Printed in the Federal Republic of Germany.

Foreword to the First Edition

Metallurgical, materials, ceramic and chemical engineers worldwide will welcome this new compilation of thermochemical data by Professor Barin. Here they will find the most comprehensive tables yet available for the thermodynamic properties of pure substances as a function of temperature at 100° intervals. Almost twenty-four hundred substances are included – the elements, and compounds of two, three, and four elements. The vast majority of substances are inorganic, but Dr. Barin has included a generous selection of the more common hydrocarbons, carbohydrates, and a few chlorinated hydrocarbons. The format of the tables conforms to that of the JANAF tables, and SI units are employed.

To better appreciate the value of Dr. Barin's work, I have compared it below with other compilations that I regularly use.

JANAF tables. These tables are critically evaluated, each table is accompanied by a text that describes the data considered and reasons for the choice between conflicting values. The effort is directed at substances of importance to the sponsors of the project (U.S. Air Force and Department of Energy). As a result the stress is on substances of importance to fuel combustion, jet and rocket propulsion, and air pollution. Many elements and compounds of importance to metallurgy and related fields have not yet been included. For example, there are no tables for the elements and compounds of Ag, As, Au, Bi, Cd, Ce, In, Ir, La, Pd, Pt, Se, Sn, Te, Y, and U; moreover, many compounds essential to metallurgical calculations, such as Cu_2S, NiO, $NiSO_4$, $PbSO_4$, ZnO and ZnS have yet to be included.

U.S. Bureau of Mines Bull. 672, 674, and 677. Bulletins 672 and 674 cover the elements, binary oxides and binary halides in a very complete fashion. Bulletin 677, summarizes the values from Bulletins 672 and 674, and adds a modest selection of tables for arsenides, antimonides, borides, carbides, carbonates, hydrides, nitrides, phosphides, selenides, silicates, silicides, sulfates, sulfides and tellurides. The coverage of these added compound types, however, is far from complete; for example, there are no tables for $PbSO_4$, $SnSO_4$, GaS and Li_2S. The only ternary compounds included are the carbonates, sulfates and silicates, and no quaternary compounds are listed except for a limited number of hydrated compounds. Only brief references are given to the data sources, without attempt to explain the choice between conflicting values.

The Barin tables are far more complete in coverage than any of the sources described above. All of the natural elements and their compounds are included. In addition to the substance types listed in USBM Bull 677, the Barin tables include a large number of ternary oxides – aluminates, arsenates, borates, chromates, molybdates, nitrates, oxy-halides, phosphates, titanates, tungstates, selenates, vanadates, zirconates, etc. – as well as cyanides, hydroxides, complex silicates and inter-metallic compounds. The only substances not included by Barin, for which tables can be found elsewhere, are the ionized-gas species and a limited number of gas species important only at very high temperatures, which are listed in the JANAF tables. For each table Dr. Barin gives references for each of the major thermochemical values employed (enthalpy of formation and entropy at 298 K, and heat capacity). Like the USBM Bulletins, no attempt is made to discuss the choice between conflicting data sources.

Regarding quality of the values listed, Dr. Barin has wisely relied heavily on critically evaluated data (CODATA and JANAF) in cases where such values are available. For other substances he has drawn on a wide variety of sources, including the USBM Bulletins, other compilations, the periodical literature, and his own estimation of some thermochemical data. As new measurements are made, and as new critical evaluations become available, many of the Barin tables will require revision, but this is a characteristic of any attempt to compile thermochemical data. Anyone making thermochemical calculations who insists on the best possible data, will use a compilation, such as that of Barin or JANAF, as a starting place, but he will then check the recent periodical literature for new measurements that may have rendered the compiled values obsolete. This in no way detracts from the value of the compilation by Dr. Barin, which offers a starting place that is far more comprehensive than others, particularly for those concerned with metallurgical and similar systems.

The accomplishment of Dr. Barin in producing this volume is more remarkable in that it is largely an individual effort. The writer appreciates, from his own modest efforts to accumulate thermochemical data, the magnitude of the effort represented by this work.

Preface to the Third Edition

It has become necessary to produce a third edition after a relatively short time. There have been no significant changes in the existing preliminary text. In part IV and in the subsequent sections the inclusion of natural materials, such as minerals, ores, coal, and waste, in the thermodynamic calculations has been explained in detail. In the tables some errors have been corrected and new substances listed. Here, substantial support was given by the following experts: W. Härtel (Freiburg, Germany), H. Kleykamp (Karlsruhe, Germany), K. Supiyama (Kamihama Tsu, Japan), H. Nielson (Copenhagen, Denmark), F. J. J. van Loo, R. H. Eijkelberg (Eindhoven, Netherlands) among others. The number of tables has risen to 2518, including more than 230 organic substances. The whole book contains 3297 data sets for the thermodynamic description of substances and substance phases.

I would particularly like to thank my co-workers at the ZEUS Institute, especially Mr. F.-R. Zenz, Mr. M. Westphal, and Mrs. D. Dokupil for their valuable support.

The new edition has been greatly supported by VCH Verlagesgesellschaft, in particular by Dr. Ebel, Mrs. K. Sora and Mr. Maier.

Aachen/Duisburg, 1994/95 Ihsan Barin

Preface to the Second Edition

The first edition of this book has found wide-spread acceptance and been received with a great deal of interest. The constructive advice and criticism of colleagues from various countries have been of valuable help in preparing the second edition.

The preliminary text, an introduction to chemical thermodynamics, has been corrected, revised, and expanded to provide a sound basis for the calculation of the tabulated functions and their scientific/technical application.

The enthalpy H and Gibbs energy G have been more accurately defined and several errors in the tables have been corrected.

The work has been supported by VCH Verlagsgesellschaft, in particular by Dr. Ebel, Dr. G. Schulz, Mr. Maier, and Ms. Hillenbrand, Dipl.-Ing. F. Sauert, Bergisch-Gladbach, deserves special thanks for performing the calculations. I would also like to thank my co-workers at the ZEUS Institute. My family has given me immense support throughout the entire project.

Finally, I would like to gratefully acknowledge Thyssen Engineering GmbH, Essen, Gesellschaft Deutscher Metallhütten und Bergleute (GDMB), Clausthal, and Stifterverband Metalle, Düsseldorf, for their financial support.

Duisburg, 1993 Ihsan Barin

Preface to the First Edition

Thermodynamic calculations are often used for the analysis and description of the changes of state associated with the transfer of matter and energy. These calculations are an indispensable part of today's technical and scientific investigations in various fields such as chemistry, metallurgy, chemical engineering, energy technology, and environmental technology. The recent improvement in computer capabilities has enhanced the application of thermochemical calculations in the developemnt of new processes as well as for the improvement of existing techniques.

The reliability of the results of thermochemical calculations depends, in the first instance, on the accuracy of the thermochemical data used. On the other hand, the practical relevancy of the results is determined by the comprehensiveness of inclusion of the various species which are often quite numerous in real systems.

In this sense the present work may contribute to the application of thermochemical calculations to a wide variety of substances. The values of the thermochemical functions of 2372 pure substances [including 91 elements and the electron e^- (gas)] are tabulated at temperature intervals of 100 K. The substances include about 100 organic compounds. The data of gaseous species are tabulated separately.

Complete sets of basic data needed for the calculation of thermochemical functions are available only for a relatively small number of substances. Very often the data have to be completed by analysing values from different sources as well as by appropriate estimations before they can be used for calculations and they may well then be less accurate. Such estimates have been made especially for S (298.15) and C_p (T).

The layout of the tables and the functions quoted correspond to conventions which are also used in standard works such as the JANAF Tables and the Tables of the U.S. Bureau of Mines. The following thermochemical functions are tabulated: heat capacity C_p, entropy S, Gibbs energy function $-Gef = -[G-H(298.15)]/T$, enthalpy H, enthalpy increment $H-H(298.15)$, Gibbs energy $G=H-TS$, and the formation quantities $\Delta H_f, \Delta G_f$ and $\log K_f$. The formation reactions refer to the reference states of the elements, which are given in a separate table.

A preliminary text serves to introduce the subject of thermodynamics and includes a short description of the fundamental relations of chemical thermodynamics. The calculation of thermochemical functions is elucidated on the basis of these relations. This is followed by a description of the contents and structure of the tables. A relatively large amount of space is devoted to the examples in order to demonstrate the use of tables to those who are not well acquainted with thermodynamic calculations.

The data listed in the tables in Part VII also form the database for EQUITHERM, a software system authored by I. Barin, G. Eriksson, F. Sauert, M. Zeitler, B. Wittig, and W. Schmidt, which is available from the publishers of the book. EQUITHERM can be used to carry out thermodynamic calculations on multi-component, multi-phase systems made up of any of the substances listed in this work. Thus, the publishers are in the unique position of being able to offer both a printed compilation of thermodynamic data for pure substances and a software package for the calculation of equilibria in multi-species systems.

Cologne/Aachen, 1988 Ihsan Barin

Acknowledgment

The present work is the result of an individual effort without any support from public authorities. The facilities of KHD Humboldt Wedag AG, Cologne, were used in the compilation of the tables. The support of the management of the company and staff of the research and development center is gratefully acknowledged. The input of data was carried out over a long period by Ms. Wang Shu Sheng outside the working hours. Dipl. Ing. F. Sauert and Dr. E. Schultze-Rhonhof provided computer methods and aided in the examination of the consistency of selected data.

Kind encouragement was provided during the course of the work by Dr. N. A. Gokcen, US Bureau of Mines, Albany, Oregon, and Dr. N. Themelis, Columbia University, New York, N.Y., and by many other colleagues and friends.

VCH Verlagsgesellschaft, Weinheim, has supported the work in all its phases.

Dr. F. and Mrs. J. A. Hampson, Saarbrücken, are acknowledged for the translation of the introductory text.

I particularly wish to thank my family for their patience, help, and understanding while I was preparing this book.

Aachen, 1988 Ihsan Barin

Contents

Volume 1

List of chemical symbols and names of substances in the order of tabulation (Formulae index) XIII

List of chemical symbols for substances according to the alphabetical order of elements (modified Hill indexing system) XXXVII

Part I Basic Principles

1 Thermodynamic functions and relations I-1

1.1 The basic concepts I-1
1.1.1 Thermodynamic system I-1
1.1.2 State functions I-1
1.1.3 Changes in state I-1
1.1.4 The Zeroth Law of thermodynamics . I-2
1.1.5 Equations of state I-2

1.2 The First Law of thermodynamics ... I-3
1.2.1 Work I-3
1.2.2 Energy and heat I-4
1.2.3 Internal energy I-4
1.2.4 Enthalpy I-5
1.2.5 Heat capacities I-5
1.2.6 Changes in U and H of closed systems I-6

1.3 Joule-Thomson effect I-7

1.4 The Second Law of thermodynamics . I-7
1.4.1 Entropy I-7
1.4.2 Entropy changes, thermodynamic temperature I-9
1.4.3 Temperature dependence of entropy .. I-9

1.5 The Third Law of thermodynamics (Nernst Heat Theorem) I-10

1.6 Fundamental relations of thermodynamics I-11
1.6.1 Helmholtz energy, Gibbs energy I-11
1.6.2 Temperature and pressure dependence of Gibbs energy I-12
1.6.3 Natural changes and equilibrium state in a closed system I-12
1.6.4 Characteristic functions I-13

1.7 Closed system with reactions I-13
1.7.1 Reaction equation and conventions .. I-13
1.7.2 Reaction quantities I-14
1.7.3 Enthalpy and entropy of transition, Clausius-Clapeyron equation I-14

1.8 Chemical potential I-15
1.8.1 Open systems I-15
1.8.2 Definition of the chemical potential, Gibbs fundamental equation I-15
1.8.3 Standard state for chemical potential, definition of activity I-15

1.9 Chemical equilibrium I-16
1.9.1 Gibbs fundamental equation for closed systems I-16
1.9.2 Conditions for chemical equilibrium . I-16
1.9.3 Equilibrium constant I-16

1.10 Mixtures I-17
1.10.1 Gibbs-Duhem equation I-17
1.10.2 Standard states for activities and activity coefficients I-17

1.11 Gibbs phase rule I-18

1.12 Electrochemical reactions I-18
1.12.1 Electrochemical work I-18
1.12.2 Electrochemical potential I-19
1.12.3 Electrochemical equilibrium I-19

1.13 References for chapter 1 ..... I-20

2 Calculation of thermochemical functions I-21

2.1 Units and conventions (see Sections 10.1 – 10.3) I-21

2.2 Calculation of the thermochemical functions of pure substances I-21
2.2.1 $C_p(T)$, heat capacity I-21
2.2.2 $H(T)$, enthalpy I-22
2.2.3 $S(T)$, entropy I-24
2.2.4 $G(T)$, Gibbs energy I-24
2.2.5 $Gef(T)$, Gibbs energy function (free enthalpy function) I-25
2.2.6 $\Delta H_f(T)$, $\Delta G_f(T)$, $\log K_f(T)$ Molar quantities of formation reaction I-25

2.3 Equilibrium calculations I-27
2.3.1 $K(T)$, equilibrium constant I-27
2.3.2 $p^0(T)$, vapor pressure I-27
2.3.3 $E^0(T)$, standard emf I-27

2.4 Entropy production and "exergy" I-28
2.4.1 Entropy production I-28
2.4.2 Exergy I-29
2.4.3 Exergy losses by irreversibilities I-29
2.4.4 References for exergy relations I-30

2.5 Enthalpy and entropy of natural materials I-30

Part II Compilation and Presentation of Thermochemical Data

3 Compilation of thermochemical data . I-33
3.1 Basic thermochemical data I-33
3.2 Existing compilations I-33
3.3 Thermochemical tables I-33
3.4 References for Section 3.2 and 3.3 ... I-34

Part III Tables in the Present Work

4 Preparation of the tables I-35
4.1 General remarks I-35
4.2 Data sources, accuracy I-35
4.3 Units I-35
4.4 Standard states I-36
4.5 Reference phases for the elements at 298.15 K and 1 bar I-36

5 Construction of the tables I-37
5.1 Arrangement of substances in the tables I-37
5.2 Order of the phases in the tables I-37

6 Contents and structure of the tables . I-38
6.1 Formula, name and relative molar mass I-38
6.2 Tabulated functions I-38
6.3 Sequence of temperatures I-38
6.4 Phase transitions I-38
6.5 The final temperature in the tables ... I-38
6.6 Additional information, remarks I-39
6.7 References for the sources of data ... I-39
6.8 Abbreviations and symbols I-39

Part IV Examples of the Use of the Tables

7 Examples of thermodynamic calculations I-41
7.1 Enthalpy changes I-41
7.1.1 Enthalpy of air I-41
7.1.2 Heating and melting a metal I-41
7.1.3 Final temperature in an adiabatic process I-42
7.1.4 Enthalpy balance for heat exchange .. I-43
7.1.5 Enthalpy change in a system with reactions I-43
7.2 Exergy and entropy balance calculations I-44
7.3 Equilibrium calculations I-45
7.3.1 Calculation of equilibrium constants of chemical reactions I-45
7.3.2 Vapor pressure calculations I-46
7.3.3 Equilibrium concentration of NO in hot air I-46
7.3.4 Equilibrium concentration of NO in exhaust gases I-47
7.4 Equilibrium in simplified systems with several phases and components . I-47
7.4.1 Equilibrium in the C-CO-CO_2 system I-47
7.4.2 Predominance area diagram for the system Zn-O-C I-48
7.4.3 Predominance area diagram for the system Zn-O-S I-49
7.5 Electrochemical energy conversion, high temperature fuel cell I-51
7.6 The calculation of equilibria in multi-phases, multicomponent systems I-52
7.7 Thermodynamic calculation of technical processes with reactions of natural materials I-53
7.7.1 Incineration of waste materials in a fluidized bed furnace I-53
7.7.2 Sewage sludge incineration at 1600 °C I-54
7.7.3 Combustion of coal in the slag tap boiler I-56

Part V Information on the Tables

8 Fundamental constants and conversion factors I-59
8.1 Fundamental constants I-59
8.2 Conversion factors for energy units .. I-60
8.3 Conversions for entropies of gases ... I-61
8.4 Relative atomic masses of the elements based on $A_r = 12$ for ^{12}C I-62

Part VI Symbols, Abbreviations and References

9 Symbols and abbreviations used in the tables I-63
10 Reference phases of elements at 1 bar I-64
11 References for the data in the tables . I-68

Part VII The Tables

12 Tables of thermochemical data of pure substances I-71
Ag–Kr 1

Volume 2

List of chemical symbols and names of substances in the order of tabulation (Formulae index) VII

List of chemical symbols for substances according to the alphabetical order of elements (modified Hill indexing system) XXXI

1 Thermodynamic functions and relations

General remarks

The main object of this work is the presentation of thermochemcial properties of a relatively large number of pure substances in a uniform system. The information given in form of tables may serve to extend the application of chemical thermodynamics in science and technology dealing with materials and energy conversion.

The significant use of thermochemical data for analyzing and solving practical problems requires the understanding of the fundamental principles and relations of thermodynamics.

The theory of thermodynamics has been known since the end of the 19th century. This and the substantial contributions provided in the 20th century have established thermodynamics as a self-contained system of knowledge. The verified methods of thermodynamics are efficient and serve as elementary tools of today's engineers and scientists.

As is the case in the applied sciences, chemical thermodynamics work with a number of empirical definitions, conventions, standardizations and simplifications some of which may be chosen arbitrarily in accordance with basic principles. This is one of the main reasons why users of thermochemical data who are not specialized in thermodynamics unknowingly make mistakes.

This work starts with a summary of the fundamental principles of thermodynamics and relations derived from them. It provides a basis for the exact description of tabulated thermochemical data and their practical applications.

The relationships included in this brief treatise are only intended to provide the elementary tools for thermochemical calculations in a uniform system. For further information and explanation a large number of textbooks and standard works are available, which treat thermodynamics in detail. Some such textbooks are listed at the end of Chapter 1.

1.1 The basic concepts

1.1.1 Thermodynamic system

The macroscopic part of the universe being considered for thermodynamic purposes is known as *the system* (e.g. a chemical reactor containing substances). The part of the universe outside the system is termed *the surroundings.*

A *homogeneous system* (phase) is one with the same physical properties and constant composition in every part of it. A *heterogeneous system* is made up of several phases.

An *open system* can exchange mass and heat with its surroundings; an open system can also perform work and have work done on it.

A *closed system* cannot exchange mass with its surroundings. Heat exchange and work performance are possible.

An *isolated system* can exchange neither mass nor heat and it is impossible for the system to perform work or have work done on it.

A *thermally isolated system* is a special case of the closed system, where no transfer of mass or heat can take place but the performance of work is allowed. A process taking place in a thermally isolated system is referred to as an *adiabatic process.*

1.1.2 State functions

In thermodynamics the properties in the current state of a system are represented by state functions which are themselves described using appropriate *variables of state.* The following state functions are employed in chemical thermodynamics:

p pressure
T temperature
V volume
U internal energy
H enthalpy $= U+pV$
S entropy
A Helmholtz energy (free energy) $= U-TS$
G Gibbs energy (free enthalpy) $= H-TS$

V, U, H, S, A, and G are *extensive properties*, i.e., they depend on the amount of material present in the system. p and T as well as all molar quantities are *intensive properties.*

The state functions are properties of the present state of the system and do not depend on the path by which that state was reached. The differential of a state function is an exact differential; its integral between the initial and the final state is independent of the path taken.

1.1.3 Changes in state

The change in state of a system by modification of its variables of state is called a *process.*

A *reversible change* means an idealized, quasi-static process performed by infinitesimal modifications of a

variable whereby the system passes through a consecutive series of states in equilibrium with its surroundings. In a reversible cycle the system returns to its initial state and the surroundings remain unchanged.

In the case of an *irreversible process* the system does not pass through equilibrium states and afterwards changes remain in the surroundings. The *natural changes* (real changes) are irreversible.

In the *equilibrium state* no macroscopic changes in the system can be observed.

1.1.4 The Zeroth Law of thermodynamics

Thermal equilibrium

The thermal state of a substance is qualitatively described by the attributes "cold" and "warm" resulting from our sense of perception.

It is a common experience that when a cold substance (e.g., a gold coin) is brought into contact with a warm one (e.g. hot water) in an isolated vessel, the cold substance becomes warmer and the warm one cooler. This process accompanied by measurable volume changes finally comes to a standstill representing the *thermal equilibrium* where no changes in state can be observed.

The Zeroth Law of thermodynamics

Two systems in thermal equilibrium with a reference system are also in thermal equilibrium with each other.

All systems of any composition in mutual thermal equilibrium with each other have the same state property called *temperature*. Temperature is a state function.

Temperature

The equality of temperature is the necessary condition for thermal equilibrium between two systems.

The temperature of a system A can be determined empirically by measuring the changes in volume, pressure or other properties of a reference system (*thermometer*) being in thermal equilibrium with A.

The Celsius scale of temperature is based on the following stipulation:

melting point of ice $\Theta_{mp} = 0\,°C$

boiling point of water $\Theta_{bp} = 100\,°C$

in each case under 1.01325 bar (= 1 atm) presssure.

The Kelvin scale of temperature is a consequence of the perfect gas laws leading to the construction of the **constant-volume gas thermometer.** The fixed point of Kelvin temperature (absolute temperature) is defined with reference to the triple point of water (where ice water and water vapour coexist).

International convention

Temperature of the triple point of water

$$\Theta_{trp} = 273.16\,K\ .$$

The **thermodynamic temperature** T which is introduced by the Second Law (see Section 1.4.2) without any reference to special substances coincides with the empirical Kelvin temperature. The single fixed point of T is 273.16 K = temperature of the triple point of water.

Freezing point of water under 1 atm **(ice point)**:

$$T = 273.15\,K\ .$$

Boiling point of water under 1 atm:

$$T = 373.15\,K\ .$$

Celsius temperature:

$$t_c / [°C] = T/[K] - 273.15\ .$$

1.1.5 Equations of state

The following equations of state apply to a homogeneous system (comprising a single phase)

$$V = V(p, T, n)\ ,$$

$$p = p(V, T, n)$$

where V is the volume, p the pressure, T the temperature and n the amount of substance in moles. For each given set of values for T, p and n, V has a corresponding value.

V and p are state functions. For a homogeneous substance of fixed n

$$dV = (\partial V/\partial p)_T\, dp + (\partial V/\partial T)_p\, dT$$

and, hence

$$(\partial V/\partial T)_p = -(\partial V/\partial p)_T\,(\partial p/\partial T)_V\ .$$

Appropriate substitutions in this equation give

$$\alpha = \kappa \gamma_t\, p$$

with the following definitions:

$$\alpha = \frac{1}{V}(\partial V/\partial T)_p \quad [K^{-1}]$$

(expansion coefficient)

$$\kappa = -\frac{1}{V}(\partial V/\partial p)_T \quad [Pa^{-1}]$$

(isothermal compressibility)

$$\gamma_t = \frac{1}{p}(\partial p/\partial T)_V \quad [K^{-1}]$$

(tension coefficient).

Ideal gas equation of state

$$pV = nRT .$$

For $n = 1$ mol

$$\alpha = \gamma_t = 1/T , \quad \kappa = 1/p .$$

Gas constant

$$R = 8.31441 \quad J\,K^{-1}\,mol^{-1}$$

Boyle-Mariotte's law

$pV =$ constant at constant n, T .

Gay-Lussac's law

$V \sim T$ at constant n, p

$p \sim T$ at constant n, V .

Avogadro's principle

$V \sim n$ at constant p, T .

Equal volumes of gases at the same p and T contain the same number of molecules.

Molar volume

$$V_m = RT/p$$

$$V_m = 22.414 \quad l\,mol^{-1}$$

at $T = 273.15$ and $p = 1.013$ bar:

Standard Temperature and Pressure = **STP** .

Dalton's law

The total pressure exerted by a mixture of ideal gases is the sum of partial pressures which are exerted when the mixture volume is occupied by the mixture components alone.

Total pressure:

$$p_t = \sum_i p_i = \frac{RT}{V}\sum_i n_i .$$

Partial pressure:

$$p_i = \frac{RT}{V} n_i .$$

Mol

The basic SI unit for amount of substances is the **mole** (mol):

$$n = N/N_A$$

where N is the number of entities (molecules, atoms, ions) contained in a given homogeneous substance and

$$N_A = 6.022\times10^{23} \quad [mol^{-1}]$$

the **Avogadro's constant.**

Convention: 1 mol is the amount of a substance which contains the same number of entities as there are C atoms in 12 g of ^{12}C.

Mol fraction

$$x_i = n_i / \sum_i n_i$$

$$p_i = x_i p_t$$

Real gas equations of state

$$p = RT/(V_m - b) - a/V_m^2$$

(van der Waals equation)

$$p = (RT/V_m)\,[1 + B(T)/V_m + C(T)/V_m^2 + \ldots]$$

(virial equation) .

$V_m = V/n$ is the molar volume, a and b are the van der Waals constants and B, C etc. are the virial coefficients.

1.2 The First Law of thermodynamics

Every thermodynamic system is characterized by a state property which is called energy E.

The energy of a system increases with the heat transferred to the system and decreases with the work done by the system on the surroundings.

The energy of an isolated system is constant.

1.2.1 Work

The mechanical work required to move an object an infinitesimal distance dl against an opposing force F is defined by

$$đW = -F\,dl .$$

đW is an inexact differential, its integral depends on the path taken.

An example of mechanical work related to a closed system is the expansion or compression of a gas by quasistatic movement of a piston in a cylinder containing the gas. The infinitesimal-volume work is then given by

$$đW = -p\,dV$$

where p is the pressure exerted on the system **(external pressure)**.

This relation implies

$đW < 0$ = work is done by the system

$đW > 0$ = work is done on the system by the surroundings.

The performance of quasistatic work on closed systems is involved not only in deformation processes (change in volume, length and surface) but also in changes of electrical and magnetic properties (charge transfer, polarisation).

In a **real process** the work done on a system exceeds that in a quasistatic process, provided the change in state is the same. In the real process part of the work is employed for spontaneous phenomena such as friction, reactions resulting from charge transfer etc. occurring inside the system. In the case of internal state changes the total work done on a system is given by

$$W_t = W + W_{add}$$

where W is the real quasistatic work and W_{add} the additional work such as friction work, electrical work etc. The electrical work performed on a system by charge transfer is given by

$$đW_e = \phi\,dq$$

where ϕ is the electrical potential and q the charge.

1.2.2 Energy and heat

As proven empirically, the work done on a *thermally isolated system* is independent of the type of work and of the route by which this is carried out.

In the case under consideration (*adiabatic process*) the transition of the system from state 1 to state 2 is represented by the change of a state function called **energy** E:

$$W_{ad} = E_2 - E_1 = \Delta E$$

where W_{ad} is the (adiabatic) work carried out and ΔE the change in energy of the system.

In an adiabatic process the work done on or by the system corresponds to the change in the energy of the system. The value of ΔE is independent of the path. E is a state function.

$W_{ad} > 0$ work is done on the system , $\Delta E > 0$

$W_{ad} < 0$ work is done by the system , $\Delta E < 0$.

As proven empirically, furthermore, the energy of a *closed system* can be changed not only by work performance but also by another interaction with the surroundings which is the exchange of **heat** Q:

$$Q + W = \Delta E$$

$Q > 0$: heat is transferred from the surroundings to the system,

$Q < 0$: heat is transferred from the system to the surroundings.

For an infinitesimal change in state of a *closed system*:

$$dE = đQ + đW$$

where $đW$ and $đQ$ are inexact differentials, in contrast to dE, and ought strictly to have been characterized as such in the way they are written.

For an *isolated system* where heat transfer and work performance do not take place

$dE = 0$ i.e. ,

E = constant .

The energy of an isolated system is constant.

1.2.3 Internal energy

The total energy of a closed system is made up of its kinetic energy E_{kin}, its potential energy E_{pot} and its internal energy U:

$$E = E_{kin} + E_{pot} + U\ .$$

The law of conservation of energy for an *isolated system* is expressed by

$$E_{kin} + E_{pot} + U = \text{constant}$$

and in case of internal state changes

$$U = \text{constant.}$$

U is a state function that depends on the internal state variables of the system considered.

Change in internal energy for different systems:

$\Delta U = W$ thermally isolated system

$\Delta U = 0$ isolated system

$\Delta U = Q + W$ closed system

$\Delta U = Q$ closed system , V = constant.

For an infinitesimal change in state of a closed system without additional work the following relations apply:

$$dU = đQ + đW$$

$$= đQ - p\,dV$$

$$= đQ \text{ at } V = \text{constant} .$$

Here again, $đQ$ is an inexact differential.

The internal energy U of a closed homogeneous system of constant composition is described by

$$U = U(V, T) ,$$

$$dU = (\partial U/\partial V)_T\,dV + (\partial U/\partial T)_V\,dT .$$

The internal energy is a state property that depends on the current state of the system. The numerical value of the internal energy of a system can only be given in relation to a standard state which can be chosen arbitrarily considering practical aspects of calculations.

1.2.4 Enthalpy

The enthalpy of a system at constant pressure is defined by

$$H = U + pV .$$

After differentiation and substitution of

$$dU = đQ - p\,dV$$

this gives, for internal state changes in a closed system without performance of additional work

$$dH = đQ + V\,dp$$

$$dH = đQ \quad \text{at } p = \text{constant} .$$

Changes in internal state:

$$\Delta H = 0$$

for an isobaric adiabatic process,

$$\Delta H = V \Delta p$$

for an isolated system,

$$\Delta H = Q$$

for a closed system at p = constant.

In the case of isobaric processes (p = constant) in closed systems the heat exchanged with the surroundings is equal to the change in enthalpy of the system. For this reason the enthalpy is an important state function in thermochemistry.

The application of the energy law to stationary flow processes often involves setting up enthalpy balance relations.

Like U, H is a state function and for a closed homogeneous system of constant composition is described by the internal state variables p and T:

$$H = H(p, T) ,$$

$$dH = (\partial H/\partial p)_T\,dp + (\partial H/\partial T)_p\,dT .$$

The enthalpy of a system is only determined with respect to a standard state.

1.2.5 Heat capacities

For a closed homogeneous system of constant composition the heat capacity at constant volume (C_V) and constant pressure (C_p) are defined as follows:

$$C_V = (\partial U/\partial T)_V = |đQ/dT|_V ,$$

$$C_p = (\partial H/\partial T)_p = |đQ/dT|_p .$$

The total differentials of U and H can then be expressed by

$$dU = C_V\,dT + (\partial U/\partial V)_T\,dV ,$$

$$dU = C_p\,dT + (\partial H/\partial p)_T\,dp .$$

$C_p - C_V$

The heat Q transferred to a gas confined by a vessel (piston) results in a higher temperature in the system at constant V than in the case of constant p.

The difference $C_p - C_V$ in the case of an ideal gas corresponds to the work performed for expansion of the system on heating at constant pressure.

From the equations given above it follows that

$$C_p - C_V = (\partial H/\partial T)_p - (\partial U/\partial T)_V .$$

Insertion of $H = U + pV$ gives

$$C_p - C_V = (\partial U/\partial T)_p - (\partial U/\partial T)_V + (\partial(pV)/\partial T)_p .$$

Calculations using the relations for partial derivatives yield

$$(\partial U/\partial T)_p - (\partial U/\partial T)_V = (\partial U/\partial V)_T (\partial V/\partial T)_p \ ,$$

$$(\partial (pV)/\partial T)_p = p(\partial V/\partial T)_p \ .$$

Insertion of these equations into the last equation for $C_p - C_V$ gives

$$C_p - C_V = [(\partial U/\partial V)_T + p](\partial V/\partial T)_p \ .$$

Transformations using Maxwell relations (see Section 1.6.4) and relations for partial derivatives lead to

$$(\partial U/\partial V)_T = T(\partial p/\partial T)_V - p \ .$$

Inserting this expression into the last equation with use of partial derivatives gives

$$C_p - C_V = TV\alpha^2/\kappa$$

where α denotes the expansion coefficient and κ the isothermal compressibility as defined in Section 1.1.5.

For **ideal gases,**

$$\alpha = 1/T$$

$$\kappa = 1/p$$

$$C_p - C_V = R \ .$$

For **condensed phases** the difference between C_p and C_V is determined by the constants α and κ and, thus varies from substance to substance.

Example: AgCl (solid)

$$C_p = 52.886 \text{ J K}^{-1} \text{ mol}^{-1} \quad \text{at} \quad T = 298.15 \text{ K}$$

(see Tables).

The following values for α, κ and ϱ (density) are reported in "D'ans. Lax" (E. Lax: Taschenbuch für Chemiker and Physiker Vol. 1, Springer-Verlag, Berlin, 1967):

$$\alpha = 10.3 \times 10^{-5} \text{ K}^{-1}$$

$$\kappa \approx 2.4 \times 10^{-6} \text{ bar}^{-1} = 2.4 \times 10^{-11} \text{ Pa}^{-1}$$

$$M = 143.321 \text{ g/mol} \ , \quad \varrho = 5.56 \text{ g/cm}^3$$

$$V = 143.321/5.56 = 25.777 \text{ cm}^3 \text{ mol}^{-1}$$
$$= 25.777 \times 10^{-6} \text{ m}^3 \text{ mol}^{-1}$$

so that

$$C_p - C_V = 3.4 \text{ J K}^{-1} \text{ mol}^{-1} \ .$$

This difference amounts to 6.4% of C_p.

1.2.6 Changes in U and H of closed systems

The internal energy U and the enthalpy H of a closed homogeneous system of constant composition are described by the internal state variables p, V and T which are related to each other via the equation of state.

In the following the variations of U and H with T, V and p are summarized.

$U(T)_V$, $H(T)_p$:

$$(\partial U/\partial T)_V = C_V$$

$$(\partial H/\partial T)_p = C_p \ .$$

$U(V)_T$, $H(p)_T$:

Transformations on the total differentials of $U(T, V)$ and $H(T,p)$ using relations between partial derivatives as well as Maxwell relations yield:

$$(\partial U/\partial V)_T = \pi_T \quad \text{(internal pressure)}$$
$$= -p + T\alpha/\kappa$$

$$(\partial H/\partial p)_T = V(1 - T\alpha)$$

where α is the expansion coefficient and κ the isothermal compressibility.

For **ideal gases,**

$$\pi_T = 0 \quad \text{(definition of the ideal gas)}$$

$$(\partial U/\partial V)_T = 0$$

$$(\partial H/\partial p)_T = 0 \ .$$

$U(T)_p$, $H(T)_V$:

$$(\partial U/\partial T) = C_V + \alpha \pi_T V$$

$$(\partial H/\partial T)_V = C_p (1 - \alpha \mu_{JT}/\kappa)$$

where

$$\mu_{JT} = (\partial T/\partial p)_H \ \textbf{(Joule-Thomson coefficient).}$$

For **ideal gases,**

$$\mu_{JT} = 0$$

$$(\partial U/\partial T)_p = C_V$$

$$(\partial H/\partial T)_V = C_p$$

$U(T,V)$, $H(T,p)$:

$$dU = C_V\,dT + [-p + T\alpha/\kappa]\,dV$$

$$dH = C_p\,dT + [V(1-T\alpha)]\,dp \ .$$

For **ideal gases,**

$$dU = C_V\,dT$$

$$dH = C_p\,dT \ .$$

The terms $[-p+T\alpha/\kappa$ and $V(1-T\alpha)]$ have to be taken into account in the case of **condensed phases.** In many cases the quantity $[V(1-T\alpha)]$ is negligibly small with respect to the enthalpy changes occurring with temperature and, in particular, with respect to enthalpies of reactions or phase transitions.

Example:
Iron at $T = 298.15$ K;
$\alpha = 11.7\times10^{-6}\ K^{-1}$ and
$V = M_{Fe}/\varrho_{Fe} = 7.1\ cm^3\cdot mol^{-1} = 7.1\times10^{-6}\ m^3\,mol^{-1}$
(α and $\varrho_{Fe} = 7.87\ g\cdot cm^{-3}$ from Landoldt-Börnstein, 4331/p. 132).

If the pressure is increased by 100 bar = 10^7 Pa then

$$[V(1-T\alpha)]\,\Delta p$$
$$= [7.1\times10^{-6}(1-298.15\times11.7\times10^{-6})]\ 10^7$$
$$= 70.8\ J\ mol^{-1} \ .$$

The enthalpy change involved in increasing the temperature from 298.15 K to 300 K (i.e. by 1.85 K) amounts to 46 J mol^{-1}.

In general the **enthalpy changes occurring in condensed phases** at moderate pressures can be adequately described by the relation

$$dH = C_p\,dT \ .$$

For reactions among solid substances

$$dU \approx dH \ .$$

1.3 Joule-Thomson effect

The Joule-Thomson effect is the cooling of a real gas by an adiabatic expansion (without additional work).

The experiment conceived by Joule and Thomson (Kelvin) demonstrated that on adiabatic expansion, without performing additional work, the enthalpy of a gas (ideal or real) remains constant. From this it follows that the internal energy U of an ideal gas is independent of the volume and is, thus, determined by the temperature alone.

For an isenthalpic process in a closed homogeneous system of constant composition

$$dH = (\partial H/\partial p)_T\,dp + (\partial H/\partial T)_p\,dT = 0 \ .$$

$$\mu_{JT} = (\partial T/\partial p)_H = -(\partial H/\partial p)_T/C_p \ .$$

μ_{JT} is the Joule-Thomson coefficient. From this it follows that

$$(\partial H/\partial p)_T = -\mu_{JT}\,C_p$$

$$(\partial H/\partial T)_V = (1-\alpha\,\mu_{JT}/\kappa)\,C_p \ .$$

For an **ideal gas,**

$$\mu_{JT} = 0$$

$$H(T,p_1) = H(T,p_2) \ .$$

For a **real gas,**

$$\mu_{JT} = [2a/RT - b]/C_p$$

where a and b are the van der Waals constants.

The value of μ_{JT} has the following consequences in the T–p diagram:

$\mu_{JT} > 0$ region of cooling, the gas is cooled as it expands (e.g. N_2, O_2 at 298.15 K)

$\mu_{JT} < 0$ area of warming, the gas becomes heated on expansion (e.g. He, H_2 at 298.15 K)

$\mu_{JT} = 0$ boundary curve at $T = T_I$.

T_I is the inversion temperature. For a van der Waals gas

$$T_I = 2a/Rb = 2\,T_B$$

where T_B is the Boyle temperature.

For CO_2 at $T = 298.15$ K and $p = 1$ bar

$$\mu_{JT} = 1.1\ K\ bar^{-1} \ .$$

This means that the temperature of CO_2 decreases by 1.1 K as a result of a pressure decrease of 1 bar.

In thermochemistry, gases are frequently regarded as ideal gases. That is, no account is taken of the change in enthalpy with pressure. It is possible to check the validity of this simplification for a given gas on the basis of the relation

$$(\partial H/\partial p)_T = -\mu_{JT}\,C_p \ .$$

1.4 The Second Law of thermodynamics

1.4.1 Entropy

The First Law leads to the definition of the internal energy (U) and of the heat Q.

The Second Law introduces simultaneously the entropy (S) and the thermodynamic temperature (T) as state variables and, furthermore, determines the direction of natural processes.

With reference to Sommerfeld, Becker and Haase (see Section 1.13) the implications of the Second Law can be summarized as follows:

- Every thermodynamic system possesses an extensive property called entropy (S) that depends on internal state variables only. The change in entropy of a closed homogeneous system is determined by bringing the system from an arbitrary initial state to a final state, whereby the system passes through a series of quasistatic changes consisting of consecutive isothermal and adiabatic steps. At each isothermal step the quantity of heat $đQ$ is exchanged between the system and its surroundings. Division of $đQ$ by the absolute temperature T (which remains to be defined), and summation of the quotients $đQ/T$ over all the steps, yields the change in entropy of the system for the change of state in question.

  From the reversible cyclic process carried out in a closed homogeneous system by combination of infinite number of consecutive **carnot cycles** it follows that:

$$\oint \frac{đQ_{rev}}{T} = 0$$

  and hence

$$\frac{đQ_{rev}}{T} = dS \ .$$

  Entropy is a state function.

- The increase in the entropy of a closed system for any change of state can be divided into two parts:

$$\Delta S = \Delta S_e + \Delta S_i \ .$$

  The first term corresponds to the entropy change occuring in the system as a result of heat exchange with its surroundings. In case of an open system ΔS_e also implies the exchange of mass. The second term represents the entropy changes resulting from the process taking place within the system.

- The entropy of a thermally isolated system can only increase in a natural (irreversible) change of state

  Irreversible adiabatic process:

$$\Delta S > 0$$

$$\Delta S_e = 0$$

$$\Delta S_i > 0$$

  Reversible adiabatic process:

$$\Delta S = 0$$

$$\Delta S_e = 0$$

$$\Delta S_i = 0 \ .$$

  The change in entropy of the closed system at constant temperature is described by the following general relation:

$$\frac{\Delta S}{T} \geq \int \frac{đQ}{T}$$

  where $đQ$ represents the infinitesimal heat quantity transferred to the system from the surroundings at the temperature T.

Maximum work

The **Carnot cycle** is a reversible process that is carried out using an ideal gas as working fluid. It involves consecutive isothermal and adiabatic steps. At the end of the cycle, the system has the same state (defined by V and p) and internal energy as at the start, $\Delta U = 0$.

The process begins with the isothermal expansion of the gas confined in a piston whereby the quantity of heat Q_h is transferred to the system from a hot source. The second step is adiabatic expansion which leads to the cooling of the system. The third step is isothermal compression whereby Q_c is transferred from the system to a cold source. The final step is adiabatic compression with heating up to the gas.

For this cycle the following relation follows from the First Law:

$$Q_h - Q_c - W = 0 \ ,$$

$$W = Q_h - Q_c \ ,$$

where W is the expansion work performed by the system.

The **Carnot efficiency** is defined by

$$\eta = \frac{\text{work performed}}{\text{heat supplied}}$$

$$= \frac{W}{Q_h} = 1 - \frac{Q_c}{Q_h} \ .$$

In the first instance, the temperatures of the hot source and cold sink are represented by the empirical temperatures θ_h and θ_c. It is found that

$$\frac{Q_h}{Q_c} = \frac{f(\theta_h)}{f(\theta_c)}$$

and, furthermore,

$$T = f(\theta)$$

where T is the **thermodynamic temperature.**

The Carnot efficiency of a heat engine can then be given by

$$\eta = 1 - T_c / T_h$$

where T_h is the temperature of the heat source and T_c the temperature of the environment in K (Kelvin).

As follows from the above equation, the maximum Carnot efficiency can theoretically be obtained in the following limiting cases

$$\eta \rightarrow 1 \quad \text{as} \quad T_c \rightarrow 0 \quad \text{or} \quad T_h \rightarrow \infty \ .$$

1.4.2 Entropy changes, thermodynamic temperature

The entropy change in a closed system in thermal equilibrium with its surroundings (isothermal process) is described by

$$S_2 - S_1 = \Delta S \geq \int_1^2 đQ / T$$

or in the simplified form

$$dS_{sys} \geq đQ_{sys} / T_{sys} \quad \textbf{(Clausius inequality)} \ .$$

Where $đQ$ represents the infinitesimal quantity of heat transferred to the system and T the temperature of the system during the isothermal process.

Entropy changes:

$\Delta S \geq Q / T$ isothermal process

$\Delta S = Q_{rev} / T$ isothermal, reversible process.

If there is no additional work besides expansion work in the isothermal process the following relations apply:

at constant V, T: $dQ = dU$,

$$dS - dU/T \geq 0 \ ,$$

$$T\,dS \geq dU \ ;$$

at constant p, T: $dQ = dH$,

$$dS - dH/T \geq 0 \ ,$$

$$T\,dS \geq dH \ .$$

For a reversible change in state of a closed system of constant composition, whereby the only work performed is expansion work, the combination of relations of First and Second Law

$$dU = đQ + dW = đQ - p\,dV$$

$$dS = đQ / T$$

produces the **fundamental equation**

$$dU = T\,dS - p\,dV \ .$$

After transformation,

$$dS = (dU + p\,dV) / T$$

$$dS = (dH - V\,dp) / T$$

thus leading to the following relations

$$(dS)_{U,V} \geq 0 \ , \quad (dU)_{S,V} \leq 0 \ ,$$

$$(dS)_{H,p} \geq 0 \ , \quad (dH)_{S,p} \leq 0 \ ,$$

where the equality applies to reversible and the inequality to irreversible processes respectively.

As follows from the fundamental equation

$$U = U(S, V) \ ,$$

$$dU = (\partial U/\partial S)_V\,dS + (\partial U/\partial V)_S\,dV \ .$$

Comparison of this equation with the fundamental equation leads to a formal definition of the **thermodynamic temperature** T:

$$(\partial U/\partial S)_V = T \ .$$

Comment on relations between entropy and temperature*)

The intensive porperty: Temperature is supplemented by a complementary extensive property, entropy. In the case of energy in form of heat it gives the number of degrees of freedom among which the average energy of motion (of the material particles involved), characterized by the temperature, is distributed. Entropy and temperature are complementary state variables.

1.4.3 Temperature dependence of entropy

The entropy of a closed homogeneous system of constant composition is described by

*) Manfred Eigen, Von der Entropie zur Information – die physikalische Chemie der belebten Materie, Ber. Bunsenges. Phys. Chem. 98 (1994) 1351–1364.

$$S = S(T, V) \ ,$$

$$S = S(T, \mathrm{p})$$

so

$$\mathrm{d}S = (\partial S/\partial T)_V \, \mathrm{d}T + (\partial S/\partial V)_T \, \mathrm{d}V$$
$$= (\mathrm{d}U + p \, \mathrm{d}V)/T \ ,$$

$$\mathrm{d}S = (\partial S/\partial T)_p \, \mathrm{d}T + (\partial S/\partial p)_T \, \mathrm{d}p$$
$$= (\mathrm{d}H - V \, \mathrm{d}p)/T \ .$$

Together with the equations from Section 1.2.6

$$\mathrm{d}U = C_V \, \mathrm{d}T + [-p + T\alpha/\kappa] \, \mathrm{d}V \quad \text{and}$$

$$\mathrm{d}H = C_p \, \mathrm{d}T + [V(1 - T\alpha)] \, \mathrm{d}p$$

they yield

$$\mathrm{d}S = (C_V/T) \, \mathrm{d}T + (\alpha/\kappa) \, \mathrm{d}V \ ,$$

$$\mathrm{d}S = (C_p/T) \, \mathrm{d}T - V\alpha \, \mathrm{d}p \ .$$

For **ideal gases** these equations become

$$\mathrm{d}S = (C_V/T) \, \mathrm{d}T + R \, \mathrm{d}V/V$$

$$\mathrm{d}S = (C_p/T) \, \mathrm{d}T - R \, \mathrm{d}p/p \ .$$

The entropy of an ideal gas increases on expansion at constant temperature. If the pressure of an ideal gas is reduced in this way from 1 atm to 1 bar then the entropy of the gas is increased by 0.109442 $\mathrm{J\,K^{-1}\,mol^{-1}}$.

For **pure condensed phases** the change in entropy as a result of pressure changes is often negligible in comparison with the entropy changes resulting from changes in temperature and from chemical reactions or phase transitions. So here the following equation applies:

$$\mathrm{d}S = (C_p/T) \, \mathrm{d}T$$

if the pressure change is not too high.

For iron at 298.15 K (see example in Section 1.2.6) the entropy change resulting from the change in $\alpha V \, \mathrm{d}p$ on raising the pressure from 1 to 101 bar is given by

$$V\alpha\Delta p = 7.1\times10^{-6}\times11.7\times10^{-6}\times10^{7}$$
$$= 8.3\times10^{-4}\ \mathrm{J\,K^{-1}\,mol^{-1}} \ .$$

1.5 The Third Law of thermodynamics (Nernst Heat Theorem)

It is impossible to cool a substance to the absolute zero by means of a process that passes through a finite number of steps.

Nernst: All state changes such as reactions and transformations between solid phases in internal equilibrium take place in the vicinity of the absolute zero ($T = 0\,\mathrm{K}$) without a change in entropy,

$$\Delta S \to 0 \quad \text{as} \quad T \to 0 \ .$$

According to this all perfect solids must have the same entropy at absolute zero, which does not necessarily have to be zero. $S(T = 0) = 0$ is an agreement.

Planck's formulation: The entropy of pure phases in internal equilibrium approaches a constant value (independent of pressure, phase state and crystal structure) as the temperature approaches zero.

Standardization: The entropy of pure phases in internal equilibrium is zero at $T = 0\,\mathrm{K}$.

Lewis and Randall: If the entropy of each element in some crystalline state be taken as zero at $T = 0\,\mathrm{K}$, every substance has a finite positive entropy; but at $T = 0\,\mathrm{K}$ the entropy may become zero, and does so become in the case of perfect crystalline substances.

From this general formulation it follows explicitly that the entropies of different modifications of the elements and compounds which are in internal equilibrium (in the perfect crystalline state) are assigned the value zero at $T = 0\,\mathrm{K}$. Thus when

$$S(T = 0) = 0$$

then, in general,

$$S(T) = \int_0^T (C_p/T) \, \mathrm{d}T \quad \text{at constant } p \ .$$

The entropy values based on the condition

$$S(T = 0) = 0$$

are known as "Third Law entropies" or **"absolute entropies".**

Comments on residual entropy *)

For most pure crystalline substances it is possible to determine the entropy on the basis of the Third Law ($S(T = 0) = 0$) from calorimetric data alone, i.e. $C_p(T)$ and heats of transitions.

In the case of many gases (H_2, O_2, N_2...) the entropy is not determined from calorimetric data but calculated from the equations of statistical mechanics.

*) Carl Wagner, private communication, 1974.

The Boltzmann equation for the relation between entropy and thermodynamic probability is the basis for this:

$$\Delta S(\mathrm{I} \rightarrow \mathrm{II}) = \int_{\mathrm{I}}^{\mathrm{II}} đQ_{\mathrm{rev}} / T = k \ln [\Omega(\mathrm{II}) / \Omega(\mathrm{I})] \ .$$

Where k is Boltzmann constant and Ω the weight of configuration (thermodynamic probability). Ω is defined as the number of microstates forming a macrostate. With

$$S(\mathrm{II}) - S(\mathrm{I}) = k \ln \Omega(\mathrm{II}) - k \ln \Omega(\mathrm{I})$$

it is possible to set the following condition:

$$S = 0 \quad \text{if} \quad \Omega = 1$$

and hence

$$S = k \ln \Omega \ .$$

This procedure would be rational but it is not normally employed. The following convention is used instead:

$$S = k \ln \Omega \ (\text{conventional}) = k \ln \Omega_{\mathrm{C}} \ .$$

Ω_{C} does not take into account those microstates resulting from differing orientations and the exchange of isotopes of atomic nuclei. The numbers of such microstates do not change in chemical reactions. It is, therfore, justifiable to ignore them in thermochemical calculations.

In the case of **ideal gases** it is possible to calculate Ω_{C} for particular values of p and T from spectroscopic data using the formulae of statistical mechanics.

The calculation of Ω_{C} is more difficult for **crystals**, here the entropy is calculated from

$$S(T) = k \ln \Omega_{\mathrm{C}}(T = 0) + \int_{0}^{T} (C_{\mathrm{p}} / T) \, \mathrm{d}T \ .$$

For **perfect crystals**:

$$\Omega_{\mathrm{C}}(T = 0) = 1 \ , \quad \text{i.e.} \quad S(T = 0) = 0 \ .$$

In some solids a degree of disorder remains at absolute zero. Certain pure solids, such as amorphous phases (glasses) and crystalline mixtures, possess a residual entropy. Because of differing molecular orientations (CO) and variations in interatomic bonding (H_2O), it holds that $S(T = 0) > 0$.

Further conclusions from the Third Law:

$$C_{\mathrm{V}} \ , \quad C_{\mathrm{p}} \ , \quad \alpha \quad \text{and} \quad \gamma \rightarrow 0 \quad \text{as} \quad T \rightarrow 0 \ ,$$

1.6 Fundamental relations of thermodynamics

1.6.1 Helmholtz energy, Gibbs energy

Definitions:

Helmholtz energy $A = U - TS$

Gibbs energy $G = H - TS$.

On changes of state in a closed system of constant composition after substitution of the relations (from Section 1.4.2)

$$\mathrm{d}U - T\,\mathrm{d}S \leq 0$$

$$\mathrm{d}H - T\,\mathrm{d}S \leq 0$$

the following relations are obtained:

$$(\mathrm{d}A)_{\mathrm{T,V}} \leq 0$$

$$(\mathrm{d}G)_{\mathrm{T,p}} \leq 0 \ .$$

It follows from this that A and G in closed systems must decrease in a natural process and reach a minimum at equilibrium.

For reversible changes of state at constant temperature

$$\mathrm{d}A = dU - T\,\mathrm{d}S \quad \text{at} \quad T = \text{constant}$$

$$\mathrm{d}G = \mathrm{d}H - T\,\mathrm{d}S \quad \text{at} \quad T = \text{constant} \ .$$

In the case of a closed system only performing work by change of volume

$$\mathrm{d}A = -p\,\mathrm{d}V - S\,\mathrm{d}T$$

$$\mathrm{d}G = V\,\mathrm{d}p - S\,\mathrm{d}T \ .$$

The functions A and G combine together the statements of the First and Second Laws and are of fundamental importance.

The changes of A and G in closed systems correspond to the **maximum work** performed by or on the system. $\mathrm{d}A$ is identical to the work carried out during an isothermal reversible change. $\mathrm{d}G$ is identical to the non-expansion work carried out under isothermal, isobaric, reversible conditions. In other words $-\mathrm{d}G$ corresponds to the maximum non-expansion work (e.g. electrical work) that can be generated by a closed system at constant p and T.

The main function of interest in chemical thermodynamics is $G(p, T)$ since p and T can be specified in most technical processes.

Most chemical processes take place in reactors operating under constant pressure.

It should be noted that the definition

$$G = H - TS$$

applies to the Gibbs energy of a homogeneous system at uniform temperature.

If a system consists of different phases (φ) existing at different temperatures (T_φ) the enthalpy H, entropy S and Gibbs energy G of the total system are given by

$$H = \sum_\varphi H_\varphi$$

$$S = \sum_\varphi S_\varphi$$

$$G = H - \sum_\varphi (TS)_\varphi \ .$$

If the temperature is uniform throughout the whole system, i.e. if $T = T_\varphi$, then

$$G = H - TS \ .$$

1.6.2 Temperature and pressure dependence of Gibbs energy

For a closed homogeneous system of constant composition G is described by

$$\mathrm{d}G = (\partial G/\partial p)_\mathrm{T}\,\mathrm{d}p + (\partial G/\partial T)_\mathrm{p}\,\mathrm{d}T \ .$$

With

$$\mathrm{d}G = V\,\mathrm{d}P - S\,\mathrm{d}T \ ,$$

it follows for the temperature and pressure dependence of G that

$$(\partial G/\partial T)_\mathrm{p} = -S$$
$$= (G-H)/T$$

$$(\partial (G/T)/\partial T)_\mathrm{p} = -H/T^2$$

(Gibbs-Helmholtz equation)

$$(\partial G/\partial p)_\mathrm{T} = V$$

The temperature dependences of H and S have been described in Sections 1.2.6 and 1.4.3; $G(T)$ is given by

$$G(T) = H(T) - TS(T) \ .$$

From the pressure dependence of G it follows that:

in the case of an **ideal gas** consisting of n moles

$$\mathrm{d}G = nRT\,\mathrm{d}p/p \quad \text{at constant } T$$

and in the case of **pure condensed phases**

$$\mathrm{d}G = V\,\mathrm{d}p \qquad \text{at constant } T \ .$$

The change in the Gibbs energy of pure condensed phases as a result of changes in pressure is often negligible in comparison with that resulting from changes in temperature and from chemical reactions.

In the case of iron at 298.15 K the change in Gibbs energy on increasing the pressure from 1 to 101 bar is

$$\Delta G = V\Delta p = 7.1\times10^{-6}\times10^{7} = 71\ \mathrm{J\ mol^{-1}} \ .$$

This is much less than the change in G resulting from a temperature increase of 5 K.

Hence, in many cases involving condensed phases, it can be taken that

$$(\partial G/\partial p)_\mathrm{T} = 0 \ .$$

However, this does not apply to geophysical processes where account has to be taken of the very high pressures involved. The equation $\mathrm{d}G = V\,\mathrm{d}p$ must be integrated in such cases.

The Gibbs energy of pure substances is reported for a standard state, i.e. at 1 bar; by definition such values (G^0 values) are not dependent on pressure.

1.6.3 Natural changes and equilibrium state in a closed system

According to the Second Law and the Clausius inequality in particular (see Section 1.4.2) it follows for a closed system of constant composition, which can exchange heat with its surroundings at constant temperature, that

$$\mathrm{d}S - \mathrm{d}Q/T \geq 0 \quad (T = T_\mathrm{sys})$$

$$\mathrm{d}S - \mathrm{d}U/T \geq 0 \quad \text{at constant } V,\ T$$

$$\mathrm{d}S - \mathrm{d}H/T \geq 0 \quad \text{at constant } p,\ T \ .$$

If the only work allowed is that occurring on volume change then

$$T\,\mathrm{d}S \geq \mathrm{d}U \quad \text{at constant } V$$

$$T\,\mathrm{d}S \geq \mathrm{d}H \quad \text{at constant } p$$

$$(\mathrm{d}S)_{\mathrm{U,V}} \geq 0 \qquad (\mathrm{d}S)_{\mathrm{H,p}} \geq 0$$

$$(\mathrm{d}U)_{\mathrm{S,V}} \leq 0 \qquad (\mathrm{d}H)_{\mathrm{S,p}} \leq 0$$

$$(\mathrm{d}A)_{\mathrm{T,V}} \leq 0 \qquad (\mathrm{d}G)_{\mathrm{T,p}} \leq 0 \ .$$

These relations express the **direction of natural changes** of closed systems in terms of inequalities.

The **equilibrium state** is characterized by the corresponding equality.

On derivation of general equilibrium criteria the concept of *virtual variation* of state functions of an isolated system is applied. Here, virtual shifts from the equilibrium to the neighboring non-equilibrium states are imagined (which represent impossible changes).

The analysis of such variations leads finally to

$$\delta S_{U,V} = 0 \ ,$$

$$\delta G_{T,p} = 0 \ .$$

In the state of equilibrium the entropy of the system reaches a maximum

$$S(U, V) \rightarrow \text{maximum}$$

and the Gibbs energy a minimum

$$G(T,p) \rightarrow \text{minimum} \ .$$

1.6.4 Characteristic functions

Summarizing the characteristic (extensive energetic) functions of state and their differentials for a closed homogeneous system of constant composition involving only expansion work, yields the following list:

$U(S, V)$	$dU = dQ_{rev} - p\,dV$
	$dU = T\,dS - p\,dV$
$H(S,p)$	$dH = T\,dS + V\,dp$
$A(T, V)$	$dA = -S\,dT - p\,dV$
$G(T,p)$	$dG = -S\,dT + V\,dp$.

The following **Maxwell equations** are derived from these

$$(\partial T/\partial V)_S = -(\partial p/\partial S)_V$$

$$(\partial T/\partial p)_S = (\partial V/\partial S)_p$$

$$(\partial p/\partial T)_V = (\partial S/\partial V)_T$$

$$(\partial V/\partial T)_p = -(\partial S/\partial p)_T \ .$$

These relations allow the representation of the change of some properties as functions of readily determinable quantities. Use is made of this in deriving the temperature dependence of U and H (see Section 1.2.6). $(\partial U/\partial V)_T$ is found to be $[-p + T(\partial p/\partial T)_V]$ with the aid of Maxwell's 3rd equation.

1.7 Closed system with reactions

1.7.1 Reaction equation and conventions

In a closed system the reactions that take place can be represented by

$$\nu_{R1} R_1 + \nu_{R2} R_2 + \ldots \rightarrow \nu_{P1} P_1 + \nu_{P2} P_2 + \ldots$$

where ν_i is the stoichiometric coefficient of i and R_i and P_i denote the reactants and products respectively.

According to the convention

$\nu_i < 0$ for reactants

$\nu_i > 0$ for products

$\Sigma \nu_i$ being the change in number of moles on reaction.

In the case of closed homogeneous system the following relations apply to changes in amount of reaction component

$$n_i / n_j = \nu_i / \nu_j$$

$$dn_i / \nu_i = dn_j / \nu_j = d\xi$$

whereby ξ is the extent (progress variable) of a chemical reaction. $d\xi = 1$ mol corresponds to a complete reaction where ν_i mol of i have reacted. ξ is a state variable of the closed homogeneous system.

In the case of a closed system where the reaction components κ_1, κ_2... may be contained in different phases φ_1, φ_2... the following relation applies

$$\frac{1}{\nu_{\kappa_i}} \sum_j dn_{\kappa_i(\varphi_j)} = d\xi \ .$$

Here ν_{κ_i} is the stoichiometric coefficient of the component κ_i and $n_{\kappa_i(\varphi_j)}$ the mole number of κ_i in the phase φ_j.

The amount of "inert" components (e.g. noble gases) that do not take part on reaction remains the same,

$$\sum_j dn_{\kappa_i(\varphi_j)} = 0 \ .$$

The relation

$$(\partial H/\partial \xi)_{T,p} = |\,đQ/d\xi\,|_{T,p}$$

corresponds to the heat exchanged with the surroundings for a complete reaction at constant temperature and constant pressure. In a phase change it is known as the "enthalpy of transition" and in a chemical reaction as the "enthalpy of reaction".

Futhermore, the Gibbs energy of reaction is defined by

$$(\partial G/\partial \xi)_{T,p} = \Delta G_r \ .$$

With

$$\partial / \partial \xi = \Delta$$

the following definition applies to the change in the quantity Z during a reaction

$$\Delta Z = \Sigma \nu_i Z_i$$

1.7.2 Reaction quantities

$\Delta n_r = \Sigma \nu_i$ change in total moles during reaction

$\Delta V_r = \Sigma \nu_i V_i$ reaction volume

$\Delta C_{Vr} = \Sigma \nu_i C_{Vi}$ reaction heat capacity at const. V

$\Delta C_{pr} = \Sigma \nu_i C_{pi}$ reaction heat capacity at const. p

$\Delta U_r = \Sigma \nu_i U_i$ energy of reaction

$\Delta H_r = \Sigma \nu_i H_i$ enthalpy of reaction

$\Delta H_r < 0$ exothermic reaction

$\Delta H_r > 0$ endothermic reaction

$\Delta S_r = \Sigma \nu_i S_i$ entropy of reaction

$\Delta A_r = \Sigma \nu_i A_i$ Helmholtz energy of reaction

$\Delta G_r = \Sigma \nu_i G_i$ Gibbs energy of reaction

Relations between ΔU_r and ΔH_r

With $H = U + pV$ then

$$\Delta H_r = \Delta U_r + p \Delta V_r \ .$$

For reactions between **ideal gases** where

$$p \Delta V = \Delta n R T \quad \text{and} \quad \Delta n = \Sigma \nu_i$$

then

$$\Delta H_r = \Delta U_r + \Delta V_r R T \ .$$

In the case of reactions between **pure condensed phases,**

$$\Delta V_r \approx 0$$

$$\Delta H_r \approx \Delta U_r \ .$$

When gaseous and condensed phases are both involved in a reaction, if the ideal gas equation is employed and the volume changes in the condensed phases are neglected, then

$$\Delta H_r = \Delta U_r + R T \Delta n_{gas} \ .$$

This equation is important for the **calorimetric determination of enthalpy changes,** since calorimeters are generally equipped with rigid walls and measurement therefore leads initially to changes in internal energy. Correction with the above equation then allows ΔH to be calculated from the ΔU that is actually determined.

Relations for ΔG_r

From $G = H - TS$ it follows that for reactions

$$\Delta G_r(T) = \Delta H_r(T) - T \Delta S_r(T) \ .$$

For reactions between substances which do not undergo phase transitions over a particular temperature range, ΔC_{pr} is usually small, so that the following approximation applies in such cases

$$\Delta G_r(T) \approx \Delta H_r(T_0) - T \Delta S_r(T_0)$$

(Ulich's approximation) .

As reported before (Section 1.6.1), the maximum non-p, V work that a reaction system can perform at constant p and T is given by $-\Delta G_r$.

1.7.3 Enthalpy and entropy of transition, Clausius-Clapeyron equation

Enthalpy of transition

For an isothermal isobaric change in state of a closed pure substance

$$\Delta H_t = (\partial H / \partial \xi)_{p,Tt} = |dQ / d\xi|_{p,Tt} \ .$$

T_t is the transition temperature. As defined before, ΔH_t is the enthalpy difference between the final and initial states (phases).

Entropy of transition

With

$$\Delta S = Q / T = \Delta H / T \quad \text{at constant } p, T$$

it follows that

$$\Delta S_t = (\partial S / \partial \xi)_{p,T} = \Delta H_t / T_t \ .$$

Gibbs energy of transition

$$\Delta G_t = \Delta H_t - T_t \Delta S_t = 0$$

corresponding to the equilibrium state at

$$T = T_t \ .$$

Clausius-Clapeyron equation

Transformation with

$$(\partial \Delta G_t / \partial p)_{T_t} = -\Delta S_t$$

leads to the Clausius-Clapeyron equation for the first-order transition

$$(dT/dp) = (\Delta V_t / \Delta S_t) = (\Delta V_t / \Delta H_t)\, T_t \ .$$

First order transition:

$$\Delta H_t = \Delta S_t\, T_t \neq 0 \ ,$$

$$dC_p / dT \rightarrow \pm \infty \ .$$

Second order transition:

$$\Delta H_t = 0 \ , \quad \Delta S_t = 0 \ ;$$

C_p is discontinuous.

Lambda transition:

$$\Delta H_t = 0 \ , \quad \Delta S_t = 0 \ ;$$

course of $C_p(T)$ in λ form (see Fig. 21).

1.8 Chemical potential

1.8.1 Open systems

The closed system can exchange heat and work performance with its surroundings. The open system can, in addition, exchange matter with its surroundings. The Gibbs energy of the open homogeneous system is described by

$$G = G(T, p, n_1, n_2 \ldots)$$

where $n_1, n_2 \ldots$ are the numbers of moles of the chemical components of the system.
The total differential of G yields

$$dG = (\partial G/\partial p)_{T, n_i} dp + (\partial G/\partial T)_{p, n_i} dT + \Sigma (\partial G/\partial n_i)_{p, T, n_{j \neq i}} dn_i \ .$$

The first two differential coefficients express the change in Gibbs energy with T and p at constant composition as reported in Sections 1.6.2 and 1.6.4. After inserting these relations the change in G is described by

$$dG = V\, dp - S\, dT + \Sigma (\partial G/\partial n_i)_{p, T, n_{j \neq i}} dn_i \ .$$

The last term of this equation summarizes the changes in Gibbs energy resulting from the change of composition of the open homogeneous system at constant T, p.

1.8.2 Definition of the chemical potential, Gibbs fundamental equation

The chemical potential for an open homogeneous system is defined by

$$\mu_i = (\partial G/\partial n_i)_{p, T, n_{j \neq i}} \ .$$

Thus the chemical potential corresponds to the change in Gibbs energy of a homogeneous multicomponent system on the introduction of an infinitesimal amount of a component into the mixture at constant p, T and constant amounts of the other components.

For a **pure substance** (consisting of a pure single phase) μ_i represents the **molar Gibbs energy** of the substance i and is denoted as μ_i^0.

Substitution of μ_i into the total differential of G produces the **Gibbs fundamental equation**

$$dG = V\, dp - S\, dT + \Sigma \mu_i\, dn_i \ .$$

1.8.3 Standard state for chemical potential, definition of activity

The chemical potential is divided into a standard and a relative potential according to the following definition:

$$\mu_i = \mu_i^0 + R\, T\, \ln a_i \ .$$

μ_i^0 is the standard chemical potential. This is the value of μ at a given temperature T and standard pressure p^0. a_i is the activity of i and is defined by

$$a_i = p_i / p_i^0 \ .$$

The standard state is so chosen that

$$\mu_i = \mu_i^0 \quad \text{at} \quad a_i = 1 \ .$$

In general:

$$p^0 = 1 \text{ bar} \quad \text{for gases}$$

$$a = 1 \quad \text{for pure condensed phases.}$$

Note:

For the equilibrium between a homogeneous condensed mixture and a gas phase, in the equation

$a_i = p_i / p_i^0$, p_i is the vapor pressure of the component at the same temperature in the pure state.

1.9 Chemical equilibrium

1.9.1 Gibbs fundamental equation for closed systems

As a consequence of the conservation of the mass of the elements, the following holds for a closed system with several components in which a chemical reaction is taking place:

$$dn_i = \nu_i \, d\xi$$

and when $d\xi = 1$ mol,
then $dn_i = \nu_i$.

The Gibbs fundamental equation, therefore, takes the following form for the closed system

$$dG = V\,dp - S\,dT + \Sigma \nu_i \mu_i \ .$$

1.9.2 Conditions for chemical equilibrium

The Gibbs energy of the reaction system reaches a minimum for the equilibrium at costant p and T, i.e.

$$\Delta G_r = (\partial G / \partial \xi)_{p,T} = 0 \ .$$

The slope of the Gibbs energy with respect to ξ represents the Gibbs energy of reaction. It is zero as the reaction system approaches the equilibrium composition at constant p and T. This relation is used as the calculation basis for determining equilibria, especially for complex systems consisting of a large number of components and phases.

In accordance with the above relation the equilibrium state is, furthermore, characterized by

$$dG_{T,P} = 0$$

$$\Sigma \nu_i \mu_i = 0 \ .$$

This equilibrium equation is also a general formulation of the **law of mass action**. It follows from this that at equilibrium the chemical potential of a particular component is the same in all phases of the system.

1.9.3 Equilibrium constant

The equilibrium relation

$$\Sigma \nu_i \mu_i = 0$$

and the separation of the chemical potential into a standard and a relative potential as shown

$$\mu_i = \mu_i^0 + R\,T \ln a_i$$

yields the following relations and definitions:

$$\Sigma \nu_i \mu_i = \Sigma \nu_i \mu_i^0 + \Sigma \nu_i R\,T \ln a_i = 0 \ ,$$

$$\Delta G_r^0 = \Sigma \nu_i \mu_i^0 \ ,$$

(standard Gibbs energy of reaction)

$$K = \Pi (a_i)^{\nu i} \ ,$$

(equilibrium constant)

$$\Delta G_r^0 = -R\,T \ln K \ .$$

The activity product of reaction components at specified concentrations which may exist, for example, at the beginning of a reaction

$$K' = \Pi (a_i')^{\nu i}$$

is called the **reaction quotient**. The same standard state is applied to a_i' as to a_i. At equilibrium

$$K' = K = \exp(-\Delta G_r^0 / R\,T) \ .$$

Temperature dependence of K

With $\Delta G_r^0 = \Delta H_r^0 - T\,\Delta S_r^0$ follows:

$$\partial (\Delta G_r^0 / T) / \partial T = -\Delta H_r^0 / T^2 \ ,$$

(Gibbs-Helmholtz equation)

$$d(\ln K)/dT \quad = \Delta H_r^0 / R\,T^2 \ ,$$

$$d(\ln K)/d(1/T) = -\Delta H_r^0 / R \ .$$

(van't Hoff isochore)

These relations, particularly the later, are used to determine the enthalpy of reaction from the values of K obtained at various temperatures.

Limiting cases:

At low temperatures the influence of reaction entropy is small:

$$\Delta G_r^0 \approx H_r^0 \ .$$

At high temperatures the influence of reaction entropy dominates:

$$\Delta G_r^0 \approx -T\,\Delta S_r^0 \ .$$

Pressure dependence of K

The standard Gibbs energy of reaction is defined with respect to a standard pressure (1 bar). Therefore, K is

dependent only on temperature and is independent of pressure

$$\partial K/\partial p = 0 \ .$$

In a reaction system a change in the pressure alters the system according to **the principle of Le Châtelier**, however the equilibrium constant remains the same.

1.10 Mixtures

1.10.1 Gibbs-Duhem equation

For a mixture, G is a homogeneous function of first degree in n_i,

$$G(p, T, \lambda n_i) = \lambda G(p, T, n_i) \ .$$

Euler's theorem for homogeneous equations yields

$$G = \Sigma \mu_i n_i$$

whereby

$$\mu_i = (\partial G/\partial n_i)_{p, T, n_{j \neq i}} \ .$$

This then yields

$$dG = \Sigma n_i \, d\mu_i + \Sigma \mu_i \, dn_i \ .$$

Comparison with

$$dG = V \, dp - S \, dT + \Sigma \mu_i \, dn_i$$

yields

$$V \, dp - S \, dT + \Sigma n_i \, d\mu_i = 0$$

(Gibbs-Duhem equation).

$$\Sigma n_i \, d\mu_i = 0 \quad \text{for constant } p, \ T$$

after division by Σn_i

$$\Sigma x_i \, d\mu_i = 0 \quad \text{for constant } p, \ T \ .$$

1.10.2 Standard states for activities and activity coefficients

The activity a of component i in a mixture is defined by

$$\mu_i = \mu_i^0 + R \, T \ln a_i$$

with

$$a_i = \gamma_i x_i = p_i / p_i^0$$

where μ_i^0 is the chemical potential of component i when this is in its standard state (i.e. for $a_i = 1$), γ_i is the defined activity coefficient and x_i is the mole fraction of i in the mixture as defined in Section 1.1.5. p_i and p_i^0 are the vapor pressures of i in the mixture and in the standard state respectively.

Depending on the problem the following **standard states for activity** are used:

- pure substance

$$\mu_i = \mu_i^0 + R \, T \ln a_i$$

$$a_i = \gamma_i x_i$$

$$\gamma_i \rightarrow 1 \quad \text{as} \quad x_i \rightarrow 1 \ .$$

For **ideal solutions**

$$a_i = x_i$$

$$\gamma_i = 1 \ .$$

Raoult's Law:

$$p_i = x_i \, p_i^0 \ .$$

- hypothetical pure solute with properties as at infinite dilution (obeying Henry's Law)

$$\mu_i = \mu_i' + R \, T \ln a_i'$$

$$a_i' = \gamma_i' x_i$$

$$\gamma_i' \rightarrow 1 \quad \text{as} \quad x_i \rightarrow 0 \ .$$

Ideal dilute solutions

$$\gamma = \gamma_H \quad \text{at} \quad x_i \rightarrow 0$$

$$a_i(H) = \gamma_H x_i \ .$$

Henry's Law:

$$p_i = K_H x_i$$

where K_H is a constant.

The molality m or percentage by weight (%) can be used instead of the mole fraction x.

$$\mu_i = \mu_i'' + R \, T \ln a_i''$$

$$a_i'' = \gamma_i'' (m/m_0) \ ; \quad m_0 = 1 \text{ mol/kg}$$

$$\gamma'' \rightarrow 1 \quad \text{as} \quad m \rightarrow 0 \ .$$

$$\mu_i = \mu_i''' + R \, T \ln a_i'''$$

$$a_i''' = \gamma_i''' \ (\%\ \text{i})$$

$$\gamma_i''' \rightarrow 1 \quad \text{as} \quad \%\ \text{i} \rightarrow 0 \ .$$

1.11 Gibbs phase rule

The phase rule answers the question as to the maximum number of phases which can co-exist in equilibrium in a system with a prescribed number of components. The variance (degrees of freedom) of the system is given by

$f = c+2-p$

f = number of degrees of freedom (variance)

c = number of independent components

p = number of phases

According to Gibbs the term "phase" means a state of matter that is uniform throughout, not only in chemical composition but also in the physical state.

The number of independent components c is the minimum number of independent species necessary to define the composition of all the phases present in the system. Correspondingly c is determined by the number of elements contained in the system and by their chemical interactions. However, under certain conditions these interactions cannot be properly effective. Thus, for example, the elements of a compound which are completely dissociated at high temperatures behave like inert species.

Examples:

- pure substance

  $f = 1+2-1 = 2$,

  (bivariant system)

  i.e. 2 independently chosen variables of state, for example, p and T (bivariant system).

- pure substance in 2-phase equilibrium: solid–liquid or liquid–gas

  $f = 1-2-2 = 1$, e.g. $p = f(T)$.

  (monovariant system)

- pure substance in 3 phases: solid–liquid–gas,

  $f = 1-2-3 = 0$,

  (invariant system)

  the triple point in the $p-T$ diagram at which e.g. ice, liquid water and water vapour coexist.

- 3-phase equilibrium

  $Fe_3O_4 - FeO - Fe$

  $4\,FeO = Fe_3O_4 + Fe$

  $p = 3$: Fe_3O_4, FeO, Fe

  $c = 2$: Fe, FeO or Fe, Fe_3O_4 or FeO, Fe_3O_4

  $f = 2+2-3 = 1$: T or p

  (pressure on the system) .

- NH_4Cl dissociation

  NH_4Cl (solid) = NH_3 (gas) + HCl (gas)

  $p = 2$: solid (NH_4Cl), gas

  $c = 1$: both phases are defined by NH_4Cl

  $f = 1+2-2 = 1$ e.g. T or p_{HCl} .

- ZnS dissociation

  ZnS (solid) = Zn (gas) + $1/2\,S_2$ (gas)

  $p = 2$: ZnS (solid), gas

  $c = 1$: ZnS

  $f = 1+2-2 = 1$: T or p_{Zn} .

- $ZnCO_3$ decomposition

  $ZnCO_3$ (solid) = ZnO (solid) + CO_2 (gas)

  $p = 3$: $ZnCO_3$ (solid), ZnO (solid), gas

  $c = 2$: $ZnCO_3$, CO_2 or ZnO, CO_2

  $f = 2+2-3 = 1$: T or p_{CO} .

- Equilibrium system

  ZnO (solid), Zn (gas), CO (gas), CO_2 (gas)

  ZnO (solid) + CO = Zn + CO_2

  $p = 2$: ZnO (solid), gas

  $c = 3$: ZnO, CO, Zn or CO, CO_2, Zn

  $f = 3+2-2 = 3$: e.g. p_{CO}, p_{CO_2}, p_{Zn} or T, p_{CO}, p_{CO_2} .

1.12 Electrochemical reactions

1.12.1 Electrochemical work

The infinitesimal electrical work dW_{el} performed on the transfer of the charge dq into a phase at the Galvani potential ϕ is described by (Section 1.2.1)

$$đW_{el} = \phi \, dq \ .$$

On transfer of dN_e electrons with the charge $-e$

$$dq = -e \, dN_e \ ,$$

and in the case of dn_e mol electrons

$$dq = -N_A e \, dn_e$$

where N_A is Avogadro's constant. With

$$N_A e = F \ \textbf{(Faraday constant)}$$

the following equations apply:

$$dq = -F \, dn_e$$

$$đW_{el} = -F\phi \, dn_e \ .$$

In the case of transfer of dn_i moles of an ion i with the charge number z_i

$$đW_{el} = -z_i F\phi \, dn_i \ .$$

As described in Sections 1.6.1 and 1.7.1 the *maximum electrical work* done on or by a closed system of constant composition is given by

$$đW_{el} = dG_{p,T} = \Delta G_r \, d\xi$$

where $d\xi$ is the infinitesimal extent of reaction accompanying transfer of a charged species (at zero current).
After inserting

$$dn_i = \nu_i \, d\xi$$

into the last two equations for dW_{el}, the following relation is obtained

$$\Delta G_r = -\nu_i z_i F\phi$$

and after relating to 1 mol i by dividing by ν_i

$$\Delta G_r(\text{mol}) = -z_i F\phi \ .$$

This is the maximum electrical work performed by transfer of 1 mole of i.

1.12.2 Electrochemical potential

The change in Gibbs energy of an open system on transfer of a charged or uncharged species i into the phase at the galvani potential ϕ is defined as follows

$$(\partial G / \partial n_i)_{p,T,n_{j \neq i}} = \eta_i$$

where η_i is the **electrochemical potential.**
η is represented by

$$\eta_i = \mu_i + z_i F\phi \ .$$

Where μ_i is the chemical potential as defined in Section 1.8.2. This equation applies to both charged and neutral species.

For neutral species

$$z_i = 0$$

$$\eta_i = \mu_i \ .$$

The work done by transfer of a charged component i from phase α into phase β is given by

$$\Delta\eta = \Delta\mu_i + z_i F \Delta\phi$$

where

$$\Delta\phi = \phi_\beta - \phi_\alpha \ .$$

1.12.3 Electrochemical equilibrium

At the equilibrium state, the electrochemical potentials of the transferable charged species are the same in both phases

$$\eta_i(\alpha) = \eta_i(\beta) \ .$$

Hence, it follows that

$$\Delta\mu_i = -z_i F \Delta\phi$$

Galvani potential difference

With

$$\mu_i = \mu_i^0 + RT \ln a_i \quad \text{and}$$
$$\Delta\mu_i = \mu_i(\beta) - \mu_i(\alpha)$$

it follows from the equilibrium equation that

$$\Delta\phi = \phi_\beta - \phi_\alpha$$
$$= -\Delta\mu_i^0 / (z_i F) - (RT / z_i F) \ln [a_i(\beta) / a_i(\alpha)] \ .$$

$\Delta\phi$ is the difference between the electric potentials of two phases and is known as the **Galvani potential difference.** It is not possible to determine its value and, in the case of aqueous ionic solutions, it is measured with respect to the standard hydrogen electrode with $\Delta\phi = 0$.

In the case of ions at unit activity the Galvani potential difference is given by

$$\Delta\phi^0 = -\Delta\mu_i^0 / (z_i F)$$

(standard potential difference)

emf

The combination of electrode compartments into an electrochemical cell makes it possible to measure the series of the Galvani potential differences as the **electromotive force (emf)** of the cell.

Cell reactions

Electrochemical cells are classified into different types depending on the construction and substances employed. For example, a simple electrochemical cell is a galvanic cell consisting of two electrodes dipping into an electrolyte.

The maximum electrical work which a cell can supply is given by

$$\Delta G = -zF\,\mathrm{E}\ .$$

Here ΔG is the Gibbs energy of the cell reaction, z the number of charges transferred per formula unit, F Faraday's constant and E the electromotive force (emf) of the cell.

Convention:

$\mathrm{E} > 0$ when $\Delta G < 0$

(spontaneous process) .

In equilibrium

$$\Delta G^0 = -zF\,\mathrm{E}^0 = -RT\ln K$$

where ΔG^0 is the standard Gibbs energy and E^0 the **standard emf** of the cell reaction.

ΔG^0 is defined for standard pressure (1 bar), therefore, E^0 depends only on temperature.

With

$$\Delta G = \Delta G^0 + RT\ln\Pi(a_i)^{\nu_i}\ ,$$

$$\mathrm{E} = \mathrm{E}^0 - RT/(zF)\ln\Pi(a_i)^{\nu_i}$$

(Nernst equation)

where E is the cell potential at zero current for all concentrations of activities of the species reacting at constant p and T. Here a_i is the activity and ν_i the stoichiometric coefficient of the species i at a specified concentration. $\Pi(a_i)^{\nu_i}$ is the reaction coefficient K' introduced in Section 1.9.3.

At equilibrium the product $\Pi(a_i)^{\nu_i}$ is identical to the equilibrium constant K of the cell reaction and with

$$\mathrm{E}^0 = (RT/zF)\ln K$$

$$\mathrm{E} = 0\ .$$

2 Calculation of thermochemical functions

2.1 Units and conventions (see Sections 10.1–10.3)

Units

As recommended by international organizations such as IUPAC (International Union of Pure and Applied Chemistry) and CODATA (The Committee on Data for Science and Technology) the thermodynamic quantities are to be given in the "System of International Units" (SI units).

Temperature	K
Pressure	Pa, MPa or bar
Molar volume	$l\,mol^{-1}$ or $dm^3\,mol^{-1}$
Energy (H, G, U, A)	$J\,mol^{-1}$ or $kJ\,mol^{-1}$
Heat capacity (C_V, C_p)	$J\,K^{-1}\,mol^{-1}$
Entropy (S)	$J\,K^{-1}\,mol^{-1}$

Conventions

The **standard state** of a substance is its pure form in internal equilibrium under a pressure of 1 bar and at a given temperature.

The standard states of elements are denoted as **reference phases.** (See Section 4.5 and Chapter 10).

Standard state pressure = 1 bar
Reference temperature = 298.15 K.

2.2 Calculation of the thermochemical functions of pure substances

The calculations described below apply to the thermochemical functions of pure substances in their standard states. The superscript (^{0}) is used only to indicate standard states where special clarity in differentiation is required.

2.2.1 $C_p(T)$, heat capacity

The temperature function of the heat capacity ($C_p(T)$) belongs to the category of basic thermochemical data. These must be known to describe quantitatively the thermochemical properties of a substance in the form of temperature functions.

The values of the temperature functions of enthalpy H, entropy S and Gibb's energy G at standard state pressure are determined by integration using $C_p(T)$.

The heat capacities of condensed phases are usually determined by calorimetric measurements, and of gases by calculation methods of statistical mechanics using molecular constants.

In this work the temperature functions of the heat capacities have been:

- taken from standard works or calculated from known C_p values by polynomial approximation
- estimated on the basis of empirical rules using individual values given for a specified temperature which is usually the reference temperature (298.15 K). For a few substances $C_p(T)$ is estimated using data of "similar" substances, when all property data except the heat capacity are known.

The molar heat capacities of pure substances can be described with sufficient accuracy over a relatively wide range of temperature by means of the following polynomial.

$$C_p(T) = a + bT + cT^2 + dT^3 + eT^{-2} + fT^{-3} \quad .$$

For many **gases** it is not necessary to employ all the terms of the polynomial, particularly if the temperature range is not very wide. C_p is usually constant in the case of **liquids.** For **crystalline phases** the temperature dependence of C_p is not adequately described by a rigorous mathematical approximation. This is particularly true in the vicinity of λ-transition points. In such cases it is necessary to achieve the required accuracy of approximation by limiting the temperature range sharply. Figure 2.1 illustrates two examples of the change of C_p as a function of temperature.

Note

In this book the values of C_p are given at the temperature of 298.15 K, at intervals of 100 K starting at 300 K, and also at the transition temperatures. The polynomial coefficients of $C_p(T)$ have not been given.

The polynomial coefficients of $C_p(T)$ are obtained from numerical evaluations to the best possible approximation, and in many cases have no physical meaning. For certain substance phases several polynomials with up to 6 coefficients are necessary, which would require the use of up to 10 characters to present as figures. **All basic thermochemical values including alpha-numerical information are stored in databases. For personal use only, they can be requested from the publisher or the author.** These data are also included in the thermodynamic software system equiTherm*), which is a very useful supplement to this book.

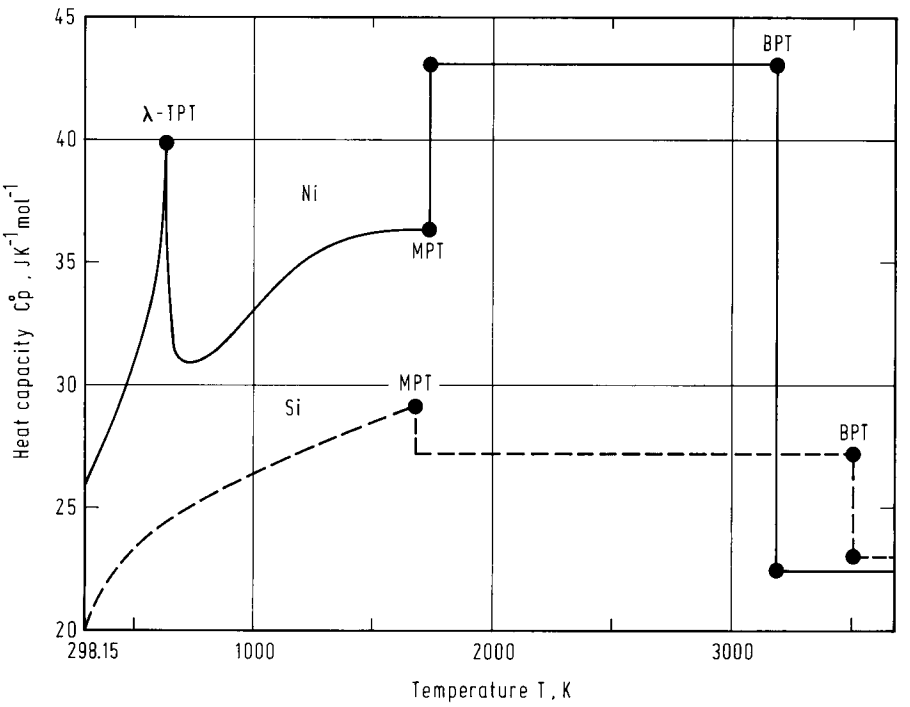

Fig. 2.1: Heat capacities of Ni and Si at 1 bar as functions of temperature. λ-TPT = lambda transition point, MPT = melting point, BPT = boiling point.

2.2.2 $H(T)$, enthalpy

The enthalpy of a pure substance is completely described by the independent internal state variables T and p. The state function $H(T)$ at constant p is determined apart from an additive constant which remains undeterminate and can be chosen arbitrarily. In other words, the absolute value of the enthalpy of any system can not be determined. It is, e.g., possible to measure the change in enthalpy of substances using a calorimeter, where

$$\Delta H = Q \quad \text{at } p = \text{constant} \ .$$

Therefore, enthalpy has sometimes been called the "heat content" and the enthalpy increment

$$H(T) - H(298.15)$$

"sensible heat".

Starting from Hess' Law the concept of the formation reaction is employed for the numerical determination of enthalpy changes. In general the reaction for the formation of a pure substance B from its element is

$$\nu_1 \varepsilon_1 + \nu_2 \varepsilon_2 + \ldots = \mathrm{B}$$

where ε_i are the elements in the compound B and ν_1 are the stoichiometric coefficients.

The standard enthalpy of the formation (previously known as the heat of formation) of B at $p = 1$ bar is defined by

$$\Delta H^0_{\mathrm{f,B}}(T) = H^0_{\mathrm{B}}(T) - \Sigma \nu_{\varepsilon_i} H^0_{\varepsilon_i}(T) \ .$$

$H^0_{\varepsilon_i}(T)$ is the standard enthalpy of the element i in its reference phase at a specified temperature T and a pressure of 1 bar.

In this work the following convention is employed: the standard enthalpies of elements in their reference phases at $p = 1$ bar and $T = 298.15$ K are set to Zero,

$$H^0_{\varepsilon_i} = 0 \quad \text{at } p = 1 \text{ bar and } T = 298.15 \text{ K} \ .$$

This is an extension of the commonly used convention:

The standard enthalpies of formation of elements in their reference phases are zero at all temperatures.

For the "null" reaction

$$\varepsilon_i = \varepsilon_i$$

$$\Delta H^0_{\mathrm{f},\varepsilon_i}(T) = H^0_{\varepsilon_i}(T) - H^0_{\varepsilon_i}(T) = 0 \ .$$

The convention employed here is a standardization enabling the efficient description of enthalpy changes in technical processes.

The following **comment on the convention** adopted in this work was made **by C. Wagner***):

"In my lectures I have explicitly emphasized that only energy differences and enthalpy differences can be

*) Carl Wagner, private communication, Letter to the author dated 7th December 1977, Göttingen.

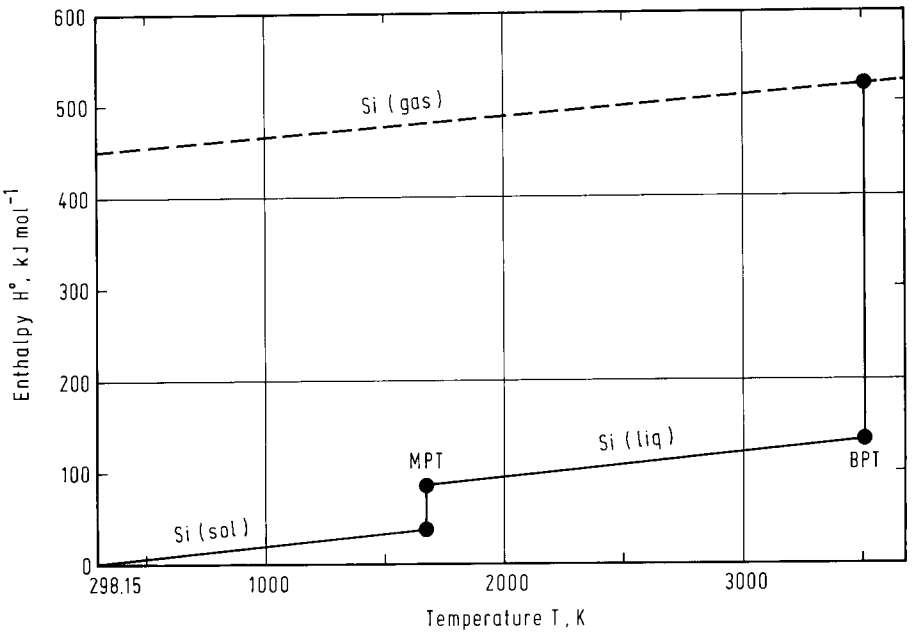

Fig. 2.2: Enthalpy of solide, liquid and gaseous silicon as a function of temperature at 1 bar.

measured – similar to the situation in geodesy where only altitudes can be measured. In accordance with this, the values for $H^0(T) - H^0(298.15\ \mathrm{K})$ are cited in many works. In my lectures I have, however, also stated that the convention of average sea level altitude = 0 (altitude per se) has been introduced in geodesy too.

An analogous approach can be taken in thermodynamics, but various conventions exist. The convention you have chosen (the enthalpies of the elements in their most stable state at 1 bar and 298.15 K are zero) seems reasonable to me. However caution must be exercised when data from your tables are compared with those from other sources".

The reference phase of the elements at 298.15 K and other temperatures are listed in Chapter 10. The reference phase of an element is, in general, its most stable form at the temperature under consideration.

There is one conventionally accepted exception in the tables given in Chapter 10:

"white phosphorus" is taken to be the reference phase of phosphorus at 298.15 K and 1 bar because this allotrope is more common (reproducible) than the most stable form which is "red phosphorus". In the compilation of Pankratz, Stuve and Gökcen (see Chapter 11, Reference Pa3), S_2 (ideal gas) is taken as the standard state of reference instead of S (rhombic) which is the most stable form at 298.15 K and 1 bar. **In use of enthalpy data from different sources attention must given to the standard states of reference.**

The convention employed in this work leads to the following relation for the formation reaction given above

$$H_B^0(298.15) = \Delta H_{f,B}^0(298.15)\ .$$

This and the equations from Sections 1.2.5, 1.2.6 and 1.7.3 yield the following equation for the calculation of the enthalpy of a pure substance with reference to the standard state (the superscript ° is omitted).

$$H(T) = H(298.15) + \int_{298.15}^{T_{t1}} C_{p1}(T)\mathrm{d}T + \Delta H_{t1} + \int_{T_{t1}}^{T_{t2}} C_{p2}(T)\mathrm{d}T + \Delta H_{t2} + \ldots$$

With this the enthalpy increment $[H(T)-H(298.15)]$ can also be calculated. Here $H(298.15)$ is the enthalpy of formation of the pure substance at 1 bar and 298.15 K, $C_p(T)$ the temperature function of the heat capacity in the integration range involved, ΔH_{ti} the enthalpy of phase transition i at $T = T_{ti}$.

Figure 2.2 illustrates the change of enthalpy of silicon with temperature. In the case of a first order transition there is a discontinuity in the course of enthalpy. At this point C_p is infinite (see Section 1.7.3).

The enthalpy function $H(T)$ employed in this work is particularly suitable for the calculation of enthalpy changes in technical processes. More calculation is involved if $[H(T)-H(298.15)](T)$ in combination with $\Delta H_f(T)$ is employed for the same purpose. The latter enthalpy values are listed alone in many other tabular compilations.

The functions $C_V(T)$ and $U(T)$ can be calculated with the aid of the relations given in Sections 1.2.5, 1.2.6 and 1.7.3. The properties of substances required for this, such as α and κ, must be reported separately.

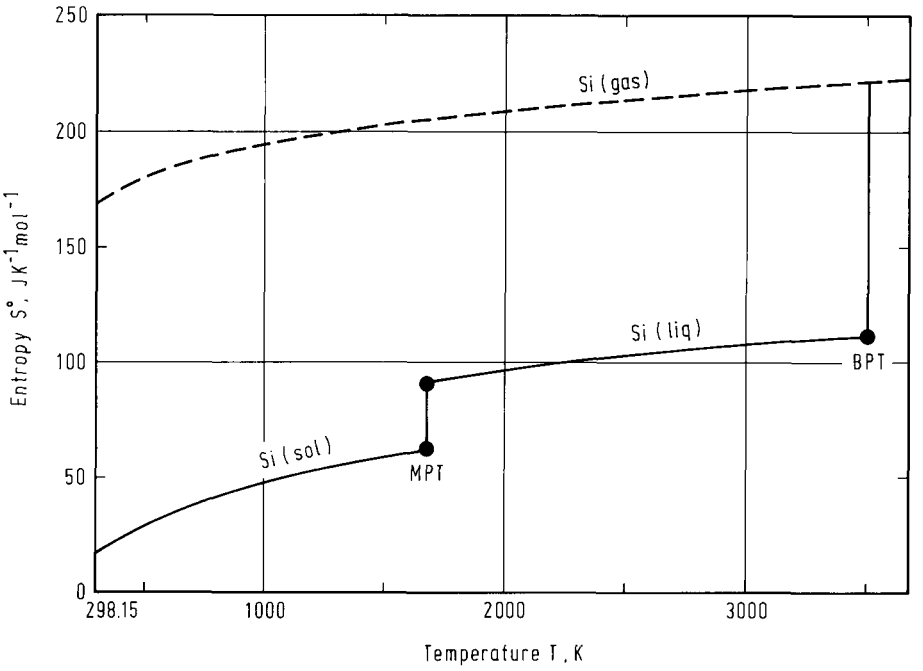

Fig. 2.3: Entropy of solid, liquid and gaseous silicon as a function of temperature at 1 bar.

Standard works (e.g. JANAF Thermochemical Tables) should be referred to for the values of $H(T)$ and $C_p(T)$ below room temperature and particularly in the region of absolute zero.

2.2.3 $S(T)$, entropy

The equations given in Sections 1.4.3, 1.5 and 1.7.3 yield the following relation for the calculation of the entropy function

$$S(T) = S(298.15) + \int_{298.15}^{T_{t1}} \frac{C_{p1}(T)}{T}\,dT + \frac{\Delta H_{t1}}{T_{t1}} + \ldots$$

$S(298.15)$ is the standard entropy of the pure substance at 298.15 K. The change of the entropy of silicon with temperature is illustrated in Fig. 2.3. As can be seen, the increase in entropy on evaporation is appreciably greater than it is on melting. This is because $k \ln \Omega$ (see Section 1.5) is appreciably greater for gases than for condensed phases.

The definition of standard entropy at 298.15 K ($S(298.15)$) follows from the considerations discussed in Section 1.5 (Third Law):

In general

$$S(298.15) = S(T=0) + \int_{0}^{298.15} dH/T$$

at $p = 1$ bar.

Phase changes (melting, evaporation) must be taken into account when this integration is carried out. For perfect crystals

$$S = 0 \quad \text{i.e. } \Omega_C = 1 \quad \text{at } T = 0 \ .$$

The integration can be carried out in the temperature range $0 \leq T \leq T_{bp}$ (boiling point) using calorimetric data. At temperatures above the boiling point, the formulas of statistical mechanics apply.

2.2.4 $G(T)$, Gibbs energy

As defined in Sections 1.6.1 and 1.6.2 the Gibbs energy $G(T)$ of a pure substance at 1 bar is calculated according to

$$G(T) = H(T) - TS(T)$$

where $H(T)$ is the standard enthalpy and $S(T)$ the standard entropy of the substance under consideration.

As follows from the above equation, **the value of the function $G(T)$ involves the convention employed for $H(T)$.** Thus the Gibbs energy of an element E in its reference phase at 298.15 K and 1 bar is given by

$$G_\varepsilon(298.15) = -TS_\varepsilon(298.15) \ .$$

Within a particular phase the course of $G(T)$ is approximately linear. The slope of $G(T)$ at the transition points is discontinuous.

Figure 2.4 shows the temperature dependence of the Gibbs energy of silicon.

$$\Delta G_t = 0 \quad \text{at} \quad T = T_t \ .$$

The function $G(T)$ defined here is particularly suited to the representation of the thermodynamic

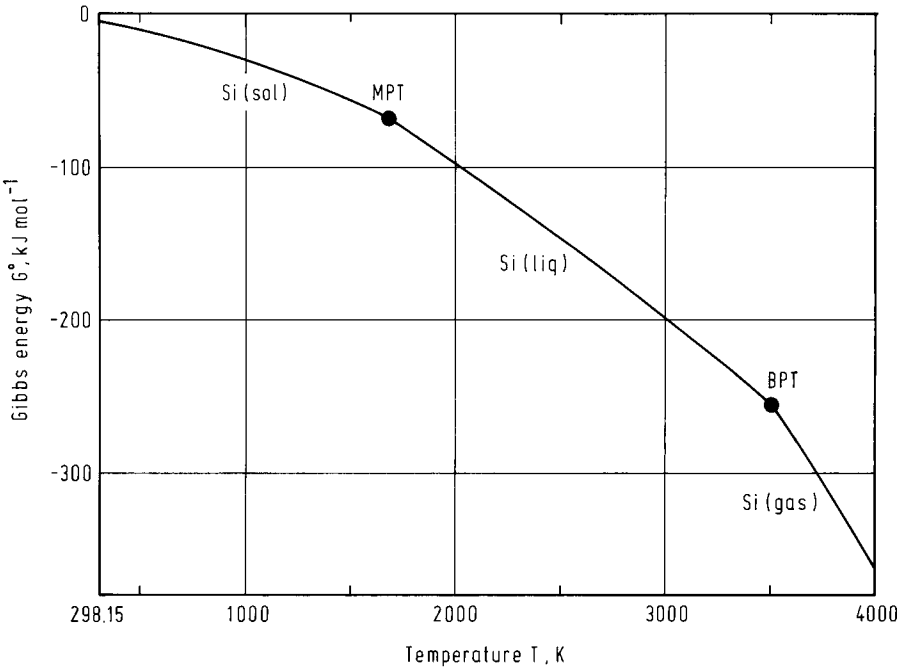

Fig. 2.4: Gibbs energy of silicon as a function of temperature at 1 bar.

properties of substances as all basic thermodynamic data can be expressed in terms of this function. In order to save storage space and shorten computing time, substance-related data are often stored in data bases as coefficients of the function $G(T)$.

2.2.5 *Gef*(T), Gibbs energy function (free enthalpy function)

Definition:

$$-Gef(T) = -[G(T)-H(298.15)]/T \ .$$

In accordance with this definition the value of the Gibbs energy function of any pure substance at 298.15 K and 1 bar is identical with $S(298.15)$:

$$-Gef(298.15) = S(298.15) \ .$$

It also follows from the definition that the following equation can be employed for the calculation of the equilibrium constant of a reaction:

$$-R \ln K = \Sigma \nu_i \, Gef_i - \Sigma \nu_i \, H_i(298.15)/T \ .$$

ν_i is positive for products and negative for reactants.

The negative of *Gef* of silicon is plotted as a function of temperature in Fig. 2.5a and 2.5b.

As can be seen from this, *Gef* changes relatively slowly with changing temperature. In addition *Gef*(T) can be represented relatively well by linear functions both for the temperature range within a phase and for the whole temperature range covering several phase transitions. For this reason *Gef*(T) is very often employed for the evaluation of thermochemical data by the "Third Law method".

If $S^0(298.15)$ and $C_p(T)$ for a substance are known, it is possible to determine the value of $\Delta H_f(298.15)$ relatively easily from the experimentally determined $G(T)$ values by the use of *Gef*(T).

For a chemical reaction:

$$-\Delta Gef_r(T) = -\Delta G_r(T)/T + \Delta H_r(298.15)/T \ .$$

If the Gibbs energy or the equilibrium constant of a reaction is determined experimentally at a temperature >298.15 K (e.g. by emf measurements), then every measurement yields a value of $\Delta H_r(298.15)$. However, a condition for this is that $S(T)$ and $[H(T)-H(298.15)]$ are known. This precondition means that the increment of the Gibbs energy, i.e. $G(T)-G(298.15)$ must be known. This reveals that the function $G(T)$ is sufficient for analysis by the "Third Law method". Nevertheless, the changes in $G(T)$ and $\Delta G(T)$ are greater than is the case for *Gef*(T) and $\Delta Gef(T)$, so that these latter are often preferred for a "Third Law" analysis.

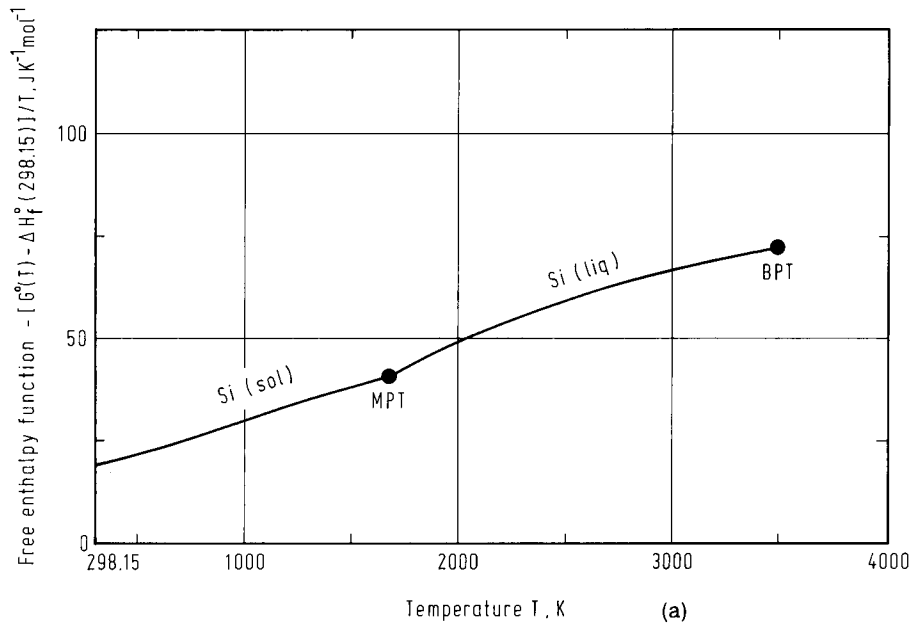
2.2.6 $\Delta H_f(T)$, $\Delta G_f(T)$, $\log K_f(T)$ Molar quantities of formation reaction

The following equations apply to the formation of a compound B from its elements E_i in their reference phases at 1 bar and at a given temperature

$$\Delta H_{f,B}(T) = H_B(T) - \Sigma \, |\nu_{\varepsilon_i}| \, H_{\varepsilon_i}(T)$$

$$\Delta G_{f,B}(T) = G_B(T) - \Sigma \, |\nu_{\varepsilon_i}| \, G_{\varepsilon_i}(T)$$

$$\log K_{f,B}(T) = -\Delta G_{f,B}(T)/(R \, T \ln 10)$$



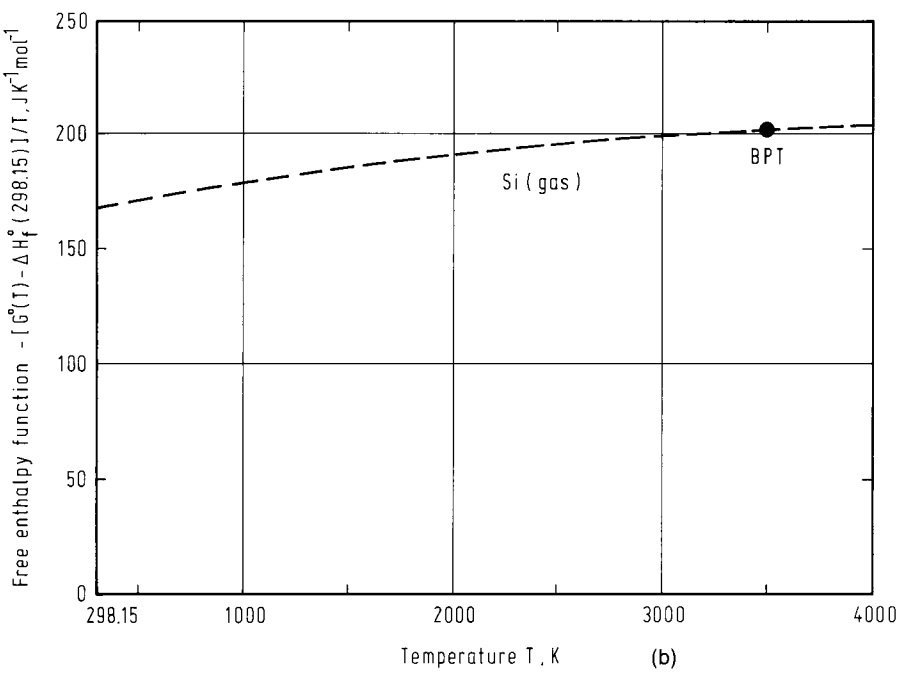


Fig. 2.5: Gibbs energy function (free enthalpy function) of silicon for the solid and liquid phases (a) and the gaseous phase (b) as a function of temperature at 1 bar.

$\Delta H_{f,B}$	enthalpy of reaction for the formation of B from the elements ε_i
H_B	enthalpy of B
H_{ε_i}	enthalpy of the element ε_i
$\Delta G_{f,B}$	Gibbs energy of the reaction for the formation of B from the elements ε_i
G_B	Gibbs energy of B
G_{ε_i}	Gibbs energy of the element ε_i
$\log K_{f,B}$	Logarithm of the equilibrium constant of the reaction for the formation of B from the elements.

The formation reactions are formulated on the basis of the standard state pressure of 1 bar and with respect to the reference phases of the elements at the given temperature. Accordingly, for the **elements in their reference phases**, if follows that

$$\Delta H_{f,\varepsilon} = 0$$

$$\Delta G_{f,\varepsilon} = 0$$

$$\log K_{f,\varepsilon} = 0 \ .$$

The quantities of formation ΔH_f, ΔG_f and $\log K_f$ allow an immediate assessment of the stability of the substance.

In the case of substances, which are produced from elements in the same phase and without phase change, ΔH_f only changes slightly. If the state of aggregation of the elements changes (melting, evaporation) this makes itself evident in the value of ΔH_f. For instance, large changes occur in ΔH of the compounds Na_2O, NaO (gas) as a result of the melting and vaporization of Na. Such changes also appear in ΔG_f for NaO (gas), while ΔG_f Na_2O (solid, liquid) increases uniformly with temperature. Because ΔG_f $(Na_2O) < 0$ the absolute value decreases with increasing temperature, when the activities of Na and O_2 are maintained constant.

Note

The numerical values of molar quantities of formation, as is the case for H and G, change by changing the reference phases of elements involved in the reaction of formation. This should be born in mind during calculations using data from different sources.

In the present tables the molar quantities of formation of sulfur compounds (sulfides, sulfates, etc.) are calculated with regard to the following reference states for sulfur:

$$S(sol_1) \rightarrow S(sol_2) \rightarrow S(liq) \rightarrow S_2(gas)$$

(see Table in Chapter 10) .

Nevertheless, there are thermochemical tables where S_2(gas) is considered as reference state at all temperatures, beginning with $T = 298.15$ K.

2.3 Equilibrium calculations

2.3.1 $K(T)$, equilibrium constant

The equilibrium constants of reactions can be calculated from the tabulated $\log K_f$ values by simple summation.

For the general reaction

$$\nu_{R1} R_1 + \nu_{R2} R_2 + \ldots = \nu_{P1} P_1 + \nu_{P2} P_2 + \ldots$$

where R_i represents the reactants and P_i the products.

With

$$K = \Pi (a_i)^{\nu_i}$$

K can be calculated from

$$\log K = \Sigma \nu_i \log K_{f,i} .$$

As explained in Section 1.9, $\log K$ and $\log K_{f,i}$ are only functions of temperature.

Examples for calculation of $\log K$:

$$ZnS + \frac{3}{2} O_2 = ZnO + SO_2$$

$$\log K = \log K_f(ZnO) + \log K_f(SO_2) - \log K_f(ZnS) - \frac{3}{2} \log K_f(O_2) .$$

The $\log K_f$ values of the elements are zero by definition when the elements are in their reference phases.

In reactions where a substance is formed from the elements (in their reference phases) the equilibrium constant can be determined directly from the $\log K_f$ values of that substance:

$$\frac{1}{2} O_2 + C = CO \qquad \text{(a)}$$

$$\log K_a = \log K_f(CO)$$

$$\frac{1}{2} H_2 = H \qquad \text{(b)}$$

$$\log K_b = \log K_f(H)$$

$$NO = \frac{1}{2} N_2 + \frac{1}{2} O_2 \qquad \text{(c)}$$

$$\log K_c = -\log K_f(NO) .$$

2.3.2 $p^0(T)$, vapor pressure

The vapor pressures of condensed substances can be calculated from the values of $\log K_f$ on the basis of the equilibrium reaction for evaporation.

Example:

$$NaCl\,(liq) = NaCl\,(gas)$$

$$\log p^0\,(NaCl) = \log K_f\,(NaCl\ (gas)) - \log K_f\,(NaCl\ (liq)) .$$

In the case of elements, the values of $\log K_f$ for vapor phases are identical with $\log p$, where p is the vapor pressure related to 1 bar.

Example:

$$Ag\ (sol, liq) = Ag\ (gas)$$

$$\log p^0\ (Ag) = \log K_f\ (Ag\ (gas)) , \quad \text{at } T \leq T_{bp}$$

where T_{bp} is the boiling point. When $T > T_{bp}$ the $\log K_f$ values for condensed phases have to be taken into account.

2.3.3 $E^0(T)$, standard emf

Aqueous solutions

The Gibbs energy of reaction between ions in solution is calculated by summation of the Gibbs energy of

formation of the ions concerned. Here it is set by convention in the half cell

$$H_2(Pt)|H^+_{aq}\ , \quad \text{at } p_{H_2} = 1 \text{ bar}\ , \quad T = 298.15$$

(reference half cell) that

$$1/2\ H_2 = H^+_{aq} + e^-\ ,$$
$$\Delta G^0_f(H^+_{aq}) = 0\ .$$

The standard Gibbs energy of formation of the proton in water is zero.

The standard Gibbs energies of ions in aqueous solution are reported on the basis of this convention (e.g. in the NBS Tables of Chemical Thermodynamic Properties, Termicheskie Konstanty Veshestv) (see References, Section 3.4).

$E^0(T)$, standard emf of a cell

According to the equilibrium equation (Section 1.12)

$$\Delta G^0_r = -z F E^0 = -R\,T \ln K_r$$

or

$$E^0 = -\Delta G^0_r/(z F) = (R\,T/z F) \ln K$$

and

$$\Delta G^0_r = \Sigma\, \nu_i\, \Delta G_{fi}\ , \quad \log K = \Sigma\, \nu_i \log K_{fi}$$

it is possible to calculate $E^0(T)$ from the values of ΔG_f or of $\log K_f$.

Example:

Decomposition of $MgCl_2$:

$Mg^{2+} + 2e_L = Mg$	electrode reaction L
$2Cl^- = Cl_2 + 2e_R$	electrode reaction R
$MgCl_2 = Mg + Cl_2$	cell reaction

where $MgCl_2$ and Mg are in liquid and Cl_2 in gaseous state. Then

$$E^0 = -\Delta G^0_f(MgCl_2)/(2F)$$
$$E = E^0 - R\,T/(2F) \ln [a_{Mg} p_{Cl_2}/a_{MgCl_2}]\ .$$

When $a_{Mg} = 1$ (pure liquid) and $p_{Cl_2} = 1$ bar (ideal gas) E can be calculated if T and the current activity of $MgCl_2$ in the molten salt are known.

2.4 Entropy production and "exergy"

Entropy balances are employed for the analysis and optimization of energy utilization in technical processes. To do this the total technical facility is divided up into individual balance volumes (component units) which are connected to each other by mass and energy exchange.

The calculation of entropy fluxes for each unit leads to quantitative evaluation of the potential "working performance" of a system. For this purpose in technical thermodynamics a variable known as exergy*) is introduced.

The exergy ε of a system is a measure (defined with respect to the surroundings) of the ability of the system to perform technical work. Exergy is maintained for reversible processes and is lost in irreversible processes.

Exergy calculations essentially imply the quantitative determination of enthalpy and entropy changes. If the numerical values of enthalpy and entropy are not available, exergy cannot be determined.

The determination of the entropy production in the individual process steps as a consequence of irreversible heat and material exchanges is important for testing the quality of the use of energy in a process.

2.4.1 Entropy production

As stated in Section 1.4.1, the entropy change in a closed system is described by the following equation:

$$\Delta S = \Delta S_e + \Delta S_i$$

in which ΔS_e is the change in entropy of the system as a result of heat exchange with its surroundings and $\Delta S_i \geq 0$ is the change in entropy resulting from changes within the system.

A simple example of entropy production is the heat exchange between two bodies at different temperatures. For an isolated total system g, consisting of the two component systems a and b, which represent two large heat reservoirs at the constant tempertures T_a and T_b, where $T_a > T_b$, the following equations hold for the transfer of a relatively small quantity of heat Q from a to b:

$$\Delta S_g = \Delta S_{g,e} + \Delta S_{g,i}$$
$$= \Delta S_a + \Delta S_b$$
$$\Delta S_a = -Q/T_a\ , \quad T_a = \text{constant}$$
$$\Delta S_b = Q/T_b\ , \quad T_b = \text{constant}$$
$$\Delta S_{g,e} = 0\ , \quad \text{isolated system g}$$
$$\Delta S_{g,i} = Q(T_a - T_b)/T_a T_b\ .$$

*) For such a purpose the introduction of a new function with the incomprehensible name exergy is not an absolute necessity. (The introduction of the artificial word "entropy" by R. Clausius is justified. For more information on entropy see M. Eigen, Ber. Bunsenges., Phys. Chem. 98 (1994) 1351–1364).

$\Delta S_{g,i} > 0$ is the amount of entropy produced in the isolated system g as a consequence of the irreversible heat transfer from component system a to component system b within the total system.

To determine the time dependence of the entropy production, the state variable entropy is differentiated with respect to time:

$$\dot{\tau} = \mathrm{d}(\Delta S_i)/\mathrm{d}t$$

To calculate $\dot{\tau}$ equations must be drawn up which describe the entropy production in the process considered. Entropy production as a dynamic process is the subject of irreversible thermodynamics, about which many good textbooks are available. For example, a readily understandable introduction has been written by A. Höpfner in P. W. Atkins, Physikalische Chemie, p. 831, VCH Verlagsgesellschaft, Weinheim 1987.

2.4.2 Exergy

Exergy of heat

The exergy ε_Q of the heat Q that is available at temperature T when the temperature of the surroundings is T_0, e.g. 298.15 K, is given by

$$\varepsilon_Q = Q(T-T_0)/T = \Delta S(T-T_0) = W \ .$$

Where ΔS is the entropy change in the system and W the work. ε_Q corresponds to the maximum work that can be performed by transfer of heat Q in passing from temperature T to T_0.

Exergy of technical work

$$\varepsilon_W = W \ .$$

The exergy of work is identical with the work. In the case of reversible processes ε_W can always be recovered as work. This also applies to the exergy of electrical energy.

Exergy of a system of substances

The exergy of a system made up of one or more substances at pressure p and temperature T is defined by

$$\varepsilon_{sys} = (H-H_0)_{sys} - T_0(S-S_0)_{sys} \ .$$

Here H and S are the enthalpy and entropy of the system at p and T, H_0 and S_0 the enthalpy and entropy of the system at p_0 and T_0 in the surroundings (e.g. $p_0 = 1$ bar, $T_0 = 298.15$ K).

Consider helium at $p = 1$ bar and $T = 1300$ K as a system with the surroundings characterized by $p_0 = 1$ bar and $T_0 = 298.15$ K, then the exergy calculated according to the above equation is the work that would be done by cooling the helium from 1300 K to 298.15 K in a reversible manner (e.g. by means of a series of Carnot cycles).

Exergy of open systems

In the case of a stationary state in a flow reactor in which the reactants enter in differing states and the products exit at pressure p and temperature T the change in exergy is given by

$$\Delta\varepsilon_r = \Delta H_r - T_0 \Delta S_r \ .$$

Here ΔH_r is the enthalpy change in the balance volume under consideration and is calculated from

$$\Delta H = \Sigma H \text{ (products)} - \Sigma H \text{ (reactants)} \ .$$

So ΔH_r and ΔS_r represent the enthalpy and entropy of a non-isothermal total reaction.

It is possible to calculate exergies (for a particular surrounding temperature T_0) from the H and S values listed in the tables by simple calculations. Here the composition of the products can correspond to the equilibrium state at p and T.

2.4.3 Exergy losses by irreversibilities

If an open system in a stationary state is considered, e.g. a chemical reactor which is exchanging heat and matter with the surroundings at T_0, then, at constant p, according to the First and Second Laws of thermodynamics the following balances pertain:

$$\Delta H_r - Q + W = 0$$

$$\Delta S_r - Q/T_0 - S_{irr} = 0 \ .$$

Here:

- ΔH_r enthalpy of the total reaction (enthalpy of the products − enthalpy of the reactants)
- Q heat transferred from the reactor to the surroundings at T_0 (heat losses by cooling)
- W mechanical or electrical work performed in operating the reactor
- ΔS_r entropy of the total reaction (entropy of the products − entropy of the reactants)
- Q/T_0 entropy leaving the system during reversible heat exchange at T_0
- S_{irr} entropy production in the reactor resulting from irreversible processes (e.g. reactions).

In the case of a reactor operating isothermally and isobarically where $W = 0$, it follows from the balance equation above that

$$S_{irr} = \Delta S_r - \Delta H_r/T_0$$

and, hence,

$$\varepsilon_r = T_0 S_{irr} \ .$$

ε_r is the exergy loss (availability) in the balance volume under consideration and is directly proportional to the entropy production. Hence irreversible processes lead to a loss of potential work which would be done by the system.

If the reactor exchanges heat with a flowing fluid (gas or liquid), then the mean heat exchange temperature T_m is given by

$$T_m = \Delta H_{fl} / \Delta S_{fl} \ .$$

ΔH_{fl} and ΔS_{fl} are the enthalpy and entropy changes in the fluid stream resulting from the heat exchange with the reactor.

The indirect heating of a reactor with hot gas is an example. In this case the exergy of the heat is

$$\varepsilon_Q = Q\,(T_m - T_0)/T_m \ .$$

The complete entropy and exergy balance would include the heat exchange with the fluid medium in the balance compartment.

2.5 Enthalpy and entropy of natural materials

Natural materials

Raw materials, such as ores, coal, crude petroleum, as well as waste materials, such as household waste and sewage sludge, are considered here as natural materials. They contain a large number of components and phases, in which the elements are distributed in the form of various compounds. Such substances are specified in practice by the following characteristics:

- elemental composition: proportions of the elements, in particular that proportions of volatile fuel components (C, H, N, O, S), and quantity and composition of the ash remaining after incineration,
- calorific value,
- thermal transformations: phase transformations, reactions, decomposition etc.,
- physical properties: density, degree of agglomeration, particle size etc.

There is a large diversity of natural materials with regard to the type of chemical species, which can only be partially determined in practice. Therefore, thermodynamic calculations for determining the changes in state, i.e. mass and energy transformations, in such complex mixtures are only possible if certain assumptions are made. Examples of calculations which are relevant to practical situations are given in Section 7.7.

The small quantities of samples used for the determination of properties of natural materials by chemical analysis and calorimetric measurement must represent a large quantity (1000 kg or more) of a highly heterogeneous material, consisting of components with very different physical and chemical properties. The careful preparation of representative samples is a prerequisite for the reliability of the results of analyses and measurements.

Enthalpy

The basis for the assignment of an "enthalpy of formation" to a natural material consists of the chemical composition, the structure information, and the calorific value. To determine the calorific value the prepared sample is completely oxidized (burned) in a calorimeter in an excess of oxygen. The heat liberated in this exothermic process is determined as the calorific value $Q_p > 0$. In the case of endothermic processes, such as calcination, Q_p would be negative.

If the species and quantities of the components of the natural material before and after the calorimetric measurement are known sufficiently well, the calorific value Q_p allows to determine an apparently standard enthalpy of formation at T = 298.15 K and p = 1 bar to be assigned to the natural material. Chemical analysis usually determines the fuel components (C, H, N, O, S) as elements, the ash components as oxides, and the heavy metals as elements.

In the case of household waste, the ash analysis gives the proportions by weight of the following species: Al_2O_3, CaO, Fe_2O_3, K_2O, MgO, Na_2O, P_2O_5, Cl^- (chlorides), SO_4^{2-} (sulfates), CO_3^{2-} (carbonates) etc.

For the heavy metals, the concentration of the elemental form is given: Hg, Pb, Cu, Zn, Cd, Cr (total), Cr^{6+} etc. The values are obtained from the analysis of the aqueous solution after dissolving the natural material or the ash in aqua regia.

With these data, as is usual in industry, the actual compounds of the elements present in the natural material cannot be specified.

For these reasons the calculation of the apparent enthalpy of the natural material on the basis of the elemental analysis and the calorific value requires particular assumptions to be made. These assumptions primarily concern the type of compound from

which the ashes are formed, as the proportion by weight of heavy metals is usually very low (minor components) and therefore has little influence on the enthalpy calculation.

The reactions taking place during the calorimetric measurement are shown in the following scheme.

Reaction				Enthalpy ΔH_r
C	+ O_2		→ CO_2	ΔH(C)
H	+ 1/4 O_2		→ 1/2 H_2O	ΔH(H)
N	+ O_2		→ NO_2	ΔH(N)
S	+ O_2		→ SO_2	ΔH(S)
NO_2	+ 1/4 O_2	+ 1/2 H_2O	→ $[HNO_3]_{aq}$	ΔH(NO_2)
SO_2	+ 1/2 O_2	+ H_2O	→ $[H_2SO_4]_{aq}$	ΔH(SO_2)
Fe	+ 3/2 O_2		→ 1/2 Fe_2O_3	ΔH(Fe)
$\Sigma \nu_{re} \varepsilon_r$	+ $\Sigma \nu_{ro} O_2$		→ $\Sigma \nu_{rb} B_r$	$\Sigma \Delta H_r$
$-\Sigma H_r(\varepsilon)$	− $\Sigma H_r(O_2)$		+ ΣH_r(B) =	$\Sigma \Delta H_r$
			Calorific value: Q_p =	$-\Sigma \Delta H_r$

In these simplified equations $\Sigma \Delta H_r$ is the total enthalpy of reaction, ΔH_r the enthalpy of reaction according to reaction r, H_r(B) the enthalpy of compound B (oxide), $H_r(\varepsilon)$ the enthalpy of the element or the component ε in the natural material, and $H_r(O_2)$ the enthalpy of oxygen.

Accordingly for T = 298.15 K and p = 1 bar it holds that

$$\Delta H_f^0(O_2) = 0 \text{ and } \Sigma H_r(O_2) = 0 \ .$$

Thus

$$-\Sigma H_r(B) + \Sigma H_r(\varepsilon) = Q_p \ .$$

$\Sigma H_r(\varepsilon)$ is the enthalpy of the natural material and can then only be calculated if the enthalpies of all the components of the natural material are known. However, this is not the case for technically important materials. It is determined approximately from the calorific value and the analysis.

If the contributions from ash-forming reactions to the total reaction enthalpy are relatively low, only the combustion of volatile fuel components can be considered for the enthalpy balance calculations. This is the case when the ash components are contained in the same form in the initial material. Furthermore, if the enthalpies (bond energies) of the fuel elements (C, H, N, O, S...) in the natural material represent relatively small quantities (in comparison to reaction enthalpies), the calorific value of a natural fuel can even be determined by a stoichiometric calculation involving the enthalpies of formation of the fuel element oxides (CO_2, H_2O, NO_2, SO_2 etc.). If the following holds:

$$|\Sigma H(\varepsilon)| \text{ (fuel elements)} \ll |\Sigma \Delta H_r| \ ,$$

then

$$Q_p = -\Sigma \Delta H_r \cong -\Sigma H_f^0(i) \text{ (fuel element oxides)}$$

in which $H_f^0(i)$ is the standard enthalpy of formation of the oxide i from the elements in their stable states under standard conditions. This approximation is frequently used in practical combustion techniques, sometimes employing additional empirical correction factors.

Entropy

As explained in Sections 1.4 and 1.5 the entropy of a substance at 298.15 K and 1 bar can be calculated from the following equation based on low temperature investigations:

$$S(298.15) = S(T = 0) + \int_0^{298.15} dH/T \ .$$

The integration requires that all order structures and the enthalpies of all transformations in the complex natural material are known at low temperatures down to the vicinity of absolute zero, i.e. are determined by means of experimental investigations and theoretical calculations. This is frequently an extensive work, even with a single pure substance. For these reasons the entropies of natural materials cannot at present be given quantitatively. However, entropy balances for different process variants can be compared numerically with each other, if the same natural material is always used as the input. An example is shown in Section 7.7.

Part II
Compilation and Presentation of Thermochemical Data

3 Compilation of thermochemical data

3.1 Basic thermochemical data

The calculation of the thermochemical functions of a pure substance over a given temperature range demands a particular set of basic thermodynamic data. These basic data are unequivocally defined in terms of standard states and reference phases and temperatures. They comprise the following quantities:

$\Delta H_f^0(298.15)$ Standard enthalpy of formation from the elements in their reference phases at $T = 298.15$ K ($p = 1$ bar).
The standard enthalpy of formation is zero for elements in reference phases. Convention employed in this work: the enthalpy of elements in their reference phases at 298.15 K and 1 bar is zero.

$S^0(298.15)$ Standard entropy of the substance at $T = 298.15$ K ($p = 1$ bar).

$C_p^0(T)$ Temperature dependence of the standard heat capacity of the substance concerned over the temperature range under consideration (at $p = 1$ bar). In general at least one $C_p(T)$ function is required for each phase of every substance.

T_t^0 Transition temperature at 1 bar.

ΔH_t^0 Standard enthalpy of transition at the transition temperature.

3.2 Existing compilations

The first compilations of thermochemical data were made about 100 years ago. Today there is a range of comprehensive tables of thermochemical data for pure substances [1–12] (see Section 3.4).

The primary data sources are individual publications reporting the results of experimental investigations and supplementary theoretical calculations. The bases for these are calorimetric determinations of enthalpies of reaction, phase transformation and heat capacities, vapor pressure determinations, emf measurements, equilibrium determinations etc.

The majority of specialist publications report one or more properties of a substance or of a limited range of substances. It is rare that the complete sets of data necessary and sufficient for the calculation of thermochemical functions over a given temperature range are reported.

Complete sets of data are produced by compilation and critical evaluation of the available data. The data included in a set must firstly be reliable and precise, i.e. correct, and, on the other hand, they must be consistent, i.e. the conclusions derived from the various pieces of information in the set must be consistent. For instance if a source A yields a temperature variation of the enthalpy of a liquid and source B the vapor pressure curve, then, if they are consistent both pieces of information must lead to the same results with respect to the boiling point and the enthalpy of evaporation.

Often only a few pieces of information are missing from a complete data set. Thus, for example, the standard entropy and heat capacity of crystalline substances (particularly of intermetallic compounds and oxides with several cations) can be determined with sufficient accuracy by estimation [8].

Methods of estimation of thermodynamic data of organic substances are discussed in [5] and especially in [11].

The consistency criterion is not only employed within a data set for a particular substance, but also between the data of various substances; the thermochemical data of a substance can be determined on the basis of several reactions [1]. Because of the large amount of both available and periodically appearing material the establishment of self-consistent data for all substances that have been the subject of thermochemical investigation is a considerable and demanding task. This task was and still is undertaken by experts in large institutes.

3.3 Thermochemical tables

The data collection named have been revised and enlarged during the last 20 years; new collections have also appeared.

The compilations of NBS [1], ANU [2] and JANAF [4] have been produced on the basis of the selfconsistency criterion. In most sets of tables the consistency is realized within a single substance data set only. Such data are also eligible and can be correct, however. The accuracy of thermochemical measurements is often not sufficient for the consistency testing that can now be carried out by computer processing.

Many substance data have been determined repeatedly in the past. In many cases the deviations may be regarded as small from the standpoint of experimental thermochemistry. CODATA [13] have set up key values by choosing from all the available data, and these can be employed as standard values, par-

ticularly for thermochemically well-investigated substances.

As far as content is concerned, it is possible to distinguish between two types of tabular compilation:

a) Tables of thermodynamic properties of substances in standard states at 298.15 K [1–3, 5, 8, 11, 12]: Compilations of NBS [1] and ANU [2] also include ΔH_f^0 to 0 K and $[H^0(298.15)-H^0(0)]$ together with the basic data for aqueous solutions of the species. Compilations [2, 3, 8, 11, 12] also contain data for phase transitions. The compilations listed under a) often do not provide the complete basic data for a substance.
b) Tables of thermochemical functions at various temperatures in steps of 100 K [3–7, 9, 10]: The data sets are complete in these compilations. In JANAF Tables [4] the values of all functions are also reported for 0 K and, furthermore, the temperature range is extended up to 6000 K in the tables of various gaseous species.

Part III
Tables in the Present Work

4 Preparation of the tables

4.1 General remarks

These tables have been compiled with the aim of including the substance states as completely as possible in thermochemical calculations. To this purpose efforts have been made to present tables in a uniform manner for as large a number of substances as possible after consideration of all available data and estimates. The intention is to provide engineers and scientists in industry, research and the universities with the capability of performing calculations on a multiplicity of substance systems.

Processing of natural raw materials and technical intermediates involves substance systems with diverse elements and phases. When appropriate methods are employed, the practical relevance of a thermochemical calculation depends not only on the accuracy of the data but also on the comprehensive inclusion of all conceivable and possible substance variants in the system under consideration.

The data presented in these tables also form the database for the thermochemical software package EQUITHERM (see Section 7.6). This system is equipped with control and calculation programs which can be employed for carrying out thermochemical calculations on personal computers. The SOLGASMIX program, for the calculation of equilibrium states and energy balances in substance systems with several elements and phases, makes up a significant part of EQUITHERM.

4.2 Data sources, accuracy

In addition to the large data collections, a range of individual publications were also employed as data sources in the compilation of these tables. A relatively large number of data (ca. 900) were determined by estimation. In general, the data in established standard works were preferred. The sources employed for the particular properties are given in the appropriate tables.

Substance data from various sources have been included in an effort to make as many substances as possible accessible to at least approximate calculations. In the case of individual substances and groups of substances the aim has been to use the data from one source. It was not possible to meet strict consistency criteria when combining data from various sources to form a data set for a substance. The inaccuracies resulting from this lie in most cases within thermochemically acceptable limits.

In some sources, the enthalpies of formation or the Gibbs energies of oxide compounds with several cations (silicates, aluminates etc.) are reported in terms of the reactions of formation from the constituent oxides. In such cases the data have been corrected with respect to the corresponding basic data of the constituent oxides presented in this work.

In the computer-aided calculation of phase diagrams (e.g. in silicate systems) considerable uncertainties in melting points (10 K and more) result from variations in enthalpy of formation of 1 kJ mol^{-1}. It must be remembered in this connection that the enthalpies of formation of some Al and Cr silicates can only be reported to an accuracy of ± 10 kJ mol^{-1}.

4.3 Units

Units of tabulated functions

Quantity	Symbol	Unit
Temperature	T	K
Heat capacity	C_p	J K^{-1} mol^{-1}
Entropy	S	J K^{-1} mol^{-1}
Gibbs energy function	Gef	J K^{-1} mol^{-1}
Enthalpy	H	kJ mol^{-1}
Enthalpy increment	$H-H(298.15)$	kJ mol^{-1}
Gibbs energy	G	kJ mol^{-1}
Enthalpy of formation	ΔH_f	kJ mol^{-1}
Gibbs energy of formation	ΔG_f	kJ mol^{-1}
Equilibrium constant of formation reaction	$\log K_f$	–

Units of various constants

Quantity	Symbol	Unit
Gas constant	R	J K^{-1} mol^{-1}
Thermochemical calorie	1 cal	4.184 J

Tables for fundamental constants, conversion factors for energy units and entropy gases are presented in Chapter 8.

4.4 Standard states

Standard ambient temperature and pressure (SATP):

$T = 298.15\ \mathrm{K}$

$p = 1\ \mathrm{bar} = 10^5\ \mathrm{Pa}$.

The **standard state of a substance** is its pure form in a defined state of aggregation at a pressure of 1 bar and a specified temperature. It is denoted by the index ^{0}, e.g. H^0, S^0, ΔH^0. The conventional reference temperature for the specification of energy functions (enthalpy) is 298.15 K = 25 ^{0}C (room temperature).

Standard state phases of pure substances

Phase of standard state	Abbreviation
Ideal gas	(gas) or (g)
Liquid	(liq) or (l)
Crystalline solid	(sol) or (cr)
Amorphous solid	(am)
Vitreous or glass solid	(glass)

4.5 Reference phases for the elements at 298.15 K and 1 bar

Reference phase	Elements
Ideal gas	Ar, Cl_2, F_2, H_2, He, Kr, N_2, Ne, O_2, Rn, Xe, e^- (electron)
Liquid	Br_2, Hg
Crystalline solid	all other elements

The reference phases for the elements covered in the present tables are specified in the table in Chapter 10. There, the temperature limits of the reference phases are also given.

5 Construction of the tables

5.1 Arrangement of substances in the tables

The tables are arranged in alphabetical order according to the usual chemical formulae of the substances.

Primary classification: All substances are arranged in alphabetical order of the first element in the chemical formula.

Secondary classification: Substances having the same first element in their formulae are arranged in alphabetical order of the second element. The secondary classification is not strictly adhered to because account is taken of particular bonding relationships.

A table is provided first for the reference phase of each substance at 298.15 K. In the case of compounds this state is that state of the substance which at 298.15 K is stable with respect to its other states (modifications).

The order in which the tables are arranged is:

1) Reference phase
2) Gaseous phase
3) Metastable phases

The data for all gaseous substances are tabulated separately for the case of an ideal gas, i.e. the gas phase is not included in the multiphase tables.

Examples:

Order of substances		
Ag	$CaZrO_3$	Pu_2O_3
⋮	Ca_3P_2	⋮
Ag_2WO_4	⋮	PuOBr
Al	CaPb	PuOCl
⋮	⋮	PuOF
CaO	GaAs	PuOl
CaO (g)	$Ga(AsO_4)_2$	⋮
CaO_2	$GaBr_3$	ZrO_2 (g)
⋮	⋮	$ZrSiO_4$
$Ca_2F_2O_5$	Ga_2O_3	ZrS
CaOH (g)	⋮	ZrS_2
$Ca(OH)_2$	Pu_2C	e^-
⋮	⋮	

Several tables for one substance
Ag (sol, liq)
Ag (gas)
SiO_2 (low quartz, high quartz, high cristabolite, liq)
SiO_2 [CR] (low cristabolite)
ZnS (wurtzite, liq)
ZnS (gas)
ZnS [S] (sphalerite)

All substances contained in the tables are listed with formula and name in the **chemical formula index** in alphabetical order. In order to simplify the search for substances in the tables, the formulae of the substances are also listed in a **modified Hill index**. In this index the formulae are listed according to the alphabetical order of the elements (see Chapter 12).

5.2 Order of the phases in the tables

The order of the phases in a table follows the order of stability of the condensed phases. Insofar as data are available for them, all condensed phases of a substance are included in a table.

Examples for the order of phases:	
Fe	Iron
SOL-A	(α, crystalline solid)
SOL-C	(γ, crystalline solid)
SOL-D	(δ, crystalline solid)
LIQ	(liquid)
Fe (g)	Iron (gas)
GAS	(Ideal gas)
Si	Silicon
SOL	(crystalline solid)
LIQ	(liquid)
Si (g)	Silicon (gas)
GAS	(ideal gas)

The abbreviations for phase description are defined in the **list of symbols** in Chapter 9.

6 Contents and structure of the tables

6.1 Formula, name and relative molar mass

Each substance is identified by the usual form of its chemical formula and by its most commonly employed chemical name. In some cases, with intermetallic compounds in particular, the name corresponds to a list of the chemical elements in the formula. The molar masses ($g\,mol^{-1}$) are calculated from the relative atomic masses of the elements taking $A_r = 12$ for ^{12}C and are reported at the beginning or end of the first line.

6.2 Tabulated functions

All values relate to standard states. The quantities of formation relate to the reactions for the formation of the substance from its elements in their reference phases.

The order of the columns in the tables was chosen by consideration of the dimensions and corresponds to the internationally accepted form.

Tabulated functions

T	Temperature
C_p	$C_p^0(T)$, heat capacity
S	$S^0(T)$, entropy
$-(G-H298)/T$	$-[G^0(T)-\Delta H_f^0(298.15)]/T$, Gibbs energy function, $-Gef$ (Free enthalpy function)
H	$H^0(T)$, enthalpy
$H-H298$	$H^0(T)-\Delta H_f^0(298.15)$, enthalpy increment
G	$G^0(T)$, Gibbs energy (Free enthalpy)
ΔH_f	$\Delta H_f^0(T)$, enthalpy of formation reaction
ΔG_f	$\Delta G_f^0(T)$, Gibbs energy of formation reaction
$\log K_f$	$\log K_f^0$, logarithm of the equilibrium constant of formation reaction

6.3 Sequence of temperatures

Each table starts with data for 298.15 K. At this temperature

$$S = S^0(298.15)$$

$$H = \Delta H_f = \Delta H_f^0(298.15)\ .$$

The temperatures are then raised in steps of 100 K beginning with 300 K.

6.4 Phase transitions

In the case of a phase transition between two condensed phases the values of the functions at the transition temperature are quoted for each phase. The enthalpy of transition and the entropy of transition calculated from it are reported in a separate line under H and S in the appropriate dimensions.

6.5 The final temperature in the tables

The tables for solid and liquid substances end either with a phase transition point or with an upper calculation limit, below which data were available. The final temperature is always a calculation limit in the case of gaseous substances. With condensed substances there are the following special cases for the final temperature T_e:

a) T_e = BPT: boiling point, where the vapor pressure of the substance, which evaporates congruently, is 1 bar.

b) T_e = NBPT: natural (normal) boiling point, at which the vapor pressure is 1.01325 bar = 1 atm. This case especially applies to substances which evaporate with the formation of various gas-phase species, e.g. associates.

c) T_e = SPT: sublimation point, at which the sum of the partial pressures of the gaseous species Σp_i (gas) amounts to 1 bar.

d) T_e = NSPT: normal sublimation point, where Σp_i (gas) = 1 atm.

e) T_e = DPT: decomposition point, at which the substance is transformed to other substances, e.g. SOL-A into SOL-B and a liquid mixture (peritectic reaction in binary systems). However, dissociation processes with the formation of gaseous substances are also included. At T = DPT, Σp_i (gas) = 1 bar.

f) T_e = NDPT: normal decomposition point, Σp_i (gas) = 1 = atm.

g) T_e = MPT: melting point.

h) T_e = transtion point.

i) $T_e = T$, an arbitrary temperature, which represents

an upper calculation limit. The phase transition data (e.g. of evaporation) of some substances are not known with sufficient accuracy. In such cases the calculations are terminated shortly below of above the transition temperature.

Apart from the last case (i) the final temperature is specified, in most cases, at the end of the table.

6.6 Additional information, remarks

The particular features of the substances in the sense of their differentiation and characterization, and explanations of substance-specific properties are given in the form of short remarks at the end of the tables, together with the substance phase to which they refer.

Elements and compounds in the same aggregate state are differentiated by conventional signs, such as solid-α, solid-γ etc. These differentiations are specified in certain cases by giving the crystal structure, such as bcc (body-centered cubic), fcc (face-centered cubic) etc.

Many substances undergo changes in their chemical composition during transformations such as melting and evaporation. Congruent transformations of several compounds at elevated temperatures are only possible if the chemical potentials of constituent elements can be maintained at certain level. Gas molecules such as S_2, SO_2, SO_3, NH_3, NH_4OH can only exist at elevated temperatures when high partial pressures of the constituent elements (S, S_2, N_2, H_2, Cl_2) are established and effective in the system.

On heating Fe_2O_3 a melt corresponding to the molar ratio Fe:O = 2:3 can only be maintained under a high partial pressure of O_2. As can readily be seen from phase diagrams for binary systems, some compounds undergo transformations into other liquid or solid phases. In such cases, an indicative note, such as dissociation, decomposition etc. is given, if it appears necessary and is known. This also applies to temperature values for normal boiling point (NBT) and normal decomposition point (NDPT) at which the total pressure of the gaseous species is 1.01325 bar (1 atm).

6.7 References for the sources of data

The references covering the basis data, additional information and comments are given separately for each phase at the foot of the table.

Where

$H = \Delta H_f^0(298.15)$ or

ΔH_t^0 (enthalpy of transition)

$S = S^0(298.15)$

$C_p = C_p(T)$

Remarks = additional information and remarks.

Example to explain the presentation of references:

	H/S
H and *S* from source A	A
H from A, *S* from B	A/B
ΔH_t from B	B
H from A, *S* estimated	A/e
H and *S* from A but altered	A, e
H and *S* obtained from A and supplemented by estimates	A, e

The references for additional information are at the beginning of the line concerned (under "Remarks").

The abbreviations used for references are listed in Chapter 11.

6.8 Abbreviations and symbols

The abbreviations employed in the tables are listed in Chapter 9.

Part IV
Examples of the Use of the Tables

7 Examples of thermodynamic calculations

7.1 Enthalpy changes

7.1.1 Enthalpy of air

1 m^3 of air 1 atm and 298.15 K (1.1846 kg of air) is heated to 800 K at a constant pressure of 1 atm. Calculate the quantity of heat needed.

Assumptions:

Air is assumed to be an ideal mixture of 79% N_2 by volume and 21% O_2 by volume. No chemical reactions take place (the formation of NO compounds can be neglected at temperatures below 1000 K).

Ideal gas equation: $p\,V = n\,R\,T$.

Gas constant:

$$R = 83.1441\ cm^3\ bar\ K^{-1}\ mol^{-1}$$
$$= 82.0568\ cm^3\ atm\ K^{-1}\ mol^{-1}$$
$$1\ atm = 1.01325\ bar\ .$$

The enthalpy of ideal gases is independent of the pressure. Hence the values of the enthalpies for N_2 and O_2 at 1 bar also apply to 1 atm. The enthalpy changes between 298.15 K and 800 K result from the heat transferred at 1 bar.

Solution:

According to the ideal gas equation and the conditions assumed above 1 m^3 of air at 1 atm and 298.15 K contains 32.291 mol N_2 and 8.584 mol O_2.

The following values are to be found in the tables for N_2 and O_2:

Substance	T [K]	$H-H298$ [kJ mol^{-1}]
N_2	800	15.046
O_2	800	15.836

Multiplications of the enthalpy changes by the molar quantities, followed by addition, yields the heat requirement

$$Q = 621.18\ kJ\ .$$

Note:

N_2 and O_2 are both diatomic gases. Hence their C_p values and enthalpy changes differ little from one another.

7.1.2 Heating and melting a metal

Question:

What is the quantity of energy required to heat 1 kg aluminium from 298.15 K to 1000 K at a pressure of 1 bar? Aluminium is liquid at 1000 K.

Assumptions:

The temperature of aluminium is increased by transfer of heat from an electrical or gas heater (furnace).

The heat entering the mass of aluminium at constant pressure is equal to the enthalpy change of aluminium.

Solution:

The table for aluminium yields:

Atomic mass = 26.982 g mol^{-1}

1 kg aluminium contains 37.062 mol Al.

$$[H-H298] = 30.950\ kJ\ mol^{-1} \quad \text{at} \quad T = 1000\ K\ .$$

So

$$Q = 37.062 \times 30.950 = 1147.069\ kJ\ .$$

Note:

If the melting process takes place within 5 minutes in an electric furnace, then the power output of the furnace must be

$$1147.069/(5 \times 60) = 3.8\ kW\ .$$

However, on application of this calculation in practice, account must be taken of the fact that only part of the electrical energy supplied to the electric furnace will be "transferred" to the aluminium. An appreciable part of the energy output is transmitted to the surroundings as heat. In addition the duration of the heating process depends on the heat transfer rate, which depends on the construction of the furnace and on the geometrical and physical properties of the body being heated. Hence, the energy requirements and power outputs calculated are minimum values and serve as a reference point.

7.1.3 Final temperature in an adiabatic process

a) Reactants at room temperature

The following reaction is to take place in a vessel insulated against heat exchange and continuously maintained at a pressure of 1 bar

$$CH_4 + 2O_2 + 7.524N_2 + CaCO_3 \rightarrow$$
$$2CO_2 + 2H_2O + 7.524N_2 + CaO \ .$$

At the beginning the reactants are at 298.15 K.

Question:

What is the final temperature in the vessel?

Explanation:

Initial state: 1 mol CH_4, 2 mol O_2, 7.524 mol N_2 (ideal gases), 1 mol $CaCO_3$, Pressure = 1 bar, Temperature = 298.15 K

Final state: 2 mol CO_2, 2 mol H_2O, 7.524 mol N_2 (ideal gases), 1 mol CaO, Pressure = 1 bar, Temperature = T_f

The molar quantities of oxygen and nitrogen have been chosen to correspond to the composition of the air.

Basis:

The enthalpy of the isolated system at constant pressure is constant. This means that the question to be answered is: At what temperature is the sum of the enthalpies of the products the same as the sum of the enthalpies of the reactants?

Solution:

Classical graphical methods will be employed to simplify the explanation.

The enthalpy values of the substances involved in the reaction are listed in the table given below.

Figure 7.1 is a plot of the sums of the enthalpies of the reactants and products as functions of temperature. As can be seen the enthalpies of the products increase almost linearly over the chosen temperature range. Linear interpolation yields a final temperature T_f of 1599 K.

b) Adiabatic processes in systems with preheated reactants

T_f for the example in Section 7.1.3a will be recalculated for the case that the air supply is preheated to 900 K, i.e. 7.524 mol N_2 and 2 mol O_2 are initially at 900 K.

$H(900) = 18.222\ \text{kJ mol}^{-1}$ for N_2 and
$H(900) = 19.241\ \text{kJ mol}^{-1}$ for O_2

so

$$\Sigma \nu_i H_i \text{ (reactants)} = -1281.794 + 175.584$$
$$= -1106.210\ \text{kJ} \ .$$

Linear interpolation between the sums of the enthalpies of the products at 1600 K and 2000 K reveals that $T_f = 1922$ K. This means that preheating the air

Substance	n mol	H[kJ mol^{-1}]				
		298.15 K	1400 K	1500 K	1600 K	2000 K
CH_4	1	−74.873				
O_2	2	0				
N_2	7.524	0				
$CaCO_3$	1	−1206.921				
$\Sigma n_i H_i$ (reactants)		−1281.794				
CO_2	2		−337.606	−331.796	−325.932	−302.062
H_2O	2		−198.334	−193.676	−188.919	−169.037
N_2	7.524		+34.936	+38.405	+41.904	+56.137
CaO	1		−577.926	−572.321	−566.671	−543.628

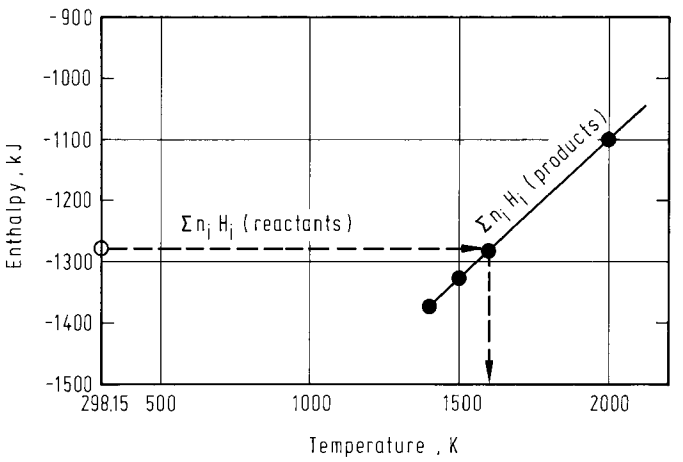

Fig. 7.1: Determination of the final temperature in an adiabatic process by plotting the enthalpies of reactants and products over the temperature range.

Reaction: $CH_4 + 2O_2 + 2\frac{79}{21}N_2 + CaCO_3 \rightarrow 2CO_2 + 2H_2O + 2\frac{79}{21}N_2 + CaO$.

supplied from 298.15 K to 900 K raises the temperature of the products from 1599 to 1922 K.

This preheating can be achieved by indirect heat exchange between hot product gases. This is practised in the manufacture of **cement clinker**. The clinker is cooled in process air, which is thus preheated for the precalcination step. The next calculation example treats a simplified case of this type.

7.1.4 Enthalpy balance for heat exchange

Heating air by cooling a hot material:

Question:

How much air (in terms of its volume at 273.15 K and 1 bar) can be heated from 298.15 to 600 K when the heat is provided by the cooling of 1 t CaO from 1600 to 600 K at 1 bar?

Calculation:

The process mentioned above can be described by the following table:

Reactants	CaO	N_2	O_2
n [mol]	x	0.79y	0.21 y
T [K]	1600	298.15	298.15
H [kJ mol^{-1}]	−566.671	0	0
Products:	**CaO**	**N_2**	**O_2**
n [mol]	x	0.79 y	0.21 y
T [K]	600	600	600
H [kJ mol^{-1}]	−620.773	8.894	9.224

Since $H(298.15)$ is zero for N_2 and O_2 the following relation applies:

$$x\,[H(CaO, 600) - H(CaO, 1600)] + y\,[0.79H(N_2, 600) + 0.21H(O_2, 600)] = 0$$

With $M_r(CaO) = 56.077$ g mol^{-1} it follows that for 1000 kg Mg CaO, $x = 17.833 \times 10^3$ mol.

On substituting for x and the values of the enthalpy, the following equation is obtained for the enthalpy change in kJ:

$$-964801 + y\,(7.026 + 1.937) = 0$$
$$y = 107643 \text{ mol "air"} .$$

With $V = 22.711 \times 10^{-3}$ m^3/mol at 1 bar and 273.15 K the amount of air heated is 2444.7 m^3 related to 1 bar and 273.15 K.

7.1.5 Enthalpy change in a system with reactions

Hydrogen is to be heated to 4000 K. At this temperature H_2 is completely dissociated according to the following reaction:

$$H_2 \rightarrow 2H .$$

Question:

Which quantity of energy is necessary to heat H_2 from 298.15 to 4000 K?

The proportion of H^+ ions at 4000 K is negligibly small.

Solution:

Substance	H_2	H
T [K]	298.15	4000
H [kJ mol^{-1}]	0	294.946

$$\Delta H = 2 \times 294.946 - 0 = 589.892 \text{ kJ/mol } H_2 .$$

Note:

Only 76.947 kJ are required to heat 1 mol argon from 298.15 to 4000 K (see Table for argon). The heat capacity and, hence, the enthalpy increment of a monatomic gas is less than it is for a diatomic gas. The diatomic gas can take up more energy on being heated. For this reason H_2 is often employed in plasma technology to increase the energy of the plasma gas beam.

The recombination of H to H_2 is an exothermic process in which the energy of dissociation is "liberated". This energy also contributes to an increase in the temperature of the plasma beam.

The enthalpies of ionization of H and Ar

$$H \rightarrow H^+ + e^-$$

$$Ar \rightarrow Ar^+ + e^-$$

are about the same so that the larger energy uptake of hydrogen is also maintained on coupling with the ionization energy.

7.2 Exergy and entropy balance calculations

Calculation of the exergy change occurring on cooling an exhaust gas from 1000 to 400 K at 1 bar pressure.

Exhaust gas composition (% by volume): 17% CO_2, 8% H_2O, 69% N_2, 6% O_2

Amount of exhaust gas: 1 m^3 at 1 bar and 273.15 K

Initial state 1 bar, 1000 K = T_1
Final state 1 bar, 400 K = T_2.

Additional information

Mole fraction: $x_i = n_i / \Sigma n_i$

$\Sigma n_i = p\,V / R\,T$

$V = 1\ m^3$ related to 1 bar and 273.15 K

$R = 0.0831441\ m^3\ bar^{-1}\ mol^{-1}$.

Change in exergy

$\Delta\varepsilon = \Sigma n_i (\Delta H - T_0\,\Delta S)$

$\Delta H = \Sigma x_i\,[H_i(T_2) - H_i(T_1)] = \Sigma x_i\,\Delta H_i$

$\Delta S = \Sigma x_i\,[S_{fi}(T_2) - S_i(T_1)] = \Sigma x_i\,\Delta S_i$

$T_0 = 298.15$ K, $T_1 = 1000$ K, $T_2 = 400$ K .

The calculation process using the table given below is summarized as follows:

H [kJ mol^{-1}], S [J K^{-1} mol^{-1}] .

$\Sigma x_i\,\Delta H_i = -20.741$ kJ mol^{-1}

$\Sigma x_i\,\Delta S_i = 31.287$ J K^{-1} mol^{-1}

$\Sigma n_i = 44.032$ mol

$\Delta\varepsilon = 44.032[-20.741\times10^{-3} - 298.15\times(-31.287)]$

$= -502.5$ kJ.

This value represents the maximum work which could be done by performing the process in a reversible manner. On account of the irreversibility the work done in a real process is less.

Note:

In the calculation the values of the standard entropies of the gases (at a pressue of 1 bar) were employed since the molar quantities and, hence, the partial pressures of the gaseous components remain constant on cooling.

Gas	CO_2	H_2O	N_2	O_2	Σ
vol%	17	8	69	6	100
x	0.17	0.08	0.69	0.06	1

ΔS	−43.989	−33.950			
$x\Delta S$	−7.478	−2.716	−19.311	−1.782	−31.287

7.3 Equilibrium calculations

7.3.1 Calculation of equilibrium constants of chemical reactions

a) Equilibrium constant of the reaction

$$C + H_2O = CO + H_2 \quad (a)$$

at 1000, 1100 and 1200 K.

Equilibrium constant

$$K_a = P_{CO} P_{H_2} / (a_C P_{H_2O})$$

If $a_C = 1$ (in the presence of solid carbon) then

$$K_a = P_{CO} P_{H_2} / P_{H_2O} \ .$$

The following equation is employed for the calculation of K_a:

$$\log K_a = \Sigma \nu_i \log K_f(i) \ .$$

The calculation is followed through in the next table (a).

The value of K is greater than 1 and increases with increasing temperature. The standard Gibbs energy of the reaction is negative in the temperature range from 1000 to 1200 K. The products CO and H_2 are accordingly the dominant equilibrium components in the gas phase.

b) Calculation of the equilibrium constant of the reaction

$$CO + H_2O = CO_2 + H_2 \quad (b)$$
(water gas equilibrium)

at 1000, 1100 and 1200 K

$$K_b = P_{CO_2} P_{H_2} / (P_{CO} P_{H_2O})$$

$$\log K_b = \Sigma \nu_i \log K_f(i) \ .$$

For data and results, see table (b)

Linear interpolation of $\log K_a = f(1/T)$ yields $K_a = 1$ at ca. $T = 1091$ K. Below this temperature the right-hand side of the equilibrium (products; CO_2, H_2) dominates and above this temperature the left-hand side (reactants; CO, H_2O) is dominant.

If the system is in equilibrium at, say, 1000 K and the temperature is then raised to 1200 K then CO_2 and H_2 are consumed with the production of CO and H_2 until the system reaches the new equilibrium state.

a)

Substances	C	H_2O	CO	H_2
ν	−1	−1	+1	+1

T [K]	$\log K_f$				$\log K_a$	K_a
	C	H_2O	CO	H_2		
1000	0	10.062	10.461	0	0.399	2.506
1100	0	8.888	9.927	0	1.039	10.940
1200	0	7.899	9.480	0	1.581	38.107

1200	9.480	7.904	17.238	0	−0.146	0.715

7.3.2 Vapor pressure calculations

The vapor pressures of substances are most simply calculated with the aid of the $\log K_f$ values in the tables on the basis of the two-phase equilibria solid-gas and liquid-gas.

For the evaporation of a substance A at temperature T:

$$A\,(sol, liq) = A\,(gas)$$

$$\log K = \log K_f\,(A\,(gas)) - \log K_f\,(A\,(sol, liq))$$
$$= \log [p\,(A\,(gas))/a(A\,(sol, liq))] \ .$$

p is the vapor pressure and a the activity of A in the condensed phase.

In general, for the evaporation of pure substances

$$\log K = \Sigma \nu_i \log K_f(i)$$
$$= \log p^0(i) \ .$$

When elements in their reference phases evaporate congruently

$$\log p^0(i) = \log K_f(i, gas) \qquad T \leq T_{bp} \ .$$

The vapor pressure reaches 1 bar at the boiling point:

$$p^0 = 1 \text{ bar} \qquad \text{at } T = T_{bp} \ .$$

Several gaseous species are produced when substances such as S, Te, PbO, etc. evaporate (e.g. S evaporates with the formation of S_1, S_2, ... S_8).

Many substances dissociate into other compounds on evaporation. In such cases the vapor pressure or dissociation pressure can be calculated using the equation

$$\log K = \Sigma \nu_i \log K_f(i) \ .$$

Example:

a) Vapor pressure of metals and compounds

$Al\,(liq) = Al\,(gas)$, $T = 1500$ K

$Pb\,(liq) = Pb\,(gas)$, $T = 1500$ K

$Pb\,(liq) = 1/2\ Pb_2\,(gas)$, $T = 1500$ K

$CCl_4\,(liq) = CCl_4\,(gas)$, $T = 300$ K

b) Dissociation pressure of ZnS at 1800 K

$$ZnS\,(sol) = Zn\,(gas) + 1/2\ S_2\,(gas) \qquad (b)$$

$$K_b = p_{Zn}(p_{S_2})^{1/2}, \quad p_{Zn} = 2\,p_{S_2}$$

Substance	T [K]	$\log K_f$	p^0 [bar]
Al (liq)	1500	0	
Al (gas)	1500	−4.878	1.32×10^{-5}
Pb (liq)	1500	0	
Pb (gas)	1500	−1.604	2.49×10^{-2}
Pb_2 (gas)	1500	−4.977	1.05×10^{-5}
CCl_4 (liq)	300	10.814	
CCl_4 (gas)	300	10.080	0.185
ZnS (w, sol)	1800	−1.009	($K_b = 0.098$)
Zn (gas)	1800	0	$p_{Zn} = 0.268$
S_2 (gas)	1800	0	$p_{S_2} = 0.134$

7.3.3 Equilibrium concentration of NO in hot air

A series of compounds is known in the N−O system, e.g. N_2O, NO, NO_2, N_2O_4, N_2O_5... N_xO_y. NO is produced by the reaction of N_2 and O_2 (thermal NO) at high temperatures. It is metastable in the atmosphere and can be transformed into NO_2 and other toxic compounds.

Example:

Calculation of the equilibrium concentration of NO in air at 1 bar pressure at the temperatures 1000, 1500 and 2000 K taking into account the species N_2, O_2 and NO.

Elucidation:

System: N−O

Components: N_2, O_2, NO (ideal gases)

Conditions: air, 79% N_2 and 21% O_2 by volume,

$p_{N_2}/p_{O_2} = 79/21$,

$p_{N_2} + p_{O_2} = 1$ bar ,

$T = 1000, 1500, 2000$ K .

Reaction:

$$1/2\ N_2 + 1/2\ O_2 = NO$$

$$K = p_{NO}/(p_{N_2}\,p_{O_2})^{1/2}$$

$$\log K = \log K_f(NO) - 1/2 \log K_f(N_2) - 1/2 \log K_f(O_2)$$
$$= \log K_f(NO) - 0 - 0 \ .$$

$$\log p_{NO} = \log K + 1/2 \log (p_{N_2} \times p_{O_2})$$
$$= \log K + 1/2 \log (0.79 \times 0.21) \ .$$

vpm (vol. per million) of NO $= p_{NO} \times 10^6$.

Data and results of calculation

T [K]	$\log K_f(NO)$	$\log p_{NO}$	NO content [vpm]
1000	−4.062	−4.452	35.32
1500	−2.487	−2.877	1327.39
2000	−1.699	−2.089	8147.04

As can be seen, at temperatures above 1000 K the NO content increases rapidly. In order to prevent the formation of thermal NO in combustion processes it is necessary to

- employ low combustion temperatures, e.g. $T \leq 1200$ K
- employ as little excess air as possible for combustion so that the partial pressures of N_2 and O_2 in the combustion chamber are kept low (see equation for $\log p_{NO}$).

7.3.4 Equilibrium concentration of NO in exhaust gases

Gas composition:

17% CO_2, 8% H_2O, 69% N_2, 6% O_2 (by volume).

Pressure = 1 bar

Temperatures: 1200 and 1500 K.

Assumptions:

The gas mixture is regarded as an ideal gas. The equilibrium concentrations of NO are calculated from the following equations:

$$1/2\ N_2 + 1/2\ O_2 = NO$$

$$K = p_{NO} / (p_{N_2} \times p_{O_2})^{1/2}$$

$$\log p_{NO} = \log K + 1/2 \log (p_{N_2} \times p_{O_2})$$
$$= \log K_f(NO) + 1/2 \log (0.69 \times 0.06) \ .$$

Calculation:

T [K]	$\log K_f(NO)$	NO content vpm
1200	−3.275	108.02
1500	−2.487	662.98

Note:

The equilibrium concentration of NO increases by more than a factor of 6 on raising the temperature by 300 K.

The gas composition chosen for the calculation corresponds approximately to that emitted by coal-fired power stations. The temperature of the exhaust gases as they leave the combustion chamber is about 1200 K for fluidized bed combustion and 1500 K for grate combustion. The composition of the exhaust gases from technical plants changes by a few percent on cooling. The NO content of untreated exhaust gases from coal combustion plants is about 500 to 600 ppm in the case of fluidized bed combustion and 700 to 1000 ppm after grate combustion. The exhaust gases from lignite combustion contain less NO. The nitrogen compounds contained in the fuel are of importance for NO formation in combustion processes. In addition, the same temperature is not maintained throughout the combustion chamber. The occurrence of local temperature peaks will increase the NO production considerably. This is the reason why calculated equilibrium concentrations are often lower than those actually measured in the exhaust gases from industrial combustion plants.

7.4 Equilibrium in simplified systems with several phases and components

7.4.1 Equilibrium in the C−CO−CO_2 system

Element system: C−O

Phases	Components
solid	C (graphite)
gas	CO, CO_2 (ideal gases)

This system has 2 independent variables according to the Gibbs phase rule:

$$f = 2+2-2 = 2 \ ,$$

e.g p_{CO}, T or p_{CO}, p_{CO_2} etc.

Exercise:

Calculation of the proportion of CO in the CO−CO_2 equilibrium mixture as a function of temperature.

Reaction:

$$C + CO_2 = 2\ CO \quad \textbf{(Boudouard equilibrium)}$$

$$K = p_{CO}^2 / p_{CO_2}$$

$$\log K = 2 \log K_f(CO) - \log K_f(CO_2)$$
$$- [\log K_f(C) = 0] \ .$$

Solution:

$$p_t = p_{CO} + p_{CO_2}$$

$$p_t = p_{CO} + p_{CO}^2 / K$$

$$p_{CO}^2 + K p_{CO} - K p_t = 0$$

$p_t = 1$ bar, vol% CO $= 100 \times p_{CO}$

$$\text{vol\% CO} = 100 \times K/2\ [(1+4/K)^{1/2} - 1] \ .$$

The calculation with $\log K_f$ values is summarized in the following table.

In Fig. 7.2 p_{CO} is plotted as a function of T. The curve for the two-phase equilibrium where C_{sol} and the gas phase coexist is known in metallurgy as the Boudouard curve.

At low temperatures the gas phase consists primarily of CO_2 and at higher temperatures mainly of CO. Consequently CO is not stable at room temperature and a pressure of 1 bar and should decompose with the formation of C and CO_2. However, CO exists at room temperature as a metastable gas. The decomposition of CO occurs at temperatures above 800 K, especially in the presence of catalytic substances such as metallic iron.

In accordance with Le Châtelier's principle, the CO content of the gas phase is reduced when the total pressure is increased at constant temperature, i.e. the Boudouard curve is displaced to the right. The displacement can be calculated with the aid of the equations given.

T [K]	$\log K_f(CO_2)$	$\log K_f(CO)$	$\log K$	K	vol% CO
400	51.535	19.112	−13.311	4.37×10^{-14}	2.20×10^{-5}
600	34.400	14.320	−5.760	1.74×10^{-6}	0.013
700	29.501	12.948	−3.605	2.483×10^{-4}	1.56
800	25.825	11.916	−1.993	1.016×10^{-2}	9.59
900	22.965	11.109	−0.747	0.179	34.30
1000	20.675	10.461	0.247	1.766	71.25
1100	18.801	9.927	1.053	11.298	92.44
1200	17.238	9.480	1.722	52.723	98.17
1400	14.780	8.772	2.764	580.764	99.83

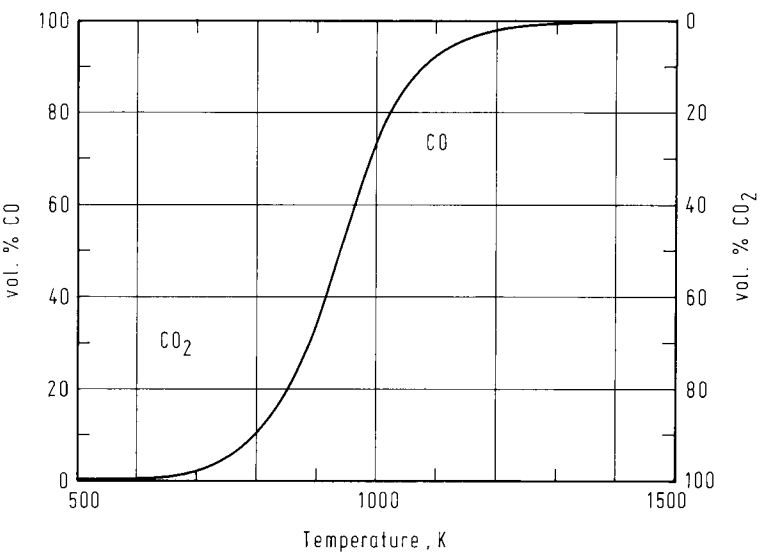

Fig. 7.2: Concentration of CO and CO_2 in the CO–CO_2 mixture in equilibrium with solid carbon (graphite) as a function of temperature at 1 bar.

7.4.2 Predominance area diagram for the system Zn–O–C

System: Zn–O–C.

Components: ZnO (sol), Zn (liq, gas), CO (gas), CO_2 (gas).

Exercise:

Calculation of the equilibrium

$$ZnO + CO = Zn + CO_2$$

$$K = p_{CO_2} a_{Zn} / (p_{CO} a_{ZnO})$$

and representation of the regions of stability of ZnO and Zn by plotting $\log (p_{CO}/p_{CO_2})$ against $1000/T$ over the temperature range from 800 to 1800 K.

The basic equations are

$$\log K = \Sigma \nu_i K_f(i) = \log [p_{CO_2} a_{Zn} / (p_{CO} a_{ZnO})]$$

$$\log p_{CO}/p_{CO_2} = -\log K + \log a_{Zn}$$

$a_{ZnO} = 1$ for ZnO (sol)

$a_{Zn} = 1$ for Zn (pure liquid)

$a_{Zn} = p_{Zn}$ for Zn (gas) .

T [K]	$\log K_f$				$\log K$	$\log (p_{CO}/p_{CO_2})$ for $a_{Zn} = 1$
	ZnO	CO	Zn	CO_2		
800	17.612	11.916	0	25.825	−3.703	3.703
1000	12.962	10.461	0	20.675	−2.748	2.748
1200	9.777	9.480	0	17.238	−2.019	2.019
1500	5.703	8.487	0	13.796	−0.394	0.394
1800	3.017	7.812	0	11.499	+0.670	−0.670

The calculation is summarized in the following table.

Figure 7.3 illustrates a plot of $\log p_{CO}/p_{CO_2}$ against $1000/T$. The equilibrium lines have mainly been approximated by straight lines. The solid line with a bend at the boiling point of zinc is the coexistence line where Zn and ZnO exist in equilibrium together. Zinc is stable above this line and ZnO below it. Thus, the diagram indicates the regions of stability of Zn and ZnO under a gas phase comprising Zn, CO and CO_2.

The coexistence line ZnO/Zn (gas) applies to $p_{Zn} = 1$ bar. Its position changes with $+\log p_{Zn}$ according to the equation

$$\log (p_{CO}/p_{CO_2}) = -\log K + \log p_{Zn} \ .$$

This line is displaced 1 scale unit downwards when $p_{Zn} = 0.1$ bar.

Figure 7.3 also shows the position of the equilibrium calculated in the previous example (Boudouard equilibrium)

$$CO_2 + C = 2CO$$

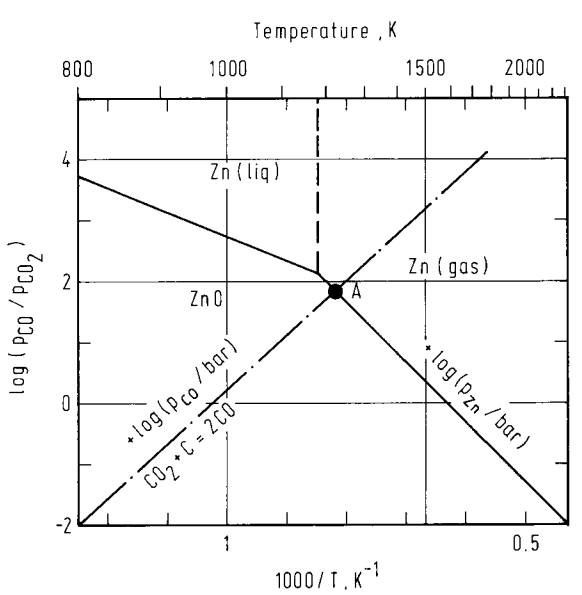

Fig. 7.3: Predominance area diagram for the system Zn−O−C. The line for the Boudouard equilibrium crosses the coexistence line for ZnO/Zn (gas) at the point A at unit pressures of CO and Zn (gas). When $T \geq T_A$ then ZnO can be reduced to Zn using solid carbon.

at $p = 1$ bar. This line is also displaced parallel downwards when p_{CO} is reduced.

The point of intersection A is of importance for the reduction of ZnO in the presence of solid carbon.

When $p_{Zn} + p_{CO} + p_{CO_2} = 1$ bar, i.e. $p_{Zn} < 1$ bar and $p_{CO} < 1$ bar, then it follows from the position of intersection A that the reduction of ZnO in the presence of solid carbon always leads to the formation of gaseous and not liquid zinc. If the gas produced, consisting of Zn, CO and CO_2 (less than Zn and CO), is cooled, then because of the position of the Boudouard line, reoxidation should take place to ZnO. However, the CO decomposition taking place during this process is inhibited kinetically, so that cooling the Zn−CO mixture yields liquid zinc.

7.4.3 Predominance area diagram for the system Zn−O−S

Exercise:

Calculation of the predominance area diagram for the system Zn−O−S in the $\log p = f(p_{CO_2})$ diagram at 1600 and 1900 K.

The following elements and compounds will be considered in the description of the equilibrium between the species. Zn (gas), ZnO (sol), ZnS (sol), O_2 (gas), S_2 (gas).

The equilibrium between S_2, O_2 and SO_2 also requires calculation at 1600 and 1900 K in order to explain the technical relevance of the equilibrium calculation.

Reactions between zinc species

$$Zn + 1/2\, O_2 = ZnO \qquad (1)$$
$$K_1 = (p_{O_2})^{-1/2} (p_{Zn})^{-1}$$

$$Zn + 1/2\, S_2 = ZnS \qquad (2)$$
$$K_2 = (p_{S_2})^{-1/2} (p_{Zn})^{-1}$$

$$ZnO + 1/2\, S_2 = ZnS + 1/2\, O_2 \qquad (3)$$
$$K_3 = (p_{O_2})^{1/2} (p_{S_2})^{-1/2} \ .$$

Calculation of the equilibrium constants

$$\log K_1 = \log K_f(\mathrm{ZnO})$$
$$\log K_2 = \log K_f(\mathrm{ZnS})$$
$$\log K_3 = \log K_f(\mathrm{ZnS}) - \log K_f(\mathrm{ZnO}) = -\log K_1 + \log K_2 \ .$$

Calculation of $\log p_{O_2}$ and $\log p_{S_2}$

$$\log (p_{O_2})_1 = -2 \log K_1 - 2 \log (p_{Zn})_1$$
$$\log (p_{S_2})_2 = -2 \log K_2 - 2 \log (p_{Zn})_2$$
$$\log (p_{O_2})_3 = 2 \log K_3 + \log (p_{S_2})_3 \ .$$

Calculation results

T [K]	$\log K_1$	$\log K_2$	$\log K_3$
1600	4.692	2.340	−2.352
1900	2.316	0.453	−1.863

T [K]	$\log (p_{O_2})_1$ p_{Zn} = 1 bar	$\log (p_{S_2})_2$ p_{Zn} = 1 bar	$\log (p_{O_2})_3$ p_{S_2} = 1 bar
1600	−9.384	−4.680	−4.704
1900	−4.632	−0.906	−3.762

Equilibrium in the system S−O with the species S_2, O_2 and SO_2:

$$1/2\ S_2 + O_2 = SO_2 \qquad (4)$$

$$K_4 = p_{SO_2} (p_{O_2})^{-1} (p_{S_2})^{-1/2}$$
$$\log K_4 = \log K_f(SO_2)$$
$$\log (p_{O_2})_4 = -\log K_4 - 1/2 \log p_{S_2} + \log p_{SO_2} \ .$$

T [K]	$\log K_4$	$\log (p_{O_2})_4 + \log p_{S_2}$ at p_{SO_2} = 1 bar
1600	7.995	−7.995
1900	6.136	−6.136

Figure 7.4 shows the coexistence lines of systems Zn/ZnS, Zn/ZnO and ZnS/ZnO. The solid lines apply to T = 1600 K and the broken lines to T = 1900 K. At each temperature there is a point at which the three coexistence lines meet. This point where all three zinc-containing species coexist is known as a triple point. In contrast to the triple point in the phase diagram of H_2O, the triple point in the $p = f(T)$ diagram of the system Zn−O−S is not invariant. Its position changes with p_{Zn}.

It can be concluded from the position of the equilibrium line for SO_2 that ZnO is produced when ZnS is roasted in O_2 at 1600 K. The SO_2 content of the exhaust gases in technical processes is from 5 to 80% by volume. ZnO is the stable zinc compound under these circumstances. In contrast the SO_2 line at 1900 K lies in the stability area of gaseous zinc. So roasting at 1900 K can yield zinc vapor as well as SO_2.

When zinc-containing copper concentrates are smelted in high temperature reactors (flash smelting, cyclone smelting) the temperatures rise appreciably

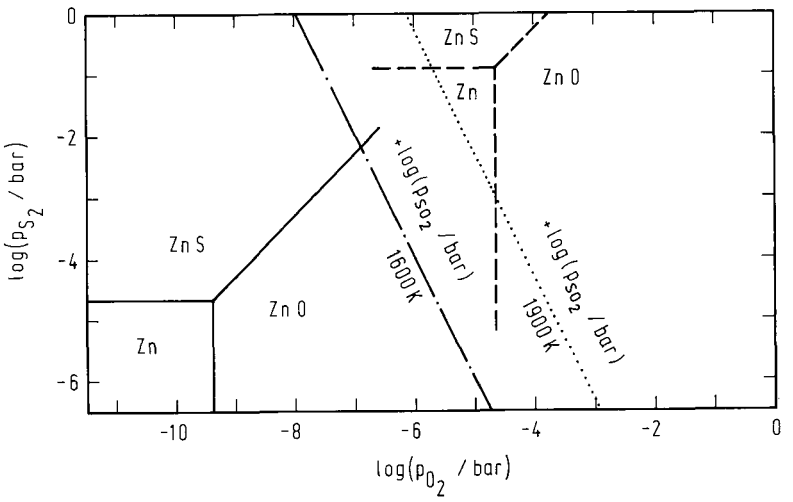

Fig. 7.4: Stability areas of the components in the system Zn−O−S at 1600 K and 1900 K with p_{Zn} = 1 bar. The equilibrium line for the reaction $\frac{1}{2}S_2 + O_2 = SO_2$ is plotted for p_{SO_2} = 1 bar.

over 2000 K. Zinc is, thus, transferred into the gaseous phase. In the case of cyclone smelting it is possible to separate most of the zinc by vaporization thereby simplifying the metallurgical steps that follow.

7.5 Electrochemical energy conversion, high temperature fuel cell

High temperature cells with solid electrolytes of zirconium dioxide have been investigated for the electrolysis of H_2O vapor and as fuel cells for the generation of electric power. Examples include the combustion of synthesis gas ($CO-H_2$ mixtures) in cells at temperatures of 1300 K.

The following equation must be considered in a discussion of the thermodynamic aspects of fuel cells

$$H_2 + 1/2\,O_2 = H_2O\ (gas)\ .$$

The following can be read from the table for H_2O (gas):

T [K]	ΔH_f kJ mol^{-1}	ΔG_f kJ mol^{-1}
298.15	−241.826	−228.620
1300	−249.475	−175.934

The formation reaction is strongly exothermic at both temperatures. The maximum work that must be done to the system to cause electrolysis is very much less at 1300 K than at 298.15 K. The work that the system can do, on the other hand, is less at the higher temperature.

The maximum efficiency of the fuel cell $\varepsilon_{max} = \Delta G_r / \Delta H_r$ is 94.5% at 298.15 K and 70.5% at 1300 K. Practical efficiencies are in the region of 45 to 60%.

However, these chemical thermodynamic considerations are important but not decisive for the technical exploitation of high temperature fuel cells. One practical important factor is the decrease in the electrokinetically determined overvoltage so that smaller losses occur in comparison with low temperature operation and, thus, higher efficiencies are obtained. Another difficulty is the direct utilization of the fuels which are produced at high temperatures (steam from condensers, H_2 and CO from coal gasification) and, hence, avoidance of the losses inevitable in irreversible heat-exchange processes.

Calculation of the cell voltage

A high temperature solid electrolyte fuel cell (SOFC) will be considered now. Modern SOFC technology employs calcia-stabilized zirconia as the support tube and yttria-stabilized zirconia as the solid electrolyte. In addition, special oxide ceramic materials are employed as electrodes and interconnection materials. These materials and the solid electrolyte are deposited as thin layers on the support tube by electrochemical vapor deposition.

The emf of the cell when burning H_2 with O_2 can be calculated from

$$H_2 + 1/2\,O_2 = H_2O(r)$$

$$K_r = p_{H_2O}\,(p_{H_2})^{-1}\,(p_{O_2})^{-1/2}$$

$$E_O = -\Delta G_r/(zF) = RT/(zF)\ln K_r\ .$$

For

$$T = 1300\ K \text{ with}$$

$$\Delta G_r = \Delta G_f(H_2O) = -175.934\ kJ\ mol^{-1}$$

and

$$F = 96484.6\ C\ mol^{-1} = 96484.6\ J\ V^{-1}\ mol^{-1}$$

$$E_O = 0.912\ V\ .$$

In comparison, the cell voltage is displaced to 1.229 V at 298.15 K with

$$\Delta G_r = -237.141\ kJ\ mol^{-1} \quad \text{for } H_2O\ (liquid)\ .$$

If air is employed as oxidant, the partial pressure of oxygen at the oxidation electrode (anode) can be taken as 0.21 bar. The partial pressure of H_2 at the fuel electrode (cathode) falls as a result of H_2O formation. Under equilibrium conditions the O_2 partial pressure at the cathode is given by

$$p_{O_2} = [(p_{H_2O}/p_{H_2})/K_r]^2\ .$$

This, together with

$$\log K = \log K_f(H_2O) = 7.069 \text{ at } T = 1300\ K$$

yields

$$p_{O_2} = 7.278\times10^{-15}\ bar \text{ for } p_{H_2O}/p_{H_2} = 1$$

or

$$p_{O_2} = 10^{-17}\ bar \text{ for } p_{H_2O}/p_{H_2} = 0.03707\ .$$

The latter corresponds to the state where $p_{H_2}+p_{H_2O} = 1$ bar with 3.57% H_2O by volume in the H_2-H_2O mixture in the cathode space. The ratio of the O_2 partial pressures p_{O_2} (anode)/p_{O_2} (cathode) is, thus, of the order of 10^{13} to 10^{16}. If the latter value is substituted into the Nernst equation then for the open cell circuit

$$E = (RT/2F)\times[\ln(10^{16})^{1/2}]$$
$$= 0.056\times 18.421$$
$$= 1.032\ \text{V}\ .$$

The cell potential is less when current is flowing. A cell voltage of ca. 0.5 V has been measured at a current density of 400 mA/cm^2.

7.6 The calculation of equilibria in multiphase, multicomponent systems

The calculation of the equilibria in systems with several elements and phases requires the employment of suitable computer methods.

Consider, for instance, the system C–H–O. Even if the equilibrium components are limited to CH_4, CO, CO_2, H_2 and H_2O, when the total pressure p, the temperature and two stoichiometric parameters ($\Sigma n_H/\Sigma n_C$, $\Sigma n_O/\Sigma n_C$) are known, the following equations apply:

$$p = p_{CH_4} + p_{CO} + P_{CO_2} + p_{H_2} + p_{H_2O} \qquad (1)$$

$$CO + H_2O = CO_2 + H_2 \quad \text{(a)}$$

$$K_a = p_{CO_2}\,p_{H_2}/(p_{CO}\,p_{H_2O}) \qquad (2)$$

$$CH_4 + H_2O = CO + 3H_2 \quad \text{(b)}$$

$$K_b = p_{CO}\,p_{H_2}^3/(p_{CH_4}\,p_{H_2O}) \qquad (3)$$

$$\Sigma n_H/\Sigma n_C = (4p_{CH_4} + 2p_{H_2} + 2p_{H_2O})/(p_{CH_4} + p_{CO} + p_{CO_2}) \qquad (4)$$

$$\Sigma n_O/\Sigma n_C = (p_{CO} + 2p_{CO_2} + p_{H_2O})/(p_{CH_4} + p_{CO} + p_{CO_2})\ . \qquad (5)$$

The solution of these nonlinear system of equations by established methods of numerical mathematics with the aid of a computer program yields the partial pressures of the gaseous components. If the system is enlarged to include components such as C_{sol} (solid carbon), N_2 etc. then it is necessary to set up and solve a new system of equations. The amount of calculation involved increases as the number of components increases [1].

However, computer programs are available nowadays which are capable of calculating equilibrium states for given element combinations and equilibrium parameters [2–5].

The database and computing system equiTherm [5, 6] contains the computing program SOLGASMIX [4] coupled with the data set published in these Tables. equiTherm allows the calculation of equilibria using personal computers *for* systems of up to 15 elements and 20 phases (up to a total of 120 species).

The computer program SOLGASMIX [4] calculates the equilibria according to the principle of Gibbs energy minimisation at a constant pressure and temperature.

The total Gibbs energy of a system is given by

$$G = \Sigma n_i \mu_i$$

where n_i represents the number of moles of substance and μ_i their chemical potentials. The following relations apply:

for gas mixtures:

$$\mu = \mu_i^0 + RT\ln p + RT\ln x_i$$

for condensed phases

$$\mu_i = \mu_i^0 + RT\ln\gamma_i + RT\ln x_i$$

for stoichiometrically composed pure solid substance

$$\mu_i = \mu_i^0\ .$$

When p and T are given it is still necessary to take account of further restrictions depending on the masses of the elements, which are, in general, formulated as follows:

$$\Sigma n_{\varepsilon ij}\, n_i = b_j\ .$$

Where $n_{\varepsilon ij}$ is the number of moles of the element j in one mole of the species i, n_i is the number of moles

of species i and b_j is the total number of moles of element j in the system.

The introduction of the Lagrangian multiplier λ with the associated conditions yields the equations:

for gases

$$\mu_i^0 + RT \ln p + RT \ln x_i - \Sigma n_{\varepsilon ij} \lambda_j = 0$$

for mixtures in condensed phase

$$\mu_i^0 + RT \ln \gamma_i + RT \ln x_i - \Sigma n_{\varepsilon ij} \lambda_j = 0$$

for stoichiometric phases in the condensed state

$$\mu_i^0 - \Sigma n_{\varepsilon ij} \lambda_j = 0 \ .$$

These relations lead, on expansion in a Taylor series around an estimated equilibrium composition, to a set of linear equations. The number of unknowns is reduced to the number of elements and phases assumed to be present in the equilibrium. The solution approximates to the Gibbs energy surface on application of an iteration algorithm. Further explanation is given in references [4] and [6].

7.7 Thermodynamic calculation of technical processes with reactions of natural materials

7.7.1 Incineration of waste materials in a fluidized bed furnace

Sewage sludges from community facilities as well as from industrial plants are very often disposed of by incineration in fluidized bed furnaces [1]. The incineration is a combustion process at a relatively low temperature. The preheated air is blown through a distributor into the fluidized bed. Sand is frequently used as the fluidized bed material. The dehydrated sewage sludge (water content ≤ 75 wt%) is introduced to the fluidized bed from above. Through intensive heat and mass exchange in the fluidized bed the incineration of the organic sewage sludge components takes place almost completely at temperatures of $\leq 900\,°C$. At higher temperatures melt phases can be formed, which can lead to agglomerations in the fluidized bed (lump formation).

The fluidized bed incineration has a number of advantages compared with high-temperature incineration: lower energy requirement for the process, lower emission of harmful substances (such as NO), lower entropy production, use of simpler and cheaper plant materials, simplification of reactor design and process execution etc.. However, the fluidized bed technique requires fluidizable particle sizes and can only be used if the desired chemical reactions are possible without the formation of extended melt phases.

Calculations on the simulation of the incineration of moist sewage sludge (H_2O content = 43.75 wt%) and the high-temperature incineration of dried sewage sludge (H_2O content = 2.83 wt%) are compared below.

The composition of the dried sewage sludge with a net calorific value of 9 MJ/kg is shown in Table 7.1.

The material and energy balance of the incineration process is summarized in Table 7.2. Because of the relatively low incineration temperature at 850 °C the energy requirement for the incineration process is correspondingly low. Thus the degree of drying can be low, i.e. the water content of the sewage sludge can be high.

The calculation is carried out for a sludge with a water content of 43.75 wt%. The composition of the sewage sludge given in Table 7.1 changes with the increased proportion of water and the calorific value is then only 4.181 MJ/kg. The process enthalpy must be sufficiently large for the total heat loss from the furnace to be compensated at an average process temperature of 850 °C.

Table 7.1: Composition of the dried sewage sludge. Net calorific value = 9 MJ/kg

Components	Mass%	Components	Mass%
C	20.13	Al_2O_3	5.92
H	2.95	CaO	12.37

Process enthalpy	−2.1951E+08 J	
Process entropy	+6.8608E+06−X J/K	

Table 7.3 shows the composition of the products. It can be seen that potassium and sodium are present in the waste gas in the form of different compounds. The main components of the ashes are considered to be pure oxides. Phosphorus is in the form of sodium phosphate. The total interaction between the oxides (silicate formation etc.) has not been included in the considerations.

The SO_2 content of the waste gas given in Table 7.3 does not correspond to the equilibrium state. When a equilibrium is set up in the presence of CaO, SO_2 is almost completely bound through $CaSO_4$ formation (flue gas desulfurization). However, $CaSO_4$ formation proceeds more slowely through the kinetic inhibition of the previous reaction steps (chemisorption of SO_2 on CaO with subsequent oxidation to SO_3) and through the coating of CaO by a dense $CaSO_4$ layer. Therefore the practical reaction conditions are reflected in the calculations by assuming that only part of the CaO brought in with the sewage sludge is effective for the reactions.

7.7.2 Sewage sludge incineration at 1600 °C

In Fig. 7.5 two plant flow sheets for the thermal disposal of sewage sludge are shown. Plant (a) uses a fluidized bed incinerator. Before entering the furnace the sewage sludge still has a water content of 43.75 wt%. The calculations for plant (a) were given in the previous section (7.7.1).

In the case of plant (b) a high-temperature reactor (e.g. smelting cyclone) is used [2]. The sewage sludge has an initial water content of ≥75 wt% and must be dried to one of 2.83 wt%, before entering the furnace.

Because of the high process temperature the reactions in the reactor (cyclone) proceed rapidly. Accordingly, the specific throughput, i.e. the quantity of sewage sludge incinerated per unit time and reactor volume, of this type of reactor is larger than that of an incinerator operating at 850 °C. The high process temperature leads to formation of an oxide melt (slag) from the ash components of the sewage sludge. The reactor wall must therefore be protected by suitable refractory lining and cooling (e.g. with water).

The energy flow from the reactor as a result of cooling increases the total energy requirement and the cooling process indicates high entropy production in the surroundings of the system. On cooling, the heat is transferred from a system at 1600 °C to one at a lower temperature (H_2O at e.g. 50 °C), which is a process showing high irreversibility.

The composition of the sewage sludge introduced to the smelting reactor is shown in Table 7.1.

Table 7.4 shows the summarized material and energy balance. Compared with Table 7.2, the large quantity of waste gas and the use of high-value pure materials, such as CH_4 and O_2, are noteworthy. The enthalpies of the input and output materials are

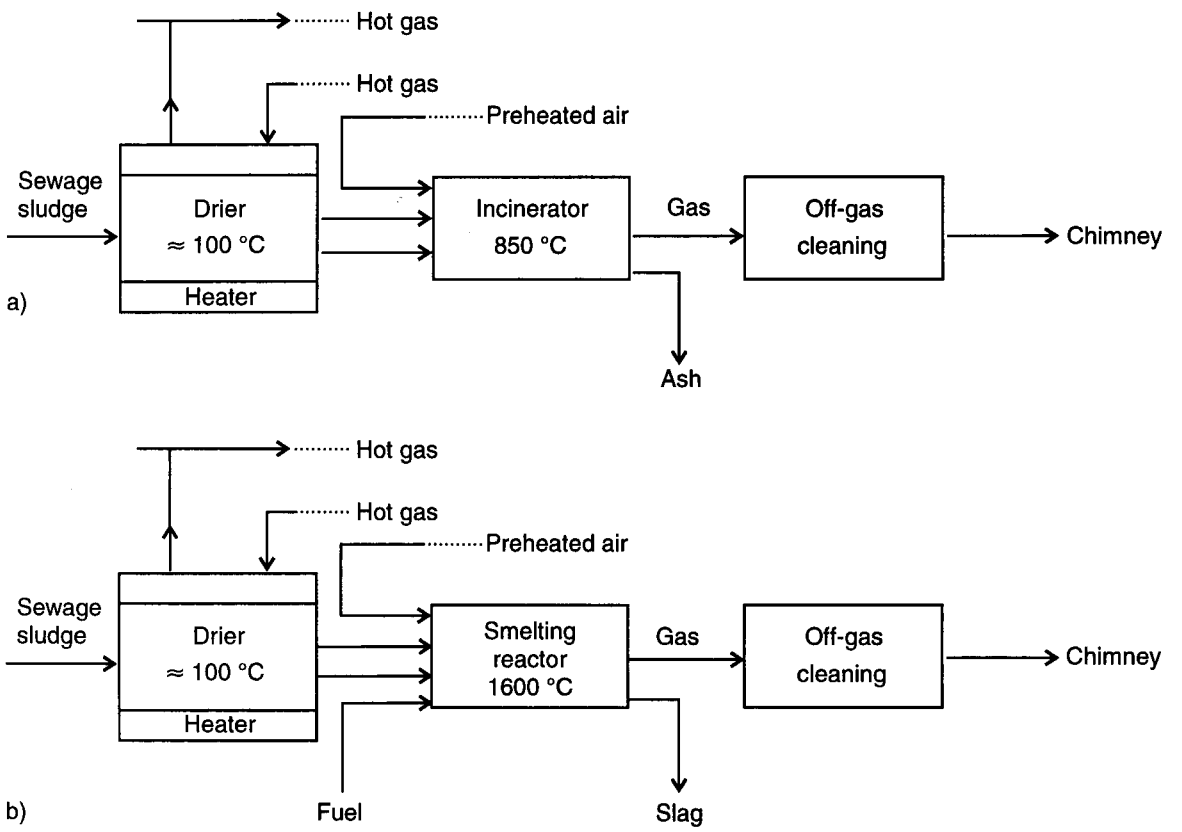

Fig. 7.5: The simplified flow-sheet of two plants for thermal disposal of sewage sludges using a fludizied-bed incinerator (a) and a high-temperature furnace for smeltings combustion (b). Hot gas for the drier operation and the preheated air as well are produced by heat exchange in the off-gas system.

higher on the energy scale. Also the quantity of process enthalpy is almost one power of ten higher than in process (a).

In this comparison the energy for the drying process, which is necessary to reduce the water content to 2.83 wt%, must also be taken into consideration. Compared with the process described under 7.7.1, this means that from 1398 kg of sewage sludge with 43.75 wt% water, ca. 398 kg water must be removed by evaporation (using the energy of the hot off-gas from the furnace) to achieve the composition shown in Table 7.1.

Table 7.4: Material and energy balance for the smelting combustion of dried sewage sludge

	Temperature	Quantity
Input		
Sewage sludge	25 °C	1 000 kg
Combustion air	240 °C	2933 m^3
Transport air	25 °C	200 m^3
O_2	25 °C	100 m^3
CH_4	25 °C	50 m^3
Products		
Off-gas	1600 °C	3657 m^3
Slag	1600 °C	438 kg
Enthalpy of input	−8.0279E+09 J	
Enthalpy of products	−8.5505E+09 J	
Process enthalpy	−5.2265E+08 J	
Process entropy	9.2834E+06−X J/K	

If the drying process according to

$$H_2O\ (liq., 298.15\ K) \longrightarrow H_2O\ (gas, 400\ K)$$

is considered, for 398 kg water the process enthalpy is 1.051×10^9 J and the process entropy 2.586×10^6 J/K. This means that the process values given in Table 7.4 for the enthalpy and entropy change by incorporation of these quantities.

The compositions of the products of the high temperature process are given in Table 7.5. As expected, the hot gas leaving the reactor contains high amount of NO. Alkali metals are present both in elemental form and as halides and oxides. The SO_2 content is high, as no binding of sulfur (as CaS or $CaSO_4$) is possible in the slag because of the high oxygen potential and/ or high temperature. As sewage sludge has a high phosphate content (a constituent of organism), in the high-temperature incineration the phosphorus is mainly transferred to the gas phase in the form of PO_2. If sufficient quantities of alkali and alkaline

Table 7.5: Composition of the produced gas and slag

Gas		**Slag**	
Components	Vol.%	Components	Mass%
CO	0.020	Al_2O_3	13.517
CO_2	11.613	CaO	28.253
H_2O	13.023	FeO	5.169
K	0.003	Fe_3O_4	0.530
Na	0.058	K_2O, Na_2O	1.299
KCl	0.005	P_2O_5	0.891
NaCl	0.027	PbO	0.008
KOH	0.079	SiO_2	49.994
NaOH	0.493		
N_2	67.449	ZnO	0.335
NO	0.282	Residual	0.004
O_2	6.146		
SO_2	0.334		
PO_2	0.429		
Zn	0.006		
Residual	0.033		

earth oxides are present in the slag, part of the phosphorus can be bound as phosphate.

The slag is regarded as resistant to elution. Because of this and because of its glassy nature and high density the slag is more highly valued than the ash from the incineration process. The latter has to be disposed off if it cannot be fractionated by suitable measures in the off-gas cleaning process.

According to Tables 7.1 and 7.4 the process entropy is

6.8608 E + 06. – X J/K for the incineration and
9.2834 E + 06. – X J/K for the high temperature smelting process.

For the same sewage sludge with the same initial water content the increase in entropy in the high-temperature smelting process is larger than in the incineration process.

The cooling of the smelting furnace, the granulation of the slag in the water bath, the differences in quality between the solid and liquid phases, and the differences in waste gas scrubbing must be determined in detail for a technically relevant energy and entropy balance. Such balances provide the basis for the technical and economic assessment of processes. The comparative entropy balance also offers, if it is complete, an ecological guidance on the basis of the second law of thermodynamics.

7.7.3 Combustion of coal in the slag tap boiler

In this type of combustion facility pulverized coal is burned with air in a reactor in the form, for example, of a horizontal cyclone. In this reactor high temperatures of ca. 1600 °C are achieved and the ash components of the coal are melted to form slag. The liquid slag collects on the reactor wall as a result of the fluid-flow characteristics in the reactor. It flows out of the reactor through the tap hole and is then granulated in a water bath. The waste gas is cooled in boilers, whereby high-pressure steam is produced, which is used to drive steam turbines for power generation.

Because of the high temperatures in the furnace the gas phase produced also contains components (metals, halogens etc.), which condense in the boiler system on cooling and can lead to the formation of deposits on the heat exchanger pipes. The solid particles (fly ash) carried in the waste gas can also form part of these deposits, which is an interference factor for the operation of the power station and must be removed during shut-down periods.

The process involving the high-temperature combustion of coal at 1600 °C and subsequent cooling of the waste gas to 700 °C is calculated on the basis of

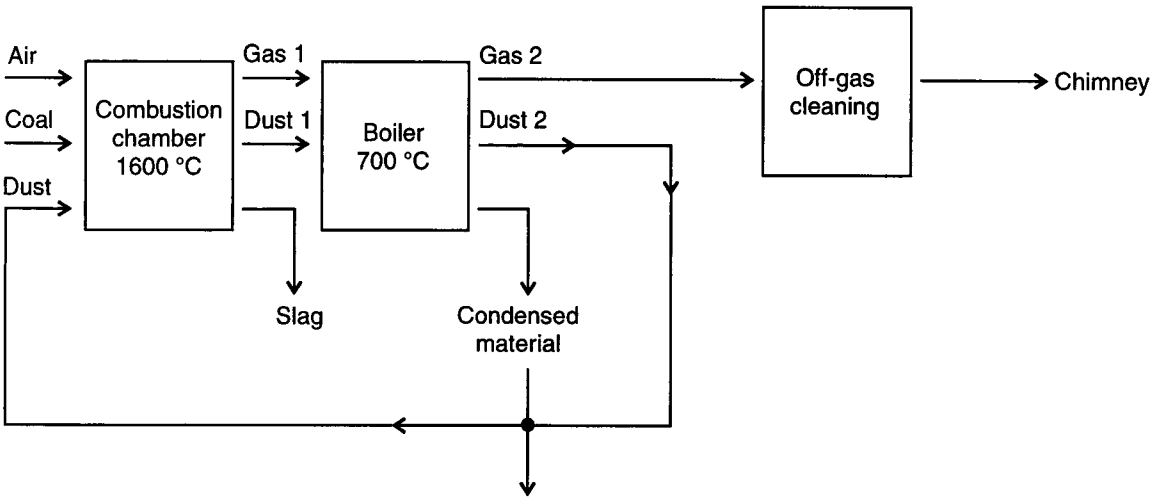

Fig. 7.6: Thermodynamic calculation model of the high-temperature part of a coal combustion plant for power generation. Flowsheet simulation of a process consisting in two steps.

simplifying assumptions. The model for the simulation of this process is shown schematically in Fig. 7.6.

The composition of the input coal is shown in Table 7.6. The combustion process should take place at 1600 °C leading to a gas product with an O_2 content of about 3 vol% on dry basis (gas without H_2O).

In the smelting chamber the coal does not react completely. This applies in particular to the solid carbon and the ash-forming components, while the so-called volatile fuel components (H, N, O, S) are completely oxidized. To simulate this fact, the degrees of conversion of the input materials or their components are restricted. For simplification it is first assumed that the unreacted portion of the coal leaves the reactor at the process temperature.

The dust removed in the flue gas scrubbing system is recycled to the combustion furnace together with the coal. A recycling system is thus achieved, in which the flow of material is only approximately quasi-stationary after several cycles. As a result of dust recycling, the gas phase becomes enriched with volatile components (alkali compounds) which condense on cooling the flue gas, and a proportion of them return to the combustion furnace together with the dust, where they vaporize again. The composition of the dust fed to the combustion chamber together with the coal is given in Table 7.6.

The material balance of the process is summarized in Table 7.7. The quantities and composition of the

dust fed to the combustion chamber are empirical data and are specific to the process carried out in a particular industrial plant. The compositions of the gas phase produced and the slag are given in Table 7.9. Because of the high process temperature of 1600 °C, alkali metals, chlorine, and phosphorus are mainly transferred to the gas phase.

On cooling the gas phase some gas components condense and thus lead to the formation of deposits in the boiler. Table 7.9 shows the composition of the condensed phases and the residual waste gas. The change in concentration of the main gas components is low on rapid cooling from 1600 to 700 °C. The condensed phases mainly consist of compounds of K and Na with Cl, P, and S. The low-melting sulfates, phosphates, and chlorides form first a liquid layer where solid dust particles can be deposited by sticking. The composition of the input fuel (coal, and waste material) besides the temperature and O_2 partial pressure in the combustion chamber, determine the quantity and composition of the condensate. The calculations show that the compositions of the codensate and the fly ash change significantly during the first five cycles. In subsequent cycles the changes become smaller and the process achieves a quasi-stationary state.

Part VI
Symbols, Abbreviations and References

9 Symbols and abbreviations used in the tables

AM	Amorphous
BPT	Boiling point in K, p(gas) = 1 bar
bcc	body-centered cubic crystal structure
bct	body-centered tetragonal crystal structure
C_p	C_p^0, Heat capactiy at 1 bar
DPT	Decomposition point in K at p = 1 bar
ΔG_f	ΔG_f^0, Gibbs energy of formation from the elements in their reference phases
ΔH_f	ΔH_f^0, Enthalpy of formation from the elements in their reference phases
fcc	face-centered cubic crystal structure
G	G^0, Gibbs energy
$-(G-H298)/T$	$-[G^0(T)-\Delta H_f^0(298.15)]/T =$ $-Gef$, Gibbs energy function (free enthalpy function)
GAS	Ideal gas
H	H^0, Enthalpy
hcp	hexagonal close packed crystal structure
L	Transition enthalpy in kJ/mol given as Remark at the bottom of the tables
LIQ	Liquid
$\log K_f$	$\log K_f^0$, Logarithm of the equilibrium constant of formation from the elements in their reference phases
MPT	Melting point in K at 1 bar
NBT	Normal boiling point in K, p(gas) = 1 atm
NDPT	Normal decomposition point in K, p = 1 atm
NSPT	Normal sublimation point in K, p(gas) = 1 atm
S	S^0, Entropy
SOL	Solid crystalline
SOL-A	Solid crystalline-α
SOL-B	Solid crystalline-β
SOL-C	Solid crystalline-γ
SOL-D	Solid crystalline-δ
SOL-1	Solid crystalline-I
SOL-2	Solid crystalline-II
SPT	Sublimation point in K at p(gas) = 1 bar
TPT	Transition point in K at 1 bar
298	298.15
