537, **10** I 271, **10** II 378, **10** III 2408, **10** IV 2259.]

Chlorohydroquinone (2-chloro-1,4-dihydroxybenzene) *[615-67-8]* **M 144.6, m 106°, b 263°, pK_1^{25} 8.81, pK_2^{25} 10.78.** Crystallise the hydroquinone from $CHCl_3$ or toluene. [*Beilstein* **6** IV 5767.]

4-Chloroiodobenzene *[637-87-6]* **M 238.5, m 53-54°, 56.2°, b 104.2°/16mm, d_4^{57} 1.886.** Distil it in a vacuum then recrystallise it from EtOH. [Sugden *J Chem Soc* 1173 *1924*, *Beilstein* **5** H 221, **5** III 579, **5** IV 695.]

5-Chloro-2-methoxyaniline (2-amino-4-chloroanisole) *[95-03-4]* **M 157.6, m 81-83°, 82-84°, 84°, pK^{25} 3.56.** Purify the aniline by steam distillation and recrystallisation from H_2O or 40% aqueous EtOH. The *N-acetate* forms needles from hot H_2O with **m** 104°, the *N-benzoyl* derivative forms needles from aqueous EtOH with **m** 77-78°, and the *picrate* has **m** 194°(dec). [Raiford & Colbert *J Am Chem Soc* **48** 2657 *1926*, *Beilstein* **13** IV 879.]

3-Chloro-4-methoxyphenethylamine *[7569-87-1]* **M 149.6, b 140°/0.6mm, d_4^{25} ~1.081, n_D^{20} ~1.553, pK^{25} ~9.8.** This strong base is prepared by reduction of *3-chloro-4-methoxyphenylacetonitrile* (176mmol, b 140-145°/0.1-0.1mm, m 55-56°, [7569-58-6]) in THF (100ml) with $LiAlH_4$ (8.0g, 210mmol) suspended in THF (250ml) under reflux for 5 hours. The greenish coloured solution is carefully decomposed with ice cold H_2O, the solids are filtered off, washed with Et_2O, the combined organic liquids are dried (Na_2SO_4), filtered, evaporated and the crude brown residual amine is distilled in as high a vacuum as possible to give a clear oil (11.4g, 35%). It absorbs CO_2 from air and is best stored in an inert atmosphere. Its ^1H NMR [60MHz, $CDCl_3$] has δ at 7.20 (d, 1H, Ar*H*2), 7.04 (q, 1H, Ar*H*6), 6.83 (d, 1H, Ar*H*5), 3.88 (s, 3H, OCH_3), 3.12-2.20 (m, 4H, $PhCH_2CH_2N$), 1.28 (s, 2H, NH_2) ppm from TMS [Charifson et al. *J Med Chem* **31** 1941 *1988*]. *Alternatively*, the amine is prepared from the respective phenethyl bromide and dry NH_3 in EtOH followed by dilution with Et_2O, washing with aqueous NaOH, and evaporation. The residue is dissolved in 5% aqueous HCl and evaporated to dryness to give ***3-chloro-4-methoxyphenethylamine hydrochloride*** [7569-60-0] **M 186.1, m 192-195°,** as an apparently amorphous white powder when crystallisation from EtOH/Et_2O is attempted [Fosdick et al. *J Am Chem Soc* **68** 840 *1946*]. The ***N-benzoyl*** derivative [115514-67-5] **m 137-140°** is a colourless solid which is insoluble in Et_2O. [*Beilstein* **13** III 1650.]

9-Chloromethyl anthracene *[24463-19-2]* **M 226.7, m 141-142°(dec), 141-142.5°.** If it is free from OH in the IR then recrystallisation from hexane/*C_6H_6 or *C_6H_6 (as needles). If OH is present, then some solvolysis has occurred. In this case treat 8.5g of it with $SOCl_2$ (4.8g) in dioxane (60ml) and reflux for 5 hours, then evaporate to dryness and wash the residue with cold *C_6H_6 and recrystallise it. With KI/Me_2CO it forms the *iodomethyl* derivative. [Fierens et al. *Helv Chim Acta* **38** 2009 *1955*, Hunter et al. *J Org Chem* **21** 1512 *1956*, *Beilstein* **5** III 3152, **5** IV 2313.]

4-Chloro-2-methylphenol *[1570-64-5]* **M 142.6, m 49°, b 112-114°/18mm, 225°/760mm, pK^{25} 9.71.** Purify the phenol by crystallisation from petroleum ether (**m** 51°) and by zone melting. [*Beilstein* **6** H 359, **6** I 174, **6** II 332, **6** III 1264, **6** IV 1987.]

4-Chloro-3-methylphenol *[59-50-7]* **M 142.6, m 66°, b 238°/760mm, pK^{25} 9.55.** Crystallise the phenol from petroleum ether or *C_6H_6. [*Beilstein* **6** H 381, **6** I 187, **6** II 355, **6** III 1315, **6** IV 2064.]

4-Chloro-2-methylphenoxyacetic acid (MCPA) *[94-74-6]* **M 200.6, m 113-117°, 120°, 122-123°, pK^{20} 3.62(3.05).** It is insoluble in H_2O (solubility is 0.55g/L at 20°) and recrystallises from *C_6H_6 or chlorobenzene as plates [Jönsson et al. *Acta Chem Scand* **6** 993 *1952*]. The *S-benzylisothiouronium salt* has **m** 164-165°, and the Cu^{2+} salt has **m** 247-249°(dec) [Armarego et al. *Nature* **183** 1176 *1959*, UV: Duvaux & Grabe *Acta Chem Scand* **4** 806 *1950*, IR: Jöberg *Acta Chem Scand* **4** 798 *1950*]. [*Beilstein* **6** IV 1991.] It is a plant growth substance and a herbicide.

2-Chloromethyl-2-phenylpropane (neophyl chloride, 1-chloro-2-methyl-2-phenylpropane, β-chloro-*tert*-butylbezene) *[515-40-2]* **M 168.7, b 53°/1.0mm, 95.1-95.2°/10mm, 97°/13.0mm, 104°/18.0mm, 120°/30mm, 111°/90.0mm, 222°/741mm (dec), d_4^{25} 1.5228, n_D^{20} 1.5250.** It is prepared by adding β-methalyl chloride (603g, 6.66 moles, CH_2=C(Me)-CH_2Cl, 3-chloro-2-methyl-1-propene, prepared by the chlorination of butylene, b 71.5-72.5°/760mm, d_4^{20} 0.9165, n_D^{20} 1.4274 [563-47-3], *Beilstein* **1** IV 803) into a vigorously stirred mixture of

*benzene (1404g, 18.5 moles, washed twice with conc H_2SO_4 and used as such) and concentrated H_2SO_4 (104g, 1 mole) at 20° which required 12 hours, and stirring is continued for a further 11 hours at room temperature. The organic layer is collected, excess of $*C_6H_6$ is distilled off and the residue is fractionated through an 8-plate column to give pure (99.1 ±0.3% by acetolysis) *neophyl chloride* (765.5g, 68%). It is less reactive than neopentyl chloride towards Na metal and less reactive still towards EtNa, and both are inert towards most basic reagents. [Whitmore et al. *J Am Chem Soc* **65** 1469 *1943*, Smith & Sellas *Org Synth* Coll Vol **IV** 702 *1963*, *Beilstein* **5** IV 1048.]
It readily forms the Grignard reagent ***neophyl magnesium chloride*** [35293-35-7] **M 193.0**, with Mg in Et_2O; and a 0.5M solution of this reagent in Et_2O is available commercially. It reacts with solid CO_2 to give an 82% yield of *β-phenylisovaleric acid* [1010-48-6] (**m 58-59.5°,** from petroleum ether b 60-90°); and oxidation provides a 72% yield of *2-methyl-2-phenylpropan-1-ol* [2173-69-5] (**b 131°/30mm, n_D^{20} 1.5261**) whose *phenylurethane* has **m 59.5-60.5°**, α-*naphthylurethane* has **m 91.5-92.5°**, and its *p-toluenesulfonate* has **m 74-75°**. [Whitmore et al. *J Am Chem Soc* **65** 1469 *1943*, Fainberg & Winstein *J Am Chem Soc* **78** 2763*1956*, Winstein et al. *J Am Chem Soc* **74** 1113 *1952*.]

Chloromethyl phenyl sulfide *[7205-91-6]* **M 158.7, b 63°/0.1mm, 98°/12mm, 113-115°/20mm, d_4^{20} 1.184, n_D^{20} 1.5950.** Dissolve the sulfide in CH_2Cl_2 or CCl_4 and dry it ($CaCl_2$), or pass it through a tube of $CaCl_2$ and distil it using a fractionating column. ***Harmful*** *vapours.* It gives the *sulfone* [7205-98-3] (**b** 130°/1mm and **m** 53° from EtOH) [*Beilstein* **6** IV 1507] on oxidation with permonophthalic acid. [Böhme et al. *Justus Liebigs Ann Chem* **563** 54 64 *1949*.] [*Beilstein* **6** III 1002.]

***N*-(Chloromethyl)phthalimide** *[17564-64-6]* **M 195.6, m 131-135°, 134-135°, 136.5°.** Purify the imide by recrystallisation from EtOAc or CCl_4 or *via* the 1:1 complex with pyridine [Sakellarios *J Am Chem Soc* **70** 2822 *1948*, Böhme et al. *Chem Ber* **92** 1258 *1959*]. [*Beilstein* **21/10** V 372.]

1-Chloronaphthalene *[90-13-1]* **M 162.6, f -2.3°, b 136-136.5°/20mm, 259.3°/760mm, d_4^{20} 1.194, n_D^{20} 1.6326.** Wash the chloronaphthalene with dilute $NaHCO_3$, then dry it with Na_2SO_4 and fractionally distil it *in vacuo*. *Alternatively*, before distillation, it is passed through a column of activated alumina, or dried with $CaCl_2$, then distilled from sodium. It can be further purified by fractional crystallisation by partial freezing or by crystallisation of its *picrate* to constant melting point (**m** 132-133°) from EtOH, and recovering it from the picrate. [*Beilstein* **5** H 541, **5** III 1570, **5** IV 1658.]

2-Chloronaphthalene *[91-58-7]* **M 162.6, m 59.5-60°, 61°, b 121-122°/12mm. 264-266°/760mm.** Distil 2-chloronaphthalene in a vacuum, then crystallise it from 25% EtOH/water, then dry it under vacuum (see also the 1-isomer above). [*Beilstein* **5** H 541, **5** I 262, **5** II 445, **5** III 1573, **5** IV 1660.]

1-Chloro-2-naphthol *[633-99-8]* **M 178.6, m 70°, 71°, pK_{Est} ~8.3.** Crystallise the naphthol from petroleum ether. The *acetate* has **m** 42-43°. [*Beilstein* **6** I 315, **6** II 603, **6** III 2990, **6** IV 4289.]

2-Chloro-1-naphthol *[606-40-6]* **M 178.6, m 64-65°, 65°, pK^{20} 9.9 (aqueous EtOH).** Crystallise the naphthol from petroleum ether. [*Beilstein* **6** I 308, **6** II 581, **6** III 2933, **6** IV 4230.]

4-Chloro-1-naphthol *[604-44-4]* **M 178.6, m 116-117°, 120-121°, pK^{25} 8.86, 10.7 (aqueous EtOH).** Crystallise the naphthol from EtOH or $CHCl_3$. [*Beilstein* **6** H 611, **6** II 582, **6** III 2933, **6** IV 4233.]

4-Chloro-2-nitroaniline *[89-63-4]* **M 172.6, m 114-115°, 116-116.5°, pK^{25} -0.99.** Crystallise the aniline from hot H_2O (**m** 115.8-116°), EtOH, EtOH/H_2O or $*C_6H_6$, and dry it for 10 hours at 60° *in vacuo*. It has **m** 115.5-116° after sublimation. [*Beilstein* **12** H 729, **12** I 355, **12** II 396, **12** III 1649, **12** IV 1669.]

2-Chloro-4-nitrobenzamide *[3011-89-0]* **M 200.6, m 170-171°, 172°.** Crystallise the amide from EtOH. [Jensen & Ploug *Acta Chem Acta* **3** 15 *1949*, *Beilstein* **9** H 404, **9** III 1768.]

2-Chloro-1-nitrobenzene *[88-73-3]* **M 157.6, m 32.8-33.2°.** Crystallise it from EtOH, MeOH or pentane (charcoal). [*Beilstein* **5** IV 721.]

3-Chloro-1-nitrobenzene *[121-73-3]* **M 157.6, m 45.3-45.8°.** Crystallise the nitrobenzene from MeOH or 95% EtOH (charcoal), then pentane. [*Beilstein* **5** IV 722.]

4-Chloro-1-nitrobenzene *[100-00-5]* **M 157.6, m 80-83°, 83.5-84°, b 113°/8mm, 242°/atm, d $_4^{100.5}$ 1.2914.** Crystallise the nitrobenzene from 95% EtOH (charcoal) and sublime it *in vacuo*. [Emmons *J Am Chem Soc* **76** 3470 *1954*, Newman & Forrest *J Am Chem Soc* **69** 1221 *1947*, *Beilstein* **5** IV 723.]

3-Chloroperbenzoic acid (MCPBA) *[937-14-4]* **M 172.6, m 92-94°(dec), pK^{25} 7.57.** Recrystallise MCPBA from CH_2Cl_2 [Traylor & Mikztal *J Am Chem Soc* **109** 2770 *1987*]. Peracid of 99+% purity can be obtained by washing commercial 85% material with phosphate buffer pH 7.5 and drying the residue under reduced pressure. *Alternatively*, the peracid can be freed from *m*-chlorobenzoic acid by dissolving 50g/L of *benzene and washing with an aqueous solution buffered at pH 7.4 (NaH_2PO_4/NaOH) (5 x 100ml). The organic layer is dried over $MgSO_4$ and carefully evaporated under vacuum. *Necessary care should be taken in case of* **EXPLOSION**. The solid is recrystallised twice from CH_2Cl_2/Et_2O and stored at 0° in a plastic container as glass catalyses the decomposition of the peracid. The acid is assayed iodometrically. [Schwartz & Blumbrgs *J Org Chem* **29** 1976 *1964*, Bortolini et al. *J Org Chem* **52** 5093 *1987*, McDonald et al. *Org Synth* Coll Vol **VI** 276 *1988*, *Beilstein* **9** IV 972.]

2-Chlorophenol *[95-57-8]* **M 128.6, m 8.8°, b 61-62°/10mm, 176°/760mm, pK^{25} 8.34.** Pass 2-chlorophenol at least twice through a gas chromatography column. It has also been purified by fractional distillation. [*Beilstein* **6** IV 782.]

3-Chlorophenol *[108-43-0]* **M 128.6, m 33°, b 44.2°/1mm, 214°/760mm, pK^{25} 9.13.** It could not be obtained solid by crystallisation from petroleum ether. It is best purified by distillation under reduced pressure. [*Beilstein* **6** IV 810.]

4-Chlorophenol *[106-48-9]* **M 128.6, m 43°, 100-101°/10mm, pK^{25} 9.38.** Distil the phenol, then crystallise it from petroleum ether (b 40-60°) or hexane, and dry it under vacuum over P_2O_5 at room temperature. [Bernasconi & Paschalis *J Am Chem Soc* **108** 2969 *1986*, *Beilstein* **6** IV 820.]

Chlorophenol Red (3,3'-dichlorophenolsulfonephthalein) *[4430-20-0]* **M 423.3, m dec on heating, λ_{max} 573nm, pK^{25} 5.96.** Crystallise the dye from glacial acetic acid. It is yellow at pH 4.8 and violet at pH 6.7. [*Beilstein* **19/3** V 458.]

4-Chlorophenoxyacetic acid *[122-88-3]* **M 186.6, m 157°, pK^{20} 3.00, 4.15 (50% aqueous EtOH).** Crystallise the acid from EtOH. It is a plant growth substance and a herbicide. [*Beilstein* **6** IV 845.]

(±)-α-4-Chlorophenoxypropionic acid *[3307-39-9]* **M 200.6, m 116°, pK$_{Est}$ ~3.2.** Crystallise the acid from EtOH or HCOOH (**m** 114.5-115.5°). It is a plant growth substance. The *R(+)*- and *S(–)-enantomers* have **m** 103-104° (from petroleum ether) and $[\alpha]_D^{25}$ ±41° (c 1, EtOH). [*Beilstein* **6** III 695, **6** IV 850.]

ß-4-Chlorophenoxypropionic acid *[3284-79-5]* **M 200.6, m 138°, pK$_{Est}$ ~4.2.** Crystallise the acid from EtOH. It is a plant growth substance. [*Beilstein* **6** III 696, **6** IV 851.]

3-Chlorophenylacetic acid *[1878-65-5]* **M 170.6, m 74°, pK^{25} 4.11.** Crystallise the acid from EtOH/water, or as needles from *C_6H_6 or H_2O (charcoal). The *acid chloride* (prepared by boiling with $SOCl_2$) has **b** 127-129°/15mm. [Dippy & Williams *J Chem Soc* 161 *1934*, Misra & Shukla *J Indian Chem Soc* **28** 480 *1951*, *Beilstein* **9** III 2263, **9** IV 1674.]

4-Chlorophenylacetic acid *[1878-66-6]* **M 170.6, m 105°, 106°, pK^{25} 4.12.** Purify it as for 3-chlorophenylacetic acid. [*Beilstein* **9** III 2263, **9** IV 1674.]

4-Chloro-1-phenylbutan-1-one *[939-52-6]* **M 182.7, m 19-20°, b 134-137°/5mm, d $_4^{20}$ 1.149, n $_D^{20}$ 1.55413.** Fractionate the ketone several times using a short column. It recrystallises from petroleum ether at -20° in

glistening white rosettes and is filtered at 0°, and dried in a vacuum desiccator over H_2SO_4. The *semicarbazone* has **m** 136-137°. [Conant et al. *J Am Chem Soc* **46** 1882 *1924*, Cloke *J Chem Soc* 1174 *1929,* Hart & Curtis *J Am Chem Soc* **79** 931 *1957*, *Beilstein* **7** IV 711.]

1-(2-Chlorophenyl)-1-(4-chlorophenyl)-2,2-dichloroethane (Mitotane, *o,p'*-DDD) *[53-19-0]* **M 320.1, m 75.8-76.8°, 76-78°.** Purify Mitotane by recrystallisation from pentane, MeOH or EtOH. It is soluble in isooctane and CCl_4. [Haller et al. *J Am Chem Soc* **67** 1600 *1945*, *Beilstein* **5** IV 1883.]

3-(4-Chlorophenyl)-1,1-dimethylurea (Monuron) *[150-68-5]* **M 198.7, m 171°.** Crystallise monuron from MeOH. [*Beilstein* **12** IV 1191.]

4-Chloro-1,2-phenylenediamine *[95-83-0]* **M 142.6, m 69-70°, pK_1^{25} -0.27 (aqueous H_2SO_4), pK_2^{25} 3.35 (3.67).** Recrystallise the diamine from petroleum ether. [*Beilstein* **13** IV 68.]

4-Chlorophenyl isocyanate *[104-12-1]* **M 153.6, m 28-31°, 31-32°, 32°, 32.5°, b 80.6-80.9°/9.5mm, 115-117°/45mm.** Purify the isocyanate by recrystallisation from petroleum ether (b 30-40°) or better by fractional distillation. **TOXIC irritant.** [*Beilstein* **12** H 616, **12** III 1376, **12** IV 1213.]

4-Chlorophenyl isothiocyanate *[2131-55-7]* **M 169.6, m 44°, 43-45°, 45°, 46°, 47°, b 110-115°/4mm, 135-136°/24mm.** Check the IR first to see if free from OH frequencies. Triturate it with petroleum ether (b 30-60°) and decant the solvent. Repeat this 5 times. The combined extracts are evaporated under reduced pressure to give almost pure compound as a readily crystallisable oil with a pleasant anise odour. It can be recrystallised from the minimum volume of EtOH at 50° (do not boil too long as it could react). It can be purified by vacuum distillation. [van der Kerk et al. *Org Synth* Coll Vol **V** 223 *1973*, *Beilstein* **12** IV 1214.] **It is an IRRITANT and causes dermatitis; use gloves.**

4-Chlorophenyl 2-nitrobenzyl ether *[109669-56-9]* **M 263.7, m 44.5°, b 154-156°/3mm, 208°/11mm.** Distil it under reduced pressure, and it crystallises from EtOH (**m** 44-45°) or MeOH (**m** 46°) as yellow needles. [*Beilstein* **6** II 210, **6** III 801, **6** IV 1253.]

4-Chlorophenyl 4-nitrobenzyl ether *[5442-44-4]* **M 263.7, m 77°, b 215°/12mm.** Distil it in a vacuum and crystallise it from EtOH, MeOH (**m** 75.5-76°) or petroleum ether (**m** 76°, 77°). Its UV has λ_{max} at 222 and 302nm (EtOH). [*Beilstein* **6** II 222, **6** III 821, **6** IV 1288.]

4-Chlororesorcinol *[95-88-5]* **M 144.6, m 105°, $pK_{Est(1)}$~9.2, $pK_{Est(2)}$~10.1.** Crystallise it from boiling CCl_4 (10g/L, charcoal) and dry it in air. [*Beilstein* **6** II 818.] **IRRITANT.**

5-Chlorosalicaldehyde *[635-93-8]* **M 156.6, m 98.5-99°, 99.5°, 101°, pK^{25} 7.4.** Steam distil it, then crystallise it from aqueous EtOH or $*C_6H_6$ (**m** 100°). It forms complexes with Cu^{2+} and Fe^{2+}. [*Beilstein* **8** H 53, **8** II 45, **8** III 181, **8** IV 224.]

4-Chlorothiophenol *[106-54-7]* **M 144.6, m 51-52°, 53.5-54°, pK^{25} 6.14.** Recrystallise the thiophenol from aqueous EtOH. The *SMe ether* has **m** 129° and the *SEt ether* has **m** 64°. [D'Sousa et al. *J Org Chem* **52** 1720 *1987*, *Beilstein* **6** H 326, **6** I 149, **6** III 1034.]

2-Chlorotoluene *[95-49-8]* **M 126.6, b 159°, d_4^{20} 1.083, n_D^{20} 1.5255.** Dry 2-chlorotoluene for several days with $CaCl_2$, then distil it from Na using a glass helices-packed column. [*Beilstein* **5** IV 805.]

3-Chlorotoluene *[108-41-8]* **M 126.6, m -48°, b 161-163°, d_4^{20} 1.072, n_D^{20} 1.522.** Purify it as for 2-chlorotoluene above. [*Beilstein* **5** IV 806.]

4-Chlorotoluene *[106-43-4]* **M 126.6, m 7.2°, b 162.4°, d_4^{20} 1.07, n_D^{20} 1.521.** Dry it with BaO, fractionally distil it, then fractionally crystallise it by partial freezing. [*Beilstein* **5** IV 806.]

Chrysene *[218-01-9]* **M 228.3, m 255-256°.** Purify chrysene by chromatography on alumina from petroleum ether in a darkened room. Its solution in $*C_6H_6$ is passed through a column of decolorising charcoal, then crystallised by concentrating the eluate. It has also been purified by crystallising from $*C_6H_6$ or $*C_6H_6$/petroleum ether, and by zone refining. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*]. It is freed from 5*H*-benzo[*b*]carbazole by dissolving it in *N,N*-dimethylformamide and successively adding small portions of alkali and iodomethane until the fluorescent colour of the carbazole anion no longer appears when alkali is added. The chrysene (and alkylated 5*H*-benzo[*b*]carbazole) separate on addition of water. Final purification is by crystallisation from ethylcyclohexane and/or from 2-methoxyethanol [Bender et al. *Anal Chem* **36** 1011 *1964*]. It can be sublimed in a vacuum. [*Beilstein* **5** IV 2554.]

Chrysoidine G (4-phenylazo-1,3-benzenediamine monohydrochloride, basic orange 2) *[532-82-1]* **M 248.7, m 118-118.5°, pK_1 3.32, pK_2 5.21.** It is a red-brown powder which is recrystallised from H_2O. It gives a yellow solution in conc H_2SO_4 which turns orange on dilution. Its solubility at 15° is 5.5% (H_2O), 4.75% (EtOH), 6.0% (cellosolve), 9.5% (ethylene glycol), 0.005% (xylene) and is insoluble in $*C_6H_6$. The *hydroiodide* has **m** 184° (from EtOH) and the *picrate* forms red needles with **m** 196°. [Muramatsu *Bull Chem Soc Jpn* **31** 864 *1958*, *Beilstein* **6** IV 561.]

***trans*-Cinnamaldehyde** *[14271-10-9]* **M 132.2, m -4°, -7.5°, -9°, b 80°/0.4mm, 85.8°/1.1mm, 125-128°/11mm, 152.2°/40mm, 163.7°/60mm, 199.3°/200mm, 246°/760mm (dec), d_4^{20} 1.0510, n_D^{20} 1.623.** Purify the aldehyde by steam distillation (solubility is 1 in 700 parts H_2O) followed by distillation *in vacuo*. The *cis*-isomer has **b** 67-69°/40mm and d_4^{20} 1.0436 and n_D^{20} 1.5937. The *trans-semicarbazone* has **m** 210°(dec) from $CHCl_3$/MeOH (*cis-semicarbazone* has **m** 196°), the *trans-phenylsemicarbazone* has **m** 177° from $CHCl_3$/MeOH (the *cis-phenylsemicarbazone* has **m** 146°), the *trans-2,4-dinitrophenylhydrazone* has **m** 250°(dec) from MeOH as the *cis*-isomer [Gamboni et al. *Helv Chim Acta* **38** 255 *1955*, Holum *J Org Chem* **26** 4814 *1961*]. [*Beilstein* **9** IV 984.]

***cis*-Cinnamic acid (*Z*-3-phenyl-2-propenoic acid)** *[102-94-3]* **M 148.2, m 68° (for *allo*-form), pK^{25} 3.93.** The *cis*-acid is prepared by catalytic reduction of phenylpropiolic acid and after distillation in a high vacuum at ~95° it gives the most stable *allo*-isomer **m** 68°. Recrystallisation from petroleum ether yields **Liebermann's *iso*-cinnamic acid m 58°**. When the *allo*-acid (**m** 68°) is heated at 20° above its melting point in a sealed capillary for 0.5 hours and allowed to cool slowly, **Erlenmyer's *iso*-cinnamic acid m 42°** is formed. This form can also be obtained in larger amounts by heating the *allo*-acid at 80° for 3 hours, and on cooling it remains liquid for several weeks but gives the **m** 42° acid on innoculation with the crystals from the capillary tube. This form is unchanged in 6 weeks when kept in a dark cupboard. All three forms have the same pK values and the same rate of bromination. There is also a very labile form with **m** 32°. [Liebermann, *Chem Ber* **26** 1572 *1893*, Claisen & Crismer *Justus Liebigs Ann Chem* **218** 135 *1883*, Robinson & James *J Chem Soc* 1453 *1933*, Berthoud & Urech *Helv Chim Acta* **13** 437 *1930*, McCoy & McCoy *J Org Chem* **33** 2354 *1968*, *Beilstein* **9** IV 2001.]

***trans*-Cinnamic (*E*-3-phenyl-2-propenoic) acid** *[140-10-3, 621-82-9 for E-Z mixture]* **M 148.2, m 134.5-135°, pK^{25} 4.42 (4.50).** Crystallise the acid from *benzene, CCl_4, hot water, water/EtOH (3:1), or 20% aqueous EtOH. Dry it at 60° *in vacuo*. It is steam volatile. [*Beilstein* **9** IV 2002.]

***trans*-Cinnamic anhydride** *[538-56-7]* **M 278.4, m 136°.** Crystallise the anhydride from $*C_6H_6$ or toluene/petroleum ether (b 60-80°) or EtOH (**m** 135-136°). [*Beilstein* **9** III 2703, **9** IV 2018.]

***trans*-Cinnamoyl chloride** *[102-92-1]* **M 166.6, m 35-37°, b 101°/2mm, 154°/25mm, 256-258°/atm, $d_4^{37.6}$ 1.6202, $n_D^{37.6}$ 1.1632.** Refractionate it in a vacuum until the distillate solidifies on cooling, and recrystallise it from petroleum ether. The *trans-amide* has **m** 145-150° (from H_2O) [*Beilstein* **9** III 2711]. [Adams & Ulich *J Am Chem Soc* **42** 605 *1920*, Bergmann et al. *J Chem Soc* 2524 *1952*, *Beilstein* **9** H 587, **9** I 233, **9** II 390, **9** III 2710, **9** IV 2020.]

***N*-Cinnamoyl-*N*-phenylhydroxylamine** *[7369-44-0]* **M 239.3, m 158-163°.** Recrystallise the hydroxylamine from EtOH.

Cinnamyl alcohol *[104-54-1]* **M 134.2, m 33°, b 143.5°/14mm, λ_{max} 251nm (ε 18,180 M^{-1} cm^{-1}).** Crystallise the alcohol from diethyl ether/pentane. [*Beilstein* **6** I 281.]

Congo Red (4B) (cotton red B) *[573-58-0]* **M 696.7,** m **>360°, λ_{max} 497nm, pK_2^{28} 4.19.** Crystallise the dye from aqueous EtOH (1:3). Dry it in air. [*Beilstein* **6** I 342.]

Coniferyl alcohol [4-hydroxy-3-methoxy-cinnamyl alcohol, 3-(4-hydroxy-3-methoxy-phenyl)-2-propen-1-ol] *[458-35-5]* **M 180.2, m 73-75°, b 163-165°/3mm, pK^{25} 9.54.** It is soluble in EtOH and insoluble in H_2O. It can, however, be recrystallised from EtOH and distilled in a vacuum. It polymerises in dilute acid. The *benzoyl* derivative has **m** 95-96° (from petroleum ether), and the *tosylate* has **m** 66°. [Derivatives: Freudenberg & Achtzehn *Chem Ber* **88** 10 *1955*, UV: Herzog & Hillmer *Chem Ber* **64** 1288 *1931*, *Beilstein* **6** II 1093.]

Coronene *[191-07-1]* **M 300.4, m 438-440°, 442°, b 525°, λ_{max} 345nm (log ε 4.07).** Crystallise coronene from *benzene or toluene, then sublime it in a vacuum. [*Beilstein* **5** III 2651.]

***o*-Cresol** *[95-48-7]* **M 108.1, m 30.9°, b 191°/760mm, n_D^{41} 1.536, n_D^{46} 1.534, pK^{25} 10.22.** It can be freed from *m*- and *p*-isomers by repeated fractional distillation, It crystallises from *benzene by addition of petroleum ether. It has been fractionallly crystallised by partial freezing of its melt. The *3,5-dinitrobenzoate* (prepared from 3,5-dinitrobenzoyl chloride in dry pyridine, and recrystallised from EtOH or aqueous Me_2CO) has **m** 138°. [*Beilstein* **6** IV 1940.]

***m*-Cresol** *[108-39-4]* **M 108.1, f 12.0°, b 202.7°, d_4^{20} 1.034, n_D^{20} 1.544, pK^{25} 0.09.** Separation of the *m*- and *p*-cresols requires chemical methods, such as conversion to their sulfonates [Brüchner *Anal Chem* **75** 289 *1928*]. An equal volume of H_2SO_4 is added to *m*-cresol, stirred with a glass rod until solution is complete. Heat for 3 hours at 103-105°. Dilute carefully with 1-1.5 volumes of water, heat to boiling point and steam distil until all unsulfonated cresol has been removed. Cool and extract the residue with ether. Evaporate the solution until the boiling point reaches 134° and steam distil off the *m*-cresol. Another purification method involves distillation, fractional crystallisation from the melt, then redistillation. Free from *p*-cresol by solution in glacial acetic acid and bromination by about half of an equivalent amount of bromine in glacial acetic acid. The acetic acid is distilled off, then fractional distillation of the residue under vacuum gives bromocresols from which 4-bromo-*m*-cresol is obtained by crystallisation from hexane. Addition of the bromocresol in glacial acetic acid slowly to a reaction mixture of HI and red phosphorus or (more smoothly) of HI and hypophosphorus acid, in glacial acetic acid, at reflux, removes the bromine. After an hour, the solution is distilled at atmospheric pressure until layers are formed. Then it is cooled and diluted with water. The cresol is extracted with ether, washed with water, $NaHCO_3$ solution and again with water, dried with a little $CaCl_2$ and distilled [Baltzly et al. *J Am Chem Soc* **77** 2522 *1955*]. The *3,5-dinitrobenzoate* (prepared from 3,5-dinitrobenzoyl chloride in dry pyridine, and recrystallised from EtOH or aqueous Me_2CO) has **m** 165°. [*Beilstein* **6** IV 2035.]

***p*-Cresol** *[106-44-5]* **M 108.1, m 34.8°, b 201.9°, n^{41} 1.531, n^{46} 1.529, pK^{25} 10.27.** It can be separated from *m*-cresol by fractional crystalisation of its melt. Purify it by distillation, by precipitation from *benzene solution with petroleum ether, and *via* its benzoate, as for phenol. Dry it under vacuum over P_2O_5. It has also been crystallised from petroleum ether (b 40-60°) and by conversion to sodium *p*-cresoxyacetate which, after crystallisation from water is decomposed by heating with HCl in an autoclave [Savard *Ann Chim (Paris)* **11** 287 *1929*]. The *3,5-dinitrobenzoate* (prepared from 3,5-dinitrobenzoyl chloride in dry pyridine, and recrystallised from EtOH or aqueous Me_2CO) has **m** 189°. [*Beilstein* **6** II 2093.]

***o*-Cresolphthalein complexon (Metalphthalein)** *[2411-89-4]* **M 636.6, m 186°(dec), λ_{max} 575nm, pK_1 2.2, pK_2 2.9, pK_3 7.0, pK_4 7.8, pK_5 11.4, pK_6 12.0.** *o*-Cresolphthalein (a complexon precursor without the two bis-carboxymethylamino groups) is a contaminant and is one of the starting materials. It can be removed by dissolving the reagent in H_2O and adding a 3-fold excess of sodium acetate and fractionally precipitating it by dropwise addition of HCl to the clear filtrate. Wash the precipitate with cold H_2O and dry the *monohydrate* at 30° in a vacuum. The pure material gives a single spot on paper chromatography (eluting solvent EtOH/water/phenol, 6:3:1, and developing with NaOH). [Anderegg et al. *Helv Chim Acta* **37** 113 *1954*.] It complexes with Ba, Ca, Cd, Mg and Sr. [*Beilstein* **18** III/IV 8141.]

***o*-Cresol Red** *[1733-12-6]* **M 382.4, m 290°(dec), pK^{25} 1.26.** Crystallise it from glacial acetic acid. Dry it in air. Dissolve it in aqueous 5% $NaHCO_3$ solution and precipitate it from a hot solution by dropwise addition of aqueous HCl. Repeat the procedure till the UV maximum does not increase. [*Beilstein* **19** IV 1133.]

***o*-Cresotic acid (3-methylsalicylic acid)** *[83-40-9]* **M 152.2, m 163-164°, 165°, pK_1^{25} 3.32.** Crystallise the acid from water. [*Beilstein* **10** H 220, **10** II 131, **10** III 505, **10** IV 601.]

***m*-Cresotic acid (4-methylsalicylic acid)** *[50-85-1]* **M 152.2, m 176°, 177°, (182-183°), pK_1^{25} 3.15, pK_2^{25} 13.35.** Crystallise the acid from water. It sublimes at 130°/11mm. [*Beilstein* **10** H 233, **10** II 137, **10** III 521, **10** IV 617.]

***p*-Cresotic acid (5-methylsalicylic acid)** *[89-56-5]* **M 152.2, m 151°, 152°, 151-154°, pK_1^{25} 3.40, pK_2^{25} 13.45.** Crystallise the acid from H_2O. [*Beilstein* **10** H 227, **10** II 134, **10** III 516, **10** IV 610.]

Crystal Violet Chloride {Gentian violet, *N*-4[bis[4-(dimethylaminophenyl)methylene]-2,5-cyclohexadien-1-ylidene]-*N*-methylmethaninium chloride} *[548-62-9]* **M 408.0, pK 9.36.** Crystallise the dye from water (20ml/g), the crystals being separated from the chilled solution by centrifugation, then wash them with chilled EtOH (solubility is 1g in 10 ml of hot EtOH) and diethyl ether and dry under vacuum. It is soluble in $CHCl_3$ but insoluble in Et_2O. The carbinol is precipitated from an aqueous solution of the dye-hydrochloride, using excess NaOH, then dissolve in HCl and recrystallise it from water as the chloride [UV and kinetics: Turgeon & La Mer *J Am Chem Soc* **74** 5988 *1952*]. The *carbinol base* has **m** 195° (needles from EtOH). The *diphthalate* (blue and turns red in H_2O) crystallises from H_2O, **m** 153-154°(dec at 185-187°)[Chamberlain & Dull *J Am Chem Soc* **50** 3089 *1928*]. [*Beilstein* **13** H 233, **13** IV 2284.]

Cumene (isopropyl benzene) *[98-82-8]* **M 120.2, b 69-70°/41mm, 152.4°/760mm, d_4^{20} 0.864, n_D^{20} 1.49146, n_D^{25} 1.48892.** Usual purification is by washing it with several small portions of conc H_2SO_4 (until the acid layer is no longer coloured), then with water, 10% aqueous Na_2CO_3, again with water, and drying with $MgSO_4$, $MgCO_3$ or Na_2SO_4, followed by fractional distillation. It can then be dried with, and distilled from, Na, NaH or CaH_2. Passage through columns of alumina or silica gel removes oxidation products. It has also been steam distilled from 3% NaOH, and azeotropically distilled with 2-ethoxyethanol (which is subsequently removed by washing out with water). [*Beilstein* **5** IV 985.]

Cumene hydroperoxide *[80-15-9]* **M 152.2, b 60°/0.2mm, d_4^{20} 1.028, n_D^{24} 1.5232.** Purify the hydroperoxide by adding 100ml of 70% material slowly and with agitation to 300ml of 25% NaOH in water, keeping the temperature below 30°. The resulting crystals of the sodium salt are filtered off, washed twice with 25 ml portions of *benzene, then stirred with 100ml of *benzene for 20 minutes. After filtering off the crystals and repeating the washing, they are suspended in 100ml of distilled water and the pH is adjusted to 7.5 by addition of 4M HCl. The free hydroperoxide is extracted into two 20ml portions of *n*-hexane, and the solvent is evaporated under vacuum at room temperature, the last traces being removed at 40-50°/1mm [Fordham & Williams *Canad J Res* **27B** 943 *1949*]. Petroleum ether, **but not diethyl ether**, can be used instead of *benzene, and powdered solid CO_2 can replace the 4M HCl. [*Beilstein* **6** IV 3221.] *The material is potentially* **EXPLOSIVE.**

Cuminaldehyde (4-isopropylbenzaldehyde) *[122-03-2]* **M 148.2, b 82-84°/3.5mm, 120°/23mm, 131-135°/35mm, 235-236°/760mm, d_4^{20} 0.978, n_D^{20} 1.5301.** A likely impurity is the benzoic acid. Check the IR for the presence of OH from CO_2H, and the CO frequencies. If the acid is present, then dissolve the aldehyde in Et_2O, wash it with 10% $NaHCO_3$ until effervescence ceases, then with brine, dry over $CaCl_2$, evaporate and distil the residual oil, preferably under vacuum. It is almost insoluble in H_2O, but soluble in EtOH and Et_2O. The *thiosemicarbazone* has **m** 147° after recrystallisation from aqueous EtOH, MeOH or *C_6H_6. [Crounse *J Am Chem Soc* **71** 1263 *1949*, Bernstein et al. *J Am Chem Soc* **73** *906* 1951, Gensler & Berman *J Am Chem Soc* **80** 4949 *1958*, *Beilstein* **7** H 318, **7** II 347, **7** III 1095, **7** IV 723.]

9-Cyanoanthracene (anthracene-9-carbonitrile) *[1210-12-4]* **M 203.2, m 134-137°, 173-177°.** Crystallise the nitrile from EtOH or toluene, and sublime it in a vacuum in the dark under N_2 [Ebied et al. *J Chem Soc, Faraday Trans 1* **76** 2170 *1980*, Kikuchi et al. *J Phys Chem* **91** 574 *1987*]. [*Beilstein* **9** I 304.]

9-Cyanoanthracene photodimer *[33998-38-8]* **M 406.4, dec to monomer above ~147°.** Purify the dimer by dissolving it in the minimum amount of $CHCl_3$ followed by addition of EtOH at 5° [Ebied et al. *J Chem Soc, Faraday Trans 1* **75** 1111 *1979*, Ebied et al. *J Chem Soc, Faraday Trans 1* **76** 2170 *1980*].

***p*-Cyanobenzoic acid** *[619-65-8]* **M 147.1, m 219°, 219-221° (dec), pK^{25} 3.55.** Crystallise the acid from water and dry it in a vacuum desiccator over Sicapent. [*Beilstein* **9** IV 3324.]

4-Cyanobenzoyl chloride *[6068-72-0]* **M 165.6, m 68-70°, 69-70°, 73-74°, b 132°/8mm, 150-151°/25mm.** If the IR shows the presence of OH, then treat it with $SOCl_2$ boil for 1 hour, evaporate and distil it in a vacuum. The distillate solidifies and can be recrystallised from petroleum ether. It is moisture sensitive and an **IRRITANT.** [Ashley et al. *J Chem Soc* 103 *1942*, Fison et al. *J Org Chem* **16** 648 *1951*, [*Beilstein* **9** III 4255, **14** IV 3327.]

p*-Cyanophenol** (p*-hydroxybenzonitrile)** *[767-00-0]* **M 119.1, m 113°, pK^{25} 7.97.** Crystallise the phenol from petroleum ether, *benzene or water and keep it under vacuum over P_2O_5. [Bernasconi & Paschelis *J Am Chem Soc* **108** 2969 *1986*.] [*Beilstein* **10** H 167, **10** IV 441.]

Cyclohexylbenzene (phenylcyclohexane) *[827-52-1]* **M 160.3, f 6.8°, b 237-239°, d_4^{20} 0.950, n_D^{20} 1.5258.** Purify it by fractional distillation, and by fractional freezing. [*Beilstein* **5** IV 1424.]

Cyclopropyldiphenylcarbinol (cyclopropyldiphenylmethanol) *[5785-66-0]* **M 224.3, m 86-87°.** Crystallise the carbinol from *n*-heptane or *C_6H_6/pentane (**m** 82-83°). It sublimes at 60°/0.001mm. The *2,4-dinitrobenzoate* has **m** 140°. [*Beilstein* **6** III 3517, **6** IV 4888.]

***p*-Cymene (4-isopropyltoluene)** *[99-87-6]* **M 134.2, b 177.1°/760mm, d_4^{20} 0.8569, n_D^{20} 1.4909, n_D^{25} 1.4885.** Wash *p*-cymene with cold, conc H_2SO_4 until there is no further colour change, then repeatedly with H_2O, 10% aqueous Na_2CO_3 and H_2O again. Dry it over Na_2SO_4, $CaCl_2$ or $MgSO_4$, and distil it. Further purification steps include steam distillation from 3% NaOH, percolation through silica gel or activated alumina, and a preliminary reflux for several days over powdered sulfur. Store it over CaH_2. [*Beilstein* **5** IV 1060.]

Deoxybenzoin *[451-40-1]* **M 196.3, m 60°, b 177°/12mm, 320°/760mm.** Crystallise deoxybenzoin from EtOH and/or distil it in a vacuum. [*Beilstein* **7** II 368, **7** III 2098, **7** IV 1393.]

(±)-Desyl bromide (α-bromo-desoxybenzoin, ω-bromo-ω–phenyl acetophenone) *[484-50-0]* **M 275.2, m 57.1-57.5°.** Crystallise it from 95% EtOH. [*Beilstein* **7** H 436, **7** II 370, **7** III 2122.]

(±)-Desyl chloride (α-chloro-desoxybenzoin, ω-chloro-ω–phenyl acetophenone) *[447-31-4]* **M 230.7, m 62-64°, 66-67°, 67.5°, 68°.** For the purification of small quantities recrystallise it from petroleum ether (b 40-60°), but use MeOH or EtOH for larger quantities. For the latter solvent, dissolve 12.5g of chloride in 45ml of boiling EtOH (95%), filter and the filtrate yields colourless crystals (7.5g) on cooling. A further crop (0.9g) can be obtained by cooling in an ice-salt bath. It turns brown on exposure to sunlight but it is stable in sealed dark containers. The *R(+)-enantiomer* has **m** 75-76° (from petroleum ether) and $[\alpha]_{546}$ +168.4° (c 0.6, Me_2CO) [Roger & Wood *J Chem Soc* 811 *1954*]. [Henley & Turner *J Chem Soc* 1182 *1931*, Ward *Org Synth* Coll Vol **II** 159 *1943*, *Beilstein* **7** H 436, **7** I 234, **7** II 369, **7** III 2106, **7** IV 1396.]

Diacetoxyiodobenzene (iodobenzenediacetate) *[3240-34-4]* **M 322.1, m 163-165°.** The purity of diacetoxyiodobenzene can be checked by treatment with H_2SO_4 then KI, and the liberated I_2 is estimated with standard thiosulfate. It has been recrystallised from 5M acetic acid and dried overnight in a vacuum desiccator over $CaCl_2$. The surface of the crystals may become slightly yellow but this does not affect its usefulness. [Sharefkin & Saltzman *Org Synth* Coll Vol **V** 600 *1973*, *Beilstein* **5** IV 693.]

1,2-Diacetyl benzene *[704-00-7]* **M 162.2, m 39-41°, 41-42°, b 110°/0.1mm, 148°/20mm.** Purify it by

distilling and by recrystallising from petroleum ether. The *bis-2,4-dinitrophenylhydrazone* has **m** 221° (dec). [Halford & Weissmann *J Org Chem* **17** 1646 *1952*, Riemschneider & Kassahn *Chem Ber* **92** 1705 *1959*, [*Beilstein* **7** III 3501, **7** IV 2155.]

1,4-Diacetyl benzene *[1009-61-6]* **M 162.2, m 113-5-114.2°, b 128-130°/3mm.** Crystallise it from EtOH (**m** 114°) or *benzene and dry it in a vacuum over $CaCl_2$. Also purify it by dissolving it in acetone, treating with Norit, evaporating and recrystallising from MeOH. The *dioxime* has **m** 248-259°. [Wagner et al. *J Am Chem Soc* **108** 7727 *1986*]. [*Beilstein* **7** H 686, **7** II 624, **7** III 3504, **7** IV 2156.]

1,4-Diaminoanthraquinone *[128-95-0]* **M 238.3, m 268°.** Purify the anthraquinone by thin-layer chromatography on silica gel using toluene/acetone (9:1) as eluent. The main band is scraped off and extracted with MeOH. The solvent is evaporated, and the quinone is dried in a drying pistol [Land et al. *J Chem Soc, Faraday Trans 1* **72** 2091 *1976*]. It crystallises from EtOH (**m** 269°) in dark violet crystals. Store it in sealed ampoules in the dark. [*Beilstein* **14** H 197, **14** II 113, **14** III 437, **14** IV 458.]

1,5-Diaminoanthraquinone *[129-44-2]* **M 238.3, m 319°.** Recrystallise it from aniline (**m** 313-314°), EtOH or acetic acid [Flom & Barbara *J Phys Chem* **89** 4481 *1985*]. [*Beilstein* **14** H 303, **14** I 467, **14** II 116, **14** III 466, **14** IV 479.]

2,6-Diaminoanthraquinone *[131-14-6]* **M 238.3, m 310-320°.** Crystallise it from pyridine or nitrobenzene (red needles). Column-chromatography on Al_2O_3/toluene is used to remove a fluorescent impurity, then it is recrystallised from EtOH. [*Beilstein* **14** H 215, **14** I 471, **14** II 120, **14** III 480, **14** IV 486.]

3,3'-Diaminobenzidine tetrahydrochloride ($2H_2O$) *[7411-49-6]* **M 396.1, m >300°(dec), $pK_{Est(1)}$ ~3.3, $pK_{Est(2)}$ ~4.7 (free base).** Dissolve the salt in water and precipitate it by adding conc HCl, then drying it over solid NaOH. [*Beilstein* **13** IV 530.]

3,4-Diaminobenzoic acid *[619-05-6]* **M 152.2, m 213°(dec), 228-229°, pK_1^{25} 2.57 (4-NH_2), pK_2^{25} 3.39 (3-NH_2), $pK_{Est(3)}$ ~5.1 (CO_2H).** Crystallise it from H_2O or toluene. [*Beilstein* **15** IV 1503.]

3,5-Diaminobenzoic acid *[535-87-5]* **M 152.2, m 235-240°(dec), pK^{25} 5.13 (CO_2H), pK^{25} 7.12 (in 80% aqueous 2-$MeOCH_2CH_2OH$).** Crystallise the acid from water. The *dihydrochloride* has **m** 226-228°(dec). [*Beilstein* **14** H 453, **14** III 1179, **14** IV 1304.]

3,4-Diaminobenzophenone *[39070-63-8]* **M 212.3, m 116-117°, $pK_{Est(1)}$ ~ <0, $pK_{Est(2)}$ ~2.5.** Crystallise it from *C_6H_6/petroleum ether and sublime it *in vacuo* [Ayyanger et al. *Org Prep Proced Int* **23** 627 *1991*].

4,4'-Diaminobenzophenone *[611-98-3]* **M 212.3, m 242-244°, 243-245°, 246.5-247.5° (after sublimation at 0.0006mm), pK_1^{25} 1.37, pK_2^{25} 2.92.** Purify the phenone by recrystallisation from EtOH and by sublimation in high vacuum. The *dihydrochloride* has **m** 260°(dec) (from EtOH), and the *thiosemicarbazone* has **m** 207-207.5°(dec) (from aqueous EtOH). [Kuhn et al. *Chem Ber* **75** 711 *1942*, *Beilstein* **14** IV 255.]

1,2-Diamino-4,5-dichlorobenzene *[5348-42-5]* **M 177.0, m 162°, 162-163°, 163°, $pK_{Est(1)}$~1.0, $pK_{Est(2)}$~2.9.** Reflux the amine with activated charcoal in CH_2Cl_2, followed by recrystallisation from Et_2O/petroleum ether or petroleum ether [Koolar & Kochi *J Org Chem* **52** 4545 *1987*]. *Alternatively*, recrystallise the diamine from hexane, *C_6H_6, petroleum ether or H_2O (Na_2SO_4), and sublime it at 150°/15mm. [*Beilstein* **13** IV 72.]

4,4'-Diamino-3,3'-dinitrobiphenyl *[6271-79-0]* **M 274.2, m 275°, pK_{Est} ~ -0.2.** Crystallise the biphenyl from aqueous EtOH or pyridine/EtOH. [*Beilstein* **13** H 236, **13** I 68, **13** II 108, **13** III 415, **13** IV 387.]

4,4'-Diaminodiphenylamine *[537-65-5]* **M 199.3, m 158°, pK_{Est} ~5.0.** Crystallise the amine from water (its solubility at 25° is 0.42%). [*Beilstein* **13** H 110, **13** I 36, **13** II 55, **13** III 256, **13** IV 203.]

4,4'-Diaminodiphenyl ether (4,4'-oxydianiline, DADPE) *[101-80-4]* **M 200.2, m 185°, 186-187°, 188-192°,**

pK^{25} 5.12 (50% EtOH). This base has been prepared by several syntheses including, condensation of *p*-nitrophenol with *p*-chloroaniline, nitration of diphenyl ether to 4,4'-dinitrodiphenyl ether and reduction with hydrazine and Raney Ni [Shamis & Dashevski *J Org Chem, USSR Engl Transl* **3** 1005 *1967*], a Friedel-Crafts reaction of diphenyl ether (AcCl, $AlCl_3$) to 4,4'-diacetyldiphenyl ether (m 99-100°), conversion to the dioxime (m 180-183°), and a bis-Beckman rearrangement (AcOH, Ac_2O, HCl gas) gives 4,4'-bis-acetamidodiphenyl ether (90%). This amide (46g) in H_2O (600ml) and concentrated HCl (60ml) is refluxed for 2 hours until it all dissolved, filtered (charcoal), the filtrate is basified with Na_2CO_3 solution, the precipitate is filtered off, washed with H_2O, and dried at 100-110° to give the *free base* (32g). It is purified by zone melting and/or by sublimation at high vacuum. In the UV it has λ_{max} at 248 and 300nm in EtOH. [Franovskii et al. *J Org Chem, USSR Engl Transl* **6** 2315 *1970*.] The *benzenesulfonate salt* crystallises from MeOH with **m 286-288°(dec)**. [*Beilstein* **13** H 441, **13** I 148, **13** III 106, **13** IV 1038.]

4,4'-Diaminodiphenylmethane *[101-77-9]* **M 198.3, m 91.6-92°, 92-93°, b 232°/9mm, pK$_{Est}$ ~4.9.** Crystallise the amine from water, 95% EtOH or *benzene. [*Beilstein* **13** IV 390.]

4,4-Diaminodiphenyl sulfide (4,4'-thioaniline) *[139-65-1]* **M 216.3, m 108-109°, pK^{20} 2.28 (1:1 EtOH/H_2O).** It separates as needles from EtOH and is a **possible mutagen**. The free base is used for the detection of NO_3^- ions. The *diacetate* crystallises from aqueous AcOH with **m** 182° and the *sulfoxide*, [119-59-5] **m** 184°, forms prisms from EtOH or H_2O. [Fuson & Melamed *J Org Chem* **13** 690 I1948*, Beilstein* **13** III 1246, **13**, IV 1246.]

2,7-Diaminofluorene *[524-64-4]* **M 196.3, m 165°, pK$_{Est}$ ~4.6.** Recrystallise it from H_2O. [*Beilstein* **13** IV 449.]

1,5-Diaminonaphthalene *[2243-62-1]* **M 158.2, m 190°, pK^{25} 4.12.** Recrystallise the amino-naphthalene from boiling H_2O, but this is wasteful due to poor solubility. Boil it in chlorobenzene (charcoal), filter hot and cool the filtrate (preferably under N_2). This gives colourless crystals. Dry it in a vacuum till free from chlorobenzene (odour), and store it in sealed ampoules under N_2 away from light. [*Beilstein* **13** IV 340.]

1,8-Diaminonaphthalene *[479-27-6]* **M 158.2, m 66.5°, b 205°/12mm, pK^{25} 4.44.** Crystallise 1,8-diaminonaphthalene from water or aqueous EtOH, and sublime it in a vacuum. The *N,N'-dimethyl* derivative [20734-56-9] has **m** 103-104° and **pK^{25}** 5.61, the *N,N,N'-trimethyl-* derivative [20734-57-0] has **m** 29-30° and **pK^{25}** 6.43. [Hodgson et al. *J Chem Soc* 202 *1945*, *Beilstein* **13** IV 344.]

2,3-Diaminonaphthalene *[771-97-1]* **M 158.2, m 199°, pK^{21} 3.54 (in 50% aqueous EtOH).** Crystallise the diamine from water, or dissolve it in 0.1M HCl, by heating to 50°. After cooling, the solution is extracted with decalin to remove fluorescent impurities and centrifuged. [*Beilstein* **13** IV 346.]

2,5-Di-*tert*-amylhydroquinone *[79-74-3]* **M 250.4, m 185.8-186.5°.** Crystallise the hydroquinone under N_2 from boiling AcOH (7ml/g) plus boiling water (2.5ml/g). [Stolow & Bonaventura *J Am Chem Soc* **85** 3636 *1963*]. Store it in sealed ampoules under N_2 away from light. [*Beilstein* **6 H 952,** 6 III 4748.]

Di-n-amyl phthalate (dipentyl phthalate) *[131-18-0]* **M 306.4, b 204-206°/11mm, d_4^{25} 1.023, n_D^{20} 1.489.** Wash the ester with aqueous Na_2CO_3, then distilled water. Dry it with $CaCl_2$ and distil it in a vaccum. Store it in a vacuum desiccator over P_2O_5. [*Beilstein* **9** IV 3178.]

Diazoaminobenzene (1,3-diphenyltriazene) *[136-36-6]* **M 197.2, m 99°, 100°.** Crystallise the triazene from petroleum ether (b 60-80°) (**m** 94-96°), 60% MeOH/water or 50% aqueous EtOH (charcoal) containing a small amount of KOH. Its solubility in petroleum ether (b 60-80°) is ~6%. Also purify it by chromatography on alumina/toluene and elute with toluene/petroleum ether. Store the pale yellow needles in the dark. [Hartman & Dickey *Org Synth* Coll Vol **II** 163 *1943*, *Beilstein* **16** H 687, **16** I 404, **16** II 351, **16** III 643, **16** IV 904.]

Dibenzalacetone [1,5-diphenyl-1,4-dien-3-one, 1,5-(bisphenyl)-penta-1*E*,4*E*-diene-3-one] *[538-58-9]* **M 234.3, m 107-113°, 112°, 120-122°.** Purify the ketone by flash chromatography (150 mesh Al_2O_3 deactivated with 6% v/w H_2O) using petroleum ether 40-60°/EtOAc (4/1, v/v), and the yellow solid is recrystallised by

layering a concentrated CH_2Cl_2 solution with hexane (i.e. CH_2Cl_2/hexane, 1:4, v/v). Also recrystallise the ketone from hot ethyl acetate (2.5ml/g) or EtOH. The IR (CH_2Cl_2) has ν_{max} at 1657m, 1651m (C=O), 1627vs (C=C), 1591w (C=C aromatic), 1574w (C=C aromatic), 983m (CH trans) cm^{-1}; and UV has λ_{max} (THF) at 233 (π-π*) and 321 (n- π*) nm; the ^1H NMR (400MHz, $CDCl_3$) has δ at 7.65-7.15 (m, 10 H, ArH), 4.4 (dd, J = 5.8, 10.0 Hz, 1 H, C3a-H), 3.45-3.30 (m, 1 H, C6-H), 3.15-3.00 (m, 1 H, C6-H), 1.90-1.55 (m, 3 H, C4-H, C5-H_2), 0.95-0.75 (m, 1 H, C4-H), 0.40 (s, 3 H, B-CH_3). [*Beilstein* **7** IV 1747.]

Dibenz[*a,h*]anthracene (1,2:5,6-dibenzanthracene) *[53-70-3]* **M 278.4, m 266-267°.** The yellow-green colour (due to other pentacyclic impurities) is removed from it by crystallising from *benzene or by selective oxidation with lead tetraacetate in acetic acid [Moriconi et al. *J Am Chem Soc* **82** 3441 *1960*]. [*Beilstein* **5** IV 2722.]

***trans*-1,2-Dibenzoylethylene (*trans*-1,4-diphenyl-2-butane-1,4-dione)** *[959-28-4]* **M 236.3, m 109-112°, 111°.** It crystallises from MeOH or EtOH as yellow needles [Koller et al. *Helv Chim Acta* **29** 512 *1946*]. The *dioxime* has **m** 210-211°(dec) from AcOH. [IR: Kuhn et al. *J Am Chem Soc* **72** 5058 *1950*, Yates *J Am Chem Soc* **74** 5375 *1952*, Erickson et al. *J Am Chem Soc* **73** 5301 *1951*, *Beilstein* **7** IV 2578.]

Dibenzoylmethane (1,3-diphenyl-1,3-propanedione) *[120-46-7]* **M 224.3, m 80°.** Crystallise dibenzoylmethane from petroleum ether or MeOH. [*Beilstein* **7** IV 2512.]

2,3,6,7-Dibenzphenanthrene (pentaphene) *[222-93-5]* **M 276.3, m 255-256°, 257°.** Purify pentaphene through Al_2O_3 with $^*C_6H_6$ or xylene as eluant. It crystallises from xylene as yellow plates and sublimes in high vacuum. The *dipicrate* forms orange needles **m** 184° from $^*C_6H_6$. (Clar & John *Ber* **64** 986 *1931*, Clar & Stewart *J Chem Soc* 3215 *1951*, *Tet Lett* 3023 *1965*, French & Zander *Ber* **99** 396 *1966*.]

Dibenzyl amine *[103-49-1]* **M 197.3, m -26°, b 113-114°/0.1mm, 174-175°/6mm, 270°/250mm, 300° (partial dec), d_4^{20} 1.027, n_D^{20} 1.576, pK^{25} 8.52.** Purify the amine by distillation in a vacuum. **It causes burns to the skin.** The *dihydrochloride* has **m** 265-266° (from MeOH/HCl), and the *tetraphenyl boronate* has **m** 129-133°. [Bradley & Maisey *J Chem Soc* 247 *1954*, Hall *J Phys Chem* **60** 63 *1956*, Donetti & Bellora *J Org Chem* **37** 3352 *1972*, *Beilstein* **12** IV 2179.]

Dibenzyl disulfide *[150-60-7]* **M 246.4, m 71-72°, 74-75°, b 142-148°/0.05-0.1mm, 210-216°/18mm.** Crystallise the disulfide from EtOH (**m** 77°), petroleum ether or CS_2 (**m** 72°) or distil it. The $AgNO_3$ complex has **m** 103°. [*Beilstein* **6** H 465, **6** I 229, **6** II 437, **6** III 1635, **6** IV 2760.]

Dibenzylethylenediamine (benzathine, DBED) *[140-28-3]* **M 240.4, m 26°, b 195°/4mm, d_4^{20} 1.02, n_D^{20} 1.563, $pK_{Est(1)}$~ 5.9, $pK_{Est(2)}$~ 8.9.** Dissolve DBED in acid, extract with toluene, basify, extract it with Et_2O, dry over solid KOH, evaporate and fractionate it *in vacuo*. The *diacetate* crystallises from H_2O by addition of EtOH and has **m** 111° (solubility in H_2O is ~25%). The *dihydrochloride* has **m** 306-308° (from H_2O) and the *dipicrate* has **m** 212°(dec) (from H_2O). [Frost et al., *J Am Chem Soc* **71** 3842 *1949*, *Beilstein* **12** H 1067, **12** III 2304.]

Dibenzyl ketone (1,3-diphenyl-2-propanone) *[102-04-5]* **M 210.3, m 34.0°.** Fractionally crystallise it from its melt, then crystallise it from petroleum ether. Store it in the dark. [*Beilstein* **7** IV 1420.]

Dibenzyl malonate *[15014-25-2]* **M 284.3, b 188-190°/0.2mm, 193-196°/1mm, d_4^{20} 1.158, n_D^{20} 1.5452.** Dissolve the ester in toluene, wash it with aqueous $NaHCO_3$, H_2O, dry over $MgSO_4$, filter, evaporate and distil it at high vacuum. [Ginsburg & Pappo *J Am Chem Soc* **75** 1094 *1953*, Baker et al. *J Org Chem* **17** 77 *1952*, *Beilstein* **6** IV 2270.]

Dibenzyl sulfide *[538-74-9]* **M 214.3, m 48.5°, 50°.** Crystallise the sulfide from EtOH/water (10:1), or repeatedly from Et_2O. It has also been purified by chromatography on Al_2O_3 (pentane as eluent), then recrystallised from EtOH [Kice & Bowers *J Am Chem Soc* **84** 2390 *1962*]. Dry it in a vacuum at 30° over P_2O_5, fused under nitrogen and re-dried. [*Beilstein* **6** IV 2649.]

2,4-Dibromoaniline *[615-57-6]* **M 250.9, m 79-80°, pK^{25} 1.87.** Crystallise the aniline from aqueous EtOH. The *picrate* has **m** 124°. [*Beilstein* **12** H 655, **12** I 326, **12** II 356, **12** III 1471, **12** IV 1532.]

9,10-Dibromoanthracene *[523-27-3]* **M 336.0, m 222-224°, 226°.** Recrystallise it from toluene, xylene or CCl_4 (yellow needles), and sublime it in a vacuum [Johnston et al. *J Am Chem Soc* **109** 1291 *1987*]. [Heilbron & Heaton *Org Synth* Coll Vol **I** 207 *1941*, *Beilstein* **5** H 665.]

***p*-Dibromobenzene** *[106-37-6]* **M 235.9, m 87.8°.** Steam distil the dibromobenzene, then crystallise it from EtOH or MeOH and dry it in the dark under vacuum. Purify it by zone melting. [*Beilstein* **5** IV 683.]

2,5-Dibromobenzoic acid *[610-71-9]* **M 279.9, m 157°, pK$_{Est}$ ~1.5.** Crystallise the acid from water or EtOH. [*Beilstein* **9** H 358, **9** I 147, **9** II 237, **9** III 1428, **9** IV 1027.]

4,4'-Dibromobiphenyl *[92-86-4]* **M 312.0, m 164°, b 355-360°/760mm.** Crystallise it from MeOH. [*Beilstein* **5** IV 1820.]

(±)-2,2'-Dibromo-1,1'-binaphthyl *[74866-28-7, (±) 76284-65-6]* **M 412.1, m 178-183°, 180.5-181°.** Purify the binaphthyl by chromatography through a silica gel column (70-230mesh) using hexane as eluent. It gives pale yellow crystals from EtOH with **m** 187.3-187.9°. The *R*-(+)-*enantiomer* [86688-08-6] crystallises from hexane with **m** 157-157.5° and $[\alpha]_D^{25}$ +32.9° (c 1, pyridine) [Brown et al. *J Org Chem* **50** 4345 *1985*]. [Okamoto et al. *J Am Chem Soc* **103** 6971*1981*, *Beilstein* **5** III 2465.]

α,α-Dibromodeoxybenzoin *[15023-99-1]* **M 354.0, m 111.8-112.7°.** Crystallise α,α-dibromo deoxybenzoin from acetic acid, 50% aqueous EtOH (prisms, **m** 109-112°) or Et_2O (**m** 112°). [Curtius & Lang *J Prakt Chem* **44** 547 *1891, Beilstein* **7** H 436, **7** III 2114.]

2,5-Dibromonitrobenzene *[3460-18-2]* **M 280.9, m 84°, 85-86°.** It crystallises from Me_2CO or EtOH. [*Beilstein* **5** H 250, **5** II 190, **5** III 621, **5** IV 732.]

2,6-Dibromo-4-nitrophenol *[99-28-5]* **M 280.9, m 143-144°, pK^{25} 3.39.** Crystallise the phenol from aqueous EtOH, 50% aqueous AcOH (**m** 144-145°, dec varies with rate of heating). Dry it in an oven at 40-60° or *in vacuo* over NaOH. [Hartman & Dickey *Org Synth* Coll Vol **II** 173 *1943*, *Beilstein* **6** H 246, **6** I 123, **6** II 234, **6** III 849, **6** IV 1366.]

2,4-Dibromophenol *[615-58-7]* **M 251.9, m 37°, 41-42°, b 154°/10mm, 239°/760mm, pK^{25} 7.79.** Crystallise the phenol from $CHCl_3$ at -40°, or distil it in a vacuum. [*Beilstein* **6** H 202, **6** I 106, **6** II 188, **6** III 753, **6** IV 1061.]

2,6-Dibromophenol *[608-33-3]* **M 251.9, m 56-57°, b 138°/10mm, 255-256°/740mm, pK^{25} 6.67.** Distil the phenol under vacuum (at 10mm), then crystallise it from cold $CHCl_3$ or from EtOH/water. [*Beilstein* **6** H 202, **6** I 106, **6** II 188, **6** III 755, **6** IV 1064.]

α,α'-Dibromo-*o*-xylene *[91-13-4]* **M 264.0, m 95°, 95-96°, 98-99°, b 129-130°/4.5mm.** Crystallise it from $CHCl_3$ or petroleum ether, and/or distil it under vacuum. [Wenner *Org Chem* **17** 527 *1952*, *Beilstein* **5** H 366, **5** I 180, **5** II 285, **5** III 819, **5** IV 929.]

α,α'-Dibromo-*m*-xylene *[626-15-3]* **M 264.0, m 77°, 78-79°, b 156-160°/12mm.** Crystallise it from acetone or *benzene, and fractionally distil it under vacuum. [Wenner *Org Chem* **17** 527 *1952*, *Beilstein* **5** H 374, **5** I 184, **5** II 294, **5** III 839, **5** IV 946.]

α,α'-Dibromo-*p*-xylene *[623-24-5]* **M 264.0, m 143.4°, 142-144°, 145-147°, b 155-158°/12-15mm, 245°/760mm.** Distil it under a vacuum and recrystallise it from EtOH, *benzene or chloroform. [Wenner *Org Chem* **17** 527 *1952*, *Beilstein* **5** H 385, **5** I 187, **5** II 301, **5** III 859, **5** IV 970.]

α-Dibutylamino-α-(*p*-methoxyphenyl)acetamide (Ambucetamide) *[519-88-0]* **M 292.4, m 134°.** Crystallise ambucetamide from EtOH containing 10% diethyl ether. [Janssen *J Am Chem Soc* **76** 6192 *1954*, *Beilstein* **14** IV 2101.]

2,5-Di-*tert*-butyl aniline *[21860-03-7]* **M 205.4, m 103-104°, 103-106°, pK^{25} 3.34 (50% aqueous MeOH), 3.58 (90% aqueous MeOH).** The aniline recrystallises from EtOH in fine needles after steam distillation. It has a pKa^{25} of 3.58 (50% aqueous EtOH). The *tosylate* has **m** 164° (from AcOH). [Bell & Wilson *J Chem Soc* 2340 *1956*, Carpenter et al. *J Org Chem* **16** 586 *1951*, Bartlett et al. *J Am Chem Soc* **76** 2349 *1954*, *Beilstein* **12** IV 2891.]

***p*-Di-*tert*-butylbenzene** *[1012-72-2]* **M 190.3, m 80°, 236°/760mm.** Crystallise it from Et_2O or EtOH and dry it under vacuum over P_2O_5 at 55°. [Tanner et al. *J Org Chem* **52** 2142 *1987*, *Beilstein* **5** II 344.]

2,6-Di-*tert*-butyl-1,4-benzoquinone *[719-22-2]* **M 220.3, m 66-67°.** It can be recrystallised from MeOH and sublimes in a vacuum. [*Beilstein* **7** IV 2116.]

3,5-Di-*tert*-butyl-*o*-benzoquinone *[3383-21-9]* **M 220.3, m 112-114°, 113-114°.** It can be recrystallised from MeOH or petroleum ether, and forms fine red plates or rhombs. [Flaig et al. *Justus Liebigs Ann Chem* **597** 196 *1955*, IR: Ley & Müller *Chem Ber* **89** 1402 *1956*, *Beilstein* **7** IV 2113.]

3,5-Di-*tert*-butyl catechol *[1020-31-1]* **M 222.3, m 99°, 99-100°, pK$_{Est(1)}$~11.0, pK$_{Est(2)}$~13.1.** Recrystallise the catechol from petroleum ether. [Ley & Müller *Chem Ber* **89** 1402 *1956*, UV Flaig et al. *Z Naturforschung* **10b** 668 *1955*.] Also purify it by crystallising three times from pentane [Funabiki et al. *J Am Chem Soc* **108** 2921 *1986*].

2,6-Di-*tert*-butyl-*p*-cresol (2,6-di-*tert*-butyl-4-methylphenol, butylatedhydroxytoluene, BHT or DBPC) *[128-37-0]* **M 230.4, m 71.5°, pK^{25} 12.23.** Dissolve BHT in *n*-hexane at room temperature, then cool with rapid stirring, to -60°. The precipitate is separated, redissolved in hexane, and the process is repeated until the mother liquor is no longer coloured. The final product is stored under N_2 at 0° [Blanchard *J Am Chem Soc* **82** 2014 *1960*]. It has also been recrystallised from EtOH, MeOH, *benzene, *n*-hexane, methylcyclohexane or petroleum ether (b 60-80°), and is dried in a vacuum. [*Beilstein* **6** IV 3511.]

2,6-Di-*tert*-butyl-4-dimethylaminomethylphenol *[88-27-7]* **M 263.4, m 93-94°, b 172°/30mm, pK$_{Est}$ ~12.0.** Crystallise it from *n*-hexane. [*Beilstein* **13** IV 2014.]

Di-*tert*-butyldiperphthalate *[2155-71-7]* **M 310.3, m (48°) 57-57.5°, decomposes at 108°.** Crystallise the perphthalate from Et_2O or petroleum ether and dry it over H_2SO_4. The IR has ν_{max} at 1772cm^{-1} in CCl_4. [Milas & Surgemor *J Am Chem Soc* 68 642 *1946*, Milas & Kelin *J Org Chem* **36** 2900 *1971*, *Beilstein* **9** III 4190, **9** IV 3260.] **CARE**, potentially **EXPLOSIVE**.

2,6-Di-*tert*-butyl-4-ethylphenol *[4130-42-1]* **M 234.4, m 42-44°, pK$_{Est}$ ~12.3.** Crystallise the phenol from aqueous EtOH or *n*-hexane. [*Beilstein* **6** IV 3529.]

2,5-Di-*tert*-butylhydroquinone *[88-58-4]* **M 222.3, m 222-223°.** Crystallise the hydroquinone from *C_6H_6 or AcOH. [*Beilstein* **6** III 4741.]

2,6-Di-*tert*-butyl-4-isopropylphenol *[5427-03-2]* **M 248.4, m 39-41°, 38-42°, b 105-106°/0.3mm, pK$_{Est}$ ~12.3.** Crystallise the phenol from *n*-hexane or aqueous EtOH. It is used for making the respective *phenoxyl radical*. [Cook & Norcross *J Am Chem Soc* **78** 3797 *1956*, *Beilstein* **6** III 3534.]

2,6-Di-*tert*-butylphenol *[128-39-2]* **M 206.3, m 37-38°, pK^{25} 11.70.** Crystallise the phenol from aqueous EtOH or *n*-hexane. [*Beilstein* **6** III 2061.]

Dibutyl phthalate (DBP, butyl phthalate) *[84-74-2]* **M 278.4, f -35°, b 44°/2.5x10^{-4}mm, 182°/5mm,**

206°/20mm, 340°/760mm, d_4^{20} 1.4929, d^5 1.0426, n_D^{25} 1.490. Wash DBP with H_2O (to free it from alcohol), then dilute NaOH (to remove any butyl hydrogen phthalate or acid), aqueous $NaHCO_3$ (charcoal), then distilled water. Dry it ($CaCl_2$), distil it at 10torr or less, and store it in a desiccator over P_2O_5. [*Beilstein* **9** II 586, **9** III 4102, **9** IV 3175.]

Dichloramine-T (*N,N*-dichloro-*p*-toluenesulfonamide) *[473-34-7]* **M 240.1, m 83°.** Crystallise it from petroleum ether (b 60-80°) or $CHCl_3$/petroleum ether. Dry it in air <55° and store in the dark. It is soluble in $CHCl_3$ (~1:1), *C_6H_6 (~1:1) and CCl_4 (~1:2.5). It is a germicide and antibacterial as it readily liberates chlorine, and it should not smell strongly of chlorine; otherwise it should be purified. *Alternatively*, dissolve ~15g of reagent in 75ml of hot acetic acid and precipitate it by addition of 37ml of N/10 bleaching powder solution (NaOCl), filter off, wash it with a dilute solution of the latter, dry it as above (**m** 78-84°) and recrystallise it. Excessive drying, "Sharp drying", will decompose it. [Orton & Bradfield *J Chem Soc* 993 *1927*, Krauss & Crede *J Am Chem Soc* **39** 2720 *1917*, Soper *J Chem Soc* 1899 *1924*; see also chloramine-T (monochloramine T Na salt) in "Compounds of As, B, P, S, Si.." in this Chapter.] [*Beilstein* **11** H I07, **11** I 27, **11** II 63, **11** III 301.]

2,4-Dichloroaniline *[554-00-7]* **M 162.0, m 63°, pK^{25} 2.02.** Crystallise the aniline from EtOH/water. It also crystallises from EtOH and is dried *in vacuo* for 6 hours at 40° [Moore et al. *J Am Chem Soc* **108** 2257 *1986*, Edidin et al. *J Am Chem Soc* **109** 3945 *1987*]. [*Beilstein* **12** IV 1241.]

3,4-Dichloroaniline *[95-76-1]* **M 162.0, m 71.5°, pK^{25} 2.97.** Crystallise the aniline from MeOH. [*Beilstein* **12** IV 1257.]

9,10-Dichloroanthracene *[605-48-1]* **M 247.1, m 214-215°.** Purify it by crystallising it from MeOH, EtOH, *C_6H_6 or Me_2CO (**m** 210-211°) followed by subliming *in vacuo*. [Masnori & Kochi *J Am Chem Soc* **107** 7880 *1985*, *Beilstein* **5** H 664, **5** I 324, **5** II 575, **5** III 2134, **5** IV 2293.]

2,4-Dichlorobenzaldehyde *[874-42-0]* **M 175.0, m 72°.** Crystallise the aldehyde from EtOH or ligroin. [*Beilstein* **7** IV 575.]

2,6-Dichlorobenzaldehyde *[83-38-5]* **M 175.0, m 70.5-71.5°.** Crystallise the aldehyde from EtOH/H_2O or petroleum ether (b 30-60°). [*Beilstein* **7** IV 576.]

***o*-Dichlorobenzene (ODCB)** *[95-50-1]* **M 147.0, b 81-82°/31-32mm, 180.5°/760mm, d_4^{20} 1.306, n_D^{20} 1.551, n^{25} 1.549.** Contaminants may include the *p*-isomer and trichlorobenzene [Suslick et al. *J Am Chem Soc* **106** 4522 *1984*]. It should be shaken with conc or fuming H_2SO_4, washed with water, dried with $CaCl_2$, and distilled from CaH_2 or sodium in a glass-packed column. Low conductivity material (*ca* 10^{-10} mhos) has been obtained by refluxing with P_2O_5, fractionally distilling and passing it through a column packed with silica gel or activated alumina: it is stored in a dry-box under N_2 or with activated alumina. [*Beilstein* **5** IV 654.]

***m*-Dichlorobenzene** *[541-73-1]* **M 147.0, b 173.0°/atm, d_4^{20} 1.289, n_D^{20} 1.54586, n_D^{25} 1.54337.** Wash it with aqueous 10% NaOH, then with water until neutral, dry and distil it. Conductivity material (*ca* 10^{-10} mhos) has been prepared by refluxing over P_2O_5 for 8 hours, then fractionally distilling, and storing with activated alumina. *m*-Dichlorobenzene dissolves rubber stoppers. [*Beilstein* **5** IV 657.]

***p*-Dichlorobenzene** *[106-46-7]* **M 147.0, m 53.0°, b 174.1°, d_4^{20} 1.241, n_D^{60} 1.52849.** *o*-Dichlorobenzene is a common impurity. The *p*-isomer has been purified by steam distillation, crystallisation from EtOH or boiling MeOH, air-dried and dried in the dark under vacuum. It has also been purified by zone refining. [*Beilstein* **5** IV 658.]

2,2'-Dichlorobenzidine *[84-68-4]* **M 253.1, m 165°, $pK_{Est(1)}$ ~3.0, $pK_{Est(2)}$ ~4.0.** Crystallise the benzidine from EtOH or H_2O. [*Beilstein* **13** H 234, **13** I 66, **13** II 106, **13** III 477, **13** IV 384.]

3,3'-Dichlorobenzidine *[91-94-1]* **M 253.1, m 132-133°, $pK_{Est(1)}$ ~4.8, $pK_{Est(2)}$ ~5.7.** Crystallise the benzidine from EtOH, petroleum ether (**m** 133°) or *benzene. [*Beilstein* **13** H 234, **13** I 67, **13** II 106, **13** III 477,

13 IV 384.] **CARCINOGEN.**

2,3-Dichlorobenzoic acid *[50-45-3]* **M 191.0, m 168.3°, 169-170°, pK^{25} 2.67.** Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*.] Crystallise the acid from H_2O, aqueous EtOH, or 30% aqueous AcOH and several times from *C_6H_6, then dry it *in vacuo* at 40° overnight. The *methyl ester* has **m 35-39°**. [Hope & Riley *J Chem Soc* **123** 2478 *1923*, Lock *Monatsh Chem* **90** 687 *1959*, Shorter & Mather *J Chem Soc* 4744 *1961*, *Beilstein* **9** II 228, **9** IV 998.]

2,4-Dichlorobenzoic acid *[50-84-0]* **M 191.0, m 163-164°, pK^{25} 2.68.** Crystallise the acid from aqueous EtOH (charcoal), then *benzene (charcoal). It can also be recrystallised from water. [*Beilstein* **9** IV 998.] It can be freed from isomeric acids (to <0.05%) *via* the (±)-α-methylbenzylamine salt as follows: dissolve the dichloro-acid (10g, 50.2mmol) in isopropanol (200ml), heat to 60° and add the (±)-benzylamine (5.49g, 45.3mmol), then stir it at 60° for 1 hour. Cool the mixture to room temperature, filter the slurry, wash it with isopropanol (25ml) and dry it *in vacuo* at 40° overnight to give 79% of the *salt* with **m** 185.2°. Dissolve the salt (5g) in H_2O (50ml) and MeOH (20ml), then heat to 60° and add concentrated HCl to pH <2.0. Cool the solution to room temperature add H_2O (12ml), filter it, wash it with H_2O (30ml) and dry it *in vacuo* at 40° overnight to give 94% of the *acid* with **m** 162.0°. [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*.]

2,5-Dichlorobenzoic acid *[50-79-3]* **M 191.0, m 154°, b 301°/760mm, pK^{25} 2.47.** Crystallise the acid from water. [*Beilstein* **9** IV 1005.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*.]

2,6-Dichlorobenzoic acid *[50-30-6]* **M 191.0, m 141-142°, pK^{25} 1.59.** Crystallise the acid from EtOH and sublime it *in vacuo*. [*Beilstein* **9** IV 1005.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*.]

3,4-Dichlorobenzoic acid *[51-44-5]* **M 191.0, m 206-207°, pK^{25} 3.64.** Crystallise the acid from aqueous EtOH (charcoal) or acetic acid. [*Beilstein* **9** IV 1006.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*.]

3,5-Dichlorobenzoic acid *[51-36-5]* **M 191.0, m 188°, pK^{25} 3.54.** Crystallise the acid from EtOH and sublime it in a vacuum. [*Beilstein* **9** IV 1008.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*.]

2,6-Dichlorobenzonitrile *[1194-65-6]* **M 172.0, m 145°.** Crystallise the nitrile from acetone. [*Beilstein* **9** IV 1006.]

4,4'-Dichlorobenzophenone *[90-98-2]* **M 251.1, m 145-146°.** Recrystallise it from EtOH [Wagner et al. *J Am Chem Soc* **108** 7727 *1986*]. The *oxime* has **m** 135.2-136.9° (from MeOH, Sieger & Klein *J Org Chem* **22** 953 *1957*). The *semicarbazone* has **m** 192-193° (from H_2O). [*Beilstein* **7** H 420, **7** I 228, **7** II 359, **7** III 2076, **7** IV 1376.]

2,5-Dichloro-1,4-benzoquinone *[615-93-0]* **M 177.0, m 161-162°, 163°.** Recrystallise it twice from 95% EtOH to give yellow needles [Beck et al. *J Am Chem Soc* **108** 4018 *1986*]. The *dioxime* has **m** 278°(dec). [*Beilstein* **7** H 632, **7** I 346, **7** II 580, **7** III 3376, **7** IV 2081.]

2,6-Dichloro-1,4-benzoquinone *[697-91-6]* **M 177.0, m 122-124°.** Recrystallise the quinone from petroleum ether (b 60-70°). It sublimes at 41°/17.6μ. [Carlson & Miller *J Am Chem Soc* **107** 479 *1985*, *Beilstein* **7** II 580. **7** III 3376.]

2,6-Dichlorobenzoyl chloride *[4659-45-4]* **M 209.5, m 15-17, b 122-124°/15mm, d_4^{20} 1.464.** Reflux the acid chloride for 2 hours with excess of acetyl chloride (3 volumes), distil off AcCl followed by the benzoyl chloride. Store it away from moisture. It is an **IRRITANT**. [*Beilstein* **9** III 1377.]

3,4-Dichlorobenzyl alcohol *[1805-32-9]* **M 177.0, m 38-39°, 148-151°/760mm.** Crystallise the alcohol from EtOH (**m** 32-34°) or water (**m** 38°, needles). Its solubility at 20° is 1g in 1250ml of H_2O. [*Beilstein* **6** H 445, **6** III 1558, **6** IV 2598.]

2,3-Dichloro-5,6-dicyano-*p*-benzoquinone (DDQ) *[84-58-2]* **M 227.0, m 203°(dec), 213-216°, (210-215°)(dec).** Crystallise DDQ from $CHCl_3$, $CHCl_3$/*benzene (4:1), or *benzene and store it at 0°. [Pataki & Harvey *J Org Chem* **52** 2226 *1987*, *Beilstein* **10** H 902, **10** II 635, **10** IV 3521.]

2,4-Dichloro-6-methylphenol (2,4-dichloro-*o*-cresol) *[1570-65-6]* **M 177.0, m 55°, b 111-113°/16mm, 129-132°/40mm, 231.6-231.9°/760mm, pK^{20} 8.14.** Crystallise the cresol from Et_2O (**m** 55°) or water; it has **m** 53-54° after sublimation. [*Beilstein* **6** H 359, **6** II 332, **6** III 1267, **6** IV 2001.]

2,4-Dichloro-1-naphthol *[2050-76-2]* **M 213.1, m 106-107°, pK_{Est} ~7.7.** Crystallise the naphthol from MeOH. The *1-methyl ether* has **m** 58° (from EtOH). [*Beilstein* **6** H 612, **6** I 308, **6** II 582, **6** III 2934, **6** IV 4233.]

2,3-Dichloro-1,4-naphthoquinone *[117-80-6]* **M 227.1, m 193°.** Crystallise the quinone from EtOH. [*Beilstein* **7** IV 2426.]

2,5-Dichloro-4-nitroaniline *[6627-34-5]* **M 207.0, m 153-154°, 157-158°, pK^{25} -0.74 (aqueous H_2SO_4).** Recrystallise it from EtOH, then sublime it *in vacuo*. [*Beilstein* **12** H 735, **12** II 400.]

2,6-Dichloro-4-nitroaniline (Dichloran) *[99-30-9]* **M 207.0, m 193°.** Crystallise Dichloran from aqueous EtOH or *benzene/EtOH. [*Beilstein* **12** IV 1681.]

2,5-Dichloro-1-nitrobenzene (1,4-dichloro-4-nitrobenzene) *[89-61-2]* **M 192.0, m 56°, 266-269°/atm.** Crystallise the nitrobenzene from absolute EtOH. [*Beilstein* **5** IV 726.]

3,4-Dichloro-1-nitrobenzene (1,2-dichloro-4-nitrobenzene) *[99-54-7]* **M 192.0, m 43°.** Crystallise it from absolute EtOH. [*Beilstein* **5** IV 726.]

2,4-Dichloro-6-nitrophenol *[609-89-2]* **M 208.0, m 122-123°, pK_{Est} ~5.0.** Crystallise the chloronitrophenol from AcOH. [*Beilstein* **6** IV 1358.]

2,6-Dichloro-4-nitrophenol *[618-80-4]* **M 208.0, m 125°(dec), pK^{25} 3.55.** Crystallise the chloronitrophenol from EtOH and dry it *in vacuo* over anhydrous $MgSO_4$. [*Beilstein* **6** IV 1361.]

Dichlorophen [2,2'-methylenebis(4-chlorophenol)] *[97-23-4]* **M 269.1, b 177-178°, pK_{Est} ~9.7.** Crystallise dichlorophen from toluene. [*Beilstein* **6** III 5406.]

2,3-Dichlorophenol *[576-24-9]* **M 163.0, m 57°, pK^{25} 7.70.** Crystallise it from ether. [*Beilstein* **6** IV 883.]

2,4-Dichlorophenol *[120-83-2]* **M 163.0, m 42-43°, pK^{25} 7.89.** Crystallise it from petroleum ether (b 30-40°). Purify it also by repeated zone melting, using a P_2O_5 guard tube to exclude moisture. It is very *hygroscopic* when dry. [*Beilstein* **6** IV 885.]

2,5-Dichlorophenol *[583-78-8]* **M 163.0, m 58°, b 211°/744mm, pK^{25} 7.51.** Crystallise it from ligroin and sublime it in a vacuum or distil it. [*Beilstein* **6** IV 942.]

3,4-Dichlorophenol *[95-77-2]* **M 163.0, m 68°, b 253.5°/767mm, pK^{25} 8.58.** Crystallise 3,4- dichlorophenol

from petroleum ether/*benzene mixture and/or distil it. [*Beilstein* **6** IV 952.]

3,5-Dichlorophenol *[591-35-5]* **M 163.0, m 68°, b 122-124°/8mm, 233-234°/760mm, pK^{25} 8.81.** Crystallise 3,5-dichlorophenol from petroleum ether/*benzene mixture and/or distil it. [*Beilstein* **6** IV 957.]

2,4-Dichlorophenoxyacetic acid (2,4-D) *[94-75-7]* **M 221.0, m 146°, pK^{25} 2.90.** Crystallise 2,4-D from MeOH. It is a plant growth substance, a herbicide and is **TOXIC.** [*Beilstein* **6** IV 908.]

(±)-α-(2,4-Dichlorophenoxy)propionic acid (2,4-DP, Dichloroprop) *[120-36-5]* **M 235.1, m 117°, pK^{20} 2.86.** Crystallise 2,4-DP from MeOH. It is a plant growth substance, a herbicide and is **TOXIC.** The *R(+)- and S(–)- enantiomers* have **m** 124° (from *C_6H_6) and $[\alpha]_D^{25}$ ±35.2° (c 1, Me_2CO). [*Beilstein* **6** H 189, **6** III 708, **6** IV 922-923.]

2,4-Dichlorophenylacetic acid *[19719-28-9]* **M 205.0, m 131°, 132-133°, pK$_{Est}$ ~4.0.** Crystallise the acid from aqueous EtOH. [*Beilstein* **9** III 2271.]

2,6-Dichlorophenylacetic acid *[6575-24-2]* **M 205.0, m 157-158°, pK$_{Est}$ ~3.8.** Crystallise the acid from aqueous EtOH. [*Beilstein* **9** III 2272.]

3-(3,4-Dichlorophenyl)-1,1-dimethyl urea (Diuron) *[330-54-1]* **M 233.1, m 153-154°, 155°.** Recrystallise it from 95% EtOH [Beck et al. *J Am Chem Soc* **108** 4018 *1986*]. [*Beilstein* **12** IV 1263.]

4,5-Dichlorophthalic acid *[56962-08-4]* **M 235.0, m 200° (dec to anhydride), pK$_{Est(1)}$ 2.2, pK$_{Est(2)}$~4.7.** Crystallise the acid from water. It has been purified by converting to the anhydride, reacting it with boiling EtOH to form the *monoethyl ester* (**m** 133-134°), and hydrolysing it back to the diacid (see next entry). [*Beilstein* **9** III 4205.]

3,6-Dichlorophthalic anhydride *[4466-59-5]* **M 189-191°, 191-191.5°, b 339°.** Boil the anhydride in xylene (allowing any vapours which would contain H_2O to be removed, e.g. Dean and Stark trap), which causes any acid present to dehydrate to the anhydride, and cool. Recrystallise it from xylene [Villiger *Chem Ber* **42** 3539 *1909*, Fedoorow *Izv Akad Nauk SSSR Otd Khim Nauk* 397 *1948*, *Chem Abstr* 1585 *1948*]. [*Beilstein* **17/11** V 260.]

2,6-Dichlorostyrene *[28469-92-3]* **M 173.0, m 8°, b 72-73°/2mm, d_4^{20} 1.4045, n_D^{20} 1.5798.** Purify the styrene by fractional crystallisation from the melt and by distillation *in vacuo*. [*Beilstein* **5** III 1174.]

2,4-Dichlorotoluene *[95-73-8]* **M 161.1, m -13.5°, b 61-62°/3mm, d_4^{20} 1.250, n_D^{20} 1.5513.** Recrystallise 2,4-dichlorotoluene from EtOH at low temperature or fractionally distil it. [*Beilstein* **5** IV 815.]

2,6-Dichlorotoluene *[118-69-4]* **M 161.1, b 199-200°/atm, d_4^{20} 1.254, n_D^{20} 1.548.** Fractionally distil it and collect the middle fraction. [*Beilstein* **5** IV 815.]

3,4-Dichlorotoluene *[95-75-0]* **M 161.1, m -16°, b 205°/atm, d_4^{20} 1.2541, n_D^{20} 1.549.** Recrystallise it from EtOH at very low temperature or fractionally distil it. [*Beilstein* **5** IV 815.]

α,α'-Dichloro-*p*-xylene *[623-25-6]* **M 175.1, m 100°, 254°/atm.** Crystallise the xylene from *benzene and dry it under vacuum. [*Beilstein* **5** IV 967.]

Dicinnamalacetone (1,9-diphenyl-1,3,6,8-nonatetraen-5-one) *[622-21-9]* **M 314.4, m 144°, 146°.** Crystallise the ketone from *benzene/isooctane (1:1). The *1,3,5-trinitrobenzene complex* (1:1) has **m** 113° (from EtOH), and the *1,3,5-trinitrobenzene complex* (1:2) has **m** 110° (from EtOH). [*Beilstein* **7** H 524, **7** I 293, **7** II 484, **7** III 2756, **7** IV 1834.] The *2,4-dinitrophenylhydrazone* has **m** 199-200°.

Dicumyl peroxide *[80-43-3]* **M 270.4, m 39-40°.** Crystallise the peroxide from 95% EtOH (charcoal). Store

it at 0°. *Potentially* **EXPLOSIVE.** [*Beilstein* **6** IV 3220.]

9,10-Dicyanoanthracene *[1217-45-4]* **M 228.3, m 340°.** Recrystallise the dinitrile twice from pyridine [Mattes & Farid *J Am Chem Soc* **108** 7356 *1986*]. [*Beilstein* **9** IV 3667.]

1,4-Dicyanobenzene (terephthalonitrile) *[623-26-7]* **M 128.1, m 222°.** Crystallise the dinitrile from EtOH or AcOH, and has **m** 221.5-222.5° after sublimation. [*Beilstein* **9** H 846, **9** I 376, **9** II 613, **9** III 4255, **9** IV 3328.]

1,4-Dicyanonaphthalene *[3029-30-9]* **M 178.2, m 206°.** Purify it by recrystallisation from EtOH (charcoal), **m** 208°, and sublime it *in vacuo*. [Bradbrook & Linstead *J Chem Soc* 1742 *1936*, *Beilstein* **9** H 917, **9** II 651, **9** III 464.]

***trans*-4-(Diethylamino)azobenzene** *[3588-91-8]* **M 320.5, m 171° pK^{26} 3.08 (50% aqueous EtOH).** Purify the azobenzene by column chromatography on alumina, elute with, and crystallise it from, toluene, [Albini et al. *J Chem Soc Perkin Trans 2* 1393 *1982*, Flamigni & Monti *J Phys Chem* **89** 3702 *1985*]. The *deoxycholate (1:4) complex* has **m** 194-194° (from EtOH). [*Beilstein* **16** H 341, **16** I 311, **16** III 342, 16 IV 455.]

***N,N*-Diethylaniline** *[91-66-7]* **M 149.2, b 216.5°/atm, d_4^{20} 0.938, n_D^{20} 1.5409 pK^{25} 6.57.** Reflux the base for 4 hours with half its weight of acetic anhydride, then fractionally distil it under reduced pressure (**b** 92°/10mm). [*Beilstein* **12** IV 252.]

Di-(2-ethylhexyl)phthalate ('di-iso-octyl' phthalate) *[117-81-7]* **M 390.6, b 384°, 256-257°/1mm, d_4^{20} 0.9803, n_D^{20} 1.4863.** Wash the ester with Na_2CO_3 solution, then shake it with water. After the resulting emulsion has been broken by adding ether, the ethereal solution is washed twice with water, dried ($CaCl_2$), and evaporated. The residual liquid is distilled several times under reduced pressure, then stored in a vacuum desiccator over P_2O_5 [French & Singer *J Chem Soc* 1424 *1956*]. [*Beilstein* **9** IV 3184.]

Diethyl phenyl orthoformate (diethoxy phenoxy ethane) *[14444-77-0]* **M 196.3, b 111°/11mm, 122°/13mm, d_4^{20} 1.0099, n_D^{20} 1.4799.** Fractionate the ortho-ester through an efficient column under vacuum [Smith *Acta Chem Scand* **10** 1006 *1956*].

Diethyl phthalate *[84-66-2]* **M 222.2. b 172°/12mm, b 295°/760mm, d_4^{25} 1.1160, n 1.5022.** Wash the ester with aqueous Na_2CO_3, then distilled water, dry ($CaCl_2$), and distil it under reduced pressure. Store it in a vacuum desiccator over P_2O_5. [*Beilstein* **9** IV 3172.]

Diethyl 2-phthalimidomalonate *[56680-61-5]* **M 305.3, m 72-74°, 73-74°, pK^{25} 9.17.** Dissolve it in xylene and when the temperature is 30° add petroleum ether (b 40-60°) and cool to 20° whereby the malonate separates as a pale brown powder [Booth et al. *J Chem Soc* 666 *1944*]. *Alternatively*, dissolve it in *C_6H_6, dry it over $CaCl_2$, filter, evaporate and the residual oil solidifies. Grind this with Et_2O, filter and wash it with Et_2O until white in colour, and dry it in a vacuum. It forms a yellow *sodium salt* **m** 280°(dec). The anion has λ_{max} at 254nm (ε 18.5K) [Clark & Murray *Org Synth* Coll Vol **I** 271 *1941*, UV of Na salt: Nnadi & Wang *J Am Chem Soc* **92** 4421 *1970*]. [*Beilstein* **21** H 487, **21** I 379, **21** III/IV 5264.]

Diethylstilboesterol [stilbesterol, stilboesterol, (*E*)-3,4-bis(4-hydroxyphenyl)-3-hexene] *[56-23-1]* **M 268.4, m 169-172°.** Crystallise stilbesterol from *benzene. [*Beilstein* **6** IV 6856.]

Diethyl terephthalate *[636-09-0]* **M 222.2, m 44°, 142°/2mm, 302°/760mm.** Crystallise the ester from toluene and distil it under reduced pressure. [*Beilstein* **9** H 8, **9** I 374, **9** III 4250, **9** IV 3304.]

4,4'-Di-*n*-heptyloxyazoxybenzene *[2635-26-9]* **M 426.6, m 75°, 95° (smectic ∅ nematic) and 127° (nematic ∅ liquid), pK_{Est} ~ -5.** Purify azoxybenzene by chromatography on Al_2O_3 (*benzene), recrystallise it from hexane or 95% EtOH and dry it by heating under vacuum. The liquid crystals can be sublimed *in vacuo*. [Mellifiori et al. *Spectrochim Acta Part A* **37(A)** 605 *1981*, Dewar & Schroeder *J Am Chem Soc* **86** 5235 *1964*, Weygand & Glaber *J Prakt Chem* **155** 332 *1940*, *Beilstein* **16** III 600, **16** IV 5264.]

9,10-Dihydroanthracene *[613-31-0]* **M 180.3, m 110-110.5°, b ~312°/atm, d_4^{20} 0.880.** Crystallise it from EtOH [Rabideau et al. *J Am Chem Soc* **108** 8130 *1986*]. [*Beilstein* **5** H 641, **5** IV 2182.]

Dihydrochloranil (tetrachloro-1,4-hydroquinone) *[87-87-6]* **M 247.9, m 240.5°.** Crystallise the quinone from EtOH or AcOH/EtOH. Sublime it at 77°/0.6x10^{-3}mm. The *dibenzoyl* derivative has **m** 233°. [Conant & Fieser *J Am Chem Soc* **45** 2207 *1923*, Rabideau et al. *J Am Chem Soc* **108** 8130 *1986*, *Beilstein* **6** H 851, **6** I 417, **6** II 846, **6** III 4436, **6** IV 5775.]

1,4-Dihydro-1,4-epoxynaphthalene *[573-57-9]* **M 144.2, m 53-54.5°, 53-56°, 55-56°.** Dissolve it in Et_2O, wash it with H_2O, dry it over K_2CO_3, filter, evaporate and dry the residue at 15mm, then recrystallise it from petroleum ether (b 40-60°), dry it at 25°/0.005mm and sublime it (sublimes slowly at room temperature)[Wittig & Pohmer *Chem Ber* **89** 1334 *1956*, Gilman & Gorsich *J Am Chem Soc* **79** 2625 *1957*]. [*Beilstein* **17** III/IV 548.]

1,8-Dihydroxyanthraquinone (Danthrone) *[117-10-2]* **M 240.1, m 193-197°, pK_1^{25} 8.30, pK_2^{25} 12.46.** Crystallise Danthrone from EtOH and sublime it in a vacuum. [*Beilstein* **8** IV 3217.]

2,4-Dihydroxyazobenzene (Sudan orange G) *[2051-85-6]* **M 214.2, m 143-146°, 228°, $pK_{Est(1)}$ <0, $pK_{Est(2)}$ ~7.3, $pK_{Est(3)}$ ~9.3.** Crystallise the dye from hot EtOH (charcoal). Has UV max at 350nm. [*Beilstein* **16** IV 264.]

2,3-Dihydroxybenzaldehyde *[24677-78-9]* **M 138.1, m 135-136°, pK_1^{20} 7.73, pK_2^{20} 10.91.** Crystallise the aldehyde from water. [*Beilstein* **8** III 1979.]

2,4-Dihydroxybenzoic acid (β-resorcylic acid) *[89-86-1]* **M 154.1, m 226-227°(dec), pK_1^{25} 3.30, pK_2^{25} 9.12, pK_3^{25} 15.6.** Crystallise the acid from water. [*Beilstein* **10** IV 1420.]

2,5-Dihydroxybenzoic acid (Gentisic acid, 5-hydroxysalicylic acid) *[490-79-9]* **M 154.1, m 204.5-205°, pK^{25} 2.95.** Crystallise gentisic acid from hot water or *benzene/acetone. Dry it in a vacuum desiccator over silica gel. [*Beilstein* **10** H 384, **10** IV 1441.]

2,6-Dihydroxybenzoic acid (γ-resorcylic acid) *[303-07-1]* **M 154.1, m 167°(dec), pK^{25} 1.05.** Dissolve the acid in aqueous $NaHCO_3$ and the solution is washed with ether to remove non-acidic material. The acid is precipitated by adding H_2SO_4, and recrystallised from water. Dry it under vacuum and store it in the dark [Lowe & Smith *J Chem Soc, Faraday Trans 1* **69** 1934 *1973*]. [*Beilstein* **10** IV 1456.]

2,4-Dihydroxybenzophenone *[131-56-6]* **M 214.2, m 145.5-147° $pK_{Est(1)}$ ~7.0, $pK_{Est(2)}$ ~12.0.** Recrystallise it from MeOH. [*Beilstein* **8** IV 2442.]

4,4'-Dihydroxybenzophenone *[611-99-4]* **M 214.2, m 210°, 213-214°, 213-215°, 216.6-217.1°, pK_{Est} ~7.0.** The benzophenone was prepared by a Friedel-Crafts reaction between 4-methoxybenzoyl chloride and anisole with anhydrous $AlCl_3$ in anhydrous CS_2, followed by demethylation with $AlCl_3$ in boiling toluene. It could also be made directly from 4-hydroxybenzoic acid and an equivalent of phenol by heating with three parts of freshly fused anhydrous $ZnCl_2$ at 125-140° for 45 minutes; the cooled mass is treated with dilute HCl, the solid is filtered off, washed thoroughly with aqueous $NaHCO_3$ solution, H_2O, dried *in vacuo* and recrystallised from H_2O, aqueous EtOH, or dilute HCl. [Russell & Butler *J Am Chem Soc* **71** 3663 *1949*.] The *oxime* has **m 266-267° (dec) [**Zigeuner & Ziegler *Monatsh für Chemie* **89** 359 *1949*], and the *2,4-dinitrophenylhydrazone* has **m 190-192°** (from EtOH). [*Beilstein* **8** H 316, **8** I 641, **8** II 355, **8** III 2648, **8** IV 2452.]

2,5-Dihydroxybenzyl alcohol (Gentisyl alcohol) *[495-08-9]* **M 140.1, m 47-48°, $pK_{Est(1)}$ ~9.3, $pK_{Est(2)}$ ~11.3.** Crystallise the alcohol from ligroin, $CHCl_3$, AcOH or H_2O. Sublime it at ~70° under high vacuum. [*Beilstein* **6** II 1084, **6** III 6326.]

2,2'-Dihydroxybiphenyl *[1806-29-7]* **M 186.2, m 108.5-109.5°, pK_1^{25} 7.56, pK_2^{25} 11.80.** Crystallise the biphenyl repeatedly from toluene, then sublime it at 60°/10^{-4}mm. [*Beilstein* **6** IV 6645.]

4.4'-Dihydroxybiphenyl (4,4'-biphenol) *[92-88-6]* **M 186.2, m 280.5°, 280-285°, $pK_{Est(1)}$ ~3.6, $pK_{Est(2)}$ ~11.8.** Recrystallise the biphenol from aqueous EtOH preferably under N_2 to avoid oxidation to the extended qiunone. It is characterized as the *dimethyl derivative (4,4'-dimethoxybiphenyl)* from which it is prepared by demethylation. The dimethoxy derivative has **m** 176.5-177° (from AcOH, EtOH, hexane or $*C_6H_6$) and sublimes *in vacuo*. [Williamson & Rodebush *J Am Chem Soc* **63** 3019 *1941*, *Beilstein* **6** I 485, **6** II 962, **6** III 6389, **6** IV 6651.]

1,8-Dihydroxy-3-methylanthraquinone (chrysophanic acid) *[481-74-3]* **M 245.3, m 196°, $pK_{Est(1)}$ ~8.2, $pK_{Est(2)}$ ~12.4.** Crystallise chrysophanic acid from EtOH or *benzene and has **m** 195.6-196.2°, after sublimation it in a vacuum. The yellow *mono-acetate* has **m** 188-190° (from MeOH or Me_2CO). It forms Ni^{2+}, Co^{2+} and Cu^{2+} complexes. [*Beilstein* **8** H 470, **8** I 725, **8** II 510, **8** III 3808, **8** IV 3277.]

1,5-Dihydroxynaphthalene (1,5-naphthalenediol) *[83-56-7]* **M 160.7, m 258°, 260°, 265°, $pK_{Est(1)}$ ~9.0, $pK_{Est(2)}$ ~11.0.** The diol (~30g) is purified by making into a thick paste with H_2O and suspending this in 3L of H_2O containing 200ml of EtOH, boiling under reflux for 3 hours, cooling to 30°, saturating with SO_2, digesting below the boiling point for 1 hour and filtering fast through a large hot filter paper. The hot filtrate is poured onto crushed ice whereby the diol (15-20g) separates as colourless needles (**m** 258°) [Wheeler & Ergle *J Am Chem Soc* **52** 4873 *1930*]. Recrystallise it from H_2O or nitromethane under N_2 to avoid oxidation. The *dibenzoyl* derivative has **m** 245° (from EtOH). The *5-methoxy-1-naphthol* derivative [prepared from the diol in MeOH/HCl (1:30 weight to volume ratio) and set aside at 25° for 9-10days] crystallised from petroleum ether (**m 135-136°**) or from CH_2Cl_2/hexane (needles **m 140°**) [Bell & McCaffrey *Aust J Chem* **46** 731 *1993*]. [*Beilstein* **6** I 477, **6** II 950, **6** III 5265, **6** IV 6554.]

1,6-Dihydroxynaphthalene *[575-44-0]* **M 160.2, m 138-139° (with previous softening), pK_{Est} ~9.4.** Crystallise it from *benzene or *benzene/EtOH after treatment with charcoal. [*Beilstein* **6** IV 6557.]

2,5-Dihydroxyphenylacetic acid (homogentisic acid) *[451-13-8]* **M 168.2, m 152°, 154-152°, pK^{20} 4.14 (COOH).** Crystallise homogentisic acid from EtOH/$CHCl_3$ or H_2O (solubility is 85% at 25°). [*Beilstein* **10** IV 1506.]

3,4-Dihydroxytoluene (4-methylcatechol) *[452-86-8]* **M 124.1, m 65-66°, 68°, b 112°/3mm, 241°/760mm, pK_1^{25} 9.44 (9.7), pK_2^{25} 10.90 (11.9).** Crystallise the catechol from $*C_6H_6$. The purity is checked by TLC. Crystallise it from high-boiling petroleum ether and distil it in a vacuum. [*Beilstein* **6** IV 5878.]

1,4-Diiodobenzene *[624-38-4]* **M 329.9, m 132-133°.** Crystallise it from EtOH or boiling MeOH, then dry it in air. [*Beilstein* **5** IV 700.]

***trans*-4,4'-Dimethoxyazobenzene** *[501-58-6]* **M 242.3, m 162.7-164.7°, 165-166°, pK_{Est} ~0.** Chromatograph it on basic alumina and elute with *benzene. Then crystallise the residue from 2:2:1 (v/v) methanol/ethanol/*benzene or Me_2CO. [*Beilstein* **16** H 112, **16** I 237, **16** II 43, **16** III 93, **16** IV 172.]

3,5-Dimethoxybenzaldehyde *[7331-34-4]* M 166.2, **m 45.5°, 46-47°, 45-48°, b 151°/16mm.** The aldehyde was prepared by reduction of the corresponding acid chloride with 5%Pd/$CaCO_3$ in xylene, and was purified by distillation in a vacuum and by recrystallisation from hexane (**m 48°**), ligroin, petroleum ether (**m 45-46°**) or 70% aqueous EtOH. The *oxime* (**m 115°**) crystallises from $*C_6H_6$, the *thiosemicarbazone* (**m 211-212°**) crystallises from aqueous EtOH, and the *2,4-dinitrophenylhydrazone* (**m 260-261°**) forms orange needles from aqueous EtOH. [Mongolusk et al. *J Chem Soc* 2231 *1957*, Lambooy *J Am Chem Soc* **76** 133 *1954*, *Beilstein* **8** II 291, **8** III 2073, **8** IV 1786.]

1,2-Dimethoxybenzene (veratrole) *[91-16-7]* **M 137.2, m 23°, b 208.5-208.7, d_4^{20} 1.085, n_D^{25} 1.53232.** Steam distil veratrole, then fractionally distil it from BaO, CaH_2 or Na. Crystallise it from *benzene or low-boiling petroleum ether at 0°. Fractionally crystallise it from its melt. Store it over anhydrous Na_2SO_4. [*Beilstein* **6** IV 5564.]

1,3-Dimethoxybenzene *[151-10-0]* **M 137.2, b 212-213°, d_4^{20} 1.056, n_D^{20} 1.5215.** Extract it with aqueous NaOH, and water, then dry it. Fractionally distil it from BaO or Na. [*Beilstein* **6** IV 5663.]

1,4-Dimethoxybenzene *[150-78-7]* **M 137.2, m 57.2-57.8°.** Steam distil 1,4-dimethoxybenzene, then crystallise it from hexane or *benzene, and from MeOH or EtOH, but these are wasteful due to high solubilities. Dry it under vacuum. It also sublimes under vacuum. [*Beilstein* **6** IV 5718.]

2,4-Dimethoxybenzoic acid *[91-52-1]* **M 182.2, m 107.3°, 109°, pK^{25} 4.36.** Crystallise the acid from water and dry it in a vacuum desiccator over H_2SO_4. The *S-benzylisothiuronium salt* has **m** 158-159° (from $CHCl_3$). [*Beilstein* **10** H 379, **10** I 177, **10** II 252, **10** III 1371, **10** IV 1422.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*.]

2,6-Dimethoxybenzoic acid *[1466-76-8]* **M 182.2, m 186-187°, 188-191°, pK^{25} 3.44.** Crystallise the acid from water or 1,1-dichloroethane (**m** 187.5-188.5°). [*Beilstein* **10** H 388, **10** I 185, **10** II 259, **10** III 1401, **10** IV 1456.]

3,4-Dimethoxybenzoic acid (veratric acid) *[93-07-2]* **M 182.2, m 181-182°, 185-186°, pK^{25} 4.43.** Crystallise the acid from Et_2O, H_2O or aqueous acetic acid. It has **m** 180-181° after sublimation at 80°/1mm. [*Beilstein* **10** H 393, **10** I 188, **10** II 261, **10** III 1404, **10** IV 1406.]

3,5-Dimethoxybenzoic acid *[1132-21-4]* **M 182.2, m 185-186°, pK^{25} 3.97.** Crystallise the acid from water, EtOH or aqueous acetic acid and dry it in a vacuum. [*Beilstein* **10** H 405, **10** I 195, **10** III 1446, **10** IV 1501.]

p,p'-**Dimethoxybenzophenone** *[90-96-0]* **M 242.3, m 144.5°.** Crystallise the ketone from absolute EtOH, aqueous EtOH or EtOH/AcOH. The *2,4-dinitrophenylhydrazone* has **m** 199-200°. [*Beilstein* **8** H 317, **8** I 641, **8** II 355, **8** III 2649, **8** IV 2453.]

2,6-Dimethoxy-1,4-benzoquinone *[530-55-2]* **M 168.1, m 255-256°, 256°(dec), 262-263°.** Crystallise the quinone from H_2O or acetic acid. It sublimes at 175-180°/1mm. It has UV with λ_{max} at 287 and 377nm ($CHCl_3$). [*Beilstein* **8** H 385, **8** I 683, **8** II 433, **8** III 3354, **8** IV 2710,]

5,6-Dimethoxy-1-indanone *[2107-69-9]* **M 192.2, m 118-120°.** Crystallise the indanone from MeOH, then sublime it in a vacuum. [*Beilstein* **8** IV 1985.]

1,4-Dimethoxynaphthalene *[10075-62-4]* **M 188.2, m 87-88°.** Crystallise the naphthalene from EtOH, MeOH (**m** 85-86°) or petroleum ether. [*Beilstein* **6** H 984, **6** III 5261, **6** IV 6546.]

1,5-Dimethoxynaphthalene *[10075-63-5]* **M 188.2, m 183-184°, b 179°/13mm.** Crystallise it from EtOH, AcOH (**m** 178-180°) or $*C_6H_6$. Also distil it in a vacuum. [*Beilstein* **6** III 5266, **6** IV 6554.]

3,4-Dimethoxy-6-nitrobenzaldehyde (6-nitroverataldehyde) *[20357-25-9]* **M 211.2, m 132°, 133.5-134.5°.** The aldehyde is purified by dissolving 9g in 200ml of boiling 95% EtOH, and set aside overnight to crystallise. It is then dried *in vacuo* at 50° and recrystallised from 110ml of 95% EtOH to give 6-7g of aldehyde with **m** 132-133°. Crystallisation from aqueous EtOH provides light yellow needles. It is light sensitive and should be stored in the dark [Fetscher *Org Synth* Coll Vol **4** 735 *1963*]. [*Beilstein* **8** H 262, **8** I 610, **8** II 290, **6** III 2065, **6** IV 1785.]

2,6-Dimethoxyphenol (pyrogallol-1,3-diethylether) *[91-10-1]* **M 154.2, m 54-56°, pK_{Est} ~9.6.** Purify the phenol by zone melting or sublimation in a vacuum. [*Beilstein* **6** IV 7329.]

3,5-dimethoxyphenol (phloroglucinol dimethylether) *[500-99-2]* **M 154.2, m 42-43°, b 115°/0.04mm, pK^{25} 9.35.** Purify the phenol by distillation followed by sublimation in a vacuum. [*Beilstein* **6** IV 7362.]

3,4-Dimethoxyphenyl acetic acid (homoveratric acid) *[93-40-3]* **M 196.2, m 97-99°, pK^{25} 4.33.** Crystallise homoveratric acid from H_2O or *C_6H_6/ligroin. The *amide* has **m** 142° (from H_2O). [*Beilstein* **10** H 409, **10** I 197, **10** II 268, **10** III 1459, **10** IV 1509.]

3,5-Dimethoxyphenylacetonitrile *[13388-75-5]* **M 177.1, m 53°.** Crystallise the nitrile from MeOH or petroleum ether (b 90-110°). [Adams et al. *J Am Chem Soc* **70** 664 *1948*, Sankaraman et al. *J Am Chem Soc* **109** 5235 *1987*, *Beilstein* **10** I 198, **10** II 269, **10** III 1470.]

4,4'-Dimethoxythiobenzophenone *[958-80-5]* **M 258.3, m 120°.** Recrystallise the thioketone from a mixture of cyclohexane/dichloromethane (4:1) or EtOH (**m** 119°). [Bergmann & Wagenberg *Chem Ber* **63** 2590 *1930*, *Beilstein* **8** H 319, **8** II 355, **8** III 2658, **8** IV 2457.]

2,6-Dimethoxytoluene *[5673-07-4]* **M 152.2, m 39-41°, b 97-99°/15mm, 219-220°/731mm.** Sublime 2,6-dimethoxytoluene *in vacuo*. Distil it (preferably under reduced pressure) and/or recrystallise it from pentane, EtOH or aqueous MeOH. [Sankaraman et al. *J Am Chem Soc* **109** 5235 *1987*]. [*Beilstein* **6** H 872, **6** III 4513, **6** IV 5877.]

4,4'-Dimethoxytrityl chloride (DMT) *[40615-36-9]* **M 338.8, m 114°.** DMT crystallises from cyclohexane/acetyl chloride as the hydrochloride. Dry it over KOH pellets in a desiccator. When dissolved in *C_6H_6 and air is blown through, HCl is removed. It crystallises from Et_2O. [Baeyer & Villiger *Chem Ber* **36** 2788 *1903*, Smith et al. *J Am Chem Soc* **84** 430 *1962*, Smith et al. *J Am Chem Soc* **85** 3821 *1963*.] If it has hydrolysed considerably (see OH in IR), then repeat the crystallisation from cyclohexane/acetyl chloride — excess of AcCl is removed in a vacuum over KOH, then recrystallise it from Et_2O. [*Beilstein* **6** IV 1042.]

***p*-Dimethylaminoazobenzene (Dimethyl Yellow)** *[60-11-7]* **M 225.3, m 118-119°(dec), pK$_1^{25}$ -5.34 (aqueous H_2SO_4), pK$_2^{25}$ 2.96.** Crystallise the dye from acetic acid or isooctane, or from 95% EtOH by adding hot water and cooling. Dry it over KOH under vacuum at 50°. [*Beilstein* **6** IV 448.] **CARCINOGEN.**

4-*N*,*N*′-Dimethylaminoazobenzene-4'-isothiocyanate {DABITC, 4-[(4-isocyanatophenyl)-azo]-*N*,*N*′-dimethylaniline} *[7612-98-8]* **M 282.4, m 170-171°, pK$_{Est}$~2.5.** Crystallise DABITC by dissolving 1g in 150ml of boiling Me_2CO, filtering hot and allowing to cool at -20° overnight, collecting the solid and drying it in a vacuum. Solutions in pyridine should be used immediately, otherwise it decomposes. It is moisture sensitive. [Chang *Methods Enzymol* **91** 79, 455 *1983*.]

***p*-Dimethylaminobenzaldehyde (Ehrlich's Reagent, DMAB)** *[100-10-7]* **M 149.2, m 74-75°, pK$_{Est}$ ~2.6.** Crystallise DMAB from water, hexane, or from EtOH (2ml/g), after charcoal treatment, by adding excess of water. *Alternatively*, dissolve it in aqueous acetic acid, filter, and precipitate it with ammonia. Finally recrystallise it from EtOH. It is used for the detection of pyrroles [Iyer et al. *J Org Chem* **59** 6038 *1994*]. [*Beilstein* **14** IV 51.]

***p*-Dimethylaminobenzoic acid** *[619-84-1]* **M 165.2, m 242.5-243.5°(dec), pK$_1$ 2.51, pK$_2$ 6.03.** Crystallise the acid from EtOH/water. [*Beilstein* **14** IV 1164.]

***p*-Dimethylaminobenzophenone** *[530-44-9]* **M 225.3, m 92-93°, pK$_{Est}$ ~2.7.** Crystallise the pale green *p*-dimethylaminobenzophenone from EtOH. Dissolve 100g in 600ml of boiling EtOH, add 5g of charcoal, cool, isolate the solid by centrifugation and similarly wash the pale crystals with ice-cold EtOH. When filtered by suction, EtOH solution remains on the crystals and turns deep green in air. Dry it in a vacuum and store it in the dark. The *hydrazone* has **m** 128-130° and forms a ketyl with potassium. [Hurd & Webb *Org Synth* Coll Vol **I** 217 *1941*, *Beilstein* **14** H 82, **14** I 288, **14** III 218, **14** IV 248.]

***N*,*N*-Dimethylamino-*p*-chlorobenzene (*p*-chloro-*N*,*N*-dimethylaniline)** *[698-69-1]* **M 155.6, m 32-33.5°, 35.5°, b 231°/atm.** Purify it by vacuum sublimation [Guarr et al. *J Am Chem Soc* **107** 5104 *1985*]. The *picrate* has **m** 126-128° (from methanol).

4-Dimethylamino cinnamaldehyde *[6203-18-5]* **M 175.2, m 141°.** The aldehyde crystallises from EtOH or ligroin and is dried *in vacuo*. The *oxime* has **m** 157° (from ligroin). The *phenylhydrazone* has **m** 169° (form MeOH). It is used as a reagent for amines (with NH_3, UV has λmax at 630nm). [König et al. *Chem Ber* **61** 2075 *2075,* Quareshi & Kahn *Anal Chim Acta* **86** 309 *1976*, *Beilstein* **14** III 184, **14** IV 197.]

4-Dimethylamino cinnamic acid *[1552-96-1]* **M 191.2, m 225° (effervesces), $pK_{Est(1)}$ ~2.2, $pK_{Est(2)}$ ~4.6.** Recrystallise the acid from EtOH. The *methyl ester* has **m** 134-135° (from Me_2CO), and the *ethyl ester* has **m** 77-78° (from aqueous EtOH). [Shoppee *J Chem Soc* 982 *1938*, Galat *J Am Chem Soc* **68** 376 *1946*, *Beilstein* **14** H 522, **14** II 318, **14** III 1306, **14** IV 1716.]

2*S*,3*R*-(+)-4-Dimethylamino-1,2-diphenyl-3-methyl-2-butanol *[38345-66-3]* **M 283.4, m 55-57°, $[\alpha]_{546}^{20}$+9.3° (c 9.6, EtOH), $[\alpha]_D^{20}$ +7.7° (c 9.6, EtOH), pK_{Est} ~10.0.** Purify the *hydrochloride* by dissolving 1.5g in 13.5 ml of 5N HCl, heat to boiling and evaporate in a vacuum. Recrystallise the *hydrochloride* three times from MeOH/EtOAc giving **m** 189-190°, $[\alpha]_D$ -33.7° (c 1, H_2O) {enantiomer has +34.2°}. The *hydrochloride* in the minimum volume of water is basified with aqueous 5N NaOH and extracted with Et_2O. The extract is dried (K_2CO_3) and evaporated, leaving a residue which is stored in a desiccator over solid KOH as a low melting solid. It can be recovered using these procedures from asymmetric reductions with LAH, and re-used. [Pohland & Sullivan *J Am Chem Soc* **77** 3400 *1955*, Sullivan et al. *J Org Chem* **28** 2483 *1963*, *Beilstein* **13** IV 2221.]

***N*,*N*-Dimethylaniline** *[121-69-7]* **M 121.2, f 2°, b 84°/15mm, 193°/760mm, d_4^{20} 0.956, n_D^{25} 1.5556, pK^{25} 5.07.** Primary and secondary amines (including aniline and monomethylaniline) can be removed by refluxing for 4-5 hours with excess acetic anhydride, and then fractionally distilling. Crocker and Jones (*J Chem Soc* 1808 *1959*) used four volumes of acetic anhydride, then distilled off the greater part of it, and dissolved the residue in ice-cold dilute HCl. Non-basic materials were removed by ether extraction, then the dimethylaniline was liberated with ammonia, extracted with ether, dried, and distilled under reduced pressure. Metzler and Tobolsky (*J Am Chem Soc* **76** 5178 *1954*) refluxed with only 10% (w/w) of acetic anhydride, then cooled and poured it into excess 20% HCl, which, after cooling, was extracted with diethyl ether. (The amine hydrochloride remains in the aqueous phase.) The HCl solution was cautiously made alkaline to phenolphthalein, and the amine layer was drawn off, dried over KOH and fractionally distilled under reduced pressure, under nitrogen. Suitable drying agents for dimethylaniline include NaOH, BaO, $CaSO_4$, and CaH_2.
Other purification procedures include the formation of the *picrate* (**m** 163° from Me_2CO or EtOH/H_2O), prepared in *benzene solution and crystallised to constant melting point, then decomposed with warm 10% NaOH and extracted into ether: the extract was washed with water and distilled under reduced pressure. The *oxalate* salt has also been used for purification. The base has been fractionally crystallised by partial freezing and also from aqueous 80% EtOH then from absolute EtOH. It has been distilled from zinc dust, under nitrogen. [*Beilstein* **12** H 141, **12** I 151, **12** II 2, **12** III 245, **12** IV 243.]

2,3-Dimethylaniline [2,3-xylidine (*vic, o*)] *[87-59-2]* **M 121.2, m 2°, b 106°/15mm, 223°/760mm, d_4^{20} 1.570, n_D^{20} 0.991, pK^{25} 4.70.** Purify *vic*-xylidine by conversion into a derivative (see below), recrystallise the derivative, decompose the derivative with aqueous NaOH and fractionally distil the liquid base. The *acetyl* derivative has **m** 135° (from EtOH), and the *formyl* derivative has **m** 102° (from EtOH). [*Beilstein* **12** H 1101, **12** III 2438, **12** IV 2497.]

Dry over KOH and fractionally distil. The *acetyl* derivative has **m** 142° (from H_2O or toluene), and the *benzoyl* derivative has **m** 140° (from EtOH). [*Beilstein* **12** H 1135, **12** IV 2567.]

2,6-Dimethylaniline [2,6-xylidine (*vic, m*)] *[87-62-7]* **M 121.2, m 11°, b 98°/14mm, 210-211°/736mm, 215°/760mm, d_4^{20} 0.974, n_D^{20} 1.5604, pK^{25} 3.95.** Convert *vic*-xylidine to a derivative (see below) which, after recrystallisation, is decomposed with alkali to give the free base. Dry it over KOH and fractionally distil. The ***formyl derivative*** [*N*-(2,6-dimethylphenyl)formamide] **M 149.2,** [607-92-1] has **m** 168-170°, the *acetyl* derivative has **m** 177°, the *benzoyl* derivative has **m** 168°, and the *picrate* has **m** 180°. [*Beilstein* **12** H 1107, **12** I 482, **12** II 604, **12** III 2462, **12** IV 2521.]

3,4-Dimethylaniline [3,4-xylidine] *[95-64-7]* **M 121.2, m 51°, b 116-118°/25mm, b 226°/760mm, pK^{25} 5.17.** Crystallise it from ligroin and distil it under vacuum. [*Beilstein* **12** H 1103, **12** IV 2502.]

3,5-Dimethylaniline [3,5-xylidine (*sym, m*)] *[108-69-0]* **M 121.2, b 105-106°/15mm, 221-222°/atm, d_4^{20} 0.974, n_D^{20} 1.557, pK^{25} 4.91.** Convert *sym*-xylidine to a derivative (see below) which, after recrystallisation, is decomposed with alkali to give the free base. Dry it over KOH and fractionally distil it. The *acetyl* derivative has **m** 144°, the *benzoyl* derivative has **m** 136° and the *picrate* has **m** 209° (from H_2O, EtOH or 10% AcOH). [*Beilstein* **12** H 1131, **12** IV 2561.]

9,10-Dimethylanthracene *[781-43-1]* **M 206.3, m 180-181°.** Purify 9,10-dimethylanthracene by crystallising from EtOH, and by recrystallising from the melt. [*Beilstein* **5** IV 2329.]

7,12-Dimethylbenz[*a*]anthracene (DMBA) *[57-97-6]* **M 256.4, m 122-123°.** Purify DMBA by chromatography on alumina/toluene or *benzene. Crystallise it from acetone/EtOH. [*Beilstein* **5** IV 2587.]

2,3-Dimethylbenzoic acid *[603-79-2]* **M 150.2, m 146°, pK^{25} 3.72.** Crystallise the acid from EtOH. It is volatile in steam. The *amide* has **m** 156° (from H_2O). [*Beilstein* **9** H 531, **9** III 2434, **9** IV 1797.]

2,4-Dimethylbenzoic acid *[611-01-8]* **M 150.2, m 125-126°, 126-127°, b 267°/727mm, pK^{25} 4.22.** Crystallise the acid from EtOH or H_2O, and sublime it in a vacuum. [*Beilstein* **9** H 531, **9** III 2436, **9** IV 1801.]

2,5-Dimethylbenzoic acid *[610-72-0]* **M 150.2, m 134°, b 268°/760mm, pK^{25} 4.00.** Steam distil the acid, then crystallise it from EtOH or H_2O (**m** 134-134.5°). [*Beilstein* **9** H 534, **9** IV 1802.]

2,6-Dimethylbenzoic acid *[632-46-2]* **M 150.2, m 117°, b 118-119°/2.5mm, pK^{25} 3.35.** Steam distil the acid, and crystallise it from EtOH or H_2O (**m** 116.3-116.7°). The *N-dimethylamide* has **m** 62-63° (from Et_2O). [*Beilstein* **9** H 531, **9** IV 1798.]

3,4-Dimethylbenzoic acid *[619-04-5]* **M 150.2, m 166°, pK^{25} 4.50.** Crystallise it from EtOH or H_2O (**m** 168-168.5°), and sublime it *in vacuo*. The *phenyl ester* has **m** 68° (from EtOH or petroleum ether) and **b** 155-157°/2mm. [*Beilstein* **9** II 353, **9** III 2441, **9** IV 1803.]

3,5-Dimethylbenzoic acid *[499-06-9]* **M 150.2, m 170°, pK^{25} 4.30.** Distil the acid in steam, crystallise it from H_2O (**m** 171.2-171.7°) or EtOH, and sublime it *in vacuo*. [*Beilstein* **9** H 536, **9** III 244, **9** IV 1806.]

4,4'-Dimethylbenzophenone *[611-97-2]* **M 210.3, m 95°, b 150-152/2mm. 333-334°/725mm.** Purify the benzophenone by zone refining or distllation, preferably in a vacuum. [*Beilstein* **7** III 2181, **7** IV 1434.]

2,5-Dimethyl-1,4-benzoquinone *[137-18-8]* **M 136.1, m 124-125°, 126-127°.** Crystallise the quinone from EtOH. [*Beilstein* **7** IV 2090.]

2,6-Dimethyl-1,4-benzoquinone (Phloron) *[527-61-7]* **M 136.1, m 72° (sealed tube).** Crystallise the quinone from water/EtOH (8:1). [*Beilstein* **7** IV 657, **7** III 3402, **7** IV 2096.]

3,3'-Dimethylcarbanilide (*N,N'*-bis-[*m*-tolyl]urea) *[620-50-8]* **M 240.3, m 220°, 225°.** Crystallise urea from ethyl acetate. The UV has λ_{max} at 258nm (EtOH). The *hydrochloride* has **m** 162°. [*Beilstein* **12** III 1970, **12** IV 1829.]

1,1-Dimethyl-1*H*-indene *[18636-55-0]* **M 144.2, b 57°/4.8mm, 115°/20mm.** Purify the oily indene by gas chromatography or by fractional distillation. [Bosch & Brown *Can J Chem* **42** 1718 *1964*, cf. *Beilstein* **5** I 251, **5** III 1377.]

1,5-Dimethylnaphthalene *[571-61-9]* **M 156.2, m 81-82°, b 265-266°.** Crystallise it from 85% aqueous EtOH. [*Beilstein* **5** IV 1709.]

2,3-Dimethylnaphthalene *[581-40-8]* **M 156.2, m 104-104.5°.** Steam distil the naphthalene and crystallise it from EtOH. [*Beilstein* **5** IV 1713.]

2,6-Dimethylnaphthalene *[581-42-0]* **M 156.2, m 110-111°, b 122.5-123.5°/10mm**, **261-262°/760mm.** Distil it in steam and crystallise it from EtOH. [*Beilstein* **5** IV 1714.]

3,3'-Dimethylnaphthidine (4,4'-diamino-3,3'-dimethyl-1,1'-binaphthyl) *[13138-48-2]* **M 312.4, m 213°.** Recrystallise the naphthidine from EtOH or petroleum ether (b 60-80°). [*Beilstein* **13** IV 493.]

***N,N*-Dimethyl-*m*-nitroaniline** *[619-31-8]* **M 166.1, m 60°, 61°, pK^{25} 2.63.** Crystallise the aniline from EtOH. The *picrate* has **m** 119° (from EtOH). [*Beilstein* **12** H 701, **12** III 1544, **12** IV 1591.]

***N,N*-Dimethyl-*p*-nitroaniline** *[100-23-2]* **M 166.1, m 164.5-165.2°, pK^{25} 0.61 (0.92).** Crystallise the nitroaniline from aqueous EtOH, EtOH or MeOH (**m** 163.5-164°). Dry it *in vacuo*. The *N-methiodide* has **m** 161°(dec) (from H_2O). [*Beilstein* **12** H 714, **12** III 1584, **12** IV 1616.]

***N,N*-Dimethyl-*p*-nitrosoaniline (4-nitroso-*N,N*-dimethylaniline)** *[138-89-6]* **M 150.2, m 86-87°, 92.5-93.5°, b 191-192°/100mm, pK^{25} 4.54.** Recrystallise the nitroso-aniline from petroleum ether or $CHCl_3$/CCl_4 and dry it in air. *Alternatively*, suspend it in H_2O, heat to boiling and add HCl until it dissolves. Filter, cool and collect the *hydrochloride [42344-05-8]* with **m** 177° after recrystallisation from H_2O containing a small amount of HCl. The *hydrochloride* (e.g. 30g) is made into a paste with H_2O (100ml) in a separating funnel. Add cold aqueous 2.5 NaOH or Na_2CO_3 to a pH of ~8.0 (green color due to the free base) and extract with toluene, $CHCl_3$ or Et_2O. Dry the extract (K_2CO_3), filter, distil off the solvent, cool the residue and collect the crystalline free base. Recrystallise it as above and dry it in air. [*Beilstein* **12** IV 1558.]

***R*-(+)-*N,N'*-Dimethyl-1-phenethylamine** *[19342-01-9]* **and *S*-(-)-*N,N'*-Dimethyl-1-phenethyl-amine** *[17279-31-1]* **M 149.2, b 81°/16mm, [α] $^{20}_{D}$ (+) and (-) 50.2° (c 1, MeOH), d $^{20}_{4}$ 0.908, pK$_{Est}$ ~9.0 (for *RS*).** The amine is mixed with aqueous 10N NaOH and extracted with toluene. The extract is washed with saturated aqueous NaCl, dried over K_2CO_3, and transferred to fresh K_2CO_3 until the solution is clear, and is filtered. The filtrate is distilled. If a short column packed with glass helices is used, the yield is reduced but a purer product is obtained. [Ingersoll *Org Synth* **25** 89 *1945*, Snyder & Brewster *J Am Chem Soc* **71** 291 4165 *1949*, Cope et al. *J Am Chem Soc* **71** 3931 *1949*.] The (–)-*picrate* has **m** 140-141° (from EtOH). The *racemate [1126-71-2]* has **b** 88-89°/16mm, 92-94°/30mm, 194-195°/760mm, d $^{20}_{4}$ 0.908. [*Beilstein* **13** III 2392.]

2,3-Dimethylphenol *[526-75-0]* **M 122.2, m 75°, b 120°/20mm, 218°/760mm, pK^{25} 10.54.** Crystallise 2,3-xylenol from aqueous EtOH. [*Beilstein* **6** IV 3096.]

2,5-Dimethylphenol *[95-87-4]* **M 122.2, m 73°, b 211.5°/762mm, pK^{25} 10.41.** Crystallise 2,5-xylenol from EtOH/ether. [*Beilstein* **6** IV 3164.]

2,6-Dimethylphenol *[576-26-1]* **M 122.2, m 49°, b 203°/760mm, pK^{25} 10.61.** Fractionally distil 2,6-xylenol under nitrogen, crystallise it from *benzene or hexane, and sublime it at 38°/10mm. [*Beilstein* **6** IV 3122.]

3,4-Dimethylphenol *[95-65-8]* **M 122.2, m 62.5°, 65°, 65-68°, 67°, b 142°/50mm, 225°/757mm, pK^{25} 10.36.** Heat 3,4-xylenol with an equal weight of conc H_2SO_4 at 103-105° for 2-3 hours, then dilute it with four volumes of water, reflux it for 1 hour, and either steam distil or extract it repeatedly with diethyl ether after cooling to room temperature. The steam distillate is also extracted and evaporated to dryness. (The purification

process depends on the much slower sulfonation of 3,4-dimethylphenol than most of its likely contaminants.) It can also be crystallised from water, hexane or petroleum ether, and sublimed in a vacuum. [Kester *Ind Eng Chem (Anal Ed)* **24** 770 *1932*, Bernasconi & Paschalis *J Am Chem Soc* **108** 2969*1986*, *Beilstein* **6** IV 3099.]

3,5-Dimethylphenol *[108-68-9]* **M 122.2, m 68°, b 219°, pK^{25} 10.19.** Purify it as for 3,4-dimethylphenol. [*Beilstein* **6** IV 3141.]

2,6-Dimethylphenylisocyanide *[2769-71-3]* **M 131.2, m 72-76°, 72-75°.** Like most isocyanides (isonitriles, carbylamines), it reacts with transition metals to form aldimines [Malatesta & Bonati *Isonitrile Complexes of Metals* Wiley Interscience, NY *1969*, SBN 470 565551, Treichel in *Advances in Organometallic Chemistry* **Vol 11**, (Stone & West Eds) Academic Press NY *1973*], and because of the crowded area around the nitrogen atom it coordinates with the metal in metal catalysts to enhance their stereoselectivity. The isocyanide can function as a nucleophile, electrophile, carbene, radical acceptor or pseudohalogen [Ugi (ed.) *Isonitrile Chemistry Academic Press NY 1971*, Library of Congress No 73-84156]. Among the general methods for preparing isocyanides the one that uses the ***Vilsmeier reagent*** {(chloromethylene)dimethyliminium chloride, $[ClCH{=}NMe_2]^+$ Cl^-, **M 128.0, m 132°(dec)**, [3724-43-4]} has been commonly used, and in this case it is prepared *in situ*. Thus a solution of redistilled $SOCl_2$ (0.5mol) in DMF (150ml) is added slowly to a stirred solution of ***N-(2,6-dimethylphenyl) formamide** (0.5mol, see below) {**M 149.2, m 165°**, see [607-92-1]} under N_2 and the temperature is kept below -50°. On completion, the cooling bath is momentarily removed to allow the temperature to rise to -45°, then the cooling bath is replaced while anhydrous Na_2CO_3 (1mol) is added very carefully with rapid stirring till evolution of CO_2 ceases. Stirring is continued while the mixture is heated to 35°, then kept at ~25° for 1 hour, diluted with ice-water and extracted into pentane. The extract is separated, dried (Na_2SO_4), and evaporated to give *2,6-dimethylphenylisocyanide* as a crystalline colourless solid in 74% yield. It can be recrystallised from pentane, and should be stored under N_2 between 2° to 8°. It is **toxic**. [Periasamy and Walborsky *Org Prep Proc Int* **11** 295 *1979*.]
***N-(2,6-Dimethylphenyl)formamide**, *[607-92-1]* **M 149.2, m 164°** (**164-5°**, **168-170°** also reported, and **176-177°** on rapid heating) is prepared by heating 2,6-dimethylaniline (see [87-62-7]) with formic acid, pouring into H_2O, filtering, drying and recrystallising from EtOH. [Hodgkinson & Limpach *J Chem Soc* **77 65 (**67) *1900*, *Beilstein* **12** H 1109, **12** I 604.]

Dimethyl phthalate *[131-11-3]* **M 194.2, b 282°/760mm, d_4^{20} 1.190, d_4^{25} 1.1865, n_D^{20} 1.5149.** Wash the ester with aqueous Na_2CO_3, then distilled water, dry ($CaCl_2$) and distil it under reduced pressure (**b** 151-152°/0.1mm). [*Beilstein* **7** IV 3170.]

2,4-Dimethylresorcinol *[634-65-1]* **M 138.1, m 111°, 112°, $pK_{Est(1)}$ ~9.8, $pK_{Est(2)}$ ~11.7.** Crystallise the resorcinol from petroleum ether (b 60-80°), *C_6H_6/petroleum ether or toluene/BuOAc. It sublimes at 100-110°/1mm. [*Beilstein* **6** H 918, **6** II 891, **6** III 4588, **6** IV 5955.]

Dimethyl terephthalate *[120-61-6]* **M 194.2, m 141.5-141.8°**, **142°.** Purify it by recrystallisation from aqueous EtOH, MeOH or CCl_4; or by zone melting. [*Beilstein* **6** H 843, **6** III 4250, **6** IV 3303.]

.
***N,N*-Dimethyl-*o*-toluidine** *[609-72-3]* **M 135.2, b 68°/10mm, 211-211.5°/760mm, d_4^{20} 0.937, n_D^{20} 1.53664, pK^{25} 6.11.** Isomers and other bases are removed by heating in a water bath for 100 hours with two equivalents of 20% HCl and two and a half volumes of 40% aqueous formaldehyde, then making the solution alkaline and separating the free base. After washing well with water, it is distilled at 10mm pressure and redistilled at ambient pressure [von Braun & Aust *Chem Ber* **47** 260 *1914*]. Other procedures include drying with NaOH, distilling from zinc in an atmosphere of nitrogen under reduced pressure, and refluxing with excess of acetic anhydride in the presence of conc H_2SO_4 as catalyst, followed by fractional distillation in a vacuum. The *picrate* has **m** 124-125°. [*Beilstein* **12** H 857, **12** III 1843, **12** IV 1747.]

***N,N*-Dimethyl-*m*-toluidine (*m*-methyl-*N,N*-dimethylaniline)** *[121-72-2]* **M 135.2, b 72-74°/5mm, 128°/57mm, 211.5-212.5°/760mm, d_4^{20} 0.93, n_D^{20} 1.5500, pK^{25} 5.34.** Reflux it for 3 hours with 2 molar equivalents of Ac_2O, then fractionally distil it under reduced pressure. *Alternatively*, dry over BaO, distil and store it over KOH. The *hydrochloride* has **m** 176° (from EtOH) and the *picrate* has **m** 131°. Methods described

for *N,N*-dimethylaniline are applicable. [*Beilstein* **12** H 857, **12** III 1953, **12** IV 1815.]

***N,N*-Dimethyl-*p*-toluidine (*p*-methyl-*N,N*-dimethylaniline)** *[99-97-8]* **M 135.2, b 76.5-77.5°/4mm, 93-94°/11mm, b 211°/760mm, d_4^{20} 0.937, n_D^{20} 1.5469, $pK^{21.5}$ 5.56, pK^{25} 5.63.** Reflux for 3 hours with 2 molar equivalents of Ac_2O, then fractionally distil it under reduced pressure. *Alternatively*, dry it over BaO, distil and store it over KOH. The *picrate* has **m** 128° (from EtOH). Methods described for *N,N*-dimethylaniline are applicable here. [*Beilstein* **12** H 902, **12** III 2026, **12** IV 1874.]

2,4-Dinitroaniline *[97-02-9]* **M 183.1, m 180°, ε_{348} 12,300 in dilute aqueous $HClO_4$, pK^{25} -4.27 (aqueous H_2SO_4).** Crystallise the nitroaniline from boiling EtOH by adding one-third volume of H_2O and cooling slowly. Dry it on a steam oven. The *N-acetyl* derivative has **m** 180°. [*Beilstein* **12** IV 1689.]

2,6-Dinitroaniline *[606-22-4]* **M 183.1, m 139-140°, pK^{25} -5.37 (aqueous H_2SO_4).** Purify the nitroaniline by chromatography on alumina, then crystallise it from *benzene or EtOH. The *N-acetyl* derivative has **m** 197° (from EtOH). [*Beilstein* **12** IV 1729.]

2,4-Dinitroanisole *[5327-44-6]* **M 198.1, m 87-88°(metastable), 94-95°. m 206-207°/12mm.** Crystallise the anisole from aqueous EtOH. The *naphthalene complex* has **m** 50° (from EtOH). [*Beilstein* **6** H 254, **6** III 858, **6** IV 1372.]

3,5-Dinitroanisole *[119-27-7]* **M 198.1, m 105-106°.** Purify the anisole by repeated crystallisation from EtOH, MeOH or H_2O and dry it in a vacuum desiccator over P_2O_5. The *naphthalene complex* has **m** 69° (from EtOH). [*Beilstein* **6** III 869, **6** IV 1385.

1,2-Dinitrobenzene *[528-29-0]* **M 168.1, m 116.5°.** Crystallise it from EtOH. [*Beilstein* **5** IV 738.]

1,3-Dinitrobenzene *[99-65-0]* **M 168.1, m 90.5-91°.** Crystallise 1,3-dinitrobenzene from alkaline EtOH solution (20g in 750ml 95% EtOH at 40°, plus 100ml of 2M NaOH) by cooling and adding 2.5L of H_2O. The precipitate, after filtering off, is washed with H_2O, sucked dry, and crystallised from 120ml, then 80ml of absolute EtOH [Callow et al. *Biochem J* **32** 1312 *1938*]. *Alternatively*, crystallise it from MeOH, CCl_4 or EtOAc. It can be sublimed in a vacuum. [Tanner *J Org Chem* **52** 2142 *1987*, *Beilstein* **5** IV 739.]

1,4-Dinitrobenzene *[100-25-4]* **M 168.1, m 173°.** Crystallise 1,4-dinitrobenzene from EtOH or EtOAc. Dry it under vacuum over P_2O_5. It can be sublimed in a vacuum. [*Beilstein* **5** IV 741.]

2,4-Dinitrobenzenesulfenyl chloride *[528-76-7]* **M 234.6, m 96°.** Crystallise the sulfenyl chloride from CCl_4. [*Beilstein* **6** II 316.]

2,4-Dinitrobenzenesulfonyl chloride *[1656-44-6]* **M 266.6, m 102°.** Crystallise the sulfonyl chloride from *benzene or *benzene/petroleum ether. [*Beilstein* **11** H 78, **11** IV 214.]

2,4-Dinitrobenzoic acid *[610-30-3]* **M 212.1, m 183°, pK^{25} 1.42.** Crystallise the acid from aqueous 20% EtOH (10ml/g) and let it dry at 100°. [*Beilstein* **9** II 279, **9** III 1776, **9** IV 1239.]

2,5-Dinitrobenzoic acid *[610-28-6]* **M 212.1, m 179.5-180°, pK^{25} 1.62.** Crystallise the acid from distilled H_2O. Dry it in a vacuum desiccator. [*Beilstein* **9** II 279, **9** III 1778, **9** IV 1241.]

2,6-Dinitrobenzoic acid *[603-12-3]* **M 212.1, m 202-203°, pK^{25} 1.14.** Crystallise the acid from water. [*Beilstein* **9** II 279, **9** III 1778, **9** IV 1242.]

3,4-Dinitrobenzoic acid *[528-45-0]* **M 212.1, m 166°, pK^{25} 2.81.** Crystallise the acid from EtOH by addition of water. [*Beilstein* **9** III 1778, **9** IV 1242.]

3,5-Dinitrobenzoic acid *[99-34-3]* **M 212.1, m 205°, pK^{25} 2.73 (2.79).** Crystallise the acid from distilled H_2O or 50% EtOH (4ml/g). Dry it in a vacuum desiccator or at 70° over BaO under a vacuum for 6 hours. [*Beilstein* **9** II 279, **9** III 1779, **9** IV 1242.]

4,4'-Dinitrobenzoic anhydride *[902-47-6]* **M 406.2, m 192°, 195-195.5°.** Crystallise the anhydride from Me_2CO, toluene, *C_6H_6/EtOAc or EtOAc. [*Beilstein* **9** H 393, **9** II 268, **9** III 1684.]

3,5-Dinitrobenzoyl chloride *[99-33-2]* **M 230.6, m 69.5°.** Crystallise it from CCl_4 or petroleum ether (b 40-60°). It reacts readily with H_2O and should be kept in sealed ampoules. [*Beilstein* **9** IV 1350.]

2,2'-Dinitrobiphenyl *[2436-96-6]* **M 244.2, m 123-124°, b 194°/4mm.** Crystallise the biphenyl from EtOH, AcOH (**m** 124.5°) or petroleum ether (**m** 125.5-126°). [*Beilstein* **5** H 538, **5** III 1759, **5** IV 1826.]

2,4'-Dinitrobiphenyl *[606-81-5]* **M 244.2, m 92.7-93.7°.** Crystallise the biphenyl from EtOH. [*Beilstein* **5** H 538, **5** I 274, **5** II 491, **5** III 1759, **5** IV 1827.]

4,4'-Dinitrobiphenyl *[1528-74-1]* **M 244.2, m 240.9-241.8°.** Crystallise the biphenyl from *C_6H_6, EtOH (charcoal) or Me_2CO. Dry it under vacuum over P_2O_5. It sublimes at ~138°/2.9×10^{-3}mm. [*Beilstein* **5** H 584, **5** III 1760, **5** IV 1827.]

2,6-Dinitro-*p*-cresol (2,6-dinitro-4-methylphenol) *[609-93-8]* **M 198.1, m 78-79°, 80.5°, 81-82°, 85°, pK$_{Est}$~3.7.** Recrystallise the cresol from EtOH. It is steam volatile. The *piperidine salt* has **m** 195°. [*Beilstein* **6** H 414, **6** II 391, **6** III 1390, **6** IV 2152.] **TOXIC IRRITANT.**

4,6-Dinitro-*o*-cresol (4,6-dinitro-2-methylphenol) *[534-52-1]* **M 198.1, m 85-86°, 86-87°, 87°, pK^{25} 4.70.** The cresol crystallises from aqueous EtOH. [*Beilstein* **6** H 369, **6** III 1276.]

2,4-Dinitrodiphenylamine *[961-68-2]* **M 259.2, m 157°, 160°, pK$_{Est}$ <0.** The amine forms red crystals from aqueous EtOH or $CHCl_3$/EtOH (**m** 158°). The UV has λ_{max} at 335nm (cyclohexane). [*Beilstein* **12** H 751, **12** III 1683, **12** IV 1692.]

4,4'-Dinitrodiphenylurea [1,3-bis-(4-nitrophenyl)urea] *[587-90-6]* **M 302.2, m 312°(dec).** Crystallise the urea from EtOH (**m** 364°, long heating), EtOH/Me_2CO (**m** 301-303°, 300-304° dec, 318-319°) or Me_2CO (**m** 289° dec). It sublimes *in vacuo*. [*Beilstein* **12** H 723, **12** II 393, **12** III 1619, **12** IV 1646.]

2,4-Dinitrofluorobenzene (Sanger's reagent) *[70-34-8]* **M 186.1, m 25-27°, b 133°/2mm, 140-141°/5mm, d$_4^{20}$ 1.483.** Crystallise the reagent from Et_2O or EtOH. Distil it in a vacuum through a Todd Column. If it is to be purified by distillation *in vacuo*, the distillation unit must be allowed to cool before air is allowed into the apparatus; otherwise the residue carbonises spontaneously and an **EXPLOSION** may occur. The material is a **skin irritant** and may cause serious dermatitis. [*Beilstein* **5** IV 742.]

1,8-Dinitronaphthalene *[602-38-0]* **M 218.2, m 170-171°, 171.3°.** Crystallise it from *benzene. [*Beilstein* **5** H 559, **5** II 455, **5** III 1608.]

2,4-Dinitro-1-naphthol (Martius Yellow) *[605-69-6]* **M 234.2, m 81-82°, pK$_{Est}$ ~3.7.** Crystallise the naphthol from *benzene or aqueous EtOH. [*Beilstein* **6** IV 4240.]

2,4-Dinitrophenetole *[610-54-8]* **M 240.2, m 85-86°, 210-211°/15mm.** Crystallise it from aqueous EtOH. The 1:1 *naphthalene complex* has **m** 41° and is obtained by fusing the compound with naphthalene in various ratios, then crystallising the solidified mix from a little EtOH (Dermer & Smith *J Am Chem Soc* **61** 748 *1939*). [*Beilstein* **6** H 254, **6** III 858, **6** IV 1373.]

2,4-Dinitrophenol *[51-28-5]* **M 184.1, m 114°, pK^{25} 4.12.** Crystallise it from *benzene, EtOH, EtOH/H_2O or H_2O acidified with dilute HCl, dry it, then recrystallise it from CCl_4. Dry it in an oven and store it in a vacuum

desiccator over $CaSO_4$. The *benzoate* has **m** 132° (from EtOH). [*Beilstein* **6** IV 1369.]

2,5-Dinitrophenol *[329-71-5]* **M 184.1, m 108°, pK^{25} 5.20.** Crystallise 2,5-dinitrophenol from H_2O with a little EtOH. [*Beilstein* **6** IV 1383.]

2,6-Dinitrophenol *[573-56-8]* **M 184.1, m 63.0-63.7°, pK^{25} 3.73.** Crystallise it from H_2O, aqueous EtOH, *C_6H_6/cyclohexane, or *C_6H_6/petroleum ether (b 60-80°, 1:1). [*Beilstein* **6** III 867, **6** IV 1383.]

3,4-Dinitrophenol *[577-71-9]* **M 184.1, m 138°, pK^{25} 5.42.** Steam distil and crystallise it from H_2O then dry it in air. **EXPLOSIVE** when dry, store it with 10% H_2O. [*Beilstein* **6** III 868, **6** IV 1384.]

3,5-Dinitrophenol *[586-11-8]* **M 184.1, m 126°, pK^{25} 6.68.** Crystallise it from *C_6H_6 or $CHCl_3$/petroleum ether. Store it with 10% water as it is **EXPLOSIVE** when dry. [*Beilstein* **6** III 869, **6** IV 1383.]

2,4-Dinitrophenylacetic acid *[643-43-6]* **M 226.2, m 179°(dec), pK^{25} 3.50.** Crystallise the acid from H_2O. [*Beilstein* **9** IV 1691.]

2,4-Dinitrophenylhydrazine (DNPH) *[119-26-6]* **M 198.1, m 200°(dec), pK$_{Est}$ ~2.0.** Crystallise DNPH from butan-1-ol, dioxane, EtOH, *C_6H_6 or EtOAc. The *hydrochloride* has **m** 186° (dec). [*Beilstein* **15** IV 380.]

2,4-Dinitroresorcinol *[519-44-8]* **M 200.1, m 212.5-214.5°, pK^{25} 3.05 (3.79).** Crystallise the resorcinol from aqueous EtOH. Its solubility at 25° is 0.25% in EtOH and 0.08g/L in H_2O. **EXPLOSIVE.** [*Beilstein* **6** II 824, **6** III 4352, **6** IV 5696.]

3,5-Dinitrosalicylic acid *[609-99-4]* **M 228.1, m 173-174°, pK$_1^{25}$ 0.70, pK$_2^{25}$ 7.40.** Crystallise the acid from H_2O. [*Beilstein* **10** IV 270.]

2,6-Dinitrothymol *[303-21-9]* **M 240.2, m 54.5-55°, 80-81°, 81°.** Crystallise 2,4-dinitrothymol from aqueous EtOH or petroleum ether. [Ganguly & LeFévre *J Chem Soc* 851 *1934*, *Beilstein* **6** H 543, **6** III 1911.]

2,3-Dinitrotoluene *[602-01-7]* **M 182.1, m 59.2°, 63°.** Distil the toluene in steam and crystallise it from H_2O or *benzene/petroleum ether. Store it with 10% H_2O as it could be **EXPLOSIVE** when dry. [*Beilstein* **5** H 339, **5** III 758, **5** IV 865.]

2,4-Dinitrotoluene *[121-14-2]* **M 182.1, m 70.5-71.0°, 71.8-72.2°.** Crystallise it from Me_2CO, isopropanol or MeOH. Dry it in a vacuum over H_2SO_4. It has also been purified by zone melting. Store it with 10% of H_2O. *It could be* **EXPLOSIVE** *when dry*. [*Beilstein* **5** H339, **5** IV 865, **5** III 759.]

2,5-Dinitrotoluene *[619-15-8]* **M 182.1, m 50.3°, 51.2°.** Crystallise it from *benzene. Store it with 10% of H_2O. **EXPLOSIVE** *when dry*. [*Beilstein* **5** III 760, **5** IV 866.]

2,6-Dinitrotoluene *[606-20-2]* **M 182.1, m 64.3°, 66.1°.** Crystallise it from acetone. Store it with 10% of H_2O. **EXPLOSIVE** *when dry*. [*Beilstein* **5** III 761, **5** IV 866.]

3,4-Dinitrotoluene *[610-39-9]* **M 182.1, m 58.5°, 60°, 61°.** Steam distil it and crystallise it from *C_6H_6/petroleum ether. Store it with 10% of H_2O to avoid **EXPLOSION. [***Beilstein* **5** H 341, **5** III 761, **5** IV 866.]

3,5-Dinitro-*o*-toluic acid *[28169-46-2]* **M 226.2, m 206°, 207.5-208°, pK$_{Est}$ ~3.0.** Crystallise the acid from H_2O or aqueous EtOH. The *ammonium salt* forms yellow crystals from EtOH with **m** 218-219°, and the *urea salt* has **m** 189-190° (prisms from EtOH). [*Beilstein* **9** H 474, **9** II 323, **9** III 2316.]

2,4-Dinitro-*m*-xylene *[603-02-1]* **M 196.2, m 83-84°.** Crystallise the yellow 2,4-dinitro-*m*-xylene from EtOH. [*Beilstein* **5** H 379, **5** II 295, **5** III 844.]

Dinonyl phthalate (mainly 3,5,5-trimethylhexyl phthalate isomer) *[14103-61-8, 28553-12-0, 84-76-4]* **M 418.6, m 26-29°, b 170°/2mm, d_4^{20} 0.9640, n_D^{20} 1.4825.** Wash the ester with aqueous Na_2CO_3 then shake it with water. Ether is added to break the emulsion, and the solution is washed twice with water, and dried ($CaCl_2$). After evaporating the ether, the residual liquid is distilled three times under reduced pressure. It is stored in a vacuum desiccator over P_2O_5. [*Beilstein* **9** IV 3183.]

4,4'-Di-*n*-pentyloxyazoxybenzene *[64242-26-8]* **M 370.5, m 124.5° (with phase change at 82°, becomes clear and remelts at 119°).** Crystallise it from Me_2CO, and dry it by heating under vacuum. [*Beilstein* **16** III 599, **16** IV 175.]

Diphenic acid (diphenyl-2,2'-dicarboxylic acid) *[482-05-3]* **M 242.2, m 228-229°, pK^{25} 3.46.** Crystallise diphenic acid from water. Hot Ac_2O provides the *anhydride* below. [*Beilstein* **9** H 922, **9** IV 3552.]

Diphenic anhydride (diphenyl-2,2'-dicarboxylic anhydride) *[6050-13-1]* **M 466.3, m 217°, 222-224°.** After removing free acid by extraction with cold aqueous Na_2CO_3, the residue is crystallised from acetic anhydride and dried at 100°. Acetic anhydride converts the acid to the anhydride. It also crystallises from *C_6H_6 (**m** 219°) or chlorobenzene (**m** 224.5-225.5°). [*Beilstein* **17** H 526, **17** II 495, **17** III/IV 6425.]

***N,N*-Diphenylacetamidine** *[621-09-0]* **M 210.3, m 131°.** Crystallise it from EtOH, then sublime it under vacuum at *ca* 96° onto a "finger" cooled in solid CO_2/MeOH, with continuous pumping to free it from occluded solvent. [*Beilstein* **12** H 248, **12** II 144, **12** III 471, **12** IV 384.]

Diphenylacetic acid *[117-34-0]* **M 212.3, m 147.4-148.4°, pK^{25} 3.94.** Crystallise the acid from *benzene, H_2O or aqueous 50% EtOH. [*Beilstein* **9** H 673, **9** IV 2492.]

Diphenylacetonitrile *[86-29-3]* **M 193.3, m 73-75°.** Crystallise the nitrile from EtOH or petroleum ether (b 90-100°). [*Beilstein* **9** H 674, **9** IV 2505.]

Diphenylacetylene (tolan) *[501-65-5]* **M 178.2, m 62.5°, b 90-97°/0.3mm.** Crystallise tolan from EtOH. [*Beilstein* **5** H 656, **5** IV 2276.]

Diphenylamine *[122-39-4]* **M 169.2, m 62.0-62.5°, pK^{25} 0.77 (aqueous H_2SO_4).** Crystallise diphenylamine from petroleum ether, MeOH, or EtOH/water. Dry it under vacuum. [*Beilstein* **12** H 174, **12** IV 271.]

Diphenylamine-2-carboxylic acid (*N*-phenylanthranilic acid) *[91-40-7]* **M 213.2, m 182-183°, 184°, pK_1^{25} -1.28 (aqueous H_2SO_4), pK_2^{25} 3.86(CO_2H).** Crystallise the acid from EtOH (5ml/g) or AcOH (2ml/g) by adding hot water (1ml/g). [*Beilstein* **14** IV 1019.]

Diphenylamine-2,2'-dicarboxylic acid (2,2'-iminodibenzoic acid) *[579-92-0]* **M 257.2, m 298°(dec), 302°(dec), 320°(dec, long heating), pK_1^{35} 6.05, pK_2^{35} 7.02 (in 50% aqueous dioxane).** Crystallise the acid from EtOH. It complexes with Cu^{2+}, Zn^{2+}, Cd^{2+}, Co^{2+} and Ni^{2+}. [*Beilstein* **14** H 354, **14** I 545, **14** III 942, **14** IV 1058.]

9,10-Diphenylanthracene *[1499-10-1]* **M 330.4, m 248-249°.** Crystallise the anthracene from acetic acid or xylene [Baumstark et al. *J Org Chem* **52** 3308 *1987*]. [*Beilstein* **5** IV 2807.]

***N,N'*-Diphenylbenzidine** *[531-91-9]* **M 336.4, m 245-247°, 251-252°, pK^{25} 0.30.** Crystallise the benzidine from toluene or ethyl acetate. Store it in the dark. [*Beilstein* **13** H 223, **13** IV 368.]

***trans-trans*-1,4-Diphenylbuta-1,3-diene** *[538-81-8]* **M 206.3, m 153-153.5°.** Its solution in petroleum ether (b 60-70°) is chromatographed on an alumina-Celite column (4:1), and the column is washed with the same solvent. The main zone is cut out, eluted with ethanol and transferred to petroleum ether, which is then dried and evaporated [Pinckard et al. *J Am Chem Soc* **70** 1938 *1948*]. Recrystallise it from hexane. [*Beilstein* **5** H 676, **9** IV 2319.]

***sym*-(1,5)-Diphenylcarbazide** *[140-22-7]* **M 242.3, m 172°.** A common impurity is phenyl-semicarbazide which can be removed by chromatography: ~8g in H_2O is placed on a column (polyamide 6 powder, Macherey-Nagel-GmbH-Germany, washed several times with MeOH), eluted with H_2O/MeOH/AcOH (1:3:0.04) at 7-8 drops/second, then eluted with the same solvent mixture but diluted 5 fold with H_2O. The purification is followed by UV light at 280nm. The effluent is evaporated to dryness *in vacuo* at ~28°. [chromatography, IR & UV: Willems et al. *Anal Chim Acta* **51** 544 *1970*]. Recrystallise it from EtOH by adding CCl_4 to induce crystallisation, or AcOH to give a white crystalline powder which turns pink in air. It is air and light sensitive and should be stored in the dark under N_2. [*Beilstein* **15** H 292, **15** IV 182.]

1,5-Diphenylcarbazone (phenyldiazinecarboxylic acid 2-phenylhydrazide) *[538-62-5]* **M 240.3, m 124-127°, 156-159°(dec).** It crystallises from EtOH (*ca* 5ml/g), and dry the orange-red needles at 50°. A commercial sample, nominally *sym*-diphenylcarbazone (**m** 154-156°) was a mixture of diphenylcarbazide and diphenylcarbazone. The former was removed by dissolving 5g of the crude material in 75ml of warm EtOH, then adding 25g Na_2CO_3 dissolved in 400ml of distilled water. The alkaline solution was cooled and extracted six times with 50ml portions of diethyl ether (discarded). Diphenylcarbazone was then precipitated by acidifying the alkaline solution with 3M HNO_3 or glacial acetic acid. It was filtered off, air dried, and stored in the dark [Gerlach & Frazier *Anal Chem* **30** 1142 *1958*]. Other impurities are phenylsemicarbazide and diphenylcarbodiazone. Impurities can be detected by chromatography [Willems et al. *Anal Chim Acta* **51** 544 *1970*]. It is used for detection and estimation of Hg, Zn, Cd, Cr, Cu, Fe and Mo [Cheng et al. *Handbook of Organic Analytical Reagents,* Boca Baton 277 *1982*, *Beilstein* **16** H 24, **16** IV 17.]

Diphenyl carbonate (phenyl carbonate) *[102-09-0]* **M 214.2, m 80°, 168°/15mm, 306°/760mm.** Purify it by distillation under reduced pressure, sublimation, or by gas chromatography with 20% Apiezon on Embacel, and crystallisation from EtOH. [*Beilstein* **6** H 158, **6** IV 629.]

Diphenylcyclopropenone (Diphencyprone) *[886-38-4]* **M 206.2, m 87-90°(hydrate), 119-121°(anhydrous).** Crystallise it from cyclohexane. Its UV (MeCN) has λ_{max} at 226, 282, 297nm. [*Beilstein* **17** IV 1736.]

Diphenyl disulfide (phenyl disulfide) *[882-33-7]* **M 218.3, m 60.5°.** Crystallise the disulfide from MeOH. [Alberti et al. *J Am Chem Soc* **108** 3024 *1986*]. Also crystallise it repeatedly from hot Et_2O, then dry it in a vacuum at 30° over P_2O_5, fuse it under N_2 and re-dry it; the whole procedure being repeated, with a final drying under a vacuum for 24 hours. *Alternatively*, recrystallise it from hexane/EtOH solution. [Burkey & Griller *J Am Chem Soc* **107** 246 *1985*, *Beilstein* **6** H 323, **6** IV 1560.]

1,1-Diphenylethanol *[599-67-7]* **M 198.3, m 80-81°, 81-81.5°, 87°, 90°, b 144-145°/12mm, 260°/760mm (dec), d^{15} 1.1057.** Crystallise 1,1-diphenylethanol from *n*-heptane and/or distil it under vacuum. The *benzoyl* derivative has **m** 115° and the *phenylurethane* has **m** 119°. [Bromberg et al. *J Am Chem Soc* **107** 83 *1985*, *Beilstein* **6** H 685, **6** I 330, **6** II 639, **6** III 3395, **6** IV 4713.]

1,1-Diphenylethylene *[530-48-3]* **M 180.3, m 6°, b 101°/2mm, 134°/10mm, 268-270°/760mm, d_4^{20} 1.024, n_D^{20} 1.6088.** Distil it under reduced pressure from KOH. Dry it with CaH_2 and redistil it. [*Beilstein* **5** H 639, **5** III 1975, **5** IV 2173.]

***N,N'*-Diphenylethylenediamine (Wanzlick's Reagent)** *[150-61-8]* **M 212.3, m 67.5°, b 178-182°/2mm $pK_{Est(1)}$ ~0.5, $pK_{Est(2)}$ ~3.8.** Crystallise the reagent from aqueous EtOH or MeOH. [*Beilstein* **12** H 543, **12** IV 986.]

***(1S,2S)*-1,2-diphenylethylenediamine bis-triflamide** *[121788-77-0]* **M 478.4, m 213-214°, $[\alpha]_D^{23}$ -6.6° (c 1.4, $CHCl_3$).** The bis-amide is obtained from (1*S*,2*S*)-(–)-1,2-diphenylethylenediamine (see [*cis*-1-aminoindan-2-ol -69-8]) by treatment with triflic anhydride (358-23-6), Et_3N and 4-dimethylaminopyridine (DMAP, see [1122-58-3]) in CH_2Cl_2; and purified by flash chromatography on silica gel (15% EtOAc-hexane, v/v). Its ^1H NMR (400MHz, $CDCl_3$, TMS) has δ_H at 4.81(s, 2H), 6.80 (br s, 2H), 7.25 (s, 6H), 7.0 (s, 4H); and its ^{13}C NMR (100MHz, $CDCl_3$) has δ at 63.7, 127.0, 129.1 (2C), 135.1. It is a useful reagent for enantioselective Diels-Alder and aldol reactions using a chiral controller system. [Corey et al. *J Am Chem Soc* **111** 5493 *1989*, Pikul &

Corey *OrgSynth* **71** 30 *1993* and references herein.]

***N,N′*-Diphenylformamidine** *[622-15-1]* **M 196.2, m 142°, 137°, 136-139°.** Crystallise it from absolute EtOH. The *hydrate* is obtained from aqueous EtOH. [*Beilstein* **12** H 236, **12** IV 372.]

1,3-Diphenylguanidine *[102-06-7]* **M 211.3, m 148°, pK^{25} 10.12.** Crystallise it from toluene, aqueous acetone or EtOH, and dry it in a vacuum. [*Beilstein* **12** H 369, **12** IV 769.]

1,6-Diphenyl-1,3,5-hexatriene *[1720-32-7]* **M 232.3, m 200-203°.** Crystallise the hexatriene from $CHCl_3$ or EtOH/$CHCl_3$ (1:1). [*Beilstein* **5** H 691, **5** IV 2425.]

1,1-Diphenylhydrazine *[530-50-7]* **M 184.2, m 34.5°, 44°, b 120°/1.1mm, 220°/40-50mm, pK$_{Est}$ ~9.1.** Purify it *via* the *hydrochloride* [530-47-2], which has **m** 165-170°(dec) after crystallisation from aqueous EtOH (plus a few drops of HCl) and recover the free base with aqueous NaOH, extract it into Et_2O, dry it (KOH), filter, evaporate and distil the residue under a vacuum. The distillate crystallises on cooling. The *benzoyl* derivative has **m** 194° (from Me_2CO), and the *4-nitrophenyl hydrazone* (with the aldehyde) has **m** 131-132°. [Koga & Anselme *J Org Chem* **33** 3963 *1968*, *Beilstein* **15** IV 55.]

1,2-Diphenylhydrazine (hydrazobenzene) *[122-66-7]* **M 184.2, m 124-126°, b 175°/10mm, 222°/40mm, pK$_{Est}$ ~1.7.** Crystallise hydrazobenzene from hot EtOH containing a little ammonium sulfide or H_2SO_3 (to prevent atmospheric oxidation), preferably under N_2. Dry it in a vacuum desiccator, and store it in the dark or under N_2. It has been distilled in a vacuum. *Alternatively*, crystallise it from petroleum ether (b 60-100°) to constant absorption spectrum. It is almost colourless but in air it turns yellow, then red with the formation of azobenzene. The *hydrochloride* crystallises from EtOH and has **m** 163-164°(dec); however, hydrazobenzene readily rearranges to *benzidine* in the presence of acid. The *picrate* crystallises from *C_6H_6 and has **m** 123°(dec). [*Beilstein* **15** H 123.]

Diphenylmethane *[101-81-5]* **M 168.2, m 25.4°, b 74°/0.4mm, 260.5°/764.5mm.** Sublime it under vacuum, or distil it at 72-75°/0.4mm. Recrystallise it from cold EtOH. It has also been purified by fractional crystallisation from the melt. [Armarego *Aust J Chem* **13** 95 *1960*, *Beilstein* **5** II 498, **5** IV 1841.]

1,1-Diphenylmethylamine (benzhydrylamine, aminodiphenylmethane) *[91-00-9]* **M 183.2, m 12°, 34°, b 166°/12mm, 295°/atm, d$_4^{25}$ 1.063, n$_D^{20}$ 1.596, pK$_{Est}$ ~9.1.** Crystallise the amine from H_2O. The *free base* absorbs CO_2 from the atmosphere; store it accordingly. The *hydrochloride* [5267-34-5] **M** 219.7 **m** 293-295°, crystallises from H_2O. [*Beilstein* **12** H 1323, **12** IV 3282.]
§A polymer bound *benzhydrylamine hydrochloride* is commercially available.

Diphenylmethyl chloride (benzhydryl chloride) *[90-99-3]* **M 202.7, m 17.0°, b 140°/3mm, 167°/17mm, n 1.5960.** Dry the chloride with Na_2SO_4 and fractionally distil it under reduced pressure. [*Beilstein* **5** H 590, **5** I 278, **5** II 500, **5** III 1790, **5** IV 1847.]

***all-trans*-1,8-Diphenyl-1,3,5,8-octatetraene** *[3029-40-1]* **M 258.4, m 235-237°.** Crystallise the octatetraene from EtOH. [*Beilstein* **5** H 709, **5** II 620, **5** III 2328, **5** IV 2508.]

***N,N′*-Diphenyl-*p*-phenylenediamine** *[74-31-7]* **M 260.3, m 148-149°, b 219-224°/0.7mm, pK$_{Est}$ <0.** Crystallise the diamine from EtOH, chlorobenzene/petroleum ether or *benzene. It has also been crystallised from aniline, then extracted three times with absolute EtOH. [*Beilstein* **13** H 80.]

1,1-Diphenyl-2-picrylhydrazine *[1707-75-1]* **M 395.3, m 174°(dec), 178-179.5°(dec).** Crystallise the hydrazine from $CHCl_3$, or *benzene/petroleum ether (1:1), then degas it at 100° and $<10^{-5}$mm Hg for *ca* 50 hours to decompose the 1:1 molar complex formed with *benzene. [*Beilstein* **15** II 221, **15** IV 1210.]

2,2-Diphenylpropionic acid *[5558-66-7]* **M 226.3, m 173-174°, pK$_{Est}$ ~3.8.** Crystallise the acid from EtOH. [*Beilstein* **9** II 474.]

3,3-Diphenylpropionic acid *[606-83-7]* **M 226.3, m 155°, pK_{Est} ~4.5.** Crystallise the acid from EtOH. [*Beilstein* **9** H 680.]

Diphenyl sulfide *[139-66-2]* **M 186.3, b 145°/8mm, d_4^{20} 1.114, n_D^{20} 1.633.** Wash the sulfide with aqueous 5% NaOH, then water. Dry it with $CaCl_2$, then with sodium. The sodium is filtered off, and the diphenyl sulfide is distiiled under reduced pressure. [*Beilstein* **2** H 299, **6** IV 1488.]

Diphenyl sulfone *[127-63-9]* **M 218.3, m 125°, b 378°(dec).** Crystallise the sulfone from diethyl ether. It has been purified by zone melting. [*Beilstein* **6** H 300, **6** IV 1490.]

***sym*-Diphenylthiourea (thiocarbanilide)** *[102-08-9]* **M 228.3, m 154°.** Crystallise the thiourea from boiling EtOH by adding hot water and allowing to cool. [*Beilstein* **12** H 394, **12** IV 810.]

1,1-Diphenylurea *[603-54-3]* **M 212.3, m 238-239°.** Crystallise 1,1-diphenylurea from MeOH. [*Beilstein* for 1,3 **12** IV 741.]

2,6-Di-*iso*-propylaniline *[24544-04-5]* **M 177.3, m -45°, b 120-122°/10mm, 257°/atm, d_4^{25} 0.9367, n_D^{20} 1.5330, pK_{Est} ~0.** Nitration of 1,3-di-*iso*-propylbenzene in AcOH/Ac_2O (2:1 v/v) with 96% HNO_3 (1.24-2.05 equivalents) below 45-50°/24 hours gave, on fractionation through a 2.5 x 180cm column at 5-10mm, a mixture of lower boiling 4-nitro- (74%) and the higher boiling 2-nitro-1,3-di-*iso*-propylbenzene (24%). Reduction of the later in *iso*-propanol with H_2 (~1200psi, <100°) catalysed by Raney Ni (5-10% by weight), followed by filtration, evaporation of the solvent and fractionation through a 180cm column at 10mm, with a reflux ratio of 20:1 and a rate of 0.33ml/minute gave *2,6-di-iso-propylaniline* as a colourless oil in 94.9% yield. The *benzoyl derivative* separated as an oil which solidifies and provides a white crystalline powder, **m 106.0-106.7°**, on recrystallisation form *iso*-octane. [Newton *J Am Chem Soc* **65** 2434 *1943*.] *Alternatively*, aniline (300g), $AlCl_3$ (18g), and Al powder (6g) are heated in a pressure vessel at 290°, and propylene is pumped into the vessel to a pressure of 250 atmospheres. From time to time more propylene is added to sustain the pressure. After *ca* 8 hours the pressure ceased to decrease, the vessel is opened and the product is shaken with dilute aqueous NaOH and fractionated under a vacuum. The three fractions that separate are *2,6-di-iso-propylaniline* (78%), 2-*iso*-propylaniline (15%), and a small amount of 2,4,6-tri-*iso*-propylaniline [Stroh et al. *Angew Chem* **69** 124 *1957*, also report **m 184.5-187°** for the *acetyl* derivative, and **m 254-256°** for the *benzoyl* derivative.] [*Beilstein* **12** III 2764.]
It is used for making NHCs for metal catalysed α-arylation of acyclic ketones, e.g. propiophenones, and amination of haloarenes [Matsubara et al. *J Org Chem* **72** 5069 *2007*]. It has been sulfonated for making sulfonated anilines, and consequently sulfonated NHCs, which provide water soluble Pd-NHCs used for Suzuki coupling of arylhalides with arylboronic acids in aqueous medium [Fleckenstein et al. *Chem Commun* 2870 *2007*].
N-*Trimethylsilyl 2,6-di-isopropylaniline* *[78923-65-6]*, prepared by reaction of Me_3SiCl and the Li salt of the aniline in Et_2O, is purified by distillation in vacuum. It is used in preparing the key intermediate for the Schrock-Hoveyda molybdenum catalyst (see [205815-80-1]), and sometimes it is prepared *in situ* without isolating it while using Et_3N instead of Li as base. [Schrock et al. *J Am Chem Soc* **112** 3875 *1990*, Alexander et al. *Organometallics* **19** 3700 *2000*].

***N,N*-Di-*n*-propylaniline** *[2217-07-4]* **M 177.3, b 127°/10mm, 238-241°/760mm, pK^{23} 5.68.** Reflux the aniline for 3 hours with acetic anhydride, then fractionally distil under reduced pressure.

Dithizone (diphenylthiocarbazone) *[60-10-6]* **M 256.3, m 168°(dec), ratio of $\varepsilon_{620nm}/\varepsilon_{450nm}$ should be ≥1.65, ε_{620} 3.4 x 10^4 ($CHCl_3$), pK_2 4.6.** The crude dithizone is dissolved in CCl_4 to give a concentrated solution. This is filtered through a sintered glass funnel and shaken with 0.8M aqueous ammonia to extract dithizonate ion. The aqueous layer is washed with several portions of CCl_4 to remove undesirable materials. The aqueous layer is acidified with dilute H_2SO_4 to precipitate pure dithizone. This is dried in a vacuum. When only small amounts of dithizone are required, purification by paper chromatography is convenient. [Cooper & Hibbits *J Am Chem Soc* **75** 5084 *1933*.] Instead of CCl_4, $CHCl_3$ can be used, and the final extract, after washing with water, can be evaporated in air at 40-50° and dried in a desiccator. It complexes with Cd, Hg, Ni and Zn.

[*Beilstein* **16** H 26, **16** IV 18.]

Di-*p*-tolyl carbonate *[621-02-3]* **M 242.3, m 115°.** Purify the carbonate by GLC with 20% Apiezon on Embacel followed by sublimation *in vacuo* and recrystallisation from EtOH (**m** 114°). [*Beilstein* **6** H 398, **6** I 201, **6** II 380, **6** III 1366.]

***N,N'*-Di-*o*-tolylguanidine** *[97-39-2]* **M 239.3, m 179° (175-176°), pK^{18} 9.62.** The guanidine crystallises from aqueous EtOH. The *sulfate* has **m** 253-254°(dec, H_2O). [*Beilstein* **12** H 803, **12** II 445, **12** III 1871, **16** IV 1764.]

Di-*p*-tolylphenylamine *[20440-95-3]* **M 273.4, m 108.5°, b 250°/20-40mm, pK$_{Est}$ ~ -5.0.** Crystallise the amine once from EtOAc, then twice from EtOH to give pale yellow needles. [Marsden *J Chem Soc* 627 *1937*, *Beilstein* **12** III 2033.]

Di-*p*-tolyl sulfone *[599-66-6]* **M 278.3, m 158-159°, 163.5°, b 405°/760mm.** Crystallise the sulfone repeatedly from Et_2O or EtOH. It has been purified by zone melting. [*Beilstein* **6** H 419, **6** II 395, **6** III 1405, **6** IV 2174.]

1,2-Divinylbenzene *[1321-74-0]* **M 130.2, b 53°/3mm, 79.2-79.6°/15mm, 195°//760mm, d^{20} 0.919, n$_D^{20}$ 1.573.** Purify divinylbenzene by dissolving in Et_2O, shaking with H_2O, drying over $CaCl_2$, filtering, evaporating and distilling *in vacuo*. It polymerises within 2-3days unless 4-*tert*butylcatechol (0.05%) is added as stabiliser. [Fries & Bestian *Chem Ber* **69** 715 *1936*, *Beilstein* **5** III 1366.]

Duroquinone (tetramethylbenzoquinone) *[527-17-3]* **M 164.2, m 110-111°, 111-112°.** Crystallise duraquinone from 95% EtOH. Dry it *in vacuo*. [*Beilstein* **7** H 669, **7** III 3417, **7** IV 2101.]

Ellagic acid (4,4',5,5',6,6'-hexahydroxydiphenic acid dilactone) *[476-66-4]* **M 338.2, m >360°, pK$_{Est(1)}$~8, pK$_{Est(2)}$~11.** This antioxidant crystallises from pyridine. It forms a dark green solution in aqueous *N* NaOH. The *tetraactetate dilactone* crystallises from Ac_2O, with **m** 340°. [*Beilstein* **19** H 261, **19** III/IV 3164, **19/7** V 108.]

Emodine (1,3,8-trihydroxy-6-methyl-9,10-anthracenedione, archin) *[518-82-1]* **M 270.2, m 253-257°, 255-256°, 256-257°, 262°, 264° (phenolic pKs 7—10).** Archin forms orange needles from EtOH, Et_2O, *C_6H_6, toluene or pyridine. It sublimes above 200° at 12mm. [Tutin & Clewer *J Chem Soc* **99** 946 *1911*, IR: Bloom et al. *J Chem Soc* 178 *1959*, UV: Birkinshaw *Biochem J* **59** 495 *1955*, Raistrick *Biochem J* **34** 159 *1940*.]

1*R*,2*S*-(-)Ephedrine see (–)-ephedrine (1*R*,2*S*-2-methylamino-1-phenylpropanol) in "Miscellaneous" in Chapter 7.

(±)-Epichlorohydrin *[106-89-8]* **M 92.5, b 115.5°/760mm d$_4^{25}$ 1.183, n$_D^{20}$ 1.438.** Distil epichlorohydrin at 760mm, heat it on a steam bath with one-quarter its weight of CaO, then decant and fractionally distil it. [*Beilstein* **17** H 6, **17** III/IV 20.]

***R*(-)Epinephrine** See adrenalin in "Miscellaneous" in Chapter 7.

3-Ethoxy-*N,N*-diethylaniline *[1846-92-2]* **M 193.3, b 145°/14mm, 268-270°/760mm, n$_D^{25}$ 1.5325, pK$_{Est}$ ~6.1.** Reflux it for 3 hours with Ac_2O, then fractionally distil it, preferably under reduced pressure. The *3-nitroso* derivative has **m** 72.5° (green crystals from petroleum ether/*C_6H_6). [Klaassens & Schoot *Rec Trav Chim Pays Bas* **48** 1272 *1929*.]

1-Ethoxynaphthalene *[5328-01-8]* **M 172.2, b 136-138°/14mm, 282°/760mm, d$_4^{20}$ 1.061, n$_D^{20}$ 1.604.** Fractionally distil it (twice) under a vacuum, then dry it with, and distil it under a vacuum from sodium. The *picrate* has **m** 118.5-119° (from EtOH). [*Beilstein* **6** H 606, **6** II 578, **6** III 2924, **6** IV 4212.]

2-Ethoxynaphthalene *[93-18-5]* **M 172.2, m 35.6-36.0°, b 142-143°/12mm, 280°/760mm.** Crystallise it from petroleum ether or EtOH (**m** 37-38°). Dry it *in vacuo*, or distil it in a vacuum. The *picrate* has **m** 104.5° (from EtOH or $CHCl_3$). [*Beilstein* **6** H 606, **6** II 578, **6** III 2972, **6** IV 4257.]

Ethyl *p*-aminobenzoate (Benzocaine) *[94-09-7]* **M 165.2, m 92°, pK^{25} 2.39.** Crystallise Benzocaine from EtOH/H_2O or EtOH (**m** 93-94°), and dry it in air. [*Beilstein* **14** H 422, **14** IV 1129.]

***p*-Ethylaniline** *[589-16-2]* **M 121.2, b 88°/8mm, d_4^{20} 0.975, n_D^{20} 1.554, pK^{25} 5.00.** Dissolve *p*-ethylaniline in *benzene, then acetylate it. Recrystallise the *acetyl* derivative (**m** 93-94°, Hickinbottom & Waine *J Chem Soc* 1565 *1930*) from *C_6H_6/petroleum ether or EOH, and hydrolyse it by refluxing 50g with 500ml of H_2O and 115ml of conc H_2SO_4 until the solution becomes clear. The amine sulfate is isolated, suspended in H_2O and solid KOH is added to generate the free base, which separates. Dry it (KOH), and distil it from zinc dust in a vacuum [Berliner & Berliner *J Am Chem Soc* **76** *6179 1954*]. The *picrate* has **m** 171-172° (from 1,2-dichloroethane). [*Beilstein* **12** H 1090, **12** III 2380, **12** IV 2419.]

***trans*-Ethyl cinnamate** *[103-36-6]* **M 176.2, f 6.7°, b 127°/6mm, 272.7°/768mm, d_4^{20} 1.040, n_D^{20} 1.55983.** Wash the ester with aqueous 10% Na_2CO_3, then water, dry ($MgSO_4$), and distil it. The purified ester is saponified with aqueous KOH, and, after acidifying the solution, cinnamic acid is isolated, washed and dried. The ester is reformed by refluxing for 15 hours the cinnamic acid (25g) with absolute EtOH (23g), conc H_2SO_4 (4g) and dry *benzene (100ml), after which it is isolated, washed, dried and distilled under reduced pressure [Jeffery & Vogel *J Chem Soc* 658 *1958*]. [*Beilstein* **9** IV 2006.]

(±)-Ethyl α,β-dibromo-β-phenylpropionate *[5464-70-0, erythro 30983-70-1]* **M 336.0, m 75°.** Crystallise the propionate from petroleum ether (b 60-80°), EtOH or aqueous EtOH (**m** 78°, and an unstable form **m** 65°). [*Beilstein* **9** H 512, **9** I 202, **9** III 2406, **9** IV 1772.]

Ethylene di(*p*-toluenesulfonate) (ethylene glycol ditosylate) *[6315-52-2]* **M 370.44, m 124-127°, m 126-127°, m 128°.** It is prepared from ethylene glycol (0.5mole) and *p*-toluenesulfonyl chloride (1.0mole) are stirred in Me_2CO (100ml) in the presence of 25% aqueous NaOH (175ml, 44g, 1.1mole) at 2-10° for ~4 hours. Excess of ice-water is added, the solid is filtered off, washed with large volumes of H_2O, dried *in vacuo* and recrystallised from dry *C_6H_6 (absolute EtOH has also been used) to give the *di-tosylate* (**m 128°**) in 76% yield [Drahowzal & Klamann *Monatsh* **82** 452 *1951*]. *Alternatively*, ethylene glycol (0.25mole), *p*-toluenesulfonyl chloride (0.52mole) in dry pyridine (80g, 1mole) are stirred gently at -10° to -4° for 2 hours then treated with excess of ice-water as above gave the *diester* in 87.3% yield [Drahowzal & Klamann *Monatsh* **82** 460 *1951*]. The latter method is superior as there is no H_2O in the reaction medium. Note that attempts to prepare the *mono-p-tosylate ester* using equimolar amounts of glycol and sulfonyl chloride always produced the *diester* which crystallised as white plates (**m 126°**) from hot EtOH [Butler et al. *J Am Chem Soc* **57** 575 *1935*]. [*Beilstein* **11** II 296, **11** III 225, **11** IV 290.]

S,S'-Ethylene di(*p*-toluenethiosulfonate) (ethylene dithiotosylate) *[2225-23-2]* **M 402.5, m 75-76°.** This reagent is the lower homologue of *1,3-trimethylene di(thiotosylate) [3866-79-3]*, and is made from potassium thiotosylate (45g, 0.20 mole, see below [28519-50-8]) and 1,2-dibromoethane (18.8g, 0.1 mole) in EtOH (200ml, containing 10-20mg of KI to activate the dibromide) by refluxing, with stirring in the dark under a N_2 atmosphere, for 8 hours. The solvent is evaporated *in vacuo*, and the white solid residue is washed, by decantation, with a mixture of EtOH (80ml) and H_2O (150ml), and then with H_2O (3 x 50ml), and recrystallised from EtOH (~150ml) to provide the crude thioester (28.7g) with m 72-75°. The pure thioester (24g, 60%), **m 75-76°**, is obtained as white crystals after three recrystallisations from EtOAc/EtOH; and its ^{1}H NMR ($CDCl_3$, TMS) has δ at 2.47 (s, 6H, 2C***H***$_3$), 3.31 (s, 4H, C***H***$_2$C***H***$_2$), 7.48 (d, *J* = 9Hz, 4H, Aromatic H) and 7.97 (d, *J* = 9Hz, 4H, Aromatic H). [Woodward et al. *Org Synth* Coll Vol **V** 1016 *1988*, *Org Synth* **54** 33 *1974*.]
Like the trimethylene homologue below it can form 1,3-dithiolanes with activated methylene groups and carbonyl compounds.

Ethyl gallate *[831-61-8]* **M 198.2, m 150-151°, 163-165°.** Recrystallise the gallate from 1,2-dichloroethane. Its UV has λ_{max} (neutral species) at 275nm (ε 10,000), (anion) at 235nm (ε 10,300), 279nm (ε 11,400) and

324nm (ε 8 500) [Campbell & Coppinger *J Am Chem Soc* **73** 2708 *1951*]. [*Beilstein* **10** IV 2002.]

Ethyl *p*-nitrobenzoate *[99-77-4]* **M 195.2, m 56°.** Dissolve it in Et_2O and wash it with aqueous alkali, then the ether is evaporated and the solid recrystallised from EtOH. [*Beilstein* **13** H 3787, **13** IV 1074.]

***o*-Ethylphenol** *[90-00-6]* **M 122.2, f 45.1°, b 210-212°, d_4^{20} 1.020, n_D^{20} 1.537, pK^{25} 10.20.** Purify as for *p*-ethylphenol below. [*Beilstein* **6** H 470, **6** IV 3011.]

***p*-Ethylphenol** *[123-07-9]* **M 122.2, m 47-48°, b 76°/1mm, 153°/100mm, 218.0°/762mm, n_D^{25} 1.5239, pK^{25} 10.21.** Non-acidic impurities are removed by passing steam through a boiling solution containing 1 mole of the phenol and 1.75 moles of NaOH (as an aqueous 10% solution). The residue is cooled and acidified with 30% (v/v) H_2SO_4, and the free phenol is extracted into diethyl ether. The extract is washed with water, dried with $CaSO_4$ and the ether is evaporated. The phenol is distilled at 100mm pressure through a Stedman gauze-packed column. It is further purified by fractional crystallisation by partial freezing, and by zone refining, under N_2 [Biddiscombe et al. *J Chem Soc* 5764 *1963*]. *Alternatively*, purify it *via* the benzoate, as for phenol. The *4-nitrophenylbenzoate* has **m** 80° (from EtOH). [*Beilstein* **6** H 470, **6** III 1663, **5** IV 3020.]

Ethyl phenylacetate *[101-97-3]* **M 164.2, b 99-99.3°/14mm, d_4^{20} 1.030, n_D^{20} 1.499.** Shake the ester with saturated aqueous Na_2CO_3 (three times), aqueous 50% $CaCl_2$ (twice) and saturated aqueous NaCl (twice). Dry with $CaCl_2$ and distil it under reduced pressure. [*Beilstein* **9** H 434, **9** IV 1618.]

Ethyl Red [2-(4-diethylaminophenylazo)benzoic acid] *[76058-33-8]* **M 297.4, m 135°, 150-152°, pK_1 2.5, pK_2 9.5.** Crystallise the acid dye from EtOH/diethyl ether or toluene. It is an indicator: pH 4.4 (red) and 6.2 (yellow). Its UV has λ_{max} at 447nm. [*Beilstein* **16** I 316.]

Ethynyl *p*-tolylsulfone *[13894-21-8]* **M 180.2, m 65-67°, 73-74°.** Recrystallise the sulfone from petroleum ether, *C_6H_6 or EtOH (**m** 66°), and dry it in a vacuum. [*Beilstein* **6** III 1397, **6** IV 2160.]

Eugenol (4-allyl-2-methoxyphenol) *[97-53-0]* **M 164.2, b 253°/760mm, 255°/760mm, d_4^{20} 1.066, n_D^{20} 1.540, pK^{25} 10.19.** Fractional distillation of eugenol gives a pale yellow liquid which darkens and thickens on exposure to air. It should be stored under N_2 at -20°. [Waterman & Priedster *Rec Trav Chim Pays Bas* **48** 1272 *1929*, *Beilstein* **6** H 961, **6** IV 6337.]

Eugenol methyl ether (4-allyl-1,2-dimethoxybenzene) *[93-15-2]* **M 178.2, m -4°, b 127-129°/11mm, 146°/30mm, 154.7°/760mm, d_4^{20} 1.0354, n_D^{20} 11.53411.** Recrystallise the ether from hexane at low temperature and redistil it (preferably *in vacuo*). [Hillmer & Schorning *Z Phys Chem* [A] **167** 407 *1934*, Briner & Fliszár *Helv Chim Acta* **42** 2063 *1959*, *Beilstein* **6** H 963, **6** IV 6337.]

Fluoranthene (benzo[*j,k*]fluorene) *[206-44-0]* **M 202.3, m 110-111°, b 384°/760mm.** Purify it by chromatography of CCl_4 solutions on alumina, with *benzene as eluent. Crystallise it from EtOH, MeOH or *benzene. Also purify it by zone melting. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*, *Beilstein* **5** I 344, **5** IV 2463.]

Fluorene *[86-73-7]* **M 166.2, m 114.7-115.1°, b 160°/15mm, 298°/atm.** Purify fluorene by chromatography of CCl_4 or petroleum ether (b 40-60°) solution on alumina, with *benzene as eluent. Crystallise it from 95% EtOH, 90% acetic acid and again from EtOH. Crystallisation using glacial acetic acid retains an impurity which is removed by partial mercuration and precipitation with LiBr [Brown et al. *J Am Chem Soc* **84** 1229 *1962*]. It has also been crystallised from hexane, or *benzene/EtOH, distilled under vacuum and purified by zone refining. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*, *Beilstein* **5** IV 2142.]

Fluorene-2,7-diamine *[525-64-4]* **M 196.3, m 165-166°.** Crystallise the diamine from hot H_2O or aqueous EtOH, dry it *in vacuo* and store it in the dark. [*Beilstein* **13** H 266, **13** II 123, **12** III 507, **13** IV 449.]

9-Fluorenone *[486-25-9]* **M 180.2, m 82.5-83.0°, 85-86°, b 341°/760mm.** Crystallise 9-fluorenone from absolute EtOH, MeOH or *benzene/pentane. [Ikezawa *J Am Chem Soc* **108** 1589 *1986*.] Also recrystallise it twice from toluene and sublime it in a vacuum [Saltiel *J Am Chem Soc* **108** 2674 *1986*]. It can be distilled under high vacuum. The *oxime* has **m 195°**, **198°** (yellow crystals from $*C_6H_6$ or xylene, Anet et al. *Can J Chem* **35** 180 *1957*, Wislicenus & Waldmuller *Chem Ber* **41** 3335 *1908*.) [*Beilstein* **7** H 465, **7** III 2330, **7** IV 1629.]

9-Fluorenylmethyl chloroformate (FMOC-Cl) *[28920-43-6]* **M 258.7, m 61-63°, 61.4-63°.** If the IR contains no OH bands (at ~3000 cm^{-1}) due to the hydrolysis product 9-fluorenylmethanol, then purify it by recrystallisation from dry Et_2O. Its IR ($CHCl_3$) has a band at 1770 cm^{-1} (C=O), and the ^1H NMR ($CDCl_3$) has δ at 4-4.6 (m 2H, C*H*CH_2) and 7.1-7.8 (m, 8 aromatic *H*). The *azide* (*FMOC-*N_3) has **m** 89-90° (from hexane) and IR ($CHCl_3$) at 2135 (N_3) and 1730 (C=O) cm^{-1}, and the *carbazate* (*FMOC-*$NHNH_2$) has **m** 171°(dec) (from nitromethane) with IR (KBr) at 3310, 3202 (NH) and 1686 (CONH) cm^{-1}. [Caprino & Han *J Org Chem* **37**, 3404 *1972*, *J Am Chem Soc* **92** 5748 *1970*, Koole et al. *J Org Chem* **59** 1657 *1989*, Fürst et al. *J Chromatogr* **499** 537 *1990*.]

9-Fluorenylmethyl succinimidyl carbonate *[82911-69-1]* **M 337.3, m 147-151°(dec), 151° (dec).** Recrystallise the carbonate from $CHCl_3/Et_2O$, or from petroleum ether (b 40-60°). [Pauet *Can J Chem* **60** 976 *1982*, Lapatsaris et al. *Synthesis* 671 *1983*.]

Fluorobenzene *[462-06-6]* **M 96.1, b 84.8°/760mm, d_4^{20} 1.025, n_D^{20} 1.46573, n_D^{30} 1.4610.** Dry fluorobenzene for several days with P_2O_5, then fractionally distil it. [*Beilstein* **5** H 198, **5** IV 632.]

o-**Fluorobenzoic acid** *[445-29-4]* **M 140.1, m 127°, d^{25} 1.460, pK^{25} 3.27.** Crystallise the acid from 50% aqueous EtOH, dilute HCl or $*C_6H_6$, then purify it by zone melting or vacuum sublimation at 130-140°. [*Beilstein* **9** H 333. **9** III 1324, **9** IV 950.]

m-**Fluorobenzoic acid** *[445-38-9]* **M 140.1, m 124°, 125°, d^{25} 1.474 pK^{25} 3.86.** Crystallise the acid from 50% aqueous EtOH or $*C_6H_6$, then sublime it *in vacuo* at 130-140°. [*Beilstein* **9** H 333, **9** IV 952.]

p-**Fluorobenzoic acid** *[456-22-4]* **M 140.1, m 182°, d^{25} 1.479, pK^{25} 4.15.** Crystallise the acid from 50% aqueous EtOH, then purify it by zone melting or vacuum sublimation at 130-140°. [*Beilstein* **9** H 333, **9** III 1327, **9** IV 953.]

3-Fluoro-4-hydroxyphenylacetic acid *[458-09-3]* **M 170.1, m 33°, $pK_{Est(1)}$ ~4.4, $pK_{Est(2)}$ ~9.4.** Crystallise the acid from water. [*Beilstein* **10** III 440.]

4-Fluoro-2-methylbenzaldehyde *[63082-45-1]* **M 138.1, d_4^{25} 1.144, n_D^{25} 1.526.** The aldehyde has been purified by gas chromatography and should be kept under N_2 as it readily oxidises in air [Burgess et al. *Aust J Chem* **30** 543 *1977*].

2-Fluoro-4-nitroaniline *[369-35-7]* **M 156.1, m 134-135°, 135-136°, pK^{25} -0.44 (aqueous $HClO_4$).** The aniline forms yellow crystals on recrystallisation from aqueous MeOH or EtOH. The *acetyl* derivative has **m** 203-204° (from EtOH). [Wepster & Verkade *Rec Trav Chim Pays Bas* **68** 86 *1949*, *Beilstein* **12** III 1647.]

1-Fluoro-4-nitrobenzene *[350-46-9]* **M 141.1, m 27°(stable form), 21.5°(unstable form), b 86.6°/14mm, 95-97.5°/22mm, 205.3°/735mm.** Crystallise it from EtOH or distil it in a vacuum. [*Beilstein* **5** H 241, **5** IV 719.]

1-Fluoro-4-nitronaphthalene *[341-92-4]* **M 191.2, m 80°.** It crystallises from EtOH as yellow needles [Bunce et al. *J Org Chem* **52** 4214 *1987*]. [*Beilstein* **5** III 1596, **5** IV 1675.]

4-Fluoro-3-nitrophenylazide *[28166-06-5]* **M 182.1, m 53-55°, 54-56°.** Dissolve the azide in Et_2O, dry it over $MgSO_4$, filter, evaporate and recrystallise the residue from petroleum ether (b 20-40°) to give orange needles. Store it in a stoppered container at ~0°. The ^1H NMR has δ at 7.75 (m 1H) and 7.35 (m 2H) in $CDCl_3$. [Hagedorn et al. *J Org Chem* **43** 2070 *1978*.]

***o*-Fluorophenol** *[367-12-4]* **M 112.1, m 16°, b 53°/14mm, 171-172°/714mm, d_4^{20} 1.257, n_D^{20} 1.514, pK^{25} 8.70.** Pass *o*-fluorophenol at least twice through a gas chromatographic column for small quantities; otherwise fractionally distil it under reduced pressure. [*Beilstein* **6** I 97, **6** IV 770.]

***p*-Fluorophenoxyacetic acid** *[405-79-8]* **M 170.1, m 104.2-104.6°, 106°, pK^{25} 3.13.** Crystallise the acid from EtOH or H_2O. [Hayes & Branch *J Am Chem Soc* **65** 1555 *1943*, *Beilstein* **6** III 971, **6** IV 776.]

4-Fluorophenylacetic acid *[405-50-5]* **M 154.1, m 86°, 94°, b 164°/2mm, pK^{25} 4.22.** Crystallise it from heptane, but it is best purified by distillation at high vacuum. [Bergmann et al. *J Am Chem Soc* **78** 6037 *1956*, *Beilstein* **9** III 2261, **9** IV 1672.]

4-Fluorophenyl isocyanate *[1195-45-5]* **M 137.1, b 55°/8mm, n_D^{20} 1.514.** Purify the isocyanate by repeated fractionation through an efficient column. If its IR indicates that there is too much urea (in the presence of moisture the symmetrical urea is formed), then dissolve it in dry EtOH-free $CHCl_3$, filter, evaporate and distil it. **It is a pungent LACHRYMATORY liquid, TOXIC.** [See Hardy *J Chem Soc* 2011 *1934*, and Hickinbottom *Reactions of Organic Compounds* Longmans p493 *1957*.]

4-Fluorophenyl isothiocyanate *[1544-68-9]* **M 153.2, m 24-26°, 26-27°, b 66°/2mm, 215°/atm, 228°/760mm, n_D^{20} 1.6116.** A likely impurity is the symmetrical thiourea. Dissolve the isothiocyanate in dry $CHCl_3$, filter and distil the residue in a vacuum. It can also be steam distilled, the oily layer is separated, dried over $CaCl_2$ and distilled *in vacuo*. *Bis-(4-fluorophenyl)thiourea* has **m** 145° (from aqueous EtOH). [Browne & Dyson *J Chem Soc* 3285 *1931*, Buu Hoi et al. *J Chem Soc* 1573 *1955*, Olander *Org Synth* Coll Vol **I** 448 *1941*].

***p*-Fluorophenyl-*o*-nitrobenzyl ether** *[448-37-3]* **M 247.2, m 62°.** Crystallise the ether from EtOH. [Jones *J Chem Soc* 1416 *1938*, *Beilstein* **6** III 1564, **6** IV 2608.]

***o*-Fluorotoluene** *[95-52-3]* **M 110.1, m -62°, b 114.4°/760mm, d_4^{20} 1.005, n_D^{20} 1.475.** Dry *o*-fluorotoluene with P_2O_5 or $CaSO_4$ and fractionally distil it through a silvered vacuum-jacketed glass column with 1/8th-in glass helices. A high reflux ratio is necessary because of the closeness of the boiling points of the *o*-, *m*- and *p*-isomers [Potter & Saylor *J Am Chem Soc* **37** 90 *1951*]. [*Beilstein* **5** H 290, **5** III 676, **5** IV 799.]

***m*-Fluorotoluene** *[352-70-5]* **M 110.1, m -87°, b 116.5°/760mm, d_4^{20} 1.00, n_D^{27} 1.46524.** Purify it as for *o*-fluorotoluene. [*Beilstein* **5** H 290, **5** III 676, **5** IV 799.]

***p*-Fluorotoluene** *[352-32-9]* **M 110.1, m -56°, 116.0°/760mm, d_4^{20} 1.00, n_D^{20} 1.46884.** Purify it as for *o*-fluorotoluene. [*Beilstein* **5** H 290, **5** III 677, **5** IV 799.]

Formanilide *[103-70-8]* **M 121.1, m 50°, b 166°/14mm, 216°/120mm, d_4^{20} 1.14.** Crystallise formanilide from Et_2O (**m** 45.3°), Et_2O/petroleum ether (**m** 46°), petroleum ether (**m** 47.6°), ligroin/xylene, or distil it preferably under reduced pressure. [*Beilstein* **12** H 230, **12** II 135, **12** III 453.]

Gallic acid (H_2O) (3,4,5-trihydroxybenzoic acid) *[5995-86-8 (H_2O), 149-91-7 (anhydrous)]* **M 188.1, m 253°(dec), pK_1^{25} 4.27, pK_2^{25} 8.68.** Crystallise gallic from water. The *tri-O-acetyl* derivative has **m** 172° (from MeOH), and the *anilide* has **m** 207°(from EtOH). [*Beilstein* **10** H 470, **10** IV 1993.]

Galvinoxyl [2,6-di-*tert*-butyl-α-(3,5-di-*tert*-butyl-4-oxo-2,5-cyclohexadiene-1-ylidene)-*p*-tolyloxy] *[2370-18-5]* **M 421.65, m 153.2-153.6°, 158-159°.** It is a stable free radical scavenger of short-lived free radicals with odd electrons on C or O. It is best prepared freshly by oxidation of 3,3',5,5'-tetra-*tert*-butyl-4,4'-dihydroxydiphenyl-methane [**m** 154°, 157.1-157.6°, obtained by gently heating for 10-15 minutes 2,6-di-*tert*-butylphenol, formaldehyde and NaOH in EtOH and recrystallised from EtOH (20g/100ml) as colourless plates, Karasch & Joshi *J Org Chem* **22** 1435 *1957*, Bartlett et al. *J Am Chem Soc* **82** 1756 *1960* and **84** 2596 *1962*]. Oxidation is carried out under N_2 with PbO_2 in Et_2O or isooctane [Galvin A. Coppinger *J Am Chem Soc* **79** 501 *1957*, Bartlett et al. above] or with alkaline potassium ferricyanide [Karasch & Joshi, above], whereby

Galvinoxyl separates as deep blue crystals and is recrystallised twice under N_2 from *C_6H_6 solution by suction evaporation at 30°. The VIS spectrum has λ_{max} at 407nm (ε 30,000), 431nm (ε 154,000) and weak absorption at 772.5nm, and IR has ν_{max} at 1577 and 2967cm^{-1}, and is estimated by iodometric titration. It is sensitive to O_2 in the presence of OH^- ions and traces of strong acid in hydroxylic or hydrocarbon solvents. At 62.5° in a 0.62mM solution in *C_6H_6 the radical decays with a first order $k = 4 \times 10^{-8}$ sec^{-1} (half life 1.7×10^{17} sec, ~200 days) as observed by the change in OD at 550nm [see Green & Adam *J Org Chem* **28** 3550 *1963*].

***R(–)*-Guaiaretic acid [guaiacic acid, 4,4'-(2,3-dimethyl-1-butene-(1,4-diyl)-bis-(2-methoxyphenol)]** *[500-40-3]* **M 328.4, m 99-100.5°, $[\alpha]_D^{16}$ -91° (c 1.1, EtOH), pK_{Est} ~10.0.** Crystallise the acid once from petroleum ether (b 60-80°), twice from 60% aqueous MeOH and finally from EtOH (**m** 100-101°). Its UV has λ_{max} at 207 and 260nm (logε 4.64 and 4.28). [King et al. *J Chem Soc* 4011 *1964*, Schrecker & Hartwell *J Org Chem* **21** 381 *1956*.]

Guaiacol (2-methoxyphenol) *[90-05-1]* **M 124.1, m 32°, b 106°/24mm, 205°/746mm, pK^{25} 9.90.** Crystallise guaiacol from *benzene/petroleum ether or distil it in a vacuum. [*Beilstein* **6** H 768, **6** IV 5563.]

Guaiacol carbonate *[553-17-3]* **M 274.3, m 88.1°, 89°.** Crystallise the carbonate from EtOH. It is estimated by bromination to the *monobromo guaiacol carbonate* **m** 178° (from EtOH) [Chernoff *J Am Chem Soc* **51** 3073 *1929*]. [*Beilstein* **6** H 776, **6** I 386, **6** II 784, **6** III 4233.]

Guaiazuline (1,4-dimethyl-7-isopropylazulene) *[489-84-9]* **M 198.3, m 31.5°, b 153°/7mm, d^{25} 0.976.** It forms blue-violet plates from EtOH. Also redistil it *in vacuo* until distillate solidifies. Its UV has λ_{max} at 284nm (log ε 4.6, heptane). The *picrate* has **m** 122°(EtOH). [*Beilstein* **5** III 1677, **5** IV 1751.]

Guanabenz (1-[2,6-dichlorobenzylideneamino]guanidine WY-8677) *[5051-62-7]* **M 231.1, m 227-229°(dec), pK_{Est} ~9.** Crystallise the guanidine from MeCN and store it in a CO_2-free atmosphere. The *monoHCl* [23256-5-0] has **m** 178°(dec) [solubility w% at 25° is 1.1(H_2O), 5(EtOH), 0.1(EtOAc), 0.06($CHCl_3$)]. It is an antihypertensive drug. [Holmes et al. *Drugs* **26** 212 *1983*.]

Hexachlorobenzene

[118-74-1] **M 284.8, m 230.2-231.0°, b 323-326°/atm.** Crystallise hexachlorobenzene repeatedly from *benzene. Dry it under vacuum over P_2O_5. [*Beilstein* **5** H 205, **5** IV 670.]

Hexachlorophene (2,2'-methylenebis[3,4,6-trichlorophenol]) *[70-30-4]* **M 406.9, m 166-167°, pK_1^{20} 5.41, pK_2^{20} (30% aqueous MeOH).** It forms needles from MeOH, $C_2H_4Cl_2$, or toluene. The *diacetate* has **m** 175-176° (EtOH). A disinfectant is also available in MeOH (5mg/l). [*Beilstein* **6** III 5407, **6** IV 6659.]

Hexadecyl 3-hydroxynaphthalene-2-carboxylate *[531-84-0]* **M 412.6, m 73-74°, d^{135} 0.824.** Recrystallise the ester from hot EtOH and sublime it in a vacuum. It is soluble in *C_6H_6, petroleum ether and AcOH. [Oshima & Hayashi *J Soc Chem Ind Jpn* **44** 821 *1941*, *Chem Abs* **42** 2108 *1948*, *Beilstein* **5** H 471, **5** I 227, **5** II 358, **5** III 1106, **5** IV 1208.]

Hexaethylbenzene *[604-88-6]* **M 246.3, m 128.7-129.5°.** Crystallise this hydrocarbon from *C_6H_6, or *C_6H_6/EtOH. The *1,3,5-trinitrobenzene complex (1:1)* has **m** 174°(EtOH). [*Beilstein* **5** III 3038, **5** IV 1137.]

Hexafluorobenzene *[392-56-3]* **M 186.1, m 5.1°, b 79-80°/760mm, d_4^{20} 1.61, n_D^{20} 1.378.** Main impurities are incompletely fluorinated benzenes. Purify it by standing in contact with oleum for 4 hours at room temperature, repeating until the oleum does not become coloured. Wash it several times with water, then dry it with P_2O_5. Finally purify it by repeated fractional crystallisation. [*Beilstein* **5** III 523, **5** IV 640.]

Hexamethylbenzene *[87-85-4]* **M 162.3, m 165-165.5°, 165.75°, b 264°/atm.** It is prepared, in an efficient fume cupboard, by passing a solution of phenol (100g, 1.06moles) in MeOH (1L) dropwise at a rate of 110ml/hour through a column (5.08cm diameter × 40.6cm long) packed with Al_2O_3 (300g, 4-8 or 8-14 mesh) as

catalyst held at 370-380°, and arranged so that effluent is connected to a receiver that allows the exit gasses (CO, CH_4 and H_2) into the fume cupboard. The yellow product (112-115g, 65-67%, m 134-145°) from the effluent which solidifies is washed with cold MeOH, and purified by recrystallisation from EtOH (50g/ 650ml) with 65-67% recovery, or from *C_6H_6 (50g/130ml) with 60% recovery to give pure colourless *hexamethylbenzene* **m 165-166°.** [Cullinane et al. *Org Synth* Coll Vol **IV** 520 *1963*.] It is also formed in >80% yields when *hexamethyl-Dewar benzene* [HMDB, 7641-77-2] comes into contact with anhydrous Al_2Cl_3 in hot *benzene (highly exothermic) [Schäfer & Hellmann *Angew Chem Internat Edn* **6** 518 *1967*]. It has been purified by sublimation, then recrystallisation from abolute EtOH, *benzene, EtOH/*benzene or EtOH/cyclohexane. It has also been purified by zone melting. Dry it in a low vacuum over P_2O_5. It forms 1:1 addition compounds with *2.4.7-trinitrofluorenone* (m 165-166.3°), *1,3,5-trinitrobenzene* (m 173°), *2,4,6-trinitrotoluene* (m 123°), *2-chloro-1,3,5-trinitrobenzene* (m 151°), and 1:1 complexes with Ag^+, $Cr(CO)_3$ and $W(CO)_3$. Its FT-IR (Nujol) has ν_{max} at 1300.8, 1249.1, 1180.6, 1129.2, 1057.1, 994.9, 943.5, 794.7 and 772.0 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 2.22 (s, 18H, Me_6); and the ^{13}C NMR (15MHz, $CDCl_3$, TMS) has δ at 17.72 (6-Me C) and 132.89 (6-aromatic C). [*Beilstein* **5** H 450, **5** I 213, **5** II 341, **5** III 1038, **5** IV 1137.]

Homophthalic acid *[89-51-0]* **M 180.2, m 180-181°, 182-183°, 189-190°, (depends on heating rate) $pK_{Est(1)}$ ~3.5, $pK_{Est(2)}$ ~4.3.** Crystallise the acid from boiling H_2O (25ml/g; 63ml/g at 20°), aqueous AcOH (**m** 180°) Dry it at 100°. The *S-benzylisothiuronium salt* has **m** 155-156° (from EtOH). [Price *Org Synth* **22** 61 *1942*, Grummitt et al. *Org Synth* Coll Vol **III** 449 *1955*, *Beilstein* **9** H 857, **9** II 617, **9** III 4266, **9** IV 3343.] The *anhydride* [703-59-3] **M** 162.1 has **m** 141-142°. [*Beilstein* **17/11** V 270.]

Homoveratronitrile (3,4-dimethoxybenzylnitrile) *[93-17-4]* **M 177.2, m 62-64°, 68°, b 184°/20mm, 195-196°/2mm, 208°/atm.** Its solubility is 10% in MeOH, and it has been recrystallised from EtOH or MeOH. Purify it also by distillation followed by recrystallisation. [Price & Rogers *Org Synth* Coll Vol **III** 174 *1955*, Niederl & Ziering *J Am Chem Soc* **64** 885 *1952*, Julian & Sturgis *J Am Chem Soc* **57** 1126 *1935*, *Beilstein* **10** I 198.]

Homoveratrylamine (2-[3,4-dimethoxyphenyl]ethylamine) *[120-20-7]* **M 181.2, b 99.3-101.3°/0.5mm, 168-170°/15mm, d_4^{20} 1.091, n_D^{20} 1.5460, pK_{Est} ~9.8.** Purify the amine by fractionation through an efficient column in an inert atmosphere as it is a relatively strong base. [Horner & Sturm *Justus Liebigs Ann Chem* **608** 12819 *1957*, Jung et al. *J Am Chem Soc* **75** 4664 *1953*.] The *hydrochloride* has **m** 152°, 154°, 156° (from EtOH, Me_2CO or EtOH/Et_2O), the *picrate* has **m** 165-167°(dec), and the *4-nitrobenzoyl* derivative has **m** 147° [Buck *J Am Chem Soc* **55** 2593 *1933*]. [*Beilstein* **13** H 800, **13** IV 2604.]

Hordenine {4-[(2-dimethylamino)ethyl]phenol} *[539-15-1]* **M 165.2, m 117-118°, b 173-174°/11mm, pK^{25} 9.46 (OH).** Crystallise Hordenine from EtOH or H_2O and sublime it at 105°/5mm. The *4,4'-dichlorodiphenyl disulfimide salt* has **m** 145-146° (from Me_2CO/H_2O) [Runge et al. *Chem Ber* **88** 50 *1955*]. [*Beilstein* **13** H 626, **13** I 236, **13** II 356, **13** III 1640, **13** IV 1790.]

4-Hydrazinobenzoic acid *[619-67-0]* **M 152.2, m 217° (dec), pK^{25} 4.13.** The acid crystallises from water. [*Beilstein* **15** H 631, **15** IV 1372.] The *hydrochloride* [24589-37-3] **M** 188.6, has **m** 253°(dec) [*Beilstein* **15** III 837].

Hydrobenzamide [1-phenyl-*N,N'*-bis(phenylmethylene)-methanediamine] *[92-29-5]* **M 298.4, m 101-102°, 107-108°.** Crystallise hydrobenzamide from absolute EtOH, petroleum ether (**m** 107-108°), *C_6H_6 (**m** 103°), or cyclohexane/*benzene. Dry it under vacuum over P_2O_5. [Pirrone *Gazz Chim Ital* ***67*** 534 *1937*, *Beilstein* **7** H 215, **7** I 120, **7** II 166, **7** III 838.]

***dl*-Hydrobenzoin (1,2-diphenyl-1,2-ethanediol, *iso*-hydrobenzoin)** *[492-70-6]* **M 214.3, m 120°.** Crystallise the diol from Et_2O/petroleum ether or H_2O (**m** 121-122°) [*Beilstein* **6** H 1004, **6** I 490, **6** II 969, **6** III 5431.] The *R,R-(+)-* and *S,S-(–)- enantiomers* have **m** 148.5-149.5°(dec), $[\alpha]_D^{20}$ + and -94.0° (c 2, EtOH) [Eisenlohr & Hill *Chem Ber* **70** 942 *1937*].

***meso*-Hydrobenzoin** *[579-43-1]* **M 214.3, m 139°, 139-140°.** Crystallise it from EtOH or water. [*Beilstein* **6**

H 1003, **6** I 490, **6** II 967. **6** III 5429, **6** IV 6682.]

Hydroquinone (1,4-dihydroxybenzene, quinol) *[123-31-9]* **M 110.1, m 175.4, 176.6°, pK_1^{20} 9.91, p K_2^{20} 11.56.** Crystallise quinol from acetone, *benzene, EtOH, EtOH/*benzene, water or acetonitrile (25g in 30ml), preferably under nitrogen. Dry it under vacuum. [Wolfenden et al. *J Am Chem Soc* **109** 463 *1987*, *Beilstein* **6** H 836, **6** IV 5712.]

p-**Hydroxyacetophenone** *[99-93-4]* **M 136.2, m 109°, 111°, 147-148°/3mm, pK^{25} 8.01.** Crystallise it from diethyl ether, aqueous EtOH or *benzene/petroleum ether. [*Beilstein* **8** H 87, **8** IV 339.]

3-Hydroxyanthranilic acid (2-amino-3-hydroxybenzoic acid) *[548-93-6]* **M 153.1, m >240°(dec), 245-265°(dec), 253-154°, 252-255°, λ_{max} 298nm, log ε 3000 (0.1M HCl), pK_1^{20} 2.7, pK_2^{20} 5.19, pK_3^{20} 10.12.** Crystallise the acid from H_2O or EtOH (**m** 254-255°). Sublime it at 170°/0.1mm. The *hydrochloride* has **m** 227° (from dilute HCl). [*Beilstein* **14** H 587, **14** III 1463, **14** IV 2071.] **Possible carcinogen.**

5-Hydroxyanthranilic acid (2-amino-5-hydroxybenzoic acid) *[394-31-0]* **M 153.1, m 233-234°, 235-236°, 248°(dec), pK_1^{25} 2.72, pK_2^{25} 5.37, pK_3^{20} 10.12.** Crystallise the acid from water. The *benzamide* has **m** 240-242° (from AcOH). It is a **hypoglycemic agent**. [*Beilstein* **14** H 591, **14** II 357, **14** III 1468, **14** IV 2080.]

m-**Hydroxybenzaldehyde** *[100-83-4]* **M 122.1, m 108° pK_1^{25} 8.98, pK_2^{25} 15.81.** Crystallise the aldehyde from water. [*Beilstein* **8** H 58, **8** IV 240.]

p-**Hydroxybenzaldehyde** *[123-08-0]* **M 122.1, m 115-116°, 117-119°, pK^{25} 7.61.** Crystallise it from water (containing some H_2SO_4). Dry it over P_2O_5 under vacuum. [*Beilstein* **8** H 64, **8** IV 251.]

m-**Hydroxybenzoic acid** *[99-06-9]* **M 138.1, m 200.8°, pK_1^{25} 4.08, pK_2^{25} 9.98.** Crystallise the hydroxyacid from absolute EtOH. [*Beilstein* **10** IV 315.]

p-**Hydroxybenzoic acid** *[99-96-7]* **M 138.1, m 213-214°, pK_1^{25} 4.50, pK_2^{25} 9.11.** Crystallise the hydroxyacid from water. [*Beilstein* **10** IV 345.]

2-Hydroxybenzyl alcohol (saligenine) *[90-01-7]* **M 124.1, m 86-87°, 87°, pK^{25} 9.92.** Crystallise saligenine from water or EtOH/*C_6H_6 (**m** 89°). [*Beilstein* **6** III 4537, **6** IV 5896.]

3-Hydroxybenzyl alcohol *[620-24-6]* **M 124.1, m 71°, pK^{25} 9.83.** Crystallise the alcohol from *C_6H_6 or $CHCl_3$. [*Beilstein* **6** III 4545, **6** IV 5907.]

4-Hydroxybenzyl alcohol *[623-05-2]* **M 124.1, m 122°, 127°, 132°, pK^{25} 9.82.** Crystallise the alcohol from H_2O, *C_6H_6 (**m** 124°), *C_6H_6/EtOH or $ClCH_2CH_2Cl$ (**m** 122°). [*Beilstein* **6** III 4546, **6** IV 5909.]

2-Hydroxybiphenyl *[90-43-7]* **M 170.2, m 56°, b 145°/14mm, 275°/760mm, pK^{20} 10.01.** Crystallise it from petoleum ether. [*Beilstein* **6** IV 4579.]

4-Hydroxybiphenyl (4-phenylphenol) *[92-69-3]* **M 170.2, m 164-165°, b 305-308°/760mm, pK^{23} 9.55.** Crystallise the phenol from aqueous EtOH, *C_6H_6, and dry it in a vacuum over $CaCl_2$ [Buchanan et al. *J Am Chem Soc* **108** 7703 *1986*]. [*Beilstein* **6** IV 4600.]

***trans*-4-Hydroxycinnamic acid (*p*-coumaric acid)** *[501-98-4]* **M 164.2, m 210-213°, 214-215°, 215°, pK_1^{25} 4.64, pK_2^{25} 9.45.** Crystallise *p*-coumaric acid from H_2O (charcoal). It forms needles from concentrated aqueous solutions as the *anhydrous acid*, but from hot dilute solutions the *monohydrate acid* separates on slow cooling. The acid (33g) has been crystallised from 2.5L of H_2O (1.5g charcoal) yielding 28.4g of recrystallised acid, **m** 207°. It is insoluble in *C_6H_6 or petroleum ether. The UV in 95% EtOH has λ_{max} at 223 and 286nm (ε 14,450 and 19000 $M^{-1}cm^{-1}$). [UV Wheeler & Covarrubias *J Org Chem* **28** 2015 *1963*, Corti *Helv Chim Acta* **32** 681 *1949*, *Beilstein* **10** IV 1005.]

3-(4-Hydroxy-3,5-dimethoxyphenyl)acrylic acid (sinapinic acid) *[530-59-6]* **M 234.1, m 204-205°(dec), $pK_{Est(1)}$ ~4.6, $pK_{Est(2)}$ ~9.3.** Crystallise it from water. [*Beilstein* **10** H 508, **10** IV 2104.]

4-Hydroxydiphenylamine *[122-37-2]* **M 185.2, m 72-73°, pK_{Est} ~10.0.** Crystallise the amine from chlorobenzene/petroleum ether, pentane (**m** 72°) or *C_6H_6/petroleum ether (**m** 70°). [*Beilstein* **13** III 1019, **13** IV 1052.]

2-Hydroxy-4-(*n*-dodecyloxy)benzophenone *[2985-59-3]* **M 382.5, m 50-52°, pK_{Est} ~7.1.** Recrystallise it from *n*-hexane and then 10% (v/v) EtOH in acetonitrile [Valenty et al. *J Am Chem Soc* **106** 6155 *1984*].

4-Hydroxyindane *[1641-41-1]* **M 134.2, m 49-50°, b 120°/12mm, pK^{25} 10.32.** Crystallise 4-hydroxyindane from petroleum ether, pentane (**m** 50-50.5°) or *C_6H_6 (**m** 39.5-40°). It has UV with λ_{max} at 277nm (cyclohexane). The *acetyl* derivative has **m** 30-32° (from EtOH), **b** 127°/14mm and the *3,5-dinitrobenzoyl* derivative has **m** 114°. [Dallacker et al. *Chem Ber* **105** 2568 *1972*, *Beilstein* **6** III 2427, **6** IV 3827.]

5-Hydroxyindane *[1470-94-6]* **M 134.2, m 55°, b 127°/14mm, 255°/760mm, pK^{23} 10.24.** Crystallise 5-hydroxyindane from petroleum ether (**m** 56°) or pentane (**m** 59-60°). It has UV with λ_{max} at 283.5nm (cyclohexane). The *3,5-dinitrobenzoyl* derivative has **m** 156°. [*Beilstein* **6** III 2428, **6** IV 3829.]

4-Hydroxy-3-methoxyacetophenone (apocynin) *[498-02-2]* **M 166.2, m 115°, pK_{Est} ~7.9.** Crystallise apocynin from water, or EtOH/petroleum ether. [*Beilstein* **8** IV 1814.]

***trans*-4-Hydroxy-3-methoxycinnamic acid (ferulic acid)** *[537-98-4; 1135-24-6]* **M 194.2, m 174°, pK_1^{25} 4.58, pK_2^{25} 9.39.** Crystallise ferulic acid from H_2O. [*Beilstein* **10** H 436, **10** IV 1776.]

4-Hydroxy-2-methylazobenzene (3-methyl-4-phenylazophenol) *[1435-88-7]* **M 212.2, m 100-101°, 112°, pK_{Est} ~9.5.** Crystallise the phenol from hexane. [*Beilstein* **16** II 61, **16** IV 195.]

4-Hydroxy-3-methylazobenzene (2-methyl-4-phenylazophenol) *[621-66-9]* **M 212.2, m 125-126°.** Crystallise the phenol from hexane or petroleum ether (**m** 130°). [*Beilstein* **16** II 59, **16** III 104, **16** IV 193.]

3-Hydroxy-4-methylbenzaldehyde *[57295-30-4]* **M 136.1, m 73°, pK_{Est} ~10.2.** Crystallise it from water or *C_6H_6 (**m** 71-71°). The *O-methyl ether* has **m** 45-46° (from Et_2O/hexane). [Sedgwick & Allott *J Chem Soc* 2820 1923, Flitsch et al. *Justus Liebigs Ann Chem* 1413 *1985*, *Beilstein* **8** H 100, **8** II 103, **8** IV 368.]

5-Hydroxy-2-methyl-1,4-naphthaquinone (plumbagin) *[481-42-5]* **M 188.2, m 78-79°, $pK_{Est(1)}$~9.5, $pK_{Est(2)}$~11.0.** It crystallises in yellow needles from aqueous EtOH. It is soluble in organic solvents, it is steam volatile and it sublimes on heating in a vacuum. [Fieser & Dunn *J Am Chem Soc* **58** 572 *1936*, *Beilstein* **8** III 2576, **8** IV 2376.]

6-Hydroxy-2-methyl-1,4-naphthaquinone *[633-71-6]* **M 188.2, pK_{Est} ~10.0.** Crystallise the naphthaquinone from aqueous EtOH and sublime it in a vacuum.

2-Hydroxy-1-naphthaldehyde *[708-06-5]* **M 172.2, m 82°, b 139-142°/4mm, 192°/27mm, pK^{25} 8.27 (50% aqueous EtOH).** Crystallise the aldehyde from EtOH (1.5ml/g), aqueous EtOH, aqueous AcOH (**m** 84°), EtOAc or H_2O. [Russell & Lockhart *Org Synth* Coll Vol **III** 463 *1955*, *Beilstein* **8** H 143, **8** I 564, **8** II 171, **8** III 1108, **8** IV 1160.]

2-Hydroxy-1-naphthaleneacetic acid *[10441-45-9]* **M 202.2, m 147-148°, $pK_{Est(1)}$ ~4.2, $pK_{Est(2)}$ ~8.3.** Crystallise the acid from EtOH/water (1:9, v/v, activated charcoal), H_2O (**m** 157°) or xylene (**m** 147°). Dry it under vacuum, over silica gel, in the dark. Store it in the dark at -20° [Gafni et al. *J Phys Chem* **80** 898 *1976*]. It forms a cyclic lactone (**m** 107°) readily. [*Beilstein* **10** II 218, **10** III 1102, **10** IV 1201.]

6-Hydroxy-2-naphthalenepropionic acid *[553-39-9]* **M 216.2, m 180-181°, $pK_{Est(1)}$ ~4.6, $pK_{Est(2)}$~9.0.** Crystallise the acid from aqueous EtOH or aqueous MeOH. [Ormancey & Horeau *Bull Soc Chim Fr* 962 *1955*, *Beilstein* **10** III 1113.]

3-Hydroxy-2-naphthalide (Naphthol AS) *[92-77-3]* **M 263.3, m 248.0-248.5°, CI 37505.** Crystallise it from xylene or AcOH which forms plates **m** 243-244° [Schnopper et al. *Anal Chem* **31** 1542 *1959*]. [*Beilstein* **12** H 505.]

3-Hydroxy-2-naphtho-4'-chloro-*o*-toluidide *[92-76-2]* **M 311.8, m 243.5-244.5°.** Crystallise it from xylene [Schnopper et al. *Anal Chem* **31** 1542 *1959*].

3-Hydroxy-2-naphthoic-1'-naphthylamide *[123-68-3]* **M 314.3, m 217-.5-218.0°.** Crystallise the amide from xylene [Schnopper et al. *Anal Chem* **31** 1542 *1959*].

3-Hydroxy-2-naphthoic-2'-naphthylamide *[136-64-8]* **M 305.3, m 243.5-244.5°, and other naphthol AS derivatives.** Crystallise it from xylene [Schnopper et al. *Anal Chem* **31** 1542 *1959*].

2-Hydroxy-1,4-naphthoquinone (Lawsone B, Neutral Orange 6, tautomeric with 4-hydroxy-1,2-naphthoquinone) *[83-72-7]* **M 174.2, m 192°(dec), CI 75480 pK_1^{25} -5.6 (C=O protonation), pK_2^{25} 2.38, pK_3^{25} 4.00 (phenolic OH).** Crystallise Lawsone B from *C_6H_6 or AcOH (**m** 192.5°, 195-196°). It sublimes in a vacuum (**m** 194°). It has UV with λ_{max} at 455nm (aqueous NaOH). [*Beilstein* **8** H 300, **8** I 635, **8** II 344, **8** III 2543, **8** IV 2360.]

5-Hydroxy-1,4-naphthoquinone (Juglone) *[481-39-0]* **M 174.2, m 155°, 164-165°, pK^{25} 8.7.** Crystallise Juglone from *benzene/petroleum ether or petetroleum ether. [*Beilstein* **8** III 2558, **8** IV 2368.]

6-Hydroxy-2-naphthyl disulfide *[6088-51-3]* **M 350.5, m 221-222°, 226-227°, pK_{Est} ~9.0.** It crystallises as leaflets from AcOH and is slightly soluble in EtOH, and AcOH, but is soluble in *C_6H_6 and in alkalis to give a yellow solution. [Zincke & Dereser *Chem Ber* **51** 352 *1918*.] The *acetoxy* derivative has **m** 198-200° (from AcOH or dioxane/MeOH), and the *diacetyl* derivative has **m** 167-168° (from AcOH). A small amount of impure disulfide can be purified by dissolving it in a small volume of Me_2CO and adding a large volume of toluene, filter rapidly and concentrate to one-third of its volume. The hot toluene solution is filtered rapidly from any tarry residue, and crystals separate on cooling. Recrystallisation from hot acetic acid gives crystals with **m** 220-223° [Barrett & Seligman *Science* **116** 323 *1952*]. [*Beilstein* **6** I 481.]

2-Hydroxy-5-nitrobenzyl bromide (Koshland's reagent) *[772-33-8]* **M 232.0, m 147°, pK_{Est} ~8.0.** Crystallise the bromide from *benzene or *benzene/ligroin. It is slightly soluble in EtOH, soluble in *C_6H_6 and AcOH, and very soluble in ligroin. [*Beilstein* **6** H 367.]

2-Hydroxyphenylacetic acid *[614-75-5]* **M 152.2, m 148-149°, 152-153°, b 240-243°/760mm, $pK_{Est(1)}$~4.3, $pK_{Est(2)}$~10.1.** Crystallise the acid from ether or chloroform (**m** 147°, m from latter solvent is always lower). [*Beilstein* **10** H 187, **10** I 81, **10** II 112, **10** III 422, **10** IV 536.]

3-Hydroxyphenylacetic acid *[621-37-4]* **M 152.2, m 137°, $pK_{Ext(1)}$~4.3, $pK_{Ext(2)}$~10.** Crystallise the acid from *C_6H_6/ligroin or EtOAc/cyclohexane (**m** 131-132°). [*Beilstein* **10** H 189, **10** I 82, **10** II 112, **10** III 428, **10** IV 541.]

4-Hydroxyphenylacetic acid *[156-38-7]* **M 152.2, m 150-151°, 152°, pK_1 4.28, pK_2 10.1.** Crystallise the acid from water or Et_2O/petroleum ether. The *p-bromophenacyl ester* has **m** 117° (from EtOH). [*Beilstein* **10** II 112, **10** III 430, **10** IV 543.]

***N*-(4-Hydroxyphenyl)-3-phenylsalicylamide** *[550-57-2]* **M 305.3, m 183-184°, pK_{Est} ~9.5.** Crystallise the amide from aqueous MeOH. [*Beilstein* **13** IV 224.]

L-2-Hydroxy-3-phenylpropionic acid (3-phenyl lactic acid) *[20312-36-1]* **M 166.2, m 125-126°, $[\alpha]_D^{12}$ -18.7° (EtOH), $[\alpha]_D^{20}$ -22° (c 1, H_2O), pK see below.** Crystallise the acid from water, MeOH, EtOH or *benzene. [*Beilstein* **10** IV 653.]

***dl*-2-Hydroxy-3-phenylpropionic acid** *[828-01-3]* **M 166.2, m 97-98°, b 148-150°/15mm, pK_{Est} ~3.7.** Crystallise the propionic acid from *benzene or chloroform. [*Beilstein* **10** IV 653.]

3-*p*-Hydroxyphenylpropionic acid (phloretic acid) *[501-97-3]* **M 166.2, m 129-130°, 131-133°, $pK_{Est(1)}$~4.7, $pK_{Est(2)}$~10.1.** Crystallise phloretic acid from ether or H_2O. [*Beilstein* **10** IV 631.]

p-**Hydroxyphenylpyruvic acid** *[156-39-8]* **M 180.2, m 220°(dec), pK_{Est} ~2.3.** Crystallise it three times from 0.1M HCl/EtOH (4:1, v/v) immediately before use [Rose & Powell *Biochem J* **87** 541 *1963*], or from Et_2O. The *3,4-dinitrophenylhydrazone* has **m** 178°. [*Beilstein* **10** IV 3630.]

***N*-Hydroxyphthalimide** *[524-38-9]* **M 163.1, m 230°, ~235°(dec), 237-240°, pK^{30} 7.0.** Dissolve the imide in H_2O by adding Et_3N to form the salt and while hot, acidify, cool and pour into a large volume of H_2O. Filter off the solid, wash it with H_2O and dry it over P_2O_5 in a vacuum. [Nefken & Teser *J Am Chem Soc* **83** 1263 *1961*, Fieser **1** 485 *1976,* Nefkens et al. *Rec Trav Chim Pays Bas* **81** 683 *1962*] The *O-acetyl* derivative has **m** 178-180° (from EtOH). [*Beilstein* **21/11** V 100.]

4'-Hydroxypropiophenone *[70-70-2]* **M 150.2, m 149°, b 140-145°/0.5mm, pK^{25} 8.05.** Crystallise the phenone from H_2O (**m** 149.8-150.2°) or EtOH (**m** 147°). The *benzoyl derivative* has **m** 117°, and the *semicarbazone* has **m** 183° (EtOH). [*Beilstein* **8** H 102, **8** II 104, **8** III 379.]

***trans*-4-Hydroxystilbene** *[6554-98-9]* **M 196.3, m 189°.** Crystallise it from *C_6H_6, MeOH (**m** 186-187°) or acetic acid. [*Beilstein* **6** H 693, **6** II 657, **6** III 3497, **6** 4855.]

Hydroxy(tosyloxy)iodobenzene [phenyl(hydroxyl)tosyloxyiodine, hydroxy(4-methylbenzenesulfonato-O)phenyliodine, Koser's reagent] *[27126-76-7]* **M 392.2, m 134-136°, 135-138°, 134-136°, 136-138.5°.** Possible impurities are tosic acid (removed by washing with Me_2CO) and acetic acid (removed by washing with Et_2O). It is purified by dissolving in the minimum volume of MeOH, adding Et_2O to cloud point and setting aside for the prisms to separate [Koser & Wettach *J Org Chem* **42** 1476 *1977*, NMR: Koser et al. *J Org Chem* **41** 3609 *1976*]. It has also been crystallised from CH_2Cl_2 (needles, **m** 140-142°) [Neiland & Karele *J Org Chem, USSR (Engl Transl)* **6** 889 *1970*].

9-Hydroxytriptycene *[73597-16-7]* **M 270.3, m 245-246.5°.** Crystallise it from *benzene/petroleum ether. Dried it at 100° in a vacuum [Bartlett & Greene *J Am Chem Soc* **76** 1088 *1954*, Imashiro et al. *J Am Chem Soc* **109** 729 *1987*].

Hypericin (hypericum, 4,5,7,4',5',7'-hexahydroxy-2',2'-dimethylnaphthodianthrone) *[548-04-9]* **M 504.4, m 320°(dec).** Crystallise hypericin from pyridine by addition of methanolic HCl. [*Beilstein* **8** IV 3761.]

Ibuprofen [*(S+)* and *(R-)* 4-*iso*butyl-α-methylphenylacetic acid, Brufen, Nurofen, Motrui] *[(S +) 51146-56-6, (R —) 51146-57-7]* **M 206.3, m 52-53°, $[\alpha]_D^{20}$ +59° (c 2, EtOH).** Crystallise the (+) and (–) acids from EtOH or aqueous EtOH. The *racemate,* which crystallises from petroleum ether with **m** 75-77°, is sparingly soluble in H_2O and has IR (film) with ν_{max} at 1705 (C=O), 2300—3700 (OH broad) cm^{-1}. It is used as a non-steroidal anti-inflammatory. [Shiori et al. *J Org Chem* **43** 2936 *1978,* Kaiser et al. *J Pharm Sci* **65** 269 *1976*, *J Pharm Sci* **81** 221 *1992*, Freer *Acta Cryst* (C) **49** 1378 *1993* for the *(S+)-enantiomer*.]

1,3-Indandione *[606-23-5]* **M 146.2, m 129-132°, pK^{18} 7.2 (1% aqueous EtOH).** Recrystallise it from EtOH or *C_6H_6. In dilute alkali it gives a deep yellow solution of the enol. [Bernasconi & Paschalis *J Am Chem Soc* **108** 2969 *1986*]. [*Beilstein* **7** IV 2344.]

Indane (indan, hydrindene, 1,2-trimethyenebenzene) *[496-11-7]* **M 118.1, f –51.4°, b 79°/29mm, 177-179.5°/760mm, d_4^{20} 0.960, n_D^{20} 1.536.** Shake indane with conc H_2SO_4, then water, dry (Na_2SO_4) and fractionally distil it. [*Beilstein* **5** H 486, **5** I 234, **5** II 376, **5** III 1200, **5** IV 1371.]

Indene *[95-13-6]* **M 116.2, f -1.5°, m -5° to -3°, b 114.5°/100mm, 181-182°/atm, d_4^{20} 0.994, n_D^{20} 1.5763.** Shake indene with 6M HCl for 24 hours (to remove basic nitrogenous material), then reflux it with 40% NaOH for 2 hours (to remove benzonitrile). Fractionally distil, then fractionally crystallise it by partial freezing. The higher-melting portion is converted to its sodium salt by adding a quarter of its weight of sodamide under nitrogen and stirring for 3 hours at 120°. Unreacted organic material is distilled off at 120°/1mm. The sodium salts are hydrolysed with water, and the organic fraction is separated by steam disillation, followed by fractional distillation. Before use, the distillate is passed, under nitrogen, through a column of activated silica gel. It turns yellow in air as it readily oxidises and polymerises. Store it in the presence of *tert*-butylcatechol (50-100ppm) as antioxidant. [Russell *J Am Chem Soc* **78** 1041 *1956*, *Beilstein* **5** IV 1532.]

2-Iodoaniline *[615-43-0]* **M 219.0, m 60-61°, pK^{25} 2.54.** Distil 2-iodoaniline with steam and crystallise it from *benzene/petroleum ether. The *N-acetyl* derivative has **m** 110°. [*Beilstein* **12** IV 1542.]

4-Iodoaniline *[540-37-4]* **M 219.0, m 62-63°, pK^{25} 3.81.** Crystallise it from petroleum ether (b 60-80°) by refluxing, then cool it in an ice-salt bath freezing mixture. Dry it in air. *Alternatively*, crystallise it from EtOH and dry it *in vacuo* for 6 hours at 40° [Edidin et al. *J Am Chem Soc* **109** 3945 *1987*]. The *N-acetyl* derivative has **m** 184° (from MeOH). [*Beilstein* **12** IV 1544.]

4-Iodoanisole *[696-62-8]* **M 234.0, m 51-52°, b 133-133.3°/25mm, 139°/35mm, 237°/726mm.** Crystallise 4-iodoanisole from aqueous EtOH and/or distil it under vacuum. [*Beilstein* **6** H 208, **6** I 109, **6** II 199, **6** III 744, **6** IV 1075.]

Iodobenzene *[591-50-4]* **M 204.0, b 63-65°/10mm, 188°/atm, d_4^{20} 1.829, n_D^{25} 1.6169.** Wash it with dilute aqueous $Na_2S_2O_3$, then water. Dry it with $CaCl_2$ or $CaSO_4$, decolourise with charcoal and distil it under reduced pressure then store it with mercury or silver powder to stabilise it. [*Beilstein* **5** IV 688.]

***o*-Iodobenzoic acid** *[88-67-5]* **M 248.4, m 161-162°, 161.6-162°, 162°, 162.7-163.5°, 164°, pK^{20} 2.93, pK^{25} 2.84 (H_2O), pK^{20} 2.93 (1% EtOH), pK –7.78 (H_2SO_4).** Crystallise the acid repeatedly from water (charcoal), EtOH, aqueous EtOH, aqueous Me_2CO, Me_2CO/Et_2O or $*C_6H_6$. Sublime it under vacuum at 100°. *o*-Iodobenzoic acid is prepared by the following procedure: anthranilic acid (31.9g, 233mmol, see [118-92-3]) is dissolved in dilute H_2SO_4 (50g, 27ml, 98% acid, 500mmol, in 250ml of H_2O), cooled to 0°; and while stirring $NaNO_2$ (20g, 290mmol) in H_2O (40ml) is added dropwise keeping the temperature below 10° (add crushed ice to the mixture if necessary). Diazotisation is complete when starch-iodide paper wetted with a drop of the mixture turns blue or brown due to the presence of excess of HNO_2. A solution of KI (60g, 360mmol) in H_2O (100ml) is gradually added with stirring, the mixture is set aside for 1 hour then heated at ~100° until effernescence (N_2 liberated) ceases. The mixture is cooled in ice, the brown iodo-acid (~92%) is filtered off, washed well with H_2O and dried *in vacuo.* The brown colour is not easily removed by recrystallisation so the acid is converted into the ethyl ester e.g. by Fischer and Speier's method [Fischer & Speier *Chem Ber* **28** 2250 *1895*]. Dry HCl gas is bubbled through EtOH (~200ml) cooled in ice-water until the increase in weight is ~4g. The crude iodobenzoic acid is added to it and the mixture is boiled under reflux for 2 hours, or until an aliquot poured into H_2O does not deposit a solid. The mixture is poured into cold H_2O, the heavy oil that separated is extracted into Et_2O, the extract is washed with H_2O, saturated aqueous $NaHCO_3$ (care-effervescence), brine, dried ($CaCl_2$), filtered, evaporated and the residual oil is distilled to give a 73% yield of pure *ethyl* o-*iodobenzoate* **M 276.0** [1829-28-3], **b 151-152°/12-13mm (163-165°/23mm, 275°/atm).** This ester is dissolved in 0.5 *N* alcoholic KOH (from 7g of KOH dissolved in 7ml of H_2O and diluted to 250ml with EtOH) in the ratio of 1g:25ml, and refluxed for 30 minutes (or until a drop added to H_2O dissolves completely), poured it into H_2O, and the clear solution of the potassium salt is acidified to pH <0 when pure iodobenzoic acid (theoretical yield) separates. It is collected, washed with cold H_2O, and dried *in vacuo*. [Baker et al. *J Chem Soc* 3721 *1965*, Cohen & Raper *J Chem Soc* 1271 *1904*.] The FT-IR (Nujol) has ν_{max} at 3061.7, 2646.1, 1683.9, 1582.4, 1405.0,

1269.8, 1015.8, 739.0 and 679.7 cm^{-1}; the ^1H NMR (DMSOd_6, TMS) has δ at 7.25 (t of d, 1H, J = 7 Hz and 1.5 Hz, H-5), 4.85 (t, 1H, J = 7 Hz, H-4), 7.72 (d of d, 1H, J = 7 and 1.5 Hz, H-6) and 8.01 (d, 1H, J = 7 Hz, H-3); and the ^{13}C NMR (DMSOd_6, TMS) has δ at 167.93, 140.32, 136.72, 132.25, 129.88 127.97 and 93.92.
The *acid chloride* has **M 266.4** [609-67-6], **m 35-40°, b 135°/19mm (159°/27mm)**, and the *amide* has **M 247.0** [3930-83-4], **m 183°** (needles from H_2O). The *4-bromobenzylisothiuronium salt* has **m 154°** (from EtOH), and the *4-chlorobenzylisothiuronium salt* has **m 162°** (from dioxane). [*Beilstein* **9** H 363, **9** I 148, **9** II 239, **9** III 1432, **9** IV 1030.]

m-**Iodobenzoic acid** *[618-51-9]* **M 248.4, m 185-186°, 186.6-186.8°, 189°, 189-189.2°, pK^{25} 3.85, pK^{50} 3.97, pK –7.64 (H_2SO_4).** Crystallise the acid repeatedly from water, EtOH, aqueous EtOH, Me_2CO or aqueous AcOH. Sublime it under vacuum at 100°. *Ethyl* m-*iodobenzoate* **M 276.0** [58313-23-8] has **b 150.5°/15mm (165-166°/24mm)**, the m-*acid chloride* has **M 266.4** [1711-10-0], **b 104-105°/1mm (159-150°/23mm)**, and the m-*amide* has **M 247.0** [10388-19-9], **m 186°** (needles from H_2O). The *4-bromobenzylisothiuronium salt* has **m 152°** (from EtOH), and the *4-chlorobenzylisothiuronium salt* has **m 154°** (from dioxane). [Fieser *Org Synth* Coll Vol **II** 353 *1948*, *Beilstein* **9** H 365, **9** I 148, **9** II 240, **9** III 1437, **9** IV 1033.]

p-**Iodobenzoic acid** *[619-58-9]* **M 248.4, m 269-270°, 271-272°, 272.5°, 273°, pK^{25} 4.00, pK –7.50 (H_2SO_4).** Crystallise the acid repeatedly from water, aqueous EtOH, aqueous Me_2CO, aqueous AcOH. Sublime it under vacuum at 200°/0.4mm. *Ethyl* p-*iodobenzoate* **M 276.0** [51934-41-9] has **b 154°/15mm**, the p-*acid chloride* has **M 266.4** [1711-02-0] has **m 83° (77-78°)** (needles from Et_2O)**, b 126°/9mm (163-164°/32mm)**, and the p-*amide* has **M 247.0** [3956-07-8], **m 217.6° (209°)** (needles from H_2O). The *4-bromobenzylisothiuronium salt* has **m 181°** (from EtOH), and the *4-chlorobenzylisothiuronium salt* has **m 177°** (from dioxane). [Whitmore & Woodward *Org Synth* Coll Vol **II** 325 *1948*, *Beilstein* **9** H 366, **9** I 149, **9** II 240, **9** III 1442, **9** IV 1035.]

4-Iodobiphenyl *[1591-31-7]* **M 280.1, m 113.7-114.3°, b 207°/28mm.** Crystallise 4-iodobiphenyl from EtOH/*C_6H_6, and dry it *in vacuo* over P_2O_5. [*Beilstein* **5** H 581, **5** I 273, **5** II 486, **5** III 1748, **5** IV 1821.]

1-Iodo-2,4-dinitrobenzene *[709-49-9]* **M 294.0, m 88°.** Crystallise it from EtOAc. [*Beilstein* **5** H 270.]

1-Iodo-4-nitrobenzene *[636-98-6]* **M 249.0, m 171-172°.** Precipitate it from acetone by addition of water, followed by recrystallisation from EtOH. [*Beilstein* **8** H 523, **8** H 523, **8** II 191, **8** III 623, **8** IV 743.]

o-**Iodophenol** *[533-58-4]* **M 280.1, m 43°, pK^{25} 8.51.** Crystallise 2-iodophenol from $CHCl_3$ or diethyl ether. The *acetate* has **m** 65-66° (from MeOH). [*Beilstein* **6** H 208, **6** II 198, **6** III 774, **6** IV 1074.]

p-**Iodophenol** *[540-38-5]* **M 280.1, m 94°, 138-140°/5mm, pK^{25} 9.30.** Crystallise 4-iodophenol from petroleum ether (b 80-100°) or distil it *in vacuo*. If the material has a brown or violet colour, then dissolve it in $CHCl_3$, shake it with 5% sodium thiosulfate solution until is colourless. Dry (Na_2SO_4) the orgnic layer, fikter, evaporate and disil the residue *in vacuo*. [Dains & Eberly *Org Synth* Coll Vol **II** 355 *1943*, *Beilstein* **6** IV 1074.]

5-Iodosalicylic acid (2-hydroxy-5-iodobenzoic acid) *[119-30-2]* **M 264.0, m 197° pK_1^{25} 2.65, pK_2^{25} 13.05.** Crystallise the acid from water. [*Beilstein* **10** H 112.]

o-**Iodosobenzoic acid** *[304-91-6]* **M 264.0, m >200°, pK_{Est} ~2.6.** Crystallise the acid from EtOH and dry it *in vacuo*. [*Beilstein* **9** H 363.]

p-**Iodotoluene** *[624-31-7]* **M 218.0, m 35°, b 211-212°.** Crystallise 4-iodotoluene from EtOH and.or distil it. [*Beilstein* **5** IV 840.]

Isonitrosoacetophenone (phenylglyoxaldoxime) *[532-54-7]* **M 149.2, m 126-128°.** Crystallise it from water. [*Beilstein* **7** IV 2132.]

Isophthalic acid (benzene-1,3-dicarboxylic acid) *[121-91-5]* **M 166.1, m 345-348°, pK_1^{25} 3.70, pK_2^{25} 4.60.**

Crystallise the acid from aqueous EtOH. [*Beilstein* **9** IV 3292.]

4,4'-Isopropylidenediphenol (Bisphenol A, 2,2-bis[4-hydroxyphenol]propane) *[80-05-7]* **M 228.3, m 158°, pK_{Est} ~10.3.** Crystallise bisphenol from acetic acid/water (1:1). It is used for making polycarbonate bottles and leaches out slowly on heating. It is a known "estrogenic chemical" shown to disrupt chemical signalling in the complex network of glands, hormones and cell receptors which make up the endocrine system. It causes low sperm count and damages the ecosystem by the feminisation of fish, reptiles and birds. [cf Chapter 1, p 3, *Beilstein* **6** IV 6717.]

***N*-Isopropylidene-*N′*-2-nitrobenzenesulfonyl hydrazine (IPNBSH, isopropylidenehydrazide *o*-nitrobenzenesulfonic acid** *[6655-27-2]* **M 257.3, m 132-135°, 139-140°.** IPNSBH is more stable than NBSH (*vide infra*) from which it is readily prepared by dissolving it (1.14g, 1 equivalent) in Me_2CO (8ml) at 0°, and after 30 minutes the solvent is removed *in vacuo*, the residue is re-dissolved in Me_2CO (4ml), and added slowly into 150ml of hexanes. The fine powder is filtered off, rinsed with hexanes (2 × 5ml) and dried *in vacuo* to give IPNBSH as a white solid (1.20g, 89%; TLC has R_F 0.7, 66% EtOAc in hexanes). Its FTIR (thin film) has ν_{max} at 1177s, 1347m, 1375s, 1551s, 3264s cm^{-1}; its ^1H NMR [400MHz, $CDCl_3$, 20°] has δ at 8.30-8.28 (m, 1H), 7.87-7.85 (m, 2H), 7.79-7.77 (m, 2H), 1.96 (s, 3H), 1.92 (s, 3H), and its ^{13}C NMR [500MHz, $CDCl_3$, 20°] has δ at 158.9, 134.2, 133.5, 132.9.2, 132.0, 125.4, 25.5, 17.2. IPNBSH promotes the same reactions as NBSH except that it is more stable. A solution of 0.02M IPNBSH in DMSO is undecomposed at 50° during 30 minutes, whereas NBSH is 60% decomposed, and at is stable at 75° or 100° for 30 minutes so it can be stored at room temperature for several months without deterioration; all the same, store it under argon (as it is possibly flammable), and use gloves due to its toxicity.
It is a reagent used for allylic transposition, de-bromination and reduction of alcohols in the presence of DEAD and Ph_3P. [Movassaghi et al. *Angew Chem. Int Ed Engl* **45** 5859 *2006*, Movassaghi & Ahmad *J. Org. Chem.* **72** 1838 *2007*].

Isopropyl *p*-nitrobenzoate *[13756-40-6]* **M 209.2, m 105-106°.** Dissolve it in Et_2O, wash it with aqueous alkali, then H_2O and dry it. Evaporate the ether and recrystallise it from EtOH to give pure material. It gives yellow crystals from petroleum ether (**m** 109°, 110°). [*Beilstein* **9** H 391, **9** II 258, **9** III 1543, **9** IV 1075.]

Isovanillin (3-hydroxy-4-methoxybenzaldehyde) *[621-59-0]* **M 152.2, m 117°, b 175°/14mm, pK^{25} 8.89.** Crystallise isovaniline from H_2O or $*C_6H_6$. The *oxime* has **m** 147°. [*Beilstein* **8** IV 1764.]

Isoviolanthrone *[128-64-3]* **M 456.5, m 510-511°(uncorrected).** Dissolve isoviolanthrone in 98% H_2SO_4 and precipitate it by adding water to reduce the acid concentration to about 90%. It sublimes *in vacuo* to give dark green-violet needles [Parkyns & Ubblehode *J Chem Soc* 4188 *1960*]. [*Beilstein* **7** I 465, **7** II 815, **7** III 4538, **7** IV 2747.]

Janus Red B {3-[(2-hydroxy-1-naphtholenyl)azo-2-methylphenylazo]*N,N,N*-trimethyl-benzenaminium chloride} *[2636-31-9]* **M 460.0.** Crystallise the dye from EtOH/H_2O (1:1 v/v) and dry in vacuum. Store it in a dark bottle. [*Beilstein* **16** II 149.]

Ketone moschus (4-*tert*-butyl-2,6-dimethyl-3,5-dinitroacetophenone, Musk ketone) *[81-14-1]* **M 294.3, m 134-137°, 137-138°.** Purify the ketone by recrystallisation from MeOH. It has a strong odour of musk and is used in perfumery. [Fuson et al. *J Org Chem* 12 587 *1947*, *Beilstein* **7** IV 808.]

Lapachol [2-hydroxy-3-(3-methyl-2-butenyl)-1,4-naphthalenedione, Neutral Yellow 16] *[84-79-7]* **M 242.3, CI 7549, m 140°.** Crystallise Lapachol from petroleum ether/EtOH, EtOH or Et_2O. [*Beilstein* **8** H 326, **8** I 644, **8** II 365, **8** III 2720.]

Leucomalachite Green *[129-73-7]* **M 330.5, m 92-93°, pK^{25} 6.90 (several pK's).** Crystallise it from 95% EtOH (10ml/g), then from *benzene/EtOH, and finally from petroleum ether. [*Beilstein* **13** H 275, **13** II 89, **13** II 135, **13** III 529, **13** 481.]

Malachite Green (carbinol) *[510-13-4]* **M 346.4, m 112-114°, CI 42000, pK^{24} 6.84.** The *oxalate* [2437-29-8] [*Beilstein* **8** H 326, **13** IV 2279.] is recrystallised from hot water and dried in air. The carbinol is precipitated from the oxalate (1g) in distilled water (100ml) by adding M NaOH (10ml). The precipitate is filtered off, recrystallised from 95% EtOH containing a little dissolved KOH, then washed with ether, and crystallised from petroleum ether. Dry it in a vacuum at 40°. An acid, almost colourless, solution (2×10^{-5}M in 6×10^{-5}M H_2SO_4) rapidly reverts to the coloured dye. [Swain & Hedberg *J Am Chem Soc* **72** 3373 *1950*, *Beilstein* **13** H 243, 744.]

Mandelic acid (α-hydroxyphenylacetic acid) *[S-(+)- 17199-29-0, R-(–)- 611-71-2]* **M 152.2, m 130-133°, 133°, 133.1° (evacuated capillary), 133-133.5°, [α] $^{20}_{546}$ (+) and (-) 188° (c 5, H_2O), [α] $^{20}_{D}$ (+) and (-) 155° (c 5, H_2O) and (+) and (-) 158° (c 5, Me_2CO), pK^{25} 3.41.** Purify the mandelic acids by recrystallisation from H_2O, *C_6H_6 or $CHCl_3$. [Roger *J Chem Soc* 2168 *1932*, Jamison & Turner *J Chem Soc* 611 *1942*.] They have solubilities in H_2O of *ca* 11% at 25°. [Banks & Davies *J Chem Soc* 73 *1938*.] The *S-benzylisothiuronium salts* has **m** 180° (from H_2O) and [α] $^{25}_{D}$ (+) and (–) 57° (c 20, EtOH) [El Masri et al. *Biochem J* **68** 199 *1958*]. [*Beilstein* **10** IV 564.]

***RS*-(±)-Mandelic acid** *[61-72-3]* **M 152.2, m 118°, 120-121°.** Purify mandelic acid by Soxhlet extraction with *C_6H_6 (about 6ml/g) and allow the extract to crystallise. It can also be recrystallised from $CHCl_3$. The *S-benzylisothiuronium salt* has **m** 169° (166°) (from H_2O). Dry it at room temperature under vacuum. [*Beilstein* **10** IV 565.]

Mescaline sulfate [2-(3,4,5-trimethoxyphenyl)ethylamine sulfate] *[5967-42-0]* **M 309.3, m 181-184°, 183-184°, 186-189°, pK$_{Est}$ ~9.7.** The salt crystallises from water with $2H_2O$ or from hot MeOH. The *acid sulfate* has **m** 158°. [Slomon & Bina *J Am Chem Soc* **68** 2403 *1946*, *Beilstein* **13** I 338, **13** II 521, **13** III 2375, **13** IV 2919.]

Mesitylene (1,3,5-trimethylbenzene) *[108-67-8]* **M 120.2, m -44.7°, b 99.0-99.8°/100mm, 166.5-167°/760mm, d $^{20}_{4}$ 0.865, n $^{25}_{D}$ 1.4967.** Dry it with $CaCl_2$ and distil it from Na in a glass helices-packed column. Treat it with silica gel and redistil it. *Alternative* purifications include vapour-phase chromatography, or fractional distillation followed by azeotropic distillation with 2-methoxyethanol (which is subsequently washed out with H_2O), drying and fractional distilling. More exhaustive purification uses sulfonation by dissolving in two volumes of conc H_2SO_4, precipitating with four volumes of conc HCl at 0°, washing with conc HCl and recrystallising from $CHCl_3$. The mesitylene sulfonic acid is hydrolysed with boiling 20% HCl and steam distilled. The separated mesitylene is dried ($MgSO_4$ or $CaSO_4$) and distilled. It can also be fractionally crystallised from the melt at low temperatures. [*Beilstein* **5** IV 1016.]

Metanilic acid (3-aminobenzenesulfonic acid) *[121-47-1]* **M 173.2, m <300°(dec), pK $^{25}_{1}$ <1, pK $^{25}_{2}$ 3.74.** Crystallise the acid from water (as the hydrate), under CO_2 in a semi-darkened room. The solution is photosensitive. Dry it over 90% H_2SO_4 in a vacuum desiccator. [*Beilstein* **14** H 688, **14** IV 2640.]

p-**Methoxyacetophenone** *[100-06-1]* **M 150.2, m 39°, b 139°/15mm, 264°/736mm.** Crystallise the ketone from diethyl ether/petroleum ether. The *oxime* has **m 86°, 87°** (from petroleum ether, v. Auwers et al. *Chem Ber* **58** 41 *1925*). [*Beilstein* **8** H 87, **8** I 536, **8** II 84, **8** III 277, **8** IV 340.]

p-**Methoxyazobenzene** *[2396-60-3]* **M 212.3, m 54-56°.** Crystallise 4-methoxyazobenzene from EtOH. [*Beilstein* **16** IV 162.]

3-Methoxybenzanthrone *[3688-79-7]* **M 274.3, m 173°.** Crystallise it from *benzene, EtOH or Me_2CO to give yellow needles. [*Beilstein* **8** II 239, **8** III 1629, **8** IV 1476.]

***m*-Methoxybenzoic acid (*m*-anisic acid)** *[586-38-9]* **M 152.2, m 110°, pK^{25} 4.09.** Crystallise *m*-anisic acid from H_2O (**m** 109°, 110.5°) or EtOH/water. The *S-benzylisothiuronium salt* has **m** 176° (from EtOH). [*Beilstein* **10** II 80, **10** III 244, **10** IV 316.]

***p*-Methoxybenzoic acid (*p*-anisic acid)** *[100-09-4]* **M 152.2, m 184.0-184.5°, pK^{25} 4.51.** Crystallise *p*-anisic acid from EtOH, water, EtOH/water or toluene. The *S-benzylisothiuronium salt* has **m** 189° (from EtOH). [*Beilstein* **10** II 91, **10** III 280, **10** IV 346.]

4-Methoxybenzyl chloride (anisyl chloride) *[824-94-2]* **M 156.6, m -1°, b 76°/0.1mm, 95°/5mm, 110°/10mm, 117-117/5°/14mm, 117°/18mm, d $^{20}_{4}$ 1.15491, n $^{20}_{D}$ 1.55478.** Purify 4-anisyl chloride by fractional distillation under vacuum, and the middle fraction is redistilled at 10^{-6} mm at room temperature by intermittent cooling of the receiver in liquid N_2, and the middle fraction is collected. [Mohammed & Kosower *J Am Chem Soc* **93** 2709 *1971*, *Beilstein* **6** IV 2137.]

"Methoxychlor", (1,1-bis[*p*-methoxyphenyl]-2,2,2-trichloroethane, DMDT) *[72-43-5]* **M 345.7, m 78-78.2°, or 86-88°.** Free the insecticide from 1,1-bis(*p*-chlorophenyl)-2,2,2-trichloroethane by crystallising from EtOH. It is dimorphic and also crystallises from Et_2O/EtOH (**m** 92°). [Fritsch & Feldmann *Justus Liebigs Ann Chem* **306** 77 *1899*, Smith et al. *Aust J Chem* **29** 743 *1976*, *Beilstein* **6** H 1007.]

***trans*-*p*-Methoxycinnamic acid** *[830-09-1, 943-89-5 (trans)]* **M 178.2, m 173.4-174.8°, pK^{25} 4.54.** Crystallise the acid from MeOH to constant melting point and UV spectrum. [*Beilstein* **10** IV 1005.]

6-Methoxy-1-indanone *[13623-25-1]* **M 162.2, m 151-153°.** Crystallise it from MeOH, then sublime it at high vacuum. [*Beilstein* **8** IV 894.]

1-Methoxy-4-nitronaphthalene *[4900-63-4]* **M 203.2, m 85°.** Purify it by chromatography on silica gel, then recrystallise it from MeOH or EtOH (yellow needles). [Hodgson & Habeshaw *J Chem Soc* 47 *1942*, Bunce et al. *J Org Chem* **52** 4214 *1987*, *Beilstein* **6** H 616, **6** III 2938.]

***p*-Methoxyphenol** *[150-76-5]* **M 124.1, m 54-55°, b 243°/atm, pK^{25} 10.21.** Crystallise 4-methoxyphenol from *benzene, petroleum ether or H_2O, and dry it under vacuum over P_2O_5 at room temperature. Sublime it *in vacuo*. [Wolfenden et al. *J Am Chem Soc* **109** 463 *1987*, *Beilstein* **6** IV 5717.]

α-Methoxyphenylacetic acid (*O*-methyl mandelic acid), *[R-(–)- 3966-32-3, S-(+)- 26164-26-1]* **M 166.2, m 62.9°, 62-65°, 65-66°, [α] $^{20}_{546}$ (-) and (+) 179° (169.8°), [α] $^{20}_{D}$ (-) and (+) 150.7° (148°) (c 0.5, EtOH), pK$_{Est}$ ~3.1.** Purify the acids by recrystallising from *C_6H_6/petroleum ether (**b** 80-100°). [Neilson & Peters *J Chem Soc* 1519 *1962*, Weizmann et al. *J Am Chem Soc* **70** 1153 *1948*, Pirie & Smith *J Chem Soc* 338 *1932*, NMR: Dale & Mosher *J Am Chem Soc* **95** 512 *1973*, for resolution: Roy & Deslongchamps *Can J Chem* **63** 651 *1985,* Trost et al. *J Am Chem Soc* **108** 4974 *1986*.] The *racemic mixture* has **m** 72°, **b** 121-122°/0.4mm, 165°/18mm (from petroleum ether) [Braun et al. *Chem Ber* **63** 2847 *1930*]. [*Beilstein* **10** IV 566.]

***o*-Methoxyphenylacetic acid** *[93-25-4]* **M 166.2, m 124-125°, pK$_{Est}$ ~4.4.** Crystallise the acid from H_2O, EtOH or aqueous EtOH, petroleum ether/Et_2O and dry it in a vacuum desiccator over Sicapent. The *amide* has **m** 131° (from EtOH). [*Beilstein* **10** H 188, **10** III 422, **10** IV 536.]

***m*-Methoxyphenylacetic acid** *[1798-09-0]* **M 166.2, m 66-67°, 68-69°, 71.0-71.2°, pK$_{Est}$ ~4.3.** Crystallise the acid from H_2O, or aqueous EtOH. The *S-benzylisothiuronium salt* has **m** 160-161° (from EtOH). [*Beilstein* **10** I 82, **10** III 428, **10** IV 541.]

***p*-Methoxyphenylacetic acid (homoanisic acid)** *[104-01-8]* **M 166.2, m 85-87°, b 138-140°/2-3mm, pK^{25} 4.36.** Crystallise the acid from EtOH/water, EtOAc/petroleum ether (**m** 87°) or *C_6H_6/petroleum ether (**m** 84-86°). [*Beilstein* **10** III 431, **10** IV 544.] The *acid chloride* [4693-91-8] has **M** 184.6, **b** 143°/10mm, **d** $^{25}_{4}$ **1.208.** [*Beilstein* **10** III 434.]

***N*-(*p*-Methoxyphenyl)-*p*-phenylenediamine** *[101-64-4]* **M 214.3, m 102°, b 200°/2mm, 238°/12mm, pK^{25} 6.6 (5.9).** Crystallise the diamine from ligroin or *C_6H_6/petroleum ether (**m** 99-100°). The *picrate* has **m** 164° (from EtOH). [*Beilstein* **13** III 1161, **13** IV 1243.]

α-Methoxy-α-trifluoromethylphenylacetic acid (MTPA, Mosher's acid) *[R-(+)- 20445-31-2, S-(–)- 17257-71-5]* **M 234.2, m 43-45°, 90°/0.1mm, 105-107°/1mm, $[\alpha]_{546}^{20}$ (+) and (-) 87°, $[\alpha]_{D}^{20}$ (+) and (-) 73° (c 2, MeOH), pK_{Est} ~2.5.** A likely impurity is phenylethylamine from the resolution. Dissolve the acid in Et_2O/*benzene (3:1), wash with 0.5N H_2SO_4, then water, dry over magnesium sulfate, filter, evaporate and distil it. [Dale et al. *J Org Chem* **34** 2543 *1969*, *J Am Chem Soc* **75** 512 *1973*.]

α-Methoxy-α-trifluoromethylphenylacetyl chloride *[R-(–)- 39637-99-5, S-(+)- 20445-33-4]* **M 252.6, b 54-56°/1mm, 213-214°/760mm, d_4^{20} 1.353, n_D^{20} 1.468, $[\alpha]_{546}^{20}$ (-) and (+) 167°, $[\alpha]_{D}^{20}$ (-) and (+) 137° (c 4, CCl_4), $[\alpha]_{D}^{24}$ (-) and (+) 10.0° (neat).** The most likely impurity is the free acid due to hydrolysis and should be checked by IR. If free from acid, then distil, taking care to keep moisture out of the apparatus. Otherwise add $SOCl_2$ and reflux for 5 hours and distil it. Note that shorter reflux times result in a higher boiling fraction (**b** 130-155°/1mm) which has been identified as the anhydride. [Dale et al. *J Org Chem* **34** 2543 *1969*, for enantiomeric purity see Dale & Mosher *J Am Chem Soc* **97** 512 *1973*.]

***N*-Methylacetanilide** *[579-10-2]* **M 149.2, m 102-104°, b 145-146°/30mm, 225°/760mm.** Crystallise the anilide from water, ether, petroleum ether (b 80-100°) or *C_6H_6 (**m** 105°). The *BF_3 salt* has **m** 114° (from Me_2CO/diisopropyl ether). [*Beilstein* **12** III 465, **12** IV 378.]

***p*-Methylacetophenone** *[122-00-9]* **M 134.2, m 22-24°, b 93.5°/7mm, 110°/14mm, d_4^{20} 1.000, n_D^{20} 1.5335.** Impurities, including the *o*- and *m*-isomers, are removed by forming the *semicarbazone* (**m** 212-213.5°) which, after repeated crystallisation, is hydrolysed to the ketone. [Brown & Marino *J Am Chem Soc* **84** 1236 *1962*.] It can also be purified by distillation under reduced pressure, followed by low temperature crystallisation from isopentane. The *oxime* has **m 87-88°** (from MeOH then cyclohexane Pearson & Ball *J Org Chem* **14** 125 *1949*). [*Beilstein* **7** H 307, **7** I 154, **7** II 238, **7** III 1060, **7** IV 701.]

1-Methylaminoanthraquinone *[82-38-2]* **M 237.3, m 166.5°, pK_{Est}~2.** Crystallise it to constant melting point from butan-1-ol, then from EtOH. It can be sublimed under vacuum. [*Beilstein* **7** IV 2574.]

***N*-Methyl-*o*-aminobenzoic acid (*N*-methylanthranilic acid)** *[119-68-6]* **M 151.2, m 178.5°, pK_1^{25} 1.97, pK_2^{25} 5.34.** Crystallise the acid from water, MeOH (**m** 177°) or EtOH. [Casulich & Smith *J Am Chem Soc* **70** 1923 *1948*, *Beilstein* **14** H 323, **14** III 895, **14** IV 1015.]

3-(Methylamino)benzoic acid *[51524-84-6]* **M 151.1, m 129°, pK_1^{25} 3.08, pK_2^{25} 5.10.** Crystallise the acid from H_2O (needles), petroleum ether (plates) or $CHCl_3$ (**m** 127°). The *hydrochloride* has **m** 244° (plates from EtOH). [*Beilstein* **14** H 391, **14** I 559.]

***p*-Methylaminophenol sulfate (Photol, Metol)** *[55-55-0]* **M 344.4, m 260°(dec), pK^{25} 5.9.** Crystallise this photographic developer from H_2O (needles **m** 250-260°) (its solubility is 5% at 20° and 17% at 100°) or MeOH. It is used for determining Ag. [Palit et al. *Indian J Chem, Sect B* **28** 64 *1989*.]

***N*-Methylaniline** *[100-61-8]* **M 107.2, b 57°/4mm, 81-82°/14mm, d_4^{20} 0.985, n_D^{20} 1.570, pK^{25} 4.56.** Dry it with KOH pellets and fractionally distil it under vacuum. Acetylate, and the *acetyl* derivative is recrystallised to constant melting point (**m** 101-102°), then hydrolysed with aqueous HCl and distilled from zinc dust under reduced pressure. [Hammond & Parks *J Am Chem Soc* **77** 340 *1955*, *Beilstein* **12** IV 241.]

***N*-Methylaniline hydrochloride** *[2739-12-0]* **M 143.7, m 123.0-123.1°.** Crystallise the salt from dry *benzene/$CHCl_3$ and dry under vacuum. [*Beilstein* **12** IV 241.]

Methyl *p*-anisate *[121-98-2]* **M 166.2, m 48°, b 123.8°/12mm, 24-245°/760mm.** Distil the ester and/or crystallise it from EtOH. [*Beilstein* **10** H 159, **10** III 297, **10** IV 360.]

4-Methyl anisole *[104-93-8]* **M 122.2, b 56.2°/9mm, 67°/20mm, 175-176°/760mm, d_{15}^{15} 0.9757, n_D^{20} 1.512.** Dissolve 4-methyl anisole in diethyl ether, wash it with M NaOH, water, dry (Na_2CO_3), evaporate and distil it under vacuum. The *picrate* has **m** 103° (from aqueous EtOH). [*Beilstein* **6** IV 2098.]

2-Methylanthracene *[613-12-7]* **M 192.3, m 204-206°.** Chromatograph it on silica gel with cyclohexane as eluent and then recrystallise it from EtOH [Werst *J Am Chem Soc* **109** 32 *1987*]. [*Beilstein* **5** IV 2311.]

4-Methylanthracene *[779-02-2]* **M 192.3, m 77-79°, b 196-197°/12mm, d_4^{20} 1.066.** Chromatograph it on silica gel with cyclohexane as eluent and recrystallise it from EtOH [Werst *J Am Chem Soc* **109** 32 *1987*]. [*Beilstein* **5** IV 2312.]

2-Methylanthraquinone *[84-54-8]* **M 222.3, m 176°, b 236-238°/10mm.** Crystallise the quinone from EtOH, then sublime it. It has λ_{max} at 257, 275 and 330nm (EtOH). [Hersbery & Fieser *J Am Chem Soc* **63** 2562 *1941*, *Beilstein* **7** H 809, **7** III 4104, **7** IV 2574.]

Methylarenes (see also pentamethyl- and hexamethyl-benzenes). Recrystallise them from EtOH and sublime them in a vacuum [Schlesener et al. *J Am Chem Soc* **106** 7472 *1984*].

Methyl benzoate *[93-58-3]* **M 136.2, b 104-105°/39mm, 199.5°/760mm, d_4^{20} 1.087, n^{15} 1.52049, n_D^{20} 1.51701, pK^{20} -8.11, -6.51 (H_0 scale, aqueous H_2SO_4).** Wash the ester with dilute aqueous $NaHCO_3$, then water, dry with Na_2SO_4 and fractionally distil it in a vacuum. [*Beilstein* **9** IV 283.]

p-**Methylbenzophenone** *[134-84-9]* **M 196.3, m 57°, b 154-155°/3mm, 183-184°/15mm, 277-281°/3mm, d^{20} 0.9926.** Crystallise the ketone from MeOH, Et_2O (**m** 58-59°) or petroleum ether. The *cis-oxime* has **m** 154°(153-156°) (from EtOH), and the *trans-oxime* has **m** 114-116° (from petroleum ether). [*Beilstein* **7** H 440, **7** III 2127, **7** IV 1403.]

Methyl-1,4-benzoquinone (*p*-toluoquinone) *[553-97-9]* **M 122.1, m 68-69°.** Crystallise *p*-toluoquinone from heptane or EtOH, dry rapidly (vacuum/P_2O_5) and stored in a vacuum. [*Beilstein* **7** IV 2088.]

Methyl benzoylformate (methyl phenylglyoxalate) *[15206-55-0]* **M 164.2, m 246-248°.** Purify the ester by radial chromatography (diethyl ether/hexane, 1:1), and dry it at 110-112°/6mm. [Meyers & Oppenlaender *J Am Chem Soc* **108** 1989 *1986*, *Beilstein* **10** IV 2738.]

2-Methyl-3,4-benzphenanthrene (2-methylbenzo[*c*]phenanthrene) *[652-04-0]* **M 242.3, m 70°, 80.6-81.4°, b 200°/0.4mm.** Crystallise it from EtOH (**m** 81-82.5°). The *picrate* has **m** 118-118.5° (yellow needles from MeOH). [*Beilstein* **5** III 2394, **5** IV 2570.]

***R*-(+)-α-Methylbenzylamine** *[R(+) 3886-69-9, RS(±) 618-36-0]* **M 121.2, b 187-188°/atm, $[\alpha]_{546}^{20}$ +35° (c 10, EtOH), $[\alpha]_D^{25}$ +39.7° (neat), pK 9.08 (for *RS*).** Dissolve the amine in toluene, dry over NaOH and distil; fraction boiling at 187-188°/atm is collected. Store it under N_2 to avoid forming the carbamate and urea. Similarly for the *S*-(–) *enantiomer [2627-86-3]*. [Ingersoll *Org Synth* Coll Vol **II** 503 *1943*, Robinson & Snyder *Org Synth* Coll Vol **III** 717 *1955*, *Beilstein* **12** IV 2424, 2425.]

p-**Methylbenzyl chloride** *[104-82-5]* **M 140.6, b 80°/2mm, 98-101°/27mm, d_4^{20} 1.085, n_D^{20} 1.543.** Dry the chloride with $CaSO_4$ and fractionally distil it under vacuum. [*Beilstein* **5** H 384, **5** III 854, **5** IV 966.]

Methyl *o*-bromobenzoate *[610-94-6]* **M 215.1, b 131.4-132°/16mm, 234-244°/760mm.** A solution of the ester in ether is washed with 10% aqueous Na_2CO_3, water, then dried and distilled. [*Beilstein* **9** H 348, **9** III 1385, **9** IV 1012.]

Methyl *p*-bromobenzoate *[619-42-1]* **M 215.1, m 79.5-80.5°.** Crystallise the ester from MeOH. EtOH (**m** 81°, also 80.5°, 79.5°) or *C_6H_6/petroleum ether (**m** 78-79°). [*Beilstein* **9** H 352, **9** III 1405, **9** IV 1017.]

(±)-3'-Methyl-1,2-cyclopentenophenanthrene (16,17-dihydro-17-methyl-15*H*-cyclopenta-[*a*]-phenanthrene *[549-38-2]* **M 232.3, m 126-127°.** Crystallise it from AcOH or EtOH (plates, **m** 125.5-126°). The *picrate* has **m** 130-131° (orange-red needles from EtOH). [Tatta & Bardhan *J Chem Soc (C)* 893 *1968*, *Beilstein* **5** IV 2433.]

Methyl 2,4-dichlorophenoxyacetate *[1928-38-7]* **M 235.1, m 43°, b 119°/11mm.** Crystallise the herbicide ester from MeOH. [Branch & Jones *J Chem Soc* 2924 *1955*, *Beilstein* **6** III 705, **6** IV 909.]

3,4-Methylenedioxyaniline *[14268-66-7]* **M 137.1, m 44.5-45.5°, 45-46°, b 108°/1mm, 144°/14mm, 156°/30mm, pK_{Est} ~3.8.** Crystallise the base from petroleum ether and/or distil it in a vacuum. The *hydrochloride* has **m** 198°(dec). [Sonn & Benirschke *Chem Ber* **54** 1734 *1921*, *Beilstein* **19** H 328, **19** II 341, **19** III/IV 4056.]

***trans*-3,4-Methylenedioxycinnamic acid** *[2373-80-0]* **M 192.2, m 243-244°(dec), pK_{Est} ~4.6.** Crystallise the acid from glacial AcOH, EtOH (**m** 247°) or aqueous EtOH (**m** 240-242°), and it has **m** 242° after sublimation. [*Beilstein* **19** H 278, **19** II 299, **19** III/IV 3548.]

5,5'-Methylenedisalicylic acid *[122-25-8; 27496-82-2]* **M 288.2, m 238°(dec).** Crystallise the acid from Me_2CO, *C_6H_6 or $CHCl_3$/MeOH (**m** 268-268°). It has λ_{max} at 312nm (ε 7530)in EtOH. [Cushman & Kanamathareddy *Tetrahedron* **46** 1406 *1990*.]

***N*-Methylephedrine (2-dimethylamino-1-phenylpropanol)** *[1*S*,2*R*-(+)- *42151-56-4*, 1*R*,2*S*-(–)- *552-79-4]* **M 179.3, m 85-86°, 87-87.5°, 90°, b 115°/2mm, $[\alpha]_{546}^{20}$ (+) and (-) 35°, $[\alpha]_{D}^{20}$ (+) and (-) 30° (c 4.5, MeOH), pK^{26} 9.22.** *N*-Methylephedrine has been recrystallised from Et_2O, petroleum ether, of aqueous EtOH or aqueous MeOH and has been distilled under reduced pressure. [Smith *J Chem Soc* 2056 *1927*, Tanaka & Sugawa *Yakugaku Zasshi (J Pharm Soc Japan) 72* 1548 *1952* (*Chem Abstr* **47** 8682 *1953*), Takamatsu *Yakugaku Zasshi (J Pharm Soc Japan)* **76** 1227 *1956*, *Chem Abstr* **51** 4304 *1957*.] The *hydrochloride* has **m** 192-193° and $[\alpha]_{D}^{20}$+30° (c 5,H_2O) [Prelog & Hüfliger *Helv Chim Acta* **33** 2021 *1950*]. [*Beilstein* **13** IV 1884.]

Methyl gallate *[99-24-1]* **M 184.2, m 202°.** Crystallise the gallate ester from MeOH. [*Beilstein* **10** IV 1998.]

Methyl Green *[82-94-0, 7114-03-6 ($ZnCl_2$ salt)]* **M 458.5, m >200°(dec).** Crystallise the dye from hot water. [*Beilstein* **13** IV 2286.]

Methyl 4-hydroxybenzoate *[99-76-3]* **M 152.2, m 127.5°, pK_{Est} ~9.3.** Fractionally crystallise the ester from its melt, and recrystallise it from *benzene, then from *benzene/MeOH and dry it over $CaCl_2$ in a vacuum desiccator. [*Beilstein* **10** IV 360.]

Methyl 3-hydroxy-2-naphthoate *[883-99-8]* **M 202.2, m 73-74°, pK_{Est} ~9.0.** Crystallise the ester from MeOH (charcoal) containing a little water. [*Beilstein* **10** IV 1186.]

3-Methylmercaptoaniline *[1783-81-9]* **M 139.2, b 101.5-102.5°/0.3mm, 163-165°/16mm, d_4^{20} 1.147, n_D^{20} 1.641, pK^{25} 4.05.** Purify the aniline by fractional distillation in an inert atmostphere. It has UV max at 226 and 300nm. [Bordwell & Cooper *J Am Chem Soc* **74** 1058 *1952*.] The *N-acetyl* derivative has **m** 78-78.5° (from aqueous EtOH). The *hydrochloride* has **m** 260-261° (aqueous EtOH/HCl) or **m** 225-227° (EtOH/Et_2O). [*Beilstein* **13** H 533, **13** III 1221, **13** IV 1289.]

4-Methylmercaptoaniline *[104-96-1]* **M 139.2, b 140°/15mm, 151°/25mm, 155°/23mm, d_4^{20} 1.137, n_D^{20} 1.639, pK^{25} 4.40.** Purify the aniline by fractional distillation in an inert atmosphere. The *hydrochloride* has **m** 242-246° (from aqueous EtOH/HCl). The *sulfone* has **m** 137° (from H_2O), pK^{25} 1.48, and the *sulfone hydrochloride* has **m** 260-261° (from aqueous EtOH/HCl). [Lumbroso & Passerini *Bull Soc Chim Fr* 311 *1957*, Mangini & Passerini *J Chem Soc* 4954 *1956*, *Beilstein* **13** H 533, **13** II 297, **13** IV 1221.]

1-Methylnaphthalene *[90-12-0]* **M 142.2, f -30°, b 244.6°, d_4^{20} 1.021, n_D^{20} 1.6108.** Dry 1-methylnaphthalene for several days with $CaCl_2$ or by prolonged refluxing with BaO. Fractionally distil it through a glass helices-

packed column from sodium. Purify it further by solution in MeOH and precipitation of its *picrate complex* by adding to a saturated solution of picric acid in MeOH. The picrate, after crystallisation to constant melting point (**m** 140-141°) from MeOH, is dissolved in *benzene and extracted with aqueous 10% LiOH until the extract is colourless. Evaporation of the *benzene solution under vacuum gives 1-methylnaphthalene [Kloetzel & Herzog *J Am Chem Soc* **72** 1991 *1950*]. However, neither the picrate nor the styphnate complexes satisfactorily separate 1- and 2-methylnaphthalenes. To achieve this, 2-methylnaphthalene (10.7g) in 95% EtOH (50ml) has been precipitated with 1,3,5-trinitrobenzene (7.8g) and this complex has been crystallised from MeOH to **m** 153-153.5° (**m** of the 2-methyl isomer is 124°). [*Alternatively*, 2,4,7-trinitrofluorenone in hot glacial acetic acid could be used, and the derivative (**m** 163-164°) is recrystallised from glacial acetic acid]. The 1-methylnaphthalene is regenerated by passing a solution of the complex in dry *benzene through a 15-in column of activated alumina and washing with *benzene/petroleum ether (b 35-60°) until the coloured band of the nitro compound had moved down near the end of the column. The complex can also be decomposed using tin and acetic-hydrochloric acids, followed by extraction with diethyl ether and *benzene; the extracts are washed successively with dilute HCl, strongly alkaline sodium hypophosphite, water, dilute HCl and water. [Soffer & Stewart *J Am Chem Soc* **74** 567 *1952*.] It can be freed from anthracene by zone melting [*Beilstein* **5** IV 1687.]

2-Methylnaphthalene *[91-57-6]* **M 142.2, m 34.7-34.9°, b 129-130°/25mm.** Fractionally crystallise repeatedly from its melt, then fractionally distil under reduced pressure. It has been crystallised from *benzene and dried under vacuum in an Abderhalden pistol. It can be purified *via* its *picrate* (**m** 114-115°) or better *via* the *1,3,5-trinitrobenzene complex* as for 1-methylnaphthalene (above). [*Beilstein* **5** IV 1693.]

6-Methyl-2-naphthol *[17579-79-2]* **M 158.2, m 128-129°, b 177.5-178°/15mm, pK_{Est} ~9.8.** Crystallise the naphthol from EtOH or ligroin. Sublime it *in vacuo*. [*Beilstein* **6** II 618, **6** III 3028.]

7-Methyl-2-naphthol *[26593-50-0]* **M 158.2, m 118°, pK_{Est} ~9.7.** Crystallise the naphthol from EtOH or ligroin. It has **m** 118° after sublimation *in vacuo*. [Halsall & Thomas *J Chem Soc* 2564 *1956*, *Beilstein* **6** IV 3029.]

Methyl 1-naphthyl ether (1-methoxynaphthalene) *[2216-69-5]* **M 158.2, b 90-91°/2mm, d_4^{20} 1.095, n_D^{26} 1.6210.** Steam distil the ether from alkaline solution. The distillate is extracted with Et_2O. After drying ($MgSO_4$) the extract and evaporating Et_2O, the methyl naphthyl ether is then fractionated under reduced pressure from CaH_2. The *picrate* has **m** 129.5-130.5° (from EtOH). [*Beilstein* **6** IV 4211.]

Methyl 2-naphthyl ether (2-methoxynaphthalene, Nerolin) *[93-04-9]* **M 158.2, m 73.0-73.6°, b 138°/10mm 273°/760mm.** Fractionally distil the ether under vacuum. Crystallise it from absolute EtOH, aqueous EtOH, *C_6H_6, petroleum ether or *n*-heptane, and dry it under vacuum in an Abderhalden pistol or distil it *in vacuo*. The *picrate* has **m** 118° (from EtOH or $CHCl_3$). [Kikuchi et al. *J Phys Chem* **91** 574 *1987*, *Beilstein* **6** III 2969, **6** IV 4257.]

2-Methyl-3-nitroaniline *[603-83-8]* **M 152.2 m 92°, b 305°/760mm, pK_{Est} ~ 2.3.** Crystallise the nitrotoluidine from EtOH or *C_6H_6. It is steam volatile. The *acetyl* derivative crystallises from aqueous EtOH and has **m** 164°. [*Beilstein* **12** I 395, **12** II 460, **12** III 1944, **2** IV 1811.]

***N*-Methyl-4-nitroaniline** *[100-15-2]* **M 152.2, m 152.2°, pK^{25} 0.55.** Crystallise the aniline from aqueous EtOH. [*Beilstein* **12** H 714.]

2-Methyl-4-nitroaniline *[99-52-5]* **M 152.2 m 129°, pK_{25} 0.93.** Crystallise the nitrotoluidine from EtOH. The *acetyl* and *benzoyl* derivatives have **m** 200° and 174° (EtOH) respectively. [*Beilstein* **12** IV 1809.]

2-Methyl-5-nitroaniline *[99-55-8]* **M 152.2, m 109°, pK^{25} 2.35.** Acetylate the aniline, and the acetyl derivative is crystallised to constant melting point; then hydrolyse it with 70% H_2SO_4 and the free base is regenerated by treatment with NH_3 [Bevan et al. *J Chem Soc* 4284 *1956*]. [*Beilstein* **12** H 844. **12** IV 1807.]

4-Methyl-3-nitroaniline *[119-32-4]* **M 152.2, m 81.5°, pK^{25} 3.02.** Crystallise the aniline from hot water

(charcoal), then ethanol and dry it in a vacuum desiccator. [*Beilstein* **12** H 966.]

2-Methyl-5-nitroanisole *[4837-88-1]* **M 176.2, m 54-56°.** 2-Methyl-5-nitroanisole crystallises from MeOH (yellow needles) and sublimes *in vacuo*. [Kuffner *Monatsh Chem* **91** 1152 *1960*, *Beilstein* **6** I 178.]

Methyl 3-nitrobenzoate *[618-95-1]* **M 181.2, m 78°.** Crystallise the benzoate from MeOH (1g/ml). [*Beilstein* **9** H 378, **9** I 153, **9** II 248, **9** III 1493, **9** IV 1056.]

Methyl 4-nitrobenzoate *[619-50-1]* **M 181.2, m 95-95.5°.** Dissolve the benzoate in diethyl ether, then wash it with aqueous alkali; the ether is evaporated and the ester is recrystallised from EtOH. [*Beilstein* **9** H 390, **9** IV 1074.]

3-Methyl-2-nitrobenzoic acid *[5437-38-7]* **M 181.2, m 220-222.5°, pK^{20} 2.91 (1% aqueous EtOH).** Recrystallise it from EtOH. The *methyl ester* has **m** 74° (from MeOH), and the *amide* [60310-07-8] **M** 180.1, has **m** 192° (needles from H_2O, prisms from EtOH). [*Beilstein* **9** H 480, **9** IV 1722.]

4-Methyl-3-nitrobenzoic acid (3-nitro-*p*-toluic acid) *[96-98-0]* **M 181.2, m 190-191°, pK^{20} 3.62 (1% aqueous EtOH).** Recrystallise the acid from EtOH. The *S-benzylisothiuronium salt* has **m** 167-168° (EtOH). The *acid chloride* [10397-30-5] has **m** 20-21°, **b** 185°/36mm, and the *methyl ester* [7356-11-8] crystallises as pale yellow needles from MeOH with **m** 51°. [*Beilstein* **9** H 502, **9** II 334, **9** III 2359.]

***N*-Methyl-4-nitrosoaniline** *[10595-51-4]* **M 136.2, m 114-115°, 118°, pK_{Est} ~1.0.** Crystallise it from *C_6H_6. The *picrate* has **m** 166°(dec) (from MeOH or $CHCl_3$). [*Beilstein* **7** III 3370, **12** IV 1228.]

***N*-Methyl-*N*-nitroso-*p*-toluenesulfonamide (Diazald)** *[80-11-5]* **M 214.2, m 62°.** Crystallise diazald from *benzene by addition of petroleum ether and store it in a refrigerator. It is soluble in most organic solvents including Et_2O, and liberates diazomethane on treatment with alkali. Store it in the cold. It remains active for many months if it is kept in a stoppered bottle in a cold room at >10°. [deBoer & Backer *Org Synth* **34** 96 1954, *Org Synth* Coll Vol **VI** 943 *1963*, *Beilstein* **11** I 29.]

4-Methylphenylacetic acid (*p*-tolylacetic acid) *[622-47-9]* **M 150.2, m 94°, pK^{25} 4.37.** Crystallise the acid from heptane or water. [*Beilstein* **9** IV 1795.]

1-Methyl-1-phenylhydrazine sulfate *[33008-18-3]* **M 218.2, pK^{25} 4.98 (free base).** Crystallise the sulfate from hot H_2O by addition of hot EtOH. [*Beilstein* **15** IV 53 for free base.]

***N*-Methylphthalimide** *[550-44-7]* **M 161.1, m 133.8°.** Recrystallise the imide from absolute EtOH or AcOH (**m** 134°). The IR has ν_{max} at 1780 and 1380cm^{-1}. [*Beilstein* **21** H 461, **21** III/IV 5030.]

Methyl Red (4-dimethylaminoazobenzene-2'-carboxylic acid) *[493-52-7]* **M 269.3, m 181-182°, CI 13020, pK_1^{25} 2.30, pK_2^{25} 4.82.** The acid is extracted with boiling toluene using a Soxhlet apparatus. The crystals which separate on slow cooling to room temperature are filtered off, washed with a little toluene and recrystallised from glacial acetic acid, *benzene or toluene followed by pyridine/water. *Alternatively*, dissolve it in aqueous 5% $NaHCO_3$ solution, and precipitate it from a hot solution by dropwise addition of aqueous HCl. Repeat this until the extinction coefficients do not increase. [*Beilstein* **16** IV 504.]

Methyl salicylate (methyl 2-hydroxybenzoate, oil of winter green) *[119-36-8]* **M 152.2, m -8.6°, b 79°/6mm, 104-105°/14mm, 223.3°/atm, d_4^{20} 1.1149, n_D^{20} 1.5380, pK^{25} 10.19.** Dilute the ester with Et_2O, wash with saturated $NaHCO_3$ (it may effervesce due to the presence of free acid), brine, dry $MgSO_4$, filter, evaporate and distil it. Its solubility is 1g/1.5L of H_2O. The *benzoyl* derivative has **m** 92° (**b** 270-280°/120mm), and the *3,5-dinitrobenzoate* has **m** 107.5°, and the *3,5-dinitrocarbamoyl* derivative has **m** 180-181°. [Hallas *J Chem Soc* 5770 *1965*, *Beilstein* **10** IV 143.]

α-Methylstyrene (monomer, 2-phenylpropene) *[98-83-9]* **M 118.2, b 57°/15mm, d_4^{20} 0.910, n_D^{20} 1.5368.**

Wash the monomer three times with aqueous 10% NaOH (to remove inhibitors such as quinol), then six times with distilled water, dry with $CaCl_2$ and distil it under vacuum. The distillate is kept under nitrogen, in the cold, and redistilled if kept for more than 48 hours before use. It can also be dried with CaH_2. Add stabiliser if it is to be stored for long periods. [*Beilstein* **5** IV 1364.]

***trans*-ß-Methylstyrene (1-phenylpropene)** *[873-66-5]* **M 118.2, b 64-65°/10mm, 176°/760mm, d_4^{20} 0.910, n_D^{20} 1.5496.** Distil it under N_2 from powdered NaOH through a Vigreux column, and pass it through activated neutral alumina before use [Wong et al. *J Am Chem Soc* **109** 3428 *1987*]. [*Beilstein* **5** III 1184, **5** IV 1359.]

4-Methylstyrene *[622-97-9]* **M 118.2, b 60°/12mm, 106°/10mm, d_4^{20} 0.9173, n_D^{20} 1.542.** Purify it as the above styrenes and add a small amount of antioxidant if it is to be stored. It has UV in EtOH at λ_{max} at 285nm (log ε 3.07), and in EtOH + HCl 295nm (log ε 2.84) and 252nm (log ε 4.23). [Schwartzman & Carson *J Am Chem Soc* **78** 322 *1956*, Joy & Orchin *J Am Chem Soc* **81** 305 *1959*, Buck et al. *J Chem Soc* 2377*1949*, *Beilstein* **5** IV 1369.]

Methyl 4-toluenesulfonate *[80-48-8]* **M 186.2, m 25-28°, 28°, b 144.6-145.2°/5mm, 168-170°/13mm, d_4^{20} 1.23, n_D^{20} 1.5172.** The ester is purified by distillation *in vacuo* and could be crystallised from petroleum ether or Et_2O/petroleum ether at low temperature. It is a powerful methylating agent, is **TOXIC** and is a **skin irritant**, so it is better to purify it by repeated distillation. [IR: Schreiber *Anal Chem* **21** 1168 *1949*, Buehler et al. *J Org Chem* **2** 167 *1937*, Roos et al. *Org Synth* Coll Vol **I** 145 *1941*, *Beilstein* **11** IV 247.]

Methyl Violet 2B [4,4'-bis-(diethylamino)-4"-methyliminotriphenylmethyl hydrochloride) *[8004-87-3]* **M 394.0, m 137°(dec), CI 42535, λ_{max} ~580nm.** Crystallise the dye from EtOH by precipitation with Et_2O during cooling in an ice-bath. Filter it off and dry it at 105°. [*Beilstein* **13** IV 2283.]

Michler's ketone [4,4'-bis(dimethylamino)benzophenone] *[90-94-8]* **M 268.4, m 179°, pK^{25} 9.84.** Dissolve the ketone in dilute HCl, filter and precipitate it by adding ammonia (to remove water-insoluble impurities such as benzophenone). Then crystallise it from EtOH or petroleum ether. [Suppan *J Chem Soc, Faraday Trans1* **71** 539 *1975*.] It is also purified by dissolving in *benzene, then washing with water until the aqueous phase is colourless. The *benzene is evaporated off, and the residue is recrystallised three times from *benzene and EtOH [Hoshino & Kogure *J Phys Chem* **72** 417 *1988*]. [*Beilstein* **14** IV 255.]

Naphthacene **(benz[b]anthracene, 2,3-benzanthracene, rubene)** *[92-24-0]* **M 228.3, m >300°, 341° (open capillary), 349°, 357°.** Naphthacene crystallises in orange needles from EtOH, $*C_6H_6$ or toluene. Dissolve it in sodium-dried *benzene and pass it through a column of alumina. The eluent is evaporated under vacuum, and the chromatography is repeated using fresh *benzene. Finally, the naphthacene is sublimed *in vacuo* at 186°. [Martin & Ubblehode *J Chem Soc* 4948 *1961*, UV: Clar *Chem Ber* **65** 517 *1932,* Clar *Chem Ber* **69** 607 *1936*, IR: Cannon & Sutherland *Spectrochim Acta* **4** 373 *1951*, *Beilstein* **5** H 718, **5** IV 2545.]

1-Naphthaldehyde *[66-77-3]* **M 156.2, m 2°, b 160-161°/15mm, pK^{20} -7.04 (aqueous H_2SO_4).** Distil 1-naphthaldehyde with steam, extract the distillate into Et_2O, dry (Na_2SO_4), filter, evaporate the filtrate and distil the residue in a vacuum. [*Beilstein* **7** IV 1286.]

2-Naphthaldehyde *[66-99-9]* **M 156.2, m 59°, b 260°/19mm, pK^{20} -7.04 (aqueous H_2SO_4).** Distil 2-naphthaldehyde with steam then crystallise it from water or EtOH. [*Beilstein* **7** IV 1288.]

Naphthalene *[91-20-3]* **M 128.2, m 80.3°, b 87.5°/10mm, 218.0°/atm, d_4^{20} 1.0253, d_4^{100} 0.9625, n^{85} 1.5590.** Crystallise naphthalene once or more times from the following solvents: EtOH, MeOH, CCl_4, $*C_6H_6$, glacial acetic acid, acetone or diethyl ether, followed by drying at 60° in an Abderhalden drying apparatus. It has also been purified by vacuum sublimation and by fractional crystallisation from its melt. Other purification procedures include refluxing in EtOH over Raney Ni and chromatography of a CCl_4 solution on alumina with *benzene as eluting solvent. Baly and Tuck [*J Chem Soc* 1902 *1908*] purified naphthalene for spectroscopy by

heating with conc H_2SO_4 and MnO_2, followed by steam distillation (repeating the process), and formation of the *picrate* which, after recrystallisation (**m** 150°) is decomposed with base and the naphthalene is steam distilled. It is then crystallised from dilute EtOH. It can be dried over P_2O_5 under vacuum (take care not to make it sublime). Also purify it by sublimation and subsequent crystallisation from cyclohexane. *Alternatively*, it has been washed at 85° with 10% NaOH to remove phenols, with 50% NaOH to remove nitriles, with 10% H_2SO_4 to remove organic bases, and with 0.8g $AlCl_3$ to remove thianaphthalenes and various alkyl derivatives. Then it is treated with 20% H_2SO_4, 15% Na_2CO_3 and finally distilled. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*.] Zone refining purified naphthalene from anthracene, 2,4-dinitrophenylhydrazine, methyl violet, benzoic acid, methyl red, chrysene, pentacene and indoline. [*Beilstein* **5** IV 1640.]

Naphthalene-1,4-disulfonic acid *[92-41-1]* **M 288.2, pK_{Est} <0.** Crystallise the acid from conc HCl. The *disulfonamide* has **m** 273° (from EtOH). [*Beilstein* **11** II 119, **11** III 463.]

Naphthalene-1-sulfonic acid *[85-47-2]* **M 208.2, m ($2H_2O$) 90°, (anhydrous) 139-140°, pK^{20} -0.17.** Crystallise the acid from conc HCl and twice from H_2O. The *S-benzylisothiuronium salt* has **m** 137° (from aqueous EtOH). [*Beilstein* **11** H 155, **11** III 383, **11** IV 521.]

Naphthalene-2-sulfonic acid *[120-18-3]* **M 208.2, m 91°, pK_{Est} <1.** Crystallise the acid from conc HCl. The *S-benzylisothiuronium salt* has **m** 192° (from aqueous EtOH). [Berger *Acta Chem Scand* **8** 432 *1954*, *Beilstein* **11** H 171, **11** IV 527.]

Naphthalene-1-sulfonyl chloride *[85-46-1]* **M 226.7, m 64-67°, 68°, b 147.5°/0.9mm, 147.5°/13mm.** If the IR indicates the presence of OH, then treat it with an equal weight of PCl_5 and heat it at *ca* 100° for 2 hours, cool and pour onto ice + H_2O, stir well and filter off the solid. Wash the solid with cold H_2O and dry the solid in a vacuum desiccator over P_2O_5 + solid KOH. Extract the solid with petroleum ether (b 40-60°), filter off any insoluble solid and cool. Collect the crystalline sulfonyl chloride and recrystallise it from dry Et_2O, petroleum ether or *C_6H_6/petroleum ether. If large quantities are available, then it can be distilled under high vacuum. [Fierz-Davaid & Weissenbach *Helv Chim Acta* **3** 2312 *1920*.] The *sulfonamide* crystallises from EtOH **(m** 150.5°) or H_2O **(m** 153°). [*Beilstein* **11** H 175, **11** II 93, **11** IV 383.]

Naphthalene-2-sulfonyl chloride *[93-11-8]* **M 226.7, m 74-76°, 78°, 79°, 83°, b 148°/0.6mm, 201°/13mm.** Distil the chloride in a vacuum and/or recrystallise it (twice) from *benzene/petroleum ether (1:1 v/v). Purify it as the 1-sulfonyl chloride above. [Fierz-Davaid & Weissenbach *Helv Chim Acta* **3** 2312 *1920*.] The *sulfonamide* has **m** 217° (from EtOH). [*Beilstein* **11** III 399, **11** IV 529.]

1,8-Naphthalic acid (naphthalene-1,8-dicarboxylic acid) *[518-05-8]* **M 216.9, m 270°, $pK_{Est(1)}$~ 2.1, $pK_{Est(2)}$~ 4.5.** Crystallise the acid from EtOH or aqueous EtOH. [Raecke & Schrip *Org Synth* **40** 71 *1960*, *Beilstein* **9** II 651, **9** III 4466.]

1,8-Naphthalic anhydride *[81-84-5]* **M 198.2, m 274°, 274-275°.** Extract it with cold aqueous Na_2CO_3 to remove free acid, then crystallise from acetic anhydride. [*Beilstein* **17** III/IV 6392, **17/11** V 492.]

2-Naphthamide (2-naphthoic acid amide) *[2243-82-5]* **M 171.2, m 195°, pK^{20} -2.30 (H_0 scale, aqueous H_2SO_4).** Crystallise it from EtOH (197°). [Clemo & Spence *J Chem Soc* 2818 *1928*, *Beilstein* **9** H 657, **9** II 45, **9** IV 2417.]

Naphthazarin (5,8-dihydroxy-1,4-naphthoquinone) *[475-38-7]* **M 190.2, m ~ 220-230°(dec), m 225-230°, pK_1^{20} 8.2, p K_2^{20} 10.2.** It crystallises in red-brown needles with a green shine from EtOH. It also crystallises from hexane and is further purified by sublimation at 2-10mm. [Huppert et al. *J Phys Chem* **89** 5811 *1985*.] It is sparingly soluble in H_2O but soluble in alkalis. The *diacetate* forms golden yellow prisms from $CHCl_3$, **m** 192-193° and the *5,8-dimethoxy* derivative has **m** 157° (155°) (from petroleum ether) [Bruce & Thompson *J Chem Soc* 1089 *1955*, IR: Schmand & Boldt *J Am Chem Soc* **97** 447 *1975*, NMR: Brockmann & Zeeck *Chem Ber* **101** 4221 *1968*]. The *monothiosemicarbazone* has **m** 168°(dec) from EtOH [Gardner et al. *J Am Chem Soc* 74 2106 *1952*]. [*Beilstein* **8** H 412, **8** III 3600.]

Naphthionic acid (4-aminonaphthalene-1-sulfonic acid) *[84-86-6]* **M 223.3, m > 300°(dec), pK^{25} 2.68.** It crystallises from H_2O as needles of the 0.5 hydrate. Salt solutions fluoresce strongly blue. The *S-benzylisothiuronium salt* has **m** 195° (from aqueous EtOH). [*Beilstein* **14** IV 2793.]

1-Naphthoic acid *[86-55-5]* **M 172.2, m 162.5-163.0°, pK^{25} 3.60.** Crystallise the acid from toluene (3ml/g) (charcoal), petroleum ether (b 80-100°), or aqueous 50% EtOH. The *amide* has **m** 202° (from EtOH). [*Beilstein* **9** IV 2402.]

2-Naphthoic acid *[93-09-4]* **M 172.2, m 184-185°, pK^{25} 4.14.** Crystallise the acid from EtOH (4ml/g), aqueous 50% EtOH or Me_2CO (**m** 185-186°). Dry it at 100°. The *acid chloride* has **m** 52-52° (from *C_6H_6/petroleum ether) and **b** 160-162°/11mm [Hersberg & Carson *Org Synth* Coll Vol **III** 629 *1955*], the *amide* has **m** 192° (from EtOH), and the *N-Methyl amide* has **m** 109-109.5° (form *C_6H_6). [*Beilstein* **9** H 656, **9** III 3174, **9** IV 2402.]

1–Naphthol *[90-15-3]* **M 144.2, m 95.5-96°, pK^{25} 9.34.** Sublime 1-naphthol, then crystallise it from aqueous MeOH (charcoal), aqueous 25% or 50% EtOH, *C_6H_6, cyclohexane, heptane, CCl_4 or H_2O. Dry it over P_2O_5 *in vacuo*. The *4-nitrobenzoate* has **m** 143° (from EtOH). [Shizuka et al. *J Am Chem Soc* **107** 7816 *1985*, *Beilstein* **8** H 596, **6** IV 4208.]

2-Naphthol *[135-19-3]* **M 144.2, m 122.5-123.5°, pK^{25} 9.57.** Crystallise 2-naphthol from aqueous 25% EtOH (charcoal), H_2O, *benzene, toluene or CCl_4. *Alternatively*, extract it repeatedly with small amounts of EtOH, followed by dissolution in a minimum volume of EtOH and precipitation with distilled water, then drying over P_2O_5 under vacuum. It has also been dissolved in aqueous NaOH and precipitated by adding acid (repeat several times), then precipitated from *benzene by addition of heptane. Final purification can be by zone melting or sublimation *in vacuo*. The *4-nitrobenzoate* has **m** 104° (from EtOH). [Bardez et al. *J Phys Chem* **89** 5031 *1985*, Kikuchi et al. *J Phys Chem* **91** 574 *1987*, *Beilstein* **6** IV 4253.]

Naphthol AS-D (3-hydroxy-2-naphthoic-*o*-toluide) *[135-61-5]* **M 277.3, m 196-198°.** Purify it by recrystallisation from xylene. This gives yellow-green fluorescent solutions at pH 8.2-9.5. [IR: Schnopper et al. *Anal Chem* **31** 1542 *1959*.] The *naphthol AS-D acetate* is obtained with AcCl, **m** 168-169°, and with chloroacetyl chloride *naphthol AS-D-chloroacetate* is obtained [Moloney et al. *J Histochem Cytochem* **8** 200 *1960*, Burstone *Arch Pathology* **63** 164 *1957*]. [*Beilstein* **12** H 505.]

α-Naphtholbenzein [bis-(α-{4-hydroxynaphth-1-yl})-benzyl alcohol] *[6948-88-5]* **M 392.5, m 122-125°, pK_{Est} ~ 9.3.** Crystallise the alcohol from EtOH, aqueous EtOH or glacial acetic acid. [*Beilstein* **6** H 1150.]

1-Naphthol-2-carboxylic acid (1-hydroxy-2-naphthoic acid) *[86-48-6]* **M 188.2, m 203-204°, $pK_{Est(1)}$~2.5, $pK_{Est(2)}$~12.** Successively crystallise the acid from EtOH/water, diethyl ether and acetonitrile, with filtration through a column of charcoal and Celite. [Tong & Glesmann *J Am Chem Soc* **79** 583 *1957*, *Beilstein* **10** H 331, **10** IV 1194.]

3-Naphthol-2-carboxylic acid (3-hydroxy-2-naphthoic acid) *[92-70-6]* **M 188.2, m 222-223°, pK_1^{25} 2.79, pK_2^{25} 12.84.** Crystallise it from water or acetic acid. The *S-benzyisothiuronium salt* has **m** 216-217° (from EtOH). It forms many metal complex salts. [*Beilstein* **10** H 333, **10** III 1084.]

1,2-Naphthoquinone *[524-42-5]* **M 158.2, m 140-142°(dec).** Crystallise the quinone from ether (red needles) or *benzene (orange leaflets). [*Beilstein* **7** IV 2417.]

1,4-Naphthoquinone *[130-15-4]* **M 158.2, m 125-125.5°.** Crystallise the quinone from diethyl ether (charcoal). It distils in steam. It also crystallises from *benzene or aqueous EtOH and sublimes in a vacuum. [*Beilstein* **7** IV 2422.]

β-Naphthoxyacetic acid *[120-23-0]* **M 202.2, m 156°, pK_{Est} ~3.0.** Crystallise the acid from hot water or *benzene. [*Beilstein* **6** IV 4274.]

β-Naphthoyltrifluoroacetone (4,4,4-trifluoro-2-naphthylbutan-1,3-dione) *[893-33-4]* **M 266.2, m 70-71°, 74-76°, pK^{20} 6.35.** Crystallise the dione from EtOH. The *mono oxime* crystallises from H_2O or aqueous EtOH and has **m** 137-138°. [Reid & Calvin *J Am Chem Soc* **72** 2948 *1950*, *Beilstein* **7** IV 2478.]

Naphthvalene (2,3-dihydro-1,2,3-metheno-1*H*-indene) *[34305-47-0]* **M 128.1, m dec at 175° to benzvalene.** Purify it by chromatography on alumina and eluting with pentane, also by reverse phase (ODS) HPLC using MeCN as solvent. It is stable at room temperature [Kjell et al. *J Am Chem Soc* **108** 4111 *1986*, Abelt et al. *J Am Chem Soc* **107** 4148 *1985*]. The ^{1}H NMR in CCl_4 has τ 3.18 (4H), 6.17 (t *J* 1.5Hz, 2H), 7.60 (t *J* 1.5Hz 2H).

1-Naphthyl acetate *[830-81-9]* **M 186.2, m 45-46°, 48-49°, b 114-115°/1mm.** Chromatograph the acetate on silica gel and crystallise as the 2-isomer below. The *2,4,7-trinitrofluoren-9-one complex* has **m** 120° (from EtOH). [*Beilstein* **6** H 608, **6** III 2928, **6** IV 4217.]

2-Naphthyl acetate *[1523-11-1]* **M 186.2, m 71°, 71-72°, b 133-134°/2mm.** Distil the acetate in a high vaccum and/or crystallise it from petroleum ether (b 60-80°) or dilute aqueous EtOH. The *picrate* has **m** 80° (from EtOH). [*Beilstein* **6** H 644, **6** I 313, **6** II 600, **5** III 2982, **6** IV 4267.]

1-Naphthylacetic acid *[86-87-3]* **M 186.2, m 132°, pK^{25} 4.23.** Crystallise the acid from EtOH or water. [*Beilstein* **9** H 666, **9** IV 2424.]

2-Naphthylacetic acid *[581-96-4]* **M 186.2, m 143.1-143.4°, pK^{25} 4.30.** Crystallise the acid from water or *benzene. [*Beilstein* **9** H 666, **9** IV 2431.]

1-Naphthylamine *[134-32-7]* **M 143.2, m 50.8-51.2°, b 160°, pK^{25} 3.94.** Sublime the amine at 120° in a stream of nitrogen, then crystallise it from petroleum ether (b 60-80°), or absolute EtOH then diethyl ether. Dry it *in vacuo* in an Abderhalden pistol. It has also been purified by crystallisation of its *hydrochloride* (see below) from water, followed by liberation of the free base and distillation; it is finally purified by zone melting. The *styphnate* has **m** 181-182° (from EtOH). [*Beilstein* **12** III 2846, **12** IV 3009.] **CARCINOGEN.**

1-Naphthylamine hydrochloride *[552-46-5]* **M 179.7, m 240-250° sublimes on heating.** Crystallise the salt from water (charcoal). [*Beilstein* **12** III 2849, **12** IV 3009.]

2-Naphthylamine *[91-59-8]* **M 143.2, m 113°, pK^{25} 4.20.** Sublime the amine at 180° in a stream of nitrogen. Crystallise it from hot water (charcoal) or *benzene. Dry it under vacuum in a drying pistol. The *styphnate* has **m** 194-195° (from EtOH). [*Beilstein* **12** H 1265, **12** III 2989, **12** IV 3122.] **CARCINOGEN**.

2-Naphthylamine-1-sulfonic acid *[81-16-3]* **M 223.3, m >200°(dec), pK$_1^{25}$ <1, pK$_2^{25}$ 2.35 (NH$_2$).** Crystallise the acid under nitrogen from boiling water and dry it in a steam oven [Bryson *Trans Faraday Soc* **47** 522, 527 *1951*]. [*Beilstein* **14** III 2240, **14** IV 2792.]

5-Naphthylamine-1-sulfonic acid *[84-89-9]* **M 223.3, m >200°(dec), pK$_{Est(1)}$<1, pK$_2^{25}$ 3.69 (NH$_2$).** Crystallise the acid under nitrogen from boiling water and dry it in a steam oven [Bryson *Trans Faraday Soc* **47** 522, 527 *1951*]. [*Beilstein* **14** IV 2800.]

2-Naphthylamine-6-sulfonic acid *[93-00-5]* **M 223.3, m >200°(dec), pK^{25} 3.74.** Crystallise the acid from a large volume of hot water. The *diethylamine salt* has **m** 190.5-192° (from EtOH/*iso*BuOH), and the *S-benzylisothiuronium salt* has **m** 330° (from *n*BuOH). [*Beilstein* **14** H 760, **14** II 463, **14** III 2249, **14** IV 2804.]

1-(1-Naphthyl) ethanol *[R-(+)- 42177-25-3, S-(–)- 15914-84-8]* **M 172.2, m 46°, 45-47.5°, 48°, [α]$_{546}^{20}$ (+) and (-) 94°, [α]$_D^{20}$ (+) and (-) 78° (c 1, MeOH).** Purify the alcohol by recrystallisation from Et_2O/petroleum ether, Et_2O, hexane [Balfe et al. *J Chem Soc* 797 *1946*, IR, NMR: Theisen & Heathcock *J Org Chem* 53 2374 *1988*, see also Fredga et al. *Acta Chem Scand* **11** 1609 *1957*]. The *RS-alcohol [57605-95-5]* has **m** 63-65°, 65-66° from hexane. [*Beilstein* **6** III 3034, **6** IV 4346.]

1-(1-Naphthyl)ethylamine *[R-(+)- 3886-70-2, S-(–)- 10420-89-0]* **M 171.2, b 153°/11mm, 178-181°/20mm, d_4^{20} 1.067, n_D^{20} 1.624, $[\alpha]_{546}^{20}$ (+) and (-) 65°, $[\alpha]_D^{20}$ (+) and (-) 55° (c 2, MeOH), $[\alpha]_D^{17}$ (+) and (-) 82.8° (neat), pK_{Est} ~9.3.** Purify the amine by distillation in a good vacuum. [Mori et al. *Tetrahedron* **37** 1343 *1981*, cf Wilson in *Topics Stereochem* (Allinger and Eliel eds) **vol 6** 135 *1971*, Fredga et al. *Acta Chem Scand* **11** 1609 *1957*.] The *hydrochlorides* crystallise from H_2O $[\alpha]_D^{18}$ ±3.9° (c 3, H_2O), and the *sulfates* recrystallise from H_2O as *tetrahydrates* **m** 230-232°. The *RS-amine* [42882-31-5] has **b** 153°/11mm, 156°/15mm, 183.5°/41mm [Blicke & Maxwell *J Am Chem Soc* **61** 1780 *1939*]. [*Beilstein* **12** III 3111.]

***N*-(α-Naphthyl)ethylenediamine dihydrochloride** *[1465-25-4]* **M 291.2, m 188-190°, $pK_{Est(1)}$~3.8, $pK_{Est(2)}$~9.4.** Crystallise the salt from water. [*Beilstein* **12** II 699.]

1-Naphthyl isocyanate *[86-84-0]* **M 169.2, m 3-5°, b 140-142°/12mm, 269-270°/760mm, d_4^{20} 1.1774.** Distil the isocyanate at atmospheric pressure or in a vacuum. It can be crystallised from petroleum ether (b 60-70°) at low temperature. *It has a pungent odour, is* **TOXIC** *and is absorbed through the skin.* [*Beilstein* **12** H 1244, **12** III 2948.]

1-Naphthyl isothiocyanate *[551-06-4]* **M 185.3, m 58-59°.** Crystallise the isothiocyanate from hexane (1g in 9 ml). It forms white needles and is soluble in most organic solvents but is insoluble in H_2O. *It is absorbed through the skin and may cause dermatitis.* [Cymmerman-Craig et al. *Org Synth* Coll Vol **IV** 700 *1963*, *Beilstein* **12** H 1244, **12** III 2948.]

2-(2-Naphthyloxy)ethanol *[93-20-9]* **M 188.2, m 72-74°, 76.7°.** Crystallise it from *benzene/petroleum ether. [Yoshino et al. *Bull Chem Soc Jpn* **46** 553 *1973*.]

***N*-1-Naphthylphthalamic acid (Naptalam)** *[132-66-1]* **M 291.3, m 189° (dec), 203°.** Crystallise the herbicide from EtOH (**m** 183-185°). The *Na salt* has **m** 185°. [*Beilstein* **12** H 1236, **12** I 525, **12** III 2876.]

2-Naphthyl salicylate (Betol) *[613-78-5]* **M 264.3, m 94.4°, 95°, pK_{Est} ~10.0.** Crystallise Betol from EtOH. It is *dimorphic* with **m**'s at ~55° and ~96°. [*Beilstein* **10** H 80, **10** II 53, **10** III 136, **10** IV 158.]

1-Naphthyl thiourea (ANTU) *[86-88-4]* **M 202.2, m 198°.** Crystallise ANTU from EtOH. [*Beilstein* **12** III 2941, **12** IV 3086.]

1-Naphthyl urea *[6950-84-1]* **M 186.2, m 215-220°.** Crystallise the urea from EtOH (**m** 213-214° also 215°). [*Beilstein* **12** H 1238, **12** IV 3076.]

2-Naphthyl urea *[13114-62-0]* **M 186.2, m 212°, 219-220°.** Crystallise the urea from EtOH. [*Beilstein* **12** H 1292, **12** III 3029, **12** IV 3149.]

Narcein {6-[6-(2-dimethylaminoethyl)]-2-methoxy-3,4-(methylenedioxy)phenylacetyl]-2,3-dimethoxybenzoic acid} *[131-28-2]* **M 445.4, m 176-177° (145° anhydrous), pK_1^{15} 3.5, pK_2^{15} 9.3.** Recrystallise Narcein from water (as trihydrate). The *styphnate* has **m** 185-189° (from EtOH), and the *picrate* has **m** 200° (from EtOH). [*Beilstein* **19** H 370, **19** I 797, **19** II 386, **19** IV 4382.]

Neostigmine [(3-dimethylcarbamoylphenyl)trimethylammonium] bromide *[114-80-7]* **M 303.2, m 176°(dec), 181°(dec).** Crystallise neostigmine bromide from EtOH/diethyl ether. Its solubility in H_2O is ~50%. [*Beilstein* **13** III 939.] (It is cholinergic and *highly* **TOXIC**.) The starting material **3-dimethylcarbamoyl-*N,N*-dimethylaniline** *[59-99-4]* has **b 195°/20mm** [*Beilstein* **13** III 936], and its *picrate* has **m** 138° (from EtOH).

Neostigmine methyl sulfate (Prostigmine B) *[51-60-5]* **M 334.4, m 142-145°.** Crystallise the sulfate from EtOH or Me_2CO (**m** 143-144°). Its solubility in H_2O is ~10%. [*Beilstein* **13** III 939.] (It is cholinergic and *highly* **TOXIC**.)

Ninhydrin (1,2,3-triketohydrindene hydrate) *[485-47-2]* **M 178.1, m 241-243°(dec), pK^{30} 8.82.** Crystallise ninhydrin from hot water (charcoal). Dry it under vacuum and store it in sealed brown containers. [*Beilstein* **7** IV 2786.]

2-Nitroacetanilide *[552-32-9]* **M 180.2, m 93-94°, pK_{Est} <0.** Crystallise the anilide from H_2O, aqueous EtOH (**m** 92-93°) or EtOH (**m** 92.5-93.5°). [*Beilstein* **12** II 371, **12** III 1523, **12** IV 1574.]

4-Nitroacetanilide *[104-04-1]* **M 180.2, m 217°, pK_{Est} <0.** Precipitate the anilide from 80% H_2SO_4 by adding ice, then wash with water, and crystallise from aqueous EtOH. Dry it in air. [*Beilstein* **12** IV 1632.]

3-Nitroacetophenone *[121-89-1]* **M 165.2, m 81°, b 167°/18mm, 202°/760mm.** Distil the ketone in steam and crystallise it from EtOH. [*Beilstein* **7** IV 656.]

4-Nitroacetophenone *[100-19-6]* **M 165.2, m 80-81°, b 145-152°/760mm.** Crystallise the ketone from EtOH or aqueous EtOH. [*Beilstein* **7** IV 657.]

3-Nitroalizarin (1,2-dihydroxy-3-nitro-9,10-anthraquinone, Alizarin Orange) *[568-93-4]* **M 285.2, m 244° (dec), $pK_{Est(1)}$ ~4.6, $pK_{Est(2)}$ ~9.6.** Crystallise the dye from AcOH (**m** 244-245°). It has λ_{max} at 494nm (H_2SO_4) and forms Cu salts. [*Beilstein* **8** H 447, **8** II 491, **8** III 3774, **8** IV 2359.]

o-**Nitroaniline** *[88-74-4]* **M 138.1, m 72.5-73.0°, pK^{25} -0.25 (-0.31).** Crystallise the aniline from hot water (charcoal), then from aqueous 50% EtOH, or EtOH, and dry it in a vacuum desiccator. It has also been chromatographed on alumina, then recrystallised from *benzene. [*Beilstein* **12** IV 1563.]

m-**Nitroaniline** *[99-09-2]* **M 138.1, m 114°, pK^{25} 2.46.** Purify it as for *o*-nitroaniline. **Warning: it is absorbed through the skin. [***Beilstein* **12** IV 1589.]

p-**Nitroaniline** *[100-01-6]* **M 138.1, m 148-148.5°, pK^{25} 1.02.** Purify it as for *o*-nitroaniline. It also crystallises from acetone. It is freed from *o*- and *m*-isomers by zone melting and sublimation. [*Beilstein* **12** IV 1613.]

o-**Nitroanisole (2-methoxynitrobenzene)** *[91-23-6]* **M 153.1, f 9.4°, b 265°/737mm, d_4^{20} 1.251, n_D^{20} 1.563.** Purify it by repeated vacuum distillation in the absence of oxygen. [*Beilstein* **6** IV 1249.]

p-**Nitroanisole (4-methoxynitrobenzene)** *[100-17-4]* **M 153.1, m 54°.** Crystallise it from petroleum ether or hexane and dry it *in vacuo*. [*Beilstein* **6** IV 1282.]

9-Nitroanthracene *[602-60-8]* **M 223.2, m 142-143°.** Purify it by recrystallisation from EtOH or MeOH. Further purify it also by sublimation or TLC. [*Beilstein* **5** H 666, **5** II 578, **5** III 2136, **5** IV 2296.]

o-**Nitrobenzaldehyde** *[552-89-6]* **M 151.1, m 44-45°, b 120-144°/3-6mm.** Crystallise the aldehyde from toluene (2-2.5ml/g) by addition of 7ml petroleum ether (b 40-60°) for 1ml of solution. It can also be distilled under reduced pressures. [*Beilstein* **7** IV 584.]

m-**Nitrobenzaldehyde** *[99-61-6]* **M 151.1, m 58°.** Crystallise the aldehyde from water or EtOH/water, then sublime it twice at 2mm pressure at a temperature slightly above its melting point. [*Beilstein* **7** IV 591.]

p-**Nitrobenzaldehyde** *[555-16-8]* **M 151.1, m 106°.** Purify it as for *m*-nitrobenzaldehyde above. [*Beilstein* **7** IV 589.]

Nitrobenzene *[98-95-3]* **M 123.1, f 5.8°, b 84-86.5°/6.5-8mm, 210.8°/760mm, d_4^{20} 1.206, n^{15} 1.55457, n_D^{20} 1.55257, pK^{18} -11.26 (aqueous H_2SO_4).** Common impurities include nitrotoluene, dinitrothiophene, dinitrobenzene and aniline. Most impurities can be removed by steam distillation in the presence of dilute H_2SO_4, followed by drying with $CaCl_2$, and shaking with, then distilling at low pressure from BaO, P_2O_5, $AlCl_3$

or activated alumina. It can also be purified by fractional crystallisation from absolute EtOH (by refrigeration). Another purification process includes extraction with aqueous 2M NaOH, then water, dilute HCl, and water, followed by drying ($CaCl_2$, $MgSO_4$ or $CaSO_4$) and fractional distillation under reduced pressure. The pure material is stored in a brown bottle, in contact with silica gel or CaH_2. It is very *hygroscopic*. [*Beilstein* **5** H 233, **5** I 124, **5** II 171, **5** III 591, **5** IV 708.]

4-Nitrobenzene-azo-resorcinol (magneson-I) *[74-39-5]* **M 259.2, m 185°(dec), 199-200°(dec).** Crystallise the dye from EtOH. [*Beilstein* **16** H 181, **16** IV 1266.]

4-**Nitrobenzenediazonium fluoroborate** *[456-27-9]* **M 236.9.** It crystallises from water. Drain it well and use it as soon as possible. Do NOT store it. [Whetsch et al. *J Am Chem Soc* **78** 3360 *1956*, *Beilstein* **16** IV 816.] **It can be EXPLOSIVE when dry.**

2-Nitrobenzenesulfenyl chloride (NPS-Cl) *[7669-54-7]* **M 189.6, m 73-74.5°, 74.5-75°, 74-76°.** Recrystallise it from CCl_4 (2ml/g), filter off the solution at 5° (recovery 75%). It has also been recrystallised from petroleum ether (b 40-60°), dried rapidly at 50° and stored in a brown glass bottle, sealed well and stored away from moisture. [Hubacher *Org Synth* Coll Vol **II** 455 *1943*, Ito et al. *Chem Pharm Bull Jpn* **26** 296 *1978*, *Beilstein* **6** I 157.]

o*-Nitrobenzenesulfonyl chloride** *[1694-92-4]* **M 221.6, m 63-67°, 68-69°, 69.5-69.7°.** It is prepared by the oxidation of di-*o*-nitrophenyldisulfide with Cl_2 [Wertheim *Org Synth* Coll Vol **II** 471 *1943*] or from *o*-nitrobenzenesulfonic acid and PCl_5, then pouring into H_2O, washing the solid with H_2O, drying it *in vacuo* and recrystallising it from petrol, Et_2O/petrol, petroleum ether/CCl_4 or petroleum ether. With ammonia it is converted to the ***sulfonamide [5455-59-4] **M 202.1, m 193°,** which forms needles from hot aqueous EtOH; and with phenol/pyridine or Na_2CO_3, the ***phenyl ester*****, m 57°,** is obtained which crystallises from EtOH. The ***sulfonylazide***, **m 71-73°**, separates as needles from petroleum ether [Leffler et al. *J Org Chem* **28** 902 *1963*]. [*Beilstein* **11** H 67, **11** I 20, **11** II 32, **11** III 114, **11** IV 174.]

m*-Nitrobenzenesulfonyl chloride** *[121-51-7]* **M 221.6, m 61-62°, 63.9-64.2°.** It can be prepared from *m*-nitrobenzenesulfonic acid and PCl_5 as for the isomer above and crystallised from petroleum ether/CCl_4 or petroleum ether in needles. With ammonia it is converted to the ***sulfonamide [121-52-8] **M 202.1, m 167-168°,** which forms needles from hot aqueous EtOH and is a moderately strong base with **pK^{20} 9.20**. With phenol/pyridine or Na_2CO_3, the ***phenyl ester*****, m 94°,** is obtained which crystallises from acetic acid. [Gilbert *Synthesis* 315 *1977*, *Beilstein* **11** H 69, **11** I 21, **11** II 33, **11** III 126, **11** IV 182.]

p*-Nitrobenzenesulfonyl chloride (Nosyl chloride)** *[98-74-8]* **M 221.6, m 66-70°, 78-80°, 80°, b 143-144°/1.5mm, 180-181°/17mm.** It is prepared in the same way as for the *m*-isomer above from *p*-nitrobenzenesulfonic acid, and is purified by vacuum distillation and/or by recrystallisation from petroleum ether or Et_2O/petroleum ether. With ammonia it is converted to the ***sulfonamide [6325-93-5] **M 202.1, m 179-180°,** which forms prisms from hot aqueous EtOH and is a moderately strong base with **pK^{20} 9.14**. [Prinsen et al. *Rec Trav Chim Pays Bas* **84** 24 *1965*, *Beilstein* **11** H 72, **11** I 21, **11** II 34, **11** III 136, **11** IV 192.]
It is highly efficient in solid phase peptide synthesis when using *N-nosyl-α-amino acids* [Leggio et al. *Tetrahedron* **63** 8164 *2007*.]

***o*-Nitrobenzenesulfonylhydrazine (NBSH)** *[606-26-8]* **M 217.2, m 100-101°, 101° (dec).** NBSH is unstable unless handled properly. If the material is suspect, it is preferable to prepare freshly thus: hydrazine monohydrate (12.1ml, 2.5 equivalents) is added to a solution of *o*-nitrobenzenesulfonyl chloride (22.2g, 1 equivalent) in dry THF (100ml) at -30° under argon whereby the solution became brown, white N_2H_4.HCl deposited and after 30 minutes TLC (2/1, EtOAc/hexanes) indicated that all the sulfonyl chloride was used up. EtOAc (200ml, at 23°) is added to the cold mixture and washed repeatedly with ice-cold 10% aqueous NaCl (5 × 150ml, contact time with each wash should not be >1 minute; the use of just distilled H_2O results in much lower yields). The organic layer is washed, dried (Na_2SO_4 at 0°), then added slowly to a stirred solution of hexanes (1.2L) at 23° during 5 minutes. The off-white NBSH that precipitates within 10 minutes is isolated by vacuum filtration, the solid is washed with hexanes (2 × 50ml, 23°) and dried at 23°/<1.5mm for 14 hours to provide pure

NBSH as an off-white powder (17.6g, 81%; TLC has R_F 0.19, EtOAc/hexanes 2/1). Store it at ~0-5° under argon, and use gloves due to its toxicity. Its IR (EtOAc) has ν_{max} at 1165, 1352, 1547, 3400—3100 cm^{-1} and its ^1H NMR [300MHz, CD_3CN] has δ: 8.17-8.03 (1H, m), 7.91-7.78 (3H, m), 5.97 (1H, bs), 3.90 (2H, bs); and its ^{13}C NMR [75MHz, CD_3CN] has δ: 149.4, 135.5, 133.4, 133.2, 130.8 and 125.8. [Meyers et al. *J Org Chem* **62** 7507 *1997*, Dunn & Davies *J Chem Soc* 1050 *1929*.]
NBSH is a versatile reagent for synthesising allenes from propargyl alcohols [Meyers & Zheng *J Am Chem Soc* **118** 4492 *1996*], reductive transposition of allylic alcohols [Meyers & Zheng *Tetrahedron Lett* **37** 4841 *1996*], and deoxygenation of unhindered alcohols; each of which proceeds by Mitsunobu displacement of an alcohol with NBSH followed by *in situ* elimination of *o*-nitrobenzoylsulfinic acid to produce mono-alkyl diazene intermediates under mild reaction conditions, i.e. neutral pH and less than 23°, particularly useful with substrates that have sensitive substituents. [Mitsunobu *Synthesis* 1 *1981*, Hughes *Org React* **42** 335 *1992*.] For the success of these reactions it is imperative that the reagent is as pure as possible. Solutions of NBSH in THF that are pale yellow are still suitable for these applications.

4-Nitrobenzhydrazide *[606-26-8]* **M 181.1, m 124°.** Crystallise the hydrazide from EtOH or EtOAc (**m** 120°). [*Beilstein* **9** H 375, **9** I 152, **9** II 246, **9** III 1481, **9** IV 1052.]

2-Nitrobenzoic acid *[552-16-9]* **M 167.1, m 146-148°, pK^{25} 2.21.** Crystallise the acid from *benzene (twice), *n*-butyl ether (twice), then water (twice). Dry and store it in a vacuum desiccator. [Le Noble & Wheland *J Am Chem Soc* **80** 5397 *1958*.] It has also been crystallised from EtOH/H_2O. The *amide* has **m** 176.5° (from H_2O). [*Beilstein* **9** III 1466, **9** IV 1046.]

3-Nitrobenzoic acid *[121-92-6]* **M 167.1, m 143-143.5°, pK^{25} 3.46.** Crystallise the acid from *benzene, H_2O, EtOH (charcoal), glacial acetic acid or MeOH/H_2O. Dry and store it in a vacuum desiccator. The *amide* has **m** 143° (from H_2O or $*C_6H_6$). [*Beilstein* **9** III 1489, **9** IV 1055.]

4-Nitrobenzoic acid *[62-23-7]* **M 167.1, m 241-242°, pK^{25} 3.43.** Purify it as for 3-nitrobenzoic acid above. The *amide* has **m** 201.6° (from H_2O). [*Beilstein* **9** III 1537, **9** IV 1072.]

4-Nitrobenzoyl chloride *[122-04-3]* **M 185.6, m 75°, b 155°/20mm.** Crystallise the acid chloride from dry petroleum ether (b 60-80°), $*C_6H_6$ or CCl_4. Distil it under vacuum. **Irritant**. [Adama & Jenkins *Org Synth* Coll Vol **I** 394 *1941*, *Beilstein* **9** III 1709, **9** IV 1191.]

4-Nitrobenzyl alcohol *[619-73-8]* **M 153.1, m 93°.** Crystallise the alcohol from EtOH and sublime it *in vacuo*. Purity should be at least 99.5%. Sublimed samples should be stored in the dark over anhydrous $CaSO_4$ (Drierite). If the IR contains OH bands, then the sample should be resublimed before use. [Mohammed & Kosower *J Am Chem Soc* **93** 2709 *1979*, *Beilstein* **6** IV 2611.]

4-Nitrobenzyl bromide *[100-11-8]* **M 216.0, m 98.5-99.0°.** Recrystallise the bromide four times from absolute EtOH, then twice from cyclohexane/hexane/*benzene (1:1:1), followed by sublimation at 0.1mm and final recrystallisation from the same solvent mixture. [Lichtin & Rao *J Am Chem Soc* **83** 2417 *1961*.] It has also been crystallised from petroleum ether (b 80-100°, 10ml/g, charcoal). It slowly decomposes even when stored in a desiccator in the dark. **IRRITANT. [***Beilstein* **5** IV 861.]

m-**Nitrobenzyl chloride** *[619-23-8]* **M 171.6, m 45°.** Crystallise the chloride from petroleum ether (b 90-120°). **IRRITANT**. [*Beilstein* **5** IV 855.]

p-**Nitrobenzyl chloride** *[100-14-1]* **M 171.6, m 72.5-73°.** Crystallise the chloride from CCl_4, dry diethyl ether, or *n*-heptane, and dry it under vacuum. **IRRITANT**. [*Beilstein* **5** IV 856.]

p-**Nitrobenzyl cyanide** *[555-21-5]* **M 162.2, m 117°.** Crystallise the nitrile from EtOH. **TOXIC**. [*Beilstein* **9** H 456, **9** I 183, **9** II 313, **9** III 2291.]

2-Nitrobiphenyl *[86-00-0]* **M 199.2, m 36.7°, 37°, b 185-195°/20-30mm.** *o*-Nitrobiphenyl has been prepared

by a Gomberg reaction between diazotised 2-nitroaniline and $*C_6H_6$ [Elks et al. *J Chem Soc* 1282 *1940*] or by the nitration of biphenyl [Morgan & Walls *J Soc Chem Ind* **49** 15T *1930*]. Although the respective yields are ~45% and ~25%, the latter method is by far more convenient to perform experimentally. Crystallise it from EtOH (seeding required) or petroleum ether (b 40-60°). Sublime it under vacuum. [*Beilstein* **5** H 582, **5** I 273, **5** II 487, **5** III 1750.]

3-Nitrocinnamic acid *[555-68-0]* **M 193.2, m 200-201°, pK^{25} 2.58 (*trans*).** Crystallise the acid from $*C_6H_6$ or EtOH. The *p-bromophenacyl ester* has **m** 178° (from AcOH). [*Beilstein* **9** III 271, **9** IV 2043.]

4-Nitrocinnamic acid *[882-06-4]* **M 193.2, m 143° (*cis*), 286°(*trans*), pK_{Est} ~2.6 (*trans*).** Crystallise the acid from H_2O. The *p-bromophenacyl ester* has **m** 191° (from AcOH). [*Beilstein* **9** H 606, **9** III 2744.]

4-Nitrodiphenylamine *[836-30-6]* **M 214.2, m 133-134°, pK^{25} -2.5.** Crystallise the amine from EtOH or aqueous EtOH (**m** 135-136°) and has **m** 131.5-132° after sublimation *in vacuo*. [*Beilstein* **12** H 715, **12** III 1586.]

2-Nitrodiphenyl ether *[2216-12-8]* **M 215.2, b 106-108°/0.01mm, 137-138°/0.5mm, 161-162°/4mm, 188-189°/12mm, 195-200°/25mm, d_4^{20} 1.241, n_D^{25} 1.600.** Purify the ether by fractional disillation. Its UV (EtOH) has λ_{max} at: 255, 315mm (ε 6200 and 2800), and the IR (CS_2) has bands at 1350 (NO_2) and 1245, 1265 (COC) cm^{-1} [UV, IR: Dahlgard & Brewster *J Am Chem Soc* **80** 5861 *1958*, Tomita & Takase *Yakugaku Zasshi (J Pharm Soc Japan)* **75** 1077 *1955*, Fox & Turner *J Chem Soc* 1115 *1930*, Henley *J Chem Soc* 1222 *1930*]. [*Beilstein* **6** H 218, **6** II 210, **6** III 801.]

Nitrodurene (1,2,4.5-tetramethyl-3-nitrobenzene) *[3463-36-3]* **M 179.2, m 113-114°, b 143-144°/10mm.** Distil nitrodurene in a vacuum and/or crystallise it from EtOH (yellow prisms, **m** 113-113.5°), MeOH, acetic acid, petroleum ether or chloroform. It has been crystallised by dissolving in hexane and kept at -20° for crystals to form (**m** 111-112°). Its UV has λ_{max} at 238 and 400nm (iso-octane). [Masnovi et al. *J Am Chem Soc* **111** 2263 *1989*, cf Powell & Johnson *Og Synth* Coll Vol **II** 449 *1943*, *Beilstein* **5** H 432, **5** III 982, **5** IV 1080.]

3-Nitrofluoranthene *[892-21-7]* **M 247.3, m 159-160°.** Recrystallise it from AcOH or EtOAc (yellow crystals) and/or sublime it at high vacuum. It is soluble in CH_2Cl_2, Me_2CO or $*C_6H_6$, soluble in warm EtOH and very soluble in Et_2O. [Kloetzel et al. *J Am Chem Soc* **78** 1165 *1956*, *Beilstein* **5** III 2279.]

2-Nitrofluorene *[607-57-8]* **M 211.2, m 156°.** Crystallise 2-nitrofluorene from aqueous acetic acid or Me_2CO (**m** 158-158.5°, also 160-160.5°). [*Beilstein* **5** H 628, **5** III 1948.]

Nitromesitylene (2-nitro-1,3,5-trimethylbenzene) *[603-71-4]* **M 165.2, m 44°, b 255°/760mm.** Crystallise it from EtOH, or a small volume of MeOH and cool in an ice-salt bath (**m** 43.5°). [Powell & Johnson *Org Synth* Coll Vol **II** 449 *1943*, *Beilstein* **5** H 410, **5** III 923, **5** IV 1028.]

Nitromethylphenylsulfone *[21272-85-5]* **M 201.2, m 78-79°.** Recrystallise the sulfone from $CHCl_3$, or 95% EtOH, then sublime it at 100-120°/0.1 Torr and recrystallise again. It is an acidic analogue of nitromethane used for the general synthesis of aliphatic acids and nitriles and in cycloaddition reactions with olefins to form heterocycles. [Wade et al. *J Org Chem* **46** 765 *1981*, **49** 4595 *1984*, *Beilstein* **6** II 292.]

1-Nitronaphthalene *[86-57-7]* **M 173.2, m 57.3-58.3°, b 30-40°/0.01mm.** Fractionally distil 1-nitronaphthalene under reduced pressure, then crystallise it from EtOH, aqueous EtOH or heptane. Chromatograph it on alumina with *benzene/petroleum ether as eluent. It sublimes *in vacuo*. The *1:1 picrate complex* has **m** 72° (from EtOH). [*Beilstein* **5** H 553, **5** III 1593, **5** IV 1673.]

2-Nitronaphthalene *[581-89-5]* **M 173.2, m 79°, b 165°/15mm.** Distil it in a vacuum and/or crystallise it from aqueous EtOH and sublime in a vacuum. The 1:1 *1,3,5-trinitrobenzene complex* has **m** 75.5° (from EtOH). [*Beilstein* **5** H 555, **5** III 1596, **5** IV 1675.]

1-Nitro-2-naphthol *[550-60-7]* **M 189.2, m 103°, b 115°/0.05mm, pK^{25} 5.93.** Distil it under high vacuum and/or crystallise the naphthol (repeatedly) from *benzene/petroleum ether (b 60-80°)(1:1). [*Beilstein* **6** H 653, **6** III 3002, **6** IV 4370.]

2-Nitro-1-naphthol *[607-24-9]* **M 189.2, m 127-128°, pK^{25} 5.89.** Crystallise the naphthol (repeatedly) from EtOH. [*Beilstein* **6** H 615, **6** III 2938, **6** IV 4236.]

2-Nitrophenol *[88-75-5]* **M 139.1, m 44.5-45.5°, b 214-215°/760mm, pK^{25} 7.23.** Crystallise 2-nitrophenol from EtOH/water, water, EtOH, *benzene or MeOH/petroleum ether (b 70-90°). It can be steam distilled. Petrucci and Weygandt [*Anal Chem* **33** 275 *1961*] crystallised it from hot water (twice), then EtOH (twice), followed by fractional crystallisation from the melt (twice), drying over $CaCl_2$ in a vacuum desiccator and then in a drying pistol. The *4-nitrobenzoate* had **m** 141° (from EtOH). [*Beilstein* **6** IV 1246.]

3-Nitrophenol *[554-84-7]* **M 139.1, m 96°, b 160-165°/12mm, pK^{25} 8.36.** Crystallise 3-nitrophenol from water, $CHCl_3$, CS_2, EtOH or petroleum ether (b 80-100°), and dry it under vacuum over P_2O_5 at room temperature. It can also be distilled at low pressure. The *4-nitrobenzoate* had **m** 174° (from EtOH). [*Beilstein* **6** IV 1269.]

4-Nitrophenol *[100-02-7]* **M 139.1, m 113-114°, pK^{25} 7.16.** Crystallise 4-nitrophenol from water (which may be acidified, e.g. with *N* H_2SO_4 or 0.5*N* HCl), EtOH, aqueous MeOH, $CHCl_3$, *benzene or petroleum ether, then dry it *in vacuo* over P_2O_5 at 25°. It can be sublimed at 60°/10^{-4}mm. The *4-nitrobenzoate* had **m** 159° (from EtOH). [*Beilstein* **6** IV 1279.]

2-Nitrophenoxyacetic acid *[1878-87-1]* **M 197.2, m 150-159°, 158.2-158.5°, pK^{25} 2.90.** Crystallise the acid from water, and dry it over P_2O_5 *in vacuo*. The *S-benzylisothiuronium salt* has **m** 155-156° (from EtOH). [Hayes & Brooch *J Am Chem Soc* **65** 1577 *1943*, *Beilstein* **6** H 220, **6** II 211, **6** III 804, **6** IV 1261.]

***p*-Nitrophenyl acetate** *[830-03-5]* **M 181.2, m 78-79°.** Recrystallise the ester from absolute EtOH [Moss et al. *J Am Chem Soc* **108** 5520 *1986*]. [*Beilstein* **6** IV 1298.]

2-Nitrophenylacetic acid *[3740-52-1]* **M 181.2, m 141-142.5°, pK^{25} 3.95.** The acid crystallises as yellow needles from EtOH, EtOH/water and dry it over P_2O_5 under vacuum. The *amide* has **m** 160-161° (from *C_6H_6 plates or EtOH, needles). [*Beilstein* **9** III 2282, **9** IV 1687.]

4-Nitrophenylacetic acid *[104-03-0]* **M 181.2, m 153.4-154.6°, pK^{25} 3.92.** Crystallise the acid from EtOH/water (1:1), then from sodium-dried diethyl ether and dry it over P_2O_5 *in vacuo*. The *styphnate* has **m** 196.5-197° (prisms from EtOH). The *amide* has **m** 191° (from EtOH). [*Beilstein* **9** III 2284, **9** IV 1698.]

4-Nitro-1,2-phenylenediamine *[99-56-9]* **M 153.1, m 201°, pK$_1^{25}$ 1.39 (1-NH_2), pK$_2^{25}$ 2.61 (2-NH_2).** Crystallise the diamine from water. [*Beilstein* **13** IV 75.]

1-(4-Nitrophenyl)ethylamine hydrochloride *[R-(+)- 57233-86-0, S-(–)- 132873-57-5]* **M 202.6, m 225°, 240-242°(dec), 243-245°(dec), 248-250°, [α] $_D^{20}$ (+) and (-) 72° (c 1, 0.05 M NaOH), (+) and (-) 0.3° (H_2O), pK$_{Est}$ ~8.6.** To ensure dryness, the hydrochloride (*ca* 175 g) is extracted with EtOH (3×100ml) and evaporated to dryness (any residual H_2O increases the solubility in EtOH and lowers the yield). The hydrochloride residue is triturated with absolute EtOH and dried *in vacuo*. The product is further purified by refluxing with absolute EtOH (200 ml for 83g) for 1 hour, and cool to 10° to give 76.6g of hydrochloride **m** 243-245°(dec). The *free base* is prepared by dissolving in N NaOH, extracting with CH_2Cl_2 (3 x 500ml), drying (Na_2CO_3), filtering, evaporating and distilling it. It has **m** 27°, **b** 119-120°/0.5mm (105-107°/0.5mm, 157-159°/9mm, d $_4^{20}$ 1.1764, n $_D^{20}$ 1.5688, [α] $_D^{24}$ ±17.7° (neat) [Perry et al. *Synthesis* 492 *1977*, ORD: Nerdel & Liebig *Justus Liebigs Ann Chem* **621** 142 *1959*]. [*Beilstein* **12** IV 2451.]

4-Nitrophenylhydrazine *[100-16-3]* **M 153.1, m 158°(dec), pK$_1^{25}$ -9.2 (aqueous H_2SO_4), pK$_2^{25}$ 3.70.** Crystallise the hydrazine from EtOH. The *hydrochloride* has **m** 212°(dec) (from EtOH, also **m** 202-203° dec).

[*Beilstein* **15** III 331, **15** IV 317.]

3-Nitrophenyl isocyanate *[3320-87-4]* **M 164.1, m 52-54°, b 130-131°/11mm.** Distil the isocyanate in a vacuum, and/or recrystallise it from petroleum ether (b 28-38°) or toluene/petroleum ether (**m** 52°). [*Beilstein* **12** H 708, **12** III 1573.]

4-Nitrophenyl isocyanate *[100-28-7]* **M 164.1, m 53°, b 137-138°/11mm, 162-164°/20mm.** Distil the isocyanate in a vacuum, and/or recrystallise it from petroleum ether (b 28-38°), *C_6H_6/petroleum ether (**m** 58°) or CCl_4 (**m** 56-57°). [*Beilstein* **12** H 725, **12** III 1630.]

2-Nitrophenylpropiolic acid *[530-85-8]* **M 191.1, m 157°(dec), 160.5-161°, 166-167°(dec), pK^{25} 2.83 (50% aqueous dioxane), 3.39 (50% aqueous EtOH).** Digest the acid with boiling $CHCl_3$, then crystallise it from H_2O. The *amide* has **m** 159° (plates, from H_2O). [Schofield & Simpson *J Chem Soc* 516 *1945*, *Beilstein* **9** H 636, **9** I 267, **9** II 438, **9** III 3067, **9** IV 2330.]

4-Nitrophenyl trifluoroacetate *[658-78-6]* **M 235.1, m 37-39°, b 120°/12mm.** Recrystallise the ester from $CHCl_3$/hexane [Margolis et al. *J Biol Chem* **253** 7891 *1978*]. It sublimes *in vacuo* (**m** 36-38°). It is *moisture sensitive*. [Sakakibara & Inukai *Bull Chem Soc Jpn* **37** 1231 *1964*.]

4-Nitrophenyl urea *[556-10-5]* **M 181.2, m 232°(dec), 238°, 242°.** Crystallise the urea from EtOH or hot water. Its UV has λ_{max} at 322nm (EtOH). [*Beilstein* **12** II 392, **12** III 1617, **12** IV 1645.]

3-Nitrophthalic acid *[603-11-2]* **M 211.1, m 216-218°, pK^{25} 3.93.** Crystallise 3-nitrophthalic acid from hot water (1.5ml/g). Dry it in air. The *amide* has **m** 201° (from EtOH). [*Beilstein* **9** H 823, **9** IV 3275.]

4-Nitrophthalic acid *[610-27-5]* **M 211.1, m 165°, pK^{25} 4.12.** Crystallise 4-nitrophthalic acid from Et_2O, EtOAc or *C_6H_6 (**m** 166°). The *amide* has **m** 200° (from EtOH). [*Beilstein* **9** H 828, **9** IV 4234.]

3-Nitrophthalic anhydride *[641-70-3]* **M 193.1, m 164°.** Crystallise it from *C_6H_6, *C_6H_6/petroleum ether, Me_2CO, AcOH, or Ac_2O (**m** 164-165°). Dry it at 100°. [*Beilstein* **17** III/IV 6149, **17/11** V 266.]

4-Nitrophthalic anhydride *[5466-84-2]* **M 193.1, m 120-121.5°, b 196-197°/8mm.** Distil the anhydride in a vacuum and/or recrystallise it from *C_6H_6 or Et_2O/petroleum ether. Dry it *in vacuo*. It forms addition compounds with anthracene (**m** 118°), and phenanthrene (**m** 96°). [*Beilstein* **17** III/IV 6150, **17/11** V 267.]

5-Nitro-2-*n*-propoxyaniline *[553-79-7]* **M 196.2, m 47.5-48.5°, 49°. pK$_{Est}$ ~2.32.** Crystallise the aniline from *n*-propyl alcohol/petroleum ether or H_2O (136mg/L at 20°). [*Beilstein* **13** III 878, **13** IV 897.]

2-Nitroresorcinol *[601-89-8]* **M 155.1, m 81-81°, pK$_1^{20}$ 6.37, pK$_2^{20}$ 9.46.** Recrystallise 2-nitroresorcinol from aqueous EtOH. [*Beilstein* **6** H 823.]

4-Nitrosalicylic acid *[619-19-1]* **M 183.1, m 235-238°(dec), pK^{25} 2.23.** Crystallise the acid from H_2O (**m** 236-238°) or aqueous EtOH (**m** 235-236° dec). [*Beilstein* **10** III 194, **10** IV 231.]

5-Nitrosalicylic acid *[96-97-9]* **M 183.1, m 233°, pK$_1^{25}$ 2.32, pK$_2^{25}$ 10.34.** Crystallise the acid from Me_2CO (charcoal), then twice more from Me_2CO alone, aqueous EtOH (**m** 234-236°) or H_2O (**m** 232-233°). [*Beilstein* **10** III 197, **10** IV 255.]

Nitrosobenzene *[586-96-9]* **M 107.1, m 67.5-68°, b 57-59°/18mm.** Steam distil nitrosobenzene, then crystallise it from a small volume of EtOH with cooling below 0°, dry it over $CaCl_2$ in a dessicator at atmospheric pressure, and store it under N_2 at 0°. *Alternatively*, it can be distilled onto a cold finger cooled with brine at ~–10° in a vacuum at 17mm (water pump), while heating in a water bath at 65-70° [Robertson & Vaughan *J Chem Educ* **27** 605 *1950*]. [*Beilstein* **5** IV 702.]

4-Nitrosodiphenylamine (tautomer of benzoquinone-1,4-phenylimine oxime) *[156-10-5]* **M 198.2, m 144-145°(dec), 145.4-146.6°, 144-148°.** The amine forms dark green crystals from EtOH or *C_6H_6 (**m** 143°). It has UV with λ_{max} at 421nm (EtOH), and it is used for detecting Pd and Rh. *It is highly toxic and a possible carcinogen*. [*Beilstein* **12** H 207, **12** II 122, **12** III 347, **12** IV 1860ß.]

1-Nitroso-2-naphthol *[131-91-9]* **M 173.2, m 110.4-110.8°, pK^{25} 7.63.** Crystallise the naphthol from petroleum ether (b 60-80°, 7.5ml/g). [*Beilstein* **7** H 712, **7** IV 2419.]

2-Nitroso-1-naphthol *[132-53-6]* **M 173.2, m 162-164°, pK^{25} 7.24.** Purify the naphthol by recrystallisation from petroleum ether (b 60-80°) or by dissolving it in hot EtOH, followed by successive addition of small volumes of water (**m** 158° dec). It also crystallises from *C_6H_6 or H_2O. Crystallisation from *C_6H_6/petroleum ether gives **m** (106-109 °, also 109.5°). It has λ_{max} at 274.5 and 382nm ($CHCl_3$). It complexes with metals. [*Beilstein* **7** H 712, **7** I 385, **7** II 647, **7** III 3688, **7** IV 2419.]

4-Nitroso-1-naphthol *[605-60-7]* **M 173.2, m 198°(dec), pK^{25} 8.18.** Crystallise the naphthol from *C_6H_6 or H_2O (**m** 197°, dec). and sublime it at 75-80°/0.2mm. It has λ_{max} at 336nm (EtOH). [*Beilstein* **7** H 715, **7** II 653, **7** III 3700, **7** IV 2424.]

2-Nitroso-1-naphthol-4-sulfonic acid ($3H_2O$) *[3682-32-4]* **M 316.3, m 142-146°(dec), pK_{Est} ~6.3 (OH).** Crystallise the acid from dilute HCl solution. The crystals are dried over $CaCl_2$ in a vacuum desiccator. It has also been purified by dissolution in aqueous alkali and precipitation by addition of water. It is a reagent for cobalt. [*Beilstein* **11** H 331, **11** II 189, **11** III 621, **11** IV 668.]

4-Nitrosophenol (benzoquinone mono oxime) *[104-91-6]* **M 123.1, m >124°(dec), pK^{25} 6.36.** 4-Nitrosophenol forms yellow crystals from xylene, *C_6H_6 (**m** ~144°) or Et_2O (**m** 128-129°, dec). [*Beilstein* **7** H 622, **7** II 574, **7** III 3367.]

***N*-Nitroso-*N*-phenylbenzylamine** *[612-98-6]* **M 212.2, m 58°.** Crystallise the amine from absolute EtOH (yellow needles) and dry it in air. It is slightly soluble in organic solvents. [*Beilstein* **12** H 1071, **12** II 335, **12** III 2335.]

***trans*-β-Nitrostyrene** *[5153-67-3]* **M 149.2, m 60°.** Crystallise the styrene from absolute EtOH, or three times from *benzene/petroleum ether (b 60-80°) (1:1). [*Beilstein* **5** III 1180, **5** IV 1352.]

4-Nitrostyrene *[100-13-0]* **M 149.2, m 20.5-21°.** Crystallise it from $CHCl_3$/hexane. Purify it by addition of MeOH to precipitate the polymer, then crystallise it at -40° from MeOH. It has also been crystallised from EtOH. [Bernasconi et al. *J Am Chem Soc* **108** 4541 *1986*, *Beilstein* **5** H 478, **5** III 1180, **5** IV 1351.]

2-Nitro-4-sulfobenzoic acid *[552-23-8]* **M 247.1, m 111°, pK_{Est} ~1.65.** Crystallise the acid from dilute HCl. It is *hygroscopic*. [*Beilstein* **11** H 391, **11** III 685.]

2-Nitrotoluene *[88-72-2]* **M 137.1, m -9.55° (α-form), -3.85° (β-form), b 118°/16mm, 222.3°/760mm, d_4^{20} 1.163, n_D^{20} 1.545.** Crystallise 2-nitrotoluene (repeatedly) from absolute EtOH by cooling in a Dry-ice/alcohol mixture. Further purify it by passing an alcoholic solution through a column of alumina. [*Beilstein* **5** IV 845.]

3-Nitrotoluene *[99-08-1]* **M 137.1, m 16°, b 113-114°/15mm, 232.6°, d_4^{20} 1.156, n_D^{20} 1.544.** Dry 3-nitrotoluene over P_2O_5 for 24 hours, then fractionally distil it under reduced pressure. [Clark & Taylor *Org. Synth* Coll Vol **I** 415 *1941*, *Beilstein* **5** IV 847.]

4-Nitrotoluene *[99-99-0]* **M 137.1, m 52°.** Crystallise 4-nitrotoluene from EtOH, MeOH/water, EtOH/water (1:1) or MeOH. Dry it in air, then dry it in a vacuum desiccator over H_2SO_4. [Wright & Grilliom *J Am Chem Soc* **108** 2340 *1986*, *Beilstein* **5** IV 848.]

5-Nitrovanillin (nitroveratric aldehyde) *[6635-20-7]* **M 197.2, m 172-175°, 176°, 178°.** It forms yellow

plates from AcOH and needles from EtOH [Slotta & Szyszke *Chem Ber* **68** 184 *1935*]. With diazomethane, 5-nitro-3,4-dimethoxyacetophenone is formed [Brady & Manjunath *J Chem Soc* **125** 1067 *1924*]. The *methyl ether* crystallises from EtOAc or AcOH, **m** 88°, 90-91°, and the *phenylhydrazone* has **m** 108-110° (from aqueous EtOH). [Finger & Schott *J Prakt Chem* [2] **115** 288 *1927*.] The *oxime* has **m** 216° (from EtOH or AcOH), and the *oxime acetate* has **m** 147° (from aqueous EtOH) [Vogel *Monatsh Chem* **20** 384 *1899*, Brady & Dunn *J Chem Soc* **107** 1861 *1915*]. [*Beilstein* **8** III 2064.]

Nordihydroguaiaretic [1,4-bis(3,4-dihydroxyphenyl)-2,3-dimethylbutane] acid *[500-38-9]* **M 302.4, m 184-185°, $pK_{Est(1)}$ ~9.7, $pK_{Est(2)}$ ~12.** Crystallise the acid from dilute acetic acid. [*Beilstein* **6** IV 7771.]

1,2,3,4,6,7,8,9-Octahydroanthracene *[1079-71-6]* **M 186.3, m 73°, 73.5°, 78°, d_4^{80} 0.9703, n_D^{80} 1.5372.** Crystallise the octahydro compound from EtOH, then purify it by zone melting. [*Beilstein* **5** III 1400.]

***n*-Octylammonium 9-anthranilate** *[88020-99-9]* **M 351.5, m 134-135°, pK^{25} 10.65 (for octylamine).** Recrystallise the ester several times from ethyl acetate.

4-Octylbenzoic acid *[3575-31-3]* **M 234.3, m 99-100°, pK^{25} 6.5 (80% aqueous EtOH), pK_{Est} ~4.5 (H_2O).** When crystallised from EtOH it has **m** 139°, but when crystallised from aqueous EtOH it has **m** 99-100°. It forms liquid crystals. [*Beilstein* **9** H 571, **9** III 2611.]

4-(*tert*-Octyl)phenol *[140-66-9]* **M 206.3, m 85-86°, b 166°/20mm, pK_{Est} ~10.4.** Crystallise the phenol from *n*-hexane and/or distil it in a vacuum. [*Beilstein* **6** III 2051, **6** IV 3484.]

Opianic acid (2-formyl-4,5-dimethylbenzoic acid) *[519-05-1]* **M 210.2, m 150°, pK^{25} 3.07.** Crystallise the acid from water. [*Beilstein* **10** H 990, **10** I 484, **10** II 719, **10** III 4511, **10** IV 3863.]

Orcine monohydrate (orcinol hydrate, 3,5-dihydroxytoluene) *[6153-39-5]* **M 142.2, m 56°, 56-58°, 58°, b 147°/5 mm, pK_1^{20} 9.48 (9.26), pK_2^{20} 11.20 (11.66).** Purify orcine by recrystallisation from H_2O as the *monohydrate*. It sublimes *in vacuo*, and the *anhydrous* compound has **m** 106.5-108° (110°, 108°). It can be recrystallised from $CHCl_3$ (plates) or *C_6H_6 (needles or prisms). [UV: Kiss et al. *Bull Soc Chim Fr* 275 *1949*, Adams et al. *J Am Chem Soc* **62** 732 *1940*.]

Orcinol (5-methylresorcinol) *[504-15-4; 6153-39-5 H_2O]* **M 124.2, m 107.5°, m 59-61° (hydrate cf orcine), pK_1^{20} 9.36 (9.48), pK_2^{20} 11.6 (11.20).** Crystallise orcinol from $CHCl_3$/*benzene (2:3). See *hydrate* in previous entry. [*Beilstein* **6** H 882, **6** IV 5892.]

Orthanilic acid (2-aminobenzenesulfonic acid) *[88-21-1]* **M 173.2, m >300°(dec), pK^{25} 2.49.** Crystallise orthanilic acid from aqueous solution, containing 20ml of conc HCl per L, then crystallise it from distilled water, and dry it in a vacuum desiccator over Sicapent (**m** 315°). When an aqueous solution is chilled below 13.5°, the hydrated form of the acid is obtained. It is used for the determination of nitrite and nitrate. The *S-benzylisothiuronium salt* has **m** 137° (from H_2O). [Wertheim *Org Synth* Coll Vol **II** 471 *1943*, *Beilstein* **14** H 681, **14** I 714, **14** II 429, **14** III 1896, **14** IV 2638.]

[2.2]-Paracyclophane (tricyclo[8.2.2.2^{4,7}]hexadeca-4,6,10,12,13,15-hexaene) *[1633-22-3]* **M 208.3, m 284°, 285-287°, 286-288°, 288-290°.** Purify it by recrystallisation from AcOH. ^{1}H-NMR δ: 1.62 (Ar-H) and 1.71 (CH_2) [Waugh & Fessenden *J Am Chem Soc* **79** 846 *1957*, IR and UV: Cram et al. *J Am Chem Soc* **76** 6132 *1954*, Cram & Steinberg *J Am Chem Soc* **73** 5691 *1951*. Para Red (1-(4-nitrophenylazo]-2-naphthol) *[6410-10-2]* **M 293.3, m 250-251°, pK_{Est} ~9.3.** Crystallise this

dye from AcOH or xylene and dry it *in vacuo*. It has λ_{max} at 488nm. [*Beilstein* **16** II 70.]

Pargyline hydrochloride (Eutonyl, *N*-methyl-*n*-propargylbenzylamine hydrochloride) *[306-07-0]* **M 195.7, m 154-155°, 155°, pK^{25} 6.9.** Recrystallise the salt from EtOH/Et_2O and dry it *in vacuo*. It is very soluble in H_2O, in which it is unstable. The *free base* has **b** 101-103°/11mm. It is a glucuronyl transferase inducer and a monoamine oxidase inhibitor. [von Braun et al. *Justus Liebigs Ann Chem* **445** 205 *1928*, Yeh & Mitchell *Experientia* **28** 298 *1972*, Langstrom et al. *Science* **225** 1480 *1984*, *Beilstein* **12** II 548.]

Pavatrine hydrochloride [fluorine-9-carboxylic acid, 2-(diethylamino)ethyl ester hydrochloride] *[548-65-2]* **M 333.7, m 143-144°, pK$_{Est}$ ~9.0** Recrystallise the salt from isopropanol, EtOAc/isoPrOH and dry it over P_2O_5 *in vacuo*. The *metho-bromide* has **m** 111-117° (from butanone). [*Beilstein* **9** III 3412, **9** IV 2596.]

Pentabromophenol *[608-71-9]* **M 488.7, m 229-230°, pK$_{Est}$ ~4.5.** Purify it by crystallisation (charcoal) from toluene then from CCl_4. Dry it for 2 weeks at *ca* 75°. The *diethylammonium salt* has **m** 191-193° (from MeOH). [*Beilstein* **6** H 206, **6** I 108, **6** II 197, **6** III 766, **6** IV 1069.]

1-Pentacene *[135-48-8]* **M 278.4, m 300°.** It forms blue crystals from *benzene or nitrobenzene and sublimes in a vacuum. [Clar & John *Ber* **62** 940 *1929*, **64** 981 *1931*, *Beilstein* **5** IV 2721.]

Pentachloronitrobenzene *[82-68-8]* **M 295.3, m 144-145°, 146°.** Crystallise it from EtOH. [*Beilstein* **5** H 247, **5** II 188, **5** III 618.]

Pentachlorophenol *[87-86-5]* **M 266.3, m 190-191°, pK^{25} 4.8.** Crystallise it twice from toluene/EtOH. Sublime it *in vacuo*. [*Beilstein* **6** IV 1025.]

Pentachlorothiophenol *[133-49-3]* **M 282.4, m between 228° and 235° , pK$_{Est}$ ~1.1.** Crystallise from *benzene, toluene (**m** 243°) or AcOH (**m** 240° also 242-244°). [*Beilstein* **6** IV 1642.]

Pentafluorobenzene *[363-72-4]* **M 168.1, b 85°/atm, 85-86°/atm, 88-89°/atm, d_4^{20} 1.524, n_D^{20} 1.3931.** Purify it by distillation and by gas chromatography. Its IR (film) has bands at 1535 and 1512 cm^{-1} (*C_6H_6 ring). [Stephen & Tatlow *Chem Ind (London)* 821 *1957*, Nield et al. *J Chem Soc* 166 *1959*, *Beilstein* **5** IV 639.]

2,3,4,5,6-Pentafluorobenzoic acid *[602-94-8]* **M 212.1, m 101-103°, 104-105°, 106-107°, pK^{25} 1.75.** Dissolve the acid in Et_2O, treat it with charcoal, filter, dry ($CaSO_4$), filter again, evaporate and recrystallise the residue from petroleum ether (b 90-100°) after adding a little toluene, to give large colourless plates. Its UV (H_2O) has λ_{max} at 265nm (ε 761) (H_2O). The *S-benzylisothiuronium salt* has **m** 187° (from H_2O). [McBee & Rapkin *J Am Chem Soc* **73** 1366 *1951*, Nield et al. *J Chem Soc* 166 *1959*, *Beilstein* **9** IV 956.]

***O*-(2,3,4,5,6-Pentafluorobenzyl)hydroxylamine hydrochloride (PFBHA.HCl)** *[57981-02-9]* **M 249.6, m 215°, 215-216°, pK$_{Est}$ ~1.1.** Recrystallise the salt from EtOH to form colourless leaflets. Drying the compound at high vacuum and elevated temperature will result in losses by sublimation. [Youngdale *J Pharm Sci* **65** 625 *1976*, Wehner & Handke *J Chromatog* **177** 237 *1979*, Nambara et al. give incorrect **m** as 115-116° *J Chromatogr* **114** 81 *1975*.]

2,3,4,5,6-Pentafluorophenol *[771-61-9]* **M 184.1, m 33-35°, 38.5-39.5°, b 72-74°/48mm, 142-144°/atm, 143°/atm, n_D^{20} 1.4270 (liquid prep), pK^{25} 5.53.** It is a *hygroscopic* low melting solid not freely soluble in H_2O. Purify it by distillation, preferably in a vacuum [Forbes et al. *J Chem Soc* 2019 *1959*, IR and pKa: Birchall & Haszeldine *J Chem Soc* 13 *1959*]. IR of a film has ν_{max} 3600 (OH) and 1575 (fluoroaromatic breathing) cm^{-1}. The *benzoyl* derivative has **m** 74-75°, *3,4-dinitrobenzoyl* derivative has **m** 107°, the *tosylate* has **m** 64-65° (from EtOH) and the *K salt* crystallises from Me_2CO, **m** 242°(dec), with *1H_2O-salt* the **m** is 248°(dec) and the *2H_2O-salt* has **m** 245°(dec). [*Beilstein* **6** IV 782.]

1-(Pentafluorophenyl)ethanol *[R-(+)- 104371-21-3, S-(–)- 104371-20-2]* **M 212.1, m 41-42°, 42°, 42.5-43°, $[\alpha]_{546}^{20}$ (+) and (-) 9°, $[\alpha]_D^{20}$ (+) and (-) 7.5° (c 1, *n*-pentane).** Recrystallise the ethanol from *n*-pentane at -40°

and sublime it at 25°/0.3mm (use ice-cooled cold finger). It has also been purified by column chromatography through Kieselgel 60 (0.063-0.2mm mesh, Merck) and eluted with EtOAc/*n*-hexane (1:5), then recrystallised from *n*-pentane and sublimed in a vacuum. It has R_F on Kieselgel 60 F_{254} TLC foil and eluting with EtOAc/*n*-hexane (1:5). [Meese *Justus Liebigs Ann Chem* 2004 *1986*.]
The *racemate [75853-08-6]* has **m** 32-34°, **b** 77-79°/8mm, 80-82°/37mm, n_D^{20} 1.4426, and the *3,4-dinitrobenzoate* has **m** 83° [Nield et al. *J Chem Soc* 166 *1959*]. [*Beilstein* **6** IV 3044.]

Pentamethylbenzene *[700-12-9]* **M 148.3, m 53.5-55.1°.** Successively crystallise it from absolute EtOH, aqueous EtOH, MeOH, toluene *C_6H_6, and dry it under vacuum. [Rader & Smith *J Am Chem Soc* **84** 1443 *1962*.] It has also been sublimed. The *1,3,5-trinitrobenzene complex (1:1)* has **m** 121° (EtOH). Its FT-IR (neat) has ν_{max} at 2939.4, 2728.0, 1568.1, 1475.5, 1381.8, 1067.6, 1013.9, 860.7 and 524.6 cm^{-1}; [*Beilstein* **5** H 443, **5** III 1010, **5** IV 1109.]

Perbenzoic acid *[93-59-4]* **M 138.1, m 41-43°, b 97-110°/13-15mm, pK_{Est} ~7.7.** Crystallise the peracid from *benzene or petroleum ether. It sublimes readily and is steam volatile. It is soluble in $CHCl_3$, CCl_4 and Et_2O. [Braun *Org Synth* Coll Vol **I** 431 *1941*.] **EXPLOSIVE.**

Perylene *[198-55-0]* **M 252.3, m 273-274°.** Purify perylene by silica-gel chromatography of its recrystallised picrate. [Ware *J Am Chem Soc* **83** 4374 *1961*.] Crystallise it from *benzene, toluene or EtOH and sublime it at 142° in a flow of oxygen-free nitrogen. It forms a 1:1 **benzene-complex* (**m** 223-224.5° needles from *C_6H_6), and a 1:2 **benzene-complex* (**m** 154-155° from *C_6H_6 or H_2O). The *2,4,7-trinitrofluoren-9-one* has **m** 270-271° (from EtOH/*C_6H_6). [Gorman et al. *J Am Chem Soc* **107** 4404 *1985,* Johansson et al. *J Am Chem Soc* **109** 7374 *1987*, *Beilstein* **5** III 2521, **5** IV 2689.]

Phenanthrene *[85-01-8]* **M 178.2, m 98°, 98.7-99°, 99.15°, 100.8-101.3°, b 148-149°/1mm, d^{25} 1.175.** Likely contaminants include anthracene, carbazole, fluorene and other polycyclic hydrocarbons. Purify it by distillation from sodium under vacuum, boiling with maleic anhydride in xylene, crystallisation from acetic acid, sublimation and zone melting. It has also been recrystallised repeatedly from EtOH, *benzene or petroleum ether (b 60-70°), with subsequent drying under vacuum over P_2O_5 in an Abderhalden pistol. Feldman, Pantages and Orchin [*J Am Chem Soc* **73** 4341 *1951*] separated most of the anthracene impurity by refluxing phenanthrene (671g) with maleic anhydride (194g) in xylene (1.25L) under nitrogen for 22 hours, then filtered. The filtrate was extracted with aqueous 10% NaOH, the organic phase was separated, and the solvent was evaporated. The residue, after stirring for 2 hours with 7g of sodium, was distilled in a vacuum, then recrystallised twice from 30% *benzene in EtOH. It was then dissolved in hot acetic acid (2.2ml/g), and to it was slowly added an aqueous solution of CrO_3 (60g in 72ml H_2O plus 2.2L of acetic acid), followed by slow addition of conc H_2SO_4 (30ml). The mixture was refluxed for 15 minutes, diluted with an equal volume of water and cooled. The precipitate was filtered off, washed with water, dried and distilled, then recrystallised twice from EtOH. Further purification is possible by chromatography from a $CHCl_3$ solution on activated alumina, with *benzene as eluent, and by zone refining. The *picrate (1:1)* forms golden yellow needles with **m** 146°, and the *styphnate (1:1)* has **m** 138-139° (plates or needles from EtOH or EtOH/H_2O respectively). [Dornfeld et al. *Org Synth* Coll Vol **III** 134 *1955*, *Beilstein* **5** H 667, **5** I 327, **5** II 579, **5** III 2136, **5** IV 2297.]

Phenanthrene-9-aldehyde *[4707-71-5]* **M 206.3, m 102-103°, pK^{25} -6.39 (aqueous H_2SO_4).** Crystallise the aldehyde from EtOH and sublime it at 95-98°/0.07mm. The *2,4-dinitrophenylhydrazone* has **m** 272-273°. [*Beilstein* **7** III 2532, **7** IV 1740.]

9,10-Phenanthrenequinone *[84-11-7]* **M 208.2, m 208°, pK^{25} -7.1 (aqueous H_2SO_4).** Crystallise the quinone from dioxane or 95% EtOH and dry it under vacuum. [*Beilstein* **7** IV 2565.]

Phenethylamine *[64-04-0]* **M 121.2, b 87°/13mm, d_4^{20} 0.962, n_D^{20} 1.535, pK^{25} 9.88.** Distil the amine from CaH_2, under reduced pressure, just before use. [*Beilstein* **12** H 1096, **12** IV 2453.]

Phenethyl bromide *[103-63-9]* **M 185.1, b 92°/11mm, d_4^{20} 1.368, n_D^{20} 1.557.** Wash the bromide with conc H_2SO_4, water, aqueous 10% Na_2CO_3 and water again, then dry it with $CaCl_2$ and fractionally distil it just before

use. [*Beilstein* **5** IV 907.]

(±)-*N*-1-Phenethyl urea (*N*-α-phenethyl urea) *[60295-51-4]* **M 164.2, m 137°.** Crystallise the urea from H_2O, EtOAc or *C_6H_6. [Buck *J Am Chem Soc* **56** 1607 *1934*, *Beilstein* **12** I 1096, **12** IV 1440.]

(+)-*S*-*N*-1-Phenethyl urea (*R*-*N*-α-phenethyl urea) *[16849-91-5]* **M 164.2, m 121-122°, $[\alpha]_D^{25}$ +48.8° (c 2, EtOH), $[\alpha]_D^{25}$ +46.2° (c 4.0, EtOH).** Crystallise the (+)-urea from H_2O or EtOH (**m** 122-123°). [Marckwald & Meth *Chem Ber* **38** 808 *1905*, Cairns *J Am Chem Soc* **63** 871 *1941*, *Beilstein* **12** I 1092, **12** III 2398.]

(-)-*S*-*N*-1-Phenethyl urea (*S*-*N*-α-phenethyl urea) *[25144-64-3]* **M 164.2, m 121-122°, $[\alpha]_D^{25}$ -43.6° (c 14, EtOH), $[\alpha]_D^{25}$ -52.1° (c 3.6, EtOH).** Crystallise the (–)-urea from H_2O or EtOH. [Lovén *J Prakt Chem* [2] **72** 313 *1905*, *Beilstein* **12** I 1094, **12** III 2398.]

***N*-2-Phenethyl urea** *[2158-04-5]* **M 164.2, m 112°.** Crystallise the (±)-urea from H_2O (**m** 112-113°) or EtOH. The *picrate* has **m** 113-115° (from H_2O) [Spica *Gazzetta* **9** 567 *1879*, Shapiro et al. *J Am Chem Soc* **81** 2224 *1959*]. [*Beilstein* **12** 1099, **12** III 2423, **12** IV 2470.]

Phenetole *[103-73-1]* **M 122.2, b 60°/9mm, 77.5°/31mm, 170.0°/760mm, d_4^{20} 0.967, n_D^{20} 1.50735, n^{25} 1.50485.** Small quantities of phenol can be removed by shaking with NaOH, but this is not a very likely contaminant of commercial material. Fractional distillation from sodium, at low pressures, probably gives adequate purification. It can be dissolved in diethyl ether and washed with 10% NaOH (to remove phenols), then water. The ethereal solution is evaporated, and the phenetole is fractionally distilled under vacuum. [*Beilstein* **6** H 140, **6** I 80, **6** II 142, **6** III 545.]

Phenocoll hydrochloride (4-ethoxyaniline, *p*-phenetidine HCl) *[536-10-6]* **M 230.7, m 234°, pK^{28} 5.20.** Crystallise the salt from water then sublime it *in vacuo*. [*Beilstein* **13** IV 1017.]

Phenol *[108-95-2]* **M 94.1, m 40.9°, b 85.5-86.0°/20mm, 180.8°/760mm, d_4^{20} 1.06, n_D^{41} 1.54178, n_D^{46} 1.53957, pK^{25} 9.86 (10.02).** Steam is passed through a boiling solution containing 1mole of phenol and 1.5-2.0moles of NaOH in 5L of H_2O until all non-acidic material has distilled. The residue is cooled, acidified with 20% (v/v) H_2SO_4, and the phenol is separated, dried with $CaSO_4$ and fractionally distilled under reduced pressure. It is then fractionally crystallised several times from its melt [Andon et al. *J Chem Soc* 5246 *1960*]. Purification *via* the benzoate has been used by Berliner, Berliner and Nelidow [*J Am Chem Soc* **76** 507 *1954*]. The *benzoate*, (**m** 70°, **b** 314°/760mm), is crystallised from 95% EtOH, then hydrolysed to the free phenol by refluxing with two equivalents of KOH in aqueous EtOH until the solution becomes homogeneous. It is acidified with HCl and extracted with diethyl ether. The ether layer is freed from benzoic acid by thorough extraction with aqueous $NaHCO_3$, and, after drying and removing the ether, the phenol is distilled.
Phenol has also been crystallised from a 75% w/w solution in water by cooling to 11° and seeding with a crystal of the hydrate. The crystals are centrifuged off, rinsed with cold water (0-2°), saturated with phenol, and dried. It can be crystallised from petroleum ether [Berasconi & Paschalis *J Am Chem Soc* **108** 2969 *1986*].
Draper and Pollard [*Science* **109** 448 *1949*] added 12% water, 0.1% aluminium (can also use zinc) and 0.05% $NaHCO_3$ to phenol, and distilled it at atmospheric pressure until the azeotrope was removed, The phenol was then distilled at 25mm. Phenol has also been dried by distillation from the *benzene solution to remove the water/*benzene azeotrope and the excess *benzene, followed by distillation of the phenol at reduced pressure under nitrogen. Processes such as this are probably adequate for analytical grade phenol which has as its main impurity water. Phenol has also been crystallised from petroleum ether/*benzene or petroleum ether (b 40-60°). The purified material is stored in a vacuum desiccator over P_2O_5 or $CaSO_4$. [*Beilstein* **6** IV 531.]

Phenol-2,4-disulfonic acid *[96-77-5]* **M 254.2, pK_1 <1, pK_2 <1, pK_3 ~8.3.** Crystallise the acid from EtOH/diethyl ether. [*Beilstein* **11** H 250, **11** I 58, **11** II 139, **6** III 522.]

Phenolphthalein *[77-09-8]* **M 319.2, m 263°, $pK_{Est(1)}$~ 4.2, $pK_{Est(2)}$~ 9.8.** Dissolve it in EtOH (7ml/g), then dilute it with eight volumes of cold water, filter and heat on a water-bath to remove most of the alcohol and the phenolphthalein that precipitates is filtered off and dried *in vacuo*. [*Beilstein* **18** II 119, **18** III/1V 1945, **18/4** V

188.]

Phenolphthalol *[81-92-5]* **M 306.3, m 201-202°, pK_{Est} ~ 9.8.** Crystallise it from aqueous EtOH. [*Beilstein* **6** H 1146, **6** II 1110, **6** IV 7623.]

Phenoxyacetic acid *[122-59-8]* **M 152.2, m 98-99°, pK^{25} 3.18.** Crystallise the acid from water or aqueous EtOH. [*Beilstein* **6** IV 634.]

Phenoxyacetyl chloride *[701-99-5]* **M 170.6, b 112°/10mm, 102°/16mm, 225-226°/atm, d_4^{20} 1.235, n_D^{20} 1.534.** If it has no OH band in the IR then distil it in a vacuum, taking precautions for the moisture-sensitive compound. If it contains free acid (due to hydrolysis, OH bands in the IR), then add an equal volume of redistilled $SOCl_2$, reflux for 2-3 hours, evaporate and distil the residue in a vacuum as before. The *amide* has **m** 101°. [McElvain & Carney *J Am Chem Soc* **68** 2592 *1946*, *Beilstein* **6** III 613.]

4-Phenoxyaniline *[139-59-3]* **M 185.2, m 95°, pK^{20} 4.44 (50% aqueous EtOH).** Crystallise 4-phenoxyaniline from water. [*Beilstein* **13** IV 1020.]

Phenoxybenzamine [*N*-(2-chloroethyl)-*N*-(1-methyl-2-phenoxyethyl)benzylamine] *[59-96-1]* **M 303.5, m 38-40°, hydrochloride** *[63-92-3]* **M 340.0, m 137.5-140°, pK_{Est} ~4.2.** The free base is crystallised from petroleum ether, and the *HCl* is crystallised from EtOH/diethyl ether. [*Beilstein* **12** IV 2204.]

2-Phenoxybenzoic acid *[2243-42-7]* **M 214.2, m 113°, b 355°/760mm, $pK^{15/25}$ 3.53.** Crystallise the acid from aqueous EtOH or H_2O (**m** 114°). [*Beilstein* **10** H 65, **10** I 28, **10** II 40, **10** III 99, **10** IV 132.]

3-Phenoxybenzoic acid *[3739-38-6]* **M 214.2, m 145°, pK^{25} 3.95.** Crystallise the acid from aqueous EtOH. [*Beilstein* **10** H 138, **10** III 247, **10** IV 316.]

Phenoxybutyric acid *[6303-58-8]* **M 180.2, m 64°, 65-66°, 82-83°, 99°, b 180-185°/12mm, pK 3.17.** It has been purified by recrystallisation from petroleum ether, $*C_6H_6$, Et_2O/petroleum ether, EtOH and from H_2O. It can be steam distilled or distilled in a good vacuum. [UV: Ramart-Lucas & Hoch *Bull Soc Chim Fr* [4] **51** 824 *1932*, Dann & Arndt *Justus Liebigs Ann Chem* **587** 38 *1954*.] The *acid chloride* has **b** 154-156°/20mm [Hamford & Adams *J Am Chem Soc* **57** 921 *1935*], and the *amide* crystallises from $*C_6H_6$ as needles with **m** 113°. [*Beilstein* **6** IV 645.]

2-Phenoxypropionic acid (lactic acid *O*-phenylether) *[940-31-8]* **M 166.2, m 115-116°, b 105-106°/5mm, 265-266°/758mm, pK^{25} 3.11.** Crystallise the acid from water. [*Beilstein* **6** H 163, **6** II 158, **6** III 614.]

Phensuximide (*N*-methyl-2-phenylsuccinimide) *[86-34-0]* **M 189.2, m 71-73°.** Crystallise phensuximide from hot 95% EtOH (**m** 72-73°). At 25° 1g of the imide dissolves in 1g of $*C_6H_6$, 18g of Et_2O, 9.5g of EtOH, 5.1g of MeOH and 235g of H_2O. [*Beilstein* **21** II 300, **21** III/IV 5465.]

Phenylacetamide *[103-81-1]* **M 135.2, m 158.5°.** Crystallise the acetamide repeatedly from absolute EtOH, EtOAc (**m** 160-161°) or H_2O (**m** 159-160°). Dry it *in vacuo* over P_2O_5. [*Beilstein* **9** H 347, **9** III 2193, **9** IV 1632.]

Phenyl acetate *[122-79-2]* **M 136.2, b 78°/10mm, d_4^{20} 1.079, n_D^{22} 1.5039.** Phenyl acetate acid is freed from phenol and acetic acid by washing (either directly or as a solution in pentane) with aqueous 5% Na_2CO_3, then with saturated aqueous $CaCl_2$, drying with $CaSO_4$ or Na_2SO_4, and fractionally distilling under reduced pressure. [*Beilstein* **6** II 153, **6** III 595, **6** IV 611.]

Phenylacetic acid *[103-82-2]* **M 136.2, m 76-77°, b 140-150°/20mm, pK_1 -7.59 (aqueous H_2SO_4), pK_2 4.31.** Crystallise the acid from petroleum ether (b 40-60°), isopropyl alcohol, 50% aqueous EtOH or hot water (**m** 77.8-78.2°). Dry it *in vacuo*. It can be distilled under a vacuum. [*Beilstein* **9** II 294, **9** III 2169.]

Phenylacetone (1-phenylpropan-2-one) *[103-79-9]* **M 134.2, b 69-71°/3mm, d_4^{20} 1.00, n_D^{20} 1.516.** Convert the ketone to the *semicarbazone* and crystallise it three times from EtOH (**m** 186-187°). The semicarbazone is then hydrolysed with 10% phosphoric acid, and the ketone is distilled. [Kumler et al. *J Am Chem Soc* **72** 1463 *1950*, *Beilstein* **7** H 303, **7** I 161, **7** II 223, **7** III 1037, **7** IV 687.]

4'-Phenylacetophenone *[92-91-1]* **M 196.3, m 120.3-121.2°, b 196-210°/18mm, 325-327°/760mm.** Crystallise it from EtOH or acetone. It can also be distilled under reduced or atmospheric pressure. The *semicarbazone* has **m** 131-132° (aqueous EtOH). [*Beilstein* **7** H 443, **7** III 2134, **7** IV 1407.]

Phenylacetylene *[536-74-3]* **M 102.1, b 75°/80mm, d_4^{20} 0.930, n_D^{25} 1.5463, pK ~19.** Distil phenylacetylene through a spinning band column. It should be filtered through a short column of alumina before use [Collman et al. *J Am Chem Soc* **108** 2988 *1986*; for pK see Brandsma *Preparative Acetylenic Chemistry,* 1st Edn Elsevier 1971, p. 15, ISBN 0444409475]. [*Beilstein* **5** IV 1525.]

Phenylalaninol (2-amino-3-phenylpropan-1-ol) *[R-(+)- 5267-64-1, S-(–)- 3182-95-4]* **M 151.2, m 91-92°, 91.5°, 92-94°, b 80°/11mm (Kügelrohr), $[\alpha]_{546}^{20}$ (+) and (-) 28°, $[\alpha]_D^{20-25}$ (+) and (-) 23-28.7° (c 1-5, EtOH), pK_{Est} ~9.3.** It can be recrystallised from Et_2O, *C_6H_6/petroleum ether (b 40-60°) or toluene and distilled in a vacuum. It has been purified by dissolving in Et_2O, drying over K_2CO_3, filtering, evaporating to a small volume, cooling in ice and collecting the plates. Store them in the presence of KOH (i.e. CO_2-free atm). [Karrer & Ehrhardt *Helv Chim Acta* **34** 3203 *1951*, Oeda *Bull Chem Soc Jpn* **13** 465 *1938*.] The *picrate* has **m** 141-141.5° (from EtOH/petroleum ether). The *hydrogen oxalate* has **m** 177°, 161-162° [Hunt & McHale *J Chem Soc* 2073 *1957*]. The *racemate* has **m** 87-88° from *C_6H_6/petroleum ether (75-77° from Et_2O), and the *hydrochloride* has **m** 139-141° [Fodor et al. *J Chem Soc* 1858 *1951*]. [*Beilstein* **13** IV 1920.]

3-Phenylallyl chloride (cinnamyl chloride) *[E: 18685-01-3, Z: 39199-93-4]* **M 152.6, *trans*: m 7-8°, b 92-93°/3mm, d_4^{25} 1.086, n_D^{25} 1.5802, *cis*: 85°/3mm, d_4^{25} 1.0891, n_D^{25} 1.5746.** Distil the chloride under vacuum three times from K_2CO_3. [Hatch & Alexander *J Am Chem Soc* **72** 643 *1950*, *Beilstein* **5** III 1186.]

Phenyl 4-aminosalicylate (Phenamisal) *[133-11-9]* **M 229.2, m 153°, $pK_{Est(1)}$~2.0 (NH_2), $pK_{Est(2)}$~9.7 (OH).** Crystallise the ester from EtOH (**m** 155°, also 149-150.5°), aqueous EtOH (**m** 147-149°), or isopropanol. It is **tuberculostatic**. [*Beilstein* **13** IV 1979.]

4-Phenylanisole (4-methoxybiphenyl) *[361-37-6]* **M 184.2, m 89.9-90.1°.** Crystallise the biphenyl from *benzene/petroleum ether. Dry it under vacuum in an Abderhalden pistol. It has λ_{max} at 259.5nm (hexane). [*Beilstein* **6** H 674, **6** II 625, **6** III 3321, **6** IV 4600.]

9-Phenylanthracene *[602-55-1]* **M 254.3, m 153-154°, 156°, b 417°/760mm.** Chromatograph it on alumina in *C_6H_6 and recrystallise it from AcOH or toluene. [*Beilstein* **5** H 725, **5** II 639, **5** III 2462.]

***p*-Phenylazobenzoyl chloride** *[104-24-5]* **M 244.7, m 93°.** Crystallise the acid chloride from petroleum ether (b 60-80°). [*Beilstein* **16** III 224.]

4-Phenylazo-1-naphthylamine *[131-22-6]* **M 247.3, m 125-125.5°.** Crystallise the dye from cyclohexane or aqueous EtOH. [Brode et al. *J Am Chem Soc* **74** 4641 *1952*, *Beilstein* **16** H 361, **16** III 406, **16** IV 546.]

4-Phenylazophenacyl bromide *[62625-24-5]* **M 317.3, m 103-104°.** Purify the bromide on a column silica gel, using petroleum ether/ Et_2O (9:1 v/v) as solvent. It forms orange yellow crystals from *C_6H_6 (**m** 113-114°) or petroleum ether/Et_2O (**m** 114.5-115°). [*Beilstein* **16** II 22, **16** III 53, **16** IV 79.]

4-Phenylazophenol (4-hydroxyazobenzene) *[1689-82-3]* **M 198.2, m 155°, pK_1^{25} -0.93, pK_2^{25} 8.2.** Crystallise the dye from *benzene or 95% EtOH. [*Beilstein* **16** II 38, **16** III 86, **16** IV 159.]

Phenyl benzenethiosulfonate (diphenyldisulfoxide) *[1212-08-4]* **M 250.3, m 36-37°, 45-46°, 45-47°.** Recrystallise the disulfoxide from EtOH or MeOH. It has also been purified from phenylsulfide impurities by

dissolving in $CHCl_3$, washing with aqueous saturated $NaHCO_3$, drying (Na_2SO_4), filtering, evaporating the filtrate, and the residual oil is passed through a silica gel column (600g) and eluted with hexane/*C_6H_6 (1L, 4:1, eluting PhSSPh) then *C_6H_6 (1L) which elutes $PhSSO_2Ph$. [Trost & Massiot *J Am Chem Soc* **99** 4405 *1977*, Knoevenagel & Römer *Chem Ber* **56** 215 *1923*, *Beilstein* **11** IV 220.]

Phenyl benzoate *[93-99-2]* **M 198.2, m 69.5°, b 198-199°.** Crystallise the ester from EtOH using *ca* twice the volume needed for complete dissolution at 69°. [*Beilstein* **9** IV 303.]

Phenyl-1,4-benzoquinone *[363-03-1]* **M 184.2, m 114-115°.** Crystallise the quinone from heptane, petroleum ether (b 60-70°), *C_6H_6 (**m** 113.5-114.5°) or EtOH (**m** 112-113°) and sublime it *in vacuo*. [Carlson & Miller *J Am Chem Soc* **107** 479 *1985*, *Beilstein* **7** H 740, **7** III 3764.]

1-Phenylbiguanide *[102-02-3]* **M 177.2, m 144-146°, pK_1^{32} 2.16, pK_2^{32} 10.74.** Crystallise the biguanide from water or toluene. [*Beilstein* **12** H 370, **12** I 236, **12** III 807.]

***N*-Phenyl-bis(trifluoromethanesulfonimide) [ditriflic phenylimide, *N,N*-bis(trifluoromethylsulfonyl) aniline]** *[37595-74-7]* **M 357.3, m 93-94°, 100-102°.** This ditriflic imide is a very stable triflating agent. If hydrolysis appears to have occurred; it would be better to prepare anew from purified aniline with 2 mols of redistilled trifluoroacetic anhydride in CH_2Cl_2 at -78°, with 2 mols of Et_3N in order to keep the aniline as the free base and to mop up the free acid formed. It is then evaporated *in vacuo* to give the crystalline reagent. [Murry & Scott *Tetrahedron Lett* **24** 979 *1983*, Crisp & Scott *Synthesis* 335 *1985*, Hendrickson & Bergeron *Tetrahedron Lett* 4607 *1973*, Mascarenas et al. *Tetrahedron* **47** 3485 *1991*.]

***S*-(-)-1-Phenylbutanol** *[22135-49-5]* **M 150.2, m 46-47°, 46-48°, 49°, b 90-92°/2mm. $[\alpha]_D^{18}$ -51.4° (c 5, $CHCl_3$), -44.7° (c 5.13, *C_6H_6).** Purify the alcohol by distillation, and the distllate crystallises on cooling. The *hydrochloride* has $[\alpha]_D^{20}$ +45.1° (c 4.8, *C_6H_6). The (–)-*hydroperoxide* has **b** 58°/0.005mm, n_D^{20} 1.5123, α_D^{18} -2.14°, (*l* = 0.5dcm, neat). [Holding & Ross *J Chem Soc* 145 *1954*, Davies & Feld *J Chem Soc* 4637 *1958*.] The (±)-*racemate* has **b** 73°/0.05mm, and its *4-nitrophenylhydrazone* has **m** 58°. [*Beilstein* **6** IV 3272.]

2-Phenylbutyramide *[90-26-6]* **M 163.2, m 86°, 87°.** Crystallise the amide from H_2O, EtOH, Et_2O/petroleum ether or *C_6H_6. [*Beilstein* **9** I 212, **9** II 356, **9** III 2466.]

2-Phenylbutyric acid *[R-(–)- 938-79-4, S-(+)- 4286-15-1]* **M 164.2, b 102-104°/760mm, d_4^{20} 1.056, n_D^{20} 1.521, $[\alpha]_D^{20}$ (+) and (-) 96° (c 2.5, *C_6H_6), $[\alpha]_D^{23}$ (-) and (+) 5.8° (neat), pK_{Est} ~4.3.** Purify the acids by distillation at atmospheric pressure using an efficient column. The *acid chlorides* have **b** 106-107°/20mm, $[\alpha]_D^{18}$ (–) and (+) 108° (c 2, *C_6H_6). [Levene et al. *J Biol Chem* **100** 589 *1933*, Gold & Aubert *Helv Chim Acta* **41** 1512 *1958*, ORD in heptane: Rothen & Levene *J Chem Phys* **7** 975 *1939*, *Beilstein* **9** III 2461.]

3-Phenylbutyric acid *[R-(–)- 772-14-5, S-(+)- 772-15-6]* **M 164.2, b 94-95°/3mm, 134°/4mm, d_4^{26} 1.066, n_D^{25} 1.5167, $[\alpha]_D^{20}$ (-) and (+) 57° (c 1, *C_6H_6), pK^{25} 4.40.** Purify the acids as the 2-isomer above, i.e. by distillation, but under a good vacuum. [Prelog & Scherrer *Helv Chim Acta* **42** 2227 *1959*, Levene & Marker *J Biol Chem* **93** 761 *1932,* **100** 685 *1933*, Cram *J Am Chem Soc* **74** 2137 *1952*.] The *R-amide* crystallises from H_2O, with **m** 101.5-102°, and $[\alpha]_D^{20}$ -16.5° (c 1.2, EtOH). The *racemic acid* has **m** 39-40°, **b** 134-136°/6mm, 158°/12mm [Marvel et al. *J Am Chem Soc* **62** 3499 *1940*]. [*Beilstein* **9** IV 1813.]

4-Phenylbutyric acid *[1821-12-1]* **M 164.2, m 50°, pK^{25} 4.76.** Crystallise the acid from petoleum ether (b 40-60°). [*Beilstein* **9** IV 1811.]

***O*-Phenyl chlorothionoformate** *[1005-56-7]* **M 172.6, b 81-83°/6mm, 91°/10mm, d_4^{20} 1.276, n_D^{20} 1.585.** Purify it by dissolving in $CHCl_3$, washing with H_2O, drying ($CaCl_2$), filtering, evaporating and distilling twice under a vacuum to give a clear yellow liquid. **It is reactive and POISONOUS—work in a fume cupboard.** Store it in sealed ampoules under N_2. A possible impurity is *O,O'-diphenyl thiocarbonate* which has **m** 106° and remains behind in the distilling flask. [Bögemann et al. in *Methoden Der Organischen Chemie (Houben-Weyl)* 4th edn (E. Müller Ed.) **Vol 9** *Schwefel-Selen-Tellur Verbindungen* pp. 807-808 *1955*, Rivier & Schalch *Helv*

Chim Acta **6** 612 *1923*, Kalson *Chem Ber* **20**, 2384 *1987*, Rivier & Richard *Helv Chim Acta* **8** 490 *1925*, Schönberg & Varga *Justus Liebigs Ann Chem* **483** 176 *1930*, Schönberg & Vargha *Chem Ber* **64** 1390 *1931*, *Beilstein* **6** III 609.]

Phenyl cinnamate *[2757-04-2]* **M 224.3, m 75-76°, b 205-207°/15mm.** Crystallise the cinnamate from EtOH (2ml/g). It can also be distilled under reduced pressure. [Womack & McWhirter *Org Synth* Coll Vol **III** 715 *1955*, *Beilstein* **9** H 583, **9** II 387, **9** III 2689, **9** IV 2011.]

α-Phenylcinnamic acid (2,3-diphenylprop-2-enoic acid) *[cis-E 91-48-5, trans-Z 91-47-4]* **M 224.3, m 174°(*cis*), m 138-139°(*trans*), pK^{25} 4.8 (60% aqueous EtOH).** Crystallise the acid from Et_2O/petroleum ether. Crystallise the *cis-isomer* from petroleum ether or EtOH (**m** 174°) and has a pK^{25} of 4.44, and the *cis-amide* from aqueous Me_2CO (**m** 174°). Crystallise the *trans-isomer* from Et_2O/petroleum ether or EtOH (**m** 140°), and the *trans-amide* from $CHCl_3$/petroleum ether (**m** 167-168°). [*Beilstein* **6** H 691, **9** III 3414.]

o-**Phenylenediamine** *[95-54-5]* **M 108.1, m 100-101°, pK_1^{25} 0.67 (aqueous H_2SO_4), pK_2^{25} 4.47 (4.85).** Crystallise the diamine from aqueous 1% sodium hydrosulfite (charcoal), wash it with ice-water and dry it in a vacuum desiccator, or sublime it *in vacuo*. It has been purified by recrystallisation from toluene and zone refined [Anson et al. *J Am Chem Soc* **108** 6593 *1986*]. Purification by refluxing a CH_2Cl_2 solution containing charcoal is also carried out followed by evaporation and recrystallisation [Koola & Kochi *J Org Chem* **52** 4545 *1987*], protect from light. The *acetate* has **m** 186°. [*Beilstein* **13** IV 38.]

m-**Phenylenediamine** *[108-45-2]* **M 108.1, m 61-63°, 62-63°, 62.5°, 63-64°, b 146°/22mm, 282-284°/760mm, 284-287°/atm, d_{10}^{10} 1.1422, $n_D^{57.7}$ 1.6340, pK_1^{25} 2.41, pK_2^{25} 4.98.** Purify the diamine by distillation under a vacuum followed by recrystallisation from EtOH (rhombs) and if necessary redistillation. It should be protected from light; otherwise it darkens rapidly. [Neilson et al. *J Chem Soc* 371 *1962*, IR: Katritzky & Jones *J Chem Soc* 3674, 2058 *1959*, UV: Forbes & Leckie *Can J Chem* **36** 1371 *1958*.] The *hydrochloride* has **m** 277-278°, and the *bis-4-chlorobenzenesulfonyl* derivative has **m** 220-221° from H_2O (214-215°, from MeOH/H_2O) [Runge & Pfeiffer *Chem Ber* **90** 1737 *1957*]. The *acetate* has **m** 191°. [*Beilstein* **13** IV 79.]

p-**Phenylenediamine** *[106-50-3]* **M 108.1, m 140°, pK_1^{25} 2.89, pK_2^{25} 6.16.** Crystallise the diamine from EtOH or *benzene, and sublime it *in vacuo*; protect it from light. The *acetate* has **m** 304°. [*Beilstein* **13** IV 104.]

o-**Phenylenediamine dihydrochloride** *[615-28-1]* **M 181.1, m 180°.** Crystallise the salt from dilute HCl (60ml conc HCl, 40ml water, with 2g stannous chloride), after treatment of the hot solution with charcoal by adding an equal volume of conc HCl and cooling in an ice-salt mixture. The crystals are washed with a small amount of conc HCl and dried in a vacuum desiccator over NaOH. [*Beilstein* **13** IV 38.]

1,4-Phenylene diisothiocyanate (bitoscanate) *[4044-65-9]* **M 192.3, m 129-131°, 130-131°, 132°.** Purify bitoscanate by recrystallisation from AcOH, petroleum ether (b 40-60°), Me_2CO or aqueous Me_2CO. [van der Kerk et al. *Rec Trav Chim Pays Bas* **74** 1262 *1955*, Leiber & Slutkin *J Org Chem* **27** 2214 *1962*, *Beilstein* **13** IV 174.]

1-Phenyl-1,2-ethanediol *[R-(–)- 16355-00-3, S-(+)- 25779-13-9]* **M 138.2, m 64-67°, 65-66°, $[\alpha]_D^{24}$ (-) and (+) 40.5° (c 2.8, H_2O), $[\alpha]_D^{20}$ (-) and (+) 39° (c 3, EtOH).** Purify the diol by recrystallisation from *C_6H_6/ligroin and sublime it at 1-2mm. [Arpesella et al. *Gazetta* **85** 1354 *1955,* Prelog et al. *Helv Chim Acta* **37** 221 *1954*, *Beilstein* **6** IV 5939.]

***dl*-1-Phenylethanol (*dl*-α-methylbenzyl alcohol)** *[98-85-1; 13323-81-4]* **M 122.2, b 60.5-61.0°/3mm, 106-107°/22-23mm, d_4^{20} 1.01, n_D^{25} 1.5254.** Purify the alcohol *via* its hydrogen phthalate. [See Houssa & Kenyon *J Chem Soc* 2260 *1930*.] Shake it with a solution of ferrous sulfate, and the alcohol layer is washed with distilled H_2O, dried ($MgSO_4$) and fractionally distilled. [*Beilstein* **6** II 444.]

2-Phenylethanol *[60-12-8]* **M 122.2, b 215-217°, d 1.020.** Purify the ethanol by shaking it with a solution of ferrous sulfate, and the alcohol layer is washed with distilled water and fractionally distilled. [*Beilstein* **6** IV

3067.]

Phenyl ether (diphenyl ether) *[101-84-8]* **M 170.2, m 27.0°, b 83-84°/1mm, 138°/21mm, 257°/760mm, d_4^{20} 1.074, $n_D^{30.7}$ 1.57596.** Crystallise the ether from 90% EtOH. Melt it, wash it with 3M NaOH and water, dry it with $CaCl_2$ and fractionally distil it under reduced pressure. Fractionally recrystallise it from its melt and store over P_2O_5. [*Beilstein* **6** IV 562.]

1-Phenylethyl isocyanate (α-methylphenyl isocyanate) *[R-(+)- 33375-06-3, S(–)- 14649-03-7]* **M 147.2, b 82-83°/12-14mm, d_4^{20} 1.045, n_D^{20} 1.513, $[\alpha]_D^{24}$ (+) and (-) 2° (c 3.5, *C_6H_6), (+) and (-) 10.5° (neat).** Purify the isocyanates by fractional distillation under a vacuum. With ammonia they give the *ureido* derivatives which crystallise from H_2O with **m** 121-122°, $[\alpha]_D^{25}$ (+) and (–) 48.8°. [Cairns *J Am Chem Soc* **63** 870 *1941*.] The *racemate* has **b** 90-94°/3mm, 96°/18mm [Seiftan *Justus Liebigs Ann Chem* **562** 75 *1949*]. [*Beilstein* **12** IV 2443.]

(±)-*p*-α-Phenylethylphenol *[1988-89-2]* **M 198.3, m 56.0-56.3°, 64°, b 126°/0.4mm, 165-170°/5mm, 315-316°/742.2mm, pK_{Est} ~10.3.** Crystallise the phenol from petroleum ether. *S-(+)-enantiomer* has $[\alpha]_D$ +10.3° (*C_6H_6). [Okamoto et al. *Bull Chem Soc Jpn* **39** 303 *1966*.]

5-(α-Phenylethyl)semioxamazide *[93-95-8]* **M 207.1, m 167-168° (*l*-), 157° (*dl*-).** Crystallise it from EtOH. The *l-enantiomer* has $[\alpha]_D^{25}$ -102.5° (c 1, $CHCl_3$). [Leonard & Boyer *J Org Chem* **15** 42 *1950*.]

9-Phenyl-3-fluorone (2,6,7-trihydroxy-9-phenylxanthen-3-one) *[975-17-7]* **M 320.3, m >300°(dec), 350°, λ_{max} 462nm (ε 4.06 x 10^4, in 1M HCl aqueous EtOH).** Recrystallise it from warm, acidified EtOH by addition of ammonia. The crude material (1g) can be extracted with EtOH (50ml) in a Soxhlet apparatus for 10 hours to remove impurities. Impurities can be detected by paper electrophoresis. The *triacetate* forms yellow needles from EtOH (**m** 230-233°). [Petrova et al. *Anal Lett* **5** 695 *1972*, *Beilstein* **18** H 199, **18** I 404, **18** III/IV 2824.]

Phenylhydrazine *[100-63-0]* **M 108.1, m 23°, b 71.8°/1mm, 137-138°/18mm, 241-242°/760mm, d_4^{20} 1.10, n_D^{20} 1.607, pK_1^{20} -5.2 (aqueous H_2SO_4), pK_2^{25} 5.27.** Purify phenylhydrazine by chromatography, then crystallise it from petroleum ether (b 60-80°)/*benzene. Store it in the dark under N_2 as it turns yellow, then red, on exposure to air. It is best stored as the *hydrochloride salt*; see below. [Coleman *Org Synth* Coll Vol **I** 442 *1941*, Shaw & Stratton *J Chem Soc* 5004 *1962*, *Beilstein* **15** IV 50.]

Phenylhydrazine hydrochloride *[59-88-1]* **M 144.5, m 244°, 250-254°(dec).** Dissolve 100g of phenylhydrazine hydrochloride in 200ml of warm H_2O (60-70°) during 1-3 hours, then add 1L of boiling EtOH. The solution is filtered, while still hot, through Whatman No 2 filter paper and cooled in a refrigerator. The precipitate is collected on a medium sintered-glass filter and recrystallised twice this way, then washed with cold EtOH, dried thoroughly and stored in a stoppered brown bottle. [Peterson et al. *Anal Chem* **29** 144 *1957*.] Hough, Powell and Woods [*J Chem Soc* 4799 *1956*] boiled the hydrochloride with three times its weight of water, filtered hot (charcoal), added one-third volume of concentrated HCl and cooled to 0°. The crystals were washed with acetone, and dried over P_2O_5 under vacuum. The salt has also been crystallised from 95% EtOH, and it can be sublimed. [Coleman *Org Synth* Coll Vol **I** 442 *1941*, *Beilstein* **15** III 71.]

Phenylhydroxylamine (*N*-hydroxyaniline) *[100-65-2]* **M 109.1, m 81°, 82°, 83-84°, pK^{25} 3.2.** Impure base deteriorates rapidly. Crystallise it from H_2O, *C_6H_6 or *C_6H_6/petroleum ether (40-60°). The *picrate* has **m** 186° (from EtOH), and the *benzenesulfonate salt* has **m** 70° (dec)(EtOH/*C_6H_6). [*Beilstein* **15** H 2, **15** I 3, **15**, II 4, **15** III 5. **15** IV 4.]

2-Phenyl-1,3-indandione *[83-12-5]* **M 222.2, m 149-151°, pK^{20} 4.12 (1% aqueous MeOH).** Crystallise the dione from EtOH (**m** 156°) or $CHCl_3$ (**m** 148-150°). [*Beilstein* **7** H 808, **7** III 4100, **7** IV 2570.]

Phenylisocyanate *[103-71-9]* **M 119.1, b 45-47°/10mm, d_4^{20} 1.093, n_D^{20} 1.536.** Distil phenylisocyanate under reduced pressure from P_2O_5. [*Beilstein* **12** IV 864.]

Phenylisothiocyanate (phenyl mustard oil) *[103-72-0]* **M 135.2, m -21°, b 95°/12mm, 117.1°/33mm, 221°/760mm, d_4^{25} 1.1288, $n_D^{23.4}$ 1.64918.** It is insoluble in H_2O, but soluble in Et_2O and EtOH. If impure (due to formation of thiourea), then steam distil it into a receiver containing 5-10ml of N H_2SO_4. Separate the oil, dry over $CaCl_2$ and distil it under vacuum. [Dains et al. *Org Synth* Coll Vol **I** 447 *1941*, *Beilstein* **12** IV 867.]

8-Phenylmenthol *[1R,2S,5R-(–)- 65253-04-5, 1S,2R,5S-(+)- 57707-91-2]* **M 232.4, $[\alpha]_D^{20}$ (–) and (+) 26° (c 2, EtOH).** Dissolve the menthol in toluene, dry (Na_2SO_4), evaporate and chromatograph it on a silica gel column and eluting with 5% Et_2O in petroleum ether to give an oil with the desired rotation. Its IR has ν_{max} at 3420cm^{-1} (OH) with consistent ^1H NMR [Corey & Ensley *J Org Chem* **43** 1610 *1978*, Whitesell et al. *Tetrahedron* **42** 2993 *1986*, Bednarski & Danishefsky *J Am Chem Soc* **108** 7060 *1986*].

Phenyl methanesulfonate *[16156-59-5]* **M 172.1, m 61-62°.** Crystallise the sulfonate from MeOH or from H_2O (**m** 61.5°). [*Beilstein* **6** H 176, **6** III 650, **6** IV 689.]

Phenyl methanesulfonyl fluoride (PMSF) *[329-98-6]* **M 174.2, m 90-91°, 92-93°.** Purify PMSF by recrystallisation from *C_6H_6, petroleum ether or $CHCl_3$/petroleum ether. [Davies & Dick *J Chem Soc* 483 *1932*, cf Tullock & Coffman *J Org Chem* **23** 2016 *1960*.] It is a general protease inhibitor (specific for trypsin and chymotrypsin) and is a good substitute for diisopropylphosphorofloridate [Fahrney & Gould *J Am Chem Soc* **85** 997 *1963*]. [*Beilstein* **11** III 331.]

2-Phenylnaphthalene *[612-94-2]* **M 204.3, m 102-103°, 103.5°, 103-104°, b 185-190°/5mm, 357-358°/760mm.** Chromatograph it on alumina in *benzene and crystallise it from aqueous EtOH or MeOH/EtOH. It has been sublimed. It has λ_{max} at 248 and 286nm (methylcyclohexane). The *2,4,7-trinitrofluoren-9-one* has **m** 169.5-170.5° (from EtOH/*C_6H_6). [*Beilstein* **5** H 687, **5** II 603, **5** III 2231, **5** IV 2412.]

***N*-Phenyl-1-naphthylamine** *[90-30-2]* **M 219.3, m 63.7-64.0°, pK_{Est} ~0.1.** Crystallise it from EtOH, petroleum ether or *C_6H_6/EtOH. Dry it under vacuum in an Abderhalden pistol. [*Beilstein* **12** H 1224.]

***N*-Phenyl-2-naphthylamine** *[135-88-6]* **M 219.3, m 107.5-108.5°, 110°, pK_{Est} ~0.5.** Crystallise it from EtOH, MeOH, glacial acetic acid or *benzene/hexane. [*Beilstein* **12** H 1275, **12** I 535, **12** II 716, **12** III 2991.]

4-Phenylphenacyl bromide *[135-73-9]* **M 275.2, m 126°.** Crystallise (charcoal) the bromide from EtOH (15ml/g), or ethyl acetate/petroleum ether (b 90-100°). [*Beilstein* **7** III 2137.]

2-Phenylpropanal *[93-53-8]* **M 134.2, b 206°/760mm, d_4^{20} 1.001, n_D^{20} 1.5183.** It may contain up to 15% of acetophenone. Purify it *via* the bisulfite addition compound [Lodge & Heathcock *J Am Chem Soc* **109** 3353 *1987*] and see Chapter 2 for preparation and decomposition of bisulfite adducts. [*Beilstein* **7** IV 695.]

Phenylpropiolic acid *[637-44-5]* **M 146.2, m 137.8-138.4°, pK^{25} 2.23.** Crystallise the acid from *benzene, CCl_4 (**m** 136°) or aqueous EtOH. The *S-benzylisothiuronium salt* has **m** 184-186° (from EtOH). [*Beilstein* **9** II 436, **9** III 3061, **9** IV 2327.]

***RS*-2-Phenylpropionic acid** *[492-37-5]* **M 150.2, m 16-16.5°, b 153-155°/20mm, 189°/48mm, 260-262°/760mm, d_4^{20} 1.10, n_D^{20} 1.522, pK^{25} 4.3.** Fractionally distil the acid, or recrystallise it from petroleum ether (b 40-60°) with strong cooling (see references below). [*Beilstein* **9** II 348.]

2-Phenylpropionic acid *[R-(–)- 7782-26-5, S-(+)- 7782-24-3]* **M 150.2, m 30.3-31°, 30-32°, b 115°/1-2mm, 142°/12mm, $[\alpha]_D^{20}$ (-) and (+) 99.7° (l = 1 dcm, neat), (-) and (+) 89.1° (c 1.7, EtOH), (-) and (+) 75° (c 1.6, $CHCl_3$).** Purify the acids by vacuum distillation and by recrystallisation from petroleum ether. The *S-anilide* has **m** 103-104° (from H_2O or $CHCl_3$/*C_6H_6), $[\alpha]_D^{25}$ +47° (c 9, Me_3CO) [Argus & Kenyon *J Chem Soc* 916 *1939*, Campbell & Kenyon *J Chem Soc* 25 *1946*, Levene et al. *J Biol Chem* **88** 27, 34 *1930*]. [*Beilstein* **9** III 2417, **9** IV 1779.]

3-Phenylpropionic acid (hydrocinnamic acid) *[501-52-0]* **M 150.2, m 48-48.5°, pK^{25} 4.56.** Crystallise the acid from *benzene, $CHCl_3$ or petroleum ether (b 40-60°). Dry it in a vacuum. [*Beilstein* **9** H 508.]

3-Phenylpropyl bromide *[637-59-2]* **M 199.1, b 110°/12mm, 128-129°/29mm, d $_4^{20}$ 1.31.** Wash the bromide successively with conc H_2SO_4, water, 10% aqueous Na_2CO_3 and again with water, then dry it with $CaCl_2$ and fractionally distil it just before use. [*Beilstein* **5** IV 982.]

Phenylpyruvic acid *[156-06-9]* **M 164.2, m 150-154°, 158-159°, pK$_{Est}$ ~2.1.** Recrystallise the acid from *C_6H_6. The *phenylhydrazone* has **m** 173° [Zeller *Helv Chim Acta* **26** 1614 *1943*, Hopkins & Chisholm *Can J Research* [B] **24** 89 *1946*]. The *2,4-dinitrophenylhydrazone* has **m** 162-164° (189°, 192-194°) [Fones *J Org Chem* **17** *1952*]. [*Beilstein* **10** IV 2760.]

Phenyl salicylate (Salol) *[118-55-8]* **M 214.2, m 41.8-42.6°, pK$_{Est}$ ~9.9.** Fractionally crystallise salol from its melt, then crystallise it from *benzene. [*Beilstein* **10** IV 154.]

3-Phenylsalicylic acid *[304-06-3]* **M 214.3, m 186-187.5°, pK$_{Est(1)}$~2.8 (CO_2H), pK$_{Est(2)}$~11.0 (OH).** Dissolve the acid in *ca* 1 equivalent of saturated aqueous Na_2CO_3, filter and precipitate it by adding 0.8 equivalents of M HCl. Crystallise it from ethylene dichloride (charcoal), and sublime it at 0.1mm. [Brooks et al. *J Chem Soc* 661 *1961*.]

1-Phenylsemicarbazide *[103-03-7]* **M 151.2, m 172°, 173.5°.** Crystallise it from water and dry it in a vacuum over KOH. [*Beilstein* **15** H 287, **15** II 106, **15** III 184, **15** IV 180.]

4-Phenylsemicarbazide *[537-47-3]* **M 151.2, m 122°.** Crystallise it from water and dry it in a vacuum over KOH. [*Beilstein* **12** II 221, **12** III 822.]

Phenylsuccinic acid *[R-(–)- 46292-93-7, S-(+)- 4036-30-1]* **M 194.2, m 173-176°, 178.5-179°, 179-180°, [α] $_D^{25}$ (-) and (+) 171° (c 2, Me_2CO), [α] $_D^{26-30}$ (-) and (+) 148° (c 0.27-5, EtOH), pK $_1^{25}$ 3.78, pK $_2^{25}$ 5.55.** Purify the acids by re-precipitation from alkali and recrystallisation from H_2O. [Naps & Johns *J Am Chem Soc* **62** 2450 *1940*, Fredga & Matell *Bull Soc Chim Belg* **62** 47 *1953*, Wren & Williams *J Chem Soc* **109** 572 *1916*.] The *racemate [635-51-8]* has **m** 166-168°, 168° after recrystallisation from H_2O or MeCN. Its *S-benzylisothiuronium salt* has **m** 164-165° (from EtOH) [Griediger & Pedersen *Acta Chem Scand* **9** 1425 *1955*]. [*Beilstein* **9** IV 3351.]

1-Phenylthiosemicarbazide *[645-48-7]* **M 167.2, m 200-201°(dec).** Crystallise it from EtOH. [*Beilstein* **15** IV 183.]

4-Phenylthiosemicarbazide *[5351-69-9]* **M 167.2, m 140°.** Crystallise it from EtOH. [*Beilstein* **12** IV 827.]

1-Phenyl-2-thiourea *[103-85-5]* **M 152.1, m 154°.** Crystallise the thiourea from water and dry it at 100° in air. [*Beilstein* **12** IV 804.]

Phenyltoloxamine [2-(2-dimethylaminoethoxy)-diphenylmethane] hydrochloride *[6152-43-8]* **M 291.8, m 119-120°, pK^{25} 9.3 (free base).** Crystallise the salt from isobutyl methyl ketone. The *free base* has **b 144°/1mm**. [*Beilstein* **6** III 3351, **6** IV 4630.]

Phenyl 4-toluenesulfonate *[640-60-8]* **M 248.2, m 94.5-95.5°, 95.8-97.8°.** Crystallise the ester from MeOH or glacial acetic acid. [*Beilstein* **11** H 99, **11** II 47, **11** III 200, **6** IV 271.]

Phenyl 4-tolylcarbonate *[13183-20-5]* **M 228.2, m 94°.** Purify the carbonate by preparative GLC with 20% Apiezon on Embacel, and sublime it *in vacuo*. [*Beilstein* **6** H 398.]

1-Phenyl-2,2,2-trifluoroethanol *[R-(–)- 10531-50-7, S-(+)- 340-06-7]* **M 176.1, b 74-76°/10mm, 125-127°/760mm, d $_4^{20}$ 1.301, n $_D^{20}$ 1.4632, [α] $_D^{20}$ (-) and (+) 31° (neat).** Purify the chiral alcohols by fractional

distillation preferably in a vacuum. [Morrison & Ridgeway *Tetrahedron Lett* 573 *1969*, NMR: Pirkle & Beare *J Am Chem Soc* **90** 6250 *1968*.] The *racemate [340-05-6]* has **b** 52-54°/2mm, 57-59°/2mm, 64-65°/5mm, d_4^{20} 1.293, n_D^{20} 1.457, and the *2-carbobenzoyl* derivative has **m** 137-138° [Mosher et al. *J Am Chem Soc* **78** 4374 *1956*]. [*Beilstein* **6** IV 3043.]

Phenylurea *[64-10-8]* **M 136.2, m 148°, pK^{25} -1.45 (aqueous H_2SO_4).** Crystallise the urea from boiling water (10ml/g) or amyl alcohol (**m** 149°). Dry it in a steam oven at 100°. The 1:1 *resorcinol complex* has **m** 115° (from EtOAc/*C_6H_6). [*Beilstein* **12** H 346, **12** II 204, **12** III 760, **12** IV 734.]

Phloroacetophenone ($2H_2O$) (2',4',6'-trihydroxyacetophenone) *[480-66-0]* **M 186.2, m 218-219°, $pK_{Est(1)}$~7.9, $pK_{Est(2)}$~12.0.** Crystallise the ketone from hot H_2O (35ml/g). [*Beilstein* **8** IV 2729.]

Phloretin [2',4',6'-trihydroxy-3-(*p*-hydroxyphenyl)propiophenone] *[60-82-2]* **M 274.3, m 264-271°(dec), $pK_{Est(1)}$~7.5, $pK_{Est(2)}$~8.0, $pK_{Est(3)}$~10, $pK_{Est(4)}$~12 (phenolic OH's).** Crystallise phloretin from aqueous EtOH. [Zemplen & Bognár *Chem Ber* **75** 1040 *1942*, Zemplén *Chem Ber* **76** 386 *1943*, *Beilstein* **8** IV 3518.]

Phloroglucinol ($2H_2O$) (benzene-1,3,5-triol) *[6099-90-7 ($2H_2O$), 108-73-6 (anhydrous)]* **M 126.1, m 217-219°, 117° (anhydrous), pK_1^{25} -7.74 ($HClO_4$), pK_2^{20} 7.97, pK_3^{20} 9.23.** Crystallise the triol from water, and store it in the dark under nitrogen. [*Beilstein* **6** IV 7361.]

o-**Phthalic acid** *[88-99-3]* **M 166.1, m 211-211.5°, pK_1^{25} 2.76 (3.05), pK_2^{25} 4.92 (4.73).** Crystallise phthalic acid from water. [*Beilstein* **9** IV 3167.]

Phthalic anhydride *[85-44-9]* **M 148.1, m 132°, b 295°.** Distil the anhydride under reduced pressure. Purify it from the acid by extracting with hot $CHCl_3$, filtering and evaporating. The residue is crystallised from $CHCl_3$, CCl_4 or *benzene, or sublimed. Fractionally crystallise it from its melt. Dry it under vacuum at 100°. [Saltiel *J Am Chem Soc* **108** 2674 *1986*, *Beilstein* **17/11** V 253.]

Phthalide *[87-41-2]* **M 134.1, m 72-73°, pK -7.98 (aqueous H_2SO_4).** Crystallise phthalide from water (75ml/g) and dry it in air on filter paper. [*Beilstein* **17/10** V 7.]

Phthalimide *[85-41-6]* **M 147.1, m 235°, 238°, pK 8.30.** Crystallise the imide from EtOH (20ml/g) (charcoal), or sublime it. For potassium phthalimide see entry in "Metal-organic Compounds", Chapter 5. [*Beilstein* **21/10** V 270.]

Phthalonitrile (1,2-dicyanobenzene) *[91-15-6]* **M 128.1, m 141°.** Crystallise the nitrile from EtOH, toluene or *benzene. It has also been distilled under high vacuum. It is steam volatile. [*Beilstein* **9** H 815, **9** II 602, **9** III 4199, **9** IV 3268.]

Phthalylsulfacetamide *[131-69-1]* **M 362.3, m 304°.** It is prepared by hydrolysis of N-acetamidosulfophenylpthalimide by boiling for 3 hours in 15% aqueous KOH followed by treatment with Norit, filtration and acidification with AcOH. Crystallise the phthalamide from hot H_2O or EtOH [Jain et al. *J Indian Chem Soc* **24** 174 *1947*]. It is **antibacterial**. [*Beilstein* **14** III 2073.]

Phthiocol (2-hydroxy-3-methylnaphtha-1,4-quinone) *[483-55-6]* **M 188.1, m 173-174°, pK_{Est} ~4.2.** Crystallise the quinone from diethyl ether/petroleum ether. [*Beilstein* **8** III 2568, **8** IV 2375.]

Physodic acid [4,4',6'-trihydroxy-6-(2-oxoheptyl)-2'-pentyl-2,3'-oxydibenzoic acid 1,5-lactone] *[84-24-2]* **M 470.5, m 205°, $pK_{Est(1)}$~3.0, $pK_{Est(2)}$~10, $pK_{Est(3)}$~13.** Crystallise the acid from MeOH. The *diacetate* has **m** 155-156° (from Me_2CO/CS_2). [*Beilstein* **19** II 329, **19** III/IV 3988.]

Picene *[213-14-3]* **M 278.3, m 364°, 366-367°, 367-369°.** Crystallise picene from isopropylbenzene/xylene. After sublimation at 300°/2mm followed by crystallisation from xylene (charcoal), it gives white glistening leaflets with **m** 366-366.5° [Newman *J Org Chem* **9** 524 *1944*]. The *2,4,7-trinitrofluoren-9-one* has **m** 257-

257.8° (from *C_6H_6). [*Beilstein* **5** H 735, **5** I 369, **5** III 2555, **5** IV 2724.]

Picric acid *[88-89-1]* **M 229.1, m 122-123°, pK^{25} 0.33 (0.37).** Crystallise the acid first from acetic acid, then acetone, toluene, $CHCl_3$, aqueous 30% EtOH, 95% EtOH, MeOH or H_2O. Dry it in a vacuum for 2 hours. *Alternatively*, dry it over $Mg(ClO_4)_2$ or fuse (CARE) and allow it to solidify under a vacuum three times. Because it is **EXPLOSIVE**, picric acid should be stored moistened with H_2O, and only small portions should be dried at any one time. The dry acid should **NOT** be heated. [*Beilstein* **6** IV 1388.]

Picryl chloride (2-chloro-1,3,7-trinitrobenzene) *[88-88-0]* **M 226.3, m 83°.** Crystallise the chloride from $CHCl_3$ or EtOH. The 2:1 **C_6H_6-complex* has **m** 39° (from *C_6H_6). [*Beilstein* **5** II 205, **5** III 645, **5** IV 757.]

Picryl iodide (2-iodo-1,3,7-trinitrobenzene) *[4436-27-5]* **M 340.0, m 164-165°.** Crystallise the iodide from *benzene. [*Beilstein* **5** III 647, **5** IV 758.]

Pinacyanol chloride (Quinaldine Blue] *[2768-90-3]* **M 388.9, m 270°(dec).** Crystallise the chloride from EtOH/diethyl ether. [*Beilstein* **23** I 90.]

Piperic acid [*trans,trans*-5-(3,4-methylenedioxyphenyl)-2,4-pentadieneoic acid] *[136-72-1]* **M 218.2, m 217°, pK_{Est} ~4.7.** Crystallise the acid from EtOH. It turns yellow in light. It sublimes with partial decomposition. It has UV with λ_{max} at 340nm (MeOH). [*Beilstein* **19** H 281, **19** II 30, **19** III/IV 3565.]

Piperonal *[120-57-0]* **M 150.1, m 37°, b 140°/15mm, 263°/760mm.** Crystallise piperonal from aqueous 70% EtOH or EtOH/water. [*Beilstein* **19/4** V 225.]

Piperonylic acid *[94-53-1]* **M 166.1, m 229°, pK^{25} 4.50.** Crystallise the acid from EtOH or water. [*Beilstein* **19/7** V 300.]

Polystyrene (PS) *[9003-53-6]***.** Precipitate polystyrene repeatedly from $CHCl_3$ or toluene solution by addition of MeOH. Dry it *in vacuo*. [Miyasaka et al. *J Phys Chem* **92** 249 *1988*.]

Procaine [4-(2-diethylaminomethoxycarbonyl)aniline] *[59-46-1]* **M 236.3, m 51° (dihydrate), 61° (anhydrous), pK_1^{15} 2.45, pK_2^{15} 8.91.** Procain crystallises as the *dihydrate* from aqueous EtOH and as the *anhydrous* material from petroleum ether or diethyl ether. The latter is *hygroscopic*. [*Beilstein* **14** IV 1138.]

***p*-(1-Propenyl)phenol** *[cis/trans 6380-21-8, 539-12-8]* **M 134.2, m 93-94°, pK_{Est} ~10.2.** Crystallise the phenol from water. [*Beilstein* **6** III 2394, **6** IV 3796.]

1-Propyl-3-(*p*-chlorobenzenesulfonyl) urea *[94-20-2]* **M 260.7, m 126-128°, 127-129°.** Crystallise the urea from aqueous EtOH. [*Beilstein* **11** IV 119.]

***n*-Propyl gallate** *[121-79-9]* **M 212.2, m 150°.** Crystallise the ester from aqueous EtOH or *C_6H_6 (**m** 146-146.5°). [*Beilstein* **10** III 2078, **10** IV 2003.]

Protocatechualdehyde (3,4-dihydroxybenzaldehyde) *[139-85-5]* **M 138.1, m 153°.** Crystallise the aldehyde from water or toluene and dry it in a vacuum desiccator over KOH pellets or shredded wax respectively. [*Beilstein* **8** IV 1762.]

***1S,2S*-Pseudoephedrine (1-hydroxy-1-phenyl-2-methylaminopropane)** *[90-82-4]* **M 165.2, m 118-119°, $[\alpha]_D^{20}$ +53.0° (EtOH), +40.0° (H_2O), pK^{25} 9.71.** Crystallise the amine from dry diethyl ether, or from water and dry it in a vacuum desiccator. [*Beilstein* **13** IV 1878.]

***1S,2S*-Pseudoephedrine hydrochloride** *[345-78-8]* **M 210.7, m 181-182°, 185-188°, $[\alpha]_D^{20}$ +61° (c 1 H_2O).** Crystallise the salt from EtOH. [*Beilstein* **13** IV 1878.]

Purpurin (1,2,4-trihydroxy-5,10-anthraquinone) *[81-54-9]* **M 256.2, m 253-256°, $pK_{Est(1)}$~7.0 (2-OH), $pK_{Est(2)}$~9.0 (4-OH), $pK_{Est(3)}$~11.1 (1-OH).** Crystallise purpurin from aqueous EtOH, dry it at 100°. [*Beilstein* **8** IV 3568.]

Pyrene (benzo[*def*]phenanthrene) *[129-00-0]* **M 202.3, m 149-150°.** Crystallise pyrene from EtOH, glacial acetic acid, *benzene or toluene. Purify it also by chromatography of CCl_4 solutions on alumina, with *benzene or *n*-hexane as eluent. [Backer & Whitten *J Phys Chem* **91** 865 *1987*.] It can also be zone refined and purified by sublimation. Marvel and Anderson [*J Am Chem Soc* **76** 5434 *1954*] refluxed pyrene (35g) in toluene (400ml) with maleic anhydride (5g) for 4 days, then added 150ml of aqueous 5% KOH and refluxed for 5 hours with occasional shaking. The toluene layer was separated, washed thoroughly with H_2O, concentrated to about 100ml and allowed to cool. Crystalline pyrene was filtered off and recrystallised three times from EtOH or acetonitrile. [Chu & Thomas *J Am Chem Soc* **108** 6270 *1986*, Russell et al. *Anal Chem* **50** 2961 *1986*.] The material is free from anthracene derivatives. Another purification step involves passage of pyrene in cyclohexane through a column of silica gel. It can be sublimed in a vacuum and zone refined. The *picrate* has **m** 224°. [Kano et al. *J Phys Chem* **89** 3748 *1985*, *Beilstein* **5** IV 2467.]

Pyrene-1-aldehyde *[3029-19-4]* **M 230.3, m 125-126°.** Recrystallise the aldehyde three times from aqueous EtOH. [*Beilstein* **7** IV 1821.]

1-Pyrenebutyric acid *[3443-45-6]* **M 288.4, m 184-186°, pK_{Est} ~4.1.** Crystallise the butyric acid from *benzene, EtOH, EtOH/water (7:3 v/v) or *C_6H_6/AcOH. Dry it over P_2O_5. [Chu & Thomas *J Am Chem Soc* **108** 6270 *1986*, *Beilstein* **9** IV 2731.]

1-Pyrenecarboxylic acid *[19694-02-1]* **M 230.3, m 274-274°, pK_{Est} ~3,2.** Crystallise the acid from *C_6H_6, chlorobenzene, nitrobenzene or 95% EtOH. [*Beilstein* **9** H 712, **9** III 3575.]

1-Pyrenesulfonic acid *[26651-23-0]* **M 202.2, m >350°, pK_{Est} <0.** Crystallise the sulfonic acid from EtOH/H_2O. The *sulfonyl chloride* has **m** 120°(dec). [Vollmann et al. *Justus Liebigs Ann Chem* **531** 32 *1937* and *Justus Liebigs Ann Chem* **540** 189 *1939*, *Beilstein* **11** H 198, **11** III 448.]

1,3,6,8-Pyrenetetrasulfonic acid *[6528-53-6]* **M 522.2, m >400°, pK_{Est} <0.** Crystallise the tetrasulfonic acid from water. The tetra-Na salt crystallises also from H_2O. [Tietz & Bayer *Justus Liebigs Ann Chem* **540** 189 *1939*, *Beilstein* **11** III 486.]

***p*-Quaterphenyl** *[135-70-6]* **M 306.4, m 312-314°, b 428°/18mm.** Recrystallise *p*-quaterphenyl from dimethyl sulfoxide at *ca* 50°. [*Beilstein* **5** II 669.]

Quinalizarin (1,2,5,8-tetrahydroxy-9,10-anthraquinone) *[81-61-8]* **M 272.2, m 275°, $pK_{Est(1)}$~7.1 (1-OH), $pK_{Est(2)}$~9.9 (8-OH), $pK_{Est(3)}$~11.1 (5-OH), $pK_{Est(4)}$~11.8 (2-OH).** Crystallise the quinone from acetic acid or nitrobenzene. It can be sublimed *in vacuo*. The Cu salt forms red crystals. [*Beilstein* **8** H 549, **8** I 755, **8** II 584.]

Quinhydrone (1:1 complex of hydroquinone and benzoquinone) *[106-34-3]* **M 218.2, m 168°, 167-172°.** Crystallise quinhydrone from H_2O at 65°**,** then dry it *in vacuo*. [*Beilstein* **7** H 617, **7** IV 2069.]

Quinizarin (1,4-dihydroxy-9,10-anthraquinone) *[81-64-1]* **M 240.2, m 200-202°, pK_1^{25} 9.90 (9.5), pK_2^{25} 11.18.** Crystallise quinizarin from glacial acetic acid. [*Beilstein* **8** H 450, **8** IV 3260.]

***p*-Quinquephenyl (*p*-pentaphenyl)** *[61537-20-0]* **M 382.5, m 388.5°.** Recrystallise *p*-pentaphenyl from boiling dimethyl sulfoxide (**b** 189°, lowered to 110°). The solid obtained on cooling is filtered off and washed repeatedly with toluene, then with conc HCl. The final material is washed repeatedly with hot EtOH. It is also recrystallised from pyridine, then sublimed *in vacuo*. [Campbell & McDonald *Org Synth* Coll Vol **V** 986 *1973*, *Beilstein* **5** II 709, **5** III 2680, **5** IV 2874.]

Resorcinol *[108-46-3]* **M 110.1, m 111.2-111.6°, pK_1^{25} 9.23, pK_2^{25} 13.05.** Crystallise resorcinol from *benzene, toluene or *benzene/diethyl ether. The *benzoate* has **m** 117°. [*Beilstein* **6** IV 2069.]

Retene (1-methyl-7-*iso*propylphenanthrene) *[483-65-8]* **M 234.3, m 89°, 90°, 99°, 100.5-101°, b 208°/10mm.** Crystallise retene from EtOH. The *picrate* has **m** 126° (from EtOH). The 1:1 *1,3,5-trinitrobenzene-complex* has **m** 144° (from EtOH). [*Beilstein* **5** H 683, **5** II 598, **5** III 2199.]

***Para*Rosaniline (4,4',4"-triaminotrityllium [triphenylmethane] carbonium ion, para-fuschin, paramagenta)** *[467-62-9]* **M 305.4, pK^{25} 7.57 and free base has pK >13.** Dissolve the dye in EtOH (1.16g in 30ml), filter and add aqueous NH_3 till neutral (colourless) and precipitate it by adding H_2O giving 0.8g, **m** 247°(dec, sintering at 230°). Dissolve it in EtOH, neutralise with NH_3 till colourless, add 0.1g of charcoal, filter, and repeat, then add H_2O (100ml) to precipitate the colourless *carbinol* (pseudo-base) and dry it *in vacuo*, **m** 257°(dec, also 205°, sintering at 232°). [Weissberger & Theile *J Chem Soc* 148 *1934*.] The *carbinol* is slightly soluble in H_2O but is soluble in acids (e.g. HCl to give the coloured *chloride* [569-61-9]) and EtOH [pK: Goldacre & Phillips *J Chem Soc* 172 *1949*]. The *perchlorate* (dark red with a green shine) has **m** 300° and explodes at 317° [Dilthey & Diaklage *J Prakt Chem* [2] 129 *1931*]. [*Beilstein* **13** IV 2283.]

Rosaniline HCl (Magenta I, Fuschin) *[632-99-5]* **M 337.9, m >200°(dec).** Purify the dye by dissolving it in EtOH, filtering and adding H_2O. Filter or centrifuge it and wash the precipitate with Et_2O and dry it in air. It has also been recrystallised from water and dried *in vacuo* at 40°. The crystals have a metallic green lustre. It has UV with λ_{max} in EtOH at 543nm (ε 93,000). Its solubility in H_2O is 0.26%. A carmine red colour is obtained in EtOH. It is paraRosaniline with a methyl group. [Scalan *J Am Chem Soc* **57** 887 *1937*.]

***p*-Rosolic acid (4-[bis-{4-hydroxyphenyl}methylene]-2,5-cyclohexadien-one, 4',4"-di-hydroxy-fuschson, aurin, corallin)** *[603-45-2]* **M 290.3, m 292°, 295-300° (dec with liberation of phenol), 308-310°(dec), pK_1 3.11, pK_2 8.62.** It forms green crystals with a metallic luster, but the colour depends on the solvent used. When recrystallised from brine (saturated aqueous NaCl) acidified with HCl, it forms red needles, but when recrystallised from EtO/AcOH, the crystals have a beetle iridescent green colour. It has been recrystallised from Me_2CO (although it dissolves slowly), methyl ethyl ketone, 80-95% AcOH and from AcOH/*C_6H_6. An aqueous KOH solution is golden yellow, and a 70% H_2SO_4 solution is deep red in colour. An *alternative* purification is to dissolve this triphenylmethane dye in 1.5% of aqueous NH_3, filter, and heat to 70-80°, then acidify with dilute AcOH by adding it slowly with vigorous stirring, whereby the aurin separates as a brick-red powder or as purplish crystals depending on the temperature and period of heating. Filter off the solid, wash it with H_2O and a little dilute AcOH, then H_2O again. Stir this solid with Et_2O to remove any ketones and allow it to stand overnight in the Et_2O, then filter and dry it in air then in a vacuum. [Gomberg & Snow *J Am Chem Soc* 47 202 *1925*, Baines & Driver *J Chem Soc* 123 1216 *1923*, UV: Burawoy *Chem Ber* **64** 462 *1941*, *Beilstein* **8** IV 2646.]

Salicylaldehyde (*o*-hydroxybenzaldehyde) *[90-02-8]* **M 122.1, b 93°/25mm, 195-197°/760mm, d_4^{20} 1.167, n 1.574, pK^{25} 8.37.** It is precipitated as the bisulfite addition compound by pouring the aldehyde slowly and with stirring into a 25% solution of $NaHSO_3$ in 30% EtOH, then standing for 30 minutes. The precipitate, after filtering at the pump, and washing with EtOH, is decomposed with aqueous 10% $NaHCO_3$, and the aldehyde is extracted into diethyl ether, dried with Na_2SO_4 or $MgSO_4$, and distilled, under reduced pressure. *Alternatively*, salicylaldehyde is precipitated as its Cu complex by adding it to warm, saturated aqueous $Cu(OAc)_2$, shaking and standing in ice. The precipitate is filtered off, washed with EtOH, then Et_2O, and decomposed with 10% H_2SO_4; the aldehyde is extracted into Et_2O, dried and vacuum distilled. It was also purified by dry column chromatography on Kieselgel G [Nishiya et al. *J Am Chem Soc* **108** 3880 *1986*]. The *acetyl* derivative has **m** 38-39° (from petroleum ether or EtOH) and **b** 142°/18mm, 253°/atm. The *oxime*, [94-67-7] **M 137.1**, crystallises $CHCl_3$/petroleum ether (b 40-60°) with m 57°. [*Beilstein* **8** IV 176, 203.]

Salicylamide *[65-45-2]* **M 137.1, m 142-144°, pK^{20} 8.37.** Crystallise the amide from water or repeatedly from $CHCl_3$ [Nishiya et al. *J Am Chem Soc* **108** 3880 *1986*]. [*Beilstein* **10** IV 169.] The *anilide* [87-17-2] **M 213.2**, **m** 135° crystallises from H_2O. [*Beilstein* **12** H 500, **12** I 268, **12** II 256, **12** 944.]

Salicylhydroxamic acid *[89-73-6]* **M 153.1, m 179-180°(dec), pK_1^{30} 2.15, pK_2^{30} 7.46, pK_3^{30} 9.72.** Crystallise the hydroxamic acid from acetic acid. [*Beilstein* **10** H 98.]

Salicylic acid (2-hydroxybenzoic acid) *[69-72-7]* **M 138.1, m 157-159°, 158-160°, 159.5°, 159-160°, 162°, b 211°/20mm, pK_1^{25} 3.01, pK_2^{25} 13.43 (13.01).** It has been purified by steam distillation, by recrystallisation from H_2O (solubility is 0.22% at room temperature and 6.7% at 100°), absolute MeOH, or cyclohexane and by sublimation in a vacuum at 76°. The *acid chloride* (needles) has **m** 19-19.5°, **b** 92°/15mm, the *amide* has **m** 133° (yellow needles from H_2O), the *O-acetyl* derivative has **m** 135° (rapid heating and the liquid resolidifies at 118°), and the *O-benzoyl* derivative has **m** 132° (aqueous EtOH). [IR: Hales et al. *J Chem Soc* 3145 *1954*, Bergmann et al. *J Chem Soc* 2351 *1950*]. [*Beilstein* **10** IV 125.]

Solochrome Violet R [4-hydroxy-3-(2-hydroxynaphthyl-1-ylazo)benzenesulfonic acid] *[2092-55-9]* **M 367.3, CI 15670, λ_{max} 501nm, pK_2^{25} 7.22 (OH), pK_3^{25} 13.39 (OH).** Convert the acid to the monosodium salt by precipitation with NaOAc/AcOH buffer of pH 4, then purify by precipitation of the free acid from aqueous solution with conc HCl, washing and extracting with EtOH in a Soxhlet extractor. The acid precipitates on evaporating the EtOH and is reconverted to the sodium salt as described for *Chlorazole Sky Blue FF*. Dry it at 110°. It is *hygroscopic*. [Coates & Rigg *Trans Faraday Soc* **57** 1088 *1961*, *Beilstein* **16** II 127.]

***cis*-Stilbene** *[645-49-8]* **M 180.3, b 145°/12mm.** Purify it by chromatography on alumina using hexane and distil it under vacuum. (The final product contains *ca* 0.1% of the *trans*-isomer.) [Lewis et al. *J Am Chem Soc* **107** 203 *1985*, Saltiel *J Phys Chem* **91** 2755 *1987*, *Beilstein* **5** H 630.]

***trans*-Stilbene (*trans*-1,2-diphenylethylene)** *[103-30-0]* **M 180.3, m 125.9°, b 305-307°/744mm, d_4^{20} 0.970.** Purify it by vacuum distillation. (The final product contains about 1% of the *cis* isomer.) Crystallise it from EtOH. It has also been purified by zone melting. The *styphnate* (see next entry) has **m** 142°. [Lewis et al. *J Am Chem Soc* **107** 203 *1985*, Bollucci et al. *J Am Chem Soc* **109** 515 *1987*, Saltiel *J Phys Chem* **91** 2755 *1987*, *Beilstein* **5** IV 2156.]

Styphnic acid (2,4,6-trinitroresorcinol) *[82-71-3]* **M 245.1, m 177-178°, 179-180°, pK_1^{25} 0.06 (1.74), pK_2^{25} 4.23 (4.86).** Crystallise the phenol from ethyl acetate or water containing HCl [**EXPLODES violently on rapid heating.]** Its solubility in H_2O is 0.7% at 20° and 3% at 100°. It forms *addition compounds* with aromatic hydrocarbons, e.g. naphthalene (**m** 168°), anthracene (**m** 180°), phenanthrene (**m** 142°), fluorene (**m** 134°) and retene (**m** 141°). [*Beilstein* **6** H 830, **6** III 4354, **6** IV 5699.]

Styrene (vinylbenzene) *[100-42-5]* **M 104.2, b 41-42°/18mm, 145.2°/760mm, d_4^{20} 0.907, n_D^{20} 1.5469, n_D^{25} 1.5441.** Styrene is difficult to purify and keep pure. Usually it contains added inhibitors (such as a trace of hydroquinone). Wash it with aqueous NaOH to remove inhibitors (e.g. *tert*-butanol), then with water, dry it for several hours with $MgSO_4$ and distil it at 25° under reduced pressure in the presence of an inhibitor (such as 0.005% *p-tert*-butylcatechol). It can be stored at -78°. It can also be stored and kept anhydrous with Linde type 5A molecular sieves, CaH_2, $CaSO_4$, BaO or sodium, being fractionally distilled, and distilled in a vacuum line just before use. *Alternatively*, styrene (and its deuterated derivative) are passed through a neutral alumina column before use [Woon et al. *J Am Chem Soc* **108** 7990 *1986*, Collman *J Am Chem Soc* **108** 2588 *1986*]. [*Beilstein* **5** IV 1334.]

(±)-Styrene glycol (±-1-phenyl-1,2-ethanediol) *[93-56-1]* **M 138.2, m 67-68°, 272-274°/755mm.** Crystallise the diol from petroleum ether, Et_2O, Et_2O/*C_6H_6 (**m** 69-70°) or *C_6H_6. The *dibenzoyl dervative* has **m** 96-97°. [*Beilstein* **6** H 907, **6** I 444, **6** II 887, **6** III 4572, **6** IV 5939.]

Styrene oxide *[96-09-3]* **M 120.2, b 84-86°/16.5mm, d_4^{20} 1.053, n_D^{25} 1.535.** Fractional distillation under reduced pressure does not remove phenylacetaldehyde. If this material is present, the styrene oxide is treated with hydrogen under 3 atmospheres pressure in the presence of platinum oxide. The aldehyde, but not the oxide, is reduced to ß-phenylethanol, and separation is now readily achieved by fractional distillation. [Schenck & Kaizermen *J Am Chem Soc* **75** 1636 *1953*, *Beilstein* **17/1** V 577.]

Sudan II (Sudan Blue, Solvent Blue 35, 1,4-bis-(butylamino)-9,10-anthraquinone) *[17354-14-2]* **M 350.5, m 122°, λ_{max} 604, 652nm, pK_{Est} ~9.5 (OH).** It is formed from quinizarin (2g see [81-64-1]), 33% EtOH/*n*-$BuNH_2$ (20ml) and $Na_2S_2O_4$ (2g) at 140°/8 hours, evaporate, extract with toluene, chromatograph (Al_2O_3), the intense blue band in toluene is evaporated, and the residue gave purple needles (Cu lustre) from petroleum ether (b 60-80°) (1.1g, 38%) [Peters & Walker *J Chem Soc* 1429 *1956*, *Beilstein* **14** IV 460]. It forms Cu and Ni salts.

Sudan III [Solvent Red 23, 1-(*p*-phenylazo-phenylazo)-2-naphthol] *[85-86-9]* **M 352.4, m 199°(dec), CI 26100, λ_{max} 354, 508 nm, pK_{Est} ~9.0.** Crystallise the dye from EtOH, EtOH/water or *benzene/absolute EtOH (1:1). [*Beilstein* **16** II 75, **16** III 148, **16** IV 248.]

Sudan IV [Solvent Red 24, 1-(4-*o*-tolylazo-*o*-tolylazo)-2-naphthol] *[85-83-6]* **M 380.5, m ~184°(dec), CI 26105, λ_{max} 520nm, pK_{Est} ~9.0.** Crystallise the dye from EtOH/water or acetone/water. [*Beilstein* **16** IV 249.]

Sulfaguanidine *[57-67-0]* **M 214.2, m 189-190°, pK_1 0.48, pK_2 2.75.** Crystallise the antibacterial from hot water (7ml/g). [*Beilstein* **14** III 1970, **14** IV 2668.]

Sulfanilic acid (4-aminobenzenesulfonic acid) *[121-57-3]* **M 173.2, pK_1^{25} <1, pK_2^{25} 3.23.** Crystallise the acid (as *dihydrate*) from boiling water. Dry it at 105° for 2-3 hours, then over 90% H_2SO_4 in a vacuum desiccator. The *S-benzylisothiuronium salt* has **m** 187° (from aqueous EtOH). [*Beilstein* **14** IV 2655.]

***o*-Sulfobenzoic acid (H_2O)** *[123333-68-6 (H_2O), 632-25-7]* **M 202.2, m 68-69°, $pK_{Est(1)}$<1, $pK_{Est(2)}$~3.1 (CO_2H).** Crystallise the acid from water. The *S-benzylisothiuronium salt* has **m** 205.5-206.5° (from aqueous EtOH). [*Beilstein* **1** II 215, **1** III 658.] The *monoammonium salt [6939-89-5]* **M 219.5**, crystallises from water.

5-Sulfosalicylic acid *[5965-83-3]* **M 254.2, m 108-110°, pK_1^{25} <0, pK_2^{25} 2.67, pK_3^{25} 11.67.** Crystallise the acid from H_2O. *Alternatively*, it is converted to the monosodium salt which is crystallised from H_2O and washed with a little H_2O, EtOH and then Et_2O. The acid is recovered by acidifying. The *S-4-chlorobenzylisothiuronium salt* has **m** 181° (from dioxane). [*Beilstein* **11** H 411, **11** II 232, **11** III 704.]

Syringaldehyde (3,5-dimethoxy-4-hydroxybenzaldehyde) *[134-96-3]* **M 182.2, m 113°, pK_{Est} ~8.** Crystallise syringaldehyde from petroleum ether. [*Beilstein* **8** H 391, **8** IV 2718.]

Syringic acid (3,5-dimethoxy-4-hydroxybenzoic acid) *[530-57-4]* **M 198.2, m 204-205°, 206.5°, 206-209°, 209-210°, pK_1^{25} 4.34, pK_2^{25} 9.49.** Recrystallise syringic acid from H_2O using charcoal [Bogert & Coyne *J Am Chem Soc* **51** 571 *1929*, Anderson & Nabenhauer *J Am Chem Soc* **48** 3001 *1926*.] The *methyl ester* has **m** 107° (from MeOH), the *4-acetyl* derivative has **m** 190° and the *4-benzoyl* derivative has **m** 229-232°. [Hahn & Wassmuth *Chem Ber* **67** 2050 *1934*, UV: Lemon *J Am Chem Soc* **69** 2998 *1947* and Pearl & Beyer *J Am Chem Soc* **72** 1743 *1950*, *Beilstein* **10** IV 1995.]

Terephthalaldehyde *[623-27-8]* **M 134.1, m 116°, b 245-248°/771mm.** Crystallise terephthalaldehyde from water. [*Beilstein* **7** IV 2140.]

Terephthalic acid (benzene-1,4-dicarboxylic acid) *[100-21-0]* **M 166.1, m sublimes >300° without melting, pK_1^{20} 3.4, pK_2^{20} 4.34.** Purify the acid *via* the sodium salt which, after crystallisation from water, is re-converted to the acid by acidification with mineral acid. Filter off the solid, wash it with H_2O and dry it in a vacuum. The *S-benzylisothiuronium salt* has **m** 204° (from aqueous EtOH). [*Beilstein* **9** IV 3301.]

Terephthaloyl chloride *[100-20-9]* **M 203.0, m 80-82°.** Crystallise the acid chloride from dry hexane. [*Beilstein* **9** IV 3318.]

***o*-Terphenyl** *[84-15-1]* **M 230.3, m 58-59°, b 337°/atm.** Crystallise *o*-terphenyl from EtOH. Also purify it by chromatography of CCl_4 solution on alumina, with petroleum ether as eluent, followed by crystallisation from petroleum ether (b 40-60°) or petroleum ether/*C_6H_6. It also distils under vacuum. [*Beilstein* **5** III 2292, **5** IV

2478.]

m-**Terphenyl** *[92-06-8]* **M 230.3, m 88-89°, b 379°/atm.** Purify it as for *o*-terphenyl above. [*Beilstein* **5** IV 2480.]

p-**Terphenyl (1,4-diphenylbenzene)** *[92-94-4]* **M 230.3, m 212.7°, b 389°/atm.** Crystallise *p*-terphenyl from nitrobenzene or trichlorobenzene. It is also purified by chromatography on alumina in a darkened room, using petroleum ether, and then crystallising from petroleum ether (b 40-60°) or petroleum ether/*benzene. It is a fluorophore for scintillation counting and has λ_{ex} 286nm : λ_{em} 343nm in DMF, and λ_{max} at 277nm (logε 4.50). [*Beilstein* **5** IV 2483.]

Terreic acid (2-hydroxy-3-methyl-1,4-benzoquinone-5,6-epoxide) *[121-40-4]* **M 154.1, m 127-127.5°, $[\alpha]_D^{22}$ +74° (pH 4, phosphate buffer), -17° ($CHCl_3$), pK^{25} 4.5.** Crystallise terreic acid from *C_6H_6, *C_6H_6/petroleum ether or hexane. Sublime it 80-100°/1mm. [*Beilstein* **17** IV 6698.]

3',3",5',5"-Tetrabromophenolphthalein ethyl ester *[1176-74-5]* **M 662.0, m 212-214°.** Crystallise the ester from *benzene, dry at 120° and keep it under vacuum. [*Beilstein* **10** III 4490.]

2,3,4,5-Tetrachloroaniline *[634-83-3]* **M 230.9, m 117-118°, 119-120°, pK_{Est} ~–0.26.** Crystallise it from EtOH. The *acetyl* derivative has **m** 165-166° (from EtOH). [*Beilstein* **12** H 630, **12** I 313, **12** II 340, **12** IV 1286.]

2,3,5,6-Tetrachloroaniline *[3481-20-7]* **M 230.9, m 107-108°, pK_{Est} ~–1.8.** Crystallise it from EtOH. The *acetyl* derivative has **m** 213-214° (from EtOH). [*Beilstein* **12** II 340, **12** III 1414, **12** IV 1287.]

1,2,3,4-Tetrachlorobenzene *[634-66-2]* **M 215.9, m 45-46°, 47.5°, b 254°/760mm.** Crystallise it from EtOH. [*Beilstein* **5** H 204, **5** II 156, **5** III 550, **5** IV 667.]

1,2,3,5-Tetrachlorobenzene *[634-90-2]* **M 215.9, m 50-51°, 51°, 54-55°, b 246°/760mm, d^{10} 1.7344.** Crystallise it from EtOH. [*Beilstein* **5** II 157, **5** III 551, **5** IV 668.]

1,2,4,5-Tetrachlorobenzene *[95-94-3]* **M 215.9, m 139.5-140.5°, b 240°/760mm.** Crystallise it from EtOH, ether, *benzene, *benzene/EtOH or carbon disulfide. [*Beilstein* **5** IV 668.]

3,4,5,6-Tetrachloro-1,2-benzoquinone (*o*-chloranil) *[2435-53-2]* **M 245.9, m 130°.** Crystallise *o*-chloranil from AcOH. Dry it in vacuum desiccator over KOH. [*Beilstein* **7** IV 2068.]

Tetrachloro-*N*-methylphthalimide *[14737-80-5]* **M 298.9, m 209.7°.** Crystallise the imide from absolute EtOH. [*Beilstein* **21** H 505, **17/11** V 260.]

2,3,4,6-Tetrachloronitrobenzene (1,2,3,5-tetrachloro-4-nitrobenzene) *[879-39-0]* **M 260.9, m 41-42°, 42°.** Crystallise it from aqueous EtOH. [*Beilstein* **5** II 187, **5** III 617, **5** IV 728.]

2,3,5,6-Tetrachloronitrobenzene (1,2,4,5-tetrachloro-3-nitrobenzene) *[117-18-0]* **M 260.9, m 99-100°.** Crystallise it from aqueous EtOH or H_2O. [*Beilstein* **5** III 617, **5** IV 728.]

2,3,4,5-Tetrachlorophenol *[4901-51-3]* **M 231.9, m 116-117°, pK^{25} 6.95.** Crystallise the phenol from petroleum ether. The *benzoate* has **m** 110° (from EtOH). [*Beilstein* **6** II 182, **6** III 729, **6** IV 1020.]

2,3,4,6-Tetrachlorophenol *[58-90-2]* **M 231.9, m 70°, b 150°/15mm, pK^{25} 5.38.** Crystallise the phenol from petroleum ether. The *benzoate* has **m** 116° (from EtOH). [*Beilstein* **6** H 193, **6** III 729, **6** IV 1021.]

2,3,5,6-Tetrachlorophenol *[935-95-5]* **M 231.9, m 115°, pK^{25} 5.48.** Crystallise the phenol from petroleum ethers. The *benzoate* has **m** 136° (from EtOH). [*Beilstein* **6** II 182, **6** III 730, **6** IV 1025.]

Tetrachlorophthalic anhydride *[117-08-8]* **M 285.9, m 255-257°.** Crystallise the anhydride from chloroform or *benzene, then sublime it in a vacuum. [*Beilstein* **17/11** V 260.]

1,2,4,5-Tetracyanobenzene *[712-74-3]* **M 178.1, m 270-272° (280°).** Crystallise the tetra-nitrile from EtOH and sublime *in vacuo*. [Lawton & McRitchie *J Org Chem* **24** 26 *1959*, Bailey et al. *Tetrahedron* **19** 161 *1963*, *Beilstein* **9** IV 3800.]

Tetrahydroxy-*p*-benzoquinone ($2H_2O$) *[5676-48-2; 123334-16-7 $2H_2O$]* **M 208.1, pK_1^{30} 4,80, pK_2^{30} 6.8.** Crystallise the quinone from water. [*Beilstein* **8** H 534, **8** II 572, **8** III 4204, **8** IV 3604.]

Tetralin (1,2,3,4-tetrahydronaphthalene) *[119-64-2]* **M 132.2, m –35.79° (from CF_2Cl_2), b 65-66°/5mm, 207.6°/760mm, d_4^{20} 0.968, n_D^{20} 1.5413.** Wash tetralin with successive portions of conc H_2SO_4 until the acid layer is no longer coloured, then wash it with aqueous 10% Na_2CO_3, and then distilled water. Dry ($CaSO_4$ or Na_2SO_4), filter, reflux and fractionally distil it under under reduced pressure from sodium or BaO. It can also be purified by repeated fractional freezing.
Bass [*J Chem Soc* 3498 *1964*] freed tetralin, purified as above, from naphthalene and other impurities by conversion to ammonium tetralin-6-sulfonate. Concentrated H_2SO_4 (150ml) is added slowly to stirred tetralin (272ml) which is then heated on a water bath for about 2 hours for complete solution. The warm mixture, when poured into aqueous NH_4Cl solution (120g in 400ml water), gives a white precipitate which, after filtering off, is crystallised from boiling water, washed with 50% aqueous EtOH and dried at 100°. Evaporation of its boiling aqueous solution on a steam bath removes traces of naphthalene. The pure salt (229g) is mixed with conc H_2SO_4 (266ml) and steam distilled from an oil bath at 165-170°. An ether extract of the distillate is washed with aqueous Na_2SO_4, and the ether is evaporated, prior to distilling the tetralin from sodium. Tetralin has also been purified *via* barium tetralin-6-sulfonate, conversion to the sodium salt and decomposed in 60% H_2SO_4 using superheated steam. [*Beilstein* **5** H 491, **5** III 1219, **5** IV 1388.]

Tetralin hydroperoxide *[771-29-9]* **M 164.2, m 55.7-56°, 56°.** Crystallise the tetralin hydroperoxide from hexane, toluene at -30° (**m** 54.0-54.5°). The oxygen content should be ~9.70%. [Knight & Swern *Org Synth* Coll Vol **1V** 895 *1963*.]

α-Tetralone (1,2,3,4-tetrahydro-1-oxonaphthalene) *[529-34-0]* **M 146.2, m 2-7°, 7.8-8.0°, b 75-85°/0.3mm, 89°/0.5mm, 94-95°/2mm, 132-134°/15mm, 143-145°/20mm, d_4^{20} 1.0695, n_D^{20} 1.5665.** Check the IR first. Purify α-tetralone by dissolving 20ml in Et_2O (200ml), washing with H_2O (100ml), 5% aqueous NaOH (100ml), H_2O (100ml), 3% aqueous AcOH (100ml), 5% $NaHCO_3$ (100ml) then H_2O (100ml) and dry the ethereal layer over $MgSO_4$. Filter, evaporate and fractionate the residue through a 6in Vigreux column under reduced pressure to give a colourless oil (~17g) with **b** 90-91°/0.5-0.7mm. [Snyder & Werber *Org Synth* Coll Vol **III** 798 *1955*.] It has also been fractionated through a 0.5metre packed column with a heated jacket under reflux using a partial take-off head. It has λ_{max} at 247.5 and 290nm (hexane). The *phenylhydrazone* has **m** 83°. The *2,4,6-trinitrophenylhydrazone* has **m** 247.5-248° (from EtOH). [Olson & Bader *Org Synth* Coll Vol **IV** 898 *1963*, *Beilstein* **7** H 370, **7** III 1416, **7** IV 1015.]

β-Tetralone (1,2,3,4-tetrahydro-2-oxonaphthalene) *[530-93-8]* **M 146.2, m 17-18°, ~18°, b 93-95°/2mm, 104-105°/4mm, 114-115°/4-5mm, 140°/18mm, d_4^{20} 1.1000, n_D^{20} 1.5598.** If reasonably pure, then fractionate it through an efficient column. Otherwise purify it *via* the *bisulfite adduct*. To a solution of $NaHSO_3$ (32.5g, 0.31mol) in H_2O (57ml) is added 95% EtOH (18ml) and set aside overnight. Any bisulfite-sulfate that separated is removed by filtration, and the filtrate is added to the tetralone (14.6g, 0.1mol) and shaken vigorously. The adduct separates in a few minutes as a white precipitate and is kept on ice for ~3.5 hours with occasional shaking. The precipitate is collected, washed with 95% EtOH (13ml), then with Et_2O (4 × 15ml, by stirring the suspension in the solvent, filtering and repeating the process). The colourless product is dried in air and stored in air tight containers in which it is stable for extended periods (yield is ~17g). This bisulfite (5g) is suspended in H_2O (25ml), and $Na_2CO_3.H_2O$ (7.5g) is added (pH of solution is ~10). The mixture is then extracted with Et_2O (5 × 10ml, i.e. until the aqueous phase does not test for tetralone — see below). Wash the combined extracts with 10% aqueous HCl (10ml), H_2O (10ml, i.e. until the washings are neutral), dry ($MgSO_4$), filter, evaporate and distil the residual oil using a Claisen flask under reduced pressure and in a N_2 atmosphere. The pure

tetralone is a colourless liquid **b** 70-71°/0.25mm (see also above). The yield is ~2g. **Tetralone test:** Dissolve a few drops of the tetralone solution (ethereal or aqueous) in 95% EtOH in a test tube and add 10 drops of 25% NaOH down the side of the tube. A deep blue colour develops at the interface with air. [Soffer et al. *Org Synth* Coll Vol **IV** 903 *1963*, Cornforth et al. *J Chem Soc* 689 *1942*, UV: Soffer et al. *J Am Chem Soc* 1556 *1952*.] The *phenylhydrazone* has **m** 108° [Crawley & Robinson *J Chem Soc* 2001 *1938*]. [*Beilstein* **7** H 370, **7** II 295, **7** III 1422, **7** IV 1018.]

1,2,3,4-Teteramethylbenzene (prehnitine) *[488-23-3]* **M 134.2, m -6.3°, b 79.4°/10mm, 204-205°/760mm, d_4^{20} 0.905, n_D^{20} 1.5203.** Dry it over sodium and distil under reduced pressure. The *picrate* has **m** 92-95° (EtOH). [*Beilstein* **5** H 430, **5** I 206. **5** II 329, **5** III 974, **5** IV 1072.]

1,2,3,5-Tetramethylbenzene (isodurene) *[527-53-7]* **M 134.2, m -23.7°, b 74.4°/10mm, 198°/760mm, d_4^{20} 0.890, n_D^{20} 1.5130.** Reflux isodurene over sodium and distil it under reduced pressure. [Smith *Org Synth* Coll Vol **II** 248 *1943*, *Beilstein* **5** H 430, **5** II 329, **5** III 976, **5** IV 1073.]

1,2,4,5-tetramethylbenzene (durene) *[95-93-2]* **M 134.2, m 79.5-80.5°, 191-192°/760mm.** Chromatograph durene on alumina, and recrystallise it from aqueous EtOH or *benzene. Zone-refining removes duroaldehydes. Dry it under vacuum. [Yamauchi et al. *J Phys Chem* **89** 4804 *1985*.] It has also been sublimed *in vacuo* [Johnston et al. *J Am Chem Soc* **109** 1291 *1987*]. [*Beilstein* **5** H 431, **5** I 207, **5** II 329, **5** III 979, **5** IV 1076.]

***N,N,N′,N′*-Tetramethylbenzidine** *[366-29-0]* **M 240.4, m 195.4-195.6°, $pK_{Est(1)}$~3.4, $pK_{Est(2)}$~4.5.** Crystallise the benzidine from EtOH or petroleum ether, then from petroleum ether/*benzene, and sublime it in a vacuum. [Guarr et al. *J Am Chem Soc* **107** 5104 *1985*.] Dry it *in vacuo* in a drying pistol, or a vacuum line. It has **m** 195-196° after sublimation. [*Beilstein* **13** H 221, **13** I 61, **13** II 97, **13** III 429, **13** IV 368.]

***p,p′*-Tetramethyldiaminodiphenylmethane [bis(*p*-dimethylaminophenyl)methane, Michler's base, (*p,p′*-methylene-bis-(*N,N*-dimethylaniline)]** *[101-61-1]* **M 254.4, m 89-90°, b 155-157°/0.1mm, $pK_{Est(1)}$~5.8, $pK_{Est(2)}$~5.1.** Crystallise the base from EtOH (2ml/g) or 95% EtOH (*ca* 12ml/g). It sublimes on heating. [*Beilstein* **13** IV 390.]

***N,N,N′,N′*-Tetramethyl-1,8-naphthalenediamine [Proton sponge, 1,8-bis-(dimethylamino)-naphthalene** *[20734-58-1]* **M 214.3, m 45-48°, 47-48°, b 144-145°/4mm, pK_1 -10.5 (from half protonation in 86% aqueous H_2SO_4, diprotonation), pK_2 12.34 (monoprotonation).** It is prepared by methylating 1,8-diaminonaphthalene, and likely impurities are methylated products. The tetramethyl compound is a stronger base than the unmethylated, di and trimethylated derivatives. The pKa values are: 1,8-$(NH_2)_2$ = 4.61, 1,8-$(NHMe)_2$ = 5.61, 1-NHMe-8-$NHMe_2$ = 6.43 and 1,8-$(NMe_2)_2$ = 12.34. The mixture is then treated with H_2O at pH 8 (where all but the required base are protonated) and extracted with Et_2O or $CHCl_3$. The dried extract (K_2CO_3) yields the tetramethyldiamine on evaporation which can be distilled. It is a strong base with weak nucleophilic properties, e.g. it could not be alkylated by refluxing with EtI in MeCN for 4 days; and on treatment with methyl fluorosulfonate only the fluorosulfonate salt of the base is obtained. [NMR: Adler et al. *J Chem Soc, Chem Commun* 723 *1968*, Brown & Letang *J Am Chem Soc* **63** 358 *1941*, Brzezinski et al. *J Chem Soc Perkin Trans 2* 857 *1991*.] *Alternatively*, crystallise proton sponge from EtOH and dry it in a vacuum oven. Store it in the dark in a CO_2-free atmosphere. [Benoit et al. *Can J Chem* **65** 996 *1987*, *Beilstein* **13** IV 344.]

***N,N,N′,N′*-Tetramethyl-1,4-phenylenediamine** *[100-22-1]* **M 164.3, m 51°, b 135°/14mm, 260°/760mm, pK_1^{20} 2.29, pK_2^{20} 6.35.** Crystallise the amine from petroleum ether or water. It can be sublimed or dried carefully in a vacuum line, and stored in the dark under nitrogen. It has been recrystallised from its melt. [*Beilstein* **13** H 74, **13** I 22, **13** II 40, **13** III 111, IV 107.]

***N,N,N′,N′*-Tetramethyl-1,4-phenylenediamine dihydrochloride (Wurster's Reagent)** *[637-01-4]* **M 237.2, m 222-224°.** Crystallise the salt from isopropyl or *n*-butyl alcohols, saturated with HCl. Treat it with aqueous NaOH to give the *free base* (see previous entry) which is filtered, dried and sublimed in a vacuum. [Guarr et al. *J Am Chem Soc* **107** 5104 *1985*, *Beilstein* **13** H 74.] Oxidase reagent (1% aqueous solution) used for testing cytochrome +ve aerobic microorganisms.

Tetra(*p*-nitrophenyl)ethylene *[47797-98-8]* **M 512.4, m 298-299°.** Crystallise it from dioxane or AcOH (**m** 292°, yellow needles), and dry it at 150°/0.1mm. [Gorvin *J Chem Soc* 678 *1959*, Schlenk *Justus Liebigs Ann Chem* **394** 214 *1913*, *Beilstein* **5** H 744, **5** IV 2780.]

Tetraphenylethylene *[632-51-9]* **M 332.4, m 223-224°, b 415-425°/760mm.** Crystallise the ethylene from dioxane or from EtOH/*C_6H_6. Sublime it under high vacuum. [*Beilstein* **5** H 743, **5** IV 2780.]

Tetraphenylhydrazine *[632-52-0]* **M 336.4, m 147°, pK_{Est} ~0.** Crystallise the hydrazine from 1:1 $CHCl_3$/toluene, 1:5 $CHCl_3$/EtOH (**m** 149°), *C_6H_6 or *C_6H_6/petroleum ether. Store it in a refrigerator, in the dark. [*Beilstein* **15** H 125, **15** I 29, **15** III 77, **15** IV 59.]

***trans*-1,1,4,4-Tetraphenyl-2-methylbutadiene** *[20411-57-8]* **M 372.5.** Crystallise it from EtOH.

5,6,11,12-Tetraphenylnaphthacene (Rubrene) *[517-51-1]* **M 532.7, m>315°, 322°, d_4^{20} 1.255.** Rubrene forms orange crystals on sublimation at 250-260°/3-4mm [UV Badger & Pearce *Spectrochim Acta* **4** 280 *1950*]. It has also been recrystallised from *benzene under red light because it is chemiluminescent and light sensitive. [*Beilstein* **5** IV 2968.]

1,2,3,4-Tetraphenylnaphthalene *[751-38-2]* **M 432.6, m 199-201°, 204-204.5°.** Crystallise the naphthalene from MeOH or EtOH. [Fieser & Haddadin *Org Synth* **46** 107 *1966*, *Beilstein* **5** IV 2918.]

Thioacetanilide *[677-53-6]* **M 151.2, m 75-76°, 76-79°, pK_{Est} ~13.1.** Crystallise thioacetanilide from H_2O and dry it *in vacuo*. [*Beilstein* **12** H 245, **12** I 193, **12** II 142, **12** III 464, **12** IV 378.]

Thiobenzanilide *[636-04-4]* **M 213.2, m 101.5-102°, pK_{Est} ~12.6.** Crystallise thiobenzanilide from MeOH at Dry-ice temperature.

Thio-Michler's Ketone [4,4'-bis(dimethylamino)thiobenzophenone] *[1226-46-6]* **M 284.4, m 102-106°, λ_{max} 457 nm (ε 2.92 × 10^4 in 30% aqueous *n*-propanol).** Purify the thioketone by recrystallisation from hot EtOH or by trituration with a small volume of $CHCl_3$, followed by filtration and washing with hot EtOH [Terbell & Wystrade *J Phys Chem* **68** 2110 *1964*]. Also it recrystallises from $CHCl_3$/ MeOH. [*Beilstein* **14** H 101, **14** I 395, **14** II 60.]

1-Thionaphthol *[529-36-2]* **M 160.2, b 106°/1.5mm, 208.5°/200mm, d_4^{20} 1.161, n_D^{20} 1.6802, pK^{25} 6.34.** It is steam volatile and is purified by distillation in the absence of O_2, as it oxidises to the disulfide. It is soluble in Et_2O and EtOH but very slightly soluble in H_2O and dilute alkalis. The *S-ethyl* derivative [17539-31-0] **M** 188.2, has **b** 175-176°/25mm, and **d°** 1.120. [*Beilstein* **6** III 2943, **6** IV 4241.]

2-Thionaphthol *[91-60-1]* **M 160.2, m 81.8-82.4°, 82°, b 153.5°/15mm, 286°/760mm, pK^{25} 6.47.** It is steam volatile. It has to be distilled under Ar or N_2, as it oxidises to the disulfide, and crystallises from EtOH. The *S-methyl* derivative has **m** 104-105° (from *C_6H_6/petroleum ether), and the *S-ethyl* derivative [32551-87-4] **M** 188.2, has m 16° and b 175-170.5°/15mm. The *S-acetate* [831-23-2] has **m** 53.5° and **b** 191°/15mm, and the *diethylamine salt* forms yellow needles **m** 107° from dioxane. [*Beilstein* **6** H 657, **6** I 316, **6** II 610, **6** III 3006, **6** IV 4312.]

Thiophenol (benzenethiol) *[108-98-5]* **M 110.2, f -14.9°, b 46.4°/10mm, 168.0°/760mm, d_4^{20} 1.073, n_D^{20} 1.5897, pK^{25} 6.62.** Dry thiophenol with $CaCl_2$ or $CaSO_4$, and distil it at 10mm pressure or at 100mm (**b** 103.5°) in a stream of nitrogen. The *2,4-dinitrophenyl thioether* has **m** 121° (from EtOH), and the *2,4-dinitrophenyl sulfone* has **m** 161° (from EtOH). [*Beilstein* **6** IV 1463.]

Thiosalicylic (2-mercaptobenzoic) acid *[147-93-3]* **M 154.2, m 164-165°, pK_1^{25} 3.54, pK_2^{25} 8.80.** Crystallise the thio acid from hot EtOH (4ml/g), after adding hot distilled water (8ml/g) and boiling with charcoal. The hot solution is filtered, cooled, the solid is collected and dried *in vacuo* (P_2O_5). Crystallise it from AcOH and sublime *in vacuo*. [*Beilstein* **10** IV 272.]

Thymol (2-isopropyl-5-methylphenol) *[89-83-8]* **M 150.2, m 49-51°, 51.5°, b 232°/atm, d^{25} 0.965, n_D^{25} 1.5204, pK^{20} 10.62.** It occurs in the volatile oils of *Thymus vulgaris* and *Moranda punctate* L. from which it was first isolated [Arppe *Justus Liebigs Ann Chem* **58** 41 *1846*]. It is quite volatile at 100°, and is steam volatile, separating as white crystals which have a characteristic pungent odour, with a caustic taste. It should be stored in the dark, preferably under N_2 as it oxidises slowly in air. It possesses antimould properties, is an internal and external antiseptic, and has nematode anthelmintic activity. The *acetate* [528-93-2] is a yellow irritating oil, **b 243.5-245.5°/atm, d^0 1.009**, with the odour of thymol, and is soluble in most organic solvents, but almost insoluble in H_2O. [*Beilstein* **6** IV 3334.]

Thymolphthalein complexone *[1913-93-5]* **M 720.8, m 190°(dec), $pK_1^{18.2}$ 7.35, $pK_2^{18.2}$ 12.25.** Purify it as for phthalein complexone except that it is synthesised from thymolphthalein instead of cresolphthalein. [*Beilstein* **18/4** V 194.]

o-**Tolidine (3,3'-dimethylbenzidine)** *[119-93-7]* **M 212.3, m 131-132°, pK^{25} 4.45.** Dissolve the tolidine in *benzene by percolation through a column of activated alumina and crystallise it from *benzene/petroleum ether. [*Beilstein* **13** IV 410.]

p-**Tolualdehyde** *[104-87-0]* **M 120.2, b 83-85°/0.1mm, 199-200°/760mm, d_4^{20} 1.018, n_D^{20} 1.548.** Steam distil the aldehyde, dry it with $CaSO_4$, then fractionally distil it. [*Beilstein* **7** IV 672.]

o-**Toluamide** *[527-85-5]* **M 135.2, m 141°, 144-145°.** Crystallise *o*-toluamide from hot water (10ml/g) and dry in air. [Noller *Org Synth* Coll Vol **II** 586 *1943*, *Beilstein* **9** H 465, **9** II 319, **9** III 2304.]

Toluene *[108-88-3]* **M 92.1, b 110.6°, d_4^{10} 0.87615, d_4^{25} 0.86231, n_D^{20} 1.49693, n_D^{25} 1.49413.** Dry toluene with $CaCl_2$, CaH_2 or $CaSO_4$, and dry further by standing with sodium, P_2O_5 or CaH_2. It can be fractionally distilled from sodium or P_2O_5. Unless specially purified, toluene is likely to be contaminated with methylthiophenes and other sulfur-containing impurities. These can be removed by shaking with conc H_2SO_4, but the temperature must be kept below 30° if sulfonation of toluene is to be avoided. A typical procedure consists of shaking toluene twice with cold conc H_2SO_4 (100ml of acid per L), once with water, once with aqueous 5% $NaHCO_3$ or NaOH, again with H_2O, then drying successively with $CaSO_4$ and P_2O_5, with final distillation from P_2O_5 or over $LiAlH_4$ after refluxing for 30 minutes. *Alternatively*, the treatment with $NaHCO_3$ can be replaced by boiling under reflux with 1% sodium amalgam. Sulfur compounds can also be removed by prolonged shaking of the toluene with mercury, or by two distillations from $AlCl_3$, the distillate then being washed with water, dried with K_2CO_3 and stored with sodium wire. Other purification procedures include refluxing and distillation of sodium dried toluene from diphenylpicrylhydrazyl, and from $SnCl_2$ (to ensure freedom from peroxides). It has also been co-distilled with 10% by volume of ethyl methyl ketone, and again fractionally distilled. [Brown & Pearsall *J Am Chem Soc* **74** 191 *1952*.] For removal of carbonyl impurities see **benzene*. Toluene has been purified by distillation under nitrogen in the presence of sodium benzophenone ketyl. Toluene has also been dried with $MgSO_4$, after the sulfur impurities have been removed, and then fractionally distilled from P_2O_5 and stored in the dark [Tabushi et al. *J Am Chem Soc* **107** 4465 *1985*]. Toluene can be purified by passage through a tightly packed column of Fuller's earth.
Rapid purification: Alumina, CaH_2 and 4A molecular sieves (3% w/v) may be used to dry toluene (6 hours stirring and standing). Then the toluene is distilled, discarding the first 5% of distillate, and is stored over molecular sieves (3A, 4A) or Na wire. [*Beilstein* **5** H 280, **5** I 144, **5** II 209, **5** III 651, **5** IV 766.]

Toluene-2,4-diamine (4-methyl-*m*-phenylenediamine) *[95-80-7]* **M 122.2, m 99°, b 148-150°/8mm, 292°/760mm, $pK_{Est(1)}$~2.5, $pK_{Est(2)}$~4.4.** Recrystallise the diamine from water containing a very small amount of sodium dithionite (to prevent air oxidation), and dry it under vacuum. It also crystallises from *benzene. [*Beilstein* **13** IV 235.]

o-**Toluenesulfonamide** *[88-19-7]* **M 171.2, m 155.5°.** Crystallise the amide from hot H_2O (**m** 153°), then from EtOH or Et_2O/petroleum ether. The *N*-o-*toluenesulfonylphthalimide* has **m** 182° (from EtOH). [Evans & Dehn *J Am Chem Soc* **51** 3652 *1929*, *Beilstein* **11** H 86, **11** I 23, **11** II 39, **11** III 167, **11** IV 229.]

p-**Toluenesulfonamide** *[70-55-3]* **M 171.2, m 137-137.5°, 138°.** Crystallise the amide from hot water, then from EtOH or Et_2O/petroleum ether. [*Beilstein* **11** H 104, **11** IV 376.]

p-**Toluenesulfonic acid** *[6192-52-5]* **M 190.2, m 38° (anhydrous), m 105-107° (monohydrate), pK^{25} 1.55.** Purify the acid by precipitation from a saturated solution at 0° by introducing HCl gas. It can also be crystallised from conc HCl, then crystallised from dilute HCl (charcoal) to remove benzenesulfonic acid. It has been crystallised from EtOH/water. Dry it in a vacuum desiccator over solid KOH and $CaCl_2$. *p*-Toluenesulfonic acid can be dehydrated by azeotropic distillation with *benzene or by heating at 100° for 4 hours under water-pump vacuum. The anhydrous acid can be crystallised from *benzene, $CHCl_3$, ethyl acetate, anhydrous MeOH, or from acetone by adding a large excess of *benzene. It can also be dried under vacuum at 50°. The *S-benzylisothiuronium salt* has **m** 182° (from aqueous EtOH). [*Beilstein* **11** IV 241.]

Toluenesulfonic acid hydrazide (tosylhydrazide) *[1576-35-8]* **M 186.2, m 108-110°, 109-110°.** Dissolve the hydrazide in hot MeOH (~1g/4ml), filter through Celite and precipitate the material by adding 2-2.5 volumes of distilled H_2O. Dry it in air or in a vacuum. [Fiedman et al. *Org Synth* Coll Vol **V** 1055 *1973*, *Beilstein* **11** II 66.]

p-**Toluenesulfonyl chloride (tosyl chloride)** *[98-59-9]* **M 190.7, m 66-69°, 67.5-68.5°, 69°, b 138-139°/9mm, 146°/15mm, 167°/36mm.** Material that has been standing for a long time contains tosic acid and HCl and has **m** *ca* 65-68°. It is purified by dissolving (10g) in the minimum volume of $CHCl_3$ (*ca* 25ml) filtered, and diluted with five volumes (i.e. 125ml) of petroleum ether (b 30-60°) to precipitate impurities. The solution is filtered, clarified with charcoal and concentrated to 40ml by evaporation. Further evaporation to a very small volume gives 7g of white crystals which are analytically pure, **m** 67.5-68.5°. (The insoluble material is largely tosic acid and has **m** 101-104°.) [Pelletier *Chem Ind (London)* 1034 *1953*.]
It also crystallises from toluene/petroleum ether in the cold, from petroleum ether (b 40-60°) or *benzene. Its solution in diethyl ether has been washed with aqueous 10% NaOH until colourless, then dried (Na_2SO_4) and crystallised by cooling in powdered Dry-ice. It has also been purified by dissolving in *benzene, washing with aqueous 5% NaOH , then dried with K_2CO_3 or $MgSO_4$, and distilled under reduced pressure and can be sublimed at high vacuum [Ebel *Chem Ber* **60** 2086*1927*]. [*Beilstein* **11** IV 375.]

p-**Toluenethiol (*p*-thiocresol)** *[106-45-6]* **M 124.2, m 43.5-44°, pK^{25} 6.82.** Crystallise the thiol from petroleum ether (b 40-70°). The *2,4-dinitrophenyl thioether* has **m** 103° (from EtOH), and the *2,4-dinitrophenyl sulfone* has **m** 190° (from EtOH). [*Beilstein* **6** IV 2153.]

***p*-Toluenethiosulfonic acid potassium salt (potassium *p*-toluenethiosulfonate)** *[28519-50-8]* **M 226.4, m 227-229°.** When a solution of KOH (64.9g, 86.5%, 1.0 mole) in H_2O (28ml) is cooled in an ice bath while it is saturated with H_2S (in an efficient **fume cupboard**) and excess of H_2S is flushed out with N_2 (important to remove excess of H_2S), a fresh solution of KHS is obtained. This is diluted with H_2O (117ml) and stirred, under N_2 at 55-60°, while ground *p*-toluenesulfonyl chloride (95.3g, 0.5mole, freed from any acid by dissolving in *C_6H_6, washing with 5% aqueous NaOH, drying with Na_2SO_4, evaporating and distilling at 146°/15mm) at such a rate as not to allow the temperature to rise above 60°. The deep yellow colour of the solution disappears after 90g is added and the chloride ceases to dissolve. The mixture is filtered rapidly with suction through a warmed funnel, and the filtrate is set aside at 0-5° for many hours. The solid is filtered off, dissolved in hot 80% EtOH (200ml), filtered to remove traces of S, cooled for many hours at 0-5°, and the white crystals of *potassium* p-*toluenethiosulfonate* (48-55g, 42-49%) are collected and air dried. [Woodward et al. *Org Synth* Coll Vol **V** 1016 *1988*, *Org Synth* **54** 33 *1974*, *Beilstein* **11** IV 482.]

Toluhydroquinone (2-methylbenzene-1,4-dione) *[95-71-6]* **M 124.1, m 128-129°, pK$_1^{20}$ 10.15, pK$_2^{20}$ 11.75.** Crystallise the quinone from EtOH. [*Beilstein* **6** IV 5866.]

o-**Toluic acid** *[118-90-1]* **M 136.2, m 102-103°, b 258-259°/760mm, pK^{25} 3.91.** Crystallise the acid from *benzene (2.5ml/g) and dry in air. The *S-benzylisothiuronium salt* has **m** 146° (from aqueous EtOH). [*Beilstein* **9** IV 1697.]

m-**Toluic acid** *[99-04-7]* **M 136.2, m 111-113°, b 263°/760mm, pK^{25} 4.27.** Crystallise the acid from water. [*Beilstein* **9** IV 1712.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*]. The *S-benzylisothiuronium salt* has **m** 140° (from aqueous EtOH).

p-**Toluic acid** *[99-94-5]* **M 136.2, m 178.5-179.5°, b 274-275°/760mm, pK^{25} 4.37.** Crystallise the acid from water, water/EtOH (1:1), MeOH/water or *benzene. [*Beilstein* **9** IV 1724.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*]. The *S-benzylisothiuronium salt* has **m** 164° (from aqueous EtOH).

o-**Toluidine (2-methylaniline)** *[95-53-4]* **M 107.2, f -16.3°, b 80.1°/10mm, 200.3°/760mm, d $_4^{20}$ 0.999, n $_D^{20}$ 1.57246, n $_D^{25}$ 1.56987, pK^{25} 4.45.** In general, methods similar to those for purifying aniline can be used, e.g. distillation from zinc dust, at reduced pressure, under nitrogen. Berliner and May [*J Am Chem Soc* **49** 1007 *1927*] purified it *via* the oxalate. Twice-distilled *o*-toluidine is dissolved in four times its volume of diethyl ether, and the equivalent amount of oxalic acid needed to form the dioxalate is added as its solution in diethyl ether. (If *p*-toluidine is present, its oxalate precipitates and can be removed by filtration.) Evaporation of the ethereal solution gives crystals of *o*-toluidine dioxalate [*Beilstein* **12** III 1494, **12** IV 1817]. These are filtered off, recrystallised five times from water containing a small amount of oxalic acid (to prevent hydrolysis), then treated with dilute aqueous Na_2CO_3 to liberate the amine which is separated, dried ($CaCl_2$) and distilled under reduced pressure. The *benzoyl* derivative has **m** 144° (from EtOH). [*Beilstein* **12** H 772, **12** I 372, **12** II 429, **12** III 1837, **12** IV 1744.]

m-**Toluidine (3-methylaniline)** *[108-44-1]* **M 107.2, f -30.4°, b 82.3°/10mm, 203.4°/ 760mm, d $_4^{20}$ 0.989, n $_D^{20}$ 1.56811, n $_D^{25}$ 1.56570, pK^{25} 4.71.** It can be purified as for aniline. Twice-distilled, *m*-toluidine is converted to the hydrochloride using a slight excess of HCl, and the salt is fractionally crystallised from 25% EtOH (five times), and from distilled water (twice), rejecting, in each case, the first material that crystallised out. The amine is regenerated and distilled as for *o*-toluidine. The *benzoyl* derivative has **m** 125° (from EtOH). [Berliner & May *J Am Chem Soc* **49** 1007 *1927*, *Beilstein* **12** H 853, **12** I 397, **12** II 463, **12** III 1949, **12** IV 1813.]

p-**Toluidine (4-methylaniline)** *[106-49-0]* **M 107.2, m 44.8°, b 79.6°/10mm, 200.5°/ 760mm, d $_4^{20}$ 0.962, n $_D^{20}$ 1.5636, n $_D^{59.1}$ 1.5534, pK^{25} 5.08.** In general, methods similar to those for purifying aniline can be used. It can be separated from the *o*- and *m*-isomers by fractional crystallisation from its melt. *p*-Toluidine has been crystallised from hot water (charcoal), EtOH, *benzene, petroleum ether or EtOH/water (1:4), and dried in a vacuum desiccator. It can also be sublimed at 30° under vacuum. For further purification, use has been made of the oxalate, the sulfate and acetylation. The oxalate, formed as described for *o*-toluidine, is filtered, washed and recrystallised three times from hot distilled water. The base is regenerated with aqueous Na_2CO_3 and recrystallised three times from distilled water. [Berliner & May *J Am Chem Soc* **49** 1007 *1927*.] *Alternatively*, *p*-toluidine is converted to its acetyl derivative which, after repeated crystallisation from EtOH, is hydrolysed by refluxing (50g) in a mixture of 500ml of water and 115ml of conc H_2SO_4 until a clear solution is obtained. The amine sulfate is isolated, suspended in water, and NaOH is added. The free base is distilled twice from zinc dust under vacuum. The *p*-toluidine is then recrystallised from petroleum ether and dried in a vacuum desiccator or in a vacuum for 6 hours at 40°. The *benzoyl* derivative has **m** 158° (from EtOH). [Berliner & Berliner *J Am Chem Soc* **76** 6179 *1954*, Moore et al. *J Am Chem Soc* **108** 2257 *1986*, *Beilstein* **12** H 880, **12** I 140, **12** II 482, **12** III 2017, **12** IV 1866.]

p-**Toluidine hydrochloride** *[540-23-8]* **M 143.6, m 245.9-246.1°.** Crystallise the salt from MeOH containing a few drops of conc HCl or aqueous EtOH. Dry it under vacuum over paraffin chips. [*Beilstein* **12** II 587, **12** III 2021, **12** IV 1869.]

2-*p*-Toluidinylnaphthalene-6-sulfonic acid *[7724-15-4]* **M 313.9, pK$_{Est}$ ~0.** Crystallise the acid twice from 2% aqueous KOH and dry it under high vacuum for 4 hours at room temperature. It also crystallises from H_2O. It is tested for purity by TLC on silica gel with isopropanol as solvent. The free acid is obtained by acidifying a saturated aqueous solution. [*Beilstein* **14** H 762.]

o-**Tolunitrile** *[529-19-1]* **M 117.2, b 205.2°, d $_4^{20}$ 0.992, n $_D^{20}$ 1.5279.** Fractionally distil the nitrile, wash it with conc HCl or 50% H_2SO_4 at 60° until the smell of isonitrile has gone (this also removes any amines), then wash it with saturated $NaHCO_3$ and dilute NaCl solutions, then dry it with K_2CO_3 and redistil it. [*Beilstein* **9** IV 1703.]

m-**Tolunitrile** *[620-22-4]* **M 117.2, b 209.5-210°/773mm, d $_4^{20}$ 0.986, n $_D^{20}$ 1.5250.** Dry the nitrile with $MgSO_4$, fractionally distil it, then wash it with aqueous acid to remove possible traces of amines, dry and redistil it. [*Beilstein* **9** H 477, **9** I 191, **9** II 325, **9** III 2324, **9** IV 1717.]

p-**Tolunitrile** *[104-85-8]* **M 117.2, m 29.5°, b 104-106°/20mm.** Melt the nitrile, dry it with $MgSO_4$, fractionally crystallise it from its melt, then fractionally distil it under reduced pressure in a 6-in spinning band column. [Brown *J Am Chem Soc* **81** 3232 *1959*.] It can also be crystallised from *benzene/petroleum ether (b 40-60°). [*Beilstein* **9** H 489, **9** I 194, **9** II 330, **9** III 2348, **9** IV 1738.]

4-Tolyl-2-benzoic acid (4'-methylbiphenyl-2-carboxylic acid) *[7148-03-0]* **M 212.2, m 138-139°, 146-148°, pK^{25} 3.64.** Crystallise the acid from toluene or *C_6H_6 (**m** 147-148°). [*Beilstein* **9** H 677, **9** IV 2523.]

p-**Tolyl carbinol (4-methylbenzyl alcohol)** *[589-18-4]* **M 122.2, m 59.5-60°, 61°, b 116-118°/20mm, 217°/760mm.** Crystallise the alcohol from petroleum ether (b 80-100°, 1g/ml), Et_2O, pentane or H_2O (**m** 61-62.1°). It can also be distilled in a vacuum. [*Beilstein* **6** H 498, **6** I 248, **6** II 469, **6** III 1779.]

p-**Tolyl disulfide** *[103-19-5]* **M 246.4, m 45-46°, 168°/45mm.** Purify it by chromatography on alumina using hexane as eluent, then crystallise it from MeOH, and/or distil it in a vacuum. [Kice & Bowers *J Am Chem Soc* **84** 2384 *1962*, *Beilstein* **6** H 245, **6** I 212, **6** II 400, **6** III 1432, **6** IV 3206.]

Tolylene-2,4-diisocyanate (toluene-2,4-diisocyanate) *[584-84-9]* **M 174.2, m 19.5-21.5°, 20-22°, 28°, b 126°/11mm, 124-126°/18mm, 250°/760mm.** It is purified by fractionation in a vacuum and should be stored in a dry atmosphere. It is soluble in organic solvents but reacts with H_2O, alcohols (slowly) and amines, all of which could cause explosive polymerisation. It darkens on exposure to light. It has a sharp pungent odour, is **TOXIC** and is **IRRITATING TO THE EYES.** [Siefken *Justus Liebigs Ann Chem* **562** 75, 96, 127 *1949*, Bayer *Angew Chem* **59** 257 *1947*.] It is a reagent for covalent crosslinking of proteins [Wold *Methods Enzymol* **25** 623 *1972*.] [*Beilstein* **13** IV 243.]

Tolylene-2,6-diisocyanate (2-methyl-*m*-phenylenediisocyanate) *[91-08-7]* **M 174.2, b 129-133°/18mm, d^{25} 1.225.** It is purified by fractional distillation in a vacuum. Store it under N_2 in sealed dark ampoules as it is water and light sensitive. Like the preceding 2,4-isomer, it has a sharp pungent odour, is **TOXIC** and is **IRRITATING TO THE EYES.** [*Beilstein* **13** IV 259.]

***p*-Tolylsulfonylmethyl isocyanide (tosylmethyl isocyanide, TOSMIC)** *[36635-61-7]* **M 195.2, m 114-115°(dec), 116-117°(dec).** Use an efficient fume cupboard. Purify TOSMIC by dissolving (50g) in CH_2Cl_2 (150ml) and passing it through a column (40×3cm) containing neutral alumina (100g) in CH_2Cl_2 and eluting with CH_2Cl_2. A nearly colourless solution (700ml) is collected, evaporated *in vacuo* and the residue (42-47g) of TOSMIC (**m** 113-114° dec) is recrystallised once from MeOH (**m** 116-117° dec). [Hoogenboom et al. *Org Synth* **57** 102 *1977*, Lensen *Tetrahedron Lett* 2367 *1972*.] It also crystallises from EtOH (charcoal) [Saito & Itano, *J Chem Soc, Perkin Trans 1* 1 *1986*].
If the reagent had deteriorated considerably it can be synthesised in two steps. *Firstly N-(p-tolylsulfonylmethyl)formamide* is prepared by adding a mixture of aqueous 34-37% formalin (378g, 350ml, ~4.4moles), H_2O (750ml), excess of formamide (680g, 600ml, 15.5moles) and formic acid (244g, 200ml, 5.3moles) to sodium *p*-toluenesulfinate (267g, 1.5moles), and stirring at 90° to form a clear solution; and then heating at 90-95° is continued for 2 hours (prolonged heating diminishes the yield). The mixture is cooled (ice-salt bath) with continuous stirring, and set aside at -20° overnight after seeding. The white solid is collected, washed by stirring with ice-H_2O (3×250ml) and drained well. To removed occluded H_2O, the solid is dissolved in CH_2Cl_2, H_2O is removed (separating funnel), the organic layer is dried ($MgSO_4$), filtered, evaporated, and the residue is dried (over P_2O_5 at 70°) *in vacuo*, to give crude product (134-150g, 42-47%, m 106-110°) which is used in the following step. Pure *N-(p-tolylsulfonylmethyl)formamide*, **m 108-110°,** can be obtained by

recrystallisation from *C_6H_6 or 95% aqueous EtOH.
In the *second step*, with exclusion of moisture, $POCl_3$ (84g, 50ml, 0.55mole) in 1,2-dimethoxyethane (60ml) is added dropwise to a stirred solution of the crude preceding formamide (107g, 0.50mole) in 1,2-dimethoxyethane (250ml), anhydrous Et_2O (100ml) and Et_3N (255g, 350ml, 2.52moles) cooled to -5° (ice-salt bath), at such a rate as to keep the temperature between -5° and 0° (requires ~1 hour). During the reaction, the formamide dissolves, white Et_3NH^+ salts separate, and at the end of the reaction the suspension turns brown in colour. If the mixture is not brownish in colour then more $POCl_3$ needs to be added. Finally the mixture is stirred for 30 minutes at 0° and ice-H_2O (1.5L) is added to give a clear brown solution before a fine brown crystalline solid separates. Stir the mixture for 30 minutes at 0°, collect the solid, wash it with cold H_2O (250ml), dissolve the solid in warm *C_6H_6 (400ml at 40-60°), separate the H_2O, dry the organic layer ($MgSO_4$), filter, add charcoal (2g), heat at 60° for 5 minutes, filter, and add petroleum ether (1L, b 40-60°) with swirling. After 30 minutes, the solid is filtered off, dried *in vacuo* to give crude TOSMIC (74-82g, 76-84%) m 111-114° (dec), which can be used for most purposes. Analytically pure product can be obtained by a *third* purification through neutral Al_2O_3 as stated above. It has IR (Nujol) with ν_{max} at 2150 (N=C), 1320 and 1155 (SO_2) cm^{-1}, and the ^1H NMR ($CDCl_3$) has δ at 7.7 (q, 4H, C_6H_4), 4.6 (s, 2H, CH_2) and 2.5 (s, 3H, CH_3). [Hoogenboom et al. *Org Synth* Coll Vol **VI** 987 *1988*.] It is a versatile reagent, provides a formaldehyde anion or dianion equivalent, is used for the synthesis of various keto compounds and under reducing conditions amino and methylamino compounds have been prepared from the same intermediates, and it has been used for the preparation of several classes of heterocyclic compounds [van Leusen *Lect Heterocycl Chem* **5** S111 *1980*, see also a supplementary issue of Vol **17** of *J Heterocycl Chem*].

p-**Tolyl urea** *[622-51-5]* **M 150.2, m 181°.** Crystallise the urea from H_2O (**m** 186°), EtOH/water (1:1) or aqueous AcOH (**m** 184°). [*Beilstein* **12** H 941, **12** I 425, **12** II 512, **12** III 2084, **12** IV 1923.]

Tribenzylamine *[620-40-6]* **M 287.4, m 93-94°, 230°/13mm, pK_{Est} <0.** Crystallise the amine from absolute EtOH or petroleum ether. Dry it in a vacuum over P_2O_5 at room temperature. The *hydrochloride* has **m** 226-228° (from EtOH) and the *picrate* has **m** 191° (from H_2O or aqueous EtOH). [*Beilstein* **12** IV 2183.]

2,4,6-Tribromoacetanilide *[607-93-2]* **M 451.8, m 232°, 238-240°, 240°.** Crystallise the anilide from EtOH. [*Beilstein* **12** II 359, **12** III 1478.]

2,4,6-Tribromoaniline *[147-82-0]* **M 329.8, m 120°, 122°, pK_{Est} ~-0.5 (aqueous H_2SO_4).** Crystallise the aniline from MeOH. The *benzenesulfonamide* derivative has **m** 198°. [*Beilstein* **12** H 663, **12** I 329, **12** II 358, **12** III 1477, **12** IV 1538.]

***sym*-Tribromobenzene (1,3,5-tribromobenzene)** *[626-39-1]* **M 314.8, m 122°.** Crystallise it from glacial acetic acid/water (4:1), then wash with chilled EtOH and dry in air. [*Beilstein* **5** H 213, **5** IV 685.]

2,4,6-Tribromophenol *[118-79-6]* **M 330.8, m 94°, pK^{25} 6.00.** Crystallise the phenol from EtOH or petroleum ether. Dry it under vacuum over P_2O_5 at room temperature. [*Beilstein* **6** IV 1067.]

***sym*-Tri-*tert*-butylbenzene** *[1460-02-2]* **M 246.4, m 73.4-73.9°.** Crystallise it from EtOH. [*Beilstein* **5** IV 1206.]

2,4,6-Tri-*tert*-butylphenol *[732-26-3]* **M 262.4, m 129-132°, 131-131.2°, b 131°/1mm, 147°/10mm, 278°/760mm, pK^{25} 12.19.** Distil the phenol under reduced pressure and/or recrystallise it from *n*-hexane or several times from 95% EtOH until the EtOH solution is colourless [Balasubramanian & Bruice *J Am Chem Soc* **108** 5495 *1986*]. It has also been purified by sublimation [Yuan & Bruice *J Am Chem Soc* **108** 1643 *1986*, Wong et al. *J Am Chem Soc* **109** 3428 *1987*]. Purification has also been achieved by passage through a silica gel column followed by recrystallisation from *n*-hexane [Kajii et al. *J Phys Chem* **91** 2791 *1987*]. [*Beilstein* **6** III 2094, **6** IV 3539.]

Trichloroacetanilide *[2563-97-5]* **M 238.5, m 93.5-94°, 95°.** Crystallise the anilide from *benzene or 90% EtOH (**m** 93.5-95.5°). [Sukornick *Org Synth* Coll Vol **V** 1074 *1973*, *Beilstein* **12** H 224, **12** I 193, **12** II 142, **12**

III 464, **12** IV 377.]

2,3,4-Trichloroaniline *[634-67-3]* **M 196.5, m 67.5°, b 292°/774mm, pK_{Est} ~1.3.** Crystallise the aniline from ligroin. The *acetanilide* has **m** 120-122° (from EtOH or *C_6H_6). [*Beilstein* **12** H 626.]

2,4,5-Trichloroaniline *[636-30-6]* **M 196.5, m 96.5°, b 270°/760mm, pK 1.09.** Crystallise the aniline from ligroin. [*Beilstein* **12** H 627, **12** IV 1277.]

2,4,6-Trichloroaniline *[634-93-5]* **M 196.5, m 78.5°, b 127°/14mm, 262°/746mm, pK^{25} 0.03.** Crystallise the aniline from ligroin. The *benzoyl* derivative has **m** 174° (from EtOH). [*Beilstein* **12** H 627, **12** IV 1281.]

1,2,3-Trichlorobenzene *[87-61-6]* **M 181.5, m 52.6°.** Crystallise it from EtOH. [*Beilstein* **5** IV 664.]

1,2,4-Trichlorobenzene *[120-82-1]* **M 181.5, m 17°, b 210°.** Separate it from a mixture of isomers by washing with fuming H_2SO_4, then water, drying with $CaSO_4$ and slowly fractionally distilling. [Jensen et al. *J Am Chem Soc* **81** 3303 *1959*, *Beilstein* **5** IV 664.]

1,3,5-Trichlorobenzene *[108-70-3]* **M 181.5, m 64-65°.** Recrystallise it from dry *benzene or toluene. [*Beilstein* **5** IV 666.]

3,4,5-Trichloro-*o*-cresol (3,4,5-trichloro-2-methylphenol) *[608-92-4]* **M 211.5, m 77°, pK_{Est} ~7.6.** Crystallise the cresol from petroleum ether.

2,3,5-Trichloro-*p*-cresol (2,3,,5-trichloro-4-methylphenol) *[608-91-3]* **M 211.5, m 66-67°, pK_{Est} ~6.9.** Crystallise the cresol from petroleum ether. [Datta & Mitter *J Am Chem Soc* **41** 2034 *1919*, *Beilstein* **6** I 204.]

2,4,5-Trichloro-1-nitrobenzene (1,2,4-trichloro-5-nitrobenzene) *[89-69-0]* **M 226.5, m 57°.** Crystallise it from EtOH. [*Beilstein* **5** IV 728.]

3,4,6-Trichloro-2-nitrophenol *[82-62-2]* **M 242.4, m 92-93°, pK_{Est} ~4.1.** Crystallise the nitro-phenol from petroleum ether or EtOH. [*Beilstein* **6** III 842.]

2,4,5-Trichlorophenol *[95-95-4]* **M 197.5, m 67°, b 72°/1mm, 248°/740mm, pK^{25} 7.0.** Crystallise the phenol from EtOH or petroleum ether. [*Beilstein* **6** IV 962.]

2,4,6-Trichlorophenol *[88-06-2]* **M 197.5, m 67-68°, b 246°/760mm, pK^{25} 6.23.** Crystallise the phenol from *benzene, EtOH or EtOH/water. [*Beilstein* **6** IV 1005.]

3,4,5-Trichlorophenol *[609-19-8]* **M 197.5, m 100°, pK^{25} 7.84.** Crystallise the phenol from petroleum ether/*benzene mixture. [*Beilstein* **6** III 729.]

2,4,5-Trichlorophenoxyacetic acid (2,4,5-T) *[93-76-5]* **M 255.5, m 153°, 155-158°, pK^{25} 2.83.** Crystallise this herbicide from *benzene. **[***Beilstein* **6** III 721.] **(CANCER SUSPECT)**

1,2,4-Triethylbenzene *[877-44-1]* **M 162.3, b 96.8-97.1°/12.8mm, d_4^{20} 0.8738, n_D^{20} 1.5015.** For separation from a commercial mixture see Dillingham and Reid [*J Am Chem Soc* **60** 2606 *1938*]. [*Beilstein* **5** IV 1133.]

1,3,5-Triethylbenzene *[102-25-0]* **M 162.3, b 102-102.5°, d_4^{20} 0.8631, n_D^{20} 1.4951.** For separation from a commercial mixture see Dillingham and Reid [*J Am Chem Soc* **60** 2606 *1938*]. [*Beilstein* **5** IV 133.]

4-(Trifluoromethyl)acetophenone *[709-63-7]* **M 188.2, m 31-33°, b 79-81°/9mm.** Purify the ketone by distillation or sublimation *in vacuo*. [*Beilstein* **7** IV 1404.]

3-Trifluoromethyl-4-nitrophenol *[88-30-2]* **M 162.1, m 81°, b 135-138°/0.01mm, pK_{Est} ~6.1.** Crystallise

the nitrophenol from *benzene or from petroleum ether/*benzene mixture. [*Beilstein* **6** III 1328.]

α,α,α-Trifluorotoluene (benzotrifluoride) *[98-08-8]* **M 144.1, b 102.5°, d_4^{20} 1.190, n^{30} 1.4100.** Purify benzotrifluoride by repeated treatment with boiling aqueous Na_2CO_3 (until no test for chloride ion is obtained), dry it with K_2CO_3, then with P_2O_5, and fractionally distil it. [*Beilstein* **5** IV 802.]

2,3,4-Trihydroxybenzoic acid *[610-02-6]* **M 170.1, m 207-208°, $pK_{Est(1)}$ ~3.4, $pK_{Est(2)}$ ~7.8, $pK_{Est(3)}$ >12.** Crystallise the acid from water. [*Beilstein* **10** IV 1971.]

2,4,6-Trihydroxybenzoic acid *[83-30-7]* **M 170.1, m 205-212°(dec), $pK_{Est(1)}$ ~1.5, $pK_{Est(2)}$ ~8.0, $pK_{Est(3)}$ >12.** Crystallise the acid from water. [*Beilstein* **10** IV 1987.]

3,4,5-Triiodobenzoic acid *[2338-20-7]* **M 499.8, m 289-290°, 293°, pK^{25} 0.65.** Crystallise the acid from aqueous EtOH or water. [*Beilstein* **9** H 367, 9 III 1475.]

3,4,5-Triiodobenzyl chloride *[52273-54-8]* **M 504.3, m 138°.** Crystallise the chloride from CCl_4/petroleum ether (charcoal).

Trimellitic (benzene-1,2,4-tricarboxylic) acid *[528-44-9]* **M 210.1, m 218-220°, pK_1^{25} 2.42, pK_2^{25} 3.71, pK_3^{25} 5.01.** Crystallise the acid from acetic acid or aqueous EtOH. [*Beilstein* **9** IV 3746.]

1,2,3-Trimethoxybenzene *[634-36-6]* **M 168.2, m 45-46°.** Sublime it under vacuum. [*Beilstein* **6** H 1081, **6** I 540, **6** II 1066, **6** III 6265, **6** IV 7329.]

1,3,5-Trimethoxybenzene *[621-23-8]* **M 168.2, m 53°.** Sublime it under vacuum. [*Beilstein* **6** III 635, **6** IV 7362.]

3,4,5-Trimethoxyphenol (Antiarol) *[642-71-7]* **M 184.2, m 146°, 145-149°, pK_{Est} ~9.4.** Recrystallise the phenol from 10 times its weight of H_2O (white needles, **m** 148°). The *acetyl* derivative crystallises as elongated prisms from EtOH with **m** 74°. [Chapman et al. *J Chem Soc* 3028 *1927*, Shriner et al. *J Am Chem Soc* **61** 2325 *1939*, *Beilstein* **6** H 1154, **6** II 1118, **6** III 6656.]

1,2,4-Trimethylbenzene (pseudocumene) *[95-63-6]* **M 120.2, m -43.8°, b 51.6°/10mm, 167-168°/760mm, d_4^{20} 0.889, n_D^{20} 1.5048.** Reflux pseudocumene over sodium and distil it under reduced pressure. [*Beilstein* **6** H 1088, **6** I 542, **6** II 1072, **6** III 6278, **6** IV 7339.]

2,4,6-Trimethylbenzoic acid (mesitoic acid) *[480-63-7]* **M 164.2, m 155°, pK^{25} 3.45.** Crystallise mesitoic acid from water, ligroin or carbon tetrachloride [Ohwada et al. *J Am Chem Soc* **108** 3029 *1986*]. [*Beilstein* **9** H 553, **9** I 214, **9** II 360, **9** III 2489, **9** IV 1854.]

Trimethyl-1,4-benzoquinone *[935-92-2]* **M 150.1, m 29-30°, 36°, b 98°/10mm, 108°/18mm.** Distil the quinone in a vacuum or sublime it *in vacuo* before use. [Smith et al. *J Am Chem Soc* **60** 318 *1939*, *Beilstein* **7** H 161, **7** III 3407, **7** IV 2098.]

1,3-S,S'-Trimethylene di(*p*-toluenethiosulfonate) [1,3-di(*p*-tosylthio)propane, 1,3-trimethylene di(thiotosylate)] *[3866-79-3]* **M 416.6, m 64-67°.** This reagent is prepared from potassium thiosulfonate (40g, 0.18 mole, see above [28519-50-8]) and 1,3-dibromopropane (20g, 0.1 mole) which are added to a solution of 95% EtOH (150ml) containing KI (10-20mg, to activate the dibromide), and the stirred mixture is boiled under reflux in the dark under N_2 for 8 hours. After cooling to ~25°, the mixture is diluted with an equal volume of cold H_2O and shaken. After the mixture settles, the supernatant is removed by decantation, the pale yellow residual oil is washed with cold H_2O (3 × 200ml), once with cold 95% EtOH (100ml) and once with cold absolute EtOH (100ml) also by decantation. The oil is then dissolved in Me_2CO (10ml), diluted with hot absolute EtOH (80ml), and stirred under N_2 at 0°. If some oil separates, it should be re-dissolved by adding enough Me_2CO (say ~5ml). The solution is seeded with crystals (a small portion of the oil stored at -30° for a few days crystallises and is

used as seed*), stirred under N_2 at 0° for 1 hour then for several hours at -30°. The microcrystals are collected (20.2g) and have **m 63.5-65.0°.** This can be used for reactions; but if purer material is required then it should be recrystallised three times from EtOH (180ml, 9 parts) to provide white needles (17.2g, 41%) with **m 66-67°**. The *thioester* always separates as an oil when solutions are cooled to room temperature.
*If it is difficult to crystallise the ester then seed crystals could be obtained by chromatography through a column of Woelm neutral alumina (Activity Grade I) and eluting with *C_6H_6. The centre fractions giving solid with m 67° are combined and recrystallised from EtOH (9parts) to give the pure *trimethylene dithiotosylate* with **m 67.5°**. On a Durapak-Carbowax 400/Poracil C column (Waters Associates, 3ft x 0.125in) with $CHCl_3$ as eluent it exhibits a single peak. It has IR ($CHCl_3$) with ν_{max} at 810 (m), 1015 (w), 1075 (s), 1140 (s), 1180 (w), 1300 (m), 1325 (s), 1410 (w), 1440 (w), 1490 (w), 1590 (w), 2930 (w), and 3030 (w) cm^{-1}; and the ^1H NMR ($CDCl_3$, TMS) has δ at 1.98 (quintet, *J* = 7Hz, 2H, $CH_2C\boldsymbol{H}_2CH_2$), 2.43 (s, 6H, $2C\boldsymbol{H}_3$), 2.97 (t, *J* = 7Hz, 4H, $C\boldsymbol{H}_2CH_2C\boldsymbol{H}_2$), 7.30 (d, *J* = 9Hz, 4H, Arom) and 7.75 (d, *J* = 9Hz, 4H, Arom). [Woodward et al. *Org Synth* Coll Vol **V** 1016 *1988*, *Org Synth* **54** 33 *1974*.]
This reagent is useful for the synthesis of 1,3-dithianes from carbonyl compounds and activated methylene groups. Thus a ketone (0.163mmol), reagent (0.218mmol) and dry NaOK (0.907mmol) in EtOH (6ml) are refluxed for 6 hours, dilute with CH_2Cl_2, wash with aqueous $NaHCO_3$, evaporate extract and purify the residue through a silica gel column by eluting with 1:2 EtOAc/hexane containing 2% of *N*-methylpyrrolidine to give the desired 1,3-dithiane [McMurray et al. *J Org Chem* **49** 3803 *1984*, see also Saksena & Ganguli *Tetrahedron Lett* **22** 5227 *1981*]. It also forms 1.3-dithianes, e.g. 2,2-(trimethylenedithio)cyclohexanone, from the respective enamine, i.e. 1-pyrrolidinecyclohex-1-ene [Woodward et al. *Org Synth* **54** 39 *1974*].

Trimethyl-1,4-hydroquinone (2,3,5-trimethylbenzene-1,4-diol) *[700-13-0]* **M 152.2, m 173-174°, $pK_{Est(1)}$~ 11.1, $pK_{Est(2)}$~ 12.7.** Recrystallise the hydroquinone from water, under anaerobic conditions. [*Beilstein* **6** H 931, **6** IV 5997.]

2,3,5-Trimethylphenol *[697-82-5]* **M 136.2, m 95-96°, b 233°/760mm, pK^{25} 10.67.** Crystallise the phenol from water or petroleum ether. [*Beilstein* **6** IV 3248.]

2,4,5-Trimethylphenol *[496-78-6]* **M 136.2, m 70.5-71.5°, pK^{25} 10.57.** Crystallise the phenol from water. [*Beilstein* **6** H 509, **6** I 255, **6** II 482, **6** III 1831, **6** IV 3247.]

2,4,6-Trimethylphenol *[527-60-6]* **M 136.2, m 69°, b 220°/760mm, pK^{25} 10.86.** Crystallise the phenol from water and sublime it *in vacuo.* [*Beilstein* **6** IV 3253.]

3,4,5-Trimethylphenol *[527-54-8]* **M 136.2, m 107°, b 248-249°/760mm, pK^{25} 10.25.** Crystallise the phenol from petroleum ether. [*Beilstein* **6** IV 3245.]

Trimethylphenylammonium benzenesulfonate *[16093-66-6]* **M 293.3.** Crystallise it repeatedly from MeOH (charcoal). [*Beilstein* **12** IV 249.]

2,4,6-Trinitroanisole *[606-35-9]* **M 243.1, m 68°.** Crystallise it from EtOH or MeOH. Dry it *in vacuo*. [*Beilstein* **6** H 288, **6** I 140, **6** II 280, **6** III 968, **6** IV 1456.]

1,3,6(1,2,4)-Trinitrobenzene *[99-35-4]* **M 213.1, m 122-123°.** Crystallise it from glacial acetic acid, $CHCl_3$, CCl_4, EtOH aqueous EtOH or EtOH/*benzene, after (optionally) heating with dilute HNO_3. Dry it in air. Fuse it and crystallise it under vacuum. [*Beilstein* **5** H 271, 5 I 140, **5** II 203, **5** III 643, **5** IV 754.]

2,4,6-Trinitrobenzenesulfonic acid hydrate (TNBS, picrylsulfonic acid) *[2508-19-2]* **M 293.2, m 180°, λ_{max} 240nm (ε 650 $M^{-1}cm^{-1}$), pK_{Est}~ <0.** It is also available as 0.1M and 5%w/v solutions in H_2O. Recrystallise TNBS from 1M HCl, or a mixture of EtOH (50ml), H_2O (30ml) and conc HCl (70ml) for 65g of acid, and dry it at 100°. The *diethanolamine salt* had **m** 182-183° [Golumbic *J Org Chem* **11** 518 *1946*]. [*Beilstein* **11** III 161.]

2,4,6-Trinitrobenzoic acid *[129-66-8]* **M 225.1, m 227-228°, pK^{25} 0.65.** Crystallise the acid from distilled H_2O. Dry in a vacuum desiccator. The *amide* has **m** 264° (from EtOH). [*Beilstein* **9** H 417, **9** I 168, **9** II 285, **9** III 1956, **9** IV 1362.]

2,4,6-Trinitro-*m*-cresol *[602-99-3]* **M 243.1, m 107.0-107.5°, pK^{25} 2.8.** Crystallise the cresol successively from H_2O, aqueous EtOH and *benzene/cyclohexane, then dry at 80° for 2 hours. [Davis & Paabo *J Res Nat Bur Stand* **64A** 533 *1960*, *Beilstein* **6** H 387, **6** I 194, **6** II 363, **6** III 1331, **6** IV 2079.]

2,4,7-Trinitro-9-fluorenone *[129-79-3]* **M 315.2, m 176°.** Crystallise it from nitric acid/water (3:1), wash it with water and dry it under vacuum over P_2O_5, or recrystallise it from dry *benzene. [*Beilstein* **7** II 410, **7** III 2348, **7** IV 1638.]

2,4,6-Trinitrotoluene (TNT) *[118-96-7]* **M 227.1, m 81.0-81.5°.** Crystallise TNT from *benzene and EtOH. Then fuse **(CARE)** and allow to crystallise under vacuum. Gey, Dalbey and Van Dolah [*J Am Chem Soc* **78** 1803 *1956*] dissolved TNT in acetone and added cold water (1:2:15), the precipitate was filtered off, washed free from solvent and stirred with five parts of aqueous 8% Na_2SO_3 at 50-60° for 10 minutes. This was filtered, washed with cold water until the effluent was colourless, and air dried. The product was dissolved in five parts of hot CCl_4, washed with warm water until the washings were colourless and TNT was recoverd by cooling and filtering. It was recrystallised from 95% EtOH and carefully dried over H_2SO_4. The dry solid should not be heated without taking precautions for a possible **EXPLOSION**. Work with small quantities. [*Beilstein* **5** H 347, **5** I 172, **5** II 268, **5** III 767, **5** IV 873.]

2,4,6-Trinitro-*m*-xylene *[632-92-8]* **M 241.2, m 182.2°.** Crystallise the xylene from ethyl methyl ketone. [*Beilstein* **5** H 381, **5** I 185, **5** II 295, **5** III 845, **5** IV 950.]

Triphenylamine *[603-34-9]* **M 245.3, m 127.3-127.9°, pK^{25} -5.0 (in fluorosulfuric acid).** Crystallise the amine from EtOH or from *benzene/absolute EtOH, diethyl ether and petroleum ether. It is sublimed under vacuum and carefully dried in a vacuum line. Store it in the dark under nitrogen. [*Beilstein* **12** IV 276.]

1,3,5-Triphenylbenzene *[612-71-5]* **M 306.4, m 171-172°, 173-175°, 176°, d $^{0}_{4}$ 1.205.** Purify it by chromatography on alumina using *benzene or petroleum ether as eluents. Crystallise the triphenylbenzene from EtOH (**m** 174°). [*Beilstein* **5** H 737, **5** I 370, **5** II 670, **5** III 2563, **5** IV 2732.]

Triphenylene *[217-59-4]* **M 228.3, m 198°, b 425°.** Purify triphenylene by zone refining or crystallisation from EtOH or $CHCl_3$ and sublime. [*Beilstein* **5** IV 2556.]

1,2,3-Triphenylguanidine *[101-01-9]* **M 287.3, m 144°, pK^{25} 9.10.** Crystallise the guanidine from EtOH or EtOH/water. Dry it *in vacuo*. [*Beilstein* **12** H 451, **12** I 261, **12** II 246, **12** III 907, **12** IV 866.]

Triphenylmethane *[519-73-3]* **M 244.3, m 92-93°.** Crystallise triphenylmethane from EtOH or *benzene (with one molecule of *benzene of crystallisation which is lost on exposure to air or by heating on a water bath). It can also be sublimed under vacuum. It has been given a preliminary purification by refluxing with tin and glacial acetic acid, then filtered hot through a glass sinter disc, and precipitated by addition of cold water. [*Beilstein* **5** H 698, **5** IV 2495.]

Triphenylmethanol (triphenylcarbinol) *[76-84-6]* **M 260.3, m 164°, b 360-380° (without dec), pK^{25} -6.63 (aqueous H_2SO_4).** Crystallise the carbinol from EtOH, MeOH, CCl_4 (4ml/g), *benzene, hexane or petroleum ether (b 60-70°). Dry it at 90°. [Ohwada et al. *J Am Chem Soc* **108** 3029 *1986*, *Beilstein* **6** IV 5014.]

Triphenylmethyl chloride (trityl chloride) *[76-83-5]* **M 278.9, m 111-112°, b 230-235°/20mm.** Crystallise trityl chloride from iso-octane. Also crystallise it from 5 parts of petroleum ether (b 90-100°) and 1 part of acetyl chloride using 1.8g of solvent per g of chloride. Dry it in a desiccator over soda lime and paraffin wax. [Bachman *Org Synth* Coll Vol **III** 841 *1955*, Thomas & Rochow *J Am Chem Soc* **79** 1843 *1957*, Moisel et al. *J Am Chem Soc* **108** 4706 *1986*, *Beilstein* **5** H 750, **5** I 346, **5** II 615, **5** III 2315, **5** IV 2497.] It is moisture

sensitive, store in a well sealed container. **LACHRYMATORY**.

***dl*-Tropic [(3-hydroxy-2-phenylpropionic) acid, Tropaic acid]** *[529-64-6]* **M 166.2, m 116-117°, 118°, pK^{25} 4.12.** Tropic acid crystallises from H_2O or $*C_6H_6$ in needles or plates. It is the (±)-acid component (*dl*-tropyl ester) of atropine [51-55-8]. It is best prepared from acetophenone cyanohydrin *via* atrolactic acid [515-30-0], atropic acid, *chlorohydratropic acid* followed by hydrolysis of the latter in boiling aqueous 1.73N Na_2CO_3 in high yielding steps. No racemisation occurred when chiral intermediates were used (see next entry). [McKenzie & Wood *J Chem Soc* **115** 828 *1919*, McKenzie & Strathern *J Chem Soc* **127** 86 *1925*.] [*Beilstein* **10** IV 664.]

***S*(−)-Tropic acid [(−)3-hydroxy-2-phenylpropionic acid]** *[16202-15-6]* **M 166.2, m 128-129°, $[\alpha]_D^{13}$ −72.5° (c 2.6, EtOH), $[\alpha]_D^{15}$ −79.0° (c 1.5, H_2O), $[\alpha]_D^{15}$ −83.3° (c 1.8, Me_2CO).** It is the (−)-acid component of ***l*-hyoscyamine** (i.e *l*-tropyl atropine, [101-31-5]). It has been prepared by optical resolution of (±)-tropic acid using the quinine diastereomeric salt for obtaining (+)-tropic acid, and then with the morphine diastereomeric salt for obtaining the natural (−)-tropic acid. The salts were hydrolysed with dilute H_2SO_4, extracted thoroughly into Et_2O, dried (Na_2SO_4), evaporated, and the residue was recrystallised from $*C_6H_6$ (in which it is sparingly soluble) to give lustrous needles m 128-129°. It also crystallises from H_2O in glassy needles and plates grouped in rosettes. The enantiomer, obtained in the same way, has identical properties except for opposite rotations. [McKenzie & Wood *J Chem Soc* **115** 828 *1919*, McKenzie & Strathern *J Chem Soc* **127** 86 *1925*]. The absolute configuration of the (−)-tropic acid was deduced as *S*- by conversion into (+)-alanine. [Fedor & Csepreghy *J Chem Soc* 3222 *1961*, for enzymic kinetic resolution see Klomp et al. *Tetrahedron Asymmetry* **16** 3892 *2005*.]

Tropolone (2-hydroxycyclohepta-2,4.6-trien-1-one) *[533-75-5]* **M 122.1, m 49-50°, b 81-84°/0.1mm, pK_1 -0.53 (protonation of CO, aqueous H_2SO_4), pK_2 6.67 (acidic OH).** Crystallise tropolone from hexane or petroleum ether and sublime it at 40°/4mm. Also distil it at high vacuum. [*Beilstein* **8** IV 159.]

Tyramine (4-hydroxybenzylamine) *[51-67-2]* **M 137.2, m 164-165°, b 171-181°/8mm, pK_1^{25} 9.74 (OH), pK_2^{25} 10.52 (NH_2).** Crystallise tyramine from *benzene or EtOH. [*Beilstein* **13** IV 1788.]

Tyramine hydrochloride *[60-19-5]* **M 173.6, m 274-276°.** Crystallise the hydrochloride from EtOH by addition of diethyl ether, or from conc HCl. [*Beilstein* **3** II 355.]

Vanillin (4-hydroxy-3-methoxybenzaldehyde) *[121-33-5]* **M 152.2, m 83°, b 170°/15mm, pK^{25} 7.40.** Crystallise vanillin from water or aqueous EtOH, or by distillation *in vacuo*. [*Beilstein* **8** IV 1763.]

Veratraldehyde (vanillin methyl ether) *[120-14-9]* **M 166.2, m 42-43°.** Crystallise the ether from diethyl ether, petroleum ether, CCl_4 or toluene. [*Beilstein* **8** IV 1765.]

Variamine Blue RT [4-(phenylamino)benzenediazonium sulfate (1:1)] *[4477-28-5]* **M 293.3, m 120°(dec), CI 37240, λ_{max} 377 nm.** Dissolve 10g of the dye in 100ml of hot water. Sodium dithionite (0.4g) is then added, followed by active carbon (1.5g) and is filtered hot. To the colourless or slightly yellow filtrate a solution of saturated NaCl is added, and the mixture is cooled. The needles are filtered off, washed with cold water, dried at room temperature, and stored in a dark bottle (light sensitive). [Anderson & Steedly *J Am Chem Soc* **76** 5144 *1954*, Erdey *Chem Analyst* **48** 106 *1959*, *Beilstein* **16** H 602, **16** I 371, **16** II 307, **16** III 575.]

9-Vinylanthracene *[2444-68-0]* **M 204.3, m 65-67°, b 61-66°/10mm.** Purify it by vacuum sublimation. It has also been purified by chromatography on silica gel with cyclohexane as eluent, and recrystallised from EtOH [Werst et al. *J Am Chem Soc* **109** 32 *1987*]. [*Beilstein* **5** IV 2415.]

4-Vinylbenzyl chloride (4-chloromethylstyrene) *[1592-20-7]* **M 152.6, b 58-62°/0.4mm, 75.5-79°/2mm, 229°/760mm, d^{25} 1.083, n_D^{20} 1.572.** Purify 4-vinylbenzyl chloride by dissolving it in Et_2O, washing it with 0.5% of aqueous NaOH, separating, drying the organic layer (Na_2SO_4), evaporating and distilling the residual oil under N_2 *in vacuo*. Add 0.05% of 4-*tert*-butylcatechol as stabiliser. It is **lachrymatory.** [Nishikubo et al. *Tetrahedron Lett* **22** 3872 *1981*, Tanimoto et al. *Synth Commun* **4** 193 *1974*, *Beilstein* **6** IV 3818.]

1-Vinylnaphthalene *[826-74-4]* **M 154.2, b 68-69°/0.4mm, 100-101°/3.7mm, 124-125°/15mm, d 1.040, n_D^{20} 1.653.** Commercial material can contain up to 2% of poly-1-vinylnaphthalene. Fractionally distil it under reduced pressure using a spinning-band column, dry it with CaH_2 and again distil it under vacuum. Store it in sealed ampoules in a freezer. It has λ_{max} (cyclohexane) at 210 and 320nm. The *picrate* has **m** 105-106°. [*Beilstein* **5** H 585, **5** III 1773, **5** IV 1833.] It is an **irritant**.

2-Vinylnaphthalene *[827-54-3]* **M 154.2, m 66°, 65-68°, b 76-81°/2.5mm, 135-137°/18mm.** Commercial material can contain up to 5% of MeOH. The flammable solid can be fractionally distilled under reduced pressure using a spinning-band column; dry it with CaH_2 and again distil it under vacuum. It crystallises from aqueous MeOH, EtOH (**m** 66°) or petroleum ether (**m** 66-66.5°). Store it in sealed ampoules in a freezer. The *picrate* has **m** 91-92° (from EtOH). [*Beilstein* **5** III 1775, **5** IV 1833.] It is an **irritant**.

Violanthrene (dibenzanthrene, 5,10-dihydroviolanthrene A) *[81-31-2]* **M 428.5.** Purify violanthrene by vacuum sublimation over Cu in a muffle furnace at 450°/25mm in a CO_2 atmosphere [Scholl & Meyer *Chem Ber* **67** 1229 *1934*]. [*Beilstein* **5** I 392.] *Violanthrene A* (anthro[9,1,2-*cde*]benzo[*rst*]pentaphene *[188-87-4]* **M** 426.5 has **m** 506°. [Clar *Chem Ber* **76** 458 *1943*, *Beilstein* **5** III 2778; *Violanthrene B (violanthrone) Beilstein* **7** I 466, **7** II 818, **7** III 4539.]

Xylene *[1330-20-7]* **M 106.1 (mixed isomers).** Usual impurities are ethylbenzene, paraffins, traces of sulfur compounds and water. With a very efficient still, *o*-xylene can be fractionally distilled from a mixture of isomers. Purify (and dry) by fractional distillation from $LiAlH_4$, P_2O_5, CaH_2 or sodium. This treatment can be preceded by shaking successively with conc H_2SO_4, water, aqueous 10% NaOH, water and mercury, and drying with $CaCl_2$ for several days. [*Beilstein* **5** H 360.]

***o*-Xylene** *[95-47-6]* **M 106.2, f -25.2°, b 84°/14mm, 144.4°/760mm, d_4^{20} 0.88020, d_4^{25} 0.87596, n_D^{20} 1.50543, n_D^{25} 1.50292.** The general purification methods listed under xylene are applicable [Clarke & Taylor *J Am Chem Soc* **45** 831 *1923*]. *o*-Xylene (4.4Kg) is sulfonated by stirring for 4 hours with 2.5L of conc H_2SO_4 at 95°. After cooling, and separating the unsulfonated material, the product is diluted with 3L of water and neutralised with 40% NaOH. On cooling, sodium *o*-xylene sulfonate separates and is recrystallised from half its weight of water. [A further crop of crystals is obtained by concentrating the mother liquor to one-third of its volume.] The salt is dissolved in the minimum amount of cold water, then mixed with the same amount of cold water, and with the same volume of conc H_2SO_4 and heated to 110°. *o*-Xylene is regenerated and steam distils. The distillate is saturated with NaCl, the organic layer is separated, dried and redistilled. [*Beilstein* **5** H 362, **5** I 179, **5** II 281, **5** III 807, **5** IV 917.]

***m*-Xylene** *[108-38-3]* **M 106, f -47.9°, b 139.1°/760mm, d_4^{20} 0.86417, d_4^{25} 0.85990, n_D^{20} 1.49721, n_D^{25} 1.49464.** The general purification methods listed under *xylene* are applicable. The *o*- and *p*-isomers can be removed by their selective oxidation when a *m*-xylene sample containing them is boiled with dilute HNO_3 (one part conc acid to three parts water). After washing with water and alkali, the product can be steam distilled, collected as for *o*-xylene, then distilled and purified further by sulfonation. [Clarke & Taylor *J Am Chem Soc* **45** 831 *1923*.] *m*-Xylene is selectively sulfonated when a mixture of xylenes is refluxed with the theoretical amount of 50-70% H_2SO_4 at 85-95° under reduced pressure. By using a still resembling a Dean and Stark apparatus, water in the condensate can be progressively withdrawn while the xylene is returned to the reaction vessel. After cooling, then adding water, unreacted xylenes are distilled off under reduced pressure. The *m*-xylene sulfonic acid is subsequently hydrolysed by steam distillation up to 140°, the free *m*-xylene is washed, dried with silica gel and again distilled. It is stored over molecular sieves Linde type 4A. [*Beilstein* **5** H 370, **5** I 182, **5** II 287, **5** III 823, **5** IV 932.]

***p*-Xylene** *[106-42-3]* **M 106.2, f 13.3, b 138.3°/760mm, d_4^{20} 0.86105, d_4^{25} 0.85669, n_D^{20} 1.49581, n_D^{25} 1.49325.** The general purification methods listed for *xylene* above are applicable. *p*-Xylene can readily be separated from its isomers by crystallisation from such solvents as MeOH, EtOH, isopropanol, acetone, butanone, toluene, pentane or pentene. It can be further purified by fractional crystallisation by partial freezing, and stored over sodium wire or molecular sieves Linde type 4A. [Stokes & French *J Chem Soc, Faraday Trans 1* **76** 537 *1980*, *Beilstein* **5** H 382, **5** I 185, **5** II 296, **5** III 845, **5** IV 951.]

HETEROCYCLIC COMPOUNDS

Acetaldehyde ammonia trimer (hexahydro-2,4,6-trimethyl-1,3,5-triazine trihydrate) *[76231-37-3]* **M 183.3, m 94-96°, 95-97°, 97°, b 110°(partly dec).** It crystallises from EtOH/Et_2O. When prepared, it separates as the *trihydrate* which can be dried in a vacuum over $CaCl_2$ at room temperature to give the *anhydrous* compound with the same melting point. The *dihydrate* melts at 25-28°, then resolidifies and melts again at 94-95°. *IT IRRITATES THE EYES AND MUCOUS MEMBRANES.* [Nielson et al. *J Org Chem* **38** 3288 *1973*, *Beilstein* **26** III/IV 25.]

2-Acetamido-5-nitrothiazole (Acinitrazole) *[140-40-9]* **M 187.2, m 264-265°.** Recrystallise acinitrazole from EtOH or AcOH. [Hurd & Wehrmeister *J Am Chem Soc* **71** 4007 *1949*, *Beilstein* **27** III/IV 4676.]

4-Acetamido-2,2,6,6-tetramethylpiperidine-1-oxyl (acetamidoTEMPO) *[14691-89-5]* **M 213.3, m 144-146°, 146-147°.** Dissolve the 1-oxyl in CH_2Cl_2, wash it with saturated K_2CO_3, then saturated aqueous NaCl, dry (Na_2SO_4), filter and evaporate. The red solid is recrystallised from aqueous MeOH, **m** 147.5°. [Ma & Bobbitt *J Org Chem* **56** 6110 *1991*, Rozantsev & Kokhanov *Bull Acad Sci USSR, Div Chem Sci* **15** 1422 *1966*, *Beilstein* **22/8** V 174.]

5-Acetamido-1,3,4-thiadiazole-2-sulfonamide (Acetazolamide) *[59-66-5]* **M 222.3, m 256-259° (dec).** It is recrystallised from water. [Roblin & Clapp *J Am Chem Soc* **72** 4890 *1950*, *Beilstein* **27** III/IV 8219.]

Acetoacetylpiperidide *[1128-87-6]* **M 169.2, b 88.9°/0.1mm, n_D^{52} 1.4983.** Dissolve it in *benzene, extract with 0.5M HCl to remove basic impurities, wash with water, dry, and distil it at 0.1mm [Wilson *J Org Chem* **28** 314 *1963*]. [*Beilstein* **20** IV 1121.]

4-Acetoxy-2-azetidinone *[28562-53-0]* **M 129.1, m 38-41°.** Dissolve it in $CHCl_3$, dry ($MgSO_4$), concentrate at 40°/70mm, or better at room temperature to avoid decomposition. Wash and stir the residual oil with hexane by decantation and discard the wash. Dry the oil at high vacuum when it should solidify, **m** 34°. It can be distilled at high vacuum, 80-82°/10^{-3}mm, but this results in extensive losses. The purity can be checked by TLC using Merck Silica Gel F_{254} and eluting with EtOAc. The azetidinone has R_F 0.38 (typical impurities have R_F 0.67). The spots can be detected by the **TDM spray**. This is prepared from (A) 2.5g of 4,4'-tetramethyldiaminodiphenylmethane (TDM) in 10ml AcOH and diluted with 50ml of H_2O, (B) 5g KI in 100ml of H_2O and (C) 0.3g ninhydrin in 10ml of AcOH and 90ml of H_2O. The spray is prepared by mixing (A) and (B) with 1.5ml of (C) and stored in a brown bottle. [Clauβ et al. *Justus Liebigs Ann Chem* 539 *1974*, Michel et al. *Org Synth* **65** 135 *1987*, *Beilstein* **21/12** V 4.]

3*R*,4*R*,1'*R*-4-Acetoxy-3-[1-(*tert*-butylmethylsilyloxy)ethyl]-2-azetinone. See in "Miscellaneous As, B, P, Si, S, Se and Te Compounds" in this Chapter.

***N*-Acetylcaprolactam (1-acetylazepan-2-one, 1-acetylhexahydro-2*H*-azepin-2-one)** *[1888-91-1]* **M 155.2, b 85-86°/0.05mm, 119.5-222° /11mm, 134-135° /26mm, d_4^{25} 1.094, n_D^{20} 1.489.** Distil the lactam in a vacuum, but if the IR has broad OH bands (*ca* ν_{max} at ~3300cm^{-1}), then add *ca* one half volume or more of Ac_2O, reflux for 2 hours and distil or dissolve it in toluene add MeCOCl heat at 100°/2 hours and distil in a vacuum. Its IR has ν_{max} at 1730cm^{-1} (film). [Stoll & Griehl *Helv Chim Acta* **48** 1805 *1965*, Bose et al. *Tetrahedron* **30** 3 *1974*, *Beilstein* **21** III/IV 3210, **21/6** V 460.]

3-Acetyl-2,5-dimethylthiophene *[2530-10-1]* **M 154.2, b 62°/0.25mm, 105-108°/15mm, 224°/atm, d_4^{25} 1.086, n_D^{20} 1.544.** Distil the thiophene in a vacuum, or dissolve it in *C_6H_6, shake this with 6M HCl, then wash with H_2O, dry the organic layer, evaporate, and distil the residue preferably in a vacuum. [Glaze et al. *J Chem Soc Perkin Trans 1* 957 *1985*, *Beilstein* **17** H 298.]

***N*-Acetylimidazole** *[2466-76-4]* **M 110.1, m 101.5-102.5°, pK^{25} 3.6.** It is recrystallised from isopropenyl acetate and dried in a vacuum over P_2O_5. [Riordan & Valee *Methods Enzymol* **25** 500 *1972*, *Beilstein* **23/4** V 218.]

1-Acetylindole *[576-15-8]* **M 159.2, b 123-125°/8mm, 148-150°/10mm, 152-153°/15mm, d $^{25}_{4}$ 1.387, n $^{20}_{D}$ 1.6100.** It has been prepared by phase transfer catalysis of a mixture of AcCl/NaOH and Indole [Illi *Synthesis* 387 *1979*]. Purify it by distillation in a vacuum, but if it is very discoloured, then distil it in steam, separate the layers, dry the organic layer (Na_2SO_4), filter it, and distil it in a vacuum. The *picrate* has **m 98-99°**. *1,3-Diacetylindole* is formed when indole is treated with Ac_2O at 180-200°, and distils with 1-acetylindole. The latter distils in steam, whereas the diacetylindole remains behind. It is hydrolysed by boiling alkali to yield indole, and can be acetylated further to *1,3-diacetylindole* **m 151°**. [For NMR see Elguero et al. *Org Mag Res* **7** 445 *1975*, Ciamecian & *Chem Ber* ***22*** 1977 *1889*, Zatti & Ferratini *Chem Ber* **23** 1357 *1890*, Plieninger & Werst *Chem Ber* **89** 2783, 2788 *1956*, *Beilstein* **20** H 309, **20** II 200, **20** III/IV 3182, **20/7** V 19.]

3-Acetylindole *[703-80-0]* **M 159.2, m 189°, 188-190°, 188-192°, 191-193°, 194°, pK^{25} 12.99 (acidic NH).** It is formed by reaction of indole-MgCl and AcCl, and also by hydrolysis of 1,3-diacetylindole (see above). It is purified by recrystallisation from MeOH, *C_6H_6 containing a little EtOH or *C_6H_6; and by sublimation *in vacuo*. The *phenylureido* derivative has **m** 154°. The *(E)-oxime* has **m 144-145°** (also **149°** reported) (from H_2O) [Kostyuchenko et al. *J Org Chem USSR (Engl Trans)* **8** 2471 *1972*], and the *(Z)-oxime* has **m 95°** [Kostyuchenko et al. *J Org Chem USSR (Engl Trans)* **8** 2469, 2473 *1972*]. The *(E)-O-methyloxime* crystallises from EtOH with **127-129°**. [Oddo & Sessa *Gazz Chim Ital* **41** 234 *1911*, Baker *J Chem Soc* 461 *1946*, *Beilstein* **21** H 316, **21** I 300, **21** II 264, **21** III/IV 3775, **21/8** V 297.]

4-Acetylmorpholine *[1696-20-4]* **M 129.2, m 13.8-14°, 14°, 14.5°, b 96-97°/6mm, 113-128°/22mm, 242-247°/760mm, d $^{20}_{4}$ 1.0963, n $^{20}_{D}$ 1.4830.** Distil it through an 8inch Fenske (glass helices packing) column with a manual take-off head. Purify it by fractional distillation. The *hydrobromide* has **m** 172-175°. [Brace *J Am Chem Soc* **75** 357 *1953*, deBenneville et al. *J Org Chem* **21** 1072 *1956*, *Beilstein* **27** III/IV 274.]

***N*-Acetyl-D-penicillamine (*N*-acetyl-3-mercapto-D-valine)** see in "Miscellaneous Compounds", Chapter 7.

1-Acetylpiperazine *[13889-98-0]* **M 128.2, m 32-34°, 52°, pK^{25} 7.94.** Purify 1-acetylpiperazine by recrystallisation from 40% aqueous EtOH or from EtOH/Et_2O. It is an **irritant**, and is *hygroscopic*. The *hydrochloride* has **m** 191° (from EtOH), and the *tosylate salt* has **m** 148-149° (from EtOH/EtOAc, 1:16). The free base, however, cannot be isolated by basifying the tosylate salt and extraction with CH_2Cl_2. [Jacobi *Chem Ber* **66** 113 *1933*, Mosher et al. *J Am Chem Soc* **75** 4949 *1953*, Hall *J Am Chem Soc* **78** 2570 *1956*, *Beilstein* **23** IV 1786.]

1-Acetyl-4-piperidone *[32161-06-1]* **M 141.2, b 124-128°/0.2mm, 218°/760mm, d $^{25}_{4}$ 1.1444, n $^{20}_{D}$ 1.5023.** Purify it by fractional distillaton through a short Vigreux column (15mm). The *2,4-dinitrophenylhydrazone* has **m** 212-213° (from EtOH). It is freely soluble in H_2O but insoluble in Et_2O. [McElvain & McMahon *J Am Chem Soc* **71** 901 *1949*, *Beilstein* **21/6** V 246.]

3-Acetylpyridine *[350-03-8]* **M 121.1, m 13-14°, b 65-66°/1mm, 92-95°/8-9mm, 105°(113°)/16mm, 219-221°/760mm, d $^{20}_{4}$ 1.1065, n $^{20}_{D}$ 1.1065, pK^{25} 3.18.** It is purified by dissolving in HCl, extracting with Et_2O to remove the possible impurity of nicotinic acid, basified with NaOH and extracted with Et_2O. The dried extract is filtered, evaporated and the residual oil is distilled. If the NMR spectrum indicates further impurities, then convert it to the *phenylhydrazone* (**m** 137°, yellow needles from EtOH). This is hydrolysed with HCl [Engler & Kiby *Chem Ber* **22** 597 *1889*], the phenylhydrazine HCl is removed by filtration, $NaNO_2$ is added, the solution is basified with aqueous NaOH and extracted with Et_2O as before and distilled at atmospheric pressure to give 3-acetylpyridine as a colourless oil. Purification can also be achieved by shaking with 50% aqueous KOH, extracting with Et_2O, drying the extract and distilling it at atmospheric pressure or *in vacuo*. [Kloetzel & Chubb *J Am Chem Soc* **79** 4226 *1957*.] The *hydrochloride* has **m** 180-181° (from MeOH/EtOH), the *picrate* has **m** 133.8-134.8° (from H_2O), and the *phenylhydrazone* has **m** 137° (129-130°)(needles, from EtOH) [Webb & Webb *J Am Chem Soc* **71** 2285 *1949*]. The *ketoxime* has **m** 112° (from EtOH or *C_6H_6). [Strong & McElvain

J Am Chem Soc **55** 816 *1933*, Kolloff & Hunter *J Am Chem Soc* **63** 490 *1941*, *Beilstein* **21/7** V 394.]

2-Acetylthiazole *[24295-03-2]* **M 127.2, b 89-91° (90-95°)/12mm, 95-105°/15mm, d_4^{20} 1.23, n_D^{20} 1.55.** Check NMR spectrum; if it is not too bad, distil it through an efficient column in a vacuum. Otherwise purify it *via* the oxime. The *oxime* sublimes at 140-145°, **m** 159°, and when crystallised from H_2O has **m** 163-165.5°. [Erlenmeyer et al. *Helv Chim Acta* **31** 1142 *1948*, Waisvisz et al. *J Am Chem Soc* **79** 4524 *1957*, Menasseé et al. *Helv Chim Acta* **40** 554 *1957*, *Beilstein* **27** IV 2617.]

2-Acetylthiophene (methyl 2-thienyl ketone) *[88-15-3]* **M 126.2, m 9.2-10.5°, 10.45°, 10-11°, b 77°/4mm, 89-91°/9mm, 94.5-96.5°/13mm, 213-214°/atm, d_4^{20} 1.17, n_D^{20} 1.5666.** Fractionally distil the thiophene through a 12-plate column, and fraction **b** 77°/4mm is collected. Also wet the acetylthiophene in order to remove and free thiophene which forms an azeotrope with H_2O, **b** 68°. Store it in a brown bottle, and the clear colourless liquid remains thus for extended periods. [Kosak & Hartough *Org Synth* Coll Vol **III** 14 *1955*, Hartough & Kosak *J Am Chem Soc* **69** 3093 *1947*.] The red *4-nitrophenylhydrazone* crystallises from EtOH with **m** 181-182°. [*Beilstein* **17/9** V 387.]

3-Acetylthiophene (methyl 3-thienyl ketone, acetothienone) *[1468-83-3]* **M 126.2, m 57°, 60-63°, b 106-107°/25mm, 208-210°/748mm.** Recrystallise the thiophene from petroleum ether (b 30-60°) or EtOH. The *2,4-dinitrophenylhydrazone* crystallises from $CHCl_3$, **m** 265°, and the *semicarbazone* crystallises from EtOH, **m** 174-175°. [Campaigne & Le Suer *J Am Chem Soc* **70** 1555 *1948*, *Beilstein* **17/9** V 399.]

Aconitine *[302-27-2]* **M 645.8, m 204°, $[\alpha]_{546}$ +20° (c 1, $CHCl_3$), pK^{15} 8.35.** Crystallise it from EtOH, $CHCl_3$ or toluene. [*Beilstein* **21/6** V 310.]

Aconitine hydrobromide *[6034-57-7]* **M 726.7, m 207°.** Crystallise the salt from water or EtOH/ether. [*Beilstein* **21/6** V 310.]

Acridine (2,3-benzoquinoline) *[260-94-6]* **M 179.2, m 111° (sublimes), b 346°, pK^{25} 5.58 (pK^{25} of excited state 10.65).** Acridine has been crystallised twice from *benzene/cyclohexane, or from aqueous EtOH, then sublimed, removing and discarding the first 25% of the sublimate. The remainder is again crystallised and sublimed, discarding the first 10-15% [Wolf & Anderson *J Am Chem Soc* **77** 1608 *1955*].
Acridine can also be purified by crystallisation from *n*-heptane and then from ethanol/water after pre-treatment with activated charcoal, or by chromatography on alumina with petroleum ether in a darkened room. *Alternatively*, acridine can be precipitated as the hydrochloride from *benzene solution by adding HCl, after which the base is regenerated, dried at 110°/50mm, and recrystallised to constant melting point from petroleum ether [Cumper et al. *J Chem Soc* 4518 *1962*]. The regenerated free base may be recrystallised, chromatographed on basic alumina, then vacuum-sublimed and zone-refined. [Williams & Clarke, *J Chem Soc, Faraday Trans 1* **73** 514 *1977*, Albert, *The Acridines* Arnold Press *1966*.] It can exist in five crystalline forms and is steam volatile. It is a strong IRRITANT to skin and mucous membranes and can become a chronic irritant— handle it with CARE. [*Beilstein* **20/8** V 199.]

Acridine Orange (3,6-bisdimethylaminoacridine) *[494-38-2]* **M 349.94, m 165°(dec), 181-182°, 184-186° (free base)**, **pK_1^{20} -3.3, pK_2^{20} 0.2, pK_3^{20} 10.1.** The double salt with $ZnCl_2$ (6g) is dissolved in water (200ml) and stirred with four successive portions (12g each) of Dowex-50 ion-exchange resin (K^+ form) to remove the zinc. The solution is then concentrated in vacuum to 20ml, and 100ml of ethanol is added to precipitate KCl which is removed. Ether (160ml) is added to the solution from which, on chilling, the dye crystallises as its chloride. It is separated by centrifugation, washed with chilled ethanol and ether, and dried under vacuum, before being recrystallised from ethanol (100ml) by adding ether (50ml), and chilling. Yield 1g. [Pal & Schubert *J Am Chem Soc* **84** 4384 *1962*].
It was recrystallised twice as the free base from ethanol or methanol/water by dropwise addition of NaOH (less than 0.1M). The precipitate was washed with water and dried under vacuum. It was dissolved in $CHCl_3$ and chromatographed on alumina: the main sharp band was collected, concentrated and cooled to -20°. The precipitate was filtered off, dried in air, then dried for 2 hours under vacuum at 70°. [Stone & Bradley *J Am*

Chem Soc **83** 3627 *1961*, Blauer & Linschitz *J Phys Chem* **66** 453 *1962*, Albert *J Chem Soc* 244 *1947, Beilstein* **22** III/IV 5490, **22/11** V 326.]

Acridine Yellow G (2,7-dimethylacridine-3,6-diamine hydrochloride) *[135-49-9]* **M 273.8, m 325° (free base), CI 46025, pK_1^{20} -3.0, pK_2^{20} 0.5, pK_3^{20} 8.9.** Note that the hydrochloride is normally called Acridine Yellow G and not the free base. The free base recrystallises from 1:1 *benzene/methanol, or from 800 parts of EtOH. It is converted to the sparingly soluble hydrochloride with dilute HCl, filtered off and dried. [Albert *J Chem Soc* 248 *1947*, *Beilstein* **22** III/IV 5499, **22/11** V 340.]

***N*-(9-Acridinyl)maleimide (NAM)** *[49759-20-8]* **M 274.3, m 248°, 255-258°.** Purify NAM by chromatography on silica gel using CH_2Cl_2 as eluant. Evaporation of pooled fractions that gave the correct NMR spectra gave a solid which was crystallised from Me_2CO as pale yellow prisms. Its IR(nujol) has ν_{max} at 1710 (imide); the UV (MeOH) has λ_{max} (nm) (ε $M^{-1}cm^{-1}$) at 251 (159 500), 343 shoulder (7,700), 360 (12,400) and 382 shoulder (47,000). [Mashida et al. *Chem Pharm Bull Jpn* **26** 596 *1978*, Schuldiner et al. *Eur J Biochem* **25** 64 *1972*,]

Acridone *[578-95-0]* **M 195.2, m >300°, pK_1 -0.32 (basic), pK_2 12.80 (14.0, acidic).** Dissolve ~1g in *ca* 1% NaOH (100ml), add 3M HCl to pH 4 when acridone separates as a pale yellow solid with **m** just above 350° (sharp). It can be recrystallised from large volumes of H_2O to give a few mg. It is soluble in 160 parts of boiling EtOH (540 parts at 22°) [Albert & Phillips *J Chem Soc* 1294 *1956*]. A few decigms are best crystallised as the *hydrochloride* from 400 parts of 10N HCl (90% recovery) from which the free base is obtained by washing the salt with H_2O. A small quantity can be recrystallised (as the neutral species) from boiling AcOH. Larger quantities are best recrystallised from a mixture of 5 parts of freshly distilled aniline and 12.5 parts of glacial acetic acid. Acridone distils unchanged at atmospheric pressure, but the boiling point was not recorded, and some sublimation occurs below 350°. It has UV with λ_{max} at 399nm. [see Albert, *The Acridines* Arnold Press pp 201, 372 *1966*; for pKa see Kalatzis *J Chem Soc (B)* 96 *1969*, *Beilstein* **23/9** V 7.]

Acriflavine *[8048-52-0]* **M 196.2, pK^{25} >12.** Treat acriflavin twice with freshly precipitated AgOH to remove proflavine, then recrystallise it from absolute methanol [Wen & Hsu *J Phys Chem* **66** 1353 *1962*]. [*Beilstein* **22** III/IV 218.]

Acriflavin Mixture (Euflavin, 3,6-diamino-10-methylacridinium chloride) *[8063-24-9]* **M 259.7, m 179-181°.** Purify it by dissolving in 50 parts of H_2O, shaking with a small excess of freshly precipitated and washed Ag_2O. The mixture is set aside overnight at 0° and filtered. The cake is not washed. The pH of the filtrate is adjusted to 7.0 with HCl and evaporated to dryness. The residue is then crystallised twice from MeOH, twice from H_2O and dried at 120°. Its UV spectrum has λ_{max} at 452nm and a logε value of 4.67. It is a red powder which readily absorbs H_2O. The solubility is increased in the presence of proflavin. The *dihydrochloride* is a deep red crystalline powder. It is available as a mixture of 3,6-diaminoacridinium chloride (35%) and its 10-metho-chloride (65%). [See Albert, *The Acridines* Arnold Press p 346 *1966*, Benda *Chem Ber* **45** 1787 *1912*]. [*Beilstein* **23** I 650.]

Adenine (6-aminopurine, vitamin B_4) *[73-24-5]* **M 135.1, m 360-365°(dec rapid heating), pK_1^{25} 4.12, pK_2^{25} 9.83.** Crystallise adenine from distilled water. [*Beilstein* **26** III/IV 3561.]

Adenosine *[58-61-7]* **M 267.3, m 235-236°, $[\alpha]_{546}$ -85° (c 2, 5% NaOH), $[\alpha]_D^{24}$ -61.2° (c 1, H_2O), pK_1^{25} 3.48, pK_2^{25} 12.5.** Crystallise adenosine from distilled water and dry it at 110°. It has been purified *via* the *picrate*, where ethanolic picric acid is added to adenosine and the *picrate* is filtered off and recrystallised from EtOH. It has **m** 180-185°(dec). Adenosine is recovered by dissolving 0.4g of the picrate in 80ml of hot H_2O, treated with a small quantity of Dowex 1 anion exchange resin in the chloride form, and the resin is filtered off. The filtrate is treated with more resin and filtered again. One equivalent of aqueous NaOH is added to the colourless filtrate which is evaporated to 4ml and cooled to give 0.176g of adenosine **m** 236°. [Davoll et al. *J Chem* Soc 967 *1948*, Davoll & Lowy *J Am Chem Soc* **73** 1650 *1951*, *Beilstein* **26** III/IV 3598.]

Adrenochrome (3-hydroxy-1-methyl-5,6-indoline-dione) *[54-06-8]* **M 179.2, m 125-130° (dec).** It was

crystallised from MeOH/formic acid, as red crystals of the *hemihydrate*, and stored in a vacuum desiccator. The *mono-semicarbazone (Carbazochrome)* [69-81-8] M 236.2, crystallises as orange-red crystals from dilute EtOH with **m** ~203°(dec) and is haemostatic. [Heacock *Chem Rev* **59** 181 *1959*, *Beilstein* **21** III/IV 6434.]

Aetioporphyrin I (2,4,6,8-tetraethyl-1,3,5,7-tetramethylporphyrin) *[448-71-5]* **M 478.7, m 360-363°, pK^{25} 18.** Purify it by chromatography on an Al_2O_3 column (300g/300mg of porphyrin) and elute with CH_2Cl_2, evaporate the eluate and crystallise the residue from CH_2Cl_2/MeOH, pyridine or $CHCl_3$/petroleum ether (purple prisms, **m** > 300°) [Smith *J Chem Soc Perkin Trans 1* 1471 *1972*]. The copper salt crystallises as red needles from pyridine/AcOH. It complexes with metals. The *dihydrobromide* [69150-58-9] **M** 640.5 separates from aetioporphyrin I in Et_2O on addition of 10% of aqueous HBr after 2 days [Fischer & Treibs *Justus Liebigs Ann Chem* **457** 241 *1927*, Treibs & Dieter *Justus Liebigs Ann Chem* **513** 88-91 *1934*]. [*Beilstein* **26** III/IV 1915.]

Agroclavin *[548-42-5]* **M 238.3, m 198-203°(dec), 205-206°, 210-212°, $[\alpha]_D^{20}$ -155° (c 1, $CHCl_3$), pK_{Est} ~8.0.** It crystallises from diethyl ether or Me_2CO. The *hydrochloride* crystallises from H_2O and has **m** 265-266°, $[\alpha]_D^{20}$ -110° ($CHCl_3$). [Plieninger et al. *Justus Liebigs Ann Chem* **743** 95 *1971*, *Beilstein* **23** III/IV 1623.]

Ajmalicine (δ-yohimbine, Raubacine) *[483-04-5]* **M 352.4, m 250-252°(dec), 257°(dec), 261-263°(dec), $[\alpha]_{546}$ -76° (c 0.5, $CHCl_3$), $[\alpha]_D^{20}$ -45° (c 0.5, pyridine), -39° (c 0.25, MeOH), pK^{25} 5.7(90% aqueous 2-methoxyethanol), 6.46(66% aqueous Me_2NCHO).** It crystallises from MeOH, EtOH or EtOAc. [*Beilstein* **27** III/IV 7927.]

Ajmalicine hydrochloride *[4373-34-6]* **M 388.9, m 290°(dec), 294-295°(dec), $[\alpha]_D$ –18.5° (c 0.5, MeOH).** This hydrochloride crystallises from MeOH or EtOH. Its solubility is 0.315g/100g of H_2O at 100°. [*Beilstein* **27** III/IV 7928.]

Ajmaline (γ-yohimbine) *[4360-12-7]* **M 326.4, m 160° (MeOH), 205-206° (anhyd), $[\alpha]_D^{20}$ +144° (c 0.8, $CHCl_3$), pK^{25} 8.15(80% aqueous 2-methoxyethanol), 8.4(60%aqueous Me_2NCHO).** Ajmaline crystallises from MeOH or EtOAc containing a little H_2O to give the *trihydrate* **m** 158-160°. This loses $1H_2O$ at 110° and all H_2O at 150°. [*Beilstein* **23** III/IV 3212.]

Ajmaline hydrochloride *[4410-48-4]* **M 388.9, m 140°.** It crystallises from water as the *dihydrate* **m** 140°, and the *anhydrous salt* has **m** 252-255°, and $[\alpha]_D^{40}$ +84.6° (c 1, H_2O). The *dihydrochloride* crystallises from EtOH/Et_2O with **m** 305-306°. [*Beilstein* **23** III/IV 3212.]

Alizarin (1,2-dihydroxyanthraquinone) *[72-48-0]* **M 240.2, m 290°, d_4^{20} 0.884, CI 58000, pK_1^{25} 7.45, pK_2^{25} 11.80.** Alizarin crystallises from glacial acetic acid or 95% EtOH. It can also be sublimed at 110°/2mm. It is an indicator with λ_{max} at 452nm (pH 5.8) and 520nm (pH 7.2). [*Beilstein* **8** IV 3256.]

Alizarin-3-methyliminodiacetic acid (Alizarin Complexone) ($2H_2O$) *[3952-78-1]* **M 421.4, m 189°(dec), $pK_{Est(1)}$~4.9, $pK_{Est(2)}$~7.5.** It is purified by suspending it in 0.1M NaOH (1g in 50ml), filtering the solution and extracting alizarin with 5 successive portions of CH_2Cl_2. Then add HCl dropwise to precipitate the reagent, stirring the solution in an ice bath. Filter the precipitate onto a glass filter, wash it with cold water and dry it in a vacuum desiccator over KOH [Ingman *Talanta* **20** 135 *1973*, *Beilstein* **14** IV 931].

Alizarin Yellow R [5-(4-nitrophenylazosalicylic acid), Mordant Orange I] *[2243-76-7]* **M 287.2, m 253-254°(dec), >300°, CI 14030, pK^{25} 11.17.** The free acid is precipitated by adding HCl to an aqueous solution of the Na salt. After 2 recrystallisations from aqueous AcOH, it has **m** 255°(dec); [**m** 253-254°(dec) was reported by Hewitt & Fox *J Chem Soc* **79** 49 *1901*]. The free acid recrystallises from dilute AcOH as orange brown needles. The Na salt changes colour from yellow to red when the pH is increased from 10.2 to 12.0. [Woodland et al. *J Am Chem Soc* **75** 5835 *1953*, *Beilstein* **16** IV 372.]

***RS*-Allantoin** *[97-59-6]* **M 158.1, m 238°(dec).** It crystallises from water or EtOH [Hartman et al. *Org Synth* Coll Vol **II** 21 *1943*]. [*Beilstein* **25** III/IV 4071.]

Alloxan [2,4,5,6(1*H*,3*H*]pyrimidine, tetrone] *[50-71-5]* **M 142.0, m ~170°(dec), pK^{25} 6.64.** Crystallisation from water gives the *tetrahydrate*. *Anhydrous* crystals are obtained by crystallisation from acetone, glacial acetic acid or by sublimation *in vacuo*. [See below and *Beilstein* **24** H 500, **24** I 428, **24** II 301, **24** III/IV 2137.]

Alloxan monohydrate *[2244-11-3]* **M 160.1, m 255°(dec), pK^{25} 6.64.** Recrystallisation from H_2O gave the *tetrahydrate* in large prisms or rhombs. On heating at 100°, or on exposure to air, this is converted to the *monohydrate*. Dissolve it in its own weight of boiling H_2O and cool it for several days below 0°; the *tetrahydrate* crystallises from solution much more slowly when free from HNO_3. It is less soluble in bicarbonate solutions than in H_2O. Drying the solid over H_2SO_4 yields the *monohydrate*. The *anhydrous* crystals can be obtained by recrystallisation from dry Me_2CO or AcOH followed by washing with dry Et_2O, or by sublimation in a vacuum. On heating it turns pink at 230° and decomposes at *ca* 256°. It is acidic to litmus. [Hartman & Sheppard *Org Synth* Coll Vol **III** 37 *1955*.] It forms a compound with urea which crystallises from H_2O in yellow needles that become red at 170° and decompose at 185-186°. [*Beilstein* **24** H 500, **24** I 428, **24** II 301, **24** III/IV 2137.]

Alloxantin *[76-24-4]* **M 286.2, m 253-255°(dec) (yellow at 225°).** Alloxantin crystallises from water or EtOH and is kept under nitrogen. It turns red in air. [*Beilstein* **26** III/IV 2782.]

1-Allyl-6-amino-3-ethyluracil (Aminometradine) *[642-44-4]* **M 195.2, m 143-144° (anhydrous).** It crystallises from water (as monohydrate). It is a diuretic. [*Beilstein* **24** III/IV 4133.]

1-*N*-Allyl-3-hydroxymorphinan (Levallorphan) *[152-02-3]* **M 283.4, m 180-182°, [α] $^{20}_{D}$ -89° (c 3, MeOH).** It crystallises from aqueous EtOH. It is a narcotic antagonist. [Schneider & Grüssner *Helv Chim Acta* **34** 2211 *1951*, Hellerbach *Helv Chim Acta* **39** 429 *1956*.]

5-Allyl-5-*iso*butylbarbituric acid *[77-26-9]* **M 224.3, m 139°, 139-140°, 140-142°, pK^{18} 12.36.** It can be recrystallised from H_2O or dilute EtOH, and sublimes at 100-120°/8-12mm. It is soluble in $*C_6H_6$, cyclohexane, tetralin and petroleum ether at 20°. [Butler et al. *J Am Chem Soc* **77** 1486 *1955*, *Beilstein* **24** III/IV 2006.]

9-Aminoacridine [9-acridineamine] *[90-45-9]* **M 194.2, m 241°, pK^{20} 9.95.** It crystallises from EtOH or acetone and sublimes at 170-180°/0.04mm [Albert & Ritchie *Org Synth* Coll Vol **III** 53 *1955*, for hydrochloride, see below]. [*Beilstein* **22** H 463, **21** II 280, **21** III/IV 4174.]

9-Aminoacridine hydrochloride monohydrate (Acramine yellow, Monacrin) *[52417-22-8]* **M 248.7, m >355°, pK $^{20}_{1}$ 4.7, pK $^{20}_{2}$ 9.99.** Recrystallise it from boiling H_2O (charcoal; 1g in 300 ml) to give pale yellow crystals with a neutral reaction. It is one of the most fluorescent substances known. At 1:1000 dilution in H_2O it is pale yellow with only a faint fluorescence, but at 1:100,000 dilution it is colourless with an intense blue fluorescence. [Albert & Ritchie *Org Synth* Coll Vol **III** 53 *1955*; Falk & Thomas *Pharm J* **153** 158 *1944*, *Beilstein* **22** H 463, **21** II 280, **21** III/IV 4174.] See previous entry for the free base.

2-Amino-4-anilino-*s*-triazine (Amanozine) *[537-17-7]* **M 168.2, m 235-236°, pK$_{Est}$ ~5.5.** It crystallises from dioxane or 50% aqueous EtOH. [*Beilstein* **26** III/IV 1195.]

4-Aminoantipyrine *[83-07-8]* **M 203.3, m 109°.** It crystallises from EtOH or EtOH/ether. [*Beilstein* **25** III/IV 3554.]

2-Aminobenzothiazole *[136-95-8]* **M 150.2, m 132°, pK^{20} 4.48.** The thiazole cystallises from H_2O, aqueous EtOH, $*C_6H_6$ or petroleum ether. The *hydrochloride* crystallises from dilute HCl and has **m** 240.5°. [*Beilstein* **27** H 182, **27** III/IV 4824.]

6-Aminobenzothiazole *[533-30-2]* **M 150.2, m 87°, pK$_{Est}$ ~3.** It crystallises from aqueous EtOH, petroleum ether or $*C_6H_6$/petroleum ether. The *hydrochloride* has **m** 305°(dec) from dilute HCl, and the *picrate* has **m** 185°(dec) from Me_2CO. [Boggust & Cocker *J Chem Soc* 360 *1949*, *Beilstein* **27** III/IV 4884.]

3-*o*-Aminobenzyl-4-methylthiazolium chloride hydrochloride *[534-94-1]* **M 277.4, m 213°(dec).** The *hydrochloride* crystallises from aqueous EtOH, and the *iodide hydroiodide* has **m** 273° (from aqueous HI). [*Beilstein* **27** III/IV 973.]

4-Amino-1-benzylpiperidine *[50541-93-0]* **M 190.3, b ~180°/20mm, d_4^{20} 0.933, n_D^{20} 1.543, $pK_{Est(1)}$ ~8.3 $pK_{Est(2)}$ ~10.4.** Purify it by distillation *in vacuo* and store it under N_2 because it absorbs CO_2. The *dihydrochloride salt* [1205-72-7] has **m** 270-273° (255°) after recrystallisation from MeOH/EtOAc or EtOH. [Brookes *J Chem Soc* 3165, 3172 *1957*.] The *4-methylamino-1-benzylpiperidine* derivative has **b** 168-172°/17mm, n_D^{20} 1.5367 [Reitsema & Hunter *J Am Chem Soc* **70** 4009 *1948*]. The *1-(1-benzyl-4-piperidinyl)-3-cyano-2-methylisothiourea* derivative has **m** 160° from $CHCl_3/Et_2O$ [Preparation, IR, NMR: Ried et al. *Chem Ber* **116** 1547 *1983*, *Beilstein* **22** III/IV 3752].

2-Amino-4-chloro-6-methylpyrimidine *[5600-21-5]* **M 143.6, m 184-186°, pK_{Est} ~1.0.** Recrystallise it from EtOH. [*Beilstein* **24** H 84.]

2-Amino-5-chloropyridine *[1072-98-6]* **M 128.6, m 135-136°, pK^{25} 4.38.** Recrystallise this base from petroleum ether. It sublimes at 50°/0.5mm. [*Beilstein* **22** II 332, **22/8** V 541.]

2-Amino-4-chloropyrimidine *[3993-78-0]* **M 129.55, m 168-169°, m 170°, pK_{Est} ~1.2.** The pyrimidine crystallises in glistening plates from EtOH (**m** 170°, sintering at 167°). It has also been purified by sublimation in a vacuum and recrystallisation from H_2O. [Hilbert & Johnson *J Am Chem Soc* **52** 1155 *1930*, *Beilstein* **24** H 80, **25** III/IV 2117.]

2-Amino-3,5-dibromopyridine *[35486-42-1]* **M 251.9, m 103-104°, pK_{Est} ~2.4.** Steam distil it and recrystallise it from aqueous EtOH or petroleum ether. [*Beilstein* **22** H 431, **22** II 333, **22** III/IV 4041.]

3-Amino-2,6-dichloropyridine *[62476-56-6]* **M 164.0, m 119°, b 110°/0.3mm, pK_{Est} ~2.0.** Recrystallise it from water. [*Beilstein* **22** III/IV 4093.]

2-Amino-4,6-dimethylpyridine *[5407-87-4]* **M 122.2, m 69-70.5°, pK^{25} 7.84.** Recrystallise this base from hexane, ether/petroleum ether or *benzene. Residual *benzene is removed over paraffin-wax chips in an evacuated desiccator. The *dipicrate* crystallises from EtOH and has **m** 205-207°(dec). [*Beilstein* **22** III/IV 4210.]

2-Amino-4,6-dimethylpyrimidine *[767-15-7]* **M 123.2, m 152-153°, pK^{25} 4.95.** Recrystallisation from water gives the pyrimidine with **m** 197°, but recrystallisation from acetone gives **m** 153°. [*Beilstein* **25** III/IV 2205.]

2-(Aminomethyl)piperidine *[22990-77-8]* **M 114.2, b 66-67°/12mm, 80-81°/18mm, d_4^{20} 0.9406, n_D^{20} 1.4854, pK_1^{20} 6.33, pK_2^{20} 9.70.** Dry (over Na_2SO_4) and distil the piperidine under vacuum from KOH. It has been purified *via* the *Reinekate salt* (**m** 173-174°) and its *dipicrate salt* (**m** 201°, from H_2O). [Norton et al. *J Am Chem Soc* **68** 1330 *1946*, Mortimer *Aust J Chem* **11** 84 *1958*, Augustine *J Am Chem Soc* **81** 4667 *1959*, *Beilstein* **22** III/IV 3765.]

4-Amino-3-hydrazino-5-mercapto-1,2,4-triazole (Purpald) *[1750-12-5]* **M 146.2, m 228-230°(dec), 234-235°(dec), $pK_{Est(1)}$ ~2, $pK_{Est(2)}$ ~3 (NH_2), $pK_{Est(3)}$ ~8 (SH).** Recrystallise Purpald from H_2O (0.6g in 300-400ml). The *benzylidene* derivative has **m** 245-246°(dec) from *i*-PrOH [Hoggarth *J Chem Soc* 4817 *1952*, Dickinson & Jacobson *J Chem Soc, Perkin Trans I* 975 *1975*. [*Beilstein* **26** III/IV 547.]

5-Amino-8-hydroxyquinoline hydrochloride *[3881-33-2]* **M 196.7, pK_1^{20} 5.67, pK_2^{20} 11.24.** Dissolve the hydrochloride in the minimum volume of MeOH, then add Et_2O to initiate crystallisation. The crystals are filtered off and dried [Lovell et al. *J Phys Chem* **88** 1885 *1984*]. The *dihydrochloride* [21302-43-2] has **M 233.1, m 279°(dec).** [*Beilstein* **22** III/IV 5866.]

4-Aminoimidazole-5-carboxamide hydrochloride (AICAR HCl) *[72-40-2]* **M 162.6, m 255-256°(dec), $pK_{Est(1)}$ ~3.5, $pK_{Est(2)}$ ~9.4.** Recrystallise the hydrochloride from EtOH. [Kuroda & Hakko *J Heterocycl Chem* **30** 593 *1993*, Alhede et al. *J Org Chem* **56** 2139 *1991*, Cheru et al. *Heterocycles* **24** 1133 *1992*, *Beilstein* **25** II 221, **25** III/IV 4329.]

6-Aminoindazole *[6967-12-0]* **M 133.2, m 210°, pK^{25} 3.99.** It is recrystallised from H_2O or EtOH and sublimes in a vacuum. [*Beilstein* **25** H 317.]

2-Amino-3-iodopyridine *[104830-06-0]* **M 220.1, m 78-91°, 90-91.5°, pK_{Est} ~4.9.** Purify this pyridine by recrystallisation from hexane. The *N-Me* derivative [113975-23-8] has **m 50°,** and distils at **b 129°/14mm**. [Sakamoto et al. *Chem Pharm Bull, Japan* **33** 4764 *1985*, Estel et al. *J Org Chem* **53** 2740 *1988*.]

2-Amino-4-iodopyridine *[552331-00-7]* **M 220.1, m 163-164°, pK_{Est} ~5.1.** Purify this pyridine by recrystallisation from H_2O. The *picrate* has **m 253-254°** (from H_2O), the *N-acetyl* derivative has **m 150°** (from H_2O), and the *N-benzoyl* derivative has **m 167-168°** (from aqueous EtOH). [Graf *Chem Ber* **64** 21 (25) *1931*.]

2-Amino-5-iodopyridine *[20511-12-0]* **M 220.1, m 128-131°, 129-130°, 130°, pK_{Est} ~4.5.** The pyridine can be purified by steam distillation. Separate the solid from the cooled distillate by filtration, acidify the filtrate, decolorise it with charcoal, concentrate it to ~200ml, make alkaline with KOH and cool. Filter the solid, add it to the original solid that was collected, and dry it *in vacuo*. It crystallises from *C_6H_6 in white needles. The *picrate* separates as yellow needles from hot EtOH or Me_2CO, **m 240°**. [Caldwell et al. *J Am Chem Soc* **66** 1479 *1944*.]

5-Amino-2-iodopyridine *[29958-06-0]* **M 220.1, m 132°, pK_{Est} ~2.6.** Purify it by recrystallisation from EtOH (white needles). [Caldwell et al. *J Am Chem Soc* **66** 1479 *1944*.]

3-Amino-5-mercapto-1,2,4-triazole *[16691-43-3]* **M 116.1, m 298°, $pK_{Est(1)}$~ 3.0, $pK_{Est(2)}$~ 9.** Recrystallise the triazole from H_2O and dry it *in vacuo*. The *acetyl* derivative has **m** 325° (dec) after recrystallisation from H_2O. [*Beilstein* **26** III/IV 1351.] It has also been recrystallised from EtOH/ H_2O (3:1, 1g in 50 ml, 50% recovery), **m** 300-302° (dec subject to heating rate), (λ_{max} 263nm, log ε 4.12). The *S-benzyl* derivative, when crystallised from *C_6H_6/EtOH (20:1), or $CHCl_3$/Et_2O has **m** 109-111° [Godfrey & Kruzer *J Chem Soc* 3437 *1960*, *Beilstein* **26** III/IV 1351.]

2-Amino-4-methoxy-6-methylpyrimidine *[7749-47-5]* **M 139.2, m 157-159°, 158-158.5°, 158-160°, pK_{Est} ~6.0.** Recrystallise it from H_2O. The *picrate* has **m** 220-221°(dec). [Baker et al. *J Am Chem Soc* **69** 3072, 3075 *1947*, Sirakawa et al. *Yakugaku Zasshi* **73** 598 *1953*, Backer & Grevenstuk *Rec Trav Chim Pays Bas* **61** 291 *1942*, *Beilstein* **25** III/IV 3385.]

8-Amino-6-methoxyquinoline *[90-52-8]* **M 174.2, m 41-42°, 51°, b 137-138°/1mm, $pK^{70.1}$ 3.38.** Distil it under N_2 and at high vacuum, then recrystallise it several times from MeOH (0.4ml/g). It remains colourless for several months when purified in this way [Elderfield & Rubin *J Am Chem Soc* **75** 2963 *1953*]. The *hydrobromide* [312693-53-1] **M** 255.1 has **m** 238°(dec). [*Beilstein* **22** III/IV 5934.]

7-Amino-4-methylcoumarin *[26093-31-2]* **M 175.2, m 224-229°(dec), pK_{Est} ~3.2.** Dissolve it in 5% HCl, filter and basify with 2M ammonia. The precipitate is dried in a vacuum and recrystallised from dilute EtOH. It yields a blue solution and is light sensitive. [Sigler *Synthesis* 614 *1980*, Kanaoka et al. *Chem Pharm Bull Jpn* **30** 1485 *1982*, *Beilstein* **18/11** V 445.]

2-Amino-3-methylpyridine (2-amino-3-picoline) *[1603-40-3]* **M 108.1, m 33.2°, b 221-222°, pK^{25} 7.24.** Recrystallise the picoline three times from *benzene, most of the residual *benzene being removed from the crystals by standing over paraffin wax chips in an evacuated desiccator. The amine is also transferred to a separating funnel under N_2, and left in contact with NaOH pellets for 3 hours with occasional shaking. It is then placed in a vacuum distilling flask where it is refluxed gently in a stream of dry N_2 before fractionally distilling it. [Mod et al. *J Phys Chem* **60** 1651 *1956*, *Beilstein* **22/9** V 212].

2-Amino-4-methylpyridine (2-amino-4-picoline) *[695-34-1]* **M 108.1, m 99.2°, b 230°, pK^{25} 7.48.** Crystallise it from EtOH or a 2:1 *benzene/acetone mixture, and dry it under vacuum as in the prevous entry. [*Beilstein* **22/9** V 325.]

2-Amino-5-methylpyridine (6-amino-3-picoline) *[1603-41-4]* **M 108.1, m 76.5°, b 227°, pK^{25} 7.22.** Crystallise it from acetone. [*Beilstein* **22/9** V 289.]

2-Amino-6-methylpyridine (6-amino-2-picoline) *[1824-81-3]* **M 108.1, m 44.2°, b 208-209°, pK^{25} 7.41.** Crystallise it three times from acetone and dry it under vacuum at *ca* 45°. *Alternatively*, keep it in contact with NaOH pellets for 3 hours, with occasional shaking, decant and fractionally distil it [Mod et al. *J Phys Chem* **60** 1651 *1956*]. It also recrystallises from CH_2Cl_2 on addition of petroleum ether. [Marzilli et al. *J Am Chem Soc* **108** 4830 *1986*, *Beilstein* **22/9** V 210.]

2-Amino-4-methylpyrimidine *[108-52-1]* **M 109.1, m 159-160°, 161°, pK^{20} 4.15.** Crystallise the pyrimidine from H_2O or EtOH and sublime it in a vacuum. The *picrate* crystallises from EtOH and has **m** 235-236°(dec). **[***Beilstein* **24** H 84, **25** III/IV 2152.]

2-Amino-5-methylpyrimidine *[50840-23-8]* **M 109.1, m 193.5°, pK_{Est} ~4.0.** Crystallise it from water or *benzene/petroleum ether and sublime it at 50°/0.5mm. [*Beilstein* **24** H 87.]

4-Amino-2-methylquinoline (4-aminoquinaldine) *[6628-04-2]* **M 158.2, m 168°, b 333°/760mm, pK^{20} 9.42.** Recrystallise it from *benzene/petroleum ether. [*Beilstein* **22/10** V 347.]

6-Aminonicotinic acid *[3167-49-5]* **M 138.1, m 312°(dec), $pK_{Est(1)}$~2.2 (CO_2H), $pK_{Est(2)}$ ~6.5.** Crystallise the acid from aqueous acetic acid. Dry it *in vacuo* at 70°. [*Beilstein* **22** III/IV 6726.]

6-Aminopenicillanic acid *[551-16-6]* **M 216.2, m 208-209°**, **$[\alpha]_{546}$ +327° (in 0.1M HCl), pK_1^{25} 2.30, pK_2^{25} 4.90.** This acid crystallises from water. [Kleppe & Stroninger *J Biol Chem* **254** 4856 *1979*, *Beilstein* **27** III/IV 2858.]

2-Aminoperimidine *[28832-64-6]* **M 183.1, m 239°, b 170-175°/1.5mm, pK_{Est} ~7.9 (free base).** It crystallises from EtOH/H_2O (1:1). It precipitates as the *hydrochloride* with dilute HCl which has **m** 282°. [Dasgupta et al. *Anal Chim Acta* **94** 205 *1977*, *Beilstein* **24** H 193, **25** III/IV 2677.]

2-Aminoperimidine hydrobromide *[40835-96-9]* **M 264.1, m 299°, pK_{Est} ~7.9 (free base).** Purify the hydrobromide by boiling a saturated aqueous solution with charcoal, filtering and leaving the salt to crystallise. Store this *dihydrate salt* in a cool, stoppered flask in the dark place. The *anhydrous salt* is obtained by heating at 80°/4 hours, and it is hygroscopic. The solubilities of the hydrobromide at 26° are 2.4% in EtOH, 0.6% in H_2O, 0.3% in Et_2O, 0.1% in Me_2CO and 0.003% in $*C_6H_6$. [Dasgupta et al. *Anal Chim Acta* **94** 205 *1977*, Dasgupta & West *Microchim Acta* **2** 505 *1978*, Dasgupta et al. *Anal Chem* **50** 1793 *1978, Beilstein* **24** H 193, **25** III/IV 2677.]

2-Aminopyridine *[504-29-0]* **M 94.1, m 58°, b 204-210°, pK_1^{25} -7.6, pK_2^{25} 6.71.** It crystallises from *benzene/petroleum ether (b 40-60°) or $CHCl_3$ /petroleum ether. [*Beilstein* **22/8** V 280.]

3-Aminopyridine *[462-08-8]* **M 94.1, m 64°, b 248°, pK_1^{25} -1.5, pK_2^{25} 6.03.** It crystallises from *benzene, $CHCl_3$/petroleum ether (b 60-70°), or *benzene/petroleum ether (4:1). [*Beilstein* **22/9** V 3.]

4-Aminopyridine *[504-24-5]* **M 94.1, m 160°, b 180°/12-13mm, pK_1^{25} -6.55, pK_2^{25} 9.11 (9.18).** Crystallise the aminopyridine from *benzene/EtOH, then recrystallise it twice from water, then crush and dry it for 4 hours at 105° [Bates & Hetzer *J Res Nat Bur Stand* **64A** 427 *1960*]. It has also been crystallised from EtOH, *benzene, *benzene/petroleum ether, toluene and sublimes in a vacuum. [*Beilstein* **22/9** V 106.]

2-Aminopyrimidine *[109-12-6]* **M 95.1, m 126-127.5°, pK^{20} 3.45.** Crystallise 2-aminopyrimidine from *C_6H_6, EtOH or H_2O. [*Beilstein* **25** III/IV 2071.]

4-Aminopyrimidine *[591-54-8]* **M 95.1, m 149-151°, 154-156°, pK^{25} 5.69.** Recrystallise 10.6g of aminopyrimidine from hot EtOAc (200ml) to give 7.4g colourless needles as first crop; evaporation to 25ml gives a second crop of 1.7g. The *hydroiodide* has **m** 180°. The *picrate* has **m** 225°. [Brown *J Soc Chem Ind* (London) **69** 353 *1950*, *Beilstein* **24** H 81, **24** III/IV 2130.]

5-Aminopyrimidine *[591-55-9]* **M 95.1, m 171-172° (with sublimation), pK^{25} 2.52.** It is purified by conversion to the $MgCl_2$ complex in a small volume of H_2O. The complex (~ 5g) is dissolved in the minimum volume of hot H_2O, passed through a column of activated Al_2O_3 (200g), and the column is washed with EtOH. Evaporation of the EtOH gives a colourless residue of the aminopyrimidine which is recrystallised from *C_6H_6 (toluene could also be used) which forms needles at first, then prisms. It melts with sublimation. Acetylation yields *5-acetamidopyrimidine* which crystallises from *C_6H_6, **m** 148-149°. [Whittaker *J Chem Soc* 1565 *1951*.]

Aminopyrine (4-dimethylaminoantipyrene) *[58-15-1]* **M 231.3, m 107-109°, 108°, pK$_1^{25}$ -2.22, pK$_2^{25}$ 4.94.** It crystallises from petroleum ether, sublimes between 80° and 90°, and forms metal complexes. [*Beilstein* **25** H 452, **25** III/IV 3555.]

3-Aminoquinoline *[580-17-6]* **M 144.2, m 93.5°, pK$_1^{20}$ -0.58, pK$_2^{20}$ 4.94.** It crystallises from *C_6H_6, toluene, hexane and aqueous EtOH. [*Beilstein* **22** III/IV 4605, **22/10** V 233.]

4-Aminoquinoline *[578-68-7]* **M 144.2, m 155-155.5°, 158°, pK$_1^{25}$ -7.11(5.99), pK$_2^{20}$ 9.13.** It has been purified by zone refining and recrystallisation from *C_6H_6, EtOH or H_2O. The *hydrochloride* has **m** 308° (from MeOH), and the *picrate* has **m** 277° (from EtOH). [Albert et al. *J Chem Soc* 2240 *1948*, *Beilstein* **22** III/IV 4611, **22/10** V 341.]

5-Aminoquinoline *[611-34-7]* **M 144.2, m 110°, b 184°/10mm, 310°/760mm, pK$_1^{20}$ 0.97(0.49), pK$_2^{20}$ 5.42.** It crystallises from pentane and from *benzene or EtOH. The *picrate* has **m** 209-210°(dec) (202° dec) (from aqueous EtOH). [*Beilstein* **22** III/IV 4669, **22/10** V 297.]

6-Aminoquinoline *[580-15-4]* **M 144.2, m 117-119°, 120°, b 146°/0.3mm, 192-195°/14mm, pK$_1^{20}$ 1.63, pK$_2^{20}$ 5.59.** It is purified by column chromatography on a SiO_2 column using $CHCl_3$/MeOH (4:1) as eluent. It crystallises from *C_6H_6 or *C_6H_6/petroleum ether and is an **irritant**. The *styphnate* has **m** 239-240° (from EtOH) and **m** 242-243° (from aqueous Me_2CO). [Barrett et al. *J Chem Soc* 50, 57 1953, *Beilstein* **22** III/IV 4681, **22/10** V 303.]

8-Aminoquinoline *[578-66-5]* **M 144.2, m 70°, b 140.5-141°/7mm, 123°/5mm, pK$_1^{20}$ -0.52, pK$_2^{20}$ 3.95.** 8-Aminoquinoline crystallises from EtOH, ligroin, octane or H_2O, and complexes with metals. [*Beilstein* **22** III/IV 4708, **22/10** V 316.]

2-Aminothiazole *[96-50-4]* **M 108.1, m 93°, b 140°/11mm, pK^{20} 5.36.** It crystallises from petroleum ether (b 100-120°), or EtOH. [*Beilstein* **27** III/IV 4574.]

1-Amino-1,2,4-triazole *[24994-60-3]* **M 84.1, m 91-93°, pK$_{Est}$ ~2.** The triazole crystallises from water. [Barszez et al. *J Chem Soc, Dalton Trans* 2025 *1986*, Temple & Montgomery *1,2,4-Triazoles —The Chemistry of Heterocyclic Compounds* Vol 37 (Weissberger & Taylor eds.). Wiley & Sons NY *1981*, ISBN 0-471-0656-6.]

3-Amino-1,2,4-triazole (Amitrol) *[61-82-5]* **M 84.1, m 159°, pK$_1^{20}$ 4.04, pK$_2^{20}$ 11.08.** It crystallises from EtOH (charcoal), then three times from dioxane [Williams et al. *J Phys Chem* **61** 261 *1957*]. [*Beilstein* **26** H 137.] **Possible carcinogen. [***Beilstein* **26** H 137, Temple & Montgomery *1,2,4-Triazoles —The Chemistry of Heterocyclic Compounds* Vol 37 (Weissberger & Taylor eds.). Wiley & Sons NY *1981*, ISBN 0-471-0656-6.]

4-Amino-1,2,4(4*H*)-triazole *[584-13-4]* **M 84.1, m 80-81°, pK^{25} 3.23.** It crystallises from EtOH/ Et_2O or H_2O. The *hydrochloride* has **m** 151-152° (from EtOH, 1g/10ml). [Allen & Bell *Org Synth* Coll Vol **III** 96 *1955*, Barszez et al. *J Chem Soc, Dalton Trans* 2025 *1986*, *Beilstein* **26** H 16, **26** II 7, **26** III/IV 40, Temple & Montgomery *1,2,4-Triazoles —The Chemistry of Heterocyclic Compounds* Vol 37 (Weissberger & Taylor eds.). Wiley & Sons NY *1981*, ISBN 0-471-0656-6.]

7-Amino-4-(trifluoromethyl)coumarin, *[53518-15-3]* **M 229.1, m 222°, pK$_{Est}$ ~3.1.** Purify the coumarin by column chromatography on a C18 column, elute with acetonitrile/0.01M H_2O/HCl (1:1), and recrystallise it from isopropanol. *Alternatively*, it is eluted from a silica gel column with CH_2Cl_2, or by extracting a CH_2Cl_2 solution (4g/L) with 1M aqueous NaOH (3 x 0.1L), followed by drying ($MgSO_4$), filtration and evaporation. [Bissell *J Org Chem* **45** 2283 *1980*, Zimmermann et al. *Anal Biochem* **70** 258 *1976*.]

4(6)-Aminouracil (4-amino-2,6-dihydroxypyrimidine) *[873-83-6]* **M 127.1, m >350°, pK$_1^{20}$ 0.00 (basic), pK$_2^{20}$ 8.69 (acidic), pK$_3^{20}$ 15.32 (acidic).** Purify the aminouracil by dissolving it in 3M aqueous NH_3, filtering hot, and adding 3M formic acid until precipitation is complete. Cool, filter off (or centrifuge), wash well with cold H_2O, then EtOH and dry it in air. Dry it further in a vacuum at ~80°. [Barlin & Pfeiderer *J Chem Soc (B)* 1424 *1971*, *Beilstein* **25** III/IV 4107.]

Amodiaquin [4-(3-dimethylaminomethyl-4-hydroxyanilino)-7-chloroquinoline] *[86-42-0]* **M 355.9, m 208°(dec).** Amodiaquin crystallises from 2-ethoxyethanol or EtOH. [Burckhalter et al. *J Am Chem Soc* **70** 1363 *1948*, *Beilstein* **22** III/IV 4647.]

2-*n*-Amylpyridine (2-*n*-pentylpyridine) *[2294-76-0]* **M 149.2, b 63.0°/2mm, 206.5-207°/~760mm, n$_D^{26}$ 1.4861, pK^{25} 6.00.** Dry it with NaOH for several days, then distil it from CaO under reduced pressure, taking the middle fraction and redistilling it. The *picrate* has **m** 72-72.8° (from EtOH). [*Beilstein* **20** III/IV 2835.] *3-n-Pentylpyridine*, purified as the 2-isomer, has **b** 110-112°/20mm, 224-226°/748mm, and the *picrate* has **m** 79.5-80°(from EtOH). [*Beilstein* **20** III/IV 2835.]

4-*n*-Amylpyridine *[2961-50-4]* **M 149.2, b 78.0°/2.5mm, 229-230°/~760mm, n$_D^{20}$ 1.4908, pK$_{Est}$ ~6.1.** It is dried with NaOH for several days, then distilled from CaO under reduced pressure, taking the middle fraction and redistilling it. The *picrate* has **m** 104° (from EtOH). [*Beilstein* **20** III/IV 2836.]

Antipyrine [2,3-dihydro-1,5-dimethyl-3-oxo-2-phenylpyrazole] *[60-80-0]* **M 188.2, m 114°, b 319°, pK^{25} 1.45.** Antipyrine crystallises from EtOH/water mixture, *benzene, *benzene/petroleum ether or hot water (charcoal), and the crystals are dried under a vacuum. [*Beilstein* **24** H 27, **24** III/IV 75.]

Aspergillic acid (2-hydroxy-3-isobutyl-6-[1-methylpropyl]pyrazine 1-oxide) *[490-02-8]* **M 224.3, m 97-99°, pK^{25} 5.5, [α]$_D^{20}$ +13.3° (c 4, EtOH).** It is recrystallised from MeOH and is sublimed at 80°/10^{-3}mm. [Dutcher *J Biol Chem* **171** 321 *1947*, *Beilstein* **24** III/IV 235.]

Atropine [tropine (±)-tropate] *[51-55-8]* **M 289.4, m 114-116°, pK$_1^{20}$ 4.35, pK^{18} 9.85.** It crystallises from acetone or hot water, and sublimes at ~100°/high vacuum. Its solubility is 0.22%(~20°) and 1.3%(100°) in H_2O, and 83%(60°). The *sulfate monohydrate* has **m 190-194°**. [*Beilstein* **21** IV 183, **21/1** V 235.] *Antispasmodic*.

8-Azaadenine *[1123-54-2]* **M 136.1, m 345°(dec), pK$_1^{20}$ 2.65, pK$_2^{20}$ 6.29.** 8-Azaadenine crystallises from H_2O. [*Beilstein* **25** III/IV 4157.]

2-Azacyclotridecanone (laurolactam) *[947-04-6]* **M 197.3, m 152°.** 2-Azacyclotridecanone crystallises from $CHCl_3$ and is stored over P_2O_5 in a vacuum desiccator. [*Beilstein* **26/1** V 566.]

8-Azaguanine *[134-58-7]* **M 152.1, m >300°, pK$_1^{20}$ 1.04, pK$_2^{20}$ 6.29.** Dissolve it in hot M NH_4OH, filter, and cool. Recrystallise it, and wash it with water, then dry it in a vacuum. [*Beilstein* **26** III/IV 4171.]

7-Azaindole (1*H*-pyrrolo[2,3b]pyridine) *[271-63-6]* **M 118.1, m 105-106°, pK^{20} 4.57.** Recrystallise it

repeatedly from EtOH, then sublime it in a vacuum [Tokumura et al. *J Am Chem Soc* **109** 1346 *1987*]. The *N-acetate* has **m** 65-66° (from $*C_6H_6$), and the *picrate* has **m** 232-233° (from Me_2CO) [Clemo & Swan *J Chem Soc* 603 *1945*, *Beilstein* **23** III/IV 1105.]

1-Azaindolizine (1,7a-diazaindene, imidazo[1,2-a]pyridine) *[274-76-0]* **M 118.1, b 72-73°/1mm, pK^{20} 1.43 (in aqueous HCl).** 1-Azaindolizine is purified by distillation or gas chromatography. [Bower & Ramage *J Chem Soc* 4506 *1957*, Armarego *J Chem Soc* 4226 *1964*, *Beilstein* **23** II 1554, **23** III/IV 1104.]

8-Azapurine (1*H*-1,2,3-triazolo[4,5-*d*]pyrimidine, 1,2,3,4,6[3*H*]penta-azaindene) *[273-40-5]* **M 121.1, m 174-175° (effervescence, m depends on heating rate), pK_1^{20} 2.05 (equilib with covalent hydrate), pK_2^{20} 4.84.** Sublime 8-azapurine at 120-130°/0.01mm and recrystallise it from 3 parts of EtOH. [Albert *J Chem Soc(B)* 427 *1966*, *Beilstein* **26** III/IV 4108.]

Azetidine (trimethyleneimine) *[503-29-7]* **M 57.1, b 19°/132.5mm, 61.3-61.5°/760mm, d_4^{20} 0.846, n 1.432, pK^{25} 11.29.** Azetidine is a flammable, hygroscopic liquid smelling of ammonia, which absorbs CO_2 from air and should be kept under Argon. Purify it by drying it over solid KOH and distilling it through a short Vigreux column (p 11) at atmospheric pressure (under Argon) and keeping the pot temperature below 210°. It is moisture sensitive. The *hydrochloride* [36520-39-5] **M 93.6** has **m** > 300° and the *hydroiodide* has **m** 146.5°(from EtOH). The *N-Me* derivative has **m** 112°(from $*C_6H_6$/petroleum ether), and the *N-phenylcarbamoyl* derivative has **m** 189-190°(from EtOH). [Searles et al. *J Am Chem Soc* **78** 4917 *1956*, *Beilstein* **20** H 2, **20** I 3, **20** II 3, **20** III/IV 53, **20/1** V 136.]

Aziridine (ethyleneimine) *[151-56-4]* **M 43.1, b 55-56°/756mm, 56°/760mm, d_4^{24} 0.8321, pK^{25} 8.00.** Redistil it in an Ar or N_2 atmosphere in a fume hood, and store it over KOH in sealed bottles in a refrigerator. Commercial aziridine has been dried over sodium and distilled from the metal through an efficient column before use [Jackson & Edwards *J Am Chem Soc* **83** 355 *1961*, Wenker *J Am Chem Soc* **57** 2328 *1935*]. It is a weaker base than Me_2NH (pK^{25} 10.87) but is caustic to the skin. It should not be inhaled, causes inflammation of the eyes, nose and throat, and one may become sensitised to it. It is soluble in H_2O, has an ammoniacal smell and reacts with CO_2. Pure aziridine is comparatively stable but polymerises in the presence of traces of H_2O and is occasionally explosive in the presence of acids. CO_2 is sufficiently acidic to cause polymerisation (forms linear polymers) which is not free radical promoted. It is stable in the presence of bases. The violet *2:1 Cu complex* crystallises from EtOH containing a few drops of aziridine and adding Et_2O, and has **m** 142°(dec). The *picrate* has **m** 142°. [O'Rourke et al. *J Am Chem Soc* **78** 2159 *1956*.] It has also been dried over BaO and has been distilled from sodium under nitrogen. [Allen et al. *Org Synth* Coll Vol **IV** 433 *1963*, *Beilstein* **20** III/IV 1.] **TOXIC.**

Azuleno(1,2-b)thiophene *[25043-00-9]* **M 184.2.** It is crystallised from cyclohexane, then sublimed *in vacuo*.

Azuleno(2,1-b)thiophene *[248-13-5]* **M 184.2.** It is crystallised from cyclohexane, then sublimed *in vacuo*.

Azure A (3-amino-7-dimethylaminophenazin-5-ium chloride) *[531-53-3]* **M 291.8, CI 52005, m > 290°(dec), λ_{max} 633nm, pK^{25} 7.2.** Azure A has been twice recrystallised from H_2O and dried at 100°/1 hour in an oven. [*Beilstein* **27** III/IV 5151.]

Azure B (3-dimethylamino-7-methylaminophenazin-5-ium chloride) *[531-55-5]* **M 305.8, CI 52010, m > 201°(dec), λ_{max} 648nm, pK^{25} 7.4.** Azure B has been twice recrystallised from H_2O and dried at 100°/1 hour in an oven. [*Beilstein* **27** III/IV 5151.]

Azure C (3-amino-7-methylaminophenazin-5-ium chloride) *[531-57-7]* **M 277.8, λ_{max} 616nm, pK^{25} 7.0.** Azure C has been twice recrystallised from H_2O, and dried at 100°/1 hour in an oven.

Barbituric acid [6-hydroxypyrimidin-2,4-dione] *[67-52-7]* **M 128.1, m 250°(dec), pK_1^{25} 3.99, pK_2^{25} 12.5.** Recrystallise it twice from H_2O, then dry it for 2 days at 100°. [*Beilstein* **24** III/IV 1873.]

Benzimidazole *[51-17-2]* **M 118.1, m 172-173°, pK_1^{25} 5.53, pK_2^{25} 11.70.** It crystallises from water or aqueous EtOH (charcoal) and is dried at 100° for 12 hours. [*Beilstein* **23** H 131, **23/6** V 196.]

2-Benzimidazolylacetonitrile *[4414-88-4]* **M 157.2, m 200-205°(dec), 209.7-210.7°(corrected), 210°.** It is recrystallised from aqueous EtOH. It has also been recrystallised from hot H_2O using charcoal, and finally from aqueous EtOH. [Copeland & Day *J Am Chem Soc* **65** 1072 *1943*, *Beilstein* **25** III/IV 820.]

Benzo-15-crown-5 *[14098-44-3]* **M 268.3, m 78-80°.** It is recrystallised from *n*-heptane. **IRRITANT.** [Vögtle ed, Host Guest Complex Chemistry in *Topics in Current Chemistry* p98 *1981*, *Beilstein* **19/10** V 618.]

Benzo-18-crown-6 *[14098-24-9]* **M 312.2, m 42-45°, 43-43.5°.** Purify it by passage through a DEAE cellulose column in cyclohexane. It recrystallises from *n*-hexane. Its *thiourea complex* has **m** 127° [5-6 mol of urea to ether, Pedersen *J Org Chem* ***36*** 1690 *1971*]. The stability constants of the Na^+, K^+, Rb^+, Cs^+, Tl^+ and Ba^{2+} complexes are described in Hofmanova et al. *Inorg Chim Acta* **28** 73 *1978*. [NMR: Live & Chan *J Am Chem Soc* **98** 3769 *1976*]. [*Beilstein* **19/12** V 618.] **IRRITANT.**

Benzo[3,4]cyclobuta[1,2-*b*]quinoxaline *[259-57-4]* **M 204.2, m dec >250°.** It is purified by sublimation under reduced pressure.

Benzofuran (coumarone) *[271-89-6]* **M 118.1, b 62-63°/15mm, 97.5-99.0°/80mm, 170-173°/atm, 173-175°(169)/760mm, d_4^{20} 1.0945, n_D^{20} 1.565.** Benzofuran is steam distilled, dissolved in Et_2O, washed with 5% aqueous NaOH, saturated NaCl, dried (Na_2SO_4), evaporated and redistilled. The UV has λ_{max} at 245, 275, 282nm (log ε 4.08, 3.45, 3.48). The *picrate* has **m** 102-103°. [Burgstahler & Worden *Org Synth* Coll Vol **V** 251 *1973*, NMR: Black & Heffernan *Aust J Chem* **18** 353 *1965*, *Beilstein* **17/2** V 3.]

2-Benzofurancarboxylic acid *[496-41-3]* **M 162.1, m 192-193°, pK_{Est} ~3.2.** The acid crystallises from water. [*Beilstein* **18/6** V 419.]

Benzofurazan *[273-09-6]* **M 120.1, m 55°.** Purify benzofurazan by steam distillation from a dilute alkaline solution, crystallisation from EtOH (long white needles) and by sublimation. [Green & Rowe *J Chem Soc* **101** 2456 *1912*, Green & Rowe *J Chem Soc* **111** 618 *1917*, Ghosh et al. *J Med Chem* **15** 255 *1972*, *Beilstein* **27** H 568, **27** I 573, **27** III/IV 7115.]

Benzofuroxan (benzofurazan-1-oxide, benz[1,2,5]oxadiazol-1-oxide) *[480-96-6]* **M 136.1, m 70-71°, 72-73°.** Purify the 1-oxide by dissolving 3.6g in 45ml of 95% EtOH + 15ml H_2O, boil, filter hot and cool to 25°. The yellow crystalline solid is steam volatile (but less so than benzofurazan, above) and has a peculiar pungent odour. Its UV has λ_{max} at 355nm (EtOH). It was used as a dehydrogenation oxidant (Pätzold et al. *Synth Commun* **22** 281 *1992*]. [Mallory *Org Synth* Coll Vol **IV** 74 *1963*, Boulton & Ghosh *Adv Heterocyclic Chem* **10** 1 *1969*, Bo et al. *J Am Chem Soc* **79** 1750 *1977*, *Beilstein* **27** I 622, **27** II 629, **27** III/IV 7115.]

5,6-Benzoquinoline (benzo[f]quinoline) *[85-02-9]* **M 179.0, m 93°, 94°, b 350°, pK^{20} 5.11.** Purify as 3,4-benzoquinoline above. The *picrate* has **m** 258.1-259° (from EtOH or H_2O). [Albert et al. *J Chem Soc* 2240 *1948*, *Beilstein* **20** III/IV 4009, **20/8** V 220.]

7,8-Benzoquinoline (benzo[h]quinoline) *[230-27-3]* **M 179.0, m 52.0-52.5°, pK^{20} 4.21.** Purify it as for 3,4-benzoquinoline above. The *picrate* has **m** 196°(from Me_2CO). [*Beilstein* **20** H 463, **20** III/IV 4003, **20/8** V 215.]

1,2,3-Benzothiadiazole *[273-77-8]* **M 136.2, m 35°, 36-37°, b 63°/0.5mm, pK_{Est} ~<0.** 1,2,3-Benzothiadiazole crystallises from petroleum ether, and has λ_{max} at 264 and 306nm in hexane. [Overberger et al. *J Org Soc* **24** 1407 *1959*, *Beilstein* **27** III/IV 7113.]

2,1,3(1,2,5)-Benzothiadiazole *[272-13-2]* **M 136.2, m 44°, b 206°/760mm, pK_{Est} <0.** 2,1,3-Benzothiadiazole crystallises from petroleum ether and has UV with λ_{max} at 221-222, 304 and 330nm in EtOH. [Sanvicki & Carr

J Org Soc **22** 503 *1959*, *Beilstein* **27** III/IV 7118.]

1-Benzothiophene (benzo[b]thiophene, thianaphthene) *[95-15-8]* **M 134.2, m 29-32°, 30°, 31-32°, 32°, b 100°/16mm, 103-105°/20mm, 221-222°/760mm, $d_4^{32.2}$ 1.1484, n_D^{39} 1.6306.** 1-Benzothiophene has the odour of naphthalene. If the IR spectrum is not very good, then suspend it in a faintly alkaline aqueous solution and steam distil it. Extract the distillate with Et_2O, dry the extract ($CaCl_2$), filter, evaporate the solvent and fractionate the residue. The distillate sets solid. The *sulfoxide* has **m** 142°, the *picrate* has **m** 148-149° (yellow crystals from EtOH) and the *styphnate* has **m** 136-137°. [Hansch & Lindwall *J Org Chem* **10**, 381 *1945*, Meyer & Meyer *Chem Ber* **52B** 1249 *1919*, Weisgerber & Kruber **53** 1551 *1920*, Iddon & Scrowston *Adv Heterocycl Chem* **11** 177 *1970*, *Beilstein* **17/2** V 6.]

1,2,3-Benzotriazole *[95-14-7]* **M 119.1, m 96-97°, 98.5°, 100°, b 159°/0.2mm, 204°/15mm, pK_1^{20} 1.6, pK_2^{20} 8.64.** 1,2,3-Benzotriazole crystallises from toluene, $CHCl_3$, Me_2NCHO or a saturated aqueous solution, and is dried at room temperature or in a vacuum oven at 65°. Losses are less if the material is distilled in a vacuum. **CAUTION: may EXPLODE during distillation; necessary precautions must be taken.** [Damschroder & Peterson *Org Synth* Coll Vol **III** 106 *1955*, *Beilstein* **26** III/IV 93.]

***O*-Benzotriazol-1-yl-*N,N,N′,N′*-tetramethyluronium hexafluorophosphate (HBTU)** *[94790-37-1]* **M 379.2, m 200° (dec), 250°, 254°(dec).** Wash the salt with H_2O (3x), CH_2Cl_2 (3x), dry and recrystallise it from MeCN. Dry it in a vacuum and store it cold in the dark [Dourtoglou et al. *Tetrahedron Lett* 1269 *1978*, NMR: Dourtoglou and Gross *Synthesis* 572 *1984*].

Benzoxazolinone (2-hydroxybenzoxazole) *[59-49-4]* **M 135.1, m 137-139°, 142-143°(corrected), b 121-213°/17mm, 335-337°/760mm.** Benzoxazolinone is purified by recrystallisation from aqueous Me_2CO followed by distillation at atmospheric pressure, then in a vacuum. The *methyl mercury salt* recrystallises from aqueous EtOH and has **m** 156-158°. [Bywater et al. *J Am Chem Soc* **67** 905 *1945*, *Beilstein* **27** III/IV 2677.]

***S*-(+) and *R*-(-) 1-Benzoyl-2-*tert*-butyl-3-methyl-4-imidazolinone** *[R- 101055-57-6] [S-101055-56-5]* **M 260.3, m 142-143°, 145.6-146.6°, 145-147°, $[\alpha]_{546}^{20}$ (+) and (-) 155°, $[\alpha]_D^{20}$ (+) and (-) 133° (c 1, $CHCl_3$).** Recrystallise these chiral imidazolinones from boiling EtOH (solubility is 1.43g/ml) or better by dissolving in CH_2Cl_2 and adding pentane, filtering and drying for at least 12 hours at 60°/0.1mm and sublime them at 135°/0.01mm. They have also been purified by flash column chromatography through Merck silica gel at 0.04-0.063mm and using Et_2O/petroleum ether/MeOH (60:35:5) as eluent. They are then recrystallised from EtOH/petroleum ether. [IR, NMR: Seebach et al. *Helv Chim Acta* **70** 237 *1987*, Fitzi & Seebach *Angew Chem, Int Ed Engl* **25** 345 *1986*.] The *racemate* is purified in a similar manner and has **m** 104-105° [NMR: Seebach et al. *Helv Chim Acta* **68** 949 *1985*].

2-Benzoylpyridine *[91-02-1]* **M 183.2, m 41-43°, 48-50°, 72°/0.02mm, 104-105°/0.01mm, n_D^{24} 1.6032, pK_{Est} ~2.4.** Dissolve 2-benzoylpyridine in Et_2O, shake it with aqueous $NaHCO_3$, H_2O, dry it over $MgSO_4$ and evaporate. The residue solidifies on cooling. The solid can be recrystallised from petroleum ether. Its *hydrochloride* crystallises from Me_2CO, **m** 126-127°, and the *2,4-dinitrophenylhydrazone* has **m** 193-195°. It distils at high vacuum. [Kinkerton & Thames *J Organomet Chem* **24** 623 *1970*, *Beilstein* **21/8** V 566.]

***N*^{6}-Benzyladenine** *[1214-39-7]* **M 225.3, m 231-232°, 232.5°(dec), $pK_{Est(1)}$~ 4.2, $pK_{Est(2)}$~ 10.1.** It is purified by recrystallisation from aqueous EtOH. It has λ_{max} at 207 and 270nm (H_2O), 268 nm (pH 6), 274nm (0.1 N HCl) and 275nm (0.1 N NaOH). [Daly *J Org Chem* **21** 1553 *1956*, Bullock et al. *J Am Chem Soc* **78** 3693 *1956*, *Beilstein* **26** III/IV 3575.]

1-Benzyl-1-aza-12-crown-4 (10-benzyl-1,4,7-trioxa-10-azacyclododecane) *[84227-47-4]* **M 265.4, 122-125°/0.03mm, 140-143°/0.05mm, d_4^{20} 1.09, n_D^{20} 1.52, pK_{Est} ~ 7.7.** Dissolve it in CH_2Cl_2 or CCl_4 (1g in 30ml), wash it with H_2O (30ml), brine (30ml), H_2O (30 ml) again, dry ($MgSO_4$ or Na_2SO_4), and evaporate. The residue in CH_2Cl_2 is chromatographed through Al_2O_3 (eluting with 10% EtOAc in hexane); evaporate, collect the correct fractions and distil (Kügelrohr) them. Log K_{Na} in dry MeOH at 25° for Na^+ complex is 2.08. [White et al. *Tetrahedron Lett* **26** 151 *1985*, Arnold et al. *J Org Chem* **53** 5652 *1988*.]

2-Benzyl-1,3-dioxolane *[101-49-5]* **M 164.2, b 98-99°/1mm, 110°/5mm, 137-138°/34mm, 240-242°/atm, d $_4^{20}$ 1.087, n $_D^{20}$ 1.532.** Dissolve 2-benzyl-1,3-dioxolane in CH_2Cl_2, wash well with 1M NaOH, dry over K_2CO_3, filter, evaporate and distil it through a short path still (Kügelrohr). It has also been purified by preparative gas chromatography. [Raber & Guida *Synthesis* 808 *1974*, Lloyd & Luberoff *J Org Chem* **34** 3949 *1969*, *Beilstein* **19** III/IV 220.]

***S-(+)-* and *R-(-)-* Benzyl glycidyl ether (1-benzyloxyoxirane)** *[S:14618-80-5] [R:16495-13-9]* **M 164.2, b 68°/10^{-4} mm, 105°/0.4mm, d $_4^{20}$ 1.072, n $_D^{20}$ 1.517, [α] $_{546}^{20}$ (+) and (-) 5.5°, [α] $_D^{20}$ (+) and (-) 5.1° (c 5, toluene), [α] $_D^{20}$ (+) and (-) 1.79° (c 5.02, $CHCl_3$), [α] $_D^{21}$ (+) and (-) 15.3° (neat).** This ether in EtOAc is dried (Na_2SO_4), then purified by flash chromatography using petroleum ether/EtOAc (5:1) as eluent. The ether distils through a short path distillation apparatus (Kügelrohr) as a colourless liquid. *Alternatively*, dissolve it in $CHCl_3$, wash it with H_2O, dry (Na_2SO_4), evaporate and purify by silica gel chromatography. [Anisuzzamen & Owen *J Chem Soc* 1021 *1967*, Takano et al. *Heterocycles* **16** 381 *1981*, Lipshutz et al. *Org Synth* **69** 82 *1990*, Takano et al. *Synthesis* 539 *1989*, Honda et al. *Chem Pharm Bull Jpn* **39** 1385 *1991*, *Beilstein* **12** IV 2277.]

3-Benzyl-5-(2-hydroxyethyl)-4-methylthiazolinium chloride *[4568-71-2]* **M 269.8, m 142-144°, 145-147°.** Purify the chloride by recrystallisation from EtOH or H_2O. If placed in a bath at 125° and heated at 2°/minute, the melting point is 140.5-141.4°. [Livermore & Sealock *J Biol Chem* **167** 699 *1947,* Maier & Metzler *J Am Chem Soc* **79** 4386 *1957*, *Beilstein* **27** III/IV 1758.]

5-Benzyloxyindole *[1215-59-4]* **M 223.3, m 96-97°; 100-103°, 104-106°, pK^{25} <0.** It is recrystallised from *C_6H_6/petroleum ether or petroleum ether. The *picrate* forms red crystals from *C_6H_6 and has **m** 142-143°. [Burton & Leong *Chem Ind (London)* 1035 *1953*, Ek & Witkop *J Am Chem Soc* **76** 5579 *1954*, fluorescence: Bridges & Williams *Biochem J* **107** 225 *1968*, *Beilstein* **27** III/IV 1758.]

1-Benzyl-4-piperidone *[3612-20-2]* **M 189.3, b 107-108°/0.2mm, 114-116°/0.3mm, 143-146°/5mm, 157-158°/11mm, d $_4^{20}$ 1.059, n $_D^{20}$ 1.538.** If the physical properties show contamination, then dissolve it in the minimum volume of H_2O, made strongly alkaline with aqueous KOH, extract it with toluene several times, dry the extract with K_2CO_3, filter, evaporate and distil the residue at high vacuum using a bath temperature of 160-190°, and redistil it. [Brookes & Walker *J Chem Soc* 3173 *1957*, Bolyard *J Am Chem Soc* **52** 1030 *1930*.] The *hydrochloride* has **m** 159-161° (from Me_2CO/Et_2O), and the *picrate* has **m** 174-182° (from Me_2CO/Et_2O). [Grob & Brenneisen *Helv Chim Acta* **41** 1184 *1958*, *Beilstein* **21/6** V 424.]

2-Benzylpyridine *[101-82-6]* **M 169.2, b 98.5°/4mm, d $_4^{20}$ 1.054, n $_D^{26}$ 1.5771, pK^{25} 5.13.** Dry it with NaOH for several days, then distil it from CaO under reduced pressure, and redistil the middle fraction. [*Beilstein* **20/7** V 556.]

4-Benzylpyridine *[2116-65-6]* **M 169.2, b 110.0°/6mm, d $_4^{20}$ 1.065, n $_D^{26}$ 1.5814, pK^{25} 5.59.** Dry it with NaOH for several days, then distil it from CaO under reduced pressure, and redistil the middle fraction. [*Beilstein* **20/7** V 561.]

Berbamine *[478-61-5]* **M 608.7, m 197-210°, [α] $_D^{20}$ +115° ($CHCl_3$), pK^{20} 7.33. (70% aqueous EtOH).** Crystallise berbamine from petroleum ether or *C_6H_6 (with 1*C_6H_6 **m** 129-134°). [Bick *Aust J Chem* **9** 111, 118 *1956*, *Beilstein* **27** II 891, **27** III/IV 8732.]

Berberine *[2086-83-1]* **M 336.4, m 145°, 147-148°, pK $_1^{20}$ 2.47, pK $_2^{20}$ 11.73 (pseudobase?).** Berberine crystallises from petroleum ether or ether as yellow needles or from H_2O. [*Beilstein* **27** II 567, **27** III/IV 6539.]

Berberine chloride ($2H_2O$) (Neutral Yellow 18) *[633-65-8 (anhydrous), 5956-60-5 ($2H_2O$)]* **M 407.9, m 204-206°(dec), CI 75160, pK^{20} 2.47.** Berberine chloride crystallises from water to give the *dihydrate*. The anhydrous salt may be obtained by recrystallisation from EtOH/Et_2O, wash the crystals with Et_2O and dry them in a vacuum. The *iodide* has **m** 250°(dec) (from EtOH). [Perkin *J Chem Soc* **113** 503 *1918*, Kametani et al. *J Chem Soc(C)* 2036 *1969*, *Beilstein* **27** I 515, **27** II 567.]

Bicuculline See entry in "Miscellaneous", Chapter 7.

Bilirubin *[635-65-4]* **M 584.7, m >360°, ε_{450nm} 55,600 in $CHCl_3$, pK_{Est} ~3.0.** An acyclic tetrapyrrole bile pigment with impurities which can be eliminated by successive Soxhlet extraction with diethyl ether and MeOH. It crystallises from $CHCl_3$ as deep red-brown rhombs, plates or orange-red prisms from chlorobenzene (**m** 330° dec) and is dried to constant weight at 80° under vacuum. [Gray et al. *J Chem Soc* 2264, 2276 *1961*, *Beilstein* **26** III/IV 3268.]

Biliverdine *[114-25-0]* **M 582.6, m >300°, pK^{25} 3.0.** This is the precursor of bilirubin (above) and forms dark green plates or prisms, with a violet reflection, from MeOH. The *dimethyl ester*, when crystallised from MeOH has **m** 215°(209°), and when crystallised from $CHCl_3$/petroleum ether gives blue-green crystals with **m** 202°. [Gray et al. *J Chem Soc* 2264 *1961*, Sheldrick *J Chem Soc, Perkin Trans 2* 1457 *1976*, *Beilstein* **26** III/V 3272.]

2-(4-Biphenylyl)-5-phenyl-1,3,4-oxadiazole (BPD) *[852-38-0]* **M 298.4, m 166-167°, 167-170°.** BPD is recrystallised from toluene. It is a good scintillation material [Brown et al. *Discussion Faraday Soc* **27** 43 *1959*]. [*Beilstein* **27** III/IV 7283.]

2,2'-Bipyridyl *[366-18-7]* **M 156.2, m 70.5°, b 273°, pK_1^{25} -0.52, pK_2^{25} 4.44.** 2,2'-Bipyridyl crystallises from hexane, or EtOH, or (after charcoal treatment of a $CHCl_3$ solution) from petroleum ether. Also, it precipitates from a concentrated solution in EtOH by addition of H_2O. Dry it in a vacuum over P_2O_5. It can be further purified by chromatography on Al_2O_3 or by sublimation. Its UV (EtOH) has λ_{max} at 280nm (logε 4.13). [Airoldi et al. *J Chem Soc, Dalton Trans* 1913 *1986*, *Beilstein* **23** H 199, **23/8** V 16.]

4,4'-Bipyridyl *[553-26-4]* **M 156.2, m 73°(hydrate)** *[123333-55-1]***, 114° (171-171°)(anhydrous), b 305°/760mm, 293°/743mm, pK_1^{20} 3.17, pK_2^{20} 4.82.** It crystallises from water, *benzene/petroleum ether, ethyl acetate and sublimes *in vacuo* at 70°. Also purify it by dissolving in 0.1M H_2SO_4 and twice precipitating by addition of 1M NaOH to pH 8. Then recrystallise it from EtOH. For the *dihydrochloride* see Viologen below. [Collman et al. *J Am Chem Soc* **109** 4606 *1987*, *Beilstein* **23** H 800, **23** III/IV 1371, **23/8** V 28.]

2,2'-Biquinolin-4,4'-dicarboxylic (2,2'-bicinchoninic) acid *[1245-13-2]* **M 344.3, m 367°, $pK_{Est(1)}$ ~1.5, $pK_{Est(2)}$ ~4.0.** Dissolve the acid in dilute NaOH and precipitate it with acetic acid, filter, wash swell with H_2O and dry it at 100° in a vacuum oven. Attempts to form a picrate failed. The *methyl ester* ($SOCl_2$-MeOH) has **m** 165.6-166°. [Lesesne & Henze *J Am Chem Soc* **64** 1897 *1942*, Brown et al. *J Am Chem Soc* **68** 2705 *1946*, *Beilstein* **25** III/IV 1148.] For the di-K salt see entry in "Metal-organic Compounds" in Chapter 5.

2,2'-Biquinolyl (α,α'-diquinolyl) *[119-91-5]* **M 256.3, m 196°, pK_{Est} ~4.2.** Decolourise 2,2'-biquinolyl in $CHCl_3$ solution (charcoal), then crystallise it to constant melting point from EtOH or petroleum ether [Cumper et al. *J Chem Soc* 1188 *1962*]. [*Beilstein* **23/10** V 8.]

2,5-Bis(4-aminophenyl)-1,3,4-oxadiazole (BAO) *[2425-95-8]* **M 252.3, m 252-255°, 254-255°.** BAO is recrystallised from EtOH using charcoal and under N_2 to avoid oxidation. It is a fluorescent stain for DNA [Yataghanas et al. *Exptl Cell Res* **56** 59 *1969*]. [*Beilstein* **27** III/IV 8158.]

2,5-Bis(2-benzothiazolyl)hydroquinone *[33450-09-8]* **M 440.3, m dec >200°.** Purify the hydroquinone by repeated crystallisation from dimethylformamide followed by sublimation in vacuum [Erusting et al. *J Phys Chem* **91** *1404 1987*].

2,5-Bis(4-biphenylyl)-1,3,4-oxadiazole (BBOD) *[2043-06-3]* **M 374.5, m 229-230°, 235-238°.** BBOD is recrystallised from heptane or toluene. It is a good scintillant. [Hayes et al. *J Am Chem Soc* **77** 1850 *1955*.]

3,3-Bis(chloromethyl)oxacyclobutane (3,3-bis-[chloromethyl]oxetane) *[78-71-7]* **M 155.0, m 18.9°, b 65°/5mm, 80°/10mm, 103°/30mm, 198°/atm, d_4^{20} 1.290, n_D^{20} 1.486**. Shake it with aqueous $NaHCO_3$ or $FeSO_4$ to remove peroxides, separate, dry with anhydrous Na_2SO_4, then distil it under reduced pressure from a little CaH_2 [Dainton et al. *Trans Faraday Soc* **56** 1784 *1960*, Farthing *J Chem Soc* 3648 *1955*]. The *3,3-bis-*

(phenoxymethyl) derivative is described below. [*Beilstein* **17** III/IV 68.] **Lachrymatory.**

***N,N'*-Bis(nicotinic acid) hydrazide** *[840-78-8]* **M 227-228°, m dec 200°, pK_{Est} ~3.3.** The hydrazide crystallises from water; it is also soluble in hot EtOH but insoluble in *C_6H_6, petroleum ether or $CHCl_3$. [Graf *J Prakt Chem* [2] **138** 290 *1933*, *Beilstein* **22** III/IV 455.]

3,3-Bis(phenoxymethyl)oxacyclobutane (**3,3-bis-[phenoxymethyl]oxetane)** *[1224-69-7]* **M 270.3, m 67.5-68°, b 143°/0.05mm.** Distil it under high vacuum, then crystallise the solidified distillate from MeOH. [Farthing *J Chem Soc* 3648 *1955*, *Beilstein* **17** III/IV 2010.]

Blue Tetrazolium (tetrazolium blue chloride) *[1871-22-3]* **M 727.7, m 254-255°(dec).** Crystallise the chloride from 95% EtOH/anhydrous diethyl ether to constant absorbance at 254nm. [*Beilstein* **26** III/IV 1789.]

1-*N*-Boc-piperidine (*N-tert*-butoxycarbonylpiperidine, 1-piperidincarboxylic acid 1,1-dimethylethyl ester) *[75844-69-8]* **M 185.3, b 79°/0.05mm, d_4^{25} 0.964, n_D^{20} 1.454.** It is purifed by bulb-to-bulb distillation at 65°/1mm. If it is discoloured then dissolve it in Et_2O, wash it with brine, separate, dry the Et_2O layer over K_2CO_3, filter, evaporate, and distil in a vacuum. Its IR has ν_{max} at 1695 (CO) cm^{-1} (film). [IR, NMR, MS: Dieter & Li *J Org Chem* **62** 7726 *1997*, Beak & Lee *J Org Chem* **58** 1109 *1993*].

1-*N*-Boc-2-piperidone (1-*N-tert*-butoxycarbonyl-2-piperidone) *[85908-96-9]* **M 199.3, m 30-33°, 32-34°, 33-35°, 36°, b 110°/0.1mm.** This useful synthetic starting material is prepared by using the same principles as for the 4-oxo isomer below. Thus to a solution of γ-valerolactam (2-piperidone, 6.0g, 60.5mmol, [675-20-7]), DMAP (1.85g, 15.1mmol, 0.2 equiv, [1122-58-3] and Boc_2O (26.6g, 121.0mmol, 2.0 equiv, [24074-26-8]) in CH_2Cl_2 (70ml) at ~25° is added Et_3N (17.8g, 127.7mmol, 2.1 equiv) and is stirred for 32 hours, then quenched with 1.2N HCl (10ml). The aqueous layer is extracted with CH_2Cl_2, the combined CH_2Cl_2 solutions are washed with saturated aqueous $NaHCO_3$ (20ml), brine (30ml), dried ($MgSO_4$), filtered and evaporated *in vacuo*. The crude product is purified by flash chromatography through Kieselgel 60 (230-240 mesh with cyclohexane/EtOAc 8:2 elution) to give *1-N-Boc-2-piperidone* (9.71g, 48.7mmol, 81%) as a colourless low melting solid **m 36°**. It has R_F 0.40 (TLC on Kieselgel $60F_{254}$, cyclohexane/EtOAc 7:3), and its IR (KBr) has ν_{max} at 1713, 1302, 1249, 1159 and 1138 cm^{-1}; the ^1H NMR (300MHz, $CDCl_3$, with residual $CHCl_3$ as internal standard at δ 7.27) has δ at 3.66 (m, 2H, H-6,6), 2.50 (m, 2H, H-3,3), 1.90-1.74 (4H, H-3,3,4,4) and 1.53 (s, 9H, *t*-Bu); the ^{13}C NMR (75MHz, $CDCl_3$, with residual $CDCl_3$ as internal standard at δ 77.1) has δ at 171.1 (s), 152.4 (s), 82.5 (s), 46.0 (t), 34.6 (t), 27.7 (q), 22.5 (t) and 20.2 (t); and the EI MS has *m/z* (relative intensity) at 199 (M^+ 0.3), 144 (52), 126 (21), 100 (38), 99 (31), 98 (31), 82 (24), 57 (100), 56 (38) and 55 (30). [Cossy et al. *New J Chem* **27** 475 *2003*.] This synthesis has also been carried out in MeCN/DMAP at ~25°/24 hours (74% yield) without further base [Moody & Taylor *J Chem Soc, Perkin Trans 1* 721 *1989*].
1-N-Boc-2-piperidone is hydrolysed at ambient temperature by LiOH (30 minutes, 90%), or undergoes methanolysis by MeONa/MeOH (15 minutes, 94%) to provide γ-$BocNH(CH_2)_4CO_2H$ (after acidification) or γ-$BocNH(CH_2)_4CO_2Me$ without losing the Boc protecting group, respectively [Flynn et al. *J Org Chem* **54** 2424 *1989*]

1-*N*-Boc-3-piperidone (1-*N-tert*-butoxycarbonyl-3-piperidone) *[98977-36-7]* **M 199.3, m 35-40°, b 104-105°/0.4mm.** 3-Piperidone used to prepare the Boc derivative was obtained by hydrogenolysis of *N*-benzyl-3-piperidone hydrochloride hydrate (4.2g, 18.6mmol, [50606-58-1]) catalysed by 10% Pd/C (0.8g) and H_2 at 55 psi while stirring for 16 hours in degassed MeOH (200ml). This was filtered (Celite) and evaporated *in vacuo*. The crude oily 3-piperidone was dissolved in THF (200ml), treated with Boc_2O (5.27g, 24.1mmol) and saturated aqueous Na_2CO_3 (50ml), stirred for 4 hours and evaporated *in vacuo.* The white solid was partitioned between EtOAc and 1N HCl, the organic layer was collected, washed with 1N NaOH and brine, dried ($MgSO_4$), filtered, and evaporated *in vacuo* to give an oil which was purified by flash chromatography (silica gel, hexane/EtOAc 3:1) to give *1-N-Boc-3-piperidone* (2.93g, ~100%) as a colourless oil. [Lucca et al. *J Med Chem* **48** 2195 *2005*.] Its ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 3.99 (s, 2H, 2,2-H), 3.58 (t, *J* = 6.3 Hz, 2H, 6,6-H), 2.46 (t, *J* = 6.3 Hz, 2H 4,4-H), 1.97 (t, *J* = 6.3 Hz, 2H, 5,5-H), and 1.45 (s, 9H, *t*-Bu); and the HRMS has

m/z 200.1285 and calculated for $C_{10}H_{18}NO_3$ (M + H) was 200.1287. *Alternatively*, and almost similar preparation, was carried out except that saturated aqueous Na_2CO_3 was replaced by Et_3N (3 equiv) to give an 81% yield of *1-N-Boc-3-piperidone* which was distilled at high vacuum undecomposed. [Brehm et al. *J Med Chem* **29** 224 *1986*.]
In a completely different synthesis, involving catalysed intramolecular cyclisation, *(5-oxo-6-dimethyl-sulfoxonium-hexyl)-carbamic acid tert-butyl ester* (250mg, 0.901mmol) in CH_2Cl_2 (8.0ml, purged with N_2 for 30 minutes) was added *via* a syringe pump over 18 hours to a solution of $[Ir(COD)Cl]_2$ (6.05mg, 9.01μmol, 0.01 equiv, [12112-67-3]) in degassed CH_2Cl_2 (4.0ml) at 70°. The mixture was then evaporated *in vacuo*, and the residue was purified through a silica gel column and eluting with hexanes/EtOAc (3:2) to afford *1-N-Boc-3-piperidone* (147mg, 82%) identical with the above. [Mangion et al. *Org Lett* **11** 3566 *2009*.]

1-*N*-Boc-4-piperidone (1-*N*-*tert*-butoxycarbonyl-4-piperidone) *[98977-36-7]* **M 199.3, m 68-69°, 70-72°, 72°, 73-75°, 74-75°, 74.4-75.2°.** It is prepared by dissolving 4-piperidone (1g, 6.5mmol [41661-47-6]) and EtN(*iso*-Pr)$_2$ (2.8ml, 16mmol, DIPEA [7087-68-5]) in dioxane/H_2O (4:1, 10ml), adding Boc_2O (2.2g, 9.8mmol, [24074-26-8]) slowly with stirring at ~25° for 24 hours. The solvent is removed *in vacuo*, the residue is dissolved in CH_2Cl_2, washed with H_2O (3 x), dried ($MgSO_4$), filtered and evaporated *in vacuo*. The residue is triturated with Et_2O, the white residue is collected by filtration and recrystallised from hexane to give the *Boc-piperidone* (75%), **m 73.5°**. It also crystallises from petroleum ether**,** toluene or EtOAc and can be dried in a vacuum desiccator over shredded paraffin wax. It has R_F 0.74 (TLC on Kieselgel $60F_{254}$, hexane/EtOAc 4:6), and its IR (KBr) has ν_{max} at 1715 and 1680 cm^{-1}. Its ^1H NMR (300MHz, $CDCl_3$) has δ at 3.72 (t, *J* = 6.3 Hz, 4H, 3,5-H), 2.44 (t, *J* = 6.3 Hz, 4H 2,6-H) and 1.50 (s, 9H, *t*-Bu); and the ^1H NMR (300MHz, DMSOd_6) has δ at 3.6 (t, 4H, 3,5-H), 2.4 (t, 4H, 2,6-H) and 1.4 (s, 9H, *t*-Bu). It has been used extensively to introduce a piperidine ring for making drugs because the 4-oxo group can be functionalised in various ways and deprotection of the nitrogen allows bonding to this atom. [Houssin et al. *J Med Chem* **45** 533 *2002*, Ellis et al. *J Med Chem* **51** 2170 *2002*.]

Brazilin (6a*S*-*cis*-7,11b-dihydrobenzo[b]indeno[1,2-d]pyran-3,6a,9,10(6*H*)-tetraol) *[474-07-7]* **M 269.3, m 130°(dec), 250°, $pK_{Est(1)}$ ~9.3, $pK_{Est(2)}$ ~10.0, $pK_{Est(3)}$ ~12.5 (all phenolic), CI 75280.** Brazilin crystallises from EtOH as yellow crystals which become orange when exposed to light and air, and is yellow in dilute acid but crimson in dilute alkali. When crystallised from H_2O, it has **m** 247-248°. It forms coloured metal salts and is oxidised in air to *Brazilein*, the quinonoid form. The *(±)-form has been resolved, and the (+)-enantiomer* has $[\alpha]_D^{20}$ +121° (c 1, MeOH). [Craig et al. *J Org Chem* **30** 1573 *1965*, Morsingh & Robinson *Tetrahedron* **26** 281 *1970*, *Beilstein* **17** H 194, **17** II 244, **17** III/IV 2711.]

Brilliant Cresyl Blue (*NN*-diethyl-3-imino-8-methyl-3*H*-phenoxazin-7-amine hydrochloride) *[4712-70-3]* **M 332.8, pK^{25} 3.2.** Crystallise the dye from petroleum ether. It has λ_{max} at 625nm (H_2O) and 622nm (95% aqueous EtOH). [*Beilstein* **27** H 400, **27** II 454, **27** III/IV 5160.]

5-Bromocytosine *[2240-25-7]* **M 190.0, m 245-255°(dec), 250°(dec), pK_1^{25} 3.04, pK_2^{25} 10.33.** 5-Bromocytosine is recrystallised from H_2O or 50% aqueous EtOH. *Alternatively*, dissolve *ca* 3g in conc HCl (10ml) and evaporate to dryness. Dissolve the residual hydrochloride in the minimum volume of warm H_2O and make faintly alkaline with aqueous NH_3. Collect the crystals and dry them in a vacuum at 100°. [Hilbdert & Jensen *J Am Chem Soc* **56** 134 *1934*, *Beilstein* **25** III/IV 3689.]

2-(2-Bromoethyl)-1,3-dioxane *[33884-43-4]* **M 195.1, b 67-70°/2.8mm, 71-72°/4mm, 95°/15mm, d_4^{20} 1.44, n_D^{20} 1.4219**. Purify it by vacuum fractionation. Also dissolve it in Et_2O, wash with aqueous $NaHCO_3$, dry the extract (Na_2SO_4), filter and fractionate at high vacuum. Its ^{1}HNMR in CCl_4 has δ at 1.3 (m, 1H), 2.1 (m, 3H), 3.36 (t, 2H), 3.90 (m, 4H) and 4.57 (t, H). [Stowell *J Org Chem* **41** 560 *1976*, NMR, MS: Schwarz & Franke *Tetrahedron* **35** 1969 *1979*, Kriesat & Gisvold *J Pharm Sci* **60** 1250 *1971*, *Beilstein* **19/1** V 69.]

2-(2-Bromoethyl)-1,3-dioxolane *[18742-02-4]* **M 181.1, b 68-80°/8mm, 68-73°/10mm, 78-80°/20mm, d_4^{20}**

1.510, n_D^{20} 1.479. Dissolve it in pentane, wash with 5% aqueous $NaHCO_3$, dry (Na_2SO_4), and evaporate. Distil the residue. [NMR: Büchi & Wüest *J Org Chem* **34** 1122 *1969*, Kriesat & Gisvold *J Pharm Sci* **60** 1250 *1971*, *Beilstein* **19/1** V 69.]

6-Bromo-5-fluoro-1*H*-indole *[259860-08-7]* **M 214.0, m 83-84°, $pK_{Est(1)}$ ~ −4.05 (basic), $pK_{Est(2)}$ ~15.9 (acidic).** There are several preparations of this indole. In a patent (to Vernallis Research Ltd, US6380238, *2002*] *N,N*-dimethylformamide dimethylacetal (8.5ml, 60mmol) was added to a stirred solution of 4-bromo-5-fluoro-2-nitrotoluene (11.8g, 50mmol) in DMF (30ml) in one portion under argon at ~25°, then heated at 120° for 16 hours and evaporated *in vacuo*. The residual oil crystallised from MeOH/CH_2Cl_2 (4:1) to give a purple solid (4.5g) which was dissolved in MeOH/THF (1:1, 30ml), mixed with Raney Ni (1g), cooled to 0° and $N_2H_4.H_2O$ (0.8ml, 16mmol) was added all at once. After stirring for 90 minutes, more $N_2H_4.H_2O$ (0.8ml) was added and stirred at 0° for 30 minutes. The mixture was filtered through Celite and the filter cakes was washed with THF. The combined filtrates were evaporated *in vacuo*, and the residue was purified by chromatography [SiO_2 with heptane/CH_2Cl_2 (4:1) as eluent] to give the *indole* (1.7g, 16%) as an off-white solid. In a second patent [to M.P. Dillon et al. US2004/224973, *2004*, see also Batcho & Leimgruber *Org Synth* **63** 214 *1985*] crude [2-(4-bromo-5-fluoro-2-nitrophenyl)vinyl]-dimethylamine and Raney Ni in THF gave after flash chromatography through a silica gel column (eluting with 10% EtOAc in hexane) which gave the indole as a light green solid (61%). However, when the same enamine (1.89g, 4.38mmol) in EtOH (35ml) was treated with a mixture of Fe (4.42g, 79mmol) in AcOH (35ml) and stirred at 90° overnight, then filtered, evaporated and the residue purified by chromatography as above, pure *6-bromo-5-fluoro-1H-indole* (0.83g, 89%) was obtained as a yellow solid [Patent to the Board of Trustees of the University of Illinois; WO2008/77138 *2008*]. It had IR (nujol) with ν_{max} at 3395, 2925, 2855, 1570, 1469, 1451, 1408, 1314, 1145, 1105, 865, 763 and 505 cm^{-1}; and the ^1H NMR (400MHz, $CDCl_3$) had δ at 7.85 (br s, 1H), 7.55 (dd, 1H, *J* = 5.6 and 0.9 Hz), 7.34 (d, 1H, *J* = 9.0 Hz), 7.23 (t, 1H, *J* = 2.8 Hz) and 6.45-6.51 (m, 1H).
6-Bromo-5-fluoro-1-methylindole was obtained as a colourless solid in 99% yield by converting the indole to its *N-sodio*- derivative with NaH (1.5mol) in DMF at 0°/30 minutes, followed by MeI (1.2mol) for 1 hour at ~25°, then purified by column chromatography as above. Its ^1H NMR (400MHz, $CDCl_3$) had δ at 3.66 (s, 3H, *N*-Me), 6.43 (d, 1H, *J* = 2.7 Hz), 7.05 (d, 1H, *J* = 2.7 Hz), 7.34 (d, 1H, *J* = 9.3 Hz) and 7.44 (d, 1H, *J* = 5.4 Hz) [Patent to the Board of Trustees of the University of Illinois; WO2008/77138 *2008*].

3-Bromofuran *[22037-28-1]* **M 147.0, b 38.5°/40mm, 50°/110mm, 102.5-103°/atm, d_4^{20} 1.661, n_D^{20} 1.4970.** Purify 3-bromofuran by two steam distillations and dry it over fresh CaO. It can be dried over Na metal (no obvious reaction) and fractionated. It is not very soluble in H_2O but is soluble in organic solvents. When freshly distilled, it is a clear oil, but darkens on standing and eventually resinifies. It can be stored for long periods by covering the oil with an alkaline solution of hydroquinone and is redistilled when required. It forms a characteristic *maleic anhydride adduct*, **m** 131.5-132°. [Shepard et al. *J Am Chem Soc* **52** 2083 *1930*, Huhes & Johnson *J Am Chem Soc* **53** 737 *1931*, adduct: van Campen & Johnson *J Am Chem Soc* **55** 430 *1933*, *Beilstein* **17/1** V 295.]

5-Bromoindole *[10075-50-0]* **M 196.1, m 90.5-91°, 90-92°, pK^{25} 16.13 (NH).** Purify it by steam distillation from a faintly alkaline solution. Cool the aqueous distillate, collect the solid, dry it in a vacuum desiccator over P_2O_5 and recrystallise it from aqueous EtOH (35% EtOH) or petroleum ether/Et_2O. Its UV in MeOH has λ_{max} at 279, 287 and 296nm (logε 3.70, 3.69 and 3.53). The *picrate* has **m** 137-138°(dec) (from Et_2O/petroleum ether). [UV: Thesing et al. *Chem Ber* **95** 2205 *1962*, UV and NMR: Lallemand & Bernath *Bull Soc Chim Fr* 4091 *1970*, *Beilstein* **20/7** V 36.]

5-Bromoisatin *[87-48-9]* **M 226.0, m 245°(dec), 251-153°, 255-256°.** 5-Bromoisatin forms red prisms or needles from EtOH. The *N-acetate* crystallises as yellow prisms from $*C_6H_6$, **m** 170-172°, and the *N-methyl* derivative forms orange-red needles from MeOH, **m** 172-173°. [Heller *Chem Ber* **53** 1545 *1920*, Buu-Hoi *Rec Trav Chim Pays Bas* **73** 197 *1954*, Baker etal. *Tetrahedron Lett* 215 *1978*, *Beilstein* **21** H 453, **21** III/IV 5009.]

6-Bromoisatin *[6326-79-0]* **M 226.0, m 270°, pK^{25} 10.35.** 6-Bromoisatin recrystallises from AcOH (yellow needles). It is a plant growth substance. Its IR ($CHCl_3$) has ν_{max} at 1320 and 3440cm^{-1}. [Sadler *J Org Chem*

21 169 *1956*, *Beilstein* **21** III/IV 5012.]

2-Bromo-3-methylindole (2-bromoskatole) *[1484-28-2]* **M 210.1, m 102-104°, pK_{Est} <0.** Purify 2-bromoskatole by chromatography on silica gel in $CHCl_3$/petroleum ether (1:2) followed by crystallisation from aqueous EtOH. [Phillips & Cohen *J Am Chem Soc* **108** 2023 *1986*, cf *Beilstein* **20** III/IV 3205.]

4-(Bromomethyl)-7-methoxycoumarin *[35231-44-8]* **M 269.1, m 208-209°, 213-215°, 216-218°.** The coumarin is crystallised from boiling AcOH, the crystals are washed with AcOH, EtOH and dried in a vacuum; The ^{1}HNMR (TFA) has δ at 3.97s, 4.57s, 6.62s, 6.92-7.19m and 7.80d. [Secrist et al. *Biochem Biophys Res Commun* **45** 1262 *1971*, Dünges *Anal Chem* **49** 442 *1977*, *Beilstein* **18** III/IV 348.]

5-Bromonicotinic acid *[20826-04-4]* **M 202.0, m 178-182°, 189-190°, pK_{Est} ~4.4, pK^{25} 4.02 (50% aqueous EtOH).** The acid is recrystallised from H_2O and then from EtOH using charcoal. The *amide* has **m** 219-219.5° (from aqueous EtOH), and the *methyl ester*, prepared by addition of ethereal diazomethane, can be purified by sublimation in a vacuum and has **m** 98-99°. The *acid chloride* also can be sublimed in *vacuo* and has **m** 74-75° and gives the *methyl ester* in MeOH. [Graf *J Prakt Chem* **138** 244 *1933*, Bachman & Micucci *J Am Chem Soc* **70** 2381 *1948*, Garcia et al. *J Am Chem Soc* **82** 4430 *1960*, Misic-Vokovic et al. *J Chem Soc* 34 *1978*, *Beilstein* **22/2** V 181.]

2-Bromopyridine *[109-04-6]* **M 158.0, b 49.0°/2.7mm, d_4^{20} 1.660, n_D^{20} 1.5713, pK^{25} 0.90.** Dry 2-bromopyridine over KOH for several days, then distil it from CaO under reduced pressure, and taking the middle fraction. [*Beilstein* **20/5** V 422.]

8-Bromotheophylline (bromo-1,3-dimethyl-2,6(1*H*,3*H*)-purinedione) *[10381-75-6]* **M 259.1, m 309°, 315-320° (with browning and dec), $pK_{Est(1)}$ ~5.5, $pK_{Est(2)}$ ~9.2.** It is purified by dissolving in the minimum volume of dilute NaOH (charcoal), filtering and acidifying to pH *ca* 3.5-4. The solid that separates is collected, dried *in vacuo* at 100° and stored in a dark container. It has also been recrystallised from EtOH or AcOH. [Blitz & Beck *J Prakt Chem* [2] **118** 158 *1928*, Fischer & Ach *Chem Ber* **28** 3142 *1895*, *Beilstein* **26** H 476, **26** II 227, **26** III/IV 2447.]

5-Bromothiazole *[3034-55-7]* **M 164.0, b 62-63°/15mm, d_4^{20} 1.835, n_D^{20} 1.5955, n_D^{25} 1.5976, pK_{Est} ~2.0.** If bromothiazole is too coloured, then suspend it in dilute NaOH and steam distil it. Add NaCl to the aqueous distillate, extract it with Et_2O, dry it (Na_2SO_4), evaporate and fractionate the residue in a vacuum. The $HgCl_2$ *salt* crystallises from EtOH with **m** 148° (dec). [Beyerman et al. *Rec Trav Chim Pays Bas* **73** 330 *1954*, *Beilstein* **27** III/IV 962.]

2,3-Bromothiophene *[3140-93-0]* **M 241.9, m -17.5°, b 89-91°/13mm, 212-213°/atm, 218.6-219.6°/atm, d_4^{25} 2.137, n_D^{20} 1.632.** Purify the dibromothiophene by fractional distillation, preferably in a vacuum. Low temperature crystallisation from a small volume of petroleum ether (use Et_2O/CO_2 bath) removes the more soluble 2,4-dibromothiophene isomer. Nitration with Ac_2O/HNO_3 at 50-55° yields *2,3-dibromo-5-nitrothiophene* **m 75°** (from EtOH). [Steinkopf et al. *Justus Liebigs Ann Chem* **512** 149-151 *1934*, Gronowitz et al. *Acta Chem Scand* **46** 654 *1992*, NMR: Fujikara et al. *Bull Chem Soc Jpn* **32** 201 *1959*, *Beilstein* **17/1** III/IV 247, **17/1** V 308.]

Bufotenine hydrogen oxalate (3-[2-{dimethylamino}ethyl]-5-hydroxyindole hydrogen oxalate]) *[2963-79-3]* **M 294.3, m 96.5°, pK_1^{25} ~4.9(estimated), pK_2^{25} 9.8 (5-OH), pK_3^{25} 11.2 (NMe_2), pK_4^{25} ~18.2 (estimated acidic indole NH).** The hydrogen oxalate crystallises from Et_2O, EtOH/Et_2O (gave *monohydrate*) or MeOH/Et_2O. [Wieland et al. *Justus Liebigs Ann Chem* **513** 11 *1934*, *Beilstein* **22** III/IV 5672.]

4-*tert*-Butylcalix[4]arene *[60705-62-6]* **M 648.9, m >300°(dec), 380°(dec), 344-346°.** The calixarene recrystallises from $CHCl_3$ in large solvated prisms (**m** 380° dec); it effloresces on drying in air. Its *tetra-acetate* crystallises from Ac_2O in colourless prisms **m** 332-333°(dec). It crystallises from CCl_4 or chlorobenzene /EtOH (**m** >300°) and the *tetra-acetate* crystallises from $CHCl_3$/EtOH **m** >290°(dec). It also crystallises from toluene in white plates with toluene of crystallisation **m** 344-346° (330-332°); the *tetra-acetate* crystallises with 1AcOH of crystallisation **m** 383-386° (softening at 330-340°, also **m** 283-286°), but acetylation with

Ac_2O/NaOAc gives the *triacetate* which recrystallises from AcOH with 1AcOH of crystallisation **m** 278-281°. 4-*tert*-Butylcalix[4]arene (100mg) is unchanged after boiling for 4 hours with 10N KOH (0.04ml) in xylene (4ml). [*Br J Pharmacol* **10** 73 *1955*, Kämmerer et al. *Monatsh Chem* **109** 767 *1978*, Gutsche et al. *J Am Chem Soc* **103** 3782 *1981*; see also Kluawer in *Calixarenes*, Vicens & Böhner eds Academic Press *1991*, *Beilstein* **6** IV 7858.]

4-*tert*-Butylcalix[6]arene *[78092-53-2]* **M 972.3, m >300°, 380-381°.** It is recrystallised from $CHCl_3$ or $CHCl_3$/MeOH to give a white solid from the mother liquors of the calix[8]arene preparation. The *hexa-acetate* (Ac_2O/H_2SO_4) crystallises from $CHCl_3$/MeOH with **m** 360-362°(dec), and the *$(SiMe_3)_6$* derivative crystallises from $CHCl_3$/MeOH with **m** 410-412°. Its stability in KOH-xylene is the same as for the 4-*tert*-butylcalix[4]arene. [Gutsche et al.*J Am Chem Soc* **103** 3782 *1981*. See also Kluawer in *Calixarenes*, Vicens & Böhner eds Academic Press *1991*, *Beilstein* **6** IV 7858.]

4-*tert*-Butylcalix[8]arene *[68971-82-4]* **M 1297.8, m 411-412°.** The calixarene recrystallises from $CHCl_3$ in fine colourless, glistening needles. It melts sharply between 400-401° and 411-412° depending on the sample and is sensitive to traces of metal ions. On TLC with silica gel (250µm thick) and elution with $CHCl_3$/hexane (3:4) it has R_F 0.75. The *octa-acetate* is prepared from 8g in Ac_2O (50ml) and 2 drops of conc H_2SO_4 and refluxed for 2 hours. On cooling, a colourless precipitate separates and is recrystallised from Ac_2O (1.2g 48%) with **m** 353-354°. The *$(SiMe_3)_8$* is prepared from 4-*tert*-butylcalix[8]arene (0.65g) in pyridine (4ml) with excess of hexamethyldisilazane (1ml) and trimethylchlorosilane (0.5ml) and refluxed under N_2 for 2 hours. Cool, evaporate the pyridine, triturate the gummy residue with MeOH. Chromatograph on silica gel using hexane/CH_2Cl_2 gave 0.5g (61%) with one spot on TLC. Recrystallise it from hexane/Me_2CO to give colourless needles **m** 358-360°. [Gutsche et al. *J Am Chem Soc* **103** 3782 *1981*, Gutsche & MuthuKrishnan *J Org Chem* **43** 4905 *1978*, Gutsche & MuthuKrishnan *J Org Chem* **44** 3962 *1979*, Andretti et al. *J Chem Soc, Chem Commun* 533 *1981*; see Kluawer in *Calixarenes*, Vicens & Böhner eds Academic Press *1991*.]

8-*sec*-Butylmetrazole *[25717-83-3]* **M 194.3, m 70°.** Crystallise it from petroleum ether and dry it for 2 days under vacuum over P_2O_5. [*Beilstein* **26** II 213 for Metrazole.]

***N*-(*n*-Butyl)-5-nitro-2-furamide** *[14121-89-2]* **M 212.2, m 89-90°, b 190°/10mm.** Distil the amide in a vacuum and recrystallise it twice from EtOH/water mixture or petroleum ether. [Gliman & Yale *J Am Chem Soc* **72** 3593 *1950*, *Beilstein* **18** III/IV 3995.]

Butyloxirane (1-hexene oxide) *[1436-34-6]* **M 100.2, b 116-117°/atm, 116-119°/atm, d_4^{20} 0.833, n_D^{20} 1.44051.** Purify it by fractional distillation through a 2ft helices-packed column at atmospheric pressure in a N_2 atmosphere. [Pasto & Cumbo *J Org Chem* **30** 1271 *1965*, Howarth et al. *J Chem Soc* 2433 *1927*, ^{13}C NMR Davies & Witham *J Chem Soc Perkin Trans 2* 861 *1975*, *Beilstein* **17/1** V 103.]

4-*tert*-Butylpyridine *[3978-81-2]* **M 135.2, f -44.4°, b 194-197°atm, 197°/765mm, d_4^{20} 0.923, n_D^{20} 1.495, pK^{25} 5.82.** Dry 4-*tert*-butylpyridine over solid KOH and purify it by fractional distillation through an efficient column under dry N_2. Its *picrate* has **m** 153.9-154°, and the *hydrochloride* has **m** 151.7-154.8° (from Me_2CO). [Brown & Murphey *J Am Chem Soc* **73** 3308 *1951*, IR: Arnett & Chawla *J Am Chem Soc* **100** 214 *1978*, Kyle et al. *J Chem Soc* 4454 *1960*, *Beilstein* **20/6** V 123.]

Cacotheline **(2,3-dihydro-4-nitro-2,3-dioxo-9,10-*seco*strychnidin-10-oic acid)** *[561-20-6]* **M 508.4, $pK_{Est(1)}$ ~4.4 (CO_2H), $pK_{Est(2)}$ ~10.2 (N).** Cacotheline gives yellow crystals from H_2O. It is then dried over H_2SO_4 which gives the *dihydrate*, and in a vacuum over H_2SO_4 at 105° it forms the *anhydrous* compound. The *hydrochloride* separates as the *hydrate* (on heating in vacuum at 80°) in orange-yellow prisms or plates, **m** 250°(dec) and forms a *resorcinol complex* which gives brown crystals from EtOH, **m** 325°; and a *hydroquinone complex* as dark red crystals from EtOH, **m** 319°. [Leuchs & Leuchs *Chem Ber* **43** 1042 *1910*, Teuber *Chem Ber* **86** 232, (UV: 242) *1953*; complexes: Gallo *Gazz Chim Ital* **85** 1441 *1955*.] It is used in the titrimetric estimation of Sn^{2+} ions [Szrvas & Lantos *Talanta* **10** 477 *1963*]. [*Beilstein* **27** III/IV 8014.]

Caffeine (1,3,7-trimethylxanthine) *[58-08-2]* **M 194.2, m 237°, pK_1^{40} -0.10, pK_2^{55} 1.22.** Caffeine crystallises from water or absolute EtOH. [*Beilstein* **26** III/IV 2338.]

Cannabinol *[521-35-7]* **M 310.4, m 76-77°, b 185°/0.05mm, 225°, pK_{Est} ~10.5 (phenolic OH).** Cannabinol crystallises from petroleum ether and sublimes in a vacuum. [Meitzer et al. *Synthesis* 985 *1981*, *Beilstein* **17** II 151, **17** III/IV 1652.]

ε-Caprolactam (azepan-2-one, aza-2-cycloheptanone, 2-oxohexamethyleneimine) *[105-60-2]* **M 113.2, m 70°, 70.5-71.5°, 70-71°, 262.5°/760mm.** The lactam is distilled under reduced pressure, recrystallised from acetone or petroleum ether and redistilled. It can be purified by zone melting. It is very *hygroscopic* and discolours in contact with air unless small amounts (0.2g/L) of NaOH, Na_2CO_3 or $NaBO_2$ are present. It has been crystallised from a mixture of petroleum ether (185ml of **b** 70°) and 2-methyl-2-propanol (30ml), from acetone, or petroleum ether. It is then distilled under reduced pressure and stored under nitrogen. [Pellegata et al. *Synthesis* 614 *1978*, *Beilstein* **21/6** V 444.]

Caprylolactam (azanon-2-one, azacyclononan-2-one, 8-aminooctanoic acid lactam, cyclooctanone isooxime) *[935-30-8]* **M 141.2, m 72°, 73°, 74-76°, 75°, 76-77°, b 119-122°/0.7mm, 150-151°/7-8mm, 164°/14mm, d_4^{73} 1.009, n_D^{73} 1.489, pK^{25} 0.55 (AcOH).** Dissolve it in $CHCl_3$, decolorise it with charcoal, evaporate to dryness and recrystallise it from $CHCl_3$/hexane. Sublime it at high vacuum. The *oxime* has **m** 117° (from $*C_6H_6$ or petroleum ether). [Guggisberg *Helv Chim Acta* **61** 1050 *1978*, Olah et al. *Synthesis* 538 *1979*, Behringer & Meier *Justus Liebigs Ann Chem* **607** 67 *1957*, *Beilstein* **21** III/V 3260.]

***1S,2'S*-Captopril (*S*-1-[3-mercapto-2-methyl-1-oxopropyl]-L-proline)** *[62571-86-2]* **M 217.3, m 103-104°(polymorphic unstable form m 86°, melts at 87-88° solidifies and then melts again at 104-105°), $[\alpha]_D^{22}$ -131° (c 1.7, EtOH), pK_1 3.7, pK_2 9.8.** Purify it by recrystallisation from EtOAc/hexane. It is also purified by dissolving in EtOAc and chromatographed on a column of Wakogel C200 using a linear gradient of MeOH in EtOAc (0-100°) and fractions which give a positive nitroprusside test (for SH), are combined, evaporated and recrystallised from EtOAc/hexane (1:1), to give white crystals with $[\alpha]_D^{20}$ -128.2° (c 2.0, EtOH). [Nam *J Pharm Sci* **73** 1843 *1984*]. *Alternatively*, dissolve it in H_2O, apply to a column of AG-50Wx2 (BioRad) and elute with H_2O. The free acid is converted to the *dicyclohexylamine salt* in MeCN by addition of the amine until the pH is 8-9. The salt is converted to the free acid by shaking with EtOAc and 10% aqueous $KHSO_4$ or passage through an AG50Wx2 column. The EtOAc solution is dried ($MgSO_4$), evaporated to dryness and the residue is recrystallised as above from EtOAc/hexane [Cushman et al. *Biochemistry* **16** 5484 *1977*, NMR and IR: Horii & Watanabe *Yakugaku Zasshi (J Pharm Soc Japan)* **81** 1786 *1961*]. It is an antihypertensive because it is a potent competitive inhibitor of the angiotensive convertive enzyme (ACE-inhibitor) with a Ki value of 0.0017μM [Shimazaki et al. *Chem Pharm Bull Jpn* **30** 3139 *1982*].

Carbamazepine (5*H*-dibenzo[*b*,*f*]azepine-5-carboxamide) *[298-46-4]* **M 236.3, m 190-193°, 191-192°.** Recrystallise from EtOH/$*C_6H_6$, and dry *in vacuo*. It is soluble in Me_2CO EtOH and propylene glycol, but not in H_2O. Anticonvulant and Na channel inhibitor. [Stenger & Roulet *Med Exp* **11** 191 *1964*.]

Carbazole *[86-74-8]* **M 167.2, m 240-243°, pK^{25} <0.** Dissolve carbazole (60g) in conc H_2SO_4 (300ml), extract with three 200ml portions of *benzene, then stir this into 1600ml of an ice-water mixture. The precipitate is filtered off, washed with a little water, dried, recrystallised from *benzene and then from pyridine/*benzene [Feldman et al. *J Am Chem Soc* **73** 4341 *1951*]. It has also been recrystallised from EtOH or toluene, sublimed in vacuum, zone-refined, and purified by TLC. [UV: Armarego in *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press) **Vol III** 158 *1971*, *Beilstein* **20/8** V 9.]

9-Carbazoleacetic acid *[524-80-1]* **M 225.2, m 215°, pK_{Est} ~3.5.** Crystallise the acid from ethyl acetate. [Fan et al. *Anal Chim Acta* **367** 1 *1998*, *Beilstein* **20** III/IV 3841.]

Carbazole-9-carbonyl chloride *[73500-82-0]* **M 300.0, m 100-103°, 103.5-104.5°.** Recrystallise the acid chloride from $*C_6H_6$. If it is not very pure (presence of OH or NH bands in the IR), dissolve it in pyridine, shake it with phosgene in toluene, evaporate and recrystallise the residue. Carry out this experiment in a good

fume cupboard as $COCl_2$ is very **TOXIC**, and store the product in the dark. It is moisture sensitive. The *amide* has **m** 246.5-247°, and the *dimethylaminoethylamide hydrochloride* has **m** 197-198°. [Weston et al. *J Am Chem Soc* **75** 4006 *1953*, *Beilstein* **20** III/IV 3841.]

1-Carbethoxy-4-methylpiperazine hydrochloride *[532-78-5]* **M 204.7, m 168.5-169°, pK^{25} 7.31.** Crystallise the hydrochloride from absolute EtOH. Its solubility is 280g/100g of H_2O at 25°. The *free base ester* has **b** 97-98°/8mm. [*Beilstein* **23** III/IV 223.]

γ-Carboline (9*H*-pyrido[3,4-b]indole) *[244-69-9]* **M 168.2, m 225°, 230-233°, pK^{25} ~0.** Crystallise it from water or EtOAc. [Robinson & Thornley *J Chem Soc* **12S** 2169 *1924*, Dalton et al. *Aust J Chem* **22** 185 *1969*, Staab & Wendel *Org Synth* **48** 44 *1968*, *Beilstein* **23** II 223, **23** III/IV 1572.]

***N,N'*-Carbonyldiimidazole** *[530-62-1]* **M 162.2, m 115.5-116°.** Crystallise it from *benzene or tetrahydrofuran in a dry-box and store it dry. [Hearn *Methods Enzymol* **135** 102 *1987*, *Beilstein* **23/4** V 245.]

1,1'-Carbonyldi(1,2,4-triazole) (CDT) *[41864-22-6]* **M 164.1, m 134-136°, 145-150°.** Dissolve CDT in tetrahydrofuran and evaporate at 10mm until it crystallises. Wash the crystals with cold tetrahydrofuran and dry them in a vacuum desiccator over P_2O_5 in which it can be stored for months. [Bergmann & van den Brink *Rec Trav Chim Pays Bas* **80** 1372 *1961*, Potts *J Org Chem* **27** 2631 *1962*, Staab *Justus Liebigs Ann Chem* **106** 75 *1957*.]

(±)-Catechin *[7295-85-4]* **M 272.3, m 177° (anhydrous).** Crystallise it from hot water and dry it at 100°. [*Beilstein* **17/8** V 448.]

Cetylpyridinium chloride (H_2O) (hexadecylpyridinium chloride) *[6004-24-6]* **M 358.0, m 80-83°.** Crystallise the chloride from MeOH or EtOH/diethyl ether and dry it *in vacuo*. [Moss et al. *J Am Chem Soc* **108** 788 *1986*, Lennox & McClelland *J Am Chem Soc* **108** 3771 *1986*, *Beilstein* **20** V 233.]

Chelerythrine (1,2-dimethoxy-12-methyl[1,3]benzodioxolo[5,6-*c*]phenanthridinium] *[34316-15-9]* **M 389.4, m 207°.** Chelerythrine crystallises from $CHCl_3$ on addition of MeOH [Manske *Can J Res* **21B** 140 *1943*, UV: Hruban et al. *Col Czech Chem Commun* **35** 3420 *1970*]. The *pseudo base* is colourless while the salts are yellow in aqueous solution and are fluorescent.

Chelidonic acid (4-oxopyran-2,6-dicarboxylic acid) *[99-32-1]* **M 184.1, m 262°, pK_2^{25} 2.36.** The acid crystallises from aqueous EtOH. Dry it first at 100°/2 hours, then at 160° to constant weight to remove water of crystallisation. It decarboxylates at 220-230° in a vacuum. [Riegel & Zwilgmeyer *Org Synth* Coll Vol **II** 126 *1943*, *Beilstein* **18** H 490**, 18/8** V 646.]

2-Chlorobenzothiazole *[615-20-3]* **M 169.6, m 21°, 90-91.4°/4mm, 135-136°/28mm, d_4^{20} 1.303, n_D^{20} 1.6398.** It is purified by fractional distillation *in vacuo*. The *2-chloro-3-methylbenzothiazolinium 2,4-dinitrobenzenesulfonate* crystallises from Ac_2O, **m** 162-163°(dec). [Young & Amstutz *J Am Chem Soc* **73** 4773 *1951*, Brower et al. *J Org Chem* **19** 1830 *1954*, Hunter & Jones *J Chem Soc* 2190 *1930*, *Beilstein* **27** H 44, **27** II 18, **27** III/IV 1072.]

***o*-Chlorobenzotrifluoride** *[88-16-4]* **M 180.6, b 152.3°, d_4^{20} 1.371, n_D^{20} 1.456.** Dry it over $CaSO_4$, and distil it at high reflux ratio. [*Beilstein* **5** III 692.]

2-Chlorobenzoxazole *[615-18-9]* **M 153.6, b 95-96°/20mm, 198-202°/atm, d_4^{20} 1.331, n_D^{20} 1.570.** Purify it by fractional distillation, preferably in a vacuum. [Siedel *J Prakt Chem* **42** 456 *1890*, Katz *J Am Chem Soc* **75** 712 *1953*, Meyer & Sigel *J Org Chem* **42** 2769 *1977*, *Beilstein* **27** H 43**, 27** II 17.]

2-(4-Chlorobutyl)-1,3-dioxolane *[118336-86-0]* **M 164.6, b 56-58°/0.1mm, d_4^{20} 1.106, n_D^{20} 1.457.** If the IR has no CHO band, then just distil it in a vacuum. If it is present, then dissolve it in Et_2O, wash it with H_2O, then saturated $NaHCO_3$, dry over $MgSO_4$, evaporate and distil it. [*cf* Kriesat & Gisvold *J Pharm Sci* **60** 1250

1971, Loftfield *J Am Chem Soc* **73** 1365 *1951*.]

4-Chloro-2,6-diaminopyrimidine (2,4-diamino-6-chloropyrimidine) *[156-83-2]* **M 144.6, m 198°, 199-202°, pK^{25} 3.57.** It recrystallises from boiling H_2O (charcoal) as needles; it also crystallises from Me_2CO. [Büttner *Chem Ber* **36** 2232 *1903*, Roth *J Am Chem Soc* **72** 1914 *1950*, UV: Brown & Jacobsen *J Chem Soc* 3172 *1962*, *Beilstein* **24** H 318**, 25** III/IV 2788.]

2-Chloro-4,6-dimethylpyrimidine *[4472-44-0]* **M 142.6, m 34-38°, 38°, b 223°/atm, pK^{20} -0.68.** The chloro-pyrimidine has been distilled at atmospheric pressure, and solidifies on cooling. Purify it by recrystallisation from petroleum ether (b 40-60°). The 2-chloro-substituent is readily subject to nucleophilic substitution, and the kinetics of reaction with morpholine and piperidine are reported in detail (cf Chapman & Rees). It is a very weak base and requires 2N HCl to form the cation species. The UV has λ_{max} (logε) at 255 (3.65) and 263 (infl 3.49) nm at pH 2.0 (neutral species); and 261nm (3.87) in ~2N HCl (H_o -3.0, cation). [Boarland & McOmie *J Chem Soc* 1218 *1952*, Boarland & McOmie 3722 *1952*, Chapman & Rees *J Chem Soc* 1190 *1954*, Brown & England *J Chem Soc, C* 1922 *1967*, Matsukawa & Ohta *J Pharm Soc, Jpn* **69** 491 *1949*, *Chem Abstr* **44** 3456 *1950*, Andrisano & Modena *Gazz Chem Ital* **81** 405 *1951*, Angerstein *Chem Ber* **34** 3956 *1901*, *Beilstein* **23** H 95, **23** IV 918.]

2-Chloro-3,5-dinitropyridine *[2578-45-2]* **M 203.5, m 62-65°, 63-65°, 64°, pK$_{Est}$ <–5.** Dissolve it in $CHCl_3$, shake it with saturated $NaHCO_3$, dry ($MgSO_4$), evaporate and apply to an Al_2O_3 column, elute with petroleum ether (b 60-80°), evaporate and recrystallise it from *C_6H_6 or petroleum ether. [Ochiai & Kaneko *Chem Pharm Bull Jpn* **8** 28 *1960*, Plazek *Rec Trav Chim Pays Bas* **72** 573 *1953*, *Beilstein* **20/5** V 458.]

1-(2-Chloroethyl)pyrrolidine hydrochloride *[7250-67-1]* **M 170.1, m 167-170°, 173.5-174°, pK$_{Est}$ ~8.5 (free base).** Purify the hydrochloride by recrystallisation from isopropanol/di-isopropyl ether (charcoal) and recrystallise it twice more. The *free base*, **b** 55-56°/11mm, 60-63°/23mm and 90°/56mm, is relatively unstable and should be converted to the hydrochloride immediately, by dissolving in isopropanol and bubbling dry HCl through the solution at 0°, filtering off the hydrochloride and recrystallising it. The *picrate* has **m** 107.3-107.8° (from EtOH) [Cason *J Org Chem* **24** 247 *1959*, Wright et al. *J Am Chem Soc* **70** 3098 *1948*]. [*Beilstein* **20** III/IV 66.]

5-Chloroindole *[17422-32-1]* **M 151.6, m 69-71°, 72-73°, b 120-130°/0.4mm, pK$_{Est}$ <0.** It is distilled at high vacuum and recrystallises from petroleum ether (b 40-60°) or (b 80-100°) as glistening plates. The *picrate* has **m** 147° (146.5-147.5°)(from *C_6H_6). [Rydon & Tweddle *J Chem Soc* 3499 *1955*, Sugasawa *J Org Chem* **44** 578 *1979*, *Beilstein* **20/4** V 34.]

2-Chloro-6-(methylamino)purine *[82499-02-3]* **M 183.6, m >220°, > m 300°, pK$_{Est(1)}$ ~3.0, pK $_{Est(2)}$ ~10.0.** Purify by recrystallisation from glacial acetic acid or *C_6H_6/$EtOCH_2CH_2OH$, and dry *in vacuo*. Its UV has λ_{max}(ε) at 267(14400) (0.1N HCl), 271(15000) (aqueous pH 7.0); and 226(15300) and 272(5340) (0.1N NaOH in EtOH) [Montgomery & Holum *J Am Chem Soc* **80** 404 *1958*]. [Kim et al. *J Med Chem* **43** 746 *2000*, *Beilstein* **26** III/IV 3724.]

2-Chloro-3-methylindole (2-chloroskatole) *[51206-73-6]* **M 165.6, m 114.5-115.5°, pK$_{Est}$ <0.** Purify 2-chloroskatole by chromatography on silica gel in CH_2Cl_2/petroleum ether (1:2), followed by recrystallisation from aqueous EtOH, aqueous AcOH or petroleum ether (**m** 113.5°). The *picrate* has **m** 121-122°(dec) (orange-red crystals from petroleum ether). [Phillips & Cohen *J Am Chem Soc* **108** 2023 *1986*, *Beilstein* **20** H 317, **20** III/IV 3212.]

4-(Chloromethyl)pyridine hydrochloride *[1822-51-1]* **M 164.0, m 170-175°, 172-173°, pK$_{Est}$ ~5.6.** Purify it by recrystallisation from EtOH or EtOH/dry Et_2O. It melts between 171° and 175°, and the clear melt resolidifies on further heating at 190° and turns red to black at 280° but does not melt again. The *picrate-hydrochloride* (prepared in EtOH) has **m** 146-147°. The *free base* is an oil. [Mosher & Tessieri *J Am Chem Soc* **73** 4925 *1951*, *Beilstein* **20** III/IV 2752.]

2-Chloro-1-methylpyridinium iodide *[14338-32-0]* **M 255.5, m 203-205°, 205-206°(dec), 207°.** Purify it by dissolving in EtOH and adding dry Et_2O. The solid is washed with Me_2CO and dried at 20°/0.35mm. Store it in the dark. Attempted recrystallisation from Me_2CO/EtOH/petroleum ether (b 40-60°) causes some exchange of the Cl substituent by I. The *picrate* has **m** 106-107°, and the *perchlorate* has **m** 212-213°. [Jones et al. *J Am Chem Soc* **111** 1157 *1989*, UV and solvolysis: Barlin & Benbow *J Chem Soc, Perkin Trans 2* 790 *1974*, *Beilstein* **20/5** V 405.]

6-Chloronicotinic acid *[5326-23-8]* **M 157.6, m 190-193°, 198-199°(dec), pK^{25} 4.22 (50% aqueous EtOH).** Purify it by recrystallisation from hot H_2O and sublime it in a vacuum. [Pechmann & Welsch *Chem Ber* **17** 2384 *1884*, Herz & Murty *J Org Chem* **26** 122 *1961*, *Beilstein* **22/2** V 177.]

4-Chloro-7-nitrobenzofurazane (7-chloro-4-nitrobenzoxadiazole, NBD-chloride) *[10199-89-0]* **M 199.6, m 96.5-97°, 97°, 99-100°.** Wash the solid with H_2O, and it recrystallises from aqueous EtOH (1:1) as pale yellow needles. It sublimes in a vacuum [Gosh & Whitehouse *Biochem J* **108** 155 *1968*, UV, NMR: Bolton et al. *J Chem Soc* 1004 *1966*].

2-Chloro-3-nitropyridine *[5470-18-8]* **M 158.5, m 100-103°, 101-102°, 103-104° (sublimes), pK^{20} -2.6.** It forms needles from H_2O. Purify it by continuous sublimation over a period of 2 weeks at 50-60°/0.1mm [Barlin *J Chem Soc* 2150 *1964*]. The *N-oxide* has **m** 100°(from CH_2Cl_2/Et_2O). [Taylor & Driscoll *J Org Chem* **25** 1716 *1960*, Ochiai & Kaneko *Chem Pharm Bull Jpn* **8** 28 *1960*, *Beilstein* **20/5** V 451.]

2-Chloro-5-nitropyridine *[4548-45-2]* **M 158.5, m 108°, pK_{Est} ~-2.6.** It crystallises from *benzene or *benzene/petroleum ether. [*Beilstein* **20/5** V 452.]

9-Chloro-9-phenylxanthene (Pixyl chloride) *[42506-03-6]* **M 292.8, m 105-106°.** A possible impurity is 9-hydroxy-9-phenylxanthene. If the material contains a lot of the hydroxy product, then boil 10g of it in $CHCl_3$ (50ml) with redistilled acetyl chloride (1ml) until liberation of HCl is complete. Evaporation leaves the chlorophenylxanthene as the hydrochloride which on heating with *benzene loses HCl; and on adding petroleum ether prisms of chlorophenylxanthene separate and contain 0.5mol of *benzene. The *benzene-free compound is obtained on drying, and it melts to a colourless liquid. [Gomberg & Cone *Justus Liebigs Ann Chem* **370** 142 *1909*.] The 9-phenylxanthyl group is called "pixyl" and is a good protecting group [Chattopadhyaya & Reese *J Chem Soc, Chem Commun* 639 *1978*, *Beilstein* **17** III/IV 1704.]

Chlorophylls *a* and *b* See entries in "Miscellaneous Compounds", Chapter 7.

6-Chloropurine *[87-42-3]* **M 154.6, m 179°(dec), pK_1^{20} 0.45, pK_2^{20} 7.88.** 6-Chloropurine crystallises from water. The UV in water at pH 1 has λ_{max} 264nm (logε 3.94). [*Beilstein* **26** III/IV 1742.]

2-Chloropyrazine *[14508-49-7]* **M 114.5, b 62-63°/31mm, 153-154°/atm, d_4^{20} 1.302, n_D^{24} 1.535, pK_{Est} <0.** Fractionally distil it through a short column packed with glass helices. It has a penetrating, mildly pungent odour with a high vapour pressure at room temperature. [Erickson & Spoerri *J Am Chem Soc* **68** 400 *1946*, Hetman & O.Donnell *J Org Chem* **28** 1682 *1963*, *Beilstein* **23/5** V 366.]

2-Chloropyridine *[109-09-1]* **M 113.6, b 49.0°/7mm, d_4^{20} 1.20, n_D^{20} 1.532, pK^{20} 0.49 (0.72).** Dry 2-chloropyridine with NaOH for several days, then distil it from CaO under reduced pressure. [*Beilstein* **20/5** V 402.]

3-Chloropyridine *[626-60-8]* **M 113.6, b 148°, d_4^{20} 1.194, n_D^{20} 1.533, pK^{20} 2.84.** Distil 3-chloropyridine from KOH pellets. [*Beilstein* **20/5** V 406.]

4-Chloropyridine *[626-61-9]* **M 113.6, b 85-86°/100mm, 147-148°/760mm, pK^{20} 3.84.** Pour 4-chloropyridine into distilled water, and excess of 6M NaOH is added to give pH 12. The organic phase is separated and extracted with four volumes of diethyl ether. The combined extracts are filtered through paper to

remove water, and the solvent is evaporated. The dark brown residual liquid is kept under high vacuum [Vaidya & Mathias *J Am Chem Soc* **108** 5514 *1986*]. It can be distilled, but readily darkens and is best kept as the *hydrochloride [7379-35-3]* **M** 150.1, **m** 163-165°(dec). [*Beilstein* **20/5** V 410.]

2-Chloropyrimidine *[1722-12-9]* **M 114.5, m 63-65°, 66°, b 91°/26mm, pK^{20} -1.90.** It has been recrystallised from *C_6H_6, petroleum ether or a mixture of both. It sublimes at 50°/18mm and can be distilled in a vacuum. [IR: Short & Thompson *J Chem Soc* 168 *1952*, Boarland & McOmie *J Chem Soc* 1218 *1951*, *Beilstein* **23/5** V 343.]

2-Chloroquinoline *[612-62-4]* **M 163.6, m 34°, b 147-148°/15mm, d_4^{35} 1.235, n_D^{25} 1.629, pK_{Est} ~0.3.** Purify it by crystallisation of its *picrate* to constant melting point (123-124°) from *benzene, regenerating the base and distilling it under vacuum [Cumper et al. *J Chem Soc* 1183 *1962*]. 2-Chloroquinoline can be crystallised from EtOH. Its *picrate* has **m** 123-124° (from EtOH). [*Beilstein* **20** H 359, **20/7** V 312.]

4-Chloroquinoline *[611-35-8]* **M 163.6, m 29-32°, 31°, b 130°/15mm, 261°/744mm, pK^{25} 3.72.** Possible impurities include the 2-isomer. It is best purified by converting to the *picrate* (**m** 212-213° dec) in EtOH and recrystallising it from EtOH (where the picrate of the 2-chloroquinoline remains in solution) or EtOAc. The picrate is decomposed with 5% aqueous NaOH, extracted in $CHCl_3$, washed with H_2O, dried ($MgSO_4$), evaporated and distilled in a vacuum. It can be steam distilled from slightly alkaline aqueous solutions, the aqueous distillate is extracted with Et_2O, evaporated and distilled. The distillate solidifies on cooling. [Bobránski *Chem Ber* **71** 578 *1938*, *Beilstein* **20/7** V 314.]

8-Chloroquinoline *[611-33-6]* **M 163.6, b 171-171.5°/24mm, d_4^{20} 1.278, n_D^{20} 1.644, pK^{20} 3.12.** Purify it by crystallisation of its $ZnCl_2$ complex (**m** 228°) from aqueous EtOH. [*Beilstein* **20** III/IV 3381, **20/7** V 315.]

5-Chloroquinolin-8-yl trifluoromethanesulfonate (5-chloro-8-quinoline triflate) *[157437-38-2]* **M 311.7, m 79-83°.** If it is discoloured dissolve it in CH_2Cl_2, wash it with N NaOH and half saturated K_2CO_3, dry the organic layer over solid K_2CO_3, filter, evaporate and dry the solid *in vacuo*, (cf 2-methyl-5-pyridine triflate). [Matthew et al. *Tetrahedron Lett* **35** 5177 *1994*, Tilley & Zawoiski *J Org Chem* **53** 386 *1988,* Ellingboe et al. *J Med Chem* **37** 542 *1994*.]

8-Chlorotheophylline (8-chloro-1,3-dimethyl-2,6(1*H*,3*H*)-purinedione) *[85-18-7]* **M 214.6, m 311°(dec), $pK_{Est(1)}$ ~5.4, $pK_{Est(2)}$ ~9.1.** It crystallises from H_2O or EtOH (**m** 304°, dec). The *choline salt* crystallises from H_2O with **m** 60-62° (2 H_2O) and **m** 97-99° (anhydrous). [*Beilstein* **26** H 473, II 276, **26** III/IV 2442.]

2-Chlorothiophene (2-thienyl chloride) *[96-43-5]* **M 118.6, b 126-128°, 128°/~760mm, d_4^{20} 1.285, n_D^{20} 1.551.** Purify it by fractional distillation at atmospheric pressure or by gas chromatography. [Conde et al. *Synthesis* 412 *1976*, *Beilstein* **17/1** V 303.]

5-Chlorouracil (5-chloro-2,4(6)-dihydroxypyrimidine) *[1820-81-1]* **M 146.5, m 314-418°(dec), 324-325°(dec), pK_1^{25} 7.95, pK_2^{25} >13.** It recrystallises from hot H_2O (4g/500ml) using charcoal. [McOmie et al. *J Chem Soc* 3478 *1955*, West & Barrett *J Am Chem Soc* **76** 3146 *1954*, *Beilstein* **24** III/IV 1231.]

4-Chromanone (2,3-dihydro-4*H*-1-benzopyran-4-one) *[491-37-2]* **M 148.2, m 35-37°, 39°, 41°, b 92-93°/3mm, 130-132°/15mm, 160°/50mm.** It has been recrystallised from petroleum ether, or purified by dissolving in *C_6H_6 washing with H_2O, drying ($MgSO_4$), evaporating and distilling in a vacuum, then recrystallising the residue. The liquid has a pleasant lemon-like odour. The *semicarbazone* has **m** 227°. [Loudon & Razdan *J Chem Soc* 4299 *1954*.] The *oxime* is prepared from 3g of chromanone, 3g $NH_2OH.HCl$ in EtOH (50ml), 6g K_2CO_3 and refluxed on a water bath for 6 hours. The solution is poured into H_2O, the solid is filtered off, dried and dissolved in hot *C_6H_6 which on addition of petroleum ether yields the *oxime* as glistening needles **m** 140°. Hydrolysis of this gives very pure chromanone. The *benzal derivative* is prepared from 3g of chromanone and 4g PhCHO in 50ml EtOH, heated to boiling, 10ml of conc HCl are added dropwise and set aside for several days. The derivative separates and is recrystallised from EtOH to give yellow needles, **m** 112° [Powell *J Am Chem Soc* **45** 2711 *1923*]. Reaction with $Pb(OAc)_4$ yields the *3-acetoxy derivative* **m** 74°

(from petroleum ether + trace of EtOAc) [Cavill et al. *J Chem Soc* 4573 *1954*, *Beilstein* **17/10**V 14].

Cinnoline *[253-66-7]* **M 130.2, m 38°, 40-41°, b 114°/0.35, pK^{20} 2.37.** It is distilled at high vacuum, then recrystallised from petroleum ether. Keep it under N_2 in sealed tubes in the dark at 0°. The *hydrochloride* [5949-24-6] **M** 166.6 crystallises from EtOH/Et_2O and has **m** 156-158° (yellow *monohydrate*), and dehydrates on sublimation at 110-115°/3mm. The *picrate* has **m** 196-196.5°. [*Beilstein* **23** H 173, **23** III.IV 1217.]

Citrazinic acid (2,6-dihydroxyisonicotinic acid) *[99-11-6]* **M 155.1, m >300°, pK$_1$ 3.0, pK$_2$ 4.76.** The acid is normally a yellow powder with a greenish shade, but is white when ultra pure and turns blue on long standing. It is insoluble in H_2O but slightly soluble in hot HCl and soluble in alkali or carbonate solutions. It is purified by precipitation from alkaline solutions with dilute HCl, and dried in a vacuum over P_2O_5. The *ethyl ester* has **m** 232° (evacuated tube) and a pKa of 4.81 in $MeOCH_2CH_2OH$ [IR: Pitha *Col Czech Chem Comm* **28** 1408 *1963*]. [*Beilstein* **22/7** V 24.]

Clioquinol (5-chloro-8-hydroxy-7-iodoquinoline *[130-26-7]* **M 305.5, m 181°, pK$_1^{25}$ 2.7, pK$_2^{25}$ 7.9.** It crystallises from AcOH or xylene and dry it at 70° *in vacuo*. [*Beilstein* **21** III/IV 1190**.]**

Clofazimine [2-(4-chloroanilino)-3-isopropylimino-5-(4-chlorophenyl)-3,4-dihydrophenazine] *[2030-63-9]* **M 473.5, m 210-212°, pK^{20} 8.37 (8.51).** Clofazimine recrystallises from acetone as dark red crystals. Its solubility in $CHCl_3$ and EtOH is 7% and 0.1%, respectively, at room temperature. It is insoluble in H_2O. It is antibacterial. [Barry et al. *J Chem Soc* 859 *1958*, *Beilstein* **25** III/IV 3033.]

Colforsin, see **Forskolin.**

Conessine *[546-06-5]* **M 356.6, m 125°, 127-128.5°, [α]$_D^{20}$ -1.9° (in $CHCl_3$) and +26° (c 3, EtOH), pK$_{Est(1)}$~10.4 , pK$_{Est(2)}$~10.7.** It crystallises from acetone, sublimes at 95°/0.01mm and boils at 0.1mm with bath temperature at 220°. The *dihydrochloride* has **m** >340° (browns at 235° and decomposes at 338-240°) and has [α]$_D^{20}$ +9.3° (c 2, H_2O). [Marshall & Johnson *J Am Chem Soc* **84** 1458 *1962*, *Beilstein* **22** III/IV 4382.]

Coproporphyrin I *[531-14-6]* **M 654.7, λ$_{max}$ 591, 548, 401nm in 10% HCl.** It crystallises from pyridine/glacial acetic acid. The *dihydrochloride [69477-27-6]* has M 727.7 and λ_{max} at 395nm in water. [*Beilstein* **26** III/IV 3094.]

Coumalic acid (2-pyrone-5-carboxylic acid) *[500-05-0]* **M 140.1, m 205-210°(dec), pK$_{Est}$ ~0.** The acid crystallises from MeOH. The *methyl ester* has **m** 73-74° (from petroleum ether) and **b** 178-180°/60 mm. [*Beilstein* **18/8** V 120.]

Coumarin *[91-64-5]* **M 146.2, m 68-69°, b 298°, pK^{25} -4.97 (aqueous H_2SO_4).** Coumarin crystallises from ethanol or water and sublimes *in vacuo* at 43° [Srinivasan & deLevie *J Phys Chem* **91** 2904 *1987*]. [*Beilstein* **17/10** V 143.]

Coumarin-3-carboxylic acid *[531-81-7]* **M 190.2, m 188°(dec), pK$_{Est}$ ~1.5.** The acid crystallises from water. [*Beilstein* **18/8** V 323.]

γ-Crotonolactone [2(5*H*)-furanone] *[497-23-4]* **M 84.1, m 3-4°, 76-77°/3.5mm, 90.5-91°/11.5mm, 92-93°/14mm, 107-109°/24mm, 212-214°/760mm, d$_4^{20}$ 1.197, n$_D^{20}$ 1.470.** Fractionally distil the lactone under reduced pressure. Its IR(CCl_4) has 1784 and 1742 cm^{-1}, UV no max above 205nm (ε 1160 cm^{-1} M^{-1}) and ^{1}HNMR (CCl_3) has τ at 2.15 (pair of triplets 1H), 3.85 (pair of triplets 1H) and 5.03 (triplet 2H). [Price & Judge *Org Synth* Coll Vol **V** 255 *1973*, Smith & Jones *Can J Chem* **37** 2007, 2092 *1959*, *Beilstein* **17/9** V 112.]

15-Crown-5 *[33100-27-5]* **M 220.3, b 93-96°/0.1mm, d$_4^{20}$ 1.113, n$_D^{20}$ 1.465.** Dry it over 3A molecular sieves and distil it in a high vacuum. [*Beilstein* **19/12** V 252.]

18-Crown-6 *[17455-13-9]* **M 264.3, m 37-39°.** Recrystallise it from acetonitrile and dry it in a vacuum.

Purify it also by precipitating the 18-crown-6/nitromethane 1:2 complex with Et_2O/nitromethane (10:1 mixture). The complex is decomposed in vacuum whereby 18-crown-6 distils off under the reduced pressure. [*Beilstein* **19/12** V 601.]

Cryptopine *[482-74-6]* **M 369.4, m 220-221°, 220-223°, pK^{25} 8.09.** It crystallises from *benzene, hot EtOH (0.25% cold, 1.2% at boiling), petroleum ether or methyl ethyl ketone. The *perchlorate* crystallises from aqueous MeOH with **m** 226-228°(dec). [Thomas et al. *Can J Chem* **33** 570 *1955*, Howarth & Perkin *J Chem Soc* 1769 *1926*, *Beilstein* **27** III/IV 6652.]

Cupreine (6'-hydroxycinchonidine) *[524-63-0]* **M 310.4, m 202°(anhydrous), [α] $^{17}_{D}$ -176° (c 0.5, MeOH), pK^{15} 7.63.** Cupreine crystallises from EtOH (*anhydrous* crystals) and wet Et_2O (as *dihydrate* crystals). It has K_b 2.7x10^{-7} [Kolthoff *Biochem Z* **162** 323]. The *sulfate* forms needles, **m** 257°(dec), from MeOH, amyl alcohol or H_2O, with [α] $^{20}_{D}$-197.9° (c 1.2, H_2O). [*Beilstein* **22** I 165, **22** II 416.]

5-Cyanoindole *[15861-24-2]* **M 142.2, m 106-108°, 107-108°, pK^{25} <0.** Dissolve the nitrile in 95% EtOH, boil it in the presence of charcoal, filter, evaporate to a small volume and add enough H_2O to cause crystallisation and cool. Recrystallise it directly from aqueous EtOH and dry it in a vacuum. Its UV has λ_{max} at 276 nm (log ε 3.6) in MeOH. [Lindwall & Mantell *J Org Chem* **18** 345 *1953*, **20** 1458 *1955*, Thesing at al. *Chem Ber* **95** 2205 *1962*, NMR: Lallemend & Bernath *Bull Soc Chim Fr* 4091 *1970*, *Beilstein* **22/3** V 45.]

3-Cyanopyridine *[100-54-9]* **M 104.1, m 50°, pK^{25} 1.38.** It is recrystallised to constant melting point from *o*-xylene/hexane. [*Beilstein* **22/2** V 115.]

4-Cyanopyridine *[100-48-1]* **M 104.1, m 76-79°, pK^{25} 1.86.** It crystallises from dichloromethane/diethyl ether mixture. [*Beilstein* **22/2** V 214.]

Cyanuric acid (2,4,6-trichloro-1,3,5-triazine) *[108-80-5]* **M 120.1, m >300°, pK^{25} 6.78.** It crystallises from water. Dry it at room temperature in a desiccator in a vacuum. [*Beilstein* **26** III/IV 632.]

Cyanuric chloride (TCT, 2,4,6-trichloro-1,3,5-triazine) *[108-77-0]* **M 184.4, m 146-149°, 154°, b 190°.** TCT crystallises from CCl_4 or petroleum ether (b 90-100°) and is dried under vacuum. It has also been recrystallised twice from anhydrous *benzene immediately before use [Abuchowski et al. *J Biol Chem* **252** 3582 *1977*]. [*Beilstein* **26** III/IV 66.]

Cycloheximide (Actidione) *[66-81-9]* **M 281.4, m 119.5-121°, [α] $^{20}_{546}$ +9.5° (c 2, H_2O).** It crystallises from H_2O /MeOH (4:1), amyl acetate, isopropyl acetate/isopropyl ether or H_2O. [*Beilstein* **21/13** V 434.]

1-Cyclohexyl-5-methyl-1*H*-tetrazole *[7707-57-5]* **M 166.2, m 124-124.5°.** Crystallise it from absolute EtOH or H_2O (heavy needles), then sublime it at 115°/3mm. [Harvill et al. *J Org Chem* **15** 662, 668 *1950*, Billuber Inc USP 2507337 *1946*, *Beilstein* **26** III/IV 1661.]

Cyclotrimethylenetrinitramine (RDX, Cyclonite, 1,3,5-trinitrohexahydro-1,3,5-triazine) *[121-82-4]* **M 222.2, m 203.8°(dec), 205-206°(dec).** RDX crystallises from acetone. [Bachmann & Sheehan *J Am Chem Soc* **71** 1842 *1949*, *Beilstein* **26** II 5, **26** III/IV 22.] **EXPLOSIVE.**

Cytisine (7*R*,9*S*-7,9,10,11,12,13-hexahydro-7,9-methano-12*H*-pyrido[1,2-*a*][1,5]diazocin-8-one, Laburnine, Ulexine) *[485-35-8]* **M 190.3, m 152-153°, 155°, b 218°/2mm, [α] $^{17}_{D}$ -120° (H_2O), [α] $^{25}_{D}$ -115° (c 1, H_2O), pK $^{15}_{1}$ 1.20, pK $^{15}_{2}$ 8.12 [also stated are pK$_1$ 6.11, pK$_2$ 13.08].** Crystallise cytisine from acetone and sublime it in a vacuum. Its solubilities are: 77% (H_2O), 7.7% (Me_2CO), 28.6% (EtOH), 3.3% (*C_6H_6), 50% ($CHCl_3$) but it is insoluble in petroleum ether. The *tartrate* has **m** 206-207° [α] $^{24}_{D}$ +45.9°, the *N-tosylate* has **m** 206-207°, and the *N-acetate* has **m** 208°. [Bohlmann et al. *Angew Chem* **67** 708 *1955*, van Tamelen & Baran *J Am Chem Soc* **77** 4944 *1955*, Isolation: Ing *J Chem Soc* 2200 *1931*, Govindachari et al. *J Chem Soc* 3839 *1957*, Abs config: Okuda et al. *Chem Ind (London)* 1751 *1961*, *Beilstein* **24** H 134, **24** I 244, **24** II 70, **24** III/IV 321.] **TOXIC.**

Cytosine (4-amino-2-hydroxypyrimidine) See entry in "Miscellaneous Compounds", Chapter 7.

***cis*-Decahydroisoquinoline** *[2744-08-3]* **M 139.2, b 97-98°/15mm, 208-209°/730mm, pK^{20} 11.32.** The free base is treated with saturated aqueous picric acid, allowed to stand for 12 hours, filtered, washed with MeOH to remove the more soluble *trans* isomer and recrystallised from MeOH to give pure cis-*picrate* **m** 149-150°. The picrate (~5g) is shaken with 5M aqueous NaOH (50ml) and Et_2O (150ml) while H_2O is added to the aqueous phase to dissolve insoluble Na picrate. The Et_2O extract is dried over solid NaOH and then shaken with Al_2O_3 (Merck for chromatography) until the yellow color of traces of picric acid disappears (this color cannot be removed by repeated shaking with 5-10 M aqueous NaOH). The extract is concentrated to 50ml and dry HCl is bubbled through until separation of the white crystals of the cis-*HCl* is complete. These are washed with Et_2O, dried at 100° and recrystallised from EtOH/EtOAc to yield pure cis-*hydrochloride* **m** 182-183° (dried in a vacuum desiccator over KOH) with IR (KBr) ν_{max} 2920, 2820, 1582, 1470, 1445, 1410, 1395, 1313, 1135, 1080, 990, 870 cm^{-1}. The pure *free base* is prepared by dissolving the *hydrochloride* in 10 M aqueous NaOH, extracted with Et_2O, dried over solid KOH, filtered and distilled in a vacuum. It has IR (film) ν_{max} 2920, 2820, 2720, 2560, 1584, 1470, 1445, 1415, 1395, 1315, 1300, 1135, 1080, 1020, 990, 873 cm^{-1}. The ^{1}HNMR in $CDCl_3$ is characteristically different from that of the *trans*-isomer. [Armarego *J Chem Soc (C)* 377 *1967*, Gray & Heitmeier *J Am Chem Soc* **80** 6274 *1958*, Witkop *J Am Chem Soc* **70** 2617 *1948*, Skita *Chem Ber* **57** 1982 *1924*, Helfer *Helv Chim Acta* **6** 799*1923*, *Beilstein* **20** II 73, **20** III/IV 2026.]

***trans*-Decahydroisoquinoline** *[2744-09-4]* **M 139.2, b 106°/15mm, pK^{20} 11.32.** This is purified as the *cis*-isomer above. The trans-*picrate* has **m** 175-176°, and the trans-*hydrochloride* has **m** 221-222° and has IR (KBr) has ν_{max} at 2930, 3800, 1589, 1450, 1400, 1070, 952, 837 cm^{-1}. The pure *free base* is prepared as above and had IR (film) with ν_{max} at 2920, 2820, 2720, 2560, 1584, 1470, 1445, 1415, 1395, 1315, 1300, 1135, 1080, 1020, 990, 873 cm^{-1}. The ^{1}HNMR in $CDCl_3$ is characteristically different from that of the *cis*-isomer. (references as above and Helfer *Helv Chim Acta* **9** 818 *1926*). [*Beilstein* **20** II 73, **20** III/IV 2026.]

***cis*-Decahydroquinoline** *[10343-99-4]* **M 139.2, b 207-208°/708mm, pK^{20} 11.29.** It is available as a *cis-trans*-mixture (**b** 70-73°/10mm, Aldrich, ~18% *cis*-isomer *[2051-28-7]*), but the isomers can be separated by fractionating in a spinning band column (1~1.5 metre, type E) at atmospheric pressure and collecting 2ml fractions with a distillation rate of 1 drop in 8-10 seconds. The lower boiling fraction solidifies and contains the *trans*-isomer (see below, **m** 48°). The higher boiling fraction **b** 207-208°/708mm remains liquid and is mostly pure *cis*-isomer. This is reacted with PhCOCl and M aqueous NaOH to yield the *N-benzoyl derivative* **m** 96° after recrystallisation from petroleum ether (b 80-100°). It is hydrolysed with 20% aqueous HCl by refluxing overnight. $PhCO_2H$ is filtered off, the filtrate is basified with 5M aqueous NaOH and extracted with Et_2O. The dried extract (Na_2SO_4) is saturated with dry HCl gas, and the *cis-decahydroquinoline hydrochloride* which separates has **m** 222-224° after washing with Et_2O and drying at 100°; and has IR (KBr) with ν_{max} at 2900, 2780, 2560, 1580, 1445, 1432, 1403, 1165, 1080, 1036, 990, 867 cm^{-1}. The *free base* is obtained by dissolving the *hydrochloride* salt in 5M aqueous NaOH, extracting with Et_2O and drying the extract (Na_2SO_4), evaporating and distilling the residue; it has IR (film) with ν_{max} at 2900, 2840, 2770, 1445, 1357, 1330, 1305, 1140, 1125, 1109, 1068, 844 cm^{-1}. The ^{1}H NMR in $CDCl_3$ is characteristically different from that of the *trans*-isomer. [Armarego *J Chem Soc (C)* 377 *1967*, Hückel & Stepf *Justus Liebigs Ann Chem* **453** 163 *1927*, Bailey & McElvain *J Am Chem Soc* **52** 4013 *1930*, *Beilstein* **20** H 157, **20** I 35, **20** II 72-73, **20** III/IV 2017.]

***trans*-Decahydroquinoline** *[767-92-0]* **M 139.2, m 48°, b 205-206°/708mm, pK^{20} 11.29.** The lower boiling fraction from the preceding spinning band column fractionation of the commercial *cis-trans*- mixture (~ 20:60; see the *cis*-isomer above) solidifies readily (**m** 48°), and the receiver has to be kept hot with warm water. It is further purified by conversion to the *hydrochloride* **m** 285-286° after recrystallisation from EtOH/AcOEt. This has IR (KBr) with ν_{max} at 2920, 2760, 2578, 2520, 1580, 1455, 1070, 1050, 975, 950, 833 cm^{-1}. The *free base* is prepared as for the *cis*-isomer above and distilled; and has IR (film, at ca 50°) with ν_{max} at 2905, 2840, 2780, 1447, 1335, 1305, 1240, 1177, 1125, 987, 900, 835 cm^{-1}. The ^{1}HNMR in $CDCl_3$ is characteristically different from that of the *cis*-isomer. [Armarego *J Chem Soc (C)* 377 *1967*, Hückel & Stepf *Justus Liebigs Ann Chem* **453** 163 *1927*, Bailey & McElvain *J Am Chem Soc* **52** 4013 *1930*, Prelog & Szpilfogel *Helv Chim Acta* **28** 1684 *1945*, *Beilstein* **20** H 157, **20** I 35, **20** II 72-73, **20** III/IV 2017.]

Delphinine *[561-07-9]* **M 559.7, m 197-199°, $[\alpha]_D^{20}$ +26° (c 1, EtOH).** It crystallises from EtOH with 198-200° uncorrected (187.5-188.5°) and from Et_2O or Me_2CO. Its solubility at ~25° in EtOH, $CHCl_3$ and Et_2O is 4, 5 and 10% respectively. In c 1, EtOH, it has $[\alpha]_D^{20}$ +22° changing to +19° in 4 hours. [Markwood *J Am Chem Soc* **16** 931 *1927*.] The *hydrochloride* has **m** 214°(dec) from MeOH or MeOH/Et_2O. [Weissner et al. *Can J Chem* **50** 1925 *1972*, Jacobs & Craig *J Biol Chem* **127** 363 *1939*, *Beilstein* **21** III/IV 2867.]

3,6-Diaminoacridine hydrochloride *[952-23-8]* **M 245.7, m 270°(dec), ε_{456} 4.3 x 10^4, pK_1^{20} 1.5, pK_2^{20} 9.60 (9.65 free base).** It is first purified by precipitation of the free base by adding aqueous NH_3 solution to an aqueous solution of the hydrochloride or hydrogen sulfate (see below), drying the precipitate and subliming at 0.01mm Hg [Müller & Crothers *Eur J Biochem,* **54** 267 *1975*]. [*Beilstein* **22** H 487.]

3,6-Diaminoacridine sulfate (proflavin sulfate) *[1811-28-5]* **M 516.6, m >300°(dec), λ_{max} 456nm.** An aqueous solution, after treatment with charcoal, is concentrated, chilled overnight, filtered and the precipitate is rinsed with a little diethyl ether. The precipitate is dried in air, then overnight in a vacuum oven at 70°. [*Beilstein* **22** I 650, **22/11** V 323.]

4,5-Diamino-2,6-dihydroxypyrimidine (diamino uracil) sulfate *[32014-70-3]* **M 382.3, m >300°, pK_1^{20} 1.7, pK_2^{20} 3.20, pK_3^{25} 4.56.** The salt is quite insoluble in H_2O but can be converted to the free base which is recrystallised from H_2O and converted to the sulfate by addition of the required amount of H_2SO_4. The *hydrochloride* has **m** 300-305°(dec) and can be used to prepare the sulfate by addition of H_2SO_4; it is more soluble than the sulfate. The *perchlorate* has **m** 252-254°. The free base has λ_{max} at 260nm (log ε 4.24) in 0.1M HCl. [Bogert & Davidson *J Am Chem Soc* **86** 1668 *1933*, Bredereck et al. *Chem Ber* **86** 850 *1953*, Sherman & Taylor *Org Synth* Coll Vol **IV** 247 *1963*, Barlin & Pfleiderer *J Chem Soc (B)* 1425 *1971*, *Beilstein* **25** II 382.]

5,6-Diamino-1,3-dimethyluracil hydrate (5,6-diamino-1,3-dimethyl-2-pyrimidine-2,4-dione hydrate) *[5440-00-6]* **M 188.2, m 205-208°(dec), 209°(dec), 210° (dec), pK_1 1.7, pK_2 4.6.** It recrystallises from EtOH. The *hydrochloride* has **m** 310° (from MeOH), and the *perchlorate* has **m** 246-248°. [UV: Bredereck et al. *Chem Ber* **92** 583 *1959*, Taylor et al. *J Am Chem Soc* **77** 2243 *1955*, *Beilstein* **25** III/IV 4133.]

6,9-Diamino-2-ethoxyacridine (Ethacridine) *[442-16-0]* **M 257.3, m 226°, pK^{20} 11.6.** It crystallises from 50% EtOH or EtOH as orange-yellow crystals. It also crystallises as a *monohydrate* **m** 116-118°. It has a pK^{20} of 11.04 in 50% aqueous EtOH. The *methiodide* is soluble in H_2O and has **m** 332-334° (dec) (from aqueous Me_2CO). [Albert & Gledhill *J Soc Chem Ind* **61** 159 *1942*, Foye et al. *J Pharm Sci* **57** 1795 *1968*, Albert & Goldacre *J Chem Soc* 708 *1946*, *Beilstein* **22** II 458, **22** III/IV 6679, **22/12** V 243.]

6,9-Diamino-2-ethoxyacridine *dl*-lactate moohydrate (Rivanol, Acrinol) *[6402-23-9]* **M 361.4, m 235° (dark at ~200°), pK^{20} 11.6.** It forms yellow crystals from 90% EtOH/Et_2O. Its solubility in H_2O is ~15% at 25° and ~9% at 100°, and its solutions have a yellow fluorescence which is stable on boiling. It is an antiseptic. See ethacridine above, *Beilstein* **22** II 458, **22** III/IV 6680, **22/12** V 243.]

2,4-Diamino-6-hydroxypyrimidine *[56-06-4]* **M 126.1, m 260-270°(dec), pK_1^{25} 1.34, pK_2^{25} 3.27, pK_3^{25} 10.83.** It recrystallises from H_2O. [*Beilstein* **25** III/IV 3642.]

4,5-Diamino-6-hydroxypyrimidine hemisulfate *[102783-18-6]* **M 350.3, m 268°, 270°, pK_1^{25} 1.34, pK_2^{25} 3.57, pK_3^{25} 9.86.** It recrystallises from H_2O. The *free base* also crystallises from H_2O (**m** 239°). [Mason *J Chem Soc* 2071 *1954*, Elion et al. *J Am Chem Soc* **74** 411 *1952*, *Beilstein* **25** III/IV 3645.]

2,4-Diamino-5-phenylthiazole (Amiphenazole) *[490-55-1]* **M 191.3, m 163-164°(dec).** The thiazole crystallises from aqueous EtOH or water. Store it in the dark under N_2. The *hydrochloride* has **m** 273-274°(dec) (from MeOH/EtOAc), and the *picrate* has **m** 189-191°(dec) (from H_2O). [Davies et al. *J Chem Soc* 3491 *1950*, Dodson & Turner *J Am Chem Soc* **73** 4517 *1951*, *Beilstein* **27** III/IV 5139.]

2,3-Diaminopyridine *[452-58-4]* **M 109.1, m 116°, pK_1^{25} -0.50, pK_2^{25} 6.92.** It crystallises from *benzene

and sublimes *in vacuo*. [*Beilstein* **22/11** V 241.]

2,6-Diaminopyridine *[141-86-6]* **M 109.1, m 121.5° $pK_{Est(1)}$ <-6.0, $pK_{Est(2)}$ ~7.3.** It crystallises from *benzene and sublimes *in vacuo*. [*Beilstein* **22** III/IV 255.]

3,4-Diaminopyridine *[54-96-6]* **M 109.1, m 218-219°, pK_1^{20} 0.49, pK_2^{20} 9.14.** It crystallises from *benzene and is stored under N_2 because it is *deliquescent* and absorbs CO_2. [*Beilstein* **22/11** V 266.]

3,5-Diamino-1,2,4-triazole (Guanazole) *[1455-77-2]* **M 99.1, m 206°, pK_1^{20} 4.43, pK_2^{20} 12.12.** The triazole crystallises from water or EtOH. [*Beilstein* **26** III/IV 1161.]

1,3-Diazaazulene (cycloheptimidazole) *[275-94-5]* **M 130.1, m 110-112°, 120°.** It is recrystallised repeatedly from de-aerated cyclohexane in the dark or from petroleum ether/*C_6H_6 and forms yellow needles. It is soluble in H_2O, EtOH and *C_6H_6, and forms a *monohydrate* which loses H_2O at 60°. The *picrate* has **m** 207°(dec). [Nozoe et al. *J Am Chem Soc* **76** 3352 *1954*, Nukai et al. *Bull Chem Soc Jpn* **40** 1967 *1967*, *Beilstein* **23** III/IV 1216.]

1,5-Diazabicyclo[4.3.0]non-5-ene (DBN, 2,3,4,,6,7,8-hexahydropyrrolo[1,2-*a*]-pyrimidine) *[3001-72-7]* **M 124.2, b 96-98°/11mm, 100-102°/12mm, 118-121°/32mm, d_4^{20} 1.040, n_D^{20} 1.520, pK^{25} >13.0.** Distil DBN from BaO. It forms a *hydroiodide* on addition of 47% HI; dry it and dissolve it in MeCN, evaporate and repeat; recrystallise from EtOH, dry at 25°/1mm for 5 hours, then at 80°/0.03mm for 12 hours and store and dispense it in a dry box, **m** 154-156° [Jaeger et al. *J Am Chem Soc* **101** 717 *1979*]. The *methiodide* is recrystallised from $CHCl_3$/Et_2O, **m** 248-250°, and *hydrogen fumarate* has **m** 159-160° and is crystallised from *iso*-PrOH [Rokach et al. *J Med Chem* **22** 237 *1979*, Oediger et al. *Chem Ber* **99** 2012 *1966*, Reppe et al. *Justus Liebigs Ann Chem* **596** 210 *1955*]. [*Beilstein* **23/5** V 239.]

1,4-Diazabicyclo[2.2.2]octane (DABCO, triethylenediamine, TED) *[280-57-9]* **M 112.2, m 156-157° (sealed tube), pK_1^{25} 2.97, pK_2^{25} 8.82.** DABCO crystallises from 95% EtOH, petroleum ether or MeOH/diethyl ether (1:1). Dry it under vacuum over $CaCl_2$ and BaO. It can be sublimed *in vacuo*, and readily at room temperature. It has also been purified by removal of water during azeotropic distillation of a *benzene solution. It is then recrystallised twice from anhydrous diethyl ether under argon, and stored under argon [Blackstock et al. *J Org Chem* **52** 1451 *1987*]. [*Beilstein* **23/3** V 487.]

1,8-Diazabicyclo[5.4.0]undec-7-ene (DBU, 2,3,4,6,7,8,9,10-octahydropyrimidino[1,2-*a*]-azepine) *[6674-22-2]* **M 152.2, b 115°/11mm, d_4^{20} 1.023, n_D^{20} 1.522, pK_{Est} ~ >13.** Fractionally distil DBU under vacuum. Also purify it by chromatography on Kieselgel and eluting with $CHCl_3$/EtOH/25% aqueous NH_3 (15:5:2) and checking by IR and MS. [Oediger et al. *Chem Ber* **99** 2012 *1962*, *Angew Chem, Int Ed Engl* **6** 76 *1967*, Guggisberg et al. *Helv Chim Acta* **61** 1057 *1978*, *Beilstein* **23/5** V 271.]

1,8-Diazabiphenylene *[259-84-7]* **M 154.2, m 156-158.5°, pK_{Est} ~4.4.** Recrystallise it from cyclohexane, then sublime it in a vacuum. [Barton & Walker *Tetrahedron Lett* 569 *1975*, Deroski & Marhgraf *Can J Chem* **62** 2235 *1984*.]

2,7-Diazabiphenylene *[31857-42-8]* **M 154.2, m 192-192.5°, pK_{Est} ~4.5.** It forms yellow crystals from cyclohexane, and sublimes in a vacuum. [MacBride *J Chem Soc, Chem Commun* 359 *1974*, Kramer & Berry *J Am Chem Soc* **94** 8336 *1972*.]

1,8-Diazafluorenone (cyclopenta[1.2-*b*:4,3-*b'*]dipyridin-9-one) *[54078-29-4]* **M 182.2, m 205°, 229-231°, pK_{Est} ~2.6.** Recrystallise it from Me_2CO. The *oxime* has **m** 119-200°. [Druey & Schmid *Helv Chim Acta* **33** 1080 *1950*, *Beilstein* **24** III/IV 622.]

Dibenzo-18-crown-6 *[14187-32-7]* **M 360.4, m 163-164°.** Crystallise it from *benzene, *n*-heptane or toluene and dry it under vacuum at room temperature for several days. [Szezygiel *J Phys Chem* **91** 1252 *1987*, Vögtle ed. *Top Corr Chem* (Host Guest Complex Chemistry) **98** *1981*.]

Dibenzo-18-crown-8 *[14174-09-5]* **M 448.5, m 103-106°.** Recrystallise it from EtOH, and dry in a vacuum at 60° over P_2O_5 for 16 hours. [Delville et al. *J Am Chem Soc* **109** 7293 *1987*, Vögtle ed. *Top Corr Chem* (Host Guest Complex Chemistry) **98** *1981*.]

Dibenzofuran *[132-64-9]* **M 168.2, m 82.4°.** Dissolve dibenzofuran in diethyl ether, then shake it with two portions of aqueous NaOH (2M), wash it with water, separate and dry ($MgSO_4$) it. After evaporating the ether, dibenzofuran is crystallised from aqueous 80% EtOH and then dried under vacuum. [Cass et al. *J Chem Soc* 1406 *1958*.] High purity material is obtained by zone refining. [*Beilstein* **17** V 234.]

Dibenzothiophene *[132-65-0]* **M 184.3, m 99°.** Purify dibenzothiophene by chromatography on alumina with petroleum ether, in a darkened room. Recrystallise it from water or EtOH. [*Beilstein* **17** V 239.]

1,3-Dibromo-5,5-dimethylhydantoin *[77-48-5]* **M 285.9, m 190-192°(dec), 190-193°(dec).** Recrystallise it from H_2O. Its solubility in CCl_4 is 0.003 mol/L at 25° and 0.024 mol/L at 76.5°. [*Beilstein* **24** III/IV 1101.]

4',5'-Dibromofluorescein *[596-03-2]* **M 490.1, m 285°.** Crystallise it from aqueous 30% EtOH. [*Beilstein* **19/6** V 462.]

5,7-Dibromo-8-hydroxyquinoline *[521-74-4]* **M 303.0, m 196°, pK_1^{25} 5.84, pK_2^{25} 9.56.** Crystallise it from acetone/EtOH. It can be sublimed. [*Beilstein* **21/3** V 290.]

2,6-Dibromopyridine *[626-05-1]* **M 236.9, m 117-119°, 118.5-119°, b 249°/757.5mm, pK_{Est} <0.** Purify 2,6-dibromopyridine by steam distillation, then recrystallise it twice from EtOH. It does not form an $HgCl_2$ salt. [den Hertog & Wibaut *Rec Trav Chim Pays Bas* **51** 381 *1932*, *Beilstein* **20/5** V 435.]

3,4-Dibromothiophene *[3141-26-2]* **M 241.9, m 4-5°, b 94-95°/12mm, 212-213° (atm), 221-222°(atm), d_4^{25} 2.188, n_D^{20} 1.640.** Distil it in a vacuum, but if it is discoloured then dissolve it in Et_2O, wash it with 2M NaOH solution, separate the layers, filter, dry the Et_2O layer over $CaCl_2$, filter, evaporate, and distil the residual oil in a vacuum. Nitration with Ac_2O/HNO_3 at 60° yields *3,4-dibromo-2-nitrothiophene* **m 115-116°** (from EtOH). [Steinkopf et al. *Justus Liebigs Ann Chem* **512** 149-151 *1934*, *Beilstein* **17** III/IV 248, **17/1** V 308.]

2,6-Di-*tert*-butyl-4-methylpyridine *[38222-83-2]* **M 205.4, m 31-32°, 33-36°, b 148-153°/ 95mm, 223°/760mm, n_D^{20} 1.476, pK_{Est} ~5.7.** A possible impurity is 2,6-di-*tert*-butyl-4-neopentylpyridine. Attempts to remove coloured impurities directly by distillation, acid-base extraction or treatment with activated charcoal were unsuccessful. Pure material is obtained by dissolving 0.3mole of the alkylpyridine in pentane (150ml) and introducing it at the top of a cold water jacketed chromatographic column (40 x 4.5cm) (cooling is necessary because the base in pentane reacts exothermically with alumina) containing activated and acidic alumina (300g). The column is eluted with pentane using a 1L constant pressure funnel fitted at the top of the column to provide slight pressure. All the pyridine is obtained in the first two litres of eluent (the progress of elution is monitored by spotting a fluorescent TLC plate and examining under short wave UV light—a dark blue spot is evidence for the presence of the alkylpyridine). Elution is complete in 1 hour. Pentane is removed on a rotovap with 90-93% recovery yielding a liquid which solidifies on cooling, **m** 31-32°, and the base can be distilled. The *H_2PtCl_6 salt* has **m** 213-314°(dec), and the *CF_3SO_3H salt* has **m** 202.5-203.5° (from CH_2Cl_2). [Anderson & Stang *Org Synth* Coll Vol **VII** 144 *1981*, *Beilstein* **20/6** V 190.]

2,6-Di-*tert*-butylpyridine *[585-48-8]* **M 191.3, b 100-101°/23mm, d_4^{25} 0.852, n_D^{20} 1.473, pK^{25} 5.02.** Redistil it from KOH pellets. [*Beilstein* **20** III/IV 2868.]
§ Polystyrene supported version is commercially available [107054-29-5] 200-400 mesh, crosslinked with 1% divinyllbenzene containing ~1.8mmol N/g polymer.

3,5-Dicarbethoxy-1,4-dihydro-2,4,6-collidine *[632-93-9]* **M 267.3, m 131-132°.** Crystallise the ester from hot EtOH/water mixture. [*Beilstein* **22** H 147, **22** I 529, **22** II 100, **22** III/IV 1594.]

(+) and (-) (8,8-Dichlorocamphorylsulfonyl)oxaziridine *[127184-05-8]* **M 298.2, m 178-180°, 183-186°, $[\alpha]_D^{20}$ (+) and (-) 88.3° (c 1.3, $CHCl_3$), (+) and (-) 91° (c 5, $CHCl_3$).** Recrystallise the enantiomers from EtOH [Davis & Weismiller *J Org Chem* **55** 3715 *1990*].

1,3-Dichloro-5,5'-dimethylhydantoin *[118-52-5]* **M 197.0, m 132-134°, 136°.** Purify it by dissolving in conc H_2SO_4 and diluting with ice H_2O, collect the solid, dry it in a vacuum and recrystallise it from $CHCl_3$. It sublimes at 100° in a vacuum. It exhibits time-dependent hydrolysis at pH 9. [Petterson & Grzeskowiak *J Org Chem* **24** 1414 *1959*, *Beilstein* **24** III/IV 1100.]

4,5-Dichloro-3*H*-1,2-dithiol-3-one *[1192-52-5]* **M 187.1, m 52-56°, 61°, b 87°/0.5mm, 125°/11mm.** Dissolve it in CH_2Cl_2 (1g in 250ml), filter, wash it twice with H_2O, evaporate and distil the residue *in vacuo* and then recrystallise it from petroleum ether. Its IR has ν_{max} at 1650 cm^{-1}. [Boberg *Justus Liebigs Ann Chem* **679** 109 *1964*, Boberg *Justus Liebigs Ann Chem* **693** 212 *1966*, *Beilstein* **19/4** V 72.]

5,7-Dichloro-8-hydroxyquinoline *[773-76-2]* **M 214.1, m 180-181°, pK_1 1.89, pK_2 7.62.** Crystallise the dichloro-oxine from acetone/EtOH. [*Beilstein* **21** H 95.]

6,9-Dichloro-2-methoxyacridine (**3,9-Dichloro-7-methoxyacridine)** *[86-38-4]* **M 278.1, m 160-161°, 164°, 163-165°.** Crystallise it from *benzene or 1,2-dichloroethane (**m** 162-163°). [Hall & Turner *J Chem Soc* 697 *1945*, *Beilstein* **21** III/IV 1553.]

5,7-Dichloro-2-methyl-8-hydroxyquinoline (5,7-dichloro-8-hydroxyquinaldine) *[72-80-0]* **M 228.1, m 114-115°, $pK_{Est(1)}$ ~2.0, $pK_{Est(2)}$ ~8.4.** Crystallise it from EtOH. [*Beilstein* **21/3** V 346.]

4,6-Dichloro-5-nitropyrimidine *[4316-93-2]* **M 194.0, m 100-103°, 101-102°, pK_{Est} <0.** If too impure, then dissolve it in Et_2O, wash it with H_2O, dry it over $MgSO_4$, evaporate it to dryness and recrystallise it from petroleum ether (b 85-105°) to give a light tan solid. It is soluble in *ca* 8 parts of MeOH [Boon et al. *J Chem Soc* 96 *1951*, Montgomery et al. in *Synthetic Procedures in Nucleic Acid Chemistry* Zorbach & Tipson eds, Wiley & Sons, NY, p76 *1968*]. [*Beilstein* **23** III/IV 899.]

2,6-Dichloropurine *[5451-40-1]* **M 189.0, m 180-181.5°, 181°, 185-195°(dec), 188-189°, pK_1^{20} 1.16 (aqueous H_2SO_4), pK_2^{20} 7.06.** It can be recrystallised from 150 parts of boiling H_2O and dried at 100° to constant weight. It is soluble in EtOAc. The *$HgCl_2$* salt separates from EtOH solution. It has UV with λ_{max} at 275nm (ε 8.9K) at pH 1; and 280nm (ε 8.5K) at pH 11 [Elion & Hitchings *J Am Chem Soc* **78** 3508 *1956*, Schaeffer & Thomas *J Am Chem Soc* **80** 3738 *1958*, Beaman & Robins *J Appl Chem (London)* **12** 432 *1962*, Montgomery *J Am Chem Soc* **78** 1928 *1956*]. [*Beilstein* **26** III/IV 1747.]

2,6-Dichloropyridine *[2402-78-0]* **M 148.0, m 87-88°, pK^{25} -2.86 (aqueous H_2SO_4).** It crystallises from EtOH. [*Beilstein* **20/5** V 416.]

3,5-Dichloropyridine *[2457-47-8]* **M 148.0, m 64-65°, 66-67°, b 178-178°/~760mm, pK^{25} 0.67.** Crystallise 3,5-dichloropyridine from EtOH, or distil it. [den Hertog et al. *Rec Trav Chim Pays Bas* **69** 685 *1950*, *Beilstein* **20** H 23, **20** III/IV 2502, **20** V 417.]

2,6-Dichloropyridine-3-carboxylic acid (2,6-dichloronicotinic acid) *[38496-18-3]* **M 192.0, m 146-148°, 147°, $pK_{Est(1)}$ ~ -1.** Purify the acid by recrystallisation from H_2O or Et_2O/petroleum ether (colourless needles), and the IR(KBr) has ν_{max} at 1738 cm^{-1}, and λ_{max} (ε) at 228.5(4700) and 273.5(8300)nm. The *acid chloride* [58584-83-1] **M 210.4, b 72-74°/0.01mm, 117-118°/45mm, n_D^{20} 1.5944**, was obtained by treatment with $SOCl_2$/DMF/*C_6H_6 and converted into the *amide* [70445-62-4] **M 191.0, m 148-148.5°**, or the *hydrazide* **m 171-173°** which crystallised from a large volume of MeCN. [Muterer et al. *Helv Chim Acta* **59** 222 *1976*, Newcome et al. *J Org Chem* **44** 2693 *1979*, *Beilstein* **22** H 44.] A pharmaceutical research building block acid of 90% grade is also available.

2,6-Dichloropyridine-4-carboxylic acid (2,6-dichloroisonicotinic acid) *[5398-44-7]* **M 192.0, m 210°, 209-212°, $pK_{Est(1)}$ ~ -1.** Purify the acid by crystallisation from H_2O, and it forms needles or platelets from EtOH. The *methyl ester* crystallises from aqueous MeOH with **m 82°**, the *ethyl ester* from aqueous EtOH has **m 66°**, and the *amide* from H_2O has **m 207-208°**. [Meyer et al. *Monatsh Chem* **36** 731 *1915*, Levelt & Wibaut *Rec Trav Chim Pays Bas* **48** 469 *1929*.]

5,6-Dichloropyridine-3-carboxylic acid (5,6-dichloronicotinic acid) *[41667-95-2]* **M 192.0, m 160-161°, 164-168°, 168°, $pK_{Est(1)}$ ~ 0.5.** Recrystallisation of the acid from H_2O provides the *monohydrate* which becomes *anhydrous* (**m 161-162°**) on heating at 100°. The *acid chloride* distils at **125°/~24mm**, solidifies on cooling, and crystallises from petroleum ether with **m 48-49°**. The *methyl ester* has **m 67-68°** (from aqueous MeOH), and the *amide* forms colourless plates from aqueous EtOH with **m 218-220°**. [Räth & Schiffmann *Justus Liebigs Ann Chem* **487** 133 *1931*, Meyer & Graf *Chem Ber* **61** 2212 *1928*, *Beilstein* **22** H 44, **22** II 36, **22** III/IV 511, **22/2** V 80.]

4,7-Dichloroquinoline *[86-98-6]* **M 198.1, m 86.4-87.4°, b 148°/10mm, pK^{25} 2.80.** Crystallise the dichloroquinoline from MeOH or 95% EtOH. [*Beilstein* **20/7** V 316.]

2,3-Dichloroquinoxaline *[2213-63-0]* **M 199.0, m 152-153°, 152-154°, pK_{Est} <0.** Recrystallise it from *C_6H_6 and dry it in a vacuum [Cheeseman *J Chem Soc* 1804 *1955*, *Beilstein* **23/7** V 144].

***cis*-Dicyclohexyl-18-crown-6** *[16069-36-6]* **M 372.5, m 47-50°.** Purify it by chromatography on neutral alumina and elute with an ether/hexane mixture [see Izatt et al. *Inorg Chem* **14** 3132 *1975*]. Dissolve it in ether at *ca* 40°, and spectroscopic grade MeCN is added to the solution, which is then chilled. The crown ether precipitates and is filtered off. It is dried *in vacuo* at room temperature [Wallace *J Phys Chem* **89** 1357 *1985*]. [Vögtle ed. *Top Corr Chem* (Host Guest Complex Chemistry) **98** *1981*.] **SKIN IRRITANT.**

5,5-Diethylbarbituric acid (Barbital) *[57-44-3]* **M 184.2, m 188-192°, pK_1^{25} 8.02, pK_2^{25} 12.7.** Crystallise barbital from water or EtOH and dry it in a vacuum over P_2O_5. [*Beilstein* **24** III/IV 1901.]

1,1'-Diethyl-2,2'-cyanine iodide *[977-96-8]* **M 454.4, m 274°(dec).** It crystallises from EtOH and is dried in a vacuum oven at 80° for 4 hours. [*Beilstein* **23** II 267.]

2,3-Dihydrobenzofuran (coumaran) *[496-16-2]* **M 120.2, m -21.5°, 72-73°/12mm, 84°/17mm, 188° /atm, d_4^{20} 1.065, n_D^{20} 1.5524.** Suspend coumaran in aqueous NaOH and steam distil it. Saturate the distillate with NaCl and extract it with Et_2O, dry the extract ($MgSO_4$), filter, evaporate and distil the residue. It gives a strong violet colour with $FeCl_3$ + H_2SO_4 and forms a yellow *picrate*, **m** 76° (from EtOH or *C_6H_6) which loses coumaran in a desiccator [Bennett & Hafez *J Chem Soc* 287 *1941*, Baddeley et al. *J Chem Soc* 2455 *1956*]. [*Beilstein* **17/1** V 581.]

Dihydropyran (3,4-dihydro-2*H*-pyran) *[110-87-2]* **M 84.1, b 84.4°/742mm, 85.4-85.6°/760mm, d_4^{20} 0.9261, n_D^{20} 1.4423, pK_{Est} ~ 4.2.** Partially dry dihydropyran with Na_2CO_3, then fractionally distil it. The fraction **b** 84-85° is refluxed with Na until hydrogen no longer evolves when fresh Na is added. It is then dried, and distilled again through a 60 x 1.2cm column packed with glass rings [Brandon et al. *J Am Chem Soc* **72** 2120 *1950*, UV: Elington et al. *J Chem Soc* 2873 *1952*, NMR: Bushweller & O'Neil *Tetrahedron Lett* 4713 *1969*]. It has been characterised as the *2-(3,5-dinitrobenzoyloxy)tetrahydropyrane* derivative, **m** 103° [prepared by dissolving 3,4-dinitrobenzoic acid (3g) in 50% excess of dihydropyran with warming, cooling, adding Et_2O (5ml), whereby the derivative crystallises out quantitatively] which forms pale yellow crystals from 80% dihydropyran/Et_2O [Woods & Kramer *J Am Chem Soc* **69** 2246 *1947*]. [*Beilstein* **17/1** V 181.]

3,4-Dihydro-2*H*-pyrido[1,2*a*]-pyrimidin-2-one *[5439-14-5]* **M 148.2, m 185-187°, 187-188°, 191-191.5°.** Dissolve it in $CHCl_3$, filter, evaporate, then recrystallise the residue from EtOH/Me_2CO (needles) which can be washed with Et_2O and dried. It can also be recrystallised from $CHCl_3$/petroleum ether or $CHCl_3$/hexane. The *hydrochloride* has **m** 295-295° (dec, from EtOH or MeOH/Et_2O), the *hydrobromide* has **m** 299-300°(dec) (from

MeOH/Et_2O) and the *picrate* has **m** 224-226°(corr), **m** 219-220° from EtOH. [Adams & Pachter *J Am Chem Soc* **74** 4906 *1952*, Lappin *J Org Chem* **23** 1358 *1958*, Hurd & Hayao *J Am Chem Soc* **77** 115 *1955*, *Beilstein* **24** III/IV 299.]

7,8-Dihydroxycoumarin (Daphnetin) *[486-35-1]* **M 178.2, m 256°(dec), $pK_{Est(1)}$ ~8.5, $pK_{Est(2)}$ ~12.3.** Crystallise it from aqueous EtOH. It can be sublimed. [*Beilstein* **18/3** V 202.].

***trans*-2,3-Dihydroxy-1,4-dioxane** *[4845-50-5]* **M 120.1, m 91-95°, 100°.** Recrystallise it from Me_2CO. With phenylhydrazine it gives *glyoxal phenylhydrazone* **m** 175° (from Me_2CO/petroleum ether). The *diacetyl* derivative has **m** 105-106° [Head *J Chem Soc* 1036 *1955*, Raudnitz *Chem Ind (London)* 166 *1956*]. [*Beilstein* **1** IV 3627.]

2,5-Dihydroxy-1,4-dithiane *[40018-26-6]* **M 152.2, m (142-147°) 150-152°, 151°.** Recrystallise the dithiane from EtOH. *2,5-Diethoxy-dithiane* has **m** 91° (92-93°); it crystallises from petroleum ether and can be sublimed at 60°/0.001mm [Hormatka & Haber *Monatsh Chem* **85** 1088 *1954*, Thiel et al. *Justus Liebigs Ann Chem* **611** 121 *1958*, Hesse & Jøeder *Chem Ber* **85** 924 *1952*]. [*Beilstein* **1** IV 3966.]

***S(-)*-4',7-Dihydroxyflavanone (3,4'-dihydroxyisoflavone, Liquiritigenin)** *[578-86-9]* **M 256.3, m 203-205° $[\alpha]_D^{20}$ -225° (c 0.95, 95%EtOH).** It crystallises from aqueous 50% EtOH. [*Beilstein* **18** III/IV 1780, **18/4** V 82.]

5,7-Dihydroxy-4'-methoxyflavone (Acacetin) *[480-44-4]* **M 284.3, m 261°, 260-265°.** Acacetin crystallises from 95% EtOH or acetic acid as pale yellow needles (m 263°). It is an anti-inflammatory. [Zemplen & Bognar *Chem Ber* **76** 452 *1943*, Pillon *Bull Soc Chim* Fr 9 *1954,* UV: Gaydou & Bianchini *Bull Soc Chim Fr* Part II 43 *1978*, *Beilstein* **18** III/IV 2683, **18/4** V 575.]

(±)-7-(2,3-Dihydroxypropyl)theophylline (Diprophylline, Dyphylline) *[479-18-5]* **M 254.3, m 158°, 160-164°, 161°, 161-164°, pK_{Est} ~ 8.7.** Recrystallise it from EtOH or H_2O. Its solubility in H_2O is 33% at 25°, in EtOH it is 2% and in $CHCl_3$ it is 1%. Its UV has λ_{max} (H_2O) at 273nm (ε 8,855). [Roth *Arch Pharm* **292** 234 *1959*.] The *4-nitrobenzoyl* derivative has **m** 178° [Oshay *J Chem Soc* 3975 *1956*]. [*Beilstein* **26** III/IV 2370.]

1,3-Diiminoisoindoline *[3468-11-9]* **M 145.2, m 193-194°(dec), 196°(dec), pK^{25} 8.27.** It crystallises from H_2O, MeOH or MeOH/Et_2O (charcoal) in colourless prisms that become green on heating. [Elvidge & Linstead *J Chem Soc* 5000 *1952*]. Its IR (nujol) has bands at 3150 and 690 cm^{-1}, and the UV has λ_{max} at 251nm (ε 12,500), 256nm (ε 12,5000) and 303nm (ε 4,600) [Elvidge & Golden *J Chem Soc* 700 *1957*, Clark et al. *J Chem Soc* 3593 *1953*]. The *thiocyanate* has **m** 250-255° (dec), the *monohydrochloride* has **m** 300-301° (turns green), and the *dihydrochloride* has **m** 326-328° (turns green) and the *picrate* crystallises from EtOH with **m** 299° (dec). [*Beilstein* **22/13** V 5.]

5,7-Diiodo-8-hydroxyquinoline *[83-73-8]* **M 397.0, m 214-215°(dec) $pK_{Est(1)}$~3.2, $pK_{Est(2)}$ ~8.2.** It crystallises from xylene and is dried at 70° in a vacuum. [*Beilstein* **21** II 58.]

6-Dimethylaminopurine *[938-55-6]* **M 163.1, m 257.5-258.5°, 259-262°, 263-264°, pK_1^{25} 3.87, pK_2^{25} 10.5.** It is purified by recrystallisation from H_2O, EtOH (0.32g in 10ml) or $CHCl_3$. [Albert & Brown *J Chem Soc* 2060 *1954*, UV: Mason *J Chem Soc* 2071 *1954*.] The *monohydrochloride* crystallises from EtOH/Et_2O, **m** 253°(dec) [Elion et al. *J Am Chem Soc* **74** 411 *1952*], the *dihydrochloride* has **m** 225°(dec) and the *picrate* has **m** 245° (235-236.5°) [Fryth et al. *J Am Chem Soc* **80** 2736 *1958*]. [*Beilstein* **26** III/IV 3566.]

1,3-Dimethylbarbituric acid *[769-42-6]* **M 156.1, m 123°, pK^{25} 4.56.** Crystallise the acid from water and sublime it in a vacuum. Also purify it by dissolving 10g in 100ml of boiling CCl_4/$CHCl_3$ (8:2) (1g charcoal), filtering and cooling to 25°. Dry it *in vacuo* [Kohn et al. *Anal Chem* **58** 3184 *1986*]. [*Beilstein* **24** III/IV 1875.]

5,6-Dimethylbenzimidazole *[582-60-5]* **M 146.2, m 205-206°, pK_1^{25} 5.96, pK_2^{25} 12.52.** Crystallise 5,6-dimethylbenzimidazole from diethyl ether. It sublimes at 140°/3mm. [*Beilstein* **23/6** V 454.]

2,3-Dimethylbenzothiophene *[31317-17-6]* **M 212.3, m 69-70°, b 123-124°/10mm, n_D^{19} 1.6171.** Fractionate it through a 90cm Monel spiral column, or other efficient fractionating or spinning band column and collect the middle fraction. It has also been purified by chromatography on basic alumina using pentane as eluent. [Tedjanulia et al. *J Heterocycl Chem* **20** 1485 *1983*, *Beilstein* **17** III/IV 161.]

4,4'-Dimethyl-2,2'-bipyridine *[1134-35-6]* **M 184.2, m 175-176°, $pK_{Est(1)}$ ~0.2, $pK_{Est(2)}$ ~4.9.** Crystallise it from ethyl acetate. [Elliott et al. *J Am Chem Soc* **107** 4647 *1985*, *Beilstein* **23/8** V 79.]

1,1'-Dimethyl-4,4'-bipyridylium dichloride ($3H_2O$; Methyl Viologen Dichloride, paraquat dichloride) *[1910-42-5]* **M 311.2, m >300°(dec).** Recrystallise the dichloride from MeOH/acetone mixture. It has also been recrystallised three times from absolute EtOH [Bancroft et al. *Anal Chem* **53** 1390 *1981*]. Dry it at 80° in a vacuum. [*Beilstein* **23/8** V 30.]

1,3-Dimethylbutadiene sulfone (1,3-dimethylsulfolene, 2,5-dihydro-2,4-dimethylthiophene) *[10033-92-8]* **M 145.2, m 40.4-41.0°.** Crystallise it from Et_2O, Et_2O/pentane or CCl_4. [Grummitt et al. *J Am Chem Soc* **72** 5167 *1950*, Bartlett et al. *J Org Chem* **32** 1290 *1967*, *Beilstein* **17** III/IV 161.]

2,2-Dimethyl-1,3-dioxan-4,6-dione (Meldrum's Acid) *[2033-24-1]* **M 144.1, m 92-96°, 94-95°, pK^{25} 5.1, 7.32.** Crystallise the dione from Me_2CO/H_2O. It is a useful synthon for the C3 malonic acid moiety. [Arnette et al. *J Am Chem Soc* **106** 6759 *1984*, Bihlmayer et al. *Monatsh Chem* **98** 564 *1967*, Review: McNab *Chem Soc, Rev* **7** 345 *1978*, Chan & Huang *Synthesis* 452 *1982*, *Beilstein* **19/5** V 8.] It is synthesised by a modified procedure in which concentrated H_2SO_4 (1.5ml) is added to a stirred suspension of powdered malonic acid (52g, 0.5 mole) in acetic anhydride (60ml, 0.6 mole), whereby the malonic acid dissolves with spontaneous cooling. Acetone (40ml, 0.55 mole) is added to the mixture while keeping the temperature at 20-25°, then cooled in a refrigerator overnight, the crystals are filtered off, washed three times with ice-water (enough to cover the crystals) and air dried. The crude product (35g, 49%) is recrystallised without heating by dssolving it (10g) in Me_2CO (20ml), filtering, and adding H_2O (40ml), with ~70% recovery of material m **94-95°**. [Pihlaja & Seilo *Acta Chem Scand* **22** 3053 *1968*.]
Alternatively concentrated H_2SO_4 (0.5ml) is added dropwise to a stirred suspension of powdered malonic acid (52g, 0.5 mole) in redistilled isoprenyl acetate (62ml, 55g, [108-22-5]), when the temperature rose from 23° to 31° in 45 minutes and all the solid dissolved within 1 hour. Treatment of the reaction as above gave Meldrum's acid (37g, 50%). [Davidson & Bernhard *J Am Chem Soc* **70** 3426 *1948*]. Its ^1H NMR ($CDCl_3$, TMS) has δ at 1.73 (s, 2-Me_2) and 3.60 (s, 5-H) [Schuster & Schuster *Tetrahedron* **25** 199 *1969*].

3,6-Dimethyl-1,4-dioxan-2,5-dione (Lactide) *[cis-RS,RS-(±) 615-95-2, cis-R,R-(+) 95-96-5, cis-S,S-(-) 4511-42-6]* **M 144.1.** This is the cyclic dilactone of lactic acid. The **(±)-*cis-racemate*** has been distilled with **b 142°/8mm**; the distillate which solidifies gives yellow needles on recrystallisation from EtOH with **m 128°**, from Et_2O with **m 129°**, or $CHCl_3$ with **m 126°**, with IR ν_{max} at 1720-1740 cm^{-1}. It hydrolyses in cold H_2O. [Carothers et al. *J Am Chem Soc* **54** 772 *1932*]. A ***trans-form*** (probably *RS,SR*) has been reported which crystallises from Et_2O with **m 42-43°** [Hummel et al. *Acta Cryst (Sect B)* **38** 1679 *1982*]. The ***R,R-(+)-lactide*** has **b 150°/2mm** and crystallises from Et_2O with **m 95°**, or **m 96.5-97.5°** (from $CHCl_3$) or **m 97.7°** (from EtOAc) and **$[\alpha]_D^{22}$ +297° (c 1.2, *C_6H_6)**. The ***S,S-(-)-lactide*** has **b 150°/2.5mm** and crystallises from EtOAc with **m 98.7°**, or **m 95°** (from $CHCl_3$) or **m 96.5-97.5°** (from CCl_4) and **$[\alpha]_D^{22}$ -297° (c 1.2, *C_6H_6)**. [Toniolo et al. *J Org Chem* **35** 6 *1970*, *Beilstein* **19** H 154, **19** I 179, **19** II 176, **19** IV 1927, **19/5** V 10.]

2,9-Dimethyl-4,7-diphenyl-1,10-phenanthroline (Bathocuproine) *[4733-39-5]* **M 360.5, m >280°, pK_{Est} ~5.6.** Purify it by recrystallisation from *benzene. [Smith & Wilkins *Anal Chem* **25** 510 *1953*, *Beilstein* **23** III/IV 2160.]

2,2-Dimethylethyleneimine (2,2-dimethylaziridine) *[2658-24-4]* **M 71.1, b 70.5-71.0°, 72°, n_D^{20} 1.405, pK^{25} 8.64.** Dry the 2,2-dimethylaziridine over solid KOH, filter and freshly distil from sodium before use, and store it under dry nitrogen. The *N-phenylthiocarbamoyl* derivative crystallises from petroleum ether containing a trace of Me_2CO with **m** 92.5-93.5°. [Hassner et al. *J Am Chem Soc* **91** 5046 *1969*, Cairns *J Am Chem Soc* **63** 871 *1941*, Lamaty et al. *Justus Liebigs Ann Chem* **726** 77 *1969*, *Beilstein* **20** III/IV 280.]

5,5-Dimethylhydantoin *[77-71-4]* **M 128.1, m 177-178° pK^{24} 9.19.** Crystallise the hydantoin from EtOH and sublime it *in vacuo.* [*Beilstein* **24** III/IV 1097.]

4,6-Dimethyl-2-hydroxypyrimidine *[108-79-2]* **M 124.1, m 198-199°, 202-205°, pK$_1^{20}$ 3.77, pK$_2^{20}$ 10.50.** Crystallise the pyrimidine from absolute EtOH (charcoal). [*Beilstein* **24/2** V 138.]

1,2-Dimethyl-1*H*-imidazole *[1739-84-0]* **M 96.1, m 38-40°, b 206°/760mm, d$_4^{20}$ 1.084, pK$_{Est}$ ~8.1.** Crystallise the imidazole from *benzene, dry and store it at 0-4°. The *picrate* crystallises from H_2O or EtOH with **m** 181°. [Balaban & Pymann *J Chem Soc* **125** 1570 *1924*, Gorun et al. *J Am Chem Soc* **109** 4244 *1987*, *Beilstein* **23** H 66, **23** II 56, **23** III/IV 594.]

1,3-Dimethyl-2-imidazolinone (DMI, *N*,*N*'-dimethylethyleneurea, DMEU) *[80-73-9]* **M 114.2, m 8.2°, b 67-68°/2mm, 104°/5mm, 106-107°/17mm, 224-226°/atm, d$_4^{25}$ 1.056, n$_D^{20}$ 1.472**. After preparation by reaction of *N*,*N*'-dimethylethylenediamine in toluene with phosgene in toluene below 15°, excess phosgene is removed by blowing air through the mixture. The hydrochloride salt that separates is removed by filtration, and washed with $CHCl_3$. The combined filtrate and washings are evaporated off, and the residue is distilled (b 129°/39mm). The crude distillate is treated with H_2O; K_2CO_3 is added to saturate the solution, and extracted with $CHCl_3$, the extract is dried (K_2CO_3), filtered, and pure *1,3-dimethylimidazolin-2-one* distils at **b 104°/5mm**. It has been used as an alternative to HMPA [see 680-31-9] as a high dielectric solvent for reactions. [Boon *J Chem Soc* 307 *1947*, Lien & Kumler *J Med Chem* **11** 241 *1968*, Kohn et al. *J Org Chem* **42** 941 *1977*, *Beilstein* **24** III/IV 9.]

3,3-Dimethyloxetane *[6921-35-3]* **M 86.1, b 79.2-80.3°/760mm, d$_4^{20}$ 0.836, n$_D^{20}$ 1.399.** Purify 3,3-dimethyloxetane by gas chromatography using a 2m silicone oil column or distil it. Fractionate it at atmospheric pressure (preferably under N_2 or Ar. [*Beilstein* **17** II 21.]

2,9-Dimethyl-1,10-phenanthroline (neocuproine hemihydrate) *[484-11-7]* **M 208.3, 217.3 (hemihydrate), m 162-164°, pK^{25} 5.85.** Purifiy it as the *hemihydrate* by crystallisation from water and as the *anhydrous* base from *benzene. [*Beilstein* **23/8** V 527.]

4,4-Dimethyl-2,6-piperidinedione (4,4-dimethylglutarimide) *[1123-40-6]* **M 141.2, m 144-146°, pK$_{Est}$ ~11.5.** Recrystallise the imide from hot H_2O or EtOH [Arnett & Harrelson *J Am Chem Soc* **109** 809 *1987*]. [*Beilstein* **21** H 391, **21** I 331, **21** II 309, **21** III/IV 4601, **21/9** V 592.]

2,5-Dimethylpyrazine *[123-32-0]* **M 108.1, b 156°, d$_4^{20}$ 0.990, n$_D^{20}$ 1.502, pK$_1^{25}$ -4.6 (aqueous H_2SO_4), pK$_2^{25}$ 1.85.** Purify it *via* its *picrate* (**m** 150°) which is decomposed with a base (e,g, KOH) and distilled. [Wiggins and Wise *J Chem Soc* 4780 *1956*]. [*Beilstein* **23/5** V 403.]

3,5-Dimethylpyrazole *[67-51-6]* **M 96.1, m 107-108°, pK^{20} 4.16.** Crystallise it from cyclohexane or water. [Barszez et al. *J Chem Soc, Dalton Trans* 2025 *1986*, *Beilstein* **23/5** V 110.]

2,3-Dimethylquinoxaline *[2379-55-7]* **M 158.2, m 106°, pK^{25} -3.84 (aqueous H_2SO_4).** It has been purified by steam distillation with the base crystallising in the distillate. Recrystallise it from distilled water or aqueous EtOH. The *sulfate* crystallises from EtOH with **m** 151-152°(dec). [Gibson *J Chem Soc* 343 1927, *Beilstein* **23** H 191, **23** II 197, **23** III/IV 1277.]

2,4-Dimethylsulfolane *[1003-78-7]* **M 148.2, b 128°/77mm, d$_D^{25}$ 1.1314, n$_D^{20}$ 1.474.** Distil the 2,4-dimethylsulfolane in a vacuum. [*Beilstein* **17/1** V 82.]

1,3-Dimethyluracil *[874-14-6]* **M 140.1, m 121-122°, pK^{25} -3.25 (aqueous H_2SO_4).** Crystallise it from EtOH/ether. [*Beilstein* **24** III/IV 1196.]

9,9-Dimethylxanthene (4,4-dimethyl-2,3:5,6-dibenzopyran) *[19814-75-6]* **M 210.3, m 36-38°, b 114-115°/0.6mm, n$_D^{20}$ 1.5973.** It is prepared under argon (Schlenk equipment) by adding Me_3Al solution (2.0M in

toluene, 320ml, 0.64mmol), *via* a septum over 50 minutes, to an ice-water cooled stirred suspension of 9-xanthone (50.0g, 0.255mol) in toluene (300ml) (exothermic reaction, no gas evolved). The dark red solution is allowed to warm to ~25° over 3 hours, and stirred for a further 14 hours. (*Alternatively* it can be heated to 60°. for ~0.5 hours.) The mixture is transferred (*via* a cannula under argon pressure) to a stirred mixture of concentrated HCl (250ml) and ice (4 L). The organic phase is separated, dried ($MgSO_4$), filtered, the solvent is evaporated *in vacuo* to give a yellow oil (51.5g, 96%) which distils at 114-115°/0.6mm, and solidifies on cooling. The ^1H NMR ($CDCl_3$, TMS) has δ at 1.63 (s, 6H, CH_3), 7.0-7.6 (m, 8H, aromatic-H); MS has *m/z* at 210 (M^+), 195 (base peak, M^+-CH_3). [Nowick et al. *J Am Chem Soc* **112** 8904 *1990*, Meisters & Mole *Aust J Chem* **27** 1655 *1974*, *Beilstein* **17** II 287.]

1,3-Dioxolan-2-one (ethylene carbonate) *[96-49-1]* **M 88.1, m 37°, 39°, 40°, b 65-67°/1mm, 126°/17mm, 238°/760mm, d_4^{20} 1.321, n^{40} 1.4199.** Dry 1,3-dioxolan-2-one over P_2O_5, then fractionally distil it at low or atmospheric pressure. Recrystallise it from dry Et_2O (plates, **m** 36.5°, 38.5-40° was also reported). It is soluble in H_2O. [*Beilstein* 19 II 135,**19** III/IV 1556, **19/4** V 6.]

1,3-Dioxane *[505-22-6]* **M 88.1, b 104.5°/751mm, d_4^{20} 1.040, n_D^{20} 1.417.** Dry the dioxane with sodium and fractionally distil it. [*Beilstein* **19/1** V 11.]

1,4-Dioxane *[123-91-1]* **M 88.1, f 11.8°, b 101.3°, d_4^{25} 1.0292, n_D^{15} 1.4236, n_D^{25} 1.42025.** It is prepared commercially either by dehydration of ethylene glycol with H_2SO_4 and heating ethylene oxide or bis(ß-chloroethyl)ether with NaOH. The usual impurities are acetaldehyde, ethylene acetal, acetic acid, water and peroxides. Peroxides can be removed (and the aldehyde content decreased) by percolation through a column of activated alumina (80g per 100-200ml solvent), by refluxing with $NaBH_4$ or anhydrous stannous chloride and distilling, or by acidification with conc HCl, shaking with ferrous sulfate and leaving in contact with it for 24 hours before filtering and purifying further.
Hess and Frahm [*Chem Ber* **71** 2627 *1938*] refluxed 2L of dioxane with 27ml conc HCl and 200ml water for 12 hours with slow passage of nitrogen to remove acetaldehyde. After cooling the solution, KOH pellets were added slowly and with shaking until no more would dissolve and a second layer had separated. The dioxane was decanted, treated with fresh KOH pellets to remove any aqueous phase, then transferred to a clean flask where it was refluxed for 6-12 hours with sodium, then distilled from it. *Alternatively*, Kraus and Vingee [*J Am Chem Soc* **56** 511 *1934*] heated it on a steam bath with solid KOH until fresh addition of KOH gave no more resin (due to acetaldehyde). After filtering through paper, the dioxane was refluxed over sodium until the surface of the metal was not further discoloured during several hours. It was then distilled from sodium.
The acetal (**b** 82.5°) is removed during fractional distillation. Traces of *benzene, if present, can be removed as the *benzene/MeOH azeotrope by distillation in the presence of MeOH. Distillation from $LiAlH_4$ removes aldehydes, peroxides and water. Dioxane can be dried using Linde type 4X molecular sieves. Other purification procedures include distillation from excess C_2H_5MgBr, refluxing with PbO_2 to remove peroxides, fractional crystallisation by partial freezing and the addition of KI to dioxane acidified with aqueous HCl. Dioxane should be stored out of contact with air, preferably under N_2.
A detailed purification procedure is as follows: Dioxane is stood over ferrous sulfate for at least 2 days, under nitrogen. Then water (100ml) and conc HCl (14ml)/ litre of dioxane are added (giving a pale yellow colour). After refluxing for 8-12 hours with vigorous N_2 bubbling, pellets of KOH are added to the warm solution to form two layers and to discharge the colour. The solution is cooled rapidly with more KOH pellets being added (magnetic stirring) until no more dissolved in the cooled solution. After 4-12 hours, if the lower phase is not black, the upper phase is decanted rapidly into a clean flask containing sodium, and refluxed over sodium (until freshly added sodium remained bright) for 1 hour. The middle fraction is collected (and checked for minimum absorbency below 250nm). The distillate is fractionally frozen three times by cooling in a refrigerator, with occasional shaking or stirring. This material is stored in a refrigerator. Before use it is thawed, refluxed over sodium for 48 hours, and distilled into a container. All joints are clad with Teflon tape.
Coetzee and Chang [*Pure Appl Chem* **57** 633 *1985*] dried the solvent by passing it slowly through a column (20g/L) of 3A molecular sieves activated by heating at 250° for 24 hours. Impurities (including peroxides) are removed by passing the effluent slowly through a column packed with type NaX zeolite (pellets ground to

0.1mm size) activated by heating at 400° for 24 hours or chromatographic grade basic Al_2O_3 activated by heating at 250° for 24 hours. After removal of peroxides the effluent is refluxed for several hours over sodium wire, excluding moisture, distilled under nitrogen or argon and stored in the dark.
One of the best tests of purity of dioxane is the formation of the purple disodium benzophenone complex during reflux and its persistence on cooling. (Benzophenone is better than fluorenone for this purpose and for the storing of the solvent.) [Carter et al. *Trans Faraday Soc* **56** 343 *1960*, *Beilstein* **19** V 16.] **TOXIC.**
Rapid purification: Check for peroxides (see Chapter 1 and Chapter 2 for test under ethers). Pre-dry with $CaCl_2$ or better over Na wire. Then reflux the pre-dried solvent over Na (1% w/v) and benzophenone (0.2% w/v) under an inert atmosphere until the blue colour of the benzophenone ketyl radical anion persists. Distil, and store it over 4A molecular sieves in the dark.

1,3-Dioxolane *[646-06-0]* **M 74.1, b 75.0-75.2°, d $^{20}_{D}$ 1.0600, n^{21} 1.3997.** Dry it with solid NaOH, KOH or $CaSO_4$, and distil it from sodium or sodium amalgam. Barker et al. [*J Chem Soc* 802 *1959*] heated 34ml of dioxalane under reflux with 3g of PbO_2 for 2 hours, then cooled and filtered. After adding xylene (40ml) and PbO_2 (2g) to the filtrate, the mixture is fractionally distilled. Addition of xylene (20ml) and sodium wire to the main fraction (**b** 70-71°) led to a vigorous reaction, following which the mixture was again fractionally distilled. Xylene and sodium additions are made to the main fraction (**b** 73-74°) before it is finally distilled. [*Beilstein* **19/1** V 6.]

5,5-Diphenylhydantoin *[57-41-0]* **M 252.3, m 293-295°.** Crystallise the hydantoin from EtOH. [*Beilstein* **24** III/IV 1748.]

1,3-Diphenylisobenzofuran *[5471-63-6]* **M 270.3, m 129-130°.** Recrystallise it from EtOH or EtOH/$CHCl_3$ (1:1) under red light (as in photographic dark rooms) or from *benzene in the dark. [*Beilstein* **17/2** V 503.]

2,5-Diphenyl-1,3,4-oxadiazole (PPD) *[725-12-2]* **M 222.3, m 70° (hydrate), 139-140° (anhydrous), b 231°/13mm, 248°/16mm.** Its solubility in $CHCl_3$ is 10%. Crystallise it from EtOH and sublime it *in vacuo*. [*Beilstein* **27** III/IV 2712.]

2,5-Diphenyloxazole (PPO) *[92-71-7]* **M 221.3, m 74°, b 360°/760mm.** Distil it in steam and crystallise it from ligroin. [*Beilstein* **27** III/IV 1437.]

2*RS*,5*RS*-(±)-2,5-Diphenylpyrrolidine (± *trans* isomer) ***[****22147-84-8]* **M 223.3, b 136°/0.3mm, n $^{25}_{D}$ 1.5866, pK_{Est} ~8.0.** A mixture of *cis-(meso)* and *trans*-(±) pyrrolidines (b ~130-145°/0.15-0.2mm, ~138g, 0.6mol) in EtOH (210ml) and concentrated HCl (100ml) was treated dropwise, during ~2 hours, with a solution of $NaNO_2$ (61.5g, 0.9mol) in H_2O (100ml) at ~0° (ice-bath cooling). The mixture was poured into H_2O (1L) and the precipitate (~160g) was collected, washed with H_2O and fractionally recrystallised from Me_2CO to give the *trans-nitroso* derivative (**m 140-140.9°**, 51%) [22147-82-6], and the *cis-nitroso* derivative (**m 97-98°**, 20%) [22147-81-5]. This *trans*-nitroso-pyrrolidine was de-nitrosated (HCl gas in Et_2O) to the *trans-hydrochloride* **m 196.5-180°** which was recrystallised from EtOH/Et_2O. The *trans-free base* was obtained by basifying an aqueous solution to pH 9-10 and extracting with Et_2O (3 x 50ml), drying the extract (Mg_2SO_4), filtering, evaporating and distilling the residual oil (**b 136°/0.3mm)**. The IR (film) has ν_{max} at 1110-1025 (three peaks, one is for C-N) and 3330 (N-H) cm^{-1}. Similarly the *cis (meso) N-nitroso derivative* gave the *2RS,5SR-diphenylpyrrolidine meso-hydrochloride* which had **m 224.7-225.5°**, and the *meso-free base* [22147-83-7] had **b 121-123.4°/0.2mm, n $^{25}_{D}$ 1.5850**. The optically active *2R,5R-(+)-diphenylpyrrolidine* enantiomer [155155-73-0] had **m 49-53°, [α] $^{22}_{D}$ +118° (c 1.0, $CHCl_3$)**. [Overberger et al. *J Am Chem Soc* **91** 687 *1969*, Breuer & Melumed *J Org Chem* **37** 3949 *1972*.]

(±)-α, α-Diphenyl-2-pyrrolidinemethanol (α, α-diphenyl-DL-prolinol) *[63401-04-7, 112022-88-55]* **M253.3, m 82-83° (76° also reported), pK_{Est} ~9.5.** It is prepared as the *(±)-hydrochloride* [16226-54-3] **M 289.8**, **m 267-269° (dec, 262-263°** was also reported**)** by dissolving the amine in Et_2O, Et_2O/MeOH or CH_2Cl_2, and dry HCl gas is bubbled through (avoid excess HCl as it may dissolve precipitated NH_4Cl), filtering,

evaporating, and the residue is recrystallised from MeOH/Me_2CO; and from which the *free base* is obtained by treatment with aqueous NaOH and extraction with Et_2O. It has psychostimulating activity. [Enders et al. *Org Synth* **58** 113 *1978*, Enders et al. *Org Synth* Coll Vol **VI** 542 *1988*, Enders et al. *Synthesis* 548 *1976*, Likhosherstov et al. *Khim Farm Z* **1** 30 *1967*, *Chem Abstr* **67** 90642 *1967*. *Beilstein* **21** III/IV 1519.]

The *picrate* has **m** 185-185°. [Jampolsky et al. *J Am Chem Soc* **74** 5222 *1952*, Chow & Fouss *J Am Chem Soc* **80** 1095 *1958*, *Beilstein* **23** III/IV 1400.]

2,5-Distyrylpyrazine *[14990-02-4]* **M 284.3, m 219°.** Recrystallise it from xylene; chromatograph it on basic silica gel (60-80 mesh) using CH_2Cl_2 as eluent, then sublime it in a vacuum on to a cold surface at 10^{-3}torr [Ebied *J Chem Soc, Faraday Trans 1* **78** 3213 *1982*]. All operations should be carried out in the dark.

1,3-Dithiane *[505-23-7]* **M 120.2, m 54°.** Crystallise the 1,3-dithiane from 1.5 times its weight of MeOH at 0°, and sublime it at 40-50°/0.1mm. [Gröbel & Seebach *Synthesis* 357 *1977*, *Beilstein* **19/1** V 13.]

2,2′-Dithiobis(benzothiazole) *[120-78-8]* **M 332.2, m 180°, 182.5-183.5°.** Crystallise it from *benzene. [*Beilstein* **27** H 109, **27** III/IV 1862.]

4,4'-Dithiodimorpholine (S,S′-di-*N,N′*-dimorpholine, dimorpholine-*N,N′*-disulfide) *[103-34-4]* **M 236.2, m 124-125°.** Crystallise it from hot aqueous dimethylformamide or EtOH. It is a fungicide. [Blake *J Am Chem Soc* **65** 1267 *1943*.]

1-Dodecylpyridinium chloride *[104-74-5]* **M 301.9, m 68-70°.** Purify the chloride by repeated crystallisation from acetone (charcoal); then recrystallise it twice from EtOH [Chu & Thomas *J Am Chem Soc* **108** 6270 *1986*]. It is *hygroscopic* and should be stored with a desiccant. [*Beilstein* **20** III/IV 2314.]

Ellipticine (5,11-dimethylpyrido[4,3:*b*]carbazole) *[519-23-3]* **M 246.3, m 311-315°(dec), 312-314°(dec), pK^{25} 5.78 (80% aqueous methoxyethanol).** This DNA intercalator is purified by recrystallisation from $CHCl_3$ or MeOH and is dried *in vacuo*. The UV has λ_{max} values in aqueous EtOH/HCl at 241, 249, 307, 335 and 426nm. [Marini-Bettolo & Schmutz *Helv Chim Acta* **42** 2146 *1959*.] The *methiodide* has **m** 360°(dec), with UV λ_{max} (EtOH/KOH) at 223, 242, 251, 311, 362 and 432nm. [Goodwin et al. *J Am Chem Soc* **81** 1903 *1959*, *Beilstein* **23/9** V 417.]

Elymoclavine (8,9-didehydro-6-methylergoline-8-methanol) *[548-43-6]* **M 254.3, m 249-253°(dec), 250-252°(dec), $[\alpha]_D^{20}$-109° (c 0.4, EtOH).** It crystallises from MeOH, $CHCl_3$, Et_2O, Me_2CO or $*C_6H_6$. [*Beilstein* **23** III/IV 2716.]

Emetine hydrochloride hydrate *[316-42-7]* **M 553.6 + aq, m 235-240°, 235-250°, 240-250°, 248-250° (depending on H_2O content), $[\alpha]_D^{20}$ -49.2° (free base, c 4, $CHCl_3$), +18° (c 6, H_2O, dry salt), pK_1 5.77, pK_2 6.64.** It crystallises from MeOH/Et_2O, MeOH or Et_2O/EtOAc. The *free base* has **m** 104-105°, and the *(-)-phenylthiourea* derivative has **m** 220-221° (from EtOAc/petroleum ether, $[\alpha]_D^{25}$ - 29.3° ($CHCl_3$)). Its IR has ν_{max} at 3413 (OH) and 2611 (NH^+) cm^{-1}; and UV λ_{max} at 230nm (ε 16 200) and 282nm (ε 6 890) [Brossi et al. *Helv Chim Acta* **42** 1515 *1959*, Barash et al. *J Chem Soc* 3530 *1959*]. [*Beilstein* **23** III/IV 3419.]

Ergocornine *[564-36-3]* **M 561.7, m 182-184°, $[\alpha]_D^{20}$ -176° (c 0.5, $CHCl_3$).** It crystallises with solvent of crystallisation from MeOH. [Stadler et al. *Helv Chim Acta* **52** 1549 *1969*, *Beilstein* **25** III/IV 963, **27** II 860.]

Ergocristine *[511-08-0]* **M 573.7, m 165-170°, $[\alpha]_D^{20}$ -183° (c 0.5, $CHCl_3$).** It crystallises with 2 molecules of solvent of crystallisation from *benzene. [Stadler et al. *Helv Chim Acta* **52** 1549 *1969*, *Beilstein* **25** III/IV 966, **27** II 860.]

Ergocryptine *[511-09-1]* **M 575.7, m 212-214°, $[\alpha]_D^{20}$ -180° (c 0.5, $CHCl_3$).** It crystallises with solvent of crystallisation, from acetone, *benzene or methanol. [Stadler et al. *Helv Chim Acta* **52** 1549 *1969*, *Beilstein* **25** III/IV 964, **27** II 860.]

Ergotamine *[113-15-5]* **M 581.6, m 212-214°(dec), $[\alpha]_D^{20}$ -160° (c 0.5, $CHCl_3$), pK^{25} 6.40.** Crystallise it from *benzene, then dry it by prolonged heating in high vacuum. It is very *hygroscopic*. [*Beilstein* **25** III/IV 964.]

Ergotamine tartrate *[379-79-3]* **M 657.1, m 203°(dec).** It crystallises from MeOH. [*Beilstein* **25** III/IV 964.]

Ergotaminine *[639-81-6]* **M 581.7, m 241-243°, $[\alpha]_D^{20}$ +369° (c 0.5, $CHCl_3$).** It forms rhombic plates from MeOH which retain solvent unlike its isomer ergotamine (previous entry). It is less soluble than ergotamine, and its solubility is 0.1% in boiling ethanol and 0.07% in methanol. [Stoll *Helv Chim Acta* **28** 1299 and 1306 *1945*, *Beilstein* **25** II 860, 862, **25** III/IV 966.]

D-Erythronic acid (3*R*-3,4-dihydroxyfuran-2-one) *[15667-21-7]* **M 118.1, m 98-100°, 103-104°, 104-105°, 105°, $[\alpha]_D^{20}$ -73.2° (c 0.5, H_2O), $[\alpha]_{546}^{20}$ -87.6° (c 4, H_2O).** Recrystallise it from EtOAc (20 parts) or isoPrOH (3 parts). [Baker & MacDonald *J Am Chem Soc* **82** 230 *1960*, Glattfeld & Forbrich *J Am Chem Soc* **56** 1209 *1934*, Weidenhagen & Wegner *Chem Ber* **72** 2010 *1939*, Musich & Rapoport *J Am Chem Soc* **100** 4865 *1978*, *Beilstein* **18/2** V 457.]

Esculetin (cichorigenin, 6,7-dihydroxycoumarin) *[305-01-1]* **M 178.2, m 272-275° (dec), 274° (dec), pK^{25} 8.60 (70% aqueous EtOH), $pK_{Est(1)}$ ~8.7, $pK_{Est(2)}$ ~12.4.** It forms prisms from AcOH, aqueous EtOH or aqueous MeOH, and provides leaflets on sublimation in a vacuum. [Kagan *J Am Chem Soc* **88** 2617 *1966*, Marby et al. *Phytochemistry* **4** 492 *1965*.] *Esculin (the 6-glucoside)* has **m** 215°(dec), $[\alpha]_D^{20}$ -41° (c 5, pyridine). [*Beilstein* **18** III/IV 1322, **18/3** V 202.]

Eserine (Physostigmine, Physostol, [(3aS-*cis*)-1,2,3,3a,8,8a-hexahydro-1,3a,8-trimethyl-pyrrolo[2,3-b]indol-5-ol methylcarbamate ester] *[57-47-6]* **M 275.4, m 102-104°, 105-106°, $[\alpha]_D^{17}$ -67° (c 1.3, $CHCl_3$), $[\alpha]_D^{25}$ -120° (*C_6H_6), pK_1^{25} 1.96, pK_2^{25} 8.08.** Eserine crystallises from Et_2O or *C_6H_6 and forms an unstable low melting form **m** 86-87° [Harley-Mason & Jackson *J Chem Soc* 3651 *1954*, Wijnberg & Speckamp *Tetrahedron* **34** 2399 *1978*]. [*Beilstein* **23/11** V 401.]

2-Ethoxy-1-ethoxycarbonyl-1,2-dihydroquinoline (EEDQ) *[16357-59-8]* **M 247.3, m 63.5-65°, 66-67°.** Dissolve EEDQ (~180g) in $CHCl_3$, evaporate to dryness in a vacuum. Add dry Et_2O (20ml) and a white solid separates on standing. Set aside for a few hours, collect the solid, wash it thoroughly with cold Et_2O and dry it in a vacuum (~140g, **m** 63.5-65°). A further crop of solid (~25g) is obtained from the filtrate on standing overnight. [Fieser & Fieser *Reagents for Organic Synthesis* **2** 191 *1969*, Belleau et al. *J Am Chem Soc* **90** 823 *1968* and **90** 1651 *1968*, *Beilstein* **21/3** V 28.]

Ethoxyquin (1,2-dihydro-6-ethoxy-2,2,4-trimethylquinoline) *[91-53-2]* **M 217.3, b 169°/12-13mm, d_4^{20} 1.000, pK_{Est} ~5.8.** Purify Ethoxyquin by fractional distillation *in vacuo* whereby the distillate solidifies to a glass. [Knoevenagel *Chem Ber* **54** 1723, 1730 *1921*.] The *methiodide* has **m** 179° (from EtOH), and the *1-phenylcarbamoyl* derivative has **m** 146-147° (from EtOH). [Beaver et al. *J Am Chem Soc* **79** 1236 *1957*, *Beilstein* **21** III/IV 95.]

2-Ethyl-1,2-benzisoxazolium tetrafluoroborate *[4611-62-5]* **M 235.0, m 107-109°, 109.5-110.2°.** Recrystallise it from MeCN/EtOAc to give magnificent crystals. It is not hygroscopic but on long exposure to moisture it etches glass. It is light-sensitive and should be stored in brown glass bottles and free from moisture. The UV (H_2O), has λ_{max} at 258nm (ε 13 100) and λ_{max} 297nm (ε 2 900); the IR (CH_2Cl_2) has ν_{max} at 1613 (C=N) and 1111-1000 (BF_4^+) [UV, IR, NMR: Kemp & Woodward *Tetrahedron* **21** 3019 *1965*].

***N*-Ethylcarbazole** *[86-28-2]* **M 195.3, m 69-70°, 69-71°, b 199-200°/15mm.** Recrystallise it from MeOH, EtOH, EtOH/water or isopropanol and dry it below 55°. [*Beilstein* **20** H 436, **20** II 282, **20** III/IV 3829.]

Ethyl 1,3-dithiane-2-carboxylate *[20462-00-4]* **M 192.3, b 75-77°/0.2mm, 96°/0.4mm, d_4^{20} 1.220, n_D^{25} 1.5379.** Dissolve the ester in $CHCl_3$, wash with aqueous K_2CO_3, twice with H_2O, dry over $MgSO_4$, filter,

evaporate and distil the residue. [Eliel & Hartman *J Org Chem* **37** 505 *1972*, Seebach *Synthesis* **1** 17 *1969*, *Beilstein* **19/7** V 227.]

Ethyl 1,3-dithiolane-2-carboxylate *[20461-99-8]* **M 178.3, b 85°/0.1mm, d_4^{20} 1.250, n_D^{20} 1.538.** Dissolve the ester in $CHCl_3$, wash it with aqueous K_2CO_3, twice with H_2O, dry it over $MgSO_4$, filter, evaporate and distil the residue *in vacuo*. [Hermann et al *Tetrahedron Lett* 2599 *1973*, Corey & Erickson *J Org Chem* **36** 3553 *1971*]. [*Beilstein* **19/7** V 225.]

Ethylene oxide (oxirane) *[75-21-8]* **M 44.0, b 13.5°/746mm, d_4^{10} 0.882, n_D^{7} 1.3597.** Dry oxirane with $CaSO_4$, then distil it from crushed NaOH. It has also been purified by passage, as a gas, through towers containing solid NaOH. [*Beilstein* **17/1** V 3.]

Ethylene thiourea (2-imidazolidinethione) *[96-45-7]* **M 102.2, m 203-204°.** Crystallise it from EtOH or amyl alcohol. [*Beilstein* **24** III/IV 22.]

Ethylene urea (2-imidazolidone) *[120-93-4]* **M 86.1, m 131°.** Crystallise it from MeOH (charcoal). [*Beilstein* **24** III/IV 6.]

(±)-2-Ethylethylenimine (2-ethylaziridine) *[2549-67-9]* **M 71.1, b 88.5-89°, pK^{25} 8.31 (K_b 5.70x10^{-7}).** Freshly distil the aziridine from sodium before use. The *picrate* has **m** 103-104°. **TOXIC.** [O'Rourke et al. *J Am Chem Soc* **78** 2159 *1956*, *Beilstein* **20** III/IV 280.]

Ethyl hydrocupreine hydrochloride (Optochin) *[3413-58-9]* **M 376.9, m 249-251°, pK_1^{25} 5.50, pK_2^{25} 9.95.** Recrystallise it from H_2O [UV: Heidt & Forbes *J Am Chem Soc* **55** 2701 *1933*]. [*Beilstein* **24** H 385, **24** III/IV 1446.]

2-Ethyl-isothionicotinamide (ethionamide, 3-ethyl 4-pyrdinecarbothioamide) *[536-33-4]* **M 166.2, m 163-164°, 164-166°(dec).** It crystallises from EtOH as lemon yellow needles. The *hydrochloride* crystallises from EtOH (+ few drops of HCl) as orange yellow needles with **m** 212-214°. [Kutscherowa et al. *J Gen Chem USSR* (English transl) **29** 915 *1959*, *Beilstein* **22** III/IV 737.] It causes peripheral and occular **neuropathy** and is **carcinogenic** and **teratogenic**.

(±)-3-Ethyl-5-phenylhydantoin (Ethotoin) *[86-35-1]* **M 204.2, m 94°.** Crystallise it from water. It is an anticonvulsant and is used in epilepsy. [Dudley et al. *J Heterocycl Chem* **10** 173 *1973*, Pinner *Chem Ber* **21** 2320 *1888*, *Beilstein* **25** III/IV 963, **27** II 860.]

***N*-Ethyl-5-phenylisoxazolinium-3'-sulfonate (Woodward's reagent K)** *[4156-16-5]* **M 253.3, m 220°(dec).** Crystallise the reagent from diethyl ether or ethyl acetate/petroleum ether. [Lamas et al. *J Am Chem Soc* **108** 5543 *1986*.] It is best purified by dissolving in excess of aqueous N HCl and precipitating with Me_2CO to give a white fluffy solid. [Woodward et al. *Tetrahedron* **22** *Suppl* **8** 321 *1966*, Fieser & Fieser *Reagents for Organic Synthesis* **1** 385, **2** 198.]

(±)-3-Ethyl-3-phenyl-2,6-piperidinedione (Glutethimide) *[77-21-4]* **M 217.3, m 84°.** Crystallise glutethimide from diethyl ether or ethyl acetate/petroleum ether. It has **m** 91-92° (from aqueous EtOH), 87-87.5° (from Et_2O/petroleum ether), 84-87° (from isopropanol), and 83-84° (from Et_2O). [Penprase & Biles *J Am Pharm Assoc* **47** 523 *1958*, Hofmann et al. *Helv Chim Acta* **40** 387, 393 *1957*, *Beilstein* **21** III/IV 5493.] The *R(+)-enantomer* crystallises from EtOAc/petroleum ether with **m** 103-104°, and $[\alpha]_D^{20}$+184° (c 1, EtOH). [Branchini *Ricerche Scientifiche* **29** 2435 *1959*, Finch et al. *Experientia* **31** 1002 *1975*.]

2-Ethylpyridine *[100-71-0]* **M 107.2, b 148.6°, d_4^{25} 0.942, pK^{25} 5.89.** Dry 2-ethylpyridine with BaO, and fractionally distil it. Purify it further by conversion to the *picrate*, recrystallisation of the picrate and regeneration of the free base followed by distillation. [*Beilstein* **20/6** V 3.]

4-Ethylpyridine *[536-75-4]* **M 107.2, b 168.2-168.3°, d_4^{25} 0.942, pK^{25} 6.02.** Dry 4-ethylpyridine with BaO, and fractionally distil it. Also purified by converting to the *picrate*, recrystalising and the free base is regenerated and distilled. [*Beilstein* **20/6** V 10.]

4-Ethylpyridine-1-oxide *[14906-55-9]* **M 123.1, m 109-110°, pK_{Est}~1.1.** Crystallise the oxide from acetone/ether. [*Beilstein* **20/6** V 10.]

Etioporphyrin I See aetioporphyrin I above.

Flavone (2-phenyl-4*H*-1-benzopyran-4-one) *[525-82-6]* **M 222.3, m 100°.** Crystallise flavone from petroleum ether. [*Beilstein* **17/10** V 552.]

Fluorescein [9-(*o*-carboxyphenyl-6-hydroxy-3*H*-xanthene-3-one] *[2321-07-5]* **M 320.0, ε_{495nm} 7.84 x 10^4 (in 10^{-3}M NaOH), pK_1 2.2, pK_2 4.4, pK_3 6.7.** Dissolve it in dilute aqueous NaOH, filter and precipitate it by adding dilute (1:1) HCl. The process is repeated twice more, and the fluorescein is dried at 100°. *Alternatively*, it has been crystallised from acetone by allowing the solution to evaporate at 37° in an open beaker. It has also been recrystallised from EtOH and dried in a vacuum oven. [*Beilstein* **19** I 721, **19** II 248, **19** III/IV 2904, **19/8** V 456.]

Fluoresceinamine (mixture of 5- and 6-aminofluorescein) *[27599-63-9]* **M 347.3, m 215-220°(dec, 5-amino) and m 314-316°(dec, 6-amino).** Dissolve it in EtOH, treat with charcoal, filter, evaporate and dry the residue in a vacuum at 100° overnight. Also recrystallise it from 6% HCl, then dissolve it in 0.5% aqueous NaOH and precipitate it by acidifying with acetic acid. The separate amines are made from the respective nitro compounds, which are best separated *via* their acetate salts. They have similar R_F of 0.26 on Silica Gel Merck F_{254} in 5 ml MeOH + 150 ml Et_2O saturated with H_2O. The IR (Me_2SO) has a band at ν_{max} 1690 cm^{-1} (CO_2^-) and sometimes a weak band at ν_{max} 1750 cm^{-1} due to the lactone. The UV (EtOH) of the 6-isomer has λ_{max} at 222nm (ε 60,000) and the 5-isomer at λ_{max} 222nm (ε 60,000) and 285nm (ε 20,600). [IR: McKinney & Churchill *J Chem Soc (C)* 654 *1970*, McKinney et al. *J Org Chem* **27** 3986 *1962*, UV: Verbiscar *J Org Chem* **29** 490 *1964*, *Beilstein* **19** III/IV 4337, **19/8** V 713.]

Fluorescein isothiocyanate isomer I (5-isothiocyanato isomer) *[3326-32-7*; *27072-45-3 **mixture of 5- and 6-isomers**]* **M 389.4, m >160°(slow dec).** It is made from the pure 5-amino isomer. Purify it by dissolving it in boiling Me_2CO, filtering and adding petroleum ether (b 60-70°) until it becomes turbid. If an oil separates, then decant it and add more petroleum ether to the supernatant and cool. Orange-yellow crystals separate, collect and dry them *in vacuo*. It should give one spot on TLC (silica gel) in EtOAc/pyridine/AcOH (50:1:1) and in $Me_2NCHO/CHCl_3$/28% NH_4OH (10:5:4). Its IR (Me_2SO) has ν_{max} at 2110 (NCS) and 1760 (C=O) cm^{-1}. The ^{1}HNMR spectra in Me_2CO-d_6 of the 5- and 6-isomers are distinctly different for the protons in the *benzene ring; the UV in phosphate buffer pH 8.0 shows a λ_{max} at ~490nm. [Sinsheimer et al. *Anal Biochem* **57** 227 *1974*, McKinney et al. *Anal Biochem* **7** 74 *1964*, *Beilstein* **19** III/IV 4337.]

3-Fluoro-4-iodopyridine *[22282-75-3]* **M 223.0, m 80-81°, 85-89°, pK_{Est} ~1.7.** Crystallise it from petroleum ether and/or sublime it *in vacuo* (**m** 87°). The *picrate* [22282-76-4] has **m** 140° (from EtOH). [Gribble & Saulnier *Tetrahedron Lett* 4137 *1980*.]

4-Fluoro-7-nitrobenzofurazan (4-fluoro-7-nitrobenzo-2-oxa-1,3-diazole) *[29270-56-2]* **M 183.1, m 52.5-53.5°, 53-56°, 53.5-54.5°.** Purify it by repeated recrystallisation from petroleum ether (b 40-60°). On treatment with MeONa in MeOH it gives *4-methoxy-7-nitrobenzo-2-oxa-1,3-diazole* **m** 115-116°. [Nunno et al. *J Chem Soc (C)* 1433 *1970*.] It is a very good fluorophore for amino acids [Imai & Watanabe *Analyt Chim Acta* **130** 377 *1981*], as it reacts with primary and secondary amines to form fluorescent adducts with λ_{ex} 470nm and λ_{em} 530nm. It gives a *glycine* derivative with **m** 185-187° [Miyano et al. *Anal Chim Acta* **170** 81 *1985*].

5-Fluorouracil (5-fluoropyrimidinedi-2,4-[1*H*,3*H*]-one, 5-FU) *[51-21-8]* **M 130.1, m 282-283° (dec),**

282-286°(dec), pK_1^{25} 8.04, pK_2^{25} 13.0. Recrystallise it from H_2O or MeOH/Et_2O and sublime it at 190-200°/0.1mm or 210-230°/0.5mm. UV: λ_{max} at 265-266nm (ε 7070). [Barton et al. *J Org Chem* **37** 329 *1972*, Duschinsky & Pleven *J Am Chem Soc* **79** 4559 *1957*, *Beilstein* **24** III/IV 1229.]

Fluram (Fluorescamine, 4-phenyl-spiro[furan-2(3*H*)-1-phthalan]-3,3'-dione) *[38183-12-9]* **M 278.3, m 153-155°, 154-155°.** Fluram is a non-fluorescent reagent that reacts with primary amines to form highly fluorescent compounds. Purify it by dissolving (~1g) in Et_2O/*C_6H_6 (1:1, 180 ml), washing with 1% aqueous $NaHCO_3$ (50ml), drying (Na_2SO_4), and evaporating in a vacuum. Dissolve the residue in warm CH_2Cl_2 (5ml), dilute with Et_2O (12ml) and refrigerate. Collect the solid and dry it in a vacuum. Its IR ($CHCl_3$) has ν_{max} at 1810, 1745, 1722, 1625 and 1600 cm^{-1}, and ^{1}HNMR ($CDCl_3$) with δ at 8.71 (s, -O**H**C=). [Weigele et al. *J Am Chem Soc* **94** 5927 *1972*, Weigele et al. *J Org Chem* **41** 388 *1976*, Lai *Methods Enzymol* **47** 236 *1977*.]

Forskolin (Colforsin, Coleonol, 5-[acetyloxy]-3-ethenyldodecahydro-6,10,10b-trihydroxy-3,4a,7,7, 10a-penta-methyl-[3*R*-{3α-4aβ, 5β, 6β, 6aα, 10α, 10 aβ, 10bα}-1*H*-naphtho[2,1-b]pyran-1-one) *[66575-29-9]* **M 410.5, m 230-232°, 228-233°, $[\alpha]_D^{25}$ -96.2° (c 1.7, $CHCl_3$).** Recrystallise it from *C_6H_6/petroleum ether, EtOAc/petroleum ether. It is an antihypertensive, a positive ionotropic, a platelet aggregation inhibitor, and it has adenylate cyclase activating properties [*Chem Abstr* **89** 244150 *1978*, de Souza et al. *Med Res Rev* **3** 201 *1983*, X-ray: Tandon et al. *Indian J Chem* **15B** 880 *1977*]. [*Beilstein* **18/5** V 55.]

Fumagillin {2,4,6,8-decatetraene-1,10-dioic acid mono[4-(1,2-epoxy-1,5-dimethyl-4-hexenyl)-5-methoxy-1-oxaspiro[2.5]oct-6-yl] ester} *[23110-15-8]* **M 458.5, m 194-195°, $[\alpha]_D^{20}$ -26.2° (in 95% EtOH), pK_{Est} ~4.5.** Forty grams of a commercial sample containing 42% fumagillin, 45% sucrose, 10% antifoam agent and 3% of other impurities are digested with 150ml of $CHCl_3$. The insoluble sucrose is filtered off and washed with $CHCl_3$. The combined $CHCl_3$ extracts are evaporated almost to dryness at room temperature under reduced pressure. The residue is triturated with 20ml of MeOH, and the fumagillin is filtered off by suction. It is crystallised twice from 500ml of hot MeOH by standing overnight in a refrigerator (yellow needles). (The long-chain fatty ester used as antifoam agent is still present, but is then removed by repeated digestion, on a steam bath, with 100ml of diethyl ether.) For further purification, the fumagillin (10g) is dissolved in 150ml of 0.2M ammonia, and the insoluble residue is filtered off. The ammonia solution (cooled in running cold water) is then brought to pH 4 by careful addition of M HCl with constant shaking in the presence of 150ml of $CHCl_3$. (Fumagillin is acid-labile and must be removed rapidly from the aqueous acid solution.) The $CHCl_3$ extract is washed several times with distilled water, dried (Na_2SO_4) and evaporated under reduced pressure. The solid residue is washed with 20ml of MeOH. The fumagillin is filtered off by suction, then crystallised from 200ml of hot MeOH. [Tarbell et al. *J Am Chem Soc* **77** 5610 *1955*.]
Alternatively, 10g of fumagillin in 100ml $CHCl_3$ is passed through a silica gel (5g) column to remove tarry material, and the $CHCl_3$ is evaporated to leave an oil which gives fumagillin on crystallisation from amyl acetate. It recrystallises from MeOH (charcoal) or Me_2CO/MeOH. The fumagillin is stored in dark bottles in the absence of oxygen and at low temperatures. [Schenk et al. *J Am Chem Soc* **77** 5606 *1955*, *Beilstein* **19** III/IV 1012.]

Furan *[110-00-9]* **M 68.1, b 31.3°, d_4^{20} 1.42, n_D^{20} 1.4214.** Shake it with aqueous 5% KOH, dry it with $CaSO_4$ or Na_2SO_4, then distil it under nitrogen, from KOH or sodium, immediately before use. A trace of hydroquinone could be added as an inhibitor of oxidation. [*Beilstein* **17** H 27, **17** I 16, **17** II 34, **17/1** V 291.]

Furan-2-carboxylic (2-furoic) acid *[88-14-2]* **M 112.1, m 133-134°, b 141-144°/20mm, 230-232°/760mm, pK_1^{25} -7.3 (O-protonation), pK_2^{25} 3.32.** Crystallise the acid from hot water (charcoal), dry it at 120° for 2 hours, then recrystallise it from $CHCl_3$, and again dry it at 120° for 2 hours. For use as a standard in volumetric analysis, good quality commercial acid should be crystallised from $CHCl_3$ and dried as above or sublimed at 130-140°/50-60mm or less. [*Beilstein* **18** I 438, **18** II 265, **18** III/IV 3914, **18/6** V 102.]

Furan-3-carboxylic (3-furoic) acid *[488-93-7]* **M 112.1, m 122-123°, 123°.5, pK^{25} 4.03.** Crystallise the acid from water or aqueous EtOH, and sublime it in a vacuum. [*Beilstein* **18** I 439, **18** III/IV 4052, **18/6** V 196.]

Furan-3,4-dicarboxylic acid *[3387-26-6]* **M 156.1, m 217-218°, 221.5-222.5°, pK_1^{25} 1.44, pK_2^{25} 7.84.**

Crystallise it from water or Et_2O/petroleum ether, and sublime it in a vacuum. [*Beilstein* **18** III/IV 4497.]

Furan-2,5-dione (maleic anhydride) *[108-31-6]* **M 98.1, m 54°, b 94-96°/20mm, 199°/760mm.** Crystallise it from *benzene, $CHCl_3$, CH_2Cl_2 or CCl_4. Sublime it under reduced pressure. [Skell et al. *J Am Chem Soc* **108** 6300 *1986*, *Beilstein* **17** III/IV 5897, **17/11** V 55.]

3-(2-Furanyl)acrylic acid *[539-47-9]* **M 138.1, (*cis*-isomer) m 106-108°, pK^{25} 3.5; (*trans*-isomer) m 141°, 143-144°, b 285°, pK^{25} 4.5 (H_2O), 5.76 (50% aqueous EtOH), 6.65 (ethoxyethanol/H_2O—80:20).** Crystallise the *cis*-isomer from *C_6H_6 and the *trans*-isomer from H_2O, *C_6H_6 or petroleum ether (b 80-100°)(charcoal). [*Beilstein* **18** H 301, **18** III/IV 4143, **18/6** V 306.]

Furfural (2-furfuraldehyde) *[98-01-1]* **M 96.1, b 54-56°/11mm, 59-60°/15mm, 67.8°/20mm, 90°/65mm, 161°/760mm, d_4^{20} 1.159, n_D^{20} 1.52608, pK^{25} -6.5 (O-protonation).** Furfural is unstable to air, light and acids. Impurities include formic acid, ß-formylacrylic acid and furan-2-carboxylic acid. Distil it in an oil bath from 7% (w/w) Na_2CO_3 (added to neutralise acids, especially pyromucic acid). Redistil it from 2% (w/w) Na_2CO_3, and then, finally fractionally distil it under vacuum. It is stored in the dark. [Evans & Aylesworth *Ind Eng Chem (Anal ed)* **18** 24 *1926*.]
Impurities resulting from storage can be removed by passage through chromatographic grade alumina. Furfural can be separated from impurities other than carbonyl compounds by the bisulfite addition compound. The aldehyde is steam volatile.
It has been purified by distillation (using a Claisen head) under reduced pressure. This is essential as is the use of an oil bath with temperatures of no higher than 130° which is highly recommended. When furfural is distilled at atmospheric pressure (in a stream of N_2), or under reduced pressure with a free flame (caution: because the aldehyde is flammable), an almost colourless oil is obtained. After a few days and sometimes a few hours, the oil gradually darkens and finally becomes black. This change is accelerated by light and occurs more slowly when it is kept in a brown bottle. However, when the aldehyde is distilled under vacuum and the bath temperature kept below 130° during the distillation, the oil develops only a slight colour when exposed to direct sunlight during several days. The distillation of very impure material should NOT be attempted at atmospheric pressure; otherwise the product darkens very rapidly. After one distillation under vacuum, a distillation at atmospheric pressure can be carried out without too much decomposition and darkening. The liquid **irritates mucous membranes.** Store it in dark containers under N_2, preferably in sealed ampoules. [Adams & Voorhees *Org Synth* Coll Vol **I** 280 *1941*, *Beilstein* **17/9** V 292.]

Furfuryl alcohol (2-furylmethanol) *[98-00-0]* **M 98.1, b 68-69°/20mm, 170.0°/750mm, d_4^{20} 1.132, n_D^{20} 1.4873, n_D^{30} 1.4801, pK^{25} 2.61.** Distil it under reduced pressure to remove tarry material, shake with aqueous $NaHCO_3$, dry it with Na_2SO_4 and fractionally distil it under reduced pressure from Na_2CO_3. It can be further dried by shaking with Linde 5A molecular sieves. [*Beilstein* **17/3** V 338.]

Furfurylamine (2-aminomethylfuran) *[617-89-0]* **M 97.1, b 54-56°/17mm, 142.5-143°/735mm, d_4^{20} 1.059, n_D^{20} 1.489, pK^{30} 8.89.** Distil it under nitrogen from KOH through a column packed with glass helices, preferably under vacuum. The *picrate* has **m** 184-184°(dec), the *hydrochloride* has **m** 147-149°, and the *oxalate* has **m** 145-147°. [*Beilstein* **18** H 584, **18** II 416, **18** III/IV 3068, **18/9** V 541.]

6-Furfurylaminopurine (Kinetin) *[525-79-1]* **M 215.2, m 266-267°, 269-271°, 270-272°, 272° (sealed capillary), pK_1 <1, pK_2 3.8, pK_3 10.** It forms platelets from EtOH and sublimes at 220°, but is best done at lower temperatures in a good vacuum. It has been extracted from neutral aqueous solutions with Et_2O. [Miller et al *J Am Chem Soc* **78** 1375 *1956*, Bullock et al. *J Am Chem Soc* **78** 3693 *1956*, *Beilstein* **26** III/IV 3586.]

Furil *[492-94-4]* **M 190.2, m 165-166°.** Furil crystallises from MeOH or *benzene (charcoal). [*Beilstein* **19** III/IV 2008.]

(±)-Furoin [1,2-di-(2-furyl)-2-hydroxyethanone] *[552-86-3]* **M 192.2, m 135-136°, 138-139°, 158-162°/9mm.** It crystallises from MeOH (charcoal) and distils in a vacuum. [Hartman & Dickey *J Am Chem Soc* **55** 1228 *1933*.] The *(-)-enantiomer* crystallises from toluene or EtOH with **m** 131-131°, and $[\alpha]_D^{20}$ -4.9°

(dioxane) [Neuberg et al. *Arch Biochem* **1** 393 *1943*, *Beilstein* **19** H 204, **19** I 710, **19** II 224, **19** III/IV 2543.]

Fusaric acid (5-*n*-butylpyridine-2-carboxylic acid) *[536-69-6]* **M 179.2, m 96-98°, 98°, 98-100°, 101-103°, pK_1 5.7, pK_2 6.16 (80% aqueous methoxyethanol).** Dissolve it in $CHCl_3$, dry (Na_2SO_4), filter, evaporate and recrystallise the residue from 50 parts of petroleum ether (b 40-60°), $CHCl_3$/petroleum ether or EtOAc, then sublime it *in vacuo*. The *amide* crystallises from MeOH with **m** 128.2-129.0°. The *copper salt* forms bluish violet crystals from H_2O and has **m** 258-259°. [Hardegger & Nikles *Helv Chim Acta* **39** 505 *1956*, Schreiber & Adam *Chem Ber* **93** 1848 *1960*, NMR and MS: Tschesche & Führer *Chem Ber* **111** 3500 *1978*, *Beilstein* **22** III/IV 764, **22/2** V 384.]

Fuschin (Magenta I) See rosaniline hydrochloride in "Aromatic Compounds" [632-99-2] in this Chapter.

Glycidol (oxirane-2-methanol) *[RS-(±)- 556-52-5; R-(+)- 57044-25-4; S-(-)- 60456-23-7]* **M 74.1, (*R,S*) b 61-62°/15mm, d_4^{20} 1.117, n_D^{20} 1.433, [*S(-)-isomer,* § also available on polymer support, has b 49-50°/7mm, 66-67°/19mm, $[\alpha]_D^{20}$ -15°(neat)], [*R(+)-isomer* has b 56-56.5°/11mm, d_4^{20} 1.117, n_D^{20} 1.429, $[\alpha]_D^{20}$ +15° (neat)].** Purify glycidol by fractional distillation. The *4-nitrobenzoates* have **m** 56° (±); **m** 60-62°, $[\alpha]_D^{20}$ -37.9° (c 3.38 $CHCl_3$) for *R-(-)*-isomer *[106268-95-5]*; **m** 60-62°, $[\alpha]_D^{20}$ +38° (c 1 $CHCl_3$) for the *S-(+)*-isomer *[115459-65-9]* and are recrystallised from Et_2O or Et_2O/petroleum ether (b 40-60°) [*S-isomer*: Burgos et al. *J Org Chem* **52** 4973 *1987*, Sowden & Fischer *J Am Chem Soc* **64** 1291 *1942*.] [*Beilstein* **17** I 50, **17** III/IV 985, **17/3** V 9.]

Gramine (3-dimethylaminoethylindole) *[87-52-5]* **M 174.3, m 134°, pK^{25} 16.00 (NH acidic), basic pK^{25} 9.2 (50% aqueous EtOH).** Crystallise gramine from diethyl ether, ethanol or acetone. It sublimes at 59°/0.001mm. The *hydrochloride* crystallises from EtOH/Et_2O with **m** 190.5-191.0°(dec). [Culvenor et al. *Aust J Chem* **17** 1301 *1964*, *Beilstein* **22** III/IV 4302**, 22/10** V 25.]

(2*S*,6'*R*)(+)-Griseofulvin *[126-07-8]* **M 352.8, m 220°, $[\alpha]_D^{22}$ +365° (c 1, acetone).** Crystallise it from *benzene or EtOH. Purify 2g of griseofulvin by chromatography on Alumina (40 x 1.5cm) and elute with *C_6H_6/MeOH (199:1) and follow the UV blue fluorescent band. [MacMillan *J Chem Soc* 1823 *1959*, *Beilstein* **18** III/IV 3160, **18/5** V 150.]

Guanosine (H_2O) *[118-00-3]* **M 283.2, m 237-237.5°(dec), 239°(dec), $[\alpha]_{546}^{20}$ -86° (c 1, 0.1M NaOH), pK_1^{25} 1.9, pK_2^{25} 9.24, pK_3^{25} 12.33.** It crystallises from water as a *dihydrate*. Dry it at 110°. [*Beilstein* **26/18** V 81.]

Guanylic acid (guanosine-5'-monophosphoric acid) *[85-32-5]* **M 363.2, m 208°(dec), pK_2^{25} 2.4, pK_3^{25} 6.66 (6.1), pK_4^{25} 9.4.** Crystallise it from water and dry it at 110°. [*Beilstein* **26** III/IV 3910.]

Harmaline (7-methoxy-1-methyl-4,9-dihydro-3*H*-β-carboline, 4,9-dihydro-7-methoxy-1-methyl-3*H*-pyrido[3,4-*b*]indole) *[304-21-2]* **M 214.3, m 229-230°, 229-231°, 235-237° (after distillation at 120-140°/10^{-3}), pK_1 4.2.** Recrystallise harmaline from MeOH and sublime it at high vacuum. It has UV in MeOH with λ_{max} at 218, 260 and 376nm (log ε 4.27, 3.90 and 4.02, respectively); IR (Nujol) with ν_{max} at 1620, 1600, 1570 and 1535cm^{-1} and in $CHCl_3$ ν_{max} at 1470 and 1629cm^{-1}. [Spenser *Can J Chem* **37** 1851 *1959*, Marion et al. *J Am Chem Soc* **73** 305 *1951*, UV Prukner & Witkop *Justus Liebigs Ann Chem* **554** 127 *1942*.] The *hydrochloride dihydrate* has **m** 234-236°(dec), the *picrate* has **m** 228-229° (sinters at 215°) from aqueous EtOH, and the *N-acetate* forms needles **m** 204-205°. [*Beilstein* **23** H 396, **23** I 119, **23** II 345, **23** III/IV 2666, **23/12** V 148.]

Histamine dihydrochloride *[56-92-8]* **M 184.1, m 249-252° (244-245°).** The dihydrochloride crystallises from aqueous EtOH. The *phosphate ($2H_3PO_4$)* [51-74-1] has **m** 132-133° (from H_2O). [*Beilstein* **25** III/IV 2049.]

Homopiperazine (1,4-diazepane) *[505-66-8]* **M 100.2, m 38-40°, 43°, b 60°/10mm, 92°/50mm, 169°/atm, pK_1^{20} 6.70, pK_2^{20} 10.41.** Purify it by fractionation through a column of 10 theoretical plates with a reflux ratio of 3:1. It boils at 169°, and the cool distillate crystallises in plates **m** 43°. [Poppelsdorf and Myerly *J Org Chem* **26** 131 *1961*.] Its pKa values are 6.67 and 10.09 at 29.7°, and 6.28 and 9.86 at 40° [Pagano et al. *J Phys Chem* **65** 1062 *1961*]. The *1,4-bis(4-bromobenzoyl)* derivative has **m** 194-198° (from EtOH); the *hydrochloride* has **m** 270-290° (from EtOH) and the *picrate* has **m** 265°(dec) [Lloyd et al. *J Chem Soc (C)* 780 *1966*]. [*Beilstein* **23** III/IV 388, **23/3** V 240.]

1-Hydrazinophthalazine (hydralazine) *[86-54-4]* **M 160.1, m 172-173°(dec), pK_1^{25} 2.90, pK_2^{25} 7.25 (NNH_2).** It crystallises from MeOH. Its UV has λ_{max} at 656nm at pH ~11. It complexes with Bi^{3+}, Zn^{2+}, Fe^{2+} and Co^{2+}. The *hydrochloride (hydralazine hydrochloride) [304-20-1]* **M 196.6,** also crystallises from MeOH and has **m** 172-173°(dec)**.** [Druey et al. *Helv Chim Acta* **34** 195 *1951*, *Beilstein* **25** III/IV 4552.] It is an **antihypertensive**.

2-Hydrazinopyridine *[4930-98-7]* **M 109.1, m 41-44°, 46-47°, 49-50°, b 105°/0.5mm, 128-135°/13mm.** Purify it by distillation under a vacuum and by recrystallisation from Et_2O/hexane. [Kauffmann et al. *Justus Liebigs Ann Chem* **656** 103 *1962*, Potts & Burton *J Org Chem* **31** 251 *1966*.] The *mono-hydrochloride* has **m** 183°(dec) from aqueous HCl, and the *di-hydrochloride* has **m** 214-215°. [*Beilstein* **22** II 487, **22** III/IV 7025, **22/14** V 486.]

4-Hydroxyacridine (4-acridinol, neo-oxine) *[18123-20-1]* **M 195.2, m 116.5°, 122-123°, pK_1^{15} 5.28, pK_2^{15} 9.75.** Crystallise neo-oxine from EtOH or aqueous EtOH. It complexes with Zn^{2+}, Cd^{2+}, Ga^{2+}, Pb^{2+}, Cr^{2+}, Mn^{2+}, Fe^{2+}, Co^{2+} and Ni^{2+}. The *hydrochloride* crystallises from EtOH with **m** 242°. [*Beilstein* **21** II 78, **21** III/IV 1562, **21/4** V 90.]

1-Hydroxy-1,2-benziodoxol-3(1*H*)-one (IBX, 2-iodoxybenzoic acid) *[61717-82-6]* **M 280.0, m 224-225°, 226-234°, 232-233°(dec), 233°(dec), pK <4.** IBX prepared by the Dess-Martin procedure ($KBrO_3/H_2SO_4$) [Dess & Martin *J Am Chem Soc* **113** 7277 *1991*] has been reported as being explosive and comparable to TNT [Hartman & Meyer *Chem Ber* **26** 1727 *1893*, Plumb & Harper *Chem Eng News* **(**July 16) 3 *1990*] when apparently the iodine content was below 43.5% (theoretical value is 45.32%). In an attempt to avoid this, IBX has been washed with H_2O and EtOH to render it non-explosive. Although deliberate attempts to detonate it on several occasions have been unsuccessful; operators should exercise CAUTION when working with IBX particularly with large scale preparations. This is among the substances for which it may be difficult to obtain permission to transport it, so detailed preparations are described here.

Dess-Martin method: To a vigorously stirred mixture of 2-iodobenzoic acid (85.2g, 340mmol, see [88-67-5]) and 0.73 M H_2SO_4 (730ml) in a bath at 55° is added $KBrO_3$ (76.0g, 450mmol) over 1 hour. The mixture is stirred further for 3.6 hours at 65°, cooled in an ice bath, and the solid is filtered off, washed with H_2O (1000ml) then EtOH (2 x 50ml) and dried *in vacuo* to give BTX (89.1g, 320mmol, 93%) of analytical purity. [Dess & Martin *J Am Chem Soc* **113** 7277 *1991*]

Santagostino et al.'s method: To oxone (181.0g, 290mmol, see [70693-62-8] $2KHSO_5$—$KHSO_4$—K_2SO_4 triple salt) in deionised H_2O (650ml, 450mmol) is added rapidly 2-iodobenzoic acid (50.0g, 200mmol), and kept at 70-73° for 20 minutes then stirred mechanically at 70-73° for 3 hours. Initially a thick slurry coating along the walls of the container is formed which gradually becomes finely dispersed and the now easily stirred suspension readily sediments if stirring is interrupted. The mixture is then stirred slowly at 5° for 1.5 hours, the white crystalline solid is collected onto a medium porosity sintered-glass funnel, washed with H_2O (6 x 100ml) and Me_2CO (2 x 100ml) then Et_2O, and left in dry air for 16 hours to give IBX (44,8-45.7g, ~80%). The filtrates are disposed of by treating with solid Na_2SO_3 (70g, 55mmol) and neutralising with M aqueous NaOH. Analysis indicated that the purity was ≥95% (judging by the ^1H NMR integrals of the triplets at 7.84 and 7.47 ppm, and elemental analysis), and it contained 2-iodosobenzoic acid (~4%) and 2-iodobenzoic acid (~0.5%). IBX of analytical purity (≥99%) is similarly obtained on a small scale by adding 2-iodobenzoic acid (5.0g, 20mmol) to a solution of oxone in deionised H_2O (37.2g, 61mmol, in 200ml), and the suspension is kept at 70° for 1 hour when it becomes clear. After 0.5 hours at 0-5° the white crystals that separate are collected, washed and dried as before to give analytically pure IBX (4.4g, 77%), m 233° (dec). This procedure is more environmentally friendly than the Dess-Martin procedure. [Frigerio et al. *J Org Chem* **64** 4537 *1999*.] It has IR

(film) with a ν_{max} at 1640 cm^{-1}; the ^1H NMR (DMSOd_6, TMS) has δ at 8.15 (d, 1H), 8.01 (d, 1H), 7.89 (t, 1H), and 7.84 (t, 1H); and the ^{13}C NMR (DMSOd_6, TMS) has δ at 167.49, 146.59, 133.39, 132.97, 131.36, 130.10 and 124.99 [Frigerio & Santagostino *Tetrahedron Lett* **43** 8019 *1994*].
SIBX is an even more stabilised, non-explosive formulation that has all the oxidative characteristics of IBX. It is prepared as follows: 2-iodobenzoic acid (200g) and isophthalic acid (133g, see [121-91-5]) are added into a solution of oxone (625g) in H_2O (2000ml) and kept at 70° for 3 hours, then sodium benzoate (128g) in H_2O (500ml) is added at 40°. The precipitate that is formed on cooling to 20° is filtered off, washed with H_2O (700ml) and dried in a ventilated oven at 60° to give *SBTX* (420g, 90%) containing 49% w/w of active IBX. [Ozanne et al. *Org Lett* **5** 2903 *2003*.]
SIBX and/or IBX are water tolerant, inexpensive to prepare and easy to use. They oxidise primary and secondary alcohols smoothly to aldehydes and ketones, and vicinal diols are oxidised to mono and/or dicarbonyl compounds without C-C cleavage [Frigerio & Santagostino *Tetrahedron Lett* **43** 8019 *1994*], as well as allylic and benzylic alcohols to respective aldehydes [Ozanne et al. *Org Lett* **5** 2903 *2003*.], amino alcohols to amino carbonyls without amino protection, and sensitive heterocyclic substituents are not affected [Frigeio et al. *J Org Chem* **60** 7272 *1995*]. The structure and kinetics of the reactive intermediates in the oxidation have been studied in detail [Munari et al. *J Org Chem* **61** 9272 *1961*]. The reagents are generally sparingly soluble in organic solvents such as EtOAc, THF, Me_2CO, MeCN, toluene, DMSO and *N*-methylpyrrolidine, but the reactions usually proceed in these solvents, or mixtures of them, with ease and in good to excellent yields either at room temperature or at as high as reflux temperatures.

2-Hydroxybenzothiazole (benzothiazol-2(3*H*)-one) *[934-34-9]* **M 183.1, m 140-141°.** Crystallise it from aqueous EtOH or water. [Hoggarth *J Chem Soc* 3314 *1949*, Hunter *J Chem Soc* 135 1930, *Beilstein* **27** H 182, **27** I 270, **27** II 225, **27** III/IV 2693.]

1-Hydroxybenzotriazole hydrate (HOBt) *[2592-95-2; 123333-53-9 (H_2O)]* **M 135.1, m 157°, 159-160°, pK^{20} 7.88.** Crystallise HOBt from hot aqueous EtOH or water (charcoal). It is prepared from *o*-nitrophenylhydrazine or its hydrochloride dissolved in a small volume of H_2O by treating with 25% of aqueous KOH or aqueous ammonia whereby the mixture warms up immediately and discolours. After the mixture cools to room temperature it is acidified with hydrochloric acid and the *hydroxybenzotriazole* separates as colourless needles. It is soluble in hot H_2O, EtOH and AcOH, but much less soluble in Et_2O, petroleum ether, $*C_6H_6$ and $CHCl_3$. It is an acid and forms metal salts such the ***Pb salt*** which crystallises from hot H_2O in glistening leaflets with **m 270°**. In aqueous solution it exists mainly as the zwitterionic N-oxide tautomer with H^+ on N-2. [Nietzki & Braunschweig *Chem Ber* **27** 3381 *1894*, Zincke & Schwartz *Justus Liebigs Ann Chem* **329** 329 *1900*, Boyle & Jones *J Chem Soc Perkin Trans II* 160 *1973*, Tomita & Ikawa *J Pharm Soc Jpn* **75** 449 *1955*, *Beilstein* **26** III/IV 95.] It is a useful reagent for peptide synthesis [Heusel et al. *Angew Chem Int Ed* **16** 642 *1977*].
§ A polystyrene supported version is available. For use in solid phase peptide synthesis, see Dryland & Sheppard *J Chem Soc Perkin Trans 1* 125 *1986*.

4-Hydroxycoumarin (4-hydroxy-1-benzopyran-2-one) *[1076-38-6]* **M 162.1, m 206°, 211-213°, pK_{Est} ~9.0.** Crystallise 4-hydroxycoumarin from water and dry it in a vacuum desiccator over Sicapent. [*Beilstein* **18/1** V 378.]

***N*-2-Hydroxyethylpiperazine-*N'*-2-ethanesulfonic acid (HEPES)** *[7365-45-9]* **M 238.3, pK^{20} 7.55.** Crystallise the acid from hot EtOH and water. It is a useful buffer. [*Beilstein* **23** V 376.]

3-Hydroxyflavone (Flavanol) *[577-85-5]* **M 238.2, m 169-170°, 171-172°.** Recrystallise it from MeOH (**m** 169.5-170°), EtOH, aqueous EtOH (**m** 167°) or hexane. It has also been purified by repeated sublimation under high vacuum, and dried at high vacuum pumping for at least one hour [Bruker & Kelly *J Phys Chem* **91** 2856 *1987*]. [*Beilstein* **17** H 527, **17** I 268, **17** II 498, **17** III/IV 6428.]

7-Hydroxy-4-methylcoumarin (4-methylumbelliferone(β) hydrate) *[90-33-5]* **M 194.2, m 185-186°, 188-188.5°, 194-195°, pK^{25} 7.80 (phenolic OH).** Purify it by recrystallisation from EtOH. It is very slightly soluble in cold H_2O (solubility at 37° is 0.22%), slightly soluble in Et_2O and $CHCl_3$, but soluble in MeOH and

AcOH. It has a blue fluorescence in aqueous EtOH and has UV with λ_{max} at 221, 251 and 322.5nm (MeOH). The IR has ν_{max} at 3077 br, 1667, 1592, 1385, 1267, 1156, 1130 and 1066 cm^{-1}. The *acetate* has **m** 153-154°. [Woods & Sapp *J Org Chem* **27** 3703 *1962*, *Beilstein* **18** III/IV 332, **18/1** V 439.]

2-Hydroxymethyl-12-crown-4 *[75507-26-5]* **M 206.2, b 115°/0.04mm, d_4^{20} 1.186, n_D^{20} 1.480.** Purify it by chromatography on Al_2O_3 with EtOAc as eluent to give a *hygroscopic* colourless oil, which is distilled under high vacuum and is distilled *in vacuo*. It has IR with ν_{max} at 3418 (OH) and 1103 (COC) cm^{-1}, and NMR: δ 3.70s. [Kimura et al. *J Chem Soc, Chem Commun* 492 *1983*, Pugia et al. *J Org Chem* **52** 2617 *1987*.]

***S*-(-)-5-Hydroxymethyl-2(5*H*)-furanone** *[78508-96-0]* **M 114.1, 39-42°, 40-44°, b 130°/0.3mm, $[\alpha]_{546}^{20}$ -180°, $[\alpha]_D^{20}$ -148° (c 1.4, H_2O).** It is purified by chromatography on Silica gel using hexane/EtOAc (1:1) to give a colourless oil which is distilled using a Kügelrohr apparatus, and the distillate crystallises on cooling. It has R_F 0.51 on Whatman No 1 paper using pentan-1-ol and 85% formic acid (1:1) and developing with ammoniacal $AgNO_3$. [Boll *Acta Chem Scand* **22** 3245 *1968*, NMR: Oppolzer et al. *Helv Chim Acta* **68** 2100 *1985*, *Beilstein* **18** III/IV 56, **18/1** V 54.]

5-(Hydroxymethyl)furfural *[67-47-0]* **M 126.1, m 33.5°, b 114-116°/1mm, d_{25}^{25} 1.2620, n_D^{25} 1.5533.** Crystallise it from diethyl ether/petroleum ether. [*Beilstein* **18** III/IV 100, **18/1** V 130.]

***dl*-3-Hydroxy-*N*-methylmorphinan** *[297-90-5]* **M 257.4, m 251-253°.** Crystallise it from MeOH or aqueous EtOH. The *hydrochloride* has **m** 176-177°. The *hydrobromide* has **m** 200-201° when recrystallised from EtOH/Et_2O. [Sneider & Hellerbach *Helv Chim Acta* **33** 1446 *1950*, *Beilstein* **21** III/IV 100.]

8-Hydroxy-2-methylquinoline *[826-81-3]* **M 159.2, m 74-75°, b 266-267°, pK_1^{25} 5.61, pK_2^{25} 10.16.** Crystallise the quinoline from EtOH or aqueous EtOH. Its solubility at 20° in H_2O is 0.366g/L, and in $CHCl_3$ it is 466g/L. It complexes with many metals. [*Beilstein* **21** H 106, **21** III/IV 2132.]

4-Hydroxy-2-*n*-nonylquinoline *N*-oxide *[316-66-5]* **M 287.4, m 148-149°, pK_{Est} ~6.0.** Crystallise the *N*-oxide from EtOH. Its UV has λ_{max} at 220-230nm in 0.001N NaOH. [Cornforth & James *Biochem J* **63** 124 *1956*, *Beilstein* **21** III/IV 3834.]

1-Hydroxyphenazine (Hemipyocyanine) *[528-71-2]* **M 196.2, m 157-158°, 165-166°, pK_1^{15} 1.61, pK_2^{15} 8.33 (10% aqueous MeOH).** Purify the hydroxyphenazine by chromatography on acidic alumina with *benzene/ether, and recrystallise it from aqueous EtOH, *benzene/heptane, then sublime it at 140°/1.5mm. [UV, IR: Badger et al. *J Chem Soc* 3204 *1951*, Hegedüs *Helv Chim Acta* **33** 746 *1950*, *Beilstein* **23** II 360, **23** III/IV 2753.]

2-(2-Hydroxyphenyl)benzothiazole *[3411-95-8]* **M 227.2, m 132-133°, b 173-179°/3mm.** Recrystallise it several times from aqueous EtOH or dilute AcOH and sublime it. [Itoh & Fujiwara *J Am Chem Soc* **107** 1561 *1985*, Bogert & Corbitt *J Am Chem Soc* **48** 786 *1926*, *Beilstein* **27** II 91.]

2-(2-Hydroxyphenyl)benzoxazole *[835-64-3]* **M 211.2, m 127°, b 338°/760mm.** Recrystallise it several times from aqueous EtOH or dilute AcOH and sublime it. An aqueous alkaline solution containing EtOH has a blue fluorescence. [Itoh & Fujiwara *J Am Chem Soc* **107** 1561 *1985*, *Beilstein* **27** II 91.]

3-Hydroxy-2-phenylcinchoninic acid (Oxycincophen) *[485-89-2]* **M 265.3, m 206-207°(dec).** It is precipitated from alkaline solution on acidification and crystallises from EtOH or AcOH in yellow crystals. [Marshall & Blanchard *J Pharmacol* **95** 186 *1949*, *Beilstein* **22** H 245, **22** II 183, **22** III/IV 2383.]

(±)-2-(α-Hydroxypropyl)piperidine [2-piperidinepropanol, *RS*-1-(*RS*-2-piperidyl)propan-1-ol, (±)-α-conhydrine] *[3238-62-8, 63401-12-7, 24448-89-3]* **M 143.2, m 99-100°, pK_{Est} ~10.2.** Crystallise it from ether. The [*RS-1-(SR-2)]*-isomer also crystallises from ether and has **m** 98-98.5°. The *methiodide* crystallises from Me_2CO/MeOH with **m** 127-130.5°. **POISONOUS** [Sicher & Tichy *Col Czech Chem Commun* **23** 2081 *1958*, Govindachari & Rajappa *J Chem Soc* 1306 *1958*, Stereochemistry: Hill *J Am Chem Soc* **80** 1609 *1958*,

Beilstein **21** II 21, **21** III/IV 122.]

(+)-2-(α-Hydroxypropyl)piperidine [2-piperidinepropanol, *R*-1-(*S*-2-piperidyl)propan-1-ol, (+)-α-conhydrine] *[495-20-5]* **M 143.2, m 121°, b 224-5°/720mm, $[\alpha]_D^{20}$ -9.8° (c 4, EtOH), pK_{Est} ~10.2.** This very **POISONOUS** alkaloid from hemlock crystallises in leaflets from ether. The *O,N-dibenzoyl* derivative has **m** 133-134° and $[\alpha]_D^{24}$ -13° (c 3, $CHCl_3$). [Sicher & Tichy *Col Czech Chem Commun* **23** 2081 *1958*, Stereochemistry: Hill *J Am Chem Soc* **80** 1609 *1958*, Absolute config & ORD: Fodor et al. *Canad J Chem* **47** 4393 *1969*, *Beilstein* **21** I 191, **21** II 21, **21** III/IV 122.]

(-)-2-(α-Hydroxypropyl)piperidine [2-piperidinepropanol, *R*-1-(*R*-2-piperidyl)propan-1-ol, (-)-α-conhydrine] *[495-20-5]* **M 143.2, m 121°, b 224-5°/720mm, $[\alpha]_D^{20}$ +10° (c 10, EtOH), pK_{Est} ~10.2.** Crystallise the piperidine from ether. **POISONOUS.** [Galinovsky & Mulley *Monatsh Chem* **79** 426 *1948*, *Beilstein* **21** I 191, **21** II 21, **21** III/IV 122.]

(±)-7-(2-Hydroxypropyl)theophylline (Proxyphylline, 1,3-dimethyl-3*H*,7*H*-purine-2,6-dione) *[603-00-9]* **M 238.2, m 135-136°.** Crystallise it from EtOH, aqueous MeOH or EtOAc. Roth *Archiv Pharmazie* **292** 234 *1959*, Zelnik et al. *Bull Soc Chim Fr* 1733 *1956*, *Beilstein* **26** III/IV 2366.]

6-Hydroxypurine (hypoxanthine) *[68-94-0]* **M 136.1, m 150°(dec), pK_1^{20} 1.98, pK_2^{20} 8.96, pK_3^{20} 12.18.** Crystallise it from hot water and dry it at 105°. [*Beilstein* **26** II 252, **26** III/IV 2081.]

2-Hydroxypyridine (2-pyridone) *[142-08-5]* **M 95.1, m 105-107°, b 181-185°/24mm, ε_{293nm} 5900 (H_2O) pK_1^{25} 1.25, pK_2^{25} 11.99.** Distil the pyridone under vacuum to remove coloured impurity, then recrystallise from *benzene, CCl_4, EtOH or $CHCl_3$/diethyl ether. It can be sublimed under high vacuum. [DePue et al. *J Am Chem Soc* **107** 2131 *1985*, *Beilstein* **21/7** V 106.]

3-Hydroxypyridine *[109-00-2]* **M 95.1, m 129°, 130°, pK_1^{25} 5.10, pK_2^{25} 8.6.** Crystallise 3-hydroxypyridine from *C_6H_6, water or EtOH. [*Beilstein* **21** III/IV 402, **21/2** V 68.]

4-Hydroxypyridine (4-pyridone) *[626-64-2]* **M 95.1, m 65°, 68° (hydrate), 148.5°, 151-152° (anhydr), b >350°/760mm, pK_1^{20} 3.20, pK_2^{20} 11.12.** Crystallise 4-pyridone from H_2O or wet $CHCl_3$ as the *monohydrate*. It loses H_2O on drying *in vacuo* over H_2SO_4. Store it over KOH because it is *hygroscopic*. [*Beilstein* **21** III/IV 446, **21/7** V 152.]

2(6)-Hydroxypyridine-5(3)-carboxylic acid (6-hydroxynicotinic acid) *[5006-66-6]* **M 139.1, m 304°(dec), pK_1^{20} 3.82 and pK_2^{20} 9.92.** It crystallises from water with **m** 303.4-303.7°(dec), or with **m** 325°(dec) from aqueous EtOH. The *methyl ester* crystallises from Me_2CO with **m** 166° and pK^{20} 9.92. [Albert *J Chem Soc* 1020 *1960*, *Beilstein* **22** III/IV 2147, **22/6** V 119.]

4-Hydroxypyridine-2,6-dicarboxylic acid (chelidamic acid) *[134.828-60-3]* **M 183.1, m 248°(dec, 1 H_2O), 254°(dec), 263°(dec), pK_1^{22} 1.9, pK_2^{22} 3.18, pK_3^{22} 10.85; pK_1 3.62, pK_2 4.82 (80% aqueous methoxyethanol).** It crystallises from water. The *dimethyl ester* crystallises from MeOH with **m** 167° (*monohydrate*, from H_2O), **m** 170-171° (*anhydrous*, from MeOH), and pK^{25} 6.25. [Bensaude et al. *J Am Chem Soc* **99** 4438 *1972*, *Beilstein* **22** III/IV 2583, **22/7** V 164.]

2-Hydroxypyrimidine *[557-01-7]* **M 96.1, m 179-180°, pK_1^{20} 2.24, pK_2^{20} 9.17.** It crystallises from EtOH or ethyl acetate. Its solubility in H_2O at 20° is 1g/2.2ml. [Albert *J Chem Soc* 4219 1952, *Beilstein* **24** III/IV 194.]. *2-Hydroxypyrimidine hydrochloride [38353-09-2]* M 132.5, has **m** 203-205.5°(dec) and crystallises from EtOH. [*Beilstein* **24** III/IV 173.] The *picrate* has **m** 199° and crystallises from EtOH. [Brown et al. *J Chem Soc* 211 1955.]

4-Hydroxypyrimidine *[4562-27-0]* **M 96.1, m 164-165°, pK_1^{20} 1.66, pK_2^{20} 8.63.** It crystallises from *benzene or ethyl acetate. The *picrate* has **m** 164-166° and crystallises from EtOH [Brown et al. *J Chem Soc* 4035 *1955*, *Beilstein* **24** III/IV 171.]

***R*-(+)-3-Hydroxypyrrolidine** *[(±) 2799-21-5 and 104706-47-0, R(+) 40499-83-0, S(-) 100243-39-8]* **M 87.1, b 215-216°/atm, d_4^{20} 1.078, n_D^{20} 1.490, $[\alpha]_D^{20}$ +6.5° (c 1.5, MeOH), pK_{Est} ~10.1.** The *(±)-isomer* is purified by repeated distillation (**b** 102-104°/12mm, 108-110°/18mm), and the *(±)-picrate* crystallises from EtOH with **m** 140-141°. The *R(+)-enantiomer* has **b** 70°/0.6mm and $[\alpha]_D^{20}$ +5.6° (c 3.63, MeOH). Its *hydrochloride* has a negative rotation and its *dimethiodide* has **m** 230° and $[\alpha]_D^{24}$ -8.02°. [Suyama & Kanno *Yakugaku Zasshi (J Pharm Soc Japan)* **85** 531 *1965*, Uno et al. *J Heterocycl Chem* **24** 1025 *1987*, Flanagan & Joullie *Heterocycles* **26** 2247 *1987, Beilstein* **21** III/IV 44.]

2-Hydroxyquinoline (carbostyril) *[59-31-4]* **M 145.2, m 199-200°, pK_1^{20} -0.31, pK_2^{20} 11.76.** Crystallise it from MeOH. It has **m** 200-201° after sublimation in a vacuum. The *picrate* has **m** 132° after crystallisation from Et_2O. [Gibson et al. *J Chem Soc* 4340 *1955*, *Beilstein* **21** III/IV 1057, **21/8** V 217.]

8-Hydroxyquinoline (oxine, 8-quinolinol) *[148-24-3]* **M 145.2, m 71-73°, 75-76°, 76°, b 122°/0.1mm, ~267°/atm, pK_1^{25} 4.91, pK_2^{25} 9.81.** Crystallise oxine from hot EtOH, acetone, petroleum ether (b 60-80°) or water. Crude oxine can be purified by precipitation of copper oxinate, followed by liberation of free oxine with H_2S or by steam distillation after acidification with H_2SO_4. Store it in the dark. It forms complexes with many metals. [Manske et al. *Can J Research* **27F** 359 *1949*, Phillips *Chem Rev* **56** 271 *1956*, *Beilstein* **21** III/IV 1135, **21/3** V 252.]

8-Hydroxyquinoline-5-sulfonic acid (H_2O) *[84-88-8]* **M 243.3, m 322-323°(sintering at ~305°), >310°, pK_1^{25} 4.09, pK_2^{25} 8.66.** Crystallise the acid from water (as the 1.5 *hydrate*, **m** 316-317°) or dilute HCl (*ca* 2% by weight). [*Beilstein* **22** I 620, **22** II 313, **22** III/IV 3493.]

4-Hydroxy-2,2,6,6-tetramethylpiperidine *[2403-88-5]* **M 157.3, m 130-131°, pK^{20} 10.05.** The piperidine crystallises from water as a *hydrate* and crystallises from dry ether or *C_6H_6 as the *anhydrous* base. The *hydrochloride* has **m** 282-284° (from EtOH/H_2O), and the *formate* has **m** 207°(dec, from EtOH/EtOAc). [Mailey & Day *J Org Chem* **22** 1061 *1957*, *Beilstein* **21** I 195, **21** III/IV 146, **21/1** V 159.]

4(6)-Hydroxy-2,5,6(2,4,5)-triaminopyrimidine sulfate *[35011-47-3]* **M 257.22, m >340°, pK_1 2.0, pK_2 5.1, pK_3 10.1.** This salt has very low solubility in H_2O. It is best purified by conversion into the dihydrochloride salt, which is then re-converted to the insoluble sulfate salt. The sulfate salt (2.57g, 10mmoles) is suspended in H_2O (20ml) containing $BaCl_2$ (10mmoles) and stirred in a boiling water bath for 15 minutes. After cooling, the insoluble $BaSO_4$ is filtered off and washed with boiling H_2O (10ml). The combined filtrate and washings are made acidic with HCl and evaporated to dryness. The residual hydrochloride salt is recrystallised from H_2O by adding conc HCl whereby the *dihydrochloride salt* separates as clusters which darken at 260° and dec > 300°[darkening > 360°]. [Baugh & Shaw *J Org Chem* **29** 3610 *1964*, King & Spengley *J Chem Soc* 2144 *1952*]. The hydrochloride is then dissolved in H_2O, and while hot an equivalent of H_2SO_4 is added when the sulfate separates as a white microcrystalline solid which is filtered off washed liberally with H_2O and dried in vacuum over P_2O_5. [Albert & Wood *J Appl Chem London* **3** 521 *1953*, UV: Cavalieri et al. *J Am Chem Soc* **70** 3875 *1948*; see also Pfleiderer *Chem Ber* **90** 2272 *1957*, Traube *Chem Ber* **33** 1371 *1900*.] The *hydrochloride* has **m** > 300°. [*Beilstein* **25** II 384, **25** III/IV 3648.]

3-Hydroxyxanthone *[3722-51-8]* **M 212.2, m 246°, 249-250°.** Purify the xanthone by chromatography on SiO_2 gel with petroleum ether/*benzene as eluent. Recrystallise it from *benzene or EtOH. The *acetate* has **m** 157-158°. [Itoh et al. *J Am Chem Soc* **107** 4819 *1985*, Davies et al. *J Org Chem* **23** 307 *1958*]. [*Beilstein* **18** H 46, **18** I 315, **18** II 29, **21** III/IV 601.]

Ibogaine (12-methoxybogamine) *[83-74-9]* **M 300.3, m 152-153°, $[\alpha]_D^{20}$ -54° (EtOH), pK^{25} 8.1 (80% aqueous $MeOCH_2CH_2OH$).** Crystallise this akaloid from EtOH or aqueous EtOH and sublime it at 150°/0.01mm. It is soluble in organic solvents but insoluble in H_2O. The *hydrochloride*, **m** 299-300°(dec), is soluble in H_2O and alcohols. [Büchi et al. *J Am Chem Soc* **88** 3099 *1866*, Rosenmund *Chem Ber* **108** 1871 *1975*, *Beilstein* **23** III/IV 2742.]

Imidazole (glyoxaline) *[288-32-4]* **M 68.1, m 89.5-91°, 89-90°, b 140-145°/15mm, 256°/atm, 262-264°/atm, pK_1^{25} 6.99, pK_2^{25} 14.44.** Crystallise imidazole from *benzene, CCl_4, CH_2Cl_2, EtOH, petroleum ether, acetone/petroleum ether and distilled de-ionized water. Dry it at 40° under vacuum over P_2O_5. Distil it at low pressure. It is also purified by sublimation or by zone melting. [Snyder et al. *Org Synth* Coll Vol **III** 471 *1955*, Bredereck et al. *Chem Ber* **97** 827 *1964*, Caswell & Spiro *J Am Chem Soc* **108** 6470 *1986*.] *^{15}N-imidazole* crystallises from *benzene [Scholes et al. *J Am Chem Soc* **108** 1660 *1986*]. [*Beilstein* **23** II 34, **23** III/IV 564, **23/4** V 191.]

1*H*-Indazole-3-carboxylic acid *[4498-67-3]* **M 162.2, m 265-265.5°, 268-268.5°, $pK_{Est(1)}$ ~4.5.** Purify the acid by recrystallisation from glacial acetic acid (charcoal), and dry the yellow crystals *in vacuo*. *Alternatively*, dissolve the acid in boiling H_2O, concentrate the solution to one third its volume, cool and collect the yellow powder. Its UV has λ_{max} (H_2O) at 295 (logε 3.88) nm. The *ethyl ester* (prepared *via* the acid chloride) has **m 139°** (from EtOH) and has λ_{max} (MeOH) at 393 nm, and the *N-methylamide* crystallises in tan needles from $MeNO_2$ with **m 191-191°** (**187-188.5°** was also reported). [Rousseau & Lindwall *J Am Chem Soc* **72** 3048 *1950*, Snyder et al. *J Am Chem Soc* **74** 2009 *1952*, *Beilstein* **25** H 129, **25** I 238, **25** II 128, **25** IV 808.]

1*H*, *2H*-Indazol-3-one (3-hydroxy-1*H*-indazole) *[7364-25-2]* **M 134.1, m 250-252°, 253-254°, $pK_{Est(1)}$ ~6.0.** Purify indazol-3-one by recrystallisation from $MeNO_2$ or aqueous MeOH, and sublimation at 220°/0.1mm. In the UV it has λ_{max} in MeOH at 215 and 306 nm, and it is in the 3-OH form in ethanolic solution. There appears to be some controversy regarding the tautomeric form in the solid state, but the IR peak at ν_{max} 1627 cm^{-1} (KBr) supports the keto form. [Ainsworth *J Am Chem Soc* **79** 524 *1957*, Elguero et al. *Adv Heterocycl Chem,* **Suppl 1** 354 *1976*, Chernokal'skii et al. *Khim Geterotsikl Soedin* 96 *1966*, *Beilstein* **24** H 111, **24** II 59, **24** III/IV 270.]

4′-(Imidazol-1-yl)acetophenone *[10041-06-2]* **M 186.2, m 104-107°, pK^{25} 4.54.** Recrystallise it twice from CH_2Cl_2/hexane [Collman et al. *J Am Chem Soc* **108** 2588 *1986*].

2-Iminothiolane hydrochloride (2-iminotetrahydrothiophene, Traut's reagent) *[4781-83-3]* **M 137.6, m 187-192°, 190-195°, 192-193°, 193-194°, 202-203°, pK^{25} <2 (free base).** Recrystallise the hydrochloride from MeOH/Et_2O (**m** 187-192°) or (MeOH/Me_2CO), but after sublimation at ~180°/0.2mm the melting point rises to 202-203°. It has ^{1}HNMR with δ 2.27 (2H, t), 3.25 (2H, t) and 3.52 (2H, t) in $(CD_3)_2SO$. [King et al. *Biochemistry* **17** 1499 *1978*.] The *free base* is purifed by vacuum distillation (**b** 71-72°/6mm), has IR (film) with ν_{max} at 1700 (C=N)cm^{-1} and ^{1}HNMR ($CDCl_3$) with δ at 3.58 (2H, t) and 2.10-2.8 (4H, m). The *free base* is stable on storage but slowly hydrolyses in aqueous solutions with half-lives at 25° of 390 hours at pH 9.1, 210 hours at pH 10 and 18 hours at pH 11. [Traut et al. *Biochemistry* **12** 3266 *1973*, *Biochemistry* **17** 399 *1978*, Alagon & King *Biochemistry* **19** 4343 *1980*, *Beilstein* **17/9** V 12.]

Indanthrene (*N*,*N*′-dihydro-1,2,1′,2′-anthraquinonazine) *[81-77-6]* **M 442.4, m 470-500°(dec).** Crystallise indanthrene repeatedly from 1,2,4-trichlorobenzene to give a blue powder. It is soluble in alkali and conc H_2SO_4. [Weinstein & Merritt *J Am Chem Soc* **81** 3759 *1959*, *Beilstein* **24** II 317, **24** III/IV 2193.]

Indazole *[271-44-3]* **M 118.1, m 147°, 150°, pK_1^{20} 1.32, pK_2^{20} 13.80 (acidic NH).** Crystallise indazole from water, sublime it *in vacuo*, then recrystallise it from petroleum ether (b 60-80°). The *picrate* crystallises from Et_2O with **m** 136°. [Ainsworth *Org Synth* Coll Vol **IV** 536 *1963*, *Beilstein* **23** III/IV 1055, **23/6** V 156.]
