	Solidifier				
13	Agar[g]	6.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe calls for 38.5 mg FeNaEDTA which is essentially the same as the mixture in this table.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses. If the citric acid fails to dissolve add a few drops of 0.1N KOH or NaOH.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[g]Add items 1–10 to 800 ml of distilled water (item 12), adjust pH to 5.6, add sugar (item 11), and raise volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Amino acids, hormones, and vitamins may not be heat stable and should generally be added after autoclaving. Ethanol (up to 5–7 ml or even 10 ml of 95%) can be added to warm orchid culture media without ill effects. In fact 5–7 ml may even be beneficial (Thurston, Spencer and Arditti, unpublished findings dating back to the 1970s).

Procedure. After the final sterile distilled water wash and removal of discolored tissues, explants should be placed on the first medium (Table Diuris-1) and allowed to remain on it until PLBs are formed. After being subcultured on the same medium and following the production of 10–20-mm-long shoots, the PLBs should be moved to the second medium for rooting. Rooted plants are moved to the potting mix.

Developmental Sequence. Surviving explants (3/268 stem disks and 10/67 nodes after 180 days) produced "callus-like material at the ovary end" after a month and PLBs following 45 days on the first medium (Table Diuris-1). When subcultured on the same medium (Table Diuris-1) the PLBs produced shoots after 66–79 days. Shoots with 10–20-mm-long leaves produced roots after 70 days on the second solution (Table Diuris-2). Plantlets ready for potting were produced on the second medium after 85–100 days. These plantlets grew well after being potted, with 100% survival after 10 weeks. Some flowered 11 months after the start of culture.

General Comments. Despite low initial survival percentages this is an excellent procedure made even more useful by a report (Collins and Dixon, 1992) which is clear, detailed, and very well written. The method is the first published and successful protocol for an Australian terrestrial orchid.

Micropropagation of *Diuris purdiei*

The procedure used for *Diuris longifolia* can also be utilized for *Diuris purdiei* (Collins and Dixon, 1992).

Diuris longifolia (www.members.iinetnet.au/amntee/Diuris93.htm)

Diuris purdiei (King's Park&Botanic Garden)

Doriella

W. W. Goodale Moir was an orchid breeder in Hawaii who had a penchant for indiscriminately cross pollinating orchids across generic and species lines. As a result he produced many hybrids, a number of them involving more than one genus. To explain his successes, he formulated unusual, unscientific and silly theories, one of them being that phases of the moon somehow affect fruit set in orchids. In fact the reason for his successes was simply the exceedingly large number of crosses he made. It was inevitable that some of his innumerable crosses would produce interesting hybrids. One bigeneric hybrid he produced was *Doriella* (*Drlla*). The first of these was *Doriella* Tiny (*Doritis pulcherrima* × *Kingiella philippinensis*).

As is so often the case in orchids there are taxonomic and nomenclatural problems with *Kingiella*. One is a name change since *Kingiella* Rolfe was predated by *Kingella* van Tiegh. To solve this problem Peter F. Hunt replaced *Kingiella* with *Kingidium* (Bechtel et al., 1992). The other problem is that some taxonomists include *Kingidium* (*Kingiella*) in *Phalaenopsis* (Christenson, 2001). Should this be accepted *Doriella* would have to become *Phaliella*, but the International Registration Authority for Orchid Hybrids considers *Kingiella* to be valid. And what if *Kingidium* does become accepted? Will *Doriella* become *Dorgidium*, *Dorigidium*, *Doriidium*, or *Doridium*? And what if the order was reversed? Will we have *Kingritis*, *Kinritis*, *Kintis*, or *Kinoritis*? Probably not because these names seem like those of rare diseases. All this would be funny if it was not confusing, sometimes aggravating, and always taken so very seriously by taxonomists, breeders, and some growers.

The name *Doritis* may be derived from the Greek δορυ (dory), spear, in allusion to the hastate labellum or refer to Δοριτισ (Doritis which is another name for Aphrodite).

Kingiella commemorates Sir George King (1840–1909) of Indian orchids fame.

Micropropagation of *Doriella* Tiny

An effort to induce flowering in vitro by *Doriella* Tiny produced results which can be used as a micropropagation protocol (Duan and Yazawa, 1994*b*, 1994*c*, 1995*a*).

Plant Material. Flower-stalk internode sections, 3 cm long, each with a bud are cultured.

Surface Sterilization. In the original research the two ends of each section were sealed with wax apparently to prevent entry of the sterilant into the sections. This seems to be an unnecessary precaution because the amount of sterilant which can enter the stem during the 10-min sterilization is insignificant. Even if a larger volume did penetrate, the possibility that it would affect the bud is infinitesimal. Evidence for this is the successful culture of *Phalaenopsis* stem sections that are routinely sterilized without wax on their cut ends. Also, slightly longer sections, 4.5–5 cm, could be sterilized and 1 cm can be cut from each end to remove any tissue that may have absorbed sterilant. Sections should be sterilized by shaking them for 10 min in 1% sodium hypochlorite (20 or 17 ml of a household bleach containing 5–5.2% or 6% sodium hypochlorite respectively diluted to 100 ml with distilled water) containing 0.1% Tween 20 (www.sigmaaldrich.com), mild household detergent, or baby shampoo and then rinsed three times with sterile distilled water. The wax and "bracteal leaves" should be removed after the last rinse and before the sections are placed in culture. If longer sections are used the extra tissue should be cut at this stage. If "bracteal leaves" are the bracts which cover the buds it is best to remove them before sterilization because they can cover and protect potential contaminants.

Culture Vessels. Erlenmeyer flasks, 250 ml, or other containers can be used.

Culture Conditions. Cultures should be maintained at $25 \pm 3°C$ under 16-h photoperiods of 2500 lx provided by fluorescent tubes (type and manufacturer not indicated) or standard culture room conditions.

Culture Media. Sections should be cultured first in Hyponex (www.hyponex.co.jp) medium (Table Drlla-1) supplemented with BA, coconut water, and peptone for about 40–50 days. Adventitious buds formed on the first medium (Table Drlla-1) can be subcultured on the same solution. After that or following the formation of vegetative buds it is necessary to move bud bearing explants to Vacin and Went (VW)

TABLE DRLLA-1. **Hyponex medium for the culture of *Doriella* Tiny stem sections (Duan and Yazawa, 1994*b*)**

Component	Amount l^{-1}	Component	Amount	Comments
Hyponex	3.5 g	Sucrose	25.0 g	Add all components to 700 ml of water, adjust pH
Benzyladenine (BA)	5.0 mg	Agar	10.0	to 5.6, raise volume to 1000 ml, bring to a gentle
Peptone	2.0 g	Water	To 1000 ml	boil, add agar with stirring and keep stirring until it
Coconut water	150.0 ml			is dissolved, pour into culture vessels and autoclave

medium (Vacin and Went, 1949) containing BA (Table Drlla-2). Following the formation and development of leaves the shoots should be transplanted onto VW free of BA (Table Drlla-3) for root formation. Standard VW (Table Drlla-4) will probably be suitable for plantlet development.

Procedure. Following sterilization the explants should be cultured on the Hyponex medium (Table Drlla-1) until they develop vegetative buds. Some of the buds can be excised and cultured on the same solution (Table Drlla-1) to increase the number of explants. For leaf formation and development to take place it is necessary to move the bud bearing explants to the second medium (Table Drlla-2). Shoots which form on this medium must be moved to the third solution (Table Drlla-3) for root formation. Plantlets can be cultured on standard VW (Table Drlla-4) for further development. Buds which form on the explants on the first medium (Table Drlla-1) can be subcultured.

Developmental Sequence. Vegetative buds form on the Hyponex medium (Table Drlla-1). Leaves develop from these buds on the second solution (Table Drlla-2). Roots are initiated and plantlets form on the third medium (Table Drlla-3). Plantlets will grow bigger on the last substrate (Table Drlla-4).

General Comments. This seems to be a simple yet effective procedure for the micropropagation of *Doriella*. It may also prove to be effective for *Doritis*, *Kingiella* (*Kingidium*, *Phalaenopsis*), and *Doritaenopsis*.

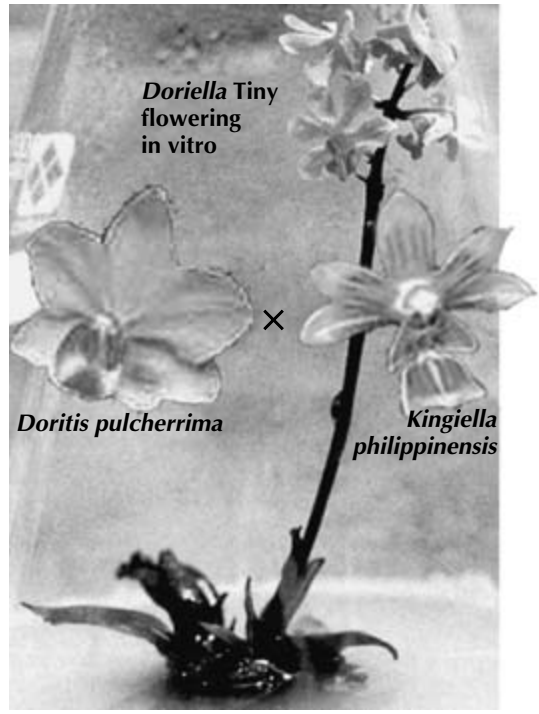

TABLE DRLLA-2. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of bud bearing *Dorriella* Tiny explants to enhance leaf growth (Duan and Yazawa, 1994*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Cytokinin				
8	Benzyladenine (BA)	10.0	1000 mg 100 ml 95% ethanol[e]	1	Or weigh
	Complex additive				
9	Coconut water[f]	150.0 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	25.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the cytokinin fails to dissolve add a few drops of 0.1N KOH or NaOH. Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[g]Add items 1, 3–7, and 9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 11), adjust pH to 5.6, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the cytokinin to the autoclaved, warm and still liquid medium, swirl or stir with a sterile tool, and distribute medium into preautoclaved culture vessels. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

TABLE DRLLA-3. **Modified Vacin and Went (VW) medium (Vacin and Went, 1949) for root induction on leaf bearing explants of *Doriella* Tiny (Duan and Yazawa, 1994*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10

	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 9) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 9) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 9), adjust pH to 5–5.4, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

In Vitro Flowering by *Doriella* Tiny

A method for in vitro flowering induction in *Doriella* Tiny was developed at the University of Kyoto to aid hybridization by reducing the period between making a cross and seeing the results (Duan and Yazawa, 1994*b*, 1994*c*, 1995*a*).

Plant Material. Flower-stalk internode sections, 3 cm long, each with a lateral bud are cultured.

Surface Sterilization. The two ends of each section were sealed with wax by the researchers probably to prevent sterilant entry of the tissue. This may be an unnecessary precaution because the volume of sterilant which can penetrate the stem during the sterilization period is insignificant and will probably do no harm. Proof of this is the successful culture of *Phalaenopsis* stem sections which are usually sterilized

without their cut ends being sealed. If there is concern about the sterilant, a simpler approach would be to sterilize sections which are 4.5–5 cm long and then cut 1 cm from each end to remove tissue that may contain sterilizing agent. The sections are sterilized by shaking them for 10 min in a 1% sodium hypochlorite solution (20 ml household bleach containing 5–5.25% sodium hypochlorite diluted to 100 ml with distilled water) containing 0.1% Tween 20 (www.sigmaaldrich.com) or mild household detergent and then rinsed three times with sterile distilled water. Wax and "bracteal leaves" should be removed after the rinses before placing the sections in culture. Should longer sections be used the extra tissue should be cut at this stage. If "bracteal leaves" are the bracts which cover the buds it is better to remove them before sterilization because they can cover up contaminants. Culturing buds which form on sections on the first medium (Table Drlla-1) will increase the number of explants.

Culture Vessels. Erlenmeyer flasks, 250 ml, or other containers can be used.

Culture Conditions. Cultures should be maintained at 25 ± 3°C under 16-h photoperiods of 2500 lx provided by fluorescent tubes (type and manufacturer not indicated).

Culture Media. Sections should be cultured first on Hyponex (www.hyponex.co.jp) medium (Table Drlla-1) supplemented with BA, coconut water, and peptone for about 40–50 days. Adventitious buds which form during this time can be subcultured on the same solution (Table Drlla-1). This "cycling propagation" increases the number of explants. After that 90-day-old shoots, 3–4 cm in height with three or four leaves, should be moved to Vacin and Went (VW) medium (Vacin and Went, 1949) containing BA and coconut water (Table Drlla-5). Following the formation of flower stalks and buds the plantlets should be returned to hormone-free Hyponex medium for flowering. The paper does not make clear whether this medium should be free of coconut water (Table Drlla-6). Therefore both versions (Tables Drlla-1 and Drlla-6) should be tested.

Procedure. Following sterilization the explants should be cultured on the Hyponex medium (Table Drlla-1) until they develop vegetative buds. These buds should be excised and cultured on the same solution (Table Drlla-1) to increase the number of propagules. For flower-bud formation shoots with three or four leaves and 3–4 cm tall are moved to the VW medium (Table Drlla-5). When flower buds form the plantlets should be moved to the Hyponex medium (Tables Drlla-1 or Drlla-6) which is most suitable for flowering (this must be determined by a comparison between the two). To enhance root formation after flowering, it may be necessary to move the shoots to a root inducing medium (Table Drlla-3). Plantlets can be cultured on standard VW medium (Table Drlla-4) for further development.

Developmental Sequence. The explants produce vegetative buds on the Hyponex medium (Table Drlla-1). Flower buds form after transfer to VW medium (Table Drlla-5). The plants flower on one or both of the Hyponex media (Tables Drlla-1 or Drlla-6). Roots are initiated and plantlets develop on another version of VW medium (Table Drlla-3).

TABLE DRLLA-5. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the induction of flower buds on *Dorriella* Tiny shoots (Duan and Yazawa, 1994*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Cytokinin				
8	Benzyladenine (BA)	5.0	500 mg 100 ml 95% ethanol[e]	1	Or weigh
	Complex additive				
9	Coconut water[f]	150.0 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	25.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the cytokinin fails to dissolve add a few drops of 0.1N KOH or NaOH. Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

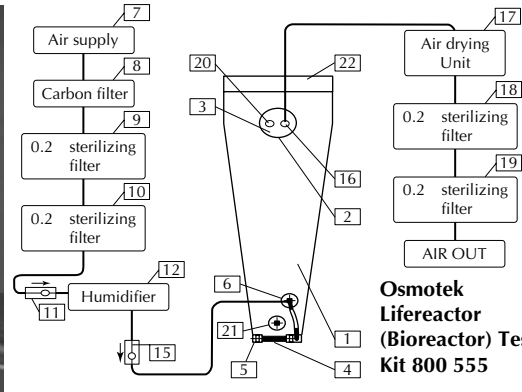
[g]Add items 1, 3–7 and 9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 11), adjust pH to 5.6, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the cytokinin to the autoclaved, warm and still liquid medium, swirl or stir with a sterile tool and distribute medium into preautoclaved culture vessels. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

TABLE DRLLA-6. **Hyponex medium for the culture of *Doriella* Tiny stem sections (Duan and Yazawa, 1994*b*)**

Component	Amount l^{-1}
Hyponex (www.hyponex.co.jp)	3.5 g
Benzyladenine (BA)	5.0 mg
Peptone	2.0 g
Sucrose	25.0 g
Agar	10.0 g
Water	To 1000 ml

Add all components to 700 ml of water, adjust pH to 5.6, raise volume to 1000 ml, bring to a gentle boil, add agar with stirring and keep stirring until it is dissolved, pour into culture vessels and autoclave. See footnote *g* in Table Drlla-5 for detailed instructions.

General Comments. This seems to be a simple yet effective procedure for flower induction in vitro in *Doriella*. It may also prove to be effective for *Doritis*, *Kingiella* (*Kingidium*, *Phalaenopsis*), and related species.



Osmotek Lifereactor (Bioreactor) Test Kit 800 555

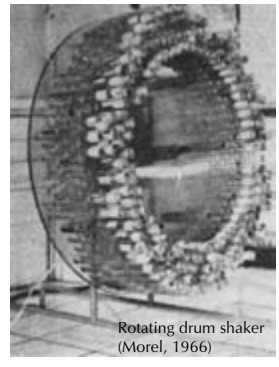
Platform shaker (www.fishersci.com)



Rotating drum shaker (Morel, 1966)

Doritaenopsis

Doritis as a genus was established by John Lindley in 1833. It is closely related to *Phalaenopsis* and separated from it by the length of the rostellum, column foot, and stipe of the pollinarium. As is so often the case with orchids some taxonomists consider these morphological differences to be important enough to justify separation of the two species and others do not. As a result taxa were transferred between the two genera at the drop of a taxonomist's whim (Freed, 1976). However, recent molecular data suggest that there is no justification for considering *Doritis* as a separate genus (Christenson, 2001). If this is accepted (as it should be because molecular data are much more powerful than personal views regarding the importance of structural features), *Doritis* will disappear and so will *Doritaenopsis*. However, for the time being *Doritis* exists and therefore so does *Doritaenopsis*, its hybrid with *Phalaenopsis*. The first *Doritaenopsis* hybrid in *Sander's List of Hybrids* is Dtps. Asahi (*Phalaenopsis lindeni* × *Doritis pulcherrima*) which was registered by Baron Toshito Iwasaki of Tokyo, Japan. At present *Doritaenopsis* hybrids are of commercial importance.

The following media in other sections of the book are used in the next procedure:

- Modified liquid Murashige–Skoog (see Table Aranda-11) or Vacin and Went (see Table Arach-5) media are used to culture explants. (As already mentioned Emil Vacin and Frits W. Went did not name their medium after themselves. Subsequent users named it by referring to it as the Vacin and Went medium. The same is true for Toshio Murashige and Folke Skoog and their medium, which is the most widely used plant tissue culture substrate.)
- Solid Vacin and Went medium (see Tables Arach-4 and Arach 5) is used for multiplication and differentiation.

Clonal Propagation of *Doritaenopsis* from Lateral Buds on Flower Stalks

A procedure for the clonal propagation of *Doritaenopsis* was developed at the Singapore Botanic Gardens (Lim-Ho, 1981).

Plant Material. Flower stalks of *Doritaenopsis* Elizabeth Waldheim (*Doritis pucherrima* × *Phalaenopsis* Lam Soon) and an unregistered hybrid were used in the original research.

Surface Sterilization. Scales that cover the buds are removed, and the stalk is washed with soap (antiseptic in the original research) and water. The washed stalks are immersed in 12–15% Clorox (12–15 ml Clorox diluted to 100 ml with distilled water) for 20 min. Although not mentioned in the original paper (Lim-Ho, 1981), several subsequent rinses with sterile distilled water are desirable.

Culture Vessels. See entries for *Aeridachnis*, *Arachnis*, *Arachnostylis*, *Aranda*, *Aranthera*, *Ascocenda*, *Burkillara*, and *Dendrobium* (Lim-Ho, 1981).

TABLE DTPS-1. **Tsuchiya's medium (Tsuchiya, 1954; Wimber 1963, 1965) for *Doritaenopsis* plantlet formation (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$	200 g	20 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated Iron**[c]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Complex additive				
7	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
8	Sucrose	2 g[d]	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	12–15 g	No stock	No stock	Weigh
	Darkening agent				
11	Active vegetable charcoal[e]	150	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe uses 28 mg ferric tartrate $[Fe_3(C_4H_4O_6)_3 \cdot 2H_2O]$ as a source of iron. Chelated iron is preferable.

[d]The original recipe includes 20 g sucrose.

[e]Add items 1–7 to 700 ml distilled water (item 9), adjust pH to 5.0–5.3, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved add the charcoal (item 11) with vigorous stirring, pour solution into culture vessels and autoclave. Omit agar if preparing liquid medium.

Culture Conditions. See entries for *Aeridachnis*, *Arachnis*, *Arachnostylis*, *Aranda*, *Aranthera*, *Ascocenda*, *Burkillara*, and *Dendrobium* (Lim-Ho, 1981).

Culture Media. Explants are first cultured in modified liquid Murashige–Skoog (see Table Aranda-11) or Vacin and Went (see Table Arach-5) media. For multiplication and differentiation the explants are moved to one of two solid modifications of the Vacin and Went medium (see Tables Arach-4 and Arach-5). Plantlet formation takes place on a solid Tsuchiya's medium (Table Dtps-1).

Procedure. Few details are given in the original paper, but it is reasonable to assume that one should section the stalks like those of *Phalaenopsis* (i.e., into 1- to 1.5-cm sections with the bud in the middle) and place them in culture. Alternately the buds only or the stalks only could be taken. Culture the explants, and transfer to a sequence of media as is done with *Aeridachnis*, *Arachnis*, *Arachnostylis*, *Aranda*, *Aranthera*, *Assocenda*, *Burkillara*, and *Dendrobium* (Lim-Ho, 1981).

Developmental Sequence. Details are lacking in the original paper, but it is possible that the buds develop like those of *Phalaenopsis*.

General Comments. This procedure should prove suitable for other crosses in this hybrid genus. Procedures developed for *Doritis* and *Phalaenopsis* could also be used. Leaves of *Doritaenopsis* were also cultured in Vacin and Went medium containing 15–50% coconut water (Sagawa and Kunisaki, 1982), but not enough details are available regarding this procedure to allow a description here.

In Vitro Culture of Flower-stalk Internodes of *Doritaenopsis*

The procedure used for *Phalaenopsis* (Lin, 1986) is suitable.

Maintenance of Embryogenic Callus of *Doritaenopsis*

Depending on the method being used to culture it, an embryogenic callus can produce protoplasts, embryoids, or PLBs, or all three, which can be used for genetic engineering or propagation. The effects of solidifiers, sugars, sugar alcohols, and coconuts on an embryogenic callus were studied at the Department of Life Sciences, Aichi University of Education in Japan (Ichihashi and Hiraiwa, 1996).

Plant Material. Callus was obtained from the Dogashima Orchid Center (2848–1 Nishina, Nishiizu-cho, Kamogun, Shizuoka 410–3514, Japan).

Surface Sterilization. There is no need to surface-sterilize callus which is growing axenically in vitro. However it should be washed with sterile distilled water to remove medium residues.

Culture Vessels. Erlenmeyer flasks, 50-ml capacity, were used in the original research. Other containers are also suitable.

Culture Conditions. The research cultures were maintained at 25°C under constant illumination of approximately 500 lx (1.2 mW cm^{-2}) provided by Plantlux (Toshiba plant growth) fluorescent tubes. Standard culture room conditions are also appropriate.

Culture Media. For maintenance and proliferation the callus should be maintained on sucrose-containing P medium (Table Dtps-2). This P medium is different from culture medium P which is used for *Ophrys* (see Table Oph-1; Hoppe and Hoppe, 1987*a*, 1987*b*, 1988). To cause the callus to become embryogenic and produce PLBs it should be cultured on a modification of the P medium which contains sorbitol (Table Dtps-3). After plantlets form roots they should be moved to banana homogenate containing Knudson C (KC; Knudson, 1946) medium (see Table Cym-24).

Procedure. Depending on the purpose, goals, or needs of a laboratory the callus can be cultured on a medium designed to maintain it (Table Dtps-2) or induce PLBs formation (Table Dtps-3). Once plantlets develop roots they should be moved to modified KC (see Table Cym-24).

TABLE DTPS-2. **P medium for maintenance of an embryogenic callus (Ichihashi and Hiraiwa, 1996)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium phosphate, $NH_4H_2PO_4$[b]	922.4	92.24 g l^{-1}	10	
2	Calcium nitrate, $CaNO_3{\cdot}4H_2O$[b]	236.2	23.62 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4{\cdot}7H_2O$	246.5	24.65 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	606.6	60.66 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	272.2	27.22 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4{\cdot}7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2{\cdot}6H_2O$	0.0125	1.25 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4{\cdot}5H_2O$	0.0125	1.25 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4{\cdot}4H_2O$	11.2	1.12 g l^{-1}		
(e)	Potassium iodide, KI	0.415	41.5 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4{\cdot}2H_2O$	0.125	12.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4{\cdot}7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
13	Coconut water[f]	125.0 ml	No stock	No stock	Measure
	Sugar				
14	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[f]	To 1000 ml			
	Solidifier				
16	Gelrite[f]	4.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved and the solution turns dark yellow.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1–13 to 750 ml of distilled water (item 15), adjust pH to 5.6 ± 0.1, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Gelrite or gellan gum [available as such from www.caissonlabs.com or as Phytagel (www.sigmaaldrich.com)] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gelrite, (gellan gum, Phytagel) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave. As a rule amino acids (item 8) and vitamins (items 10–12) are added to the hot solution after autoclaving under sterile conditions with sterilized pipettes, mixed well and the medium is then distributed into preautoclaved culture vessels. In this instance all components are added before autoclaving.

TABLE DTPS-3. **P medium for culture of embyogenic callus (Ichihashi and Hiraiwa, 1996)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium phosphate, $NH_4H_2PO_4$[b]	922.4	92.24 g l^{-1}	10	
2	Calcium nitrate, $CaNO_3 \cdot 4H_2O$[b]	236.2	23.62 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	246.5	24.65 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	606.6	60.66 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	272.2	27.22 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310.0 mg l^{-1}

10	Sorbitol	10.0	No stock	No stock	Weigh
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
14	Coconut water[f]	125.0 ml	No stock	No stock	Measure
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Gelrite[g]	4.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved and the solution turns dark yellow.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1–14 to 750 ml of distilled water (item 15), adjust pH to 5.6 ± 0.1, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Gelrite or gellan gum [available as such from www.caissonlabs.com and as Phytagel (from www.sigmaaldrich.com)] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gelrite (gellan gum, Phytagel) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave. As a rule amino acids (item 8) and vitamins (items 11–13) are added to the hot solution after autoclaving under sterile conditions with sterilized pipettes, mixed well and the medium is then distributed into preautoclaved culture vessels. In this instance all components are added before the medium is autoclaved.

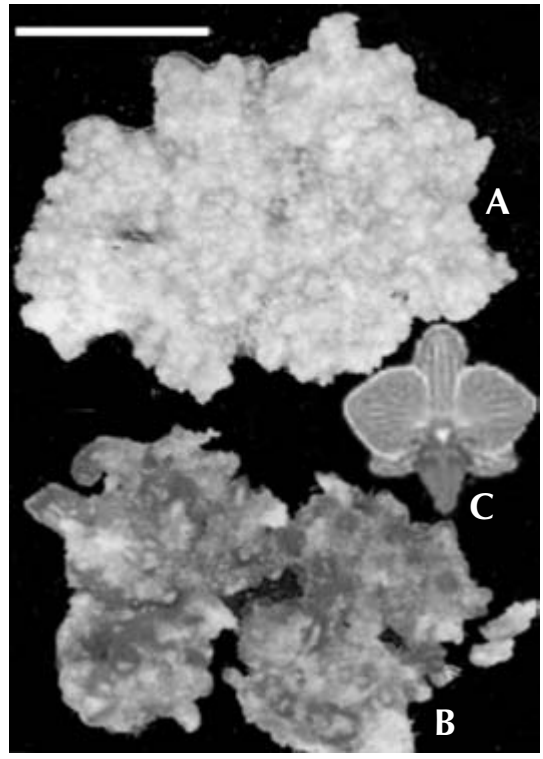

FIG. DTPS-1. **Embryogenic callus of *Doritaenopsis* New Toyohashi. A. Yellow friable callus on sucrose containing P medium. B. Green embryogenic callus on sucrose-free medium. C. *Doritaenopsis* New Toyohashi. Scale bar ≈ 1 cm. (Sources: A, B, Ichihashi and Hiraiwa, 1996; C, www.orchiddigest.com.)**

Developmental Sequence. This callus may remain friable, yellow and very prolific on one medium (Table Dtps-2) or turn green and form PLBs on the other (Table Dtps-3).

General Comments. A friable proliferating callus offers many possibilities (Fig. Dtps-1). Therefore a procedure which can generate and maintain such a callus is of considerable importance.

Micropropagation of *Doritaenopsis* through the Culture of Lateral Buds from Young Flower Stalks

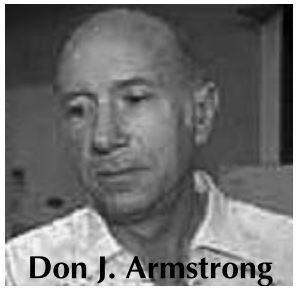
A method for the micropropagation of *Phalaenopsis* through the culture of lateral buds from young flower stalks (Ichihashi, 1992*a*, 1992*b*) can probably also be used for *Doritaenopsis*. See the *Phalaenopsis* section for more details.

Propagation of *Doritaenopsis* through the Culture of Flower-stalk Sections on Thidiazuron-containing Medium

Phalaenopsis flower-stalk sections (Rotor, 1949), not *Cymbidium* or other shoot tips (Morel, 1960), were the first orchid explants to be cultured. For *Doritaenopsis* and *Phalaenopsis* the culture of inflorescence sections is still an important means of micropropagation, but most of the available methods produce only a few plants per explants.

Chance and prepared minds: thidiazuron (TDZ) as a cytokinin

In the mid 1970s Dr. Machteld C. Mok (Departments of Horticulture and Genetics), Dr. David W. S. Mok (Department of Horticulture), and Dr. Don J. Armstrong (Department of Botany and Plant Pathology) at Oregon State University were searching for cytokinin antagonists. After they heard a talk about the cotton defoliant Dropp (TDZ) in 1978 it occurred to them that they "might have found [their] antagonist." When they "tested it in callus bioassays . . . to [their] great amazement, thidiazuron turned out to be a very potent cytokinin" (quotes from an e-mail by Machteld Mok). They reported their findings in 1979 and 1980 and published them in 1982. The discovery generated interest immediately. In 1987 Dr. Paul E. Read and his associates in Nebraska studied TDZ effects on meristem formation and shoot proliferation. Badzian et al. in Poland investigated TDZ effects on organogenesis of *Brassaia actinophylla* shoot explants in 1987. Dr. John E. Preece and his group at the University of Illinois studied the effects of TDZ in tissue culture of woody plants in 1992 and 1993. Dr. Robert Ernst at the University of California, Irvine was the first to use TDZ in orchid micropropagation and published his findings in 1994. Since then TDZ has been used successfully in a number of other orchid micropropagation procedures.



Note: Louis Pasteur is reported to have said that chance favors the prepared mind. This is a classic example of prepared minds seizing a chance.

When the extremely high cytokinin acitivity of TDZ became known, Dr. Robert Ernst at the Universisty of California, Irvine tested its effects on *Doritaenopsis* and *Phalaenopsis* stem sections (Ernst, 1994).

Plant Material. Flower stalks which finished blooming were the sources of explants. After removing the upper small-flower-bud-bearing portions and the lowermost node the stalks were cut into 3-cm sections, each with a bud in the middle.

Surface Sterilization. After sealing the ends of the sections with paraffin wax to prevent entry of sterilant into the tissues, they were wiped with 95% ethanol and then stirred for 20 min in a 1% solution of sodium hypochlorite (20 ml of household bleach containing 5–5.25% sodium hypochlorite) partially neutralized to pH 9.0 ± 0.2 with 2N hydrochloric acid [17.2 ml of concentrated HCl diluted to 100 ml with distilled water; to prevent splattering and possible injury to the operator the acid must be poured into the water (never the water into the acid) slowly with stirring while wearing a face guard and gloves]. Bracts which cover the buds were removed after that and the sections were submerged in the same sterilant for an additional 10 min. The sections were placed in culture after rinsing them three times with sterile distilled water and cutting the paraffin wax seals. The paraffin seals seem to be an unnecessary precaution which overly complicates the procedure without serving much of a useful function because the volume of sterilant which can enter the sections during 30 min is very small and will probably have no effects of any kind. Also, cutting about 0.25–0.5 cm off the ends of sections will probably remove tissue which contains sterilant. Countless *Phalaenopsis* stem sections are cultured successfully in many laboratories without being sealed. This is convincing evidence that paraffin sealing is not necessary. The neutralization of the sterilant (a procedure used with other plants before being adapted to *Doritaenopsis*; the original paper does not cite a source for it) also seems to be an excessive precaution and unnecessary complication because no other successful orchid procedures use it. Still, both the paraffin seal and sterilant neutralization should not be eliminated without a preliminary test.

Culture Vessels. Erlenmeyer flasks, 250 ml capacity containing about 50 ml medium, closed with perforated rubber stoppers plugged with cotton can be used. Other containers and/or different plugs are also suitable.

Culture Conditions. Research cultures were maintained at 23–24°C under 12-h photoperiods of approximately 25 μmol m^{-2} s^{-1} provided by Sylvania F 3OTB 30-W Gro-Lux lamps (Sylvania GTE, Versailles, KY, USA).

Culture Media. Explants should be cultured initially in a medium designated XER by its author (eXperimental Ernst, Robert) containing 0.45 μmol TDZ (Table Dtps-4). PLBs produced on the first medium should be cultured in XER medium containing 30–45% coconut water (CW) from ripe nuts (Table Dtps-5) to induce further proliferation. To enhance vegetative growth PLBs can also be cultured (before or after proliferation) on XER containing 0.2% activated charcoal (www.sigmaaldrich.com) and 5% (w/v) ripe banana pulp homogenate (Table Dtps-6).

TABLE DTPS-4. **XER medium for the culture of *Doritaenopsis* flower-stalk sections (Ernst, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	122.0	12.2 g l^{-1}	10	
4	Dibasic potassium phosphate, K_2HPO_4	30.0	3.0 g l^{-1}	10	
5	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
6	Potassium nitrate, KNO_3[b]	500.0	50.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	2.0	200.0 mg l^{-1}	10	One solution
(b)	Cobaltous chloride, $CoCl_2 \cdot 6H_2O$	0.03	3.0 mg l^{-1}		
(c)	Copper chloride, $CuCl_2 \cdot 2H_2O$	0.015	1.5 mg l^{-1}		
(d)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	2.5	250.0 mg l^{-1}		
(e)	Sodium molybdate, $NaMoO_4 \cdot 2H_2O$	0.025	2.5 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.05	5.0 mg l^{-1}		
	Cytokinin				
9	Thidiazuron	1.0	100 mg 100 ml^{-1} 1N NaOH in 95% ethanol[e]	1	
	Sugar				
10	Fructose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[e,f]	To 1000 ml			
	Solidifier				
12	Gelrite[f,g]	5.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]The original recipe does not include EDTA as a chelating agent. It is included here because iron salts tend not to stay in solution. Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. The XER original recipe for this medium calls for 28 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, l^{-1}. The difference (0.2 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored. Sticklers for accuracy can add 28 mg l^{-1}.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]To prepare the solvent (1N NaOH in ethanol) dissolve 4 g NaOH in 100 ml 95% ethanol. Use this as a sterilizing solvent for thidiazuron if the cytokinin is to be added to the medium after autoclaving. According to several reports thidiazuron can be added to the medium before autoclaving. If so it can be dissolved in aqueous 1N NaOH. In either case the stock solution should be kept frozen between uses. Thidiazuron can also be dissolved in dimethyl sulfoxide (DMSO). Both thidiazuron and DMSO can be obtained from www.sigmaaldrich.com and other sources. For more information about incorporation of thidiazuron in culture media see Mok et al., 1982; Mok and Mok, 1985; Fellman et al., 1987; Badzian et al., 1989; Bates et al., 1992; Huetterman and Preece, 1993 (excellent source of information); Neuman et al., 1993.

[f]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and bring volume to 1000 ml with distilled water (item 11). Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the gellan gum is completely dissolved pour the solution into culture vessels and autoclave.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

TABLE DTPS-5. **Coconut water-containing XER medium for proliferation of protocorm-like bodies (PLBs) produced by flower-stalk explants of *Doritaenopsis* (Ernst, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitratete, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4{\cdot}7H_2O$	122.0	12.2 g l^{-1}	10	
4	Dibasic potassium phosphate, K_2HPO_4	30.0	3.0 g l^{-1}	10

9	Coconut water from ripe nuts[e]	400.0 ml	No stock	No stock	Measure
	Sugar				
10	Fructose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f,g]	To 1000 ml			
	Solidifier				
12	Gelrite[f,g]	5.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]The original recipe does not include EDTA as a chelating agent. It is included here because iron salts tend not to stay in solution. Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. The XER original recipe for this medium calls for 28 mg ferrous sulfate, $FeSO_4{\cdot}7H_2O$, l^{-1}. The difference (0.2 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored. Sticklers for accuracy can add 28 mg l^{-1}.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endospermor "meat" inside the nut). It is preferable to use water from unripe (green) nuts except when indicated otherwise as in this case. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe nuts are not available, water from ripe (brown) ones can be used even for media which require water from green fruits. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

[g]Add items 1–9 to 500 ml of distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and bring volume to 1000 ml with distilled water (item 11). Gelrite (gellan gum, Phytagel) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the gellan gum is completely dissolved pour the solution into culture vessels and autoclave.

TABLE DTPS-6. **Banana pulp homogenate and activated charcoal-containing XER medium for enhancement of vegetative growth of plantlets produced by flower-stalk explants of *Doritaenopsis* (Ernst, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitratete, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4{\cdot}7H_2O$	122.0	12.2 g l^{-1}	10	
4	Dibasic potassium phosphate, K_2HPO_4	30.0	3.0 g l^{-1}	10	
5	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
6	Potassium nitrate, KNO_3	500.0	50.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4{\cdot}7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	10.0	1.0 g l^{-1}	10	One solution
(b)	Cobaltous chloride, $CoCl_2{\cdot}6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4{\cdot}6H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4{\cdot}4H_2O$	25.0	2.5 g l^{-1}		
(e)	Sodium molybdate, $Na_2MoO_4{\cdot}2H_2O$	0.25	25.0 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4{\cdot}7H_2O$	10.0	1.0 g l^{-1}		
	Complex additive				
9	Ripe banana pulp homogenate[e]	50.0 g	No stock	No stock	Weigh
	Sugar				
10	Fructose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f,g]	To 1000 ml			
	Solidifier				
12	Gelrite[f,g]	5.0 g	No stock	No stock	Weigh
	Darkening agent				
13	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]The original recipe does not include EDTA as a chelating agent. It is included here because iron salts tend not to stay in solution. Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. The XER original recipe for this medium calls for 28 mg ferrous sulfate, $FeSO_4{\cdot}7H_2O$, l^{-1}. The difference (0.2 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored. Sticklers for accuracy can add 28 mg l^{-1}.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Opinions differ regarding the use of banana in culture media for orchids. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable; (2) the peel rather than the pulp should be used; (3) unpeeled banana homogenate should be incorporated in media; and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective variety (Gros Michel, Raja, Pisang Susu and others). Since there is no experimental evidence to support any view regarding which is the best approach, follow the recommendations in the original reports and use what is suggested there. If there are no specific suggestions, or if there are but specific bananas are hard to find, the best approach is to use those that are easily available.

[f]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

[g]Pour 900 distilled water (item 11) into a blender, add items 1–9, homogenize throughly, adjust pH to 5.5, add sugar (item 10), homogenize again and bring volume to 1000 ml with distilled water (item 11). Gelrite (gellan gum, Phytagel) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the gellan gum is completely dissolved pour the solution into culture vessels and autoclave.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite should not be used except in special circumstances.

Procedure. Surface-sterilized sections are placed in culture and maintained on the first medium (Table Dtps-4) until PLB or plantlet formation. PLBs can be cultured on CW containing XER (Table Dtps-5) for proliferation. Plantlets or PLBs are cultured on medium supplemented with banana pulp (Table Dtps-6) for vegetative growth.

General Comments. This very useful method is the first one for orchids to use TDZ. Its important advantage is that it generates several plantlets per explant node.

Doritaenopsis Micropropagation by the Culture of Thin Sections of Leaves

There are a number of methods for the culture of *Phalaenopsis* and *Doritaenopsis*, but most of them do not produce enough plants fast enough or without somaclonal variations. A method utilizing thin sections of leaves seems to be rapid and efficient (Park et al., 2002).

Plant Material. Sections, five to seven, each 1 mm thick, were cut from leaves of 3-month-old plantlets generated from PLBs derived from flower-stalk sections of *Doritaenopsis* New Candy × (*Doritaenopsis* Mary Ames × *Doritaenopsis* Ever Spring).

Surface Sterilization. There is no need to sterilize explants taken from plants growing in vitro. However, they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Plastic Petri dishes, 10 cm in diameter containing 25 ml of medium, were used to culture the thin sections in the original research. Other containers can also be used. Erlenmeyer flasks, test tubes, jars, or other containers can be used to culture PLBs for plantlet production. Plantlets are grown in pots.

Culture Conditions. In the original research the cultures were maintained initially for a week in the dark at 27°C and then transfereed to 25 ± 1°C under 16-h photoperiods of 10 μmol m^{-2} s^{-2} photosynthetic photon flux provided by cool white fluorescent lamps (Kumho FL 40D). Cultures for plantlet production were maintained at 25°C under 16-h photoperiods of 30 μmol m^{-2} s^{-1}. Standard culture room conditions will probably also be suitable. Plantlets, 5–6 cm in height, were potted and grown in a greenhouse under 60–70% relative humidity (RH) and 16-h photoperiods of 500 μmol m^{-2} s^{-1} and 25°C. The temperature during the 8-h dark period was 15°C.

Culture Media. Thin sections should be cultured on half-strength MS medium (Murashige and Skoog, 1962) containing 2 mg TDZ l^{-1} (Table Dtps-7; the actual amount used was 9 μmol or 1982.7 μg, which can be rounded up to 2 mg). For plantlet production PLBs should be grown on modified Hyponex (KH) medium (Kano, 1965) containing potato homogenate and peptone (Table Dtps-8). Hyponex (www.hyponex.co.jp) may not be easy to find in some parts of the world, therefore banana homogenate and activated charcoal containing XER medium (Table Dtps-6) can be used instead. Plantlets should be potted in sphagnum moss.

TABLE DTPS-7. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of thin sections of *Doritaenopsis* leaves (Park et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10

15	Coconut water[h]	200.0 ml	No stock	No stock	Measure
	Sugar				
16	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[i]	To 1000 ml			
	Solidifier				
18	Agar[i]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]To prepare 0.5 N HCl pour 4.3 ml of concentrated hydrochloric acid into 95.7 ml distilled water slowly while stirring. To prevent splatter and possible injury acid must always be poured into water. Water must never be poured into acid [mnemonic by Prof Arnold S. Dunn of the University of Southern California: **A**(cid) comes before **W**(ater)]. The person preparing this solution must wear rubber gloves and a face shield. Also it is preferable to use a volumetric flask (www.fishersci.com or www.wvr.com). Adenine sulfate (www.sigmaaldrich.com, www.fishersci.com, www.wvr.com) is dissolved in 0.5N HCl to prepare the stock solution which must be kept frozen between uses.

[g]To prepare 1N NaOH dissolve 4 g of sodium hydroxide (www.sigmaaldrich.com, www.fishersci.com, www.wvr.com) in 100 ml distilled water. To prevent splatter and possible injury the NaOH pellets must always be dropped a few at a time into the water. Water must never be poured on the pellets. The person preparing this solution must wear rubber gloves and a face shield. Also it is preferable to use a volumetric flask (www.fishersci.com or www.wvr.com). Thidiazuron (www.sigmaaldrich.com) is dissolved in 1N NaOH to prepare the stock solution which must be kept frozen between uses.

[h]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not

TABLE DTPS-8. **Kano's Hyponex (KH) medium (Kano, 1965) modified for plantlet production from protocorm-like bodies derived from *Doritaenopsis* leaf sections (Park et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]
	Macroelements	
1	Hyponex[b]	3.0
	Complex additive	
2	Potato homogenate[c]	30.0
	Sugar	
3	Sucrose	20.0
	Solvent	
4	Water, distilled[d]	To 1000 ml
	Solidifier	
5	Agar[d]	5.5
	Darkening agent	
6	Activated charcoal[e]	0.5

[a]Amounts are given in g unless indicated otherwise.

[b]This is a soluble fertilizer which is becoming hard to find outside of Japan. The address in Japan is Hyponex Co., Tokyo, Japan. A website for the Hyponex brand name in the USA is www.scotts.com. If Hyponex cannot be located, modfied XER medium (Table Dtps-6) can be used instead.

[c]To prepare potato homogenate peel the potatoes, cut them into cubes approximately 1 cm^3 in size, and follow directions in footnote *d*.

[d]Add items 1 and 2 to 800 ml distilled water (item 4) in a homogenizer, homogenize thoroughly, let stand for 30–60 s and homogenize again, adjust pH to 5.5, add the sugar (item 3) and raise the volume to 1000 ml with distilled water (item 4). Bring the mixture to a gentle boil and add the agar (item 5) while stirring vigorously. When the agar is completely dissolved add the activated charcoal (AC, item 6) slowly with stirring. Keep stirring until the charcoal is dispersed completely. After that dispense the medium into culture vessels and autoclave.

[e]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources. Charcoal functions not only by darkening the medium, but also (and probably mainly) by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite should not be used except in special circumstances.

Procedure. Thin sections should be placed on the agar cut side down on the first medium (Table Dtps-7), maintained in the dark for a week, moved to 16-h photoperiods and kept there until PLBs are formed (approximately 6 weeks). Plantlets on the second medium (Table Dtps-8) should be subcultured every 8 weeks. When plantlets reach a height of 5–6 cm they should be moved to pots and grown in a greenhouse.

Developmental Sequence. Globular structures develop after 2 weeks of culture (Fig. Dtps-2A). They become distinct on the edges of the thin sections after an additional week (Fig. Dtps-2E). PLBs become evident after that (Fig. Dtps-2B, D). They are always formed near the epidermis of the sections and never from callus. The PLBs form normal plantlets on the Hyponex medium (Fig. Dtps-2C) which develop normally after being potted (Fig. Dtps-2F).

be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH as required, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels.
Agar is not added to liquid media.

First description of the Petri dish

Petri, R. J. 1887. Eine kleine Modification des Koch'schen Plattenverfahrens. *Centralblatt fur Bacteriologie und Parasitenkunde*, Vol. 1, page 279. [A small modification of Koch's plating method. Translated from the original German.]

In order to perform the gelatin plate technique of Koch, it is necessary to have a special horizontal pouring apparatus. The poured plates are then placed over one another in layers on small glass shelves in a large bell jar. In many cases it would be desirable to carry out the procedure with less equipment, especially without the pouring apparatus. Since the first of the year I have been using flat double dishes of 10–11 cm diameter and 1–1.5 cm height. The upper dish serves as a lid as usual and has a somewhat larger diameter. These dishes are sterilized by dry heat as usual and after cooling the nutrient gelatin containing the inoculum is poured in. The upper lid is lifted only slightly and used as a shield, while the tube containing the gelatin, its edge previously flamed and cooled in the usual manner, is emptied into the bottom of the dish. Under these conditions contamination from airborne germs rarely occurs. The poured layer of gelatin soon hardens into a layer several millimeters thick which can be kept and observed for a long time because of the protecting upper lid. In studies of soil samples, sand, earth, and similar substances, it is advantageous to place the material in the dish and then pour the liquid gelatin over it. The material is well mixed with the gelatin by rotating the dish with short, intermittent movements. With the dimensions given, every spot on the gelatin surface is accessible with the low power microscope. Only when high power lenses are used is the area at the edge of the dish no longer accessible. The gelatin dries in these dishes quite slowly. The gelatin can be kept moist longer if five or six dishes are placed on top of one another on a disc of moist filter paper in a flat dish over which a bell jar is inverted. These dishes can be especially recommended for agar-agar plates, since agar-agar sticks poorly to simple glass plates unless special methods are used. In addition, it is quite simple to count the colonies that have grown on the plates. The upper lid is replaced by a glass plate that has etched on it squares of known area. The colonies are then counted against a black background using a magnifier. The total area of the plate can be calculated from the diameter.

General Comments. This procedure is actually the second part of a two-step method which starts with the culture of flower stem sections (see method by Park et al., 2000 in the *Phalaenopsis* section, p. 1013, Vol. II). Plantlets produced through this method are the explant sources. Use of this two-step procedures makes possible mass rapid clonal propagation without excessive proliferation of PLBs which can bring about undesirable somaclonal variations.

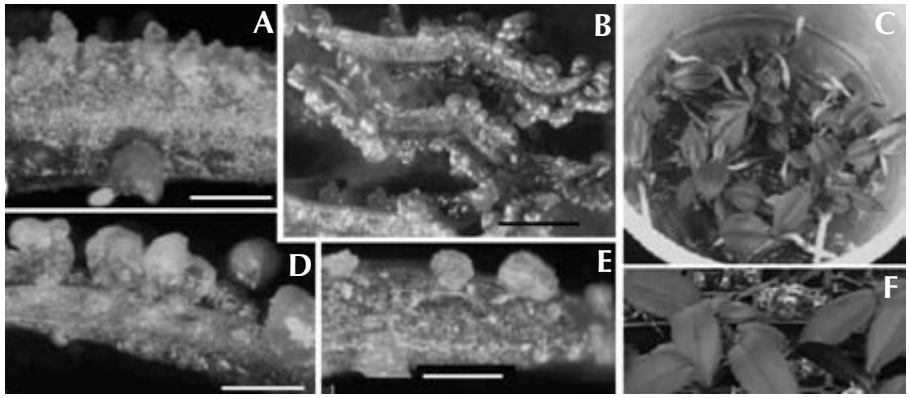

FIG. DTPS-2. **PLB production from thin leaf sections of *Doritaenopsis* and subsequent plantlet development. A. Initiation of PLBs on cut edge (scale bar = 1.5 mm). B, D. Multiple PLBs on cut surfaces after 4 and 6 weeks of culture (scale bars = 3 mm (B), 2 mm (D)). C. Plantlets developing on PLBs after 3 months on Hyponex medium. E. PLB primordia after 3 weeks of culture (scale bar = 2 mm). F. Plants in pots. (Park et al., 2002.)**

Micropropagation of *Doritaenopsis* by Culturing Shoot Tips of Flower-stalk Buds

When the popularity of *Doritaenopsis* as a pot plant increased in recent years so did the need for an efficient rapid micropropagation technique. Such a technique was developed by the Orchid Sanctuary Dogashima and the Faculty of Horticulture, Chiba University (Tokuhara and Mii, 1993).

Plant Material. Flower stalks bearing vegetative buds were taken from plants (Fig. Dtps-3A) and cut into sections leaving 15 mm above each bud and 25 mm below it (Fig. Dtps-3B). Shoot-tip explants 1 mm wide and 0.5 mm high with two or three leaf primordia (Fig. Dtps-3F) were excised following surface sterilization.

Surface Sterilization. Buds should be exposed (Fig. Dtps-3C) by removing the bracts (Fig. Dtps-3D) which cover them and the sections, and then sterilized with the supernatant of a 5% solution of calcium hypochlorite, $Ca(ClO)_2$ (5 g of calcium hypochlorite in 100 ml distilled water, stirred, allowed to stand until a precipitate forms, and stirred again repeating the process three times before decanting the liquid which must be used within 12 h or less; this solution contains about 1% available chlorine), containing a few drops of Tween 20 (www.sigmaaldrich.com, www.fishersci.com, www.vwr.com) or of a mild household detergent by a 15-min immersion with stirring. Following sterilization the buds should be washed with sterile distilled water three times before removing two or three scaly leaves (Fig. Dtps-3E) prior to excision of the explants.

Culture Vessels. Test tubes, 24 × 100 mm containing 15 ml of solid medium and covered with sterilized aluminum foil, were used. Other containers are also suitable.

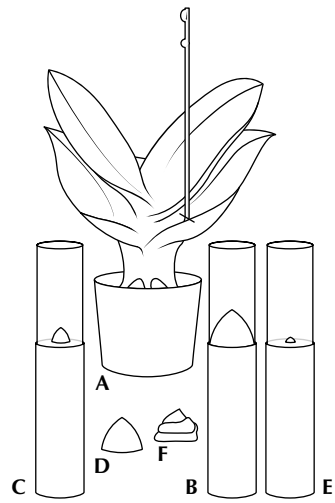

FIG. DTPS-3. **Excision of *Doritaenopsis* buds. A. Plant with bud bearing flower stalk. B. Bud-bearing section. C. Exposed bud following removal of bract which covered it. D. The bract. E. Bud after scales which cover it have been removed. F. Explant to be cultured. (Tokuhara and Mii, 1993.)**

Culture Conditions. The research cultures were maintained at $23 \pm 1°C$ under 14-h photoperiods of 33 μmol m^{-2} s^{-1} provided by Toshiba FLR40S W/M 36 lamps. Standard culture room conditions are probably also suitable.

Culture Media. New Dogashima (ND) medium containing 0.1 mg NAA l^{-1} and 1 mg BA l^{-1} (Table Dtps-9) should be used for PLB induction and subculture. Hormone-free ND medium (Table Dtps-10) is used for plantlet development from PLBs.

Procedure. Flower stalks are cut into sections after being removed from plants. The bracts which cover the buds are removed, the sections are surface sterilized and then rinsed with sterile distilled water. Scale leaves are removed from the buds after the rinse, and shoot tips are excised and placed into culture on hormone-containing medium (Table Dtps-9). When PLBs form they should be subcultured on the same medium (Table Dtps-9). To produce plantlets PLBs should be cultured on hormone-free medium (Table Dtps-10).

Developmental Sequence. Explants form PLBs on the first medium (Table Dtps-9). When subcultured on the same medium (Table Dtps-9) the PLBs proliferate. The PLBs produce plantlets on the second medium (Table Dtps-10).

General Comments. This procedure can be used for both *Doritaenopsis* and *Phalaenopsis*. The protocol is easy, simple, and efficient. With it propagation is rapid. More than 10,000 PLBs were obtained in 1 year from a few buds excised from a single flower stalk. Unfortunately, the efficiency and speed are also the major drawbacks of this protocol because rapid and excessive proliferation can and does lead

TABLE DTPS-9. **Medium for root induction on *Doritaenopsis* plantlets (Park et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	3.0	300 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylaminopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Gelrite[g,h]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin do not dissolve, add a few drops of 0.1N KOH or 0.1N HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.2–5.6, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Gelrite (gellan gum, Phytagel) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. Pour solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Solidifier is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear, and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

TABLE DTPS-10. **Medium for elongation of roots on *Doritaenopsis* plants (Park et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}

	Vitamins[f]				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			
	Solidifier				
15	Gelrite[g,h]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]There is no auxin or cytokinin in this medium.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 14), adjust pH as required, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Gelrite (gellan gum, Phytagel) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium, it will form clumps and will not gel properly after autoclaving. Add the amino acid (item 8) and vitamins (items 10–12) to the warm and still liquid solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

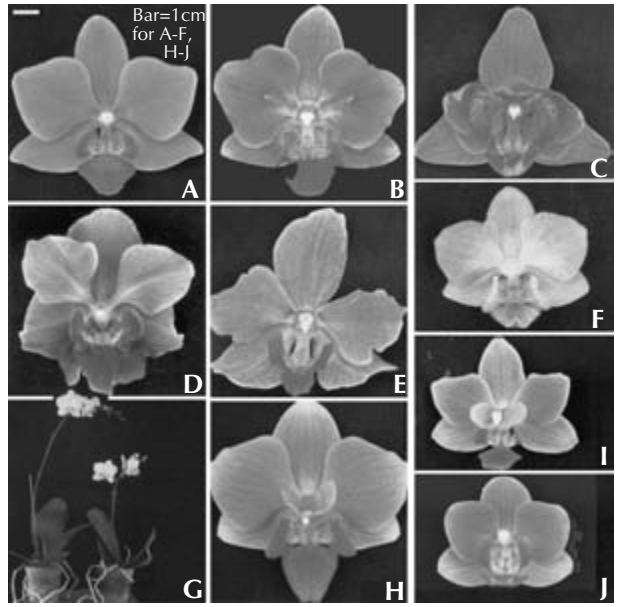

FIG. DTPS-4. **Micropropagation induced somaclonal variations in *Phalaenopsis* flowers (A–F, H–J). G. Different lengths of inflorescences in *Doritaenopsis*. (Tokuhara and Mii, 1998.)**

to mutations, somaclonal variations, and flower shapes which can be undesirable (Fig. Dtps-4; Tokuhara and Mii, 1998).

Micropropagation of *Doritaenopsis* through Root-tip Cultures

Root tips are attractive explants for micropropagation of monopodial orchids because removing them does not threaten the survival of the plants from which they are taken. Therefore a micropropagation method for *Doritaenopsis* using root tips was developed in a cooperative research project involving the Research Center for the Development of Advanced Horticultural Technology, Chungbuk National University in Korea, and the Department of Biological Science, Aichi University of Education in Japan (Park and Paek, 2001; Park et al., 2001).

Plant Material. To obtain enough roots for explants in vitro raised plantlets of *Doritaenopsis* New Candy × (*Doritaenopsis* Mary Ames × *Doritaenopsis* Ever Spring) with two to three leaves were cultured for 2 months on a medium containing 3 mg NAA (Table Dtps-9). Approximately 18 roots per plant were produced on this medium. After that the plantlets were moved to an auxin-free medium (Table Dtps-10) for a month to enhance root growth. Root tips were then excised and cultured. There is no indication in the original paper regarding the size of the explant. The only statement is "root tips." This suggests that the explants consisted of all or part of the green root tip (Fig. Dtps-5).

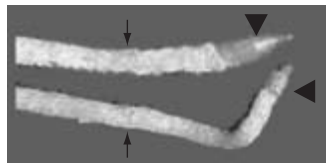

FIG. DTPS-5. **Orchid roots. Arrows indicate velamen covered part of root (which can be white, grey, or silvery). Wedges and root tip are velamen-free and are green. (Source: www.botgard.ucla.edu.)**

Surface Sterilization. It is not necessary to sterilize explants taken from plants which are grown in vitro. However they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Erlenmeyer flasks, plastic cultures vessels, or jars containing medium equal to 20–30% of their volume are suitable.

Culture Conditions. The research cultures were maintained at 26°C and 16-h photoperiods of 30 μmol m^{-2} s^{-1} (the light source is not listed). Standard culture room conditions are also suitable.

Culture Media. Plantlets (both seedlings and ones produced through micropropagation) should first be cultured on modified MS medium (Murashige and Skoog, 1962) containing 3 mg NAA l^{-1} (Table Dtps-9). After 2 months on this medium the plantlets should be moved to an auxin-free substrate (Table Dtps-10) for a month. Root-tip explants taken from plants on the second medium (Table Dtps-10) must be cultured on a third solution (Table Dtps-11) for induction of PLBs. The PLBs produce plantlets when moved to Hyponex medium (Table Dtps-8). Plantlets produced on the Hyponex medium (Table Dtps-8) are potted in sphagnum moss.

Procedure. Plantlets should be cultured on the first medium (Table Dtps-9) for 2 months to induce production of adventitious roots. Once such roots are produced (18 per plant on the average) it is necessary to move them to the second medium (Table Dtps-10) for a month so that the roots will elongate. Explants taken from the elongated roots should be moved to the third medium (Table Dtps-11) for PLB formation which will take approximately 8 weeks. The PLBs must be moved to Hyponex medium (Table Dtps-8) for plantlet production. When plantlets on the Hyponex medium are large enough they should be potted in sphagnum moss and grown in a greenhouse.

Developmental Sequence. The relatively high auxin (NAA) level in the first medium (Table Dtps-9) will induce the formation of multiple roots (an average of 18 in the original research) on the plantlets. However these roots will not elongate due to the high auxin concentration. The roots will elongate on the second medium (Table Dtps-10) because it is free of auxins. The root tips will produce PLBs on the third medium (Table Dtps-11) due to the presence of coconut water (CW) and the cytokinin TDZ. On the relatively simple Hyponex medium (Table Dtps-8) the PLBs

TABLE DTPS-11. **Medium for induction of protocorm-like bodies (PLBs) from *Doritaenopsis* root explants (Park et al., 2001)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1–7, 9 and 14 to 700 ml distilled water (item 16), adjust pH to 5.2–5.6, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 15). Gelrite (gellan gum, Phytagel) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. Pour solution into a 2-l flask and autoclave Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Solidifier is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

will produce plantlets. When potted in sphagnum moss these plantlets should become larger and flower after being moved to a standard potting mix.

General Comments. Root tips can be removed safely from a plant and because of that they are very useful as explants. However, if taken from seedlings they cannot be used to propagate desirable forms. When taken from plantlets produced through micropropagation roots tips can be used to propagate superior clones. Root tips from mature plant could be explants which can be cultured. But, roots usually contain mycorrhizal fungi which can contaminate and smother cultures. Therefore only tips from aerial roots which have not come into contact with surfaces or potting mix can be used.

Propagation of Protocorm-like Bodies in Liquid Medium

See procedure under the same name in the *Phalaenopsis* section (p. 1004, Vol. II; Park et al., 1996).

Effects of Complex Organic Additives on the Growth of *Doritaenopsis* Callus

Apple, potato, and taro extracts and coconut water (CW) enhanced the growth of *Doritaenopsis* callus depending on the quantity added. Taro at 50–200 ml per liter of new *Phalaenopsis* medium (Ichihashi, 1992*a*, 1992*b*) was the most effective of these extracts. To prepare the extract, 100 g tissue was diced and boiled for 20 min in 100 ml distilled water, the hot supernatant was filtered through a kitchen sieve, and then adjusted to 100 ml with distilled water (Ichihashi and Islam, 1999). Just in case too much of the water boils away it is wise to have available nearby a container of boiling water which can be added to the taro extract to maintain its volume.

Differences between the Capacities of *Doritaenopsis* Axillary Buds and Shoot Tips to Form Shoots and Protocorm-like Bodies

Axillary buds and shoot tips from flower stalks of eight *Doritaenopsis* hybrids were cultured on new Dogashima medium (Tokuhara and Mii, 1993) supplemented with 0.1 mg NAA l^{-1} and 1 mg or 5 mg BA l^{-1}. Approximately 70% of the explants survived after 5 months of culture. Shoot and PLB formation differed among hybrids (Yamazaki et al., 1997).

Establishment of *Doritaenopsis* Cell Suspension Cultures

There are relatively few methods for the establishment of orchid cell suspension cultures. The method described here was developed as part of a vitrification research project (Tsukazaki et al., 2000).

Plant Material. Flower stalks bearing vegetative buds were taken from plants of *Doritaenopsis* strain 343. Other *Doritaenopsis* hybrids can probably also be used. The stalks should be cut into sections leaving 15 mm above each bud and 25 mm below it (see Fig. Dtps-3B). Shoot-tip explants 1 mm wide and 0.5 mm high with one or two leaf primordia (see Fig. Dtps-3F) should be excised following surface sterilization.

Surface Sterilization. Buds should be exposed (see Fig. Dtps-3C) by removing the bracts (see Fig. Dtps-3D) which cover them and the sections, and then sterilized with the supernatant of a 5% solution of calcium hypochlorite, $Ca(ClO)_2$ (5 g of calcium hypochlorite in 100 ml distilled water, stirred, allowed to stand until a precipitate forms, and stirred again repeating the process three times before decanting the supernatant which must be used within 12 h or less; this solution contains about 1% available chlorine), by a 15-min immersion with stirring. A few drops of Tween-20 (www.sigmaaldrich.com, www.fishersci.com, www.vwr.com) or of a mild household detergent should be added to the sterilizing solution. Following sterilization the buds should be washed with sterile distilled water three times before removing two or three scaly leaves (see Fig. Dtps-3E) prior to excision of the explants.

Culture Vessels. Erlenmeyer flasks, 100-ml capacity, containing 40 ml of medium and covered with sterilized aluminum foil should be used. Other containers are also suitable.

Culture Conditions. Explant cultures were maintained at 23°C under 14-h photoperiods of 33 μmol m^{-2} s^{-1} (light sources not listed). Callus in liquid medium should be placed on rotary shakers at approximately 100 rpm at 25°C under continuous illumination of 33 μmol m^{-2} s^{-1} (white fluorescent lights were used in the original research; other sources may also be suitable). Standard culture room conditions are probably also suitable. Cells on the medium which contains 0.2 mmol sucrose l^{-1} (Table Dtps-13) should be cultured at 25°C in the dark for 2 days. For PLB production on the fourth medium (Table Dtps-14), cells should be cultured in the light. The original paper is not specific regarding the conditions, but 23°C under 14-h photoperiods of 33 μmol m^{-2} s^{-1} or standard culture room conditions will probably be appropriate.

Culture Media. A medium designated as new Dogashima (ND) containing 0.1 mg NAA l^{-1}, 1 mg BA l^{-1}, 0.56 mmol sucrose, and 8 g agar l^{-1} (Table Dtps-12) should be used to culture the explants. Explants should be cultured on the same medium, but without agar for production of cells (Table Dtps-12). After that cells can be cultured on ND containing 0.2 mmol sucrose and 2 g Gelrite l^{-1} (Table Dtps-13) for 1 month before being transferred to a fourth medium (Table Dtps-14) for PLB formation. No medium is suggested for the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C (KC) medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or the Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and

TABLE DTPS-12. **New Dogashima (ND) medium (Tokuhara and Masahiro, 1993) modified for the culture of vegetative buds of *Doritaenopsis* (Tsukazaki et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

19	Water, distilled[i]	To 1000 ml			
	Solidifier				
20	Agar[i,j]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Dissolve the adenine in up to 30 ml 0.1N hydrochloric acid and make up the solution to 100 ml with 95% ethanol.

[g]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[h]Dissolve the calcium pantothenate in 30 ml distilled water and make up the solution to 100 ml with 95% ethanol.

[i]Add items 1–17 to 900 ml of distilled water (item 19), adjust pH as required, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 19). Bring the mixture to a gentle boil and add the agar with vigorous stirring. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Amino acid (item 8), hormones (items 11, 12), and vitamins (items 13–17) are not heat stable and are often added to autoclaved and still warm and liquid media with sterilized pipettes and mixed well before distribution to preautoclaved culture vessels. In this case all components of the medium are autoclaved.

[j]Do not add agar to the liquid version of this medium.

TABLE DTPS-13. **New Dogashima (ND) medium (Tokuhara and Masahiro, 1993) as used for the culture of callus proliferation from cells of *Doritaenopsis* (Tsukazaki et al., 2000)**

14	Calcium pantothenate	1.0	100 mg 100 ml^{-1} 70% ethanol[e,h]	1	
15	Niacin (nicotinic acid)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
16	Pyridoxine (vitamin B_6)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
17	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
18	Maltose	10.0 g	No stock	No stock	Weigh
	Solvent				
19	Water, distilled[i]	To 1000 ml			
	Solidifier				
20	Gelrite[j]	30.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Dissolve the adenine in up to 30 ml 0.1 N hydrochloric acid and make up the solution to 100 ml with 95% ethanol.

[g]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[h]Dissolve the calcium pantothenate in 30 ml distilled water and make up the solution to 100 ml with 95% ethanol.

[i]Add items 1–17 to 900 ml of distilled water (item 19), adjust pH as required, add sugar (item 18), and adjust volume to 1000 ml with distilled water (item 19). Add the Gelrite (gellan gum, Phytagel) slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the gellan gum is completely dissolved pour the solution into culture vessels and autoclave. Amino acid (item 8), hormones (items 11, 12), and vitamins (items 13–17) are not heat stable and are often added to autoclaved and still warm and liquid media with sterilized pipettes and mixed well before distribution to preautoclaved culture vessels. In this case all components of the medium are autoclaved.

V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *d*).

Procedure. Flower stalks are cut into sections after being removed from plants. The bracts which cover the buds are removed, the sections are surface-sterilized and then rinsed with sterile distilled water. Scale leaves are removed from the buds after the rinse, and shoot tips are excised and placed into culture on the solid medium (Table Dtps-12). When callus is formed it should be transferred to a liquid medium of the same composition (Table Dtps-12). Cells should be collected by filtering the liquid medium through a 40-μm nylon mesh (www.spectrapor.com) and used as needed. About 3 g of fresh cells should be subcultured every 2 weeks on fresh medium (Table Dtps-12). Cells should be cultured on the third medium (Table Dtps-13 for a month before being transferred to half-strength ND medium supplemented with 1% maltose and solidified with 3 g Gelrite l^{-1} (Table Dtps-14) for PLB formation. For further growth the plantlets can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, Cym-1 to Cym-3, Cym-5, Cym-24, C-19, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without BH or AC. If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). AC should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *d*).

Developmental Sequence. Explants produce a yellow-green callus after 3–5 months in culture in the first medium (Table Dtps-12). Cells can be harvested every 2 weeks after transferring this callus to liquid medium (Table Dtps-12). They multiply on the third medium (Table Dtps-13) and produce PLBs on the fourth solution (Table Dtps-14).

General Comments. To quote the authors of this procedure, they "have produced a useful method . . . [for] *Doritaenopsis* suspension culture cells that should be applicable to . . . other Orchidaceae." Their aim was to develop a cryopreservation procedure, but the cell culture method is a valuable byproduct.

[i]Gellan gum [(available as such from www.caissonlabs.com) and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

Comparison between Hyperhydric and Normal Protocorm-like Bodies of *Doritaenopsis*

Hyperhydric PLBs (HPLBs) are translucent and turgid due to a lack of air in their intercellular air spaces. They have a lower capacity for shoot formation than PLBs. On the other hand, HPLBs have an increased ability to produce new PLBs compared to normal PLBs (NPLBs). The new HPLBs can be rendered to NPLBs by culturing them on Vacin and Went medium containing 10% (v/v) fresh potato homogenate (peeled potato slices homogenized and added to the medium), adjusted to pH 5.3, and solidified with 0.8% (w/v) agar (Zhou, 1995).

Mass Micropropagation of *Doritaenopsis* Protocorm-like Bodies using an Air-driven Periodic Immersion Bioreactor (ADPIB)

Doritaenopsis PLBs derived from flower stalks were cultured in liquid medium using an ADPIB consisting of a timer, small electronic pump, inner container, humidifier, and two plastic jars connected with silicone tubing which allows the medium to circulate between them. The results show that the ADPIB cultures are superior to conventional ones on solid medium. This suggests an economic potential for ADPIB (Liu et al., 2002).

Doritaenopsis Micropropagation in Different Types of Bioreactors

Doritaenopsis PLBs were cultured in air-driven periodic immersion, rolling bottles, spinner flask and airlift bioreactors. The best results were obtained with the air-driven periodic immersion bioreactor (ADPIB). Proliferation rates in the ADPIB ranged from 4.2- to 6.5-fold by weight. Each ADPIB can generate 100 g of PLBs, which amounts to 3000–5000 plantlets. Biomass increases in a rolling bottle bioreactor were similar. The conclusion by the authors is that these bioreactors can be used for the micropropagation of *Doritaenopsis* and *Phalaenopsis* (Liu and Wu, 2002).

Doritis

A genus consisting of a few species and small to medium-sized plants which do not have pseudobulbs, *Doritis* is found in India, Indonesia, Myanmar (formerly Burma), Nepal, Malaysia, Sri Lanka, and Thailand.

In Vitro Culture of *Doritis* Ovaries and Immature Embryos

A method has been developed for the in vitro culture of *Doritis* ovaries and immature embryos [which are erroneously called ovules in the original paper (Yasugi, 1984)]. Those wishing to culture *Doritis* explants could use this procedure as a starting point. Procedures used for *Doritaenopsis* and *Phalaenopsis* could also be tested. *Doritis* leaves have been cultured in a medium containing 15–50% coconut water (Sagawa and Kunisaki, 1982), but not enough details are presented about this procedure to allow its inclusion here.

Culture of Embryogenic Callus of *Doritis*

The culture method for embryogenic callus of *Doritaenopsis* (Ichihashi and Hiraiwa, 1996) may also be suitable for *Doritis*.

Encyclia

At one time species which now belong to the genus *Encyclia* were part of *Epidendrum*. Currently there are about 150 *Encyclia* species, most of them found in Mexico and the Caribbean with some extending into South America. Due to the close affinities between *Encyclia*, *Epidendrum*, and *Cattleya*, micropropagation methods developed for members of one of these genera can probably be used for species or hybrids in any of the other two especially since over the years a number of taxa were assigned to more than one them.

Epidendrum

A number of species and hybrids of *Epidendrum* are grown widely in greenhouses and outdoors. Some are relatively easy to propagate and others are not, but few are of as much interest as clones of *Cattleya*, *Cymbidium*, and *Dendrobium*. Therefore fewer methods have been developed for *Epidendrum* propagation from tissue culture (Scully, 1967; Churchill et al., 1970, 1971*c*, 1972*a*, 1973; Arditti et al., 1971, 1972; Stewart and Button, 1976*a*; Khaw et al., 1978*a,* 1978*b*; Kushnir and Budak, 1980). *Epidendrum* is one of the few orchids for which there is a micropropagation method using root tips (Stewart and Button, 1978) and a procedure for the culture of root explants (Churchill et al., 1972*b*). *Epidendrum* tissues have also been used in studies of hormone effects on anthocyanin production (Rudolph et al., 1972). It is interesting to note that only reed-type *Epidendrum* hybrids and species have been cultured to date. Methods used for related genera may prove suitable for pseudobulb-producing species and hybrids.

Rapid Vegetative Multiplication of *Epidendrum* O'brienianum in Vitro

Under some circumstances plantlets may develop from dormant buds on the stems and flower stalks of reed-stem *Epidendrum*. Many more dormant buds never develop. These buds can be used as explants for mass rapid clonal propagation (Stewart and Button, 1976*a*).

Plant Material. Node sections (length is not given in the original research, but 1.5–2 cm with the bud in the middle would seem appropriate) and flower-stalk sections (length also not given) with "buds [that] were damaged or removed prior to culture" of *Epidendrum* O'brienianum are used. The original paper does indicate that the stems "were separated into single node sections by cutting across the middle of the internode" and in some "instances the buds were partially or entirely removed prior to culture." It is not entirely clear from this description whether the partially removed bud or the stem with part of a bud remaining on it or both were cultured. However, the statement, ". . . despite the attempt to remove the entire bud, a high percentage of the node sections retained sufficient meristematic tissue to permit the direct development of a plantlet," suggests that perhaps the nodes were cultured. If so, the plantlets could have developed from accessory or newly formed buds. Flower-stalk nodes were presumably prepared in a similar manner.

Surface Sterilization. Leaves and sheaths are removed and the stems are washed with water and household liquid detergent. Stems are cut into node sections after that, and each section should be wiped with cotton soaked in 85% ethanol. The wiped stems are immersed in freshly prepared, filtered calcium hypochlorite (a concentration is not given in the original paper, but 7 mg per 100 ml should be appropriate) containing a few drops of Tween 20 for a period of time that was not listed (15–30 min should be enough). Following removal from the calcium hypochlorite the sections should be washed two to three times with sterile distilled water. Bleached tissue at the ends of sections should be removed at this point. It is reasonable to assume that flower-stalk nodes can be surface-sterilized by the same procedure.

Culture Vessels. Pyrex culture tubes 80×25 cm containing 10 ml medium and covered with Cap-O-Test lids were used in the original research. Other containers would also be suitable.

Culture Conditions. In the original research, cultures were maintained under 16-h photoperiods of approximately 1000 lx provided by Sylvania Gro Lux lamps and $25 \pm 2°C$.

Culture Media. Stem nodes produce plantlets on Knudson C (see Table Aranda-7), Vacin and Went (see Table Cym-5), and MS (Table Epi-1) media. Undamaged flower stalks can presumably be cultured in the same solutions. Flower-stalk node "sections whose buds were damaged or removed prior to culture" produce single plantlets on the MS (see Table Cym-10) and Lindeman–Gunckel–Davidson (see Table C-1) media. Multiple plantlets are produced on a modification of the MS medium (Table Epi-1).

Procedure. Insert node sections in the medium with their morphological bases down and allow the buds to develop. When the plantlets become large enough, pot in a potting mix. Plantlets that were part of a group will develop normally and form roots from their lowest nodes within 20 weeks. These plantlets can be moved to community pots.

Developmental Sequence. Node sections form plantlets quickly and "spontaneously." Photographs in the original paper (Stewart and Button, 1976) indicate that they develop like plantlets that form on mature plants in situ. Damaged buds form a "proliferative body" after 5 weeks in culture. Plantlets develop from this body after an additional 3 weeks. Roots and leaves develop after a further 8 weeks, and then the plantlets can be moved to pots.

General Comments. Although developed with *Epidendrum* O'brienianum, this procedure should prove suitable for other reed-type epidendrums.

Putrescine

Names:	1,4-diaminobutane; 1,4-butanediamine; putrescine; tetramethylenediamine	
Molecular formula:	$C_4H_{12}N_2$	
Percent composition:	C 54.50% H 13.73%	
	N 31.77%	$H_2NCH_2CH_2CH_2CH_2NH_2 \cdot 2HCl$
Molecular weight:	88.15 g/mol	Putresmine hydrochloride
Functional groups:	Amine	1,4-butanediamine dihydrochloride
Appearance:	Colorless oil	1,4-diaminobutane dihydrochloride
Melting point (°C):	23–24	Tetramethylenediamine dihydrochloride
Boiling point (°C):	158–160	M. W. 161.07
Solubility:	Very soluble in water	
Notes:	Putrescine is a poisonous oil present in rotting flesh and produced during decomposition of the amino acid arginine. It is partially responsible for the odor of urine and bad breath	

TABLE EPI-1. **Murashige–Skoog medium (Murashige and Skoog, 1962) for the production of multiple plantlets of *Epidendrum* (Stewart and Button, 1976*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Indoleacetic acid (IAA)	1	100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
11	Kinetin	0.04	4 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
15	Coconut water	150 ml	No stock	No stock	Weigh
	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]This medium can contain various amounts of auxin and/or cytokinin depending on specific needs. The original paper for this method (Stewart and Button, 1976*a*) states that the medium was used "alone and with the addition of 5 mg/litre . . . NAA, . . . 15 percent (v/v) coconut milk [sic correct term is 'coconut water'], . . . or both. . . ." A table shows that proliferation is best in the Murashige–Skoog medium with coconut water but gives no indication of amounts (if any) of auxin and/or cytokinin. Therefore we give the minimal amounts listed in the original recipe, since lack of these hormones can do harm. If auxin or cytokinin does not dissolve, add a few drops of KOH or HCl, respectively, to solubilize them.

[g]Keep refrigerated between uses.

[h]Add items 1–7, 9, and 15 to 700 ml distilled water (item 17). Adjust pH to 5.2–5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8 and 10–14) to hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

Clonal Propagation of *Epidendrum O'brienianum* through the Culture of Root Tips

A number of orchids produce buds and shoots from root tips. If this is "an inherent trait of the Orchidaceae which could be 'turned on,'. . . the result . . . of propagating orchids by culturing excised roots might be of considerable importance to the orchid industry" (Stewart and Button, 1978).

Plant Material. In the original research, roots were obtained from plantlets that formed in vitro from stem sections. They were divided into green root tips 1–4 mm long and sections 4–8 mm long excised 1–10 cm above the tip.

Surface Sterilization. There is no need to surface-sterilize roots taken from plantlets in vitro. Should tips be taken from mature plants growing outdoors or in pots, they should be surface-sterilized by immersing them in a 7% (w/v) solution of calcium hypochlorite (7 g calcium hypochlorite dissolved in 100 ml distilled water stirred and allowed to settle three times at 10–15-min intervals, filtered or decanted, and used within 4 h of preparation) for 5–10 min. They should be washed three times with sterile distilled water after the sterilization.

Culture Vessels. Pyrex culture tubes 80×25 cm containing 10 ml medium and covered with Cap-O-Test lids were used in the original research (Stewart and Button, 1978). Other containers would also be suitable.

Culture Conditions. In the original research, cultures were maintained under 16-h photoperiods of approximately 1000 lx provided by Sylvania Gro Lux lamps, 25 ± 2°C, and at a relative humidity of 75 ± 5%.

Culture Media. Callus formation is best on a modified Ojima–Fujiwara medium (Table Epi-2). The callus should be subcultured often on the same medium. "Callus, and callus with roots . . . [was] transferred to the media of Schenk and Hildebrand . . . [see Table Epi-3] and Knudson [C; see Table Aranda-7] without auxin." A plantlet was produced in these experiments, but it is not clear whether this happened on the Schenk–Hildebrand medium (Table Epi-3) or modified Ojima–Fujiwara medium (Table Epi-2).

Procedure. Place the tips on the first medium (Table Epi-2), and allow them to develop callus. This callus grows slowly in either medium (Tables Epi-2 and Epi-3) and should be transferred several times. PLBs and shoots, if they form, can be moved to the Knudson C medium for differentiation (see Table Aranda-7).

Developmental Sequence. Root tips either elongate or form "'disorganized' growths," which (in photographs at least) appear to consist of PLBs. The outer layers of the growth are composed of "dense layers of meristematic cells." These growths proliferate and on rare occasions produce plantlets.

TABLE EPI-2. **Modified Ojima–Fujiwara medium (Ojima and Fujiwara, 1962) modified for the culture of *Epidendrum* root tips (Stewart and Button, 1978)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	273.4	27.34 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	96	9.6 g l^{-1}	10	
3	Potassium nitrate, KNO_3[b]	20.2	4.04 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	8.16	816 mg l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
6	**Microelements**[d]				
(a)	Ammonium molybdate, $(NH_4)_2MoO_4$	0.02	2 mg l^{-1}		
(b)	Boric acid, H_3BO_3	0.02	2 mg l^{-1}		
(c)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	1.0	100 mg l^{-1}	10	One solution
(d)	Potassium iodide, KI	0.02	2 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.02	2 mg l^{-1}		
	Auxin				
7	2,4-Dichlorophenoxyacetic acid (2,4-D)	0.5	50/100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Vitamins				
8	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
9	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
10	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
11	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[f]	To 1000 ml			
	Solidifier				
13	Agar, Difco Bacto[f]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 5a) and iron salt (item 5b) to the same 1 l distilled water, and stir and/or heat until both are dissolved. The original formulation does not use chelated iron, but this form is preferable.

[d]add all microelements to the same 1 l distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1–6 in 900 ml distilled water (item 12), adjust pH to 5.2–5.5, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring solution to a gentle boil, and add agar (item 13) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add hormone and vitamins (items 7–10) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

General Comments. This method was developed with root tips from plantlets grown in vitro; it is not clear whether it would also be suitable for root explants from mature plants. If root tips from mature plants were to be used it would be necessary to select roots free of mycorrhiza. The method is slow and not very effective since only one plantlet was obtained from among many cultures. On the other hand, this is a simple method that does not endanger the plants, and it could serve as a starting point for further research.

TABLE EPI-3. **Modified Schenk–Hildebrand medium (Schenk and Hildebrand, 1972) used for the culture of *Epidendrum* root-tip explants (Stewart and Button, 1978)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium phosphate, $NH_4H_2PO_4$[c]	300	30 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot H_2O$	200	20 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	400	40 g l^{-1}	10	
4	Potassium nitrate, KNO_3[c]	2500	250 g l^{-1}	10	
5	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.9	2.79 g l^{-1}		
6	**Microelements**[e]				
(a)	Boric acid, H_3BO_3	10	1 g l^{-1}	10	One solution
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	25	2.5 g l^{-1}		
(d)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	10	1 g l^{-1}		
	Auxin				
7	2,4-Dichlorophenoxyacetic acid (2,4-D)	1	100 mg 100 ml^{-1} 95% ethanol[f]	1	
	Sugar				
8	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[g]	To 1000 ml			
	Solidifier				
10	Agar, Difco Bacto[g]	10 g	No stock	No stock	Weigh

[a]The exact modification(s) used in this case are not clear. The authors state that the medium was used with three modifications: "(i) with . . . 2,4-D at a higher concentration, and (ii) and (iii) with some of the growth substances omitted" (Stewart and Button, 1978). Table 1 in their paper shows that the highest percentage of callus formation occurred in the presence of 1 mg l^{-1} 2,4-D but does not indicate which if any other substances were omitted.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[f]This auxin can be solubilized with a few drops of dilute KOH. Refrigerate between uses.

[g]Add items 1–6 to 900 ml distilled water (item 9), adjust pH to 5.2–5.5, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l Erlenmeyer flask and autoclave. Add auxin (item 7) to the warm or hot, still liquid solution, swirl vigorously to ensure complete mixing, and dispense into preautoclaved culture vessels.

Production of *Epidendrum* Plants from Leaf Tips

Use of leaf tips as a source of explants has the advantage of not endangering or even seriously damaging a plant. The donor plant is only disfigured slightly by the removal of the explants (Churchill et al., 1970, 1971*a*, 1971*b*, 1971*c*, 1972*a*, 1973; Arditti et al., 1971*a*, 1971*b*, 1972, Arditti, 1977*a*, 1978). At the same time the use of leaves and leaf tips was a great innovation. Everyone wanted a version of the article and we obliged.

Plant Material. Leaf tips from 1-year-old (but possibly older) seedlings growing in flasks under normal conditions are used (Arditti, 1967; Harrison, 1970; Harrison and Arditti, 1970).

Surface Sterilization. This is not necessary since the seedlings are already axenic.

Culture Vessels. Use 125-ml Erlenmeyer flasks containing 50 ml medium.

Culture Conditions. Liquid cultures are placed on a reciprocating shaker moving at the rate of 60 oscillations per minute, 50 cm below banks of Sylvania Gro Lux tubes and incandescent bulbs producing 150 ft-c during 18-h photoperiods. The temperature is maintained at 22–25°C. Solid cultures are kept under the same conditions on a stationary surface.

Culture Media. A modified MS medium (Table Epi-4) is used for initial culture. Callus cultures are maintained on solid modified Linsmaier–Skoog medium (see Table C-18) or MS medium (see Table C-17). Differentiation of plantlets occurs on modified Knudson C medium (see Table C-19).

Procedure. Remove seedlings from flasks and place on sterile Petri dishes, microscope slides, or aluminum foil. Remove tips no larger than 4–5 mm (the best size being 2 mm, about the dimension of a pinhead) with sterile scalpels, razor blades, or tips of syringe needles, and suspend in culture medium. Then place the flasks on the shaker. When tissue masses form, they should be divided and placed on solid Murashige–Skoog (Table Epi-4) or Linsmaier–Skoog (see Table C-18) media. After a new tissue mass forms, it should also be subdivided. For plantlet development, portions of the mass (which are in fact PLBs) are transferred to Knudson C medium (see Table C-19).

Developmental Sequence. Leaf tips remain green without any apparent changes or growth for nearly 60 days. After that, approximately 7% form calli. When divided and transferred to solid MS or Linsmaier–Skoog media, these form large callus masses. After a while abnormal plantlets form on these media. Following 3 weeks on Knudson C medium, callus sections form normal plantlets.

General Comments. Since the explants are obtained from unflowered seedlings, the procedure cannot be used for the propagation of desirable clones. Perhaps with further research a way can be found for the culture of leaf tips from adult plants. In the meanwhile, this method can be useful for the production of *Epidendrum* callus cultures for research purposes. These cultures can apparently be subdivided indefinitely (some of our cultures are still growing well after 3 years).

TABLE EPI-4. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Epidendrum* leaf tips (Churchill et al., 1970, 1972*a*, 1973; Arditti et al., 1971*a*, 1971*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
3	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	95 g l^{-1}	20	Or weigh

9	2,4-Dichlorophenoxyacetic acid (2,4-D)	1	50 mg 25 ml^{-1} 95% ethanol[e,f]	0.5	
	Cytokinin				
10	6-Benzylaminopurine (benzyladenine)	0.5	50 mg 50 ml^{-1} 95% ethanol[e,f]	0.5	
	Vitamin				
11	Thiamine (vitamin B_1)	0.4	80 mg 100 ml^{-1} 95% ethanol[f]	0.5	
	Sugar				
12	Sucrose[g]	30 g	No stock	No stock	Weigh
	Solvent				
13	Water, distilled	To 1000 ml			
	Solidifier				
14	Agar[g]	10–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelated iron (items 6a, 6b) and all microelements (items 7a–7g) to the same 1 l of distilled water, stir and/or heat until dissolved. Add 10 ml per liter of culture medium.

[d]Keep frozen between uses.

[e]If auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively.

[f]Keep refrigerated.

[g]Add items 1–10 to 700 ml distilled water (item 13) and dissolve, adjust pH to 5.5, add sugar (item 12), and adjust volume to 1000 ml with distilled water (item 13). Sterilize by filtration and distribute into preautoclaved culture vessels. Alternately, dissolve items 1–7 and 12 in 1000 ml distilled water (item 13) and autoclave, add items 8–11 with sterile pipettes under sterile conditions to the autoclaved salt solution, and distribute into preautoclaved culture vessels. When solid medium is required, dissolve sugar (item 12) and agar (item 14) in 750 ml distilled water (item 13) and autoclave. Add items 1–11 to 250 ml distilled water (item 13), and adjust pH to 5.5. Sterilize by filtration, mix with the autoclaved solution while it is still hot and liquid, swirl to mix well, and dispense into sterile culture vessels. Alternately, add items 1–7 to 800 ml distilled water (item 13), adjust pH to 5.5, add the sugar (item 12), and bring volume to 1000 ml with more distilled water (item 13). Dissolve agar (item 14) and autoclave the solution. After autoclaving and while it is still hot and liquid, add items 8–11 with sterile pipettes under sterile conditions, swirl to mix well, and distribute into preautoclaved culture vessels.

Culture of *Epidendrum* Root Tips

It seems reasonable to assume that, since orchid root tips contain meristematic zones, they can be made to grow in vitro. If so, another logical assumption is that they can be made to form callus cultures and eventually plantlets. As of this writing, the first assumption has been proven correct. Proof for the second, at least insofar as orchids are concerned, is still lacking. *Epidendrum* root tips, then, can be cultured, but all they produce is roots, albeit longer roots (Churchill et al., 1972*b*).

Plant Material. Free-hanging, aerial, mycorrhiza-free roots must be used. Roots that have reached the potting medium, touched the pot, or crawled over benches become infected by mycorrhizal fungus, which grows out of them and contaminates the culture medium.

Surface Sterilization. Roots are soaked in saturated calcium hypochlorite solution (10 g per 140 ml water) for about 5 min.

Culture Vessels. Use 100-ml prescription bottles containing 10–20 ml solid medium that has been allowed to solidify on the under (flat) surface; 125- or 250-ml Erlenmeyer flasks containing 25 or 50 ml medium, respectively, can also be used. For the subculture of larger roots, 1000-ml prescription bottles containing 200 ml medium should be used.

Culture Conditions. The conditions employed for *Epidendrum* leaf tips (Churchill et al., 1970, 1972*b*, 1973; Arditti et al., 1971*a*, 1971*b*, 1977) should be used, except that the root explants are grown on solid medium.

Culture Medium. Modified Ojima–Fujiwara medium (Table Epi-5) is most suitable for root tips.

Procedure. Place root tips on the medium and allow to grow. After 2 months they elongate and can be subcultured by removing and transferring the tips to new medium. The procedure can be repeated 3 months later. Thereafter, transfers can be made every 6 months, or the tips can be placed in a large bottle from the outset and not transferred.

Developmental Sequence. Roots simply grow in length, but their diameters and growth rate decrease with time. After 1 year some roots may be 5–6 cm long while others reach 15 cm, but all become thinner than roots of equal length growing on plants. After 2 years in culture the roots can still grow, but they lose their chlorophyll. Detipped roots do not grow.

General Comments. The culture medium apparently does not provide roots with sufficient amounts of some or all requirements. Neither is it capable of inducing callus formation. Whether the medium is MS, Heller's, or a special "meristem" medium (Ball et al., 1971), liquid or solid, shaken or not, roots die. Some, like those of *Phalaenopsis*, swell tantalizingly, as if to form a callus, but die just the same.

TABLE EPI-5. **Modified Ojima–Fujiwara medium (Ojima and Fujiwara, 1962) for the culture of *Epidendrum* root tips (Churchill et al., 1972*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Potassium nitrate, KNO_3[b]	20.2	2.02 g l^{-1}	10	Or weigh
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	136.7	13.67 g l^{-1}	10	Or weigh
3	Monopotassium phosphate, KH_2PO_4	4.08	408 mg l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	48	4.80 g l^{-1}	10	
5	Ferric sulfate, $Fe_2(SO_4)_3$	1	1 g l^{-1}	1	
6	**Microelements**[c]				
(a)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	1	1 g l^{-1}		
(b)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.02	20 mg l^{-1}		
(c)	Potassium iodide, KI	0.02	20 mg l^{-1}	1	One solution
(d)	Boric acid, H_3BO_3	0.02	20 mg l^{-1}		
(e)	Ammonium molybdate, $(NH_4)_2MoO_4$	0.02	20 mg l^{-1}		
	Vitamins[d]				
7	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol	1	
8	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol	1	Or combine
9	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol	1	
	Complex additive				
10	Neopeptone	300	No stock	No stock	Weigh
	Sugar				
11	Sucrose[e]	20 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[e]	To 1000 ml			
	Solidifier				
13	Agar[e]	10–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all dissolved. Add 1 ml per liter of culture medium.

[d]The vitamins may be combined into one stock solution. Add 50 mg each of niacin and pyridoxine and 10 mg thiamine to the same 100 ml of 95% ethanol, and use 1 ml of this per liter of culture medium. Refrigerate between uses.

[e]Add items 1–10 to 800 ml distilled water (item 12) and dissolve, adjust pH to 5.0 (it will change to 5.1, which is the desired pH), add the sugar (item 11) and bring volume up to 1000 ml with more distilled water (item 12). For solid medium, dissolve agar (item 13) by adding it to gently boiling solution while stirring. When fully dissolved, distribute into culture vessels and autoclave. According to the original report, Ojima and Fujiwara (1962), all components of this medium were sterilized by autoclaving.

In commenting about this procedure some years ago I wrote:

> Perhaps someday a method for the production of callus cultures and plants from orchid root tips may be developed. Several orchids naturally produce buds and plants on their roots. For the time being, however, root-tip culture of orchids may be a subject for wishful thinking and a means for the production of roots to be used as experimental organs (Arditti, 1977*a*, 1977*b*).

The prediction and wishful thinking came to pass: Methods for plantlet production from root tips were developed for several orchids, including *Phalaenopsis* (by Professor K. Zimmer and his associates).

Propagation of *Epidendrum* by the Culture of Explants from Vegetative Shoots

The method was developed as part of the work with the *Cattleya* alliance (Scully, 1967). In cases described as "excepted instances," PLBs arose from *Epidendrum conopseum* explants. Subculture of the bodies was unsuccessful. This simply means that additional work is needed to perfect the method.

Proliferation, Propagation, and Organogenesis of *Epidendrum* in Vitro

Shoot-tip explants of *Epidendrum radicans* (*Epidendrum ibaguense*) cultured on modified MS medium formed PLBs and plantlets (Kusumoto, 1981*b*). The original paper is in Japanese.

Transformation of Isoprenoids by *Epidendrum* in Tissue Culture

Tissue cultures of *Epidendrum ochraceum* maintained in vitro on media used for other orchids (Kukułczanka, 1985; Kukułczanka and Wojciechowska, 1983) transformed some isoprenoids (Mironowicz et al., 1987).

Isolation of Mesophyll Protoplasts of *Epidendrum*

The procedure for the isolation of mesophyll chloroplasts of *Calanthe discolor* as used for *Dendrobium* can be employed for *Epidendrum*. Isolation was 40% after 30 min and 74.6% following 2 h (Yasugi et al., 1986).

Protoplast Isolation from Leaves and Roots of *Epidendrum radicans*

The method developed for *Acampe praemorsa* has been used to isolate 3.2×10^4 and 1.2×10^4 protoplasts from leaves and roots, respectively, of *Epidendrum radicans* (Seeni and Abraham, 1986).

Transformation of Menthyl Acetate by *Epidendrum ochraceum* Tissues in Vitro

Tissues of *Epidendrum ochraceum* cultured in the Reinert–Mohr liquid medium (constant shaking 20–24°C, 18-h photoperiods, 2000 lx) transformed a racemic mixture of menthyl acetate to menthol (Mironowicz et al., 1987).

Protocorm-like Body and Plantlet Production from Stalk Explants of *Epidendrum radicans*

There are several micropropagation procedures for *Epidendrum*, including one from our laboratory (Churchill et al., 1972*a*) which could be more efficient than it is (but it was developed during the early days of orchid micropropagation), one which is probably unreliable (Stewart and Button, 1976*a*), and another mostly intended to generate publicity if it works at all (Kuhn, 1981*a*). The procedure for *Epidendrum radicans* described here is efficient and very commendable because it utilizes several completely defined media (Chen et al., 2002*a*).

Plant Material. Sections, 10–15 cm in length, should be taken from inflorescence stalks of 2–3-year-old greenhouse grown plants when flower buds are fully formed, but before color is showing.

Surface Sterilization. Sodium hypochlorite ($NaOCl_3$, domestic bleach), 1% (17 or 19 ml of 6 or 5.25% Clorox, respectively, diluted to 100 ml with distilled water), should be used to surface-sterilize the explants. They should be immersed in this solution for 12 min and then rinsed three times with sterile distilled water.

Culture Vessels. Culture tubes, 20 × 150 mm, were used in the original research. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at 26 ± 1°C under 16-h photoperiods of 28–36 μmol m^{-2} s^{-1} provided by 40W China Electric Co. (Taiwan) daylight fluorescent tubes FL-30D/29.

Culture Media. Explants should be cultured on half-strength MS medium (Murashige and Skoog, 1962) supplemented with 0.45 μmol TDZ l^{-1} (Table Epi-6) for 40 days to bring about the formation of PLBs. The PLBs should be cultured on a medium containing 40 g sucrose l^{-1} (Table Epi-7) for proliferation. For shoot formation, PLBs should be cultured on a substrate with 10 g sucrose l^{-1} (Table Epi-8). Homogenized PLBs should be placed on a medium containing 4.44 μmol BA l^{-1} (Table Epi-9) to enhance the production of new PLBs. The homogenate should be cultured on a solution supplemented with 1.39 μmol kinetin (Table Epi-10) for maximal shoot production on. To produce plants PLBs with shoots should be cultured on the first medium (Table Epi-6). Plants should be potted in sphagnum.

Procedure. Internode sections, 5–7 mm in length should be excised from the surface-sterilized inflorescence segments and placed on the first medium (Table Epi-6). PLBs which form on this medium should be cultured on a substrate with 40 g sucrose l^{-1} (Table Epi-7) for proliferation. Shoot formation will take place on 10 g sucrose l^{-1} (Table Epi-8) or 0.44 μmol BA l^{-1} (Table Epi-9). The sucrose medium (Table Epi-8) is preferable because of the possibility (even if small) that BA (Table Epi-9) can be mutagenic. Shoots should be moved to the first medium (Table Epi-6) for plant formation. Plants are potted in sphagnum and grown in a greenhouse.

TABLE EPI-6. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the production of protocorm-like bodies (PLBs) from inflorescence explants of *Epidendrum radicans* (Chen et al., 2002*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
15	Peptone	1.0 g	No stock	No stock	Weigh
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Gelrite[h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.7, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Add the Gelrite (item 18) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com, and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require higher concentrations of gellan gum or additional calcium or magnesium salts. Gellan gum must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE EPI-7. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the proliferation of protocorm-like bodies (PLBs) produced by inflorescence explants of *Epidendrum radicans* (Chen et al., 2002*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	31.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins[e,f]				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	40.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			
	Solidifier				
15	Gelrite[h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]There are no auxins or cytokinins in this medium.

[g]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.7, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Add the Gelrite (item 15) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media.

[h]Gellan gum [(available as such from www.caissonlabs.com), and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require higher concentrations of gellan gum or additional calcium or magnesium salts. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE EPI-8. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for shoot induction on protocorm-like bodies (PLBs) produced by inflorescence explants of *Epidendrum radicans* (Chen et al., 2002*a*)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murasiqe and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Add the Gelrite (item 17) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media.

[h]Gellan gum [(available as such from www.caissonlabs.com), and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require higher concentrations of gellan gum or additional calcium or magnesium salts. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE EPI-10. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for shoot induction on protocorm-like bodies (PLBs) produced from homogenized PLBs produced by inflorescence explants of *Epidendrum radicans* (Chen et al., 2002*a*)**

	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Gelrite[h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Add the Gelrite (item 17) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com, and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require higher concentrations of gellan gum or additional calcium or magnesium salts. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

Developmental Sequence. Explants form PLBs on the first medium (Table Epi-6). PLBs proliferate on the second solution (Table Epi-7). The PLBs produce shoots on either the third (Table Epi-8) or fourth (Table Epi-9) substrate. Shoots develop into plants on the first medium (Table Epi-6).

General Comments. Like other procedures from Professor Wei-Chin Chang's laboratory, this method is well conceived and based on impressive research. The paper is clear and well written.

Isolation, Culture, and Fusion of Protoplasts of *Epidendrum radicans*

The method used for *Dendrobium* (Yasugi, 1990) is also suitable for *Epidendrum radicans*.

In Vitro Morphogenesis of *Epidendrum radicans*

When cultured on half-strength MS medium with or without TDZ for 1–2 weeks, root, stem, leaf, and flower-stalk explants formed small masses of transparent tissue on the cut surfaces. Under illumination this tissue became larger and "turned into green organized masses," which formed PLBs and proliferated on hormone-free basal half-strength MS. TDZ enhanced the proliferation. The PLBs produced plantlets on TDZ-containing half-strength MS after 1 month of culture (Chang et al., 2001).

Epiphronitis

The first hybrid was *Epiphronitis* Veitchii [*Epidendrum ibaguense* (*Epidendrum radicans*) × *Sophronitis grandiflora*] registered in 1890 by the well-known orchid establishment Messrs J. Veitch & Sons, which at that time was located at Chelsea and Slough, Bucks., England (the Slough nursery eventually became the Black and Flory Orchid Co.). Since 1890 more *Epiphronitis* hybrids have been produced by crossing additional *Epidendrum* and *Sophronitis* species.

A method for tissue culture propagation of *Epiphronitis* Veitchii was developed in Japan (Kusumoto, 1981*b*). Information that can be gleaned from illustrations and tables (the paper is in Japanese) suggests that shoot tips, and axillary buds from stems and flower stalks proliferate well and form PLBs on the MS medium (see Table Cym-11, Epi-1 and Epi-4). Best results were obtained "when axillary buds of peduncles [flower stalks] were taken. . . ." The best method for "propagating PLBs of *Epiphronitis* [is] the same as that of *Cattleya*" (Kusumoto, 1981*b*).

It is reasonable to assume that the procedures developed for *Epiphronitis* Veitchii, *Epidendrum*, *Sophronitis*, *Cattleya*, *Laelia*, and related genera would be suited for *Epiphronitis* hybrids in general.

Eulophia

Eulophia is a pantropic, chiefly Asiatic terrestrial genus consisting of approximately 200 genera. A method for clonal propagation of *Eulophia hormusjii* was developed in India (Vij et al., 1989), where the genus is represented by 26 species.

Plant Material. In the original research "rhizome segments (3–4 mm) with or without differentiated nodes" were excised from 24-week-old seedlings in vitro.

Surface Sterilization. There is no need to sterilize the explants or their sources because they are already axenic.

Culture Vessels. Test tubes, Erlenmeyer flasks, jars, and other containers are suitable.

Culture Conditions. Cultures should be maintained under 12-h photoperiods of 3500 lx at $25 \pm 2°C$. The sources of illumination are not described in the original research, but it is reasonable to assume that fluorescent and/or incandescent lamps would be suitable.

Culture Media. The explants formed PLBs in modified Mitra–Prasad–Roychowdhury (MPR) medium (Mitra et al., 1976) containing peptone (MPRP; Table Eul-1). Shoot buds developed on MPR containing yeast extract, NAA, and kinetin (MPRY; Table Eul-2). Plantlets regenerated on MPR with peptone, NAA, and kinetin (MPRN; Table Eul-3).

Procedure. Recommendations for a practical procedure are not included in the original paper. A reasonable approach would be to place the explants on MPRP until PLBs form. These should be moved to MPRY to stimulate the formation of shoot buds and to MPRN for plantlet regeneration.

Developmental Sequence. On MPRP the explants form chlorophyll-containing PLBs that elongate and become rhizomatous before organogenesis starts. Shoot buds appear on MPRY. Plantlets 3–4 cm tall develop 6 weeks after transfer to MPRN.

General Comments. Cytological studies of plantlets raised by this method suggest that the chromosome number ($2n = 54$) remains stable. This is an indication that plantlets produced by this procedure would be true to type. The method should be useful in cases where only a few seedlings of a rare form or hybrid are available.

TABLE EUL-1. **Mitra–Prasad–Roychowdhury medium (Mitra et al., 1976) as modified for the induction of protocorm-like bodies from rhizome segments from seedlings of *Eulophia hormusjii* (Vij et al., 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe used 3 ml $Na_2FeEDTA$, a preparation that may not be readily available. The substitute listed here is used very commonly in orchid tissue culture media. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1–14 to 900 ml distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense solution into culture vessels and autoclave. Omit agar if preparing liquid medium. Media that contain hormones and vitamins should not be autoclaved without first determining that this method of sterilization will have no deleterious effects. This is such a case (Mitra, 1971; Mitra, et al., 1976), so the medium may be autoclaved.

TABLE EUL-2. **Mitra–Prasad–Roychowdhury medium (Mitra et al., 1976) as modified for the induction of shoot buds on rhizome segment explants from seedlings of *Eulophia hormusjii* (Vij et al., 1989)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe used 3 ml $Na_2FeEDTA$, a preparation that may not be readily available. The substitute listed here is used very commonly in orchid tissue culture media. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]If auxin or cytokinin fails to dissolve, add a few drops of dilute KOH or HCL, respectively.

[g]Add items 1–16 to 900 ml distilled water (item 18), adjust pH to 5.6, add sugar (item 17), and adjust volume to 1000 ml with distilled water (item 18). Bring solution to a gentle boil, and add agar (item 19) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense solution into culture vessels and autoclave. Omit agar for liquid medium. Media that contain hormones and vitamins should not be autoclaved unless prior experiments have determined that this method of sterilization will have no deleterious effects. This is such a case (Mitra, 1971; Mitra, et al., 1976), so the medium may be autoclaved.

Gastrochilus

See *Saccolabium calceolare* (pp. 1097–1099, Vol. II).

Geodorum

Geodorum, a small terrestrial genus, is distributed from India, Sri Lanka and China through tropical Asia, Australia, Malaysia, Papua New Guinea and a number of Pacific islands (Seidenfaden and Wood, 1992; O'Byrne, 1994).

Isolation of *Geodorum densiflorum* Protoplasts

The method developed for *Acampe praemorsa* (Seeni and Abraham, 1986) was used to isolate 6.1×10^4 protoplasts from leaves of *Geodorum densiflorum*.

In Vitro Propagation of *Geodorum densiflorum* through the Culture of Rhizome Sections

Asymbiotic seed germination of *Geodorum densiflorum* resulted in the development of protocorms which produced rhizomes that "continue to grow and ramify without the formation of other organs for a long time and occasionally shoots are formed from rhizome apices." Sections of these rhizomes were cultured in an effort to induce organogenesis (Sheelavantmath et al., 2000).

Plant Material. Four-week-old rhizomes produced by protocorms which developed from seeds germinated on Knudson C medium (Knudson, 1946) ". . . were initially cut at nodal regions in small pieces and then internodal regions were longitudinally cut into 5–10 mm length" (Sheelavantmath et al., 2000).

Surface Sterilization. Explants taken from plants growing in vitro do not require surface sterilization.

Culture Vessels. Photographs in the original paper show that cultures were maintained in test tubes. Other containers can also be used.

Culture Conditions. The research cultures were maintained at $22 \pm 2°C$ under 12-h photoperiods of 40 μmol m^{-2} s^{-1} provided by cool white fluorescent lamps.

Culture Media. The seeds which produced the protocorms that gave rise to the 4-week-old rhizomes were germinated on Knudson C (KC) medium (Knudson, 1946) supplemented with 10% (v/v) coconut water (CW). Rhizome sections produced multiple shoots on modified MS medium (Murashige and Skoog, 1962) containing 5 μmol (1.13 mg) BA l^{-1} and 0.1% charcoal (Table Gdrm-1). The shoots rooted on MS containing 1 μmol (0.2 mg; actually 1 μmol is 0.186 mg, but this can be rounded

TABLE GDRM-1. **Modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of rhizome sections of *Geodorum densiflorum* (Sheelavantmath et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	Benzylaminopurine (BAP)	1.13	113 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	8.0 g	No stock	No stock	Weigh
	Darkening agent				
17	Activated vegetable charcoal (AC)[h]	1.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.7, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a homogenizer, add the charcoal and mix thoroughly. After that pour medium into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the warm and still liquid solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite should not be used except in special circumstances.

off to 0.2 mg which is easier to weigh; the difference of 0.014 mg is insignificant, but sticklers for accuracy can use the exact amount) NAA l^{-1} and 0.1% charcoal (Table Gdrm-2). Well-developed plants were potted in vermiculite in plastic pots and watered with half-strength MS (presumably minerals only, Table Gdrm-3).

Procedure. Seeds (harvested 30 days after pollination in the original research) should be sown on KC medium and cultured until rhizomes are formed. When the rhizomes are 4 weeks old they should be sectioned. The sections should be cultured on the BAP containing medium (Table Gdrm-1). Shoots which form on the explants after 4–6 weeks must be subcultured onto fresh medium at 4-week intervals. Well-developed shoots should be moved to the second medium (Table Gdrm-2) for rooting. Rooted plants that are large enough should be potted in vermiculite. Once well established potted plants should be moved to a greenhouse.

Developmental Sequence. Small green protuberances form on the explants after 2–4 weeks on the first medium (Table Gdrm-1). These protuberances develop into multiple shoots in 4–6 weeks (Fig. Gdrm-1). During this time the explants release into the medium phenolic compounds which can inhibit growth. Therefore the addition of charcoal which absorbs the phenolics is of great importance. The shoots are well developed after 14 weeks, but lack roots. Root development takes place after 4 weeks on the second medium (Table Grdm-2). Large plants develop after several weeks on this medium. Seedlings grow to maturity after being potted and moved to a greenhouse.

General Comments. *Geodorum densiflorum* is an endangered orchid. This micropropagation method is intended as a means of ex situ conservation. It can also be used for large scale horticultural propagation of seedlings. Other research has also shown that BA and NAA can affect PLB and rhizome development in *Geodorum densiflorum* (Roy and Banerjee, 2002).

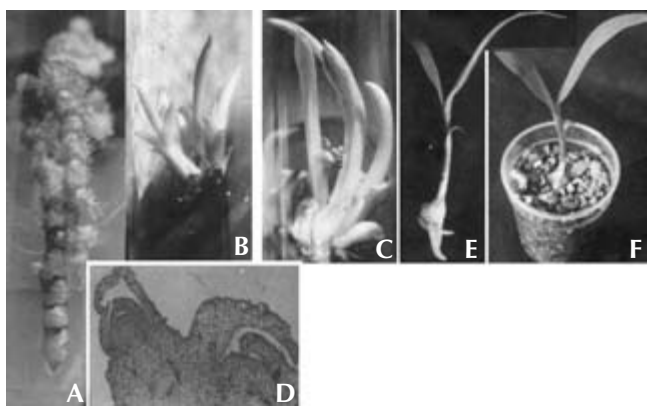

FIG. GDRM-1. **In vitro propagation of *Geodorum densiflorum*. A. Rhizome proliferating on MS with 2 µmol NAA. B, C. Multiple shoots on MS with 2 and 5 µmol BA respectively. D. Section through rhizome showing development of root primordia. E. Rooting on MS with 1 µmol of NAA. F. Plantlet in pot. (Sheelavantmath et al., 2000.)**

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH or NaOH respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.7, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a homogenizer, add the charcoal, and mix thoroughly. After that pour medium into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10) and vitamins (items 11–13) to the warm and still liquid solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite should not be used except in special circumstances.

TABLE GDRM-3. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for irrigating *Geodorum densiflorum* plants (Sheelavantmath, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	31.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Solvent				
8	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add items 7a–g to 1 l of distilled water, heat for a while if some of the salts do not dissolve, mix and use as indicated. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Add items 1–7 to 900 ml of water (item 8), adjust pH to 5.4–5.7, bring volume to 1 l, mix well and use.

Rapid Micropropagation of *Geodorum densiflorum* in Liquid Culture

At one time *Geodorum densiflorum* was very common in the forests of the north-eastern Himalayas. However its existence is being threatened by commercial exploitation (i.e., overcollection) and human encroachment (expansion of cultivated areas). A mass rapid propagation method, useful as a means of conservation and production of plants for the horticulture trade, was developed in India (Kanjilal and Datta, 2000).

Plant Material. Leaves and roots of seedlings were removed to expose the stems which were sectioned into thin transverse sections, 1–1.5 mm thick. These sections were placed in culture.

Surface Sterilization. Explants excised from plants growing in vitro do not require surface sterilization.

Culture Vessels. Flasks described as "conical [probably meaning Erlenmeyer] . . . (100 ml; Borosil)" were used to culture explants on both liquid and solid media.

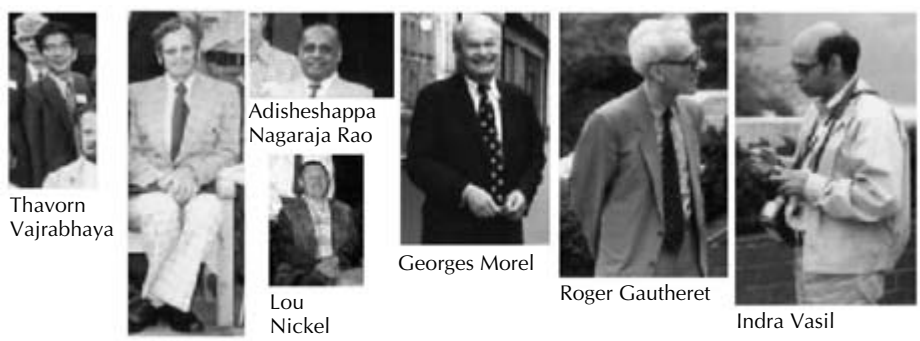
Culture Conditions. The research cultures were maintained at 25 ± 2°C under 16-h photoperiods of 25 μE m^{-2} s^{-1} provided by cool white fluorescent lamps. Standard culture room conditions are also suitable. Liquid cultures should be placed on a rotary shaker at 80–120 rpm.

Culture Media. Explants should be cultured first in liquid Knudson C (KC) medium (Knudson, 1946) supplemented with NAA, BA, and peptone (Table Gdrm-4). PLBs produced in the liquid medium should be moved to solid substrate of the same composition. Well-developed plantlets should be taken out of culture and potted in a mixture of brick pieces, coal chips, sand, and soil (in a ratio of 1 : 1 : 1 : 1, v/v/v/v).

Procedure. The explants should be placed in the liquid medium (Table Gdrm-4). When clusters of PLB form they should be separated and subcultured in liquid medium (Table Gdrm-4) for further proliferation or on solid substrate (Table Gdrm-4) for plantlet production. Subculturing may be necessary every 2 weeks. Well-developed plantlets should be washed carefully with water at body temperature, treated with Bavastin (or another suitable fungicide), and potted.

Developmental Sequence. The explants produce PLBs in the liquid version of the medium (Table Gdrm-4). Well-developed PLBs cultured on solid substrate (Table Gdrm-4) develop plantlets. Large and well-developed plantlets can be obtained in 10–12 weeks and should be moved to pots in a potting mix.

General Comments. This is a very rapid, simple, and efficient micropropagation method because shoots can be cut into several sections and every section produces many PLBs. It cannot be used to select specific cultivars because the explants are taken from seedlings.



Tissue culture pioneers. Vajrabhaya, Nickel, Rao and Morel worked with orchids. Gamborg formulated a waidely used tissue culture medium. Gautheret was a pioneer in France and for a while Morel's superior. Vasil is responsible for numerous advances and is a well known editor of journals and books.

TABLE GDRM-4. **Modified liquid and solid Knudson C (KC) medium (Knudson, 1946) for protocorm-like body (PLB) and plantlet production from shoot sections of *Geodorum densiflorum* (Kanjilal and Datta, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
7	Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
8	Benzylaminopurine (BAP)	3.0	300 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
9	Peptone[g]	2 g	No stock	No stock	Weigh
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[h]	To 1000 ml			
	Solidifier				
12	Agar[h]	8–10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Kundson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$ l^{-1}, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary those used in the Murashige–Skoog (MS) medium are suitable.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl respectively.

[f]Keep frozen between uses.

[g]Available as powder (catalog number SPPE117) from www.caissonlabs.com. There are other sources, but Caisson Laboratories is suggested here because it specializes in plant tissue culture media and chemicals.

[h]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5–5.2, add sugar (item 10), and bring volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. As a rule vitamins, hormones and other heat labile items are added after autoclaving, but in this case they can be autoclaved. No agar should be added to the medium for culturing explants because it must be liquid. Agar should be added to the medium for culturing PLBs.

The first solution for asymbiotic orchid seed germination published by Professor Lewis Knudson in 1921 and 1922 is his medium B. In 1946 he published his medium C. There is no medium A. Knudson did not name any of his media after himself. He merely designated them solutions B and C. Others started calling them "Knudson B medium" and "Knudson C medium."

Goodyera

Goodyera, a terrestrial north temperate genus, is widely distributed and found in North and Central America, Africa, Asia, Australia, Europe, Japan, Madagascar, and New Guinea. It is named after John Goodyer (1592–1664) who was considered the best British botanist of his time (Schultes and Pease, 1963; Bechtel et al., 1992; www.goodyer.com/family2002.html).

Propagation of *Goodyera schlechtendaliana* through Callus Derived from Leaf Segments

This species is found in Bhutan, China, India, Indonesia (Sumatra), Japan, Korea, Nepal, Sikkim, Taiwan, Thailand, and Vietnam (Seidenfaden, 1978). In Japan *Goodyera schlechtendaliana* is popular due to its attractive foliage variations. Like many other orchids it has a colorful nomenclatural history (for a review see Seidenfaden, 1978). Propagation through division is very slow. Therefore a method of mass rapid propagation was developed at Hirosaki University, Aomori, Japan (Tomita, 2002).*

Plant Material. Mature seeds were sown on Knudson C (KC) medium (Knudson, 1946) in 100-ml Erlenmeyer flasks containing 30 ml medium. The cultures were maintained at 22 ± 2°C under continuing illumination of 25 μmol m^{-2} s^{-1} provided by fluorescent lamps (type not described). Seedlings were transplanted onto fresh medium every 8 weeks. Leaves, up to 2 cm in length, were taken from 144-week-old seedlings and sectioned into segments measuring 5 mm × 5 mm. These segments were cultured.

Surface Sterilization. Explants taken from plants grown in vitro do not require sterilization. However, they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Polystyrene Petri dishes (9 cm diameter, Iwaki, Co., Ltd.) were used to culture explants. Callus produced by the segments should be cultured in Erlenmeyer flasks (100-ml capacity containing 30 ml medium). Other containers can also be used.

Culture Conditions. Leaf explant and callus (up to 40 weeks) cultures were kept in the dark at 20°C. Sections taken from 40-week-old calli were maintained at 22 ± 2°C under continuing illumination of 25 μmol m^{-2} s^{-1} provided by fluorescent lamps (type not described). Standard culture room conditions are probably also suitable.

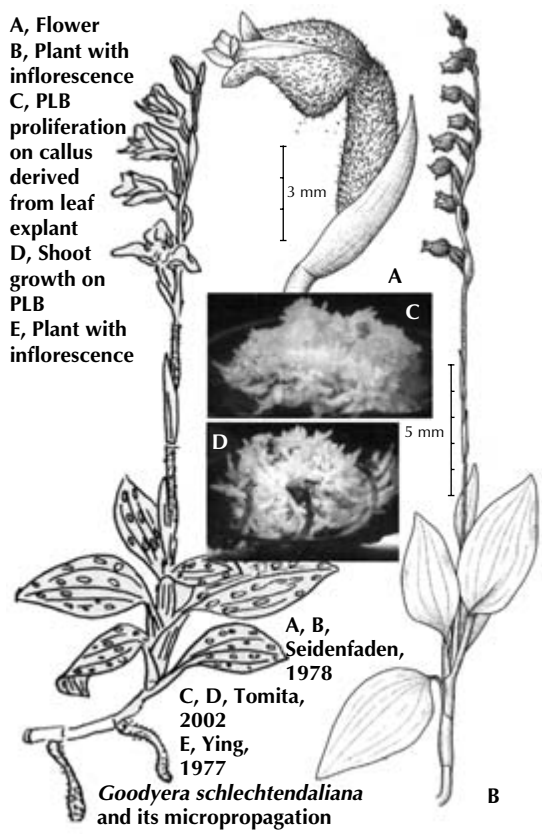
* Thanks are due to Professor Masnaori Tomita, Faculty of Agriculture and Life Science, Hirosaki University, Hirosaki 036-8561 Aomori, Japan for providing a reprint and much additional information via e-mail (tomita@cc.hirosaki-u.ac.jp).

Culture Media. Leaf explants should be cultured on modified half-strength MS medium (Murashige and Skoog, 1962) containing 2.21 mg Dicamba (3,6-dichloro-*o*-anisic acid) l^{-1} and 0.225 mg BA l^{-1} (Table Gdya-1). Callus sections are cultured on modified Norstog medium (Table Gdya-2). Shoots which form on this medium produce green plantlets on oat medium (Table Gdya-3).

Procedure. Young leaves (up to 2 cm in length) are taken from 5-month-old seedlings and cut into 5 × 5 mm sections which should be cultured, ten per dish, in Petri dishes, 9 mm in diameter. The abaxial side (that is the side away from the axis) of each segment is placed on the first medium (Table Gdya-1). Callus should be excised from the sections after 24 weeks of culture and subcultured onto the same solution (Table Gya-1) in 100-ml flasks covered with aluminum foil and maintained in the dark at 20°C. This should be done every 4 weeks. Most of them will die. The surviving callus masses should be cultured for 40 weeks (64 weeks from the start of culture) before small sections, 10–12 mm^3 in size, are taken from each mass and moved to the second medium (Table Gdya-2). Shoots will form on the second medium after 20 weeks of culture (84 weeks from the start of culture).

Developmental Sequence. The leaf segments should start to form white callus at the cut surface after 8 weeks of culture on the first medium (Table Gdya-1). When this callus is moved to the second medium (Table Gdya-2) PLBs will form on the surface of some callus masses after 12–16 weeks of culture. Green shoots should form on these PLBs after 20 weeks on the second medium (Table Gdya-2). To produce plants the shoots and PLBs should be moved to the oat medium (Table Gdya-3) with a suitable *Rhizoctonia* strain. When these plants become large enough they can be grown in a non-heated greenhouse.

General Comments. This procedure is ingenious and of considerable scientific interest. However its slow pace may be a practical drawback.



***Goodyera schlechtendaliana* and its micropropagation**

TABLE GDYA-1. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Goodyera schlechtendaliana* leaf explants (Tomita, 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10

8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Herbicide				
10	Dicamba (3,6-dichloro-*o*-anisic acid)	2.2	220 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylamionopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g,h]	To 1000 ml			
	Solidifier				
17	Gellan gum[g,h]	3.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. Dicamba is available from http://search.wako-chem.com.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses. Dicamba is available from http://search.wako-chem.com/

[f]If the herbicide or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), raise volume to 1000 ml with distilled water (item 16), add the gellan gum (item 17) in accordance with the instructions in footnote *h* below, distribute the medium into vessels and autoclave.

[h]Gellan gum (available as such from www.caissonlabs.com and as Phytagel from www.sigmaaldrich.com) or Gelrite is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE GDYA-2. **Half-strength Nortstog medium (Norstog, 1973; Tomita and Tomita, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium chloride, $CaCl_2 \cdot 2H_2O$[b]	370.0	37.0 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
3	Potassium chloride	375.0	37.5 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	455.0	45.5 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.5	50.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	3.0	300.0 mg l^{-1}		
(e)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.025	2.5 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.5	50.0 mg l^{-1}		
7	**Amino acids**[e,f]				
(a)	Alanine	50.0	500.0 mg	2	Dissolve all amino acids in the 20 ml of 70% ethanol[f]
(b)	Arginine	10.0	100.0 mg

(d)	Glutamine	400.0	4.0 g		
(e)	Leucine	10.0	100.0 mg		
(f)	Phenylalanine	10.0	100.0 mg		
(g)	Tyrosine	10.0	100.0 mg		
	Polyol[f]				
8	*myo*-inositol	50.0	5 g 100 ml^{-1} 70% ethanol[f]	1	
	Organic acid				
9	Malic acid	1.0 g	No stock	No stock	Weigh
10	**Vitamins**[e]				
(a)	Calcium pantothenate	0.25	25.0 mg	1	One solution. Dissolve all vitamins in the same 100 ml of 95% ethanol[e]
(b)	Pyridoxine·HCl	0.25	25.0 mg		
(c)	Thiamine	0.25	25.0 mg		
	Sugar				
11	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[g]	To 1000 ml			
	Solidifier				
13	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If a precipitate forms shake vigorously before dispensing into medium.

[g]Add items 1–6, 8 and 9 to 900 ml of distilled water (item 12), adjust pH to 5.5, add sugar (item 11), and raise volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acids (item 7) and vitamins (item 10) to the warm solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE GDYA-3. **Oat medium for production of *Goodyera schlechtendaliana* plants (M. Tomita, personal communication)**[a]

Oats (rolled) powdered in a blender	10 g
Agar	10 g
Distilled water	1000 ml

[a]Add oats to water, adjust pH to 5.5, bring mixture to a gentle boil, add agar, stir until the mixture is homogenous, pour 50 ml of medium per 250-ml Erlenmeyer flask (or 100 ml per 500-ml flask) and autoclave. Inoculate some of the flasks with an appropriate *Rhizoctronia* strain and transfer PLB or shoots to these flasks.

Grammatophyllum

Grammatophyllum is one of the earliest Asian orchids to be described in the Western literature. In his *Herbarium Amboinense* (published in Holland between 1741 and 1750, but completed in Ambon in 1690) Georgius Everhardus Rumphius, the blind seer of Ambon (de Wit, 1977; Wehner et al., 2002; Beekman, 2003), listed among what he called "the Aristocracy" of plants a plant he called *Angraecum scriptum*, *Bonga loki* (probably an Ambonese name), *Anggrek krinsing* (an Indonesian name) and *het geschreven Anggrek* (The Inscribed Anggrek), which is now known as *Grammatophyllum scriptum*.

Isolation of Protoplasts of *Grammatophyllum elegans*

The method developed for *Acampe praemorsa* was used to isolate 11.6×10^4 and 9.4×10^4 protoplasts from leaves and roots (the latter taken from seedlings growing in vitro), respectively, of *Grammatophyllum elegans* (Seeni and Abraham, 1986).

Callus Induction and Plant Regeneration of *Grammatophyllum scriptum*

This, Rumphius's orchid aristocrat, is found in Indonesia, the Malay archipelago, the Philippines, and the Solomon Islands. Its name is derived from the maroon blotches on its petals and sepals which Rumphius likened to Hebrew letters. A method for the micropropagation of this species was developed at the Rizal Technological University in the Philippines (Quilang et al., 2002).

Plant Material. In the original research leaf and node explants were obtained from seedlings in vitro. However the report describing the method deals only with leaf explants. Presumably, node explants should be handled in a similar manner.

Surface Sterilization. Explants taken from plants growing in vitro do not require surface sterilization. However, they must be washed to remove all medium residues.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers can be used.

Culture Conditions. For callus formation explants should be maintained at 25 ± 1°C in the dark. Callus section for plant formation should be maintained at the same temperature under 14-h photoperiods. The light intensity used in the original research was not described. Standard culture room light intensity should be suitable.

Culture Media. Explants should be cultured in a modified Vacin and Went (VW) medium (Vacin and Went, 1949) supplemented with coconut water and 4 μmol 2,4-D (Table Gram-1). Sections of the callus which formed on this medium should be cultured on a medium free of 2,4-D (Table Gram-2). No medium is suggested for the culture of plantlets to maturation. The second medium (Table Gram-2) may be

TABLE GRAM-1. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of *Grammatophyllum speciosum* leaf explants (Quilang et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	1	
	Auxin				
8	2,4-Dichlorophenoxyacetic acid (2,4-D)	0.88	88 mg 100 ml^{-1} 95% ethanol[e]	1	0.4 µmol
	Complex additive				
9	Coconut water (CW)[f]	150.0 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the 2,4-dichlorophenoxyacetic acid (2,4-D) will fail to dissolve add a few drops 0.1 N HCl. Keep frozed between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1, 3–9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 11, adjust pH to 4.8–5.0 add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

TABLE GRAM-2. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of callus obtained from *Grammatophyllum speciosum* leaf explants and for plantlet regeneration (Quilang et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock

	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1, 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), raise the volume to 900 ml with distilled water (item 10), adjust pH to 4.8–5.0, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

suitable, or plantlets can be cultured on one of the versions of the Knudson C (KC) medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or the Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for KC that does contain this darkening agent (Table Pln-1, footnote *f*).

Procedure. Explants should be cultured on the first medium (Table Gram-1) until a sufficient amount of callus for subculturing becomes available. This may take 2–4 months. Sections of this callus should be subcultured on the second medium (Table Gram-2) until plantlets are formed. These plantlets can be subcultured onto the same medium (Table Gram-2) or moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, Cym-1 to Cym-3, Cym-5, Cym-24, C-19, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without BH or AC. If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). AC should be added to the medium selected for use as suggested for KC that does contain this darkening agent (see Table Pln-1, footnote *f*).

Developmental Sequence. On being placed on the first medium (Table Gram-1) the explants will swell. This will be followed by the "formation of globular structures and protocorm-like bodies and then progress to formation and proliferation of the callus." Plantlet formation on the second medium (Table Gram-2) proceeds through somatic embryogenesis.

General Comments. The report starts by referring to leaf and node explants but dwells only on the former. However one can assume that the procedure will work for both. This procedure should also be tested with leaves from mature plants.

***Grammatophyllum scriptum* flower (courtesy J. Arditti)**

Habenaria

A mostly terrestrial genus consisting of 500–600 species, *Habenaria* is essentially circumglobal and found in Africa, the Americas, Asia, Australia, and Europe.

Micropropagation and in Vitro Flowering of *Habenaria crinifera*

In the state of Bihar, India *Habenaria crinifera* is part of an antiheadache drug formulation. It may also be suitable for commercialization in the horticultural trade, and as a more widely used drug formulation. *H. crinifera* is also one of the more important and rarer species in the Western Ghats in India. These seem to be the reasons why a micropropagation method was developed at the Tropical Botanic Garden and Research Institute, Palode, Thrivanathapuran, Kerala, India (Latha, 1999a).

Plant Material. Young plantlets collected from the ground in the field following the northeast monsoon showers in June and July were potted in 13-cm (6-inch) community pots in a potting mixture consisting of river sand, charcoal, and dried cattle manure (in a ratio of 1 : 2 : 1, v/v/v) and watered daily. Following 2 months of growth in the pots, shoots, approximately 5 cm tall, were excised below their point of attachment to the tubers from which they were growing. All leaves were removed from the shoots after that and the stems were cut into 1-cm-long segments.

Surface Sterilization. Shoot-tip segments should be washed with running water for 15 min and then soaked in 1% (v/v) solution of the detergent Teepol (www.sigmaaldrich.com) for the same length of time. After that the shoot tips should be dipped in 70% ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) for 30 s, submerged in 0.01% (w/v) mercuric chloride ($HgCl_2$; www.sigmaaldrich.com, www.fishersci.com, www.vwr.com, www.thomassci.com) for 3 min (this is a dangerous and toxic substance which should be handled with great care), and washed with sterile distilled water three times. Shoot tips excised from the stems should be immersed in 0.01% $HgCl_2$ for 2 min and washed three times (10 s per wash) with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, 250-ml capacity, containing 100 ml medium were used in the original research. Other containers are also suitable.

Culture Conditions. The original cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx (light sources not indicated). Standard culture room conditions are also suitable.

Culture Medium. Explants should be cultured on woody plant (WPM) medium (Lloyd and McCown, 1981) containing 0.5 mg BA l^{-1} (Table Hab-1) for vegetative bud and shoot formation. The shoots should be moved to WPM supplemented with 0.05 mg NAA l^{-1} (Table Hab-2) for rooting. Flower-bud formation can be induced in vitro on WPM with 0.5 mg BA l^{-1} and 0.1 mg NAA l^{-1} (Table Hab-3).

TABLE HAB-1. **Woody plant (WPM) medium (Lloyd and McCown, 1981) modified for the culture of *Habenaria crinifera* explants (Latha, 1999a)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400.0	40.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	96.0	9.6 g l^{-1}	10	
3	Calcium nitrate, $Ca(NO_3)$	556.0	55.6 g l^{-1}	10

(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
9	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
11	6-Benzyladenine (BA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	6.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. This medium was originally formulated for the culture of a woody plant, mountain laurel, *Kalmia latifolia*.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe lists $MnSO_4 \cdot H_2O$ which seems to be a typographical error because the formulae and concentrations of all other microelements are the same as in the Murashige–Skoog (MS) medium (Murashige and Skoog, 1962).

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media. As a rule it is preferable to add heat-labile substances after autoclaving. However in this case the cytokinin and vitamins can be added before sterilization.

Habenaria from the Latin *habenia* (reins) alluding to the long, strap-like divisions of the two lateral petals and the lebellum (Schultes and Pease, 1963).

TABLE HAB-2. **Woody plant (WPM) medium (Lloyd and McCown, 1981) modified for rooting of *Habenaria crinifera* shoots (Latha, 1999a)**

17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	6.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. This medium was originally formulated for the culture of a woody plant, mountain laurel, *Kalmia latifolia*.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe lists $MnSO_4 \cdot H_2O$ which seems to be a typographical error because the formulae and concentrations of all other microelements are the same as in the Murashige–Skoog (MS) medium (Murashige and Skoog, 1962).

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.2, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media. As a rule it is preferable to add heat-labile substances after autoclaving. However in this case the cytokinin and vitamins can be added before sterilization.

Procedure. Shoots, 5 cm tall, are removed from tubers, defoliated, surface-sterilized, sectioned, and shoot tips are placed in culture on BA containing medium (Table Hab-1). When shoots form they must be moved to a NAA containing substrate (Table Hab-2) to induce rooting. If the intent is to induce flowering in vitro explants should be cultured on a medium which contains both BA and NAA (Table Hab-3).

Developmental Sequence. Explants cultured on BA containing medium (Table Hab-1) produce vegetative buds which give rise to shoots (Fig. Hab-1). These shoots form roots following transfer to a medium which contains NAA (Table Hab-2). The explants flower in vitro when cultured on a substrate which includes both NAA and BA (Table Hab-3).

General Comments. This procedure is unique for two reasons. One is the source of explants. The second is the clever use of the same type of explant for both propagation and flowering in vitro.

Hetaeria

Plantlets can be produced from stem (creeping rhizome) sections by the method developed for *Bletilla striata* (Yam, 1989).

Holttumara

Richard Eric Holttum (1895–1990) was director (one could say "the legendary director") of the Singapore Botanic Gardens from 1925 to 1949, where among his other achievements he produced the first artificial (i.e., human-made) orchid hybrid in that former British colony, *Spathoglottis* Primrose. After retiring he remained active at Kew Gardens until his death at the age of 95. He was interned during the Japanese occupation but used the time and benevolent attitude of General Kwan Koriba (a botanist, former university dean, and after the war a university president; for a biography see Arditti, 1989), the Japanese wartime director of the Gardens, to write a book on the orchids of Malaya – easily one of the very best orchid books in existence. After the war Holttum became the first professor of botany at the University of Singapore, where one of his successors was the eminent A. N. Rao. The trigeneric hybrid *Holttumara* (*Arachnis* × *Renanthera* × *Vanda*) was named in his honor. The first cross, *Holttumara* Cochineal [*Aranda* Hilda Galistan (*Arachnis hookeriana* × *Vanda tricolor*) × *Renanthera storiei*], was raised at the Singapore Botanic Gardens (Anonymous, 1958). Since then several additional *Holttumara* crosses have been produced with a number of *Aranda*, *Renantanda*, *Aranthera*, *Vanda*, and *Arachnis* parents.

A method for the clonal propagation of *Holttumara* Cochineal from apical and axillary buds was developed at the Singapore Botanic Gardens (Lim-Ho, 1981). The procedure is the same as the method used for apical and axillary buds of *Aeridachnis*, *Arachnis*, *Arachnostylis*, *Aranda* Hilda Galistan, and *Aranthera* (Lim-Ho, 1981). This procedure should be suitable for other *Holttumara* crosses and clones.

Ipsea

A small terrestrial genus of approximately three species, *Ipsea* is related to *Calanthe* and *Phaius* (Bechtel et al., 1992). It is found in India and Sri Lanka. As is so often the case with orchids, at one time or another taxonomists have assigned members of this genus to *Ipsea*, *Pachystoma*, *Spathoglottis*, and *Tainia* (Pradhan, 1976–1979; Bechtel et al., 1992).

Micropropagation of the Malabar Daffodil Orchid, *Ipsea malabarica*

The Malabar daffodil orchid, *Ipsea malabarica*, is a horticulturally desirable terrestrial species found at 1000-m elevation in the Western Ghats, Southern India. It is a protected species and is not being overcollected, but its populations are too small for survival. A micropropagation method was developed "to strengthen the resource base through reintroduction and restoration" (Gangaprasad et al., 1999).

Plant Material. Seeds from immature capsules, 40–45 days after self-pollination, were germinated on liquid modified Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing 2% sucrose and 0.05% (w/v) casein acid hydrolysate (CH), peptone, or yeast extract (YE) and coconut water (CW; all available from www.alphabiosciences.com or www.plantmedia.com). Protocorms which formed on this medium were subcultured on a solid modification of the MPR medium containing 0.6% agar, 0.05% CH, 0.05% peptone, 0.05% YE, 20% CW, 0.05% activated charcoal (AC), and 3–7% banana pulp (BP). The protocorms produced seedlings with one or two small leaves. After two subcultures at 30-day intervals (i.e., a total of 60 days) the seedlings had two to four leaves and stem tubers 0.5–1.0 cm in diameter. For tissue culture (i.e., micropropagation) stem tubers of 60-day-old seedlings were dissected and cultured.

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization. However, they must be washed with sterile distilled water to remove medium residues.

Culture Vessels. Test tubes were used in the original research (Fig. Ipsea-1). Other containers can also be used.

Culture Conditions. The original cultures were maintained at 25 ± 2°C under 12-h photoperiods provided by cool white fluorescent tubes (no information was provided about the number and wattage of the tubes or light intensity). Standard culture room conditions are also suitable.

Culture Media. Explants should be cultured first in MPR medium containing 0.5 mg BA l^{-1} (Table Ipsea-1) to bring about shoot formation. After 90 days (and four transfers to fresh medium, each following 25 days of culture) shoots with two to four leaves should be moved to MPR medium supplemented with 1 mg IAA l^{-1} (Table Ipsea-2) for rooting.

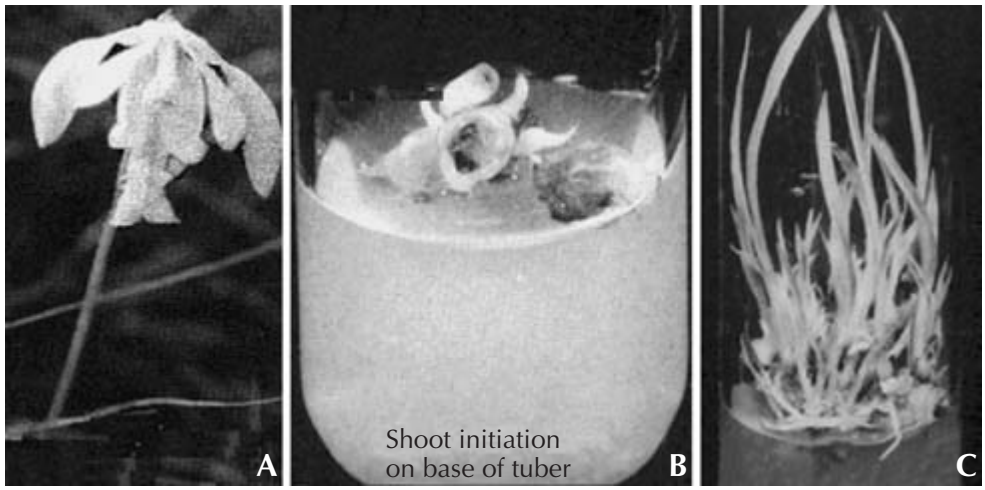

FIG. IPSEA-1. ***Ipsea malabarica*. A. Flower in tissue culture. B. Shoot initiation on base of tuber. C. Multiple shoots. (Gangaprasad et al., 1999.)**

Procedure. Explants are placed on the first medium (Table Ipsea-1). After 20–30 days the medium will turn brown due to exudations. Therefore the explants and the shoots which develop from them must be transferred to fresh medium every 30 days. Following 90 days of culture shoots should be transferred to the second medium (Table Ipsea-2) to induce root formation. If the medium turns brown the shoots/plantlets must be transferred to fresh medium at 20–30-day intervals.

Developmental Sequence. Shoots develop on the first medium (Table Ipsea-1) and roots form on the second substrate (Table Ipsea-2).

General Comments. Both the seed germination and micropropagation parts of this procedure are simple, efficient, and effective. The micropropagation protocol can be used to increase the number of plants which are obtained from one batch of seeds. However, since the explants are taken from seedlings the method cannot be used to propagate outstanding forms unless it proves to be suitable for explants from mature plants. This method could possibly also be suitable for *Ipsea speciosa*. Only experiments can determine if this method, or at least the media, can also be used with explants from mature plants.

TABLE IPSEA-1. **Mitra, Prassad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Ipsea malabarica* stem tubers (Gangaprasad et al., 1999)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses. If the cytokinin does not dissolve add a few drops of 0.1 N HCl.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976; Gangaprasad et al., 1999).

TABLE IPSEA-2. **Mitra, Prassad, and Roychowdhury medium (Mitra et al., 1976) modified for rooting of *Ipsea malabarica* stem shoots (Gangaprasad et al., 1999)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses. If the auxin does not dissolve add a few drops of 0.1 N KOH.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and bring volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976; Gangaprasad et al., 1999).

Kagawara

The first *Kagawara* (*Ascocentrum* × *Renanthera* × *Vanda*) hybrid, *Kagawara* Firebird [*Renanthera storiei* × *Ascocenda* Red Gem (*Vanda merrillii* × *Ascocentrum curvifolium*)], was registered in 1968 by R. K. Mizuta in Hawaii. Other parents have been used since then to produce additional *Kagawara* crosses.

A method for the clonal propagation of *Kagawara* Teoline Fair [*Ascocenda* Meda Arnold (*Ascocentrum curvifolium* × *Vanda* Rothschildiana) × *Renanthera coccinea*] from apical and axillary buds developed at the Singapore Botanic Gardens is the same as the procedures used for similar explants of *Aeridachnis*, *Arachnis*, *Arachnostylis*, *Aranda* Hilda Galistan, and *Aranthera* (Lim-Ho, 1981). This procedure should be suitable for other *Kagawara* crosses and clones.

Laelia

The procedures used for *Brassocattleya* (Kako, 1973) can also be employed with *Laelia*. Methods used for *Brassolaelia*, *Cattleya*, *Laeliocattleya*, and related species and hybrids should also be suitable.

Laeliocattleya

One of the earliest intergeneric orchid hybrids, *Laeliocattleya* is very popular among growers. Its name was first published in the *Botanial Journal of the Linnean Society* 24:168 (1887). The first taxon in the genus is *Laeliocattleya elegans* which is considered to be a natural hybrid, *Cattleya leopoldii* × *Laelia purpurata* (or *Laeliocattleya* Schilleriana if the hybrid is considered to be horticultural). Few methods were developed specifically for *Laeliocattleya* because procedures used for *Cattleya* are also suitable for this hybrid genus (for one example see Ishii, 1974).

Laeliocattleya Propagation by Tissue Culture

The method used for *Cattleya* is also suitable for *Laeliocattleya* (Huang, 1984).

Clonal Propagation through the Culture of *Laeliocattleya* Leaf Tips

The method developed for *Cattleya* can also be used for *Laeliocattleya* (Arditti et al., 1971; Ball et al., 1971; Churchill et al., 1971*a*, 1971*c*, 1972*a*, 1973). As with *Cattleya* it is important to keep in mind that as the leaf ages, cells and tissues at its tips may lose their regenerative capability. Therefore explants must be taken before the characteristic notch develops at the leaf tip (Fig. Lc-1).

Plant Production from Young Leaves of *Laeliocattleya*

Rather than writing something new or paraphrasing (with attribution, of course) a published statement, it is sometimes better to present a direct quote. The introduction

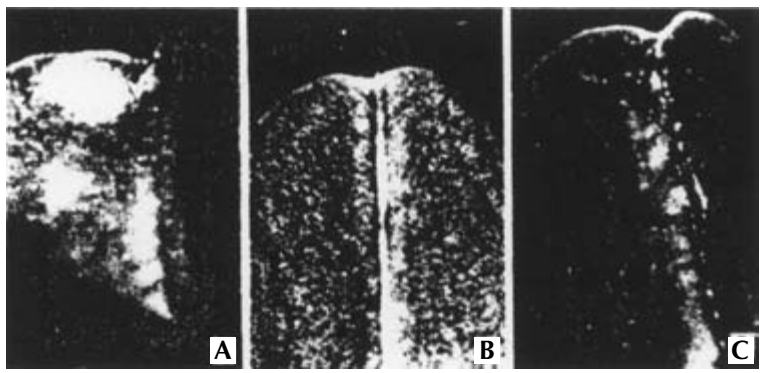

FIG. LC-1. **Notch formations on *Laeliocattleya* leaves. A. Young leaf from a mature plant. The tip is still pointed and, if cultured, is capable of callus and/or PLB formation (× 4). B. A notch starting to form (× 4). C. The notch is fully formed, and excised tips cannot be cultured (× 4.3).**

of the paper which describes this procedure states that "the propagation of orchids through tissue culture has been commercially successful due to the production of quality plants in large quantities by clonal multiplication. These facts have motivated us to study the clonal propagation of different species of orchids, testing several types of explants: apical meristems and lateral buds from *Cymbidium* and Venezuelan species of *Cattleya*; microcuttings from *Dendrobium*; complete and sectioned leaves from *Laeliocattleya*. Researchers in orchid tissue culture have been looking for an explant other than the meristem, to minimize the disturbance caused to the plant during the isolation of the explant. Leaves have been pointed out as a suitable tissue . . ." (Matos and De Garcia, 1991). The use of leaves as explants from axenic seedlings is an excellent idea. However if the purpose of micropropagation is "the production of quality plants in large quantities" it is hard to see how this can be achieved if explants are taken from seedlings because the quality of unflowered plants is not known. Use of explants is a good starting point for the development of a new protocol since it eliminates the need for surface sterilization (a process which can damage the tissues and bring about failure. But, to be useful as a means of "production of quality plants in large quantities" a procedure must be applicable to explants taken from plants of known quality.

Plant Material. In the original research "leaves 1–1.5 cm long . . . bearing their basal buds were" taken from "*Laeliocattleya* John Cunningham plantlets grown for one or two years from seed germinated in solid Knudson C medium." Since there is no mention of surface sterilization it is reasonable to assume that the "plantlets" were seedlings still growing on Knudson C medium in vitro 1–2 years after the seeds were germinated. The paper does not make clear whether the seeds were produced by *Laeliocattleya* John Cunningham through selfing or crossing with another plant of the same cultivar or by repeating the cross that gave rise to this hybrid (*Laeliocattleya* Schilleriana × *Laeliocattleya* Elegans). If it is the former, the seedlings were not *Laeliocattleya* John Cunningham as such but the F_2 generation of *Laeliocattleya* Schilleriana × *Laeliocattleya* Elegans, the cross which produced *Laeliocattleya* John Cunningham.

Surface Sterilization. There is no mention of surface sterilization in the original paper. This suggests that the explants were taken from seedlings growing in vitro. Explants from seedlings growing in vitro do not require sterilization. However they should be washed with sterile distilled water to remove medium residues.

Culture Vessels. Tubes containing 10 ml of medium were used in the original research. Other containers filled with medium to 20–30% of their volume are also suitable.

Culture Conditions. Cultures should be maintained at 27°C under continuous illumination of 7000 lx (the source of illumination was not listed) or standard culture room conditions.

Culture Media. Explants were cultured on half-strength MS medium (Murashige and Skoog, 1962) supplemented with citric acid (this organic acid is added to media to solubilize ferrous or ferric salts; the rationale of adding it to a medium which

contains chelated iron is not obvious), ascorbic acid (this is the heat labile vitamin C; how much of it will remain in a medium after autoclaving is not certain), auxin, and cytokinin (Table Lc-1). It is hard to determine which and how much hormone(s) was/were added. The "Composition" section in "Materials and methods" states that the medium contains 1 mg 2,4-D l^{-1}, but table II in the paper shows that the best results were obtained on media which did not contain this auxin. Also, the abstract states that the best yield of shoots was on BA containing medium and makes no reference to 2,4-D. In relation to BA the abstract asserts that "with 0.5–1 mg/l BA the best yield of 67 shoots per explant, was achieved after 23 weeks," but table II in the paper shows that after 23 weeks the number of shoots (presumably per explant) was 30 on 0.5 mg BA l^{-1}, 63 on 1 mg BA l^{-1}, and 67 on 2 mg BA l^{-1}. Shoot vigor was highest on the 2 mg BA l^{-1} level. The amount recommended here (Table Lc-1) is 2 mg BA l^{-1}, but those using this procedure may wish to experiment with 0.5 and 1 mg BA l^{-1}. Shoots obtained on the first medium "were transferred to [an undescribed] suitable medium to induce roots." The recommendation here is to use half-strength MS with 1 mg NAA l^{-1} (Table Lc-1). If roots are not produced on this medium the NAA concentration can be doubled, tripled, or even quintupled. In the event 1 mg NAA l^{-1} has deleterious effects the concentration can be cut in half or reduced to 0.25 mg l^{-1}.

Procedure. "One leaf was placed in each tube with the lower side in contact with the medium." This "lower side" can be the underside or the cut surfaces. Also, since "leaves bearing their basal buds" were cultured it stands to reason that the bases of the buds were on the medium. It seems that shoots formed on the first medium (Table Lc-1) were transferred to the second "suitable" medium (Table Lc-2, which is suggested here on the assumption that it may work and not because it may have been used originally).

Developmental Sequence. Shoots form on the first medium (Table Lc-1). They develop roots on the second substrate (Table Lc-2).

General Comments. As published this procedure was only used to culture leaves taken from seedlings. There is no evidence that it may be suitable for leaves from mature plants. If it is only suitable for seedling leaves this method is of limited practical value. The title of the paper suggests that plants are produced from leaves, but two statements in the paper cast doubts on whether this is the case. In "Materials and methods" the authors state that "leaves bearing their basal buds were isolated" and in "Results and discussion" they assert that "the complete leaf bearing its basal bud was required to establish a competent culture." Since buds were present it is possible that they, not the leaves, produced shoots. If this is the case this method could perhaps be used to culture axillary buds of mature plants. The paper which describes this method is: (1) unclear; (2) not detailed enough; (3) not well written; and (4) weak in the interpretation and discussion of the results it presents.

TABLE LC-1. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of young leaves of *Laeliocattleya* (Matos and de García, 1991)**

	Sugar				
16	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[i]	To 1000 ml			
	Solidifier				
18	Gelrite[i,j]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]The reason for the addition of citric acid is not clear. In some cases it is added to solubilize iron, but a chelating agent is used in this medium. There is no evidence that *Laeliocattleya* explants or those of any other orchid require citric acid.

[h]Ascorbic acid (vitamin C) is usually not added to culture media. The reasons for its addition to this medium are not clear.

[i]Add items 1–7, 9, and 10 to 900 ml of distilled water (item 17), adjust pH to 5.3, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous sitting to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the gellan gum is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 11), and vitamins (items 12–15) to the warm solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels.

[j]Gellan gum (available as such from www.caissonlabs.com, and as Phytagel www.sigmaaldrich.com or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

TABLE LC-2. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the rooting of *Laeliocattleya* shoots (Matos and de García, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	31.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}

11	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Ascorbic acid (vitamin C)[h]	150.0	Suspend in 5 ml 70% ethanol	No stock	Weigh
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
16	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[i]	To 1000 ml			
	Solidifier				
18	Gelrite[i,j]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]The reason for the addition of citric acid is not clear. In some cases it is added to solubilize iron, but a chelating agent is used in this medium. There is no evidence that *Laeliocattleya* explants or those of any other orchid require citric acid.

[h]Ascorbic acid (vitamin C) is usually not added to culture media. The reasons for its addition to this medium are not clear.

[i]Add items 1–7, 9 and 10 to 900 ml of distilled water (item 17), adjust pH to 5.3, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous sitting to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the gellan gum is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 11), and vitamins (items 12–15) to the warm solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels.

[j]Gellan gum (available as such from www.caissonlabs.com and as Phytagel, www.sigmaaldrich.com) or Gelrite is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

Liparis

Plantlets can be produced from stem sections of *Liparis nervosa* by the method developed for *Bletilla striata* (Yam, 1989). Leaf tips of *Liparis viridiflora* can be cultured by the method used for *Acampe rigida* (Yam, 1989).

Tobacco and Old DNA: The Discovery of Cytokinins

Enhancement of bud formation in tobacco callus by KH_2PO_4 led Professor Folke Skoog at the Botany Department, University of Wisconsin to an exploration of the effects of adenosine and adenine. On finding that adenine can stimulate production of buds, Skoog concluded that nucleic acids were "critically involved in plant development" (Professor Carlos Miller in an e-mail message dated April 30, 1995). By 1951 when Professor Miller joined Professor Skoog's laboratory "many chemicals . . . part of the nucleic acid area" were being tested. One recollection of events is that a new technician prepared DNA containing medium and autoclaved it. He did not know that DNA must not be sterilized by autoclaving. Tissues grew well on the autoclaved medium but failed to do so on a medium which contained filter-sterilized DNA. The tissues grew well again when DNA containing medium was autoclaved. Another recollection is that the technician prepared the medium that supported growth using DNA from an old and dusty bottle of herring sperm DNA. When all of the old herring sperm DNA was used up a fresh supply was purchased and found to be inactive. The fresh herring sperm DNA became active on standing or after being autoclaved in a weakly acid solution. A crystalline active compound was isolated from the autoclaved solution and named kinetin. Its structure was established as 6-furfurylaminopurine by Professors Miller and Skoog with the help of Professor Frank Strong and his associates in the Department of Biochemistry. Kinetin was synthesized in 1955.

Professors Robert Cleland, Carl Leopold, Carlos Miller, and Machteld Mok provided information for this box.

Ludisia (*Haemaria*)

Most orchids are grown for their flowers. Only a few are cultivated for their beautiful leaves. *Ludisia* (*Haemaria*) *discolor* is such an orchid. It is found in southern China, Burma, Indonesia, and the Malay archipelago. This species was abundant in Malaysia at one time, but its population has been reduced drastically. A tissue culture procedure was formulated at the University Sains in Penang, Malaysia, "with a view to conservation of the species" (Teo, 1978).

Plant Material. Single-node sections are taken from succulent shoots 3–4 cm long.

Surface Sterilization. Shoots are washed with detergent and water before being immersed in 10% Clorox solution (10 ml Clorox diluted to 100 ml with distilled water). A time period for this immersion is not given in the original paper, but 8–15 min should be appropriate. Following this sterilization the leaves (especially the petioles) are removed from around each node and the shoots are again immersed in 10% Clorox, this time for 5–6 min. On being removed from the Clorox solution the shoots are washed with sterile distilled water two to three times and cut into sections.

Culture Vessels. Erlenmeyer flasks were used in the original research, but other containers can also be employed.

Culture Conditions. Cultures should be maintained under continuous illumination (intensity and sources were not given, nor was temperature) and, if liquid, agitation "as is done with other orchids (Kunisaki et al., 1972; Intuwong and Sagawa, 1973; Teo et al., 1973)."

Culture Media. Liquid Knudson C medium (see Tables Aranda-7 and Cym-3 with the agar omitted) containing "either auxin or cytokinin or their combinations at varying concentrations did not" induce proliferation. Stem sections placed on solid Knudson C medium (see Tables Aranda-7 and Cym-3) produced shoots.

Procedure. Stem sections placed in liquid medium do not proliferate. After the sections are moved to solid medium they turn yellowish-green, swell, and produce leaves and shoots. Excision of the shoot tip induces branching. When the plantlets are large enough, they can be moved to community pots. It is not clear from the original paper (Teo, 1978) whether a period in liquid medium is required before the sections can grow on solid Knudson C.

Developmental Sequence. Sections in liquid medium do not proliferate. Shoots are produced only on solid medium.

General Comments. This appears to be a slow procedure since each node seems to produce only a single plant.

Luisia

Named after the explorer Don Luis de Torres by Charles Gaudichaud in 1826, the genus *Luisia* consists of approximately 40 species which are found in tropical Asia, Australia, Japan, Malaysia, Papua New Guinea, and Polynesia. The type species of the genus is *Luisia teretifolia* which was found by Gaudichaud in Guam. This species also occurs in India, Indonesia, New Caledonia, South East Asia, and Sri Lanka. Both *Luisia teretifolia* and *Luisia trichorhiza* have terete leaves.

Micropropagation of *Luisia teretifolia* through Leaf Segments

According to the noted expert on Indonesian orchids, James B. Comber, "differences between [*Luisia javanica*] and *L. teretifolia* . . . are very small if indeed they do exist." He was unable to see any difference between them. In India the leaves of *Luisia teretifolia* taper toward the apex and are 15 cm long. Methods for the culture of apical and basal explants from leaves of *L. teretifolia* leaves were developed at the Botany Department, Panjab University (Vij and Pathak, 1990).

Plant Material. Apical and basal explants, 5–10 mm long, were taken from young leaves, up to 2 cm in length, of mature plants and 16- to 40-week-old axenic seedlings.

Surface Sterilization. Explants taken from axenic seedlings do not require sterilization. However they should be washed with sterile distilled water to remove medium residues. No surface sterilization procedure is described for explants taken from mature plants. The method used to surface-sterilize *Cattleya* leaf tips (Arditti et al., 1971; Ball et al., 1971; Churchill et al., 1971*a*, 1971*c*, 1972*a*, 1973) will probably be suitable or can serve as a starting point for the development of a suitable procedure (see *Cattleya* section for details).

Culture Vessels. Test tubes, Erlenmeyer flasks, or other containers can be used.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or at standard laboratory conditions.

Culture Media. Basal explants cultured on MS medium (Murashige and Skoog, 1962) containing 1 mg kinetin l^{-1} (Table Luisia-1) produce callus and PLBs. Apical explants produce PLBs when cultured on MS containing 1 mg BA l^{-1} and 1 mg NAA l^{-1} (Table Luisia-2). The PLBs can be subcultured on Knudson C medium (Knudson, 1946) supplemented with banana homogenate (BH; see Table Cym-24) for plantlet production.

Procedure. Explants should be placed on the appropriate medium and cultured until PLBs are formed. The PLBs can be proliferated on the initial medium or moved to Knudson C with BH for plantlet production.

TABLE LUISIA-1. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of basal explants from leaves of *Luisia teretifolia* (Vij and Pathak, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	Kinetin	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	9.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.5, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media. Amino acids (item 8), hormone (item 10), and vitamins (item 11–14) are heat labile and are often added after autoclaving to the still hot and liquid solution under sterile conditions with sterilized pipettes, mixed well and the medium is distributed to preautoclaved culture vessels. In this case all components are added before sterilization.

TABLE LUISIA-2. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of apical explants from leaves of *Luisia teretifolia* (Vij and Pathak, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	9.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) are heat labile and are often added after autoclaving to the still hot and liquid solution under sterile conditions with sterilized pipettes, mixed well, and the medium is distributed to preautoclaved culture vessels. In this case all components are added before sterilization. Agar is not added to liquid media.

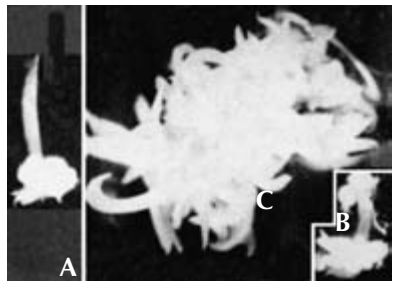

FIG. LUISIA-1. **Micropropagation of *Luisia teretifolia*. A. Protocorm-like body with leaf. B. Callus formation. C. Multiple shoots. (Vij and Pathak, 1990.)**

Developmental Sequence. Calli and/or PLBs form on the initial medium. PLBs proliferate on the same substrate and form plantlets on KC medium + BH (Fig. Luisia-1).

General Comments. This procedure is ideal because both tips and bases of leaves serve as explants which can be cultured. Also, removal of leaves does not damage the plants from which they are taken. If a plant does not have enough leaves only tips can be excised and cultured.

Leaf-segment Culture of *Luisia trichorhiza* in Vitro

Leaf segments of *Luisia trichorhiza* obtained from 16-week-old axenically grown seedlings "responded favorably" when cultured on MS medium and "its various modifications" with 1 mg l^{-1} each of auxins/cytokinins/gibberellin." PLBs were initiated from epidermal cells "at the basal, apical and/or cut ends of the explants depending on media composition."

Rapid multiplication of PLBs occurred on media containing IAA regardless of whether BA or kinetin were present. Charcoal (0.2%) in the medium enhanced further PLB formation and differentiation. Plantlets were regenerated within 18 weeks on MS medium containing IAA, BA, and charcoal. All plantlets contained $2n = 38$ chromosomes (Vij and Pathak, 1988*a*).

Micropropagation of *Luisia trichorhiza* through Leaf Segments

The procedure used for *Luisia teretifolia* can also be employed for *Luisia trichorhiza* except that both apical and basal explants should be cultured on MS containing 1 mg BA l^{-1} and 1 mg IAA l^{-1} (Fig. Luisia-2; Table Luisia-3). PLBs produced on this medium can be subcultured on it or moved to banana homogenate containing Knudson C medium (see Table Cym-24) for plantlet production (Vij and Pathak, 1990).

Protoplast Isolation from *Luisia zeylanica*

The method developed for *Acampe praemorsa* can be used to isolate 0.6×10^4 protoplasts from leaves of *Luisia zeylanica* (Seeni and Abraham, 1986).

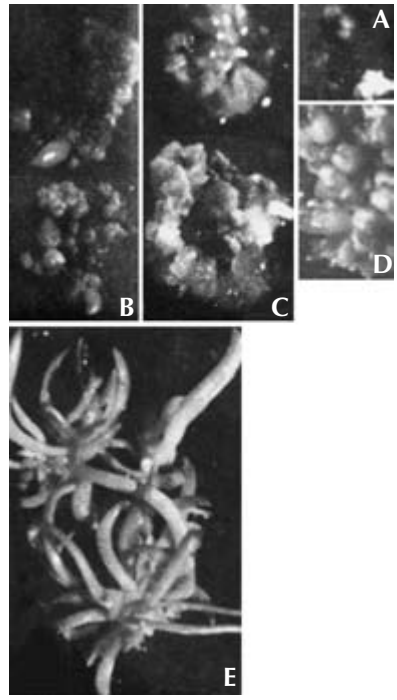

FIG. LUISIA-2. **Tissue culture propagation of *Luisia trichorhiza*. A. Callus formation by apical explant. B. PLBs on apical and basal explants. C. Callus formation by explants. D. Differentiating PLBs. E. Plantlets. (Vij and Pathak, 1990.)**

Luis de Torres (1562–1655), a converted Jew, was an interpreter for Columbus who sailed out on the Santa Maria and returned on the Niña. While exploring his new surroundings de Torres saw a large bird he called Tukki for peacock, thus naming the turkey.

TABLE LUISIA-3. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of apical and basal explants from leaves of *Luisia trichorhiza* (Vij and Pathak, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Indoleacetic acid (IAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylaminopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	9.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media. Amino acid (item 8), hormones (items 10, 11), and vitamins (items 12–14) are heat labile and are often added after autoclaving to the still hot and liquid solution under sterile conditions with sterilized pipettes, mixed well and the medium is distributed to preautoclaved culture vessels. In this case all components are added before sterilization.

Lycaste

The methods used for *Cymbidium* (Morel, 1960, 1963, 1964*a*, 1964*b*) are also suitable for *Lycaste*.

Measuring and Adjusting pH

A measure of the alkalinity or acidity of a medium, pH is an important factor. It must be measured and adjusted to within proper levels of tolerance. Desktop or hand held and portable meters or paper strips can be used to measure pH. If the pH is too high 0.1 N hydrochloric acid (HCl) should be used to reduce it. Low pH can be raised with 0.1 N potassium (KOH) or sodium (NaOH) hydroxide.

Malaxis

First described in 1788 by the Swedish botanist Olof Swartz (1760–1818), the genus *Malaxis* consists of approximately 300 species which can be found throughout most of the world in both tropical and temperate climates. Flowers which do not resupinate are an interesting characteristic of the genus.

Micropropagation of *Malaxis acuminata* through the Culture of Stem Sections

Plantlets can be produced from stem sections of *Malaxis acuminata* by the method developed for *Bletilla striata* (Yam, 1989).

Micropropagation of *Malaxis acuminata* through the Culture of Pseudobulb Segments

In India dried pseudobulbs of *Malaxis acuminata* are an important ingredient of the Ashtavarga drugs which are used in the preparation of an Ayurvedic tonic called Chyavanprash. The species is found in the Himalayas in tropical to subtropical climates and elevations ranging from 1800 to 2300 m. Collection is extensive and exceeds the natural increase in numbers. This jeopardizes species survival and has led to the development of a micropropagation method (Vij and Kaur, 1998).

Plant Material. Sections, 5–10 mm long, from young pseudobulbs shorter than 3 cm, should be cultured.

Surface Sterilization. Pseudobulbs should be washed thoroughly with running tap water and Teepol (www.sigmaaldrich.com) before sterilization with: (1) mercuric chloride (0.1% $HgCl_2$ for 7 min); (2) streptomycin (www.sigmaaldrich.com, www.fishersci.com, www.vwr.com) solution (0.1% for 10 min; 100 mg 100 ml^{-1} distilled water); and (3) 70% ethanol (73–74 ml 95% ethanol made up to 100 ml with distilled water for 10 s) followed by several rinses with sterile distilled water.

Culture Vessels. Test tubes, Erlenmeyer flasks, and other containers are suitable.

Culture Conditions. The cultures should be maintained at 25 ± 2°C and 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. Several media can be used depending on the desired end results. One possibility is to culture the explants on MS medium (Murashige and Skoog, 1962) containing 1 mg BA l^{-1} (Table Mlx-1). On this medium "a single meristematic locus differentiated into a shoot bud which developed into [one] plantlet". Another possibility is to culture the explants on MS medium containing 10 mg NAA l^{-1} (Table Mlx-2). On this medium the explants form multiple shoots and plantlets. If the intent

TABLE MLX-1. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for production of single plantlets from pseudobulb explants of *Malaxis acuminata* (Vij and Kaur, 1998)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. It is also possible to prepare this medium by adding items 1–13 prior to autoclaviing as described in Tables Luisia-1 to Luisia-3.

TABLE MLX-2. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for production of multiple plantlets from pseudobulb explants of *Malaxis acuminata* (Vij and Kaur, 1998)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust to 5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. It is also possible to prepare this medium by adding items 1–13 prior to autoclaviing as described in Tables Luisia-1 to Luisia-3.

is to produce PLBs the explants should be cultured on solid MS supplemented with 10 mg BA l^{-1}, 0.1 mg NAA l^{-1}, and 1 g casein hydrolysate (CH) l^{-1} (Table Mlx-3, agar containing). These PLBs can be proliferated on liquid medium of the same composition (Table Mlx-3, agar free). For further growth and development plantlets and PLBs can be moved to Knudson C (KC) medium containing banana homogenate (BH; see Table Cym-24).

Procedure. Young pseudobulbs are washed, surface-sterilized, rinsed with sterile distilled water, and cut into sections. These sections are placed on one of the three initial media (Tables Mlx-1, Mlx-2, or Mlx-3 with agar). If PLBs are produced they can be proliferated in liquid medium (Table Mlx-3 without agar). Plantlets and PLBs should be moved to BH-containing KC (see Table Cym-24) for growth and development.

Developmental Sequence. Only single plantlets develop on BA-containing medium (Table Mlx-1). Multiple plantlets form on the NAA-containing substrate (Table Mlx-2). The explants produce PLBs on solid BA-, NAA-, and CH-containing medium (Table Mlx-3, with agar). These PLBs proliferate if cultured in liquid solution (Table Mlx-3, without agar).

General Comments. As a result of a well thought out experimental approach explants of *M. acuminata* can be cultured on three separate media each designed to produce a different result.

TABLE MLX-3. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the production or proliferation of protocorm-like bodies (PLBs) from pseudobulb explants of *Malaxis* a*cuminata* (Vij and Kaur, 1998)**

[a]Amounts are given in mg unless indicated otherwise. Solid medium is for PLB production. Liquid medium is for proliferation of PLBs.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]Add items 1–7, 9 and 15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. Solid (agar containing) medium is for PLB production. Liquid (agar-free) medium is for proliferation of PLBs. It is also possible to prepare this medium by adding items 1–13 prior to autoclaving as described in Tables Luisia-1 to Luisia-3.

Maxillaria

Protoplasts of *Maxillaria tenuifolia* can be released from tissue of 10-cm-long leaves by the procedure used for *Agraecum giryamae* and *Dendrobium* (Price and Earle, 1984; note that this source misspells the species *A. gyrimae*). Incubation time should be 2 days, during which time 0.3×10^5 protoplasts per gram of tissue are released.

Miltonia

The methods used for *Cymbidium* (Morel, 1960, 1963, 1964*a*, 1964*b*) and for *Epidendrum* and *Epiphronitis* (Kusumoto, 1981*b*) are also suitable for *Miltonia*.

Orchid Micropropagation: The First Literature Review

The first (Rotor, 1949), second, and third (Thomale, 1956, 1957) reports on orchid micropropagation generated only limited interest. The same was true for the fourth (Wimber, 1963). Despite being little more than a publicity announcement, the fifth paper (Morel, 1960) drew the most attention, generated interest in orchid tissue culture, and elevated its author to celebrity status. Many papers on the subject were published by the mid 1970s, but they were scattered. Professor Adisheshappa Nagaraja Rao, the long time chair of the Botany Department at the University of Singapore (later the National University of Singapore), wrote the first literature review: *Tissue Culture in the Orchid Industry* (Rao, 1977). This excellent contribution provided impetus for further research, became a classic, and played an important role in establishing orchid micropropagation as a science. Another major contribution to orchid science by Professor Rao was the department he headed for about 20 years. He built it into a powerhouse of research on orchids with prominent orchid scientists like Professors P. N. "Danny" Avadhani, C. S. Hew, Y. H. Lee, S. M. Wong, and others. I spent summers and sabbatical leaves in Singapore working with Rao, Danny, and Choy Sin Hew. All of us retired by 2001, but still remain in contact and maintain our friendship.

Mokara

This trigeneric hybrid (*Arachnis* × *Ascocentrum* × *Vanda*) was produced in Singapore by C. Y. Mok. The first hybrid *Mokara* Wai Liang (*Arachnis* Ishbel × *Ascocenda* Red Gem) was registered in 1969. One of the better-known hybrids that is used extensively in the cut-flower industry in Singapore and Indonesia is *Mokara* Mak Chin On (*Aranda* Christine × *Ascocenda* Blue Boy). It was registered in 1978. This hybrid and a number of others with considerable cut-flower industry potential generated a need for mass rapid propagation procedures.

Clonal Propagation of *Mokara* from Flower Buds

Clonal propagation of orchids through the culture of shoot-tip and axillary buds "requires the sacrifice of a new growth, or even a whole plant in the case of monopodial orchids. . . ." The use of floral buds for clonal propagation causes "no harm or setback to the parent plant"; therefore a method for the clonal propagation of *Mokara* through the culture of flower buds was developed at the Singapore Botanic Gardens (Lim-Ho et al., 1984).

Plant Material. Complete flower buds, 0.5–1.0 cm, are cultured.

Surface Sterilization. Buds are first washed with distilled water (detergent is not mentioned, but the use of a mild formulation is advisable) and immersed for 45 min in 20% Clorox (20 ml Clorox diluted to 100 ml with distilled water plus 1 drop Tween 80). Pedicels are removed after that, and the buds are placed in 5% Clorox (5 ml Clorox diluted to 100 ml with distilled water) for an additional 15 min. After that the buds are rinsed three times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks were used in the original research, but other containers are also suitable.

Culture Conditions. Liquid cultures should be placed on a gyrorotatory shaker at 60 to 80 rpm for 8–12 h day^{-1}. Both liquid and solid cultures are maintained under 12-h photoperiods of 1000 lx provided by Tru-Lite tubes and 21–25°C. Sylvania Gro-Lux and other plant growth fluorescent lights, or a combination of cool white tubes and incandescent bulbs are probably also suitable.

Culture Media. Buds are first cultured on a modified liquid MS medium (Table Mkra-1) and transferred to a modification of the Knudson C solution (Table Mkra-2). Differentiation of PLBs occurs on modified Vacin and Went medium (Table Mkra-3).

Procedure. Buds are cultured in the first medium (Table Mkra-1). When PLBs form "at the base of the flower buds, the cultures are transferred to a basic Knudson C salt with hormone [Table Mkra-2], but . . . without sugar . . . for proliferation." To enhance differentiation the PLBs are moved to the modified Vacin and Went medium (Table Mkra-3). After 9–14 months the plantlets can be potted in the nursery.

TABLE MKRA-1. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Mokara* flower buds (Lim-Ho et al., 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Potassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Polyol				
8	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
9	Indoleacetic acid (IAA)	2	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin and related substance				
10	Kinetin	2	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
11	Adenine sulfate	40	No stock	No stock	Weigh
	Vitamins				
12	Niacin (nicotinic acid)	5	500 mg 100 ml^{-1} 95% ethanol[f]	1	
13	Thiamine (vitamin B_1)	1	100 mg 100 ml^{-1} 95% ethanol[f]	1	
	Sugar				
14	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[g]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference will probably have little effect.

[e]If auxin or cytokinins do not dissolve, use a few drops of KOH or HCl, respectively, to solubilize them.

[f]Keep refrigerated between uses.

[g]Add items 1–13 to 900 ml distilled water (item 15), adjust pH to 5.2, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense solution into culture vessels and autoclave for 20 min. Omit agar if preparing liquid medium. As a rule additives like hormones and vitamins should not be autoclaved, but in this case the medium was autoclaved during the original research, an indication that any changes that do occur are not deleterious.

TABLE MKRA-2. **Modified Knudson C medium (Knudson, 1946) for the culture of *Mokara* flower buds (Lim-Ho et al., 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	400	40 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	400 g	40 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	100	10 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	100	10 g l^{-1}	10	
5	**Chelated Iron**[c]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
6	**Microelements**[d]				
(a)	Aluminum chloride	0.03	3 mg l^{-1}	10	One solution
(b)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(c)	Cupric chloride, $CuCl_2$	0.03	3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}		
(e)	Potassium iodide, KI	1.0	100 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4$	8.6	860 mg l^{-1}		
	Cytokinin				
7	Benzyl adenine (BA)	2	200 mg l^{-1} 95% ethanol[e]	1	
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[f]	To 1000 ml			
	Solidifier				
10	Agar[f]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe does not include chelated iron because it was not available at the time.

[d]Add all microelements to the same 1 l of water, and heat and/or stir until they are dissolved. Water(s) of hydration, if any, are not listed for $ZnSO_4$.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1–8 to 650 ml distilled water (item 9). Adjust pH to 5.2, and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense solution into culture vessels and autoclave for 20 min. As a rule additives like hormones and vitamins should not be autoclaved, but in this case the medium was autoclaved during the original research, an indication that any changes that do occur are not deleterious. Omit agar if preparing liquid medium. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary, adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

Developmental Sequence. PLBs are first formed on the bases of the flower buds. They develop from torus tissues situated between the sepals and petals. These PLBs proliferate on the second medium. Growth is slow initially but accelerates after 6 months of subculturing. Plantlets averaging 5 cm in height are produced after 9–14 months on the second medium. Leaves generally start to appear after 6 months in culture. Roots form 3 months after that.

General Comments. Buds smaller than 0.5 cm and larger than 10 mm did not produce PLBs, while those measuring 0.5–1.0 cm did. This procedure appears to be

TABLE MKRA-3. **Modified Vacin–Went medium (Vacin and Went, 1949) for differentiation of plantlets obtained from *Mokara* flower buds (Lim-Ho et al., 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated Iron**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additives				
8	Coconut water	150	No stock	No stock	Measure
9	Banana homogenate[e]	75	No stock	No stock	Prepare
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original recipe employs 28 mg l^{-1} ferric citrate, $FeC_6H_5O_7 \cdot 5H_2O$, which is difficult to dissolve.

[e]Place 75 g of ripe but still firm banana in a homogenizer, add 150 ml water, and homogenize for 2 min, let stand for 50 min, and homogenize for another minute. Pour the homogenate into the calcium phosphate solution, wash the homogenizer with two separate portions of 50 ml of water, and add that to the mixture.

[f]Add items 1–9 to the 500 ml distilled water (item 11) that contains item 2, adjust pH to 5.2, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar for liquid medium.

ideal because: (1) the parent plant is not damaged by the removal of the explants; (2) flower buds are usually available in large numbers; and (3) it does not require elaborate excision procedures.

Micropropagation of *Mokara* through the Culture of Inflorescence Tips

Abdul Karim B. Abdul Ghani earned his Ph.D. in the laboratory of Folke Skoog, coformulator of the MS medium. Therefore it is not surprising that on returning to Malaysia to accept a position in the Botany Department at the University Kebangsaan, Malaysia, Abdul Ghani initiated an orchid tissue culture program. His

group is currently working on several orchids of interest to Malaysian horticulture and conservation including *Mokara* and *Renantanda* (Abdul Ghani, pers. comm.).*

Plant Material. In the original research, tips 2 mm in length were taken from inflorescences of *Mokara* Chark Kuan. Similar explants from other *Mokara* clones can also be cultured. The apex, which is pin sized, is exposed through the removal of bracts following surface sterilization.

Surface Sterilization. Inflorescences should be washed with water and a mild detergent (Teepol from Shell Chemical, Kuala Lumpur, Malaysia, was used in the original research, but other mild detergents are also suitable) and then rinsed with running water for 2 h. After that and before the uppermost node is excised, remove any bracts that cover the apex. The node should be submerged in 10% household (e.g., Clorox) bleach (10 ml bleach diluted to 100 ml with distilled water) for 15 min. An additional layer of bracts is removed after that, and the tips are immersed in 1% household bleach (1 ml liquid bleach diluted to 100 ml with water) for 10 min. This must be followed by a 5-min rinse with sterile distilled water before all remaining bracts are removed to expose the apex.

Culture Vessels. Erlenmeyer flasks, of 100-ml capacity and containing 50 ml medium, were used in the original research.

Culture Conditions. Cultures were maintained on a gyrorotatory shaker at 100 rpm under 8-h photoperiods of 2000 lx (provided by NEC daylight fluorescent tubes FL 20) at 25 ± 2°C.

Culture Media. PLBs are initiated on liquid modified Vacin and Went medium (Table Mkra-4). The resulting PLBs proliferate on sugar-free Vacin and Went medium (Table Mkra-4), while plantlets form on solid Vacin and Went medium with sugar (Table Mkra-4).

Procedure. Place the shoot tips in the sugar containing medium (Table Mkra-4) to form PLBs. Then move these PLBs to the same medium without sugar (Table Mkra-4) for proliferation. Finally, transfer the new PLBs to solid medium (Table Mkra-4) for plantlet induction.

Developmental Sequence. PLBs form on the explants in liquid modified Vacin and Went medium. These PLBs proliferate on sugar-free liquid Vacin and Went and form plantlets on solid Vacin and Went media.

General Comments. This is an efficient method for mass rapid clonal propagation of *Mokara* that does not endanger the donor plant.

* We thank Dr. Abdul Karim B. Abdul Ghani for allowing us to use unpublished information.

TABLE MKRA-4. **Vacin–Went medium for the germination of orchid seeds (Vacin and Went, 1949) as modified for the initiation and proliferation of protocorm-like bodies, and plantlet induction of *Mokara* (Dr. Abd. Karim Abd. Gahani, University Kebangsaan Malaysia, personal communication)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric citrate, $FeC_6H_5O_7 \cdot 5H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water	200 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose[e]	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g of chelating agent (Na_2EDTA) and 2.78 g of ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Omit sugar from the PLB proliferation medium.

[f]Add items 1 and 3–8 to the 500 ml of distilled water (item 10) that contains item 2, adjust pH to 5.2. Add sugar (item 9), but not to the PLB proliferation medium. Adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium.

Clonal Propagation of *Mokara* through the Culture of Young Leaves

When only a few plants of a clone are available, the use of axillary or flower buds as well as inflorescence tips can be restricted by the unavailability of explants. To overcome this problem a method utilizing young leaves was developed at the Botany Department, University Kebagsaan, Malaysia (Abdul Ghani and Haris, 1992).*

Plant Material. In the original research whole leaves, 0.5–1.5 cm long and 0.3–0.5 cm wide, were excised from 3-month-old plantlets of *Mokara* Chark Kuan that were produced from inflorescence tips and maintained in vitro.

* Dr. Abdul Karim B. Abdul Ghani is now retired.

Surface Sterilization. Since the explants are taken from aseptic cultures, surface sterilization is not needed.

Culture Vessels. Erlenmeyer flasks, of 100-ml capacity and containing 50 ml medium, were used in the original research. Other containers can also be used.

Culture Conditions. Cultures were maintained on a gyrorotatory shaker at 100 rpm under 8-h photoperiods of 2000 lx (provided by NEC daylight fluorescent tubes FL 20) at 25 ± 2°C.

Culture Media. Liquid Vacin and Went medium containing 10% (v/v) water from green coconuts and 1.0 mg l^{-1} kinetin (Table Mkra-5) is suitable for the induction

TABLE MKRA-5. **Vacin–Went medium for the germination of orchid seeds (Vacin and Went, 1949) as modified for the clonal propagation of *Mokara* from young leaves (Dr. Abd. Karim Abd. Gahani, University Kebangsaan Malaysia, personal communication)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10

	Sugar				
10	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g of chelating agent (Na_2EDTA) and 2.78 g of ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]If the cytokinin fails to dissolve, add a small amount of dilute HCl. The stock solution must be refrigerated or frozen.

[f]Add items 1, 3–7, and 9 to the 500 ml of distilled water (item 11) that contains item 2. Adjust pH to 5.2, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring until it is dissolved. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour the medium into a 2-l Erlenmeyer flask and autoclave. Add cytokinin (item 8) to the hot, still liquid solution, mix well, and distribute medium into preautoclaved culture vessels. Omit agar if preparing liquid medium.

of PLBs and their proliferation. PLBs cultured on solid modified Vacin and Went medium (Table Mkra-5) formed shoots.

Procedure. Place explants on the liquid modified Vacin and Went medium; when PLBs develop, move them to fresh medium. When enough PLBs become available, move some to solid medium for shoot formation.

Developmental Sequence. Explants swell after 1 week of culture. PLBs can develop on the abaxial and adaxial as well as the proximal and distal sides of explants after approximately 4 weeks of culture. Proliferation is rapid in the presence of 0.5–2 mg l^{-1} kinetin. To reduce the incidence of hormone induced mutation, it is best to use 0.5 mg l^{-1} kinetin. PLBs are produced in clumps. When cultured separately each PLB produces a new clump. Shoots differentiate after 2 months of culture.

General Comments. This procedure can be used to accelerate the clonal propagation of *Mokara* in cases where explant sources are limited.

Mass Rapid Clonal Propagation of *Mokara* through the Culture of Axillary Buds

A method for the culture of axillary buds of *Mokara* Sally Lim (*Arachnis hookeriana* × *Ascocenda* Meda Arnold) developed at the Singapore Botanic Gardens is the same as the procedure used for *Holttumara* axillary buds of *Aeridachnis*, *Arachnis*, *Arachnostylis*, *Aranda* Hilda Galistan, and *Aranthera* (Lim-Ho, 1981). This procedure should be suitable for other *Mokara* crosses and clones.

Clonal Propagation of *Mokara* through Single-cell Culture

Single cells of *Mokara* were obtained from PLBs derived through the culture of axillary buds. These cells divided in culture and formed a cell cluster. As of 1982 "no fully differentiated plantlets [were] . . . obtained from this cultures [but] there is ample indication that plantlets are forthcoming" (Teo, 1985). Approximately 40,000 cells are present on a 2 × 2 cm surface area of PLBs. This is an indication that "single cell culture should have tremendous practical implication. . . . Selected clones could be cloned and large numbers [of plantlets could be] obtained much more rapidly and efficiently than by the normal well-known method of 'meristemming' " (Teo, 1985). Such a propagation method would have the added advantage of not requiring excessive proliferation, which can result in undesirable mutations. However, it is necessary to keep in mind that some plant tissues can be mosaics of different cells, some of which can be genetically undesirable. On the other hand, some cells from a genetic mosaic can produce greatly improved clones.

Culture of Micropropagated *Mokara* Plantlets

Plantlets of *Mokara* White produced through micropropagation were used in experiments on in vitro carbon dioxide enrichments of CAM orchid plants (Hew et al., 1995). The plantlets were obtained from Multico Orchids Pte. Co. in Singapore and maintained in culture at the laboratory of Professor Choy sin Hew, Botany Department, National University of Singapore.

> Modified Vacin and Went medium (1949) supplemented with 2 g l^{-1} tryptone (Bacto, Difco Laboratories, USA), 1 ml l^{-1} Nitsch microelements (Nitsch and Nitsch, 1969) [these are the microelements in Tables C-11, Disa-2, and Disa-3], 0.1 mg l^{-1} NAA and 0.1 mg l^{-1} kinetin was used . . . 2% sucrose (BDH Limited, Poole, UK). . . . Each GA7 [culture vessel] (Magenta™, Sigma Chemical Co., USA) contains 100 ml of culture medium . . . with 1% agar (Bacteriological agar, Oxoid, UK). The pH . . . [was] adjusted to 5.3 before autoclaving . . . 26 ± 4°C, 14 h [photoperiods]. Light intensity (PPFD) 80 µmol m^{-2} s^{-1} (HPLB 700 W lamp, Philips, UK)." (Hew et al., 1995)

Elimination of Cymbidium Mosaic Virus and Odontoglossum Ringspot Virus from *Mokara*

Infections by cymbidium mosaic virus (CyMV) and odontoglossum ringspot virus (ORSV) are a worldwide problem which can have a devastating effect on producers of orchid cut flowers. Planting virus free plants is an effective control measure. A method to free *Mokara* plants of cymbidium mosaic virus and odontoglossum ringspot virus was developed at the Department of Botany, National University of Singapore by Professor Sek Man Wong and S. T. Lim who was a student at the time. Professor Wong, a plant virologist, is currently the leading international authority on orchid viruses whose compendium on the subject (Wong, 2002) is extensive, well written, and most impressive. The report which describes the method also includes Professor Chong Jin Goh (not a plant virologist who was chairman of the department at the time) as a co-author (Lim et al., 1993*b*). There are no further reports.

Plant Material. Plants of *Mokara* Chark Kuan infected with both CyMV and ORSV served as sources of explants by Wong and Lim. For general cultures meristems were excised from young axillary shoots, ca. 9 cm in length, with Aesculap No. 11 surgical blades (www.aesculap.com, other very sharp blades will probably also be suitable) and sectioned into four sizes: 0.01–0.25, 0.26–0.50, 0.51–0.75, and 0.76–1 mm. Survival after 3 months in culture was 0% for sections in the 0.01–0.5-mm range (Fig. Mkra-1). Axillary buds from young shoots were cultured to produce plantlets for thin section virus eradication cultures. Plantlets, about 2 cm in size, obtained from these explants were freed of all leaves except the uppermost two and PLBs, 5 mm in diameter, were cut transversely into 0.5-mm-thick sections for culture.

Surface Sterilization. The young axillary shoots should be washed with copious amounts of tap water, stripped of leaves, immersed in 20% Clorox (20 ml Clorox

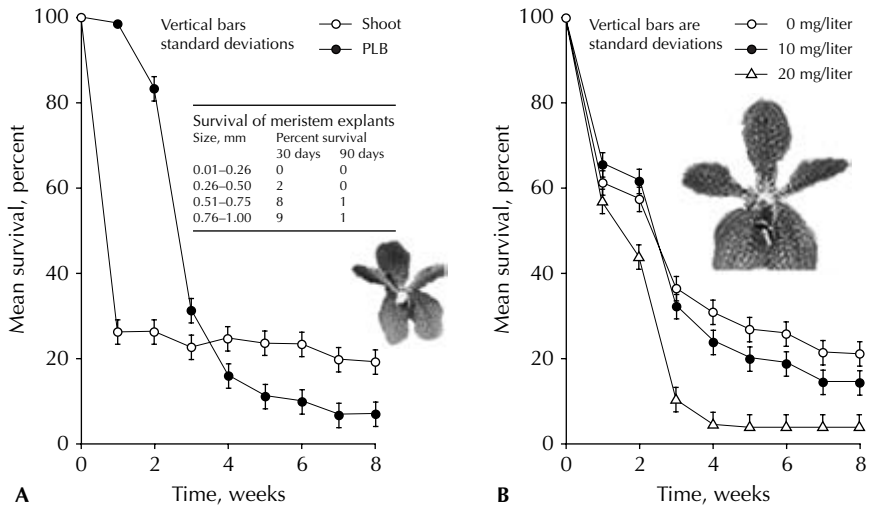

FIG. MKRA-1. **Culture and survival of *Mokara* Chark Kuan 'Pink' explants. A. Survival and culture of thin sections and PLBs. B. Effects of ribavirin on survival of thin section culture. (Modified from Lim et al., 1993*b*.)**

or another household bleach containing 5.25% sodium hypochlorite or 17.5 ml of 6% Clorox diluted to 100 ml with distilled water) with 40 drops Tween 20 (www.sigmaaldrich.com, www.vwr.com, www.fishersci.com, www.duchefa.com) per liter for 20 min and rinsed twice with sterile distilled water.

Culture Vessels. Thin sections for virus eradication should be cultured in Petri dishes, 5 cm diameter. Other explants can be cultured in Petri dishes, Erlenmeyer flasks, test tubes, or other containers.

Culture Conditions. Wong and Lim maintained their cultures at 26 ± 1°C under 14-h photoperiods of 24.5 μE m^{-2} s^{-1} provided by daylight fluorescent tubes. Standard culture room conditions are also suitable.

Culture Media. Explants should be cultured in Vacin and Went (VW) medium (Vacin and Went, 1949) containing 15% coconut water (CW), 0.1 mg NAA l^{-1}, and 0 or 10 mg ribavirin l^{-1} (Table Mkra-6).

Procedure. To free explants of virus, thin sections of both shoots and PLBs should be cultured on medium which contains 10 mg ribavirin l^{-1} (Table Mkra-6). However, virus-free plantlets can also be obtained by culturing thin sections on medium without ribavirin (Table Mkra-7).

Virus Assays. These assays may be beyond the capabilities of most orchid laboratories. Equipment and supplies are available from Agdia Inc. (www.agdia.com) which also performs assays.

TABLE MKRA-6. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for elimination of cymbidium mosaic virus (CyMV) and odontoglossum ringspot virus (ORSV) from *Mokara* Chark Kuan (Lim et al., 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	0.1	100–300 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
9	Coconut water[f]	150.0	No stock	No stock	Measure
	Antiviral agent				
10	Ribavirin (Virazole)	10.0 or none	10 mg in 2.5 ml water/95% ethanol mixture[g]		
	Sugar				
11	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[h]	To 1000 ml			
	Solidifier				
13	Agar[h]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 12) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the auxin fails to dissolve add a few drops of 0.1 N KOH. Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Ribavirin (Virazole), 1-β-D-ribofuranosyl-1H-1,2,4-triazole-3-carboxamide, CAS Number 36791-04S, melting point 165–176°C is an antiviral agent manufactured by ICN Pharmaceuticals, Inc. (3300 Hyland Avenue, Costa Mesa, CA 92626, 714–545-0100, www.icnpharm.com). According to ICN its solubility in water is approximately 0.35 g ml^{-1}. To prepare a sterile ribavirin solution for 1 l of medium dissolve 10 mg ribavirin in 0.5 ml distilled water and bring volume to 2.5 ml with 95% ethanol. Add this solution to the autoclaved, warm and still liquid medium. This medium can be made with or without ribavirin.

[h]Add items 1, 3–7, and 9 to the 500–700 ml of distilled water (item 12) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 12), adjust pH to 5–5.4, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l Erlenmeyer flask and autoclave. Add the auxin (item 8) and the antiviral agent (item 10) to the warm and still liquid medium with sterile pipettes or syringes, mix well, and dispense into preautoclaved culture vessels. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

TABLE MKRA-7. **Table 2 in the original paper showing survival of explants and production of virus-free plantlets (Lim et al., 1993): *Effect of ribavirin treatment in the production of virus-free regenerants from TS cultures of* Mokara *Char Kuan 'Pink'***

Ribavirin treatment		Virus-free plants in ribavirin-free media (%)

	20	50 (3)	0 (0)	100 (12)**	42 (5)

Abbreviations: CyMV, cymbidium mosaic virus; ORSV, odontoglossum ringspot virus; PLBs, protocorm-like bodies; TS, thin section cultures; **: $P = 0.01$, chi-square analysis of 2×2 contingency test between treatment and control (untreated) cultures. Figures in parentheses indicate the actual number of virus-free plants.

Developmental Sequence. Explant survival is relatively low, but virus-free plants can be produced from thin sections on media with and without ribavirin (Fig. Mkra-1; Table Mkra-7).

General Comments. The method developed by Wong and Lim can eliminate CyMV and ORSV from *Mokara* and other orchids. The culture procedures are relatively simple and within reach for most orchid laboratories. However the virus assay is complex and requires advanced equipment and skills. This method can also be used to propagate healthy plants.

Mormodes

An interesting orchid genus, *Mormodes* is cultivated by many growers.

Clonal Propagation of *Mormodes histrio* through the Culture of Pseudobulb Sections

Pseudobulbs of *Mormodes histrio* have many nodes depending on age. Some nodes have visible dormant buds. Hölters and Zimmer (1990*a*) induced these to produce shoots.

Plant Material. Leaves were removed since it was shown that they inhibit shoot growth. The pseudobulbs were cut into slices (no thickness given in the original paper), each having one dormant bud. Best results were obtained with basal segments. The least successful segments were the third and fourth nodes from the base.

Surface Sterilization. The plant material was decontaminated with sodium hypochlorite (NaOCl) solution. Best results were obtained with 25–35 g l^{-1} active chlorine (25 g l^{-1} is equivalent to concentrated household bleach) and an exposure time of 5 min. Although not stated, one or more distilled water rinses following sterilization are advisable.

Culture Vessels. Standard vessels (e.g., square plastic culture containers) can be used.

Culture Condition. No specific culture conditions are given, but reference is made to those in Zimmer (1978): a light intensity of 1000–3000 lx (about 100–300 ft-c), 16-h photoperiods, and 25°C.

Culture Medium. Knudson C medium was used (Table Morm-1). Addition of 0.5 mg BA l^{-1} increased the number of shoot segments per node after 5 weeks of growth (Table Morm-1).

Procedure. Cut pseudobulbs following sterilization and lay the slices flat on the nutrient. Buds form shoots that grow up into the air or down into the medium.

Developmental Sequence. The buds start to swell and form leaflets about 7 days later. After an additional 2 weeks of growth the shoots reach a length of about 20 mm and develop one to three short roots. Shoots develop only on the dormant buds. When more than one shoot develops they are either adventitious or grow from a PLB.

General Comments. This aseptic procedure was employed to obtain sufficient root material to carry on the tissue culture of root explants from *M. histrio*.

TABLE MORM-1. **Knudson C medium (Knudson, 1946) as used for the culture of *Mormodes histrio* pseudobulb explants (Hölters and Zimmer, 1990*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1000	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Cytokinin				
7	Benzylaminopurine (BAP)	0.5	50 mg/100 ml 95% ethanol[d]	1	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[d]Keep refrigerated between uses.

[e]Add items 1–6 to 900 ml of distilled water (item 9), adjust pH to 5.0, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary, adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary. Using a sterilized pipette under sterile conditions, add BAP solution (item 7) to the autoclaved medium while it is warm and still liquid, swirl to mix well, and dispense into sterile containers. Omit agar if preparing liquid medium.

Propagation of *Mormodes histrio* from Root Explants

Mormodes histrio shoots obtained as described in the previous section (Hölters and Zimmer, 1990*a*) were grown in vivo on a grating to promote root development for tissue culture (Hölters and Zimmer, 1990*b*).

Plant Material. Root systems attached to a small amount of shoot were excised below the basal node of the shoot.

Surface Sterilization. No specific decontamination procedure is given, but it can be assumed that the method employed for pseudobulb sections (Hölters and Zimmer, 1990*a*; see above) would be suitable.

Culture Vessels. No reference is made to culture containers in the original paper, but standard culture vessels can be used.

TABLE MORM-2. **Knudson C medium (Knudson, 1946) modified for the culture of *Mormodes histrio* roots (Hölters and Zimmer, 1990*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1000	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
7	Potassium naphthaleneacetate (KNA)	0.2	20 mg 100 ml^{-1} 50% ethanol[d]	1	
	Cytokinin				
8	Benzylaminopurine (BAP)	2.0	200 mg 100 ml^{-1} 95% ethanol[d]	1	
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g of chelating agent (Na_2EDTA) and 2.78 g of ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[d]Keep refrigerated between uses.

[e]Add items 1–7 to 900 ml of distilled water (item 10), adjust pH to 5.0, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary, adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary. Using a sterilized pipette under sterile conditions, add BAP solution (item 8) to the autoclaved medium while it is warm and still liquid, swirl to mix well, and dispense into sterile containers. Omit agar for liquid medium.

Culture Medium. Knudson C medium containing 0.2 mg potassium naphthaleneacetate (KNA) l^{-1} and 2.0 mg BA l^{-1} as employed (Table Morm-2).

Procedure. A specific procedure is not given, but it may be assumed that the explants were deposited on the culture medium following sterilization and rinsing with distilled water.

Developmental Sequence. The roots, attached to a small remnant of the shoot, developed PLBs at their tips. A substantial number of these PLBs gave rise to shoots.

General Comments. Root systems attached to shoots whose leaves were removed formed PLBs occasionally, but the latter did not give rise to shoots. Only root systems that were attached to a small shoot segment produced shoot-bearing PLBs.

Neofinetia

A monotypic epiphytic genus *Neofinetia* is found in China, Japan, Korea, and the Ryukyu Islands. It was first described in 1925 by the Chinese botanist H. H. Hu. The only species in the genus, *Neofinetia falcata*, has "traveled" widely through several orchid genera and was known over the years as (in alphabetical order): *Aerides thunbergii*, *Angraecopsis falcata*, *Angraecum falcatum*, *Finetia falcata*, *Holcoglossum falcatum*, *Nipponorchis falcata*, *Oeceoclades falcata*, and *Orchis falcata* (Bechtel et al., 1992).

Culture and Growth of Embryogenic Callus of *Neofinetia falcata*

The method used for *Darwinara*, *Doritaenopsis*, and *Phalaenopsis* is also suitable for *Neofinetia falcata* (Ichihashi and Hirawa, 1996).

Effects of Complex Additives on Callus Growth of *Neofinetia*

The method used for *Doritaenopsis* and *Phalaenopsis* is also suitable for *Neofinetia falcata* (Ichihashi and Islam, 1999). "Effects of T[aro]E[extract], P[otato]E[extract], and C[oconut]W[ater] on calli of . . . and N[*Neofinetia falcata*] revealed that growth was significantly higher on media supplemented with 50 ml l^{-1} of TE, PE, and CW (Fig. 3)" (Ichihashi and Islam, 1999; Fig. Neof-1).

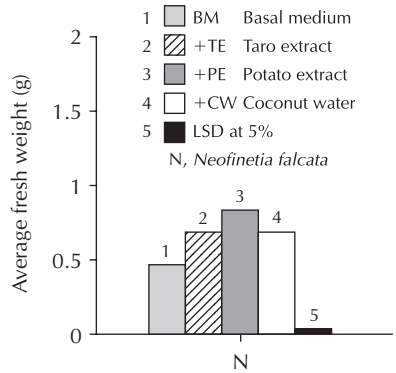

FIG. NEOF-1. **Part of figure 3 in Ichihashi and Islam, 1999; 50 ml l^{-1} of organic extracts were added to the medium. Callus (0.1 g) was transplanted on 10 ml of medium and weighed after 6 weeks.**

Micropropagation of *Neofinetia falcata* through Leaf Segments

Professor S. P. Vij and his associates have directed "efforts . . . to identify an alternate [to shoot meristems] but equally effective explant for . . ." micropropagation. They developed procedures for the culture of leaf segments of a number of orchids including *Neofinetia falcata* (Vij and Pathak, 1990).

Plant Material. Basal explants, 5–10 mm long, from leaves of 16–40-week-old seedlings growing in vitro should be used. Apical segments do not produce PLBs. Explants from leaves of mature plants died in the original experiments.

Surface Sterilization. Explants taken from axenic seedlings growing in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, test tubes, and other containers filled with medium to 20–30% of their capacity.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. Mitra, Prassad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with kinetin and IAA (Table Neof-1) must be used for the culture of leaf segments. No medium is suggested for the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or the Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to media as suggested for Knudson C that does contain this darkening agent (Table Pln-1, footnote *f*).

Procedure. Leaves are taken from plantlets, sectioned, and placed in culture on the initiation medium (Table Neof-1). Plantlets should be cultured on one of the Knudson C or Vacin and Went formulations suggested above, preferably a medium with BH and AC.

Developmental Sequence. PLBs form on the initiation medium (Table Neof-1) and give rise to plantlets (Fig. Neof-2). When transferred to Knudson C or Vacin and Went formulations with BH and AC, the plantlets develop further.

General Comments. Propagation of selected forms is not possible with this method because the explants are taken from seedlings. However it may be possible to adapt the procedure to mature plants. If only kinetin is present in the medium 75% of the explants produce an average of four PLBs (for a total of 300 PLBs per 100 explants). Plantlets produced by these PLBs formed their first leaves after 5 weeks. The first

TABLE NEOF-1. **Mitra, Prassad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Neofinetia falcata* leaf segments (Vij and Pathak, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

	Darkening agent				
19	Activated charcoal[h]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl respectively.

[f]Keep frozen between uses.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved add the charcoal with vigorous stirring to ensure complete distribution through the medium, pour the solution into culture vessels and autoclave. After autoclaving when the medium is cooling swirl the flasks to disperse the charcoal. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976; Vij and Pathak, 1990).

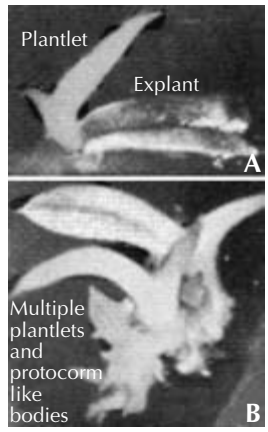

FIG. NEOF-2. **Development of *Neofinetia* plantlets from leaf segments (Vij and Pathak, 1990).**

root appeared following 14 weeks. In the presence of both kinetin and IAA only 25% of the explants produced PLBs. However every explant produced a dozen PLBs (also a total of 300 PLB per 100 explants) and roots appeared after only 10 weeks. That is why the recommendation here is for a medium which contains both hormones. *Neofinetia falcata* is apparently similar enough to *Aerides*, *Angraecopsis*, *Angraecum*, *Finetia*, *Holcoglossum*, *Nipponorchis*, *Oeceoclades*, and *Orchis* to have been assigned to these genera at one time or another. Therefore, this method could perhaps be used for at least some species in these genera.

Neofinetia means new *Finetia* because it is a second genus named in honor of the French botanist M. Achille Finet (1862–1913) who worked on the orchids of China and Japan and added much to the knowledge of angraecoid taxa (Schultes and Pease, 1963). The first genus named for him is *Finetia*.

[b]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite which are very different in nature should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

Neostylis

The methods used for *Ascofinetia* (Intuwong and Sagawa, 1973) can also be used for *Neostylis* (Sagawa and Kunisaki, 1982). A modified Vacin and Went medium containing 15% (v/v) coconut water is used for the initial culture (it is not clear whether the medium should be liquid or solidified with 8–9 g l^{-1} agar). Multiplication (i.e., proliferation) takes place in the same medium without glucose. For differentiation, tissues are cultured in a medium that contains 15% coconut water (v/v), 50 g l^{-1} homogenized green banana, and potato extract (100 g potatoes boiled for 5 min in 200 ml water). Cultures should be maintained under continuous illumination (sources not described) of 2100 lx and 26 ± 3°C.

Neottia

From the English summary (Champagnat 1971; the paper is in French) we learn that:

> . . . at the extremity of a *Neottia nidus-avis* isolated root, kept at 12 or 15°C, a renewal of apical growth is obtained, at will, which results in the formation of a protocorme [sic] quickly crowned by a bud, bearing adventitious roots. Isolation is the principal cause of the evolution.

Nervilia

Unlike most other orchids *Nervilia* has cordate leaves (Figs Nerv-1A, H and Nerv-2A, H). The genus consists of approximately 80 species which can be found in tropical Africa and Asia, northern Australia, Madagascar, the Malay archipelago, and the Pacific Islands (Bechtel et al., 1992).

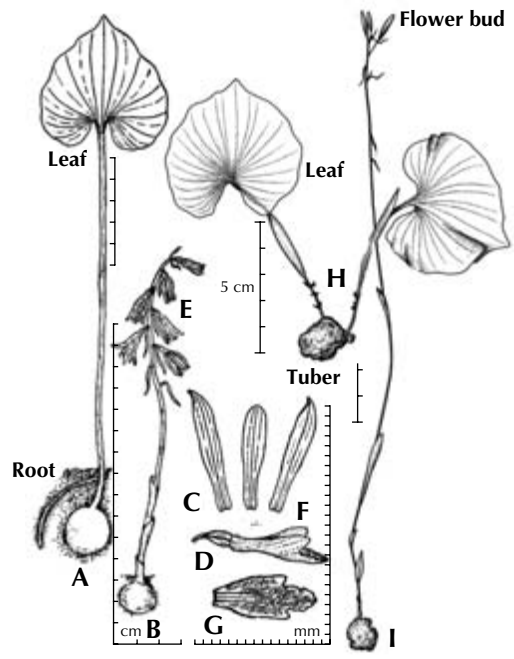

FIG. NERV-1. ***Nervilia aragoana*. A. Local tuber and root. B. Tuber and inflorescence. C. Sepals snd petals. D. Ovary. E. Flower. F. Side view of labellum. G. Flattened labellum. H. Leaves and tuber. (Sources: A–G, Joseph, 1982; H, I, Seidenfaden and Wood, 1992.)**

Nervilia is from the Latin *nervus* (vein). It is descriptive of the veins on the palmate leaves which stand out (Schultes and Pease, 1963; Bechtel et al., 1992).

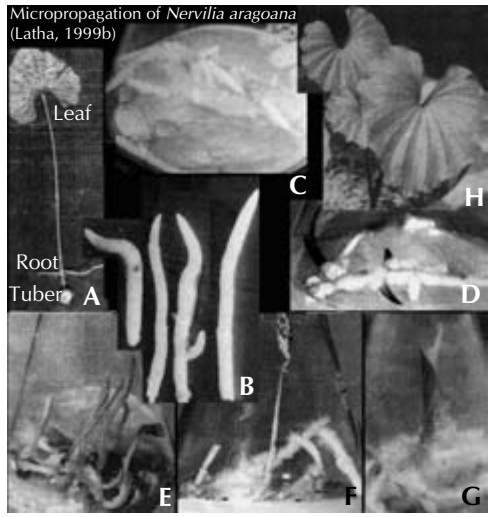

FIG. NERV-2. **Tissue culture of *Nervilia aragoana*. A. Plant with leaf, root, stolon, and tuber. B. Stolon explants. C. New stolons produced in culture. D. Leafy shoot produced in vitro. E. Leafy shoot in vitro. F. Inflorescence in vitro. G. Rooting in vitro. H. Plantlet in community pot. (Latha, 1999*b*.)**

In Vitro Culture of *Nervilia aragoana*

Nervilia aragoana is popularly known in South India as *Orilathamara* which means "single lotus plant" and alludes to its appearance and growth habit (Figs Nerv-1 and Nerv-2A). It is used widely for the preparation of indigenous medicines in India and collected extensively to meet the demand. Therefore it is an endangered species. An in vitro propagation method was developed "to save it from extinction, and to provide a means of obtaining large numbers of plants for the ayurvedic drug industry" (Latha, 1999*b*).

Plant Material. "Tender stolon segments with the growing tips, 2 cm long" (Fig. Nerv-2B) should be cultured after removal of 0.25 cm from the cut ends following sterilization.

Surface Sterilization. Explants should be soaked for 10 min in a 1% (v/v) solution of Teepol (www.sigmaaldrich.com), dipped in 70 ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) for 30 s, immersed in 5% household bleach like Clorox (Sterilig, Combii Chem, New Delhi was used in the original research) for 5 min, placed in 0.1% $HgCl_2$ (www.fishersci.com) for 3 min (this is a toxic substance and must be handled with care), and rinsed three times with sterile distilled water.

Culture Vessels. A photograph in the original paper shows that 250-ml Erlenmeyer flasks were used. Other containers are also suitable.

Culture Conditions. Cultures can be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. Explants should be cultured on woody plant medium (WPM; Lloyd and McCown, 1980) containing 0.5 mg BA l^{-1} and solidified with 0.7% agar (Table Nerv-1) for the production of new stolons. To induce leafy shoots, new stolons should be moved to the same medium solidified only with 0.4% agar (Table Nerv-2). Roots are produced on WPM with 0.5 mg NAA l^{-1} solidified with 0.7% agar (Table Nerv-3). Plantlets can be cultured on WPM or one of the versions of the Knudson C (KC) medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or the Vacin and Went (VW) solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for KC that does contain this darkening agent (Table Pln-1, footnote *f*).

Procedure. The explants should be surface-sterilized and placed on the first medium (Table Nerv-1) after removing 0.25 cm from the cut ends. Leafy shoots, 2 cm long, which form within 6–8 weeks should be moved to the second medium (Table Nerv-2) for rooting. The rooted plantlets can be moved directly to community pots or cultured for a period on BH- and AC-containing versions of WPM, KC, or VW.

Developmental Sequence. Each explant forms 3.1 ± 0.83 new stolons after 4 weeks on WPM plus 0.5 mg BA l^{-1} and 0.7% agar (Table Nerv-1). The new stolons arise from nodes and tips. They can produce additional stolons if subcultured on the same medium (Table Nerv-1). On being subcultured on WPM plus 0.5 mg BA l^{-1} and 0.4% agar (Table Nerv-2), stolons produce leafy shoots and an occasional inflorescence (Fig. Nerv-2F). These shoots form roots in the presence of NAA (Table Nerv-3).

General Comments. This method (Fig. Nerv-2) can be used to produce a large number of plants. However it is necessary to determine whether plants produced through micropropagation contain all compounds necessary for the preparation of ayurvedic drugs. Cytokinins induce flowering in vitro by some orchids and other plants. It is interesting to note that BA has a similar effect on *N. aragoana*.

TABLE NERV-1. **Woody plant (WPM) medium (Lloyd and McCown, 1980) modified for the culture of *Nervilia aragoana* explants for stolon production (Latha, 1999*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400.0	40.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	96.0	9.6 g l^{-1}	10	
3	Calcium nitrate, $Ca(NO_3)$	556.0	55.6 g l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	Potassium sulfate, K_2SO_4	990.0	99.0 g l^{-1}		
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.25	25.0 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(d)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
9	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
11	6-Benzyladenine (BA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. This medium was originally formulated for the culture of a woody plant, mountain laurel, *Kalmia latifolia*.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe lists $MnSO_4 \cdot H_2O$ which seems to be a typographical error because the formulae and concentrations of all other microelements are the same as in the Murashige–Skoog (MS) medium (Murashige and Skoog, 1962).

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media. As a rule it is preferable to add heat labile substances after autoclaving. However in this case the cytokinin and vitamins can be added before sterilization.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe lists $MnSO_4 \cdot H_2O$ which seems to be a typographical error because the formulae and concentrations of all other microelements are the same as in the Murashige–Skoog (MS) medium (Murashige and Skoog, 1962).

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media. As a rule it is preferable to add heat labile substances after autoclaving. However in this case the cytokinin and vitamins can be added before sterilization.

Nigritella

Many of the European terrestrial orchids are not of major horticultural importance (the same is true for some terrestrial species from the Americas and other areas). This is perhaps one reason for the fact that few tissue culture propagation methods have been developed for these species. The danger of extinction and the need to develop rapid propagation methods have led to the establishment of several interesting research projects (Mark Clements at the National Botanic Gardens in Canberra, Australia; Maureen Weatherhead at the University of Hong Kong, and the brothers Hoppe in Hamburg to mention a few). An earlier project (and one of the earliest in this area of orchid research) was that carried out by Dr. Norbert Franz Haas at the Justus Liebig University in Giessen, West Germany (Haas, 1977*a*, 1977*b*).

Plant Material. Tubers collected (with permission) in a nature preserve in the Bolzano-Italy (Bozen-Südtirol) area were used as sources of explants in the original research. Apical and lateral meristems and subtending buds were removed for culture following surface sterilization.

Surface Sterilization. The tubers as removed from the ground are coated with soil and debris that must be washed away before sterilization. Washed tubers are sterilized by immersing them in 0.5% sodium hypochlorite (NaOCl) solution that is equivalent to 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 15 min. Although not mentioned in the original paper it is a good idea to wash the sterilized tubers with sterile distilled water before the meristems are removed. Explants should be sterilized a second time in 0.3% sodium hypochlorite, equivalent to 6% Clorox (6 ml Clorox diluted to 100 ml with sterile distilled water) for 10 min. A distilled water wash following this sterilization is also advisable.

Culture Vessels. Erlenmeyer flasks, 250 ml, containing 80 ml of culture medium were used in the original research. Other culture vessels can also be used.

Culture Conditions. The explants were maintained under 14-h photoperiods of 2000 lx provided by Osram brand cool white fluorescent tubes and 20–22°C.

Culture Media. MS medium, one-third strength of macroelements, other components as given in the original recipe (Table Nla-1), was used in the original research. It is not clear whether hormones were used and if so at what levels. Since this is a north temperate terrestrial orchid it is possible that the media used for *Anacamptis*, *Dactylorchis*, *Dactylorhiza*, and *Orchis* may also be suitable.

Procedure. Shoot apices were excised from new shoots on tubers and placed on the culture medium.

Developmental Sequence. The explants formed tubers at their bases and shoots from their apices. Anthocyanin containing inflorescenses were formed on rare occasions.

TABLE NLA-1. **Murashige–Skoog medium (Murashige and Skoog, 1962) as used for the culture of *Nigritella* (Haas, 1977*a*, 1977*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	550	55 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	147	14.7 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	123.3	12.3 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	633.3	63.3 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	56.7	5.7 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	37.3 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Indoleacetic acid (IAA)	Not clear if any (and if so how much) was added[f]			
	Cytokinin				
11	Kinetin	Not clear if any (and if so how much) was added[f]			
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxins or cytokinin do not dissolve, add a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 16), adjust pH as required, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormones (if any), and vitamins (items 8 and 10–14) to hot solution with sterilized pipettes, mix well, and dispense medium into preautoclaved culture vessels. Omit agar if preparing liquid medium.

General Comments. Dr. Norbert F. Haas-von Schmude left the academic world and now lives in the city of Wettenberg, Germany where he and his wife Gudrun operate one of the finest commercial orchid laboratories anywhere. He no longer devotes time to pure research and his more recent tissue culture procedures remain unpublished.

Oberonia

The method developed for *Acampe praemorsa* was used to isolate 12.4×10^4 protoplasts from leaves of *Oberonia santapui* (Seeni and Abraham, 1986).

Odontioda

A hybrid genus (*Cochlioda* × *Odontoglossum*), *Odontioda* is a cool growing orchid well liked by hobby growers. It also has considerable potential as a pot plant due to its rapid growth, numerous cultivars, attractive inflorescences, and colorful flowers.

Micropropagation of *Odontioda* through Callus Cultures

There are reports that excised shoot tips ("meristems") form a large callus consisting of numerous PLBs. Each PLB can form a plantlet. Procedures used for *Cymbidium*, *Odontoglossum*, and *Odontonia* (Morel, 1960, 1963, 1964*a*, 1965*b*, 1970, 1974) can be used for *Odontioda*.

Micropropagation of *Odontioda*

A protocol for micropropagation of *Odontioda* was developed at the Aichi University of Education in Japan by Professor Syoichi Ichihashi and his associates as part of research on tissue culture of the *Odontoglossum* alliance (Ichihashi et al., 1999; Murase et al., 1999, 2002).

Plant Material. Shoot tips from young shoots or lateral buds are cultured.

Surface Sterilization. Shoots should be washed with tap water before trimming excess tissue and removing their leaves. After that they should be immersed in 1% sodium hypochlorite (19 or 17 ml of 5.25% or 6% household bleach respectively diluted to 100 ml with distilled water) for 20 min with moderate shaking and then washed three times with sterile distilled water. Following their excision the tips should be rinsed with 0.5% sodium hypochlorite (50 ml of the solution above diluted to 100 ml with distilled water) and soaked in sterile distilled water.

Culture Vessels. Test tubes (25 × 120 mm), Erlenmeyer flasks, and other containers are suitable.

Culture Conditions. Cultures should be maintained initially at 25°C under constant illumination of 650 lx provided by Plantlux (Toshiba) fluorescent lamps or standard culture room conditions. When PLBs form they should be cultured at 20–22.5°C. The effects of temperature on PLB growth can be significant, as can be seen in

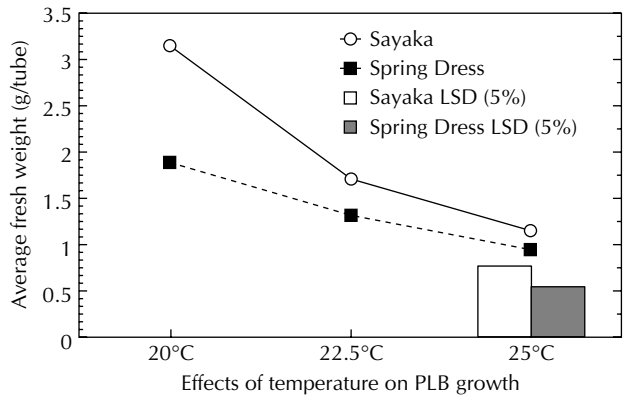

FIG. ODA-1. **Temperature effects on the growth of PLBs of *Odontioda*.**

Fig. Oda-1 which shows the response of *Odontioda* Lovely Morning "Sayaka" and *Odontioda* Shelley "Spring Dress" (Ichihashi et al., 1999).

Culture Media. New *Phalaenospis* (NP) medium (Ichihashi, 1992*a*, 1992*b*) with 20 g sucrose (Table Oda-1) should be used to culture explants and maintain PLBs. NP with banana homogenate (BH; Table Oda-2) is suitable for PLB culture and proliferation and plantlet growth. No medium is suggested for the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C (KC) medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or the Vacin and Went (VW) solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium, it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for KC that does contain this darkening agent (Table Pln-1, footnote *f*).

Procedure. The explants are cultured on the first medium (Table Oda-1) after surface sterilization. PLBs which form on this medium can be cultured on the same medium to increase their number or should be moved to the second solution (Table Oda-2) for proliferation, growth, and plantlet formation. For further growth the plantlets can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without BH or AC. If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). AC should be added to the medium selected for use as suggested for KC that does contain this darkening agent (Table Pln-1, footnote *f*).

TABLE ODA-1. **New *Phalaenopsis* (NP) medium (Ichihashi, 1992) for the culture of *Odontioda* explants and protocorm-like bodies (PLBs; Ichihashi et al., 1999; Murase et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	32.0	3.2 g l^{-1}	10	
2	Ammonium sulfate, $(NH_4)_2SO_4$	303.9	30.39 g l^{-1}	10

	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[e]	To 1000 ml			
	Solidifier				
17	Gelrite[e,f]	3.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6 ± 0.1, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 15). Add Gelrite as described in the footnote below. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[f]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] (item 17) is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum (Phytagel, Gelrite) Gellan gum must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE ODA-2. **New *Phalaenopsis* (NP) medium (Ichihashi, 1992) for the culture of *Odontioda* plantlets (PLBs; Ichihashi et al., 1999; Murase et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	32.0	3.2 g l^{-1}	10	
2	Ammonium sulfate, $(NH_4)_2SO_4$	303.9	30.39 g l^{-1}	10	
3	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$	637.6	63.76 g l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	256.4	25.64 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	424.0	42.4 g l^{-1}	10	
6	Monopotassium phosphate, KH_2PO_4	462.7	46.27 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.0125	1.25 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.0125	1.25 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.415	41.5 mg l^{-1}

10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
14	Banana homogenate[e]	75.0 ml	No stock	No stock	Weigh
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[f]	To 1000 ml			
	Solidifier				
17	Gelrite[f,g]	3.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

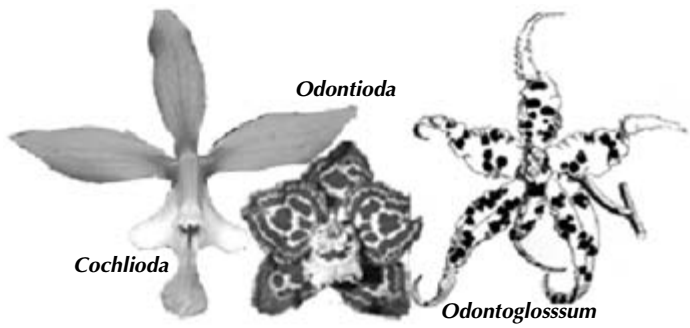
[e]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable; (2) the peel rather than the pulp should be used; (3) unpeeled banana homogenate should be incorporated in media; and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and use what is suggested there. This is the case here.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6 ± 0.1, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Add Gelrite as described in the footnote below. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite (item 17)] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium; it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

Developmental Sequence. PLBs form on the first medium (Table Oda-1). They grow and proliferate on the second medium (Table Oda-2). Plantlets form and grow on the second solution (Table Oda-2) or the other media suggested above.

General Comments. Using *Odontioda* to formulate a medium which could be suitable for the *Odontoglossum* alliance is a good idea because this hybrid genus may have requirements which are similar to those of other genera in the group (cool growing orchids like *Aliceara*, *Belleara*, *Brassia*, *Brassidium*, *Burrageara*, *Cochlioda*, *Colmanara*, *Degarmoara*, *Howeara*, *Maclellanara*, *Milpasia*, *Milpilia*, *Miltassia*, *Miltistonia*, *Miltonia*, *Miltonidium*, *Miltonioda*, *Miltoniopsis*, *Odontioda*, *Odontobrassia*, *Odontocidium*, *Odontoglossum*, *Odontonia*, *Oncidium*, *Rodricidium*, *Rodriglossum*, *Rodriguezia*, *Vuylstekeara*, *Wilsonara*, and others). This procedure is not suitable for *Odontoglossum*. Therefore it should only be used as a starting point in attempts to modify the medium for other members of the alliance.



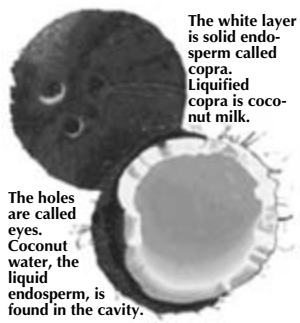
Odontoglossum

Apical and axillary buds of *Odontoglossum* have been cultured (Khaw et al., 1978*a*, 1978*b*). The procedures used for *Cymbidium* (Morel, 1960, 1963, 1964*a*, 1965*b*, 1970, 1974) are suitable.

Odontonia

The procedures employed for shoot-tip culture of *Cymbidium*, *Odontoglossum*, and *Ondontioda* (Morel, 1960, 1963, 1964*a*, 1965*b*, 1970, 1974) are also suitable for *Odontonia*. Protoplasts of *Odontonia* Debutante (*Miltonia warscewiczii* × *Odontoglossum cariniferum*) can be isolated by the procedure used for *Angraecum giryamae*, but the yield after 27 h of incubation is "few" (Price and Earle, 1984; these authors misspell *A. giryamae* as *A. gyrimae*).

Smallest and Largest Seeds: Orchids and Coconuts



Hindu mythology relates that Lord Vishnu brought the coconut tree to earth. According to the Ayurveda coconut water (CW), the clear liquid endosperm of coconuts, has many health promoting qualities for humans. In 1941 Johannes van Overbeek (1908–1988) and his associates showed that CW can also have beneficial effects on the growth of *Datura* embryos (van Overbeek et al., 1941). However, when CW was first added to a medium for *Cattleya* seed germination its effects were deleterious (Mariat, 1951). This did not deter a Hawaiian orchid grower named Herbert C. Shipman from adding "a few teaspoonfuls" to a medium he used to germinate *Dendrobium phalaenopsis*. He reported that the seedlings "began to grow like weeds" (Yamada, 1952). Subsequently CW was shown to have stimulating effects on germination of *Cattleya*, *Paphiopedilum*, and *Vanilla* (Hegarty, 1955), as well as to retard differentiation and enhance proliferation of *Phalaenopsis* seedlings (Ernst, 1967*b*). The first suggestion that CW should be used in orchid tissue culture seems to have been made in 1962 (Murashige, 1962). Copra is not used in orchid seed germination and tissue culture media. Coconut water is often referred to as coconut milk. This is incorrect. Coconut milk is a white milky liquid obtained when copra is ground, diced, squeezed, or simply liquefied in a homogenizer.

Oncidium

The development of attractive *Oncidium* hybrids, the need to propagate some species clonally, and the importance of a number of crosses as cut flowers have led to the development of several tissue culture methods.

Clonal Propagation of *Oncidium* by Means of Shoot-tip Cultures

Not many details are available about this procedure. The context in which it is mentioned (Bertsch, 1966) suggests that methods used for *Cymbidium* (More, 1960, 1963, 1964*a*, 1965*b*, 1970, 1974) can also be employed for *Oncidium*. Other methods used for *Cattleya* (Scully, 1967) and *Cymbidium* (Sagawa et al., 1966) may also be suitable. Modified Vacin and Went medium with 15% (v/v) coconut water cannot support the growth of apical and axillary buds of *Oncidium* (Sagawa and Kunisaki, 1982).

Clonal Propagation of *Oncidium* by Means of Flower-stalk-tip Cultures

Propagation methods involving the culture of flower-stem parts are non-destructive. Therefore several investigators have tried to develop culture methods for flower-stem parts of a number of species. One of these species is *Oncidium papilio* (Fast, 1973*a*).

Plant Material. Flower stalks of *O. papilio* with apical buds that are still dormant are used.

Surface Sterilization. Remove all dry sheaths and rinse sections under running water. Dip in alcohol, pass through a flame, immediately immerse in freshly filtered 5% (w/v) calcium hypochlorite, and soak for 10 min while occasionally shaking.

Culture Vessels. Use 30 × 180 mm test tubes with 10 ml liquid medium, covered with cotton buns or two-hole stoppers with cotton stuffed in their holes or 25–500-ml Erlenmeyer flasks stoppered in the same manner.

Culture Conditions. Maintain cultures under diffuse light at temperature of 20–24°C. When a rotating table is used, set it at 5 rpm.

Culture Media. A modified liquid or solid Knudson C medium (Table Onc-1) is used for callus induction. A modified liquid or solid MS medium (Table Onc-2), or a mixture of this medium and Knudson C in a 1:1 ratio (v/v), is used to increase the callus. The same media in solid form are used for plantlet differentiation. These media enriched with 5–10% (w/v) banana homogenate (medium Onc-2a) or seed-free tomato juice (medium Onc-2b), are used to enhance plantlet growth.

Procedure. Remove the top 2 cm from a flower stalk, take off all dry sheaths, and wash under running water. After surface sterilization (see above), the section must

TABLE ONC-1. **Modified Knudson C medium (Knudson, 1946) for the culture of *Oncidium* (Fast, 1973*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	1000	100 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	500	50 g l^{-1}	10	
3	Potassium chloride, KCl	250	25 g l^{-1}	10	Or weigh
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}	1	One solution
(b)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	1	1 g l^{-1}		
(b)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	1	1 g l^{-1}		
(c)	Manganese sulfate, $MnSO_4 * 4H_2O$	0.01	10 mg l^{-1}		
(d)	Cupric sulfate, $CuSO_4 \cdot 5H_2O$	0.03	30 mg l^{-1}	1	One solution
(e)	Aluminium chloride, $AlCl_3$	0.03	30 mg l^{-1}		
(f)	Nickel chloride, $NiCl_2 \cdot 6H_2O$	0.03	30 mg l^{-1}		
(g)	Potassium iodide, KI	0.01	10 mg l^{-1}		
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	12–15 g	No stock	No stock	

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, they must be kept frozen between uses.

[c]Dissolve the iron salt and chelating agent in the same 1 l of water. Stir and/or heat until both are completely dissolved.

[d]Pour all microelements in the same 1 l of water, and stir and/or heat until they are completely dissolved.

[e]Add items 1–7 to 900 ml distilled water (item 9), adjust pH to 5.0–5.5, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When the agar is completely dissolved, dispense medium into culture vessels and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary, adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower pH if necessary. Omit agar for liquid medium.

be handled with sterile forceps. Under aseptic conditions, cut off the very tip with a sterile scalpel and discard, remove the 2–3-mm section below and place it with the cut surface on the agar nutrient medium when solid medium is utilized.

Developmental Sequence. Depending on the physiological condition of the bud, a callus and subsequently PLBs will form 4–8 weeks after the start of culture. These bodies are separated and subcultured. This is repeated every 4 weeks depending on the vitality of the explant, the composition of the nutrient medium, and the season. Several thousand protocorms can be obtained 6 months after the start of propagation. Shoots and roots will form on a medium that contains tomato or banana extract. After 6 months the new plantlets should be transferred once more onto the same medium in larger flasks (500-ml Erlenmeyer flasks). This allows growth of strong plants, which are planted and treated like normal seedlings.

TABLE ONC-2. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Oncidium* (Fast, 1973*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	1650	165 g l^{-1}	10	Or weigh
2	Potassium nitrate, KNO_3	1900	190 g l^{-1}	10	Or weigh
3	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
5	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
6	Iron citrate, $FeC_6H_5O_7 \cdot 3H_2O$	25	25 g l^{-1}	10	
7	**Microelements**[c]				
(a)	Boric acid, H_3BO_3	1	1 g l^{-1}		
(b)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	7	7 g l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	0.01	10 mg l^{-1}		
(d)	Cupric sulfate, $CuSO_4 \cdot 5H_2O$	0.03	30 mg l^{-1}	1	One solution
(e)	Aluminum chloride, $AlCl_3$	0.03	30 mg l^{-1}		
(f)	Nickel chloride, $NiCl_2 \cdot 6H_2O$	0.03	30 mg l^{-1}		
(g)	Potassium iodide, KI	0.01	10 mg l^{-1}		
	Vitamins[d–f]				
8	Niacin (nicotinic acid)	1.22	100 mg 100 ml^{-1} 95% ethanol	1	
9	Thiamine (vitamin B_1)	0.5	50 mg 100 ml^{-1} 95% ethanol	1	Or combine
10	Pyridoxine·HCl (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol	1	
	Auxin[d,f,g]				
11	Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol	1	
	Cytokinin[d,f,g]				Or combine
12	Kinetin	0.05	5 mg 100 ml^{-1} 95% ethanol	1	
	Complex additive				
13	Peptone[d]	1 g	No stock	No stock	Weigh
14	**Tomato or banana pulp**[h]	50–100 g	No stock	No stock	Weigh
	Sugar[i]				
15	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[i]	To 1000 ml			
	Solidifier				
17	Agar[i]	10–12 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, they must be kept frozen between uses.

[c]Add all microelements to the same 1 l, stir and/or heat until dissolved. Add 1 ml per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[d]Add only to medium Onc-2a.

[e]All vitamins may be combined into the same 100 ml of 95% ethanol; use 1 ml per liter of culture medium. Refrigerate or freeze between uses.

[f]All vitamins and both hormones may be combined into the same 100 ml of 95% ethanol; use 1 ml per liter of culture medium. Refrigerate or freeze between uses.

[g]Both hormones may be combined into the same 100 ml of 95% ethanol; use 1 ml per liter of culture medium. Refrigerate or freeze between uses.

[h]Add banana homogenate to make medium Onc-2a and seed-free tomato juice for solution Onc-b.

[i]Mix items 1–7, 13, and 14 with 800 ml distilled water (item 19). Adjust pH to 5.0–5.5, add sugar (item 15), and bring volume to 1000 ml with more distilled water (item 16). Add agar (item 17), slowly while stirring to the gently boiling solution. When agar is fully dissolved, autoclave the medium under standard conditions. Use agar only if a solid medium is desired. Combine vitamins (items 8–10), auxin (item 11), and cytokinin (item 12), and add after medium has been autoclaved (and before it solidifies if agar had been included), using sterile glassware and under aseptic conditions. Mix well, and distribute medium into sterile culture vessels.

General Comments. *Oncidium papilio* is a very pretty orchid that can be propagated from seed or through tissue culture rather than collected from the forest and thereby brought to near extinction.

Clonal Propagation of *Oncidium* through Flower-stalk Buds

A method for the clonal propagation of *Oncidium* was developed at the Singapore Botanic Gardens as a means of causing minimal damage to existing plants (Lim-Ho and Lee, 1987).

Plant Material. Dormant buds taken from the bases of flower stalks should be cultured (Table Onc-3).

Surface Sterilization. The stems should be washed with an antiseptic soap before the bracts covering the buds are removed. After that it is best to cut the stems so that 3–6 mm are left above the bud and 2 mm remain below it. The difference in length prevents inverted planting of the buds. These stem sections should be immersed in 20% Clorox (20 ml Clorox diluted to 100 ml with distilled water) for 30 min. There is no mention in the original paper of subsequent washing with sterile distilled water, but this is advisable.

Culture Vessels. Test tubes were used in the original research (Lim Ho and Lee, 1987), but other containers can also be employed.

Culture Conditions. Cultures were maintained under 12-h photoperiods of approximately 1000 lx provided by Sylvania Gro Lux lamps and 25°C. Different illumination can also be provided.

Culture Media. Vacin and Went medium (Vacin and Went, 1949) with two auxins and one cytokinin (Table Onc-4) is suitable for plants and/or callus induction. Unmodified Vacin and Went medium (Table Onc-5) should be used for differentiation and protocorm formation.

TABLE ONC-3. **Culture of flower-stalk buds of *Oncidium* (Lim-Ho and Lee, 1987)**

Species or hybrid	Response[a]	Time to leaf formation, months
Oncidium ampliatum	Few plants, some callus	5
[(Oncidium baueri × *Oncidium ampliatum)* × *Oncidium flexuosum]*	Few plants, no callus	3
Oncidium cebolleta	Few plants, some callus	5
Oncidium Dr. Schragen	Few plants, no callus	4
Oncidium Golden Sunset "Sunspot"	Many plantlets and PLBs	1.5
Oncidium Purple Envy	Many plantlets and PLBs	1
Oncidium sphacelatum	Few plants, some callus	6

[a]Buds were cultured on several modifications of the Murashige–Skoog medium, but formed callus, protocormlike bodies (PLBs), and/or plantlets on a modification containing 0.5 ppm 2,4-dichlorophenoxyacetic acid (2,4-D), 2 ppm benzyladenine (BA), and 0.5 ppm naphthaleneacetic acid (NAA; see Table Onc-4). Unmodified Vacin and Went medium should be used for plantlet regeneration.

TABLE ONC-4. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the culture of *Oncidium* flower-stalk buds (Lim-Ho and Lee, 1987)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxins				
10	Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[f,g]	1	
11	2,4-Dichlorophenoxyacetic acid (2,4-D)	0.5	50 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
12	Benzyl adenine (BA)	2	200 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably will have little effect.

[e]Keep frozen between uses.

[f]If auxins or cytokinin do not dissolve, add a few drops of KOH or HCl respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml of distilled water (item 17); set pH as required, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8, 10–15) to hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE ONC-5. **Vacin and Went medium for the germination of orchid seeds (Vacin and Went, 1949) as used for the culture of flower-stalk buds of *Oncidium* (Lim-Ho and Lee, 1987)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml of water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1, 3–7 to the 500 ml of distilled water (item 9) that contains item 2, set pH as required, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar for liquid medium.

Procedure. The stem sections should be inserted into the medium with their long side above the agar. This positions them right side up.

Developmental Sequence. Plants, callus, and/or PLBs form after periods ranging from 1 to 6 months.

General Comments. It is interesting to note that the buds fail to develop on media that contain only 0.5 mg 2,4-D l^{-1}, or 2,4-D and 2 mg BA l^{-1}. Plantlets, callus masses, and PLBs form only on a medium that contains these hormones plus 0.5 mg l^{-1} NAA. It would be interesting to determine the effects of a medium that contains NAA and BA only.

Mericloning of *Oncidium* through the Culture of Apical-shoot Explants

A procedure for the culture of apical shoot explants of *Oncidium* developed by Helen Nair and her associates at the Botany Department, University of Malaya, Kuala Lumpur (Khaw et al., 1978*a*, 1978*b*) utilizes a "model nutrient medium . . ." (Table Onc-6). Excision, sterilization, and culture conditions should be similar to those employed in other procedures for the same genus and for *Cattleya*, *Cymbidium*, *Odontoglossum*, *Miltonia*, and *Dendrobium*.

TABLE ONC-6. **A "model medium" [actually a modified Vacin and Went solution (Vacin and Went, 1949)] for the initiation of protocorm-like bodies from apical or axillary meristems (Khaw et al., 1978*a*, 1978*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $CaH_4(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3	525	52.5 g l^{-1}	10	
6	**Iron**[d]				
(a)	Ferrous sulfate, $Fe_2(SO_4)_3$	27.8	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.3	37.3 g l^{-1}		
7	**Microelements**[e]				
(a)	Aluminum chloride, $AlCl_3$	0.014	14 mg l^{-1}	10	One solution
(b)	Ammonium molybdate, $(NH_4)_6Mo_7O_{24} \cdot 7H_2O$	0.148	148 mg l^{-1}		
(c)	Boric acid, H_3BO_3	9.99	9.99 g l^{-1}		
(d)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.03	30 mg l^{-1}		
(e)	Nickel chloride, $NiCl_2 \cdot 6H_2O$	0.031	31 mg l^{-1}		
(f)	Potassium iodide, KI	0.38	38 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	1	1 g l^{-1}		
(h)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}		
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve and it is not possible to prepare a stock solution. To facilitate the preparation of medium 200 mg of the salt should be placed in 500 ml of water, stirred and/or heated until it dissolves. The other components of the medium should be added after that.

[d]The original recipe of the Vacin and Went medium contains 28 mg l^{-1} ferric citrate $Fe_3(C_6H_4O_6)_3 \cdot 2H_2$.

[e]The original papers (Khaw et al., 1978*a*, 1978*b*) do not list the chemical formulae of all microelements. Those given here are the ones most commonly used in culture media and/or found in catalogs. Add all microelements to the same 1 l of water, mix well and dispense as needed.

[f]Add items 1, 3–8 to 500 ml of distilled water (item 10) which contain the calcium phosphate (item 2); set pH as required; add sugar (item 9), adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to cold solution which is then brought to a boil and stirred. When dissolved, distribute into culture vessels and autoclave. Omit agar when preparing liquid medium.

Clonal Propagation of *Oncidium* through the Culture of Apical Buds

Apical buds of two *Oncidium* species and an equal number of hybrids were cultured on modifications of the Vacin and Went (see Table, Onc-5, Arach-5, and Arach-6) and Knudson C media by procedures similar to those used for *Arachnis*, *Aranda*, *Aranthera*, and *Dendrobium* (Lim-Ho, 1981).

Isolation of *Oncidium* Protoplasts

The method developed for *Acampe praemorsa* was used to isolate 7.3×10^4 protoplasts from leaves of *Oncidium ampliatum* (Seeni and Abraham, 1986).

Plant Production through Somatic Embryos Formation on Leaf Explants

Oncidium hybrids are of major importance to orchid cut flower and pot plant producers as well as to hobby plant growers. Both require the production of plants through mass rapid clonal propagation. Somatic embryogenesis is of basic interest for developmental biologists and tissue culture researchers. Practical and basic aspects are combined in a method for the micropropagation of *Oncidium* (Chen et al., 1999).

Plant Material. In vitro grown 9-month-old plantlets of *Oncidium* Gower Ramsey (Fig. Onc-1G), produced from flower-stalk buds, were sources of explants. The explants were leaf segments, 5 mm long taken, from leaves, 2–4 cm and 5–7 cm long.

Surface Sterilization. There is no need to surface-sterilize explants taken from plantlets which are growing in vitro. However they must be washed with sterile distilled water to remove medium residues if any.

Culture Vessels. Test tubes, 20×150 mm were used in the original research. Erlenmeyer flasks and other containers filled with medium to 25–30% of their capacity are also suitable.

Culture Conditions. Cultures should be kept in the dark at 26 ± 2°C for 20–30 days to bring about the formation of PLBs and somatic embryos (SEs). PLBs and SEs produced in the dark should be maintained at 26 ± 2°C under 16-h photoperiods of 28–36 μmol m^{-2} s^{-1} provided by 40-W daylight fluorescent tubes (FL-30D/29, China Electric Co., Taipei, Taiwan). Standard culture room conditions will probably also be suitable for the PLBs and SEs and for shoot and root production.

Culture Media. For PLB and SE formation explants should be cultured on modified half-strength MS medium (Murashige and Skoog, 1962) containing 1 mg TDZ l^{-1} (Table Onc-7) in the dark. Once formed, PLBs and SEs should be cultured on the same medium (Table Onc-7) under illumination. Shoots which are produced on this medium should be cultured on half-strength MS containing 0.5 mg NAA l^{-1} (Table Onc-8) to induce root production. SEs and PLBs can also be cultured directly on

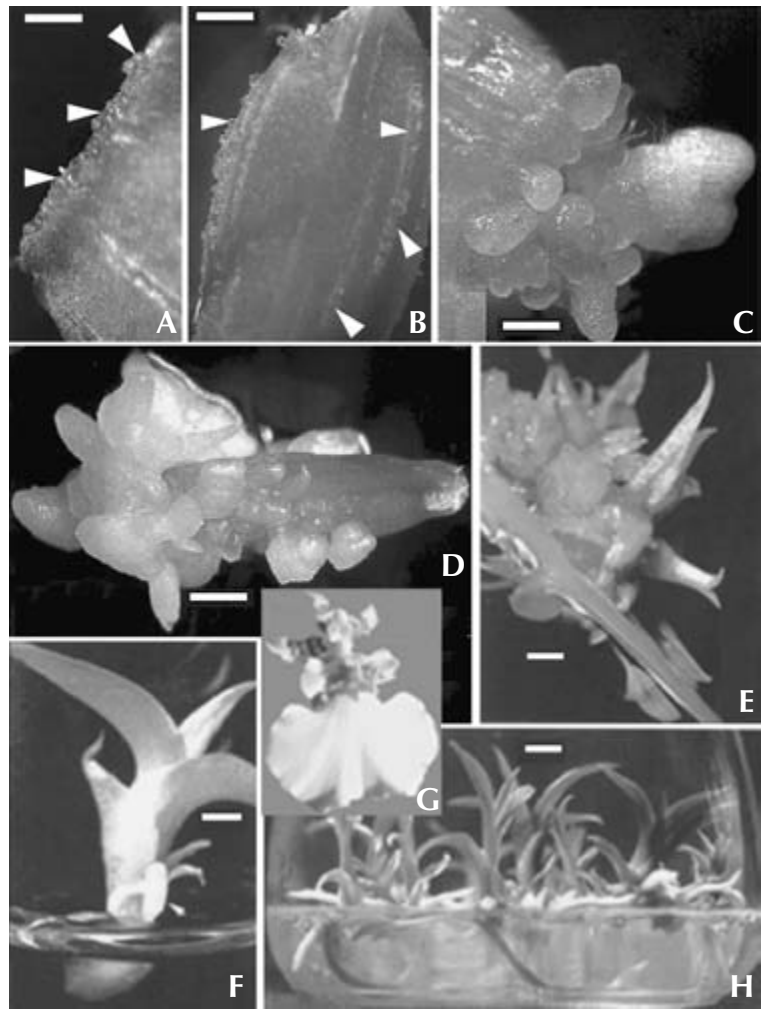


FIG. ONC-1. **Development of *Oncidium* Gower Ramsey leaf explants. A. Embryogenic nodular masses (arrowheads) emerging from wound surfaces (scale bar = 500 µm). B. Embryogenic nodular masses (arrowheads) on epidermal cell layers on explants from 5–7-mm-long leaves (scale bar = 550 µm). C. More than 20 embryos formed on the surface of a section of leaf explants (scale bar = 800 µm). D. Nodular masses on tips of leaf explants (scale bar = 500 µm). E. PLBs with shoots (scale bar = 100 mm). F. Root being produced by a plant (scale bar = 100 mm). G. Flower of *Oncidium* Gower Ramsay. Sepals and petals are yellow. Markings are dark orange to brown. H. Plantlets ready for transfer to pots (scale bar = 100 mm). (Sources: A–F, H, modified from Chen et al., 1999; G, digital photograph by Joseph Arditti.)**

TABLE ONC-7. **Modified half-strength Murashige–Skoog ($^1/_2$MS) medium (Murashige and Skoog, 1962) for the culture of leaf explants, protocorm-like bodies (PLBs) and shoots of *Oncidium* Gower Ramsey (Chen et al., 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(g)	Zinc sulfate, $ZnSO_4{\cdot}7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
9	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
11	Thidiazuron (TDZ)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
12	Peptone	1.0 g	No stock	No stock	Weigh
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Gelrite[g,h]	2.5 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]Available from www.sigmaaldrich.com.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.2, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Add the gellan gum to the cold solution as indicated in footnote *h*, distribute the medium to culture vessels, and autoclave. It is preferable not to autoclave hormones and vitamins, but in this medium they can be autoclaved for 15 min at 121°C.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE ONC-8. **Modified half-strength Murashige–Skoog ($^1/_2$MS) medium (Murashige and Skoog, 1962) for plantlet production from protocorm-like bodies (PLBs) and root induction on shoots of *Oncidium* Gower Ramsey (Chen et al., 1999)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve add a few drops of 0.1 N KOH.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.2, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Add the gellan gum to the cold solution as indicated in footnote *h*, distribute the medium to culture vessels and autoclave. It is preferable not to autoclave hormones and vitamins, but in this medium they can be autoclaved for 15 min at 121°C.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

this medium (Table Onc-8) for plantlet formation. When plantlets produced on this medium become large enough they should be potted in sphagnum moss and grown in a greenhouse.

Procedure. Explants are placed on the first medium and cultured in the dark for 20–30 days until PLBs and SEs are formed (Fig. Onc-1A–E). These should be moved to the same medium under illumination for shoot production. The shoots must be moved to the auxin-containing medium for rooting and plantlet production (Fig. Onc-1F, H).

Developmental Sequence. Structures described as "nodular masses" form on wound surfaces and leaf tips during the first 20 days (Fig. Onc-1A, B) of culture. SEs are formed during the subsequent 6–10 days. These give rise to PLBs (Fig. Onc-1C, D) and shoots (Fig. Onc-1E). Roots (Fig. Onc-1F) and individual plantlets (Fig. Onc-1H) form when shoots are transferred to the NAA-containing medium (Fig. Onc-2; Table Onc-8).

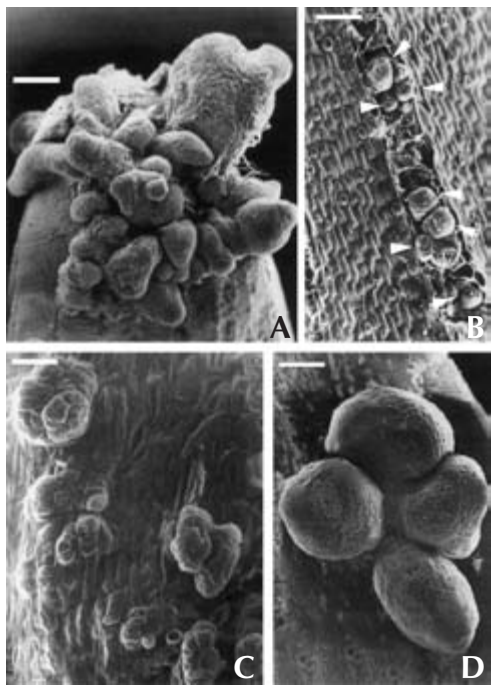

FIG. ONC-2. **Scanning electron photographs of somatic embryos (SEs) and protocorm-like bodies (PLBs) of *Oncidium* Gower Ramsey. A. Cluster of SEs at the tips of a leaf explant (scale bar = 500 μm). B. Small globular SEs (arrowheads) which formed from mesophyll cell located under the leaf surface (scale bar = 110 μm). C. Small PLBs which formed from SEs on the surface of a leaf explant (scale bar = 75 μm). D. A cluster of four PLBs which formed from SEs (scale bar = 300 μm). (Modified from Chen et al., 1999.)**

General Comments. This method is innovative and very interesting because it involves the production of SEs, which give rise to PLBs and plantlets (Fig. Onc-2). It is also very efficient because several explants can be taken from one plantlet in vitro and every explant produces many SEs and PLBs. Other favorable aspects of this procedure are the use of low hormone levels and elimination of excessive proliferation, both of which reduce the likelihood of mutations. Follow up research showed that the auxins IAA, IBA, 2,4-D, and NAA inhibited somatic embryogenesis whereas the cytokinins BA, 6-furfurylaminopurine (kinetin), 6-[4-hydroxy-3-methylbut-2-enylaminopurine (zeatin), N^6-[2-isopentenyl]-adenine (2iP), and TDZ enhanced it. TDZ at 1 mg l^{-1} was the most effective cytokinin (Chen and Chang, 2001).

Effects of Ancymidol and Paclobutrazol on Somatic Embryogenesis in Leaf Explants of *Oncidium*

Attempts to increase the production of somatic embryos by leaf explants of *Oncidium* Gower Ramsey showed that ancymidol (ANC) and paclobutrazol (PAC) can bring about higher yield (Chen and Chang, 2003). Except as indicated below the protocol is the same as in the preceding method.

Plant Material. Tips, approximately 1 cm long, were taken from the same explant sources as in the preceding procedure.

Surface Sterilization. There is no need to surface-sterilize explants taken from plantlets which are growing in vitro. However they must be washed with sterile distilled water to remove medium residues if any.

Culture Vessels. Test tubes, 20×150 mm were used in the original research. Erlenmeyer flasks and other containers filled with medium to 25–30% of their capacity are also suitable.

Culture Conditions. Cultures should be kept in the dark at 26 ± 2°C for 20–30 days to bring about the formation of PLBs and somatic embryos (SEs). PLBs and SEs produced in the dark should be maintained at 26 ± 2°C under 16-h photoperiods of 28–36 μmol m^{-2} s^{-1} provided by 40-W daylight fluorescent tubes (FL-30D/29, China Electric Co., Taipei, Taiwan). Standard culture room conditions will probably also be suitable for the PLBs and SEs and for shoot and root production.

Culture media. Two different initial media can be used:

1 Thidiazuron (TDZ) in Table Onc-7 is replaced with 2.5 mg ANC l^{-1} which must be added to the medium after autoclaving. Dissolve 2.5 mg ANC in 2 ml distilled water, bring up to 5 ml with 95% ethanol, shake vigorously and add to the autoclaved medium, mix well and distribute to preautoclaved culture vessels.
2 PAC, 10 mg l^{-1} is used to replace TDZ in Table Onc-7 and added as ANC above.

TABLE ONC-9. **Effects of ancymidol and paclobutrazol on somatic embryo formation on leaf explants of *Oncidium* Gower Ramsey (Chen and Chang, 2003)**

	Percent embryogenesis				
Substance	Leaf tip	Adaxial side	Abaxial side	Cut end	Embryos dish^{-1}
Ancymidol, 2.5 mg l^{-1}	87.5	57.5	0	27.5	154.8
Paclobutrazol, 10 mg l^{-1}	80.0	52.5	0	62.5	193.2

A large number of embryos were obtained with these substances in the original research (Table Onc-9). Both ANC and PAC are available from www.sigmaaldrich.com. PLBs and shoots formed from these embryos should be cultured on the same medium (Table Onc-8) as in the preceding method.

Procedure. The procedure is the same as that in the preceding method. Explants are cultured on the first medium (Table Onc-7 modified as in point 1 or 2 above). Somatic embryos, PLBs, and shoots obtained on the first medium are treated as in the preceding method and cultured on the second medium (Table Onc-8).

Developmental Sequence. As in the preceding method.

General Comments. Caution is necessary because it is not known whether ANC and PAC can induce undesirable mutations.

Somatic Embryogenesis in Callus Cultures of *Oncidium*

Several micropropagation methods were developed for *Oncidium* hybrids using a variety of explants. Experiments at the Institute of Botany, Academia Sinica, Taipei, Taiwan led to the establishment of totipotent calli which can be proliferated and used to produce somatic embryos (SEs) and plants (Chen and Chang, 2000*a*).

Plant Material. Stem internodes, 5 mm long; leaves, 2–4 cm and 5–7 cm long; and root tips, 1 cm long, were taken from in vitro growing plants derived from flower-stalk buds and were cultured to produce callus.

Surface Sterilization. Explants taken from plants growing in vitro do not require surface sterilization. However, they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Culture tubes, 20 × 150 mm were used in the original research. Other containers filled with medium to 25–30% of their volume can also be used.

Culture Conditions. To induce callus formation cultures should be kept in the dark at 26 ± 1°C. Cultures for somatic embryogenesis (SEG) were maintained at 26 ± 1°C under 16-h photoperiods of 28–36 μmol m^{-2} s^{-1} provided by daylight fluorescent tubes (FL-30D/29, 40 watt, China Electric Co., Taipei, Taiwan). Standard culture room conditions are also suitable for SEs.

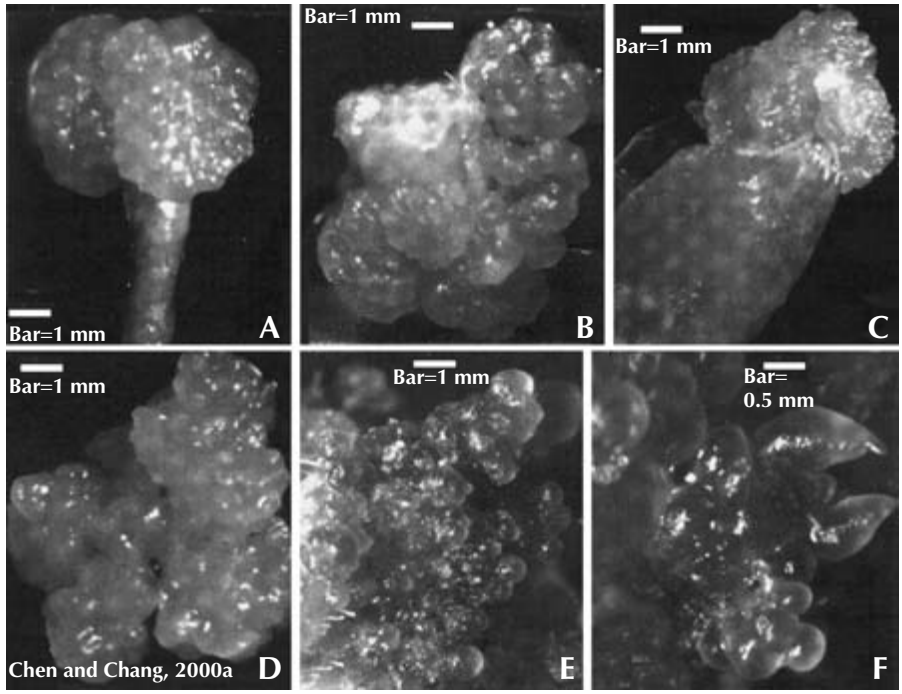

FIG. ONC-3. **Callus induction and somatic embryogenesis in *Oncidium* Gower Ramsey. A. Callus production by tip of root explant. B. Cut surfaces of stem explant producing callus. C. Callus arising from cut surface of leaf explant. D. Compact yellow callus after five subcultures. E. Callus turns green and produces somatic embryos in the light. F. Somatic embryos enlarge, elongate, and produce protocorm-like bodies. (Chen and Chang, 2000*a*.)**

Culture Media. Several media must be used depending on explant and intended results. Stem and root explants produce callus (Fig. Onc-3A, B, D, E) when placed on modified half-strength MS medium (Murashige and Skoog, 1962) supplemented with 3 mg each of 2,4-D and TDZ per liter (Table Onc-10). The callus should be subcultured on the same medium for proliferation. Leaf explants produce callus (Fig. Onc-3C) on half-strength MS containing 10 mg 2,4-D l^{-1} and 3 mg TDZ l^{-1} (Table Onc-11). The same medium (Table Onc-11) should be used to proliferate the leaf callus. Root and leaf callus forms SEs (Fig. Onc-3A, C–F) on half-strength MS with 0.1 mg NAA l^{-1} and 3 mg TDZ l^{-1} (Table Onc-12). SEs form on stem-derived callus on half-strength MS without hormones (Table Onc-13). Each callus produces PLBs and plantlets (Fig. Onc-4A–E, G) on the SE-inducing medium (Table Onc-12 for root and leaf callus and Table Onc-13 for leaf callus). Plantlets can be grown to deflasking in these media or on solutions using to grow plantlets of other species and hybrids (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Den-2, Den-12, Den-21, and Onc-5). Plantlets should be taken out of the culture vessels and potted in sphagnum moss.

TABLE ONC-10. **Modified half-strength Murashige–Skoog (½MS) medium (Murashige and Skoog, 1962) for the culture of stem and root explants of *Oncidium* Gower Ramsey (Chen and Chang, 2000*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses. If the auxin or cytokinin does dissolve add a few drops of 1 N KOH and HCl respectively.

[f]Available from www.sigmaaldrich.com.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Add the gellan gum to the cold solution as indicated in footnote *h*, distribute the medium to culture vessels and autoclave. It is preferable not to autoclave hormones and vitamins, but in this medium they can be autoclaved for 15 min at 121°C.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE ONC-11. **Modified half-strength Murashige–Skoog (½MS) medium (Murashige and Skoog, 1962) for the culture of leaf explants of *Oncidium* Gower Ramsey (Chen and Chang, 2000*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	Monosodium phosphate, NaH_2PO_4	170.0	17.0 g l^{-1}	10

14	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
16	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
17	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses. If the auxin or cytokinin does dissolve add a few drops of 1 N KOH and HCl respectively.

[f]Available from www.sigmaaldrich.com.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Add the gellan gum to the cold solution as indicated in footnote *h*, distribute the medium to culture vessels and autoclave. It is preferable not to autoclave hormones and vitamins, but in this medium they can be autoclaved for 15 min at 121°C.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

FIG. ONC-4. **Somatic embryogenesis and plantlet formation in *Oncidium* Gower Ramsey. A. Cluster of somatic embryos (SEs) and PLBs with shoot-tip-like protrusions (top) and rhizoids (bottom). B. Two young SE derived PLBs with sheath leaves. C. Several SE derived PLBs with expanding leaves. D. SE derived PLBs in the process of producing shoots. E. Rooted plantlet. F. SE derived PLBs. G. Potted plantlets with pseudobulbs. H. Young SE derived PLBs with leaf initials. I. Two SEs starting to develop on the outer layer of a callus mass. J. Two SEs with cells which are smaller than those of the callus from which they originated. (Chen and Chang, 2000*a*.)**

Procedure. Explants should be paced on callus-inducing media (Table Onc-10 for stem and root explants and Table Onc-11 for leaf explants) and cultured in the dark for induction and proliferation. Once there is enough callus sections should be moved to SE-inducing medium (Table Onc-12 for root and leaf callus and Table Onc-13 for leaf callus) in the light. There the yellowish callus will turn green and produce PLBs, SEs, and plantlets (Figs Onc-2 and Onc-3). Plantlets should be moved to fresh medium of the same type or one of the other solutions listed above.

Developmental Sequence. Explants give rise to callus on the first media (Table Onc-10 for stem and root explants and Table Onc-11 for leaf explants) in the dark. This callus is yellow-white, compact, and embryogenic. The highest percentage of

callus production (25% of explants) is by root explants. Root callus is also the best growing and has the highest proliferation rate. Stem and leaf explants have a lower percentage of callus production (5–10%) and do not proliferate as well. Almost all of the SEs produced plantlets which grew well with nearly 100% survival when potted in sphagnum moss and grown in a greenhouse.

General Comments. This is an efficient and uncomplicated procedure which should prove to be very useful in commercial laboratories. However, the high levels of 2,4-D in two media (Tables Onc-10 and Onc-11) are a reason for concern because they can cause undesirable mutations.

Effects of Culture Conditions and Explant Characteristics on Somatic Embryogenesis of *Oncidium* Gower Ramsay

A considerable amount of research was carried out at the Institute of Botany, Academia Sinica in Taiwan on micropropagation, tissue culture, and somatic embryogenesis of *Oncidium* Gower Ramsay (Chen and Chang, 2002). This research included studies on the effects of culture conditions, some medium components, and explant characteristics (Chen and Chang, 2002). The findings are with leaf sections but they may apply to other explants cultured by these investigators (Chen and Chang, 2000*a*, 2000*b*, 2001, 2002, 2003; Chen et al., 1999) as shown in the tables and parts of the abstract (taken from Chen and Chang, 2002).

Plant material. Explants were taken from 2-month-old plantlets grown in vitro.

Surface Sterilization. Explants taken from plantlets growing in vitro do not require surface sterilization. However, they should be washed with sterile distilled water to remove medium residues.

Culture Vessels. Culture tubes, 20×150 mm, were used in the original research. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at $26 \pm 1°C$ in the dark or under 16-h photoperiods of 28–36 $\mu mol\ m^{-2}\ s^{-1}$ produced by 40-W daylight fluorescent tubes FL-30D/29 manufactured by the China Electric Co. (Taipei, Taiwan). The following quotes are taken from the abstract in Chen and Chang (2002):

> Embryo formation was significantly affected by explant position. Leaf tip segments [table 1 in box] had a significantly higher embryogenic response than other segments of leaves. Adaxial-side-up orientation significantly promoted embryogenesis in comparison with abaxial-side-up orientation [table 2 in box]. . . . There was no significant effect of sucrose in a range of concentrations (10–60 $g\ l^{-1}$) [table 3 in box]. [*Comment*: The most suitable concentrations are 10 or 20 g sucrose l^{-1}.]
>
> Modified $^1/_2$MS medium (containing 85 $mg\ l^{-1}$ KH_2PO_4) supplemented with 170 $mg\ l^{-1}$ NH_2PO_4 significantly promoted direct somatic embryogenesis [table 4 in box].

Culture Medium. The results of this research suggest an optimal medium for leaf explants (Table Onc-14).

Tables of relevance to quotes from the abstract in Chen and Chang (2002)

TABLE 1. **Effect of explant position on the donor leaf on direct somatic embryogenesis from leaf explants of *Oncidium* "Gower Ramsey"**[a]

Explant position	% embryogenesis	Embryos explant^{-1}
S1 (leaf tip segment)	65 a	11.2
S2	5 b	5.0
S3	0 b	0
S4	10 b	10.8
S5	10 b	9.8
S6 (leaf base segment)	5 b	11.0

[a]Six 5-mm-long leaf segments from tip (segment 1. S1) to base (S6) were excised from 3-cm-long leaves of *in vitro* plantlets. Explants were placed adaxial side up on the surface of medium. Data were scored after 40 days in culture. Means of 20 replicates (explants) with the same letters are not significantly different at $p < 0.05$ (Duncan, 1955).

TABLE 2. **Effect of explant orientation on direct somatic embryogenesis on leaf explants of *Oncidium* "Gower Ramsey"**[a]

	% embryogenesis				
Orientation	T	Ad	Ab	C	Embryos. explant^{-1}
Ad	75 a	40 a	0 a	15 a	10.7
Ab	15 b	15 b	0 a	10 a	8.0

[a]1-cm-long *in vitro* leaves were used as explants and placed with either adaxial (Ad) or abaxial (Ab) side up. The percentage of embryo-produced explants and average embryos per embryo-producing explants were scored on various regions of leaf explants, including leaf tip (T), adaxial side (Ad), abaxial side (Ab) and cut end (C). Data were scored after 40 days in culture. Means of 20 replicates (explants) with the same letters are not significantly different at $p < 0.05$ (Duncan, 1955).

TABLE 3. **Effect of sucrose on direct somatic embryogenesis on leaf explants of *Oncidium* "Gower Ramsey"**[a]

	% embryogenesis				
Sucrose (g l^{-1})	T	Ad	Ab	C	Embryos. explant^{-1}
0	0 b	0 b	0 a	0 a	0
10	75 a	35 a	0 a	15 a	10.9
20	75 a	40 a	0 a	15 a	10.7
30	65 a	35 a	0 a	20 a	9.4
60	70 a	35 a	0 a	10 a	6.2

[a]1-cm-long *in vitro* leaves were used as explants and placed with either adaxial (Ad) or abaxial (Ab) side up. The percentage of embryo-produced explants and average embryos per embryo-producing explants were scored on various regions of leaf explants, including leaf tip (T), adaxial side (Ad), abaxial side (Ab) and cut end (C). Data were scored after 40 days in culture. Means of 20 replicates (explants) with the same letters are not significantly different at $p < 0.05$ (Duncan, 1955).

TABLE 4. **Effect of NaH_2PO_4 on direct somatic embryogenesis on leaf explants of *Oncidium* "Gower Ramsey"**[a]

	% embryogenesis				
NaH_2PO_4 (mg l^{-1})	T	Ad	Ab	C	Embryos explant^{-1}
0	45 b	25 a	0 a	5 a	9.3
17	50 ab	30 a	0 a	10 a	10.0
42.5	45 b	30 a	0 a	10 a	9.4
85	75 a	35 a	0 a	10 a	10.3
170	75 a	40 a	0 a	15 a	10.7

[a]1-cm-long *in vitro* leaves were used as explants and placed with either adaxial (Ad) or abaxial (Ab) side up. The percentage of embryo-produced explants and average embryos per embryo-producing explants were scored on various regions of leaf explants, including leaf tip (T), adaxial side (Ad), abaxial side (Ab) and cut end (C). Data were scored after 40 days in culture. Means of 20 replicates (explants) with the same letters are not significantly different at $p < 0.05$ (Duncan, 1955).

TABLE 5. **Effects of casein hydrolysate (C. H.), peptone and glutamine on direct somatic embryogenesis on leaf explants of *Oncidium* "Gower Ramsey"**[a]

Medium composition		% embryogenesis				Embryos explant^{-1}
		T	Ad	Ab	C	
Control		50 bc	35 a	0 a	5 a	9.8
C. H.	0.1 g l^{-1}	50 bc	35 a	0 a	15 a	9.8

[a]1-cm-long *in vitro* leaves were used as explants and placed with either adaxial (Ad) or abaxial (Ab) side up. The percentage of embryo-produced explants and average embryos per embryo-producing explants were scored on various regions of leaf explants, including leaf tip (T), adaxial side (Ad), abaxial side (Ab) and cut end (C). Data were scored after 40 days in culture. Means of 20 replicates (explants) with the same letters are not significantly different at $p < 0.05$ (Duncan, 1955).

TABLE ONC-14. **Modified half-strength Murashige–Skoog (½MS) medium (Murashige and Skoog, 1962) optimized for the induction of somatic embryos on leaf section explants of *Oncidium* Gower Ramsey (Chen and Chang, 2000*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	Monosodium phosphate, NaH_2PO_4	170.0	17.0 g l^{-1}	10

	Solidifier				
18	Gelrite[g,h]	2.2–2.5 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses. If the cytokinin does dissolve add a few drops of 1 N HCl.

[f]Available from www.sigmaaldrich.com.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.2, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Add the Gelrite (item 18) to the cold solution as indicated in footnote *h*, distribute the medium to culture vessels and autoclave. It is preferable not to autoclave hormones and vitamins, but in this medium they can be autoclaved for 15 min at 121°C.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

> The best response on direct embryo formation was obtained on the modified 1/2MS medium supplemented with 10–20 g l^{-1} sucrose, 170 mg l^{-1} NaH_2PO_4 and 0.5 g l^{-1} peptone. . . . Peptone at 0.5 mg l^{-1} gave significantly higher embryogenic response (80%) on leaf tips than [the] control treatment (50%) [table 5 in box]. [*Comment*: The effects of 1 g casein hydrolysate (CH) l^{-1} are nearly the same as those of 0.5 g peptone l^{-1}.]

Procedure. Explants should be placed on the optimal medium (Table Onc-14) to bring about production of somatic embryos (SEs). Once there are enough SEs they should be cultured as in the other procedures by these authors in this section.

Developmental Sequence. SEs form on the explants as described in previous procedures for *Oncidium* by the same authors(Chen and Chang, 2000*a*, 2000*b*, 2001, 2002, 2003; Chen et al., 1999).

General Comments. The optimal medium (Table Onc-14) was developed with/for leaf sections but may be suitable for other explants and should be tested not only with *Oncidium* but also related orchids. Most tissue culture and micropropagation media are developed empirically. The authors should be commended for the systematic studies of explant sources and positioning as well as the nature and concentrations of some components (their tables 1–5, as shown in the box).

Plantlet Production from Flower-stalk Explants of *Oncidium* Sweet Sugar via Embryo and Bud Formation

Culture of leaf explants taken from plantlets in vitro is an efficient means of clonal propagation for *Oncidium*, but removal of leaves from small plantlets can damage them. The culture of shoot tips may endanger an entire plant. Explants from flower stalks do not have such drawbacks and can be used for mass rapid clonal propagation (Chen and Chang, 2000*b*).

Plant Material. Explants, 5 mm in length (Fig. Onc-5), are taken from internodes of flower stalks (approximately 15–20 cm long) produced by 3–4-year-old potted plants of *Oncidium* Sweet Sugar (Figs Onc-6C and Onc-7H) when the flower buds are fully formed but before the appearance of flower color.

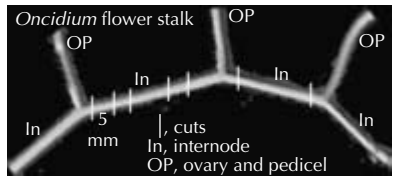

FIG. ONC-5. **Part of an *Oncidium* flower stalk showing internodes, remnants of pedicels and ovaries, and location of cuts (not to scale). (Photograph by J. Arditti.)**

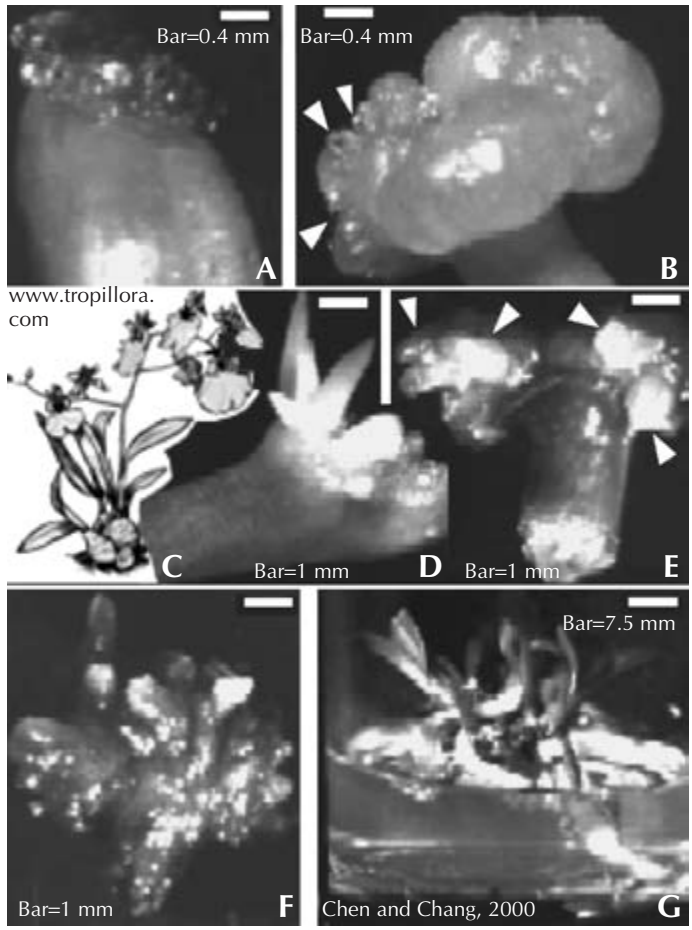

FIG. ONC-6. **Formation of somatic embryos (SEs), vegetative buds (VBs), leaves, and plantlets from flower-stalk explants of *Oncidium* Sweet Sugar. A. SEs on the wound surface of a flower-stalk explant. B. SEs (wedges) formed via nodular masses in a cut surface of a flower-stalk explant. C. *Oncidium* Sweet Sugar. D. VBs on the cut surface of a flower-stalk explant. E. VB (wedges) on the wound surfaces of a flower-stalk explant formed via nodular masses. F. SEs still on the explant forming abnormal nodular masses. G. Leaves and roots produced from the flower-stalk explant. (Sources: A, B, D–G, Chen and Chang, 2000*b*; C, www.tropillora.com.)**

Surface Sterilization. The explants should be washed with running water and a mild detergent, rinsed with water, immersed in 0.25% (w/v) mercuric chloride (www.fishersci.com, www.vwr.com, www.thomassci.com, www.sigmaaldrich.com) for 5 min (this a toxic substance which must be handled with care) and rinsed three times with sterile distilled water.

Culture Vessels. Test tubes, 20×120 mm and other culture vessels filled with medium to 20–30% of their volume are suitable.

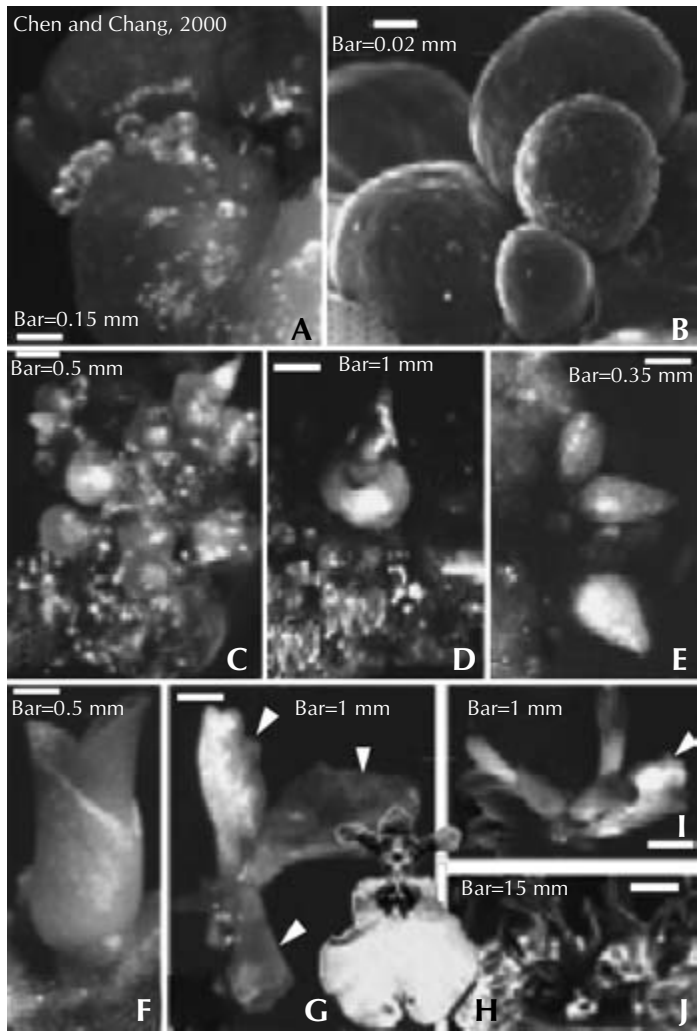

FIG. ONC-7. **Production of plantlets (P), PLBs, vegetative buds (VBs), callus, leaves, abnormal tissues, and roots by explants of *Oncidium* Sweet Sugar in vitro. A. Somatic embryos (SEs) on callus. B. Scanning electron micrograph of SEs on callus. C. Enlarged green SEs cultured under illumination. D. SEs derived from PLBs with two sheaths. E. VB on C. F. VBs with leaves. G. A yellow abnormal tissue with three petal-like structures (wedges). H. *Oncidium* Sweet Sugar flower. I. Petal-like structure (wedge) adjacent to two VBs on callus. J. Rooted plantlets with pseudobulbs ready for planting in sphagnum. (Sources: A–G, I, J, Chen and Chang, 2000*b*; H, photograph by Joseph Arditti.)**

Culture Conditions. Explants should be cultured at 26 ± 1°C in the dark for 20–30 days to induce the formation of somatic embryos (SEs) and vegetative buds (VBs). SEs and VBs should be cultured at 26 ± 1°C under 16-h photoperiods of 26–36 μmol m^{-2} s^{-1} [40-W daylight fluorescent tubes FL-30D/29 produced by China Electric Co. (Taipei, Taiwan) were used in the original research]. Standard culture room conditions should also prove to be suitable.

Culture Media. To bring about the formation of SEs and/or VBs (Figs Onc-6A, B, D, E and Onc-7E) explants should be cultured on a modified half-strength MS medium (Murashige and Skoog, 1962) containing 1 mg TDZ l^{-1} (Table Onc-15). SBs form on wound surfaces, produce leaves, and eventually form plantlets (Fig. Onc-6G) when cultured on half-strength MS containing 0.5 mg NAA l^{-1} (Table Onc-16). Tissues from the first medium (Table Onc-15) produce SEs (Fig. Onc-7A, B), callus, PLBs (Fig. Onc-7C), and eventually leaves (Fig. Onc-7D) when subcultured on a solution containing 1 mg TDZ l^{-1} and 1 mg NAA l^{-1} (Table Onc-17). PLBs form plantlets on a hormone free half-strength MS (Table Onc-18). VBs with two leaves produce roots on half-strength MS, the second medium (Table Onc-16). Plantlets (Fig. Onc-7J) taken out of flasks should be potted in sphagnum moss.

Developmental Sequence. Most developmental steps are outlined in the preceding section. If not cultured on an appropriate medium for 1.5–2 months the SEs and VBs form green abnormal structures (Fig. Onc-6F) which turn brown eventually and die. VBs produce leaves on the first medium (Fig. Onc-7F; Table Onc-15). Yellowish abnormal structures (Fig. Onc-7G, I) form if TDZ is present in the medium at 3 mg l^{-1}. SE-, VB-, and PLB-derived plants grow well on appropriate media and produce pseudobulb-bearing plantlets (Fig. Onc-7J) after 2–3 months of culture. When potted in sphagnum and grown in a greenhouse these plantlets survive very well (100%).

To Autoclave or Not to Autoclave

A frequently asked question is whether vitamins, hormones, and other organic additives can be autoclaved. A little known, but excellent publication by van Bragt et al. (1971), "Effects of sterilization on components in nutrient media," contains many answers. The information below is from it.

Vitamins: "addition of vitamins to media before [autoclaving] is not advisable."
Abscisic acid: Both the *cis* and *trans* isomers are not affected by autoclaving.
Auxins: "Sterilization by autoclaving at 110°–120° [for] 15–60 min does not destroy" NAA and 2,4-D. "IAA is [destroyed] under . . . low pH. . . ." Therefore it may not be necessary to cold-sterilize NAA and 2,4-D, but IAA should not be autoclaved.
Cytokinins: BA, isopentenyl adenosine, kinetin, and zeatin can be autoclaved.
Gibberellins: "Autoclaving reduced . . . activitiy of GA_3 by more than 90%." In other words, gibberellins should not be autoclaved.
Precautions: Despite this advice it is wise to test autoclaved media which contain these substances before using them for explants from rare and/or expensive orchids.

These substances should be added to research solutions after autoclaving during initial experiments and only subsequently before sterilization.

As a precaution the recommendations for many media in this book are to add hormones, vitamins, and other organic substances after autoclaving. They can be added following sterilization only after preliminary tests.

TABLE ONC-15. **Modified half-strength Murashige–Skoog (½MS) medium (Murashige and Skoog, 1962) optimized for the culture of flower-stalk explants of *Oncidium* Sweet Sugar (Chen and Chang, 2000*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Auxin				
11	Naphthaleneacetic acid (NAA)	1.0	100 mg 400 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
12	Thidiazuron (TDZ)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
13	Peptone	1.0 g	No stock	No stock	Weigh
	Vitamins				
14	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
16	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
17	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses. If the auxin or cytokinin does dissolve add a few drops of 1 N KOH and HCl respectively.

[f]Available from www.sigmaaldrich.com.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Add the gellan gum to the cold solution as indicated in footnote *h*, distribute the medium to culture vessels and autoclave. It is preferable not to autoclave hormones and vitamins, but in this medium they can be autoclaved for 15 min at 121°C.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE ONC-18. **Modified half-strength Murashige–Skoog (½MS) medium (Murashige and Skoog, 1962) for plantlets from protocorm-like bodies (PLBs) produced by somatic embryos derived from flower-stalk explants of *Oncidium* Sweet Sugar (Chen and Chang, 2000*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]Available from www.sigmaaldrich.com.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Add the gellan gum to the cold solution as indicated in footnote *h*, distribute the medium to culture vessels and autoclave. It is preferable not to autoclave hormones and vitamins, but in this medium they can be autoclaved for 15 min at 121°C.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

In Vitro Production of Plantlets by Proliferation of Protocorm-like Bodies of *Oncidium* Gower Ramsay

Graceful inflorescences with golden "dancing lady" flowers make *Oncidium* Gower Ramsey a very desirable cut flower orchid. Demand for plants is high. Therefore a method for mass rapid clonal propagation was developed at the C. C. Shroff Institute in Bombay, India (Badge and Sharon, 1997).

Plant Material. Apical meristems should be taken from healthy mature plants.

Surface Sterilization. Plants or parts from which explants will be taken should be washed with running water and a mild detergent (2% Teepol available from www.sigmaaldrich.com was used in the original research) until all debris, loose particles, and potting mix are removed and then rinsed three times with sterile distilled water. This was done during the original research, but rinsing with sterile distilled water prior to treatment with a surface sterilizing agent seems unnecessary – tap water is sufficient. After the rinse explants should be immersed for 15 min in 2% sodium hypochlorite (38 or 33 ml of 5.25 or 6% Clorox, respectively, made to 100 ml with distilled water) with stirring or agitation and rinsed with sterile distilled water three times (the use of sterilized water is a must at this stage).

Culture Vessels. Culture tubes with the medium dried on a slant were used in the original research (size was not indicated; 20 × 150 mm tubes are suitable). Other containers are also suitable.

Culture Conditions. Explants should be maintained at 22 ± 2°C and 65 ± 5% relative humidity in the dark for the first 48 h and after that under 16-h photoperiods of 3000 lx. Standard culture room conditions are also suitable after the initial dark period.

Culture Media. Explants should be placed on modified Vacin and Went (VW) medium (Vacin and Went, 1949) containing 150 ml coconut water (Table Onc-19) for the induction of callus. The callus should be subcultured on the same medium (Table Onc-19) for proliferation and formation and multiplication of PLBs. The PLBs produce plantlets when cultured on modified MS medium (Murashige and Skoog, 1962) containing 200 mg casein hydrolysate (CH) l^{-1} (Table Onc-20). Plantlets which form on the second medium can either be cultured on it or moved to another solution (see Tables Aranda-6 to Aranda-8, Anth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Den-2, Den-12, Den-21, Odnta-1, Onc-5, Pln-1, and V-4) for growth (this step is not part of the original paper).

Procedure. Explants are taken after the initial washing of the plants, sterilized and cultured on the first medium (Table Onc-19). When callus forms it is subcultured on the same medium (Table Onc-19) to proliferate it and to produce PLBs. The PLBs can be multiplied on this medium (Table Onc-19) or moved to modified MS (Table Onc-20) for plantlet production.

TABLE ONC-19. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of *Oncidium* Gower Ramsay meristems, callus proliferation, and protocorm-like body (PLBs) formation and multiplication (Badge and Sharon, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water[e]	150.0 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to the culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 3), bring volume to 900 ml with distilled water (item 10), adjust pH to 5.1, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

Developmental Sequence. The explants form callus on the first medium (Table Onc-19). When subcultured on the same medium (Table Onc-19) the callus proliferates and forms PLBs. The PLBs increase in number on this medium (Table Onc-19). On the second medium (Table Onc-20) PLBs continue to proliferate and older ones (1–2 months in age) form plantlets. Once formed the plantlets grow well on the second medium (Table Onc-20) or one of the other media (see Tables Aranda-6 to Aranda-8, Anth-5C-3, C6, C-19, Cym-1 to Cym-3, Cym-5, Den-2, Den-12, Den-21, Onc-5, Odnta-1, Pln-1, and V-4).

TABLE ONC-20. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for plantlet production from protocorm-like bodies of *Oncidium* Gower Ramsey (Badge and Sharon, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]

(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Complex additive				
10	Casein hydrolysate[g]	200.0	No stock	No stock	Weigh
	Auxin[f]				
	Cytokinin[f]				
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Agar[h]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]MS usually contains auxin and/or cytokinin, but there is no indication that this is the case for this modification.

[g]Add items 1–13 to 700 ml of distilled water (item 15), adjust pH to 5.7, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. As a rule amino acids and hormones should be added after a medium has been autoclaved, but in this case there is no need to do so.

General Comments. Root and leaf explants were also cultured as part of this research. Leaf explants produced callus on VW but subsequent growth was poor. Root explant cultures were overrun by internal contaminants. This is not surprising because orchid roots which grow in a potting medium or come into contact with other surfaces contain mycorrhizal fungi. Therefore root explants should be taken from aerial roots which have not come into contact with potting mix or any other surface. Such roots will probably be free of mycorrhiza and have a chance of developing in culture. A great advantage of this protocol is that it makes possible propagation of outstanding cultivars because the explants are taken from mature plants.

Plantlet Production of *Oncidium bifolium* from Leaf Explants

Oncidium bifolium, one of the southernmost members of its genus, is a relatively small orchid. A method for plantlet production was developed at the Faculdad de Ciencia Agrarias, Universidad Nacional Del Nordeste in Argentina.

Plant Material. Sections, 4×4 mm, were taken from expanded leaves of seedlings growing in vitro.

Surface Sterilization. Explants from seedlings growing in vitro do not require surface sterilization. However, they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Culture tubes, Erlenmeyer flasks and other containers filled with medium to 20–30% of their capacity are suitable.

Culture Conditions. Standard culture room conditions are appropriate.

Culture Media. PLBs and plantlets develop from the explants on half-strength MS medium (Murashige and Skoog, 1962) supplemented with 1 mg TDZ l^{-1} (Table Onc-21). Plantlets which form on this medium can be grown on one of several media (see Tables Aranda-6 to Aranda-8, Anth-5C-3, C6, C-19, Cym-5, Cym-1 to Cym-3, Den-2, Den-12, Den-21, Onc-5, Odnta-1, Pln-1, and V-4) until they are large enough to be potted in community pots.

Procedure. Explants should be cultured on the first medium (Table Onc-21) until PLBs are formed. These should be moved to fresh medium (Table Onc-21) for plantlet formation. The plantlets can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Anth-5C-3, C6, C-19, Cym-5, Cym-1 to Cym-3, Den-2, Den-12, Den-21, Onc-5, Odnta-1, Pln-1, and V-4).

Developmental Sequence. PLBs and plantlets form on the first medium (Table Onc-21) after 120 days of culture. Plantlets grow further on one of the other media.

General Comments. This protocol was developed with seedlings. Therefore it cannot be used to propagate selected forms. The method should be tested with explants from young leaves of mature plants.

TABLE ONC-21. **Modified half-strength Murashige–Skoog (½MS) medium (Murashige and Skoog, 1962) for culture of *Oncidium bifolium* leaf explants (Flachsland et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10

(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	Thidiazuron (TDZ)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Gelrite[g,h]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses. If the cytokinin does dissolve add a few drops of 1 N HCl.

[f]Available from www.sigmaaldrich.com.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.2, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Add the Gelrite (item 16) to the cold solution as indicated in footnote *h*, distribute the medium to culture vessels and autoclave. It is preferable not to autoclave hormones and vitamins, but in this medium they can be autoclaved for 15–20 min at 121°C.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

Effects of Basal Medium and Banana and Sugar Concentrations on the Growth of *Oncidium* Protocorm-like Bodies in Vitro

Oncidium PLBs grow best on MS medium (Murasghige and Skoog, 1962) containing 40 g sucrose and 100 g banana pulp l^{-1} (Kusumoto et al., 1998). This report and the one below are not in agreement regarding sucrose.

Effects of Basal Medium and Banana and Sugar Concentrations on the Growth of *Oncidium* Plantlets in Vitro

Oncidium plantlets grow best on MS medium (Murasghige and Skoog, 1962) containing 30 g sucrose and 100 g banana pulp l^{-1} (Kusumoto and Takeda, 1997). This report and the one above are not in agreement regarding sucrose.

Plantlet Production from *Oncidium varicosum* Root Tips

Professor G. B. Kerbauy in Brasil is interested in culturing orchid root tips due to the "obvious advantages offered by this source of explants in comparison with shoots" (Kerbauy, 1984*b*). His interest led him to develop a micropropagation method for root tips of *Oncidium varicosum* (Kerbauy, 1984*b*, 1993*a*, 1993*b*).

Plant Material. Root tips, approximately 5 ± 1 mm long, were taken from 4–6-cm-tall seedlings of *Oncidium varicosum* Rogersii grown asymbiotically on Knudson C (KC) medium (Knudson, 1946) with 27.8 mg Fe-EDTA l^{-1} instead of $FeSO_4$, supplemented with 60 g ripe banana (RB) l^{-1} (presumably homogenized), 1 g activated charcoal (AC) l^{-1}, and solidified with 8 g agar l^{-1}.

Surface Sterilization. Explants taken from plants growing in vitro do not require surface sterilization. If roots from mature plants are excised a number of precautions must be taken because root meristems are protected only by a thin root cap and are therefore vulnerable to injury during surface sterilization (unpublished method for roots of *Oncidium*, *Cattleya*, *Epidendrum*, and *Catasetum* and related species developed by Professor Kerbauy and kindly described in an e-mail message). Roots which will serve as sources of explants must not touch the substrate or any other surface. To prevent these roots from touching the substrate or surfaces the plants should be removed from their pots and suspended in the air in a greenhouse. High temperatures and low relative humidities must be avoided. As new roots develop they must be sprayed weekly with a fungicide and a bactericide. Professor Kerbauy warns against the use of systemic fungicides because "they are very harmful to orchids." Roots should be harvested when they reach a length of nearly 2.0 cm. The segments should be placed in a small sieve and washed with tap water. After being washed the root segments should be immersed in approximately 30 ml of sterile water which contains a few drops of mild household detergent, agitated gently for 20 min, and then rinsed with sterile distilled water. The washed roots should be dipped for 20 s

in 70% ethyl alcohol (73–74 ml 95% ethanol diluted to 100 ml with sterile distilled water), submerged with agitation for 20 min in 1% sodium hypochlorite (19 or 17 ml of 5.25 or 6% Clorox diluted to 100 ml with distilled water plus a few drops of a mild detergent), and then rinsed 3–5 times with sterile distilled water. Root-tip explants, 5 mm long, are taken from the sterilized roots and placed in culture.

Culture Vessels. Culture tubes can be used to culture explants on solid medium. Erlenmeyer flasks, 125-ml capacity, should be used for liquid medium and plantlet production.

Culture Conditions. In the original research explants, PLBs and plantlets were maintained at 25 ± 1°C under 16-h photoperiods of 500 lx provided by Gro-Lux tubes. Standard culture room conditions will probably also prove to be suitable. Liquid cultures should be "gently shaken" (Kerbauy, 1993*a* does not define "gently, but 30–50 rpm should be appropriate).

Culture Media. A modified Vacin and Went medium (Vacin and Went, 1949) is used for PLB induction and multiplication (Table Onc-22; personal communication from Professor Kerbauy). Bud formation and plantlet formation take place on what is described as "semi-solid" medium without an indication how much agar was used to solidify it. The amount suggested here (Table Onc-23) is an estimate which may require adjustment and modifications. When plantlets reach a height of 2–3 cm they should be moved to the KC medium used for seed germination (Table Onc-24).

Procedure. Explants are cultured on the first medium (Table Onc-22) until PLBs are formed. These PLBs are multiplied by subculturing them on the same medium (Table Onc-22). Once there are enough PLBs they should be moved to the second medium (Table Onc-23) for bud and plantlet formation. The plantlets should be grown to deflasking size on KC (Table Onc-24).

Developmental Sequence. BA has an inhibitory effect on callus formation and growth by root-tip explants which were "intensely green" in the presence of this hormone. Auxin had an enhancing effect even in the presence of BA. Peptone and thiamine had growth promoting effects which were not as pronounced as those of NAA. Increasing concentrations of NAA enhanced callus formation. However, high levels of this hormone could induce undesirable mutations. The plantlets "had a normal appearance similar to that of mericlones regenerated from shoot tip cultures," but mutations can show up the flowers and/or inflorescences. Therefore use of NAA and other hormones requires caution and lower concentrations are preferable. Coconut water has been shown to induce callus and/or proliferation without inducing mutation and should be used in preference to hormones whenever possible. Buds and shoot develop on a medium described as "semi-solid." Some investigators refer to all agar media as "semi-solid." Others reserve the term for a medium which is solidified with a low concentration of agar. Since the basal medium is solidified with 7 g agar l^{-1} the suggestion here is to solidify the "semi-solid" substrate with 3–5 g l^{-1}. This may or may not be appropriate. Users should try other agar concentrations (perhaps 0.5, 0.8, 1.0, or 2.0 g l^{-1}) and use the one which proves to be most effective. Plantlets

TABLE ONC-22. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of root tips of *Oncidium varicosum* (Kerbauy, 1984*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	1.0 mg	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	Benzyladenine (BA)	0.05 mm	5 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_3(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or 0.1 N HCl respectively.

[f]Keep frozen between uses.

[g]Add items 1, 3–9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

grow well on banana-containing KC medium. The accepted practice is to incorporate into culture media homogenized pulp of ripe bananas.

General Comments. The use of root tips as explants for micropropagation is an excellent idea because removing a few roots will not damage the donor plants. Explants from plants in vitro do not require surface sterilization. This is an advantage during initial research because it eliminates a step that could damage explants badly enough to prevent growth even on a suitable medium. However explants from seedlings

TABLE ONC-23. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for induction of buds and shoots from protocorm-like bodies (PLBs) derived from callus produced by root tips of *Oncidium varicosum* (Kerbauy, 1984*b*)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1, 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 10), adjust pH to 5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable. The original paper states that the medium is "semi-solid," but does not indicate how much agar to use. That is why the recommendation here is for 4 g agar l^{-1}. This amount may or may not be appropriate. Those who use this procedure may have to experiment with different agar levels if 4 g l^{-1} prove to be inappropriate.

TABLE ONC-24. **Knudson C (KC) medium (Knudson, 1946) modified for the culture of plantlets produced by protocorm-like bodies (PLBs) derived from callus produced by root-tip explants of *Oncidium varicosum* (Kerbauy, 1984*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
7	Banana homogenate[e]	60.0 g	No stock	No stock	Weigh
	Darkening agent				
8	Activated charcoal[f]	1.0 g	No stock	No stock	Weigh
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar[e]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Knudson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$ l^{-1}, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of other nutrients would be of benefit. If incorporation of additional microelements becomes necessary those used in the Murashige–Skoog (MS) medium are suitable.

[e]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable; (2) the peel rather than the pulp should be used; (3) unpeeled banana homogenate should be incorporated in media; and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective banana variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and/or use what is suggested there.

[f]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite which are very different in nature should be used only if required by a specific procedure or except under special circumstances.

[g]Pour 800 ml distilled water (item 10) in a homogenizing container, add items 1–7 and homogenize until the banana pulp is completely dispersed, adjust pH to 5.5, add sugar (item 9), and bring volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour in the darkening agent (item 8) while stirring vigorously. When the charcoal becomes distributed evenly pour the medium into culture vessels and autoclave. There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of other nutrients would be of benefit. If the incorporation of additional microelements is necessary those used in the Murashige–Skoog (MS) medium are suitable.

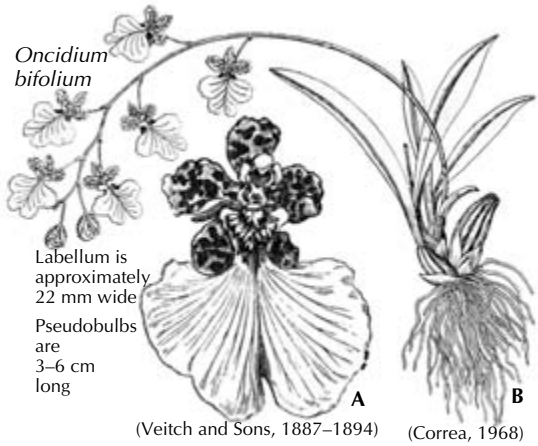
preclude selection of outstanding cultivars because the nature of each plant is not known. Therefore procedures which utilize explants from seedlings are more useful as model systems than as practical methods. Use of explants from roots of mature plants allows for selection of desirable form. However roots which have come into contact with potting mix or other surfaces may contain mycorrhizal fungi which will grow out of the explants and smother cultures. Therefore Professor Kerbauy's method for surface sterilization of roots of mature plants and the culture of explants taken from them is very valuable.

In Vitro Morphogenesis of *Oncidium*

Embryogenic callus was induced from root, stem, leaf, and flower-stalk internodes. The callus eventually produced plantlets. Direct somatic embryogenesis was induced on leaf segments cultured on modified half-strength MS medium (Chang et al., 2001).

Effects of Salt Concentration and Organic Additives on in Vitro Growth of Protocorm-like Bodies and Plantlets of *Oncidium* Gower Ramsey

PLBs of *Oncidium* Gower Ramsey "Hamana" grew best on full and half-strength MS medium (Murashige and Skoog, 1962) supplemented with banana (50 or 100 g l^{-1}), potato, and tryptone (3 g l^{-1}). Growth was also good on 2 g Hyponex l^{-1} (Chen and Chen, 1998).



(Veitch and Sons, 1887–1894) (Correa, 1968)

Ophrys

The genus *Ophrys* is well known for its flowers, which resemble flies, wasps, and bees, and for its pollination mechanisms, which involve pseudocopulation. Some *Ophrys* species have been cultured.

Tissue Culture of *Ophrys apifera*

The threat of extinction of this, "one of the most beautiful and endangered orchids in Germany," led two brothers, high school students at the time, to develop a tissue culture procedure in their home laboratory (Hoppe and Hoppe, 1987*a*, 1987*b*, 1988).

Plant Material. Seedlings (grown in vitro at the Kiel Botanical Garden) that were 2 mm long (white tubers with green tips) and 30 mm long (with two green leaves also 30 mm long), 2 and 8 months old, served as sources of explants for the original research. The shoots of the seedlings were broken off, and the remaining portions (tuber and shoot base) were cultured.

Surface Sterilization. There is no need to surface-sterilize seedlings grown in vitro.

Culture Vessels. Test tubes (30 × 200 mm) containing 20 ml medium and covered with caps fitted with cotton-filled glass tubes were used in the original research. Other containers should prove equally suitable.

Culture Conditions. The brothers Hoppe maintained their cultures on a rotary shaker at 12 rpm under continuous illumination of 2500 lx (provided by four 40-W Sylvania Gro Lux tubes) at 21 ± 1.5°C. Their shaker was built so that the direction of rotation changed every 15 s.

Culture Media. A liquid medium (P) should be used for initial culture of the smaller seedlings (Table Oph-1). A different medium (S; Table Oph-2) is more appropriate for larger seedlings. Proliferation occurs in medium P (Table Oph-1). A third medium (D) supports differentiation (Table Oph-3).

Procedure. Place explants in the appropriate liquid medium (P for smaller seedlings, S for larger ones), and allow them to form callus and PLBs. The latter are subcultured in medium P for proliferation. For plantlet production the PLBs are moved to medium D.

Developmental Sequence. Callus derived from smaller seedlings is white, covered with rhizoids. When subcultured this callus produces PLBs. These proliferate every time they are subcultured but never turn green. The larger seedlings form callus at the end of a pencil-like growth. This callus produces PLBs in medium P. The PLBs produce plantlets on medium D, which develop like normal seedlings.

TABLE OPH-1. **Culture medium P for the culture of *Ophrys* explants (Hoppe and Hoppe, 1987*a*, 1987*b*, 1988)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
2	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
3	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37	37 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	28	2.8 g l^{-1}		
4	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	10	1.0 g l^{-1}	10	One solution

[a]This medium contains components from several media. The microelements are from Murashige–Skoog solution.

[b]Amounts are given in mg unless indicated otherwise.

[c]Add chelating agent (item 3a) and iron salt (item 3b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements (items 4a–f) to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin does not dissolve, add a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Dissolve all vitamins in the same 100 ml of 70% ethanol, and add 0.5 ml of this solution per liter of medium.

[i]Cat. no. 2245, Merck & Co., Darmstad, Germany.

[j]Add items 1–4, 6, and 16 to 900 ml distilled water (item 18). Adjust pH to 5–5.5, add sugar (item 17) and adjust volume to 1000 ml with distilled water (item 18). Pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 5, 7–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium into preautoclaved culture vessels.

TABLE OPH-2. **Culture medium S for the culture of *Ophrys* explants (Hoppe and Hoppe, 1987*a*, 1987*b*, 1988)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

18	Agar[j]	10–15g	No stock	No stock	

[a]This medium contains components from several media. The microelements are from Murashige–Skoog solution.

[b]Amounts are given in mg unless indicated otherwise.

[c]Add chelating agent (item 3a) and iron salt (item 3b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements (items 4a–f) to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]Also known as *meso*-inositol, *i*-inositol, or inositol.

[g]Dissolve all vitamins in the same 100 ml of 70% ethanol, and add 0.5 ml of this solution per liter of medium.

[h]Cat. no. 2245, Merck & Co., Darmstad, Germany.

[i]From animal liver.

[j]Add items 1–4, 6, 14, 15, and 16 to 700 ml distilled water (item 17). Adjust pH to 5–5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. Pour hot solution into a 2-l flask and autoclave. Add amino acid and vitamins (items 5, 7–13) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium into preautoclaved culture vessels. Omit agar if preparing liquid medium. To prepare the green banana homogenate homgenize 5 g of pulp from an unripe (green) banana with 150 ml of distilled water.

General Comments. This procedure was developed with seedlings, but it may prove suitable for explants from mature plants.

Production and Fusion of Protoplasts of *Ophrys lutea* and *Ophrys bombylifera*

A procedure for the isolation of *Ophrys* protoplasts and fusion between them and those of *Barlia robertiana (B. longibracteata)* was developed at the Escola Polytechnica in Lisbon, Portugal (Pais et al., 1983).

Plant Material. The youngest leaves of *Ophrys lutea* and *Ophrys bombylifera* are used.

Surface Sterilization. See *Barlia robertiana* (see p. 258, Vol. I; Pais et al., 1982).

Culture Vessels. Petri dishes are suitable.

Culture Conditions. See *Barlia robertiana* (Pais et al., 1982).

Culture Media. The medium for *B. robertiana* (Pais et al., 1982) is the same, except that the molarity of sorbitol should be 0.55 and the incubation time is 3 h. Fusion medium consists of the following (per liter): 4.09 g (70 mmol) sodium chloride, NaCl; 6.15 g (75 mmol) sodium acetate, CH_3CO_2Na; 222 mg (2 mmol) calcium chloride, $CaCl_2$; 64 mg (0.35 mmol) sorbitol; and 50 g sodium alginate (a fusion agent). Total osmolarity of the medium should be 550 mOsm, and the pH is adjusted to 5.5. The percentage of fusion is observed after staining the protoplasts with a 1% solution of fluorescein diacetate in acetone.

Procedure. Protoplast suspensions, 0.5 ml containing 10^8 protoplasts, are added to 0.1 ml fusion medium and "gently soaked" for about 30 min. Staining with the fluorescein solution is for 1–5 min.

Developmental Sequence. Fusion starts immediately after the protoplasts are added to the fusion medium. Fused protoplasts were not cultured.

General Comments. This procedure should prove useful as a starting point for the development of fusion methods that may lead to viable hybrids.

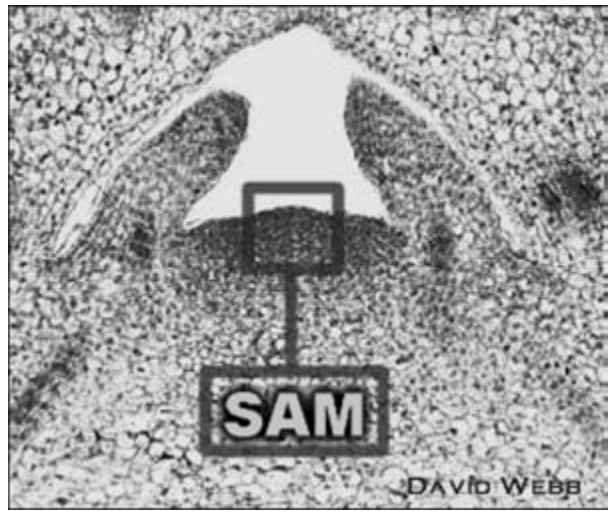
Culture of *Ophrys* Tuber Sections

Tuber sections (cubes 5 mm on each side) of *Ophrys fuciflora* and *Ophrys apifera* were taken during the rest periods of these species in July, cultured on a modified MS medium, and formed callus masses that produced PLBs (Champagnat and Morel, 1972; Morel, 1974). The exact composition of the medium is not given (Champagnat and Morel, 1972). It is only described as "*la solution minerale de Skoog*

additionnée de 3% de glucose et contenant de l'acide naphtyle acétique et de la kinétine à la concentration de 5.10^{-7} g/l." Such lack of detail is not uncommon in papers from Morel's laboratory and one can only assume that the culture medium is some sort of modification of the MS medium and contains 5.10^{-7} g each of NAA and kinetin per liter.

Orchis

A procedure for the culture of meristems of buds taken from tubers of *Orchis coriophora* has been described (Allenberg, 1976), but not in sufficient detail for inclusion here. This procedure has been criticized on several grounds (von Ramin, 1976).



Shoot apical meristem (SAM in image) of an orchid with two leaf primordia above it. Despite the common term "meristem culture," what is commonly cultured is an explant which includes the meristem and surrounding tissue. (Courtesy Professor David T. Webb's World Wide Web page, www.botany.hawaii.edu/faculty/webb/default.htm.)

Otochilus

Described by some as "a very peculiar genus of three known" epiphytic species, *Otochilus* is found from the Himalayas to Thailand and Vietnam. Its name is derived from the Greek ουσ (*ous*) or οτοσ (*otos*) meaning ear and χηειλοσ (*cheilos*) meaning lip. The reference is to auriculate (ear like) lateral lobes on the labellum which clasp the base of the gynostemium (Schultes and Pease, 1963; Bose and Bhattacharjee, 1980).

A Quick Method for the Micropropagation of *Otochilus alba*

An epiphyte described as a "bizarre orchid," *Otochilus alba* is found in the Khasia and Naga Hills and Manipur in India at altitudes of 1000–1500 m (Bose and Bhattacharjee, 1980) and as high as 2000 m (Mukhopadhyay and Roy, 1994). Its flowers (Fig. Otch-1I) are whitish pink, 1.5 cm across, and appear in June. They are

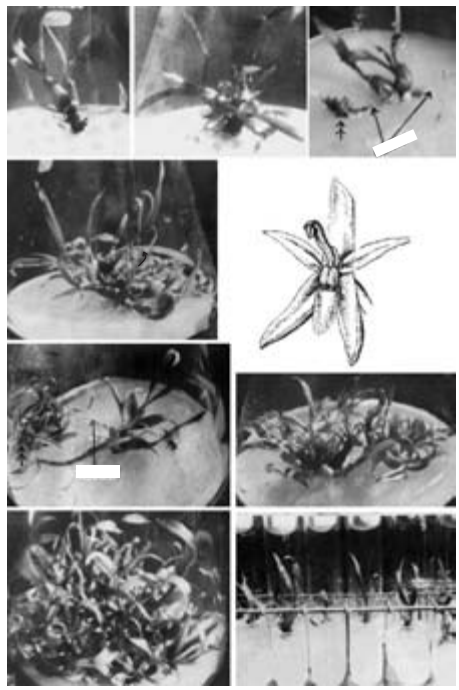


FIG. OTCH-1. **Tissue culture of *Otochilus*. A. Five-week-old shoot-derived pseudobulb. B. Multiplication of pseudobulbs on IAA-containing medium. C. Multiplication of pseudobulbs on NAA-containing medium. D. Induction of runners on Phytamax medium. Arrow points to bulbous tissue at tip. E. Development and multiplication of pseudobulbs from bulbous tissue at tip of runners (arrow). F. Multiplication of pseudobulbs on Phytamax medium. G. Many pseudobulbs after 50 days of culture. H. Root induction. I. Flower. (A–H, Mukhopadhay and Roy, 1994; I, Bose and Bhattacharjee, 1980.)**

produced on pendulous racemes which arise from the terminal pseudobulbs. A "runner mediated" micropropagation method described as "effective as well as astounding" was developed at the Botany Department, University of Calcutta, India (Mukhopadhyay and Roy, 1994).

Plant Material. Apical shoot explants, 5–6 mm long, were taken from *Otochilus alba* plants collected at an altitude of 1800–2000 meters and maintained in a greenhouse at 20 ± 2°C. Terminal leaves should be removed following surface sterilization and the apical region (2–3 mm long) is excised and cultured.

Surface Sterilization. The explants should be surface sterilized by immersing them for 6 min with gentle agitation in a 0.1% solution of mercuric chloride [1 g $HgCl_2$ dissolved in 100 ml distilled water (this is a very toxic substance which must be handled with great care); available from www.fishersci.com], and then washing them five times with sterile distilled water. Explants are removed after the last wash.

Culture Vessels. Erlenmeyer flasks (250 ml capacity containing 60 ml medium) and culture tubes with 25 ml substrate should be used. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at 22–24°C under 60% relative humidity and 16-h photoperiods of 3000 lx provided by fluorescent lamps (type not described). Standard culture room conditions are also appropriate.

Culture Media. Explants should be cultured initially on half-strength MS medium (Murashige and Skoog, 1962) containing 0.2 mg NAA l^{-1} and 10% (v/v) coconut water (Table Otch-1). Pseudobulbs which form on this medium should be transferred after 6 weeks to a medium containing 2 mg N^6-(2-isopentenyl)-adenosine (2iP) l^{-1} and 0.5 mg NAA l^{-1} for pseudobulb (Table Otch-2) and shoot (Table Otch-3) formation. To bring about the formation of runners which produce multiple plantlets the 6-week-old pseudobulbs should be cultured on the Phytamax medium (catalog number P-6393 www.sigmaaldrich.com), a commercial preparation (Table Otch-4). Pseudobulbs with leaves should be cultured on a modification (see Table Aranda-8) of the Knudson C medium (Knudson, 1946).

Procedure. Explants should be cultured on the first medium (Table Otch-1) to induce pseudobulb formation (Fig. Otch-1A). When these pseudobulbs are 6 weeks old and have between two and four terminal leaves they should be moved to a secondary medium (Tables Otch-2 and Otch-3) to induce multiplication (Fig. Otch-1B, C). To bring about the formation of runners (Fig. 1D–G), the 6-week-old pseudobulbs should be cultured on the Phytamax medium (Table Otch-4). Leaf-bearing pseudobulbs should be moved to the Knudson C medium (see Table Aranda-8) for rooting (Fig. Otch-1H).

Developmental Sequence. Single small pseudobulbs develop from the explants within 2 weeks of the start of culture on the first medium (Table Otch-1). A pair of leaves appear on these "pseudobulbs almost simultaneously." When these

TABLE OTCH-1. **Modified half-strength Murashige–Skoog (HMS) medium (Murashige and Skoog, 1962) for the culture of *Otochilus alba* shoot-tip explants (Mukhopadhyay and Roy, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Polyol				
8	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
9	Naphthaleneacetic acid (NAA)	0.2	20 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin-like substance				
10	Adenine sulfate	50.0	No stock	No stock	Weigh
	Vitamins				
11	Niacin (nicotinic acid)	5.0	500 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
13	Coconut water[g]	100.0 ml	No stock	No stock	Measure
	Sugar				
14	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Agar[h]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1–13 to 750 ml of distilled water (item 15), adjust pH to 5.6, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave.

TABLE OTCH-2. **Modified half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of shoot-tip derived leaf bearing pseudobulbs (Mukhopadhyay and Roy, 1994)**

(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Polyol				
8	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
9	Naphthaleneacetic acid (NAA)	0.2	20 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
10	N^6-(2-isopentenyl)-adenosine (2iP)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	5.0	500 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			
	Solidifier				
15	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or 1 N HCl respectively.

[g]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.6, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave.

TABLE OTCH-3. **Phytamax brand (www.sigmaaldrich.com) modified half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for induction of runners on pseudobulbs derived from shoot-tip explants of *Otochilus alba* (Mukhopadhyay and Roy, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or 0.1 N HCl respectively.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.6, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media.

TABLE OTCH-4. **Modified Knudson C (KC) medium (Knudson, 1946) for rooting of *Otochilus alba* pseudobulbs (Mukhopadhyay and Roy, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
7	Indolebutyric acid (IBA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[f]	To 1000 ml			
	Solidifier				
10	Agar[f]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Kundson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$ l^{-1}, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary those used in the Murashige–Skoog (MS) medium are suitable.

[e]If the auxin does not dissolve add a few drops of 0.1 N KOH. Keep frozen between uses.

[f]Add items 1–7 to 900 ml of distilled water (item 9), adjust pH to 5.6, add sugar (item 8), and raise volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If the incorporation of additional microelements is necessary those used in the Murashige–Skoog (MS) medium are suitable.

pseudobulbs reach 5–10 mm in length, between two and four new pseudobulbs form on each one (Fig. Otch-1A). The original explants turn brown gradually and die. Shoots multiply better on a medium containing NAA and 2iP (Fig. Otch-1B) than on IAA and 2iP (Fig. Otch-1C). Runners which produce pseudobulbs (Fig. Otch-1D–G) develop on the Phytamax medium. Rooting (Fig. Otch-1H) occurs on Knudson C (see Table Aranda-8).

General Comments. This is an interesting, clever, and apparently effective procedure. The Phytamax medium (Table Otch-4) differs from the other media used to produce pseudobulbs (Tables Otch-1 and Otch-3) by the presence of pyridoxine sulfate, peptone, and BA and the absence of adenine sulfate. Production of runners on this medium could be due to these differences. The authors have done well to list the composition of the Phytamax medium.

Pachystoma

A terrestrial tuber-producing species, *Pachystoma senile* is found in India, Sri Lanka, Malabar, Malay islands, and South China. A tissue culture procedure for it was developed at the Botany Department, Panjab University, Chandigarh, India (Vij et al., 1983).

Plant Material. Tubers of 6-month-old seedlings growing in vitro were sliced in 3- to 5-mm-thick segments.

Surface Sterilization. Seedlings growing in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other standard containers are suitable.

Culture Conditions. Cultures should be maintained under 12-h photoperiods of 3500 lx (provided in the original research by two 40-W Philips fluorescent tubes) and 25 ± 2°C.

Culture Media. Several modifications of the Mitra, Prasad, and Roychowdhury medium (Table Pach-1) were used in the original research. For callus formation the medium should contain (per liter) 1 g peptone and 1 mg NAA, or only 1 mg 2,4-D. PLBs in large numbers form in the presence of 1 g yeast extract l^{-1} (Table Pach-2). Plantlets develop from these PLBs when the basal medium contains 1 mg IAA l^{-1} (Table Pach-3).

Procedure. The explants are placed on the medium, allowed to develop, and subcultured as required.

Developmental Sequence. Some explants form PLBs, while others develop roots, shoots, plantlets, and/or callus. Callus can be formed on a medium that contains 1 mg l^{-1} 2,4-D. PLBs develop

> . . . from the cut surface of explants in the presence of either indole-3-acetic acid (IAA), naphthaleneacetic acid (NAA), kinetin (KN) or gibberellic acid (GA). . . . Regeneration frequency was enhanced by adding yeast extract. NAA caused profuse rhizogenesis. In peptone (P) and casein hydrolysate . . . supplemented combinations, shoot buds were directly initiated and their formation was enhanced in the presence of IAA or KN individually and in combination. Callusing was also noticed when NAA was used along with P. . . . (Vij et al., 1983)

General Comments. These "studies indicate that . . . tuber segments of *P. senile* can be successfully used as explants for regeneration . . . [that is] . . . dependent on . . . hormones. . . . Differentiated plantlets . . . have been successfully transferred to community pots" (Vij et al., 1983).

TABLE PACH-1. **Modified Mitra–Prasad–Roychowdhury medium (Mitra et al., 1976) for callus induction from tuber slices of *Pachystoma senile* (Vij et al., 1983)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

9	Folic acid	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
10	Niacin (nicotinic acid)	1.25	500 mg 100 ml^{-1} 95% ethanol[e]	0.25	
11	Pyridoxine (vitamin B_6)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
12	Riboflavin	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
13	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Hormone				
14	2,4-Dichlorophenoxyacetic acid (2,4-D)	1	400 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Sugar				
15	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[f]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto	9 g	No stock	No stock	Weigh
	Darkening agent				
18	Activated charcoal	2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe used 3 ml $Na_2FeEDTA$, a preparation that may not be readily available. The substitute listed here is used very commonly in orchid tissue culture media. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, add darkening agent (item 18) slowly with vigorous stirring; after it has been dispersed completely, dispense solution into culture vessels and autoclave. Omit agar for liquid medium. Media that contain hormones and vitamins should not be autoclaved unless prior experimentation has determined that this will have no deleterious effects. This is such a case (Mitra, 1971; Mitra et al., 1976), so the medium may be autoclaved.

TABLE PACH-2. **Modified Mitra–Prasad–Roychowdhury medium (Mitra et al., 1976) for the induction of protocorm-like bodies from tuber slices of *Pachystoma senile* (Vij et al., 1983)**

16	Water, distilled[f]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[f]	9 g	No stock	No stock	Weigh
	Darkening agent				
18	Activated charcoal	2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe used 3 ml $Na_2FeEDTA$, a preparation that may not be readily available. The substitute listed here is used very commonly in orchid tissue culture media. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, add darkening agent (item 18) slowly with vigorous stirring; after is has been dispersed completely, dispense solution into culture vessels and autoclave. Omit agar for liquid medium. Media that contain hormones and vitamins should not be autoclaved unless prior experimentation has determined that this will have no deleterious effects. This is such a case (Mitra, 1971; Mitra et al., 1976), so the medium may be autoclaved.

Paphiopedilum

All genera of the subfamily Cypripedioideae (*Cypripedium*, *Paphiopedilum*, *Phragmipedium*, and *Selenipedium*; and a more recent fifth genus, *Mexipedium*) present a special challenge in respect to culture in vitro. Their seeds are still more difficult to germinate than those of tropical epiphytes even now, and may require special media. And, these plants are still recalcitrant in tissue culture.

Selenipedium and *Mexipedium* explants seem not to have been cultured in vitro as yet. One report regarding the culture of *Phragmipedium* (Stokes et al., 1975) raises grave doubts (such a content-free, badly written, and highly questionable paper should not have been published at all). A second report (Fast, 1979) is of high caliber and respectable. *Cypripedium* explants were cultured in vitro only recently (Tomita, 1998; Jo et al., 2001).

Reports regarding the culture of *Paphiopedilum* vary in quality. What seems to have been the first report (Bubeck, 1973) was highly touted at the time by Dr. O. Wesley Davidson of Rutgers University as a major advance. However dissertations which contain important advances are usually published in peer reviewed journals as research paper(s). This dissertation was not published in such a manner. A second paper published (several times in different forms) shortly after that (Stewart and Button, 1975, 1976*b*, 1976*c*) raises questions. The procedure never became popular despite the fact that one of its authors (Joyce Stewart) rose to prominence in her reincarnations as an orchid taxonomist and a successful participant in international orchid petty politics, and received several gratuitous awards.

Methods for the culture of shoots and leaf tips of *Paphiopedilum* (Allenberg, 1976) did not become practically important either. One report (Holdgate, 1977), despite not being very impressive, led to highly questionable advertising claims about commercial tissue culture of *Paphiopedilum* by a heavily promoted UK laboratory. These claims had to be withdrawn because they could not be sustained.

A method developed at the University of California, Riverside under the guidance of Professor Toshio Murashige, co-formulator of the MS medium (Huang, 1988), is scientifically sound, but did not become widely used.

The slow progress in the development of micropropagation procedures for *Paphiopedilum* is due in part to the very high value of plants which means that not enough are available for experiments. Difficulties in developing an appropriate surface sterilization procedure may be another reason. Slow development of plantlets could be a third reason.

A warning: *Paphiopedilum* sap is allergenic and can cause severe rashes (Hausen, 1984). Precautions must be taken to avoid contact with the sap.

Meristem Culture of *Paphiopedilum*

What seems to be the first effort to culture *Paphiopedilum* was carried out as a Ph.D. research project. It was reported in a dissertation but apparently never published otherwise (Bubeck, 1973).

Plant Material. Explants were taken from *Paphiopedilum lawrenceanum* × *Paphiopedilum* Maudiae, *Paphiopedilum callosum, Paphiopedilum curtisii* Sanderae, *Paphiopedilum* Emerald × *Paphiopedilum* Alma Gevaert, *Paphiopedilum insigne* Harefield Hall, *Paphiopedilum villosum* × *Paphiopedilum insigne* Maulei, *Paphiopedilum nitens* Sallieri × *Paphiopedilum oenantum, Paphiopedilum callosum* × *Paphiopedilum lawrenceanum* var. *hyeanum, Paphiopedilum insigne* × *Paphiopedilum spicerianum, Paphiopedilum* Concobelatum × *Paphiopedilum niveum,* and *Paphiopedilum* Gwen Hannen × *Paphiopedilum* Phantasy. Young, actively growing shoots are taken from the plants and their leaves are removed before surface sterilization. Apices of terminal (i.e., apical) and of axillary buds are removed from the sterilized shoots.

Surface Sterilization. The shoots and explants are sterilized by placing them in a solution (per liter) of three to four drops of Tween 20 [polyoxyethylene-(20)-sorbitan monolaurate], 100 g Carbowax 4000 (polyethylene glycol 4000), and 50 ml Clorox. Tween 20 and Carbowax 4000 are dissolved in distilled water and the solution is autoclaved. Clorox is added to the autoclaved solution for the sterilization step only. Shoots are immersed in this solution for 2 min, placed in sterile distilled water for an equal period, then rinsed again, and drained on sterile paper towels.

Culture Vessels. During the original research the explants were cultured in 125-ml Erlenmeyer flasks containing 50 ml medium, but other containers can also be used.

Culture Conditions. Cultures should be maintained under illumination of 18-h photoperiods of approximately 4500 lx provided by cool white fluorescent tubes, and at a temperature of 20°C.

Culture Media. Explants are started on a modified MS medium (Table Paph-1). When they start to grow, they should be transferred to a bud-induction medium (Table Paph-2). Yet another modification (Table Paph-3) is used for root induction.

Procedure. Take explants while the shoot is immersed in the sterile Tween 20 and Carbowax 4000 solution (no Clorox). Place them on solid medium and later transfer to the bud-induction medium. When the adventitious buds that form on each explant reach 5 mm in length, excise and move them to the rooting medium. Treat plantlets that form in the last medium like seedlings.

Developmental Sequence. The explants are white when first placed in culture. They may turn yellow or pale green within 1–3 days. However, they can also remain yellow for several weeks and then turn white, brown, or green. In most cases surviving cultures can be identified in 3 weeks, but in some cases a brownish black explant may develop a green shoot after 60–90 days.

> A few cell layers of callus developed outside the area wounded during excision. However the major amount of growth took place in the area above the wound. Buds and roots and buds differentiated from vascular bundles in the area above the wound.

Root induction was fortuitous.

TABLE PAPH-1. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Paphiopedilum* explants (Bubeck, 1973)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[c]	1650	165 g l^{-1}	0.5	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	0.5	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	0.5	
4	Potassium nitrate, KNO_3[c]	1900	190 g l^{-1}	0.5	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	0.5

10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
13	Coconut water[f,h]	50 ml	No stock	No stock	Weigh
	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[i]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]The original publication is not clear in that it states that 5% or 10% of the Murashige–Skoog salts were used, but it gives a recipe for this medium that includes more than salts (Bubeck, 1973). Those who wish to use this medium should prepare two versions, one omitting items 1–7 and another containing all components. It is also not clear whether only the macroelements were used at low concentrations. We have assumed this to be the case. This recipe is given solely to provide as complete an account as possible of all micropropagation procedures for orchids; however, we do not recommend its use.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add the salts to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference will probably have little effect.

[f]Keep frozen between uses.

[g]Keep refrigerated between uses.

[h]The Murashige–Skoog medium normally includes auxins and cytokinins, but none seem to have been used for this procedure except for those that may be present in the coconut water.

[i]Add items 1–7, 9, and 13 to 800 ml of distilled water (item 15). Adjust pH to 5.2–5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid and vitamins (items 8, 10–12) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

TABLE PAPH-2. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for bud induction on *Paphiopedilum* explants (Bubeck, 1973)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]The original publication is not clear in that it states that 5% or 10% of the Murashige–Skoog salts were used, but the recipe it gives for this medium includes more than salts (Bubeck, 1973). Those who wish to use this medium should prepare two versions, one omitting items 8–13, and another containing all components. It is also not clear whether only the macroelements were used at low concentrations. We have assumed this to be the case. "Root induction was fortuitous – no case could be made for any additive." This recipe is given solely for the purpose of providing as complete a listing as possible; we do not recommend it.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[f]Keep frozen between uses.

[g]Murashige–Skoog medium normally includes auxins and cytokinins, but none seem to have been used for this procedure. Adenine is a purine and therefore a cytokinin-related substance.

[h]Keep refrigerated between uses.

[i]Add items 1–7 and 9 to 800 ml of distilled water (item 15), adjust pH to 5.2–5.5, add sugar (item 14) and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8, 10–13) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

General Comments. Like other culture methods for *Paphiopedilum* this one seems to work, but the number of surviving explants is low. This fact renders the procedure too risky for very expensive clones since it involves the removal of a shoot that would be lost if the micropropagation attempt were to fail.

Tissue Culture of *Paphiopedilum*

Initial success with the culture of *Paphiopedilum* was very limited (Lecoufle, pers. comm. cited in Morel, 1974; Stewart and Button, 1975, 1976*c*). Apices "of many *Paphiopedilum* hybrids" form plantlets on the Thomale medium (Thomale, 1954, 1957), and callus forms in the presence of 1 ppm 2,4-D (Morel, 1974). PLBs develop from the callus, and when deprived of 2,4-D they form plantlets (Morel, 1974). These experiments were not completed probably due to Morel's death, but other research projects were carried out elsewhere. One such project was initiated in 1972 at the Department of Botany, University of Natal, Pietermaritzburg, Natal, South Africa. The results were published in 1975 and 1976 (Stewart and Button, 1975, 1976*b*, 1976*c*).

Plant Material. In the original research, explants were taken from *Paphiopedilum villosum, Paphiopedilum fairieanum, Paphiopedilum insigne*, and several hybrids. Plants are taken out of the pots, cleaned (Fig. Paph-1A), and divided into shoots (Fig. Paph-1B). The expanded parts of the leaves are removed leaving a stump about 2 cm long (Fig. Paph-1C). The stem apex is exposed by removing the leaves (Fig. Paph-1D), and the stump is surface-sterilized. Tissue that is damaged by sterilization is removed (Fig. Paph-1E), leaving an approximately $5 \times 5 \times 5$ mm cube ready for culturing (Fig. Paph-1F).

Surface Sterilization. Stems are first washed with water and a detergent. After that they are sterilized in saturated calcium hypochlorite solution (10 g calcium hypochlorite in 100 ml water stirred several times at 5-min intervals and decanted or filtered before use) for 10 min with gentle agitation and rinsed several times with sterile distilled water. Leaves are removed one by one after that. The stump is rinsed with calcium hypochlorite and sterile distilled water following the removal of each leaf. At the end of this process damaged tissue is removed (Fig. Paph-1E), and the remainder (Fig. Paph-1F) is cultured.

Culture Vessels. Test tubes 80×25 containing 10 ml medium and sealed with Cap-O-Test lids were used in the original research. Similar tubes and lids or other containers can also be used.

Culture Conditions. Explants should be maintained under 12-h photoperiods (light intensity and source not given, but probably as below) at 23–27°C and then moved to the dark at 25°C until the start of proliferation. After proliferation the cultures are moved to 16-h photoperiods of 1000 lx provided by Sylvania Gro Lux tubes and 23–27°C. Explants should be moved to fresh medium every 8 weeks.

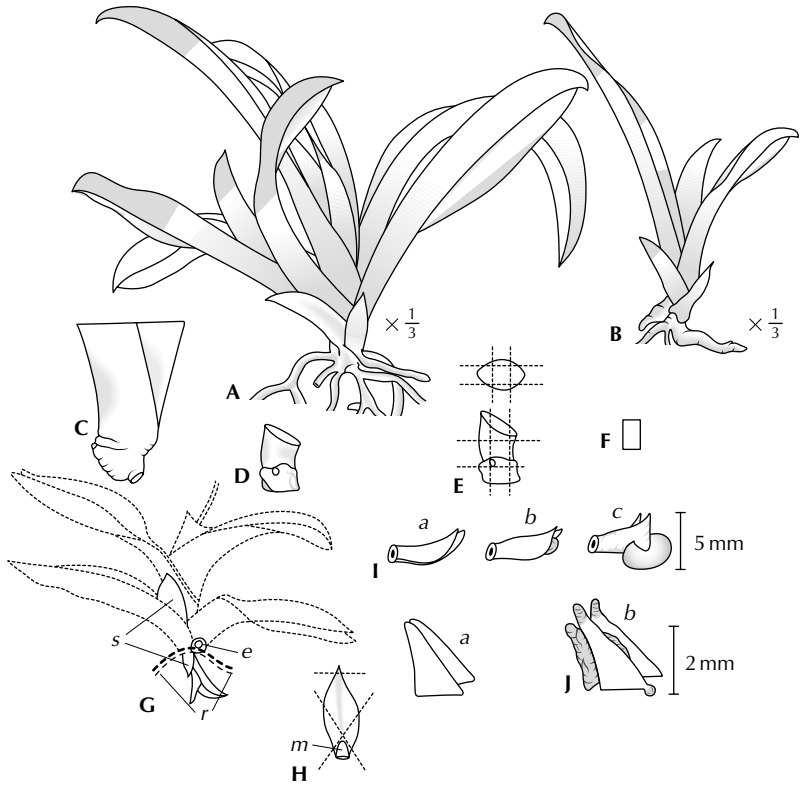

FIG. PAPH-1. **Tissue culture of *Paphiopedilum*. A. Flowering-size plant that serves as a source of explants. B. Shoot taken from the plant. C. The shoot following trimming of leaves and roots. D. After further trimming the explant is ready for surface sterilization. E. The cuts (*dotted lines*) necessary to remove tissue that was damaged by surface sterilization. F. Cubical explant ready for culture. G. Plant (*dotted lines*) with young shoots (s; *solid lines*) that will be removed for culture; e; cut remaining after removal of shoot; r; root. H. Excision (*crossing dashed lines*) of a shoot tip with meristem (m). I. Formation of protocorm-like bodies: a, start of culture; b, 19 days later; c, 24 days after b. J. Callus formation on leaf tips: a, start of culture; b, 3 months later. (A–F, Stewart and Button, 1975; G–I, Allenberg, 1976.)**

Culture Media. Modified Heller's medium (Table Paph-4) is used to culture the explants. Callus formed in this medium is "expected to continue to proliferate as long as 2,4-D is present in the medium." The subsequent treatment of this callus is not clear from the original paper. One possibility is to transfer parts of it to the same medium plus a cytokinin (Table Paph-5) to induce formation of PLBs. Other sections can be moved to Thomale GD medium plus 2,4-D (Table Paph-6) for further growth. Development of the PLBs may occur on unmodified Thomale GD medium (Table Paph-7).

Procedure. See Plant material section above.

TABLE PAPH-4. **Heller's medium (Heller, 1953) for initial culture of *Paphiopedilum* explants (Stewart and Button, 1975, 1976*b*, 1976*c*)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium chloride, $CaCl_2 \cdot 2H_2O$	75	7.5 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25.7 g l^{-1}	10	
3	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	125	12.5 g l^{-1}	10	
4	Potassium chloride, KCl	750	75 g l^{-1}	10	
5	Sodium nitrate, $NaNO_3$[c]	600	60 g l^{-1}	10	
6	**Micronutrients**[d]				
(a)	Aluminum chloride, $AlCl_3$	0.03	3 mg l^{-1}		
(b)	Boric acid, H_3BO_3	1	100 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.03	3 mg l^{-1}		
(d)	Ferric chloride, $FeCl_3 \cdot 6H_2O$	1	100 mg l^{-1}		
(e)	Manganese sulfate, $MnSO_4 \cdot H_2O$	0.1	10 mg l^{-1}	10	One solution
(f)	Nickel chloride, $NiCl_2 \cdot 6H_2O$	0.03	3 mg l^{-1}		
(g)	Potassium iodide, Kl	0.01	1 mg l^{-1}		
(h)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	1	100 mg l^{-1}		
	Auxin				
7	2,4-Dichlorophenoxyacetic acid (2,4-D)	1	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
8	Sucrose[f]	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[g]	To 1000 ml			
	Solidifier				
10	Agar, Difco Bacto[f]	12–15 g	No stock	No stock	Weigh

[a]This recipe is included for the purpose of providing as complete a listing of methods as possible; we do not recommend its use.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. It may be advisable to replace $FeCl_3$ (item 6d) with chelated iron. To prepare a chelated iron solution add 3.73 g Na_2EDTA (chelating agent) and 2.78 g $FeSO_4 \cdot 7H_2O$ to the same 1 l of distilled water, and stir and/or heat until both are dissolved. Add 10 ml of this solution to 1 l of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]Recommended by subsequent investigators.

[g]Add items 1–6 to 900 ml of distilled water (item 9), adjust pH to 5.3, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add auxin (item 7) to hot, still liquid solution under sterile conditions with a sterile pipettes, mix well, and dispense solution into preautoclaved culture vessels.

Developmental Sequence. The explants produce callus within 3 months. Depending on the medium being used this callus can be expected to (1) grow, (2) produce PLBs, and/or (3) regenerate plantlets.

General Comments. It is a pity that some information seems to be lacking from the original papers. Nevertheless, it is important to keep in mind that contamination was a major problem with these experiments and the number of successful cultures was small.

A somewhat different procedure involves the addition of a cytokinin to the medium and the utilization of another, vitamin-containing modification of Heller's solution. Of the 18 explants used for this procedure, 15 remained uncontaminated

TABLE PAPH-5. **Heller's medium (Heller, 1953) for callus induction from *Paphiopedilum* explants (Stewart and Button, 1975, 1976*b*, 1976*c*)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]This recipe is included for the purpose of providing as complete a listing of methods as possible. We do not recommend its use.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. It may be advisable to replace the $FeCl_3$ with chelated iron. To prepare a stock solution add 3.73 g Na_2EDTA (chelating agent) and 2.78 g $FeSO_4 \cdot 7H_2O$ to the same 1 l of distilled water, and stir and/or heat until both are dissolved. Add 10 ml of this solution to 1 l of culture medium.

[e]Keep refrigerated or frozen between uses. The auxin or the cytokinin can be solubilized with a few drops of dilute or HCl.

[f]Recommended by subsequent investigators.

[g]Add items 1–6 to 900 ml of distilled water (item 10), adjust pH to 5.3, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add hormones (items 7 and 8) to the hot, still liquid solution under sterile conditions with sterile pipettes, and dispense solution into preautoclaved culture vessels.

but only four survived. One explant produced a PLB that developed into a plantlet. The other three each produced a small callus that gave rise to a PLB that developed into a plantlet. Two explants became contaminated and the third formed plantlets that were separated. These plantlets produced a yellowish growth that enlarged and after 3 months "took up most of the space in the tube." Anatomical observations showed it to be "a root of unusual proportions." On a medium without auxin or cytokinin the plantlet developed normally.

Both procedures could serve as starting points for future research but should not be used to propagate valuable clones.

TABLE PAPH-6. **Modified Thomale GD medium (Thomale, 1954, 1957) for the culture of *Paphiopedilum* shoot-tip explants (Stewart and Button, 1975, 1976*b*, 1976*c*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	60	6 g l^{-1}	10	
2	Ammonium nitrate, NH_4NO_3[b]	370	37 g l^{-1}	10	
3	Magnesium nitrate, $Mg(NO_3)\cdot 6H_2O$[b]	110	11 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	300	30 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	400	40 g l^{-1}	10	
	Iron[c]				
6	Ferrous sulfate, $FeSO_4\cdot 7H_2O$	20	2.0 g l^{-1}	10	
	Vitamin[d]				
7	Niacinamide (nicotinamide)	10	1000 mg 100 ml^{-1} 95% ethanol[e]	1	
	Auxin				
8	2,4-Dichlorophenoxyacetic acid (2,4-D)	1	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Growth factors				
9	Wuchsstoff "66F"[f]	1	As purchased	As purchased	As purchased
	Sugars				
10	Fructose	10 g	No stock	No stock	Weigh
11	Glucose	10 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[g]	To 1000 ml			
	Solidifier				
13	Agar[g]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. The original recipe does not include chelated iron probably because it was not available at the time. To prepare a stock solution, dissolve 3.73 g of chelating agent (Na_2EDTA) and 2.78 g of ferrous sulfate ($FeSO_4\cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[d]This is often omitted. It can be replaced with an equal amount of niacin.

[e]Keep refrigerated or frozen between uses.

[f]This proprietary growth stimulant is available from Chemische Fabrik H. Stähler, Stade bei Hamburg, Germany.

[g]Add items 1–6 and 9 to 900 ml of distilled water (item 12), adjust pH to 5.3, add sugars (items 10 and 11), and adjust volume to 1000 ml with distilled water (item 12). Bring solution to a gentle boil, and add agar (item 13) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add the vitamin (item 7) and auxin (item 8), swirl or stir well to mix completely, and dispense medium into preautoclaved culture vessels. Alternately, add items 1–9 to 900 ml of distilled water (item 12) before pH is set, adjust volume, add sugars, and dissolve agar. Then dispense medium into culture vessels and autoclave. Omit agar for liquid medium.

TABLE PAPH-7. **Thomale GD medium for the germination of *Paphiopedilum* seeds (Thomale, 1954, 1957) and development of protocorm-like bodies from shoot-tip explants (Stewart and Button, 1975, 1976*b*, 1976*c*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

10	Glucose	10 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. The original recipe does not include chelated iron probably because it was not available at the time. To prepare a stock solution, dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4\cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[d]This is the amide of the more frequently used vitamin niacin (nicotinic acid).

[e]This proprietary growth stimulant is available from Chemische Fabrik H. Stähler, Stade bei Hamburg, Germany.

[f]Add items 1–6 and 8 to 900 ml of distilled water (item 11), adjust pH to 4.9–5.2, add sugars (items 9 and 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add vitamin (item 7), swirl or stir well to mix completely, and dispense medium into preautoclaved culture vessels. Alternately, add items 1–8 to 900 ml of distilled water (item 11) before pH is set, adjust volume, add sugars, and dissolve agar. Then dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium.

Asexual Multiplication of *Paphiopedilum* in Vitro

Since "efforts to develop tissue culture ('meristemming') techniques have been without much success" (Bubeck, 1973; Stewart and Button, 1975) a procedure was developed at the University of California, Riverside, under the guidance of Toshio Murashige, coformulator of the Murashige–Skoog medium (Huang, 1988).

Plant Material. Shoot apices are isolated from emerging laterals of flowering-age plants. After the surface-sterilization procedure the apices should be taken from the 0.005% sodium hypochlorite solution and trimmed by removing (1) all remaining leaves (with a Bard Parker No. 7 handle and disposable No. 11 blade) and (2) basal tissue except for 1 mm. The explant should be 2–3 mm tall (Fig. Paph-2A) with no vascular tissue or brown spots.

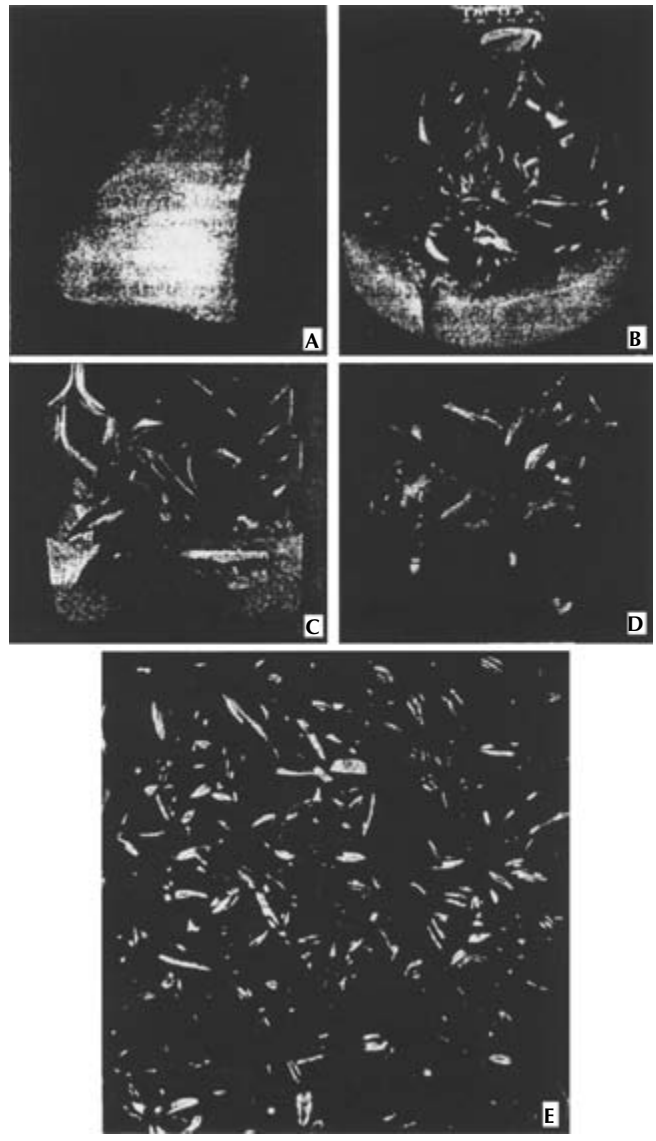

FIG. PAPH-2. **Culture of *Paphiopedilum* shoots. A. Shoot-tip explant ready for initial culture; (×50). B. Axillary shoots after 8 weeks in the second medium (Table Paph-9). Three clusters, each consisting of three shoots, were subcultured in a 250-ml Erlenmeyer flask containing 100 ml medium. C, D. Rooted shoots in the third medium (Table Paph-10). Plantlets grow better in (C) gelrite than in (D) agar. E. Tissue culture derived plantlets in the greenhouse. (Huang, 1988.)**

Surface Sterilization. Laterals are severed from the plant and washed with pHisoHex solution (an antimicrobial hexachlophene-containing detergent available in drugstores and pharmacies) or household detergent. This is followed by a rinse with distilled water and the removal of all leaves except two small upper ones that

encase the shoot apex. Most of the stem is discarded after that. To retard browning the trimmed shoots should be stored in a solution (per liter) of 100 mg ascorbic acid (do not use pills of vitamin C for human consumption because they may contain damaging additives) and 150 mg citric acid. The trimmed apices should be surface-sterilized by immersing them in 0.5% sodium hypochlorite (10 ml Purex or Clorox diluted to 100 ml with distilled water and 2 drops of Tween 20) for 15 min. At the end of this period the solution should be decanted and replaced with 0.005% sodium hypochlorite (1 ml Purex or Clorox diluted to 1000 ml with distilled water). No rinse is required after this solution.

Culture Vessels. Initial culture should be in 25 × 150 mm glass culture tubes containing 25 ml medium and capped with polypropylene closures. The medium should cool at a 30° slant. Subsequent culturing can be carried out in 250-ml Erlenmeyer flasks, Magenta GA7 vessels, or other containers containing at least 100 ml culture medium solidified horizontally.

Culture Conditions. The culture conditions vary in each of three steps.

Step 1. New cultures should be maintained in the dark and 27°C for the first passage. After 4 weeks the explants must be subcultured onto the same medium and moved to 16-h photoperiods of 1000 lx provided by Sylvania Gro Lux lamps. Explants must be subcultured every 4 weeks until they reach a length of 1.5–2 cm (two to four passages).

Step 2. Move the 1.5–2-cm-long explants to another medium (also 25 ml in 25 × 150 mm culture tubes) and to 16-h photoperiods of 3000 lx (also provided by Sylvania Gro Lux lamps) and 27°C. Shoots will multiply considerably (Fig. Paph-2B), and tissues should be subcultured every 8 weeks. After the first subculturing in this step use Erlenmeyer flasks of 250-ml capacity or magenta GA7 vessels.

Step 3. Move shoots to a third medium (in magenta GA7 vessels or Mason jars containing 100 ml medium) for rooting and place under 16-h photoperiods of 10,000 lx provided by Sylvania Gro Lux VHO tubes (Fig. Paph-2C, D). After a month the plantlets can be moved to a potting mix (Fig. Paph-2E).

Culture Media. The medium used in step 1 is a codification of the MS solution (Table Paph-8). This medium is modified for step 2 (Table Paph-9) and step 3 (Table Paph-10). Since disinfection of *Paphiopedilum* does not exclude all bacteria and fungi, antibiotics must be included in the medium for step 1. Carbenicillin and Cefotaxime, each at 100–500 mg l^{-1} (depending on the severity of infection), can be used to inhibit bacteria. Cefotaxime is inactivated by light, which is why the cultures must be kept in the dark. Benomyl will inhibit fungi according to our experience (see section on anticontaminants in Chapter 2; Thurston et al., 1979). The author of this procedure (Huang, 1988) also recommends its use but with some reservation. In our experience 50 mg l^{-1} benlate (and double that amount of commercial preparations that contain only 50% active principle) is sufficient to inhibit many fungi. That is why the recipe for the initial medium (Table Paph-8) contains benomyl (benlate).

Procedure. Since the procedure in this case is associated very closely with changing culture conditions, the section, Culture Conditions above, outlines the procedure

TABLE PAPH-8. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for *Paphiopedilum* explant culture (Huang, 1988)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10

9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin and related substance				
11	N^6-Isopentenyl adenine (2iP)	3	300 mg 100 ml^{-1} 95% ethanol[f,g]	1	
12	Adenine	30	No stock	No stock	Weigh
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
16	Coconut water	150 ml	No stock	No stock	Measure
	Anticontaminants				
17	Carbenicillin[h]	350	No stock	No stock	Weigh
18	Benomyl[h]	100	No stock	No stock	Weigh
	Sugar				
19	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
20	Water, distilled[i]	To 1000 ml			
	Solidifier				
21	Gelrite[j]	2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin do not dissolve, add a few drops of dilute KOH or HCL, respectively.

[g]Keep refrigerated between uses.

[h]Benomyl preparations obtained from commercial nurseries usually contain 50% active principle. The remainder is insoluble and inert. Carbenicillin is available from Sigma Chemical Co., (PO Box 14508, St. Louis, MO 63178, USA). To sterilize the anticontaminants, place them togenther in 2 ml 95% ethanol in a vial, shake vigorously, allow to stand for 5 min , and shake again. Repeat this shaking–resting cycle three to four times. Add the mixture to hot, still liquid medium after a vigorous shaking. Wash any powder that remains in the vial into the medium first with another 2 ml portion of 95% ethanol and then several times with sterile distilled water.

[i]Add items 1–6 to 800 ml of distilled water (item 20), adjust pH to 5.7, add sugar (item 19), and adjust volume to 1000 ml with distilled water (item 20). Bring solution to a gentle boil, and add Gelrite (item 21) slowly while stirring. Gelrite can also be added to the cold solution, which is then brought to a boil and stirred. When the Gelrite is completely dissolved, pour solution into a 2-l flask and autoclave. Add anticontaminants (items 17 and 18) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar or Gelrite when preparing liquid medium. Culture media that contain organic additives such as hormones and/or vitamins should not be autoclaved unless prior experimental evidence indicates (as it does in this case) that it can be done without deleterious effects.

[j]Agar or Gelrite are added to solid media only. *Paphiopedilum* explants grow better on media solidified with 2 g Gelrite (Scott Laboratories, Carson, CA 90746, USA).

TABLE PAPH-9. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Paphiopedilum* explants (Huang, 1988)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

20	Gelrite[j]	2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinins do not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]According to Huang (1988) 100 mg l^{-1} of this cytokinin would be toxic for most plants, but not for *Paphiopedilum*.

[i]Add items 1–17 to 800 ml of distilled water (item 19), adjust pH to 5.7, add sugar (item 18), and adjust volume to 1000 ml with distilled water (item 19). Bring solution to a gentle boil, and add Gelrite (item 20) slowly while stirring. Gelrite can also be added to cold solution, which is then brought to a boil and stirred. When Gelrite is completely dissolved, dispense solution into culture vessels and autoclave. Agar or Gelrite are not added to liquid media. Culture media which contain organic additives such as hormones and/or vitamins should not be autoclaved unless prior experimental evidence indicates (as it does in this case) that it can be done without deleterious effects.

[j]*Paphiopedilum* explants grow better on media solidified with 2 g Gelrite (Scott Laboratories, Carson, CA 90746, USA).

TABLE PAPH-10. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the rooting of plantlets derived from *Paphiopedilum* explants (Huang, 1988)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Gelrite[i]	2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of dilute KOH.

[g]Keep refrigerated between uses.

[h]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add Gelrite (item 17) slowly while stirring. Gelrite can also be added to the cold solution, which is then brought to a boil and stirred. When Gelrite is completely dissolved, dispense solution into culture vessels and autoclave. Culture media that contain organic additives such as hormones and/or vitamins should not be autoclaved unless previous experimental evidene indicates (as it does in this case) that it can be done without deleterious effects.

[i]*Paphiopedilum* explants grow better on media solidified with 2 g Gelrite (Scott Laboratories, Carson, CA 90746, USA).

in detail. In brief, this procedure utilizes three steps: Step 1 establishes aseptically growing explants; if contamination is heavy the levels of antibiotics must be increased and time periods between subcultures decreased in step 1. The second step is the multiplication of shoots by enhanced axillary branching, while rooting of shoots and hardening of the plants is the third step.

Developmental Sequence. Explants grow to a length of 1.5–2 cm during step 1 and are freed of contaminants if any. In step 2 the explants branch and multiply. They root in step 3.

General Comments. *Paphiopedilum* sap is allergenic and can cause severe rashes (Hausen, 1984). Therefore plants must be handled with caution. The first few hundred plants produced by this method have flowered and show no abnormalities. It is not clear at present whether this procedure can be used for *Cypripedium*, *Phragmipedium*, and *Selenipedium*.

Culture of *Paphiopedilum* Shoot and Leaf Tips

Shoots of *Paphiopedilum callosum* (Fig. Paph-1G) were removed and surface-sterilized by immersion in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 12 min. All except the two innermost chlorophyll-free leaves were excised after that (Fig. Paph-1H), and the shoot apex was apparently cultured in a modification of the Thomale GD medium (Table Paph-7). The author (Allenberg, 1976) refers to a "GD-D medium" without giving a reference or composition. Some of the apices cultured in this manner produced PLBs (Fig. Paph-1I*a–c*).

Leaf tips placed on GD-D medium containing l mg IAA and an equal amount of kinetin produced PLBs (Fig. Paph-1J). It is not clear whether the leaf tips were taken from seedlings in vitro or mature plants, and if the latter how they were surface-sterilized.

Induction of Lateral Buds and Plantlets on *Paphiopedilum*

This book deals with in vitro propagation procedures, but since *Paphiopedilum* plants are difficult to propagate in this manner a possible different approach will be mentioned here.

Paphiopedilum plants have been reported to produce shoots and plantlets (keikis) from their roots (Fig. Paph-3; Northen, 1982) and flower stems (Nieman, 1980; Sampolinski, 1983). Attempts to culture *Paphiopedilum* flower-stem tips have failed (Nieman, 1980; unpublished results from our laboratory), but there is no reason to believe that this cannot be done.

Efforts to induce lateral bud development on *Paphiopedilum* plants that have flowers with BA have produced some results (Stewart and Button, 1977*a*, 1977*b*). Single applications of 1 mg BA l^{-1} to leaf axils in "maximal volume . . . without permitting run off onto the supporting medium" induced 1.4 lateral shoots per plant (in an experimental population of five plants) as did four applications of a 10-mg BA l^{-1}

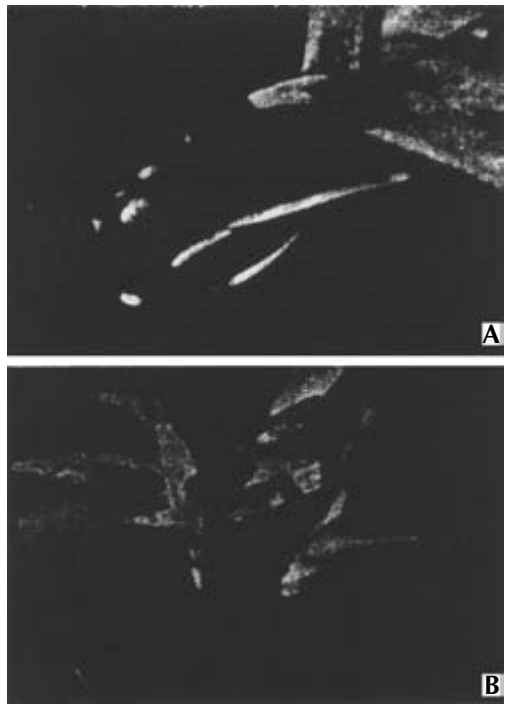

FIG. PAPH-3. **Plantlets on the roots of (A) *Paphiopedilum appletonianum* and (B) *Paphiopedilum callosum*. (Northen, 1982.)**

solution. The control produced only 0.4 shoots. Other treatments brought about, in number of shoots per plant: 1 (four applications of 1 mg BA l^{-1} and one application of 10 mg BA l^{-1}), 1.25 (two applications of 1 mg BA l^{-1}), 1.5 (two applications of 10 mg BA l^{-1}). Statistics are not presented, and it is not clear whether the differences between these numbers are significant.

It is also unclear whether the results are due to factors inherent in the plants or to the BA concentration. The highest concentration, 10 mg l^{-1} (Stewart and Button, 1977*a*) is 250–500 times weaker than the levels employed for *Phalaenopsis* (Abdullah and Arditti, 1983). Another problem with this method (Stewart and Button, 1977*a*) could be the use of an aqueous solution; BA is not water-soluble especially at the recommended levels (Stewart and Button, 1977*b*). A third difficulty may be the autoclaving of the stock solution (Stewart and Button, 1977*b*), which could affect the hormone. On purely speculative grounds it is possible to suggest that a BA paste like the one formulated by K. Zimmer of the University of Hanover and his associates (Abdullah and Arditti, 1983) could be useful.

A paste containing 3750 mg BA l^{-1} can be prepared as follows: Dissolve 440 g Vaseline (which can be purchased at any drugstore) by placing it in a 2-l beaker that has been placed in a 54°C water bath. Add to the Vaseline 5 g chemically pure parafin oil (liquid petrolatum), 9 g stearyl alcohol, and 20 g Tween 20. (These three ingredients can be obtained from Sigma Chemical Co., St. Louis, MO 63178, USA.) Stir all components well.

After that bring the mixture to a volume of 1 liter with distilled water while stirring vigorously and again mixing well. Dissolve 3.75 g (3750 mg) BA in 10–50 ml ethyl alcohol; add this to the mixture, which must be stirred well during the entire preparation. Pour the liquid mixture into containers, and store in a refrigerator at 4°C. BA concentrations can be varied by changing the amount added to the Vaseline–parafin oil–stearyl alcohol–Tween-20 mixture. This paste can be applied to flower stems, axillary buds, and roots, but we are not sure if it will be effective. More research is needed in this area. It may be wise to carry out experiments with lower concentrations at first (e.g., 1, 10, 100, 250, 500, 1000, 1500, and 2000 mg l^{-1}) before using concentrations of 3000, 3500, 3750 mg l^{-1} or more. These experiments should not be carried out with rare and/or expensive plants.

Protoplast Isolation from *Paphiopedilum villosum*

"Very few" protoplasts were isolated from yellow brown petals of *Paphiopedilum villosum* by the method used for *Angraecum eburneum (Angraecum giryamae*) and *Dendrobium* (Price and Earle, 1984).

Isolation of *Paphiopedilum* Protoplasts

The method developed for *Acampe praemorsa* was used to isolate 0.4×10^4 protoplasts from leaves of *Paphiopedilum drurii* (Seeni and Abraham, 1986).

Isolation of Mesophyll Protoplasts of *Paphiopedilum insigne*

Procedures developed for *Calanthe*, *Cymbidium*, *Dendrobium*, *Epidendrum*, and *Phalaenopsis* can be used for *Paphiopedilum insigne* (Yasugi et al., 1986).

Plant Production from Callus Cultures of *Paphiopedilum*

Since "seed setting and germination . . . of many [*Paphiopedilum*] cultivars and hybrids are extremely low" and "efforts to develop tissue culture methods have been without much success (Stewart and Button, 1975 . . . [because] a few plantlets occasionally regenerate from shoot apex-derived callus in an undefined medium, but the calli are difficult to maintain and eventually fail to survive during subcultures (Stewart and Button, 1975) . . . development of protocols for rapid and large scale clonal multiplication of selected elites is of considerable commercial value" (Lin et al., 2000). Such "a repeatable procedure" for the production of "normal plants of a *Paphiopedilum* hybrid from sub-cultured protocorm-derived calli" was developed at the Institute of Botany, Academia Sinica, Taipei, Taiwan (Lin et al., 2000).

Plant Material. Paphiopedilum seeds of the cross *Paphiopedilum callosum* "Oakhill" × *Paphiopedilum lawrenceanum* (Fig. Paph-4I) "Tradition" (this is actu-

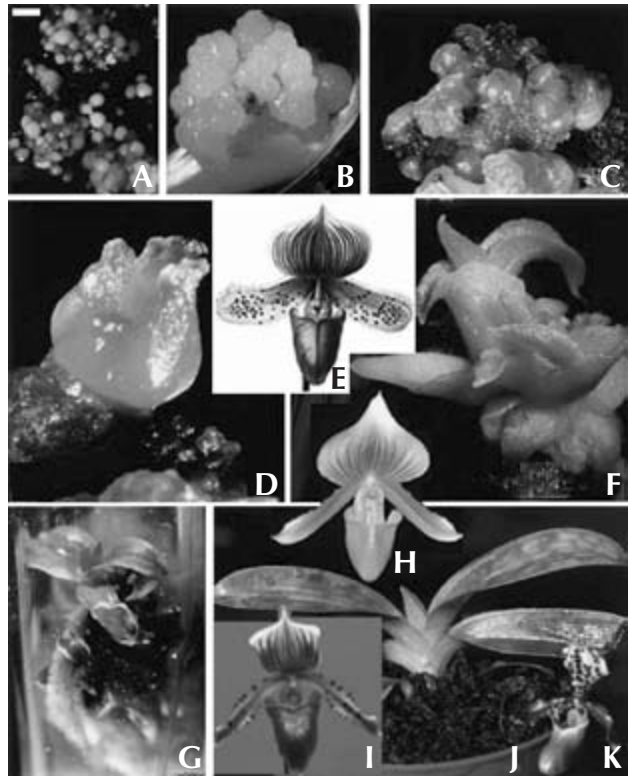

FIG. PAPH-4. **Tissue culture of *Paphiopedilum*. A. Three-month-old protocorms (scale bar = 7.2 mm). B. Subcultured protocorm-derived green callus. C. Green PLBs. D. PLBs starting to form a plantlet. E. Multicolored *Paphiopedilum* Maudiae. F. Plantlet. G. Plantlet with roots and several leaves. H. Green-colored *Paphiopedilum* Maudiae. I. *Paphiopedilum lawrenceanum*. J. Plant in sphagnum. K. *Paphipedilum henryanum*. (Sources: A–D, F, G, J, Lin et al., 2000; E, H, I, K, World Wide Web.)**

ally *Paphiopedilum* Maudiae, Fig. Paph-4E, H) from immature ("green") capsules were germinated on half-strength MS medium (Murashige and Skoog, 1962) containing 20 g sucrose and solidified with 2.5 g Gelrite l^{-1}. The cultures were maintained for 3 months at 25 ± 1°C under 10 μmol m^{-2} s^{-1} (photoperiods not described) provided by 40-W fluorescent tubes FL-30D/29 (China Electric Co., Taipei). Protocorms derived from seeds in these cultures were used to induce callus formation. Stems, root tips, and green leaves of in vitro seedlings of *Paphiopedilum henryanum* (Fig. Paph-4K) no. 1 × *Paphiopedilum philippinense* from a commercial source were also used as explant sources but they failed to produce callus.

Surface Sterilization. Protocorms and explants taken from seedlings in vitro do not require surface sterilization. However, they should be washed with sterile distilled water to remove medium residues.

Culture Vessels. Culture tubes, 20 × 150 mm containing 10 ml medium were used in the original research. Other containers filled with medium to 20–30% of their capacity are also suitable.

Culture Conditions. In the original research the cultures were maintained at 26 ± 1°C in darkness or under 16-h photoperiods of 28–36 μmol m^{-2} s^{-1} provided by 40-W daylight fluorescent tubes FL-30D/29 produced by China Electric Co., Taipei.

Culture Media. Protocorms form callus on modified half-strength MS medium (Murashige and Skoog, 1962) containing 0.1 mg TDZ l^{-1} and 10 mg 2,4-D l^{-1} (Table Paph-11). This callus should be subcultured and maintained on half-strength MS supplemented with 1 mg TDZ l^{-1} and 5 mg 2,4-D l^{-1} (Table Paph-12). PLBs and eventually plantlets will also be produced on this medium. Plantlets which reach a height of 10 mm should be moved to basal half-strength MS supplemented with potato mash (Table Paph-13). When plantlets grow to 4–5 cm in height they should be planted in sphagnum and "acclimated in a greenhouse."

Procedure. Protocorms (Fig. Paph-4A) are placed on the first medium (Table Paph-11) and cultured in the dark for 3 months. Callus produced on this medium is subcultured in the light on the second medium (Table Paph-12; Fig. Paph-4B). PLBs (Fig. Paph-4C) are cultured on the same medium until plantlets are formed (Fig. Paph-4F, G). These plantlets are moved to sphagnum (Fig. Paph-4J).

Developmental Sequence. Protocorms (Fig. Paph-4A) form callus after 3 months in the dark on the first medium (Table Paph-11). This callus turns green (Fig. Paph-4B) and forms PLBs (Fig. Paph-4C), vegetative buds (Fig. Paph-4D), and plantlets (Fig. Paph-4F, G) on the second medium (Table Paph-12). Plantlets develop normally (Fig. Paph-4J) on the third medium (Table Paph-13).

General Comments. This procedure is a major step forward in tissue culture of *Paphiopedilum*. It may serve as a starting point for methods for adult plants, but cannot be used to propagate cultivars because seed derived protocorms are used to start the cultures.

The active principle in household bleaches (Clorox, Purex, Domestos, and other brand names) is sodium hypochlorite. Its concentration varies with the brand. Clorox is probably most commonly used to surface-sterilize explants. At one time it contained 5.25% sodium hypochlorite, but the concentration was increased to the current 6% a few years ago.

TABLE PAPH-11. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for callus production by *Paphiopedilum* protocorms (Lin et al., 2000)**

17	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]Add items 1–8, 10, and 16 to 900 ml of distilled water (item 18), adjust the pH to 5.2, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Add the Gelrite (item 19) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 9), hormones (items 11, 12), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

TABLE PAPH-12. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for *Paphiopedilum* callus maintenance and plantlet production (Lin et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]Add items 1–8, 10, and 16 to 900 ml of distilled water (item 18), adjust the pH to 5.2, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Add the Gelrite (item 19) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 9), hormones (items 11, 12), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels.

TABLE PAPH-13. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for culture of *Paphiopedilum* plantlets (Lin et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2{\cdot}2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4{\cdot}7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	Monosodium phosphate, NaH_2PO_4	170.0	17.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4{\cdot}7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	31.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2{\cdot}6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4{\cdot}5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4{\cdot}4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4{\cdot}2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4{\cdot}7H_2O$	4.3	430.0 mg l^{-1}		
	Complex additive				
9	Potato mash[e]	20.0 g	No stock	Weigh	
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Gelrite[g]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]The original paper only states "fresh potato mash." Therefore it is not clear if this is freshly mashed cooked (probably peeled) potatoes or freshly homogenized (probably peeled) raw potatoes.

[f]Add items 1–8, to 850 ml of distilled water (item 11) in a homogenizer, dice the potatoes into cubes measuring $1 \times 1 \times 1$ cm, and add them to the other components, homogenize the mixture until the potatoes completely mashed, adjust the pH to 5.2, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Add the Gelrite (item 12) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite from several sources] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

---

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

Method for Clonal Propagation of *Paphiopedilum*

It would not be unreasonable to assume that after the brouhaha (or perhaps fiasco is a better word) which followed the attempt to patent orchid micropropagation (see Chapter 1) no one would try a patent again. But, Tian Su Zhou (of Nitta-machi, Japan) and Michio Tanaka (of Kagawa-ken, Japan) as inventors for Sapporo Breweries Limited, Tokyo Japan patented an "invention [which] provides a method for clone-multiplication of a *Paphiopedilum*" (United States Patent 6,060,313). Frankly, it is hard to see how such a patent can be enforced. The method is presented here strictly and only for information and not as an inducement or a suggestion, or even an implication, that attempts should be made to utilize it without permission from the patent owners.

Plant Material. Statements in the patent paper are vague, broad, or not very clear. That is why it is necessary to use direct quotes in presenting information. The "starting material is a scape terminal bud derived from a blooming stock or a bud before blooming or a young axillary shoot . . . A scape terminal bud enclosed in a floral bud before blooming is preferably selected as a starting material since it exhibits a higher survival rate after sterilization of the surface . . . A scape terminal bud or an axillary shoot obtained by a non-aseptic method as mentioned above is employed as a starting material after sterilizing the surface, while [sic, whereas is the proper word to use here] an aseptic shoot obtained by an aseptic cultivation is employed as it is . . . Cross-sectional pieces can be prepared from an aseptic shoot obtained from the scape terminal bud or axillary shoot cultivation . . . A scape terminal bud of a blooming stock of *Paphiopedilum* Sharmain and a bud of a stock before blooming were taken . . . Cross-sectional pieces from an aseptic shoot, a viable plant of a hybrid ***Paphiopedilum*** . . . which had been grown by an aseptic cultivation to the stage of 3 to 5 developed leaves . . . cutting as aseptic shoot containing a number of axillary buds." There is also a claim which refers to "a scape terminal bud or an axillary shoot . . . or an aseptic shoot . . . scape terminal bud . . . derived from a floral bud." And, the disclosure mentions "scape terminal bud or an axillary shoot . . . or an aseptic shoot . . . cut into cross sectional pieces." These statements seem to suggest the use of: (1) apical meristems taken from inflorescences or shoots; (2) perhaps flower buds; and (3) cross sections of shoots from plants growing in pots and in vitro.

Surface Sterilization. Floral buds should be washed with running water and a mild detergent and rinsed with distilled water. Following the rinse the buds should be washed three times with 70% ethanol (73–74 ml of 95% ethanol made up to 100 ml with distilled water), submerged in 70% ethanol for 10 min, and rinsed several times with sterile distilled water. After that the buds should be shaken for 10 min in saturated calcium hypochlorite (for preparation see the Liquids section under Sterilization in Chapter 2; this sterilant is also known as Wilson's solution) which contains 0.1% Tween 20 (www.sigmaaldrich.com, www.fishersci.com, www.vwr.com, www.thomassci.com, www.duchefa.com) or a few drops of baby shampoo and washed a few times with sterile distilled water. This process will probably damage the outer tissue layers, but it will not affect the inside of the bud.

Culture Vessels. Culture tubes 2.5 × 15 cm containing 8 ml medium, are listed in an example given in the patent. Rockwool (www.hummert.com, www.bghydro.com are two possible sources; additional sources can be found by using a search on the World Wide Web) plugs, 20 × 3 mm, should be placed in the test tubes before pouring medium into them. Erlenmeyer flasks and other containers, also containing Rockwool support of appropriate size, filled to 25–30% of their capacity with medium are also suitable.

Culture Conditions. Explants should be maintained at 25 ± 2°C under 16-h photoperiods (the acceptable range is 16–24 h) of 1700 lx (1000–4000 lx can be used). The patent does not specify a light source. Standard culture room conditions are also suitable.

Culture Media. Half-strength modified MS medium (Murashige and Skoog, 1962) containing 0.5 mg NAA l^{-1}, 3 mg BA l^{-1}, 10 mg adenine l^{-1}, 800 mg polyvinylpyrrolidone (PVP) l^{-1}, 20 g sucrose l^{-1}, and 15% coconut water (CW) solidified with 2 g Gellan gum l^{-1} (Table Paph-14) should be used for scape terminal buds and "bud of a stock before blooming" (this probably means a young flower bud, but it is hard to be certain; "stock" may be a misspelled "stalk," but one cannot be sure). A slightly different version of half-strength MS should be used to culture cross sections of shoots taken from aseptically grown plants. This medium contains 1 mg NAA l^{-1}, 3 mg kinetin l^{-1}, 10 ml adenine l^{-1}, 800 mg PVP l^{-1}, 15 g sucrose l^{-1}, and 15% CW solidified with 2 g Gellan gum l^{-1} plus 6 g agar l^{-1} (Table Paph-15). There are no recommendations in the patent document for a medium on which to culture plantlets that may be produced on the starting media (Tables Paph-14 and Paph-15). An appropriate culture solution for such plantlets is medium RE (Table Paph-16) which was formulated by Dr. Robert Ernst of the University of California, Irvine (Ernst, 1982; it is actually very similar to the Thomale GD medium).

Procedure. The part of the patent document which describes the procedure is not very clear: "The scape terminal bud of the blooming stock [sic the word probably should be 'stalk' which means stem] and the scape terminal bud isolated from the sterilized floral bud of the stock [sic] before blooming thus obtained were processed while reserving the scales at 0.5 cm from the base of the scape terminal bud." The word "processes" is probably intended to mean "cultured." And "in the cultivation of the cross sectional pieces from an aseptic shoot, a viable plant of a hybrid . . . was employed as . . . material, which was processed, after removal of the root, into 5 sections per seedling, each having a thickness of about 2 mm, by cutting the shoot into round slices from its base. Thus, the cross-sectional pieces thus obtained were embedded on [the] medium . . ."

Developmental Sequence. Shoots formed on both explants after 3 months of culture.

General Comments. The patent document is vague, unclear, and does not contain enough details to make possible the presentation of a workable method. But this does not really matter because the procedure is presented here for information only,

TABLE PAPH-14. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of scape terminal buds of *Paphiopedilum* (Zhou and Tanaka, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

20	Gellan gum[i,j]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively. Adenine can be solubilized with a few drops of 0.1 N H_2SO_4.

[g]Polyvinylpyrrolidone (PVP), a catalytically produced polymer of purified 1-vinyl-2-pyrrolidone, occurs as a white to tan powder. It is soluble in water, in alcohol, and in chloroform and insoluble in ether. The pH of a 1 : 20 aqueous solution is between 3 and 7. PVP is used as clarifying agent, separation and filtration aid, stabilizer, adsorbent, bodying additive, tableting compound, dispersant, and to coat fresh fruit.

[h]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[i]Add items 1–9 and 16 and 17 to 700 ml of distilled water (item 19), adjust pH to 5.5, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 19). Add the Gellan gum (item 20) in accordance with the instructions in footnote *j*. When the gellan gum is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10–12), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

[j]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE PAPH-15. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of shoot cross sections of *Paphiopedilum* (Zhou and Tanaka, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively. Adenine can be solubilized with a few drops of 0.1 N H_2SO_4.

[g]Polyvinylpyrrolidone (PVP), a catalytically produced polymer of purified 1-vinyl-2-pyrrolidone, occurs as a white to tan powder. It is soluble in water, in alcohol, and in chloroform and insoluble in ether. The pH of a 1 : 20 aqueous solution is between 3 and 7. PVP is used as clarifying agent, separation and filtration aid, stabilizer, adsorbent, bodying additive, tableting compound, dispersant, and to coat fresh fruit.

[h]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[i]Add items 1–9 and 16 and 17 to 700 ml of distilled water (item 19), adjust pH to 5.5, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 19). Add the gellan gum (item 20) in accordance with the instructions in footnote *j*. When the gellan gum is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10–12), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

[j]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE PAPH-16. **Modified Robert Ernst (RE) medium (Ernst, 1982) for the culture of *Paphiopedilum* plantlets**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400.0	40.0 g l^{-1}	10	
2	Ammonium sulfate $(NH_4)_2SO_4$[b]	150.0	15.0 g l^{-1}	10	
3	Calcium nitrate, $Ca(NO_3)_2$[b]	150.0	15.0 g l^{-1}	10	
4	Magnesium nitrate, $Mg(NO_3)_2 \cdot 6H_2O$[b]	100.0	10.5 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	300.0	30.0 g l^{-1}	10	
6	Potassium phosphate (monobasic), KH_2PO_4	300.0	30.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Complex additive				
8	Ripe banana pulp homogenate (BN)[d]	100.0 mg	No stock	No stock	Weigh
	Darkening agent				
9	Vegetable charcoal[e]	2.0 g	No stock	No stock	Weigh
	Sugar				
10	Fructose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	16.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. This medium is similar to the Thomale GD solution (Thomale, 1954, 1957) which can be used in its place (Table Paph-7). The RE medium was formulated by Dr. Robert Ernst who named it after himself.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe of the RE medium calls for 25 mg of $FeSO_4 \cdot SO_4$, but chelated iron is preferable. The difference between 25 and 27.8 mg (2.8 mg) $FeSO_4$ is insignificant and can be ignored. The Thomale GD medium contains 20 mg $FeSO_4$ l^{-1}.

[d]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable; (2) the peel rather than the pulp should be used; (3) unpeeled banana homogenate should be incorporated in media; and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective banana variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and/or use what is suggested there.

[e]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite which are very different in nature should be used only if required by a specific procedure or except under special circumstances.

[f]Dissolve items 1–7 in 600 ml of distilled water (item 11) in a homogenizer, add banana (item 8) and charcoal (item 9), homogenize for 1 min, stop and homogenize again for 1 min, add sugar and homogenize for another minute, bring volume to 1000 ml and homogenize for 30 s and adjust pH to 5.0–5.4. Heat to 80–90°C and add the agar (item 12) slowly while stirring. When the agar has dissolved completely dispense the medium into culture vessels and autoclave. The Thomale GD medium contains 10 g l^{-1} each of fructose and glucose and does not include banana homogenate, charcoal, and calcium nitrate.

not to encourage infringement of the patent. What this patent suggests is that a method for clonal propagation of *Paphiopedilum* can be formulated. However it is also possible that this method may not be practical because as this is being written (February 2003) there are no reports of mass clonal propagation of *Paphiopedilum* by commercial or hobby laboratories.

Paphiopedilum Cloning in Vitro

Freeing explants from contaminants has been the major obstacle in developing micropropagation methods for *Paphiopedilum*. That is why *Paphiopedilum* is the only orchid of major commercial and hobby interest which is being cloned routinely in vitro. Contaminants can be excluded by using very small explants but their survival is low and multiplication is limited (Huang, 1988). Another problem with research on cloning of *Paphiopedilum* is the availability and high value of mature plants. These problems were circumvented by using aseptically grown seedlings as explant sources (Huang et al., 2001).

Plant Material. Seedlings in flasks of *Paphiopedilum* Billy Cardalino (*Paphiopedilum philippinense* × *Paphiopedilum* Susan Booth) obtained from a commercial grower in Taiwan were used as explant sources for initial experiments. Findings with these explants were tested with seedlings of *Paphiopedilum bellatulum* "Big Spot" × *Paphiopedilum* Joanne's Wine and *Paphiopedilum* Taida Glaucothum (*Paphiopedilum micranthum* × *Paphiopedilum glaucophyllum*). Each of the flasks obtained from the commercial grower contained 25 seedlings. The seedlings consisted of one shoot, 1.5–2.5 cm in height, each. To increase their number these plants were cultured on shoot multiplication medium (Table Paph-9) at 26 ± 2°C under 16-h photoperiods of 26 μmol m^{-2} s^{-1} provided by cool white fluorescent lamps. "Clusters of three 4 cm tall plants served as explants for experiments . . ."

Surface Sterilization. Aseptically grown seedlings do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, 500-ml capacity, containing 125 ml medium should be used. Other containers are also suitable.

Culture Conditions. Explants should be cultured at 26 ± 2°C under 16-h photoperiods of 26 μmol m^{-2} s^{-1} provided by cool white fluorescent lamps.

Culture Media. For proliferation the seedlings should be cultured on a modified MS medium (Murashige and Skoog, 1962) with higher vitamin concentrations (Murashige and Tucker, 1969), 13 μmol BA l^{-1}, 1.6 μmol NAA l^{-1}, 0.15 μmol adenine sulfate dihydrate l^{-1}, 1.28 mmol $NaH_2PO_4 \cdot H_2O$ l^{-1} and 15% (v/v) coconut water *or* 1 g casein hydrolysate l^{-1} *or* 10 g potato tuber sections l^{-1} (Table Paph-17). Plantlets produced on this medium can be grown to a larger size on the Thomale GD (Table Paph-7; Thomale, 1954, 1957) or RE (Table Paph-16; Ernst, 1982) media.

Procedure. When enough seedlings become available clusters of three 4-cm-tall plantlets should be cultured on the first medium (Table Paph-17) for 6 weeks. Plants produced during this period should be subcultured in the same medium once or twice to increase their number. When the new plantlets start crowding the flask they should be separated from each other and cultured on the Hans Thomale GD (Table Paph-7) or Robert Ernst RE (Table Paph-16) medium or moved to community pots.

TABLE PAPH-17. **Modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for cloning of *Paphiopedilum* seedlings (Huang et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10

17	Potato tuber sections[g–i]	10.0 g[f]	No stock	No stock	Weigh[f]
	Sugar				
18	Sucrose	61.61 g	No stock	No stock	Weigh, 0.18 mol l^{-1} (MW is 342.30). Amount is higher than in other media
	Solvent				
19	Water, distilled[j]	To 1000 ml			
	Solidifier				
20	Gelrite[j,k]	10.0 g	No stock	No stock	Weigh

Developmental Sequence. The seedlings grow and proliferate on the modified MS medium (Table Paph-17). They only increase in size on the GD (Table Paph-7) and RE (Table Paph-16) media.

General Comments. This procedure can be used to increase the number of seedlings, but not to propagate selected clones. As a rule there are two obstacles in the development of a micropropagation method. One is an effective surface sterilization procedure which does not damage the explants. The second is a suitable culture medium. By formulating an appropriate medium this method can serve as a starting point for the development of more effective protocols for the cloning of mature plants. Given the high cost of selected *Paphiopedilum* clones such a protocol should utilize explants which do not endanger the original plant like leaf or flower-stem sections.

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]If coconut water from very young nuts (less than 1.2 kg in weight at harvest) is available 15% (v/v) should be used in preference to potato tuber sections which are listed. Casein hydrolysate, 1 g l^{-1}, can also be used. Potato tuber sections are recommended here because potatoes are less expensive than casein hydrolysate (see footnote *h*) and more readily available than coconut water from very young nuts (see footnote *i*) in many parts of the world. No indication is given if the potatoes were peeled before use, but peeling then is advisable. The paper states that "potato tuber sections were obtained from freshly purchased potatoes. The tubers were diced into small cubes [size not indicated, 0.5–1 cm would be appropriate], weighed and added before incorporating 0.25% Gelrite™ (Kleco) and autoclaving." An interesting speculation is whether homogenizing the potatoes might not be better.

[h]Not all casein hydrolysates are the same. Their compositions and analyses vary depending on the methods by which they were produced. A product sold by Merck (www.merck.de) as casein hydrolysate (CH) is obtained by degrading casein with hydrochloric acid; vitamins and other growth-promoting compounds are largely destroyed in this process. The CH sold by Sigma-Aldrich (www.sigmaaldrich.com) is pancreatic hydrolysate of casein. There is also a CH which is hydrolysed by enzymes. Becton, Dickinson and Company (www.bd.com) sells Difco products including a number of different casamino acid products all of which are casein hydrolysates. Therefore if a method specifies a source for the CH in its culture medium it is best to obtain the additive from the same vendor. If a source is not listed it is best to purchase CH which is described as being suitable as a supplement for culture media. Failing that, CH should be purchased from a source which specializes in tissue culture and micropropagation supplies. One such source is www.caissonlabs.com. They list casein rather than CH as Stock #: SPCA205. Another source for CH is www.duchefa.com (item 1301). Additional sources include www.fishersci.com, www.thomassci.com, and others. The casein hydrolysate used in the original research with *Paphiopedilum* in this case (Huang et al., 2001) was obtained from ICN Biochemicals (www.icinbiomed.com), but there is no indication which of their seven offerings in this area was employed.

[i]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures). In this case coconut water "(liquid endosperm of *Cocos nucifera*) was obtained from green fruits that weighed 1.2 kg or less at harvest. Large volumes were collected at each harvest, filtered through cheese cloth, mixed, divided into convenient aliquots, and frozen until needed."

[j]Add items 1–17 to 8500 ml of distilled water (item 19), adjust pH 5.7, add sugar (item 18), raise volume to 1000 ml with distilled water (item 19), add Gelrite in accordance with the instructions in footnote *k*, and mix well. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave. In the original research the flasks were closed with MEICO gas permeable stoppers obtained from Microwave Enterprises, Taipei, Taiwan.

[k]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear, and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

Plantlet Production from Nodal Explants of *Paphiopedilum*

The importance of *Paphiopedilum* and the difficulties encountered in trying to culture mature flowering plants of species and hybrids of this genus have led to the development of techniques which utilize seedlings as explant sources. One such procedure utilizes nodal explants of stems (Chen et al., 2002*b*).

Plant Material. Nodal segments of stems, 3 mm in length from in vitro grown seedlings of two *Paphiopedilum philippinense* (Fig. Paph-5) hybrids, PH59 and PH60 were cultured.

Surface Sterilization. Seedlings which are growing in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, 20 × 150 mm, containing 10 ml of medium were used in the original research. Other containers are also suitable.

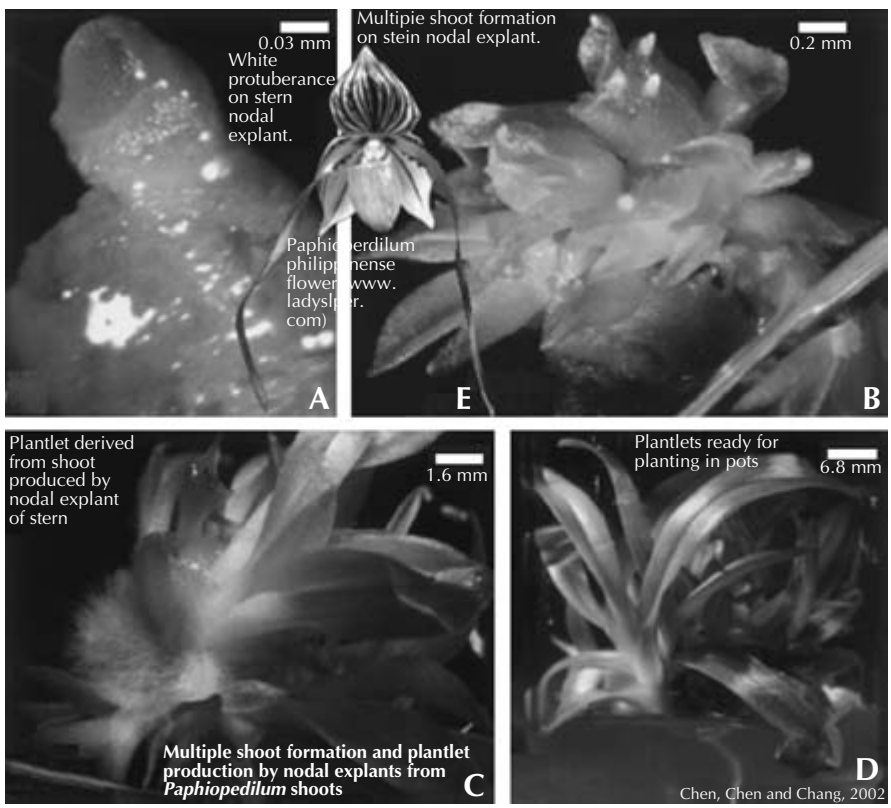

FIG. PAPH-5. **Micropropagation of seedlings of two *Paphiopedilum philippinense* hybrids. (A–D, Chen et al., 2002*b*. E, www.ladyslipper.com.)**

Culture Conditions. Cultures were maintained at 26 ± 1°C under 16-h photoperiods of 28–38 μmol m^{-2} s^{-1} provided by 40-W daylight fluorescent tubes FL-30D/29 (China Electric Co., Taipei, Taiwan). Standard culture room conditions should also prove to be suitable.

Culture Media. The basal medium should be half-strength MS medium (Murashige and Skoog, 1962) containing 170 mg NaH_2PO_4 l^{-1} and 1 g peptone l^{-1} and solidified with 2.2 g Gelrite l^{-1}. When this medium is supplemented with 4.52 μmol 2,4-D l^{-1} and 0.45 μmol TDZ l^{-1} both hybrids will produce the highest percentage of shoots (66.7 and 80%, respectively, for PH59 and PH60). Hybrid PH59 will also produce the highest number of shoots per explant (1.5) on this medium (Table Paph-18). The other hybrid, PH60 will produce the highest number of shoots per explant on a medium with only 4.52 μmol 2,4-D l^{-1} (Table Paph-19). Shoots should be cultured on hormone-free basal medium (Table Paph-20) for rooting.

Procedure. Explants, 3 mm long and each containing one node, of hybrid PH59 should be placed on the surface of the first medium (Table Paph-18) to induce shoot formation. The explants of PH60 should be placed on the second medium (Table Paph-19). When shoots form they should be transferred to the hormone-free medium (Table Paph-20) for plantlet development. Once the plantlets are large enough they should be potted in sphagnum moss and grown in a greenhouse.

Developmental Sequence. Small white protuberances appear on the explants after 2 weeks of culture (Fig. Paph-5A). Multiple shoots (Fig. Paph-5B) form after 22 weeks of culture without subculture. All of these shoots develop into plantlets (Fig. Paph-5C) after 3 months of culture on hormone-free medium. When these plantlets grow to an appropriate size (Fig. Paph-5D) they should be potted in sphagnum moss for further development.

General Comments. Like other protocols which employ explants from seedlings, this procedure cannot be used to propagate selected plants or specific clones. It can be used to increase the number of seedlings and could serve as a starting point for the development of micropropagation methods for mature plants (Fig. Paph-6).

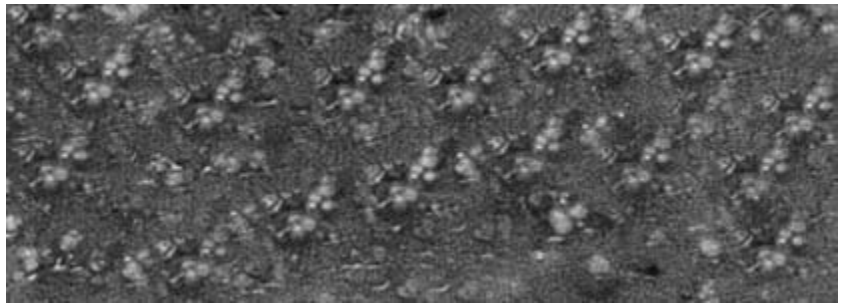

FIG. PAPH-6. **Germinating seeds and young seedlings of *Paphiopedilum* (computer enhanced image taken from http://perso.club-internet.fr/baruk/home/iv.htm).**

TABLE PAPH-18. **Modified half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of *Paphiopedilum philippinense* hybrid PH59 explants (Chen et al., 2002*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
16	Peptone	1.0 g	No stock	No stock	Weigh
	Sugar				
17	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Add the Gelrite (item 19) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved distribute the medium into culture vessels and autoclave.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite (item 19)] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE PAPH-19. **Modified half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of *Paphiopedilum philippinense* hybrid PH60 explants (Chen et al., 2002*b*)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

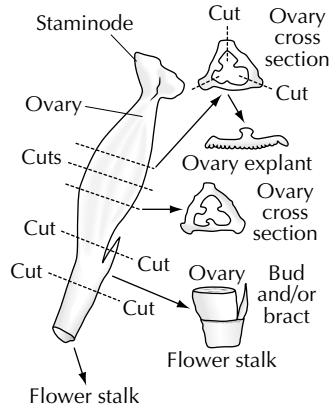
[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Add the Gelrite (item 17) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved distribute the medium into culture vessels and autoclave.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite (item 17)] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

Clonal Propagation of *Paphiopedilum* by Tissue Culture

Ovaries, flower stalks, and undeveloped flower buds of flower stalks from *Paphiopedilum* cultivars were cultured in vitro for the purpose of clonal propagation. Bacterial contamination of explants was not experienced to any degree. The rapid growth of the white material was observed on the segments of the ovaries from the open flowers, but most of it turned brown soon after and subsequently died. In the case of the non-open flowers, growth was slow, but the material produced callus-like tissue on which plantlets were then formed. Observation under a light microscope revealed that it was obvious that the white material was formed by the ovules and placenta that increased in size. The undeveloped flower buds proved to grow into a plantlet, although small in number, in the culture from the flower stalks of both open and non-open flowers. No growth was recognized on the segments of the flower stalks. The best response for clonal propagation by using ovaries and undeveloped flower buds was achieved on Vacin and Went medium containing 5 mg/l NAA, 10 mg/l BA, 20 g/l sucrose, and 8 g/l agar. (Kawase, 1990)



Ovary and flower stalk explants (Kawase, 1990).

Plant Material. "Ovaries, flowers stalks and undeveloped flower buds" were used (Kawase, 1990).

Surface Sterilization. Wash plant material with mild detergent, running water and a toothbrush, rinse with distilled water, dip in 70% ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) for 5–10 s, rinse with sterile distilled water and immerse in 5% household bleach (v/v) for 15 min, and rinse three times with sterile distilled water.

Culture Vessels. Culture tubes, 10.5 × 100 mm, filled with culture medium to 20–30% of their volume, were used in the original research. Other containers are also suitable.

Culture Conditions. In the original research the cultures were maintained at 25°C under 3000 lx illumination. Standard culture room conditions should also prove to be suitable.

Culture Media. Vacin and Went (VW) medium (Vacin and Went, 1949) containing 5 mg NAA l^{-1} and 10 mg BA l^{-1} (Table Paph-21) gave the best results with ovaries and undeveloped flower buds. Plantlets produced on this medium could be cultured to pot size on the RE medium (see Table Paph-16).

Procedure. The plant material is washed and sectioned and the sections should be placed in culture on the first medium (Table Paph-21). Callus and plantlets which form on this medium (Table Paph-21) can be subcultured on it. Plantlets can also be moved to the RE medium (see Table Paph-16).

TABLE PAPH-21. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of *Paphiopedilum* explants (Kawase, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	1-Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	6-Benzyladenine (BA)	10.0	1000 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[g]	To 1000 ml			
	Solidifier				
11	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 9) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the auxin and/or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl respectively.

[f]Keep frozen between uses.

[g]Add items 1, 3–9 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 3), bring volume to 900 ml with distilled water (item 10), adjust pH to 5–5.4, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable. Hormones (items 8, 9) are heat labile and are often added after autoclaving to the still hot and liquid solution under sterile conditions with sterilized pipettes, mixed well and the medium is distributed to preautoclaved culture vessels. In this case all components are added before sterilization.

Developmental Sequence. Segments of ovaries from opened flowers produce a "white material" which grows rapidly at first, but eventually turns brown and dies. Ovary segments from unopened flowers produce a "callus-like-tissue" which produced plantlets. Also, a small number of undeveloped flower buds produced plantlets as did flower-stalk explants.

General Comments. By using ovary and stem sections and flower buds as explants this procedure eliminates the two major problems (surface sterilization difficulties and endangering expensive plants) which have hindered the micropropagation of

Paphiopedilum. Despite producing a relatively small number of clones the method seems to be very useful. It has not attracted the attention it deserves because it was not published in English and in a widely distributed journal. It would be interesting to identify the tissue in the ovary explants which gives rise to callus and to count the chromosomes in the plants which are produced by it. Another point to consider is the level of BA used in the medium. It is relatively high and could cause undesirable mutations. Altogether this work is a major advance in the quest for a micropropagation method for *Paphiopedilum*.

Plant Regeneration through Bud Formation from Leaf Explants

Success with *Paphiopedilum* tissue culture protocols has been and, as this was being written, continues to be limited. A procedure using leaf explants was developed in an attempt to remedy the problem (Chen et al., 2004).

Plant Material. Whole leaves, 15 mm long, and leaf sections, 5 mm in length, were taken from 3-year-old in vitro seedlings of two *Paphiopedilum philippinense* hybrids (PH59 and PH60) cultured on MS medium (Murashige and Skoog, 1962) which did not contain growth regulators.

Surface Sterilization. Explants taken from plants growing in vitro do not require surface sterilization. However, they must be washed with sterile distilled water to remove medium residues.

Culture Vessels. Culture tubes, 20×150 mm, were used in the original research. Other containers are also suitable.

Culture Conditions. The research cultures were maintained at $26 \pm 1°C$ under 16-h photoperiods of 28–36 $\mu mol\ m^{-2}\ s^{-1}$ provided by daylight fluorescent tubes (FL-30D/29, 40W, China Electric Co., Taipei). Standard culture room conditions may also be suitable.

Culture Media. Modified MS medium (Murashige and Skoog, 1962) was used and supplemented with 2,4-D and TDZ. Intact leaves, leaf segments, and the two hybrids responded differently to 2,4-D and TDZ levels and combinations. Some of the most effective concentrations are high and may be mutagenic. The concentrations suggested here are lower, less effective, and probably not as likely to cause mutations (Tables Paph-22 to Paph-25). Shoots produced on any of these media should be cultured on hormone-free medium (Table Paph-24) to produce plantlets. The Hans Thomale GD (Table Paph-7) and Robert Ernst RE (Table Paph-16) media can probably also be used for plantlet production and to grow them to potting stage.

Procedure. Whole leaves of hybrid PH59 were placed on a medium containing 0.1 mg (0.44 μmol) l^{-1} TDZ (Table Paph-22). A medium containing 1 mg (4.52 μmol) 2,4-D l^{-1} (Table Paph-23) is suitable for hybrid PH60. Hormone-free medium is best for leaf sections of PH59 (Table Paph-24). Only a medium containing 2,4-D and

TABLE PAPH-22. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of whole leaves of *Paphiopedilum philippinense* hybrid PH59 (Chen et al., 2004)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.2, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Add the Gelrite in accordance with instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Agar is not added to liquid media.

[h]Gellan gum [(available as such from www.caissonlabs.com) and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require higher concentrations of gellan gum or additional calcium or magnesium salts. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TABLE PAPH-23. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of whole leaves of *Paphiopedilum philippinense* hybrid PH60 (Chen et al., 2004)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

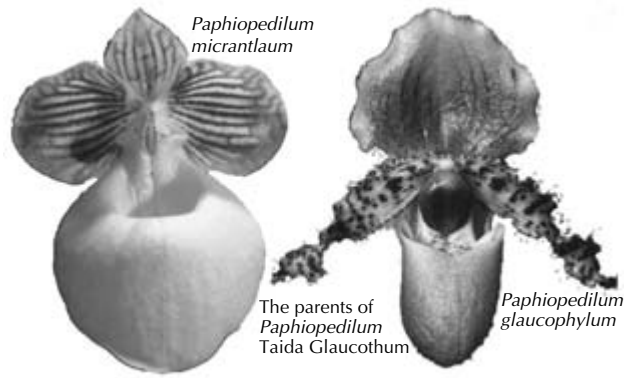
[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Add the Gelrite in accordance with instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Agar is not added to liquid media.

[h]Gellan gum [(available as such from www.caissonlabs.com) and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require higher concentrations of gellan gum or additional calcium or magnesium salts. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave.

TDZ (Table Paph-25) is suitable for leaf sections of PH60. The different responses of whole leaves, leaf sections, and two hybrids of one species suggest that these media (Tables Paph-22 to Paph-25) may or may not be suitable for other *Paphiopedilum* hybrids. If they are not suitable concentrations of TDZ ranging from 0 to 5 mg (0–22.71 μmol) l^{-1} and 2,4-D levels of 0–10 mg (0–45.25 μmol) l^{-1} should be tested singly and in various combinations.

Developmental Sequence. Buds and later shoots and roots are formed on the initial media (Tables Paph-22 to Paph-25) after 150 (entire leaves) and 170 (leaf sections) days in culture. Plantlets ready for potting develop after 22 months on the hormone-free medium (Table Paph-24). Plantlet formation may require a longer or shorter period on the GD (Table Paph-7) or RE (Table Paph-16) media. It is impossible to predict the developmental sequence of other *Paphiopedilum* species and hybrids.

General Comments. The paper which describes this procedure is excellent, like other papers from this laboratory. Its concluding statement that "a reliable protocol via direct shoot formation for *Paphiopedilum* propagation was established" is accurate as it stands. However, given the different responses of two hybrids of one species' whole leaves and leaf sections, it is not possible to predict if this procedure will also be effective with other *Paphiopedilum* plants.



Papilionanthe

See *Vanda*.

Phaius

Joao (Juan) de Loureiro, a Portuguese missionary in Cochin, China named the genus *Phaius* (sometimes spelled *Phajus* which is not correct) in his *Flora Cochinchinensis* in 1790 and taxonomists have been moving taxa in and out of it ever since. Rudolph Schlechter estimated the number of species in the genus as being around 50, but a more recent estimate by James Comber put the count at 30. The genus is distributed from Africa to India, China, South East Asia, New Guinea, Australia, and the Pacific Islands (Comber, 1990, 2002; Bechtel et al., 1992).

Tissue Culture of *Phaius tankervilleae* Flower-stalk Nodes

There are seven *Phaius* species on Java "all of which occur elsewhere" (Comber, 2002). One of these is *Phaius tankervilleae*, which is distributed from India through South and South East Asia to Australia and some Pacific Islands. This species was named in England where it was grown as far back as the 18th century (Comber, 1990), 1788 to be exact (Bechtel et al., 1992). All plants of this species that were studied by one investigator in Java are reported to be autogamous (Comber, 1990). The ones in North Sumatra are not (Comber 2002). Autogamous flowers in Java are described as lacking a rostellum (Comber, 1990). Their pollinia drop into the stigma before anthesis (Gandawijaja and Arditti, 1982) "or as soon as the flowers open. Flowers then immediately hang their heads down as if in shame" (Comber, 1990) and produce fruits (Gandawijaja and Arditti, 1982). A method for the culture of flower-stalk nodes of an autogamous plant was developed at the Bogor Botanical Garden (Kebun Raya, Bogor, Indonesia) by the late Dr. Djunaedi (Adjun) Gandawijaja (1940–1999). The method was never published due to Dr. Gandawijaja's tragic and untimely death after he was struck by a truck on a street in Bogor.

Plant Material. Explants were taken from the basal, non-flower-bearing parts of inflorescences (Fig. Phaius-1A, B).

Surface Sterilization. Stalks should be washed with a soft toothbrush, mild detergent, and running water before being cut into sections, 6–10 cm long with a node in the middle (Fig. Phaius-1C), and rinsed. The sections should be wiped quickly, but thoroughly, with cotton dipped in 95% ethanol or plunged in 70% ethanol for a second or two. After that they should be soaked in saturated (7.15 g 100 ml^{-1} distilled water) solution (see the section on liquid sterilants in Chapter 2) of calcium hypochlorite (Wilson, 1915) for 10 min and rinsed with sterile distilled water. The bracts should be removed following the rinse (Fig. Phaius-1D) and the sections should be placed in saturated calcium hypochlorite solution diluted 1 : 2 (v/v) with sterile

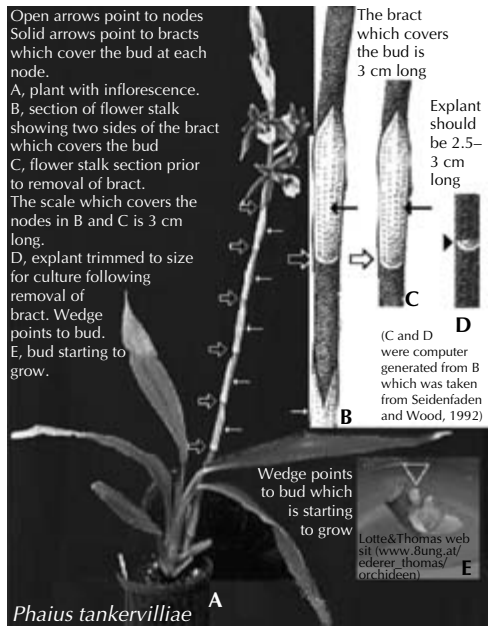


FIG. PHAIUS-1. ***Phaius*** **flower-stalk node culture.**

distilled water for 10 min, rinsed three times with sterile distilled water, and reduced in length to 2.3–3 cm (Fig. Phaius-1D) by cutting sections of the stem on each side of the bud. After this step the bud must be roughly in the center of the section (Fig. Phaius-1D).

Culture Vessels. Erlenmeyer flasks, 250-ml capacity, containing 100 ml of medium were used by Dr. Gandawijaja. Other containers are also suitable.

Culture Conditions. Dr. Gandawijaja maintained his cultures under approximately 12-h photoperiods (Bogor is located at 6° 34′ south and 106° 45′ east, which means that the days are always close to 12 h in length) of normal daylight. Temperature during the day is usually ca. 29°C. The night temperature is 25–26°C. Standard laboratory conditions are also suitable.

Culture Media. Dr. Gandawijaja used solid modified Knop medium (Knop, 1884; Mosich et al., 1973, 1974*a*, 1974*b*) containing 14.8 mg *trans*-cinnamic acid l^{-1} (Table Phaius-1) for the initial culture of the nodes and moved the resulting plantlets to potting medium when they reached a height of 4 cm. It may be wise to subculture the plantlets onto another medium for a while to obtain more vigorous growth. Suitable media are one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1), or the Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6,

TABLE PHAIUS-1. **Modified Knop medium for the culture of *Phaius tankevilliae* flower stalk nodes (D. Gandawijaja, unpublished)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

8	Thiamine (vitamin B_1)	0.4	40 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
9	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[h]	To 1000 ml			
	Solidifier				
11	Agar[h]	13.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. In his unpublished manuscript Dr. Gandawijaja refers only to "solid Knop's medium." He may have used a medium similar to the one he employed for *Dendrobium* nodes (see Table Den-19), but without cytokinins. The assumptions about Dr. Gandawijaja's medium are based on a conversation with him on the subject.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original formulation uses 10 mg ferric citrate, $FeC_3H_5O_7 \cdot 3H_2O$ l^{-1}, but chelated iron is preferable.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispenses volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect. The initial modification of the Knopp medium contains a different combination of microelements than the one used by Dr. Gandawijaja, but the formulation (from the MS solution) suggested here is used very commonly, has proven its suitability for many orchids, and is preferable.

[e]Keep frozen between uses.

[f]If the anti-auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]It is not clear whether Dr. Gandawijaja used this vitamin in his solution. Thiamine is recommended here because it is part of the initial modification, it may be required, and its presence can do no harm.

[h]Add items 1–6 to 900 ml of distilled water (item 10), adjust pH to 5.2–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the anti-auxin (item 7) and vitamin (item 8) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. The addition of 13 g agar l^{-1} will cause the medium to be more solid than usual. Agar is not added to liquid media.

Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that does contain this darkening agent (see Table Pln-1, footnote *f*).

Procedure. The stalk is washed following its removal from the plant; it is then surface-sterilized, sectioned, and placed in culture. The plants can be allowed to reach a height of approximately 4 cm on the original medium and then potted. Or, preferably, they can be moved to another medium (Knudson C with banana homogenate for example) on reaching a height of 2 cm where they are grown until they become vigorous, develop a few roots, and reach a height of 4–6 cm before being moved to pots.

Developmental Sequence. Nodes can be expected to produce shoots approximately 20 days after being placed in culture. The first root can be seen following approximately 45 days of culture and the second and third roots, 5 days after that. The plantlets reach a height of 4 cm after 90 days.

General Comments. The advantage of this procedure is that the taking of explants does not endanger the original plant. It also allows the flowers to be enjoyed before the stalk is harvested.

Dr. Djunaidi (Adjun) Gandawijaja was in the process of trying to develop a callus-inducing procedure when fate took him away from the laboratory, his wife Tatin, and daughters Iin and Wulan. He was born in Sumedang, Java, Indonesia on July 12, 1940 and was killed in a traffic accident in Bogor, Java, Indonesia on May 7, 1999. I visited his widow in Bogor several times to offer condolences and support. Adjun received his B.Sc. (1972) and Ph.D. (1992) from the Bogor Agricultural Institute (Institute Pertanian Bogor) in Indonesia and his M.Sc. from the University of Birmingham (1978) in the UK. He accepted employment at the Bogor Botanical Gardens (Kebun Raya, Indonesia) in 1972. I met him that year while teaching a summer course there with the late Professor Charles Lamoureax from the University of Hawaii. Adjun and I collaborated on several research projects after that, and published together. He referred to me once (sarcastically no doubt because I always pushed him to publish more) as his "best loved teacher and also best loved boss." We were actually close friends. His daughters called me "uncle." I am proud to have known Adjun and miss his dry humor.

Propagation of *Phaius tankervilleae*

Sometimes a simple approach will accomplish as much as or more than a high tech method. And the resourcefulness and enthusiasm of a young student can lead to useful findings. This is what happened when a student in the Kew Diploma course "undertook a project on the propagation of *Phaius tankervilleae*" (Danks, 2003).

Plant Material. "Cuttings, 15 cm long . . . from . . . spent inflorescence."

Surface Sterilization. None is required.

Culture Vessels. None are needed.

Culture Conditions. Cuttings are maintained presumably in a greenhouse or a propagation chamber "at a minimum day temperature of 12°C [night temperature is not given] . . . misted daily . . . at 70% humidity, shaded. . . ."

Growing Media. Of the three media tested, the best results were obtained with a medium consisting of one part coir (fiber obtained from coconut husks) and one part perlite. Plantlets obtained by this method should be potted in a mix consisting of equal parts of fine bark, charcoal, and pumice.

Procedure. Cuttings can be inserted into the growing medium or laid on it. Plantlets form on the nodes and should be left in place until their roots reach a length of approximately 15 cm at which point they should be removed and potted in the potting mix.

Developmental Sequence. Plantlets (keikis) form on each node 8 weeks after the cuttings are placed in the growing medium in both horizontal and vertical position. Roots are produced faster on vertically placed cuttings.

General Comments. This is not an in vitro micropropagation procedure, but is included here because it is simple, effective, and rapid.

Phaius tankervilliae plant in flower: The inflorescence is 90 cm tall (Holttum, 1964)

Phalaenopsis

Phalaenopsis is a monopodial genus and as such does not normally form offshoots. Certain of the smaller flowered species in the section *Zebrinae* such as *Phalaenopsis lueddemanniana* usually produce plantlets (keikis) on their flower stalks (Fig. Phal-1A), a phenomenon first described over a century ago (Williams and Williams, 1894). Keikis can also be formed by *Phalaenopsis* species and hybrids of other sections. For example, a watercolor of *Phalaenopsis kunstleri* in Kew Gardens, reproduced in *The genus Phalaenopsis* (Sweet, 1980), clearly shows a well-developed plantlet arising from an inflorescence node. Plantlets also form on flat roots of the Philippine species *Phalaenopsis stuartiana* (a tendency also first noted in the 19th century; Williams

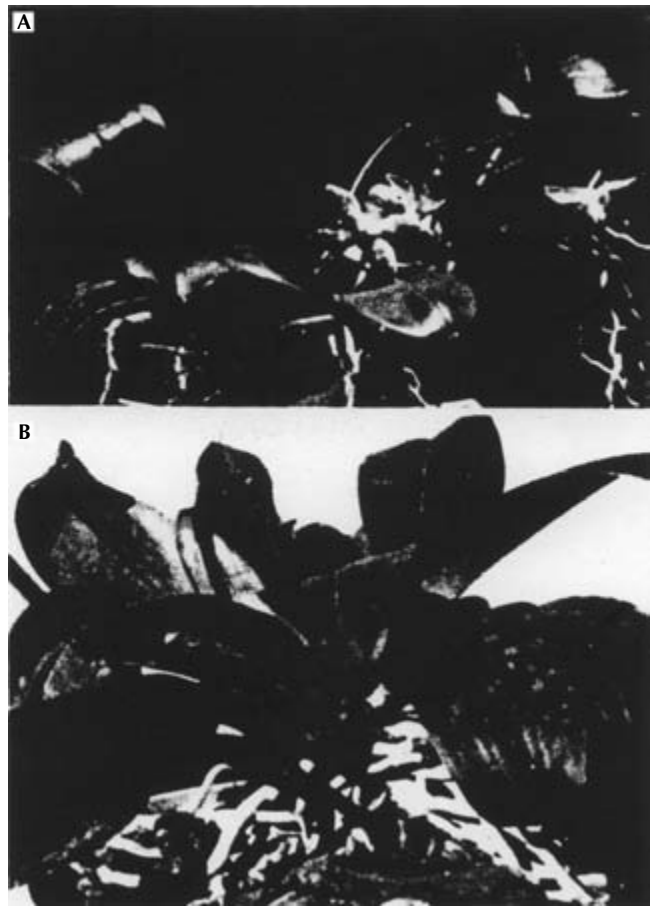

FIG. PHAL-1. **Plantlet production by *Phalaenopsis* plants. A. *Phalaenopsis lueddemannian* producing plantlets (keikis) from flower stalks under cultivation (× 0.4). B. *Phalaenopsis* Irma Anesi producing several shoots from basal buds following injury to the crown (× 0.45). (Ernst, 1986.)**

and Williams, 1894) and *Phalaenopsis schilleriana* (Davis and Steiner, 1952). Keikis developing on roots have likewise been observed in *Phalaenopsis deliciosa* (Reichenbach, 1885), which is presently known as *Kingiella decumbens* P.F. Hunt (Bechtel et al., 1981).

Phalaenopsis plants, under unfavorable culture conditions, frequently produce keikis on their flower stalks, particularly if their tips have been removed.

Clonal Propagation using Whole Shoots

Phalaenopsis plants whose crowns have been injured or severed sometimes give rise to one or several shoots from dormant buds on the base (Fig. Phal-1B). This observation led daring growers to deliberately cut the top of *Phalaenopsis* plants below the aerial roots and cultivate both parts separately in the hope of propagating a desired clone. The process is known as topping. Shoot development from the basal portion is reportedly enhanced by temperatures of 27°C, which has been described as growth promoting (Tran Thanh Van, 1974). A clone may be tripled or quadrupled in this fashion within a 10-month period (Tran Thanh Van, 1974). Vegetative shoots arise from dormant buds on the *Phalaenopsis* plant axis, two of which occur above each other in the leaf axil (Koch, 1974*a*, 1974*b*; Hölters, 1983).

Multiple shoots have also been reported to develop when *Phalaenopsis* plants were treated with morphactins such as the *n*-butyl ester of 9-hydroxyfluorene-(9)-carboxylic acid (Koch, 1974*a*; Hölters, 1983). No details were given regarding this treatment, but it was noted that this morphactin is available from Merck and Company (Koch, 1974*a*). Morphactin has been shown to stimulate carbohydrate synthesis as well as the formation of buds in the dark in lilies (Kato, 1978).

Clonal Propagation through the Production of Plantlets on Flower Stalks

Shoot production on *Phalaenopsis* flower stalks was induced by wrapping sphagnum around the inflorescence node and by keeping it moist (Shara, 1938, 1952). Sphagnum has also been used to produce plantlets from cut flower-stalk sections by a semi-aseptic method (Grimes, 1987).

In recent years, plant hormones have been used to induce the formation of plantlets on flower-stalk nodes in situ. A number of cytokinin-containing pastes are offered by commercial laboratories for this purpose (McFarlane, 1977; Haas, 1977*d*; Brasch and Kocsis, 1980). The method and hormone paste described here were devised at the Technical University of Hannover, Hannover, Germany (Zimmer and Pieper, 1979; Zimmer, 1980).

Plant Material. *Phalaenopsis* plants with fully developed inflorescences, either with buds or open flowers, gave the best results.

Culture Conditions. Greenhouse conditions suitable for *Phalaenopsis* are appropriate.

Hormone Paste. The paste consists of the following (in grams):

Vaseline (petroleum jelly)	44.0
Cetyl/stearyl alcohol	9.0
Paraffin oil (liquid petrolatum)	5.0
Tween 40	2.0
Benzylaminopurine (benzyl adenine)	0.3–0.5
Water	40.0

Vaseline (a paste available in most pharmacies) and cetyl/stearyl alcohol (a solid melting at about 50°C, sold by most chemical supply houses; see Appendix 2) are melted in a beaker placed in a hot water bath at a temperature of about 55°C. Paraffin oil and Tween 40 (both available from chemical or biochemical supply houses) are stirred into the melted mixture and after that the water is added with vigorous stirring. A mechanical stirring device is recommended. BA (available from biochemical supply houses) is dissolved in a minimum volume of ethanol (ethyl alcohol) and stirred into the warm mixture. The paste should be stored in the refrigerator (not freezer) until use.

Procedure. The paste should be applied to buds twice during a 1–3-week period following removal of the bracts. A fully developed inflorescence with buds and/or open flowers can be expected to produce best results.

Developmental Sequence. In some cases a single dormant bud can give rise to more than one shoot. Some of the dormant buds may develop into flower stems. A few can form callus tissue, and others could die (Brasch and Kocsis, 1980; Hölters, 1983). Multiple keikis on a single *Phalaenopsis* flower stem can form following application of this paste, containing 2500–5000 ppm BA (Zimmer, 1978, 1980; Zimmer and Peiper, 1979; Hölters, 1983; Schultz, 1983).

Keikis developing from flower-stem buds of *Phalaenopsis* Inspiration following application of a lanolin-based paste containing 1500 ppm of BA are shown in Fig. Phal-1A.

A gel that can be used for the same purpose (Haas-von Schmude, 1983) reportedly contains less than 50 ppm BA. No formula for the preparation of such a gel is given; however, a widely used gel-forming agent is 1–2% agar dissolved in water by heating the solution to 80–90°C until it becomes clear and allowing it to cool to ambient temperatures.

Antiauxin-containing Hormone Pastes as Plantlet Inducers

A lanolin-based keiki paste containing both the antiauxin *trans*-cinnamic acid (tCA) and the cytokinin BAP was reported to be effective in inducing shoot growth on *Phalaenopsis* inflorescence buds (Griesbach, 1984). Such a combination was used for the induction of vegetative growth of *Phalaenopsis* flower-stalk nodal sections in vitro (Ball et al., 1974/75; Reisinger et al., 1976; Arditti et al., 1977).

Plant Material. In the original research (Griesbach, 1984), inflorescences on flowering plants of *Phalaenopsis* Betty Hausermann were cut back to the third node from the base (the fifth bud usually develops into a flower). The bract covering the bud to be treated was removed prior to the application of the paste.

Culture Conditions. Plants were grown in a greenhouse under a light intensity of 80 $\mu E\ m^{-2}\ s^{-1}$ at 27°C during the day and 21°C at night, and 40% relative humidity. Photoperiods were typical for spring in Beltsville, Maryland, USA.

Hormone Paste. A lanolin paste containing 50 mg tCA and 5 mg BA per milliliter of lanolin is most effective. This paste can be prepared by the method developed at the Technical University of Hannover.

Procedure. Inflorescences of a *Phalaenopsis* hybrid were cut back to the third nodal bud from the base. The bract surrounding the bud was removed before the hormone containing lanolin paste was applied to it.

Developmental Sequence. After 4–8 weeks the buds developed into 1.25 cm inflorescences. One-eighth to one-quarter of the apex of the flower stem was cut off and the remaining bases were retreated with this same hormone/lanolin paste. Several shoots developed from each base. This was followed by root formation.

General Comments. The method of treatment is of interest because it combines the breaking of dormancy with the induction of multiple plantlets.

Vegetative Propagation of *Phalaenopsis* Species and Hybrids in Vitro

The first clonal propagation in vitro of orchids was achieved by Gavino Rotor while he was a graduate student of Lawrence McDaniels at Cornell University (Rotor, 1949). He employed sections of flower stalks each containing a lateral bud. This method is for relatively limited production of plantlets. Rotor's method seems to have been ignored at first but about 10 years later others devised new procedures (Sagawa and Niimoto, 1960; Sagawa, 1961, 1963; Kotomori and Murashige, 1965; Urata and lwanage, 1695; Scully, 1966; Tse et al., 1971; Intuwong et al., 1972*a*, 1972*b*; Ball et al., 1974/75; Koch, 1974*a*; Reisinger et al., 1976; Arditti et al., 1977; Tanaka and Sakanishi, 1977, 1978; Valmayor, 1977; Fast, 1979; Johnson et al., 1982; Ernst, 1984; Gil, 1987). To conserve the spirit of Rotor's pioneering work his method will be presented here as described in his original paper.

Plant Material.

> After the flowers have been picked the stalk is [removed,] washed in tap water and rinsed in distilled water. The bracts at nodes are then removed [Fig. Phal-2A]. These bracts cover the buds. Each bud is removed with a piece of the stem three-fourths of an inch above and below it. Usually, 1 or 2 nodes at the basal portion of the stalk have no bud. These are discarded. The upper portion which bore the flowers was also found to be useless. About 4 or 6 buds are usable [Fig. Phal-2B].

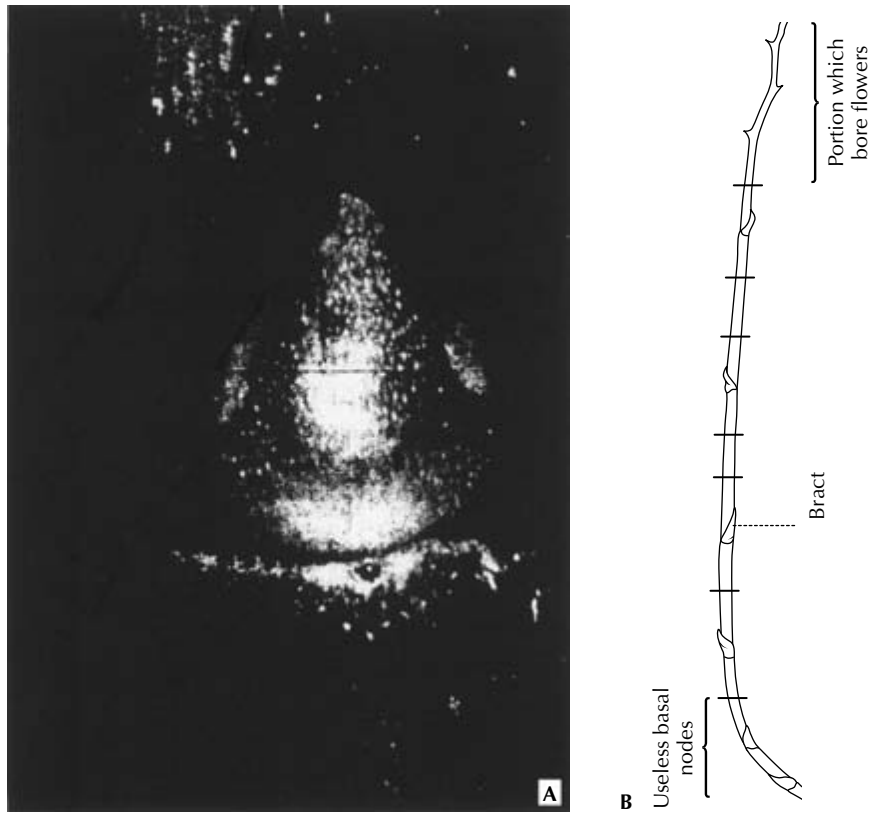

FIG. PHAL-2. **Flower-stem nodes and buds in *Phalaenopsis*. A. Node with bract removed (×16). B. Cuts separating nodes for clonal multiplication. (Sources: A, Ernst, 1986; B, Rotor, 1949.)**

These instructions are still valid at present. However, propagators may cut the flower stalks before the flowers open.

Surface Sterilization.

> The pieces are then freed of microorganisms by immersing them in a solution of calcium hypochlorite. The solution is prepared as for the disinfection of orchid seed. . . . Pieces of shoot are immersed for from two to five minutes. . . . This solution is made by dissolving 7 g calcium hypochlorite in 100 ml distilled water, stirring vigorously at 5- to 10-min intervals and decanting the supernatant or filtering the solution.

An immersion of 2–5 min is probably too short for decontamination; 15–20 min is more appropriate. Household bleach sodium hypochlorite (NaOCl), 20 ml diluted to 100 ml with water, is more commonly used as decontaminant at present. Following removal of the bracts that cover the buds, flower-stalk segments are first wiped with 95% ethanol and then immersed in the sterilant. They are shaken periodically and after about 20 min the NaOCl solution is removed and replaced with

sterile water. The rinse with sterile distilled water may be repeated two to three times. Stem sections may be left in the rinse solution until it is convenient to cut them into smaller sections for planting. These sections should consist of one bud and 1–2 cm of stem on each end.

Culture Vessels. The sections "are then planted in flasks, test tubes or bottles. . . ."

Culture Conditions. "The cultures may be kept in any room that is suitable for germination of orchid seeds." Elevated temperatures (25–30°C) promote growth (Tran Thanh Van, 1974; Tanaka and Sakanishi, 1977; Fu, 1978).

Culture Medium. "Solution [Knudson] C as used for germination of orchid seed" is employed (set Table Aranda-7). Culture media suitable for orchid seed germination are generally suitable.

Procedure. The author (Rotor, 1949) states that "in planting the pieces are simply laid on the surface of the agar." It is actually better to push the sections vertically into the agar with the bud pointing upward.

Developmental Sequence. Rotor obtained active growth (swelling of the bud and appearance of the first leaf) after 2 weeks.

> Sometimes growth may not occur until after two months. In general, conspicuous, well-developed buds grow earlier than small ones and the larger the diameter of the flower stalk, the more vigorous the plants produced. Out of 65 buds that had been cultured only 7 have failed to develop into plants. Roots appear after 2 or 3 leaves have been produced. These plants may then be transplanted to pots. It is probable that such plants will flower in a year or two.

General Comments. This procedure may have failed to receive the early attention it deserved because of low yields due to contamination. Rotor's method must be recognized as the first successful in vitro clonal propagation of orchids and perhaps of plants in general.

Phalaenopsis Flower-stalk Node Propagation

Among the numerous modifications of Rotor's method, the following employs a two-stage sterilization with Clorox (a commercial bleach) and a modified Vacin and Went medium (Table Phal-1; Vacin and Went, 1949; Intuwong et al., 1972*a*, 1972*b*).

Plant Material. Use clean, healthy, vigorous flower stalks with buds in their nodes. Stalks on which only a few flowers have bloomed are best; old stalks should be avoided.

Surface Sterilization. Wipe stalks two to three times using cheesecloth wetted with 95% ethyl alcohol (ethanol) or 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water plus two to three drops of Tween 20, a non-ionic surfactant). After sectioning, place the nodes for 15 min in 10% Clorox. Following removal of the

TABLE PHAL-1. **Vacin and Went medium (Vacin and Went, 1949) modified for propagation of flower-stalk cuttings of *Phalaenopsis* (Intuwong et al., 1972*a*, 1972*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, so it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1 and 3–7 to the 500 ml distilled water (item 9) that contains item 2, adjust pH to 5.00–5.60, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Omit agar for liquid medium.

bracts, immerse the sections in 5% Clorox (5 ml Clorox diluted to 100 ml with water plus two to three drops of Tween 20) for 10 min and dip in sterile distilled water for 3 min. If Tween 20 is not available, use two to three drops of a mild household detergent.

Culture Vessels. Use 10 × 100-mm vials containing 12 ml medium.

Culture Conditions. Maintain cultures under approximately 200 ft-c of continuous illumination. Cultures may be maintained under illumination usually employed for seedlings, which includes General Electric Power Groove white fluorescent tubes or Sylvania Gro Lux lamps. Temperatures may range from 23 to 30°C with the higher temperature levels being preferable.

Culture Medium. A modified Vacin and Went medium (Table Phal-1) is used.

Procedure. Cut flower stalks into 65-mm sections with a sterile razor blade or scalpel, leaving 25 mm above the node and 40 mm below it. Expose the bud by removing the bract that covers it with sterile forceps. Care must be taken to completely remove

the bract without injuring the bud. Then sterilize with a 5% Clorox solution (10 ml Clorox diluted to 100 ml with water). Place the sections on a sterile Petri dish or glass slide. Cut 12 mm from each end with a sterile razor blade (preferably a Valet-type blade, which has one cutting edge and a blunt side covered with a sleeve) or scalpel. All tools must be dipped frequently in 95% ethanol or 10% Clorox (or flamed using a Bunsen burner or alcohol lamp) to maintain sterility. Transfer the sections from the Petri dish or the glass slide to culture vials, inserting them at a slight angle to just below the bud with the longer portion of the section submerged; in this way the emerging shoot will always point upwards.

Developmental Sequence. Shoots generally appear within a month. Most shoots are well rooted and ready for removal from the vial after 2 months. After that the plantlets develop and should be treated like seedlings.

If inflorescences appear instead of plantlets, allow the cultures to remain undisturbed and aseptically remove the terminal portion of the new flower stalk. As a result of this step plantlets may form from the lowermost node of new inflorescence.

General Comments. The main advantage of this method is that the plant itself is not damaged or endangered. A disadvantage is the lack of callus formation. This limits propagation to the available flower-stalk buds. "In our laboratory, some buds have produced two plantlets on occasion. Also, not all sections survive and some buds fail to grow. A great improvement of this procedure would be the induction of callus, and we are currently working on that" (Intuwong et al., 1972*a*).

Use of Plant Hormones to Improve Shoot Growth of *Phalaenopsis* Stem Nodes

An early study of mass clonal multiplication of *Phalaenopsis* from flower-stem nodes showed that the addition of BA promoted the growth of shoots (Koch, 1974*a*). The weight of the shoots generally increased with increasing amounts of BA within the 0.1–3 ppm range. Formation of multiple shoots per node was not reported. Addition of 2 ppm of the synthetic auxin NAA reduced shoot formation (Tse et al., 1971). The natural auxin IAA or the synthetic auxins potassium α-naphthaleneacetate (KNA) as well as 2,4-D increased initial shoot length but inhibited development subsequently (Koch, 1974*a*, 1974*b*).

Regeneration of Multiple *Phalaenopsis* Plantlets from Flower-stalk Nodes

Our work has shown that much higher levels of cytokinins, 25–125 ppm BAP in Knudson C medium (see Table Aranda-7) or REM medium (Table Phal-2), usually induce multiple shoots (Fig. Phal-3A, B) and even rosettes of plantlets from a single flower-stem node (Fig. Phal-3C; Ernst, 1986).

Plant Material. Flower stalks are removed from *Phalaenopsis* preferably before the first flower opens or at least as soon as the flowers begin to wilt.

TABLE PHAL-2. **REM medium for the propagation of *Phalaenopsis* through the culture of flower-stalk cuttings (Ernst, 1986)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
14	Sucrose	25 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[f]	To 1000 ml			
	Solidifier				
16	Agar[f]	2 g	No stock	No stock	Weigh

[a]Except for the omission of BAP (item 13) and addition of 10% (w/v) banana homogenate, this is the same medium employed for transflasking shoots in order to develop roots.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]BAP is heat-stable and can be added to medium prior to autoclaving. It can also be added after autoclaving under sterile conditions.

[f]Add items 1–12 to 900 ml distilled water (item 15), adjust pH to 5.0–5.6, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add cytokinin (item 13) to hot solution under sterile conditions with sterilized pipette, mix well, and distribute medium to preautoclaved culture vesels. Omit agar for liquid medium.

Surface Sterilization. The flower stalk is cut into sections with about 2 cm of stalk on each side of the bud, wiped with 95% ethanol, and immersed for about 20 min in a 1% solution of sodium hypochlorite. It is convenient to dilute 20 ml of commercial household bleach with 80 ml water in a 100-ml volumetric cylinder, place the nodal sections into this sodium hypochlorite solution, and shake the cylinder intermittently several times to assure wetting of the sections. After 20 min the liquid in the cylinder is drained and sterile distilled water is poured in to rinse the explants. The nodal segments are then placed in a sterile Petri dish, and the bracts are carefully removed with sterilized forceps. These sections are then reimmersed in a 0.5% sodium hypochlorite solution (10 ml commercial bleach diluted with 90 ml distilled

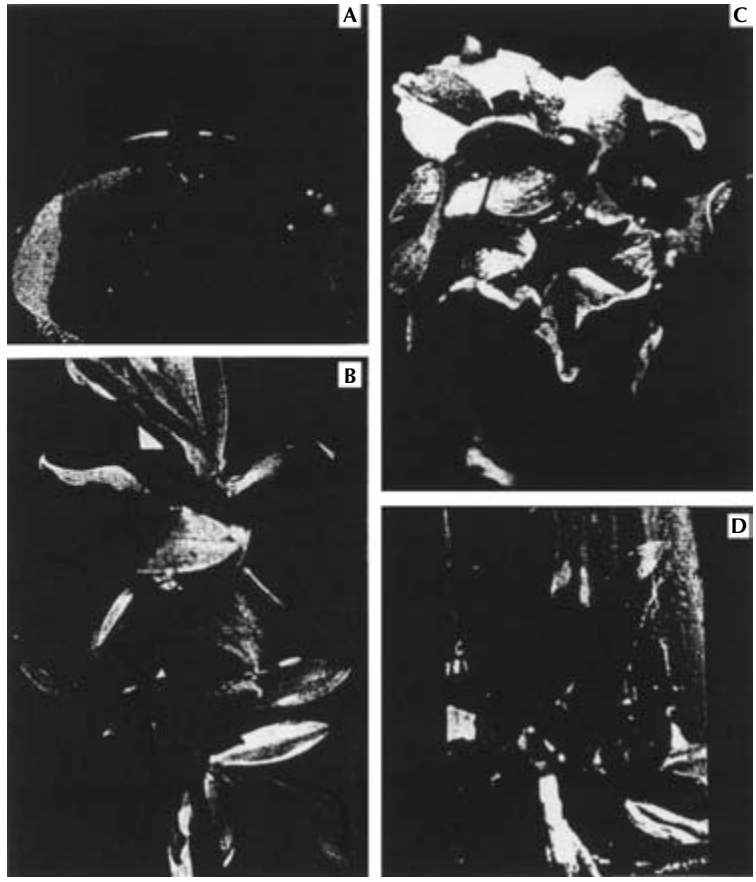

FIG. PHAL-3. **In vitro cultures of *Phalaenopsis* flower-stem nodes. A. Multiple shoots and PLBs developing from a node grown on REM medium containing 25 ppm BA (× 2). B. Multiple shoots but no roots growing from two flower-stalk nodes of a hybrid on REM medium containing 25 ppm BA (× 1.8). C. Rosette of shoots growing from one bud of a hybrid on REM medium containing 50 ppm BAP (× 3). D. Root development on multiple shoots from a single flower-stem bud, grown initially on REM medium containing 25 ppm BA and moved after 3 months to REM medium containing only 10% (w/v) ripe banana homogenate as additive (× 1.25). (Ernst, 1986.)**

water) and shaken occasionally for 10 min. After this period the bleach solution is drained once more and the cylinder is filled again with autoclaved distilled water for rinsing. Sections are then placed on a sterile Petri dish again and recut so that the stalk on each end is about 1–1.5 cm. The section can now be inserted into the nutrient medium such that the bud points upward and the section is partially inside the agar.

Culture Media. To stimulate multiple shoot formation, REM medium, which contains 25 mg l^{-1} BA (Table Phal-2), is employed. After shoots have developed, the

shoot-bearing sections are transferred without rinsing to REM medium, containing no hormone but 10% (w/v) banana homogenate (Table Phal-2) to stimulate root formation (Fig. Phal-3D).

Culture Vessels. Test tubes or small (125-ml) Erlenmeyer flasks are suitable for this procedure. Aluminum foil may serve as cover.

Developmental Sequence. Multiple shoots usually develop within 2–3 months. Roots form 1–2 months following transfer to a hormone-free medium that contains banana homogenate (Table Phal-2). The clones can then be moved to the greenhouse into a customary seedling mixture.

Shoot Growth of *Phalaenopsis* Flower-stalk Nodes in the Presence of Anti-auxin

Phalaenopsis flower-stem nodes were grown in the presence of the anti-auxin *trans*-cinnamic acid (tCA) to overcome possible dormancy of the buds (Ball et al., 1974/75; Reisinger et al., 1976; Arditti et al., 1977).

Plant Material. Use mature flower stalks. Best results are obtained with buds from nodes on the upper sections of the stalk (Fig. Phal-2B).

Surface Sterilization. Remove the bract (scale) that covers each bud. Wash the stalk section with distilled water containing 2–3 drops of a mild detergent per 100 ml. Rinse with distilled water and immerse in 50% Clorox (or any 5–5.5% sodium hypochlorite household bleach diluted with an equal volume of distilled water) for 4–6 min. Dip momentarily in sterile distilled water to remove bleach residues, and insert the sections into the culture medium.

Culture Vessels. A variety of containers can be used, including Erlenmeyer flasks (125–250-ml capacity), test tubes (150 or 250 mm × 25 mm), and prescription bottles (100 ml). Fill culture vessels with medium to approximately 25% of the containers' volume, and autoclave for 30 min at about 1 atm (15 pounds per square inch, psi).

Culture Conditions. Maintain cultures under approximately 150 ft-c and 16-h photoperiods. Sylvania Gro Lux fluorescent tubes were used in the original experiments, but other suitable lighting sources could be employed. The temperature should be 22–25°C.

Culture Medium. A modified Knop's medium (Table Phal-3) was used. The medium should contain isoleucine (13 mg l^{-1}) and tCA at a concentration that depends on the source of the stalk section:

- 1.48 mg l^{-1} tCA for upper and base section nodes;
- 14.8 mg l^{-1} tCA for mid section nodes.

TABLE PHAL-3. **Modified Knop's solution (Knop, 1884) for the culture of *Phalaenopsis* node sections (Ball et al., 1974/75)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
16	Distilled water[g]	To 1000 ml			
	Solidifier				
17	Agar[f,g]	130 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The number of waters of hydration is not given in the original paper.

[d]Knop's solution does not contain iron which should be added, preferably in chelated form. To prepare a stock solution add 3.73 g l^{-1} chelating agent (Na_2EDTA) and 2.78 g l^{-1} ferrous sulfate ($FeSO_4 \cdot 7H_2O$). Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Keep refrigerated between uses.

[f]As originally formulated, the solution does not contain sugar or agar. These components should be added as 20 g l^{-1} sucrose (item 15) and 12–16 g l^{-1} agar (item 17).

[g]Add items 1–10 and 15 to 900 ml distilled water (item 16), adjust pH to 5.0–5.6, and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add remaining organics (items 11–14) after autoclaving to the hot solution under sterile conditions with sterilized pipettes. Mix well, and distribute medium to preautoclaved culture vessels.

BA and inositol are also included because of their generally beneficial effects on tissue cultures (Murashige, 1974).

Developmental Sequence. A swelling of the buds is the first sign that a culture might be successful. This is followed by leaf development and finally by root formation. Subsequent growth resembles that of seedlings and leads to plants that should be potted in fir bark.

Clonal Propagation of *Phalaenopsis* through Injured Nodal Flower-stalk Buds

Some flower-stem buds of *Phalaenopsis* do not develop into shoots but form masses of callus (Tse et al., 1971; Hackett et al., 1973). Adventitious buds form on callus surfaces and develop into shoots. Twelve plantlets can form within 6 months on one node, and additional ones may be produced. This observation led these authors to develop methods for callus induction.

Plant Material. Inflorescences of a number of *Phalaenopsis* hybrids were used in the original research.

Surface Sterilization. Use the method employed in the section *Phalaenopsis* Flower-stalk Node Propagation (see p. 911, Vol. II).

Culture Media. Knudson C (see Table Aranda-7) or MS (Murashige and Skoog, 1962; see Table Cym-11) media, each solidified with 1% agar, are used. In some cases 2 mg l^{-1} NAA is added.

Culture Vessels. Glass vials of 10-ml capacity were used in the original research. Other culture vessels may also be used.

Procedure. Before inserting the node section into one of the media described above, injure the buds by one of the following methods:

1 Remove two-thirds of each bud by cuts that are oblique to its axis and parallel to the stem axis.
2 Bisect the buds by cutting longitudinally through their axes.
3 Puncture the buds longitudinally from apex to base with a sharp sterile needle.

Methods 1 and 3 yielded the highest callus formation (Table Phal-4). The addition of auxin (NAA) proved detrimental with Knudson C medium (see Table Aranda-7) but resulted in some improvement with MS medium (see Table Cym-11), as shown in method 1 in Table Phal-4.

Phalaenopsis comes from the Greek phalaina (moth) and opsis (moths), alluding to the resemblance of the flowers of type species to some tropical moths (Schultes and Pease, 1963).

TABLE PHAL-4. **Callus and/or shoot formation by flower-stalk node explants of *Phalaenopsis* (Tse et al., 1971)**

Injury technique	Medium[a]	NAA,[a] mg l^{-1}	Percentage of nodes forming

Mass Clonal Propagation of *Phalaenopsis* through Tissue Culture

Considerable difficulties have been encountered in the development of tissue-culture methods for *Phalaenopsis*. A common problem encountered is the high level of phenolics released by tissues. The resulting oxidation products of these substances, which diffuse into the culture media, appear to be toxic and cause the explants to turn brown or black and die (Morel, 1974; Flamee and Boesman, 1977; Fast, 1979). Numerous attempts have been made to eliminate these exudates and especially their oxidation products with antioxidants, polyphenoloxidase inhibitors, polyvinylpyrrolidone, activated charcoal, and many other adsorbents. Most effective has been the frequent transfer of explants (every 2–3 weeks) to fresh medium (Flamee and Boesman, 1977).

Clonal Propagation of *Phalaenopsis* by Shoot-tip Culture

An early, successful method for shoot-tip culture of *Phalaenopsis* was reported from the University of Hawaii (Intuwong and Sagawa, 1974).

Plant Material. *Phalaenopsis amabilis*, *Phalaenopsis* × Star of Santa Cruz, *Phalaenopsis* × Surfrider, *Phalaenopsis* × Ruby Lips, *Phalaenopsis* × Arcadia, and *Phalaenopsis cochlearis* were used. Explants were taken from vegetative shoots of adult plants with six to seven leaves or from aseptically grown plantlets obtained from flower-stalk nodes; the latter method does not sacrifice the mother plant.

Surface Sterilization. Leaves are removed and the shoot axis is then sterilized with 10% Clorox (10 ml Clorox diluted to 100 ml with water; about 0.5% NaOCl) for

15 min. The leaf bases are removed next, and the tissue is again sterilized in 5% Clorox (5 ml Clorox diluted to 100 ml with sterile distilled water) for 10 min. Explants that are 2–3 mm^3 in size and consist of the apical meristem, two to four leaf primordia, and two to three axillary buds covered with scale-like leaves are removed and rinsed in sterile distilled water before culturing. There is no need to sterilize explants taken from aseptically grown plantlets.

Culture Vessels. Use 50-ml Erlenmeyer flasks containing 20 ml medium.

Culture Conditions. Cultures are maintained under continuous illumination of 200 ft-c (General Electric Power Groove white fluorescent lamps were used in the original work) at 26 ± 2°C. Liquid cultures should be agitated at 160 rpm (a New Brunswick Model V shaker was used for the initial experiments).

Culture Medium. Solid or liquid Vacin and Went medium modified as for the culture of flower-stalk sections (Intuwong et al., 1972*a*, 1972*b*) and enriched with 15% (v/v) coconut liquid endosperm (Table Phal-5) is employed. Sucrose is omitted from

TABLE PHAL-5. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Phalaenopsis* flower-stalk cuttings (Intuwong and Sagawa, 1974)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	Or weigh
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	20 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	Or weigh
	Iron[d]

10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, so it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Then add other components of medium.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Do not add sugar for a medium used to culture PCBs.

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 10) that contains tem 2 and adjust pH to 5.0–5.6. Add sugar (item 9) for liquid modified Vacin and Went medium. Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When the agar is completely dissolved, dispense the medium into culture vessels and autoclave. Omit agar for liquid medium.

the solid medium onto which PLBs are transferred after being in liquid for a month. The solid medium used to induce further proliferation is also free of sucrose.

Procedure. Culture explants in agitated liquid medium (Table Phal-5), change every 10 days for a month, and then transfer onto a solid sucrose-free medium. Frequent subcultures to new medium without sucrose results in the production of numerous pseudobulb-like bodies.

Developmental Sequence. Yellowish PLBs are produced on axillary and terminal bud explants within a month of culture. The same happens on inflorescence nodes. On transfer to solid sucrose-free medium, the PLBs turn green. If left undisturbed on solid medium, these bodies form plantlets within 3–5 months. However, if they are frequently subcultured onto new, solid sucrose-free medium, numerous new PLBs will be produced. At first the PLBs are less than 0.5 mm in diameter, rough, and globular. On reaching a diameter of 0.5–1 mm they become shiny and develop numerous trichomes on their lower half. When they reach a diameter of 1–3 mm, a dark green spot becomes apparent (from which the first leaf later appears), and many trichomes are still present. An expanded leaf and a root near its base appear when the PLBs are 4 mm long. They are still 4 mm in diameter when the leaf enlarges, the root elongates, and velamen develops. Three months are required for this developmental process.

General Comments. Numerous plants were produced by this technique at the University of Hawaii. It should therefore prove useful to orchid propagators everywhere.

Mass Clonal Propagation of *Phalaenopsis* from Leaf Tissue

Production and proliferation of PLBs on the bases of thickened leaf sections (rather than on meristems) arising from clonal propagation of flower-stalk nodes was demonstrated in a doctoral dissertation (Koch, 1974*a*) by a student of K. Zimmer. A liquid modified Knudson C medium containing BA and potassium naphthaleneacetate (KNA) induced the formation of PLBs. Further proliferation of PLBs took place on different modifications of the Knudson C medium.

This method was extended further by Zimmer and his collaborators at the Technical University of Hannover, Germany (Zimmer and Pieper, 1976, 1978, 1979; Zimmer, 1980).

Plant Material. Flower-stalk node sections of pink *Phalaenopsis* hybrids Zada × Zada, Lipperose, and Zauberrose were used.

Surface Sterilization. Node sections, 4 cm in length, of the flower stalks are washed with a household detergent, following removal of the bracts and immersed for 5–6 min in a solution of calcium hypochlorite ($CaCl_2O$, 20 g in 140 ml distilled water, shaken a few times, and decanted). This is followed by a rinse with sterile distilled water before the bud is removed.

Buds further away from the base of the stalk tend to become less contaminated (Koch, 1974*a*).

Culture Media. Owing to the difficulty and expense of obtaining coconut endosperm in Europe, 10% (v/v) of bleeding sap of birch trees (Pieper and Zimmer, 1974, 1976*b*; Zimmer and Pieper, 1976) was added to a modified Knudson C medium (Table Phal-6; Zimmer and Pieper, 1978) for the development of PLBs.

TABLE PHAL-6. **Knudson C medium (Knudson, 1946) for the clonal propagation of *Phalaenopsis* (Koch, 1974*a*; Zimmer and Pieper, 1978)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

8	Zinc sulfate, $ZnSO_4$	1	1 g l^{-1}	1	
9	Boric acid, H_3BO_3	1	1 g l^{-1}	1	
10	Cupric sulfate, $CuSO_4$	0.03	30 mg l^{-1}	1	
11	Aluminum chloride, $AlCl_3$	0.03	30 mg l^{-1}	1	
12	Nickel chloride, $NiCl_2$	0.03	30 mg l^{-1}	1	
13	Potassium iodide, KI	1	1 g l^{-1}	1	
	Auxin				
14	Potassium naphthylacetate (KNA)	0.3	30 mg 100 ml^{-1} 95% ethanol[d]	1	
	Cytokinin				
15	Benzylaminopurine (BAP)[e]	2	200 mg 100 ml^{-1} 95% ethanol[d]	1	
	Complex additive				
16	Bleeding sap of birch trees[f]	100 g	No stock	No stock	Weigh
	Sugar				
17	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Agar[g]	5 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The microelements (items 7–13) can be dissolved together in 1 l of distilled water and 1 ml of this solution may be used for each 1000 ml medium.

[d]Keep refrigerated between uses.

[e]Add BAP to the medium only when it will be used to culture parts of broken plantlets.

[f]This can be replaced with an equal volume of filtered coconut water.

[g]Add items 1–13 to 800 ml distilled water (item 18), adjust pH to 5.0–5.6, add sugar (item 17), and bring volume to 1000 ml with distilled water (item 18). While stirring, slowly add agar (item 19) and heat the medium until it turns clear (about 80–90°C). The hormones (items 14 and 15) may be added to the final solution before or after sterilization in the autoclave, since they are sufficiently heat-stable. If added after autoclaving, incorporate them while the solution is still hot, under sterile conditions, using sterile pipettes. Mix well and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

Culture Conditions. The buds are cultivated in the dark at 26°C for 2 weeks. Then necrotic stalk tissue is removed and the node sections are transferred to fresh medium. Temperature should be lowered to 22°C and the cultures illuminated with (per square meter) two 40-W warm white fluorescent tubes and two 40-W "Fluora" tubes (similar to Sylvania Gro Lux) at a distance of 60 cm for the culture period.

Procedure. The flower stalk buds are excised following removal of the bracts by making a semicircular cut. They should be cultured as indicated above.

Developmental Sequence. After about 2 months the buds develop into plantlets. These can be divided into leaves, leaf sections, roots, and stem tissues by breaking them; this seems to be more effective than cutting with a razor blade or a scalpel. These fragments are cultured at 26°C in the dark on a modified Knudson C medium (Table Phal-6). After 2 weeks the temperature should be lowered to 22°C and the cultures must be illuminated. Leaves, leaf sections, stem tissue, and, in some cases roots, form numerous PLBs within 8 weeks (Figs Phal-4 and Phal-5). Newly grown plantlets can be broken again and cultured in the dark and the entire cycle repeated to form more PLBs and plantlets.

General Comments. About 500–1000 plants can be produced by this method from a single flower-stem bud (Zimmer and Pieper, 1978; Hölters, 1983). However, bleeding sap of birch trees may not be easy to obtain.

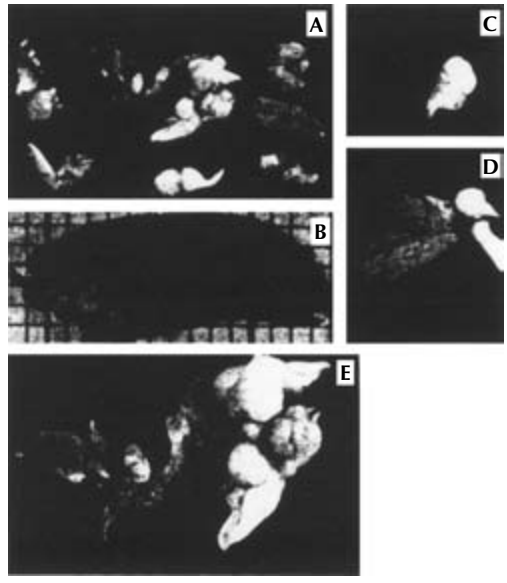

FIG. PHAL-4. **A. Development of PLBs on broken pieces of leaf, shoot, and root tissues of *Phalaenopsis*. B–E. PLBs developing on broken leaf tissue of *Phalaenopsis*. (Zimmer and Peiper, 1978; Hölters, 1983.)**

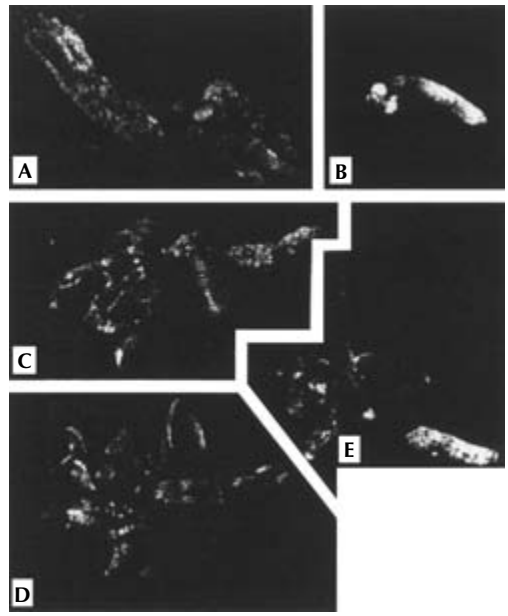

FIG. PHAL-5. **A–E. PLBs and plantlets developing on broken root parts of *Phalaenopsis* hybrid clones derived from flower-stem nodes. Proliferation on leaf, stem, and root explants. (Zimmer and Pieper, 1978; Hölters, 1983.)**

Mass Clonal Propagation of *Phalaenopsis* from Leaf Tissues

Investigations on the clonal propagation of *Phalaenopsis* from leaf tissues were carried out by M. Tanaka and his collaborators at the University of Osaka, Japan (Tanaka et al., 1974; Tanaka and Sakanishi, 1977, 1980, 1985). Initial experiments were carried out with emerging leaves on mature plants and those taken from seedlings. Leaves of mature plants did not produce PLBs, but they developed on leaf explants taken from very young seedlings. Production of PLBs was reduced with increased age of the seedlings (Tanaka et al., 1974). The method outlined here was developed with leaf tissue from nodal shoots of *Phalaenopsis* flower-stalk sections (Tanaka and Sakanishi, 1977, 1980).

Plant Material. Flower stalks were obtained from a 5–6-year-old *Phalaenopsis amabilis* hybrid.

Surface Sterilization. The flower stalks are surface-sterilized by wiping them three times with gauze wetted with 70% ethanol. They are then sliced into sections consisting of one lateral bud and 3 cm of flower stalk on each end. The sections are then treated for 10 min in a filtered aqueous solution of 7% calcium hypochlorite containing 0.1% wetting agent (Tween 20). This is followed by rinsing them three times with sterile water and removing the bracts with sterile forceps. The flower-stalk sections are then trimmed so that only 0.5–1.0 cm of the stalk on each

TABLE PHAL-7. **Vacin and Went medium (Vacin and Went, 1949) modified for the propagation of *Phalaenopsis* from leaf tissues (Tanaka and Sakanishi, 1977, 1980)**

9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[g]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, so it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]If coconut water is not available, substitute 1–1.5 mg l^{-1} benzylaminopurine.

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 10) that contains item 2, adjust pH to 5.0–5.6, add sugar (item 9), and adjust solution with distilled water (item 10) to 1000 ml. Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added while stirring to the cold solution, which is then brought to a boil. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar for liquid medium.

side of the node remains; the trimmed sections are inserted in a modified Vacin and Went medium (Table Phal-7) with the base of the node submerged.

Culture Vessels. Test tubes (25 × 200 mm) containing 16 ml medium were used in the original research. After planting the node sections the tubes were covered with aluminum foil.

Culture Conditions. Cultures should be maintained at 28°C for maximum vegetative shoot production (Fig. Phal-6; Table Phal-8; Tanaka and Sakanishi, 1978) under 16-h photoperiods and an intensity of approximately 500 lx provided by fluorescent lamps.

Culture Media. A modified Vacin and Went medium (Table Phal-7) with the addition of 2.5 ppm BAP is used. Propagation of leaf sections excised from shoots

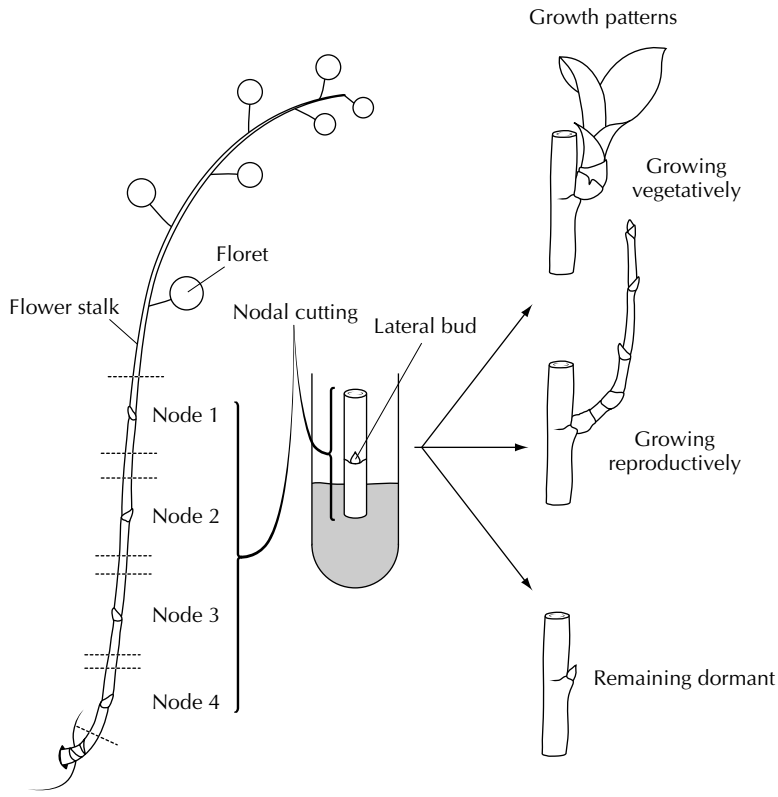

FIG. PHAL-6. ***Phalaenopsis*** **flower stalk showing node positions and different growth patterns of lateral buds from nodal cuttings (Tanaka and Sakanishi, 1977, 1978, 1980).**

TABLE PHAL-8. **Growth of *Phalaenopsis* flower-stalk buds taken from inflorescences that elongated under different temperatures (Tanaka and Sakanishi, 1978)**[a]

Temperature, °C		Number of buds		Percentage of buds growing into shoots

18	Agar[f]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep refrigerated between uses.

[f]Add items 1–9 to 900 ml distilled water (item 17), adjust pH to 5.0–5.6, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to cold solution while stirring, and then brought to a boil. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormones, vitamins, and nucleotide (items 8 and 10–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium into preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE PHAL-10. **Liquid Vacin and Went medium (Vacin and Went, 1949) modified for proliferation of leaf-tissue-derived protocorm-like bodies of *Phalaenopsis* (Tanaka and Sakanishi, 1980)**

	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, so it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Filter before using.

[f]Add items 1 and 3–7 to the 500 ml distilled water (item 10) that contains item 2, adjust pH to 5.0–5.6, add sugar (item 9) and coconut water (item 8), and adjust solution to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, dispense into culture vessels, and autoclave.

dormant buds, whereas many buds of nodes 2 and 1 remained dormant (Fig. Phal-6). When the culture temperature was lowered to 20 or 25°C, a substantial number of sections from nodes 1–4 grew reproductively (Fig. Phal-6). After the first leaf on the shoots expands, about 2 months after the start of culture on the modified Vacin and Went medium (Table Phal-7), leaf segments are excised aseptically and transplanted to modified MS medium (Table Phal-9). PLBs ranging from one to seven per segment and averaging 3.8, form on the adaxial surfaces of the explants (Figs Phal-7 and Phal-8A–C, E). These PLBs can be further proliferated in liquid Vacin and Went medium, supplemented with 20% (v/v) of coconut water (Table Phal-10) on a rotary shaker (160 rpm; Figs Phal-7 and Phal-8F; Tanaka, 1978). A solid Vacin and Went medium supplemented with 20% (v/v) coconut water (Fig. Phal-8G) can also be used. The PLBs can be differentiated on media used for seed germination of *Phalaenopsis* (Fig. Phal-9) and later grown under greenhouse conditions to the flowering stage (Fig. Phal-9B, C).

General Comments. Elevated temperatures (28–30°C) during cultivation of lateral buds may be an important factor in preventing their dormancy (Fu, 1978). Since the quality of flowers that seedlings would produce is an unknown factor, their clonal

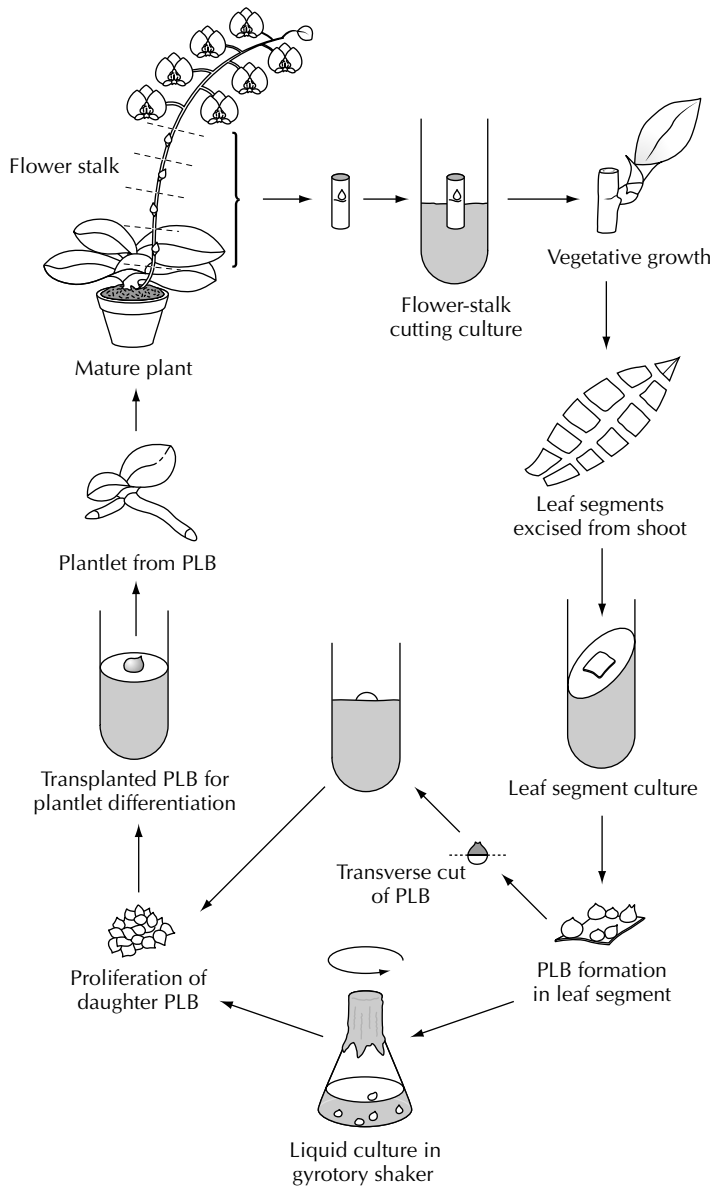

FIG. PHAL-7. **Sequence of mass clonal propagation of *Phalaenopsis* through flower-stalk cuttings followed by proliferation of PLBs cultured from their excised leaf segments (Tanaka and Sakanishi, 1978, 1980; Tanaka, 1987).**

multiplication may be of little practical use. However, clonal propagation of leaves or other tissue from aseptic plantlets obtained from flower-stalk nodes makes possible the multiplication of desirable plants. This procedure is reported to regenerate plants that produce uniform flowers (Fig. Phal-9D, E).

A problem previously discussed is the release of phenolics from *Phalaenopsis* tissues; oxidates of these phenolics gradually darken the media and prove toxic to the explants (Fig. Phal-9D).

Induction of Protocorm-like Bodies on Mature *Phalaenopsis* Leaf Explants

Additional studies by M. Tanaka and his associates showed that hormones used in the MS medium employed for leaf explants from flower-stalk buds can induce PLBs on emerging leaves of mature plants (Tanaka and Sakanishi, 1985).

Plant Material. The last emerging (uppermost) leaf of a *Phalaenopsis amabilis* hybrid (average 5 cm in length) is removed (Fig. Phal-10A).

Surface Sterilization. Leaf explants are soaked in 70% ethanol for 2–3 sec and immersed in a filtered 7% calcium hypochlorite solution containing 1 drop of Tween 20 per 100 ml bleach. After sterilization for 10 min the leaf is rinsed with sterile water. Segments, 8–10 mm^2, are excised from surface-sterilized leaves under sterile conditions with a razor blade (Fig. Phal-10B).

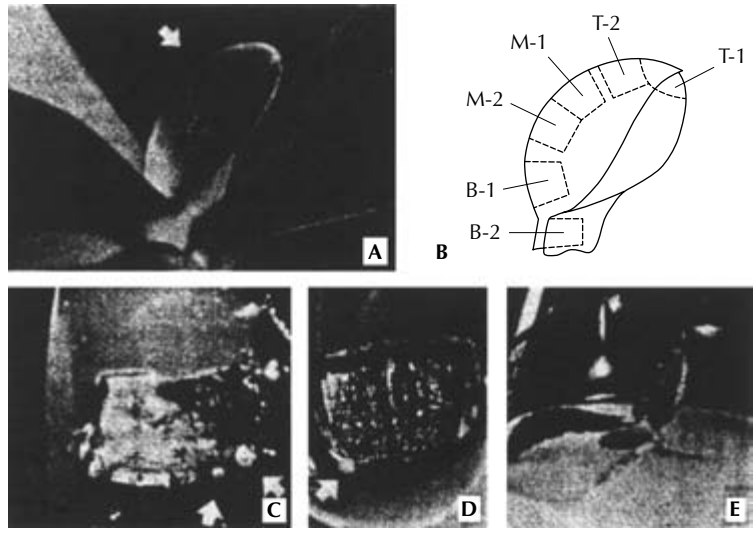

FIG. PHAL-10. **Clonal propagation of mature *Phalaenopsis* from leaf explants. A. Last emerging (uppermost) leaf (arrow), ca. 5 cm in length, which is used as a source of explants for clonal propagation of a *Phalaenopsis amabilis* hybrid. B. Explants, 8–10 mm^3, are cut from the leaf; section B-2 gave explants that produced PLBs, but only from an etiolated, proximal region. C, D. Two sections with PLBs after 173 days (C) and 239 days (D) of culture (arrows). E. A plantlet reported to have differentiated from this mature hybrid 10 months after transplanting to a Knudson C medium. (Tanaka and Sakanishi, 1985.)**

Culture Vessels. Test tubes (24 × 200 mm) containing 16 ml of nutrients were used in the original research, but other containers can be employed. The sealed tubes were sterilized at 121°C for 15 min.

Culture Conditions. In the original work, cultures were maintained at 25°C under 16-h photoperiods of approximately 500 lx provided by plant-growth fluorescent lamps.

Culture Medium. A modified MS medium (Table Phal-11) was used. PLBs were transplanted onto a modified Knudson C medium (Table Phal-12) in Erlenmeyer flasks to develop into plantlets.

Developmental Sequence. Some leaf explants turned black and died; others remained green for as much as 7 months, but failed to produce callus or PLBs. Only two segments of etiolated, proximal leaf sections from region B-2 (Fig. Phal-10B) developed one or two protuberance(s), which formed PLBs after 173 and 239 days, respectively (Fig. Phal-10C, D). Plantlet(s) were obtained from these PLBs (Fig. Phal-10E) upon culture on modified Knudson C medium (Table Phal-12).

General Comments. This method shows that emerging leaves of adult plants can be utilized in the clonal propagation of *Phalaenopsis*; however the yield is low. Success may depend largely on the plant material used.

TABLE PHAL-11. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for clonal propagation of leaf explants from adult *Phalaenopsis* plants (Tanaka and Sakanishi, 1985)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
13	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[d]Add vitamins (items 8 and 9) to medium after autoclaving and while solution is still hot, under sterile conditions with sterilized pipettes. Then dispense medium into preautoclaved culture vessels.

[e]Keep frozen between uses.

[f]Add items 1–7 to 900 ml distilled water (item 12), adjust pH to 5.0–5.6, add peptone (item 10) and sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring solution to a gentle boil, and add agar (item 13) while constantly stirring. Agar can also be added while constantly stirring, to the cold water which is then brought to a gentle boil. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Omit agar for liquid medium.

Mass Clonal Propagation of *Phalaenopsis* from Flower-stalk Nodes and their Leaves

A method that produced PLBs from flower-stalk node cuttings of *Phalaenopsis* as well as from leaf sections generated from them was developed by Dr. Norbert Haas-von Schmude (1983, 1985).

Plant Material. Flower-stem sections, 1–1.5 cm long and each having one bud, were taken from *Phalaenopsis* hybrids Münsterland Stern "Alpha," Babette "Symphony," Windspiel "Düsseldorf," and Barbara Moler "Firecracker."

Surface Sterilization. Node sections are decontaminated by soaking them for about 15 min in 0.6% sodium hypochlorite (12 ml household bleach diluted to 100 ml with distilled water). The sections are then rinsed with sterile distilled water.

Culture Conditions. The cultures were kept under artificial light for 18-h photoperiods at 27°C.

Culture Media. Two modifications of MS medium (Murashige and Skoog, 1962) are used, one for proliferation (Table Phal-13) and the second for differentiation (Table Phal-14).

Procedure. Place half of the node sections in liquid modified MS medium (Table Phal-13) and shake at 100 rpm for several weeks. Culture the other half on the same (but solidified) medium. Buds in liquid culture develop PLBs while those on solid medium produce plantlets.

After cutting the leaves produced by the plantlets cultured on the solid modified MS medium, culture these explants again on the same substrate (Table Phal-13). PLBs appear along the cut basal part, the tip, and the edges of the leaf explants. Small cells with large nuclei were seen in the embryonic tissue that forms. This tissue may be cut and shaken in liquid modified MS medium (Table Phal-13) as described above.

Developmental Sequence. The PLBs developing in liquid solution are transferred to the solid differentiation medium (Table Phal-14). The PLBs form no chlorophyll in the dark but turn green and develop normally when illuminated.

General Comments. With this method it was possible to produce more than 30,000 plantlets from one flower stalk of the *Phalaenopsis* Babette "Symphony" in 3 years. *Phalaenopsis* Münsterland Stern "Alpha" yielded 10,000 plants in 2 years, and *Phalaenopsis* Barbara Moler "Firecracker" gave 3000 plantlets in 18 months (Haas-von Schmude, 1983). All three of these hybrids have *Phalaenopsis lueddemanniana* and *Phalaenopsis fasciata* in their background. These species have a natural tendency to form keikis and may well be easier to proliferate than hybrids of *Phalaenopsis amabilis* and other large-flowered types.

The fact that not all genotypes of *Phalaenopsis* behave in the same manner under identical culture conditions has been pointed out (Reuter, 1983).

TABLE PHAL-13. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) used for proliferation in the clonal propagation of *Phalaenopsis* (Haas-von Schmude, 1983)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot H_2O$	40	4 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, Kl	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	9	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
11	Pyridoxine·HCl (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
12	Thiamine·HCl (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[f]	1	
	Complex additives				
13	Casein hydrolysate	1 g	No stock	No stock	Weigh
14	Coconut water[g]	580 ml			
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Keep refrigerated between uses.

[g]Filter before use.

[h]Add items 1–7 and 9 to 350 ml distilled water (item 16); then add sugar (item 15) and casein hydrolysate (item 13). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added while stirring, to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, add coconut water (item 14), adjust volume to 1000 ml and the pH to 5.0–5.6 with dilute KOH or HCl, as needed. Pour into a 2-l flask and autoclave. Add amino acid (item 8) and vitamins (items 10–12) to hot and still liquid solution under sterile conditions, using sterile pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE PHAL-14. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962), used for differentiation in the clonal propagation of *Phalaenopsis* (Haas-von Schmude, 1983)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10

	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Keep refrigerated between uses.

[g]Filter before use.

[h]Add items 1–7 and 9 to 700 ml distilled water (item 16). Add sugar (item 15) and casein hydrolysate (item 13). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be stirred into the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, add coconut water (item 14) and adjust volume to 1000 ml with distilled water (item 16). Bring pH to 5.0–5.6 with dilute KOH or HCl, as needed. Pour into a 2-l flask and autoclave. Add amino acid (item 8) and vitamins (items 10–12) to the hot, autoclaved solution under sterile conditions, using sterile pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

Indoleacetyl–Amino Acid Conjugates in Mass Clonal Propagation of *Phalaenopsis*

Conjugates of IAA and certain amino acids, such as indoleacetyl alanine (IAA-ala) or indoleacetyl glycine (IAA-gly), substitute well as proliferation-inducing hormones (Griesbach, 1983) in place of the combination of the auxin IAA and the cytokinin BA used by previous investigators. These conjugates have been found to increase the proliferation and differentiation of tomato and tobacco tissue cultures (Hangarter et al., 1980).

Plant Material. Two-centimeter-long sections of a flower stalk, having one dormant bud, were cut from the *Phalaenopsis* Berry Hausermann, and their bracts were removed.

Surface Sterilization. The sections are sterilized for 30 min in a 25% Clorox solution (25 ml Clorox diluted to 100 ml with water) containing 0.05% Tween surfactant (type not given). After that the sections are rinsed in sterile distilled water, dipped in 70% aq ethanol for 30 sec, and rinsed again in sterile distilled water.

Culture Conditions. All cultures are grown at 28°C under 16-h photoperiods at 65 μEM^{-2} sec^{-1}. Liquid cultures are agitated at 2–3 rpm.

Culture Media. Half-strength MS medium supplemented with 2 g l^{-1} yeast extract, 13 mg l^{-1} isoleucine, and 100 mg l^{-1} *trans*-cinnamic acid (Table Phal-15; Reisinger et al., 1976) is used. A liquid MS medium supplemented with 2 mg l^{-1} yeast, 0.5 mg l^{-1} NAA, and 2 mg l^{-1} BA (Table Phal-16) is employed. Another liquid modified MS medium, containing 2 g l^{-1} yeast extract and one of four different IAA–amino acid conjugates is used for further proliferation (Table Phal-17). Differentiation is induced on solid modified MS medium (Table Phal-18).

Procedure. Once the second leaf develops from the buds of the flower-stalk sections on solid modified MS medium (Table Phal-15), remove the basal portions of the shoots, place in liquid modified MS solution (Table Phal-16), and rotate at a speed of 2–3 rpm. PLBs develop from the basal sections of the shoots. Place these in liquid MS medium that contains not NAA and BAP, but rather one of the IAA–amino acid conjugates (Table Phal-17). Other hormone combinations (Table Phal-19; Koch, 1974*a*, 1974*b*; Zimmer and Pieper, 1978) also give good results.

Differentiation is then induced by transferring the PLBs to solid MS medium supplemented with 2 g l^{-1} Bacto-Difco peptone (Table Phal-18).

General Comments. The medium with IAA-ala induced more PLBs than did the one with IAA-gly, which brought about initiation of more shoots. It appears that IAA-ala retards differentiation when compared with IAA-gly. However, absence of statistical analysis makes it impossible to determine the significance of the small differences between the use of conventionally employed hormones and the indoleacetyl amino acids (Table Phal-19). Question: Why use uncommon chemicals when simpler ones work as well or better?

TABLE PHAL-15. **Murashige–Skoog medium (Murashige and Skoog, 1962), modified for clonal propagation of *Phalaenopsis* through the culture of flower-stalk nodes (Griesbach, 1983)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[f]	1	
	Complex additive				
13	Peptone, Bacto-Difco	2 g	No stock	No stock	Weigh
	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Keep refrigerated between uses.

[g]Add items 1–7 and 9 to 900 ml distilled water (item 15), adjust pH to 5.0–5.6, add sugar (item 14) and peptone (item 13), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil while stirring, and slowly add agar (item 16). Agar can also be added with constant stirring to the cold solution, which is then brought to a gentle boil. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid and vitamins (items 8 and 10–12) to hot solution under sterile conditions with sterile pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

Mass Clonal Multiplication of *Phalaenopsis* from Internodal Sections of Young Flower Stalks

Several procedures, in which the shoot tissue derived from nodal flower-stem sections serves as explant material in the clonal multiplication of *Phalaenopsis*, have been published (Fu, 1979*a*; Kushnir and Budak, 1980; Yoneda et al., 1983). Clonal multiplication of *Phalaenopsis* obtained by culturing thin disks of young internodal sections of flower stalks was reported by Lin (1986).

Plant Material. Flower-stalk internodes of *Phalaenopsis* hybrids grown for 3 years under greenhouse conditions are used as explants. Highest PLB yields are obtained from newly emerging, 35–45-day-old flower stalks. At this stage only two to three internodes generally develop. The production of PLBs is usually about double that obtained with 60–75-day-old stalks. No PLBs are obtained from stalks 180 or more days old. Older flower stalks yield PLBs only from internodal sections near the tips. Nodes are removed from sterilized stalks, and the internodal sections are cut into 1–1.5-mm disks under sterile conditions (Fig. Phal-11). These disks are the explants to be cultured.

Surface Sterilization. Excised flower stalks are wiped with 70% aqueous ethanol and then sterilized in 1% sodium hypochlorite solution (20 ml household bleach diluted to 100 ml with water) containing 0.05% Tween 20. The sterilized stalks are then rinsed three times with sterile distilled water.

Culture Conditions. Cultures are maintained under about 500 lx of fluorescent light (FL 40D lamps, Taiwan), 16-h photoperiods, and temperatures of 26 ± 2°C.

Culture Medium. A modified solid Vacin and Went medium is used (Table Phal-20).

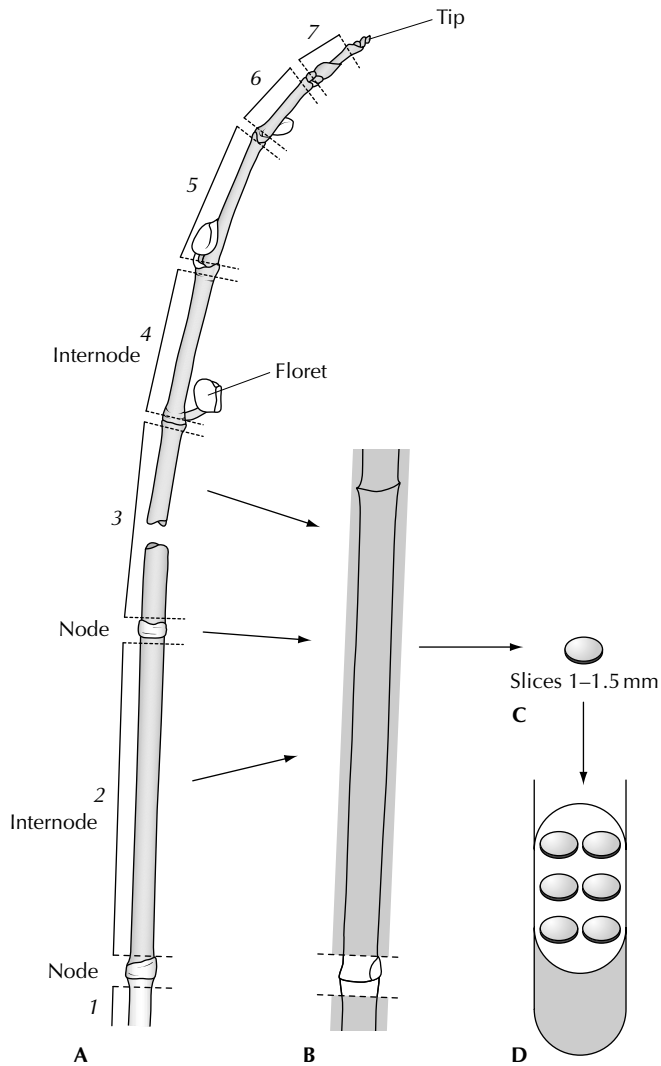

FIG. PHAL-11. **Clonal propagation of *Phalaenopsis* from a flower stalk. A. Internodal segments of young flower stalks. B–D. Slices of 1–1.5 mm, cut from the plant shown in A, are used as explants for mass clonal propagation (D). (Lin, 1986.)**

Developmental Sequence. Most sections cultured on solid medium enlarged within 15 days and produced PLBs after 30 days of culture. Within 45 days the PLBs elongated and after 2 months produced a few adventitious buds. Yellowish callus formed on some stalk sections. The frequency of callus induction was 26% on medium with 1 mg BA l^{-1} and 53% on medium with 5 mg BA l^{-1}. PLBs formed on the epidermis and cut surfaces of the sections that were cultured. After the first flower became visible, sections from the base stalks did not produce PLBs; only sections near the tip of these stalks produced such bodies (Fig. Phal-11) with a frequency of

TABLE PHAL-20. **Vacin and Went medium (Vacin and Went, 1949) modified for clonal propagation of *Phalaenopsis* from flower-stalk internode sections (Lin, 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	600	60 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	240	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	300	30 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	300	30 g l^{-1}	10	
5	Potassium nitrate, KNO_3	630	63 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	33.6	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	6	750 mg l^{-1}	10	
	Polyol				
8	*myo*-inositol	100	No stock	No stock	Weigh
	Vitamins				
9	Thiamine·HCl	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
10	Pyridoxine·HCl	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Nicotinic acid (niacin)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Cytokinin				
12	Benzylaminopurine (BAP)[f]	5	50 mg 100 ml^{-1} 95% ethanol[e]	10	
	Sugar				
13	Sucrose	20 g	No stock	No stock	Weigh
	Darkening agent				
14	Activated charcoal	2 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, so it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Keep vitamin and hormone solutions refrigerated between uses.

[f]For differentiation into plantlets divide protocorm-like bodies and subculture them on the same medium, except that the BAP concentration is reduced to 1 mg l^{-1}. The cytokinin can be solubilized with dilute HCl.

[g]Add items 1 and 3–8 to the 500 ml distilled water (item 15) that contains item 2, and adjust pH to 5.0–5.6. Add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. When agar is completely dissolved, add powdered charcoal (item 14) with rapid agitation (use a blendor or similar device), pour solution into a 2-l flask and autoclave. After autoclaving add to the still hot solution the vitamins (items 9–11) and the cytokinin (item 12) under sterile conditions using sterilized pipettes, mix well, and distribute medium to preautoclaved vessels. Omit agar for liquid medium.

27.5–44.7%. The highest frequency of PLB induction (62.9–77.1%) occurred on sections taken from flower stalks before the first flower became visible. *Phalaenopsis* stalks could still produce some PLBs (4.8–6.5%) near the tip following opening of the last flower.

The PLBs were subcultured on the same solid medium, containing 1 mg BA l^{-1} but without auxin to develop into plantlets.

TABLE PHAL-21. **Effect of growth regulators and stage of inflorescence development on the formation of protocorm-like bodies (PLBs) from young flower-stalk internode sections of *Phalaenopsis* (Lin, 1986), showing the ratio of the number of segments that formed PLBs to the total number of segments**

	Internode, number[a] from bottom (days after stalk forms)								
Growth regulators[b]	1 (30–45 days)		2 (60–75 days)		3 (90–105 days)		4 (120–135 days)		Percent PLBs formed
Control (none)	0/15	0/15	0/15	0/15	0/15	0/17	0/21	0/15	0
1 mg BAP l^{-1}	2/2	3/3	4/6	13/16	52/70	21/27	8/20	8/10	73.4
5 mg BAP l^{-1}	16/21	13/25	28/48	15/35	11/15	20/33	16/45	18/31	46.8
1 mg BAP l^{-1} + 1 mg NAA l^{-1}	0/2	0/5	0/4	2/15	5/18	3/24	11/6	2/6	12.6
5 mg BAP l^{-1} + 1 mg NAA l^{-1}	0/2	0/5	0/4	0/15	2/18	1/24	2/6	1/6	5.9
1 mg KIN l^{-1}	0/21	0/25	0/20	0/25	0/15	0/33	0/45	0/31	0

[a]See Fig. Phal-11 for intemode positions. Internode segments higher then 5 (180 days or older) produced no PLBs.
[b]BAP, benzylaminopurine; KIN, kinetin; NAA, naphthaleneacetic acid.

General Comments. The highest yield of PLBs was obtained with 1 mg BA l^{-1} and no auxin, followed by 5 mg BA l^{-1} and no auxin. Some PLBs formed when the auxin NAA (1 mg l^{-1}) was added to the cytokinin BA, but this combination reduced PLB production sharply. No PLB formation occurred with the cytokinin kinetin or with the control (Table Phal-21).

Clonal Multiplication of Stem-propagated *Phalaenopsis* Root Tissue

A procedure for root-tip culture developed by Tanaka et al. (1976) is as follows.

Plant Material. Seedlings of *Phalaenopsis amabilis* hybrids, 194 and 349 days old, were taken from aseptic culture. After removing them from the flask, root tips (3 mm long) were removed with a sterile razor blade and cultured on two solid media.

Culture Vessels. In most cases 18×180 mm test tubes plugged with cotton bungs were used as culture containers in the original research. Other vessels can also be used.

Culture Conditions. All cultures are maintained at 25°C under 16-h photoperiods provided by white fluorescent lamps (NEC Company Vita Lux or equivalent).

Culture Medium. Modified MS medium is used in which the inorganic nutrients are reduced to half their original concentration and auxins and cytokinins are omitted (Table Phal-22).

Developmental Sequence. Only four of 10 explants from the 349-day-old seedlings produced PLBs during culture periods of 120–272 days on the modified MS medium (Table Phal-22). A single culture on medium O (Ojima and Fujiwara, 1962) produced PLBs after 260 days. About 3 months later an increase in cellular

TABLE PHAL-22. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the clonal propagation of *Phalaenopsis* from root tips (Tanaka et al., 1976)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.0125	1.25 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.0125	1.25 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.15	1.115 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.415	415 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.125	12.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430 mg l^{-1}		
	Amino acid				
8	Glycine	2	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
11	Pyridoxine·HCl (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
12	Thiamine·HCl (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[f]	1	
	Sugar				
13	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			
	Solidifier				
15	Agar[g]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Keep refrigerated between uses.

[g]Add items 1–7 and 9 to 900 ml distilled water (item 14), adjust pH to 5.0–5.6, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Bring solution to a gentle boil, and add agar (item 15) slowly while stirring. Agar can also be added while stirring to the cold solution, which is then brought to a boil. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid and vitamins (items 8 and 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

activity was observed in these cases. Small bumps formed at the tip or lateral sides of the root-tip explant. These bumps differentiated into a callus from which PLBs developed gradually.

Only one culture from 10 explants of 194-day-old seedlings formed a small mass of cream-colored callus on modified MS medium (Table Phal-22). When this callus was excised and transplanted on the same medium, 12 PLBs were obtained. The PLBs can then be grown into plantlets on media suitable for seedling culture. Some of the root tips that failed to produce PLBs elongated or developed a shoot.

General Comments. Root explants from seedlings have little practical value, since their use does not allow for selection prior to multiplication. However, PLBs and plantlets have also been obtained from broken root explants of young plantlets derived from flower-stalk nodes (Zimmer and Pieper, 1978). Since the flower quality of such plants is known, this process would be useful (Zimmer and Pieper, 1978).

Isolation and Fusion of *Phalaenopsis* Protoplasts

The isolation of protoplasts from leaves of *Phalaenopsis* and subsequent intraspecific cell fusion employing polyethylene glycol, was reported by Teo and Neumann (1978*a*, 1978*b*). Also shown in these papers is a photomicrograph of interspecific cell fusion of the bigeneric hybrid *Renantanda* (*Renanthera* × *Vanda*) with *Phalaenopsis*, brought about by the use of polyethylene glycol. However, mitotic divisions or callus formation were not observed.

Plant Material. Plant material for this study was grown aseptically and therefore required no sterilization. Protoplasts were isolated from young leaves of *Phalaenopsis* and from protocorms of *Renantanda*.

Isolation of Protoplasts. Protoplasts were obtained as shown by a previous method (Teo and Neumann, 1978*c*; see also *Renantanda* entry).

Protoplast Fusion. Protoplast fusion was carried out in the presence of 28% polyethylene glycol (Elmheuser, 1977).

Protoplast Staining. To separate *Renantanda* protoplasts from those of *Phalaenopsis*, protoplasts from *Renantanda* Rosalind Cheok were stained with 0.001% bisbenzimide (available from Sigma Chemical Co., P.O. Box 14508, St. Louis, MO 63178) for 1 min and then promptly washed off with sterile nutrient. The stained nucleus emitted bright fluorescence under 490-nm light.

Histological Observations of *Phalaenopsis* Protocorm-like Bodies from Flower-stalk Internodes

Phalaenopsis flower-stalk internode sections were cultured for histological observations of PLBs (Lin, 1987).

Plant Material. Three internodes from near the tips of young flower stalks of *Phalaenopsis* (species or hybrid not given) were used as explants. Young internodes, 4–10 cm long taken from under the flower-stalk tip, were used as control explants.

Surface Sterilization. Explants to be cultured were surface-sterilized for 30 min in a 1% sodium hypochlorite solution containing 0.05% Tween 20 and then rinsed three times with sterile distilled water. They were then cut into sections 1–1.5 mm thick (see Fig. Phal-11) for culture.

Culture Vessels. The type of culture containers was not given in the original research, but test tubes were probably used (see Fig. Phal-11).

Culture Conditions. Cultures were maintained under 500 lx provided by FL-40D lamps and 16-h photoperiods at 26 ± 2°C.

Culture Medium. A modified Vacin and Went solid medium (see Table Phal-20) was used.

Developmental Sequence and Cytological Observations. After 3 days of culture (in the presence of 1 mg BA l^{-1}) no visible changes in the cultured tissues were observed. Cell division occurred in the epidermis only, after 7 days. After 11 days, cell division extended to the first layer of the cortex and to immature vascular bundles under cut surfaces. Fifteen days following the start of culture small protuberances consisting of cells that formed as a result of divisions were visible on the epidermis and cut surfaces. PLBs formed first on the epidermis and vascular bundles and became visible after 30 days of culture. PLBs formed on the epidermis and cortex, immature vascular bundles, and ground parenchyma following 45–60 days.

General Comments. These histological observations based on light microscopic examinations should be useful to others working on the micropropagation *of Phalaenopsis*.

Micropropagation of *Phalaenopsis* through the Culture of Leaf Segments

Dr. Michio Tanaka of the Laboratory of Floriculture, Faculty of Agriculture, Kagawa University, Miki-cho, Kagawa 761-07, Japan started to work on the culture of *Phalaenopsis* leaf segments in 1972. By 1990 he perfected a simple yet effective micropropagation procedure (Tanaka, 1990, 1992).

Plant Material. Leaf segments, 6–8 × 6–8 mm in size (Fig. Phal-12E1, F) were taken from the apical, median, and basal parts of the uppermost leaves (about 2 cm in length) on shoots derived from flower-stalk nodes in vitro (Fig. Phal-12A–D). Segments should be placed on the medium adaxial side up (Fig. Phal-12G). To increase production of PLBs from leaf segments, the shoots or plantlets from which the explants are taken should be cultured at 25°C under photoperiods of more than 8 h, a light

F. Leaf segments. G. Leaf segment in culture. H. PLBs produced by a leaf segment. I. Sectioning a PLB transversely. J. A PLB section in culture. K. PLBs in liquid culture. L. Proliferated PLBs. M. Plant formation from a PLB. N. Plantlet. O–R. PLBs on the adaxial surface of a leaf segment. S, T. PLBs on leaf segments after 120 days in culture. U. Proliferation on the basal part of a PLB. V. Proliferation on the apical half of a PLB. (NB there is no part P; Tanaka, 1990, 1992.)**

intensity of 180 lx, and on a medium that contains 1 or 10 mg BA l^{-1} or 20% (v/v) coconut water.

Surface Sterilization. Explants from plants in vitro do not require surface sterilization.

Culture Vessels. Test tubes, 18 × 180 mm containing 8 ml of medium, were used in the original research. Other containers can also be used.

Culture Conditions. Leaf segments should be cultured at 25°C in darkness for the initial 2 weeks and then under 16-h photoperiods of 900 lx.

Culture Media. Modified Kyoto medium (Tsukamoto et al., 1963) which employs Hyponex (N6.5:P6:K19; www.hyponex.co.jp) as a source of minerals (Table Phal-23) is used to culture leaf segments. To further enhance PLB formation and to absorb

TABLE PHAL-23. **Modified Hyponex/Kyoto medium (Tsukamoto et al., 1963) for the culture of *Phalaenopsis* leaf explants (Tanaka, 1990, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]From www.hyponex.co.jp

[c]Keep frozen between uses.

[d]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively. This stock solution may be at the limit of solubility of BA. If a precipitate forms shake well before dispensing.

[e]Suspend the adenine in 55 ml of distilled water, add 0.6 ml of 1 N sulfuric acid (H_2SO_4), and bring up volume to 200 ml with 95% ethanol. This stock solution may be at the limit of solubility of adenine. If a precipitate forms shake well before dispensing.

[f]Add items 1–7 to 900 ml of distilled water (item 9), adjust pH to 5.0 (Tsukamoto et al., 1963), add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

[g]This is the amount of agar listed in the original formulation (Tsukamoto et al., 1963). With this much agar the medium will be fairly hard.

phenolics, which are produced by the explants, and to darken the medium it is advisable to add 800 mg polyvinylpyrrolidone (PVP) l^{-1} to the medium. PLBs produced by leaf segments (Fig. Phal-12H) can be proliferated (Fig. Phal-12J–L, U, V) by cutting them transversely and placing the halves upside down on Vacin and Went medium (Vacin and Went, 1949) supplemented with 20% (v/v) coconut water (Table Phal-24). Proliferation can also be brought about by culturing the PLBs in liquid medium (Table Phal-24 without agar) with agitation. To induce plantlet development (Fig. Phal-12M, N), PLBs should be cultured on a different modification of the Hyponex/Kyoto medium (Table Phal-25).

Procedure. When shoots produced by flower-stalk nodes (Fig. Phal-12A-C) produce growths (Fig. Phal-12D) with large enough leaves, the uppermost leaf should be sectioned (Fig. Phal-12D1–F) and the sections should be placed in culture (Fig. 12G) on the first medium (Table Phal-23). After PLBs are produced (Fig. Phal-12H, O–T) they should be sectioned transversely (Fig. Phal-12I) and proliferated (Fig. Phal-12L) on solid (Fig. Phal-12J, U, V) or in liquid (Phal-12K) medium (Table Phal-25). To produce plantlets (Fig. Phal-12M, N), the PLBs should be placed on the third medium (Table Phal-25).

Developmental Sequence. Explants produce PLBs on the first medium (Table Phal-23). The PLBs proliferate when they are sectioned (Fig. Phal-12I) and the halves are placed on the second medium (Table Phal-24) in solid form. Uncut PLBs proliferate when cultured on the second medium in liquid form (Table Phal-24 without agar). Basal halves produce more PLBs than apical ones. PLBs produce plantlets on the third medium (Table Phal-25).

General Comments. This is an efficient and effective procedure for the micropropagation of *Phalaenopsis*. It can produce a large number of plants without endangering the original plants. However, excessive proliferation must be avoided because it can cause undesirable mutations. The proportion of leaf segments that produce PLBs, and the number of PLBs per segment, can vary with the hybrid being cultured. PLBs generated through this method were used to produce transgenic *Phalaenopsis* (Anzai and Tanaka, 2001).

The formation of protocorm-like bodies (PLBs) and shoot development from basal and apical sections of leaf segment-derived PLBs (Tanaka, 1992, table 1).

		Developed organ on culture				
Section	No. of cultures	PLB and shoots, %	No. of PLBs culture	PLBs, %	No. of PLBs culture	Shoot, %
Upper	16	31	1.0	38	5.3	31
Lower	16	0	–	100	13.7	0

Hybrid used: Lavender Lady × [Lavender Lady × (Clarelen × Zada)].
PLBs were transversally bisected, and cultured on Vacin and Went + coconut milk 20% (v/v) medium, at 25°C with a 16-h light (900 lx).
Data were recorded 55 days after culture.

TABLE PHAL-24. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the proliferation of leaf-segment-derived *Phalaenopsis* protocorm-like bodies (Tanaka, 1990, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Coconut water (CW)[e]	200.0 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 10), adjust pH to 5–5.4, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar should not be added to liquid medium. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

TABLE PHAL-25. **Modified Hyponex/Kyoto medium (Tsukamoto et al., 1963) for plantlet formation from protocorm-like bodies derived from *Phalaenopsis* leaf explants (Tanaka, 1990, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Darkening agent				
6	Activated charcoal[e]	2.0	No stock	No stock	Weigh
	Sugar				
7	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
8	Water, distilled[f]	To 1000 ml			
	Solidifier				
9	Agar[f]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]From www.hyponex.co.jp.

[c]These are the microelements used by Nitsch and Nitsch (1967).

[d]Keep frozen between uses.

[e]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances.

[f]Add items 1–5 to 900 ml of distilled water (item 8), adjust pH to 5.0 (Tsukamoto et al., 1963), add sugar (item 7), and adjust volume to 1000 ml with distilled water (item 8). Bring the solution to a gentle boil and add the agar (item 9) slowly while stirring. The agar can also be added to the cold water, which is brought to a boil and stirred. When the agar is completely dissolved, add the charcoal (item 6) with vigorous stirring, distribute the medium to culture vessels, and autoclave. Agar is not added to liquid media.

Callus Induction and Somatic Embryogenesis in *Phalaenopsis*

A callus that can be sectioned and cultured on a medium or media capable of inducing plant formation and/or somatic embryos that can form plantlets facilitate and accelerate micropropagation. Therefore a method for callus induction, somatic embryogenesis, and plantlet production was developed at Kagawa University in Japan (Ishii et al., 1998).

Plant Material. PLBs of *Phalaenopsis* Richard Shaffer 'Santa Cruz' obtained through the culture of leaf segments (see Micropropagation of *Phalaenopsis* through the Culture of Leaf Segments) were cut transversely (as shown here: ⊖) and the

segments were used as one type of explants. The leaf segments were obtained by cutting 2-cm-long leaves into six sections (see Fig. Phal-12E, F) taken from a shoot produced by flower-stalk node culture [see *Phalaenopsis* Flower-stalk Node Propagation (p. 911, Vol. II), Use of Plant Hormones to Improve Shoot Growth of *Phalaenopsis* Stem Nodes (p. 913, Vol. II), Shoot Growth of *Phalaenopsis* Flower-stalk Nodes in the Presence of Anti-auxin (p. 916, Vol. II), and Clonal Propagation of *Phalaenopsis* through Injured Nodal Flower-stalk Buds (p. 918, Vol. II)]. Very few leaf segments produced calli.

Surface Sterilization. Explants taken from PLBs growing in vitro do not require sterilization.

Culture Vessels. Erlenmeyer flasks, 250-ml capacity containing 40–60 ml medium, are suitable as culture vessels. Other containers can also be used.

Culture Conditions. All explants should be cultured at 25°C. PLB sections should be cultured under 16-h photoperiods (no intensity given) provided by Homolux lamps (Matsushita Electric Industrial Co.) for 8 weeks. Leaf explants must be kept in the dark for 2 weeks, moved to the same illumination as PLB sections for another 14 days, and cultured for 3 months.

Culture Media. PLB sections should be cultured on Vacin and Went medium (Vacin and Went, 1949) containing 40 g sucrose l^{-1} and 200 ml coconut water (CW) l^{-1} solidified with 2 g gellan gum l^{-1} (Table Phal-26). Leaf segments should be cultured on Vacin and Went medium solidified with gellan gum, but without CW, and containing 40 g sucrose l^{-1}, 1 mg 2,4-D l^{-1}, and 0.1 mg BA l^{-1} (Table Phal-27). Callus masses produce PLBs after being transferred to Vacin and Went medium without sucrose, supplemented with 200 ml CW l^{-1}, and solidified with 8 g agar l^{-1} (Table Phal-28). PLBs produced on the sugar-free medium (Table Phal-28) develop plantlets on a modified Hyponex medium (Table Phal-29).

Procedure. PLB sections and leaf segments should be cultured on the first medium (Table Phal-26) for at least 8 weeks under illumination. When enough callus becomes available, portions should be moved to the sugar-free medium (Table Phal-28) for PLB production. Leaf segments should be placed on the hormone-containing medium (Table Phal-27) first in the dark for 2 weeks, and then in the light for 14 weeks to produce callus. To generate PLBs from this callus, portions of it should also be moved to the sugar-free substrate (Table Phal-28). Once PLBs form on the sugar-free medium, they should be moved to the Hyponex solution (Table Phal-29) for plantlet production.

Developmental Sequence. PLB sections and leaf segments produce callus (Fig. Phal-13A) on the first medium (Tables Phal-26 and Phal-27, respectively). Regardless of its origin, the callus produces PLBs (Fig. Phal-13A) on the second medium (Table Phal-28). Histological observations suggest that the PLBs originate from somatic embryos (Fig. Phal-13B, C). Plantlets (Fig. Phal-13D) are formed on the Hyponex medium (Table Phal-29).

TABLE PHAL-26. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for callus production from sections of protocorm-like bodies of *Phalaenopsis* (Ishii et al., 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

	Sugar				
9	Sucrose	40.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Gellan gum[f,g]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), if necessary bring volume to 900 ml with distilled water (item 10), adjust pH to 5.3, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Add the gellan gum (item 11) in accordance with the instruction in footnote *g*. When the gellan gum (item 11) is completely dissolved, pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE PHAL-27. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for callus production from segments of young *Phalaenopsis* leaves (Ishii et al., 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	2,4-Dichlorophenoxyacetic acid (2,4-D)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	Benzyladenine (BA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	40.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Gellan gum[g,h]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[f]Keep frozen between uses.

[g]Add items 1 and 3–9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 11), adjust pH to 5.3, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Add the gellan gum (item 12) in accordance with the instruction in footnote *h*. When the Gellan gum (item 12) is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable. As a rule hormones should be added after autoclaving but in this case all components seem to have been incorporated in the medium before it was autoclaved.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear, and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (Gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE PHAL-28. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the induction of protocorm-like bodies from *Phalaenopsis* callus (Ishii et al., 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Coconut water (CW)[e]	200.0 ml	No stock	No stock	Weigh
	Sugar				
9	Sucrose	0 or 20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f,g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), if necessary bring volume to 900 ml with distilled water (item 10), adjust pH to 5.3, add sugar (item 9) or not (this medium can also be prepared without sugar), and raise volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar (item 11) is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

TABLE PHAL-29. **Modified Hyponex/Kyoto medium (Tsukamoto et al., 1963) for plantlet formation from protocorm-like bodies derived from *Phalaenopsis* callus (Tanaka, 1990, 1992)**

10	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]From www.hyponex.co.jp.

[c]These are the microelements used by Nitsch and Nitsch (1967).

[d]Keep frozen between uses.

[e]No information is given on how to prepare potato extract or where to purchase any. The usual sources of tissue culture supplies do not carry potato extract. One possible method of preparing the extract may be to cut a peeled potato, weigh 30 g of the cubes, boil them for 10–15 min in 100 ml of distilled water, filter the "soup" and add the liquid to the medium. Another possibility is to homogenize 30 g of cubes and add the homogenate to the medium.

[f]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances.

[g]Add items 1–6 to 900 ml of distilled water (item 9), adjust pH to 5.3, add sugar (item 8), and raise volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar (item 10) can also be added to the cold water which is brought to a boil and stirred. When the agar (item 10) is completely dissolved, add the charcoal (item 7) with vigorous stirring, distribute the medium to culture vessels, and autoclave. Agar is not added to liquid media.

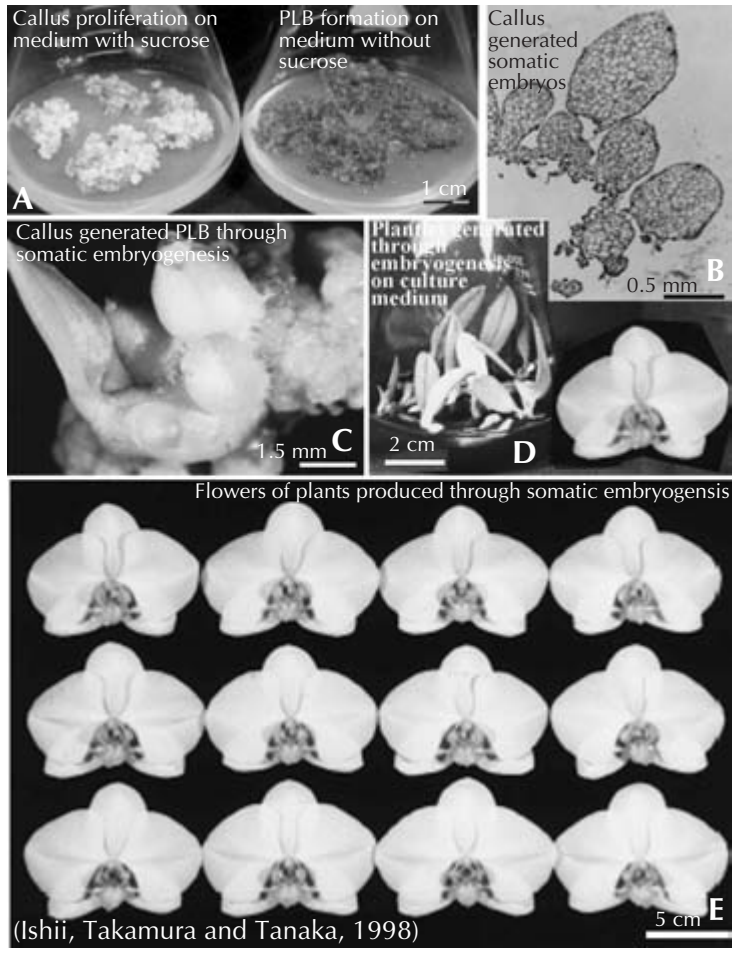

FIG. PHAL-13. **Callus induction and somatic embryogenesis in *Phalaenopsis*.**

General Comments. This method can accelerate propagation in vitro without the danger of undesirable mutations because "no variation was observed in . . . flowering plants" produced through this procedure (Fig. Phal-13E).

Micropropagation of *Phalaenopsis* by Culturing Shoot Tips of Flower-stalk Buds

The methods described in "Micropropagation of *Phalaenopsis* and *Doritaenopsis* by culturing shoot tips of flower stalk buds" (Tokuhara and Mii, 1993) are also suitable for *Phalaenopsis*. When using this method it is important to keep in mind that proliferation, especially if it is excessive, can lead to somaclonal variations and flowers which are not attractive (see Fig. Dtps-4; Tokuhara and Mii, 1998).

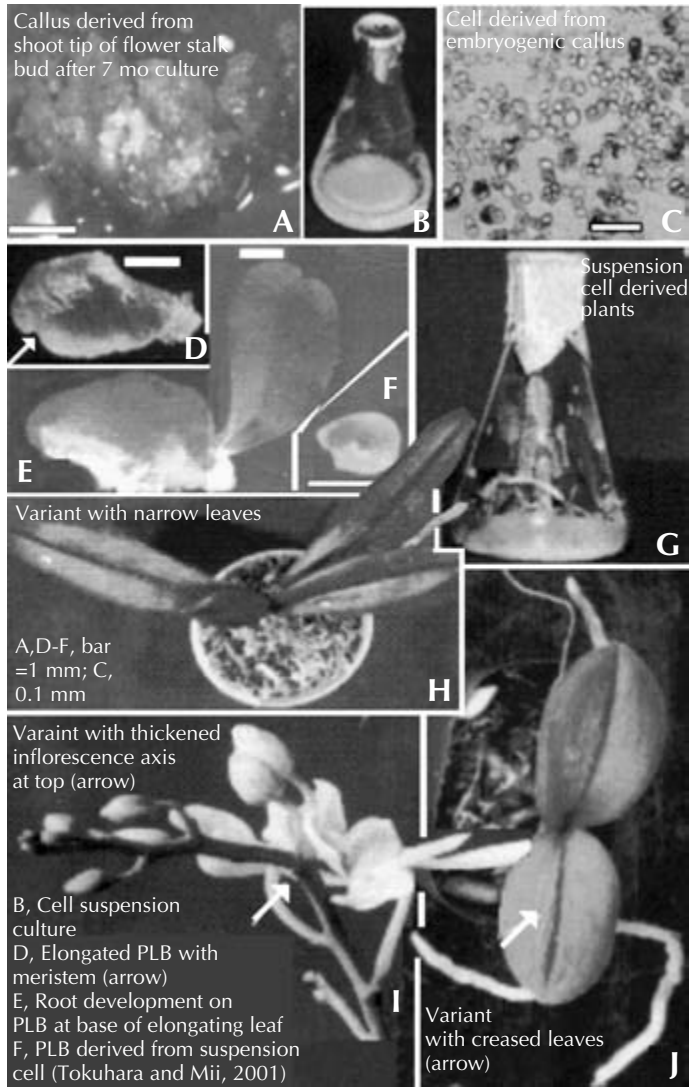

FIG. PHAL-14. **Induction of embryogenic callus and cell suspension cultures from shoot tips excised from flower-stalk buds of *Phalaenopsis* (Tokuhara and Mii, 2001).**

Induction of *Phalaenopsis* Callus and Cell Suspension Cultures from Flower-stalk Bud Tips

A method for the induction of embryogenic callus (Fig. Phal-14A) and/or totipotent cells (Fig. Phal-14B, C), and producing plants (Fig. Phal-14F–J) from them, was developed at the Dogashima Orchid Sanctuary and the Faculty of Agriculture, Chiba University in Japan (Tokuhara and Mii, 2001).

Plant Material. Shoot-tip explants should be obtained by the method used by Tokuhara and Mii (1993).

Surface Sterilization. The procedure is the same as the one used to surface-sterilize explants by Tokuhara and Mii (1993).

Culture Vessels. For callus production, explants should be cultured singly in 24×100 mm culture tubes containing 15 ml medium. To establish cell suspension cultures (Fig. Phal-14C), about 200 mg of callus should be cultured in 100-ml Erlenmeyer flasks (Fig. Phal-14B) containing 40 ml liquid medium. Petri dishes, 9 cm in diameter, containing 25 ml medium should be used for callus production from cells.

Culture Conditions. Both solid and liquid cultures should be maintained at $23 \pm 1°C$ under 14-h photoperiods of 33 μmol m^{-2} s^{-1}. Liquid cultures should be placed on a reciprocal shaker at 80 oscillations per minute (the original paper uses "rpm" or revolutions per minute, which is incorrect in this case because reciprocal shakers do not revolve, they oscillate or move back and forth or to and fro ⇄).

Culture Media. To induce callus, the explants should be cultured on the new Dogashima (ND) medium (Tokuhara and Mii, 1993) containing 0.5 μmol NAA l^{-1}, 4.4 μmol BAP l^{-1}, and 29.2 mmol sucrose l^{-1} (Table Phal-30). Callus should be moved to the same medium, but with 58.4 mmol sucrose l^{-1} (Table Phal-31), after 4 months of culture. To obtain a cell suspension, sections of callus must be cultured in liquid ND medium with 5.4 μmol NAA l^{-1} and 58.4 mmol sucrose l^{-1} (Table Phal-32). Calli and cells from cell suspension cultures produce PLBs (Fig. Phal-14D, E) on ND medium with 29.2 mmol sucrose l^{-1} and probably (the original paper is not very clear on this point) also 5.4 μmol NAA l^{-1} (Table Phal-33). To produce plantlets (Fig. Phal-14G) these PLBs should be moved to a medium free of plant growth regulators and containing potato granules (Basic American Foods, Walnut Creek, CA, USA, www.baf.com; the granules are fortified with vitamin C which probably makes no difference because this vitamin is heat-labile and probably most of it is destroyed during autoclaving), apple juice (the source for the original research was Kyoei Co. Ltd., Kuroishi, Aomori, Japan, but any apple juice completely free of additives, preservatives, and coloring substances and with additional sugar will probably be suitable) and 58.4 mmol sucrose l^{-1} (Table Phal-34).

Procedure. Shoot tips of buds from flower-stalk nodes are cultured for 7 months in test tubes on ND medium to produce embryogenic callus on a medium with 29.2 mmol sucrose (Table Phal-30). The callus is moved to a solution which contains 58.4 mmol sucrose (Table Phal-31), but is otherwise the same as the previous substrate. The callus should be subcultured monthly. To produce cell suspension cultures, the callus is cultured in agitated Erlenmeyer flasks containing liquid ND medium with 58.4 mmol sucrose (Table Phal-32). Cells should be subcultured at 1-month intervals. To induce PLBs, cells should be collected by centrifuging the suspension at $200\times g$ for 5 min and cultured on solid ND medium with 29.2 mmol glucose for 5 months. The embryogenic cells and callus on this medium should be subcultured

TABLE PHAL-30. **New Dogashima (ND) medium (Tokuhara and Mii, 1993) for callus induction from shoot-tip explants from buds of *Phalaenopsis* flower-stalk nodes (Tokuhara and Mii, 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Dissolve the adenine in up to 30 ml 0.1 N hydrochloric acid and make up the solution to 100 ml with 95% ethanol.

[g]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively. The actual amount of NAA (MW 186.2) used is 0.5 µmol which comes to (0.5 × 186.21 =) 93.11 µg or 0.093 mg, which is rounded here to 0.1 mg. BA (MW 225.2) was used at 4.4 µmol which is (4.4 × 225.26 =) 991.14 µg. That is rounded to 1 mg here.

[h]Dissolve the calcium pantothenate in 30 ml distilled water and make up the solution to 100 ml with 95% ethanol.

[i]Add items 1–18 to 900 ml of distilled water (item 20), adjust pH to 5.4, add sugar (item 19), and raise volume to 1000 ml with distilled water (item 20). Add the Gelrite (Phytagel, gellan gum) slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps (see also footnote *j*). If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave. The amino acid (item 9), hormones (items 12 and 13) and vitamins (items 14–18) are not heat-stable and are often added to autoclaved and still warm and liquid media with sterilized pipettes and mixed well before distribution to preautoclaved culture vessels. In this case all components of the medium are autoclaved. Sucrose (MW 342.30) at 29.2 mmol is 9995.16 mg, which is rounded to 10 g; 58.4 mmol is 19,990.32 mg or 20 g (rounded).

[j]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE PHAL-31. **New Dogashima (ND) medium (Tokuhara and Mii, 1993) for the maintenance of callus produced by shoot-tip explants from buds of *Phalaenopsis* flower-stalk nodes (Tokuhara and Mii, 2001)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Dissolve the adenine in up to 30 ml 0.1 N hydrochloric acid and make up the solution to 100 ml with 95% ethanol.

[g]If the auxin does not dissolve, add a few drops of 0.1 N KOH. The actual amount of NAA (MW 186.21) used is 5.4 µmol which comes to (5.4 × 186.21=) 1005.53 µg or 1.006 mg, that is rounded here to 1 mg.

[h]Dissolve the calcium pantothenate in 30 ml distilled water and make up the solution to 100 ml with 95% ethanol.

[i]Add items 1–17 to 900 ml of distilled water (item 19), adjust pH to 5.4, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 19), pour the solution into culture vessels, and autoclave. The amino acid (item 9), hormone (item 12) and vitamins (items 13–17) are not heat-stable and are often added to autoclaved and still warm and liquid media with sterilized pipettes and mixed well before distribution to preautoclaved culture vessels. In this case all components of the medium are autoclaved. Sucrose (MW 342.30) at 29.2 mmol is 9995.16 mg, which is rounded to 10 g; 58.4 mmol is 19,990.32 mg or 20 g (rounded).

TABLE PHAL-33. **New Dogashima (ND) medium (Tokuhara and Mii, 1993) modified for protocorm-like body (PLB) and plantlet production from cell suspensions derived from callus produced by shoot-tip explants from buds of *Phalaenopsis* flower-stalk nodes (Tokuhara and Mii, 2001)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Dissolve the adenine in up to 30 ml 0.1 N hydrochloric acid and make up the solution to 100 ml with 95% ethanol.

[g]If the auxin does not dissolve, add a few drops of 0.1 N KOH. The actual amount of NAA (MW 186.21) used is 5.4 µmol which comes to (5.4 × 186.21 =) 1005.53 µg or 1.006 mg, that is rounded here to 1 mg.

[h]Dissolve the calcium pantothenate in 30 ml distilled water and make up the solution to 100 ml with 95% ethanol.

[i]Add items 1–17 to 900 ml of distilled water (item 19), adjust pH to 5.4, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 19). Add the Gelrite (Phytagel, gellan gum) slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps (see also footnore *j*). If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the Gelrite is completely

in Petri dishes twice with 1-month intervals on a suitable medium (Table Phal-33). After 10 months, PLBs that form on this medium are transferred to a fifth solution (Table Phal-34) to bring about plantlet formation.

General Comments. This procedure can produce a large number of plants with somaclonal variations occurring in "less that 10% in six out of eight genotypes examined." The procedure is complex and made more difficult to follow by unclear writing in some parts of the paper, as for example on p. 458: "After proliferation in liquid medium, embryogenic cells of eight genotypes (one genotype of . . .) induced from shoot-tip culture of vegetative buds on flower stalks, on medium consisting of 0.5 μ*M* [this is incorrect usage of terminology because *M* stands for molar, the correct term here is μmoles] NAA, 4.4 μ*M* [see comment above] BA, 58.4 m*M* [see comment above] sucrose and 2 g l^{-1} gellan gum, were subcultured twice at 1-mo intervals. For each phenotype, 50–100 mg of the calluses were transferred . . . and cultured for PLB formation." Is this section dealing with embryogenic cells or with calluses? This quote above is followed by a description of a medium for plantlet induction from the PLBs. But the abstract tells a different story: "These calluses were successfully cultured as cell suspension cultures in liquid NDM supplemented with 5.4 μ*M* [see comment above] NAA and 58.4 m*M* [see comment above] sucrose. By simply reducing the sucrose concentration to 29.2 m*M* [see comment above] the cells grew into plantlets. . . ." So, what to do? Which medium to use? Should the outline in the abstract be followed? Or, is the procedure on p. 458 correct? Dr. Mii was kind enough to clarify the paper and as a result the procedure here (see above) is the one to follow. Those who wish to use this procedure will do well to read the original article and experiment with the procedures. The e-mail address of the first author as given on the paper is tokuhara@dogashima.com.

The new Dogashima culture medium derives its name from the Dogashima Orchid Sanctuary with which the first author of this paper, Ken Tokuhara, is associated. The exact name and address is the Orchid Sanctuary Dogashima, 2848-1 Nishina, Nishizu-cho, Kamo-gun, Shizuoka 410-3514, Japan. The other author, Masahiro Mii, is with the Faculty of Horticulture, Chiba University, Matsudo, Chiba 271-0092, Japan.

dissolved pour the solution into culture vessels and autoclave. The amino acid (item 8), hormone (item 12), and vitamins (items 13–17) are not heat-stable and are often added to autoclaved and still warm and liquid media with sterilized pipettes and mixed well before distribution to preautoclaved culture vessels. In this case all components of the medium are autoclaved. Sucrose (MW 342.30) at 29.2 mmol is 9995.16 mg, which is rounded to 10 g; 58.4 mmol is 19,990.32 mg or 20 g (rounded).

[f]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE PHAL-34. **New Dogashima (ND) medium (Tokuhara and Mii, 1993) modified for plantlet production from protocorm-like bodies (PLB) produced by suspension cultures derived from callus produced by shoot-tip explants from buds of *Phalaenopsis* flower-stalk nodes (Tokuhara and Mii, 2001)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Dissolve the calcium pantothenate in 30 ml distilled water and make up the solution to 100 ml with 95% ethanol.

[g]Basic American Foods, Walnut Creek, CA, USA, www.baf.com.

[h]The brand used in the original research was Kyoei Co., Ltd., Kuroishi, Aomori, Japan, but any apple juice completely free of additives or additional sugar can be used. In the original paper the amount used is given in grams which is unusual for a liquid.

[i]Add items 1–17 to 700 ml of distilled water (item 19), adjust pH to 5.4, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 19). Add the Gelrite (Phytagel, gellan gum) slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps (see also footnore *j*). If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave. The amino acid (item 9) and vitamins (items 11–15) are not heat-stable and are often added to autoclaved and still warm and liquid media with sterilized pipettes and mixed well before distribution to preautoclaved culture vessels. In this case all components of the medium are autoclaved. Sucrose (MW 342.30) at 29.2 mmol is 9995.16 mg which is rounded to 10 g; 58.4 mmol is 19,990.32 mg or 20 g (rounded).

[j]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

Propagation of *Phalaenopsis* through the Culture of Flower-stalk Sections on Thidiazuron-containing Medium

An often repeated erroneous assertion in the literature is that shoot tips (Morel, 1960) were the first orchid explants to be cultured, when in fact it was *Phalaenopsis* flower-stalk sections (Rotor, 1949). The culture of inflorescence sections is still an important means of micropropagation for *Phalaenopsis*, but most of the available methods produce only a few plants per explants. Approximately 10 years after the very high cytokinin acitivity of TDZ became known (see text box on p. 670, Vol. I in the *Doritaenopsis* section), Dr. Robert Ernst at the Universisty of California, Irvine used it to propagate *Phalaenopsis* stem sections (Ernst, 1994).

Plant Material. Explants should be taken from flower stalks which have finished blooming. The upper flower-bud-bearing portions and the lowermost node stalks should be removed. After that the stalks should be cut into 3-cm sections, each with a bud in the middle.

Surface Sterilization. In the original research, the ends of the sections were sealed with paraffin wax to prevent entry of sterilant into the tissues. This was most probably a superfluous precaution because the amount of sterilant that can enter the sections during the sterilization process is very small and will probably have no effects of any kind. Also, cutting about 0.25–0.5 cm off the ends of sections after the sterilization will probably remove tissue that contains sterilant. Numerous *Phalaenopsis* stem sections which are surface-sterilized and cultured successfully in many laboratories without paraffin sealant are excellent proof that the paraffin wax seal is not necessary. Still, it should not be eliminated without a test. The sealed node sections should be wiped with 95% ethanol and then stirred for 20 min in a 1% solution of sodium hypochlorite (20 ml of household bleach containing 5–5.25% sodium hypochlorite) partially neutralized to pH 9.0 ± 0.2 with 2N hydrochloric acid [17.2 ml of concentrated hydrochloric acid diluted to 100 ml with distilled water; to prevent splattering and possible injury to the operator the acid must be poured into the water (never the water into the acid) slowly, with stirring, while wearing a face guard and gloves]. Bracts that cover the buds should be removed before submerging the sections in the sodium hydroxide sterilant for an additional 10 min. The sections should be placed in culture after rinsing them three times with sterile distilled water and cutting the paraffin-sealed ends.

Culture Vessels. Erlenmeyer flasks, 250-ml capacity containing about 50 ml medium, closed with perforated rubber stoppers that were plugged with cotton. Other containers and/or different plugs can also be used.

Culture Conditions. Research cultures were maintained at 23–24°C under 12-h photoperiods of approximately 25 μmol m^{-2} s^{-1} provided by Sylvania F 30TB 30-W Gro-Lux lamps (Sylvania GTE, Versailles, KY). Standard culture room conditions are probably also suitable.

Culture Media. Explants should be cultured initially in a medium designated XER by its author (X stands for "experimental" and ER are the initials, last name first, of Dr. Robert Ernst who formulated the medium and named it for himself) containing 0.45 μmol TDZ (Table Phal-35). PLBs produced on the first medium should be cultured on XER medium containing 30–45% coconut water from ripe nuts (Table Phal-36) to induce further proliferation. To enhance vegetative growth, PLBs can also be cultured (before or after proliferation) on XER containing 0.2% activated charcoal (www.sigmaaldrich.com) and 5% (w/v) ripe banana pulp homogenate (Table Phal-37).

Procedure. Surface-sterilized sections are placed in culture and maintained on the first medium (Table Phal-35) until PLB or plantlet formation. PLBs can be cultured on coconut-water-containing XER (Table Phal-36) for proliferation. Plantlets or PLBs are cultured on medium supplemented with banana pulp (Table Phal-37) for vegetative growth.

General Comments. This method is the first one to use TDZ for orchids. Its main advantage is that it generates several plantlets per node explant. The method is the same as the one used for *Doritaenopsis* (Ernst, 1994).

Carl Ludwig Blume (1796–1862)

C. L. Blume established the genus *Phalaenopsis* as it is known as present.

TABLE PHAL-35. **XER medium for the culture of *Phalaenopsis* flower-stalk sections (Ernst, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	122.0	12.2 g l^{-1}	10

	Cytokinin				
9	Thidizuron (TDZ)	1.0	100 mg 100 ml 1N NaOH in 95% ethanol[e]	1	
	Sugar				
10	Fructose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Gelrite[f,g]	5.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]The original recipe does not include EDTA as a chelating agent. It is included here because iron salts tend not to stay in solution. Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. The original recipe for this medium calls for 28 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$ l^{-1}. The difference (0.2 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored. Sticklers for accuracy can add 28 mg l^{-1}.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]To prepare the solvent (1N NaOH in ethanol) dissolve 4 g NaOH in 100 ml 95% ethanol. Use this as a sterilizing solvent for thidizuron if the cytokinin is to be added to the medium after autoclaving. According to several reports thidiazuron can be added to the medium before autoclaving. If so it can be dissolved in aqueous 1N NaOH. In either case the stock solution should be kept frozen between uses. Thidiazuron can also be dissolved in dimethyl sulfoxide (DMSO). Both thidiazuron and DMSO can be obtained from www.sigmaaldrich.com and other sources. For more information about incorporation of thidiazuron in culture media see Badzian et al. (1989); Bates et al. (1992); Fellman et al. (1987); Huetterman and Preece (1993; excellent source of information); Mok and Mok (1985); Mok et al. (1982); and Neuman et al. (1993).

[f]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and bring volume to 1000 ml with distilled water (item 11). Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

TABLE PHAL-36. **Coconut-water-containing XER medium for the proliferation of protocorm-like bodies produced by flower-stalk explants of *Phalaenopsis* (Ernst, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4{\cdot}7H_2O$	122.0	12.2 g l^{-1}	10	
4	Dibasic potassium phosphate, K_2HPO_4	30.0	3.0 g l^{-1}	10	
5	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
6	Potassium nitrate, KNO_3	500.0	50.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4{\cdot}7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.5	50.0 mg l^{-1}		
(b)	Copper sulfate, $CuSO_4{\cdot}5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4{\cdot}2H_2O$	3.0	300.0 mg l^{-1}	10	One solution
(e)	Sodium molybdate, $NaMoO_4{\cdot}2H_2O$	0.025	2.5 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4{\cdot}7H_2O$	0.5	50.0 mg l^{-1}		
	Complex additive				
9	Coconut water from ripe nuts[e]	400.0 ml	No stock	No stock	Measure
	Sugar				
10	Fructose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Gelrite[f,g]	5.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]The original recipe does not include EDTA as a chelating agent. It is included here because iron salts tend not to stay in solution. Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. The original recipe for this medium calls for 28 mg ferrous sulfate, $FeSO_4{\cdot}7H_2O$ l^{-1}. The difference (0.2 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored. Sticklers for accuracy can add 28 mg l^{-1}.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts except when indicated otherwise as in this case. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe nuts are not available, water from ripe (brown) ones can be used even for media which require water from green fruits. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1–9 to 500 ml of distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and bring volume to 1000 ml with distilled water (item 11). Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

TABLE PHAL-37. **XER medium containing Banana pulp homogenate and activated charcoal for the enhancement of vegetative growth of plantlets produced by flower-stalk explants of *Phalaenopsis* (Ernst, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	122.0	12.2 g l^{-1}	10	
4	Dibasic potassium phosphate, K_2HPO_4	30.0	3.0 g l^{-1}	10	
5	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
6	Potassium nitrate, KNO_3	500.0	50.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	10.0	1.0 g l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	25.0	2.5 g l^{-1}		
(e)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	10.0	1.0 g l^{-1}		
	Complex additive				
9	Ripe banana pulp homogenate[e]	50.0 g	No stock	No stock	Weigh
	Sugar				
10	Fructose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f,g]	To 1000 ml			
	Solidifier				
12	Gelrite[f,g]	5.0 g	No stock	No stock	Weigh
	Darkening agent				
13	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]The original recipe does not include EDTA as a chelating agent. It is included here because iron salts tend not to stay in solution. Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. The original recipe for this medium calls for 28 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$ l^{-1}. The difference (0.2 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored. Sticklers for accuracy can add 28 mg l^{-1}.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable, (2) the peel rather than the pulp should be used, (3) unpeeled banana homogenate should be incorporated in media, and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and use what is suggested there.

[f]Pour 900 distilled water (item 11) into a blender, add items 1–9, homogenize thoroughly, adjust pH to 5.5, add sugar (item 10), homogenize again and bring volume to 1000 ml with distilled water (item 11). Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[g]Gellan gum [available as such rom www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite should not be used except in special circumstances.

Effect of Bract Removal Time on the Decontamination and Growth of Flower-stalk Nodes

Research at the Department of Life Science, Aichi University of Education (Ichihashi et al., 2000) has shown that:

1 Fewer cultures became contaminated (Fig. Phal-15) when the bracts were removed (Fig. Phal-16) after sterilization. These findings are not in agreement with conventional wisdom. They may prove to be applicable in all cases or be limited to the conditions at Aichi. Therefore preliminary tests are advisable. Or, the nodes should be surface-sterilized before and after the bract is removed.

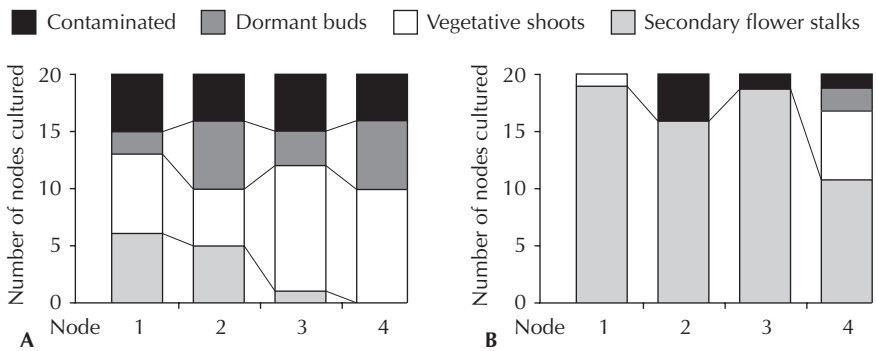

FIG. PHAL-15. **Effects of the time of bract removal on *Phalaenopsis* flower-stalk node cultures. A. Bract removed before sterilization. B. Bract removed after sterilization. (Ichihashi et al., 2000.)**

FIG. PHAL-16. ***Phalaenopsis* flower-stalk nodes before (left) and after (right) removal of the bract. In the right-hand stalk, the bud is visible. (From Lotte and Thomas website, http://www.orchideenvermehrung.at/english/index.htm.)**

TABLE PHAL-38. **Hyponex/Kyoto medium (Tsukamoto et al., 1963) modified for the culture of *Phalaenopsis* flower-stalk nodes (Ichihashi et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Hyponex[b]	3.5 g	No stock	No stock	Weigh
	Polyol				
2	*myo*-inositol	100.0	No stock	No stock	Weigh
	Amino acid				
3	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[c]	1	
	Cytokinin				
4	Benzyladenine (BA)	5.0	500 mg 100 ml^{-1} 95% ethanol[c,d]	1	
	Vitamins				
5	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[c]	1	
6	Pyridoxine·HCl	0.5	50 mg 100 ml^{-1} 95% ethanol[c]	1	
7	Thiamine·HCl (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[c]	1	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]From www.hyponex.co.jp.

[c]Keep frozen between uses.

[d]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[e]Add items 1–7 to 900 ml of distilled water (item 9), adjust pH to 5.6, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

2 Most buds developed secondary flower stalks when the bract was removed after surface sterilization. If the bract was removed before surface sterilization, most buds formed vegetative shoots. Since the intent of node culture is to produce vegetative shoots and plantlets, removing the bract before sterilization is preferable even if more nodes will become contaminated.

Nodes were cultured on a modified Hyponex medium (Table Phal-38) at 20–23°C under continuous light of 300–500 lx provided by Toshiba Plantlux FL40S tubes.

Phalaenopsis Propagation through the Culture of Sections from Cloned Plantlets Growing in Vitro

Slices, 2.5 or 5 mm thick from the basal parts, 5–10 mm in length, of plantlets 1.5 cm tall, cultured on new *Phalaenopsis* (NP) medium with coconut water and BA (Table Phal-39) at 20–23°C under 300–500 lx produce callus and shoots (Ichihashi et al., 2000).

TABLE PHAL-39. **New *Phalaenopsis* (NP) medium (Ichihashi, 1992*a*, 1992*b*) modified for the culture of plantlet sections (Ichihashi et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar[h]	3.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the cytokinin fails to dissolve add a few drops of 0.1 N HCl.

[g]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1–15 to 750 ml of distilled water (item 17), adjust pH to 5.6, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

Light Intensity and Light Quality Effects on Callus and on Callus-derived Plantlets of *Phalaenopsis*

Research with *Phalaenopsis* plantlets grown on new *Phalaenopsis* (NP) medium has shown that both light intensity and quality (i.e., color) can affect the growth and development of both callus and callus-derived plantlets (Islam et al., 2001). Cultures were grown at 25°C under 16-h photoperiods provided by Plant Lux fluorescent lamps (National, Japan). Culture flasks were wrapped with blue (8.79 μmol m^{-2} s^{-1} at plant level inside the vessel), green (22.61 μmol m^{-2} s^{-1}), red (52.17 μmol m^{-2} s^{-1}), and yellow (78.26 μmol m^{-2} s^{-1}) cellophane (Toyo, Japan) to produce the required light colors. The controls were unwrapped flasks (100 μmol m^{-2} s^{-1}). Specifically:

1. Callus grown in the dark was pale.
2. The growth of callus in sucrose-containing medium under 25 μmol m^{-2} s^{-1} illumination was significantly better than in the dark.
3. The growth of callus on sucrose-containing medium was better under red and yellow light than that of callus illuminated with other colors.
4. PLB production on maltose- or sorbitol-containing media illuminated with red or yellow light was better than the control. Green and blue illumination inhibited PLB production.
5. Fresh weight (FW), dry weight (DW), and shoot length as well as the leaf length, width, and thickness of plantlets in vitro increased significantly under illumination of 50 μmol m^{-2} s^{-1} in comparison to 25 and 100 μmol m^{-2} s^{-1}.
6. The FW and DW of plantlets under red light were significantly higher than the weights of plants under other colors and the control despite the fact that the red light intensity was about half that of the controls.

In considering light quality effects it is important to keep in mind that: (1) light transmission levels and spectra of cellophane can vary with manufacturer, and (2) cellophane is not a narrow band light transmission filter.

Micropropagation of *Phalaenopsis* through the Culture of Lateral Buds from Young Flower Stalks

By 1992 several methods were developed for micropropagation of *Phalaenopsis*, each with its shortcomings and advantages. A method using buds from young flower stalks was formulated in an attempt to overcome some of the shortcomings. Formulation of a new medium, especially suitable for *Phalaenopsis*, was another purpose of research by Professor Syoichi Ichihashi, Department of Life Science, Aichi University of Education, Hirosawa, Igaya-cho, Kariya-shi, Aichi-ken, Japan (Ichihashi, 1992*a*, 1992*b*).

Plant Material. Soft flower stalks, less than 15 cm in length, should be used before the appearance of the first flower bud (Fig. Phal-17A, O). Buds (Fig. Phal-17C) should be removed after surface sterilization by making two cuts horizontally and a pair of incisions vertically (Fig. Phal-17B, P), followed by a vertical cut. The excised buds should be rinsed several times with sterile distilled water.

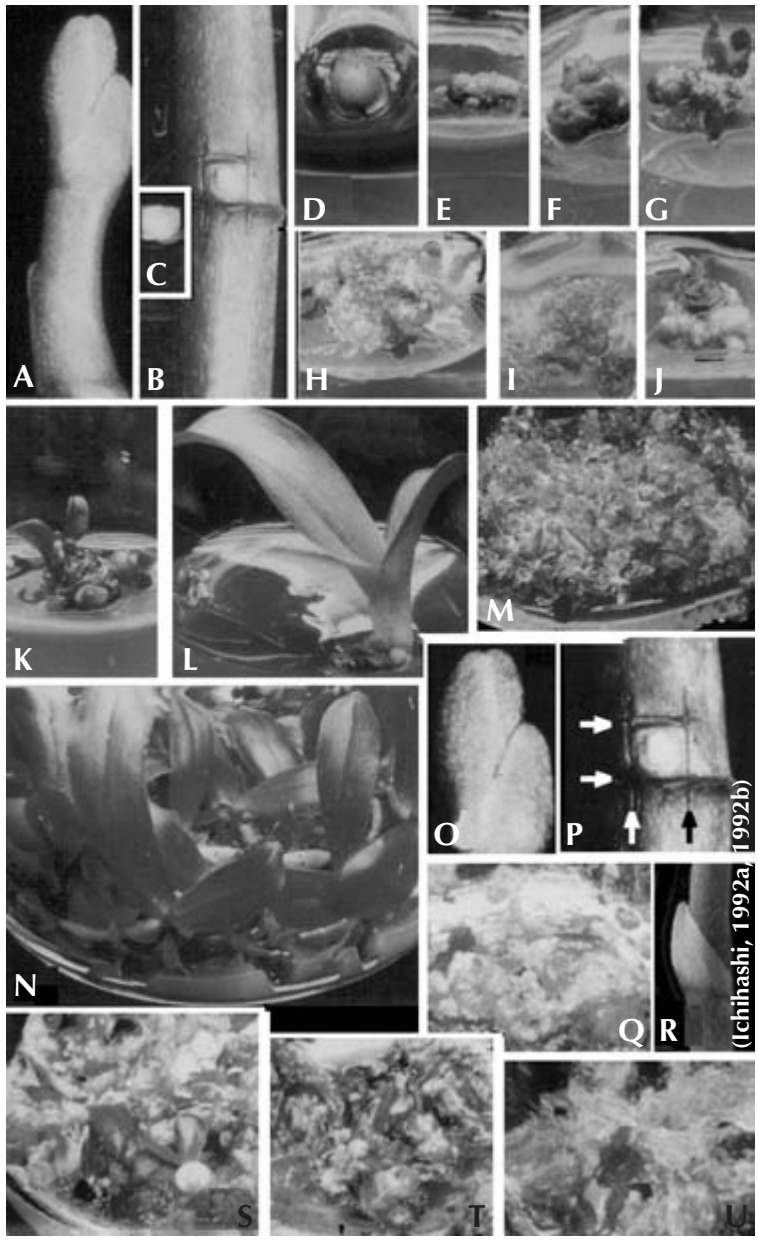

FIG. PHAL-17. **Culture of lateral buds from young flower stalks. A. Upper part of a young stalk. B. Horizontal and vertical incisions above, below, and on the side of a bud. C. Excised bud. D. Growth is starting. E. Proliferating green explant. F. PLBs being formed. G. Callus-like body (CLB). H. Proliferating CLBs. I. CLB. J. PLB. K. PLB and a small plantlet. L. Plantlet. M. CLBs. N. Plantlets formed by CLBs. O. Upper portion of stalk. P. Horizontal (white) and vertical (white and black) incisions. Q. Proliferating PLBs and CLBs. R. Bud covered with a scale. S–U. Proliferating PLBs and CLBs. (Sources: A–Q, S–U, Ichihashi, 1992*a*, 1992*b*; R, Lotte and Thomas website, http://www.orchideenvermehrung.at/english/index.htm.)**

Surface Sterilization. After removing the scales, the second to fourth nodes from the base, all with dormant buds, should be cut into sections approximately 3 cm in length (Fig. Phal-17B). These sections should be surface-sterilized using the following sequence: (1) 30-min immersion in 0.1% benzalkonium chloride, (2) three rinses with sterile distilled water, (3) 3-min immersion in 70% ethyl alcohol (73–74 ml 95% ethyl alcohol diluted to 100 ml with distilled water), (4) three rinses with distilled water, (5) 10-min immersion in 1% sodium hypochlorite (17 or 19 ml of household bleach containing 6 or 5.25% sodium hypochlorite, respectively, diluted to 100 ml with distilled water), and (6) three rinses with sterile distilled water.

Culture Vessels. Culture tubes, 25 × 150 mm or 18 × 180 mm containing 10 ml of medium were used in the original research. Other containers can also be used.

Culture Conditions. Cultures should be maintained at 25 ± 1°C under constant illumination of 1.2 mW cm^{-2} provided by Plantlux (Toshiba) fluorescent tubes. Standard culture room conditions may also be suitable.

Culture Media. The optimal balance of cations for these explants is $NH_4^+(25)$: $K^+(38)$: $Mg^{2+}(10)$. The optimal anion balance is NO_3^- (60) : $H_2PO_4^-$ (17) : SO_4^{2-} (23). A suitable medium was formulated to contain these optimal ratios (Table Phal-40). PLBs formed on this medium can be proliferated by subculturing them on the same solution (Table Phal-40) or a different one (Table Phal-36). Plantlets can be cultured on the first medium (Table Phal-40) or another substrate (Table Phal-37).

Procedure. Young flower stalks, 15 cm long or less (Fig. Phal-17A, O), should be cut from the plants, sectioned (Fig. Phal-17B) into 3-cm-long sections, and surface-sterilized before the buds are excised. The excised buds (Fig. Phal 17C) should be cultured in the first medium (Table Phal-40). PLBs (Fig. Phal-17F) or callus-like bodies (CLBs; Fig. Phal-17G) that form on this medium can be subcultured on it or proliferated on another solution (Table Phal-36). Plantlets (Fig. Phal-17L, N) can also be grown on the first medium (Table Phal-40) or another substrate (Table Phal-37).

Developmental Sequence. Buds start to grow (Fig. Phal-17D), turn green, and begin to proliferate (Fig. Phal-17E), and then form PLBs (Phal-17F, J, K) or CLBs (Fig. Phal-17G, I) which also proliferate (Fig. Phal-17H, M, Q, S–U). Plantlets are formed by PLBs (Fig. Phal-17L) and CLBs (Fig. Phal-17N).

General Comments. One of the original papers states that coconut water (CW) "eliminated growth," "inhibited or eliminated growth," "inhibited growth to none," "CW was inhibitory," but also that "addition of CW [to medium solidified with Gelrite] enhanced growth." Those who may use this method should test media with and without CW. Except for the uncertainty about CW, this procedure which was developed by a leading Japanese orchid scientist seems to be efficient, technically simple, very productive, and suitable even for a small laboratory.

TABLE PHAL-40. **Medium for the culture of excised buds from young flower stalks (Ichihashi, 1992*a*, 1992*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	32.0	3.2 g l^{-1}	10	
2	Ammonium sulfate, $(NH_4)_2SO_4$	303.9	30.39 g l^{-1}	10	
3	Calcium nitrate, $Ca(NO_3)_2$	637.6	63.76 g l^{-1}	10	
4	Magnesium nitrate, $Mg(NO_3)_2 \cdot 6H_2O$	256.4	25.64 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	424.0	42.4 g l^{-1}	10	
6	Monopotassium phosphate, KH_2PO_4	462.7	46.27 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.62	62.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.0025	0.25 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.0025	0.25 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	2.23	223.0 mg l^{-1}		
(e)	Potassium iodide, KI	0.083	0.83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.025	2.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.86	86.0 mg l^{-1}		
	Amino acid				
9	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Coconut water				
14	Coconut water (CW), optional[f]	150.0 ml	No stock	No stock	Measure
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Gelrite[g,h]	4.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1–13 to 900 ml of distilled water (item 16), adjust pH to 5.6 ± 0.1, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Add Gelrite as described in footnote *h* below. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved, pour the medium into culture vessels and autoclave.

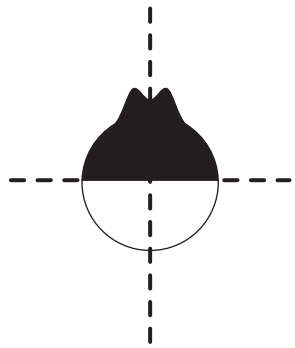

FIG. PHAL-18. **Sectioning a protocorm or a PLB into quarters (Yam et al., 1991 after Tanaka, 1987).**

Coconut Water Effects on the Proliferation of *Phalaenopsis* Protocorms

PLBs are produced by explants or callus in several *Phalaenopsis* micropropagation procedures. The plantlet yields of these procedures can be increased by proliferating the PLBs through a method that keeps undesirable mutations to a minimum. Such a method was developed for seedling protocorms of *Phalaenopsis* [Yam (mispelled as Lam) et al., 1991]. This method is presented here because PLBs and protocorms generally respond in a similar fashion to culture media and their components.

Plant Material. Protocorms or PLBs at the leaf point stage should be sectioned into quarters "by one vertical (tip to base) and one horizontal cut" (Fig. Phal-18).

Surface Sterilization. Protocorms or PLBs taken from in vitro cultures do not require surface sterilization. However, they should be washed with sterile distilled water to remove medium residues.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers filled with medium to 25–30% of their capacity are suitable.

Culture Conditions. Cultures should be maintained at 22 ± 3°C under 16-h photoperiods of 2.5 mW cm^{-2} provided by Gro-Lux fluorescent lamps. Standard culture room conditions will probably also be suitable.

Culture Media. PLB quarter sections should be cultured on XE medium ("X" is for "experimental and "E" stands for Ernst, the last name of Dr. Robert Ernst who formulated the medium and named it for himself) supplemented with 100 ml coconut water (Table Phal-41). New PLBs that form on this medium can be subcultured on it or on another solution (Table Phal-36). Plantlets should be cultured on yet another substrate (Table Phal-37).

Procedure. After the PLBs have been sectioned, the sections (quarters) should be cultured on the first medium (Table Phal-41). New PLBs should be subcultured on

TABLE PHAL-41. **XE medium for the proliferation of protocorms and protocorm-like bodies of *Phalaenopsis* (Yam et al., 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	122.0	12.2 g l^{-1}	10	
4	Dibasic potassium phosphate, K_2HPO_4[c]	30.0	3.0 g l^{-1}	10	
5	Monobasic potassium phosphate, KH_2PO_4[c]	250.0	25.0 g l^{-1}	10	
6	Potassium nitrate, KNO_3	500.0	50.0 g l^{-1}	10	
7	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[e]				
(a)	Boric acid, H_3BO_3	0.5	50.0 mg l^{-1}		
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 2H_2O$	3.0	300.0 mg l^{-1}	10	One solution
(e)	Sodium molybdate, $NaMoO_4 \cdot 2H_2O$	0.025	2.5 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.5	50.0 mg l^{-1}		
	Sugars				
9	Fructose	15.0 g	No stock	No stock	Weigh
10	Glucose	15.0 g	No stock	No stock	Weigh
	Complex additives				
11	Coconut water (CW)[f]	100.0 ml	No stock	No stock	Measure
	Solvent				
12	Water, distilled[g]	To 1000 ml			
	Solidifier				
13	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This combination of K_2HPO_4/KH_2PO_4 buffers the pH of the medium. The use of K_2HPO_4/KH_2PO_4 buffer was first suggested by Professor Hans Burgeff in Germany (Burgeff, 1936 and citations therein). He was one of the earliest students of orchid mycorrhiza and orchid seed germination.

[d]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved.

[e]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1–8 and 11 to 800 ml of distilled water (item 12), adjust pH to 5.5, add the sugars (items 9 and 10), and bring volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave.

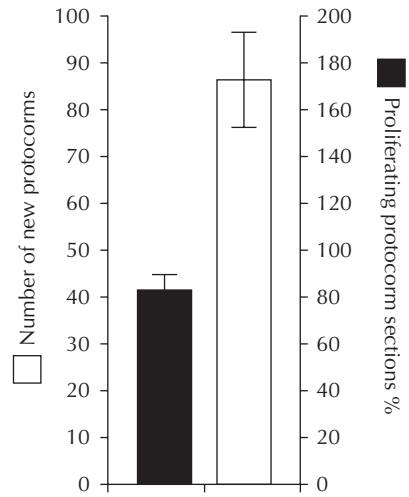

FIG. PHAL-19. **Proliferation of *Phalaenopsis* protocorm sections (modified from Yam et al., 1991).**

XE medium (Table Phal-41) or XER medium (see Table Phal-36). Plantlets should be grown on a third substrate (see Table Phal-37).

Developmental Sequence. Approximately 90% of the sections proliferate on the first medium, with the sections producing about 40 new PLBs each (Fig. Phal-19).

General Comments. The research that led to the formulation of this medium evaluated the effects on proliferation of coconut water (CW), banana homogenate (BH), and 6-(γ-γ-dimethylallylamino)-purine (DMAP) singly and in combinations of two and three of them. DMAP as a single additive completely inhibited proliferation. BH alone and BH plus DMAP reduced the number of protocorms produced by each section relative to controls and the CW-containing medium, but not the percent of sections which proliferated, except when BH was the sole additive. CW did not increase the percent of sections which proliferated except in comparison to a medium that contained only BH. However, it did increase the number of new protocorms per section in comparison to the controls and all media that contained additives. A major advantage of CW is that it brings about considerable proliferation without increasing the number of undesirable mutations.

Proliferation of *Phalaenopsis* Protocorms on a Thidiazuron-containing Medium

PLBs are very similar to protocorms in appearance and development. Therefore a method for protocorm proliferation on a TDZ-containing medium (Ernst, 1994) should also prove to be suitable for PLBs.

Plant Material. Protocorms (those of *Phalaenopsis* Happy Buddah selfed were used in the original research) or PLBs from in vitro cultures can be used.

Surface Sterilization. Protocorms or PLBs from in vitro cultures do not require surface sterilization. However, they should be washed with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, 250-ml capacity containing 50–60 ml medium, or other containers are suitable.

Culture Conditions. Cultures should be maintained at 23–25°C under 12-h photoperiods of about 25 μmol m^{-2} s^{-1} (provided in the original research by F 30TB 30-W Gro-Lux lamps from Sylvania GTE, Versailles, KY, USA) or standard laboratory conditions.

Culture Media. PLBs should be proliferated on XER medium supplemented with 1.25 μmol TDZ l^{-1} (Table Phal-42). To bring about differentiation and growth, new protocorms or PLBs should be cultured on a TDZ-free medium (Table Phal-43). A banana-homogenate-containing medium (see Table Phal-37) should be used for plantlet development.

Procedure. Protocorms or PLBs should be placed on the TDZ-containing medium (Table Phal-42) for approximately 6 months for proliferation. When new protocorms or PLBs form they should be moved to the TDZ-free medium (Table Phal-43). Plantlets are cultured on a banana-homogenate-containing medium (see Table Phal-37).

Developmental Sequence. Proliferation takes place on the first medium (Table Phal-42). Shoots and roots form on the second (Table Phal-43) and plantlets grow on the third (see Table Phal-37).

General Comments. This procedure is simple and efficient. However, use of hormones should be avoided if possible since they can cause undesirable mutations. Therefore the previous procedure (Yam et al., 1991) is preferable.

TABLE PHAL-42. **Thidiazuron-containing XER medium for the proliferation of *Phalaenopsis* protocorms and protocorm-like bodies (Ernst, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4{\cdot}7H_2O$	122.0	12.2 g l^{-1}	10	
4	Dibasic potassium phosphate, K_2HPO_4[c]	30.0	3.0 g l^{-1}	10	
5	Monobasic potassium phosphate, KH_2PO_4[c]	250.0	25.0 g l^{-1}	10	
6	Potassium nitrate, KNO_3	500.0	50.0 g l^{-1}	10	
7	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4{\cdot}7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[e]				
(a)	Boric acid, H_3BO_3	0.5	50.0 mg l^{-1}	10	One solution
(b)	Copper sulfate, $CuSO_4{\cdot}5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4{\cdot}2H_2O$	3.0	300.0 mg l^{-1}		
(e)	Sodium molybdate, $NaMoO_4{\cdot}2H_2O$	0.025	2.5 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4{\cdot}7H_2O$	0.5	50.0 mg l^{-1}		
	Cytokinin				
9	Thidiazuron (TDZ)	0.275	275 mg 100 ml^{-1} 95% ethanol[f]		
	Sugar				
10	Fructose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g,h]	To 1000 ml			
	Solidifier				
12	Gelrite[g,h]	5.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This combination of K_2HPO_4/KH_2PO_4 buffers the pH of the medium. The use of K_2HPO_4/KH_2PO_4 buffer was first suggested by Profesor hans Burgeff in Germany (Burgeff, 1936 and citations therein). He was one of the earliest students of orchid mycorrhiza and seed germination.

[d]The original recipe does not include EDTA as a chelating agent. It is included here because iron salts tend not to stay in solution. Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. The XER original recipe for this medium calls for 28 mg ferrous sulfate, $FeSO_4{\cdot}7H_2O$ l^{-1}. The difference (0.2 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored. Sticklers for accuracy can add 28 mg l^{-1}.

[e]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The XER medium is described in two papers. One deals with proliferation of *Phalaenopsis* protocorms (Yam et al., 1991). The other reported on the culture of *Phalaenopsis* flower-stalk nodes and protocorm proliferation (Ernst, 1994). Both papers state that the microelements used are those of Nitsch and Nitsch (1956). Only one of the papers (Yam et al., 1991) lists the minerals which were added. The formulation is the same as the one in this table and very different from the combination used by Nitsch and Nitsch (1956). A list of microelements is not given in the paper on the thidiazuron-containing medium. It only states that the XER medium contains "the trace elements of Nitsch & Nitsch, 1956." Therefore it is not clear if the microelements in that version of XER is the same as the one in this table. The microelements in the Nitsch and Nitsch (1956) medium are ferric citrate·$5H_2O$, 10 mg l^{-1}; $MnCl_2{\cdot}4H_2O$, 2.5 mg l^{-1}; H_3BO_3, 2 mg l^{-1}; $ZnSO_4{\cdot}7H_2O$, 0.05 mg l^{-1}; $CoCl_2{\cdot}6H_2O$, 0.03 mg l^{-1}; $CuCl_2{\cdot}2H_2O$, 0.015 mg l^{-1}, and $NaMoO_4{\cdot}2H_2O$, 0.025 mg l^{-1}.

[f]If the cytokinin fails to dissolve add a few drops of 0.1 N HCl. Keep frozen between uses.

[g]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and bring volume to 1000 ml with distilled water (item 11). If the medium is to be solidified with agar bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. If the medium is to be solidified with Gelrite, gellan gum, or Phytagel (item 12) the solidifier should be added according to the instructions in the following footnote.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite (item 12)] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into a 2-l Erlenmeyer flask and autoclave. Following the autoclaving use a sterile pipette to add the auxin to the medium while it is still liquid and warm, but no longer hot. Swirl or stir the medium with a sterile stirrer to mix the auxin thoroughly and pour the medium into presterilized culture vessels.

TABLE PHAL-43. **XER medium for the induction of shoots on *Phalaenopsis* protocorms and protocorm-like bodies (Ernst, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$[b]	500.0	50.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4{\cdot}7H_2O$	122.0	12.2 g l^{-1}	10

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This combination of K_2HPO_4/KH_2PO_4 buffers the pH of the medium. The use of K_2HPO_4/KH_2PO_4 buffer was first suggested by Profesor hans Burgeff in Germany (Burgeff, 1936 and citations therein). He was one of the earliest students of orchid mycorrhiza and seed germination.

[d]The original recipe does not include EDTA as a chelating agent. It is included here because iron salts tend not to stay in solution. Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. The XER original recipe for this medium calls for 28 mg ferrous sulfate, $FeSO_4{\cdot}7H_2O$ l^{-1}. The difference (0.2 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored. Sticklers for accuracy can add 28 mg l^{-1}.

[e]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The XER medium is described in two papers. One deals with proliferation of *Phalaenopsis* protocorms (Yam et al., 1991). The other reported on the culture of *Phalaenopsis* flower-stalk nodes and protocorm proliferation (Ernst, 1994). Both papers state that the microelements used are those of Nitsch and Nitsch (1956). Only one of the papers (Yam et al., 1991) lists the minerals which were added. The formulation is the same as the one in this table and very different from the combination used by Nitsch and Nitsch (1956). A list of microelelemnts is not given in the paper on the thidiazuron-containing medium. It only states that the XER medium contains "the trace elements of Nitsch & Nitsch, 1956." Therefore it is not clear if the microelements in that version of XER is the same as the one in this table. The microelements in the Nitsch and Nitsch (1956) medium are ferric citrate·$5H_2O$, 10 mg l^{-1}; $MnCl_2{\cdot}4H_2O$, 2.5 mg l^{-1}; H_3BO_3, 2 mg l^{-1}; $ZnSO_4{\cdot}7H_2O$, 0.05 mg l^{-1}; $CoCl_2{\cdot}6H_2O$, 0.03 mg l^{-1}; $CuCl_2{\cdot}2H_2O$, 0.015 mg l^{-1}; and $NaMoO_4{\cdot}2H_2O$, 0.025 mg l^{-1}.

[f]Add items 1–8 to 900 ml of distilled water (item 10), adjust pH to 5.5, add sugar (item 9), and bring volume to 1000 ml with distilled water (item 10). If the medium is to be solidified with agar bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. If the medium is to be solidified with Gelrite, gellan gum, or Phytagel (item 11) the solidifier should be added according to the instructions in the following footnote.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite (item 11)] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave. After the gellan gum (Phytagel, Gelrite) has dissolved, pour the medium into a 2-l Erlenmeyer flask and autoclave. Following the autoclaving use a sterile pipette to add the auxin to the medium while it is still liquid and warm, but no longer hot. Swirl or stir the medium with a sterile stirrer to mix the auxin thoroughly and pour the medium into presterilized culture vessels. Solidifier is not added to liquid media.

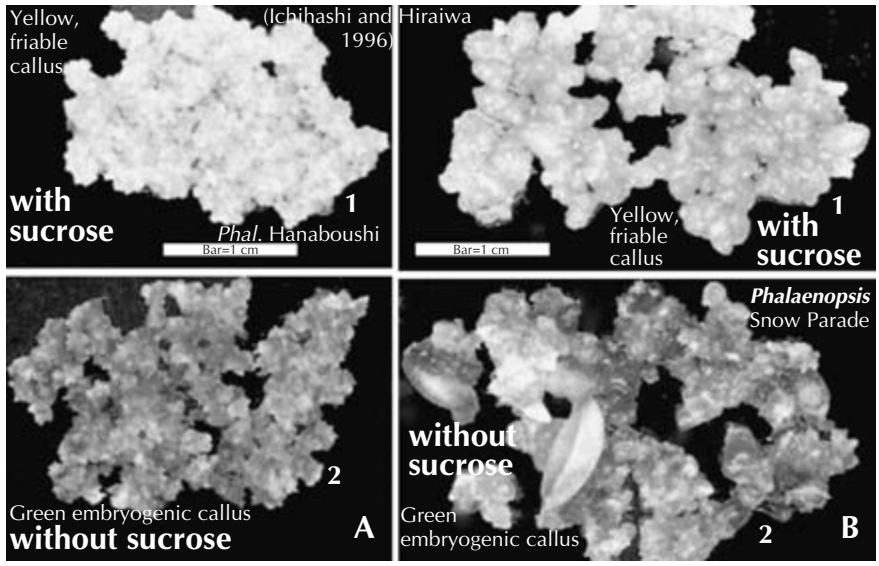

FIG. PHAL-20. ***Phalaenopsis*** **callus. Above. Yellow, friable callus in medium with sucrose (A1 and B1). Below. Green embryogenic callus in sucrose-free medium (A2 and B2). (Ichihashi and Hiraiwa, 1996.)**

Maintenance of Embryogenic Callus of *Phalaenopsis*

Depending on the method being used to culture it, an embryogenic callus can produce protoplasts, embryoids, and/or PLBs, all three of which can be used for genetic engineering or propagation. The effects of solidifiers, sugars, sugar alcohols, and coconuts on an embryogenic callus were studied at the Department of Life Sciences, Aichi University of Education in Japan (Ichihashi and Hiraiwa, 1996). The method used for *Doritaenopsis* is also suitable for *Phalaenopsis* (Fig. Phal-20). This procedure is also suitable for *Darwinara*, *Doritaenopsis*, *Neofinetia falcate*, and *Phalaenopsis* (Ichihashi et al., 1993; Ichihashi and Hiraiwa, 1996).

In Vitro Flowering by *Phalaenopsis* Pink Leopard 'Petra'

Vegetative propagation of *Phalaenopsis* Pink Leopard 'Petra' and the in vitro induction of flowers (Fig. Phal-21) were carried out using the method for *Doriella* Tiny (Duan and Yazawa, 1994*b*, 1994*c*, 1995*a*).

Culture Media. One of the reports states that "explants were transplanted into the Vacin and Went and Hyponex media supplemented with 5 mgl^{-1} [sic] BA and 25 gl^{-1} [sic] sucrose." It is not clear from this statement whether the medium used for *Phalaenopsis* was the same as the one employed for *Doriella* (see Table Drlla-1) or

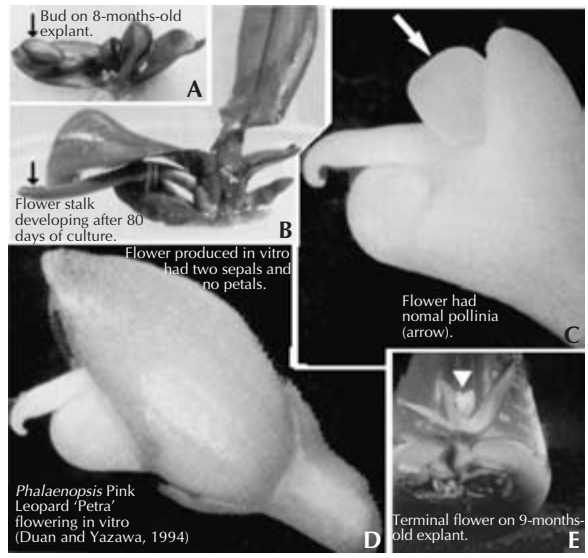

FIG. PHAL-21. **In vitro flowering of *Phalaenopsis* (Duan and Yazawa, 1994*b*).**

TABLE PHAL-44. **Hyponex medium for the culture of *Phalaenopsis* Pink Leopard 'Petra' stem sections (Duan and Yazawa, 1994*b*)**[a]

Component	Amount l^{-1}	Comments
Hyponex[b]	3.5 g	Add all components to 700 ml of water, adjust pH to 5.6, raise volume to 1000 ml, bring to a gentle boil, add agar with stirring and keep stirring until it is dissolved, pour into culture vessels, and autoclave
Peptone	2.0 g	
Coconut water	150.0 ml	
Sucrose	25.0 g	
Agar	10.0	
Water	To 1000 ml	

[a]This is one of two possible media. The other contains peptone (see Table Drlla-1).
[b]One possible source for Hyponex is www.hyponex.co.jp.

a slightly different one which does not contain peptone (Table Phal-44). The Vacin and Went medium (Vacin and Went, 1949) used for *Doriella* contains 10 mg BA l^{-1}. Therefore the solution utilized for *Phalaenopsis* (Table Phal-45) is clearly different.

Procedure. Following sterilization, the explants should be cultured on Hyponex medium (see Tables Drlla-1 or Phal-44) until they develop vegetative buds. These buds should be excised and cultured on the same solution (see Tables Drlla-1 or Phal-44) to increase the number of explants. For flower-bud formation, shoots with 3–4 leaves and 3–4 cm tall are moved to Vacin and Went medium (Table Phal-45). To enhance root formation, after flowering it may be necessary to move the shoots to a root-inducing medium (see Table Drlla-3). Plantlets can be cultured on standard Vacin and Went medium (see Table Drlla-4) for further development.

TABLE PHAL-45. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of bud-bearing *Phalaenopsis* Pink Leopard 'Petra' explants to enhance leaf growth (Duan and Yazawa, 1994*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Cytokinin				
8	Benzyladenine (BA)	10.0	1000 mg 100 ml^{-1} 95% ethanol[e]	1	Or weigh
	Complex additive				
9	Coconut water[f]	150.0 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	25.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the cytokinin fails to dissolve add a few drops of 0.1 N KOH or NaOH. Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[g]Add items 1, 3–7, and 9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 11), adjust pH to 5.6, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the cytokinin to the autoclaved, warm and still liquid medium, swirl or stir with a sterile tool and distribute medium into preautoclaved culture vessels. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

Developmental Sequence. The explants produce vegetative buds on the Hyponex medium (see Tables Drlla-1 or Phal-44). Flower buds form after transfer to Vacin and Went (Table Phal-45). The plants flower on Vacin and Went medium (Table Phal-45).

General Comments. This seems to be a simple yet effective procedure for in vitro flower induction in *Phalaenopsis*. It may also prove to be effective for *Doritis* and *Kingiella* (*Kingidium*). Unlike an unusual and bizarre report about *Dendrobium* (Goh, 1996), the authors provide full details about their procedure. They should be commended for doing it.

Use of Carbon Sources to Affect Growth and Development of Protocorm-like Bodies Derived from Callus

Orchid seeds and seedlings vary in their ability to utilize different carbohydrates and their responses to them (Arditti, 1967, 1979, 1992; Arditti and Ernst, 1984; Ernst and Arditti, 1990). The same is true for embryonic callus of *Phalaenopsis* Wedding Promenade and *Phalaenopsis* Hanaboushi × *Phalaenopsis equestris* Ilocos (Islam, Hiraiwa and Ichihashi, 1997). These differences can be used in micropropagation (Islam et al., 1998). When equimolar levels of carbohydrates were added to new *Phalaenopsis* (NP) medium (Ichihashi, 1992*a*, 1992*b*), the following were observed:

1 Few PLBs generated plantlets (Fig. Phal-22) and most produced yellowish or greenish callus-like bodies (CLBs). Nearly 80% of the unrooted shoots and 50% of the rooted plantlets formed yellowish-greenish CLBs.
2 PLBs multiplied on maltose-containing medium and produced a few plantlets (Fig. Phal-22). Approximately 44% of unrooted shoots and 24% of rooted plantlets produced green PLBs at the bases of plantlets.
3 On sorbitol-containing medium, most PLBs produced plantlets (Fig. Phal-22) and a few new PLBs.

To control growth and development, callus-derived PLBs should be placed on NP medium that contains sucrose, maltose, or sorbitol (Table Phal-46).

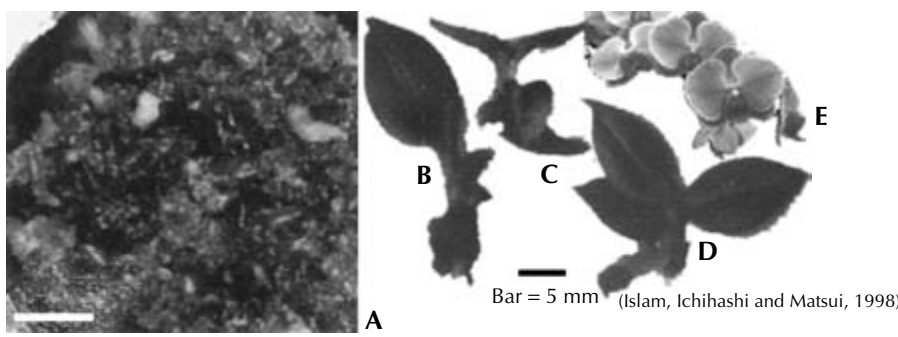

FIG. PHAL-22. **A–D. *Phalaenopsis* callus (A) and plantlets grown on different carbohydrates: sucrose (B), maltose (C), or sorbitol (D). E. Flowers of Phalaenopsis Golden Promenade. (Park et al., 2000.)**

TABLE PHAL-46. **New *Phalaenopsis* (NP) medium (Ichihashi, 1992*a*, 1992*b*) with different carbohydrates for the control of development of *Phalaenopsis* protocorm-like bodies from callus (Islam et al., 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Gelrite[g,h]	3.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Only one of these carbohydrates should be added to the medium depending on the desired results: sucrose, few plants and callus-like bodies (CLBs); maltose, new PLBs and a few plantlets; sorbitol, mostly plantlets, few new PLBs (see text for details).

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.6 ± 0.1, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Add Gelrite as described in the footnote below. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved, pour the medium into culture vessels and autoclave.

General Comments. It is important to note that equal weights of 6-carbon (sorbitol in this case) or 12-carbon (sucrose and maltose) carbohydrates are not equivalent because they represent different molarities even if they contain the same amount of carbon. For example 20 g of sorbitol is equivalent to 111.01 mmol, whereas 20 g of sucrose or maltose amount to half that at 58.43 mmol. The different molarities affect the osmolarity of media and these differences can have an effect on explants, tissues, PLBs, and plantlets. When larger sugars (tri- and oligosaccharides) are included in media, additional complications may be caused by the ability of the plants to take up, utilize, and/or hydrolyze the different sugars. Therefore Professor Ichihashi and his associates should be commended for using equimolar carbohydrate levels. However, in research with sugars that are readily utilized by orchids (like sucrose, maltose, and sorbitol) comparisons should include both equal carbon and equimolar levels. The hydrolysis of these sugars by orchids should also be studied.

Production of Plants from Callus-derived Protoplasts of *Phalaenopsis*

Callus of *Phalaenopsis* Hanaboushi × *Phalaenopsis equestris* 'Ilocos' was cultured on new *Phalaenopsis* (NP) medium (Ichihashi, 1992*a*, 1992*b*) supplemented with sucrose and coconut water (CW). It was then transferred to NP medium without CW and sucrose for 3 weeks and after that submerged for 90 min in an enzyme solution at 25°C with shaking at 77 strokes min^{-1} "under scatter light." A washing solution was added to the enzyme protoplast preparation and the mixture was filtered through "a stainless sieve of 66 g m [sic] pore size to remove undigested cell clumps and centrifuged at 100× *g* for 5 min."

Fresh washing solution was added to the sediment, mixed with ficoll (www.sigmaaldrich.com) solution, and centrifuged at 230× *g* for 30 min. A layer of protoplasts which formed after the centrifugation was taken up with a pipette, washed with washing solution, suspended in culture medium, and centrifuged at 100× *g* for 5 min.

The protoplast-containing solution was mixed with NP medium supplemented with sorbitol and was cultured at 25°C in the dark. Survival was 89% after 1 week and 60% at the end of 4 weeks. Cell divisions were first observed after 1 week; these increased in number during the fourth week and led to "colony formation and identified plant regeneration." These findings indicate that sorbitol is suitable as an osmoticum for the culture of *Phalaenopsis* protoplasts (Hirose et al., 1998).

Shoot Production from *Phalaenopsis* Flower Stalk Buds on Thidiazuron-containing Medium

TDZ was used primarily as a cotton defoliant until its cytokinin-like properties became known (Mok et al., 1982). Within a relatively short time after that it was shown to induce shoot formation in a number of plants (see Chen and Piluek, 1995 for a short review) and orchids (Ernst, 1994). This led to its use in the micropropagation of *Phalaenopsis* by researchers at Kasetsart University in Thailand and Guizhou Agricultural College in China (Chen and Piluek, 1995).

Plant Material. Nodes, each containing one bud, from flower stalks of *Phalaenopsis* hybrids should be used.

Surface Sterilization. Flower stalks should be washed with household detergent and tap water, rinsed, swabbed with 70% ethanol (73–74 ml 95% ethanol diluted to 100 ml with distilled water), and cut into nodes each with one bud. These nodes should be submerged in 10% Clorox [10 ml Clorox or another household bleach containing sodium hypochlorite diluted to 100 ml with distilled water and containing 2 drops of Tween 20 (sources: www.sigmaaldrich.com, www.fishersci.com, www.vwr.com)] for 25 min. The bracts that cover the buds should be removed after that under sterile conditions with sterilized forceps and the nodes should be immersed in 5% Clorox (5 ml Clorox or another household bleach diluted to 100 ml with distilled water and each 80 ml containing 2 drops of Tween 20) for 15 min. Three rinses with sterile distilled water should follow the immersion. The nodes should be cut to a total length of 1.0–1.5 cm after that (0.5–0.75 cm above and below the bud) and inserted into the medium.

Culture Vessels. Glass bottles, 2.5 cm in diameter and 9.0 cm in height containing 15 ml medium, were used in the original research. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at 23 ± 1°C under 12-h photoperiods of 12 μmol m^{-2} s^{-1} or standard laboratory conditions. Liquid cultures must be placed on a rotary shaker at 120 rpm.

Culture Media. Solid Vacin and Went (VW) medium (Vacin and Went, 1949) containing 15% (v/v) coconut water (CW) supplemented with 5 μmol TDZ l^{-1} (Table Phal-47) is used to induce the formation of adventitious buds on the nodes. The adventitious buds produce shoots on VW containing 15% CW (VWCW; Table Phal-48). These shoots develop roots on VWCW with 10 g sucrose l^{-1} (Table Phal-49). When cultured on VWCW supplemented with 10 μmol TDZ (Table Phal-50), shoots bearing two leaves produce new growths. These newly formed shoots grow roots on VWCW containing 10 g sucrose l^{-1} (Table Phal-49). Shoot tips from shoots with 3–4 leaves, when cultured in liquid VWCW (Table Phal-51) for 4 weeks and then transferred to solid VWCW (Table Phal-48), produce PLBs 1 month after the transfer. These PLBs can be proliferated on CW-containing XER medium (see Table Phal-36) or cultured on new Dogashima (ND) medium (see Table Phal-34) for plantlet production. ND and XER media are similar in some aspects. Plantlets should be cultured on XER medium containing banana pulp homogenate (see Table Phal-37).

Procedure. Nodes are placed on the first medium (Table Phal-47) and maintained on it until they produce adventitious buds. These buds should be moved to VWCW (Table Phal-48) until they produce shoots. When the shoots develop two leaves they can be moved to the third solution for root formation (Table Phal-49) or VWCW with 10 μmol TDZ (Table Phal-50) to bring about the growth of additional growths. Tips of shoots with three leaves cultured in liquid VWCW for 4 weeks and solid medium (Table Phal-48) for a month produce PLBs. PLBs proliferate on XER medium containing CW (see Table Phal-36) or produce plantlets on ND medium

TABLE PHAL-47. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of *Phalaenopsis* flower-stalk nodes (Chen and Piluek, 1995)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10

	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the cytokinin does not dissolve add a few drops of 0.1 N HCl. Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1 and 3–9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 11), adjust pH to 5.3, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

TABLE PHAL-48. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for shoot induction from adventitious buds on *Phalaenopsis* flower-stalk nodes (Chen and Piluek, 1995)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Coconut water (CW)[e]	150.0 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 10), adjust pH to 5.3, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

TABLE PHAL-49. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the development of shoots induced from adventitious buds on *Phalaenopsis* flower-stalk nodes (Chen and Piluek, 1995)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 10), adjust pH to 5.3, add sugar (item 9), adjust volume to 1000 ml with distilled water (item 10), pour the solution into culture vessels, and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

(see Table Phal-34). Plantlets grow well on XER medium containing banana homogenate (see Table Phal-37).

Developmental Sequence. Nodes produce adventitious buds on the first medium (Table Phal-47). These buds produce shoots on VWCW (Table Phal-48) which develop two leaves. On being moved to the third solution (Table Phal-49) these shoots form roots. They produce additional shoots on VWCW with 10 µmol TDZ (Table Phal-50). PLBs are produced by tips excised from shoots with three leaves and cultured in liquid VWCW for 4 weeks and solid medium for a month (Table Phal-48). When

cultured on CW-containing XER medium (see Table Phal-36) these PLBs proliferate. If cultured on ND medium (see Table Phal-34) they produce plantlets. The plantlets grow well on XER medium containing banana homogenate (see Table Phal-37).

General Comments. This is a multifaceted procedure that makes excellent use of *Phalaenopsis* stalk nodes, utilizes imaginatively a cytokinin which was relatively new at the time, and employs several modifications of one medium to very good advantage. Like Dr. R. Ernst, the authors used information about the culture of *Phalaenopsis* flower-stalk nodes and TDZ cleverly and formulated a novel way of propagating this popular orchid.

Effects of Solidifiers, Coconut Water, and Carbohydrates on Embryogenic Callus of *Phalaenopsis*

Some components are added to media almost due to inertia. They are used simply because: (1) media formulations list them, (2) others have used them, and/or (3) they have been used for a long time. The same is true for their concentrations. Not many investigators devote time and effort to refining media by studying some of their components. Such a study was carried out by Professor Syoichi Ichihashi and his associates at the Department of Life Science, Aichi University of Education. They used the P medium (Table Phal-52) as a basal solution to study the effects of carbohydrates and their concentrations, coconut water, and solidifiers and their levels on embryogenic callus of *Phalaenopsis* (Islam et al., 1997).

Carbohydrates

A study of D-fructose, D-galactose, D-glucose, lactose, maltose, mannitol, L-rhamnose, D-sorbitol, sucrose, and trehalose showed that they had different effects.

- A point sometimes ignored and not always fully appreciated, but properly emphasized by Professor Ichihashi and his associates, is that "osmotic pressure of a medium seems to affect callus growth considerably." This is very important both practically and as a concept because equal weights of monosaccharides and polysaccharides represent different molarities. The fact is that "molar equivalents of monosaccharides supply half the energy of disaccharides." In other words, 20 g of glucose or fructose (or any other 6-carbon monosaccharide or polyol) are not the same as 20 g of sucrose. The "addition of 10 g l^{-1} glucose and/or fructose is equivalent osmotically to 20 g l^{-1} sucrose" or 20 g maltose or 20 g trehalose.

  Another important point is that orchids may differ in their ability to take up or hydrolyze sugars, especially longer-chain oligosaccharides or polysaccharides. This means that seedlings, PLBs, or callus on 20 g each of monosaccharides (glucose or fructose, for example), disaccharides (sucrose or maltose, for instance), trisaccharides (e.g., raffinose, which consists of glucose, fructose, and galactose or maltotriose, made of three glucose molecules) are subject to different osmotic concentrations and carbon availability. They probably take up and/or hydrolyze

TABLE PHAL-52. **P medium (Ichihashi and Hiraiwa, 1996; Islam et al., 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium phosphate, $NH_4H_2PO_4$[b]	922.4	92.24 g l^{-1}	10	
2	Calcium nitrate, $CaNO_3 \cdot 4H_2O$	236.2	23.62 g l^{-1}	10

	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Gelrite[g]	4.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The balances of cations and anions in this medium are: $NH_4^+ : K^+ : Ca^{2+} : Mg^{2+} = 40 : 40 : 10 : 10$; $NO_3^- : H_2PO_4^- : SO_4^- = 40 : 50 : 10$. Total concentration of major ions is 20 milliequivalents l^{-1}.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

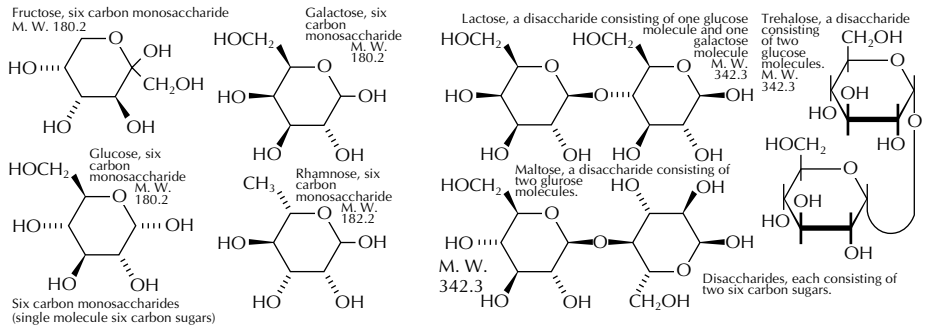
[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Iron and Na_2EDTA concentration is the same as in the Murashige–Skoog medium.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses. The levels of glycine, *myo*-inositol, and vitamins are the same as in the Murashige–Skoog medium.

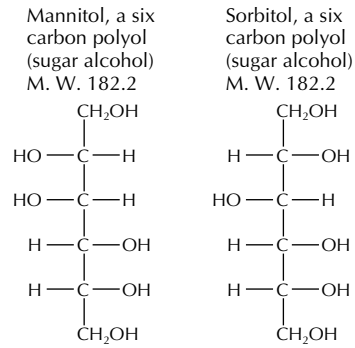
[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures). The most commonly used amount of coconut water is 150 ml l^{-1}.

[g]Add items 1–13 to 750 ml of distilled water (item 15), adjust pH to 5.6 ± 0.1, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Gelrite or gellan gum (available as such from www.caissonlabs.com and as Phytagel (from www.sigmaaldrich.com) is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gun (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave. Following the autoclaving use a sterile pipette to add the auxin to the medium while it is still liquid and warm, but no longer hot. Swirl or stir the medium with a sterile stirrer to mix the auxin thoroughly and pour the medium into presterilized culture vessels. Solidifier is not added to liquid media. As a rule amino acids (item 8), hormones (none present in this medium), and vitamins (items 10–12) are added to the hot solution under sterile conditions with sterilized pipettes, mixed well, and the medium is then distributed into preautoclaved culture vessels. In this instance all components are added before the medium is autoclaved.



Equal and unequal concentrations

- 20 g disaccharide ≠ 20 g monosaccharide ≠ 20 g trisaccharide ≠ 20 g 6-carbon polyol in terms of molarity and osmolarity, nor physiologically.
- 20 g disaccharide = 10 g monosaccharide = 30 g trisaccharide = 10 g 6-carbon polyol in terms of molarity and osmolarity, and physiologically.



the mononsaccharides and disaccharides with relative ease even if at different rates. But the trisaccharides or longer sugars would be more difficult to break down and/or absorb, which means that the orchids may not have enough sugar.

- "Callus growth on a medium containing glucose and/or fructose was better than sucrose when both glucose and/or fructose were added at 10 and 20 g l^{-1}."
- "Although growth rate among varieties different [differed] to some extent callus of most varieties grew best on media containing mannitol, sorbitol, maltose, and trehalose. . . . Growth was better on media supplemented with rhamnose, fructose, or glucose as energy sources. Lactose and sucrose also favored callus growth in many varieties . . . .Galactose was not a good energy source for callus. . . . Sucrose is the most commonly used energy source for nutrient media . . . for plant tissue culture *in vitro*." But it is not always effective.
- "Callus growth on sucrose supplemented medium remained friable and yellow or pale green . . ."
- ". . . in sugar free medium and/or sorbitol or mannitol containing medium callus changed color into green and developed somatic embryos."
- "The callus can utilize many kinds of sugar and/or sugar alcohols as sources of carbohydrates. Maltose, sorbitol, mannitol, or trehalose supported callus growth better that other energy sources tested. Rhamnose, fructose, or glucose were utilized well by calli." However, there were differences in preference for energy sources by different species.
- Galactose was inhibitory to callus growth.

Solidifiers

Agar is an algal product that has been used for a very long time to solidify culture media. Gelrite (Phytagel, gellan gum) is an extracellular polysaccharide produced by *Pseudomonas elodea*, which came into use as a media solidifier in the 1980s. The effects of solidifier concentrations on callus growth were "insignificant" after 4 weeks of culture. However, after 8 and 12 weeks callus growth was "significantly" better in a medium that was solidified with 4 g gellan gum l^{-1}. Gellan gum was better than agar as a solidifier for the P medium (Table Phal-52). Similar effects were observed with other media and orchids (Huang, 1988; Ichihashi, 1992*a*).

Coconut Water

Several levels of coconut water are used in micropropagation culture media with 150 ml l^{-1} being the most common. However, in this case 100 ml l^{-1} "favored callus growth" (Islam et al., 1997).The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). Water from unripe (green) nuts is preferable. If unripe nuts are not available, water from ripe (brown) ones can be used. It is advisable to filter the water. Canned or commercially frozen coconut water must not be used because it may contain sugars and/or preservatives.

In Vitro Propagation of *Phalaenopsis* via the Culture of Cytokinin-induced Nodes

Every micropropagation method for *Phalaenopsis* has advantages and disadvantages. A method using cytokinin-induced nodes was developed to overcome some shortcomings (Duan et al., 1996).

Plant Material. One-year-old seedlings or plantlets should be treated with BA to bring about stem elongation.

Surface Sterilization. Seedlings growing in vitro do not require surface sterilization. They should be washed with sterile distilled water to remove residual medium.

Culture Vessels. Erlenmeyer flasks, 200- or 250-ml capacity containing 70 or 80 ml medium, respectively, should be used for elongation. Culture tubes, 25×150 mm, containing 20 ml medium are suitable for culturing stem sections. Other containers can also be used.

Culture Conditions. The original cultures were maintained at $25 \pm 2°C$ under 16-h photoperiods of 2500 lx provided by fluorescent lamps (type not described). Standard culture room conditions are also suitable.

Culture Media. The elongation of seedlings or plantlets and the production of adventitious buds occur on Hyponex medium containing 5–10 mg BA l^{-1} (Table Phal-53). For maximal production of shoots, node sections should be cultured on different BA levels (Table Phal-54):

- Basal nodes, no BA in medium.
- Second nodes, 10 mg BA l^{-1}.
- Third nodes, 5 mg BA l^{-1}.
- Top nodes, 0–10 mg BA l^{-1}. Only 10% of these nodes produce shoots on any BA level (0, 5, 10, or 20 mg BA l^{-1}). They may not be worth culturing or should be cultured only if there is a shortage of plant material.

Shoots produce roots on a BA-free Hyponex medium supplemented with 2 g peptone l^{-1} (Table Phal-55). Rooted plants should be potted in sphagnum moss.

TABLE PHAL-53. **Benzyladenine (BA)-containing Hyponex medium for elongation of *Phalaenopsis* seedlings or plantlets (Duan et al., 1996)**

Component	Amount l^{-1}	Remarks
Hyponex[a]	3.5 g	Add all components to 900 ml of water. Adjust pH to 5.6, raise volume to 1000 ml, bring to a gentle boil, add agar with stirring and keep stirring until it is dissolved, pour into culture vessels, and autoclave
Benzyladenine (BA)[b]	5 or 10 mg	
Sucrose	25.0 g	
Water	To 1000 ml	
Agar	10.0	

[a]One possible source for Hyponex is www.hyponex.co.jp.

[b]To prepare a stock solution, dissolve 500 mg benzyladenine (BA) in 100 ml 95% ethanol. If it fails to dissolve add a few drops of 0.1 N HCl or NaOH or KOH. Add 1 ml per liter of medium for 5 mg BA l^{-1} or 2 ml for 10 mg BA l^{-1}. Keep frozen between uses.

TABLE PHAL-54. **Hyponex medium for the culture of stem sections of *Phalaenopsis* seedling or plantlet-stem sections (Duan et al., 1996)**

Component	Amount l^{-1}	Comments
Hyponex[a]	3.5 g	Add all components to 700 ml of water. Adjust pH to 5.6, raise volume to 1000 ml, bring to a gentle boil, add agar with stirring and keep stirring until it is dissolved, pour into culture vessels, and autoclave
Benzyladenine (BA)[b]	5 or 10 mg	
Sucrose	25.0 g	
Water	To 1000 ml	
Agar	10.0	

[a]One possible source for Hyponex is www.hyponex.co.jp.

[b]To prepare a stock solution dissolve 500 mg benzyladenine (BA) in 100 ml 95% ethanol. If it fails to dissolve add a few drops of 0.1 N HCl or NaOH or KOH. Add 1 ml per liter of medium for 5 mg BA l^{-1} or 2 ml for 10 mg BA l^{-1}. Keep frozen between uses. Basal or top sections should be cultured on BA-free medium. For second sections add 5 mg BA l^{-1} (1 ml of stock solution). Third sections should be cultured on medium containing 10 mg BA l^{-1} (2 ml stock solution).

TABLE PHAL-55. **Hyponex medium for root induction on shoots derived from stem sections of *Phalaenopsis* seedlings or plantlets (Duan et al., 1996)**

Component	Amount l^{-1}	Comments
Hyponex[a]	3.5 g	Add all components to 900 ml of water. Adjust pH to 5.6, raise volume to 1000 ml, bring to a gentle boil, add agar with stirring and keep stirring until it is dissolved, pour into culture vessels, and autoclave

FIG. PHAL-23. **In vitro propagation of *Phalaenopsis*. A. Seedling with an elongated stem on Hyponex medium containing 5 mg BA l^{-1} after 90 days of culture. B. Defoliated seedling on BA-free medium after 90 days of culture. C. Formation of shoots and multiple adventitious buds on a second node-stem section on Hyponex medium with 5 mg BA l^{-1} after 70 days of culture. D. Rooted plantlets on BA-free Hyponex medium. E–N. Micropropagation procedure. (Duan et al., 1996.)**

Procedure. Seedlings (Fig. Phal-23A, E) or plantlets are grown on a medium which contains 5–10 mg BA l^{-1} for 90–135 days until they elongate (Fig. Phal-19F) and are defoliated (Fig. Phal-19B, G). The elongated stems (about 1 cm in length) are cut into four sections: top (including the apex), second, third, and basal sections (Fig. Phal-19H–K). When plantlets are produced they should be moved to the peptone-containing, BA-free medium for rooting (Fig. Phal-19C, L, M). Rooted plants are potted.

Developmental Sequence. Plantlets and/or seedlings elongate on the first medium (Table Phal-53). Sections produce shoots on the second medium (Table Phal-54). The shoots develop roots on the third medium (Table Phal-55).

General Comments. This is a clever and efficient procedure whose major drawback could be the high levels of BA in the first medium. Such high levels of any hormone may induce undesirable mutations. Therefore this method should be approached with caution until the effects of the high BA levels become known.

Propagation of *Phalaenopsis* Protocorm-like Bodies in Liquid Medium

The growth and multiplication of PLBs have been described as two rate-limiting steps in the mass, rapid, clonal propagation of *Phalaenopsis*. A liquid culture method that increases PLB multiplication and development was formulated at Shizuoka University in Japan (Park et al., 1996).

Plant Material. The paper which describes the procedure is entitled "Efficient propagation of protocorm-like bodies of *Phalaenopsis* in liquid medium" (Park et al., 1996). Despite this "*Doritaenopsis* (*Doritaenopsis* × *Phalaenopsis* cultivar) was used to obtain PLB's." One-node flower-stalk sections were cultured in MS agar medium until the shoots which developed from the nodes formed 1–3 leaves. Segments taken from the apical, median, and basal areas of the fully expanded uppermost leaves were also cultured on MS agar medium at 25°C under 16-h photoperiods of 6.25–7.5 μmol m^{-2} s^{-1} (sources not described). Presumably PLBs obtained from these sections were used to develop the procedure.

Surface Sterilization. PLBs from cultures in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, 200-ml capacity containing 100 ml medium, were used "to investigate the effects of the liquid media on the multiplication ratio of PLB." Also:

> . . . to investigate the propagation of PLB in bioreactors, several reactors, a turbine blade reactor (TBR, Sakura Co. Ltd., Tokyo), bubble column of 45 mm in diameter and 500 mm in length, and cotton plate design were used. The TBR had a working volume of 1 liter . . . rates of agitation and aeration were 200 rpm and 0.5 vvm (volume of gas per volume of liquid per minute) as a low oxygen supply and the other 300 rpm and and 1.5 vvm as a high oxygen supply . . . the minumum agitation . . . was kept at 200 rpm . . . bubble column with a working volume was operated at two kinds of cultural conditions: the aeration rate was 0.17 vvm as a low oxygen supply, and 1.67 vvm as a high oxygen supply. (Park et al., 1996)

A cotton plate bioreactor (Fig. Phal-24) consisted of a:

> . . . small Petri dish . . . 85 mm in diameter . . . placed upside down on a plate [actually in the drawing this looks like a larger Petri dish] 120 mm in diameter. Two kinds of cotton were used: One was non-adsorbent cotton which had uneven surface; the other, adsorbent (500G, Nishio Eizai Co Ltd., Nagoya) with an even surface. The cotton pad . . . 140 mm in diameter was laid on the small plate as a support for PLBs. These cotton plates were soaked or submerged [in] liquid medium during the culture period. Fifteen excised PLBs were placed on each cotton plate. . . . The

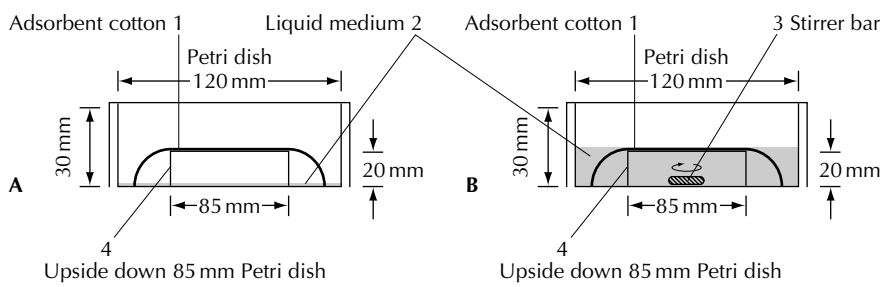

FIG. PHAL-24. **Cotton plate reactors. A. Reactor with cotton plate only. The cotton plate was soaked with medium. B. Reactor with cotton plate and stirrer bar. The cotton plate was submerged in the medium. (Park et al., 1996.)**

> thickness of the adsorbent cotton was varied from 1 to 5 mm, as was the culture [medium] volume increasing [it] to 150 ml under which conditions the PLBs were submerged. (Park et al., 1996)

Culture Conditions. Cultures should be maintained at 25°C under 16-h photoperiods of 6.25–7.50 μmol m^{-2} s^{-1}. Standard laboratory conditions are also suitable. Liquid cultures should be placed on a rotary shaker at 6 rpm.

Culture Medium. Liquid MS medium (Murashige and Skoog, 1962) containing 20% coconut water (Table Phal-56) should be used to wet the cotton layers.

Procedure. PLBs of 5–6 mm are sectioned to obtain sections 1–2 mm in size. These are placed on the 6-mm-thick cotton layers wetted with 7.2 ml g^{-1} cotton. The medium should not be stirred.

Developmental Sequence. The PLBs multiply on the cotton.

General Comments. PLBs multiply when this procedure is used, but they also increase in number when simpler methods are employed. This rather complicated and probably expensive (due to the equipment it requires) protocol does not seem to offer enough or even any advantages to warrant its use. It is presented here only because it was published.

***Phalaenopsis amabilis* from Illustrations of Orchidaceous Plants by Thomas Moore (London, 1857)**

TABLE PHAL-56. **Vacin and Went (VW) medium (Vacin and Went, 1949) for proliferation of protocorm-like bodies in a reactor (Park et al., 1996)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Coconut water (CW)[e]	200.0 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), adjust pH to 5.2–5.4, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

Propagation of *Phalaenopsis* through the Culture of Node Sections from Inflorescences following Senescence of the Flowers

If inflorescences are taken for micropropagation before the flower buds open, or while flowers are at their prime, the decorative and horticultural value of the donor plant will be lost. This can be avoided if flower stalks are taken after the flowers senesce and abscise (Jiménez and Guevara, 1996).

Plant Material. Inflorescence axes should be taken after senescence of the flowers. Apical buds, as well as median nodes below the flowers and basal ones, can all be used.

Surface Sterilization. The stems should first be washed with tap water and a mild detergent (this step is not listed in the original paper, but is advisable), wiped with cheese cloth (or gauze) wetted with 95% ethanol, and then cut into sections which have 2 cm of stem above and below the node. These sections should be soaked in a 1 : 10 dilution (or 10%) of a household bleach (9 or 10 ml, respectively, of bleach such as Clorox which contains 6 or 5.25% sodium hypochlorite and diluted to 100 ml with distilled water with a drop of Tween 80 or mild household detergent; this is 0.53% sodium hypochlorite) for 15 min and then rinsed with sterile distilled water (the rinse is not included in the original paper, but is advisable nevertheless). All steps after this should be carried out under sterile conditions. The bracts which cover the buds should be removed after that; the sections should be immersed with agitation in 5% (0.263 sodium hypochlorite) household bleach (5 ml diluted to 100 ml with distilled water with one drop of Tween 80 or a mild household detergent) for 10 min and washed three times with sterile distilled water. The stem on each side of the bud should be trimmed after the last wash so that only 1.0–1.5 cm remain above and below the bud. The cut on the basal end should be diagonal to facilitate insertion into the medium.

Culture Vessels. Culture tubes, 18 × 150 mm containing 15 ml of medium, covered with aluminum foil (cotton buns or plastic caps can also be used), were used in the original research for initial cultures. Other containers are also suitable. Baby food jars containing 25 ml medium were used to culture plantlets or shoots that form in the test tubes. Erlenmeyer flasks or other containers filled to 20–30% of their capacity with medium can be used instead of the jars.

Culture Conditions. The research cultures were maintained at 26–30°C under 24-h photoperiods of 2600 lx (source not described). Standard culture room conditions are also suitable.

Culture Media. A substantially modified MS medium (Murashige and Skoog, 1962) should be used initially (Table Phal-57) to establish the cultures. Shoots which fail to form roots and/or do not develop well, must be moved to another modification of MS (Table Phal-58). Plantlets can be potted in vermiculite in covered plastic containers for a week. The covers should be removed for part of the time in the second week.

TABLE PHAL-57. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of node sections from flower stalks after the flowers have senesced (Jiménez and Guevara, 1996)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10

	Cytokinins				
11	Benzylaminopurine (BAP)	3.0	300 mg 100 ml^{-1} 95% ethanol[e,f]	1	
12	Kinetin	0.86	86 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Purine				
13	Adenine	5.0	500 mg 100 ml^{-1} 95% ethanol[e]	1	
	Vitamins				
14	Niacin (nicotinic acid)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Pyridoxine (vitamin B_6)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
16	Thiamine (vitamin B_1)	10.0	1000 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar alcohol				
17	Manitol	10.0 g	No stock	No stock	Weigh
	Complex additive				
18	Coconut water (CW)	200.0 ml	No stock	No stock	Measure
	Sugars				
19	Fructose	10.0 g	No stock	No stock	Weigh
20	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
21	Water, distilled[g]	To 1000 ml			
	Solidifier				
22	Agar[g]	8.0 g	No stock	No stock	Weigh
	Darkening agent				
23	Activated charcoal[h]	0.5 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin, or cytokinins or purine do not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–18 to 700 ml of distilled water (item 21), adjust pH to 5.2, add the sugars (items 19 and 20), and raise volume to 1000 ml with distilled water (item 21). Bring the solution to a gentle boil and add the agar (item 22) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 23) with constant stirring to disperse it completely and dispense the solution into culture vessels. As a rule auxins, cytokinins, purines, and vitamins should be added after autoclaving, but in this case the original report indicates that they were added before the medium was autoclaved. If baby food jars are used as culture vessels the caps should be put on loosely to prevent possible explosions in the autoclave. Or, a hole should be drilled in each cap and stuffed with cotton. Agar is not added to liquid media.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

TABLE PHAL-58. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the rooting of shoots derived from sections from flower stalks after the flowers have senesced (Jiménez and Guevara, 1996)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Darkening agent				
16	Activated charcoal	500.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]Inositol and *meso*-inositol are other names for this substance.

[g]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.5, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, add the activated charcoal (item 16) with vigorous stirring of the solution to mix it wel, distribute the medium to culture vessels, and autoclave.

[h]Only activated pure vegetable charcoal should be used. Two possible sources are www.sigmaaldrich.com and http://search.wako-chem.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances.

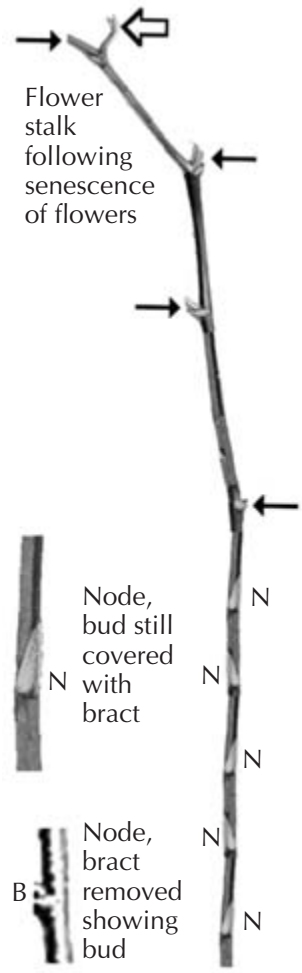

FIG. PHAL-25. **Flower stalk of *Phalaenopsis* following senescence of flowers and excised nodes before (middle left) and after (bottom left) the removal of the bract which covers the bud. Solid arrow, remnant of flower; open arrow, shoot tip; B, bud; N, node. (Jiménez and Guevara, 1996.)**

Procedure. Inflorescence axes taken after senescence of the flowers should be wiped with gauze (or cotton) dipped quickly in 95% ethanol, and then cut into sections with 2.0 cm of stalk above and below the node, surface-sterilized, and trimmed leaving 1.0–1.5 cm of stem on each side of the bud (Fig. Phal-25). The cuts below the buds should be slanted. Apical buds, as well as median nodes below the flowers and basal ones, can be used. The sections are inserted into the first medium with the bud touching the agar (Table Phal-57) following surface sterilization. Those that become contaminated can be removed from the culture vessels, resterilized, and inserted in fresh medium. Sections which form shoots or plantlets are moved to the same medium in baby food jars or other containers. Shoots which fail to develop roots or do not grow well are moved to the second medium (Table Phal-58).

Developmental Sequence. Buds on sections from the basal or apical portions of the stalk may fail to grow. Sections from the middle part of the stalk will mostly produce vegetative shoots. A few will produce floral axes. When excised and cultured, these floral axes produce vegetative shoots. Plantlets form following the transfer of shoots to fresh first medium (Table Phal-57) or the second medium (Table Phal-58). They can be transferred to a greenhouse after 4–6 months of culture.

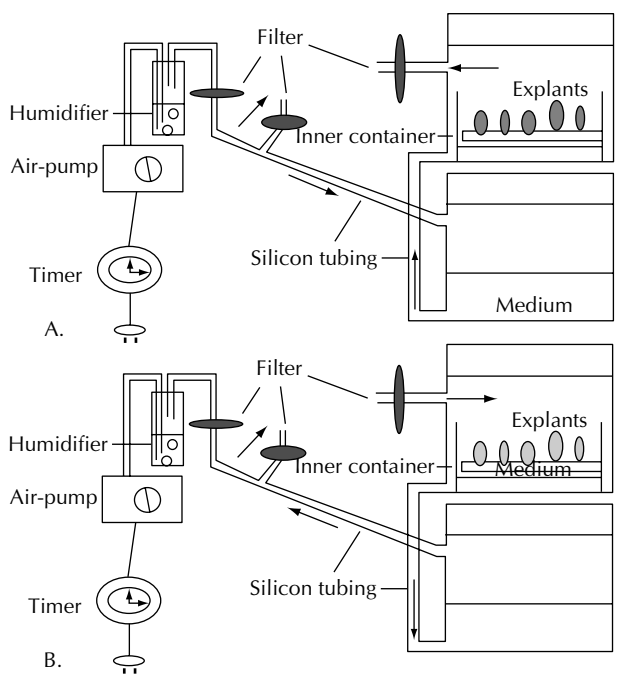
General Comments. The use of inflorescences after flowers have senesced as the explant source is ingenious. Shoots produced can be excised and cultured. Roots usually appear after leaf formation. If roots do not form the shoots should be cultured on medium devoid of hormones to induce rooting.

Differences in the Formation of Shoots and Protocorm-like Bodies from Axillary Buds and Shoot Tips of *Phalaenopsis*

See the procedure for *Doritaenopsis* (see p. 686, Vol. I; Yamazaki et al., 1997).

Abnormal Protocorm-like Bodies and Plantlets of *Doritaenopsis* and *Phalaenopsis*

Abnormal PLBs and plantlets are produced by cultures of *Doritaenopsis* and *Phalaenopsis*. The culture period and types of clones used are among the factors associated with this phenomenon (Park and Paek, 1999).



Operation mode of API bioreactor. Arrows represent the airflow or culture medium movement. A. Transfer of medium from the reservoir to the culture container. B. Transport of medium from the culture container to the reservoir.

Mass Propagation and Plantlet Production of *Phalaenopsis* Protocorm-like Bodies in a Bioreactor

Standard micropropagation protocols produce a relatively small number of plants, which means that multiplication of these plants is somewhat slower than may be required by marketing needs. To overcome this problem, a bioreactor-based, mass, rapid propagation system was developed at Chungbuk National University in Korea (Park et al., 2000). Since this method is different from standard micropropagation procedures, presentation of the procedure here will not be in the format used for other protocols.

Plant Material. Flower-stalk sections, 2 cm long, sterilized for 10 min in 0.2% mercuric chloride, and washed with sterile distilled water were cultured in solid MS medium (Murashige and Skoog, 1962) containing 45 g sucrose l^{-1} and 3 mg BA l^{-1}. Leaves produced by these explants were cut into sections, 5×10 mm, which were cultured on MS with 45 g sucrose l^{-1}, 1 mg NAA l^{-1}, and 15 mg BA l^{-1} (this is a high concentration which can cause undesirable mutations). PLBs produced by these explants after 8 weeks were cut transversely, and sections, ca. 2 mm in size, bearing apical meristems were used as explants for proliferation. There is no information in the original paper about the culture vessels and conditions that were used in these steps of the procedure.

PLB Proliferation in Flasks. Approximately 25 sections of PLBs (500 mg), cultured in 250-ml Erlenmeyer flasks containing 100 ml Hyponex medium (Kano, 1965) supplemented with 1% (probably weight/volume) potato homogenate (Table Phal-59), produced 10 PLBs per section after 8 weeks of culture. The Hyponex medium used here is described as "6.5N – 4.5P – 19K 1 g l^{-1} + 20N – 20P – 20K 1 g l^{-1}." This suggests that there are at least two different formulations of Hyponex and that 1 g of each should be used per liter. This water-soluble fertilizer is hard to find in the USA. It is available from www.hyponex.co.jp. Those who intend to use this procedure should purchase two formulations: 6.5N–4.5P–19K and 20N–20P–20K. No information is given on how to prepare the potato homogenate. One way would be to homogenize the required amount by putting cubed potatoes in a liquid medium during initial preparation. The culture conditions are 25 ± 2°C under white fluorescent lights of 60 μmol m^{-2} s^{-1} intensity. Photoperiods were probably 24 h long. Flasks must be placed on a horizontal gyrotory shaker at 100 rpm.

TABLE PHAL-59. **Hyponex medium for the proliferation of protocorm-like bodies (Park et al., 2000)**

Component	Amount l^{-1}	Comments
Hyponex[a]	3.5 g	Add all components to 900 ml of water. Adjust pH to 5.6, raise volume to 1000 ml, bring to a gentle boil, add agar with stirring and keep stirring until it is dissolved, pour into culture vessels, and autoclave
Potato homogenate	10.0 g	
Sucrose	25.0 g	
Water	To 1000 ml	
Agar	10.0 g	

[a]One possible source for Hyponex is www.hyponex.co.jp.

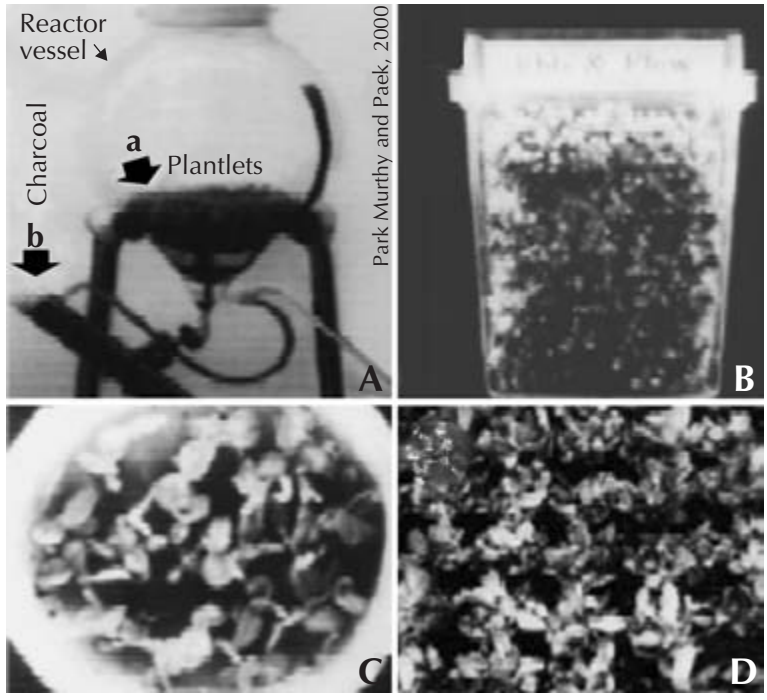


FIG. PHAL-26. **A. PLBs and plantlets proliferating in a temporary immersion bioreactor. B. PLBs harvested from the bioreactor. C. Plantlet production from PLBs on Hyponex medium. D. Acclimatized plantlets. (Park et al., 2000.)**

PLB Proliferation in a Bioreactor. Approximately 500 sections of PLBs (10 g) cultured in temporary immersion cultures, produced 13 PLBs per section after 8 weeks of culture in the same medium (Table Phal-59) and conditions as above. The sections should be placed on a plastic net inside the reactor vessel (Fig. Phal-26A). The system should be designed to immerse the sections in medium for 5 min, followed by 2 h without solution. PLBs harvested after 8 weeks (Fig. Phal-26B) should be cultured (Fig. Phal-26C) on Hyponex medium with 45 g sucrose l^{-1} and 0.5% activated charcoal (www.sigmaaldrich.com) l^{-1} (Table Phal-60) in polystyrene vessels, 115 × 50 mm (Tong Yang Moolsan C., Seoul, Korea; other containers are also suitable) at 25 ± 2°C under 16-h photoperiods of 60 μmol m^{-2} s^{-1} (light sources not described).

TABLE PHAL-60. **Hyponex medium for the proliferation of protocorm-like bodies (Park et al., 2000)**

Component	Amount l^{-1}	Comments
Hyponex[a]	3.5 g	Add all components to 900 ml of water. Adjust pH to 5.6, raise volume to 1000 ml, bring to a gentle boil, add agar with stirring and keep stirring until it is dissolved, pour into culture vessels and autoclave.
Potato homogenate	10.0 g	
Sucrose	45.0 g	
Water	To 1000 ml	
Agar	10.0	
Activated charcoal	5.0	

[a]One possible source for Hyponex is www.hyponex.co.jp.

Standard laboratory conditions are also suitable. The plantlets should be subcultured every 4 weeks. When they reach a height of 3–4 cm, the plantlets should be potted (Fig. Phal-26D) in a mix consisting of peat moss and perlite (in a ratio of 1 : 1) and grown in a greenhouse under 60–70% relative humidity, at 25°C during 16-h days of 500 μmol m^{-2} s^{-1} and at 15°C at night.

General Comments. This bioreactor-based protocol makes possible large-scale rapid micropropagation. If a bioreactor is not available, a relatively large number of PLBs can be proliferated in flasks under agitation. An unanswered question is whether this procedure might induce undesirable mutations.

Plant Production from Callus Culture of *Phalaenopsis*

This procedure is not micropropagation in the strictest sense because seedlings are induced to form callus, which serves as a source for PLBs that produce plantlets (Y.-C. Chen et al., 2000). The protocol is presented here because it can also be used to propagate plantlets which are produced clonally.

Plant Material. Seeds of self-pollinated *Phalaenopsis* Nebula, harvested 120 days after pollination, were germinated on quarter-strength MS salts (Murashige and Skoog, 1962) supplemented with 100 mg *myo*-inositol l^{-1}, 50 g banana pulp l^{-1}, 1 mg peptone l^{-1}, and 2 g charcoal l^{-1}, and solidified with 3 g Gelrite l^{-1} at 25°C under 16-h photoperiods of 10 μmol m^{-2} s^{-1} provided by daylight fluorescent tubes (FL-30D/29, 40W, China Electric Co., Taipei). Protocorms, 1–2 months old, produced by these seeds were used for callus induction. Other protocorms or PLBs obtained from culture of explants can also be used.

Surface Sterilization. Protocorms or PLBs from cultures in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers can be used.

Culture Conditions. During the callus induction phase, cultures should be maintained at 26 ± 2°C in the dark. The culture of PLBs, as well as plantlet induction and maintenance, should be under 16-h photoperiods of 28–36 μmol m^{-2} s^{-1}, presumably provided by the same light source as above.

Culture Media. To induce callus, 2-month-old PLBs or seed-derived protocorms should be cultured on half-strength MS medium (Murashige and Skoog, 1962) supplemented with TDZ and peptone (Table Phal-61). The callus can be maintained on half-strength MS with peptone, 2,4-D, and TDZ (Table Phal-62). For PLB and plantlet production, callus should be cultured on hormone-free half-strength MS (Table Phal-63).

Procedure. Seeds are germinated, and when protocorms are formed they are moved to the first medium (Table Phal-61) for callus initiation. Callus is maintained on the second medium (Table Phal-62). Sections of callus are moved to the third

TABLE PHAL-61. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for callus induction from protocorms or protocorm-like bodies of *Phalaenopsis* (Y.-C. Chen et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
18	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.2, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Add the Gelrite (item 18) according to the instructions in footnote *h*. When the Gelrite (item 18) is completely dissolved, pour the solution into culture vessels and autoclave. Gelrite is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved, pour the medium into culture vessels and autoclave.

TABLE PHAL-62. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the maintenance of callus produced by protocorms of *Phalaenopsis* (Y.-C. Chen et al., 2000)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin or auxin does not dissolve, add a few drops of 0.1 N HCl or KOH, respectively.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Add the Gelrite (item 19) according to the instructions in footnote *h*. When the Gelrite (item 19) is completely dissolved, pour the solution into culture vessels and autoclave. Gelrite is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved, pour the medium into culture vessels and autoclave.

TABLE PHAL-63. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the induction and culture of protocorm-like bodies and plantlets from callus produced by protocorms or PLBs of *Phalaenopsis* (Y.-C. Chen et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	Monosodium phosphate, NaH_2PO_4	170.0	17.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	31.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
9	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Complex additive				
11	Peptone	1.0 g	No stock	No stock	Weigh
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[e]	To 1000 ml			
	Solidifier				
17	Gelrite[e,f]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Add items 1–16 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Add the Gelrite (item 17) according to the instructions in footnote *f*. When the Gelrite (item 17) is completely dissolved, pour the solution into culture vessels and autoclave. Gelrite is not added to liquid media.

[f]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved, pour the medium into culture vessels and autoclave.

solution (Table Phal-63) for PLB and plantlet production. Plantlets are potted in sphagnum.

Developmental Sequence. Seedling protocorms produce callus on the TDZ-containing solution (Table Phal-61). The callus does not differentiate on the substrate that contains TDZ and 2,4-D (Table Phal-62). PLBs and plantlets form on the hormone-free medium (Table Phal-63).

General Comments. Since the quality of seedlings is not known, there is no point or need to propagate them clonally. However, this method can probably be used to propagate PLBs obtained through the culture of explants from mature plants of known quality.

Micropropagation of *Phalaenopsis* via the Culture of Leaf Tissue

Some red *Phalaenopsis* hybrids are reported to be difficult to propagate. A method using leaf tissues was developed to overcome these difficulties (Myint et al., 2001).

Plant Material. Fully expanded leaves, 5–8 × 2.5–3.5 cm in size, of red *Phalaenopsis* seedlings growing in pots were used in the original research. The leaves must be surface-sterilized before sections 0.5 m^2 in size can be cultured.

Surface Sterilization. The leaves should be washed with running water and a mild detergent, rinsed with distilled water, wiped with gauze or cotton wetted with 70% ethanol (73–74 ml 95% ethanol diluted to 100 ml with distilled water), immersed in 1% sodium hypochlorite (17 or 19 ml of a household detergent which contains 5.25 or 6% sodium hypochlorite, respectively, diluted to 100 ml with distilled water) for 15 min, and rinsed with sterile distilled water 3–4 times.

Culture Vessels. To induce PLBs, leaf sections should be cultured on a cotton platform, with 5 cm^2 surface and 1 cm thick, placed in a 100-ml Erlenmeyer flask and wetted with 30 ml liquid medium. For propagation, PLBs produced by the leaf sections should be cultured on 6 ml of solid medium in 15 × 180 cm culture tubes. Erlenmeyer flasks, 100-ml capacity containing 20 ml medium, can also be used.

Culture Conditions. Leaf sections should be maintained at 25 ± 1°C, in the dark for the first 2 weeks, and after that under 16-h photoperiods of 27 μmol m^{-2} s^{-1} provided by fluorescent lamps. The original paper does not describe the culture conditions for the propagation of PLBs. However, it is reasonable to assume that the conditions used under illumination for leaf sections and production of plantlets will be suitable. For plantlet regeneration, PLB sections should be maintained at 25 ± 1°C under 16-h photoperiods of 27 μmol m^{-2} s^{-1}. Standard culture room conditions will probably be suitable for cultures under illumination.

Culture Media. For PLB formation, leaf sections should be cultured in liquid modified Vacin and Went medium (Vacin and Went, 1949) on a cotton support

TABLE PHAL-64. **Modified Vacin and Went (VW) medium (Vacin and Went, 1949) for the induction of protocorm-like bodies on *Phalaenopsis* seedling leaf explants (Myint et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	10.0	1 g 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	Benzyladenine (BA)	10.0	1 g 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[f]Keep frozen between uses.

[g]Add items 1 and 3–9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 11), adjust pH to 5.2–5.4, add sugar (item 10), raise volume to 1000 ml with distilled water (item 11), pour the solution into culture vessels which have been lined with cotton on the inside, and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

containing relatively high levels of NAA and BA (Table Phal-64). PLBs proliferate on agar-solidified Vacin and Went medium containing lower levels of the same hormones (Table Phal-65). To bring about shoot formation, PLB sections should be cultured on cotton in liquid new Dogashima (ND) medium (Tokuhara and Mii, 1993) also supplemented with BA and NAA (Table Phal-66). Shoots and plantlets should be cultured on cotton platforms in liquid Hyponex medium containing the same additives as the ND medium (Table Phal-67).

Procedure. The leaves are sectioned under sterile conditions after surface sterilization. Sections of 0.5 cm^2 are cultured on the first medium (Table Phal-64), abaxial surface in contact with the medium, first in the dark for 2 weeks and after that under illumination (16-h photoperiods of 27 $\mu mol\ m^{-2}\ s^{-1}$). PLBs produced on this medium

TABLE PHAL-65. **Modified Vacin and Went (VW) medium (Vacin and Went, 1949) for the proliferation of protocorm-like bodies produced by *Phalaenopsis* seedling leaf explants (Myint et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

12	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[f]Keep frozen between uses.

[g]Add items 1 and 3–9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 11), adjust pH to 5.2–5.4, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

are proliferated on the second medium (Table Phal-65). When PLBs reach a diameter of 5–6 mm they are sectioned "into 3–4 pieces [3–4 mm in size] either transversely or dorsally." The sections are cultured on the third medium (Table Phal-66). Shoots which form on this medium are grown on the fourth solution (Table Phal-67).

Developmental Sequence. The sections produce PLBs on the first medium (Table Phal-64). These PLBs proliferate on the second solution (Table Phal-65). PLB sections produce shoots and plantlets on ND medium (Table Phal-66). Plantlets and shoots grow further on Hyponex medium (Table Phal-67).

TABLE PHAL-66. **Modified new Dogashima (ND) medium (Tokuhara and Mii, 1993) for shoot formation by *Phalaenopsis* protocorm-like bodies produced by seedling leaves (Myint et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

18	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
19	Potato homogenate[i]	30.0 g	No stock	No stock	Weigh
	Sugar				
20	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
21	Water, distilled[j]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Dissolve the adenine in up to 30 ml 0.1 N hydrochloric acid and make up the solution to 100 ml with 95% ethanol.

[g]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[h]Dissolve the calcium pantothenate in 30 ml distilled water and make up the solution to 100 ml with 95% ethanol.

[i]The original paper does not contain instructions regarding the preparation of potato homogenate. One possibility is to peel a potato, cube it and place 30 of the cubes in a homogenizer (like a domestic blender), add 100 ml of distilled water and homogenize the mixture.

[j]Add items 1–19 (see footnote *i* for preparation of the potato homogenate) to 700 ml of distilled water (item 21), adjust pH to 5.2–5.4, add sugar (item 20), adjust volume to 1000 ml with distilled water (item 21), pour the solution into culture vessels which have been lined with cotton on the inside, and autoclave. The amino acid (item 9), hormones (items 12 and 13), and vitamins (items 14–18) are not heat-stable and are often added to autoclaved and still warm and liquid media with sterilized pipettes and mixed well before distribution to preautoclaved culture vessels. In this case all components of the medium are autoclaved.

TABLE PHAL-67. **Modified Hyponex/Kyoto medium (Tsukamoto et al., 1963) for the culture of *Phalaenopsis* plantlets (Myint et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Hyponex[b]	3.5 g	No stock	No stock	Weigh
	Auxin				
2	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[c,d]	1	
	Cytokinin				
3	Benzyladenine (BA)	1.0	100 mg 100 ml^{-1} 95% ethanol[c,d]	1	
	Complex additive				
4	Potato homogenate[e]	30.0 g	No stock	No stock	
	Sugar				
5	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
6	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.
[b]Available from www.hyponex.co.jp.
[c]Keep frozen between uses.
[d]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively. This stock solution may be at the limit of solubility of BA. If a precipitate forms shake well before dispensing.
[e]The original paper does not contain instructions regarding the preparation of potato homogenate. One possibility is to peel a potato, cube it and place 30 of the cubes in a homogenizer (like a domestic blender), add 100 ml of distilled water and homogenize the mixture.
[f]Add items 1–4 to 700 ml of distilled water (item 6), adjust pH to 5.0 (Tsukamoto et al., 1963) to 5.4, add sugar (item 5), adjust volume to 1000 ml with distilled water (item 6), pour into culture vessels which have been lined with cotton, and autoclave.

General Comments. The original experiments were carried out with leaves taken from seedlings. Since the quality of seedlings is not known there is usually no reason to propagate them. Therefore, it seems reasonable to assume that the seedlings were used only as a model system. This method should also prove suitable for the culture of segments taken from leaves of plantlets produced from explants such as flower-stalk nodes, for example. The concentrations of NAA and BA (10 mg l^{-1} of each) in the first medium (Table Phal-64) are relatively high. At such levels these hormones may induce undesirable mutations.

Rapid Propagation of *Phalaenopsis* through the Culture of Leaves Produced by Flower-stalk Explants in Vitro

There is an ever-increasing demand for clonally propagated *Phalaenopsis* to meet market needs for both cut flowers and pot plants of this orchid. A method using young leaves produced by flower-stalk explants was developed in the laboratory of Professor Kee-Yoeup Paek at Chungbuk University, Cheongiu, Korea (Park et al., 2002).

Plant Material. Flower-stalk nodes, second to the fourth nodes, each with a lateral bud should be used as explants. Sections, 2 cm long, must be surface-sterilized by

immersing them for 20 min in 3% sodium hypochlorite (50 or 57 ml of household bleach containing 6.0 or 5.25% sodium hypochlorite, respectively, diluted to 100 ml with distilled water). They should be washed three times with sterile distilled water after that and placed in culture. The medium, 20 ml in 25 × 250-mm culture tubes, should be MS solution (Murashige and Skoog, 1962) containing 45 g sucrose l^{-1}, supplemented with 20.2 μmol (4.55 mt) BA l^{-1} and solidified with 7 g agar l^{-1}. Leaves which develop following 4 weeks in culture are used as explants. After removal of the first leaf, the nodes are moved to fresh medium where they develop additional leaves which are also harvested and cultured.

Surface Sterilization. Leaves taken from in vitro cultures do not require surface sterilization.

Culture Vessels. Plastic Petri dishes, 90 mm diameter and 15 mm high containing 30 ml of medium, should be used for the induction of PLBs. Erlenmeyer flasks, 100-ml capacity containing 30 ml medium, should be used for PLB proliferation. Larger flasks, 250-ml or even 500-ml capacity, containing medium equal to 25–30% of their capacity, are more suitable for plantlet production. Plants are potted in 11-cm pots.

Culture Conditions. Cultures should be maintained at 25 ± 1°C under 16-h photoperiods of 30 μmol m^{-2} s^{-1} provided by cool white fluorescent tubes. Potted plants should be grown in a greenhouse at 30/25°C (day/night) under 16-h photoperiods of 500 μmol m^{-2} s^{-1}.

Culture Media. For PLB production, leaves should be cultured on half-strength MS medium (Table Phal-68) containing BA and NAA. PLBs proliferate and plantlets grow on Hyponex medium supplemented with potato homogenate, peptone, and charcoal (Table Phal-69). Plantlets should be potted in a mixture of peat moss and perlite (in a ratio of 1 : 1). They should be fertilized with Hyponex (6.5N : 4.5P : 19K) fertilizer (www.hyponex.co.jp).

Procedure. The young leaves are cut into 5 × 10 mm sections and cultured, 25 explants per Petri dish, with the abaxial surface in contact with the first medium (Table Phal-68). For proliferation, PLBs produced in the Petri dishes are cut in half and basal sections are cultured with the cut surface in contact with the second medium (Table Phal-69). When plantlets reach a height of 3–4 cm they are potted in peat moss in 11-cm pots, grown in a greenhouse, and fertilized with Hyponex.

Developmental Sequence. Leaf explants produce PLBs when cultured on the first medium (Table Phal-68) in Petri dishes. The PLBs proliferate and produce plantlets on the second medium (Table Phal-69).

General Comments. This procedure can accelerate micropropagation of outstanding clones without endangering the original plant. However, the high concentration of BA (88.8 μmol or 20 mg l^{-1}) may be problematic because such cytokinin levels may cause undesirable mutations.

TABLE PHAL-68. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for induction of protocorm-like bodies on explants of leaves produced by flower-stalk nodes in vitro (Park et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10

	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. As a rule the amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) are added after a medium has been autoclaved. However, all components of this medium are added before sterilization. Agar is not added to liquid media.

TABLE PHAL-69. **Modified Hyponex medium (Tsukamoto et al., 1963) for proliferation of protocorm-like bodies and plantlet production (Park et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Hyponex[b]	1.0 g	No stock	No stock	Weigh
	Complex additives				
2	Potato homogenate[c]	30.0 g	No stock	No stock	
3	Peptone	2.0 g	No stock	No stock	
	Sugar				
4	Sucrose	20.0 g	No stock	No stock	Weigh
	Darkening agent				
5	Charcoal[d]				
	Solvent				
6	Water, distilled[e]	To 1000 ml			
	Solidifier				
7	Agar	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Available from www.hyponex.co.jp.

[c]The original paper does not contain instructions regarding the preparation of potato homogenate. One possibility is to peel a potato, cube it and place 30 of cubes in a homogenizer (like a domestic blender), add 100 ml of distilled water, and homogenize the mixture.

[d]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances.

[e]Add items 1–3 to 700 ml of distilled water (item 6), adjust pH to 5.2, add sugar (item 4) and adjust volume to 1000 ml with distilled water (item 6). Bring the solution to a gentle boil and add the agar (item 7) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour it in the charcoal slowly with constant stirring. When the charcoal has been mixed in completely pour the medium into culture vessels and autoclave.

Isolation of *Phalaenopsis* Protoplasts

The method used to isolate protoplasts of *Cattleya skinneri*, *Cymbidium* Kenny 'Wine Color,' *Dendrobium* Malones 'Hope,' *Epidendrum radicans*, and *Paphiopedilum insigne* are also suitable for *Phalaenopsis*. The species used in this research was *Phalaenopsis amabilis* (Yasugi, 1990).

Micropropagation of *Phalaenopsis* through the Culture of Shoot Tips of Flower Stalk Buds

A procedure developed for *Doritaenopsis* is also suitable for *Phalaenopsis* (Tokuhara and Mii, 1993).

Effects of Complex Organic Additives on the Growth of *Phalaenopsis* Callus

Findings on the effects of complex organic additives on the growth of *Doritaenopsis* and *Neofineia* callus (Ichihashi and Islam, 1999) are also relevant for *Phalaenopsis*.

Biotechnology and Bioengineering of *Phalaenopsis*

Biotechnology and bioengineering as they relate to *Phalaenopsis* (Chen et al., 1990*a*, 1990*b*, 1990*c*, 1991, 1995, 1998; Hsie et al., 1992; Belarmino and Mii, 2000) are beyond the scope of this book, but relevant papers are listed here for those who are interested in the subject.

Encapsulation of *Phalaenopsis* Shoot Tips

Shoot tips were excised under filter-sterilized antioxidant, and then dried, placed in an alginate solution, and dispensed into calcium chloride (Senarath et al., 2003).

In Vitro Morphogenesis of *Phalaenopsis*

Protocorms were induced to form callus, which produced embryo-like structures (Chang et al., 2001).

Micropropagation of *Phalaenopsis* Under Light-emitting Diode (LED) Illumination

"Highest shoot and root fresh weight were observed in plantlets grown under 80% red + 20% blue LED" (Tanaka et al., 2001).

Plant Regeneration from Protocorm-like Bodies Produced by Etiolated Leaves of *Phalaenopsis aphrodite*

Etiolated leaves of *Phalaenopsis aphrodite* were induced to produce PLBs and subsequently plantlets on a medium that contained 0.3% sucrose, 0.5 mg BA l^{-1} and 0.5 mg TDZ l^{-1} (Hsu and Chen, 2003).

Effect of Ultrasonicated Water Treated with Quartz Porphyry "Bakuhan-seki" (USW-B) on Organogenesis in Protocorm-like Bodies

The best induction of shoots with roots occurred on a medium containing 3% USW-B (Shimasaki et al., 2003*a*).

Effects of Environmental Factors on the Growth of *Phalaenopsis* Plantlets

Plantlet growth was best under high intensity illumination, blue and red light-emitting diodes, and increased carbon dioxide levels with or without sucrose (Shin et al., 2001).

Reduction of Medium and Protocorm Browning during Culture of *Phalaenopsis* in Vitro

Calcium chloride, malic acid, and α-tocopherol reduced medium browning and total phenolics. Treatment with calcium chloride, citric acid, and malic acid reduced phenylalanine ammonia-lyase activity and total phenolics in protocorms. It is reasonable to assume that these substances will have the same effects on PLBs (Shin et al., 1999).

Carbohydrate Sources for Somatic Embryogenesis and the Effects of Yeast Extract and Benzyladenine

Most culture media contain 10–30 g sucrose l^{-1} as a carbon (carbohydrate or energy) source. Even when other sugars are used, the amounts added to media are often the same. This is a mistake because equal weights of different sugars may represent different molarities. Molarity is a manner of expressing concentration. It is the number of moles of solute (in this case sugar) dissolved in 1 l of solution. The unit in this case is moles of sugar per liter of medium.

The expression *molarity* = moles of sugar/liter of medium is very different from *concentration* = weight of sugar/liter of medium.

The reason is Avogadro's number, which is the number of atoms or molecules in a mole of a chemical substance, that is 6.022×10^{23}. For example, 20 g of sucrose (MW 342.30) is 20/342.30 = 0.05843 mol, which is $0.0584 \times 6.022 \times 10^{23}$ molecules. An equal weight (20 g) of glucose (MW 180.16) is 20/180.16 = 0.111.01 mol, or twice the molarity of sucrose, which means $111.01 \times 6.022 \times 10^{23}$ molecules. And, the number of molecules determines the osmolarity of a solution.

Osmolarity is the osmotic pressure which is exerted by a solution (in this case sucrose or glucose) that is in contact with pure water across a semipermeable membrane [i.e., a membrane that prevents movement of the solute (in this case the sugar), but allows free passage of the water] compared to pure water. It is dependent on the number of particles in a solution but independent of their nature. For example, a solution of 1 mol of sucrose or glucose dissolved in 1 l of water has an osmolarity of 1 osmol (osm) l^{-1}. This means that in the example above, the osmolarity of a solution of 20 g glucose l^{-1} is twice that of 20 g sucrose l^{-1}. And, since osmolarity has an effect on cells in addition to or other than that of carbon levels, the effects of 20 g sucrose l^{-1} and 20 g glucose l^{-1} will be different.

Very few investigators, even those studying the effects and utilizations of different sugars on orchid seedlings or plantlets, have paid attention to the influence of osmolarity (for one example see Ernst and Arditti, 1990, even if the intent in this case was to carry out follow-up experiments with equimolar levels of the same sugars). Therefore, a comparative study of the effects of equimolar levels (58.4 mmol, which is 20 g of sucrose, maltose, and lactose or 10 g of glucose, fructose, and sorbitol) of carbon sources on PLBs of *Phalaenopsis* and *Doritaenopsis* (Tokuhra and Mii, 2003) is both interesting and welcome. The results show that:

1 The highest number of PLBs was produced on glucose.
2 PLB formation without callus proliferation takes place on maltose and sorbitol.

3 Callus proliferation on glucose and sucrose is the same.
4 Proliferation of callus on sucrose occurs without PLB formation.
5 Only half as much callus proliferation occurs on fructose as on glucose.
6 Lactose is an inadequate carbon source.
7 There is no PLB formation and callus proliferation on lactose.

Other findings are that:

1 Yeast extract (YE) at 0.1–1 g l^{-1} enhances cell proliferation. It inhibits cell proliferation and PLB formation at 10 g l^{-1}.
2 BA at a level of 0.4 μmol (0.1 mg l^{-1}) increases callus proliferation slightly, but inhibits PLB formation.
3 Plantlets are produced on a medium containing 58.4 mmol (20 g) sucrose l^{-1} and 1 g YE l^{-1}.
4 The most efficient PLB formation by cell suspension cultures of *Phalaenopsis* Snow Parade occurs on a medium containing 29.2 mmol (10 g) sucrose l^{-1}.
5 PLB formation by cell suspension cultures of *Phalaenopsis* Wedding Promenade takes place on 14.6 mmol (5 g) sucrose l^{-1}.

PHALAENOPSIS AT HOME (Williams and Williams, 1894)
(From the *Gardens' Chronicle*.)

Pholidota

Pholidota chinensis can be propagated from leaf tips by the method used for *Acampe rigida* (Yam, 1989). Root tips of *Pholidota cantonensis* and *P. chinesis* produce callus when cultured by the method used for *Bletilla striata* (Yam, 1989).

Phragmipedium

Although not as popular as *Paphiopedilum* hybrids, species and crosses of *Phragmipedium* are of some interest to orchid growers.

Aseptic Propagation of *Phragmipedium*

According to one report "axillary bud explants . . . obtained from *Phragmipedium* Sedenii, *Phragmipedium* Sedenii 'Candidulum' and *Phragmipedium caricinum* [were] sterilized by routine techniques [and] . . . cultured on Reinert & Mohrs' [sic] medium supplemented with varying levels of NAA and zeatin . . ." (Stokes et al., 1975). Plants produced by this method reportedly flowered 18 months after the start of culture.

This paper provides very few details and leaves the reader with many questions.

Clonal Propagation of *Phragmipedium* Sedenii through the Culture of Flower Buds

A procedure for the clonal propagation of *Phragmipedium* Sedenii was developed at the Institute for Soil Science and Plant Nutrition (F. Penningfeld, an expert in orchid mineral nutrition, was its director at the time) at Weihenstephan, Germany (Fast, 1979). The procedure is similar to the method for clonal propagation of *Oncidium* from flower-stalk tips (Fast, 1973*b*).

Plant Material. The uppermost bud and inflorescence tip above it are taken from the inflorescence.

Surface Sterilization. The sheath is removed and the explant is surface-sterilized by immersing it in 1.5% household bleach (approximately 30 ml Clorox diluted to 100 ml with distilled water) for 15 min. This concentration seems high, and it is possible that the household bleach used in the original research is different from Clorox or Purex. Therefore it may be necessary to experiment with several concentrations before sterilizing a desirable clone. After being removed from the sterilizing solution the explant should be rinsed several times with sterile distilled water.

Culture Vessels. Photographs in the original paper show that the cultures were maintained in small (25–50 ml) Erlenmeyer flasks containing 10–25 ml medium.

Culture Conditions. The cultures should be maintained under 16-h photoperiods of 3000 lx (light sources not listed) and temperatures 23–25°C.

Culture Medium. The explants are cultured on medium containing half the concentration of the MS macroelements, the microelements of Nitsch, and hormones (Table Phrag-1).

Procedure. The explants are inserted in the agar medium and allowed to form plantlets. These can be moved to Knudson C or Vacin and Went medium for further development (see Tables Aranda-7 and Cym-5).

Developmental Sequence. The explants show growth after 1 month, and several plantlets form within 3–4 months. PLBs can also develop at that time. Undisturbed plantlets form roots in 4 months.

General Comments. This is a useful and safe procedure for the propagation of *Phragmipedium* that could perhaps serve as a starting point for research that may lead to a similar method for *Paphiopedilum*.

TABLE PHRAG-1. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Phragmipedium* flower buds (Fast, 1979)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220	22 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950	95 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3O_3	0.5	500 mg l^{-1}	1	One solution
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	25 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	3	300.0 mg l^{-1}		
(d)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.025	25 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.5	500 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-Inositol	50	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.1	40 mg 100 ml^{-1} 95% ethanol[f,g]	0.25	
	Cytokinin and related substance				
11	Benzylaminopurine (BAP)	10	1000 mg 100 ml^{-1} 95% ethanol[f,g]	1	
12	Adenine sulfate[h]	40	No stock	No stock	Weigh
	Vitamins				
13	Niacin (nicotinic acid)	0.5	100 mg 100 ml^{-1} 95% ethanol[g]	0.5	
14	Pyridoxine (vitamin B_6)	0.5	100 mg 100 ml^{-1} 95% ethanol[g]	0.5	
15	Thiamine (vitamin B_1)	0.1	40 mg 100 ml^{-1} 95% ethanol[g]	0.25	
	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[i]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. The original paper used a commercial preparation (Iron Chelate Fetrilon from BASF) that may not be available outside Germany.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin do not dissolve, add a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Combine hormone and vitamin alcohol solutions (items 10, 11, and 13–15) in a small autoclaved vial and add the adenine to this solution at least 20 min before mixture is to be added to medium. Shake well several times. Let stand and shake again. Pour mixture into hot, still liquid medium. If powder remains on the vial, wash it into culture medium with sterile distilled water.

[i]Add items 1–7 and 9 to 900 ml distilled water (item 17), adjust pH as required, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil and add agar (item 18) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8, and 10–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

Pleione

> PLEIONE—The Indian Crocus—is a genus of terrestrial orchids originating from Taiwan, India and mainland China. Large, handsome flowers are produced before the leaves and both arise from basal pseudobulbs. As a result of collecting difficulties . . . species most in demand are represented by single clones which are functionally self-incompatible and must therefore be propagated vegetatively. Some . . . species and hybrids are . . . in demand and . . . must be vegetatively propagated as clones. The slow rate of vegetative reproduction pointed to the need for a rapid micropropagation system for this genus, which was said by Morel (1971*a*, 1971*b*) to be amenable to the same techniques as for *Cymbidium*. . . . However, . . . the *Cymbidium* techniques were not successful when applied to *Pleione*. . . . (Weatherhead and Harberd, 1980)

Therefore, a more suitable procedure was developed at the Department of Plant Science, University of Leeds, England (Weatherhead and Harberd, 1980). This research was a harbinger of things to come since Weatherhead, now deceased, at the Botany Department, University of Hong Kong, developed an impressive research program dealing with orchid seed germination and tissue culture.

Plant Material. Shoot tips 2–3 mm long are taken from lateral shoots 1.0–1.5 cm long excised from the bases of pseudobulbs.

Surface Sterilization. In the original research the shoots were "surface-sterilized in 5% (v/v) sodium hypochlorite (British Drug Houses) for 15 min and then rinsed three times in sterile distilled water." This concentration is probably similar to the one that could be obtained by diluting 5 ml Clorox to 100 ml with distilled water.

Culture Vessels. Test tubes, Petri dishes, Erlenmeyer flasks, or other containers can be used.

Culture Conditions. Cultures should be maintained under 16-h photoperiods of 2000 lx at 27 ± 2°C.

Culture Medium. Knudson C medium with charcoal (Table Pln-1) is used for all stages.

Procedure. Place the explants on the culture medium and allow them to develop PLBs. Section these into quarters and move to fresh medium in Petri dishes, where proliferation takes place and clumps of PLBs form. Individual PLBs can be separated from the clumps and either sectioned again or cultured separately and allowed to form shoots. Move each shoot with a basal piece of PLB attached to a test tube where roots can be expected to form within 4 weeks. The resulting plantlets can be treated as seedlings and potted in community pots.

Developmental Sequence. The PLBs originate from divisions of the epidermal cells (Fig. Pln-1A) of the shoot-tip explant. They also develop basal rhizoids. Following the sectioning of the initial PLBs, new ones arise also from divisions of the epidermal

TABLE PLN-1. **Modified Knudson C medium (Knudson, 1946) for the micropropagation of *Pleione* (Weatherhead and Harberd, 1980)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250	25 g l^{-1}	10

10	Activated charcoal[f]	3 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[d]Add items 1–6 to 900 ml distilled water (item 8), adjust pH to 5.0, add sugar (item 7), and adjust volume to 1000 ml with distilled water (item 8). Bring solution to a gentle boil and add agar (item 9) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, add charcoal, stir to mix it well, and dispense solution into culture vessels and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower pH if necessary.

[e]Add agar to solid medium only.

[f]The original paper reports that the medium was "supplemented with activated charcoal 0.3% w/v (Fisons Scientific Apparatus) . . ." but does not indicate the type of the charcoal. Our experience is that vegetable charcoal is preferable.

cells (Fig. Pln-1B). They have a basal ring of rhizoids. The development of plantlets from PLBs is similar to that of seedlings (Fig. Pln-1C–F).

General Comments. This procedure is simple and effective. It can produce approximately 100 plants from one shoot-tip explant in about 20 weeks. Its major advantage is that it uses the same simple medium for all steps. A less obvious but nevertheless very important advantage is the extremely well written paper that reports it.

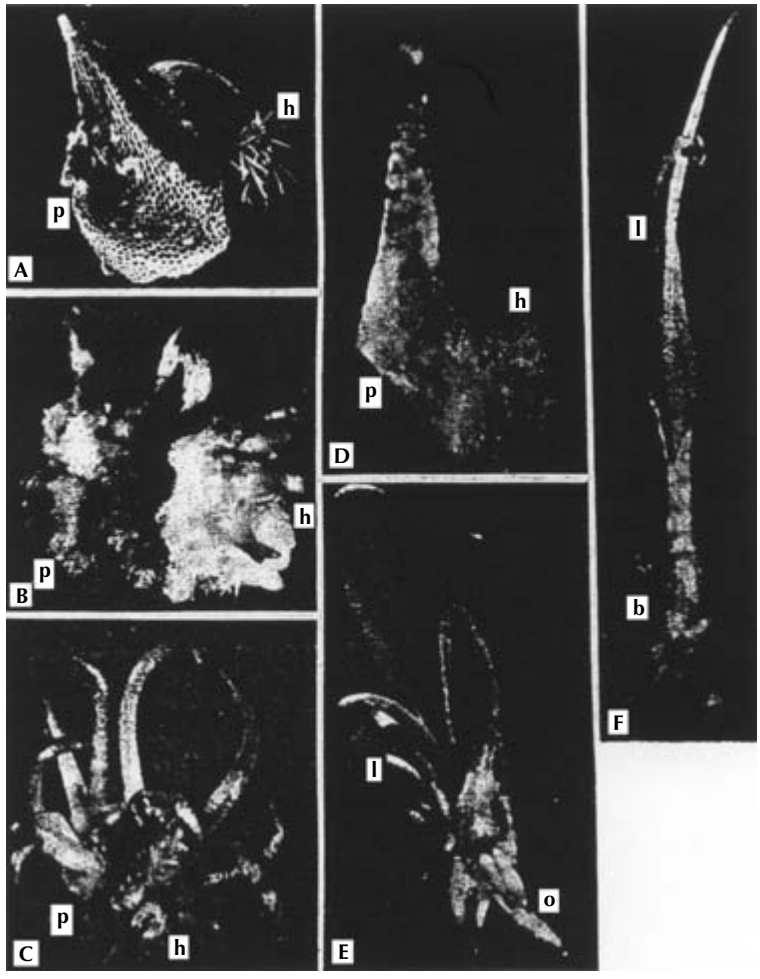

FIG. PLN-1. **PLBs and plantlet development in *Pleione*. A. A PLB (p) formed by division of the epidermal cells of the meristem; basal rhizoids (h) are clearly evident. B. A clump of PLBs (p) formed from the epidermal cells of a PLB section; each PLB has a ring of rhizoids (h). C. Several shoots arising from an individual PLB (p); rhizoids (h) are evident at the base. D. A shoot with a basal section of a PLB (p) and rhizoids (h). E. A plantlet (l) with a root (o). F. A plantlet (l) with a basal pseudobulb (b). (Courtesy Dr. M. A. Weatherhead, Botany Department, University of Hong Kong.)**

Pogonia

Species which at one time were part of *Pogonia* are currently included in *Cleistes*, *Triphora*, and *Isotria*. Because of this, *Pogonia* is a small genus now. The name is derived from the Greek πωγων (beard) or πωνωνας (*pogonias*) which means "bearded" and refers to the bearded crest on the labellum.

Micropropagation of *Pogonia japonica* through the Culture of Rhizome Segments

Pogonia japonica is a terrestrial species found in China, Japan, and Korea. It grows in lowland, barren, sunny bogs. Disruption of natural habitats due to land reclamation threatens this species with extinction. A micropropagation method (Fig. Pog-1) was developed at the Mukaishima Orchid Center and Hiroshima University to allow for the reintroduction of the species for conservation purposes (Takahashi and Kondo, 1998).

Plant Material. Seeds of *P. japonica* collected from a wild population in Higashi-Hiroshima City, Japan were surface-sterilized with 1.2% (v/v) sodium hypochlorite [presumably domestic bleach but it is not clear if the percentage refers to a bleach solution (as, for example, 1.2 ml bleach solution diluted to 100 ml) or to its active component (as, for example, 20 ml bleach diluted to 100 ml), but it is probably the latter] containing a few drops of Tween 20 (from www.sigmaaldrich.com, www.vwr.com, www.fishersci.com, www.thomassci.com, and other sources) or mild household detergent. The seeds were then rinsed three times with sterile distilled water and germinated on Hyponex medium (Kano, 1965) consisiting of 3 g Hyponex l^{-1} (www.hyponex.co.jp), 2 g peptone l^{-1} (www.sigma-aldrich.com, www.caissonlabs.com, www.duchefa.com, www.phytotechlab.com), 3% sucrose (w/v), and 0.3% Gelrite (w/v; www.sigmaaldrich.com, www.caissonlabs.com, www.duchefa.com, www.phytotechlab.com) at a pH of 5.8. The seeds germinated

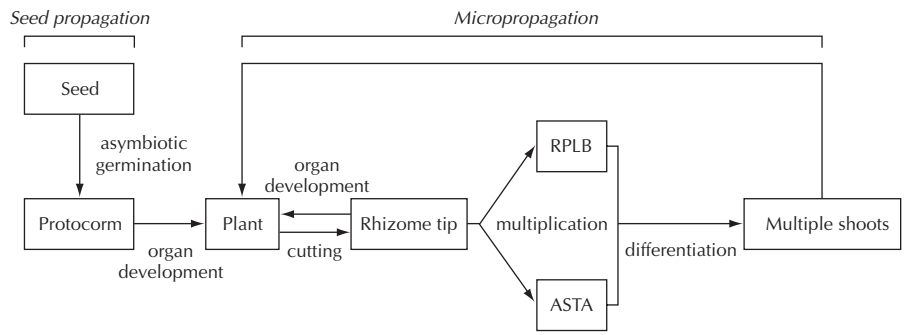

FIG. POG-1. **Propagation of *Pogonia japonica* through seed germination and tissue culture. ASTA, abnormal shoot-tip aggregation; RPLB, rhizome-derived protocorm-like bodies. (Takahashi and Kondo, 1998.)**

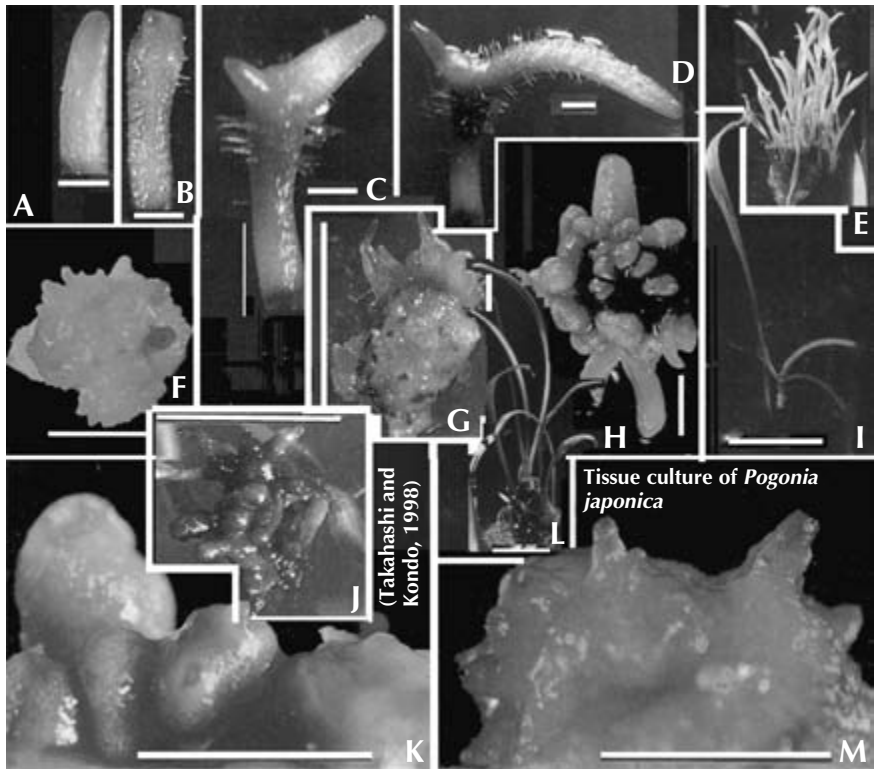

FIG. POG-2. **Micropropagation of *Pogonia japonica*. A. Rhizome-tip explant at the start of culture. B. Explant after 7 days of culture showing the start of adventitious bud formation. C. Newly formed rhizomes on a rhizome-tip explant after 14 days of culture. D. New rhizomes developing after 21 days. E. Plantlets produced from abnormal shoot-tip aggregation. F. Abnormal shoot-tip aggregation. G. Plantlets starting to develop from an abnormal shoot-tip aggregation. H. PLBs. I. A 60-day-old culture showing a well-developed juvenile plant. J. Plantlets starting to develop from a PLB. K. PLBs. L. Plantlets that formed from a PLB. M. Abnormal shoot-tip aggregation. Bars: 1 mm for A–D; 2 mm for F, H, K, M; 10 mm for E, G, I, J, L. (Takahashi and Kondo, 1998.)**

in 90–200 days and the seedlings were allowed to grow for 100 days. Rhizome tips, 2–3 mm long, were taken from these seedlings and cultured (Fig. Pog-2A).

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, 30 × 200 mm containing 20 ml medium, were used in the original research. Other containers filled to 25–30% of their volume with medium are also suitable.

Culture Conditions. Seedling cultures were maintained at 24 ± 1°C under continuous illumination of 1000 lx (source not indicated). Standard laboratory conditions will

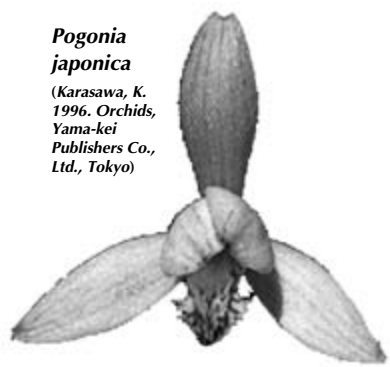
probably also be suitable. Explant cultures in liquid medium were placed on a rotary shaker at 2 rpm at 24 ± 1°C under 2000–10,000 lx of continuous illumination (source not given).

Culture Media. Explants should be cultured on liquid MS medium (Murashige and Skoog, 1962) containing 0.02 mg l^{-1} each of BA and NAA (Table Pog-1) for about 2 months until clusters of PLBs are formed (Fig. Pog-2H, K). The PLBs should be moved to solid hormone-free MS (Table Pog-2) for plantlet formation (Fig. Pog-2J, L).

Procedure. Rhizome-tip explants are cultured in liquid medium (Table Pog-1) under gentle agitation for 2 months or until PLBs are formed. These PLBs are moved to the solid medium (Table Pog-2) for plantlet formation.

Developmental Sequence. When the proper media and sequence are used (Table Pog-1 followed by Table Pog-2), normal PLBs (Fig. Pog-2H, K) and then plantlets (Fig. Pog-2J, L) will form. If the rhizome explants (Fig. Pog-2A) are placed on solid medium they form adventitious buds (Fig. Pog-2B), then new rhizomes (Fig.2-1C, D), and eventually plantlets (Fig. Pog-2I). Abnormal aggregations (Fig. Pog-2F, M), bodies (Fig. Pog-2G), and plantlets (Fig. Pog-2E) can form if the medium and/or conditions are not correct.

General Comments. As published, this procedure is for the micropropagation of seedlings and not of selected clones (Fig. Pog-1). However, since its purpose is to propagate a species for conservation and reintroduction this is not a major problem or limitation. And since orchids are generally very heterogenous, genetic pauperization of a population reintroduced in this manner is not likely.



Pogonia japonica
(*Karasawa, K. 1996. Orchids, Yama-kei Publishers Co., Ltd., Tokyo*)

TABLE POG-1. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Pogonia japonica* rhizome explants (Takahashi and Kondo, 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.02	2 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzyladenine (BA)	0.02	2 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.8, add sugar (item 15), bring volume to 1000 ml with distilled water (item 16), pour the solution into culture vessels, and autoclave. Agar is not added to liquid media. Amino acids, hormones, and vitamins are generally not heat-stable. Therefore it is preferable to sterilize them by filtration or make the stock solutions in alcohol and add them after autoclaving. In this case they are autoclaved.

TABLE POG-2. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for production of *Pogonia japonica* plantlets (Takahashi and Kondo, 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10

10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[f]	To 1000 ml			
	Solidifier				
15	Gelrite[f,g]	3.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.8, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Add Gelrite as indicated in footnote *g*. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave. The amino acid (item 8) and vitamins (items 10–12) are not heat-stable. Therefore they are often sterilized through autoclaving or their stock solutions are made in alcohol and added after autoclaving. In this case the amino acid and vitamins are autoclaved.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear, and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

Potinara

The procedures used for *Cattleya* and *Laeliocattleya* (Huang, 1984) can also be employed for *Potinara*.

Renades

The first *Renades* hybrid was produced in Hawaii half a century ago. It was *Renades* Kaulani (*Renanthera monachica* × *Aerides fieldingii*) registered in 1955 by Kirsch. According to the *Sander's One-Table List of Orchid Hybrids (1946–1960)* (Sander and Wreford, 1961) this could be either Oscar M. Kirsch or Rose B. Kirsch, both of the same address in Honolulu. Despite its vintage, *Renades* is not a very popular line of hybrids.

Clonal Propagation of Renades through the Culture of Inflorescences

Renades Arunoday [the hybrid name is spelled "Arunodoya," "Arunodya," "Arunodaya," and "Aronoday" in Ahmed et al. (1998), whereas the spelling in Sander's list is "Arunoday"] was produced by the Orchid Research Centre (ORC), State Forest Research Institute, Forest Department, Tipi Bhalukpong, Arunachal Pradesh, India and was registered in 1990 by S. N. Hegde of the same institution. The hybrid was described as having "commercial value for its long inflorescences with 18–20 . . . pale pink flowers with deep rose spots on petals and red blotches on the lobes of [the] lip" (Ahmed et al., 1998). Despite this description *Renades* is not grown as a cut-flower orchid in South East Asia, perhaps because the available hybrids do not seem to be as long lasting and as free flowering as the ones which are already in cultivation. "In order to multiply this ornamental hybrid on a mass scale" a micropropagation method using young inflorescences was developed at the ORC (Ahmed et al., 1998).

Plant Material. Young inflorescences, 8–10 mm long, were harvested, surface-sterilized and, after the final washing, "bracts were removed very carefully and inoculated . . ." (Ahmed et al., 1998). The statement in quotation marks here suggests that the bracts were placed in culture. However, the context of the report and a photograph (Fig. Rnds-1A) indicate that the young inflorescence was cultured. Therefore it may be advisable to place both the bracts and the young inflorescences in culture.

Surface Sterilization. The inflorescences should be cleansed with tap water and a soft brush (a used toothbrush is suitable) and Teepol (www.sigmaaldrich.com) or a mild household detergent and then rinsed with distilled water 3–5 times. They should then be dipped in 70% ethanol (73–74 ml 95% ethanol diluted to 100 ml with distilled water) for 3 min, washed with sterile distilled water three times, immersed in saturated calcium hypochlorite solution (7 g powdered calcium hypochlorite suspended in 100 ml distilled water, stirred vigorously, allowed to stand for 3–5 min, agitated

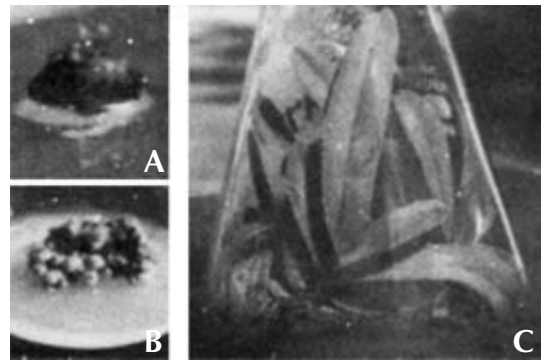

FIG. RNDS-1. **Culture of a *Renades* Arunoday inflorescence. A. Callus formation on the node area. B. Callus. C. Plantlets. (Ahmed et al., 1998.)**

again, left undisturbed for another 3–5 min, and then decanted or filtered; the liquid must be used within 12 h) for 5min and rinsed three times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks were used in the original research. Other containers are also suitable. Smaller containers (culture tubes or 50- or 125-ml Erlenmeyer flasks containing medium equal to 25–35% of their volume) should be used for the initial explants and to subculture callus. Larger flasks (250- or 500-ml capacity) can be used for plantlet production.

Culture Conditions. Cultures should be maintained at 25 ± 2°C and 16-h photoperiods of 2500 lx provided by fluorescent tubes or under standard laboratory conditions.

Culture Media. For callus induction, explants should be cultured on Vacin and Went medium (Vacin and Went, 1949) supplemented with coconut water, calcium pantothenate, pyridoxine hydrochloric acid (HCl), thiamine HCl, and NAA (Table Rnds-1). The callus produces plantlets on Vacin and Went medium with coconut water, banana homogenate, and an additive described as "starch potato" (Table Rnds-2). It is not clear if this is a particular type of potato or potato starch. Therefore, those who use this method are advised to try one version of the medium with potato homogenate and another with potato starch.

Procedure. Explants are taken from plants, surface-sterilized, and cultured on the first medium (Table Rnds-1). Callus which forms on these explants develops plantlets on the second medium (Table Rnds-2).

Developmental Sequence. Callus (Fig. Rnds-1A, B) is formed on the first medium and plantlets (Fig. Rnds-1C) develop on the second.

General Comments. This seems to be a productive micropropagation method which could perhaps be used for this hybrid genus as well as its parent genera,

TABLE RNDS-1. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of young inflorescences of *Renades* Arunoday (Ahmed et al., 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Vitamins				
8	Calcium pantothenate	0.25	25 mg in 100 ml 95% ethanol[e]	1	
9	Niacin	1.25	125 mg in 100 ml 95% ethanol[e]	1	
10	Pyridoxine HCl	0.25	25 mg in 100 ml 95% ethanol[e]	1	
11	Thiamine HCl	0.25	25 mg in 100 ml 95% ethanol[e]	1	
	Auxin				
12	Naphthaleneacetic acid (NAA)	0.1	10 mg in 100 ml 95% ethanol[e,f]	1	
	Complex additive				
13	Coconut water[g]	150.0 ml	No stock	No stock	Measure
	Solvent				
14	Water, distilled[h]	To 1000 ml			
	Solidifier				
15	Agar[h]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 14) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Keep frozen between uses.

[f]If the auxin fails to dissolve add a few drops of 0.1 N KOH.

[g]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1 and 3–13 to the 500–700 ml of distilled water (item 14) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 14), adjust pH to 5–5.4, raise the volume to 1000 ml with distilled water (item 14), bring the solution to a gentle boil, and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable. Hormone (item 12) and vitamins (items 8–11) are not heat-stable and are usually dissolved in alcohol or filter-sterilized and added after autoclaving. However in this case they are added before the medium is autoclaved.

TABLE RNDS-2. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for plantlet production from callus produced by young inflorescences of *Renades* Arunoday (Ahmed et al., 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additives				
8	Coconut water[e]	150.0 ml	No stock	No stock	Measure
9	Ripe banana[f]	100.0 g	No stock	No stock	Weigh
10	Potato starch[g]	2.0	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[h]	To 1000 ml			
	Solidifier				
12	Agar[h]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable, (2) the peel rather than the pulp should be used, (3) unpeeled banana homogenate should be incorporated in media, and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective banana variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and/or use what is suggested there.

[g]Potato starch is available from www.spicyglobe.com or www.sigmaaldrich.com.

[h]Pour the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2) into a homogenizer (a domestic type is appropriate), add items 1 and 3–10 and homogenize thoroughly. Bring volume to 900 ml with distilled water (item 11), adjust pH to 5–5.4, raise the volume to 1000 ml with distilled water, bring the solution to a gentle boil, and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

Renanthera and *Aerides*. It is unfortunate that the paper which describes it is not more detailed, written with more attention to detail, and edited with greater care.

Micropropagation of *Renades* through the Culture of Leaf Explants

Renades Arunoday was produced by the Division of Orchidology, State Forest Research Institute in Arunachal Pradesh, India. A micropropagation method using leaf explants was developed at the same institute (Sinha and Hegde, 1999).

Plant Material. Leaves, 0.8–2.0 cm in length, were taken from seedlings of *Renades* Arunoday growing in vitro. Whole leaves (Fig. Rnds-2Aa) and leaf-base segments (Fig. Rnds-2Ac, Ad) produce the best results. However, callus is also produced along the entire leaf base (Fig. Rnds-2Aa, Ac).

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization. However, they should be washed with sterile distilled water to remove medium residues.

Culture Vessels. Erlenmeyer flasks were used in the original research. Smaller flasks (125-ml flask containing 30 ml of medium) are suitable for initial cultures. Larger flasks (250- or 500-ml capacity containing medium equal to 25–30% of their volume) should be used for larger callus masses or plantlet production.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 14-h photoperiods of 2000 lx (the illumination sources used in the original research were not described). Standard laboratory conditions will probably also prove to be suitable.

Culture Media. Leaf explants should be cultured on half-strength MS medium (Murashige and Skoog, 1962) containing 1 mg BA l^{-1} and 0.5 mg NAA l^{-1} (Table Rnds-3). Callus and PLBs produced on this medium should be cultured on half-strength MS medium (Murashige and Skoog, 1962) containing 1 mg BA l^{-1} and 1 mg NAA l^{-1} (Table Rnds-4).

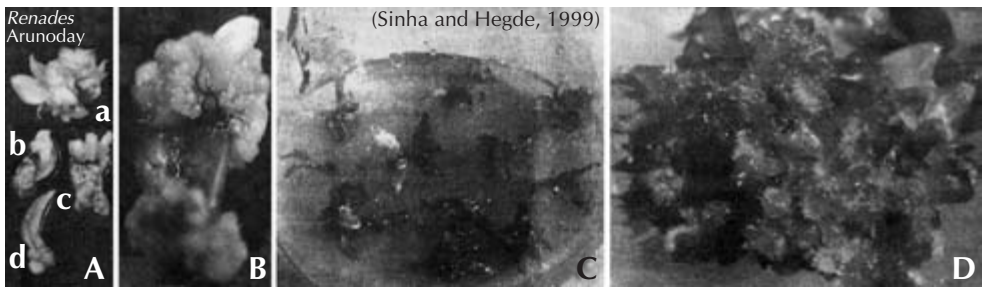

FIG. RNDS-2. **Culture of *Renades* leaves. A. Callus and plantlet formation on the entire leaf surface (a), blade and base (b), tip and base (c), and base (d). B. Formation of callus on the leaf tip and base. C. Well-developed plantlets. D. Platelets formed from PLBs. (Sinha and Hegde, 1999.)**

TABLE RNDS-3. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Renades* Arunoday seedling leaves (Sinha and Hegde, 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	31.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylaminopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution culture vessels and autoclave. Amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) are not heat-stable and are usually added to the hot solution under sterile conditions with sterilized pipettes. However in this case all components are mixed before autoclaving.

TABLE RNDS-4. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of seedling-leaf-derived *Renades* Arunoday callus and protocorm-like bodies for plantlet production (Sinha and Hegde, 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10

6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	31.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	1.0	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylaminopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) are not heat-stable and are usually added to the hot solution under sterile conditions with sterilized pipettes. However in this case all components are mixed before autoclaving.

Procedure. Leaves and leaf explants are cultured on the first medium (Table Rnds-3) until callus masses and PLBs are formed. PLBs should be moved to the second medium (Table Rnds-4) for plantlet production.

Developmental Sequence. Leaves and leaf explants start to swell within 4 weeks of the start of culture. PLBs, callus, and leaf primordia are produced within 28 weeks.

General Comments. This seems to be an effective and productive protocol with only one drawback: The explants are taken from seedlings, which means that the procedure cannot be used to select desirable clones. However, if explants are taken from plantlets produced through the previous procedure, selection of clones is possible.

A question unrelated to the procedure is the reason why *Renades* was chosen as the name of this hybrid rather than the better sounding *Aeridanthera*, which is another possibility as the name of a bigeneric hybrid is derived by combining the names of the parent genera.

Names of Media

Media names have interesting origins and histories. Some were named by those who formulated them. Examples are two different and unrelated P media (Hoppe and Hoppe, 1987*a*, 1987*b*, 1988; Ichihashi and Hiraiwa, 1996), B5 medium (Gamborg et al., 1968), new *Phalaenopsis* (NP) medium, new Dogashima medium (Tokuhara and Mii, 1993), ND medium (Tsukazaki et al., 2000), media B (Knudson B, KB; Knudson, 1922) and C (Knudson C, KC; Knudson, 1946; Knudson also used the Pfeffer solution and may have designated it as A) and GD medium (Thomale, 1954, 1957).

Subsequent users named several media for those who published or formulated them. This is the case with formulations by Nitsch and Nitsch (for obtaining haploid *Nicotiana*, simplified Knop, M_2, N_1) which are usually referred to as Nitsch or Nitsch and Nitsch followed by a date; Vacin and Went or VW for Emil Vacin and Frits W. Went's solution 5 (Vacin and Went, 1949); Murashige–Skoog medium or MS for Toshio Murashige and Folke Skoog's revised medium (Murashige and Skoog, 1962); Linsmaier and Skoog medium or LS for Elfrede Linsmaier and a Folke Skoog's revised medium or RM 1964 (Linsmaier and Skoog, 1964); Mitra, Prasad, and Roychowdhury or MPR medium for an orchid substrate (Mitra et al., 1976); and Norstog medium for Knut Norstog's barley medium II (Norstog, 1973).

Some researchers named their media after themselves. This is the case with media XE (experimental Ernst; Yam et al., 1991), XER (experimental Ernst, Robert; Ernst, 1994), RE (Robert Ernst; Ernst, 1982), REM (Robert Ernst medium; Ernst, 1986), and WS (Wannakrairoj, Surawit; Wannakrairoj and Tanyasonti, 1996).

When a medium is modified it is customary to indicate this (i.e., "modified X") rather than assign a new name.

Renanetia

Micropropagation of *Renanetia* through the Culture of Flower Bud Explants

The methods used for *Vandofinetia* (Kishi et al., 1997*a*, 1997*b*) can also be used for *Renanetia*.

Renantanda

The first cross in this hybrid genus was *Renantanda* Sanderi (*Renanthera imshootiana* × *Vanda suavis*) in 1935. Since then a large number of additional hybrids have been produced involving as parents *Renanthera coccinea*, *Renanthera monachica*, *Renanthera storiei*, *Vanda insignis*, *Vanda spathulata*, and *Vanda limbata* among species, as well as a number of hybrids.

Clonal Propagation of *Renantanda* through the Culture of Leaf Explants

Leaves are preferable as sources of explants for clonal propagation since their removal does not seriously damage or endanger the plant. A method for the clonal propagation of a *Renantanda* hybrid was developed at the National University of Singapore (Goh and Tan, 1982).

Plant Material. Young leaves of mature plants measuring 1–3 mm (generally the topmost three leaves) are removed and cultured.

Surface Sterilization. The leaves are washed with sterile distilled water, wiped thoroughly with 95% ethanol, immersed in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 10 min, and rinsed with sterile distilled water.

Culture Vessels. Erlenmeyer flasks should be used.

Culture Conditions. In the original research the cultures were maintained under natural daylight (filtered through a window) with 12-h photoperiods of approximately 2500 lx at 28 ± 2°C. Liquid cultures are placed on a shaker at 80 lateral oscillations per minute for 15 h daily.

Culture Media. Initial culture is in a modification of the Vacin and Went medium (Table Rntda-1). Callus and PLBs produced in this medium are transferred to an unmodified Vacin and Went solution (see Table Aranda-7).

Procedure. Place the explants on the first medium (Table Rntda-1), and allow them to develop callus and PLBs. Move these to the second medium (see Table Cym-5) for leaf, root, and plantlet formation. These plantlets can be cultured to a larger

TABLE RNTDA-1. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Renantanda* leaf explants (Goh and Tan, 1982)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric citrate, $FeC_6H_5O_7 \cdot 52H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water[e]	200 ml	No stock	No stock	Weigh
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Coconut water can be replaced with 1×10^{-6} mol benzyladenine and 1×10^{-6} mol 2,4-dichlorophenoxyacetic acid.

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 10) that contains item 2, adjust pH to 5.2–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense the medium into culture vessels, and autoclave. Omit agar for liquid medium.

size on the Knudson C (see Table Aranda-7) or Vacin and Went (see Table Cym-5) media.

Developmental Sequence. Papillae develop on the leaves after 2 weeks in culture. After 8 weeks the leaves show a water-soaked appearance near the area of the papillae, and callus forms at the base. PLBs form after 10 weeks and also following subculture. Two forms of PLBs can be seen. Larger PLBs are part of a loosely arranged tissue, while smaller ones form a more compact callus. The first leaves appear 2–3 weeks following subculture, and the roots are seen 2–3 weeks after that.

General Comments. Contamination was high during the initial experiments (54% in one case). However, success (i.e., uncontaminated cultures) was also high (more than 70%). Since leaves are easy to obtain, this procedure should prove of great value to those who wish to propagate *Renantanda* clones.

Clonal Propagation of *Renantanda* through the Culture of Shoot Tips

A method for the culture of *Renantanda* shoot tips was developed at the Botany Department, University Kebangsaan Malaysia, Bangi, Selangor, Malaysia (Abdul Ghani pers. comm.*; Abdul Ghani et al., 1992).

Plant Material. Shoot tips 2 mm long are excised from mature plants.

Surface Sterilization. Shoots should be washed with water and a mild detergent. (Teepol from the Shell Chemical Co., Kuala Lumpur, Malaysia, was used in the original research.) The washed shoots are rinsed with running tap water for 2 h, the upper young leaves are removed, and shoot tips with several leaf primordia are cut. These shoots should be submerged in 10% household bleach (e.g., 10 ml Clorox diluted to 100 ml with distilled water) for 15 min. After that they are moved for another 15 min to 5% bleach (5 ml Clorox diluted to 100 ml with distilled water). The sterilized shoot tips are then placed in a sterile Petri dish and all remaining leaves and leaf primordia are removed to expose the shoot apex. These shoot tips should be placed in 1% bleach (1 ml Clorox diluted to 100 ml with distilled water) for 10 min and rinsed with sterile distilled water for 5 min before the tips are excised.

Culture Vessels. Erlenmeyer flasks, of 100-ml capacity and containing 50 ml medium, were used in the original research. Flat-bottom culture vials, 2.5×10 cm and containing 20 ml medium, were used for plantlet induction. Other containers can also be used.

Culture Conditions. Liquid cultures should be placed on a gyrorotatory shaker at 100 rpm. In the original research all cultures were maintained under 8-h photoperiods of 2000 lx (provided by NEC daylight fluorescent tubes FL 20SSDD/18) at $25 \pm 2°C$.

Culture Media. Liquid Yamada II (YII) medium containing coconut water (Table Rntda-2) is suitable for the induction of PLBs. The PLBs proliferate on modified sugar-free liquid Vacin and Went (VW – s) medium (Table Rntda-3). Plantlets form on solid sugar-containing VW medium (VW + s; Table Rntda-3).

Procedure. Culture the excised shoot tips in the YII medium until PLBs form. Move the PLB to the VW – s medium for proliferation. When enough PLBs become available, move them to the VW + s medium for plantlet induction.

Developmental Sequence. PLBs form in the first medium (YII), proliferate on the second (VW – s), and produce plantlets on the third (VW + s).

* I thank Dr. Abdul Karim Adbul Ghani for allowing me to use in the first edition what was unpublished material at the time.

TABLE RNTDA-2. **Modified Yamada II medium as used for the culture of *Renantanda* explants (Abdul Ghani, pers. comm.)**

Item number	Component	Amount per liter
1	Gaviota fertilizer no. 67[a]	2.5 g
2	Peptone[b]	1.75 g
3	Coconut water[c]	200 ml
4	Tomato juice[d]	100 ml
5	Sucrose	15 g
6	Distilled water[e]	To 1000 ml
7	Agar[e]	14 g

[a]Blue Sky Agricultural Supply Co., (PTE), Ltd., Kuala Lumpur, Malaysia.

[b]Sigma Chemical Co., St. Louis, MO, USA.

[c]From green nuts; water from ripe nuts should also prove suitable.

[d]Prepared by removing seeds from 100–150 g fresh ripe tomatoes, homogenizing pulp, and filtering homogenate. The seeds must be removed since they may contain growth inhibitors. Do not use tomato juice from commercial sources since it may contain preservatives that could inhibit growth.

[e]Add items 1–4 to 600 ml distilled water and adjust pH to 5.2. Dissolve sugar (item 5), and bring total volume to 1000 ml with distilled water (item 6). Bring solution to a gentle boil, and add agar (item 7) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels, and autoclave. Omit agar if preparing liquid medium.

TABLE RNTDA-3. **Vacin and Went medium for the germination of orchid seeds (Vacin and Went, 1949) as modified for the proliferation of *Renantanda* protocorm-like bodies and for plantlet induction (Abdul Ghani, pers. comm.)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric citrate, $FeC_6H_5O_7 \cdot 5H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water from young nuts	200 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose[e]	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Omit sugar from the PLB proliferation medium (referred to in text as VW – s). Add it only to the medium for plantlet induction (VW + s).

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 10) that contains item 2; adjust pH to 5.2, add sugar (item 9), but only to medium used for plantlet induction; adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels, and autoclave. Omit agar for liquid medium.

General Comments. This is an efficient medium for mass rapid clonal propagation of *Renantanda* that does not contain hormones (except for those present in the coconut water). Such media are less apt to induce mutations.

Isolation and Culture of *Renantanda* Protoplasts

The development of methods for the isolation, culture, and fusion of protoplasts of a number of plants led to the development of similar procedures for *Renantanda* at the School of Biological Sciences, University Sains Malaysia, Penang, Malaysia, and the Institute for Plant Nutrition, Justus Liebig University, Giessen, West Germany (Teo and Neumann, 1978*b*, 1978*c*; Teo, 1980).

Plant Material. Protocorms of *Renantanda* Rosalind Cheok (*Vanda* Gilbert Triboulet × *Renanthera storiei*) were used as protoplast sources in the original research.

Surface Sterilization. Surface sterilization is not necessary for protocorms raised under aseptic conditions.

Culture Vessels. Information on culture vessels is not provided, but it is reasonable to assume that the containers used for *Angraecum eburneum* (Price and Earle, 1984) would be suitable.

Culture Conditions. Incubate protocorms for 18–20 h (temperature and illumination not described). Culture protoplasts under diffuse light (intensity and photoperiods not given) at 25°C.

Culture Media. The enzyme solution consists of 2% cellulase, 1% Macerozyme, 0.5% pectinase, 0.5% potassium dextransulphate (all w/v), and 12.75 g sorbitol per 100 ml distilled water. For sources of enzymes and equipment see Appendix 2 and procedures for *Angraecum giryamae*, *Barlia robertiana*, and *Ophrys lutea*. Protoplasts are cultured in a modified Knudson C medium (Table Rntda-4). It is not clear from the original paper whether the medium is liquid or solid. However, work with other plants and orchids indicates that it must be liquid. Viability is determined by treating the protoplasts with 0.5% fluorescein acetate and observing them after 5 min under a microscope with light of 435-nm wavelength. Viable protoplasts fluoresce bright yellow against a red background.

Procedure. Place protocorms in the enzyme solution for 18–20 h and filter the resulting cell suspension through a 90-μm sieve. Remove the cells from the sieve with sterile medium (Table Rntda-4), and culture.

Developmental Sequence. In freshly isolated protoplasts the chloroplasts are distributed throughout the cytoplasm, but can also be seen in the periphery. Raphide-containing idioblasts also occur in the suspension. Approximately 40% of the protoplasts are viable and fluoresce. "After about a week nearly 10% of the protoplasts [divide and form] clusters of 4–6 cells. Clusters of 80–100 cells can remain alive for up to 10 weeks" (Teo and Neumann, 1978*b*).

TABLE RNTDA-4. **Knudson C medium for the germination of orchid seeds (Knudson, 1946) modified for the culture of *Renantanda* protoplasts (Teo and Neumann, 1978*b*, 1978*c*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
7	2,4-Dichlorophenoxyacetic acid (2,4-D)	0.442	176.8 mg 100 ml^{-1} 95% ethanol[d]	0.25	
	Cytokinin				
8	Kinetin	0.215	86 mg 100 ml^{-1} 95% ethanol[d]	0.25	
	Sugar alcohol				
9	Sorbitol	12.75 g	No stock	No stock	Weigh
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[d]Keep refrigerated or frozen between uses.

[e]Add items 1–6 and 9 to 850 ml distilled water (item 11), adjust pH to 5.0–5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11), pour solution into a 2-l flask, and autoclave. Add hormones (items 7 and 8) to the autoclaved medium under sterile conditions and dispense into preautoclaved culture vessels. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. A dilute solution of hydrochloric acid (HCl) should be used to lower the pH if necessary.

General Comments. The authors (Teo and Neumann, 1978*b*, 1978*c*; Teo, 1980) have fused protoplasts of *Dendrobium* with *Dendrobium*, *Phalaenopsis* with *Phalaenopsis*, *Renantanda* with *Renantanda*, and *Dendrobium* and *Phalaenopsis* with *Renantanda* by treating them with polyethylene glycol. However, despite optimistic predictions there are no reports of plants being produced from fused or unfused protoplasts.

Renanthera

The genus *Renanthera* consists of approximately 15 species which are found in South East Asia. Plants are large monopodials with long stems. The gynostemium and pollinaria resemble those of *Vanda* and *Aerides*. That is why some *Renanthera* species were included in these genera at one time or another.

Micropropagation of *Renanthera imschootiana* through the Culture of Shoot Tips and Leaf Explants

Renanthera imschootiana (Fig. Ren-1A), also known as the Red *Vanda*, is of major horticultural importance both as an orchid which is grown for its own flowers and as a parent of many popular hybrids. At present it is an "extremely rare and endangered epiphytic orchid [in] north-eastern India . . . [and] Burma [now Myanmar] . . . due to indiscriminate collection and severe habitat loss . . . [therefore] large scale multiplication in botanic gardens to meet trade demands has been recommended . . ." (Seeni and Latha, 1992). A method designed to accomplish this aim was developed at the Plant Biotechnology Unit, Tropical Botanic Garden and Research Institute, Palode, Trivandrum, India (Seeni, 1990; Seeni and Latha, 1992).

Plant Material. Stem cuttings, each with six leaves, should be taken from mature plants. Following surface sterilization, shoot tips of 0.5 cm, and whole leaves,

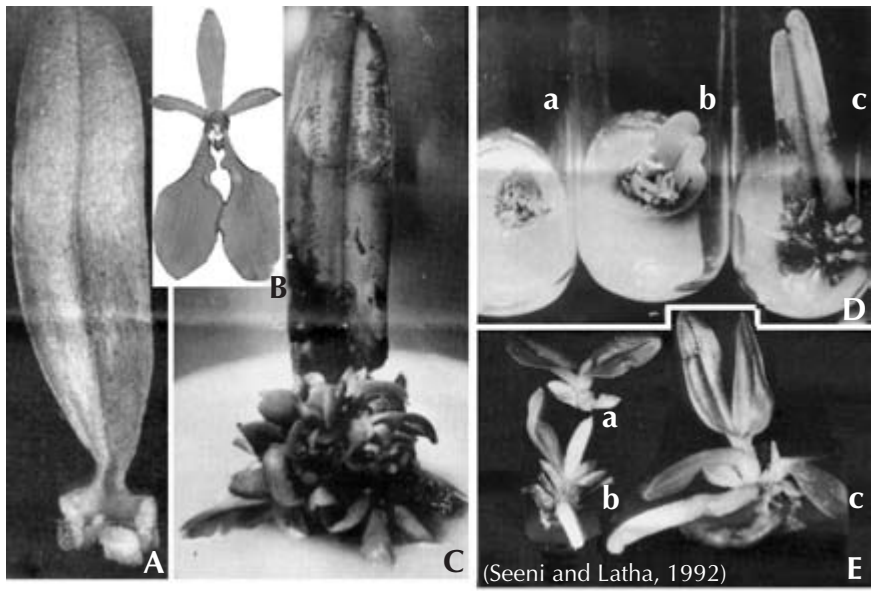

FIG. REN-1. **Micropropagation of *Renanthera imschootiana*. A. Swelling at the leaf base and early stages of vegetative bud formation after 4 weeks of culture. B. *Renanthera imschootiana* flower. C. Vegetative buds at the base of a leaf. D. Formation of vegetative buds on the first (a), second (b) and third (c) leaf of a stem. E. Plantlet development showing leaf and root formation (a–c).**

1.8–6.7 cm in length, including their sheathing bases measuring 3–8 cm should be cultured (Fig. Ren-1A, C, D).

Surface Sterilization. The stem sections should be washed with running tap water and soaked "for more than 15 min in 1% (v/v) commercial detergent (Teepol, Glaxo India, Pvt. Ltd., Bombay)" (Seeni and Latha, 1992). Teepol is also available from www.sigmaaldrich.com. A mild household detergent is also suitable. "Following the removal of the lowermost leaf" the sections should be dipped in 70% ethanol (73–74 ml 95% ethanol diluted to 100 ml with distilled water) for 30 s, immersed in 0.1% mercuric chloride ($HgCl_2$; available from most chemical supply houses, this reagent should be treated with caution since it is dangerous to humans and animals), and rinsed three times with sterile distilled water. All remaining leaves should be removed one by one following the rinse under sterile conditions, until the shoot tip with 1–2 leaf primordia is exposed. The shoot tip, ca. 5 mm in length, should be excised after that. Leaves and shoot tips should be immersed separately in 0.05% $HgCl_2$ for 2 min and washed three times with sterile distilled water.

Culture Vessels. Culture tubes, 25×150 mm, should be used for initial cultures, but larger vessels are better suited for plantlets.

Culture Conditions. Cultures should be maintained at $25 \pm 2°C$ under 15-h photoperiods of 25–50 $\mu mol\ m^{-2}\ s^{-1}$ provided by fluorescent tubes (type not described in the original paper) or standard culture room conditions.

Culture Media. Leaves should be placed first on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with BA, NAA, and peptone (Table Ren-1). Vegetative buds produced on this solution should be subcultured onto a substrate containing coconut water and pulp from ripe bananas (Table Ren-2). Shoots which develop on this medium form roots on a third version of MPR medium which contains BA, NA, and activated charcoal (Table Ren-3). Shoot tips should be cultured initially on a different modification of MPR (Table Ren-4).

Procedure. Leaf explants are planted vertically (Fig. Ren-1A, C, D) so that the leaf bases, which measure 3–8 mm, are buried 3–5 mm deep in the first version of MPR (Table Ren-1). Vegetative buds (Fig. Ren-1A, C) that form on this medium are moved to the second substrate (Table Ren-2) for shoot development. Shoots from the second medium are moved to the third solution (Table Ren-3) for rooting and plantlet formation (Fig. Ren-1E). When plantlets are large enough they are potted in community pots. Shoot tips are placed on the fourth medium (Table Ren-4). If any survive, the resulting tissues should be treated like those produced by leaf explants (Tables Ren-2 and Ren-4).

Developmental Sequence. Both leaves and shoot tips exude phenolics that cause browning of the medium. These compounds do not seem to have an ill effect on leaves, which produce 3–5 vegetative buds at their bases within 5 weeks. Up to 10 buds may be produced within 10–12 weeks on the first medium (Table Ren-1). As many as 40 shoots may develop after 12 weeks of subculture on the second medium

TABLE REN-1. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Renanthera imschootiana* leaves (Seeni, 1990; Seeni and Latha, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH (or NaOH) or HCl, respectively.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.6, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Bring the solution to a gentle boil and add the agar (item 19) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE REN-2. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for shoot production from *Renanthera imschootiana* leaf- and shoot-tip-derived vegetative buds (Seeni, 1990; Seeni and Latha, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

17	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[h]	To 1000 ml			
	Solidifier				
19	Agar[h]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable, (2) the peel rather than the pulp should be used, (3) unpeeled banana homogenate should be incorporated in media, and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective banana variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and/or use what is suggested there.

[h]Add items 1–16 to 800 ml of distilled water (item 18) in a homogenizer, homogenize thoroughly, adjust pH to 5.6, add sugar (item 17), and bring volume to 1000 ml with distilled water (item 18). Bring the solution to a gentle boil and add the agar (item 19) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE REN-3. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the rooting of *Renanthera imschootiana* shoots produced by leaf- and shoot-tip-derived vegetative buds (Seeni, 1990; Seeni and Latha, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100.0	10.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	200.0	20.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	180.0	18.0 g l^{-1}	10	
5	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	150.0	15.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.6	60.0 mg l^{-1}		
(b)	Cobalt nitrate, $Co(NO_3)_2 \cdot 6H_2O$	0.05	5.0 mg l^{-1}

(d)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	0.4	40.0 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.03	3.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.05	5.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.05	5.0 mg l^{-1}		
	Vitamins				
8	Biotin	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
9	Folic acid	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
10	Niacin (nicotinic acid)	1.25	500 mg 100 ml^{-1} 95% ethanol[e]	0.25	
11	Pyridoxine (vitamin B_6)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
12	Riboflavine (vitamin B_2)	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
13	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Auxin				
14	Naphthaleneacetic acid (NAA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
15	Benzyladenine (BA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
16	Peptone	2.0 g	No stock	No stock	Weigh
	Sugar				
17	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Agar[g]	7.0 g	No stock	No stock	Weigh
	Darkening agent				
20	Activated charcoal[g]	1.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH (or NaOH) or HCl, respectively.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.6, add sugar (item 17), and bring volume to 1000 ml with distilled water (item 18). Bring the solution to a gentle boil and add the agar (item 19) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add the darkening agent (item 20) slowly with vigorous stirring. After the darkening agent has been dispersed completely, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE REN-4. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Renanthera imschootiana* shoot tips (Seeni, 1990; Seeni and Latha, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

14	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
15	Benzyladenine (BA)	5.0	500 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
16	Peptone	2.0 g	No stock	No stock	Weigh
	Sugar				
17	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH (or NaOH) or HCl, respectively.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.6, add sugar (item 17), and bring volume to 1000 ml with distilled water (item 18). Bring the solution to a gentle boil and add the agar (item 19) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

(Table Ren-2), but 24 is more usual. Root initiation occurs within a week of moving the shoots to the third medium (Table Ren-3). Every shoot may have two to four well-developed roots at the end of 4 weeks. Shoot tips did not grow in culture.

General Comments. This protocol seems to be effective and efficient, but the high level of BA (10 mg l^{-1}) requires caution because it may cause undesirable mutations.

Renanthera imschootiana is mentioned in Rex Stout's Nero Wolfe mystery *Fourth of July Picnic* when the oversized Wolfe, upset by waiting for a witness to talk to the police, says: "I've had all the humiliation I can stand. Jumping out of my skin every time the phone rang. Did you notice how quickly I answered your ring upstairs? Afraid, by heaven, afraid to go into the tropical room to look over the *Renanthera imschootiana*!"

Micropropagation of *Renanthera imschootiana* through Axillary-Bud, Leaf-Segment, and Shoot-Tip Culture

As long as shoots are taken from a plant for micropropagation it is a good idea to attempt to culture as many parts of it as possible. A method which uses several explants from one shoot was developed at the Biotechnology Laboratory, Department of Plant Breeding and Genetics, College of Agriculture, Central Agricultural University, Imphal, Manipur, India (Laishram and Devi, 1999).

Plant Material. Shoots, 3–4 cm long, should be removed from mature plants (those used in the original research were grown in a shade house). Older leaves should be removed to expose axillary buds and the shoot tip, all of which should be excised and cultured. Young leaves should be sectioned into apical, median, and basal explants.

Surface Sterilization. Explants should be immersed with gentle agitation in 0.1% mercuric chloride ($HgCl_2$, available from most chemical supply houses, is toxic and should be handled with care) for 20 min and washed five times with sterile distilled water before being placed in the culture.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers can be used.

Culture Conditions. A temperature of 25 ± 2°C and 12-h photoperiods of 2500 lx are suitable, as are standard culture room conditions.

Culture Media. Shoot-tip explant should be cultured in Vacin and Went (VW) medium (Vacin and Went, 1949) supplemented with 20% coconut water (CW), 1 mg NAA l^{-1}, and 2 mg BA l^{-1} (Table Ren-5). VW medium with 20% CW and 1 mg each of NAA and BA per liter (Table Ren-6) should be used to culture axillary buds. Leaf segments should be cultured on VW with 20% CW, 0.1 mg NAA l^{-1} and 1.0 mg BA l^{-1} (Table Ren-7). No medium is suggested for the culture of PLBs to produce plantlets. The initial medium used for each explant may be suitable and should be tested. Other media that can be used are one or more of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables

TABLE REN-5. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of *Renanthera imschootiana* shoot tips (Laishram and Devi, 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	6-Benzylaminopurine (BAP)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
10	Coconut water[g]	200.0 ml	No stock	No stock	Measure
	Sugar				
11	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[h]	To 1000 ml			
	Solidifier				
13	Agar[h]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 12) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1 and 3–10 to the 500–700 ml of distilled water (item 12) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 12), adjust pH to 5.6, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of other nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable. Hormones are heat-labile and are usually added after autoclaving, but in this case they are incorporated into the medium before sterilization.

TABLE REN-6. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of *Renanthera imschootiana* axillary buds (Laishram and Devi, 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	6-Benzylaminopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
10	Coconut water[g]	200.0 ml	No stock	No stock	Measure
	Sugar

	Solvent				
12	Water, distilled[h]	To 1000 ml			
	Solidifier				
13	Agar[h]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 12) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1 and 3–10 to the 500–700 ml of distilled water (item 12) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 12), adjust pH to 5.6, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable. Hormones are heat-labile and are usually added after autoclaving, but in this case they are incorporated into the medium before sterilization.

TABLE REN-7. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of *Renanthera imschootiana* leaf sections (Laishram and Devi, 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10

	Solidifier				
13	Agar[h]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 12) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1 and 3–10 to the 500–700 ml of distilled water (item 12) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 12), adjust pH to 5.6, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable. Hormones are heat-labile and are usually added after autoclaving, but in this case they are incorporated into the medium before sterilization.

Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1), or VW (Vacin and Went, 1949) solution (see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C medium that contains this darkening agent (see Table Pln-1, footnote *f*). Media developed for *Renanthera* shoot formation from vegetative buds (Table Ren-2) and the rooting of these shoots (Table Ren-3) may also prove to be suitable.

Procedure. Shoot tips, axillary buds, and leaf sections are cultured on the appropriate media (Tables Ren-5, Ren-6, and Ren-7, respectively). PLBs produced on these media are moved onto one of the other solutions. When plantlets form they should be allowed to grow on the second medium until they become large enough for community pots or subcultured to fresh solution to accelerate the process.

Developmental Sequence. Seventy percent of the shoot tips start to produce PLBs 60 days after the start of culture. Only 10% of the axillary buds produce PLBs, starting 50 days after the cultures were initiated. The median and apical leaf segments do not produce PLBs. Of the basal explants, 50% start to produce PLBs 65 days after being paced on the appropriate medium. Plantlets develop from the PLBs.

General Comments. The use of a single shoot to obtain a shoot tip, several leaf explants, and a number of axillary buds is clever and economical. This procedure seems simple, effective, and productive. The hormone concentrations are relatively low and will probably not induce undesirable mutations.

Renanthera imschootiana was first imported by the firm of Messrs. Sander & Co of St. Albans in Britain. It was named in 1891 by Robert Allen Rolfe after Mr. M. A. van Imschoot of Ghent (Gand), Belgium (Bechtel et al., 1992).

Renanthera comes from the Latin *renes* for kidney and the Greek *anthera* for anther, in allusion to the kidney-shaped pollinia of the first species described by Loureiro in 1790.

Restrepia

When leaves of *Restrepia* that have already flowered are cut to include approximately 5 cm of stem and are planted in a mixture of tree fern and peat or peat only to the level of the leaf axil, they produce plantlets. "The function of the stem is merely to anchor the leaf to ensure that it will remain planted at the proper level" (Webb, 1981). Five different species of *Restrepia* have been propagated in this manner. This suggests that leaves or leaf explants of *Restrepia* could perhaps produce callus, PLBs, and/or plantlets in vitro on an appropriate culture medium. Despite not being an in vitro method for the micropropagation of *Restrepia*, this procedure is included here because it provides a means for relatively fast multiplication of this orchid.

Rhynchostele

A method for the proliferation of *Rhynchostele bictoniense* through the use of seeds and seedling explants was developed at the National University in Mexico (González, no date).

Rhynchostylis

A small genus of approximately four species, *Rhynchostylis* was first described by C. L. Blume in 1825 with the type species being *Rhynchostylis retusa*. The genus is distributed in India, Malaysia, Indonesia, and the Philippines. Some botanists have included all species in the genus *Saccolabium*. This suggests a close relationship, and it is possible that tissue culture procedures developed for one of these genera will also be suitable for the other.

Rhynchostylis gigantea

Monopodial orchids have been more difficult to propagate through tissue culture, especially of their shoot tips, than sympodial ones. The reason for this, at least in part, is probably that they have different or more complex requirements. Thus,

> after reviewing the previous . . . work on tissue and organ culture, . . . an . . . attempt was made to formulate a new medium for culturing tissues of monopodial-type orchids. . . . [The attempt was successful to a limited extent and] even though it cannot be applied easily in the commercial multiplication of this type of orchid at the present time, it may provide a clue for further developments in culturing orchid tissues. (Vajrabhaya and Vajrabhaya, 1970)

Plant Material. In the original experiment, seedlings of *Rhynchostylis gigantea* collected from the wild were utilized. Buds from leaf-covered stems and shoot tips were used as the source of explants.

Surface Sterilization. The procedure employed for *Cymbidium* (Sagawa et al., 1966) is suitable for this species.

Culture Vessels. Employ 21 × 173-mm test tubes, containing medium to a height of 35 mm, placed in an upright position.

Culture Conditions. Maintain cultures under diffuse light of an intensity ranging between 2000 and 3000 lx for 14-h photoperiods. In the original experiments, Philips TL 40/33 and TL 46/54 fluorescent tubes were used in a 1 : 1 ratio. It would seem reasonable to assume that Sylvania Gro Lux (or the equivalent) or a combination of cool white fluorescent tubes and incandescent bulbs would be equally suitable. The temperature should be 24–27°C.

Culture Medium. A semisolid medium formulated especially for this species is used (Table Rhy-1). This medium is also suitable for *Dendrobium* and *Cattleya*.

Procedure. The apical meristem is excised like that of *Cymbidium* (Sagawa et al., 1966). Only five to six explants can be secured from any one seedling of the size used in the original experiments. Place explants on the culture medium.

TABLE RHY-1. **Medium for the culture of shoot-tip and bud explants of *Rhynchostylis gigantea* (Vajrabhaya and Vajrabhaya, 1970)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Auxin				
12	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1.0	
	Amino acid				
13	Glycine	7.5	750 mg 100 ml^{-1} 95% ethanol[e]	1.0	
	Complex additives				
14	Tryptone	500	No stock	No stock	Weigh
15	Coconut water	100 ml	No stock	No stock	Measure
	Sugar				
16	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[f]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[f]	6 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe suggests 50 mg of (Fe-EDTA), a preparation which may not be readily available. The substitute given in this table is widely used in culture media for orchids and other plants. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. This can also be described as Fe_2EDTA.

[d]Add the salts to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1–7, 14, and 15 to 800 ml distilled water (item 17); adjust pH to 5.2–5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18). Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour the solution into a 2-l flask and autoclave. Add vitamins (items 8–11), hormone (item 12), and glycine (item 13) to the hot autoclaved solution with sterilized pipettes, mix well by swirling, and distribute medium to preautoclaved culture vessels. Omit agar for liquid media.

Development Sequence. During the first week of culture, most explants enlarge and some portions turn green. From weeks 2 through 4 a few produce new tissues, but some of these die. At the end of 2 months, only one explant in 30 survived in the original experiment. The survivors formed calli of up to 10 mm in diameter. Growth was slow, but no abnormalities were detected after five subcultures. If not subcultured, the calli will produce plantlets.

General Comments. Disadvantages of this method are the low rate of success and the need to destroy an entire plant or growth. However, considering the difficulties encountered with the culture of monopodial orchids, the procedure represents a significant advance in the clonal propagation of desirable clones.

Propagation of *Rhynchostylis retusa* through the Culture of Leaf Segments

"The potential of *Cymbidium* leaf tissues to produce protocorm-like bodies in culture, first demonstrated by Wimber (1965), opened up new possibilities . . . and the list of taxa propagated, using leaf tissues as explants, is . . . growing" (Vij and Pathak, 1990). One species added to this list through research at the Department of Botany, Panjab University, Chandigarh, India, is *Rhynchostylis retusa* (Vij et al., 1984).

Plant Material. Segments 0.5–1.0 cm long from young leaves of 6-month-old seedlings grown in vitro are the only ones that can be cultured successfully. Explants from mature leaves died within 12 weeks of culture.

Surface Sterilization. It is not necessary to sterilize leaves of seedlings that are growing under aseptic conditions in vitro.

Culture Vessels. Culture tubes and/or Erlenmeyer flasks are suitable as culture vessels.

Culture Conditions. Cultures should be maintained under 12-h photoperiods of 3500 lx at 25 ± 2°C.

Culture Media. A modified Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) is used for the initial culture (Table Rhy-2). An unmodified MPR medium (Table Rhy-3) is used for organogenesis.

Procedure. Place the explants on the initial medium (Table Rhy-2), and allow them to remain on it for at least 4 weeks or for as long as is necessary for the development of PLBs. Excise these and place them on the unmodified medium (Table Rhy-3) for leaf and root formation.

Developmental Sequence. Sporadic divisions in some of the epidermal cells are the first signs of growth. Groups of cells with dense cytoplasm also form. These are followed by meristematic activity and bulges that eventually form PLBs. Formation of

TABLE RHY-2. **Modified Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) for the culture of *Rhynchostylis retusa* leaf segments (Vij et al., 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

12	Riboflavin	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
13	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Auxin				
14	Naphthaleneacetic acid (NAA)	1.0	200 mg 100 ml^{-1} 95% ethanol[e]	0.5	
	Cytokinin				
15	Kinetin (6-furfurylaminopurine)	1.0	200 mg 100 ml^{-1} 95% ethanol[e]	0.5	
	Complex additive				
16	Peptone	300[f]	No stock	No stock	Weigh
	Sugar				
17	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Agar, Difco Bacto[g]	9 g	No stock	No stock	Weigh
	Darkening agent				
20	Activated charcoal[h]	2	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe used 3 ml $Na_2FeEDTA$, a preparation that may not be readily available. The substitute listed here is used very commonly in orchid tissue culture media. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]The amount used in the original study is not listed. This is an estimate based on work with *Rhynchostylis* root tips in the same laboratory (Sood and Vij, 1986; Vij et al., 1987). One can experiment by varying the amount from 250 mg to 2 g.

[g]Add items 1–16 to 900 ml distilled water (item 18), adjust pH to 5.6, add sugar (item 17), and adjust volume to 1000 ml with distilled water (item 18). Bring solution to a gentle boil, and add agar (item 19) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, add charcoal (item 20) and stir well to insure complete, uniform mixing. Dispense solution into culture vessels, and autoclave. Omit agar for liquid medium. Media that contain hormones and vitamins should not be autoclaved unless prior experimentation has determined that this has no deleterious effects. This is such a case (Mitra, 1971; Mitra et al., 1976), so the medium may be autoclaved.

[h]The original paper does not describe the charcoal. In our experience, activated vegetable charcoal is preferable to that from animal sources.

TABLE RHY-3. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) for the organogenesis of *Rhynchostylis retusa* leaf explants (Vij et al., 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

12	Riboflavin	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
13	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Sugar				
14	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[f]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[f]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe used 3 ml $Na_2FeEDTA$, a preparation that may not be readily available. The substitute listed here is used very commonly in orchid tissue culture media. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1–13 to 900 ml distilled water (item 15), adjust pH to 5.6, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense solution into culture vessels and autoclave. Omit agar for liquid medium. Media that contain vitamins should not be autoclaved unless prior experimentation has determined that this will have no deleterious effects. This is such a case (Mitra, 1971; Mitra et al., 1976), so the medium may be autoclaved.

PLBs on the initial medium (Table Rhy-2) occurs within 4 weeks. When these PLBs are excised and cultured on the second medium (Table Rhy-3), they differentiate small leaves within 5 weeks and roots following an additional 21 days. Plantlets ready for subculture into community pots develop within a total of 10 weeks.

General Comments. Methods that utilize explants that do not endanger the plant to be propagated are very desirable and necessary. The only problem with this procedure is its inapplicability to mature plants. However, Vij's scientific reputation suggests that he and his associates will overcome this hurdle.

Plantlet Regeneration in Vitro from Root Segments of *Rhynchostylis retusa*

A number of workers (Vij et al., 1987) have shifted their emphasis "toward exploring alternative plant organs for rapid propagation . . . whereby the very existence of the mother plant is not threatened." This has led to a ". . . study [which] deals with the regeneration potential of *Rhynchostylis retusa* roots *in vitro*" (Sood and Vij, 1986).

Plant Material. Root segments 0.5–1.0 cm long without tips, taken from 38-week-old seedlings, are cultured.

Surface Sterilization. It is not necessary to surface-sterilize explants taken from seedlings growing in vitro.

Culture Vessels. Culture tubes and/or Erlenmeyer flasks are suitable as culture vessels.

Culture Conditions. Cultures should be maintained under 12-h photoperiods of 3500 lx at 25 ± 2°C.

Culture Media. Explants can be cultured on several modifications of the Mitra medium, but a modified MS solution (Table Rhy-4) is more suitable for initial culture. Use the same medium or a different modification (Table Rhy-5) for leaf formation and root induction.

Procedure. Place explants with the tips removed on the initial medium (Table Rhy-4), and allow to form PLBs. Move these to the same (Table Rhy-4) or the second medium (Table Rhy-5) for plantlet formation. Transfer well-developed plantlets to community pots.

Developmental Sequence. Explants with intact tips elongate and develop root hairs. Those without tips (root-tip explants whose tips have been removed) produce PLBs within 5 weeks. (Those who use this method for the first time should try both kinds of explants.) Shoots and buds form after 12 weeks. Leaves can be seen on the second medium after approximately 2 months. Complete plants develop after 12 weeks.

General Comments. This procedure is valuable, especially as a starting point for future research. When adapted for use with roots from adult plants, this will be an extremely valuable method. Those who wish to culture roots from mature plants should select plants that have not come into contact with a source of fungi that could penetrate them.

TABLE RHY-4. **Modified MS medium (Murashige and Skoog, 1962) for the initial culture of *Rhynchostylis retusa* root segments (Vij et al., 1987)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10

(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	1	200 mg 100 ml^{-1} 95% ethanol[f,g]	0.5	
	Cytokinin				
11	Kinetin	1	200 mg 100 ml^{-1} 95% ethanol[f,g]	0.5	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin do not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour the solution into a 2-l flask and autoclave; 2 mg l^{-1} activated vegetable charcoal can be added to hot agar solution and mixed well before pouring into the 2-l flask. Add amino acid, hormones, and vitamins (items 8 and 10–14) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

TABLE RHY-5. **Modified MS medium (Murashige and Skoog, 1962) for leaf and root initiation and plantlet formation from protocorm-like bodies derived from *Rhynchostylis retusa* root segments (Vij et al., 1987)**

	Solvent				
15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[h]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxin does not dissolve, add a few drops of dilute KOH.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 15), adjust pH to 5.6, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour the solution into a 2-l flask and autoclave; 2 mg l^{-1} activated vegetable charcoal can be added to hot agar solution and mixed well before pouring into 2-l flask. Add amino acid, hormone, and vitamins (items 8 and 10–13) to hot autoclaved solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

Isolation of *Rhynchostylis* Protoplasts

The method developed for *Acampe praemorsa* was used to isolate 0.7×10^4 and 0.1×10^4 protoplasts from leaves and roots, respectively, of *Rhynchostylis retusa* (Seeni and Abraham, 1986).

Clonal Multiplication of *Rhynchostylis retusa* through Root and Leaf-tip Culture in Vitro

Root and leaf tips taken from "aseptically-grown plantlets" (probably seedlings) of *Rhynchostylis retusa* formed PLBs on a modified Vacin and Went medium supplemented with 1 ppm BA, 1 ppm IAA, and 200 ppm casein hydrolysate (CH). PLBs develop without callus formation. The plantlets proliferate with periodic subculture (every 2 months) on a medium containing 0.5 mg BA, 1 mg IAA, and 0.1 mg 2,4-D per liter. Plantlets develop well on a medium containing 0.1 ppm IAA and 200 ppm CH (Sharma and Chaturvedi, 1988).

Plantlet Production from *Rhynchostylis retusa* Root Explants

Rhyncostylis retusa is found in India, Malaysia, Myanmar, Philippines, Sri Lanka, and Vietnam. It is a popular orchid among growers and is getting rarer in nature. A method using root explants to propagate it was developed by Professor Suraj P. Vij at Panjab University (Vij et al., 1987).

Plant Material. Root-tip segments, 5–10 mm long (Fig. Rhy-1A), should be taken from 38-week-old seedlings growing in vitro.

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers are suitable.

Culture Conditions. Cultures should be maintained at $25 \pm 2°C$ under 12-h photoperiods of 3500 lx (source was not listed) or standard laboratory conditions.

Culture Media. MS medium (Murashige and Skoog, 1962) containing 1 mg NAA l^{-1} and 2 g activated charcoal l^{-1} (Table Rhy-6) should be used.

Procedure. Explants are placed on the medium and allowed to form plantlets. If/when the cultures become crowded, plantlets should be separated and subcultured onto the same medium and allowed to reach community pot size.

Developmental Sequence. Root-tip explants (Fig. Rhy-1A) form PLBs within weeks (Fig. Rhy-1B). Vegetative buds (Fig. Rhy-1C) are formed if IAA is used instead of NAA. Leaves (Fig. Rhy-1G) develop after 6 weeks on the medium (Table Rhy-6).

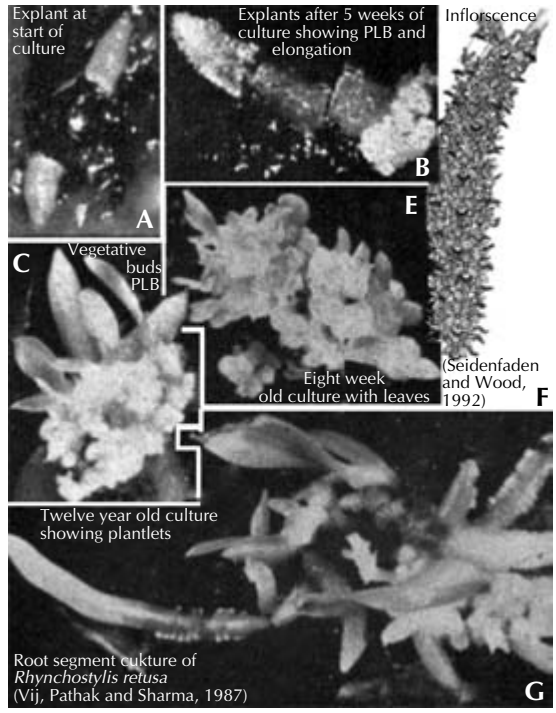

FIG. RHY-1. **Culture of *Rhynchostylis retusa* root explants (Vij et al., 1987).**

Roots appear after 8 weeks. Plantlets with 2–3 leaves and 1–2 roots (Fig. Rhy-1E) can be seen in 12 weeks.

General Comments. Root tips are useful as explants because plants have many of them and their removal does not cause roots to die. If taken from mature plants in pots or in nature, they will harbor mycorrhiza which will contaminate and overrun cultures.

Rhynchostylis from the Greek *rhynchos* (beak) and *stylis* (column) alluding to the beak-like gynostemium (Schultes and Pease, 1963).

TABLE RHY-6. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Rhynchostylis retusa* root explants (Vij et al., 1987)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh
	Darkening agent				
17	Activated charcoal[h]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.6–5.8, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved add the charcoal while stirring continuously. Once the charcoal is completely dispersed, pour the solution into culture vessels and autoclave. Amino acid (item 8), hormone (item 10), and vitamins (items 11–13) are usually added after autoclaving under sterile conditions with sterilized pipettes, but in this case they are added before sterilization. Agar is not added to liquid media.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances.

Production of *Rhynchostylis retusa* Plantlets from Foliar Peels

Foliar peels offer three advantages as explants. One is their abundance. Another is that their removal does not endanger or even damage the donor plant. And, third, they "are low in endogenous growth hormones . . . and are thus expected to be more sensitive to even slightest changes [in] the quantity and quality of . . . growth regulators" (Vij and Kaur, 1992; Vij, 1994).

Plant Material. In the original research "peels, 1–4 layers in thickness and 0.5 mm in length were . . ." taken from "juvenile leaves [of] *in vitro* raised cultures." It is not clear from this statement whether the "cultures" were of seedlings or plantlets produced through tissue culture. A photograph (Fig. Rhy-2A) suggests that the length should be 0.5 cm.

Surface Sterilization. Explants from in vitro cultures do not require sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, or other containers can be used.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Medium. Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) with 2 mg kinetin l^{-1} (Table Rhy-7) should be used.

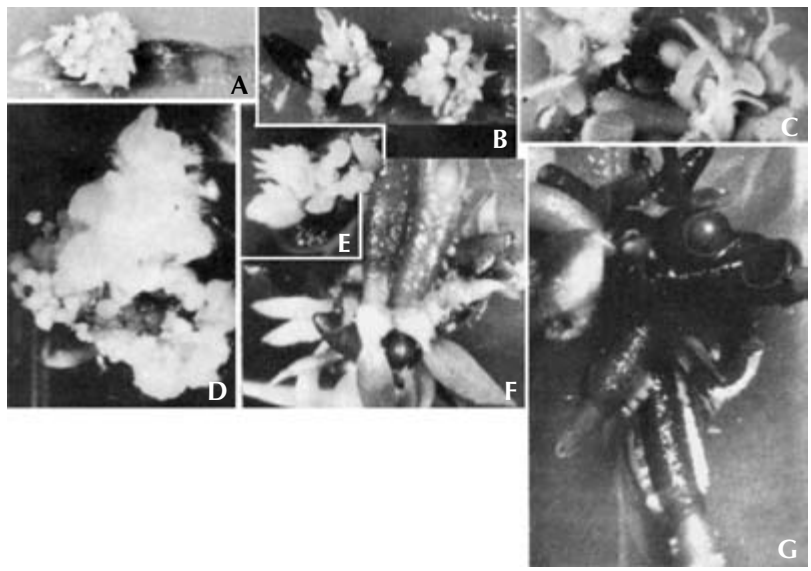

FIG. RHY-2. **Plantlet production from *Rhynchostylis retusa* from foliar peels. A. PLBs. B. Multiplication of PLBs. C. Plantlet formation. D. Organogenetic callus. E. Differentiating PLBs. F. Plantlet formation. G. Root formation and suppressed growth of leaves following prolonged culture on kinetin-containing medium. (Vij and Kaur, 1992.)**

TABLE RHY-7. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Rhynchostylis retusa* leaf peels (Vij and Kaur, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100.0	10.0 g l^{-1}	10	
2	Calcium nitrate $Ca(NO_3)_2 \cdot 2H_2O$	200.0	20.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	180.0	18.0 g l^{-1}	10	
5	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	150.0	15.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.6	60.0 mg l^{-1}	10	One solution
(b)	Cobalt nitrate, $Co(NO_3)_2 \cdot 6H_2O$	0.05	5.0 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.05	5.0 mg l^{-1}		
(d)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	0.4	40.0 mg l^{-1}		
(e)	Potassium iodide, KI	0.03	3.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.05	5.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.05	5.0 mg l^{-1}		
	Vitamins				
8	Biotin	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
9	Folic acid	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
10	Niacin (nicotinic acid)	1.25	500 mg 100 ml^{-1} 95% ethanol[e]	0.25	
11	Pyridoxine (vitamin B_6)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
12	Riboflavine (vitamin B_2)	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
13	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Cytokinin				
14	Kinetin	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1 ml	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve add a few drops of 0.1 N HCl.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

Procedure. Peels are placed on the medium (Table Rhy-7) where they form PLBs (Fig. Rhy-2A, B) and eventually plantlets (Fig. Rhy-2C, E–G). An organogenetic callus (Fig. Rhy-2D) forms in the presence of 1 mg 2,4-D l^{-1}. If cultures become crowded, PLBs or plantlets should be subcultured on the same medium.

Developmental Sequence. PLBs are produced by 75% of explants after 4 weeks of culture. Leaves appear in 6 weeks. Roots develop 2 weeks later. Plantlets with two leaves and 2–3 roots are formed after 11 weeks.

General Comments. Explants from seedlings cannot be used for cultivar selection, but this is less important for a species than for hybrids.

Micropropagation of *Rhynchostylis retusa* through the Culture of Leaf Segments

Leaf explants offer two advantages. One is abundant material because plants have many leaves. The second is that the removal of a few leaves does not endanger the donor plant. Explants from leaves of mature plants "copiously released brownish exudates (phenolics?) into the medium (irrespective of the use of A[ctive] C[harcoal]), lost their chlorophyll, and perished within 10–20 w[eeks] without showing any meristematic activity. However, those from seedlings leaves in axenic cultures proliferated along their cut ends . . ." (Vij and Pathak, 1990).

Plant Material. "Young leaves, up to 2 cm in length from . . . 16–40 w[eek] old axenic seedlings . . . were segmented into 0.5–1.0 cm long basal (with leaf base) and apical (with leaf tip) parts and used as explants" (Vij and Pathak, 1990).

Surface Sterilization. Explants from leaves growing in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers are suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. When cultured on hormone-free MS medium (Murashige and Skoog, 1962) darkened with active charcoal (Table Rhy-8), 50% of both apical and basal explants produced an average of ten PLBs (Fig. Rhy-3A–C) per explant (i.e., theoretically 100 leaves can produce 500 PLBs from apical explants and an equal number from basal ones). If IAA, NAA, kinetin, and/or BA are added to the medium alone or in several combinations, the total number of PLBs produced is smaller. PLBs should be moved to MS supplemented with NAA and kinetin (Table Rhy-9) for plantlet (Fig. Rhy-3D) production.

Procedure. The leaves are cut in half, placed on the medium, and cultured on the first medium (Table Rhy-8) until the PLBs produced by the explants are sufficient

TABLE RHY-8. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Rhynchostylis retusa* leaf explants (Vij and Pathak, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[f]	To 1000 ml			
	Solidifier				
15	Agar[f]	9.0 g	No stock	No stock	Weigh
	Darkening agent				
16	Activated charcoal (AC)[g]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.5, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, add the charcoal (item 16) with constant stirring to insure complete and even distribution, pour the solution into culture vessels, and autoclave. Amino acid (item 8) and vitamins (items 10–12) are heat-labile and are usually added after autoclaving to the hot and still liquid medium under sterile conditions with sterilized pipettes. In this case they are added before sterilization. Agar is not added to liquid media.

[g]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no real difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. Two possible sources are www.fishersci.com and www.vwr.com, but there are many others.

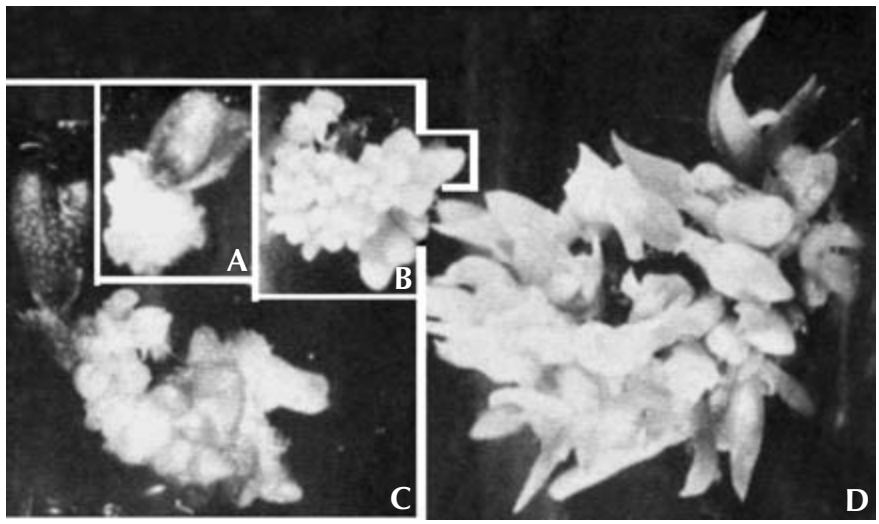

FIG. RHY-3. **Culture of *Rynchostylis retusa* leaf explants. A–C. Multiplication of PLBs. D. Plantlets. (Vij and Pathak, 1990.)**

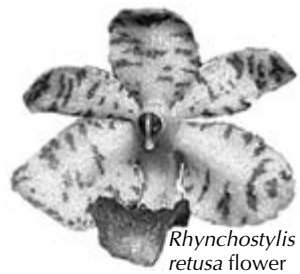
in number and large enough to be transferred to the second solution (Table Rhy-9). Once the plantlets produced on the second solution are large enough they should be moved to community pots.

Developmental Sequence. Explants produce PLBs (Fig. Rhy-3A–C) on the first medium (Table Rhy-8) 5 weeks after being placed in culture. The first leaf appears after 8 weeks. Roots form 16 weeks after cultures are initiated. Plantlets (Fig. Rhy-3D) develop well on the second substrate (Table Rhy-9).

General Comments. This seems to be a productive method, but like other procedures that utilize explants from seedlings, it cannot be used to propagate desirable clones because the quality of seedlings is not known. However this protocol can be used to propagate *Rhynchostylis retusa* plantlets that have been produced by explants taken from mature plants. The use of a hormone-free initial medium (Table Rhy-8) is an advantage because hormones can induce undesirable mutations, sometimes even when used at low concentrations.



Rhynchostylis retusa flower

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–12 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 18) with constant stirring to insure complete and even distribution, pour the solution into culture vessels, and autoclave. Amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) are heat-labile and are usually added after autoclaving to the hot and still liquid medium under sterile conditions with sterilized pipettes. In this case they are added before sterilization. Agar is not added to liquid media.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

Micropropagation of *Rhynchostylis retusa* through the Culture of Root Explants

Professor Suraj P. Vij and his associates Sanjeev Arora, Parminder Kaur, Kusant Mahant, Promila Pathak, Vishal Sharma, and Anil Sood have been imaginative and effective in identifying explants for orchid micropropagation. Use of root explants for 12 orchid taxa including *Rhynchostylis retusa* is one of their innovations (Vij, 1993).

Plant Material. Initial explants, "young and actively growing roots, with and without well developed caps were . . ." taken from both 16–30-week-old seedlings and mature plants growing under horticultural conditions. They were cut into sections, 5–10 mm long. Explants from mature plants "released brownish exudates (phenolics!) into the medium and perished within 8–10 w[eeks] of inoculation." Several root explants from seedlings proliferated and produced plantlets.

Surface Sterilization. Explants taken from axenically grown seedlings do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers can be used.

Culture Conditions. Cultures should be maintained under 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. Explants produced PLBs and plantlets on several media including hormone-free MS medium (Murashige and Skoog, 1962) darkened with activated charcoal (Table Rhy-10). This medium is recommended here because the use of hormones should be avoided whenever possible since they can cause (even if not always) undesirable mutations.

Procedure. Explants are placed on MS medium with activated charcoal and allowed to produce PLBs. The PLBs should be subcultured on the same medium for leaf, root, and plantlet production.

Developmental Sequence. Only 25% of the root explants produce PLBs. Explants on MS with NAA, or kinetin and NAA and/or IAA, respond similarly. PLBs, an average of ten per explant, are produced 6 weeks after the start of culture. Leaves (Fig. Rhy-4) appear 1 week later. Roots appear 3 weeks after that (i.e., 10 weeks after cultures were initiated).

General Comments. Despite the relatively low yields, the use of root explants is a good idea because plants have many roots and the removal of a few does not endanger the donor plant. Therefore a micropropagation method using root explants from mature plants would be very useful.

TABLE RHY-10. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Rhynchostylis retusa* leaf explants (Vij, 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.5, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 16) with constant stirring to insure complete and even distribution, pour the solution into culture vessels and autoclave. Amino acid (item 8) and vitamins (items 10–12) are heat-labile and are usually added after autoclaving to the hot and still liquid medium under sterile conditions with sterilized pipettes. In this case they are added before sterilization. Agar is not added to liquid media.

[g]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no real difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. Two possible sources are www.fishersci.com and www.vwr.com, but there are many others.

FIG. RHY-4. ***Rhynchostylis retusa* plantlet produced from root explant. (Vij, 1993.)**

Micropropagation of *Rhynchostylis retusa* from Dermal Peels of Leaves

A method developed at the Botany Department, Panjab University, for plantlet production of *Rhynchostylis retusa* foliar peels (Vij and Kaur, 1992) was refined and presented at the Nagoya International Orchid Show (Vij, 1994). The rationale behind using dermal peels as explants was the observation that root and leaf explants produce new tissues from their dermal cells (Sood and Vij, 1986; Vij and Pathak, 1990).

Plant Material. Dermal peels, 5 mm long (width not indicated) and 1–4 cell layers thick (Fig. Rhy-5A, B) were taken from juvenile leaves (presumably of seedlings) in axenic cultures.

Surface Sterilization. Explants taken from axenic plants in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers are suitable.

Culture Conditions. Cultures should be maintained under 25 ± 2°C under 12-h photoperiods or standard culture room conditions.

Culture Media. Several combinations of the Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976), activated charcoal, and hormones were tested in the original research (Table Rhy-11). The best results were obtained when the medium was supplemented only with 2 mg kinetin l^{-1} (bold in Table Rhy-11).

Procedure. Explants are placed on medium (Table Rhy-12) and cultured until PLBs form and increase in size. PLBs are subcultured on the same medium for plantlet development.

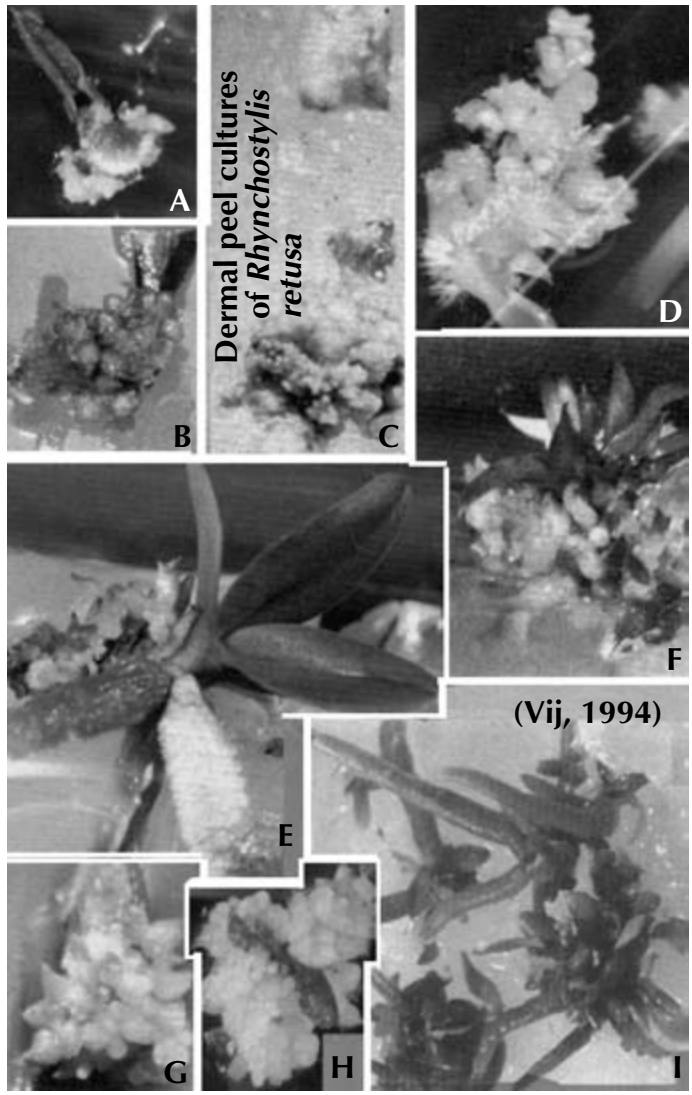

FIG. RHY-5. **Culture of dermal peels of *Rhynchostylis retusa*. A, B. Protocorm-like body development on NAA-containing medium. C, D. Callus-mediated PLB formation on 2,4-D-containing substrate. E. Plantlet. F. Plantlet differentiation on kinetin- and NAA-containing medium. G. PLB formation on solution containing kinetin (2 mg l^{-1}). H. PLB multiplication on medium containing kinetin (3 mg l^{-1}). I. Long-term cultures showing suppressed shoot growth and accelerated root development. (Vij, 1994.)**

TABLE RHY-11. **Hormone effects on dermal peels of *Rhynchostylis retusa* (Vij, 1994)**

Additives[a]	Amount, mg l^{-1}	Proportion responding, percent	PLBs per explant	Time required for development, weeks			
				PLB	Callus	Plantlets	Remarks
NAA	1	25	20	7		14	
NAA+AC	1+2	25	8	17		28	
2,4-D+AC	1+2	75	22	8	5	14	
Kinetin	**2**	**75**	**25**	**4**		**14**	
Kinetin	3	25	35	3		16	
NAA+kinetin	1+1	75	24	3		9	Deformed shoots
NAA+kinetin+AC	1+1+1	50	18	6		13	
IBA+kinetin	1+1	50		7	6		
IAA	1	0					
IBA	1	0					

[a]2,4-D, 2,4-dichlorophenoxyacetic acid; AC, activated charcoal; IAA, indoleacetic acid; IBA, indolebutyric acid; NAA, naphthaleneacetic acid; PLBs, protocorm-like bodies. The most effective treatment is in bold face.

Developmental Sequence. An average of 25 PLBs formed on 75% of the explants after 4 weeks of culture. Plantlets developed after 10 weeks after that.

General Comments. This protocol can be useful for propagating seedlings in cases when only a few seeds are available. It can also be useful for the propagation of tissue-culture-derived plantlets. If it could be adapted to young leaves of mature plants this method will also become useful for the propagation of selected cultivars of *Rhynchostylis retusa* and some of its intra- and intergeneric hybrids.

TABLE RHY-12. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Rhynchostylis retusa* leaf peels (Vij and Kaur, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Cytokinin				
14	Kinetin	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1 ml	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve add a few drops of 0.1 N HCl.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

Micropropagation of *Rhynchostylis retusa* through the Culture of Floral Buds

Floral buds attracted attention as explants because they are abundant and their removal does not endanger the donor plant. They were cultured at the Department of Botany, Panjab University (Kaur and Vij, 1995).

Plant Material. Inflorescences were excised "at different developmental stages" (Table Rhy-13) and cut into sections, 4–6 mm long.

Surface Sterilization. The sections should be washed with running water and Teepol (www.sigmaaldrich.com or other sources) or a mild liquid detergent. They should then be dipped in 70% ethanol (73–74 ml 95% ethyl alcohol diluted to 100 ml with distilled water) for 10 s, soaked in 0.01% streptomycin (www.sigmaaldrich.com, www.fishersci.com, www.vwr.com, and other sources), submerged in saturated calcium hypochlorite (7 g calcium hypochlorite in 100 ml distilled water stirred vigorously, allowed to stand until a precipitate forms, stirred again, and allowed to settle before the liquid is decanted and used) for 15 min, and rinsed three times with sterile distilled water.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers can be used.

Culture Conditions. Explant cultures should be maintained at $25 \pm 2°C$ under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. The response of the explants seems to depend on the developmental stage of the flower bud and to be affected by the medium used (Table Rhy-13). To induce PLBs, floral buds from the upper two-thirds part of the inflorescence should be cultured on MPR medium (Mitra et al., 1976) supplemented with NAA and darkened with activated charcoal (Table Rhy-14).

Procedure. The inflorescences are removed from the plant and sectioned. After surface sterilization, the sections are placed in culture. When PLBs develop they should be transferred to fresh medium of the same composition (Table Rhy-14) for plantlet formation.

Developmental Sequence. Explants from the upper two-thirds portion of inflorescences form PLBs which develop into plantlets (Table Rhy-13).

General Comments. This method makes possible the propagation of selected clones. Only buds from the upper part of the inflorescence form PLBs and eventually plantlets (Table Rhy-13). Explants from the lower two-thirds of the inflorescence produce roots but no shoots on MPR medium darkened with activated charcoal or supplemented with NAA (Table Rhy-13). It may be possible to induce shoot formation on these root-bearing explants by moving them to a medium that contains 1 mg BAP l^{-1} but no NAA or charcoal. To produce flowers in a flask (mostly

TABLE RHY-13. **Response of *Rhynchostylis retusa* floral buds to different media**[a]

Medium	Differentiated floral buds	Undifferentiated floral buds	
		Upper $^2/_3$ part of inflorescence	Lower $^2/_3$ part of inflorescence
MPR + NAA			Proximal end of explants rooted in four weeks. No shoot formation
MPR + NAA + AC		PLB formed in 5 weeks and proliferated to a count of 20. Plantlets formed in 12 weeks	Proximal end of explants rooted in four weeks. No shoot formation
MPR + NAA + CW	Flowers developed		
MPR + NAA + CW + AC	Flowers developed		
MPR + CW	Flowers developed		
MPR + CW + AC	Flowers developed		
VW + NAA + BAP		Vegetative shoots develop in six weeks. Plantlets form in 13 weeks	
VW + NAA + CW	Flowers developed		
VW + NAA + CW + AC	Flowers developed		
VW + CW	Flowers developed		
VW + CW + AC	Flowers developed		

[a]AC, activated charcoal, 2 g l^{-1}; BAP, benzylaminopurine, 1 mg l^{-1}; CW, coconut water, 150 ml l^{-1}; MPR, Mitra, Prasad, and Roychowdhury medium; NAA, naphthaleneacetic acid, 1 mg l^{-1}; VW, Vacin and Went medium. Note: Flower development requires CW, seems not to be affected one way or another by MRP, VW, NAA and AC, but is inhibited by BAP. PLB formation occurs only on MRP in the presence of NAA and AC. Vegetative shoots develop only on VW supplemented with NAA and BAP. Rooting occurs only on MPR which contains NAA; AC is not required. Response differs with the stage of development of the floral buds.

as a stunt), differentiated buds should be cultured on MPR medium supplemented with coconut water plus NAA or NAA and activated charcoal, but no BA (Table Rhy-13).

In Vitro Propagation of *Rhynchostylis retusa*

Rhynchostylis retusa was propagated in vitro on Vacin and Went medium (Vacin and Went, 1949) containing 400 mg casein hydrolysate l^{-1}, 20% (v/v) coconut water, 1 mg IAA l^{-1}, and 1 mg BA l^{-1} (Sarker and Roy, 1993).

Effects of pH and Micronutrients on Protocorm-like Bodies of *Rhynchostylis gigantea*

PLBs of *Rhynchostylis gigantea* multiply best in a medium designated as WS, which consists of Vacin and Went macronutrients (Vacin and Went, 1949), MS micronutrients (Murashige and Skoog, 1962), and 15% (v/v) coconut water, also containing 25–50 µmol iron, 25–100 µmol manganese, and 0.075 µmol copper with a presterilization pH of 4.5 and 5.0 (Wannakrairoj and Tanyasonti, 1996).

TABLE RHY-14. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of floral buds of *Rhynchostylis retusa* (Kaur and Vij, 1995)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin fails to dissolve add a few drops of 0.1 N KOH.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved add the charcoal slowly with vigorous stirring to insure even distribution. When the charcoal is completely dispersed pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

Rhynchostylis gigantea Plantlet Production from Thin Cell Layers

A monopodial orchid with considerable economic potential, *Rhynchostylis gigantea*, is endangered due to deforestation. A thin cell layer tissue culture system developed for tobacco was extended to this orchid (Le et al., 1999).

Plant Material. Transverse thin cell layers (tTCL), 0.3–0.5 mm thick, were excised from stem nodes and internodes, 3 mm in diameter, from the base to the tip of 1-year-old in-vitro-grown plantlets. It is not clear from the original papers if these were seedlings or plantlets obtained through tissue culture.

Surface Sterilization. Explants taken from plants growing in vitro do not require surface sterilization. If nodes and internodes are taken from mature plants they should be sterilized by the method used for *Rhynchostylis retusa* in the previous method before excising tTCL for culture.

Culture Vessels. The tTCL explants should be cultured in Petri dishes, 10 cm in diameter, containing 20 ml medium. Shoots and plantlets should be cultured in 250- or 500-ml Erlenmeyer flasks or other suitable containers filled with medium to 20–30% of their capacity.

Culture Conditions. Explants (tTCL) and shoots and plantlets in vitro should be maintained at 25 ± 1°C under 16-h photoperiods of 100 μmol m^{-2} s^{-1}. Standard culture room conditions may also prove to be suitable. Plantlets 3 cm tall with 2–3 roots should be grown in a greenhouse.

Culture Media. Experiments with different concentrations of BA, NAA, TDZ, and *N*-(2-chloro-4-pyridyl)-*N′*-phenylurea (forchlofenuron, CPPU) in MS medium (Murashige and Skoog, 1962) established that: (1) 3 μmol each of BA and TDZ in MS were optimal for bud induction (Fig. Rhy-6B, C; Table Rhy-15), and (2) roots were induced by 10 μmol of CPPU in MS with 10 g sucrose (Fig. Rhy-6A; Table Rhy-16).

Procedure. The thin layers are placed on the first medium (Table Rhy-15) and cultured until buds are formed (Fig. Rhy-6A, B, D, F) and start to develop (Fig. Rhy-6E). On transfer to the second medium (Table Rhy-16), the developed buds (Fig. Rhy-6E) form plantlets (Fig. Rhy-6C) which acclimatize on transfer to a greenhouse (Fig. Rhy-6G).

Developmental Sequence. PLBs, buds, and shoots are produced by the thin layers on the first medium (Table Rhy-15). The shoots form roots and develop into plantlets (Fig. Rhy-6C) on the second medium (Table Rhy-16). These plantlets mature in a greenhouse.

General Comments. If explants are taken from seedlings this method cannot be used to selected desirable cultivars. Explants taken from mature plants do not endanger the donor plant.

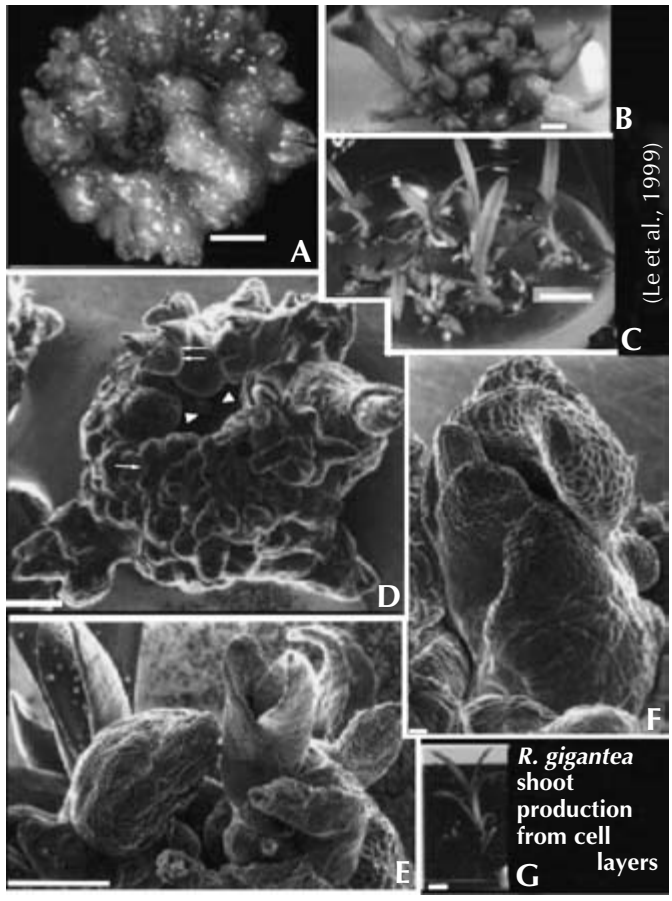

FIG. RHY-6. ***Rhynchostylis gigantea*** **plantlet production from thin cell layers. A. A transverse thin cell layer, 3 mm in diameter, forming PLBs and buds. B. Bud at advanced stage of development. F. Early stage of bud development. G. Plantlet in greenhouse. Bars are 1 mm in A–F and G; 0.1 mm in E. (Le et al., 1999.)**

TABLE RHY-15. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of thin cell layers of *Rhynchostylis retusa* (Le et al., 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Cytokinins				
8	N^6-benzyladenine (benzylaminopurine, BAP)	0.676	67.6 mg 100 ml^{-1} 95% ethanol[e,f]	1	
9	Thidiazuron (TDZ)	0.661	66.1 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If either or both cytokinins fail to dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.7, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Hormones (items 8 and 9) are heat-labile and should be added after autoclaving to the hot solution under sterile conditions with sterilized pipettes, mixed well, and distributed to preautoclaved culture vessels. In this case the cytokinins are added before autoclaving. Agar is not added to liquid media. The original paper states that the explants were cultured on "agar (Difco)-solidified medium containing Murashige and Skoog (MS) macro/micro-elements." This implies that the amino acids, polyol, and vitamins which are usually incorporated in MS were excluded. If the explants fail to grow on the medium shown in this table these components (see below) should be added. This statement does not indicate whether sugar was added to the medium or not. The amount suggested in this table is the concentration usually used for orchids.

	Amino acid			
	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol			
	myo-inositol	100.0	No stock	No stock	Weigh
	Vitamins			
	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	

TABLE RHY-16. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the rooting of shoots produced by thin cell layers of *Rhynchostylis retusa* (Le et al., 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Cytokinin				
8	*N*-(2-chloro-4-pyridyl)-*N*′-phenylurea (CPPU)	2.5 mg	250 mg 100 ml^{-1} 70% ethanol[e,f]	1	
	Sugar				
9	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[g]	To 1000 ml			
	Solidifier				
11	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]Dissolve in a minimal volume of water and bring to 100 ml with 95% ethanol.

[g]Add items 1–8 to 900 ml of distilled water (item 10), adjust pH to 5.7, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Hormones (item 8) are heat-labile and should be added after autoclaving to the hot solution under sterile conditions with sterilized pipettes, mixed well, and distributed to preautoclaved culture vessels. In this case the cytokinin is added before autoclaving. Agar is not added to liquid media. The original paper states that the explants were cultured on "agar (Difco)-solidified medium containing Murashige and Skoog (MS) macro/micro-elements." This implies that the amino acids, polyol, and vitamins which are usually incorporated in MS were excluded. If the explants fail to grow on the medium shown in this table these components (see below) should be added.

	Amino acid				
	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
	myo-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	

Saccolabium

Once upon a time there was what must have been a fairly large, highly variable genus called *Saccolabium*. But the taxonomists started to work on it and when they were done not much was left. *Saccolabium* was divided into *Abdominea*, *Acampe*, *Aerides*, *Ascocentrum*, *Ascochilopsis*, *Ascoglossum*, *Cleisostoma*, *Gastrochilus*, *Malelola*, *Micropera, Pennilabium*, *Pomatocalpa*, *Renanthera*, *Rhynchogyna*, *Rhynchostylis*, *Robiquetia*, *Schoenorchis*, *Smitinandia*, *Trichoglottis*, and perhaps additional genera. However, despite the nomenclatural gymnastics and classification changes by the taxonomists, horticulturists still refer to some former *Saccolabium* genera as *Saccolabium*. Therefore the nomenclature used here is the one employed in the original reports. References to the procedures below are also included under *Gastrochilus* for *Gastrochilus* (*Saccolabium*) *calceolare* and *Acampe* for *Acampe papillosa* (*Saccolabium papillosum*).

Isolation of *Saccolabium calceolare* (*Gastrochilus calceolare*) Protoplasts

The method developed for *Acampe praemorsa* was used to isolate 6.1×10^4 protoplasts from leaves of *Saccolabium calceolare* (*Gastrochilus calceolare*; Seeni and Abraham, 1986).

Mass Rapid Clonal Propagation of *Saccolabium calceolare* (*Gastrochilus calceolare*)

Research designed to "test the morphogenetic response of *Saccolabium calceolare* inflorescence axes *in vitro*" resulted in a method for mass rapid clonal propagation (Vij et al., 1986). *Saccolabium calceolare* is an epiphytic species from the outer Himalayan ranges that flowers during May and June.

Plant Material. "Inflorescence axes (30–40 mm) with or without differentiated buds" are cut into 10–20-mm sections following surface sterilization, "and those with intact apices [are] used as explants."

Surface Sterilization. The inflorescences are surface-sterilized first by immersing them in 95 or 70% ethanol for 1–2 min and then by placing them in 0.5% mercuric chloride solution (0.5 g $HgCl_2$ per 100 ml distilled water) with Teepol as a wetting agent (Tween 20 can also be used) for 6–7 min. (Mercuric chloride is a dangerous chemical and should be handled with care.) A rinse with sterile distilled water is advisable before the inflorescences are sectioned.

Culture Vessels. Test tubes or Erlenmeyer flasks can be used.

Culture Conditions. Cultures should be maintained under 12-h photoperiods of 3500 lx (provided by fluorescent tubes) at 25–27°C.

Culture Media. Several media were used in the original research, but the one that may prove to be the most practical is a modification of the Mitra et al. (1976) medium (Table Sccm-1). Plantlets can be subcultured on the same medium or on any of the standard culture media of seeds, protocorms, seedlings, and PLBs (see Tables Aranda-7 and Cym-11).

Procedure. Place the explants on the first medium, and allow them to form plantlets, which are excised and subcultured.

Developmental Sequence. Apices "grew into vegetative shoots, [and] floral buds slowly developed into shoot buds." Roots in this medium (Table Sccm-1) are smaller than those cultured on a solution containing (per liter) 25 mg urea and 2 mg IAA. However, flower buds form shoots only on the IAA-free medium (Table Sccm-1). Shoots form within 6–8 weeks, and roots appear after 70 days.

General Comments. "The ability of the buds to grow into a vegetative or a reproductive shoot seems to be correlated with their physiological age." Young buds form vegetative structures, whereas well-differentiated ones flower in vitro.

Acampe, from the Greek ἀκαμπή (*akampes*) meaning rigid, refers to the "small, brittle flowers, in which there is no flexibility" (Schultes and Pease, 1963). *Saccolabium* comes from the Latin *saccus* for bag and *labium*, which means lip; the combination of the two words refers to the bag-like shape of the labellum or lip (the median petal).

TABLE SCCM-1. **Modified Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) for the culture of explants from inflorescence axes of *Saccolabium calceolare* (Vij et al., 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100	10 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	200	20 g l^{-1}	10

12	Riboflavin	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
13	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Organic additive				
14	Urea	50	No stock	No stock	Weigh
	Sugar				
15	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[f]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[f]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe used 3 ml $Na_2FeEDTA$, a preparation that may not be readily available. The substitute listed here is common in orchid tissue culture media. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen.

[f]Add items 1–14 to 900 ml distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense solution into culture vessels, and autoclave. Omit agar for liquid medium. Media that contain hormones and vitamins should not be autoclaved without prior experimentation to determine that this will have no deleterious effects. This is such a case (Mitra, 1971; Mitra et al., 1976; Vij et al., 1986), so the medium may be autoclaved.

Micropropagation of *Saccolabium papillosum* (*Acampe papillosa*) through the Culture of Leaf Segments

Saccolabium papillosum Lindl. (*Acampe papillosa* Lindl.; Fig. Sccm-1K, L) is an epiphytic species found in tropical valleys (up to an elevation of 800 m) from Kumaon to Arunacal Pradesh in India. It is used therapeutically. Leaf segment capacity to produce plantlets was investigated with a view to the development of a micropropagation protocol (Kaur and Vij, 2000). The original report refers to this orchid as *Saccolabium papillosum* (Kaur and Vij, 2000). Another source lists the species as *Acampe papillosa* (Kataki, 1986). The name used here is the one preferred by the authors of the tissue culture protocol (Kaur and Vij, 2000). However, a reference to this procedure is included in the *Acampe* section.

Plant Material. The most suitable explants are leaves, either: (1) 1 cm long or less from plants growing in vitro (the original paper does not state if these were seedlings or plantlets produced through tissue culture, but the protocol could probably be used for both), or (2) 2 cm long or less from plants growing in a greenhouse.

Surface Sterilization. Leaves taken from plants growing in vitro do not require surface sterilization. However, they should be washed several times with sterile distilled water to remove medium residues. Leaves from greenhouse (and field) grown plants should first be washed with running water and a mild detergent (0.2% of Teepol, available from www.sigmaaldrich.com, was used in the original research, but a mild household detergent or baby shampoo are also suitable) and a soft brush (a used toothbrush is very suitable). After that they should be dipped in 70% ethanol (73–74 ml 95% ethanol brought to 100 ml with distilled water) three times (30 s per dip), rinsed thoroughly several times with sterile distilled water, immersed in 0.1% mercuric chloride (which should be handled with care because it is toxic) containing 1–2 drops Teepol (or a mild household detergent or baby shampoo) for 5 min, washed well with sterile distilled water several times, soaked in 0.02% streptomycin (www.sigmaaldrich.com) for 5 min, rinsed with sterile distilled water three times, submerged in 0.01% bavistin (a product of BASF) for 5 min, and finally washed very well with sterile distilled water three times.

Culture Vessels. Culture tubes or other containers are suitable. They should be filled with medium to 25–30% of their capacity.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx (the illumination source is not described in the original paper) or standard culture room conditions.

Culture Media. Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with BA should be used for leaves from greenhouse (or field) grown plants (Table Sccm-2). MPR containing BA and NAA is suitable for leaves from plants growing in vitro (Table Sccm-3). The original report does not indicate if these or other media should be used to grow plantlets to the community pot stage. If these media (Tables Sccm-2 and Sccm-3) are not suitable, plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C medium that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. The leaves are put in culture after surface sterilization, but the original report does not indicate if they should be sectioned or cultured whole and if the latter whether it is preferable to insert them into the medium or place them

TABLE SCCM-2. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Saccolabium papillosum* (*Acampe papillosa*) leaves from greenhouse-grown plants (Kaur and Vij, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

17	Agar[f]	9.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE SCCM-3. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Saccolabium papillosum* (*Acampe papillosa*) leaves from in-vitro-grown plants (Kaur and Vij, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
18	Agar[f]	9.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

horizontally on it (and if so, whether their upper or lower surface should be in contact with the substrate). PLBs and plantlets produced by the explants can be cultured on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without banana homogenate or activated charcoal. If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C medium that does contain this darkening agent (see Table Pln-1, footnote *f*).

Developmental Sequence. The leaves produce PLBs on their adaxial surface (Fig. Sccm-1). Plantlets with 2–3 leaves and 1–2 roots develop within 24 weeks. When cultured on an appropriate medium, these plantlets grow to a stage which makes them suitable for planting in community pots.

General Comments. The use of leaf explants does not endanger donor plants. Because of this, they are preferable to the utilization of shoot-tip explants. Also, mature plants have many leaves which means that explants are plentiful. Outstanding cultivars can be propagated through the use of leaf section. Leaf explants taken from seedlings grown in vitro or in a greenhouse cannot be used to propagate selected cultivars simply because their quality is not known.

Professor S. P. Vij and his associates have taken a lead in the identification and use of explants other than shoot tips. They should be congratulated for taking this initiative and for their successes. Professor Vij will probably be retired by the time this is published.

Sarcanthus

Several hundred species were included in the genus *Sarcanthus* at one point. However, many species were removed from this genus and placed in 25–30 existing or newly created genera.

In Vitro Growth of *Sarcanthus scolopendrifolius* (*Cleisostoma scolopendrifolium*)

A Korean orchid *Sarcanthus scolopendrifolius* was renamed *Cleisostoma scolopendrifolium*, but is listed here under the name used in the original report. The original paper (Lee et al., 1999) is in Korean with an English summary from which it is not clear whether the experiments were carried out with seedlings or tissue culture-derived plantlets. Table captions and one sentence in the abstract suggest that the work was carried out with seedlings, but a shortened version of the abstract is presented here just in case tissue cultured plants were also involved.

> The effective medium for shoot differentiation and seedling growth of the orchid [*S. scolopendrifolius* or *C. scolopendrifolium*] was Murashige and Skoog's basal medium supplemented with 5% sucrose and 0.7% agar, and the medium was adjusted to pH 4.0. Number of shoot and fresh weight were enhanced in the medium . . . with 500 mg L^{-1} activated charcoal, but root growth . . . decreased. Seedlings . . . died in . . . medium . . . with 1.0 mg L^{-1} NAA. However, shoot number, shoot length, leaf number, root number, root length and fresh weight . . . markedly increased in MS medium containing 10.0 ml·L^{-1} BA with 0.1 mg·L^{-1} NAA. (Lee et al., 1999)

Satyrium

As presently constituted, the genus *Satyrium* is found in Africa (tropical and southern), Australia, China, India, Indonesia, and Madagascar. The plants are assumed to have aphrodisiac properties.

Micropropagation of *Satyrium nepalense* through the Culture of Leaf Explants

A method for the micropropagation of *Satyrium nepalense* was developed at the Department of Botany, Panjab University by Professor Suraj P. Vij and his associate Promila Pathak as part of an extended research program on the micropropagation of orchids through leaf segments (Fig. Satm-1; Vij and Pathak, 1990).

Plant Material. Basal sections, 5–10 mm long, with leaf bases intact and taken from leaves up to 2 cm long of 16–40-week-old seedlings in vitro, are cultured.

Surface Sterilization. Explants taken from seedlings in vitro do not require surface sterilization.

Culture Vessels. Culture tubes or other containers can be used.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

Culture Media. Explants should be cultured initially on Knudson C medium (Knudson, 1946) supplemented with BA, NAA, and yeast extract (Table Satm-1). No medium is suggested for the culture of plantlets to the community pot stage. Plantlets can be cultured on one of the versions of Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C medium that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. Leaves are taken from seedlings and their basal parts are sectioned and placed in culture on the first medium (Table Satm-1). If necessary, plantlets can be grown in one of the other media.

Developmental Sequence. Only 33.3% of the explants produce PLBs. PLBs are first formed 4 weeks after the start of culture. Explants produce an average of 28 PLBs. The first leaf appears after 8 weeks of culture. Roots are formed after 13 weeks.

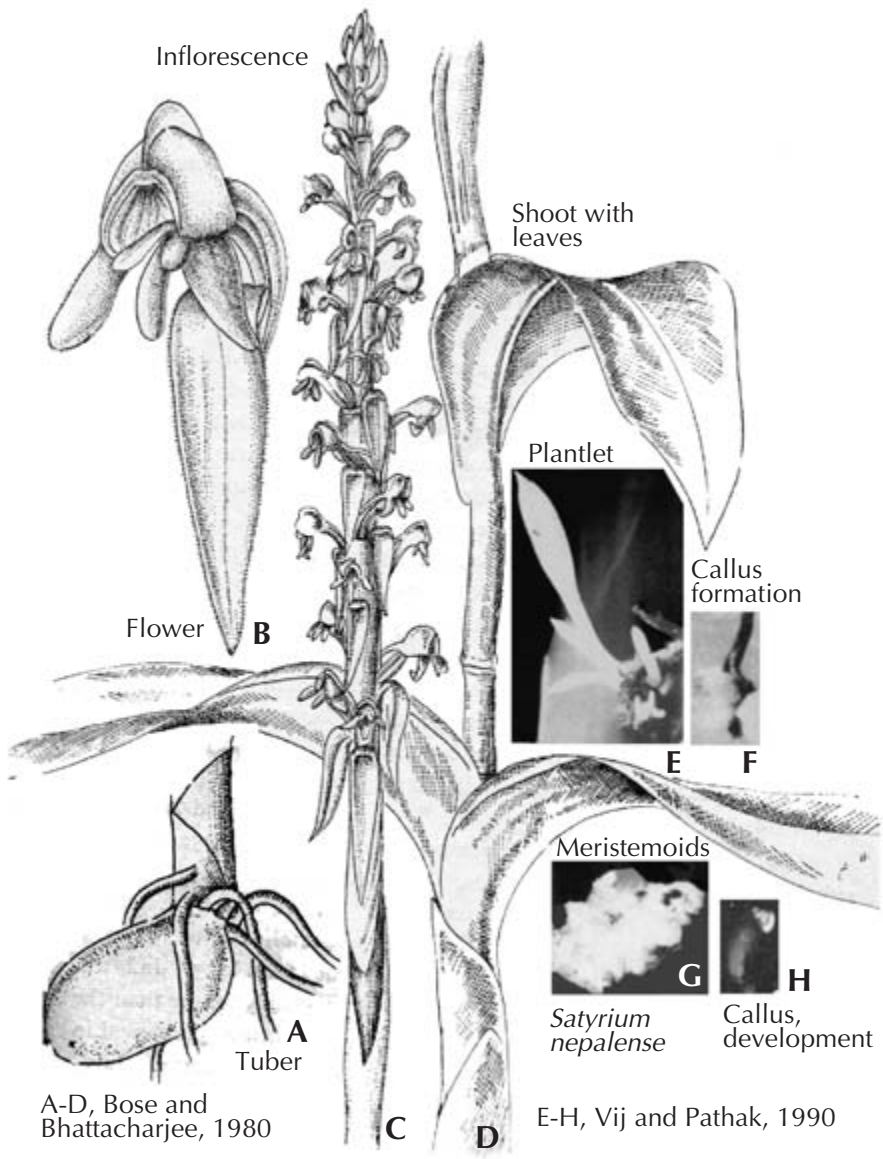

FIG. SATM-1. ***Satyrium nepalense*** **and its micropropagation.**

9	Yeast extract (YE)[g]	1.0 g	No stock	No stock	Weigh
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[h]	To 1000 ml			
	Solidifier				
12	Agar[h]	9.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Knudson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4{\cdot}7H_2O$ l^{-1}, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary, those used in the Murashige–Skoog (MS) medium are suitable.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]Available from www.phytotechlab.com or www.sigmaaldrich.com

[h]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If the incorporation of additional microelements is necessary, those used in the Murashige–Skoog (MS) medium are suitable.

General Comments. This method seems to be simple and effective, but cannot be used for the propagation of selected clones because it uses explants from seedling leaves.

Satyrium comes from *satyrion* (σατύριν), sylvan demigods (sometimes thought to be half goat, half man) of Greek mythology noted for their lasciviousness. This name was applied to the orchid because of its presumed aphrodisiac properties. The illustration is of a hurdy-gurdy-playing Satyr. (Detail from an engraving by an Italian master ca 1515; source: www.metmuseum.org.)

Schomburgkia

The method for *Cattleya* is also applicable to *Schomburgkia superbiens* (Scully, 1967).

Serapias

A genus of 19 species, *Serapias* is distributed from the Azores and Canary Islands eastward to the Caucasus, south to North Africa, and north to Britanny (Pridgeon et al., 2003). The name commemorates *Serapis*, an Egyptian god associated with licentiousness.

Vegetative Multiplication in Vitro of *Serapias olbia* and *Serapias pseudocordigera*

A method for propagating these two European orchids was developed at the Station de Botanique et de Pathologie Végétale, Antibes, France (Ponchet et al., 1985). The report is in French with an English summary which is abbreviated below.

> Meristems . . . [are] grown on a . . . medium rich in organic substances [un]till they . . . reach . . . 5 mm size (optimum . . . for further . . . propagation). Only one culture medium containing Knudson [macroelements], Murashige and Skoog microelements, B and C vitamins, sucrose and . . . benzyladenine (2 to 4 mg/ml) [this is probably a typographical error, because 2–4 mg ml^{-1} amounts to 2–4 g l^{-1}, an extremely high and probably toxic concentration; the meaning is probably 2–4 mg l^{-1}], was used to obtain . . . propagation [through buds] and . . . stoloniferous plantlets. These plantlets, after their separation from the buds, were kept on a third medium where benzyladenine was replaced with IAA (1 mg/l) [this implies that IAA and BA belong to the same group of hormones, which they do not; IAA is an auxin whereas BA is a cytokinin] to [bring about] complete development of the tubers. The transfer from in vitro conditions was carried out on . . . vermiculite under water saturated air, before the final planting in [the] ground. The tuberized plantlets were able to grow normally [like] "natural" plants. No symbiotic fungus was used during *in vitro* and *in vivo* culture.

Comments. This is an interesting paper, but being in French, will be read by few scientists and growers.

Sophrolaeliocattleya

Procedures that are suitable for *Cattleya* (particularly Kako, 1969; Ishii et al., 1976) can also be used for this genus.

Spathoglottis

A genus consisting of approximately 40 species, *Spathoglottis* is found in South East Asia, Australia, China, Indonesia, New Guinea, and the Pacific Islands. It was first described by C. L. Blume in 1825.

Tissue Culture of *Spathoglottis*

A method for *Spathgolottis* is mentioned in a paper on *Phalaenopsis* (Intuwong and Sagawa, 1974).

Culture of *Spathoglottis* Flower Buds

Flower buds of *Spathoglottis*, 5–10 mm in size, can be cultured by a method used for *Mokara* (Lim-Ho et al., 1984). The initiation of PLBs and the rate of growth were faster for *Spathoglottis* than for *Mokara*.

Root Formation in *Spathoglottis* Cultures

An attempt was made to induce callus through the culture of "excised rhizomatous portions of young seedlings of the orchid *Spathoglottis plicata*" (Bapat and Narayanaswami, 1977).

Plant Material. "Leaves and secondary roots of 6-week old seedlings were excised and discarded and the rhizomatous stock alone bearing the stem disc was cultured . . ." (Bapat and Narayanaswami, 1977).

Culture Vessels. Test tubes and Erlenmeyer flasks can be used.

Culture Conditions. Cultures should be maintained under constant illumination (sources and intensity not given) at a temperature of 25 ± 2°C and a relative humidity of 50–60%.

Culture Media. Callus forms on a modified MS medium (Table Spa-1) and is maintained on a second modification (Table Spa-2). Roots form on a third modification of the medium (Table Spa-3).

Procedure. Culture the explants on the first medium (Table Spa-1) to initiate callus, which is maintained on the second solution (Table Spa-2). Then move to the third medium (Table Spa-3) for root induction.

Developmental Sequence. The explants develop callus, which forms roots, but do not develop leaves or plantlets.

TABLE SPA-1. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for callus induction from *Spathoglottis* explants (Bapat and Narayanaswami, 1977)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	5.0	500 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
11	Kinetin	1.0	400 mg 100 ml^{-1} 95% ethanol[f,g]	0.25	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
15	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxins and cytokinins do not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7, 9, and 15 to 700 ml distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour the solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8, and 10–14) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

TABLE SPA-2. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the maintenance of callus derived from *Spathoglottis* explants (Bapat and Narayanaswami, 1977)**

	Solidifier				
18	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin do not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7, 9, and 15 to 700 ml distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour the solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8, and 10–14) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

General Comments. This method can serve as a starting point for further research and may be applicable to *Habenaria*.

Isolation of Protoplasts from *Spathoglottis plicata*

The method developed for *Acampe praemorsa* was used to isolate 2.4×10^4 protoplasts from leaves of *Spathoglottis plicata* (Seeni and Abraham, 1986).

Micropropagation of *Spathoglottis plicata* through the Culture of Leaf Bases

Spathoglottis plicata is found from Sumatra to the Philippines. Many of its forms are cultivated. Hybrids also exist. A method for the culture of leaf bases was developed at the Post-Graduate Department of Botany, Utkal University, Bhubaneswar, Orissa, India (Nayak et al., 1988).

Plant Material. Leaf bases were taken from seedlings, 5 cm high and 120 days old, grown on MS medium (Murashige and Skoog, 1962) supplemented with 2 mg NAA l^{-1} and 0.5 mg BA l^{-1} and maintained at 25 ± 1°C under continuous illumination of 2500 lx provided by cool white fluorescent lamps.

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization.

Culture Vessels. "Conical . . . Borosil" (i.e., Pyrex or equivalent Erlenmeyer) flasks of 150-ml capacity were used in the original research. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at 25 ± 1°C under 18-h photoperiods of 2500 lx provided by cool white fluorescent lamps or standard culture room conditions.

Culture Media. Explants should be cultured first on MS medium (Murashige and Skoog, 1962) containing 10 mg BA l^{-1} and 2.5 mg NAA l^{-1} (Table Spa-4). Shoots produced on this medium develop roots on MS containing 2 mg NAA l^{-1} (Table Spa-5). No medium is suggested for the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

TABLE SPA-4. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Spathoglottis plicata* leaf bases (Nayak et al., 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.8, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media.

TABLE SPA-5. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the rooting of shoots produced by leaf bases of *Spathoglottis plicata* (Nayak et al., 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media.

Procedure. Leaves are taken from seedlings and their bases are excised and placed on the first medium (Table Spa-4). Shoots which form on this medium are transferred to the second solution (Table Spa-5) for root induction. Plantlets from the second or a third medium are hardened and established in a garden or greenhouse.

Developmental Sequence. Vegetative buds and eventually shoots develop from the cut ends of the leaf bases within 5 weeks of culture on the first medium (Table Spa-4). Root initiation becomes apparent 2 weeks after the shoots are moved to the second medium (Table Spa-5). The shoots form 2–4 well developed roots after 4 weeks on the second medium (Table Spa-5) and become plantlets. For further growth the plantlets can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, Cym-1 to Cym-3, Cym-5, Cym-24, C-19, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without banana homogenate or activated charcoal. If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*). These plantlets become established and hardened on being moved to a greenhouse or garden.

General Comments. This procedure is efficient and useful, but it cannot be used to select outstanding cultivars because the quality of seedlings is not known.

Micropropagation of *Spathoglottis plicata* through the Culture of Nodal and Leaf Explants

Hybrids of *Spathoglottis plicata* can be found throughout the world. Many of them have attractive flowers. Propagation by conventional methods is slow. Therefore, a micropropagation method was developed at the Hong Kong Institute of Biotechnology and the National Pingtung Polytechnic Institute in Taiwan (Teng et al., 1997).

Plant Material. Internode sections consisting of one-half of the internodal portion above and below the node, and leaves (2–3 mm explants) were taken from 8-month-old seedlings, growing in pots. Sections of PLBs produced through this method can also be cultured.

Surface Sterilization. The surface sterilization procedure used as part of this protocol is unusual and overly complex. It is quoted here verbatim with comments in brackets:

> Eight-months-old pot-grown seedlings *S. plicata*, native to Taiwan were washed thoroughly in water, sonicated in 1% NaOCl [this is 18 or 17 ml of household bleach which contains 5.25% or 6% NaOCl, respectively, diluted to 100 ml with distilled water] for 20 min and soaked in a solution of 1000 mg/liter of both penicillin-G and streptomycin for 3 h. The antibiotic solution was prepared by adding 1 g pencillin-G and 1 g streptomycin [both are available from www.sigmaaldrich.com and other

> sources] to 20 ml of distilled water, which was then filtered through a 0.22-μm Millipore filter [in effect sterilizing the solution]. The sterile antibiotic solution was diluted to 1 l and ten drops of sterile Tween 20 [available from www.sigmaaldrich.com and other sources] were added into the solution (i.e., one drop per 100 ml of solution). The final concentration of each antibiotic was 1000 mg/l [that is 1 g l^{-1}]. The antibiotic solution was removed from the seedlings using a 400-μm polyester screen filter [plain filter paper or cheese cloth or even a paper towel used as filter paper are also suitable]. The seedlings were then rinsed thoroughly with sterile distilled water. To remove any residuals of antibiotic, the seedlings were left in constant stirring water for 5 min and then filtered to remove the water . . . [This process was repeated three times]. (Teng et al., 1997)

PLBs taken from in vitro cultures do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other containers can be used.

Culture Conditions. Explants should be cultured at 25 ± 2°C under continuous illumination of 20 μmol m^{-2} s^{-1} provided by cool white fluorescent lamps.

Culture Media. To generate PLBs, explants should be cultured on modified MS medium (Murashige and Skoog, 1962) supplemented with 5.37 μmol NAA l^{-1} and 0.44 μmol BA l^{-1} (Table Spa-6). PLBs should be cultured on MS with 2.69–10.74 μmol NAA l^{-1} and 8.88 μmol BA l^{-1} (Table Spa-7) for plantlet development. Sections of PLBs produced on the first medium should be cultured on the same solution (Table Spa-6) for further proliferation. And PLBs produced from the sections should be cultured on the second medium (Table Spa-7) to produce plantlets.

Procedure. Surface-sterilized nodal and leaf explants are cultured on the first medium (Table Spa-6) to produce PLBs (Fig. Spa-1). These PLBs can be sectioned and the sections cultured on the same medium (Table Spa-6) to produce even more PLBs. Regardless of whether they are produced from the original explants or sections, PLBs are cultured on the second medium (Table Spa-7) for plantlet development.

Developmental Sequence. Explants and PLB sections produce PLBs on the first medium (Table Spa-6). Plantlets are produced by the PLBs on the second medium (Table Spa-7).

General Comments. The reason for developing this procedure seems to have been *Spathoglottis* hybrids, which produce beautiful flowers, but whose propagation by division is very slow. However, it is not at all certain that a procedure developed with explants taken from 8-month-old seedlings will be applicable to mature plants.

TABLE SPA-6. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Spathoglottis plicata* leaf and nodal explants and PLB sections (Teng et al., 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh
	Darkening agent				
18	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 18) with constant stirring to insure complete dispersion through the medium, pour the solution into culture vessels, and autoclave. Agar is not added to liquid media.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

TABLE SPA-7. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for plantlet formation from protocorm-like bodies of *Spathoglottis plicata* (Teng et al., 1997)**

Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

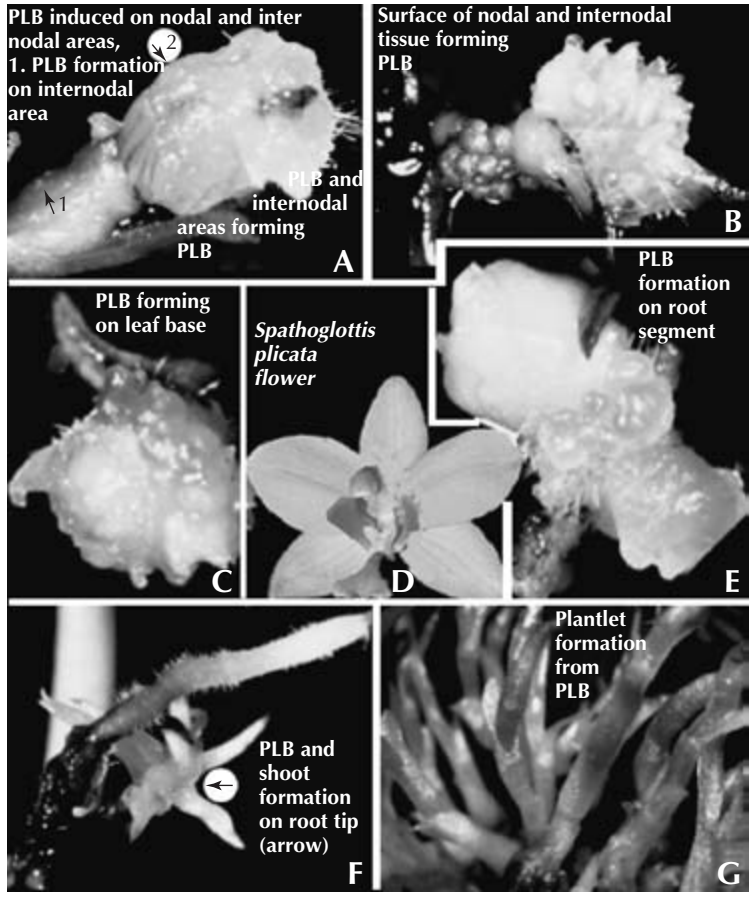

FIG. SPA-1. **PLB and plantlet formation from *Spathoglottis plicata* explants. (A–C, E–G, Teng et al., 1997; D, Joseph Arditti.)**

In Vitro Multiplication of *Spathoglottis plicata* through Tissue and Organ Culture

Several explants were used in an attempt to develop in vitro propagation procedures for *Spathoglottis plicata* because it is a very attractive terrestrial orchid "distributed in Tropical Asia and Indonesia . . . [and] also occur[ring] in Meghalaya hills and in the foot-hills of Arunachal Pradesh" (Mazumder and Bhowmik, 1993).

Plant Material. A number of explants from seedlings in vitro were cultured (Table Spa-8).

Surface Sterilization. Explants taken from seedlings in vitro do not require surface sterilization.

TABLE SPA-8. **Explants of *Spathoglottis plicata* cultured and their response**

Explant	Nature of response	Medium	Percent of explants responding
Leaf			
Apex	No response		
Base	Callus and protocorm-like body formation	Table Spa-9	95
Split longitudinally	No response		
Petiole	No response		
Whole	No response		
Pseudobulb			
Whole	Formation of protocorm-like bodies	Table Spa-9	100
Stem			
Base	Formation of protocorm-like bodies	Table Spa-10	100
Root			
Segment	Formation, proliferation and differentiation of protocorm-like bodies	Table Spa-11	100

Culture Vessels. Culture tubes, Erlenmeyer flasks, or other containers can be used.

Culture Conditions. Standard laboratory conditions are suitable.

Culture Media. Leaf bases and pseudobulbs should be cultured on MS medium (Murashige and Skoog, 1962) containing 0.5 mg IAA l^{-1} and 100 mg casein hydrolysate l^{-1} (Table Spa-9). MS supplemented with 1.0 mg 2,4-D l^{-1} and 100 mg casein hydrolysate l^{-1} (Table Spa-10) is suitable for stem bases. Root segments proliferate and produce PLBs on MS with 0.5 mg NAA l^{-1} and 100 mg casein hydrolysate l^{-1} (Table Spa-11).

Procedure. Explants are placed on the appropriate medium and kept on it until they produce PLBs and/or callus. These can be subcultured onto the initial medium for further proliferation, the production of additional PLBs, and the start of plantlet formation (Fig. Spa-2). PLBs, shoots, and/or small plantlets can be cultured to community pot size with one or two transfers to one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C medium that contains this darkening agent (see Table Pln-1, footnote *f*).

Developmental Sequence. The explants form PLBs and/or callus on the initial medium (see Table Spa-8 for explant–medium combinations) within 8–10 weeks. PLBs and callus also proliferate on these media and may perhaps form shoots and/or plantlets on them. Further growth can occur on one of the media listed under the procedure above.

TABLE SPA-9. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of leaf bases and pseudobulbs of *Spathoglottis plicata* seedlings (Mazumder and Bhowmik, 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar[h]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Not all casein hydrolysates are the same. Their compositions and analyses vary depending on the methods by which they were produced. A product sold by Merck (www.merck.de) as casein hydrolysate (CH) is obtained by degrading casein with hydrochloric acid; vitamins and other growth-promoting compounds are largely destroyed in this process. The CH sold by Sigma-Aldrich (www.sigmaaldrich.com) is pancreatic hydrolysate of casein. There is also a CH which is hydrolysed by enzymes. Becton, Dickinson and Company (www.bd.com) sells Difco products including a number of different casamino acid products, all of which are casein hydrolysates. Therefore if a method specifies a source for the CH in its culture medium it is best to obtain the additive from the same vendor. If a source is not listed it is best to purchase CH which is described as being suitable as a supplement for plant culture media. Failing that, CH should be purchased from a source which specializes in tissue culture and micropropagation supplies. One such source is www.caissonlabs.com. They list casein rather than CH as Stock #: SPCA205. Another source for CH is www.duchefa.com (item 1301). Additional sources include www.fishersci.com, www.thomassci.com, and others.

[h]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. As a rule, but not in this medium, amino acid (item 8), hormone (item 10), and vitamins (items 11–13) are added to a still warm and liquid autoclaved medium under sterile conditions with sterilized pipettes. The medium is mixed well and distributed to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE SPA-10. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of stem bases of *Spathoglottis plicata* seedlings (Mazumder and Bhowmik, 1993)**

FIG. SPA-2. **In vitro culture of *Spathoglottis plicata*. A. Formation of PLBs from a stem base. B. Plantlet development from a pseudobulb. (The original illustrations are fuzzy; Mazumder and Bhowmik, 1993.)**

General Comments. This method can be used for rapid propagation, but not for the selection of outstanding cultivars.

Micropropagation of *Spathoglottis plicata* through the Culture of Seedling Shoots

Spathoglottis plicata is appreciated and thought of as having great potential as an outdoor and garden ornamental plant. It is cultivated throughout the tropics, including Venezuela where a micropropagation method was developed using seedling shoots as explants (Perdomo and Páez de Cásares, 2000).

Plant Material. Seeds were germinated on half-strength MS medium (Murashige and Skoog, 1962). Shoots, 6–10 mm long, taken from 5-month-old seedlings are preferable as explants. However, 3–5-mm-long shoots can also be used.

Surface Sterilization. Explants taken from seedlings in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers are suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C, under 16-h photoperiods of 35 mE m^{-2} s^{-1} and 40–80% relative humidity or standard culture room conditions.

Culture Media. Explants should be cultured on quarter-strength MS with 15 g sucrose l^{-1} (Table Spa-12). Since no plant hormones are mentioned it is reasonable and perhaps even necessary to assume that none are needed. Therefore the medium suggested here (Table Spa-12) is speculative to some extent. No medium is suggested

TABLE SPA-12. **Quarter-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of shoots of *Spathoglottis plicata* seedlings (Perdomo and Páez de Cásares, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

	Solvent				
14	Water, distilled[f]	To 1000 ml			
	Solidifier				
15	Agar[f]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

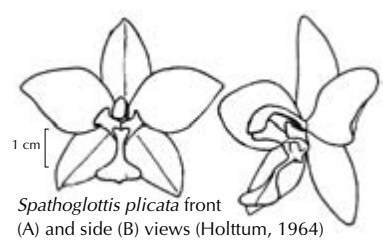
[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.5, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave.



Spathoglottis plicata front (A) and side (B) views (Holttum, 1964)

for the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. Explants are placed on the first medium (Table Spa-12) and allowed to develop new shoots. These shoots should be allowed to grow and form plantlets on the first medium (Table Spa-12) or moved to one of the other media mentioned above. When the plantlets are large enough they should be moved to community pots.

Developmental Sequence. The explants form shoots which grow, and produce roots and then plantlets.

General Comments. Not enough information is given in the original abstract to allow for a complete presentation here. Also, the procedure does not seem to offer a real advantage over propagation by seeds because it simply multiplies seedlings. Seed capsules usually contain many seeds which can produce numerous seedlings. And, since the quality of seedlings is not known, clonal propagation using them as explant sources offers no horticultural advantages (i.e., selection of superior clones is not possible).

There are several critical steps in the development of a micropropagation procedure. One is surface sterilization, which may damage the explant to the point of rendering it incapable of growth in vitro. Bypassing the surface sterilization step for the purpose of selecting a medium without having to deal with possible damage by a sterilant is fully justified. This is not such a case because there is ample literature on micropropagation and in vitro culture of *Spathoglottis* explants (Intuwong and Sagawa, 1974; Bapat and Narayanaswami, 1977; Lim-Ho et al., 1984; Arditti and Ernst, 1993; Mazumder and Bhowmik, 1993; Teng et al., 1997; Nayak et al., 1998*a*, 1999). Several media and surface sterilization procedures are known to work and could have been used to develop yet another method.

This method is presented here simply because it was published and the intent is to include in the current edition as many methods as could be found in the literature. The hope is also that the presentation of the method and this discussion will encourage future workers to: (1) develop micropropagation methods for mature plants, and (2) be more careful and detailed in their presentations (there is no indication in the abstracts whether some/all/any of the organics which are part of the MS formulation were used in this case; if one-quarter MS refers to all components or to the macroelements only; and what is the pH of the medium) and spelling (in the original abstract the generic name is consistently misspelled as *Spathoglotis* instead of the correct *Spathoglottis*).

Encapsulation in Alginate of Protocorm-like Bodies of *Spathoglottis plicata* and Subsequent Plantlet Production

The encapsulation of PLBs or somatic embryos (Hew and Yong, 2004) results in production propagules, which have been referred to as "synthetic seeds." Their use can simplify micropropagation. A protocol for large-scale propagation of *Spathoglottis plicata* using encapsulated PLBs was formulated at the Cytogenetics Laboratory, Post-Graduate Department of Botany, Utkal University, Bhubaneswar, Orissa, India (Nayak et al., 1998*b*).

Plant Material. PLBs were produced by culturing shoots taken from seedlings on MS medium (Murashige and Skoog, 1962) containing 1 mg NAA l^{-1} and 2 mg BA l^{-1} (Table Spa-13) at 25 ± 1°C under 16-h photoperiods of 35 μE m^{-2} s^{-1} provided by Philips cool white fluorescent tubes. About 85% of the explants produced an average of 7.6 PLBs per explant within 30–35 days of culture. These PLBs reached a size of 3–4 mm in 40–45 days of culture and were used for encapsulation.

Culture Vessels. Erlenmeyer flasks, 150-ml capacity, should be used for the culture of explants. Screw-cap glass jars, 200-ml capacity, or Petri dishes are suitable for in vitro germination of encapsulated PLBs. The same containers and pots can be used for horticultural germination. Developed plantlets should be planted in pots.

Culture Conditions. Suitable conditions for the germination of encapsulated PLBs are the same as those used to culture explants for the production of plant material (see above). Well-developed plantlets should be hardened in a plant growth chamber at 25 ± 1°C, 85% relative humidity, and a light intensity of 50 μE m^{-2} s^{-1} for 12–16-h photoperiods.

Low Temperature Storage. Encapsulated PLBs can be stored for up to 45 days in a refrigerator (the temperature of household refrigerators is approximately 4°C).

Alginate and Calcium Chloride Solutions. Sodium alginate solution, 4% (apparently manufactured by Reidel de Haen in Germany and purchased from CDH, Bombay) was dissolved in MS containing 2 mg NAA l^{-1} and 0.5 mg BA l^{-1} (Table Spa-14). Alginate from another source did not produce good results. Therefore it may be advisable to purchase the sodium alginate from CDH in Bombay. Sodium alginate is also available from several sources (including www.sigmaaldrich.com, www.fishersci.com, www.vwr.com, and others), but tests may be necessary to determine if sodium alginate obtained from them is suitable. If the encapsulated PLBs are to be germinated on a soil mixture, a bactericide (rose bengal at 0.2 mg l^{-1}; www.sigmaaldrich.com) and a fungicide (bavistin at 5 mg l^{-1} which is a preparation consisting of 50% carbendazim made by BASF; www.BASF.com) must be incorporated in the alginate solution (Table Spa-15). Calcium chloride ($CaCl_2 \cdot 2H_2O$), 75 mmol l^{-1}, should be dissolved in distilled water (Table Spa-16).

TABLE SPA-13. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of shoots taken from *Spathoglottis plicata* seedlings (Nayak et al., 1998*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (IAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylaminopurine (BAP)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.8, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. In general it is preferable to add the amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. All components of this medium are added before autoclaving. Agar is not added to liquid media.

TABLE SPA-14. **Sodium alginate solution in modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the encapsulation of protocorm-like bodies of *Spathoglottis plicata* which will eventually be germinated in vitro (Nayak et al., 1998*b*)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–17 to 900 ml of distilled water (item 19), adjust pH to 5.8, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 19). The original paper does not indicate whether the medium should contain agar, but it seems logical to exclude it. In general it is preferable to add the amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. All components of this medium are added before autoclaving. Agar is not added to liquid media.

TABLE SPA-16. **Calcium chloride solution for encapsulating *Spathoglottis plicata* in alginate**

Component	Weight or volume	Remarks
Calcium chloride, $CaCl_2 \cdot 2H_2O$	11.03 g	75 mmol, formula weight is 147.02
Distilled water	To 1000 ml	Solution is 75 m*M* in respect to calcium choride

Media for the Germination of Encapsulated PLBs. MS containing NAA and BA (Table Spa-17) should be used for in vitro germination of encapsulated PLBs. Soilrite (Chougule Industries, Bangalore, India) moistened with sucrose and inositol-free MS (Table Spa-18) or a good garden soil moistened with the same solution (Table Spa-18) are appropriate for germination under horticultural conditions.

Media for Plantlet Growth. No media are suggested for the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Potting Mix. A good orchid potting mix should be used to pot well-developed plantlets.

Encapsulation. PLBs, 45 days old and 4–5 mm in size, are mixed with the sodium alginate solution (Tables Spa-14 or Spa-15) and dropped into the calcium chloride solution (Table Spa-16). Small white beads are formed after 25 min. They are collected by decanting the solution in which they were formed.

Storage. See Low Temperature Storage section above. According to another report on encapsulation of PLBs, the alginate capsules may stick to each other. Dusting them with talcum powder may prevent this from happening. Capsules which will be germinated in vitro must be coated with sterilized talcum and stored under sterile conditions. Those that will be germinated horticulturally do not require sterility.

Germination in Vitro. Encapsulated PLBs should be prepared (using the alginate solution in Table Spa-14), stored, and germinated under sterile conditions on autoclaved medium (Table Spa-17). They should be allowed to germinate and develop shoots or plantlets which should be moved to one of the plant culture media once they become large enough.

Germination under Horticultural Conditions. PLBs should be encapsulated in a medium that contains a bactericide and a fungicide (Table Spa-15) and germinated on Soilrite mixture, a good garden soil, or a potting mix moistened with sucrose and

10	Benzylaminopurine (BAP)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Solvent				
14	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively. Since there is no indication in the original repport regarding the use of plant hormones the amounts suggested here are the same as in Table Spa-17.

[g]Add items 1–13 to 900 ml of distilled water (item 14), adjust pH to 5.8, and raise volume to 1000 ml with distilled water (item 14).

The very first artificial (i.e., human-made) orchid hybrid produced in Singapore was *Spathoglottis* Primrose (*Spathoglottis aurea* × *Spathoglottis plicata*). The cross was made in 1932 at the Singapore Botanic Gardens by Professor R. E. Holttum, who was the director at the time.

inositol-free MS (Table Spa-18). Once the plantlets are large enough they should be moved to an appropriate potting mix (see above).

Procedure. Explants are cultured on the first medium (Table Spa-13). When PLBs reach a size of 4–5 mm they should be encapsulated (Tables Spa-14, Spa-15, and Spa-17) and stored for up to 45 days. These encapsulated PLBs are germinated in vitro. The ones encapsulated with the solution in Table Spa-14 should be germinated on the medium in Table Spa-17 or under horticultural conditions (those encapsulated with the solution in Table Spa-15 should be placed on a mix wetted with the MS in Table Spa-18). Shoots or plantlets that develop in vitro (Fig. Spa-3A) are eventually moved to one of the growth media (see Tables Aranda-6 to Aranda-8,

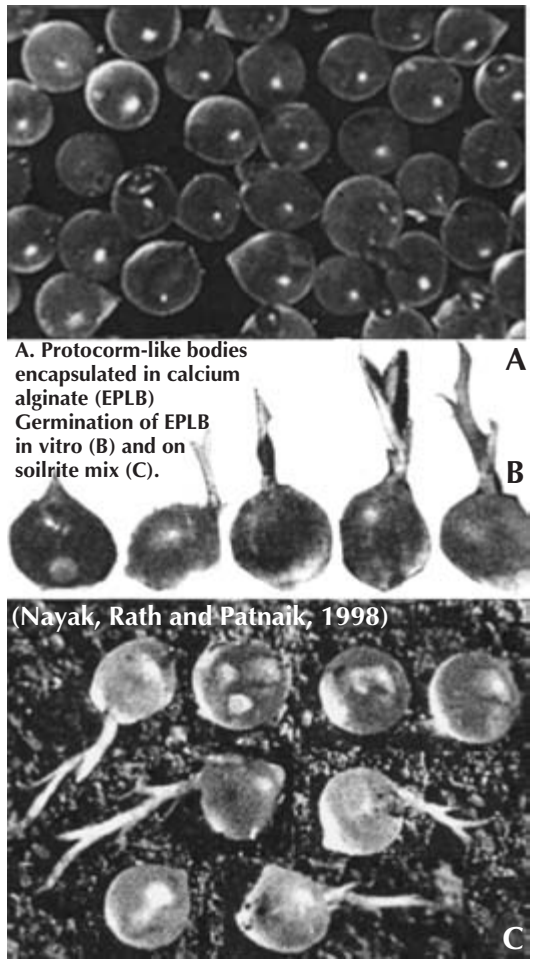

FIG. SPA-3. **Encapsulated PLBs and their germination in vitro (A) and in soil mix (B). (Modified from Nayak et al., 1998*b*.)**

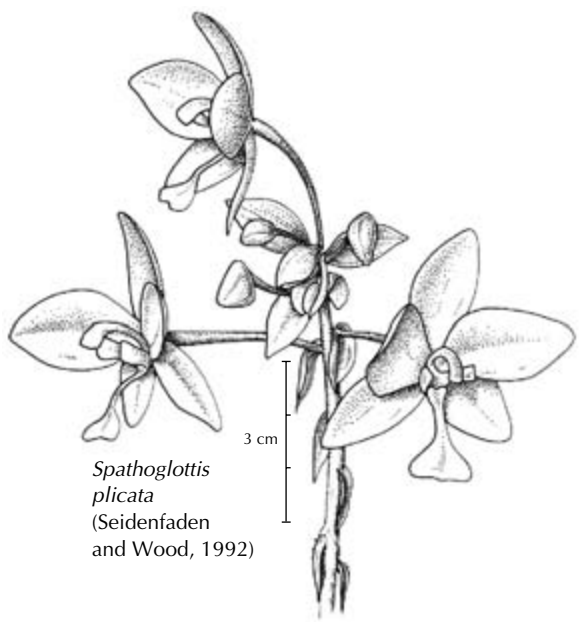
Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, or V-4). When plantlets on one of these media become large enough they are potted in pots in a potting mix. Plantlets that develop under horticultural conditions (Fig. Spa-3B) are allowed to grow to appropriate size before being potted.

Developmental Sequence. When placed on the appropriate medium (Table Spa-17) in vitro, 92–95% of the encapsulated PLBs (formed in the solutions in Tables Spa-14 and Spa-16) will germinate in 10–12 days. About 80–85% of these PLBs will multiply extensively and produce an average of 12–14 plantlets within 60 days. The plantlets can be expected to have 4–6 leaves and 3–4 roots.

When germinated under horticultural conditions, only 45–51% of the encapsulated PLBs (formed in the solutions in Tables Spa-15 and Spa-16) form plantlets.

General Comments. Encapsulation of PLBs in alginate is a new technology which may eventually play a major role in micropropagation (for a more extensive discussion of encapsulation and an excellent color photograph see Hew and Yong, 2004).

Spathoglottis is derived from the Greek *spathe* (σπάθη) which means spathe and *glotta* (γλῶττα) for tongue. The allusion is to the very broad mid lobe of the labellum (Schultes and Pease, 1963; Holttum, 1964).



Spathoglottis plicata (Seidenfaden and Wood, 1992)

Spiranthes

A terrestrial genus, *Spiranthes* consists of approximately 50 species most of which are found in the Americas. A few species occur in Europe and Asia. One is of much wider distribution. The name of the genus is derived from the Greek *speira* (σπειρα), which means coil, and *anthos* (ἄνθος) for flower and alludes to the coiled inflorescence.

Micropropagation of *Spiranthes sinensis*

Spiranthes sinensis is distributed from Sakhalin and Siberia, eastern Russia, in the north to India, the Malay Archipelago, Australia and the southwestern Pacific Islands. It grows in sunny, open, grassy, or disturbed areas up to elevations of 2000 m. A micropropagation method for this species was developed at the Laboratory of Plant Chromosomes and Gene Stock, Faculty of Science, Hiroshima University, Japan (Sato et al., 1987; Tanaka, Kondo and Sato, 1997).

Plant Material. "Shoot primordia" taken from diploid and colchicine-induced tetraploid protocorms were cultured. The protocorms were produced by germinating "10- to 13-day-old" immature seeds on a medium consisting of 2.5 g Hyponex l^{-1}, 35 g sucrose l^{-1}, 2 g peptone l^{-1}, and 9 g agar l^{-1} at 22°C under 500 lx of "full illumination" (perhaps meaning 24-h photoperiods).

Surface Sterilization. Explants taken from protocorms growing in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, 30 × 200 mm, containing 25 ml medium were used in the original research. Other containers are also suitable.

Culture Conditions. Protocorms that will be the source of the explants should be cultured in liquid medium in culture tubes or other containers placed on a rotating shaker, 1 m in diameter, rotating at 2 rpm. In the original research the cultures were maintained under 2000–10,000 lx of "full [perhaps meaning continuous or 24-h] illumination." Shoot primordia should be cultured under the same conditions. When cultured under the same conditions, PLBs produced by the primordia multiplied and produced plantlets.

Culture Media. Shoot primordia (presumably the reference is actually to shoot initials or shoot tips) should be cultured on B5 medium (Gamborg et al., 1968) supplemented with 2 mg BA l^{-1} (Table Spi-1). PLBs produced in this medium "differentiated and multiplied PLBs and later regenerated plantlets in B5 liquid medium lacking growth substance" (Table Spi-2).

Procedure. Shoot primordia (initials or tips) from seedlings are cultured on the first medium (Table Spi-1) and subcultured on the same solution every 3 weeks. PLBs should be grown on the second medium (Table Spi-2) to produce plantlets.

TABLE SPI-1. **B5 medium (Gamborg et al., 1968) modified for the culture of *Spiranthes sinensis* shoot primordia and protocorm-like bodies (Tanaka et al., 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
12	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
13	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–8 to 900 ml of distilled water (item 13), adjust pH to 5.7, add sugar (item 12), and adjust volume to 1000 ml with distilled water (item 13). Pour the solution into culture vessels and autoclave. Vitamins (items 9–11) are generally not heat-stable and it is preferable to add them to culture media after autoclaving. This is not done with the present medium.

Developmental Sequence. Explants produce PLBs on the first medium (Table Spi-1). These PLBs "differentiate and multiply" on the same solution (Table Spi-1). Plantlets are produced on the second medium (Table Spi-2).

General Comments. Seeds of terrestrial orchids from temperate climates are more difficult to germinate than those of tropical species. Explants of temperate climate orchids are also more difficult to culture in vitro. Therefore this protocol is of special interest.

Thelymitra

The method developed for *Diuris longifolia* (Collins and Dixon, 1992) is also suitable for the genus *Thelymitra* (Kingsley W. Dixon, pers. comm., Kings Park and Botanical Garden, West Perth, Australia, Kingsley.Dixon@mail.bigpond.com).

Thunia

One of the most beautiful orchids from the northeastern Himalayas, *Thunia alba* has white, mildly scented flowers. This species is slow growing and on the verge of extinction. A single shoot is produced every year, and as a result propagation is also slow. The method described here accelerates propagation without damaging or endangering an existing plant (Singh and Prakash, 1984).

Plant Material. Sections 4–6 cm long of flower stalks are removed from mature plants.

Surface Sterilization. Flower stalks should be wiped clean with cheesecloth soaked in 95% ethanol and then cut into sections. The sections should be washed with a detergent (Teepol was used in the original research, other detergents are also suitable). After that the sheaths that cover the nodes are removed, and the sections are surface-sterilized in 4% sodium hypochlorite (80 ml Clorox or another household bleach that contains 5% sodium hypochlorite diluted to 100 ml with distilled water) to which a drop of detergent has been added. The sections should be rinsed with sterile distilled water after that.

Culture Vessels. Test tubes, Erlenmeyer flasks (250-ml capacity containing 100 ml liquid medium), or other containers can be used.

Culture Conditions. Cultures should be maintained under 16-h photoperiods of 1.5 W m^{-2} (sources not described) at 25 ± 2°C. Liquid cultures are placed on a rotary shaker at 120 rpm.

Culture Media. Sections are first cultured on a modified Vacin and Went medium (Table Thu-1). After 35 days on this medium the sections should be moved to a second modification (Table Thu-2). Multiple plantlets and PLBs are induced in a liquid medium (Table Thu-3). PLBs are moved to a fourth medium (Table Thu-4) for differentiation.

Procedure. Place sections on the first (Table Thu-1) and then second (Table Thu-2) media for the production of single plantlets. If multiple plants are desired, culture the sections in the liquid medium (Table Thu-3) and move the resulting PLBs to the differentiation solution (Table Thu-4).

Developmental Sequence. Buds start to grow after 17 days and produce shoots within 35 days. Rooted plantlets are obtained 67 days following transfer to the

TABLE THU-1. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of flower-stalk buds of *Thunia alba* (Singh and Prakash, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Antiauxin				
8	*trans*-Cinnamic acid	100	No stock	No stock	Weigh
	Cytokinin				
9	Benzyl adenine (BA)	10	No stock	No stock	Weigh
	Complex additive				
10	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
11	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[e]	To 1000 ml			
	Solidifier				
13	Agar[e]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1 and 3–10 to the 500 ml distilled water (item 12) that contains item 2; adjust pH to 5.2, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring solution to a gentle boil, and add agar (item 13) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar for liquid medium. Media that contain hormones and other labile organic additives should not be autoclaved unless experimental evidence has determined that this will not have a deleterious effect. This is such a case.

second medium (Table Thu-2). PLBs form after 21–27 days in liquid solution (Table Thu-3). Multiple plantlets are obtained 41–47 days after transfer to the fourth formulation (Table Thu-4). In the original research 95 plants (out of 153, or 62.1%) survived the transfer to pots.

General Comments. Dormant flower-stalk buds "remain dormant under normal conditions. . . . [and] rarely develop into a secondary shoot. . . . [they are] induced to form multiple plantlet[s]" through this method without endangering the existing plant. These features make this a very useful, effective, and safe method for the propagation of a rare, endangered, and desirable species.

TABLE THU-2. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of growing flower-stalk buds of *Thunia alba* (Singh and Prakash, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

Dispense medium into culture vessels, and autoclave. Omit agar for liquid medium. Media that contain hormones and other labile organic additives should not be autoclaved unless prior experimental evidence indicates that this will not have a deleterious effect. This is such a case.

TABLE THU-4. **Modified Vacin and Went medium (Vacin and Went, 1949) for plantlet differentiation from protocorm-like bodies derived from flower-stalk buds of *Thunia alba* (Singh and Prakash, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
8	Indolebutyric acid (IBA)	5.0	500 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
9	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Keep refrigerated or frozen between uses. If the auxin fails to dissolve add a few drops of 0.1 N KOH.

[f]Add items 1 and 3–9 to the 500 ml distilled water (item 11) that contains item 2; adjust pH as required, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar for liquid medium. Media that contain hormones and other labile organic additives should not be autoclaved unless experimental evidence indicates this will not have a deleterious effect. This is such a case.

Trudelia

See *Vanda*.

Vanda

In Hawaii and other areas, *Vanda* blossoms are of considerable importance as cut flowers for local use and export. Furthermore, many clones are much sought after by hobby growers. *Vanda* Miss Joaquim is the national flower of Singapore; as a consequence this orchid is grown very widely in that island-city republic. For these reasons methods for mass rapid clonal propagation were needed for a long time, but the genus proved difficult to culture for a while (Morel, 1964*a*, 1965*a*, 1965*b*). Air layering was used for some *Vanda* clones (Watkins, 1942), but these methods are slow. The first experiments in *Vanda* tissue culture were carried out at the University of Singapore with callus masses derived from seedlings (Rao, 1963) and a medium that contains 2,4-D and tomato juice (Rao, 1967). In later work *Vanda* explants grew slowly, produced callus, and eventually formed PLBs (Morel, 1970). When tissue culture procedures were developed, some were used to induce polyploidy in plantlets produced by these methods (Sagawa and Sehgal, 1967; Kunisaki et al., 1972; Sanguthai and Sagawa, 1973; Teo et al., 1973).

Shoot-tip Culture of Terete-leaf *Vanda*

The culture of *Vanda* shoot tips was difficult if not impossible until a sugar-free medium was formulated (Kunisaki et al., 1972).

Plant Material. Stems of *Vanda* (Miss Joaquim in the original experiments) are removed at the node of the fifth visible leaf. Tissue above this node is still soft and succulent, and axillary buds are easy to excise.

Surface Sterilization. Before removal of the sheaths, 10% Clorox is used for 10 min, followed by 5% Chlorox for 5 min.

Culture Vessels. The vessels employed for *Cymbidium* are used (Sagawa et al., 1966).

Culture Conditions. Liquid cultures are placed on a rotator (a New Brunswick Model V shaker operated at 160 rpm was used in the original research). Solid ones are maintained on a shelf or bench. Both are kept under 200 ft-c of continuous illumination provided by General Electric Power Groove white fluorescent lamps (Sylvania Grow Lux could also prove satisfactory). The temperature should be 26 ± 3°C.

Culture Media. Explants are placed initially on solid modified Vacin and Went medium (Table V-1). The best proliferation is obtained in a sugar-free liquid modification of the same solution (Table V-2). Differentiation occurs on a third modification (Table V-3).

TABLE V-1. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of shoot tips of terete-leaf *Vanda* (Kunisaki et al., 1972)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar[e]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1 and 3–8 to the 500 ml distilled water (item 10) that contains item 2, adjust pH to 5.2–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). For solid medium bring the solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium.

Procedure. Remove leaf portions beyond the sheath, and cut stems at internodes into smaller sections. Surface-sterilize these sections in 10% Clorox for 10 min. Remove the sheaths, sterilize with 5% (v/v) Clorox for 3 min, and place on culture medium. After 45 days on solid modified medium (Table V-1) approximately 63% of the explants will form semispherical structures. At this stage, the leaves and apex should be removed from each swollen bud; otherwise proliferation will not occur and only one plantlet will be formed. Proliferation will begin approximately 60 days after the second excision. For rapid and vigorous proliferation, transfer tissue to the liquid medium (Table V-2). When plantlets are desired, the proliferating bodies are transferred to the third modification (Table V-3).

Developmental Sequence. Initial growth and proliferation occur on the first medium, increased proliferation takes place on the second, and plantlets differentiate on the third.

TABLE V-2. **Modified Vacin and Went medium (Vacin and Went, 1949) for the proliferation of shoot-tip explants of terete-leaf *Vanda* (Kunisaki et al., 1972)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	Measure
	Solvent				
9	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.
[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.
[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.
[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.
[e]Add items 1 and 3–8 to the 500 ml of distilled water (item 9) that contains item 2, set pH to 5.2–5.5, and adjust volume to 1000 ml with distilled water (item 9), dispense medium into culture vessels and autoclave.

TABLE V-3. **Modified Vacin and Went medium (Vacin and Went, 1949) for the differentiation of shoot-tip explants of terete-leaf *Vanda* (Kunisaki et al., 1972)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

	Sugar				
9	Sucrose	10 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar[e]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.
[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.
[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.
[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.
[e]Add items 1 and 3–8 to the 500 ml of distilled water (item 10) that contain item 2, adjust pH to 5.2–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium.

General Comments. This is a rapid method for clonal propagation of terete *Vanda* that requires the sacrifice of a shoot, two excisions, and several tissue transfers. Because of that it may seem a bit complicated. However, with limited practice it should be an easy procedure to master.

Stem Culture of Terete-leaf *Vanda*

Until 1967, *Vanda* clones were not being propagated fast enough to suit the needs of Hawaiian growers. In the search for faster methods, a successful attempt was made to develop methods for aseptic stem propagation of *Vanda* Miss Joaquim (Sagawa and Sehgal, 1967).

Plant Material. Clean stems cut into 45–50-mm sections are used.

Surface Sterilization. Use 10% (v/v) Clorox for 20–30 min (10 ml Clorox and 90 ml distilled water).

Culture Vessels. Employ 25 × 100 mm vials containing culture medium to a height of 30–35 mm. As plants become larger, transfer to 125- or 250-ml Erlenmeyer flasks containing 25 or 50 ml medium, respectively.

Culture Conditions. Maintain cultures under conditions appropriate for orchid seed germination (Arditti, 1967; Arditti et al., 1982).

Culture Media. Vacin and Went medium modified by the use of 8 g agar (Table V-4) is used.

Procedure. Sections should be 45–50 mm long with 12–15 mm above and 35–40 mm below the node. Using a sterile razor blade, remove the leaf, exposing the bud. Surface-sterilize with 10% Clorox for 20–30 min. On a sterile surface, using a sterilized razor blade or scalpel, remove 3–4 mm from each end (these are usually discolored portions). Then insert the sections in the medium at a slight angle with approximately 10 mm of the part below the bud in the agar. Place vials under the appropriate culture conditions. Generally, treat sections and the resulting plantlets like seedlings.

Developmental Sequence. Shoot growth may occur first, but within 2–3 months cuttings are are well rooted and ready for planting in a greenhouse.

General Comments. Up to 80% of vegetative stem cuttings produce plantlets with this method. Sections from flower stalks may swell, but the results are not as good.

TABLE V-4. **Modified Vacin and Went medium (Vacin and Went, 1949) for stem culture of terete-leaf *Vanda* (Sagawa and Seghal, 1967)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1 and 3–7 to the 500 ml distilled water (item 9) that contain item 2, adjust pH as required, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium.

Propagation of Strap-leaf *Vanda* by Shoot-tip Culture

Even as late as 1973, limited literature was available on shoot-tip or other tissue culture methods for the clonal propagation of monopodial orchids. Because of that, publication of a new method for the propagation of strap-leaf *Vanda* (*Vanda insignis* × *Vanda tessellata*) was of considerable interest (Teo et al., 1973).

Plant Material. Apical and axillary buds from seedlings of strap-leaf *Vanda* that had 8–12 leaves were used in the original experiments.

Surface Sterilization. The procedures used for *Cymbidium* (Sagawa et al., 1966) are suitable.

Culture Vessels. Vessels employed for *Cymbidium* (Sagawa et al., 1966) can be used.

Culture Conditions. Maintain cultures at 26 ± 3°C under continuous illumination of approximately 200 ft-c. In the original experiment the light sources were General

TABLE V-5. **Modified Vacin and Went medium (Vacin and Went, 1949) for culture of shoot-tip explants from strap-leaf *Vanda* (Kunisaki et al., 1972)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.
[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.
[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.
[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.
[e]Add items 1 and 3–8 to the 500 ml distilled water (item 10) that contains item 2, adjust pH to 5.2–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Dispense medium into culture vessels and autoclave.

Electric Power Groove fluorescent lamps, but others (e.g., Sylvania Gro Lux) should also prove satisfactory. Liquid cultures should be agitated (a New Brunswick Model V shaker operated at 160 rpm was used by Teo et al., 1973).

Culture Media. Modified liquid Vacin and Went medium (Table V-5) is used for initial culture. Proliferation occurs in a second modification of this solution (Table V-6). Differentiation occurs on solid Vacin and Went medium (see Table Aranda-6).

Procedure. Excise and sterilize buds according to the procedure used for the clonal propagation of *Cymbidium* through shoot-tip meristem culture (Sagawa et al., 1966). Place the explants in the initial medium (Table V-5). After 1 month, excise the leaf primordia that cover the explants. When growth and proliferation start, transfer the tissues to the second modification (Table V-6). PLBs will form and separate from each other due to the agitation. These should be moved to solid Vacin and Went medium (see Table Aranda-6) for plantlet formation.

TABLE V-6. **Modified Vacin and Went medium (Vacin and Went, 1949) for the proliferation of shoot-tip explants from strap-leaf *Vanda* (Kunisaki et al., 1972)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	Measure
	Solvent				
9	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1 and 3–8 to the 500 ml distilled water (item 9) that contains item 2, adjust pH to 5.2–5.5, and adjust volume to 1000 ml with distilled water (item 9). Dispense medium into culture vessels and autoclave. For a similar medium with sugar see Table V-5.

Developmental Sequence. Approximately 25% of all cultures can be expected to proliferate. The explants swell initially and then become spherical owing to the development of leaf primordia. If these are not removed, there will be no further proliferation. When they are excised, the tissues proliferate very well on Vacin and Went with coconut water but no sucrose, forming PLBs that are separated by the agitation. Some tissues in proliferating cultures produce PLBs continuously. Others continue to proliferate but also form plantlets. A third group may form clumps of plantlets with only leaves. On transfer to solid Vacin and Went medium, plantlets differentiate from the PLBs.

General Comments. When the buds are visible (i.e., not covered by leaf sheaths), culture contamination rates may be high. This is probably because debris accumulates in the leaf axils, facilitated by the strap leaves. To minimize contamination, it is best to obtain explants from buds that are still tightly enclosed within their sheaths. Owing to the need to perform a second excision and to transfer the tissues at least twice, the procedure may require some practice.

In Vitro Culture of *Vanda* Miss Joaquim

One of the most common and popular hybrids is *Vanda* Miss Joaquim (*Vanda teres* × *Vanda hookeriana*), the national flower of Singapore. It is not surprising, therefore, that a number of workers have used it in efforts to develop tissue culture methods for *Vanda*. One method was developed at the Botany Department of the University of Singapore (Goh, 1970).

Plant Material. Shoot tips, axillary buds, and roots excised from 15-month-old seedlings are used.

Surface Sterilization. Since the tissues are obtained from seedlings growing under sterile conditions, surface decontamination should not be needed. When necessary, tissues can be sterilized for 5 min with 5% (w/v) calcium hypochlorite (5 g calcium hypochlorite mixed with enough distilled water to bring the total volume up to 100 ml) and rinsed with sterile distilled water before being placed into culture.

Culture Vessels. Use 100- or 125-ml Erlenmeyer flasks containing 20 or 25 ml medium, respectively.

Culture Conditions. Shoot cultures should be maintained under 12-h photoperiods (light intensity and type of illumination not given) at 27°C. Root tips were kept in the dark during the initial experiments.

Culture Media. A modification of White's medium (Table V-7) is used for growing the seedlings that serve as explant sources. Shoot and root tips are cultured on another modification of this medium (Table V-8). Excised roots can also be cultured in two additional modifications (Table V-9, V-10).

Vanda Miss Joaquim: a Foundling which Rose to Prominence

Vanda Miss Joaquim is a natural hybrid between *Vanda hookeriana* and *Vanda teres*. It is not known which of them is the seed or pollen parent, but it is reasonably safe to assume that the pollinating agent was a carpenter (*Xylocopa*) bee. The original plant was discovered in 1893 in a clump of bamboo by Miss Agnes Joaquim. The hybrid became a sensation and quickly spread to many countries. *Vanda* Miss Joaquim was a mainstay of the Hawaiian orchid industry for many years, but was eventually replaced by other varieties. With time it was almost forgotten. In 1981 *Vanda* Miss Joaquim was selected to become the National Flower of Singapore and gained prominence again. At present *Vanda* Miss Joaquim can be seen in gardens and parks throughout Singapore. Its image is also on stamps, decorations, currency, jewelry, garments and even refrigerator magnets.

TABLE V-7. **Modified White's medium (White, 1943) for the culture of seedlings of *Vanda* Miss Joaquim (Goh, 1970)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[c]	200	20.0 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4$	360	36 g l^{-1}	10	
3	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	16.5	1.65 g l^{-1}	10	
4	Potassium chloride, KCl	65	6.5 g l^{-1}	10	
5	Potassium nitrate, KNO_3[c]	80	8 g l^{-1}	10	
6	Sodium sulfate, Na_2SO_4	200	20.0 g l^{-1}	10	
7	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	3.4	344 mg l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	4.66	466 mg l^{-1}		
8	**Microelements**[e]				
(a)	Boric acid, H_3BO_3[f]	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$[f]	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$[f]	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	6.65	665 mg l^{-1}		
(e)	Potassium iodide, KI	0.75	75 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$[f]	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	2.67	267 g l^{-1}		
	Amino acid				
9	Glycine	3	300 mg 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
11	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
13	Coconut water	200 ml	No stock	No stock	Measure
	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation, and modernization of the medium (Singh and Krikorian, 1981). As a result the microelements and iron vary slightly from the one used by Goh (1970).

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved. Dispense volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to add.

[g]Keep refrigerated or frozen between uses.

[h]Add items 1–8 and 13 to 700 ml distilled water (item 15), adjust pH to 5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add items 9–12 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE V-8. **Modified White's medium (White, 1943) for the culture of shoot tips and axillary buds of *Vanda* Miss Joaquim (Goh, 1970)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation, and modernization of the medium (Singh and Krikorian, 1981). As a result the microelements and iron vary slightly from the one used by Goh (1970).

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved. Dispense volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to add.

[g]Keep refrigerated or frozen between uses.

[h]Commercial tomato juice, even so-called "natural" brands, may contain preservatives that can inhibit growth. Therefore it may be advisable to squeeze fresh ripe tomatoes, filter the juice to remove all seeds (which may also contain inhibitors), and use the filtrate. Store unused portions in a freezer.

[i]Add items 1–8 and 13 to 700 ml distilled water (item 15), adjust pH to 5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add items 9–12 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE V-10. **Modified White's medium (White, 1943) for the culture of root tips of *Vanda* Miss Joaquim (Goh, 1970)**[a]

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation, and modernization of the medium (Singh and Krikorian, 1981). As a result the microelements and iron vary slightly from the one used by Goh (1970).

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved. Dispense volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to add.

[g]Keep refrigerated or frozen between uses.

[h]Add items 1–8 to 700 ml distilled water (item 15), adjust pH to 5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add 100 mg auxin (item 13) to combined items 9–12 in a small vial, shake well several times at 5-min intervals and allow mixture to stand before adding to hot solution under sterile conditions with sterilized pipettes. Mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

Procedure. Place explants into culture and allow them to develop. Remove plantlets, when formed, and culture individually.

Developmental Sequence. Rapid cell division takes place in shoot-tip explants, forming new growth centers. Some of them become organized into growing apices from which young shoots develop within about 3 months. When excised and subcultured, these shoots produce one or more plantlets.

Axillary buds give rise to side shoots when cultured on a solid medium. No roots are produced, however; therefore, plantlets are not formed.

Roots elongate in culture and turn white. Their anatomical features are the same as those of normal roots.

General Comments. Shoot-tip explants can be used for the clonal propagation of *Vanda* Miss Joaquim. On an appropriate medium, roots should develop on the shoots that arise from axillary buds. Perhaps the medium used to induce root formation on *Dendrobium* shoots (see Table Den-20) could be used.

Mericloning of *Vanda* through the Culture of Axillary Buds

The procedures employed for the culture of *Aranda*, *Dendrobium*, *Mokara*, and *Oncidium* (Khaw et al., 1978*a*, 1978*b*) can be used to culture apical and axillary buds of *Vanda*.

In Vitro Clonal Multiplication of *Vanda*

The propagation of *Vanda* from seeds and through tissue culture was studied extensively at the Plant Morphogenesis and Tissue Culture Section, Bio-Organic Division, Bhaba Atomic Research Centre, Bombay, India (Mathews and Rao, 1980, 1985*a*) leading to a tissue culture method (Mathews and Rao, 1985*b*).

Plant Material. In the original research, shoot tips 0.2–0.3 mm and 0.5 mm long and young leaves 5–15 mm in length were excised from seedlings of *Vanda* TMA × *Vanda* Miss Joaquim.

Surface Sterilization. There is no need to surface-sterilize explants taken from plants that are growing in vitro.

Culture Vessels. Test tubes and Erlenmeyer flasks can be used.

Culture Conditions. Cultures should be kept under continuous illumination of 900 lx (sources not listed) at 25 ± 2°C and 55–60% relative humidity.

Culture Media. An effective medium for the culture of shoot-tip explants and young leaves contains 2-isopentenyl adenosine (Table V-11). Other media tested during the original research also supported growth.

TABLE V-11. **Medium for the culture of *Vanda* explants (Mathews and Rao, 1980, 1985*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	500	50 g l^{-1}	10	
2	Ammonium sulfate, $(NH_4)_2SO_2$	400	50 g l^{-1}	10	
3	Calcium sulfate, $CaSO_4 \cdot 2H_2O$	80	8 g l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	180	18 g l^{-1}	10	
6	Potassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.6	60 mg l^{-1}	10	One solution
(b)	Cobalt nitrate, $Co(NO_3)_2 \cdot 6H_2O$	0.05	5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot H_2O$	0.05	5 mg l^{-1}		
(d)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	0.4	40 mg l^{-1}		
(e)	Potassium iodide, KI	0.03	3 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.05	5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.05	5 mg l^{-1}		
	Cytokinin				
9	2-Isopentenyl adenosine (2ip)	8	No stock	No stock	Weigh
	Vitamins				
10	Biotin	0.05	10 mg 100 ml^{-1} 95% ethanol[e]	0.5	
11	Folic acid	0.3	60 mg 100 ml^{-1} 95% ethanol	0.5	
12	Niacin (nicotinic acid)	1.25	250 mg 100 ml^{-1} 95% ethanol[e]	0.5	
13	Pyridoxine (vitamin B_6)	0.3	60 mg 100 ml^{-1} 95% ethanol[e]	0.5	
14	Riboflavine	0.05	10 mg 100 ml^{-1} 95% ethanol[e]	0.5	
15	Thiamine (vitamin B_1)	0.3	60 mg 100 ml^{-1} 95% ethanol[e]	0.5	
	Sugar				
16	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[f]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1–15 to 900 ml distilled water (item 17), adjust pH to 5.6–5.6, add sugar (item 16), and adjust volume to 1000 ml with distilled water (17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium. Media that contain hormones and vitamins should not be autoclaved unless prior experimentation has determined that the effects will not be deleterious. This is such a case.

Procedure. Explants are placed on the medium and allowed to form plantlets and/or PLBs. These can be moved to the same medium (Table V-11), to Knudson C solution (see Table Aranda-7), or to Vacin and Went formulation (see Table Aranda-6) for further differentiation and growth.

Developmental Sequence. Both the shoot-tip explants and young leaves produced PLBs. The main region of PLB production by leaves is the basal meristem.

General Comments. Like other procedures based on seedlings this method may or may not prove to be suitable for mature plants.

Mericloning of *Vanda* through the Culture of Root and Leaf Tips

Mass rapid clonal propagation of monopodial orchids

> "by shoot meristem culture has proved too impracticable. More often than not, the prized individual is killed as a result of excision of the only shoot meristem of the plant, and the explant also does not survive because of infection. It is, therefore, necessary to employ meristematic tissues of other organs, *viz.*, tips of leaf and root." (Chaturvedi and Sharma, 1986)

Plant Material. In the original research, root and leaf tips 2–8 mm long were excised from "aseptically established plants" (Chaturvedi and Sharma, 1986), which could refer to either seedlings or clonally propagated plantlets or both.

Surface Sterilization. There is no need to surface-sterilize plants that are growing under aseptic conditions.

Culture Vessels. Culture tubes and Erlenmeyer flasks can be used.

Culture Conditions. Cultures should be maintained at 27 ± 1°C under 14-h photoperiods of 3000 lx provided by fluorescent tubes.

Culture Media. A modified Vacin and Went medium (Table V-12) served as the basal solution. Formation of PLBs occurs on a modification of this medium (Table V-13). Plantlet development takes place on a third version (Table V-14). Unmodified Vacin and Went medium (see Table Aranda-6) can be used for growth of these plantlets.

Procedure. Place explants on the initial medium (Table V-12), and allow them to establish themselves. To form PLBs move the explants to the second modification (Table V-13). When small plants are visible, move them to the third medium (Table V-14) for development. Larger plants can be moved to unmodified Vacin and Went medium (see Table Aranda-6).

Developmental Sequence. Explants first increase in size and root tips turn green. After approximately 15 days, PLBs start to form. Bases of leaf-tip explants swell and start to form PLBs within 10 days. Explants on the second medium "showed

TABLE V-12. **Modified Vacin and Went medium (Vacin and Went, 1949) used as a basal solution for the culture of *Vanda* explants (Chaturvedi and Sharma, 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

12	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
13	Water, distilled[e]	To 1000 ml			
	Solidifier				
14	Agar[g]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved.

[f]Keep refrigerated or frozen between uses.

[g]Add items 1 and 3–8 to the 500 ml distilled water (item 13) that contain item 2, adjust pH to 5.2–5.5, add sugar (item 12), and adjust volume to 1000 ml with distilled water (item 13). Bring solution to a gentle boil, and add agar (item 14) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into a 2-l flask and autoclave. Add vitamins (items 9–11) under sterile conditions, swirl flask several times to insure complete mixing, and dispense medium into preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE V-13. **Modified Vacin and Went medium (Vacin and Went, 1949) for the induction of protocorm-like bodies from *Vanda* explants (Chaturvedi and Sharma, 1986)**

	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar[h]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.

[d]The iron salt used in the original recipe for this medium is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved.

[f]Keep refrigerated or frozen between uses.

[g]If auxins or cytokinin do not dissolve, add a few drops of KOH or HCl, respectively.

[h]Add items 1, 3–8, and 15 to the 500 ml distilled water (item 17) that contains item 2, adjust pH to 5.2–5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l Erlenmeyer flask and autoclave. Add vitamins (items 9–11) and hormones (items 12–14) under sterile conditions, swirl flask several times to insure complete mixing, and dispense medium into preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE V-14. **Modified Vacin and Went medium (Vacin and Went, 1949) for the development of *Vanda* plantlets (Chaturvedi and Sharma, 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.

[d]The iron salt used in the original recipe for this medium is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Add all microelements to the same 1 l of distilled water, and stir and/or heat until dissolved.

[f]Keep refrigerated or frozen between uses.

[g]Add items 1, 3–8, and 13 to the 500 ml distilled water (item 15) that contains item 2, adjust pH to 5.2–5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add vitamins (items 9–11) and hormone (item 12) under sterile conditions, swirl flask several times to insure complete mixing, and dispense medium into preautoclaved culture vessels. Omit agar if preparing liquid medium.

enormous proliferation of plb's and within a period of 30 days hundreds of them were formed." The PLBs develop leaves and form tiny plantlets, which become larger on the third medium.

General Comments. Like other procedures based on seedlings this method may or may not prove to be suitable for mature plants. Those who attempt to culture root tips from mature plants must select explants that do not contain fungi. It is possible, but not certain, that the tips of very young leaves of mature plants may respond to culture like leaf explants from seedlings.

Clonal Propagation of *Vanda* through the Culture of Flower Stalks and Buds

Flower buds have been used to culture a number of orchids and other plants. Research at the University of the Philippines, Los Baños has extended this approach to *Vanda* (Valmayor et al., 1986).

Plant Material. Inflorescence tips with flower buds attached are cultured. The bracts that cover or subtend each bud are removed.

Surface Sterilization. Cut the inflorescences, swab them with alcohol, surface-sterilize by immersing them in 1% calcium hypochlorite (1 g calcium hypochlorite in 100 ml distilled water stirred several times at 3–5-min intervals and filtered or decanted) for 30–40 min, and rinse three times with sterile distilled water. After that remove the bracts, immerse the explants for 30–60 s in 0.5% calcium hypochlorite (50 ml of the previous solution diluted to 100 ml with distilled water), and rinse again with sterile distilled water.

Culture Vessels. Erlenmeyer flasks are used for liquid or solid medium. Culture tubes or Erlenmeyer flasks can be employed for agar media.

Culture Conditions. Illumination and temperature regimes employed with other procedures for the culture of *Vanda* explants are suitable.

Culture Media. Explants should be cultured initially on a liquid modified Knudson C medium (Table V-15). PLBs formed on this medium differentiate well on unmodified Vacin and Went solution (see Table Aranda-6).

Procedure. Place explants in liquid medium (Table V-15; presumably on a shaker), and culture until PLBs form. These can be subcultured on the same medium (Table V-15) or moved to Vacin and Went solution (see Table Aranda-6) for differentiation and growth. The PLBs can be cultured in the initial medium (Table V-15) without subculture for 1–2 months. However, proliferation is more rapid if the PLBs are subcultured often by being moved to fresh medium (Table V-15). PLBs and plantlets can be moved to the second medium (see Table Aranda-6) containing banana homogenate after 2 months. If moved earlier they may die.

TABLE V-15. **Modified Knudson C medium (Knudson, 1946) for the culture of *Vanda* explants (Valmayor et al., 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Cytokinins				
7	Benzyladenine (BA)	1	20 mg 100 ml^{-1} 95% ethanol[d,e]	0.5	
8	Kinetin	1	20 mg 100 ml^{-1} 95% ethanol[d,e]	0.5	
	Complex additive				
9	Coconut water	150 ml	No stock	No stock	Weigh
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[d]Keep refrigerated between uses.

[e]If cytokinins fail to dissolve, add a few drops of dilute HCl.

[f]Add items 1–6 and 9 to 700 ml distilled water (item 11), adjust pH to 5.0–5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Pour solution into a 2-l flask, and autoclave. Add cytokinins (items 7 and 8) under sterile conditions, swirl well to insure complete mixing, and dispense into preautoclaved culture vessels. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in an autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl), to lower pH if necessary.

Developmental Sequence. Formation of PLBs and plantlet growth is rapid, and plantlets that can be moved to community pots grow within a relatively short period.

General Comments. This system should serve as a model since it is effective, rapid, applicable to mature plants, and does not endanger the plant that serves as a source for explants.

Micropropagation of the Blue Vanda, *Vanda coerulea*

Sometimes called the queen of the vandas, *Vanda coerulea* was discovered in the Khasi Hills of Assam, India, in 1857. Its flowers are blue and/or purple, large, numerous and long-lasting. Some plants may bloom several times a year. This beautiful orchid is a "victim to its own beauty" and was threatened with extinction due to overcollecting. One attempt at conservation through micropropagation was made at the Tropical Botanic Garden and Research Institute, Palode Trivandrum, India (Anonymous, 1987).

Plant Material. Leaf bases (0.5–0.8 cm) and intact leaves with meristematic bases, both taken from seedlings, were cultured in the original research.

Surface Sterilization. There is no need to surface-sterilize explants taken from seedlings that grow under aseptic conditions.

Culture Vessels. Culture tubes and Erlenmeyer flasks can be used.

Culture Conditions. The cultures should be maintained under 12-h photoperiods of 4000 lx provided by fluorescent tubes at 25 ± 2°C.

Culture Media. A medium consisting of 800 mg Gaviota-63 l^{-1}, 30% coconut water, 500 mg peptone l^{-1}, 1 mg NAA l^{-1}, 1 mg BA l^{-1} and 7 g agar l^{-1} gave the best results. Satisfactory results can also be obtained on a modified Mitra, Prasad, and Roychowdhury medium (Table V-16). The addition to 70 g banana l^{-1} increases plantlet production.

Procedure. Place explants on the culture medium and allow to develop. To increase proliferation section the callus with the PLBs and transfer the segments to a medium containing 70 g banana l^{-1}. When the plantlets are large enough, they should be moved to community pots.

Developmental Sequence. Leaf bases (whether the leaves have been excised or are intact) swell and produce callus masses within 3 weeks. Shoots can form directly from the callus or from PLBs. Growth of shoots continues for 12 weeks, at which time roots appear. At the end of 14 weeks it is possible to harvest up to 70 plantlets from a single leaf base. The number can be doubled on banana-containing medium.

General Comments. If enough seeds are available, a clonal propagation procedure for seedlings is more valuable as a starting point for future research and attempts to culture explants from mature plants. When seeds are not available, such a method can be used to increase the number of rare and/or valuable seedlings.

TABLE V-16. **Modified Mitra, Prassad, and Roychowdhury medium (Mitra et al., 1976) for the culture of *Vanda coerulea* explants**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original recipe used 3 ml $Na_2FeEDTA$, which may not be readily available. The substitute listed here is very common in orchid tissue culture media. Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep refrigerated or frozen between uses.

[f]If auxin or cytokinin do not dissolve, add a few drops of KOH or HCl, respectively.

[g]Add items 1–16 to 900 ml distilled water (item 18), adjust pH to 5.6, add sugar (item 17), and adjust volume to 1000 ml with distilled water (item 18). Bring solution to a gentle boil, and add agar (item 19) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium. Media that contain hormones and vitamins should not be autoclaved unless prior experiments have determined that this will have no deleterious effects. This is such a case (Mitra, 1971; Mitra et al., 1976), so medium may be autoclaved.

Development of Colchicine-treated *Vanda*

Some PLBs of *Vanda* Louise de Waldner (*Vanda* Waikiki × *Vanda teres*) treated with 0.05–0.15% colchicine for 5–20 days developed "leaves with curly tips and maroon coloration. . . . A few developed flower-like structures. . . . When potted out these variant plants" remained stunted, produced only a few roots, and died before reaching a height of 3 cm (Lim-Ho et al., 1988)

Isolation of *Vanda* Protoplasts

The method developed for *Acampe praemorsa* was used to isolate 14.1×10^4 and 5.5×10^4 protoplasts from leaves and roots, respectively, of *Vanda teres* (Seeni and Abraham, 1986).

Clonal Multiplication of *Vanda* through Root- and Leaf-tip Culture in Vitro

Root and leaf tips taken from "aseptically-grown plantlets" (probably seedlings) of *Vanda* TMA × *Vanda teres* formed PLBs on a modified Vacin and Went medium supplemented with 1 ppm BA, 1 ppm NAA, and 200 ppm casein hydrolysate (CH). The PLBs develop without callus formation. The plantlets proliferate with periodic subculture (every 2 months) on a medium containing 0.5 ppm BA, 1 ppm IAA, and 0.1 ppm 2,4-D. Plantlets develop well on a medium containing 0.1 ppm IAA and 200 ppm CH (Sharma and Chaturvedi, 1988).

Micropropagation of *Vanda coerulea* through the Culture of Leaf Bases

Leaf bases of *Vanda coerulea* seedlings formed PLBs and plantlets on "solid nutrient media in different factorial combinations of naphthaleneacetic acid (NAA) and 6-benzylaminopurine (BA) . . . in modified Mitra . . . medium and also in the Gaviota-63 fertilizer supplemented with 35 g [l^{-1}] banana pulp" and 1 ppm BA plus 0.75 ppm NAA (Seeni, 1988).

Plantlet Regeneration from Root Tips of *Vanda testacea*

Root tips without apices of *Vanda testacea* taken from 32-week-old seedlings developed

> shoot buds or . . . PLBs at their proximal regions in certain selective combinations. BAP [BA] was obligatory for PLBs regeneration, whereas [kinetin] and GA_3 [gibberellic acid] in the medium promoted only shoot buds. Shoot buds and differentiating callus were simultaneously formed when only IAA was used in the medium and seedlings complete with leaves and roots were formed within 10 weeks in this combination. (Vij and Pathak, 1988*b*)

Clonal Propagation of *Vanda* through the Culture of Leaf Explants

PLBs form on explants from seedling leaves of *Vanda* cultured by a method developed for *Phalaenopsis* (Tanaka et al., 1974).

Plantlet Production from Root Explants of *Vanda bicolor*

William Griffith (1810–1845), who was Assistant-Surgeon in Madras and Superintendent of the Calcutta Botanic Garden, named this Himalayan species. Its sepals and petals are spatulate with undulate margins and brownish-purple in color with yellow markings (Fig. V-1A, B; Teuscher, 1977).

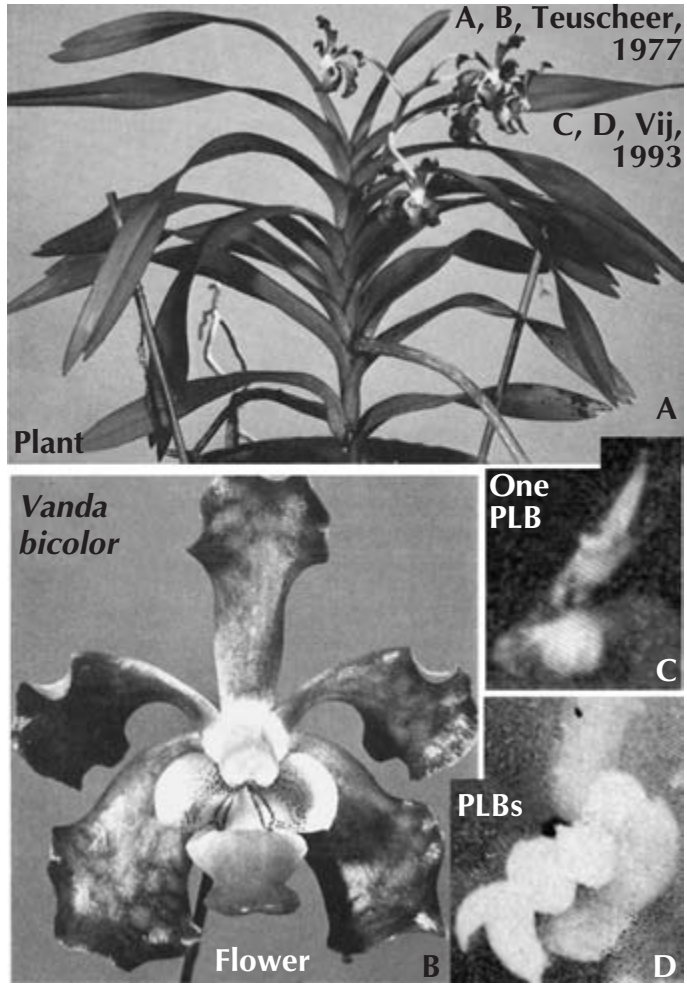

FIG. V-1. ***Vanda bicolor*** **and its micropropagation. A. The whole plant. B. Flower. C. PLBs forming on an explant. D. A proliferating PLB. (Sources: A, B, Teuscher, 1977; C, D, Vij, 1993.)**

Plant Material. Root explants (tips with and without well-developed caps) were taken from 16–30-week-old seedlings in vitro.

Surface Sterilization. Explants taken from seedlings in axenic culture do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, or other containers are suitable.

Culture Conditions. The original research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

Culture Media. To bring about the formation of PLBs, the explants should be cultured on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing 1 mg kinetin l^{-1} and 1 mg NAA l^{-1} (Table V-17). PLBs multiply on MPR with 1 mg kinetin l^{-1} (Table V-18). Media for plantlet formation and growth are not suggested in the original report. No medium/media is/are suggested for plantlet formation and the culture of plantlets to maturation. Suitable media for this may be one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. The explants are placed on the first medium (Table V-17) and cultured on it until PLBs are formed. If the explants release exudates which darken the medium they should be moved to new culture vessels with fresh substrate. PLBs are moved to the second medium (Table V-18) for proliferation. Once there are enough PLBs, shoots, and plantlets they can be cultured on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Rntda-1, V-4, and Pln-1).

Developmental Sequence. PLBs form on the explants (Fig. V-1C) on the first medium (Table V-17). They proliferate (Fig. V-1D) on the second medium (Table V-18) and may form shoots and plantlets on this solution or on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Rntda-1, V-4, and Pln-1). Leaves appear after 5 weeks and roots form 3 weeks after that.

General Comments. The removal of root tips from a plant does not endanger it. Also plants produce many root tips. Therefore using root tips as explants is a clever idea. However, a method for the micropropagation of seedlings may prove to be useful mainly for the multiplication of seedlings when only a few are produced by a cross. As a means of propagating desirable clones, a method using explants from seedlings is not useful because the quality of the plants is not known.

TABLE V-17. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Vanda bicolor* root explants (Vij, 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or the cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE V-18. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the proliferation of protocorm-like bodies of *Vanda bicolor* derived from root explants (Vij, 1993)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve add a few drops of 0.1 N HCl.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and bring volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

Micropropagation of *Vanda cristata* through the Culture of Root Explants

Found in Tibet, the Himalayas from Nepal to Bhutan, Khasia, and Bangladesh this species was discovered in Nepal by Nathaniel Wallich and named *Vanda cristata* by John Lindley. In 1986, Leslie A. Garay segregated *Trudelia* from the genus *Vanda* on the basis of floral structure and in 1988 Karheinz Senghas transferred *Vanda cristata* to the new genus as *Trudelia cristata* (Bechtel et al., 1992; Grove, 1995). A method for its micropropagation through the culture of root explants was developed at the Department of Botany, Panjab University (Vij, 1993).

Plant Material. Root explants (tips with and without well-developed caps) were taken from 16–30-week-old seedlings in vitro.

Surface Sterilization. Explants taken from seedlings in axenic culture do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, or other containers are suitable.

Culture Conditions. The original research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

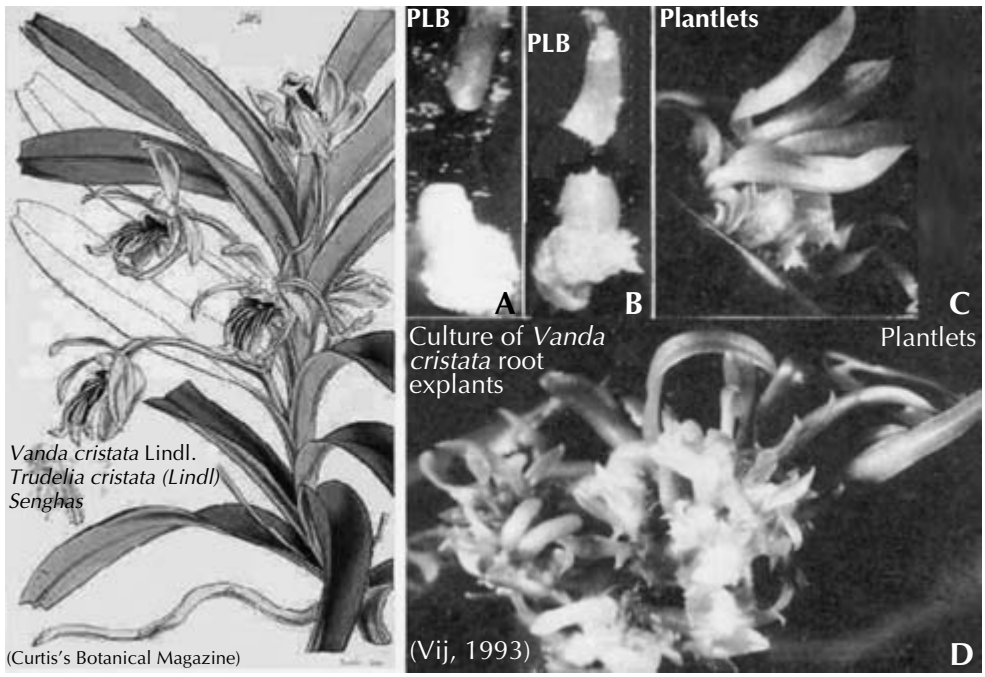

FIG. V-2. ***Vanda cristata*** **(left) and its micropropagation through the culture of root tips.**

Culture Media. To bring about the formation of PLBs, the explants should be cultured on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing 1 g peptone l^{-1} and 1 mg gibberellic acid (GA_3) l^{-1}, and 0.2% activated charcoal (Table V-19). PLBs multiply and produce plantlets on the same medium. No medium/media is/are suggested for plantlet formation and the culture of plantlets to maturation. Suitable media for this may be one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. The explants are placed on the medium (Table V-19) and cultured on it until PLBs are formed. If the explants release exudates which darken the medium they should be moved to a new culture vessel with fresh substrate. PLBs are moved to fresh medium of the same composition (Table V-19) for proliferation and plantlet formation. Once there are enough PLBs, shoots, and plantlets they can be cultured on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Rntda-1, V-4, and Pln-1).

Developmental Sequence. PLBs form (Fig. V-2A, B) on the explants after 4 weeks of culture. The first leaves appear after 5 weeks. Roots form 5 weeks after that (i.e. 10 weeks after the start of culture).

General Comments. The use of root tips as explants does not endanger the donor plant because plants produce many root tips. However, a method for micropropagation of seedlings cannot be used to propagate outstanding forms since the quality of seedlings is not known. Such a method can be of limited use in the multiplication of seedlings when only a few can be produced. This procedure is one of a few to use a GA_3-containing medium.

TABLE V-19. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Vanda cristata* root explants (Vij, 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100.0	10.0 g l^{-1}	10

14	Gibberellic acid (GA_3)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1.0	
	Complex additive				
15	Peptone[f]	1.0 g	No stock	No stock	Weigh
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	7.0 g	No stock	No stock	Weigh
	Darkening agent				
19	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Peptones can vary. It is best to use a peptone which is described as being suitable or tested for plant tissue culture media.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add the charcoal (item 19) with vigorous stirring to insure equal distribution through the solution, pour the medium into culture vessels, and autoclave. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

Root Tip Culture of *Vanda* "Kasem"

The name Kasem, that of a famed Thai *Vanda* breeder, is in quotation marks above because there is no *Vanda* by that name. However there is a hybrid named Kasem's Delight which is probably the plant from which root tips were taken for culture (Vij, 1993).

Plant Material. Root explants (tips with and without well-developed caps) were taken from 16–30-week-old seedlings in vitro.

Surface Sterilization. Explants taken from seedlings in axenic culture do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, or other containers are suitable.

Culture Conditions. The original research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

Culture Media. To bring about the formation of PLBs, the explants should be cultured on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing 1 mg IAA l^{-1} (Table V-20). PLBs multiply but there is no report that they produce plantlets on the same medium. No medium/media is/are suggested for plantlet formation. Suitable media for plantlet production and growth may be one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. The explants are placed on the medium (Table V-20) and cultured on it until PLBs are formed. If the explants release exudates which darken the medium they should be moved to a new culture vessel with fresh substrate. PLBs are moved to fresh medium of the same composition (Table V-20) for proliferation. Once there are enough PLBs, they can be cultured on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Rntda-1, V-4, and Pln-1).

Developmental Sequence. PLBs (Fig. V-3A) will form on approximately 25% of the explants after 5 weeks of culture. There is no information about plantlet production.

General Comments. The use of root tips as explants does not endanger the donor plant because plants produce many roots tips. However, a method for the

TABLE V-20. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Vanda* Kasems's Delight root explants (Vij, 1993)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve add a few drops of 0.1 N KOH.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and bring volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

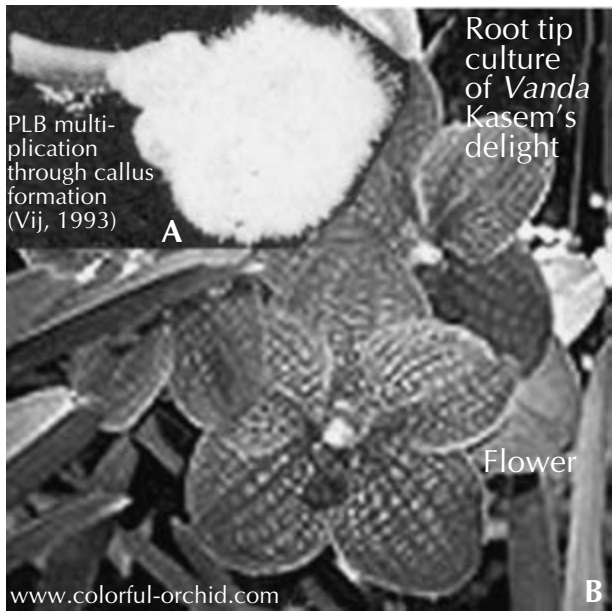

FIG. V-3. **Root-tip explant culture of *Vanda* Kasem's Delight. A. PLBs. B. Flower.**

micropropagation of seedlings cannot be used to propagate outstanding forms since the quality of seedlings is not known. Such a method can be of limited use in the multiplication of seedlings when only a few can be produced. It is possible that in this case the PLBs will not produce plantlets.

Plantlet Production of *Vanda teres* through the Culture of Root Tips

Vanda teres is distributed from the Himalayas to Burma, Laos, Thailand, and Vietnam (Hew et al., 2002). It is still grown in collections and gardens, but its main claim to fame is as a parent of the national flower of Singapore, *Vanda* Miss Joaquim (Hew et al., 2002). A method for plantlet production from its root tips was developed in India (Vij, 1993).

Plant Material. Root explants (tips with and without well-developed caps) were taken from 16–30-week-old seedlings in vitro.

Surface Sterilization. Explants taken from seedlings in axenic culture do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, or other containers are suitable.

Culture Conditions. The original research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	7.0 g	No stock	No stock	Weigh
	Darkening agent				
18	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Yeast extracts can vary. It is best to use a peptone which is described as being suitable or tested for plant tissue culture media.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and bring volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add the charcoal (item 18) with vigorous stirring to insure equal distribution through the solution, pour the medium into culture vessels and autoclave. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

Culture Media. To bring about the formation of PLB and plantlet production, the explants should be cultured on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing 1 g yeast extract l^{-1} and 2 g activated charcoal l^{-1} (Table V-21). No medium/media is/are suggested for plantlet formation. Suitable media for plantlet production and growth may be one of the versions of Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. The explants are placed on the medium (Table V-21) and cultured on it until PLBs are formed. If the explants release exudates which darken the medium they should be moved to a new culture vessel with fresh substrate. PLBs are moved to fresh medium of the same composition (Table V-21) for proliferation. Once there are enough PLBs, they can be cultured on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Rntda-1, V-4, and Pln-1).

Developmental Sequence. Approximately 12.5% of the explants will produce plantlets (Fig. V-4A) after 4 weeks of culture.

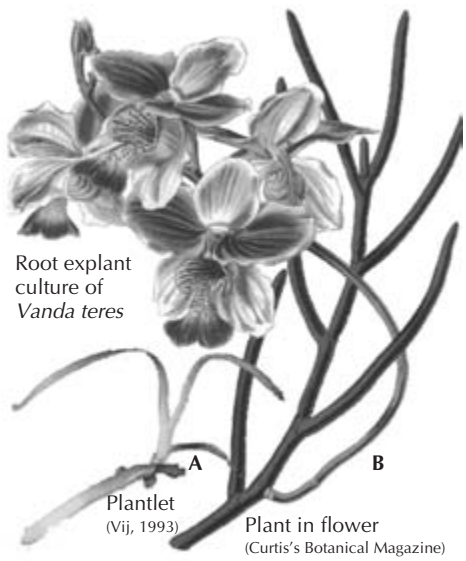

FIG. V-4. **Root explant culture of *Vanda teres*. A. Plantlet. B. Flower. (Vij, 1993.)**

General Comments. The use of root tips as explants does not endanger the donor plant because plants produce many roots tips. However, a method for the micropropagation of seedlings cannot be used to propagate outstanding forms since the quality of seedlings is not known. Such a method can be of limited use in the multiplication of seedlings when only a few can be produced. It is possible that in this case the PLBs will not produce plantlets. According to some taxonomists the correct name of this species is *Papilionanthe teres*.

Micropropagation of *Vanda testacea* through the Culture of Root Explants

Distributed in Assam, Burma, India, Nepal, Sikkim, Sri Lanka, and Thailand, *Vanda testacea* is also considered to be a synonym of *Vanda parviflora* (or vice versa). A micropropagation method using root tips was developed in India (Vij, 1993).

Plant Material. Root explants (tips with and without well-developed caps) were taken from 16–30-week-old seedlings in vitro.

Surface Sterilization. Explants taken from seedlings in axenic culture do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, or other containers are suitable.

Culture Conditions. The original research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

Culture Media. To bring about the formation of PLB and plantlet production, the explants should be cultured on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing 1 g peptone l^{-1}, 1 mg BA l^{-1}, and 2 g activated charcoal l^{-1} (Table V-22). No medium/media is/are suggested for plantlet formation. Suitable media for plantlet production and growth may be one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. The explants are placed on the medium (Table V-22) and cultured on it until PLBs are formed. If the explants release exudates which darken the medium they should be moved to a new culture vessel with fresh substrate. PLBs are moved to fresh medium of the same composition (Table V-22) for proliferation. Once there are enough PLBs, they can be cultured on the same medium (Table V-22) or on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19,

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses. If the cytokinin does not dissolve add a few drops on 0.1 N HCl.

[f]Peptones can vary. It is best to use a peptone which is described as being suitable or tested for plant tissue culture media.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add the charcoal (item 19) with vigorous stirring to insure equal distribution through the solution, pour the medium into culture vessels and autoclave. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

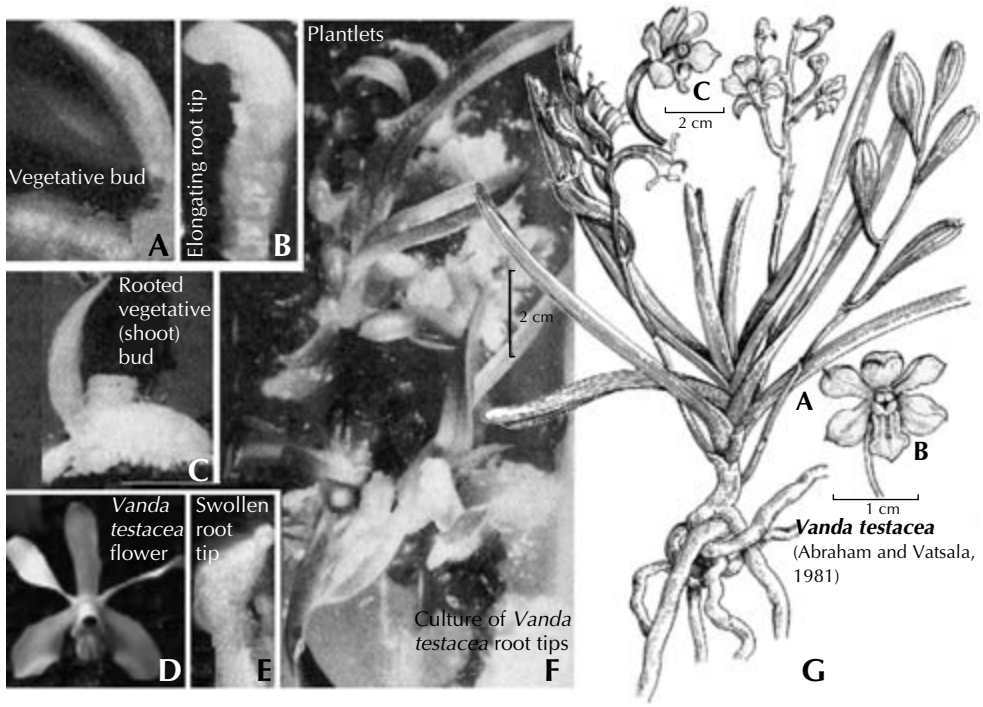

FIG. V-5. **Micropropagation of *Vanda testacea*. A. Vegetative bud. B. Elongating root tip. C. Rooted vegetative (shoot) bud. D. Flower. E. Swollen root tip. F. Plantlets. G. Botanical drawing. (Sources: A–C, E, F, Vij, 1993; D, photograph by Joseph Arditti; G, Abraham and Vatsala, 1981.)**

Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Rntda-1, V-4, and Pln-1).

Developmental Sequence. Approximately 25% of the explants respond by elongating (Fig. V-5B), swelling (Fig. V-5E), producing buds (Fig. V-5A), rooting (Fig. V-5C), and generating plantlets (Fig. V-5F) after 4–9 weeks of culture.

General Comments. The use of root tips as explants does not put the donor plant at risk because plants produce many roots tips. However, a method for the micropropagation of seedlings cannot be used to propagate outstanding forms since the quality of seedlings is not known. Such a method can only be of limited use in the multiplication of seedlings when only a few can be produced. It is possible that in this case the PLBs will not produce plantlets.

Production of *Vanda coerulea* Plantlets from Foliar Peels

Foliar peels are abundant, their removal does not endanger or even damage the donor plant, and they "are low in endogenous growth hormones . . . and are thus expected

to be more sensitive to even slightest changes [in] the quantity and quality of . . . growth regulators. . . .” Therefore, they are very suitable as explants for micropropagation of *Vanda coerulea* (Fig. V-6A) and other orchids (Vij and Kaur, 1992; Vij, 1994).

Plant Material. In the original research “peels, 1–4 layers in thickness and 0.5 mm in length were . . . [taken from] juvenile leaves [of] *in vitro* raised cultures.” It is not clear from this statement whether the “cultures” were of seedlings or plantlets produced through tissue culture. Also, photographs (see Figs Rhy-2A and V-6B, C) suggest that the length should be 0.5 cm.

Surface Sterilization. Explants from in vitro cultures do not require sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, or other containers can be used.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. Several hormone combinations in the Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) were used in the original research. MPR with 1 mg l^{-1} each of NAA and BA (Table V-23) seems most suitable.

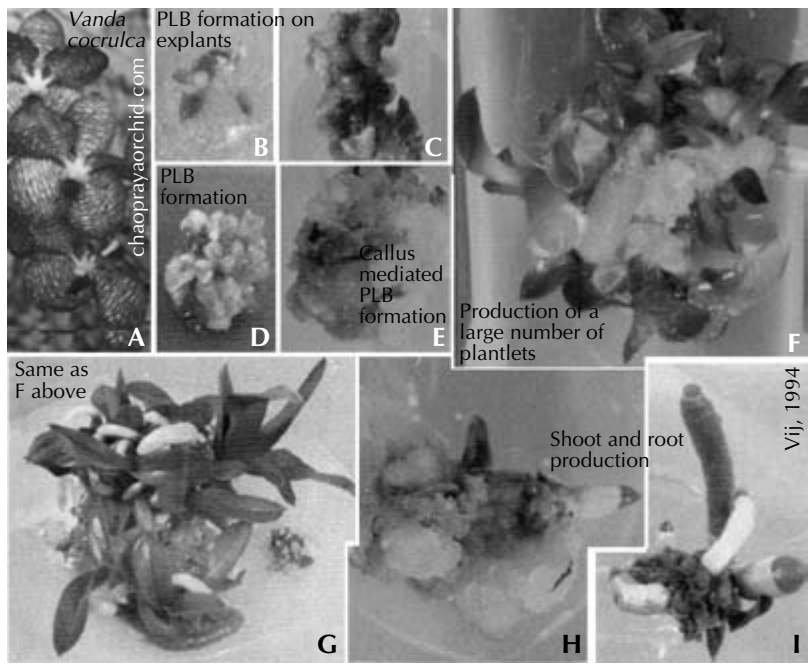

FIG. V-6. **Culture of dermal peels of *Vanda coerulea*.**

TABLE V-23. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Vanda coerulea* leaf peels (Vij and Kaur, 1992; Vij, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100.0	10.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	200.0	20.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	180.0	18.0 g l^{-1}	10	
5	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	150.0	15.0 g l^{-1}	10	
6	**Chelated iron**[c]

	Auxin				
14	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1 ml	
	Cytokinin				
15	Kinetin	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1 ml	
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCL, respectively.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.6, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

Procedure. Peels are placed on the medium (Table V-23) where they form PLBs (Fig. V-6B–E) and eventually leaves, roots and plantlets (Fig. V-6F–I). If cultures become crowded, PLBs or plantlets should be subcultured on the same medium.

Developmental Sequence. PLBs are produced by 100% of explants after 3 weeks of culture. Plantlets (up to 25 per plant) are formed after 14 weeks.

General Comments. Explants from seedlings cannot be used to propagate specific cultivars, but this is less important for species than for hybrids.

Micropropagation of the Blue *Vanda*

> Protocorm-like bodies (plbs) [of *Vanda coerulea*, the Blue *Vanda*] were easily induced in axenic seedling-derived leaf base segments and cut basal ends of whole leaves cultured in Mitra et al. agar medium (1976) supplemented with organic additives (sucrose, coconut water, peptone and casein acid hydrolysate) and a combination of 1 mg/l BA and 0.75 mg/l NAA. While all the leaves of the seedlings were regenerative, approximately 40% of the leaves of the flowering plants produced callus to varying degrees but never formed plbs or shoots. Clonal propagation was, however, achieved with the successful production of plbs and shoots in shoot tip cultures. In liquid cultures, maximum proliferation of plbs was obtained with tender leaves measuring less than 8 mm. Proliferation of additional plbs with simultaneous differentiation of shoots from the first formed ones and accelerated growth of the shoots occurred if the tissues were subcultured to medium enriched with 70 g/l banana homogenate. Whole leaves produced a larger number of shoots than leaf base segment and shoot tip cultures. A maximum of 102, 62 and 68 shoots from the whole leaf, leaf base segment and shoot tip cultures, respectively, was obtained after 24 weeks of culture.
>
> Shoots of varying size with or without roots were separated and replanted in the medium to induce rooting and further growth of the shoots. Some of the shoots produced additional suckers during this period. Eight-months-old rooted plantlets were planted in 2″ clay pots containing a potting mixture of charcoal chips and broken tiles where the survival rate exceeded 95%. Root tip squashes prepared from 25 randomly collected samples showed a chromosome complement of 2n = 38. (Seeni, 1990)

Culture of *Vanda coerulea* Shoot Tips and Leaf Segments

Vanda coerulea was first collected in 1837 by William Griffith in the Jyntea and Khasia Hills in India, but it was described 10 years later by John Lidley in the *Botanical Register* and also in *Folia Orchidcea*. The species was rediscovered in 1850, also in the Khasia Hills, by Sir Joseph Hooker and Dr. T. Thompson. Thomas Lobb, a collector for Veitch and Sone, sent a large shipment to his employers in the same year and they introduced this remarkable *Vanda* to the trade. *V. coerulea* is also found in Thailand and Burma (Bechtel et al., 1992). Its blue flower made it popular when it was first introduced. It is still grown widely throughout the world and the South Pacific Island Republic Tuvalu (the former Ellice Islands) put it on one of its stamps. *V. coerulea* is also well liked in Japan, where a method for plant production from shoot tips and leaf explants was developed at Gifu University (Fukui et al., 2001).

Plant Material. The tops of shoots with three or four unexpanded leaves were taken from seedlings maintained under horticultural conditions. Tips, described as "0.8 mm" (this seems too small and may be a misspelled 0.8 cm), were cut from these shoots after surface sterilization, and cultured. Top leaves, 15 mm long, were taken from plantlets in vitro which had "four or five expanded leaves" and cut into three sections – tip, middle, and base. These sections were cultured.

Surface Sterilization. Shoot tips were surface-sterilized by immersing them for 10 min in 100 ml of 1% sodium hypochlorite solution (20 or 17 ml, respectively, of household bleach containing 5–5.25 or 6% sodium hypochlorite diluted to 100 ml with distilled water) containing 1 drop of Tween 20 (available from www.sigmaaldrich.com or other sources) and then washing them three times with sterile distilled water. Leaf explants were not surface-sterilized because they were taken from plantlets that were growing in vitro.

Culture Vessels. Culture tubes were used in the original research. Other containers can also be used.

Culture Conditions. The research cultures were maintained at 25°C under 16-h photoperiods of 3000 lx. Standard culture room conditions should also prove to be suitable.

Culture Media. Shoot tips produce callus on Knudson C (KC) medium supplemented with 1 μmol BA l^{-1} (Table V-24). The callus proliferates on the same medium. Leaf explants produce callus in the presence of 1 μmol BA l^{-1} and 0.5 μmol NAA l^{-1} in a medium which is not named, but it is reasonable to assume that it is KC (Table V-25). The leaf-derived callus proliferates well on a medium containing 0.5 μmol BA l^{-1} and 0.1 μmol NAA l^{-1} (Table V-26). The callus produces plantlets in the presence of 0.5 μmol BA l^{-1} and 0.5 μmol NAA l^{-1} (Table V-27). No medium is suggested for the culture of plantlets to community pot size. Plantlets can be cultured on one of the versions of the KC medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for KC that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. Shoot tips are taken, surface-sterilized, and washed. Tip explants are taken after that and placed in culture on the appropriate medium (Table V-24). When callus is formed it is subcultured on the same medium (Table V-24) for proliferation. The callus should be moved to another medium (Table V-27) for plantlet formation and growth. For further growth, the plantlets can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4)

TABLE V-24. **Knudson C (KC) medium (Knudson, 1946) modified for the induction and culture of callus from shoot tips of *Vanda coerulea* (Fukui et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4{\cdot}7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4{\cdot}7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4{\cdot}4H_2O$	7.5	750.0 mg l^{-1}	10	
	Cytokinin				
7	Benzylaminopurine (BAP)	0.225	22.5 mg 100 ml^{-1} 95% ethanol[e]	1 µmole	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[f]	To 1000 ml			
	Solidifier				
10	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Kundson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4{\cdot}7H_2O$ l^{-1}, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary, those used in the Murashige–Skoog (MS) medium are suitable.

[e]If the cytokinin fails to dissolve add a few drops of 0.1 N HCl. Keep frozen between uses.

[f]Add items 1–7 to 900 ml of distilled water (item 9), adjust pH to 5–5.2, add sugar (item 8), and bring volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave.

with or without banana homogenate or activated charcoal. If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to the medium selected for use as suggested for KC that contains this darkening agent (see Table Pln-1, footnote *f*).

Leaf explants are cut and placed on the callus-inducing medium (Table V-25). Callus produced on this medium is proliferated on another solution (Table V-26). To produce plantlets, this callus is moved to a plantlet-inducing medium (Table V-27). The plantlets can be grown on one of several media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4, with or without banana homogenate or activated charcoal).

TABLE V-25. **Knudson C (KC) medium (Knudson, 1946) modified for the induction and culture of callus from leaf explants of *Vanda coerulea* (Fukui et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
7	Naphthaleneacetic acid (NAA)	0.093	9.3 mg 100 ml^{-1} 95% ethanol[e]		0.5 µmole
	Cytokinin				
8	Benzylaminopurine (BAP)	0.225	22.5 mg 100 ml^{-1} 95% ethanol[e]		1 µmole
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Knudson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$ l^{-1}, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary, those used in the Murashige–Skoog (MS) medium are suitable.

[e]If the auxin or cytokinin fail to dissolve, add a few drops of 0.1 N KOH or HCl, respectively. Keep frozen between uses.

[f]Add items 1–8 to 900 ml of distilled water (item 10), adjust pH to 5–5.2, add sugar (item 9), and bring volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave.

Developmental Sequence. Shoot tips produce callus which proliferates and eventually produces plantlets. Leaf explants produce callus, buds, and roots after 8 weeks in culture. Leaf segments produce callus as follows: 0% by tips, 5.5% by mid-leaf sections, and 38.9% by bases.

General Comments. Information about the sources of explants is not entirely clear. The opening sentence of the material and methods sections states that "seedling plants . . . were used as plant materials." These seedlings seem to have been older and not growing in vitro because the explants were surface-sterilized. The source leaf segments is described as "plantlets . . . regenerated from shoot tip culture." Since there is no mention of surface sterilization for the leaf explants it is possible that they were taken from plantlets in vitro produced from shoot tips taken from the seedlings mentioned above. If older seedlings were used as sources of shoot tips this method may prove to be suitable for similar explants from older plants.

TABLE V-26. **Knudson C (KC) medium (Knudson, 1946) modified for the proliferation of callus derived from leaf explants of *Vanda coerulea* (Fukui et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Knudson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$ l^{-1}, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary, those used in the Murashige–Skoog (MS) medium are suitable.

[e]If the auxin or cytokinin fail to dissolve add a few drops of 0.1 N KOH or HCl, respectively. Keep frozen between uses.

[f]Add items 1–8 to 900 ml of distilled water (item 10), adjust pH to 5–5.2, add sugar (item 9), and bring volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave.

Micropropagation of the Blue Vanda, *Vanda coerulea*

An epiphyte growing at elevations of 1000–1500 m, *Vanda coerulea*, the Blue Vanda of Asia, is threatened with extinction in India due to habitat destruction and overexploitation. A micropropagation procedure was used to establish clonally propagated plants in the southern forests of Western Ghats in India (Seeni and Latha, 2000).

Plant Material. Shoot tips, 5–8 mm in size, as well as the two youngest leaves, were excised from 6-month-old seedlings, and surface-sterilized top cuttings consisting of 4–5 nodes were taken from potted mature plants.

Surface Sterilization. The top cuttings were immersed in 1% (v/v) Teepol (www.sigmaaldrich.com and other sources) for 1–3 min, 70% ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) for 20 s, and 0.1% mercuric chloride ($HgCl_2$) for 3 min. After that they were washed with sterile distilled water three times. There is no need to sterilize seedlings that are growing in vitro.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers can be used.

Culture Conditions. Cultures should be maintained at 24 ± 2°C under 12-h photoperiods of 20–50 μmol m^{-2} s^{-1} provided by Philips daylight fluorescent tubes.

Culture Media. Shoot tips should be cultured initially in liquid Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with 10% coconut water, 500 mg casein hydrolysate l^{-1}, 8.8 μmol BA l^{-1}, and 4.1 μmol NAA l^{-1} (Table V-28). Leaves should be cultured on the same medium in solid form (Table V-28). Explants which form buds or PLBs should be moved to MPR containing 35 g banana pulp l^{-1}, 30% coconut water, and 1.08 μmol NAA l^{-1} (Table V-29). Shoots should be moved to MPR with 35 g banana pulp l^{-1} and 1.08 μmol NAA l^{-1} (Table V-30). Liquid medium should be agitated.

Procedure. Shoot tips are cultured in agitated liquid MPR (Table V-28) until they produce buds and/or PLBs. Leaf explants are cultured on solid MPR (Table V-28) until they also produce PLBs and/or buds. Once PLBs and/or buds are produced, they or the explants which produced them are moved to a different modification of MPR (Table V-29). Shoots produced on this medium are rooted on yet another version of MPR (Table V-30). Rooted plants should be moved to pots.

Developmental Sequence. Approximately 75% of the shoot tips on the first medium (Table V-28) produce vegetative (shoot) buds (3–12 per tip with an average of 4.2) in 12 weeks. Leaf-base explants (64–88% of those cultured on the same medium, Table V-28) give rise to PLBs (3–8 per explant) in 4–8 weeks. When the explants (shoot tip and leaf) are moved to the second medium (Table V-29), "a maximum of 70 and 100 shoots of varied length were obtained from a single shoot tip/leaf base explant after 30 weeks of culture." Shoots (3.4 cm high) on the third medium (Table V-30) form roots within 3–4 weeks. The survival of rooted plants in pots is 95–100%.

General Comments. This method can be used to increase the number of seedlings and to propagate selected forms. Plantlets produced by this procedure are "cytologically stable ($2n = 38$)" and "free from morphological, growth and flowering abnormalities."

TABLE V-28. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of shoot tip and leaf explants of *Vanda coerulea* (Seeni and Latha, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise. Shoot tips should be cultured in liquid (i.e., agar-free) medium, whereas leaf explants should be cultured on solid (i.e., agar-containing) substrate.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]Not all casein hydrolysates are the same. Their compositions and analyses vary depending on the methods by which they were produced. A product sold by Merck (www.merck.de) as casein hydrolysate (CH) is obtained by degrading casein with hydrochloric acid; vitamins and other growth-promoting compounds are largely destroyed in this process. The CH sold by Sigma-Aldrich (www.sigmaaldrich.com) is pancreatic hydrolysate of casein. There is also a CH which is hydrolysed by enzymes. Becton, Dickinson and Company (www.bd.com) sells Difco products including a number of different casamino acid products, all of which are casein hydrolysates. Therefore if a method specifies a source for the CH in its culture medium it is best to obtain the additive from the same vendor. If a source is not listed it is best to purchase CH which is described as being suitable as a supplement for culture media. Failing that, CH should be purchased from a source which specializes in tissue culture and micropropagation supplies. One such source is www.caissonlabs.com. They list casein rather than CH as Stock #: SPCA205. Another source for CH is www.duchefa.com (item 1301). Additional sources include www.fishersci.com, www.thomassci.com, and others.

[h]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[i]Add items 1–17 to 700 ml of distilled water (item 19), adjust pH to 5.6, add sugar (item 18), and bring volume to 1000 ml with distilled water (item 19). Bring the solution to a gentle boil and add the agar (item 20) slowly while stirring. The agar can also be added to the cold solution which is then brought to a boil and stirred. When the agar (item 20) is completely dissolved, pour the solution into culture vessels and autoclave. Agar should not be added if the medium is to be used to culture shoot tips. Liquid medium should be agitated. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE V-29. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for shoot production from shoot tips, leaf explants, and protocorm-like bodies of *Vanda coerulea* (Seeni and Latha, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable, (2) the peel rather than the pulp should be used, (3) unpeeled banana homogenate should be incorporated in media, and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective banana variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and/or use what is suggested there.

[h]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[i]Add items 1–16 to 500 ml of distilled water (item 18) in a homogenizer, homogenate until the banana pulp (item 15) is completely homogenized and thoroughly dispersed through the medium, raise volume to 900 ml if necessary, adjust pH to 5.6, add sugar (item 17), and bring volume to 1000 ml with distilled water (item 18). Bring the solution to a gentle boil and add the agar (item 19) slowly while stirring. The agar (item 19) can also be added to the cold solution which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE V-30. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the rooting of shoots produced by shoot tips, leaf explants, and protocorm-like bodies of *Vanda coerulea* (Seeni and Latha, 2000)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve add a few drops of 0.1 N KOH.

[g]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable, (2) the peel rather than the pulp should be used, (3) unpeeled banana homogenate should be incorporated in media, and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective banana variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and/or use what is suggested there.

[h]Add items 1–15 to 800 ml of distilled water (item 17) in a homogenizer, homogenate until the banana pulp (item 15) is completely homogenized and thoroughly dispersed through the medium, raise volume to 900 ml if necessary, adjust pH to 5.6, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar (item 18) can also be added to the cold solution which is then brought to a boil and stirred. When the agar (item 18) is completely dissolved pour the solution into culture vessels and autoclave. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

Micropropagation of *Vanda cristata* through Leaf Segments

S. P. Vij, Professor of Botany at Panjab University and a noted Indian orchid expert, and his associates have devoted some of their efforts toward the identification of explants other than shoot meristems that are just as effective for micropropagation. They formulated methods for the culture of leaf segments of several orchids including *Vanda cristata* (Vij and Pathak, 1990).

Plant Material. Basal explants, 5–10 mm long, from leaves, approximately 2 cm long, of 16–40-week-old seedlings growing in vitro should be used. Apical segments do not produce PLBs. Explants from leaves of mature plants died in the original experiments.

Surface Sterilization. Explants taken from axenic seedlings growing in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, test tubes, and other containers filled with medium to 20–30% of their capacity are suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with BA and NAA (Table V-31) must be used for the culture of leaf segments. No medium is suggested for the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If banana homogenate is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal should be added to media as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. Leaves are taken from plantlets, and are sectioned and placed in culture on the initiation medium (Table V-31). Callus and PLBs should be subcultured on the same medium for the initiation of shoots and roots. Plantlets should be cultured on one of the Knudson C or Vacin and Went formulations suggested above, preferably one with banana homogenate and activated charcoal.

Developmental Sequence. Callus and PLBs form on the initiation medium (Table V-31) 4 weeks after the start of culture and can give rise to plantlets. When transferred to Knudson C or Vacin and Went formulation with banana homogenate and activated charcoal the plantlets should develop further.

TABLE V-31. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Vanda cristata leaf* segments (Vij and Pathak, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100.0	10.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	200.0	20.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	180.0	18.0 g l^{-1}	10	
5	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	150.0	15.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.6	60.0 mg l^{-1}		
(b)	Cobalt nitrate, $Co(NO_3)_2 \cdot 6H_2O$	0.05	5.0 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.05	5.0 mg l^{-1}		
(d)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	0.4	40.0 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.03	3.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.05	5.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.05	5.0 mg l^{-1}		
	Auxin				
8	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]		
	Cytokinin				
9	Benzylaminopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]		
	Vitamins				
10	Biotin	0.05	20 mg 100 ml^{-1} 95% ethanol[f]	0.25	
11	Folic acid	0.3	120 mg 100 ml^{-1} 95% ethanol[f]	0.25	
12	Niacin (nicotinic acid)	1.25	500 mg 100 ml^{-1} 95% ethanol[f]	0.25	
13	Pyridoxine (vitamin B_6)	0.3	120 mg 100 ml^{-1} 95% ethanol[f]	0.25	
14	Riboflavine (vitamin B_2)	0.05	20 mg 100 ml^{-1} 95% ethanol[f]	0.25	
15	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[f]	0.25	
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	9.0 g	No stock	No stock	Weigh
	Darkening agent				
19	Activated charcoal[h]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same that as in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[f]Keep frozen between uses.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add the charcoal with vigorous stirring to insure complete distribution through the medium, pour the solution into culture vessels, and autoclave. After autoclaving when the medium is cooling swirl the flasks to disperse the charcoal. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976; Vij and Pathak, 1990).

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

General Comments. The propagation of selected forms is not possible with this method because the explants are taken from seedlings. However, it may be possible to adapt the procedure to mature plants.

Micropropagation of *Vanda teres* through Leaf Segments

As part of a program to identify explants that are as effective for micropropagation as shoot meristems, Professor S. P. Vij and his associates at the Department of Botany, Panjab University formulated methods for the culture of leaf segments of several orchids including *Vanda teres* (Vij and Pathak, 1990).

Plant Material. Basal explants, 5–10 mm long, from leaves approximately 2 cm long, of 16–40-week-old seedlings growing in vitro should be used. Apical segments do not produce PLBs. Explants from leaves of mature plants died in the original experiments.

Surface Sterilization. Explants taken from axenic seedlings growing in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, test tubes, and other containers filled with medium to 20–30% of their capacity are suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with yeast extract and IBA (Table V-32) must be used for the culture of leaf segments. No medium is suggested for the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to media as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. Leaves are taken from plantlets, and are sectioned and placed in culture on the initiation medium (Table V-32). PLBs should be subcultured on the same medium to bring about shoot and root production. Plantlets should be cultured on one of the Knudson C or Vacin and Went formulations suggested above, preferably one with BH and AC.

Developmental Sequence. PLBs form on the initiation medium (Table V-32) 2 weeks after the start of culture and can give rise to plantlets. When transferred to

TABLE V-32. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Vanda teres* leaf segments (Vij and Pathak, 1990)**

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]If the auxin does not dissolve add a few drops of 0.1 N KOH.

[f]Keep frozen between uses.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add the charcoal with vigorous stirring to insure complete distribution through the medium, pour the solution into culture vessels, and autoclave. After autoclaving when the medium is cooling swirl the flasks to disperse the charcoal. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976; Vij and Pathak, 1990).

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

Knudson C or Vacin and Went formulation with BH and AC, the plantlets should develop further.

General Comments. Since explants are taken from seedlings, propagation of selected forms is not possible with this method. However, it may be possible to adapt the procedure to mature plants. This species was renamed *Papilionanthe teres* but it is listed here under *Vanda* because that is the name used in the original paper.

Micropropagation of *Vanda testacea* through the Culture of Leaf Segments

Plants have many leaves and the removal of a few does not endanger the donor plant. Therefore, explants are safe and practical. Explants from leaves of mature plants released brownish (phenolic?) exudates into the medium, lose their chlorophyll, and die within 2.5–5.5 months. However, explants from axenic seedlings proliferate along their cut ends (Vij and Pathak, 1990).

Plant Material. Young leaves, up to 2 cm in length from 3.5–9-month-old axenic seedlings, should be cut into 0.5–1.0-cm-long basal (with leaf base) and apical (with leaf tip) sections and used as explants.

Surface Sterilization. Explants from leaves growing in vitro do not require surface sterilization.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers are suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

Culture Media. When cultured on MS medium (Murashige and Skoog, 1962) supplemented with peptone, kinetin, and NAA, and darkened with active charcoal (Table V-33) 37.5% of both apical and basal explants will produce an average of 30 PLBs per explant (Fig. V-7). PLBs should be moved to MS supplemented with peptone, NAA, and BA (Table V-34) for plantlet production (Fig. V-7).

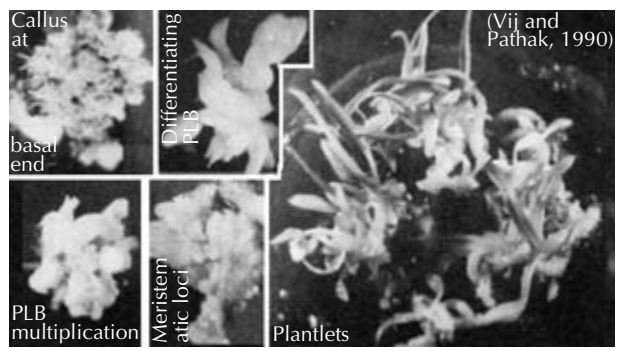

FIG. V-7. **Micropropagation of *Vanda testacea*.**

TABLE V-33. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Vanda testacea* leaf explants (Vij and Pathak, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Auxin				
13	Naphthaleneacetic acid (NAA)	1.0	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
14	Kinetin	1.0	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
15	Peptone[g]	1.0 g	No stock	No stock	Werigh
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar[h]	9.0 g	No stock	No stock	Weigh
	Darkening agent				
19	Activated charcoal (AC)[i]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin fails to dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]Peptones can vary. Therefore it is best to use one which is suitable for plant tissue culture. A possible source is www.sigmaaldrich.com.

[h]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, add the charcoal (item 19) with constant stirring to insure complete and even distribution, pour the solution into culture vessels, and autoclave.

[i]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. pH paper strips can be used for this measurement.

TABLE V-34. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for plantlet production from leaf-explant-derived protocorm-like bodies of *Vanda* testacea (Vij and Pathak, 1990)**

[g]Peptones can vary. Therefore it is best to use one which is suitable for plant tissue culture. Possible sources are www.sigmaaldrich.com.

[h]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 19) with constant stirring to insure complete and even distribution, pour the solution into culture vessels, and autoclave.

[i]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. pH paper strips can be used for this measurement.

Procedure. The leaves are cut in half, placed on the medium, and cultured in the first medium (Table V-33). Once the PLBs produced by the explants are sufficient in number and are large enough they are transferred to the second solution (Table V-34). When the plantlets produced on the second solution are large enough they should be moved to community pots.

Developmental Sequence. The explants produce PLBs (Fig. V-7) on the first medium (Table V-33) 5 weeks after being placed in culture. The first leaf appears after 8 weeks. Roots appear 16 weeks after the cultures were initiated. Plantlets (Fig. V-7) develop well on the second substrate (Table V-34).

General Comments. This is an effective method which cannot be used to propagate specific clones because the quality of seedlings is not known.

Micropropagation of *Vanda cristata* through the Culture of Labella

The ideal explant for micropropagation is a tissue or organ which is plentiful, easily accessible, simple to handle, easy to surface-sterilize, and whose removal will neither damage nor endanger the plant from which it is taken and which requires relatively simple medium or media and culture conditions. Professor Suraj P. Vij and his associates at the Botany Department, Panjab University have devoted considerable attention to the use of such explants including the use of perianth segments (Vij and Sharma, 1996).

Plant Material. Young floral buds should be taken from greenhouse-grown plants (Fig. V-8G, I). In taking buds it is important to keep in mind that "the frequency with which the explants responded decline progressively with the increase in the level of bud maturity." In other words, it is better to take younger buds. Explants taken after anthesis (i.e., after the flowers opened) do not respond. The labellum (Fig. V-8A) should be excised from the buds after surface sterilization and cut into 5 mm sections (Fig. V-8C, D), all of which should be cultured.

Surface Sterilization. Buds should first be washed gently with running water and a mild detergent (this step is not part of the procedure in the original report). After the washing, the buds should be immersed in 0.1% streptomycin (available from www.sigmaaldrich.com and other sources) for 12 min, submerged in 4% sodium hypochlorite (80 or 66.7 ml, respectively, of household bleach containing 5–5.25 or 6% sodium hypochlorite diluted to 100 ml with distilled water) for 15 min, and dipped in 70% ethanol (74 ml of 95% ethanol diluted to 100 ml with distilled water) for 3 s and finally rinsed three times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other containers are suitable.

Culture Conditions. Cultures should be maintained at 25 ± 5°C under 12-h photoperiods of 3500 lx or standard culture room conditions.

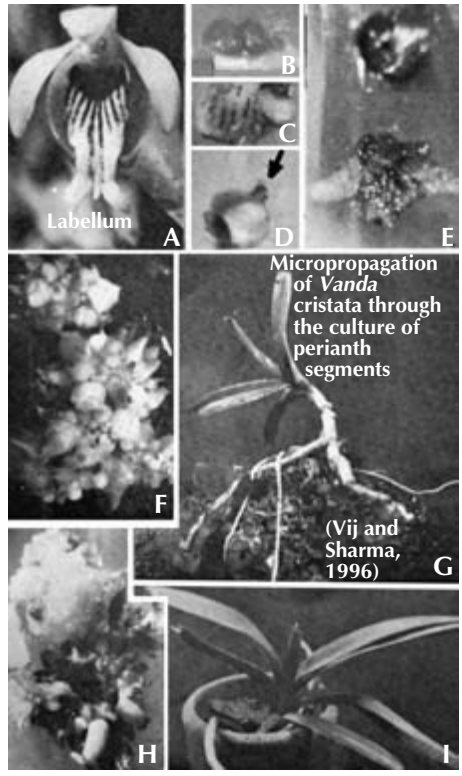

FIG. V-8. **Micropropagation of *Vanda cristata*. A. Flower. B. Compact spherical callus on an explant. C. Explant. D. Labellum explant showing hypodermal bulge which will form callus eventually. E. Callus emerging from an explant. F. PLB formation on callus. G. Three-month-old labellum-derived plant in a greenhouse. H. PLBs and plantlets on callus after 16 weeks of culture. I. Six-week-old plant in a greenhouse. (Vij and Sharma, 1996.)**

Culture Media. Explants should be cultured initially on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with 5 mg l^{-1} each of BA and NAA (Table V-35). The addition of 10 mg BA l^{-1} increases the percentage of explants which respond (from 37.5 to 50%) and the number of plantlets per explant (70 instead of 52), but high hormone levels can induce undesirable mutations and should be avoided. Callus or PLBs form on the first medium (Table V-35) and should be moved to a second version of MPR which contains 0.5 mg NAA l^{-1} and 500 mg sucrose l^{-1} (Table V-36). Plantlets will form on this medium.

Procedure. Explants are washed, surface-sterilized, and rinsed with sterile distilled water before their labella are removed and sectioned. The sections are cultured on the first medium (Table V-35) until callus and PLBs are formed. These are moved to the second medium (Table V-36) for plantlet formation. If necessary the plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin fails to dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.6, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar (item 18) can also be added to the cold water which is then brought to a boil and stirred. When the agar (item 18) is completely dissolved, pour the solution into culture vessels and autoclave. Agar (item 18) is not used in liquid media. As a rule media which contain vitamins (items 8–13), hormones (items 14 and 15), and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE V-36. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for plantlet production from callus and protocorm-like bodies produced by labella segments of *Vanda cristata* (Vij and Sharma, 1996)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin fails to dissolve add a few drops of 0.1 N KOH.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and bring volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar (item 17) can also be added to the cold water which is then brought to a boil and stirred. When the agar (item 17) is completely dissolved, pour the solution into culture vessels and autoclave. Agar (item 17) is not used in liquid media. As a rule media which contain vitamins (items 8–13), hormones (item 14), and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

(see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*). When plantlets are large enough they should be potted in a greenhouse.

Developmental Sequence. The explants (37.5%) produce callus and PLBs (Fig. V-8B, D-F) after 8 weeks in culture. The time required for plantlet production (on the medium in Table V-36) is 17 weeks.

General Comments. This seems to an effective procedure which utilizes a unique and abundant part of the plant.

Micropropagation of *Vanda cristata* through the Culture of Foliar Explants from Mature Plants

The use of shoot tips (usually and erroneously referred to as meristems) for micropropagation can be "detrimental to . . . the mother plant" especially in monopodial species. "Efforts have, therefore, been directed toward developing an equally effective multiplication system by activating adventitious meristems in organs whose excision does not endanger the survival of the source plant" (Sharma and Vij, 1997). Leaves of seedlings of a number of orchid species have been cultured (Vij and Pathak, 1990), but they do not make possible the multiplication of clones of known quality. Therefore a method was developed for the micropropagation of *Vanda cristata* by culturing explants taken from young leaves of mature plants (Sharma and Vij, 1997).

Plant Material. The youngest, still folded leaves (Fig. V-9E), up to 5 cm long, should be harvested from mature plants grown under horticultural conditions. After surface sterilization, the leaves should be cut into 5-mm sections (Fig. V-9A). Although all sections can be cultured, only the lower median section (Fig. V-9A, M_2) and the basal two (Fig. V9A, P_1 and P_2) produce callus (Fig. V-9B, C, F–H) and plantlets (Fig. V-9D, J, K).

Surface Sterilization. The leaves should first be washed with running water and a mild detergent [this step is not part of the procedure published by Sharma and Vij (1997)]. After that they should be submerged for 20 min in 0.1% streptomycin (available from www.sigmaaldrich.com), immersed in 0.1% mercuric chloride for 15 min, dipped in 70% ethanol (74 ml of 95% ethanol brought to 100 ml with distilled water) for 3 s and rinsed three times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other containers can be used.

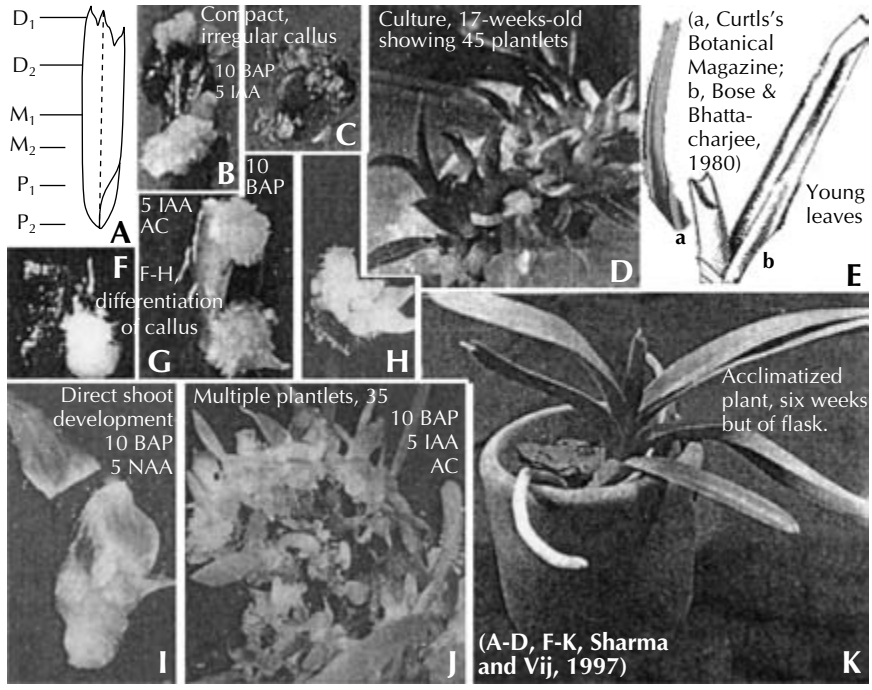

FIG. V-9. **Micropropagation of *Vanda cristata* through the culture of foliar explants. Captions are on the illustrations. AC, activated charcoal; BAP, benzylaminopurine; IAA, indoleacetic acid; the numbers associated with BA and NAA are in mg l^{-1}.**

Culture Conditions. The experimental cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx. Standard laboratory conditions should also prove suitable.

Culture Media. Explants should be cultured on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing 10 mg BA l^{-1}, 5 mg IAA l^{-1}, and 2.2 mg copper sulfate l^{-1} with or without activated charcoal (Table V-37). Callus can be subcultured on the same medium. Plantlets, 3 cm tall, should be cultured on half-strength (micro- and macroelements) MPR without vitamins, hormones, or sugar (Table V-38) until they reach a height of 4–5 cm. On reaching this height the plantlets should be potted in a mixture of moss, pine bark, brick shards, and charcoal pieces (in the ratio of 1 : 1 : 1 : 1).

Procedure. The youngest leaves of mature plants are taken, washed, surface-sterilized, and sectioned. Sections are cultured on a modified MPR medium (Table V-37). Callus can be subcultured on the same medium (Table V-37). Plantlets should be maintained on this medium (Table V-37) until they reach a height of 3 cm, when they are moved to the second solution (Table V-38) and grown on each until they are 4–5 cm high. These plantlets should be removed from the flasks, washed with

(e)	Potassium iodide, KI	0.015	1.5 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.025	2.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.025	2.5 mg l^{-1}		
	Solvent				
8	Water, distilled[e]	To 1000 ml			
	Solidifier				
9	Agar[e]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macro- and microelements are half those in the original formulation.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Add items 1–7 to 900 ml of distilled water (item 8), adjust pH to 5.6, and bring volume to 1000 ml with distilled water (item 8). Bring the solution to a gentle boil and add the agar (item 9) slowly while stirring. The agar (item 9) can also be added to the cold water which is then brought to a boil and stirred. When the agar (item 9) is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not used in liquid media.

lukewarm water to remove all agar, potted in the potting mix in small pots, and grown in 90% shade. To maintain humidity, the pots should be covered with polyethylene bags. Holes of increasing size should be cut in these bags over a period of 4 weeks at which point they should be removed and the pots should be moved to sunlight. The young plants should be sprayed with a fungicide [1% Bavistin was used by Sharma and Vij (1997)]. Approximately 80% can be expected to survive under these conditions.

General Comments. This is an ideal procedure in all aspects but one, which is the relatively high level of BA.

Micropropagation of *Vanda* Kasem's Delight 'Tom Boykin' through the Culture of Foliar Explants

Large colorful *Vanda* hybrids like *Vanda* Kasem's Delight are popular, expensive, and monopodial (i.e., they have only one shoot tip per plant). Therefore, a micropropagation method that uses foliar explants is of importance (Vij et al., 1994*b*).

Plant Material. In the original research, sections 5 mm long (Fig. V-10Aa, C, Ea) of young leaves (up to 2.5 cm in length, from plantlets produced from shoot-tip explants and growing in vitro) gave the best results. Sections from older and longer leaves died or did not proliferate.

Surface Sterilization. Explants from plantlets in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other containers are suitable.

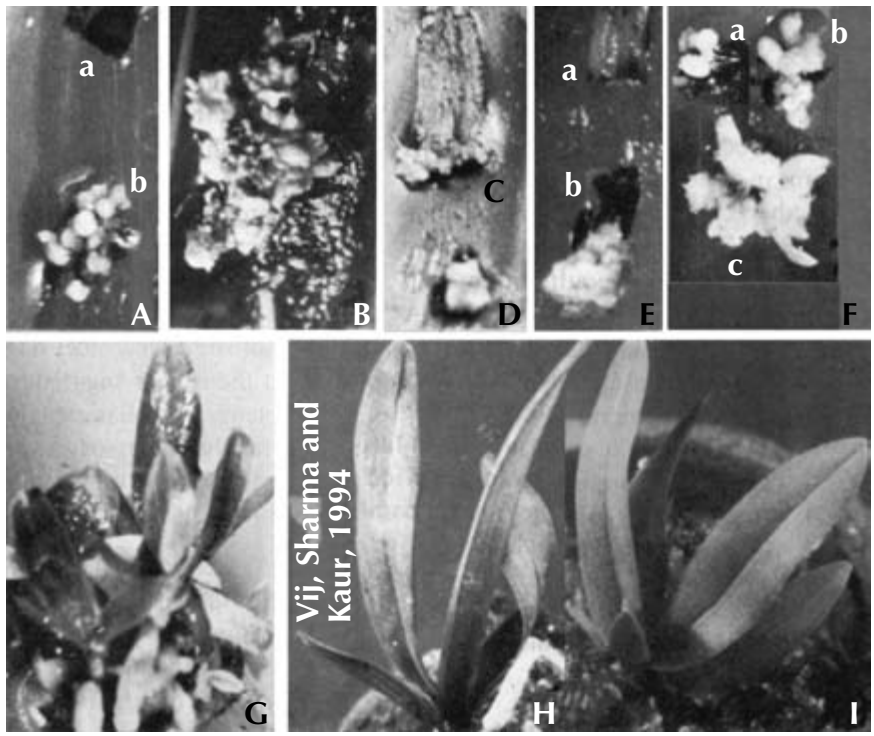

FIG. V-10. **Micropropagation of *Vanda* Kasem's Delight 'Tom Boykin'. A. Explant (a) and PLB (b) formation on a basal explant. B. Multiplication of PLBs. C, D. PLB formation on cut ends. E. Explant (a) and PLBs (b) on the basal ends of older leaves. F. PLB formation (on an explant from a younger leaf in b) and subsequent differentiation (a, c). G. Plantlets forming in 15-week-old cultures. H, I. Plantlets in pots. (Vij et al., 1994*b*.)**

Culture Conditions. The research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx. Standard culture room conditions will probably also prove to be suitable.

Culture Media. Explants should be cultured on Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing per liter 2 g peptone, 5 mg BA, and 1 mg NAA (Table V-39). PLBs produced on this medium proliferate when subcultured on it (Table V-39). PLBs are cultured on a medium containing 1 mg kinetin l^{-1} (Table V-40) and produce plantlets. Twenty-week-old plantlets should be potted in a mixture of moss, pine bark, brick shards, and charcoal pieces (in the ratio of 1 : 1 : 1 : 1) and maintained in partial shade and a relative humidity of 70%.

Procedure. Surface-sterilized leaves are sectioned and the sections (Fig. V-10Aa, C, Ea) are cultured on the first medium (Table V-39). PLBs (Fig. V-10Ab) produced on this medium (Table V-39) should be moved to the kinetin-containing solution (Table V-40) for plantlet production (Fig. V-10G). When the plantlets are 20 weeks old they should be potted and grown in a greenhouse (Fig. V-10H, I).

Developmental Sequence. PLBs are produced at the cut ends of explants (Fig. V-10C, D, Eb, F) cultured on the first medium (Table V-39). They proliferate (Fig. V-10B) when subcultured on the same solution (Table V-39). Plantlets (Fig. V-10G) are formed when the PLBs are cultured on the second medium (Table V-40). New leaves and roots are formed 3 weeks after the plantlets are potted and moved to a greenhouse (Fig. V-10H, I).

General Comments. A major drawback of this procedure is that it does not utilize explants from mature plants. However an effort should be made to culture very young leaves of mature plants. If such leaves are used the procedure may prove to be suitable. Also, even if this method was developed with *Vanda* Kasem's Delight 'Tom Boykin' the chances are that it may prove to be suitable for similar hybrids.

> The name *Vanda* is derived from a Sanskrit word which refers to a sacred mistletoe found on *Vandaca* oak trees. It was coined by Sir William Jones to describe epiphytic plants in general . . . and published posthumously in *Asiatic Researches* volume 4, page 302. (Hew et al., 2002 citing Grove, 1995)

Sir William Jones (London, 1746 to Calcutta, 1794) was a British orientalist who spoke 28 languages including Arabic, Chinese, Latin, Greek, Hebrew, Persian, and Sanskrit and also wrote extensively on Muslim and Indian law. His use of a word which refers to mistletoe in the description of an epiphytic genus is ingenious and reflects his British (i.e., northern rather than tropical) origins (Hew et al., 2002 citing Grove, 1995; Dr. David Grove, pers. comm.). For more information about Jones see Cannon (1993).

TABLE V-39. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the initial culture of foliar explants of *Vanda* Kasems's Delight 'Tom Boykin' (Vij et al., 1994*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin fails to dissolve add a few drops of 0.1 KOH or HCl, respectively.

[g]Peptones can differ. Therefore it is advisable to either use the exact same peptone used in the original research or purchase a preparation which is suitable for plant tissue culture. Possible sources are www.sigmaaldrich.com, www.caissonlabs.com, and www.phytotechlab.com.

[h]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.5, add sugar (item 17), and bring volume to 1000 ml with distilled water (item 18). Bring the solution to a gentle boil and add the agar (item 19) slowly while stirring. The agar (item 19) can also be added to the cold water which is then brought to a boil and stirred. When the agar (item 19) is completely dissolved pour the solution into culture vessels and autoclave. Agar (item 19) is not used in liquid media. As a rule media which contain vitamins (items 8–13), hormones (items 14 and 15), and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE V-40. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for plantlet production from foliar-explant-derived protocorm-like bodies of *Vanda* Kasems's Delight 'Tom Boykin' (Vij et al., 1994*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100.0	10.0 g l^{-1}	10

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and bring volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar (item 17) can also be added to the cold water which is then brought to a boil and stirred. When the agar (item 17) is completely dissolved, pour the solution into culture vessels and autoclave. Agar (item 17) is not used in liquid media. As a rule media which contain vitamins (items 8–13), hormones (item 14), and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

Micropropagation of *Papilionanthe* (*Vanda*) *teres* through the Culture of Foliar Explants

The genus *Vanda* was established in 1795 by Sir William Jones (1746, London to 1794, Calcutta). *Vanda teres* was discovered in northern India by Nathaniel Wallich (1786–1854) who introduced it into cultivation in 1829 and was named by John Lindley (1799–1865) in 1833. In 1915 Rudolph Schlechter (1872–1925) made it the type species of a *Papilionanthe*, a genus he segregated from *Vanda*. The new genus was not accepted widely until Leslie Garay treated it in 1972 (Bechtel et al., 1992). This species is one of the parents of *Vanda* Miss Joaquim, a natural hybrid and a foundling which became the national flower of Singapore (Hew et al., 2002). It is found in dry areas from the Himalayas to Burma, Thailand, and Laos. Insufficient reproduction in its native areas, habitat destruction, and overexploitation are reducing its natural population and this led to the development of a micropropagation procedure from young leaves of mature plants (Pathak and Vij, 2001).

Plant Material. "Young leaves up to 1 cm in length excised from greenhouse grown plants were segmented into 0.3–0.5 cm long basal (with leaf tip) parts and used as explants." It is not clear from this quote (taken verbatim from Pathak and Vij, 2001) which segments were used as explants because a "basal" part cannot have a "leaf tip." Therefore it is possible that what were used were either basal segments (Fig. V-11Nb), or basal and tip sections (Fig. V-11Nb, d), or explants consisting of very young short leaves (Fig. V-11M). In any case "the basal explants responded

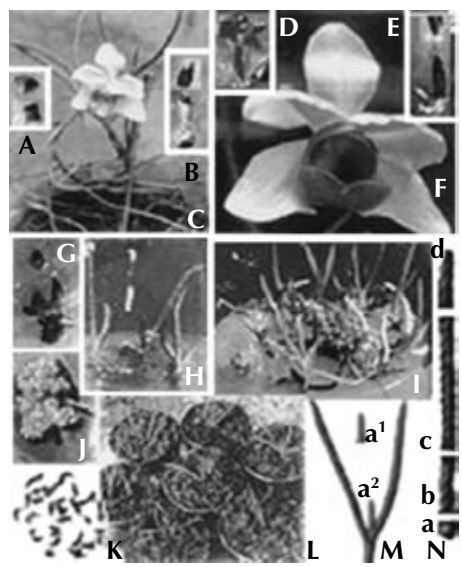

FIG. V-11. **Micropropagation of *Vanda teres*. A, B. Callus formation on basal ends. C. Plant. D, E, G. Differentiation of PLBs and subsequent plantlet formation. F. Flower. H, I. Plantlets. J. Multiplication and differentiation of PLBs. K. Somatic chromosomes, $2n = 38$. L. Potted plantlets. M. Shoot top showing different size leaves, with the youngest leaf (a^2) possibly being used as an explant (a^1). N. Sectioned leaf showing remnants of stem (a), basal (b), median (c), and tip (d) sections. (Sources: A–L, Pathak and Vij, 2001; M, N, Hew et al., 2002.)**

better than the apical ones." This suggests that the most suitable explants are basal ones (Fig. V-11Nb) or very young short leaves (Fig. V-11Ma[1]).

Surface Sterilization. Explants should first be washed with a mild detergent and running water [this step is not part of the procedure recommended by Pathak and Vij (2001)]. After the wash the explants should be dipped in 70% ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) for 5 s, immersed in 0.01% (w/v) streptomycin (available from www.sigmaaldrich.com and other sources) for 5 min, submerged in 7% calcium hypochlorite (7 g calcium hypochlorite suspended in 100 ml distilled water and agitated and allowed to settle three times before decanting and using the supernatant), and washed three times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other containers can be used.

Culture Conditions. The research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx. Standard culture room conditions will probably also prove to be suitable.

Culture Media. The explants should be cultured on MS medium (Murashige and Skoog, 1962) supplemented with 1 mg BA l^{-1} (Table V-41). Callus and PLBs that form in the initial cultures should be subcultured on the same medium (Table V-41). Plantlets formed on this medium can be cultured on it or on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. After being surface-sterilized the leaves are sectioned and the sections are cultured on the BA-containing MS (Table V-41). Callus and PLBs can be subcultured on the same medium (Table V-41) and plantlets can be grown on it. Or, they can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without BH or AC. If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). AC should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*). When plantlets are large enough they should be removed from the culture vessels and potted in community pots.

Developmental Sequence. Meristematic areas are formed 3 weeks after the explants are placed in culture. Up to ten plantlets can be obtained per explant.

General Comments. This seems to be an efficient and safe procedure.

TABLE V-41. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of foliar explants of *Vanda teres* (Pathak and Vij, 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10

14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of HCl.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Agar is not added to liquid media. Amino acids, vitamins, and hormones may be heat-labile and are generally not autoclaved. However in this case they are added before autoclaving.

Plantlet Production from Leaf Explants of *Vanda teres*

The flowers of *Vanda teres* are "large rose-colored . . . 10 cm across . . . long lasting and fragrant." A micropropagation method using leaf explants taken from aseptic seedlings was developed at the Botanical Survey and Herbarium, Department of Medicinal Plants, Kathmandu, Nepal (Niraula and Rajbhandary, 1988).

Plant Material. In the original research, 10-cm-long leaves were excised from 6–8-month-old seedlings maintained on Vacin and Went medium (Vacin and Went, 1949). Sections, 5–8 mm, of these leaves were cultured.

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, 100-ml capacity, were used in the original research. Other containers (culture tubes, jar, plastic vessels) can also be used.

Culture Conditions. The research cultures were maintained at 25°C under 16-h photoperiods of 3000 lx (the light sources were not described). Standard culture room conditions will probably also be suitable.

Culture Media. Explants should be cultured initially on MS medium (Murashige and Skoog, 1962) supplemented with 1 g casein hydrolysate (CH) l^{-1} and 5 mg l^{-1} each of IAA and kinetin (Table V-42). PLBs that form on this medium should be moved to Vacin and Went medium (Table V-43) for plantlet production.

Procedure. Leaves are taken from seedlings and sectioned. The sections are cultured on the modified MS (Table V-42). When PLBs form on this medium they are transferred to the Vacin and Went substrate (Table V-43).

Developmental Sequence. Explants cultured on the MS-based medium (Table V-42) thicken, especially at the cut ends, after 8 weeks of culture and form small, greenish structures. After 3 months of culture the explants turn brown, but the small green structures continue to develop and produce a mass of PLBs at the end of 4 months (Fig. V-12). On being moved to Vacin and Went medium (Table V-43), the PLBs produce leaves after 4–6 weeks. Roots appear later and plants are developed 6 months from the start of culture. Plants that can be potted in a greenhouse are produced after 6–8 months.

General Comments. This is an interesting procedure but it cannot be used to select specific clones since the quality of seedlings is not known. The authors seem to use the words "plantlet" and "seedling" interchangeably. This is incorrect.

TABLE V-42. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of foliar explants of *Vanda teres* (Niraula and Rajbhandary, 1988)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

	Sugar				
16	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–7, 9, and 15 to 900 ml of distilled water (item 17), adjust pH as required, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. In this case items 1–15 can be added to the medium before autoclaving.

TABLE V-43. **Vacin and Went (VW) medium (Vacin and Went, 1949) for plantlet production from protocorm-like bodies derived from foliar explants of *Vanda teres* (Niraula and Rajbhandary, 1988)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 9) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 9) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 9), adjust pH to 5–5.4, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

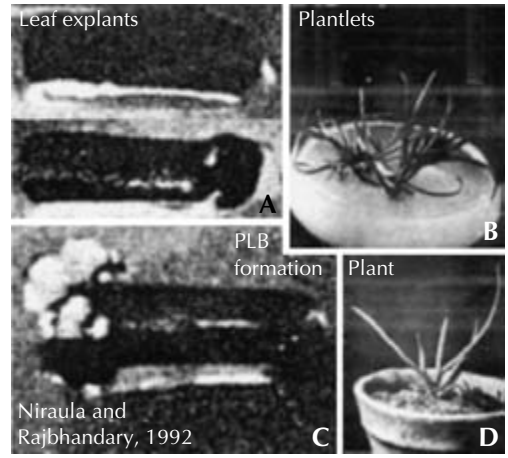

FIG. V-12. **Plantlet production from leaf explants of *Vanda teres*.**

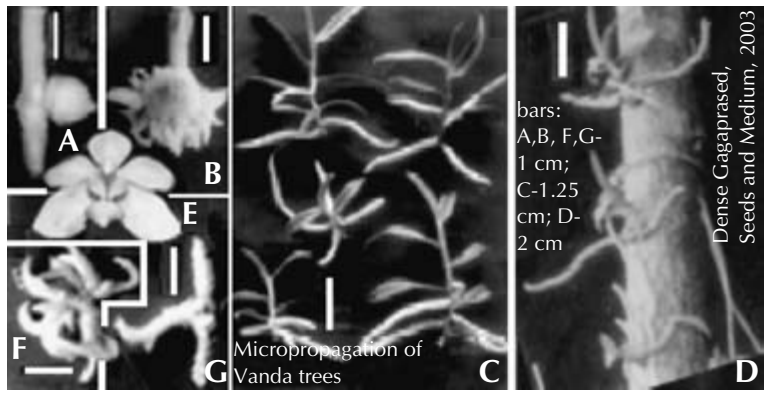

FIG. V-13. **Micropropagation of *Vanda spathulata*. A. Swollen axillary bud. B. Multiple shoot formation from an axillary bud. C. Rooted shoots. D. Plantlets established on a tree trunk 120 days after reintroduction. E. Flower. F. Axillary shoots after 120 days of culture. G. Shoots after 60 days of culture.**

Micropropagation of *Vanda spathulata*

A species with large golden flowers (Fig. V-13E), *Vanda spathulata* is used extensively in breeding and as part of an ayurvedic preparation called Guggul or Guggulu, which is presumed to lead to weight loss, promote flexible joints, support healthy heart functions, and reduce cholesterol and triglycerate levels. Its natural populations have been reduced severely as a result of overcollection and habitat destruction. A micropropagation method was developed at the Plant Biotechnology Division, Tropical Botanic Garden and Research Institute, Palode, Trivandrum, India (Decruse et al., 2003*a*, 2003*b*).

Plant Material. Terminal shoot cuttings are taken from flowering plants, trimmed to 2–2.5 cm, and inserted 3–5 mm deep in culture medium. When these explants produce 2–5-cm-long shoots (Fig. V-13F, G), nodes of 0.5–1 cm in length should be excised and cultured. This can be repeated three times.

Surface Sterilization. The cuttings should be washed with running tap water and then soaked in 2% Labolene (Qualigens Fine Chemicals, Mumbai, India, a Division of Glaxo, India) or Teepol (www.sigmaaldrich.com) for 15 min and rinsed thoroughly with running tap water. After the last tap water wash the cuttings should be submerged in 5% Steriliq (Combichem, Delhi, India) or 20% Clorox or a similar household bleach (20 ml bleach made up to 100 ml with distilled water) for 20 min, immersed in 0.1% mercuric chloride for 12 min, and rinsed three times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other containers can be used.

Culture Conditions. Cultures can be maintained at 25 ± 2°C under 12-h photoperiods of 30–50 μmol m^{-2} s^{-1} or standard culture room conditions.

Culture Media. Explants should be cultured first in Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with 44.4 μmol BA l^{-1} and 17.1 μmol IAA l^{-1} (Table V-44). MPR containing 22.2 μmol BA l^{-1} and 5.7 μmol IAA l^{-1} (Table V-45) should be used to subculture the nodal explants. One problem with this medium is that the abstract of the original paper states that 5.7 μmol l^{-1} should be added to the medium whereas the text lists the concentration as 1.7 μmol l^{-1}. The concentration recommended here is based on a graph (Decruse et al., 2003*a*, fig. 1 on p. 200) which seems to indicate that 5.7 μmol l^{-1} is suitable. For rooting, shoots should be cultured on MPR containing 75 g banana homogenate and 5.7 μmol IAA l^{-1} (Table V-46).

Procedure. Explants are placed on the first medium (Fig. V-44) and maintained on it for 3 months or until they produce buds (Fig. V-13A, B). Bud-bearing explants should be subcultured on the second medium (Table V-45) for "further multiplication." This step was repeated three times in the original research and the same can be done in practical laboratories. Shoots are moved to the third medium (Table V-46) for rooting.

Developmental Sequence. The axillary buds on the explants bulge and produce a spherical structure (Fig. V-13A) 60 days after the start of culture on the first medium (Table V-44). Within 2–3 months this structure produces numerous axillary shoots (Vig. V-13B). Nodes taken from the shoots produced in vitro produce vegetative buds within 30 days. When moved to the second medium (Table V-45), additional shoots (up to an average of 6.1 ± 4.4 per node), 3–5 cm long, are produced in 3–4 months. On being cultured on the banana-containing medium (Table V-46), more than 95% of the shoots produce 2–5 roots which can vary in length from 2 to 7 cm in 40–60 days (Fig. V-13C). When moved to community pots, 90–95% of these plants survive. After these plants become established on the pots they can be moved to ecorestoration sites (Fig. V-13D) where 43–79% can be expected to survive.

General Comments. Given the continued habitat destruction and overcollection, the use of mass, rapid, clonal propagation for ecorestoration can be justified on some levels especially since most orchids are heterozygous. However, it has also been suggested that restoration through the use of clones can lead to genetic pauperization. Since *Vanda* seeds are easy to germinate, the use of seedlings in ecorestoration may be preferable.

TABLE V-44. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Vanda spathulata* nodes (Decruse et al., 2003*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Another name for benzyladenine (BA) is benzylaminopurine (BAP). If the auxin or cytokinin fails to dissolve add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.6, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar (item 18) can also be added to the cold water (item 17) which is then brought to a boil and stirred. When the agar (item 18) is completely dissolved pour the solution into culture vessels and autoclave. Agar (item 18) is not used in liquid media. As a rule media which contain vitamins (items 8–13), hormones (items 14 and 15), and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE V-45. **Mitra, Prasad, and Roychowdhury medium (Mitra et al., 1976) modified for the culture of *Vanda spathulata* shoots produced from nodes in vitro (Decruse et al., 2003*a*)**

	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar[h]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available or if used may not be the same as that in the original formulation. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin fails to dissolve add a few drops of 0.1 N KOH.

[g]Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable, (2) the peel rather than the pulp should be used, (3) unpeeled banana homogenate should be incorporated in media, and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective banana variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view the best approach is to follow the recommendations in the original reports and/or use what is suggested there.

[h]Add items 1–15 to 800 ml distilled water (item 17) in a homogenizer and homogenize until the banana is completely dispersed, adjust pH to 5.6, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. Agar (item 18) can also be added to the cold water (item 17) which is then brought to a boil and stirred. When the agar (item 18) is completely dissolved pour the solution into culture vessels and autoclave. As a rule media which contain vitamins (items 8–13), hormones (items 14 and 15), and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

Culture of *Vanda pumila* Shoot Apices

A method for the culture of shoot apices of protocorms of *Vanda pumila* was developed as part of a cryopreservation research project (Na and Kondo, 1995, 1996; Kondo and Na, 1997).

Plant Material. Seeds from a capsule of *V. pumila* were germinated on MS medium (Murashige and Skoog, 1962). Shoot tips, 1–2 mm in diameter, were excised from 60-day-old protocorms and were cultured.

Surface Sterilization. Explants from seedlings in vitro do not require sterilization.

Culture Vessels. Culture tubes, 30 × 200 mm, containing 25 ml medium were used in the original research. Other containers are also suitable.

Culture Conditions. In the original research the cultures were maintained on a rotary shaker (2 rpm; Fig. V-14A) at 22°C under continuous illumination (a halogen light was used in the original research) of 4000–6000 lx (Na and Kondo, 1997) or 2000–10000 lx (Kondo and Na, 1997).

Culture Media. Shoot tips should be cultured on liquid B5 medium (Gamborg et al., 1968) containing 0.02 mg BA l^{-1} (Table V-47). Tissues, PLBs, and callus (Fig. V-14B, C) produced on this medium develop plantlets when cultured on half-strength hormone-free B5 (Table V-48). No medium is suggested for the culture of plantlets to more advanced stages. Plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. Seeds are germinated on MS and allowed to develop protocorms. Shoot tips are excised from these protocorms and cultured on the first medium (Table V-47). Tissue which develops on this medium (Table V-47) should be moved to the second solution (Table V-48) for plantlet production. For further growth the plantlets can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, Cym-1 to Cym-3, Cym-5, Cym-24, C-19, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without BH or AC. If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). AC should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

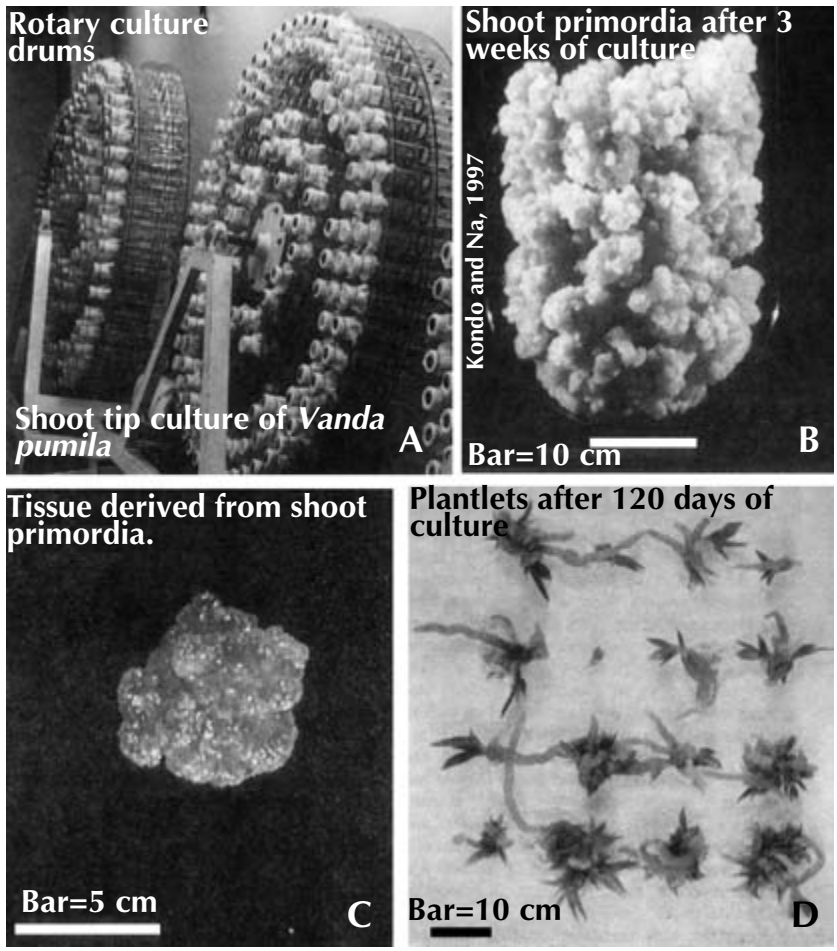

FIG. V-14. **Culture of *Vanda pumila* shoot tips.**

Developmental Sequence. The explants produce shoot primordia (Fig. V-14B, C), PLBs, and callus after 3 months of culture on B5. Plantlets develop after 120 days of culture on half-strength B5. Several additional months are required for the production of community-pot-size plants.

General Comments. The protocol was developed as a means of producing material for cryopreservation. It is not suitable for mass, rapid, clonal propagation of selected cultivars because the explants are taken from seedlings whose characteristics are not known.

TABLE V-47. **B5 medium (Gamborg et al., 1968) modified for the culture of shoot tips of *Vanda pumila* seedlings (Na and Kondo, 1995, 1996; Kondo and Na, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	134.0	13.4 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	150.0	15.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	2500.0	250.0 g l^{-1}	10	
5	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	150.0	15.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.0	300.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}

(d)	Manganese sulfate, $MnSO_4 \cdot H_2O$	10.0	1.0 g l^{-1}		
(e)	Potassium iodide, KI	0.75	75.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	2.0	200.0 mg l^{-1}		
	Polyol				
8	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
9	Benzylaminopurine (BAP)	0.02	2 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
10	Niacin (nicotinic acid)	1.0	10 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	10.0	1000 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			
	Solidifier				
15	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.8, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar (item 15) can also be added to the cold solution which is then brought to a boil and stirred. When the agar (item 15) is completely dissolved pour the medium into culture vessels and autoclave. Hormones (item 9) and vitamins (items 10–12) can be or are heat-labile. Therefore it is preferable to autoclave 1 l of medium in a 2-l flask and add heat-labile substances after autoclaving with sterilized pipettes under sterile conditions. All components are added to this medium before autoclaving.

TABLE V-48. **Half-concentration B5 medium (Gamborg et al., 1968) for plantlet production from callus, protocorm-like bodies and primordia derived from seedling shoot tips of *Vanda pumila* (Na and Kondo, 1995, 1996; Kondo and Na, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	67.0	6.7 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	75.0	7.5 g l^{-1}	10

	Solvent				
13	Water, distilled[f]	To 1000 ml			
	Solidifier				
14	Agar[f]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. In this table only the macroelements are reduced to half their concentrations in the B5 medium.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–11 to 900 ml of distilled water (item 13), adjust pH to 5.8, add sugar (item 12), and adjust volume to 1000 ml with distilled water (item 13). Bring the solution to a gentle boil and add the agar (item 14) slowly while stirring. The agar (item 14) can also be added to the cold solution which is then brought to a boil and stirred. When the agar (item 14) is completely dissolved, pour the medium into culture vessels and autoclave.

Plantlet Production from Thin Sections of *Vanda coerulea* Shoot Tips

Vanda coerulea, the Blue Vanda of Asia, is threatened with extinction in India due to overexploitation and habitat destruction. A rapid multiplication method on a medium containing the cytokinin, TDZ, was developed at the Department of Botany, Karnatak University (Malabadi et al., 2003).

Plant Material. In the original research, plants collected in the Jaintia and Khasi Hills in India and grown in a greenhouse served as explant sources. Shoot tips (4–8 mm) were harvested and surface-sterilized before longitudinal sections, 1–5 mm thick, were cut from them and cultured.

Surface Sterilization. The research shoot tips were "carefully washed with distilled water." This is not necessary. Washing with running tap water and a mild detergent is a common and effective step which can be used with these explants. After the wash the explants should be dipped in 0.1% (w/v) streptomycin (www.sigmaaldrich.com, www.vwr.com, www.fishersci.com, and other sources) for 20 s and 70% ethyl alcohol (74 ml of 95% ethanol diluted to 100 ml with distilled water) for 30 s, immersed in 0.1% (w/v) mercuric chloride ($HgCl_2$) for 2 min, and washed three times with sterile distilled water.

Culture Vessels. Glass tubes, 25 × 145 mm, containing 15 ml medium were used in the original research. Other containers can also be employed.

Culture Conditions. The research cultures were maintained at 25 ± 2°C, and a relative humidity of 55–60% under illumination of 100 μmol m^{-2} s^{-1} provided by cool white fluorescent tubes (the length of the photoperiod is not listed, but it seems reasonable to assume that 8–24-h light periods would be suitable).

Culture Media. The abstract of the original paper states that "Vacin and Went (VW) (1949) basal medium supplemented with 11.35" μmol TDZ was used. However, in the body of the paper the medium is described as "Vacin and Went's (VW) (1949) basal medium with 3.0% sucrose, 0.7% agar (Hi-media), 1.0 g l^{-1} meso-inositol, 2 g l^{-1} casein hydrolysate, 0.5 g l^{-1} L-glutamine, 250 mg l^{-1} Peptone and supplemented with . . ." TDZ. This is the medium suggested here (Table V-49). Shoots produced on this medium should be moved to half-strength Vacin and Went supplemented with 11.42 μmol IAA l^{-1} (Table V-50). "Well rooted shoots" should be potted in charcoal chips, coconut husk, and broken tiles (in a ratio of 2 : 2 : 1) or another suitable potting medium.

Procedure. Shoot tips are taken from mature plants, washed, and surface-sterilized. Explants are taken after that and placed on the first medium (Table V-49). Small bud-like structures which are formed by the explants after 2 weeks and PLBs are subcultured on fresh medium of the same kind (Table V-49) after a month. Shoots formed by the PLBs are moved to the second medium (Table V-50) for rooting.

TABLE V-49. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of shoot-tip sections of *Vanda coerulea* (Malabadi et al., 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monosobsic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Polyol				
8	*myo*-inositol	1.0 g	No stock	No stock	Weigh
	Amino acid				
9	Glutamine	500.0	No stock	No stock	Weigh
	Cytokinin				
10	Thidiazuron (TDZ)	2.5	250 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additives				
11	Casein hydrolysate	2.0 g	No stock	No stock[f]	Weigh
12	Peptone	250.0	No stock	No stock[g]	
	Sugar				
13	Sucrose	30.0 g[h]	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[i]	To 1000 ml			
	Solidifier				
15	Agar[i]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 14) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Keep frozen between uses.

[f]Not all casein hydrolysates are the same. Their compositions and analyses vary depending on the methods by which they were produced. A product sold by Merck (www.merck.de) as casein hydrolysate (CH) is obtained by degrading casein with hydrochloric acid; vitamins and other growth-promoting compounds are largely destroyed in this process. The CH sold by Sigma-Aldrich (www.sigmaaldrich.com) is pancreatic hydrolysate of casein. There is also a CH which is hydrolysed by enzymes. Becton, Dickinson and Company (www.bd.com) sells Difco products including a number of different casamino acid products all of which are casein hydrolysates. Therefore if a method specifies a source for the CH in its culture medium it is best to obtain the additive from the same vendor. If a source is not listed it is best to purchase CH which is described as being suitable as a supplement for culture media. Failing that, CH should be purchased from a source which specializes in tissue culture and micropropagation supplies. One such source is www.caissonlabs.com. They list casein rather than CH as Stock #: SPCA205. Another source for CH is www.duchefa.com (item 1301). Additional sources include www.fishersci.com, www.thomassci.com, and others.

[g]Peptones vary. Use one which is recommended or certified for plant tissue cutlure.

[h]The original formulation of the Vacin and Went medium contains 20 g sucrose l^{-1}.

[i]Add items 1 and 4–12 to the 500–700 ml of distilled water (item 14) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 14), adjust pH to 5.8, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar (item 15) can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

TABLE V-50. **Half-strength Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the rooting of shoots produced by tissues derived from shoot-tip sections of *Vanda coerulea* (Malabadi et al., 2003)**

	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	3.75	375.0 mg l^{-1}	10	
	Auxin				
8	Indoleacetic acid (IAA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. Only the concentrations of items 1–5 and 7 are reduced in half.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]If the auxin does not dissolve add a few drops of 0.1 N KOH. Keep frozen between uses.

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 10), adjust pH to 5.8, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar (item 11) can also be added to the cold water which is then brought to a boil and stirred. When the agar (item 11) is completely dissolved, pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

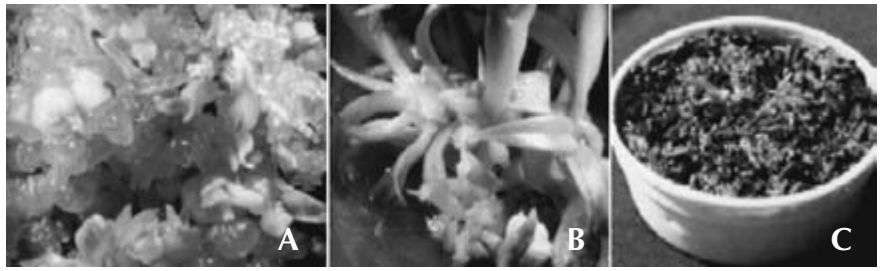

FIG. V-15. **Micropropagation of *Vanda coerulea* through the culture of thin sections of shoot tips. A. Bud-like structures that form after 2 weeks of culture. B. Shoots that form after 4–8 weeks of culture. C. Plantlets, 12 weeks old, in a pot. (Malabadi et al., 2003.)**

Developmental Sequence. The explants produce bud-like structures 2 weeks after being placed in culture (Fig. V-15A). PLBs are also formed. Shoots with 2–3 leaves are produced after 4–8 weeks (Fig. V-15B). These shoots form roots on the second medium; they are then moved to pots (Fig. V-16C), at first 2–4 per pot. After 5 months, the plants are potted individually in 22-cm pots.

General Comments. TDZ, first assumed to be a defoliant and used commercially as such, is very effective as a cytokinin in culture media. It is usually added to orchid culture media in much lower concentrations than the one employed in this protocol. What, if any, mutagenic effects the high concentration may have is not clear. The use of thin sections of shoot tips is clever and the protocol seems effective, but the paper which describes the procedure is not written as well as it should have been.

Vandofinetia

Vandofinetia is a hybrid genus. The first hybrid, *Vandofinetia* Premier, was produced in Hawaii, but many of the recent hybrids have originated in Japan.

Undescribed Method for the Micropropagation of *Vandofinetia*

A culture method is mentioned but is not described in an article on *Phalaenopsis* (Intuwong and Sagawa, 1974).

Micropropagation of *Vandofinetia* through the Culture of Flower-bud Explants

A method for mass, rapid, clonal propagation of *Vandofinetia* was developed at the Kirin Brewery Laboratory in conjunction with the Tagaki Orchid Nursery (Kishi et al., 1997*a*, 1997*b*).

Plant Material. Shoots, 10 cm long, bearing immature flower buds should be harvested and taken to the laboratory. Floral buds, 3–6 mm long, should be cut with razor blades. After surface sterilization, the buds should be sectioned into 0.5-mm cubes, which are cultured.

Surface Sterilization. The shoots should first be washed with a mild liquid detergent and running water. Gentle scrubbing with a very soft (and/or used) toothbrush is advisable but is not necessary (this initial washing is not part of the original procedure). After that, the floral buds should be washed with 10% benzalkonium chloride (www.sigmaaldrich.com, www.vwr.com, www.fishersci.com, and other sources) for 10 min and dipped for 30 s in 70% ethanol (73–74 ml 95% ethanol diluted to 100 ml with distilled water). This should be followed by a 5-min immersion in 0.5% sodium hypochlorite [10 or 8.3 ml, respectively, of household bleach which contains 5–5.25 or 6% sodium hypochlorite diluted to 100 ml with distilled water to which is added 50 mg Tween 20 (www.sigmaaldrich.com, www.vwr.com, www.fishersci.com, and other sources)], or an equal amount of a mild household detergent, and three washes with sterile distilled water.

Culture Vessels. Culture tubes, 30×200 mm containing 20 ml of medium, were used in the original research. Other containers are also suitable.

Culture Conditions. Cultures should be maintained on a drum-type rotary shaker (the one used in the original research was manufactured by Nihon Ika Kikai Co., Ltd., Tokyo, Japan) at 1 rpm, a temperature of 25 ± 2°C, and a 16-h photoperiod of 3000 ± 500 lx provided by fluorescent lamps. Standard culture room temperature and illumination will probably also be suitable.

Culture Media. Explants should be cultured on MS medium (Murashige and Skoog, 1962) containing 30 g sucrose l^{-1} (Table Vf-1). PLBs produced on this medium (Table Vf-1) can be proliferated on quarter-strength MS containing 10 g sucrose l^{-1} and 6.95 mg $FeSO_4 \cdot 7H_2O$ instead of FeEDTA (Table Vf-2). After that PLBs should be cultured on a Hyponex medium (Table Vf-3) for 2 months. Plantlets and PLBs produced on this medium (Table Vf-3) should be moved to MS (Table Vf-1) at 2-month intervals.

Procedure. Shoots are washed and after that the floral buds are removed, surface-sterilized, and rinsed with distilled water. The buds are cut into 0.5-mm cubes and these are cultured on the first medium (Table Vf-1). PLBs produced on the first medium (Table Vf-1) are proliferated on the second solution (Table Vf-2) and moved to the third substrate (Table Vf-3) for 2 months. Plantlets and PLBs produced on the third medium (Table Vf-3) are moved to the MS solution (see Tables Anct-1, Ble-1, Cym-16, Cym-19, Den-27, Phal-9, Phal-11, Phal-15, Rhy-4, and Spa-1 are all suitable). They can be subcultured on this medium for 4 months at 2-month intervals. This protocol can produce more that 10,000 plantlets ready for community pots from one bud during a single year.

Developmental Sequence. PLBs are produced on the first medium (Table Vf-1). These PLBs proliferate on the second medium (Table Vf-2). Removal of EDTA from the medium accelerates the process. Plantlet production and growth take place on the third and MS media (Table Vf-3 and other tables as listed above).

General Comments. There are two major advantages to this procedure. One is the source of explants. Flower buds are usually plentiful and their removal does not endanger the donor plant. The second is its yield of 10,000 plants from a single bud per year. However, the high yield is also a possible disadvantage because excessive proliferation can cause undesirable mutations. Fortunately in this case the frequency of somaclonal variations seems to be small.

TABLE VF-1. **One-quarter concentration of Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as used for the culture of *Vandofinetia* flower-bud explants (Kishi et al., 1997*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	412.5	41.25 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	110.0	11.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	92.5	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	475.0	47.5 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	42.5	4.25 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin[f]				
	Cytokinin[f]				
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise. Only the concentrations of macroelements are one-quarter those of the original formulation. The concentrations of iron and microelements are so small that reducing their levels to one-quarter of the original formulation would not affect the osmolarity of the solution. It is also possible that if reduced to a quarter of the original formulation the levels of these elements would become suboptimal.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. A commercial FeEDTA preparation (obtained from Wako Pure Chemical Inc., Osaka, Japan) was used in the original research at 10.525 mg l^{-1}.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]There is no mention in of hormones in the original paper. That is why there are no entries under the auxin and cytokinin headings.

[g]Add items 1–9 and 10–12 to 900 ml of distilled water (item 14), adjust to 5.8, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14), pour the solution into culture vessels, and autoclave. Heat-labile substances like amino acid (item 8), hormones, and vitamins (items 10–12) are sometimes added to the warm and still liquid solution after autoclaving under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. In this case all components are added to the medium before sterilization. Agar is not added to liquid media.

TABLE VF-2. **One-quarter concentration of Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of protocorm-like bodies derived from flower-bud explants of *Vandofinetia* (Kishi et al., 1997*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

	Auxin[f]				
	Cytokinin[f]				
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise. Only the concentrations of macroelements are one-quarter those of the original formulation. The concentrations of iron and microelements are so small that reducing their levels to one-quarter of the original formulation would not affect the osmolarity of the solution. It is also possible that if reduced to a quarter of the original formulation the levels of these elements would become suboptimal.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]The stock solution will form a brown precipitate on standing and must be shaken vigorously before dispensing an aliquot into the culture medium.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]There is no mention of hormones in the original paper. That is there are no entries under the auxin and cytokinin headings.

[g]Add items 1–9 and 10–12 to 900 ml of distilled water (item 14), adjust to 5.8, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14), pour the solution into culture vessels and autoclave. Heat-labile substances like amino acid (item 8), hormones, and vitamins (items 10–12) are sometimes added to the warm and still liquid solution after autoclaving under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. In this case all components are added to the medium before sterilization. Agar is not added to liquid media.

TABLE VF-3. **Hyponex medium for plantlet production from and culture of protocorm-like bodies derived from flower-bud explants of *Vandofinetia* (Kishi et al., 1997*b*)**

Component	Amount l^{-1}	Comments
Hyponex	2 g	Add components 1 and 2 to 900 ml of water, adjust pH to 5.8, add component 3, raise volume to 1000 ml, bring to gentle boil, add agar (component 4) slowly with stirring. When agar is dissolved pour the medium into culture vessels and autoclave. Use proteose peptone which is intended for tissue culture or microbiological use. Possible sources are www.sigmaaldrich.co, www.caissonlabs.com, www.phytotechlab.com, and others.
Proteose peptone	2 g	
Sucrose	20 g	
Agar	8 g	

Vanilla

The only orchid not grown for its ornamental value, *Vanilla* is the source of the spice vanilla (Lawler, 1984). At one time it was grown in Tahiti, Madagascar, Puerto Rico, Fiji, the Seychelles, and a number of other areas. Currently the major producer of vanilla is Madagascar. *Vanilla* is attacked by a systemic fungus that is transmitted in the cuttings used to propagate the plant. As a result new plantings are diseased from the outset. Clonal propagation through the culture of uninfected explants could be a means of producing healthy plants.

There are approximately 107 *Vanilla* species. They are found in tropical America, South East Asia, New Guinea, Africa, and Madagascar. There are no *Vanilla* species in Australia. The most important species for vanilla production is *Vanilla planifolia*. Two other species that serve as sources of vanilla are *V. pompona* and *V. tahitensis*. Additional *Vanilla* species also produce aromatic fruits, but few if any of them are cultivated to any extent.

In Vitro Propagation of *Vanilla planifolia*

To reduce dependence on cuttings, in vitro propagation of *Vanilla planifolia* was studied at Purdue University (Kononowicz and Janick, 1984).

Plant Material. Nodal stem sections are cultured.

Surface Sterilization. Explants are surface-sterilized by immersing them in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 20 min. Although not mentioned by Kononowicz and Janick (1984), several rinses with sterile distilled water are advisable following the sterilization.

Culture Vessels. Petri dishes and baby-food jars were used in the original research. Culture tubes, Erlenmeyer flasks, and other containers can also be used.

Culture Conditions. Cultures should be maintained "under low intensity illumination (25–100 μmol s^{-1} m^{-1})" from cool white fluorescent lamps for 16 h daily at 26°C.

Culture Medium. A modified MS medium (Table Vla-1) is used.

Procedure. Place the explants in the culture medium, and allow them to branch and produce plantlets.

Developmental Sequence. Shoot proliferation occurs first, and roots form later. Rooted plants can be transferred to potting medium.

TABLE VLA-1. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Vanilla* explants (Kononowicz and Janick, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2 EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Cytokinin				
10	Benzylaminopurine (BAP)	0.5	100 mg 100 ml^{-1} 95% ethanol[f,g]	0.5	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
14	Casein hydrolysate	1 g	No stock	No stock	Weigh
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If cytokinin does not dissolve, add a few drops of dilute HCl.

[g]Keep refrigerated between uses.

[h]Add items 1–7, 9, and 14 to 900 ml distilled water (item 16); adjust pH to 5.7, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormone, and vitamins (items 8 and 10–13) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

General Comments. This procedure can be useful for the production of disease-free plantlets. "Callus induction was attempted, . . . but explants did not develop" any calli.

Production of *Vanilla planifolia* Plantlets in Vitro

In an effort to find a long-range solution to the disease problem, Z. Gu, L. P. Nyman, and this author (JA) developed a procedure for callus formation and multiple plantlet production (Gu et al., 1987*a*).

Plant Material. Lateral buds are cultured, and the callus produced by them is used for propagation. Stem sections, 5–8 cm long and each containing one bud, are cut, sterilized, and trimmed to cubes measuring $5 \times 5 \times 1$ mm.

Surface Sterilization. Stem sections are first scrubbed with a very soft toothbrush under running water and then sprayed with 70% aqueous ethanol. After being sectioned the stems are immersed in 50% Clorox (50 ml Clorox diluted to 100 ml with distilled water) for 20 min and rinsed three times with distilled water.

Culture Vessels. Erlenmeyer flasks of 125- and 250-ml capacity were used in the original research. Other containers can also be utilized.

Culture Conditions. The cultures should be maintained under 16-h photoperiods of 0.8 mW cm^{-2} provided by Sylvania Gro Lux fluorescent tubes at $22 \pm 3°C$.

Culture Media. A modified Linsmaier–Skoog medium (Table Vla-2) is used for callus induction and maintenance. The callus is moved to another modification (Table Vla-3) for shoot and root production.

Procedure. Place explants on the first medium (Table Vla-2); when callus forms, subculture it on the same solution. When enough callus is available, move sections to the second medium (Table Vla-3) for plantlet formation. Fully developed plantlets can be moved to a potting mix.

Developmental Sequence. Bud explants can produce single (Fig. Vla-1A) or multiple (Fig. Vla-1B, C) shoots that develop roots (Fig. Vla-1D) or callus (Fig. Vla-1E). Shoots (Fig. Vla-1F) form on the callus and can develop into plantlets (Fig. Vla-1H). Callus can also form on leaf bases (Fig. Vla-1G). The callus forms between weeks 2 and 4, but in the original research only 14.6% of the explants produced calli. On the second medium (Table Vla-3), 53% of the callus section produced shoots and 44% formed roots.

General Comments. This procedure can be useful for the production of fungus-free plantlets.

TABLE VLA-2. **Modified Linsmaier–Skoog medium (Linsmaier and Skoog, 1965) for callus induction from *Vanilla* explants (Gu et al., 1987*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10

	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If cytokinins do not dissolve, add a few drops of dilute HCI. The original recipe for this medium gives the concentration of IAA as being "2.0 (1–30) mg/l," and the level of kinetin as "0.03–0.2 (0.001–10) mg/l" and adds in a footnote that "IAA and kinetin levels vary with the type of growth desired." In this case the intent is to induce callus formation, but the medium contains only cytokinins and no auxin(s).

[g]Keep refrigerated between uses.

[h]Add items 1–8 and 15 to 900 ml distilled water (item 17), adjust pH to 5.7, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l Erlenmeyer flask and autoclave. Add amino acid (item 9) and cytokinins (items 10 and 11) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE VLA-3. **Modified Linsmaier–Skoog medium (Linsmaier and Skoog, 1965) for plantlet production from *Vanilla* callus (Gu et al., 1987*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, Kl	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Polyol				
8	*myo*-Inositol	100	No stock	No stock	Weigh
	Amino acid				
9	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.2	80 mg 100 ml^{-1} 95% ethanol[f,g]	0.25	
	Cytokinin				
11	Benzylaminopurine (BAP)	0.1	40 mg 100 ml^{-1} 95% ethanol[f,g]	0.25	
	Vitamins				
12	Niacin	0.5	200 mg 100 ml^{-1} 95% ethanol[g]	0.25	
13	Pyridoxine	0.5	200 mg 100 ml^{-1} 95% ethanol[g]	0.25	
14	Thiamine (vitamin B_1)	0.4	160 mg 100 ml^{-1} 95% ethanol[g]	0.25	
	Complex additive				
15	Casein hydrolysate	1 g	No stock	No stock	Weigh
	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved. Dispense volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin do not dissolve, add a few drops of dilute KOH or HCl, respectively. The original recipe for this medium gives the concentration of IAA as being "2.0 (1–30) mg/l," and the level of kinetin as "0.03–0.2 (0.001–10) mg/l" and adds in a footnote that "IAA and kinetin levels vary with the type of growth desired." The medium described in this table includes the auxin NAA in place of IAA, and the cytokinin BAP instead of kinetin.

[g]Keep refrigerated between uses.

[h]Add items 1–8 and 15 to 900 ml distilled water (item 17), adjust pH to 5.7, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, auxin, and cytokinin (items 9–11) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels.

Shoot produced from a bud explant within 2 weeks of culture on modified Linsemaier–Skoog medium containing 1 mg BA l^{-1} (× 2.9). B. Multiple shoots (s) forming on a bud explant cultured on modified Linsemaier–Skoog medium (× 2.9). C. Multiple shoots (s) after 5 weeks of culture on modified Linsemaier–Skoog medium (Table Vla-2; × 2.9). D. Elongated shoot with emerging root (r) after 5 weeks of culture (× 1.8). E. Friable yellow callus with numerous surface hairs on modified Linsemaier–Skoog medium (Table Vla-2) after 3 weeks of culture (× 2.9). F. Shoots (s) forming after 4 weeks (× 2.6). G. Small callus masses (c) at the base of a young leaf on modified Linsemaier–Skoog medium (× 2.9). H. Plantlets growing in the greenhouse after 6 weeks in a potting mix (× 0.6). (Source: Professor Z.–P. Gu, Department of Biology, Lanzhou University, Lanzhou, People's Republic of China.)**

Clonal Propagation of *Vanilla planifolia* from Aerial Root Rips

As already mentioned,

> a major threat to *Vanilla* cultivation is a root rot disease (*Fusarium batatatis* var *vanillae* Tucker) which often has a devastating effect and completely destroys the plantation. . . . Techniques of rapid and large scale multiplication of disease-free plants would be of considerable value. (Philip and Nainar, 1986)

Plant Material. (1) Stem discs that are 2–3 cm long, have a node in the middle, and are excised from near apices, and (2) aerial root tips that are 2 cm long, are cultured.

Surface Sterilization. Explants are surface-sterilized by immersing them in 0.5% mercuric chloride, $HgCl_2$ (500 mg per 100 ml distilled water) for 10 min and then rinsed three times with sterile distilled water. $HgCl_2$ is a very toxic, dangerous substance and must be used with great caution.

Culture Vessels. Culture tubes and Erlenmeyer flasks can be used.

Culture Conditions. Cultures should be maintained under continuous illumination of 7000–8000 lx at 24 ± 2°C. Stem sections and root tips are first cultured on filter-paper bridges placed in liquid medium (Fig. Vla-2).

Culture Media. Stem sections produce PLBs when cultured in liquid modified Knudson C medium (Table Vla-4). Root tips are cultured on modified MS medium (Table Vla-5).

Procedure. Place stem explants on paper bridges in the first medium (Table Vla-4), and allow them to form PLBs, which eventually produce plantlets. These can be cultured on unmodified Knudson C medium (see Table Aranda-7) with and without banana homogenate. Allow root tips to remain on the paper bridges in the second medium (Table Vla-5) for 3 months, and then move them to a solid version of the same solution.

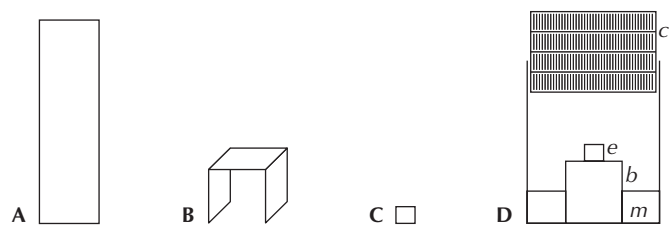

FIG. VLA-2. **Preparation of a filter-paper bridge for the culture of *Vanilla* and/or other explants. A. A rectangular strip cut from a filter-paper disk; dimensions would depend on the size of the culture tube. B. The filter-paper strip folded to form a bridge. C. Explant. D. Culture tube with cover (c), filter-paper bridge (b) in culture medium (m) with explant (e).**

TABLE VLA-4. **Modified Knudson C medium (Knudson, 1946) for the culture of *Vanilla* shoot explants (Philip and Nainar, 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
7	Naphthaleneacetic acid (NAA)	1	100 mg 100 ml^{-1} 95% ethanol[d]	1	
	Cytokinin				
8	Kinetin	0.1	40 mg 100 ml^{-1} 95% ethanol[d]	0.25	
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[d]Keep refrigerated between uses. If the auxin or cytokinin do not dissolve, add a few drops of KOH or HCl, respectively.

[e]Add items 1–6 to 900 ml distilled water (item 10), adjust pH to 5.0–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Pour solution into a 2-l flask and autoclave. Add auxin (item 7) and cytokinin (item 8) to autoclaved medium under sterile conditions with sterilized pipettes, swirl well several times to insure complete mixing, and dispense into culture vessels. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

Developmental Sequence. Each stem explant can produce 10–15 PLBs that are round, glistening, and have rhizoids. Every protocorm develops at its tip a bud that produces leaves and eventually a plantlet. The root tips swell within 2 months and after 3 months crack to expose spherical bulges. On the solid medium, multiple meristems form, which give rise to shoots and roots. Well-developed plantlets form within 9 months.

General Comments. This seems to be a useful and effective method.

Medicinal uses of vanilla include: aromatic stimulant in cases of asthenic fevers, rheumatism, and hysteria; digestion and stomach problems; general stimulant; antidote to poison and the bite of venomous animals; emmenagogue and irregular menstruation; acceleration of childbirth and abortion of dead fetuses; dissipation of flaturs; and a cure for fever (Lawler, 1984).

TABLE VLA-5. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Vanilla* root tips (Philip and Nainar, 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin do not dissolve, add a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 16), adjust pH to 5.0–5.5 as required, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Pour solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8 and 10–14) to autoclaved solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

Propagation in Vitro of *Vanilla planifolia*

Vanilla plants were propagated from axillary buds on modified MS medium (Cervera and Madrigal, 1980) by a procedure that was not described in sufficient detail to justify its inclusion here.

Isolation of *Vanilla* Protoplasts

The method developed for *Acampe praemorsa* was used to isolate 16.5×10^4 and 3.9×10^4 protoplasts from leaves and roots, respectively, of *Vanilla wightiana* (Seeni and Abraham, 1986).

In Vitro Multiplication of *Vanilla planifolia* using Axillary Bud Explants

The constantly increasing demand for vanilla flavoring has created a great demand for plants. This led to the development of a micropropagation method through the culture of axillary buds (George and Ravishankar, 1997).

Plant Material. Stem-node sections should be excised from field-grown plants. In the original research the nodes were taken from 1-year-old plants. If plants of this age are not available, nodes should be taken from young growths on older vines. Every section should be 1.5–2.0 cm long with an axillary bud in the middle (Fig. Vla-3C). Leaves should be removed by cutting the petiole flush with the stem.

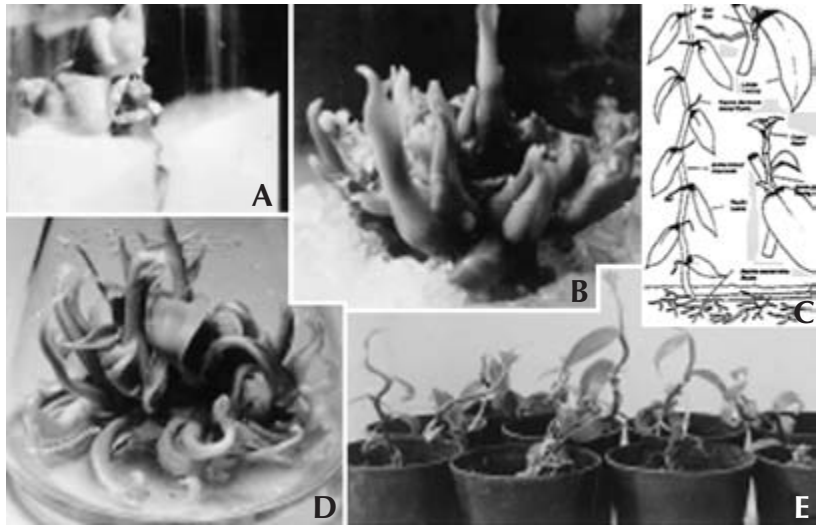

FIG. VLA-3. **Culture of *Vanilla planifolia* axillary buds. A. Explant on medium. B. Multiple shoots. C. Vine (left) and leaf explants prior to removal of leaves (right). D. Multiple shoots following proliferation. E. Potted plantlets being hardened. (George and Ravishankar, 1997.)**

Surface Sterilization. Sections should be first washed with running water and a mild liquid detergent (Tween 20 was used in the original research; it is available from www.sigmaaldrich.com, www.fishersci.com, www.vwr.com, www.duchefa.com, and other sources; a mild household liquid detergent can also be used) for 10 min. After that the explants should be immersed in 0.15% (w/v) mercuric chloride (this is a toxic substance which must be handled with care) for 5 min and then washed three times with sterile distilled water (Table Vla-6).

TABLE VLA-6. **Surface sterilization of *Vanilla* explants**

Step	Agents	Duration
1	Running water and Tween 20 or a mild household detergent	10 min
2	Running water to remove detergent	1 min
3	Mercuric chloride, 0.15% (w/v)[a]	5 min
4	Sterile distilled water rinse	3–5 min
5	Sterile distilled water rinse	1–3 min
6	Sterile distilled water rinse	1–3 min

[a]Caution, this is a very toxic substance.

Culture Vessels. Erlenmeyer flasks, culture tubes, or other containers can be used depending on the available shaker.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under continuous illumination of 37.5 μE m^{-2} s^{-1} (Philips fluorescent lamps were used in the original research). Standard culture room conditions are also suitable. Liquid cultures should be placed on a rotary shaker at 90 rpm.

Culture Media. For multiple shoot initiation, the explants should be cultured on modified MS medium (Murashige and Skoog, 1962) containing 2 mg BA l^{-1}, 1 mg NAA l^{-1}, and 10 g agar l^{-1} (Table Vla-7). Liquid MS containing 1 mg BA l^{-1} and 0.5 mg NAA l^{-1} (Table Vla-8) is used for shoot proliferation. After proliferation, n shoots should be cultured on semisolid MS (Table Vla-9). Well-developed shoots should be moved to a half concentration of MS darkened with charcoal (Table Vla-10).

Procedure. Discolored edges should be removed from explants after the final wash, leaving at least 0.5 mm of tissue on each side of the bud. The bases of explants must be inserted in the first medium (Fig. Vla-3A, Table Vla-7). Explants (Fig. Vla-3C) should be cultured on this medium for 21–28 days until multiple shoots are formed (Fig. Vla-3B). The shoots should be moved to the liquid medium (Fig. Vla-3D, Table Vla-8) and maintained on a shaker for a month or until they have proliferated well. After that, they should be transferred to MS (Table Vla-9) for 30 days or until the shoots are well developed. These shoots are moved to darkened medium (Table Vla-10) for rooting. Rooted plantlets should be potted (Fig. Vla-3E), hardened in a greenhouse for 30 days, and moved to the field.

Developmental Sequence. Explants produce multiple shoots on the first medium (Table Vla-7). These shoots proliferate on the second solution (Table Vla-8). They grow and produce leaves on the third substrate (Table Vla-9). Roots appear on the third medium (Table Vla-10), and plantlets harden in pots.

TABLE VLA-7. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of axillary-bud explants of *Vanilla planifolia* (George and Ravishankar, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	N^6-benzyladenine (BA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) are heat-labile and are often added to the warm and still liquid medium after autoclaving under sterile conditions with sterilized pipettes. In this case all components are added before sterilization.

TABLE VLA-8. **Liquid Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the proliferation of shoots produced by axillary-bud explants of *Vanilla planifolia* (George and Ravishankar, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Pour the solution into culture vessels and autoclave. Amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) are heat-labile and are often added after autoclaving under sterile conditions with sterilized pipettes. In this case all components are added before sterilization.

TABLE VLA-9. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of proliferated shoots derived from axillary-bud explants of *Vanilla planifolia* (George and Ravishankar, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[f,g]	To 1000 ml			
	Solidifier				
15	Agar[f,g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]The original paper does not indicate whether hormones were added. Therefore none are included in this formulation.

[g]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH 5.7, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution into culture vessels and autoclave. Amino acid (item 8), hormones, and vitamins (items 10–12) are heat-labile and are often added to the warm and still liquid medium after autoclaving under sterile conditions with sterilized pipettes. In this case all components are added before sterilization. The original states that semisolid medium was used. In a way this is misleading because 10 g of agar is the usual amount of solidifier for MS.

TABLE VLA-10. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the rooting of shoots derived from axillary-bud explants of *Vanilla planifolia* (George and Ravishankar, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10

	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[f]	To 1000 ml			
	Solidifier				
15	Agar[g]	10.0 g	No stock	No stock	Weigh
	Darkening agent				
16	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]The original paper does not indicate whether hormones were added. Therefore none are included in this formulation.

[g]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.7, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, add the darkening agent (item 16) slowly with vigorous stirring. When the charcoal (item 16) is completely dispersed pour the solution into culture vessels and autoclave. Amino acid (item 8), hormones, and vitamins (items 10–12) and heat-labile and are often added after autoclaving to the still hot and liquid solution under sterile conditions with sterilized pipettes, mixed well, and the medium is distributed to preautoclaved culture vessels. In this case all components are added before sterilization.

[h]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite, which are very different in nature, should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

General Comments. This protocol was described as "an efficient micropropagation system." The description may be apt, but this method may have a major weakness: If explants are taken from diseased plants, plantlets produced through this method may also carry pathogens. Also, the original paper should have been organized better.

Cell Suspension Cultures of *Vanilla*

Cell suspension cultures of *Vanilla* are used for studies of biosynthesis and metabolism of vanillin, phenolics, and other substances (for examples see Romagnoli and Knorr, 1988; Havkin-Frenkel et al., 1996; Yuanna and Verponte, 2002; for a review see Dörnenburg and Knorr, 1996). The culture method used by several investigators was developed in Switzerland (Funk and Brodelius, 1990).

Plant Material. Cell suspension cultures of *Vanilla planifolia* were provided by Danisco Biotechnology in Denmark (www.danisco.com; an inquiry to the company elicited the following reply: "We have only some confidential internal reports which we cannot reveal."). The cell suspension cultures were initiated from a callus produced in 1986 by an explant taken from a fresh fruit.

Surface Sterilization. Cell suspension cultures do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, 500-ml capacity, containing 100 ml of medium, should be used.

Culture Conditions. Cultures should be maintained on a gyratory shaker at 120 rpm in the dark at 26°C. An attempt to culture the cells on a shaker under standard laboratory conditions in the light could be worthwhile but results may not be useful.

Culture Media. Liquid MS medium (Murashige and Skoog, 1962) containing 1 mg 2,4-D l^{-1} (Table Vla-11) was used in the original research. It may be interesting to determine whether the cells will form callus masses, PLBs, or plantlets if cultured on the same medium in solid form or one of the other media used for micropropagation of *Vanilla* in the dark or under illumination.

Procedure. Cultures should be centrifuged to collect cells. Every 10 days, 7 g fresh weight (FW) of cells should be transferred to fresh medium. Introducing 10–20-ml suspension culture aliquots into fresh medium as a means of subculturing the cells may be worth trying.

Developmental Sequence. Cultures reach a growth curve plateau and a dry weight of 15 g l^{-1} 8–9 days after being started (Fig. Vla-4). During the very active growth phase (days 4–8) the doubling time is approximately 36 h.

General Comments. This may well be the only long-term orchid cell suspension culture. It is a useful achievement. The cells can be used for metabolic and biochemical research. Unfortunately no plants were produced from these cultures.

TABLE VLA-11. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for *Vanilla* cell suspension cultures (Funk and Brodelius, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	2,4-Dichlorophenoxyacetic acid (2,4-D)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.5 (this is a guess, the original paper does not list a pH), add sugar (item 14), raise volume to 1000 ml with distilled water (item 15). Pour the solution into culture vessels and autoclave. Agar is not added to liquid media. Amino acid (item 8), hormones (item 10), and vitamins (items 11–13) are heat-labile and are often added after autoclaving to the still hot and liquid solution under sterile conditions with sterilized pipettes, mixed well, and the medium is distributed to preautoclaved culture vessels. In this case all components are added before sterilization.

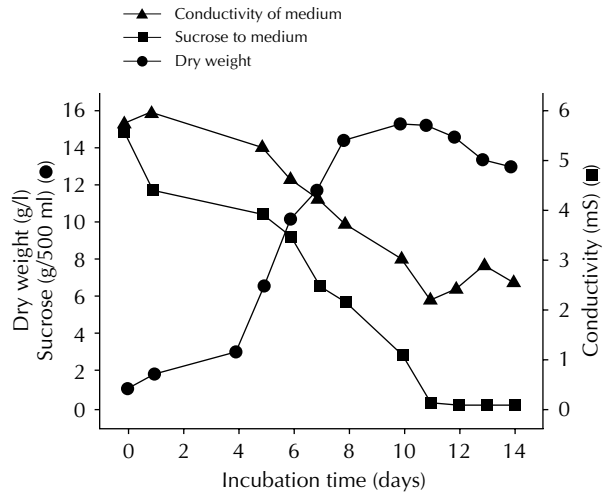

FIG. VLA-4. **Growth of *Vanilla planifolia* cells in in suspension cultures (Funk and Brodelius, 1990).**

Plantlet Production from *Vanilla* Root Tips

"In an attempt to evolve an effective method of clonal propagation of the commercial orchid, *Vanilla planifolia*, without sacrificing the monopodial mother plant" a method was developed involving "the lysis of the root cap of the explant [which] sets in train a series of histological events which leads to plantlet formation" (Philip and Nainar, 1988).

Plant Material. Aerial root tips, 2 cm long, should be cultured.

Surface Sterilization. Root tips should be washed with running water, immersed in 0.15% mercuric chloride ($HgCl_2$; this is a toxic substance which must be handled with care) for 10 min, and after that rinsed three times with sterile distilled water.

Culture Vessels. In the original research the explants were cultured on filter-paper bridges in tubes (see Fig. Vla-2). Culture tubes were probably used because it is somewhat easier to build filter-paper bridges in narrow containers. Erlenmeyer flasks, 100-ml capacity, were used for cultures maintained on solid medium.

Culture Conditions. The research cultures were maintained at 24 ± 2°C under continuous illumination of 7000–8000 lx. Similar conditions should also prove to be suitable.

Culture Media. The original paper is not very clear on this subject. It starts by stating that the explants should be cultured "on filter paper bridges [see Fig. Vla-2] in tubes containing liquid MS (Murashige and Skoog, 1962) medium supplemented with

IAA (0–10 mg l^{-1}) and 0.2 mg l^{-1} KN" (Table Vla-12). It also suggests that "2 cm long root tips excised from young aerial roots and cultured on liquid MS medium supplemented with 1–5 mg l^{-1} of IAA and 0.2 mg of KN grew in length for about 10 d[ays] . . . [but] . . . Growth in length of the young tips, however, ceases after 1 d[ay] . . ." and eventually meristemoids are produced leading to leaf whorls after 9 weeks. Roots are "initiated only after four to five leaves had formed" presumably on the filter paper bridges and the liquid medium levels (given the range suggested for IAA the concentration in Table Vla-12 is a supposition). Caution is needed with the plantlets because it is possible that the filter-paper bridges will collapse under their weight. Therefore, once leaves are formed the shoots may have to be transferred to solid medium (Table Vla-12). But this is not all. The original paper also states that "after three months . . . when the root tips had swelled considerably, the tips (approx. 7 mm length) were excised under sterile conditions and planted on . . ." solidified medium (Table Vla-12). And, figure 2D of the original paper (Philip and Nainar, 1988) shows "formation of a plantlet . . . three weeks after transfer to solidified MS medium." This suggests that the tips should be cultured on filter-paper bridges and liquid MS (Table Vla-12) until they become large enough to cause sagging and should then be transferred to solid substrate (Table Vla-12). Rooted plants can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH) or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. After sterilization the shoot tips should be placed on filter-paper bridges (see Fig. Vla-2), which are inserted in liquid MS medium (Table Vla-12). There are several possibilities after that. The tips can be allowed to remain in the original culture tubes for differing amounts of time:

- For 3 months until they swell. Then their tips (7 mm) can be cut and moved to solid medium (Table Vla-12).
- Until the tips and/or plantlets they produce cause the filter-paper bridges to sag. Then the tips and/or plants should be transferred to solid medium (Table Vla-12).
- For as long as 3 months or until they swell. Then their tips (7 mm) can be cut, moved to new filter-paper bridges in fresh medium (Table Vla-12), and cultured on it until the tips and/or plantlets they produce cause the filter-paper bridges to sag. Then the tips and/or plants should be transferred to solid medium (Table Vla-12).

In all cases plantlets can be cultured to potting size on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without BH or AC. If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and

TABLE VLA-12. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Vanilla* root tips (Philip and Nainar, 1988)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Indoleacetic acid (IAA)	2.5	250 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Kinetin	0.2	20 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.8, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels. Do not add agar to liquid medium. Amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) are heat-labile and are often added after autoclaving to the still hot and liquid solution under sterile conditions with sterilized pipettes, mixed well, and the medium is distributed to preautoclaved culture vessels. In this case all components are added before sterilization.

Cym-24). AC should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Developmental Sequence. The root tips swell considerably after 3 months in the initial culture tubes (see Fig. Vla-2, Table Vla-12). After 9 weeks of culture on filter-paper bridges and liquid medium (and perhaps also on solid medium, Table Vla-12) some explants will form shoot apices surrounded by whorls of leaves. Roots appear on these shoots only after 4–5 leaves are formed.

Root tips on liquid medium grow in length for 10 days before growth ceases. Lysis of the root cap follows. Cell division in the quiescent center becomes more frequent and after 4 weeks the number of cells increases to the point of causing the originally pointed apex to assume "a hemispherical outline." Subsequent cell divisions produce a meristemoid. These meristemoids enlarge and form shoot meristems, which give rise to leaves.

General Comments. This protocol could prove to be efficient and productive if it can be made to work. Its main advantage is the use of root tips, which are in plentiful supply. Care should be exercised in taking explants to insure that they do not contain mycorrhizal or pathogenic fungi. The research paper that describes this procedure is focused on development, not on micropropagation. Therefore it was difficult to extract enough details for a practical procedure.

Callus Formation and Shoot Regeneration in *Vanilla planifolia*

> The high demand for natural vanilla flavor led to attempts to establish [a] culture of *Vanilla planifolia* for flavor production and for shoot regeneration from callus. (Davidonis and Knorr, 1991)

Plant Material. Shoots "obtained from J. Janick (Purdue University)" were used in the original research. No other details were given. Shoots, about 2–5 cm in length, taken from young growths are probably appropriate.

Surface Sterilization. All leaves should be removed from the shoot tips after which they should be washed with a soft brush (used tooth brush) in tap water with a mild household detergent, and rinsed with distilled water after the wash (this step is not part of the original procedure). After that they should be treated with 30% hydrogen peroxide (H_2O_2; available in drug stores and pharmacies) and rinsed with sterile distilled water three times before immersing them in 20% "commercial bleach" (this presumably means 20 ml household bleach diluted to 100 ml with distilled water). The bleach should be followed by another rinse with sterile distilled water.

Culture Vessels. Culture tubes, Erlenmeyer flasks, and other containers filled with medium to 20–30% of their volume can be used.

Culture Conditions. Shoot tips should be pretreated for at least 45 days under 4.5 $\mu E\ m^{-2}\ s^{-1}$. The original paper does not list the temperature and day length during

this period, but 25 ± 2–3°C and 8–12-h photoperiods should prove to be suitable. Callus induction from shoot-tip sections and subsequent proliferation should be carried in the dark at 25°C. The culture of callus taken from the proliferation medium and conditions should be at 25 ± 2–3°C and 8–12-h photoperiods of 4.5 μE m^{-2} s^{-1}.

Culture Media. Shoot tips should be placed initially on salts of MS (SMS) medium (Murashige and Skoog, 1962) with 1 g agar l^{-1} (water-acetone agar was used in the original research but such high-purity agar is not necessary for practical applications; Table Vla-13). Sections taken from the shoot tips should be placed on another combination of SMS and supplements (Table Vla-14). Callus should be proliferated on a third medium (Table Vla-15). The callus is maintained on a fourth medium (Table Vla-16). Shoots form on a fifth combination (Table Vla-17). No medium is suggested for plantlet production or the culture of plantlets to maturation. Plantlets can be cultured on one of the versions of the Knudson C medium (Knudson, 1946) with (see Tables C-19, Cym-3, and Cym-24) or without (see Tables Aranda-7, Aranda-8, C-3, C-6, Cym-1, and Cym-2) banana homogenate (BH)or charcoal (see Table Pln-1) or Vacin and Went solution (Vacin and Went, 1949; see Tables Aranda-6, Arnth-5, Cym-5, Den-2, Den-12, Den-21, Onc-5, Rntda-1, and V-4). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). Activated charcoal (AC) should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (see Table Pln-1, footnote *f*).

Procedure. After surface sterilization, shoot tips should be placed on the first medium (Table Vla-13) in the light for 45 days. After that the shoot tips should be sectioned into 1–2-mm disks. These disks should be cultured for 2 weeks on the second medium (Table Vla-14) in the dark for callus induction. Disks that form callus should be moved to fresh medium (Table Vla-14) for an additional 2 weeks in the dark. Callus that forms on these sections should be proliferated in the dark on the third medium (Table Vla-15). The callus is maintained on the fourth medium (Table Vla-16) in the light and must be transferred to fresh medium (Table Vla-16) every 2 weeks. Callus must be moved to yet another medium (Table Vla-17) for shoot production. For further growth and plantlet development, the shoots can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without BH or AC. If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). AC should be added to the medium selected for use as suggested for Knudson C that contains this darkening agent (Table Pln-1, footnote *f*).

Developmental Sequence. The pretreatment presumably prepares the shoot tips for sectioning and the sections for callus formation. Callus is initiated when shoot sections are cultured in the dark. The callus proliferates on the proliferation medium and may develop further on the maintenance medium. Shoots form on the medium with 0.1 mg BA l^{-1} and 0.2 mg NAA l^{-1}. The shoots and plantlets grow further on the last medium.

TABLE VLA-13. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for pretreatment of *Vanilla planifolia* shoot tips (Davidonis and Knorr, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Cytokinin				
8	Benzyladenine (BA)	0.4	40 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[g]	To 1000 ml			
	Solidifier				
11	Agar[g]	1.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The original paper (Davidonis and Knorr, 1991) does not mention a sugar as part of this medium, but 20 g sucrose is suggested here. A sugar-free medium may be tested also.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–8 to 900 ml of distilled water (item 10), adjust pH to 5.8, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the solution into culture vessels and autoclave. Agar is not added to liquid media.

According to one source, *Vanilla* was first described by Olof Swartz (1760–1818) in 1799 in volume 6, page 66, figure 5 of *Nova Acta Regiae Societatis Scientarum Upsaliensis* (Schultes and Pease, 1963). Another view is that the first description was by Philip Miller in the *Gardener's Dictionary*, 4th edition, 1754 (Bechtel et al., 1992; Pridgeon et al., 2003). The name is derived from the Spanish *vainilla* which means little pod and is in reference to the long and slender fruit, which is pod-like (Schultes and Pease, 1963) but is in fact a capsule and definitely not a bean.

TABLE VLA-14. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Vanilla planifolia* shoot-tip sections (Davidonis and Knorr, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10

(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Polyol				
8	*myo*-inositol	1000.0	No stock	No stock	Weigh
	Auxin				
9	Naphthaleneacetic acid	4.0	400 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
10	Benzyladenine (BA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamin				
11	Thiamine (vitamin B_1)	5.0	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
12	Casein hydrolysate	500.0	No stock	No stock	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	7.6 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.8, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

General Comments. This is a fairly complicated procedure which is presented in a paper that does not include all the necessary details, is not well organized, and is not written as well as it should be.

TABLE VLA-15. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the proliferation of *Vanilla planifolia* callus-derived shoot-tip sections (Davidonis and Knorr, 1991)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Not all casein hydrolysates are the same. Their compositions and analyses vary depending on the methods by which they were produced. A product sold by Merck (www.merck.de) as casein hydrolysate (CH) is obtained by degrading casein with hydrochloric acid; vitamins and other growth-promoting compounds are largely destroyed in this process. The CH sold by Sigma-Aldrich (www.sigmaaldrich.com) is pancreatic hydrolysate of casein. There is also a CH which is hydrolysed by enzymes. Becton, Dickinson and Company (www.bd.com) sells Difco products, including a number of different casamino acid products all of which are casein hydrolysates. Therefore if a method specifies a source for the CH in its culture medium it is best to obtain the additive from the same vendor. If a source is not listed it is best to purchase CH which is described as being suitable as a supplement for culture media. Failing that, CH should be purchased from a source which specializes in tissue culture and micropropagation supplies. One such source is www.caissonlabs.com. They list casein rather than CH as Stock #: SPCA205. Another source for CH is www.duchefa.com (item 1301). Additional sources include www.fishersci.com, www.thomassci.com, and others.

[h]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.8, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the solution into culture vessels and autoclave. Agar is not added to liquid media.

TABLE VLA-16. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the maintenance of *Vanilla planifolia* shoot-tip-derived callus (Davidonis and Knorr, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Auxin				
8	Naphthaleneacetic acid	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[g]	To 1000 ml			
	Solidifier				
11	Agar[g]	7.6 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The original paper (Davidonis and Knorr, 1991) does not mention a sugar as part of this medium, but 20 g sucrose is suggested here. A sugar-free medium may be tested also.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–8 to 900 ml of distilled water (item 10), adjust pH to 5.8, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

At one time or another *Vanilla* was or still is cultivated, or attempts were made to cultivate it, on the Comoro Islands, Dutch East Indies (now Indonesia), Fiji, Guadeloupe, Madagascar, Martinique, Mauritius, Mexico, Philippines, Puerto Rico, Reunion, Seychelles, Ceylon (now Sri Lanka), Tahiti, and Uganda.

Professor Charles Morren at the University of Liege in Belgium was the first to hand pollinate *Vanilla* in 1836. Edmond Albius, a slave on Reunion Island, may have learned Morren's method and could have adapted it to practical use. He may not have invented the method. Albius's reward was freedom.

TABLE VLA-17. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the shoot production from *Vanilla planifolia* shoot-tip-derived callus (Davidonis and Knorr, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Auxin				
8	Naphthaleneacetic acid	0.2	20 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	Benzyladenine (BA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	7.6 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The original paper (Davidonis and Knorr, 1991) does not provide many details about this medium. Because of that the recipe in this table is based on several assumptions.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.8, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

In Vitro Shoot Multiplication of *Vanilla planifolia*

Increasing demand for vanilla and *Vanilla* plants led to the formulation of a number of micropropagation methods. One of them utilizes the auxin-like properties of phenylacetic acid (Giridhar et al., 2003).

Plant Material. In the original research, shoot tips and node explants, 2–3 cm long, were excised from 3-year-old vines. Similar explants or ones taken from young growths of more mature plants can be used in practical micropropagation.

Surface Sterilization. Explants should be washed with tap water and Tween 20 (www.sigmaaldrich.com, www.fishersci.com, www.vwr.com, www.wako-chem.co.jp/english/), baby shampoo, or a mild household detergent and then rinsed with tap water. After that they should be immersed in 0.15% (w/v) mercuric chloride ($HgCl_2$; available from the sources above; this toxic substance must be handled with care) for 10 min, and rinsed five times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, culture tubes, or other containers can be used.

Culture Conditions. Cultures should be maintained at $25 \pm 2°C$ under continuous illumination of 45 $\mu mol\ m^{-2}\ s^{-1}$. Standard culture room conditions may also be suitable.

Culture Media. Initial explants should be cultured on a modified MS medium (Table Vla-18; Murashige and Skoog, 1962). Shoots produced by them should be moved to a second modification of MS (Table Vla-19). Nodal segments from shoots on the second medium (Table Vla-19) should be moved to a third substrate (Table Vla-20). Shoots produced by the nodal segments should be cultured on an elongation medium (Table Vla-21) and then moved to a rooting substrate (Table Vla-22).

Procedure. Surface-sterilized shoot tips are cultured on the shoot initiation medium (Table Vla-18) for 60 days. The shoots they produce are moved to a second medium (Table Vla-19) for growth. Node segments taken from shoots on the second medium (Table Vla-19) are cultured on a third solution (Table Vla-20) for 4–5 weeks. Shoots produced on this solution (Table Vla-20) are moved to an elongation medium (Table Vla-21) for 30 days and cultured on a rooting substrate on reaching a height of 2.0–2.5 cm (Table Vla-22). Well-developed and rooted plantlets are potted.

Developmental Sequence. Shoots are produced on the first medium (Table Vla-18) and grow on the second solution (Table Vla-19). Nodal sections from shoots on the second solution are cultured on the third substrate (Table Vla-20). Shoots which form on this medium are moved to the fourth solution of elongation (Table Vla-21). Elongated shoots, 2.0–2.5 cm in height, are moved to the fifth medium (Table Vla-22) for rooting.

General Comments. This protocol utilizes five different media but seems to be effective. Parts of the original paper are not very clear. This meant that a number of assumptions had to be made in preparing the recipe tables (Tables Vla-18 to Vla-22).

TABLE VLA-18. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for shoot initiation on *Vanilla planifolia* shoot explants (Giridihar et al., 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Auxin				
8	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	Benzyladenine (BA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	6.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.7 ± 0.2, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to pre culture vessels and autoclave. Agar is not added to liquid media.

TABLE VLA-19. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Vanilla planifolia* shoots (Giridihar et al., 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Auxin				
8	Indole-3-butyric acid (IBA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	Benzyladenine (BA)	0.01	1 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The original paper (Giridihar et al., 2003) does not indicate whether sugar is present in this medium. Because of that the recipe in this table is based on the assumption that it does. A test with sugar-free medium is advisable.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.7 ± 0.2, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to pre culture vessels and autoclave. Agar is not added to liquid media.

TABLE VLA-20. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Vanilla planifolia* nodal segments (Giridihar et al., 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Auxin				
8	Phenylacetic acid (PAA)	1.25	125 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	Benzyladenine (BA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			
	Solidifier				
15	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively. The original report suggests 0.5–2.0 mg phenylacetic acid (PAA) l^{-1} and 2 or 5 mg benzyladenine (BA) l^{-1}; the amounts suggested here were selected as appropriate without being too small or excessive.

[g]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.7 ± 2, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

TABLE VLA-21. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the elongation of *Vanilla planifolia* nodal shoots (Giridihar et al., 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Auxin				
8	Phenylacetic acid (PAA)	1.13	113 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
9	Benzyladenine (BA)	3.0	300 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[g]	To 1000 ml			
	Solidifier				
15	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively. The original report suggests 0.5–2.0 mg phenylacetic acid (PAA) l^{-1} and 2 or 5 mg benzyladenine (BA) l^{-1}; the amounts suggested here were selected as appropriate without being too small or excessive.

[g]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.7 ± 2, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The original paper states: "Finally . . . 2.0–2.5 cm long shoots . . . were rooted on MS media [sic] containing 2.0 mg/l IBA." This implies the complete MS medium despite the fact that only parts of it are used in Tables Vla-18–Vla-21.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH. There is no cytokinin in this medium.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH as required, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

Multiplication of *Vanilla planifolia* through the Use of Silver Nitrate

Silver nitrate, an ethylene inhibitor reported to enhance shoot multiplication, was used to develop "improved methodology for micropropagation of *Vanilla* plants" (Giridhar et al., 2001).

Plant Material. Shoot tips and nodal explants, 2–3 cm long, from 3-year-old vines were used in the original research. Explants from younger vines or new growths of older ones may also be suitable. Some explants were placed on a shoot initiation medium (see Table Vla-18). Others were cultured directly on a rooting medium (Table Vla-23). Shoots and nodal sections produced in vitro were also cultured on a silver nitrate ($AgNO_3$)-containing medium (Table Vla-24).

Surface Sterilization. Explants should be washed with tap water and Tween 20 (www.sigmaaldrich.com, www.fishersci.com, www.vwr.com, www.wako-chem.co.jp/english/), baby shampoo, or a mild household detergent and then rinsed with tap water. After that they should be immersed in 0.15% (w/v) mercuric chloride ($HgCl_2$; available from the sources above; this toxic substance must be handled with care) for 10 min and then rinsed five times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, culture tubes, or other containers can be used.

Culture Conditions. Cultures should be maintained at $25 \pm 2°C$ under continuous illumination of 37.5 $\mu mol\ m^{-2}\ s^{-1}$ provided by Philips, India fluorescent (type not described) lamps. Standard culture room conditions may also be suitable.

Culture Media. Shoot tips and nodal explants should be placed in a modified MS medium (Murashige and Skoog, 1962) for shoot initiation (see Table Vla-18). Shoots that form on this medium after 60 days of culture should be moved to another modification of MS (see Table Vla-19) to bring about the production of shoots and nodal sections for further multiplication. Nodes taken from this medium can be cultured on a third modification of MS (see Table Vla-20) and placed on a fourth version of MS (see Table Vla-21) for elongation. The elongated shoots should be rooted on a rooting medium (see Table Vla-22). Explants from in vitro shoots and field-grown plants can be rooted on yet another modification of MS (Table Vla-23). In-vitro-grown nodal explants can also be cultured on a medium containing $AgNO_3$ (Table Vla-24).

Procedure. Nodal explants of shoot tips from field-grown plants are surface-sterilized and cultured first on the shoot initiation medium (see Table Vla-18) or rooted on one of the rooting media (Table Vla-23). Shoots from the shoot initiation medium are moved to another medium (see Table Vla-19) for further growth. Nodal sections and shoots from this medium are moved to a medium designed to bring about the production of new shoots (see Table Vla-20) which are moved to an elongation medium for further growth (see Table Vla-21). The elongated shoots are rooted on a rooting medium (see Table Vla-22). Shoot tips and nodal sections

TABLE VLA-23. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the rooting of nodal explants from in-vitro- and field-grown nodal sections (Giridhar et al., 2001)**

[a]Amounts are given in mg unless indicated otherwise. Silver nitrate is toxic and

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–13 to 900 ml of distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, pour the solution into a 2-l flask and autoclave. Add the silver (item 14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

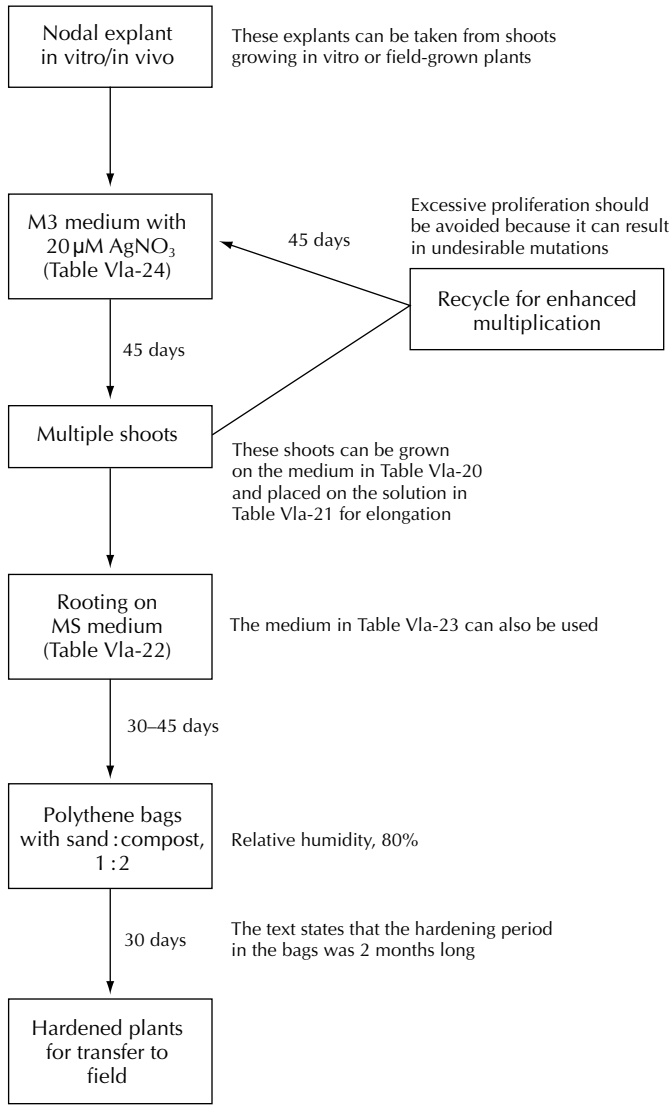

FIG. VLA-5. **Micropropagation of *Vanilla planifolia* (Giridhar and Ravishankar, 2004).**

from field-grown plants are rooted directly on a medium formulated for this purpose (Table Vla-23).

The procedure for explants that are cultured on medium containing $AgNO_3$ is outlined clearly in the original paper. This outline is presented in Fig. Vla-5 with several additions.

Preparation and Addition of Silver Nitrate. Silver nitrate can stain human skin and even cause burns. It is also absorbed by skin and subsequent exposure to light causes

it to turn black. In the event that silver nitrate gets on skin, the affected site must be rinsed immediately with plenty of water. If inhaled, silver nitrate is destructive to mucous membranes and upper respiratory tract tissues. Inhalation symptoms may include laryngitis, wheezing, coughing, shortness of breath, burning sensation, headache, nausea, and vomiting. Silver nitrate is corrosive and swallowing it can cause severe burns of the mouth, throat, and stomach. It can also cause sore throat, vomiting, and diarrhea. In some cases it can even be fatal if ingested. It can cause blurred vision, redness, pain, severe tissue burns, and eye damage on getting into eyes. Altogether, silver nitrate is a great boon to humanity because it is the basis of film photography, but it is a nasty and poisonous chemical which should be avoided. And this should be easy to do since there are no good reasons for using this protocol.

The silver nitrate stock solution should be kept in a black bottle. In the original research, the silver nitrate solution was filter-sterilized and added to the medium after autoclaving. However, since silver nitrate is very soluble in alcohol a stock solution in 95% ethanol is preferable.

Developmental Sequence. Shoots are produced on the first medium (see Table Vla-18) and grow on the second solution (see Table Vla-19). Nodal sections from shoots on the second solution produce shoots on a third medium (see Table Vla-20), and are moved to the fourth solution for elongation (see Table Vla-21). Elongated shoots, 2.0–2.5 cm in height, produce roots on the fifth medium (see Table Vla-22). Shoots from field-grown plants or in vitro cultures produce roots when placed on the appropriate solution (Table Vla-23). Explants on the medium containing $AgNO_3$ (Table Vla-24) produce shoots and roots.

General Comments. This procedure is included here only because it was published. It was formulated and published before the previous procedure (Giridhar et al., 2003) which is not only preferable for practical applications, but also much safer. The theoretical basis for the use of $AgNO_3$ is the inhibition of ethylene action by the silver ion.

Micropropagation of *Vanilla planifolia* on Media Containing Coconut Water and Several Hormones

In the never ending quest for an improved micropropagation method for *Vanilla planifolia* a protocol using coconut water (erroneously called "coconut milk" in the original paper), TDZ, and zeatin (ZN) was developed at the Plant Cell Biotechnology Department, Central Food Technological Research Institute, Mysore, India (Giridhar and Ravishankar, 2004).

Plant Material. In the original research, shoot tips and node explants, 2–3 cm long, were excised from 1-year-old field-grown vines. Similar explants or ones taken from young growths of more mature plants can probably be used in practical micropropagation.

Surface Sterilization. Explants should be washed with tap water and Tween 20 (www.sigmaaldrich.com, www.fishersci.com, www.vwr.com, www.wako-chem.co.jp/english/), baby shampoo, or a mild household detergent and then rinsed with tap water. After that they should be immersed in 0.15% (w/v) mercuric chloride ($HgCl_2$; available from the sources above; this toxic substance must be handled with care) for 10 min and then rinsed five times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, culture tubes, or other containers can be used.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under continuous illumination of 37.5 μmol m^{-2} s^{-1}. Standard culture room conditions may also be suitable.

Culture Media. Explants should be cultured on a shoot initiation medium (see Table Vla-18). Shoots which form on this medium should be maintained on a modified MS solution (see Table Vla-19; Murashige and Skoog, 1962). To induce multiple shoots, explants should be moved to a modified MS medium containing 10.56 μmol BA and 4.56 μmol ZN per liter (Table Vla-25). Explants that form axillary buds (called "shoot bud sprouts" in the original paper) should be moved to modification VS of MS (Table Vla-26) to bring about shoot proliferation and elongation. Shoots from this medium can be moved to one of two other media for further growth and root formation: a modification of the Nitsch (1969) medium designated as N69 (Table Vla-27) or a substrate designated as RS (Table Vla-28). Plants from both media N69 and RS should be moved for rooting and maturation to modified MS (see Table Vla-23). The report states that this medium contains 9.8 μmol IBA, which amounts to ($9.8 \times 203.23 = 1.99$) 2 mg, but the schematic representation (Giridihar and Ravishankar, 2004, fig. 3 on p. 118) indicates 1 mg l^{-1}. Since these authors suggest 2 mg l^{-1} in other protocols and one of their figures, this is the amount recommended here. It is also possible to culture explants on a medium containing coconut water (erroneously referred to as coconut milk) and TDZ (Table Vla-29).

Procedure. An excellent diagram (Fig. Vla-6) and an informative illustration (Fig. Vla-7) in the original report show the procedure and the manner in which explants should be inserted in media very clearly. The diagram (Fig. Vla-6) was enhanced by additional descriptions, added steps, annotations regarding figures, and references to tables which contain media recipes.

Developmental Sequence. Explants placed on the shoot induction medium (see Table Vla-18) produce shoots which grow and develop further on the maintenance solution (see Table Vla-19). Nodal explants taken from shoots on the maintenance medium (Table Vla-19) and grown either on BA and ZN (Table Vla-25) or TDZ (Table Vla-29) containing media produce shoot bud sprouts (Fig. Vla-8A, B) after 30 days in culture. These shoot buds produce multiple shoots when cultured 45 days on the VS medium (Table Vla-26). If these shoots are moved to the RS medium (Table Vla-28) they form roots. The same shoots elongate if moved to the N69 substrate (Fig. Vla-8C, D; Table Vla-27) and cultured on it for a month. Rooted plantlets from the RS medium (Table Vla-28) and elongated ones from the N69 solution (Table

TABLE VLA-25. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of nodal explants of *Vanilla planifolia* (Giridhar and Ravishankar, 2004)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	If any was used the original report does not mention it. Should an auxin be required use 1 mg naphthaleneacetic acid l^{-1}				
	Cytokinins				
11	Zeatin (ZN)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
12	Benzyladenine (BA)	2.4	250 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
16	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	6.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust to 5.7, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels. Agar is not added to liquid media.

TABLE VLA-26. **VS [modified Murashige–Skoog (MS)] medium (Murashige and Skoog, 1962) for the culture of shoot-bud sprouts of *Vanilla planifolia* (Giridhar and Ravishankar, 2004)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Auxin				
9	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
10	Benzyladenine (BA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamin				
11	Biotin	20.0	No stock	No stock	82 µmol; this is a very high concentration
	Sugar				
12	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
13	Water, distilled[g]	To 1000 ml			
	Solidifier				
14	Agar[g]	6.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The original paper states "MS basal" which suggests that the following are not part of this medium. They can be added if necessary.

	Amino acid				
	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
	myo-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–11 to 900 ml of distilled water (item 13), adjust pH to 5.7, add sugar (item 12), and raise volume to 1000 ml with distilled water (item 13). Bring the solution to a gentle boil and add the agar (item 14) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to autoclaved culture vessels. Agar is not added to liquid media.

TABLE VLA-27. **Nitsch (N69) medium (Nitsch, 1969) as used for the elongation of multiple shoots of *Vanilla planifolia* (Giridhar aand Ravishankar, 2004)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	720.0	72.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2$	166.0	16.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	68.0	6.8 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	10.0	1.0 g l^{-1}		
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	25.0	2.5 g l^{-1}	10	One solution
(d)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	10.0	1.0 g l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Gibberellin				
10	Gibberellic acid	0.01	1 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzyladenine (BA)	0.25	25 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Biotin	0.05	5 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Folic acid	500.0	No stock	No stock	1132 µmol, this is a very high concentration
14	Niacin (nicotinic acid)	5.0	500 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Pyridoxine HCl (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
16	Thiamine HCl (vitamin B_1)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
17	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the gibberellin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively. This is one of very few media which include giberrellic acid.

[g]Add items 1–16 to 900 ml of distilled water (item 18), adjust pH to 5.5, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Bring the solution to a gentle boil and add the agar (item 19) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

TABLE VLA-28. **Murashige–Skoog (MS) medium (RS; Murashige and Skoog, 1962) modified for the rooting of *Vanilla planifolia* shoots (Giridhar and Ravishankar, 2004)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10

10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
13	Malt extract	25.0	No stock	No stock	Weigh
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust to 5.7, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

TABLE VLA-29. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of nodal explants of *Vanilla planifolia* (Giridhar and Ravishankar, 2004)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Cytokinin				
8	Thidiazuron (TDZ)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
9	Coconut water (CW)[g]	100.0 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[h]	To 1000 ml			
	Solidifier				
12	Agar[h]	6.0 g	No stock	No stock	Weigh
	Amino acid				
	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
	myo-inositol	100.0	No stock	No stock	Weigh
	Auxin				
	Indoleacetic acid (IAA)	1.0–30	100–300 mg 100 ml^{-1} 95% ethanol[e,f]	1	Or another auxin
	Vitamins				
	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	

[a]Amounts are given in mg unless indicated otherwise. The original report states that basal MS medium was used and supplemented with TDZ and CW. This implies that the substances listed below were excluded because the standard use of "basal" implies only the mineral component of a medium. If necessary they can be added. There is no indication if sugar was included in this medium, but it is reasonable to assume that it should be.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1–9 to 800 ml of distilled water (item 11), adjust pH to 5.7, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

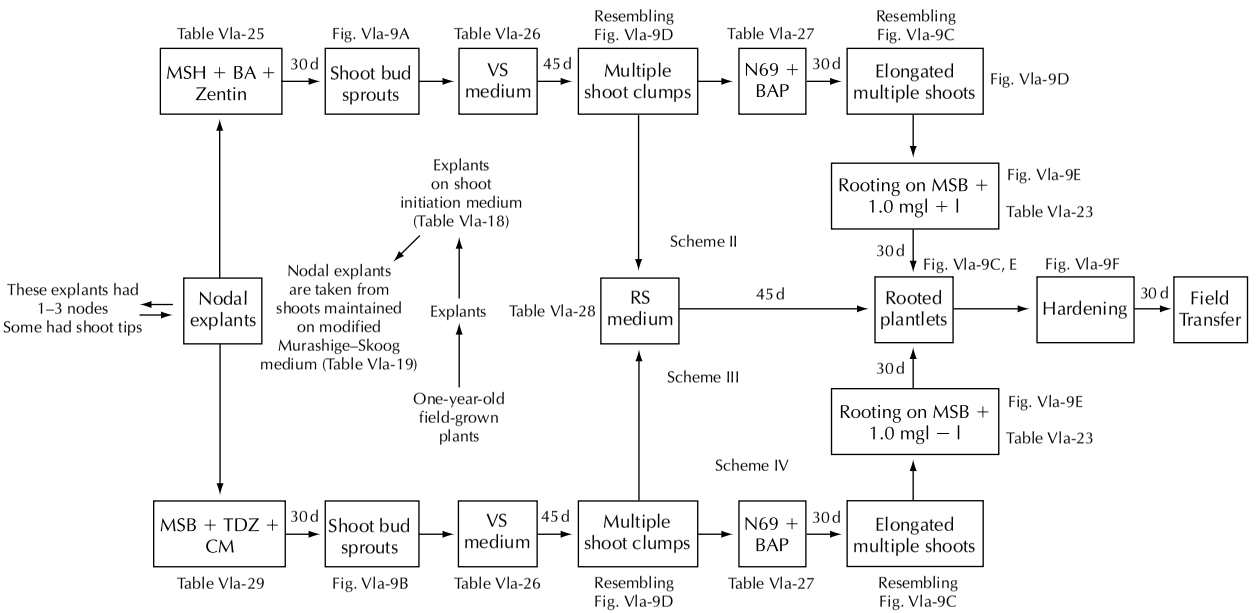

FIG. VLA-6. **Procedure for culturing *Vanilla planifolia* nodal explants (Giridhar and Shenkar, 2004 with additional annotations). BA, benzyladenine; BAP, benzylaminopurine; CM, coconut water; I, indolebutyric acid; MSB, basal Murashige–Skoog medium; N69, Nitsch (1969) medium; RS and VS, modified MS media.**

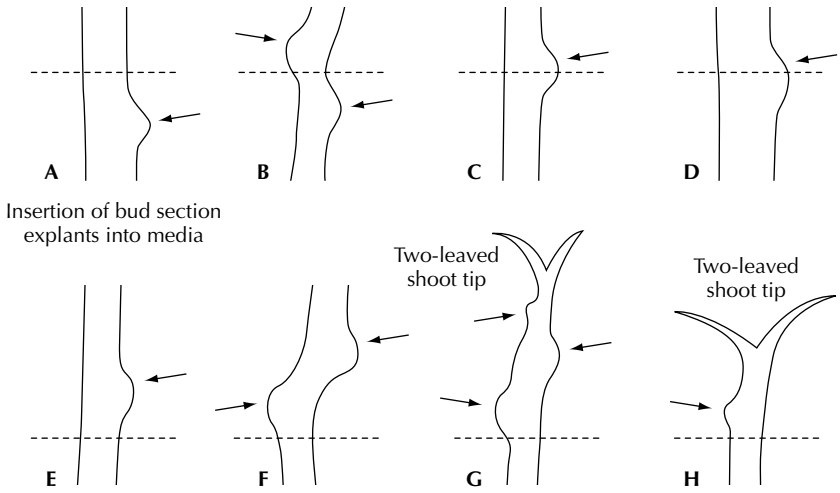

FIG VLA-7. **Insertion of *Vanilla planifolia* bud section explants in culture media. In most cases the manner of insertion makes little or no difference (Giridhar and Shankar, 2004).**

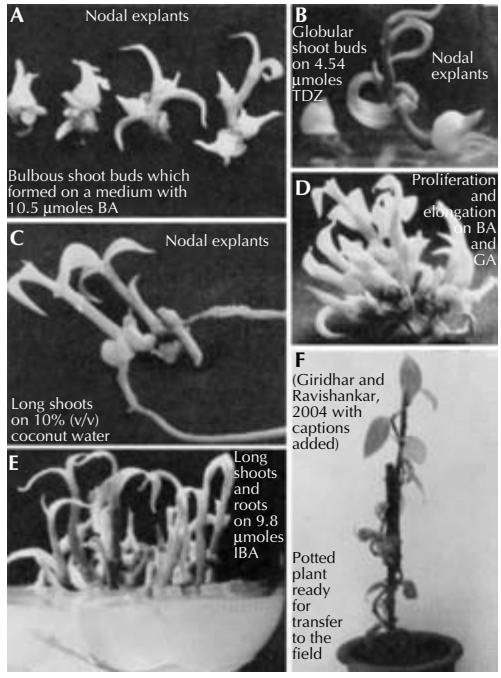

FIG. VLA-8. **Growth and development of *Vanilla planifolia* (Giridhar and Shankar, 2004).**

Vla-27) form roots (Fig. Vla-8C, E) after 30 days on the IBA-containing substrate (see Table Vla-23). The rooted plants can be planted in the field after 30 days of hardening (Fig. Vla-8F).

General Comments. This is a well thought out and carefully researched procedure which is complex and involves eight media, five vitamins, three cytokinins (BA, TDZ, and ZN), two auxins (IBA and NAA), two basal media (MS and Nitsch), one complex additive (malt extract), one gibberellin (GA_3), one polyol (*myo*-inositol), and many steps. Those who may wish to use this protocol should prepare for it in advance, plan carefully, and be sure that a simpler method will not be equally effective.

In Vitro Propagation of *Vanilla planifolia* using Two Media

"Mass propagation [of *Vanilla planifolia*] requires a simple, economical, rapidly multiplying and highly reproducible protocol without an intervening callus or protocorm phase as to give rise to true-to-type clones" (Geetha and Shetty, 2000). Such a protocol was developed by the plant tissue culture laboratory of Kahland Biotechs Private Limited in India (Geetha and Shetty, 2000).

Plant Material. Shoot tips and nodal explants can be used.

Surface Sterilization. In the original research explants were pretreated for 4 h with a solution of 0.2% Bavistin (www.BASF.com), 0.2% streptocycline, and 5–6 drops of liquid Dettol (www.dettol.com.uk), and then washed with Tween 20 (www.sigmaaldrich.com) and sterile distilled water. This step may not be necessary. A simple wash with tap water, a mild household detergent, and a soft toothbrush may be sufficient. After the wash the explants should be sterilized with 0.1% mercuric chloride ($HgCl_2$) for 10 min (this sterilant is toxic and should be handled with care) and rinsed 3–5 times with sterile distilled water.

Culture Vessels. Jars were used in the original research. Other containers are also suitable.

Culture Conditions. The research cultures were maintained at $25 \pm 1°C$ under 12-h photoperiods of 2500 lx provided by cool white fluorescent tubes. Standard culture room conditions should also prove to be suitable.

Culture Media. Explants and elongated shoots should be cultured in MS medium (Murashige and Skoog, 1962) containing 1 mg BA l^{-1} (Table Vla-30). Explants with breaking buds and initial and young proliferating shoots should be cultured on a modification of the Nitsch medium (Nitsch, 1969) for *Nicotiana* androgenesis (Table Vla-31).

Procedure. The original report includes an excellent diagram that outlines the protocol and is presented here with some additions and incorporates photographs of cultures (Fig. Vla-9).

TABLE VLA-30. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Vanilla planifolia* explants (Geetha and Sheety, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Table 1 in the original report makes no mention of an auxin. Should one prove to be necessary, 1 mg naphthaleneacetic acid l^{-1} may be appropriate				
	Cytokinin				
11	Benzylaminopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effects.

[e]Keep frozen between uses.

[f]If the auxin (should one be used) or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH as required, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

TABLE VLA-31. **Nitsch medium (Nitsch, 1969) modified for the culture of *Vanilla planifolia* shoots (Geetha and Shetty, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	720.0	72.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2$	166.0	16.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	68.0	6.8 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	10.0	1.0 g l^{-1}	10	One solution
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	25.0	2.5 g l^{-1}		
(d)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	10.0	1.0 g l^{-1}		
	Vitamins				
8	Biotin	0.05	5 mg 100 ml^{-1} 95% ethanol[e]	1	
9	Folic acid	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The original paper states that the basal medium was used and mentions only BAP, biotin, and folic acid as additives. This implies that the following substances were not included. They can be added as necessary.

	Amino acid				
	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
	myo-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
	Niacin (nicotinic acid)	5.0	500 mg 100 ml^{-1} 95% ethanol[e]	1	
	Pyridoxine HCl (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Thiamine HCl (vitamin B_1)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. This is the iron solution used for the Murashige–Skoog medium (Murashige and Skoog, 1962) and many other media, not the one listed by in the original paper describing this substrate (Nitsch, 1969).

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium to culture vessels and autoclave. Agar is not added to liquid media.

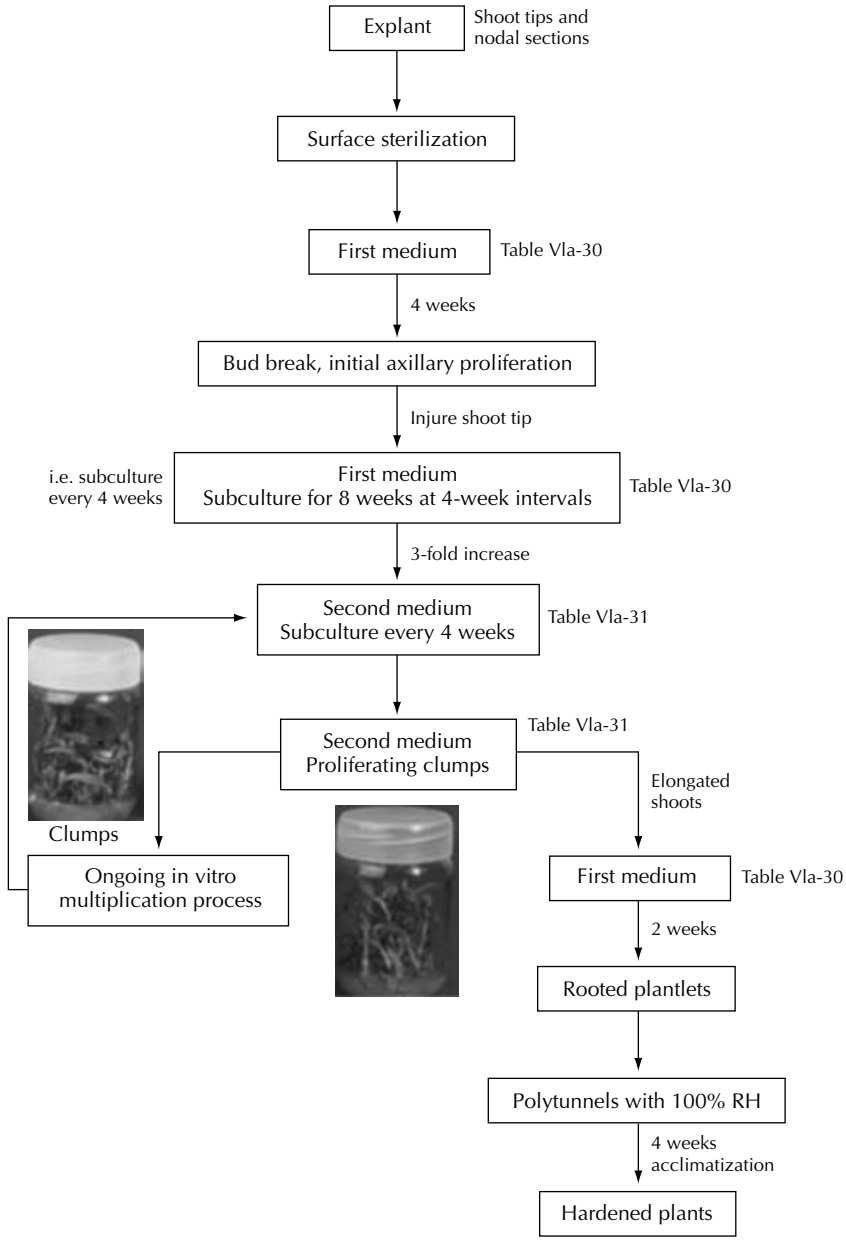

FIG. VLA-9. **Protocol for micropropagation of *Vanilla planifolia* (photographs and diagram from Geetha and Shetty, 2000).**

Developmental Sequence. The explants produce shoots that proliferate, elongate, and form roots (Fig. Vla-9), all over a relatively short period.

General Comments. This seems to be a simple procedure, which is as effective as much more complex and expensive protocols. It should be given serious consideration by those intending to propagate *Vanilla planifolia*.

Movement of *Vanilla* Plants and Germplasm

Vanilla is an important and high value crop in some parts of the world. Because of that plants are exchanged internationally. This carries the danger of accidental transport of pests and diseases. To prevent or at least reduce such incidents, the Food and Agriculture Organization (FAO) of the United Nations and the International Board of Plant Genetic Resources (IBPGR) have produced guidelines for the safe movement of *Vanilla* germplasm (Pearson et al., 1991). The intent is laudable, but the manner in which the FAO/IBPGR proceeded in respect to *Vanilla* leaves much to be desired because "the present guidelines for vanilla [sic] were not prepared by a panel meeting [presumably of experts]; instead a contract was awarded to a principal coordinating author, Dr. M. Pearson. . . ." As a result those involved in the preparation of the guidelines included only one orchid expert (Dr. Pearson, a noted orchid virologist who has published many excellent research papers in major journals) and no one with proven expertise in orchid propagation, tissue culture, or micropropagation. This is evident in the some of the technical recommendations, only a few of which will be addressed here.

Seeds

The section on the movement of seeds seems to imply, or at least creates the impression, that *Vanilla* can or maybe even should be propagated by seed germination. This is not the case for practical *Vanilla* cultivation because growers want, or at least prefer, established clones. Seed propagation is useful only for breeders and can be of interest to hobby growers. Also, the statement "preferably, seed should be germinated *in vitro*" is misleading because even if it is theoretically possible to germinate *Vanilla* symbiotically ex vitro, this is not being done and there are no published procedures for such germination. Since this book does not deal with seed germination, relevant procedures will not be discussed here.

A recommendation regarding the transfer of seeds is incomplete and incorrect. If seeds are to be surface-sterilized by soaking them in a saturated solution of calcium hypochlorite, it is necessary to dry them completely and rapidly under sterile conditions and place them in a sterilized container for shipping. Also, instructions should have been included regarding the preparation and use of saturated calcium hypochlorite.

Plantlets in Vitro

As has been pointed out elsewhere in this book and in the first edition (Arditti and Ernst, 1993), the promise that micropropagation (shoot-tip cultures, tissue culture) would free orchids of viruses was never fulfilled. In fact there are more virus-infected orchids now than before the introduction of shoot-tip culture. And, even more importantly, nodal cultures [Gu et al., 1987*a*; this method was developed in my (JA's) laboratory] in particular cannot free orchids of viruses. This is not pointed out in the guidelines, even if there is a suggestion to index each plant. However, there is a major problem with the latter also. Indexing is not simple or easy and is probably beyond the capability of most practical tissue culture laboratories. Therefore the suggestion to move plantlets in sterile cultures may do more harm than good, encouraging unqualified laboratory operators to culture infected plants and ship them to unsuspecting recipients.

Methods for freeing orchids of virus through the use of antiviral agents have been developed by several laboratories, but none are for *Vanilla*. Therefore the danger of transporting virus-infected orchid plants remains as high as ever.

Recommendations

Until proven and simple methods are developed for indexing *Vanilla* plants or freeing them of viruses through the use of antiviral agents in vitro, transport should be regulated very strictly and must be limited to laboratories with a proven ability to detect viruses. Laboratories that do not have such expertise should never assume that *Vanilla* plants propagated in vitro are virus-free. Practical growers should become thoroughly familiar with the symptoms of virus diseases of *Vanilla* [this section of the guidelines (Pearson et al., 1991) is excellent] and cull infected plants.

In the year 2000, 38,525 ha were planted with *Vanilla* worldwide and the yield was 4728 metric tonnes. The USA, Germany, and France use 60–80% of the world vanilla production. The USA alone uses 30–60%.

The Aztec Emperor Montezuma drank *choclatl*, a beverage prepared from ground cocoa seeds and flavored with vanilla, which the Aztecs called *tlilxochitl*. The word was derived from *tlili* which means black and *xochitl* meaning pod. According to legend, Cortez was also served *choclatl*. He repaid the favor with murder and pillage. The priests who accompanied him forced their religion on the Aztecs. One purveyor of religion, Bernardino de Sehagun, a Franciscan friar who came to Mexico in 1529, wrote that the Aztecs mixed vanilla with cocoa and honey, but his work was only published in 1829–1830, 300 years after he wrote it.

Francisco Hernandez, who was sent to Mexico by Spanish King Philip II, translated *tlilxochitl* as "black flower" in an illustrated description of vanilla in his *Rerum Medicarum Novae Hispaniae Thesaurus* (published in Rome in 1651). This erroneous translation remained in the literature for many years.

www.guweb2.gonzaga.edn www.learnersonline.com www.redescolarilce.edn.mx www.ihnca.edi.ni

Bernal Diaz (A), an officer serving under Herman Cortez (B) was the first European to notice vanilla. (C) Bernardino de Sahagun. (D) Francisee Hermandez.

Vascostylis

The procedure used for *Ascofinetia* (Intuwong and Sagawa, 1973) is also appropriate for *Vascostylis*.

Vuylstekeara

The procedures used for *Cymbidium* (Morel, 1960, 1963, 1964*a*, 1965*b*, 1970, 1974) were described as being also suitable for *Vuylstekeara*. A more specific procedure was developed in Poland (Kukułczanka et al., 1989).

Plant Material. In the original research, shoots that were 10–12 cm long and bearing two to three leaves were taken from plantlets of *Vuylstekeara* Cambria maintained in vitro.

Surface Sterilization. The explants are taken from axenic plantlets and need not be surface-sterilized.

Culture Vessels. Test tubes were used in the original research, but other vessels are also suitable.

Culture Conditions. The cultures were maintained at 22–26°C "in daylight supplemented by an artificial lighting with the photoperiod prolonged to 14–15 hrs" (Kukułczanka et al., 1989). Conditions used for *Cymbidium, Cattleya, Odontoglossum, Oncidium*, and *Laelia* are also suitable.

Culture Medium. A modification of the MS medium is used (Table Vuyl-1).

Procedure. Place the explants in culture, and allow them to develop offshoots. Subculture plantlets formed in this fashion, and grow them until large enough to be moved to pots.

Developmental Sequence. Lateral shoots develop after 5 weeks in culture. PLBs, adventitious shoots, and roots form after 10 weeks.

General Comments. This method could be used for the micropropagation of *Vuylstekeara*, but its suitability for explants from mature greenhouse- or field-grown plants is not clear at present.

Zygopetalum

A method used for *Cymbidium* (Morel, 1960, 1963, 1964*a*, 1965*b*, 1970, 1974) could also be employed with *Zygopetalum*.

TABLE VUYL-1. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the culture of *Vuylstekeara* Cambria (Kukułczanka et al., 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, Kl	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.2	20 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
11	Benzyladenine (BA)	0.2	20 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
15	Peptone[h]	1 g	No stock	No stock	Weigh
	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[i]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin do not dissolve, add a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]The brand of peptone used is Peptobak-Bacutil. Its composition and effects may not be the same as those of peptones available in the United States and other countries. Should the brand of peptone be critical, it may be necessary to contact the authors at the Botanical Garden, University of Wrocllaw, 50–335 Wroclaw, Poland.

[i]Add items 1–7, 9, and 15 to 900 ml distilled water (item 17). Adjust pH as required; no details are given in the original research, but pH of media used for *Cymbidium* would be suitable. Add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormone, and vitamins (items 8 and 10–14) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

CHAPTER FOUR

Summary

Tissue culture (which includes the culturing of organs, cells, and protoplasts) is still an empirical science to some extent. Much has been learned during the last decade about procedures, media, effects of and requirements for a variety substances, methods which can be used with individual plants or groups of plants, and approaches which can bring about desired results; but success often hinges on intuition, good guesses, and fortune's smile. It is usually not easy and in some cases impossible to predict the type of explant, media, and conditions that would be suitable for a specific genus, species, hybrid, or clone. And, explaining why one combination of medium components and culture conditions can lead to success whereas another brings failure remains difficult and frequently unfathomable or beyond explanation. Nevertheless, some broad generalizations can be made.

Culture Conditions

A survey of the conditions and media used for the tissue culture of orchids shows a wide diversity (Arditti, 1977*b*; Arditti and Ernst, 1993; Dodds and Roberts, 1995).

State of the Medium

Both liquid and solid media can be used, but suitability must be determined empirically. Proliferation is generally faster and more extensive in liquid media on a shaker. However, liquid media have not proved suitable for all genera. Differentiation is always better on solidified substrates or on solid supports placed in culture vessels which contain liquid media. For example, bridges made of filter paper are recommended for some procedures (Gandawijaja, 1980) which utilize a liquid medium. Glass wool was tried (Ernst, 1974) and found to be unsuitable since it is not a pleasant or safe material to work with and because roots become entwined in it so extensively that they cannot be removed without breakage and damage. Cotton gets soggy, becomes poorly aerated, and roots can also become enmeshed in it.

The best solid support for cultures on a liquid medium may well be the Life Raft™, which is produced by Osmotek Ltd (www.osmotek.com). It consists of a membrane film (0.3 or 25 μm pore size for explants which benefit from less or more contact,

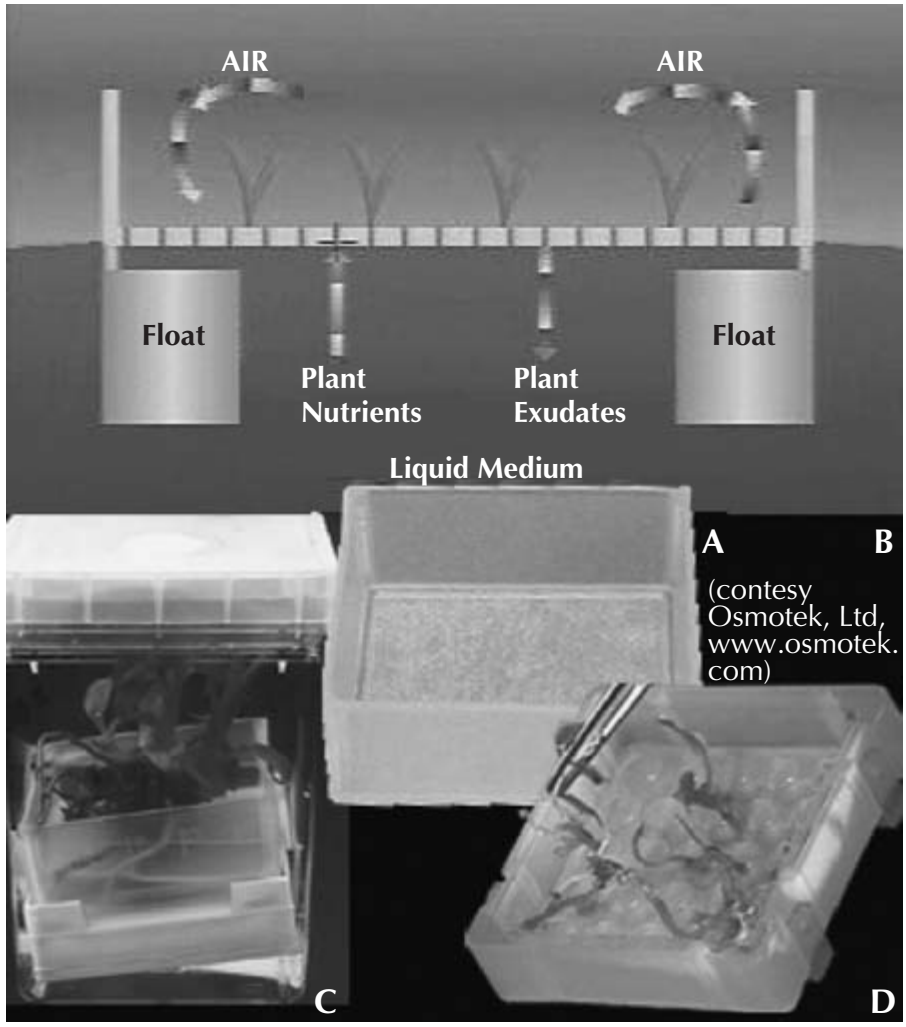

FIG. 4-1. **Life Raft™. A. An empty raft. B. Diagrammatic representation of a Life Raft™, its construction and its functions. C. Life Raft™ with plants inside a culture vessel. D. Plants inside a Life Raft™.**

respectively, with the medium) welded to a polypropylene frame which floats on the medium being supported by a buoyant float (Fig. 4-1). A solid support over liquid medium allows for better aeration as well as a quicker and faster dispersion of exudates (see also the section below, Solidifying Agents and Alternative Supporting Media).

Agitation

Liquid media should be or are usually agitated. However, there are also reports of success with stationary liquid media that are shaken only occasionally by hand (Kako,

1973). Numerous commercial shakers are available, including wheels that rotate in a horizontal or vertical plane and oscillate in a gyratory or horizontal manner. Rates of agitation vary considerably, with recommended speeds ranging from a low of 0.2 rpm (Jasper, 1966) to a high of 200 rpm (Scully, 1966). The choice of culture vessels may also influence the selection of the shakers and speed. If appropriate conditions are not specified, they must be determined experimentally. If specified, it is best to use the type and speed of rotation indicated for each procedure. There are a number of reasons why agitation may enhance the proliferation of some cultures. Among them are:

1 Elimination of polarity (sometimes referred to as disorientation).
2 Retardation and/or prevention of root and shoot development (Wimber, 1963, 1965; Scully, 1967).
3 Improved aeration.
4 Increased surface area.
5 Accelerated dilution of toxic metabolites (such as the polyphenol oxidates) and/or other exudates that can be harmful.
6 Stimulation of protocorm-like-body (PLB) formation.

As a rule liquid media and agitation are usually not beneficial when differentiation is desired.

Illumination

A wide range of light intensities seems to be suitable for orchid tissues. These range from darkness to 2000 ft-c (ft-candles; see the section on light in Chapter 2 and Appendix 4). Most cultures are illuminated by fluorescent lights, with or without additional incandescent bulbs. Numerous light sources have been listed in the literature, but they are reasonably interchangeable. However, the many units used to describe light intensity in individual papers are not always easily interconvertible due to the different characteristics of the sources of illumination. For example, the photosynthetically active radiation (PAR) in a light intensity of 2000 ft-c produced by a warm white fluorescent tube is not the same as in the same number of foot candles emitted by a halide lamp because the emission spectra of the two sources are different (see the section on light in Chapter 2 and Appendix 4).

Photoperiods

Photoperiods used for orchid tissue culture vary from continuous darkness or constant illumination to light periods of a few to many hours. The available evidence suggests that photoperiods of 12–18 h are suitable for most tissues. In general, photoperiods and light intensities useful for orchid seed germination and seedling growth are also suitable for tissue culture.

pH

As with seed culture, the pH range of most orchid tissue culture media is 4.8 to 5.5. In cases where the acidity of a medium increases during sterilization, the pH range

of the media should be adjusted slightly upward (to 5.6–5.9). There are some indications that an initial pH in the range of 4 to 8 may have no effect on PLB growth or plantlet development of several orchids (Piriyakanjanakul and Vajrabhaya, 1980). The pH of media adjusted by these researchers to 4, 5, 6, 7, and 8 changed to 4 after 2 weeks and remained near this level until the plantlets were harvested. A drop in initial pH to a level below 4 has also been observed with *Phalaenopsis* seed cultures (Ernst, 1967*a*). When the initial pH is very acid prior to autoclaving, hydrolysis or destruction of some media components may result. Hydrolysis of agar, for example, can be detrimental because it may result in semisolid solutions and toxic hydrolysis products. It should also be noted that explants, cells, and protoplasts have generally more exacting requirements than seed cultures.

Temperature

Orchid tissue cultures are usually maintained at temperatures ranging from 22 to 26°C. However, successful cultures have been maintained at much higher temperatures in the Asian tropics. Despite this relatively wide range, some tissues may have a narrower tolerance or specific optima. Therefore if specific temperatures are indicated it is best to provide them.

Media Components

Media, whether for seed culture or tissue culture, must provide the following inorganic macro- (or major) and micro- (minor) elements:

Macroelements

The terms macroelements or major elements are based on the fact that plants require large amounts of these minerals. They include nitrogen (N), phosphorus (P), potassium (K), calcium (Ca), magnesium (Mg), and iron (Fe) (Table 4-1).

Nitrogen

This element is usually supplied as nitrate (NO_3; Fig. 4-2A) and/or ammonium (NH_4; Fig. 4-2B) ions. Roots of *Dendrobium* Multico White plantlets took up ammonium faster than nitrate (Hew and Lim, 1989). The uptake of nitrate was linear in the presence or absence of sugar (Hew and Lim, 1989). However, the uptake of ammonium in the absence of sugar reached a plateau after 30 days; in the presence of sugar, the uptake of ammonium remained linear for 2 months (Hew and Lim, 1989). The plantlets took up 64.6% of the ammonium when sugar was absent and 80.3% in its presence. The parallel figures for nitrate were 15.7 and 22.1%, respectively (Hew and Yong, 1997). Callus tissue of *Aranda* Noorah Alsagoff took up nitrate at pH 4.5, 5.0, 5.5, 6.0, and 7.0 (Lee et al., 1987). The uptake of ammonium occurred only at pH 4.5 and 5.0 (Lee et al., 1987). The tissues took up ammonium preferentially at pH 5.0 and 5.5 (Lee et al., 1987). Depletion of nitrogen (nitrate and

TABLE 4-1. **Macroelements, their formula weights, and pH ranges as employed in the tissue culture of orchids**

Macroelement	Formula	Formula weight[a]	pH range, 5% solution at 25°C[b]
Ammonium chloride	NH_4Cl	53.49	4.5–5.5
Ammonium nitrate	NH_4NO_3	80.05	4.5–6.0
Monoammonium phosphate	$NH_4H_2PO_4$	115.03	3.8–4.4
Diammonium phosphate	$(NH_4)_2HPO_4$	132.07	7.7–8.1
Ammonium sulfate	$(NH_4)_2SO_4$	132.14	5.0–6.2
Calcium chloride	$CaCl_2$	110.99	4.5–8.5
Calcium chloride dihydrate	$CaCl_2{\cdot}2H_2O$	147.02	4.5–8.5
Calcium nitrate	$Ca(NO_3)_2$	164.10	5.0–7.0
Calcium nitrate tetrahydrate	$Ca(NO_3)_2{\cdot}4H_2O$	236.15	5.0–7.0
Monocalcium phosphate hydrate	$CaH_4(PO_4)_2{\cdot}H_2O$	252.07	2.80–2.90
Tricalcium phosphate	$Ca_3(PO_4)_2$	310.20	sp. sol.[c]
Calcium sulfate	$CaSO_4$	136.14	sp. sol.[c]
Calcium sulfate dihydrate	$CaSO_4{\cdot}2H_2O$	172.17	sp. sol.[c]
Ferrous chloride	$FeCl_2$	126.76	2.95–3.05
Ferrous chloride decahydrate	$FeCl_2{\cdot}10H_2O$	306.87	3.45–3.55
Ferrous citrate	$FeC_6H_6O_7{\cdot}H_2O$	263.97	
Ferric citrate	$FeC_6H_5O_7$	244.9	sp. sol.[c,d]
Ferric citrate pentahydrate	$FeC_6H_5O_7{\cdot}5H_2O$	335.03	
Ferrous oxalate dihydrate	$FeC_2O_4{\cdot}2H_2O$	179.9	sp. sol.[c]
Ferric sulfate	$Fe_2(SO_4)_3$	399.88	Slowly hydrolyzes in water
Ferrous sulfate heptahydrate	$FeSO_4{\cdot}7H_2O$	278.02	4.05–4.15
Ferric tartrate	$Fe_2(C_4H_4O_6)_3$	555.9	sp. sol.[c,d]
Magnesium chloride	$MgCl_2$	95.03	4.5–7.0
Magnesium chloride hexahydrate	$MgCl_2{\cdot}6H_2O$	203.30	4.5–7.0
Magnesium nitrate hexahydrate	$Mg(NO_3)_2{\cdot}6H_2O$	256.41	5.0–8.2
Magnesium sulfate	$MgSO_4$	120.37	5.0–8.0
Magnesium sulfate heptahydrate	$MgSO_4{\cdot}7H_2O$	246.47	5.0–8.0
Potassium chloride	KCl	74.55	5.4–8.6
Potassium nitrate	KNO_3	101.10	4.5–8.5
Monopotassium phosphate	KH_2PO_4	136.09	4.1–4.5
Dipotassium phosphate	K_2HPO_4	174.18	9.0–9.4
Dipotassium phosphate trihydrate	$K_2HPO_4{\cdot}3H_2O$	228.23	9.0–9.4
Potassium sulfate	K_2SO_4	174.26	5.5–8.5
Sodium nitrate	$NaNO_3$	84.99	5.5–8.3
Monosodium phosphate monohydrate	$NaH_2PO_4{\cdot}H_2O$	137.99	4.1–4.5
Sodium sulfate	$NaSO_4$	142.04	5.2–9.2
Sodium sulfate decahydrate	$NaSO_4{\cdot}10H_2O$	322.19	5.2–9.2

[a]Formula weight = molecular weight + weight of water of crystallization where applicable.

[b]pH ranges are given only for salts readily soluble at the temperature and concentration of test solutions.

[c]Sparingly soluble.

[d]Use not recommended; chelated iron is preferable.

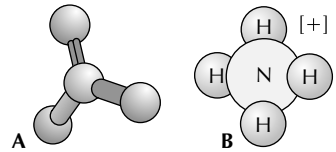

FIG. 4-2. **A. Nitrate. B. Ammonium. (Sources: A, www.chemsoc.org/examplarchem/entries/2001/anderson/acidityregulators.htm; B, www.fishdoc.co.uk/water/ammonia.htm.)**

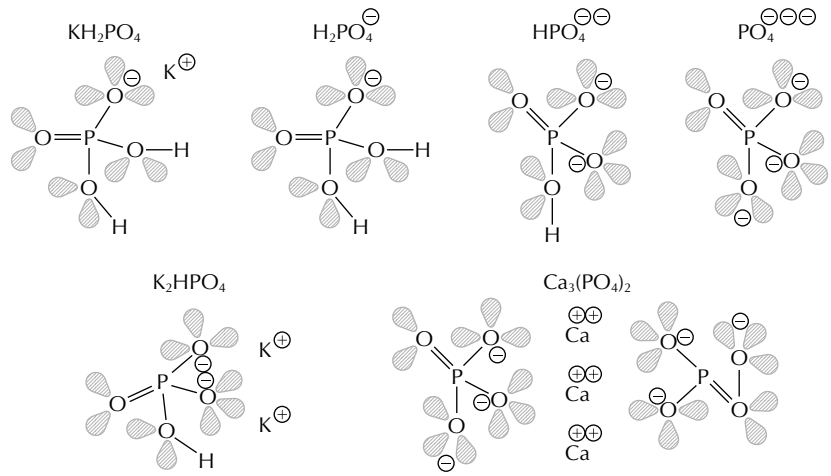

FIG. 4-3. **Phosphates. Dibasic potassium phosphate contains twice as much potassium as the monobasic salt, but the same amount of phosphorus. On a percentage basis K_2HPO_4 contains 44.89% potassium and 17.89% phosphate, whereas KH_2PO_4 has 28.73% potassium and 22.76% phosphate, but these weight-based calculations are not only irrelevant, but also bad science because what is important are the number of molecules or atoms of an element, not how much it/they weigh. (Source: www.jergym.hiedu.cz.)**

ammonium) from the culture medium was maximal at pH 5.0 (Lee et al., 1987). Plantlets of *Darwinara* Pretty Girl took up ammonium preferentially whereas those of *Dendrobium moniliforme* preferred nitrate (Kishi and Takagi, 1997*b*).

Phosphorus

This element is generally added to culture media as a monobasic (KH_2PO_4) and/or dibasic (K_2HPO_4) phosphate salt (Fig. 4-3). Phosphate is also added as calcium and ammonium salts (Fig. 4-3). The $H_2PO_4^-$ ion was absorbed completely by PLBs of *Dendrobium moniliforme* but not by those of *Darwinara* Pretty Girl (Kishi and Takagi, 1997*b*). The uptake of phosphate ions by *Dendrobium* Multico White is higher in the presence of sugar (0.32 mg day^{-1} and 33.3% of total) than in its absence (0.015 mg day^{-1} and 21.6% of total; Hew and Yong, 1997). A combination of the two salts can be used as a buffer with the pH being determined by the concentration of each salt. The German mycorrhiza expert Hans Burgeff seems to have been the first to suggest such a buffer for orchid seed germination media (Burgefff, 1936). However, it is still not clear if it is necessary to buffer media which support the growth of seedlings or plantlets. The pH of media which support seedlings or plantlets does drop, but in most cases this does not seem to have a deleterious effect.

Potassium

This element is supplied most often as salts containing the potassium ion (K^+), as for example potassium phosphate (K_2HPO_4 and KH_2PO_4; Fig. 4-3), potassium

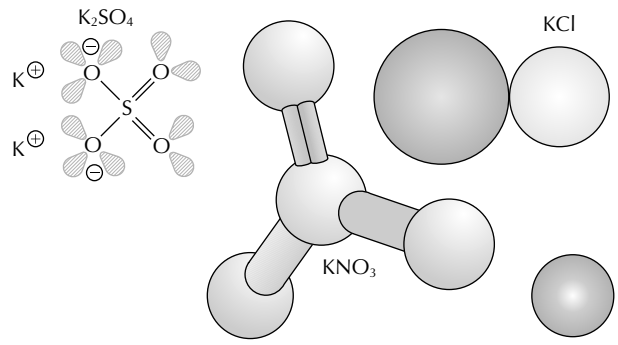

FIG. 4-4. **Potassium salts (sources: A, www.jergym.hiedu.cz; B. www.chemsoc.org).**

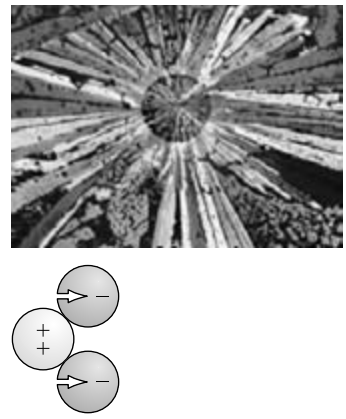

FIG. 4-5. **Magnesium salts (sources: www.mic-d.com; www.southwest.com).**

nitrate (KNO_3; Fig. 4-4), potassium chloride (KCl; Fig. 4-4), and potassium sulfate (K_2SO_4; Fig. 4-4). After 1 month of culture, PLBs of *Darwinara* Pretty Girl took up 40% of the potassium from the medium. Those of *Dendrobium moniliforme* absorbed only 54% (Kishi and Takagi, 1997*b*).

Magnesium

The bivalent cation Mg^{2+} is usually supplied as a chloride, nitrate, or sulfate salt (Fig. 4-5). PLBs of *Dendrobium monilforme* took up 24.2% of the magnesium from the medium during 1 month of culture. Those of *Darwinara* Pretty Girl used 83.5% during the same period (Kishi and Takagi, 1997*b*).

Calcium

A bivalent cation (Ca^{2+}), calcium is usually added as water-soluble nitrate or chloride salts (Fig. 4-6) but is also included in some media as the difficult to dissolve

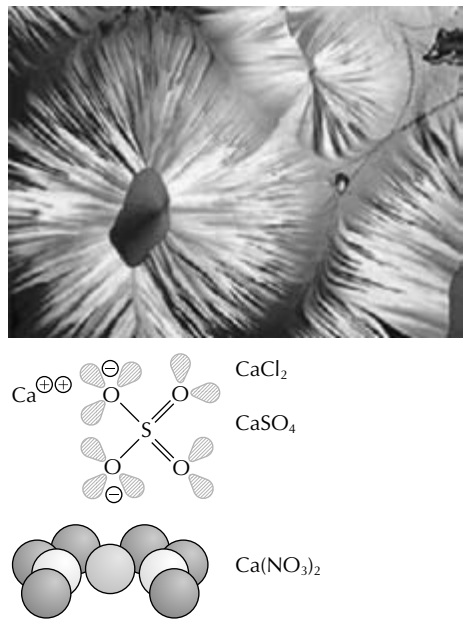

FIG. 4-6. **Calcium salts (sources: www.mic-d.com; www.jergym.hiedue.cz; www.saburchill.com).**

calcium phosphate [$Ca_3(PO_4)_2$] salt (Fig. 4-3). During 1 month of culture, PLBs of *Dawinara* Pretty Girl took up 70.5% of the calcium from the medium (Kishi and Takagi, 1997*b*). The levels of Ca^{2+} in a medium which supported *Dendrobium moniliforme* for the same period contained 119% of the initial level (Kishi and Takagi, 1997*b*).

Iron

This element is usually supplied as the ferrous (Fe^{2+}) or ferric (Fe^{3+}) sulfate salt (Fig. 4-7), and as chelated iron with ethylene diamine tetraacetic acid (EDTA) or other

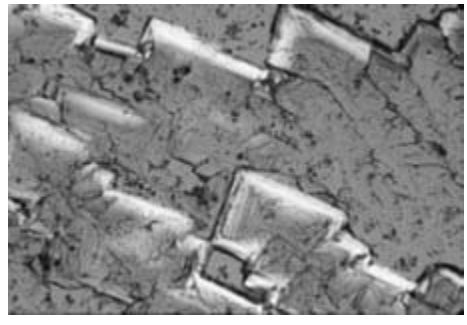

FIG. 4-7. **Ferrous sulfate (www.arsmachina.com/gallery%20micro.htm).**

chelating agents. In earlier media (those generally designed for seedling culture), iron was added as ferrous or ferric tartrate and citrate. These salts of hydroxycarboxylic acids were utilized prior to the advent of chelated iron. The sodium salt of ferric EDTA (NaFeEDTA) is a commonly used form of chelated iron. Chelation prevents the formation and precipitation of insoluble ferrous hydroxide [$Fe(OH_2)$], which can lead to a possible iron deficiency.

Microelements

The terms microelements or minor elements are based on the fact that plants require very small amounts of these minerals. Their importance in plant nutrition is not less than that of the macroelements. A number of culture media, especially older formulae such as Knudson C (Knudson, 1946) and Vacin and Went (Vacin and Went, 1949) solutions, include manganese as the sole microelement. Still other media (Knop, 1884; Morel and Muller, 1964) do not contain microelements. The reason for this is that the low required levels of these microelements are satisfied by the impurities present in nutrient salts and other media components. The same is true for Thomale GD medium (Thomale, 1954) which does not contain added microelements.

Calcium salts are also present as impurities of the agar employed in this and most other solid media. Presently supplied macroelements are much purer than those used decades ago, making the addition of microelements to seed germination media a proper and safe practice.

Micropropagation media in general are different from those used for orchid seed germination because they have included microelements since the earliest days of tissue culture. And, when orchid seed germination media are used for micropropagation, they are often supplemented with microelements. The most often used microelements are boron, chlorine, copper, manganese, molybdenum, sulfur, and zinc, but aluminum, cobalt, iodine, and nickel are also added to some media (Figs 4-8 and 4-9; Table 4-2).

TABLE 4-2. **Microelements and their formula weights as employed in the tissue culture of orchids**

Microelement	Formula	Formula weight[a]
Aluminum chloride	$AlCl_3$	133.34
Aluminum chloride hexahydrate	$AlCl_3 \cdot H_2O$	241.43
Ammonium molybdate tetrahydrate	$(NH_4)_6Mo_7O_{24} \cdot 4H_2O$	1235.86
Boric acid	H_3BO_3	61.83
Cobalt chloride hexahydrate	$CoCl_2 \cdot 6H_2O$	237.93
Cobalt nitrate hexahydrate	$Co(NO_3)_2 \cdot 6H_2O$	291.03
Cobalt sulfate heptahydrate	$CoSO_4 \cdot 7H_2O$	281.1
Cupric chloride dihydrate	$CuCl_2 \cdot 2H_2O$	170.48
Cupric nitrate di/trihydrate	$Cu(NO_3)_2 \cdot 2.5H_2O$	232.59
Cupric sulfate	$CuSO_4$	159.60
Cupric sulfate pentahydrate	$CuSO_4 \cdot 5H_2O$	249.68
Manganese chloride	$MnCl_2$	125.84
Manganese chloride tetrahydrate	$MnCl_2 \cdot 4H_2O$	197.90
Manganese nitrate	$Mn(NO_3)_2$	178.95
Manganese sulfate	$MnSO_4$	151.00
Manganese sulfate hydrate	$MnSO_4 \cdot H_2O$	169.01
Nickel chloride hexahydrate	$NiCl_2 \cdot 6H_2O$	237.71
Nickel nitrate hexahydrate	$Ni(NO_3)_2 \cdot 6H_2O$	290.81
Nickel sulfate hexahydrate	$NiSO_4 \cdot 6H_2O$	262.84
Potassium iodide	KI	166.00
Sodium molybdate dihydrate	$NaMoO_4 \cdot 2H_2O$	241.95
Zinc chloride	$ZnCl_2$	136.29
Zinc sulfate heptahydrate	$ZnSO_4 \cdot 7H_2O$	287.54
Zinc sulfate hydrate	$ZnSO_4 \cdot H_2O$	161.44

[a]Formula weight = molecular weight + weight of water of crystallization where applicable.

Aluminum

This element is added very rarely, usually as aluminum chloride.

Boron

This element is commonly supplied as boric acid (H_3BO_3; Fig. 4-8). It is required in very minute amounts and is toxic to most plants at higher levels.

Chlorine

Any chloride salt present in media will satisfy the need for this element (Fig. 4-9). Plantlets of *Dendrobium moniliforme* took up 74.5% of the chloride from the medium during 1 month of culture (Kishi and Takagi, 1997*b*). During the same period, plantlets of *Darwinara* Pretty Girl took up 29.7% percent of the Cl^- (Kishi and Takagi, 1997*b*).

Cobalt

This element(Fig. 4-9) is added as water-soluble cobaltous (Co^{2+}) chloride, sulfate, or nitrate.

Copper

Salts in which this element is present as Cu^{2+} are usually employed, the most common being copper sulfate (Fig. 4-8).

Iodine

Potassium iodide (KI) is a component of the frequently used and well-known Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) and other media.

Manganese

This element (Fig. 4-8) is added to media most often as a sulfate, but chloride and nitrate salts can also be used.

Molybdenum

Usually added as sodium molybdate (Na_2MoO_4), this element (Fig. 4-9) has also been incorporated as molybdenum trioxide (MoO_3).

Nickel

When included in media (which is rarely), nickel is added as a chloride, nitrate, or sulfate salt.

Sulfur

Media contain generally one or more sulfate salts that fully satisfy the needs for this element (Fig. 4-9).

Zinc

The sulfate salt (Fig. 4-8) is generally used, but the chloride salt can also be added.

Substitutions

Should substitutions of either micro- or macroelement salts be needed, they should be made on a molar, not weight, basis. Equal weights of salts of different molecular weights will not supply the same levels of the required minerals (see tables in Chapter 2). Any suggestions that equal weights are appropriate for substitutions are not only erroneous, they are also bad science. And, even more importantly, equal weight substitutions may result in improper or even damaging levels (sub- or supraoptimal concentrations) of a mineral. Another factor to consider in making substitutions is the other substance in a molecule because it may be toxic, undesirable, or dangerous.

Carbohydrates

Most orchid seed and tissue culture media require the addition of sugar as a source of carbon. The disaccharide sucrose (Fig. 4-10) is an entirely satisfactory and inexpensive carbon source (kitchen grade sucrose can be used for practical purposes). Its monomeric components and products of hydrolysis, glucose and fructose (Fig. 4-10), are used frequently singly or in combination. After supporting a culture of *Dendrobium moniliforme* plantlets, a medium contained more glucose and fructose than initially (131.1 and 217.6%, respectively). A medium that supported *Darwinara* Pretty Girl contained 324.9 and 253.7% (Kishi and Takagi, 1997*b*). The relative usefulness of a large number of carbohydrates for orchid culture media has been investigated (Ernst, 1967*a*). Some of them, particularly galactose, have been found to be toxic to orchids (Quednow, 1930; Ernst et al., 1971*b*). Sugar levels in orchid tissue culture media differ but are generally 2–5%. In several procedures, some steps are even carried out without added sugars (Intuwong and Sagawa, 1974).

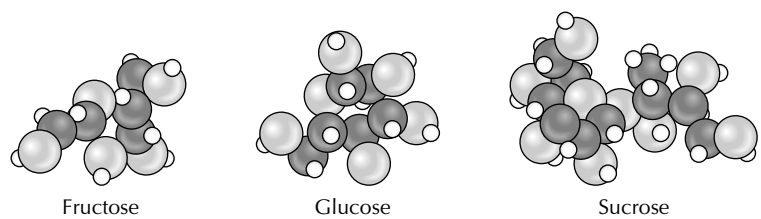

FIG. 4-10. **Sugars (source: www.iconbazaar.com).**

Since the osmolarity of solutions can affect the well being of explants it is very important to keep in mind that equal weights of sucrose and glucose or sucrose and fructose represent different molarities and therefore affect the concentrations of solutions differently. To put it differently, equal weights of sucrose and glucose or glucose and fructose are not the same in terms of concentration because they represent different molarities. Equal weights of glucose and fructose are the same in terms of molarity and concentration.

On the whole, experimental evidence shows that orchid plantlets are heterotrophic under culture conditions (for excellent reviews see Hew and Yong, 1997, 2004). Sugar uptake by *Aranda* and *Dendrobium* tissues shows linear kinetics and "is a function of initial sugar concentration" (Hew and Yong, 1997). The only word which should be added to this statement is "available" before the word "initial" because if larger sugar oligosaccharide molecules are present the tissue probably cannot take them up until after hydrolysis. One of the very best statements regarding the need, utilization, and uptake of sugars by orchid tissue can be found in a book on orchid physiology (Hew and Yong, 1997). Parts of it are quoted here with Professor Hew's permission.

> The overall rate of sugar uptake by orchid callus tissues is determined to a large extent by their surface area-to-volume ratio. The importance of sugar uptake and its subsequent utilization for growth in orchid callus tissues is demonstrated in sugar uptake kinetics studies. *Aranda* callus shows a high specific rate of glucose uptake when grown in glucose-containing media. Depending on its concentration, the rate of glucose uptake is 10–100 times higher than the specific biomass growth rate. This suggests that glucose accumulates in the cells more rapidly than it can be used for growth.

This view is substantiated by the accumulation of starch in protocorms.

> Orchid tissues of different genera show different affinities for the various sugars and this makes formulation of a standard solution difficult.

Proof of this is the preference shown by *Paphiopedilum* for fructose.

Substitution of sugars should be based on the ability of orchids to take up or break down sugar molecules (for example orchids can utilize maltose easily, but not longer glucose chains like maltopentaose), the suitability of all sugars in a molecule (e.g., orchids can utilize the glucose molecule in lactose, but the galactose moiety is toxic), molarity (equal weights of monosaccharides like glucose or fructose and disaccharides such as sucrose or maltose are not the same in terms of their effects on the properties of solutions), and preferences by specific orchids (*Paphiopedilum* seeds and seedlings prefer fructose).

Amino Acids

The amino acid glycine (Fig. 4-11) is a component of the well-known MS medium (Murashige and Skoog, 1962) and many of its modifications. Other amino acids which are added to media include (but are not limited to) isoleucine, glutamic acid, and asparagine. The fact that many orchid tissue culture media do not contain added

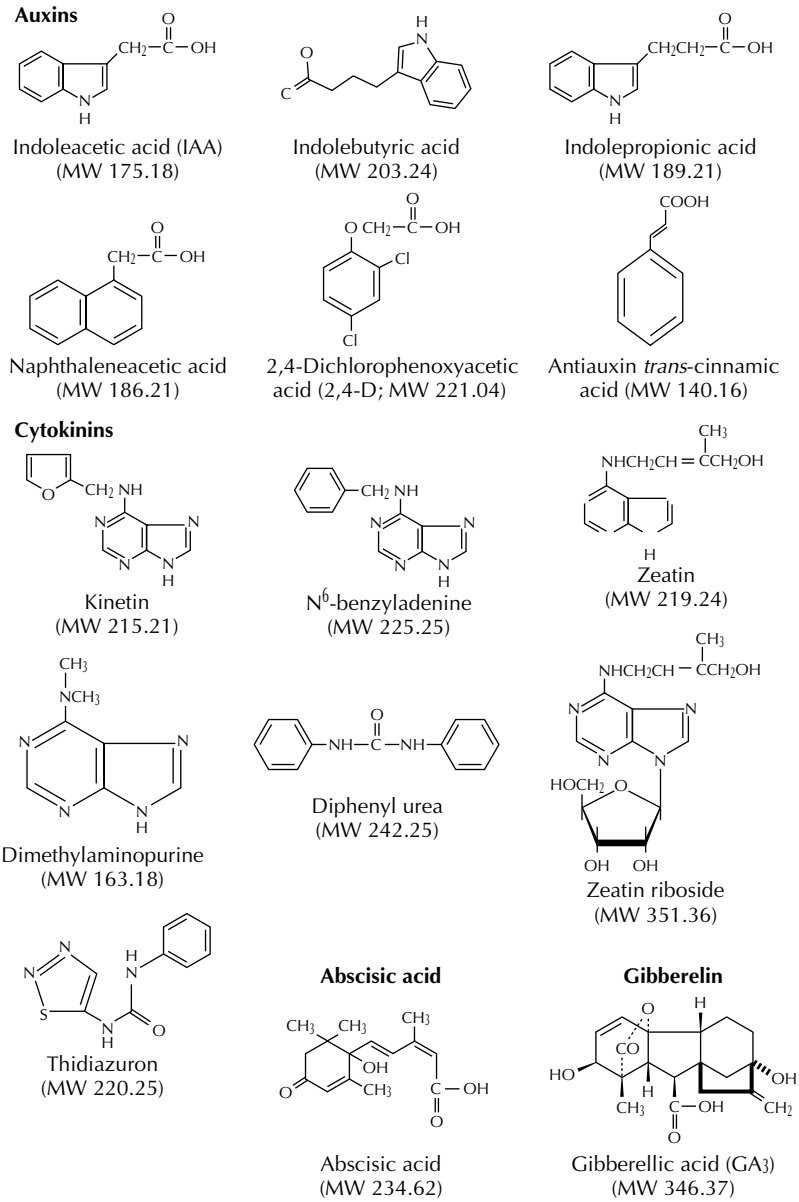

FIG. 4-11. **Vitamins, an amino acid, plant hormones and other substances which are added to media.**

amino acids raises a question as to whether they are really needed. However, it is recommended that they be added where called for in specific media. Their concentrations are generally less than 10 ppm.

To protect these compounds as well as vitamins and hormones from heat destruction, it is best to add them to autoclaved media as ethanol solutions or as

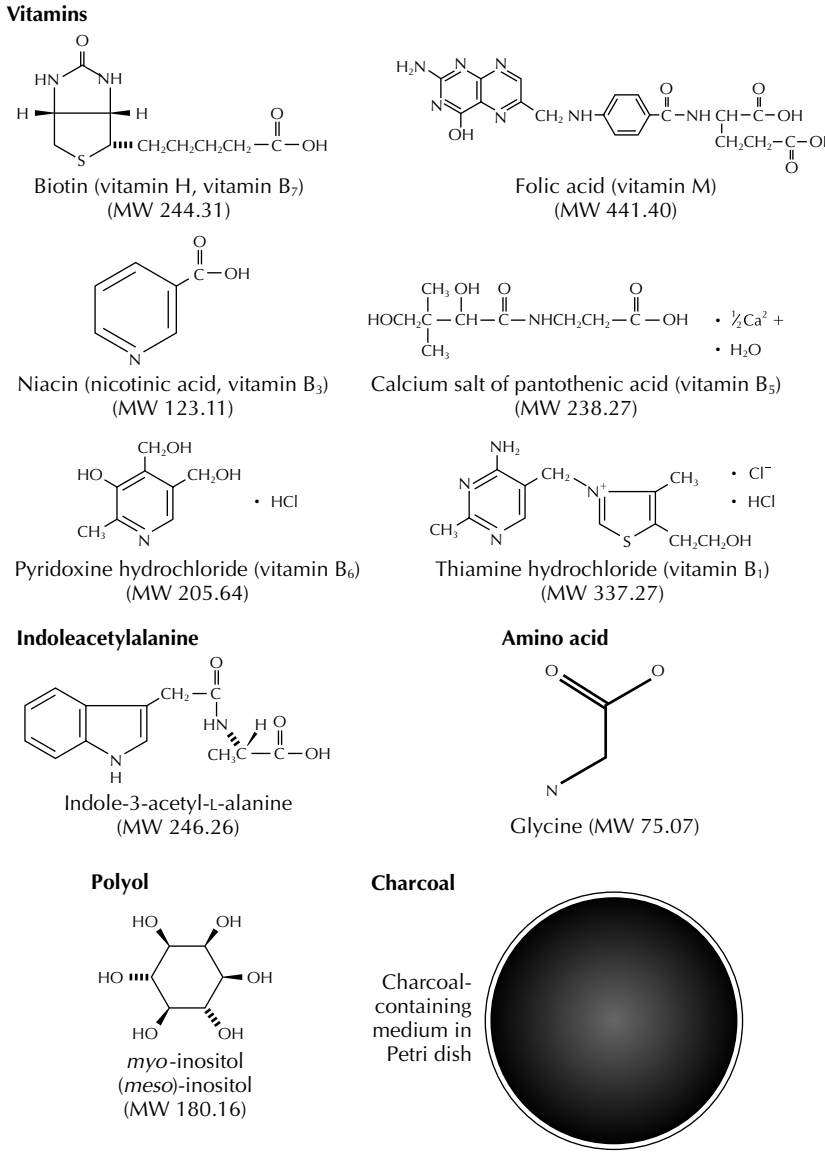

FIG. 4-11. (***Continued***)

cold-sterilized aqueous solutions. Additions should be made under sterile conditions and while the autoclaved media are still liquid to insure good dispersion on agitation.

Amino acids, vitamins, and/or hormones are often added to media before autoclaving. This suggests that: (1) they are not destroyed by the heat and the pressure; (2) a proportion of the added amino acid(s) is (are) destroyed, but the remainder is sufficient for the explants; (3) the destruction product(s) is (are) as effective as the

amino acid(s); and/or (4) all of the added amino acid(s) is (are) destroyed, but this makes no difference because it (they) is (are) not really needed.

Substitutions of amino acids should not be made (or must be made only after prior testing) because some of them may have a specific effect which another amino acid cannot replace.

Vitamins

Absolute requirements for vitamin additions to all or even some orchid media have not been established; as with amino acids, many media do not contain them. However, a large number of media include niacin (nicotinic acid), pyridoxine (vitamin B_6), or thiamine (vitamin B_1; Fig. 4-11). The latter two are added as hydrochlorides. Niacin has been reported to give a slight growth improvement in the culture of *Cymbidium* (Fonnesbech, 1972*b*). A small number of media contain biotin, pantothenic aid, folic acid, and other vitamins. According to Koch (1974*a*), PLBs of *Phalaenopsis* could be cultured for an extended time only if the medium (modified Knudson C) contained pantothenic acid (0.5 ppm); niacin, pyridoxin, and thiamine (0.2 ppm each); and glycine (5 ppm). Regardless of whether requirements for vitamins have been established with certainty or not, they should always be added if a specific recipe includes them. Vitamins are usually destroyed by excessive heat (see the discussion of heat-labile compounds in the section above, Amino Acids).

Vitamins have specific effects and cannot replace each other.

Polyols

The polyalcohol *myo*-inositol (Fig. 4-11), a constituent of coconut liquid endosperm (Pollard et al., 1961), is added to a number of tissue culture media (Murashige and Skoog, 1962; Linsmaier and Skoog, 1965; Nitsch and Nitsch, 1966; Schenk and Hildebrandt, 1972; Anderson, 1978; Gamborg, 1986). Yet, numerous successful tissue culture media do not contain *myo*-inositol. It is considered to be part of the vitamin B_1 complex and is involved in cell wall biosynthesis (Loewus, 1965, 1969). It has been reported that the addition of 100 ppm *myo*-inositol to a culture medium improved growth of *Cymbidium*, but the increase was not significant (Fonnesbech, 1972*a*). Still, it is advisable to include *myo*-inositol in media formulae that suggest it as a component, unless experiments show it not to be useful. If it is required, inositol has specific effects and cannot be replaced by another polyol.

Mannitol, a sugar alcohol, is widely used to prepare isotonic media for the culture of protoplasts. Usually 0.4–0.7-*M* solutions of mannitol are employed, depending on the osmotic potential of the cell line.

Hormones

Most orchid tissues require auxins, cytokinins, and other plant hormones (Fig. 4-11) for growth, the formation of callus or PLBs, proliferation, and plantlet development.

Where both of these hormones are present the ratio between them is usually of critical importance. For example, auxins induce root initiation at high levels, the elongation of roots at low concentrations, and stimulate shoot elongation; whereas cytokinins promote cell division.

Early work involving the tissue culture of *Cymbidium* was carried out using media without added hormones (Morel, 1960, 1964*a*, 1964*b*; Wimber, 1963), showing that not all orchid tissues require them. Indeed, many of the media listed in this book contain no hormones or include only one of them. The original paper describing the widely used MS medium lists a range of 1 to 30 ppm indoleacetic acid (IAA) and 0.4 to 10 ppm kinetin. The upper concentration proposed for the auxin may be too high for orchid tissue culture.

Auxins

Auxins commonly utilized in tissue culture are the naturally occurring indoleacetic acid (IAA) and the synthetics indolebutyric acid (IBA), α-naphthaleneacetic acid (NAA), and 2,4-dichlorophenoxyacetic acid (2,4-D, a herbicide). The synthetics are less subject to enzymatic degradation than is endogenous IAA and therefore persist in culture media for longer periods. For this reason they can be employed at lower levels. Auxins are generally added at levels of about 1–10 ppm, but other concentrations are also used. It is most convenient to add ethanolic solutions to previously autoclaved media, but in many cases auxins are added before autoclaving without deleterious effects.

IAA at 10 pmol l^{-1} (1.8 ppm) produced optimal fresh weight and vigorous PLBs in *Cymbidium* tissue culture (Fonnesbech, 1972*a*). When 2,4-D was used at 1 pmol 1^{-1}, weight increase was high but the PLBs were abnormal (Fonnesbech, 1972*a*). Optimal concentrations of NAA or 2,4-D were 0.1 ppm (Ichihashi and Kako, 1973).

Vanda tissues form roots on 1.25 ppm NAA (Payawal and de Guzman, 1972). On the other hand, *Phalaenopsis* roots produced PLBs on modified MS medium without the addition of auxin or cytokinin (Tanaka et al., 1976).

Shoot formation on *Phalaenopsis* flower-stalk nodes was reduced by the addition of 2 ppm NAA to Knudson C medium (Tse et al., 1971). IAA, NAA (as a potassium salt), or 2,4-D increased initial shoot length from *Phalaenopsis* flower-stalk nodes but inhibited subsequent development (Koch, 1974*a*). However, the combined addition of NAA (0.5–3.0 ppm potassium salt) and 2 ppm benzyladenine (BA) induced the formation of PLBs on thickened basal leaf sections of *Phalaenopsis* flower-stalk buds (Koch, 1974*a*). Care should be exercised with 2,4-D since it may cause mutations.

Acetylamino Acids

Conjugates of the amino acid alanine with IAA (IAA-ala) or of glycine with IAA (IAA-gly) were used as substitutes for the combined addition of auxins and cytokinins (?) in clonal propagation of *Phalaenopsis* from flower-stalk nodes. These conjugates were employed in a PLB proliferation step and could replace conventional auxin–cytokinin combinations (Griesbach, 1983). The question, of course, is why use exotic and costly chemicals when common and inexpensive ones can be equally

effective or more so. There are no good, compelling, scientific, practical, and/or logical reasons for the use of IAA-ala and IAA-gly.

Anti-auxin

The antiauxin effects of *trans*-cinnamic acid (*t*CA) were first observed during the middle of the last century (van Overbeek et al., 1941). *Dendrobium* buds could be released from apical dominance in culture media containing *t*CA and the cytokinin BA (Mosich et al., 1974*b*). The highest shoot development was obtained with 14.8 ppm *t*CA and 2 ppm BA. No shoot development occurred in the absence of anti-auxin. Root development was inhibited but could be initiated by transfer of the shoot-bearing explant to media that were free of these hormones but contained 15% (w/v) banana homogenate (Mosich et al., 1974*b*). A similar release from apical dominance was observed in *Phalaenopsis* flower-stalk buds on Knop's medium containing 1.48–14.8 ppm *t*CA and 2 ppm BA (Ball et al., 1974/75). Later, a "keiki paste" was developed containing 50 mg *t*CA and 5 mg BA per milliliter of lanolin (Griesbach, 1984). However, the high cytokinin content of this paste would be expected to induce plantlet formation on flower-stem buds on its own. In fact most "keiki pastes" do not contain *t*CA and work well. The reason for the formulation of a *t*CA-BA "keki paste" is not immediately apparent and does not seem to make much, if any, sense.

Cytokinins

Representative members of these hormones most often used in tissue culture media are kinetin (N^6-furfuryl adenine), benzylaminopurine (N^6-benzyladenine, BAP, or BA), zeatin [6-(4-hydroxy-3-methyl-but-2-enylamino) purine], zeatin riboside, 6-(dimethylallylamino) purine, and to a lesser extent 1,3-diphenylurea. Some cytokinin activity is exhibited by adenine (aminopurine) itself. Thidiazuron (TDZ), a compound first introduced as a defoliant and found to be a potent cytokinin (Mok et al., 1982; Malik and Saxena, 1992), is being used increasingly in orchid micropropagation media.

Kinetin, which is not a naturally occurring cytokinin, was isolated from herring sperm DNA (Miller et al., 1955*a*, 1995*b*). The first endogenous adenine-derived cytokinins identified were zeatin riboside and its 5′ monophosphate (Letham, 1968). Many substituted adenines were tested for cytokinin activity and the synthetic N^6-benzyladenine (BA) is the most widely used at present. Zeatin and zeatin riboside, both hormones contained in coconut liquid endosperm, are 10–100 times more active than kinetin in a number of growth assays (Letham, 1967, 1968). Cytokinins such as BA are added to orchid tissue culture media at levels below about 10 ppm, although higher concentrations have been used in specific procedures. Extremely high concentrations (up to 5000 ppm) are contained in the so-called "keiki pastes" (Zimmer and Pieper, 1979; Zimmer, 1980).

Root and shoot growth in *Cymbidium* were inhibited by all concentrations of kinetin that were tested (Fonnesbech, 1972*a*). On the other hand, 1–4 ppm kinetin enhanced PLB formation (Payawal and de Guzman, 1972). However, when kinetin is used in combination with NAA in *Vanda* culture, each hormone seems to counteract the other's effects (Payawal and de Guzman, 1972). Shoot development of *Phalaenopsis* flower-stalk nodes was best when a modified Knudson C medium was

supplemented with 1–3 ppm BA (Koch, 1974*a*). Multiple plantlets on *Phalaenopsis* flower-stalk nodes can be obtained with BA levels of 25–125 ppm in vitro. Shoots obtained in this manner must be transplanted onto hormone-free media, preferably containing banana homogenate, to develop roots (Ernst, 1984).

Leaf tissue of *Phalaenopsis* plantlets obtained from flower-stalk nodes can be induced to produce PLBs on a medium containing 1–5 ppm BA (Tanaka and Sakanishi, 1978).

TDZ has been shown to be very effective for a number of orchids including *Cymbidium sinense* (J. T. Chen et al., 2000*b*), *Dendrobium nobile* (Ferreira and Kerbauy, 2002), *Doritaenopsis* (Ernst, 1994), *Phalaenopsis* (Ernst, 1994; Chen and Piluek, 1995), *Vanda coerulea* (Malabadi et al., 2003), and a number of other orchids.

Some hormones are heat-sensitive (see the discussion of heat-labile compounds above in Amino Acids). However, they are often added prior to autoclaving.

Ethylene

This gaseous hormone is not added to orchid tissue cultures and there is no evidence that an exogenous source is required. Ethylene accumulates in the head space of cultures (Hew and Yong, 1997), but if it has any effects they are not obvious.

The effects of hormones (even those which belong to the same group) on particular orchids or explants seem to be specific. Therefore, substitutions or changes in concentrations should not be made without prior testing.

Coconut Water (Coconut Liquid Endosperm, "Coconut Milk")

Several dictionaries of the English language and continued misuse notwithstanding, the correct term for the clear liquid endosperm of coconuts is not coconut milk. It is coconut water (CW). Coconut milk is the milky liquid obtained by grating or squeezing the solid white endosperm, which is also known as copra. Coconut milk is not used as a tissue culture additive.

The first use of CW as an effective tissue culture medium component goes back many years (van Overbeek et al., 1941; for an historical account see Arditti and Krikorian, 1996). It was used extensively in clonal multiplication of carrots from root tissue (Caplin and Steward, 1948; Steward and Caplin, 1952*b*). The first use with orchids was in *Cattleya* seedling cultures (Mariat, 1951). In orchid seed culture of *Paphiopedilum* and *Vanilla*, the combined addition of 10% CW and 3 ppm IBA to nutrients had a stimulating effect (Hegarty, 1955). *Phalaenopsis* seedlings developing on Knudson C medium modified with 15% CW showed substantial proliferation, which did not occur with the addition of numerous other fruit endosperms tested (Ernst, 1967*b*).

The first successful use of CW in orchid tissue culture was also at 15% (v/v) in a medium for shoot tips of *Phalaenopsis* (Intuwong and Sagawa, 1974). Later a liquid Vacin and Went medium modified with 20% CW was used to proliferate PLBs from leaf tissue of *Phalaenopsis* flower-stalk plantlets (Tanaka and Sakanishi, 1977, 1980). Much larger additions of CW (53%) were used in a private micropropagation laboratory in Germany by Dr. Norbert Haas-von Schmude and Mrs. Gudrun Haas-von Schmude (Haas-von Schmude, 1983) in otherwise hormone-free

MS medium for the proliferation of *Phalaenopsis* PLBs. The latter were also differentiated on a similar solid nutrient but with reduced levels (20%) of CW (Haas-von Schmude, 1983).

CW contains a large spectrum of biochemicals that can act as growth factors individually or synergistically (Shantz and Steward, 1952). One such substance isolated from 700 gallons of coconut liquid endosperm was 1,3-diphenylurea (*N*, *N′*-diphenylurea, carbanilide), which shows cytokinin-like activity (Shantz and Steward, 1955). Later, two adenine-type cytokinins, zeatin riboside (Letham, 1968; van Staden and Drewes, 1975) and zeatin (van Staden and Drewes, 1975), were shown to be present in this endosperm. As is the case with several natural products, the activity of CW may depend on such factors as age (whether the coconut is green or ripe), season, and source. Autoclaving does not affect the active principle(s) in CW.

Some workers may not be able to obtain CW from green nuts but liquid endosperm from brown mature nuts (Fig. 4-12A–C) can also be used. In some parts of the USA there are food stores which sell unripe (green) coconuts that are trimmed and partially peeled. These nuts are white and have a conical top and a flat base (Fig. 4-12D). If not available locally from stores, markets, or directly from coconut

FIG. 4-12. **Coconuts. A. Brown mature nut with the typical three "eyes." A hole for draining the liquid endosperm can easily be made by forcing a screwdriver through a soft "eye." B. The copra in such nuts is soft and gelatinous, the backgroundshows immature unpeeled nuts. (Sources: A, www.otan.us; B, www.rpi.edu; C, www.foodsubs.com; D, E, www.thaitradesource.com.)**

plantations, CW can be obtained from suppliers of tissue culture media and their components.

The easiest and simplest method for draining a coconut is to poke a hole with a screw driver through one of the "eyes" (Fig. 4-12A), which is very soft, and invert the nut over a large funnel lined with filter paper made of several layers of cheese cloth. If the "eye" is hard, a drill or hammer and nail can be used to make a hole. To facilitate pouring, a second hole (vent) should also be made. Coconuts should be opened and poured one at a time or into separate containers because the liquid endosperm in some nuts may have fermented or become contaminated. Liquid which is brownish or smelly should be discarded.

Opinions and practices regarding the preparation of CW vary. Some workers use the water after it has been drained and filtered. Others prefer to boil the water to precipitate proteins, allow the liquid to cool, filter it again, and use the filtered CW (Dodds and Roberts, 1995). Both methods seem equally effective.

No other additive can be used in place of CW (but see Bleeding Sap of Birch Trees below). Coconut milk (i.e., the liquid obtained from grated copra, by squeezing it or as an extract) cannot be used as a CW substitute. Banana homogenate, taro extract, potato extract, tomato or apple juice, and other plant homogenates, extracts, or juices may have beneficial effects for some orchids or explants, but they must be established experimentally and tested carefully before extensive use.

Bleeding Sap of Birch Trees

Due to difficulties in obtaining CW in Europe, it was replaced with the bleeding sap of birch trees (BSBT) in the proliferation of *Phalaenopsis* tissues from plantlets derived from flower-stalk nodes (Zimmer and Pieper, 1978). Even if BSBT is as effective as CW (which may or may not be the case), it is much more difficult to find.

Other Complex Organic Additives

Many complex additives to seed and tissue culture media have been used, but comparative data are insufficient to permit a discussion of their effects (Arditti, 1977*b*). A limited number of these additives has been compared in the seed culture of *Phaleanopsis* (Ernst, 1967*b*), *Cymbidium*, *Paphiopedilum*, *Dendrobium*, and a few species of other genera (Kano, 1965). Additives other than coconut endosperm include banana homogenate (which enhances the growth of plantlets and seedlings), peptone (a byproduct of the digestion of meat protein by the enzyme pepsin), tryptone (a peptone produced by the action of trypsin), casein hydrolysate, taro (*Colocasia esculenta*) extract (all five are used to enhance the growth of explants), tomato juice (which must be filtered to remove seeds and can be used to stimulate the growth of plantlets and seedlings), and a number of other fruit homogenates and extracts. The reasons for the effects of these additives are not known. It is also not known whether the effects are due to the same or different factors. But, all this does not really matter from a practical point of view. If an additive can bring about the desired results, it should be used.

Solidifying (Gel-forming) Agents and Alternative Supporting Media

Agar was the principal gel-forming agent used in the seed and tissue culture of orchids. Commercial agar contains a wide variety of organic and inorganic impurities, and some of the cruder grades have as much as 6% ash content. For research purposes it is best to use purified grades with an ash content of 2% or below. United States Pharmacopeia (USP) purity grade contains a maximum 1% each of foreign organic and foreign insoluble matter. When using the purified grade of agar, 0.6–9 g l^{-1} are needed to solidify media, depending largely on the firmness of gel desired. Almost any agar, including kitchen grade, can be used for practical micropropagation (provided of course it is not toxic or inhibitory to the plants being propagated). In some cases kitchen grade may even be preferable simply because it is much less expensive.

More recently, gellan gum is used, available as Phytagel (trade named product sold by Sigma Chemical Co.) or Gelrite; it is a hydrocolloid produced by the microorganism *Sphingomonas elodea*. It is composed of glucuronic acid, rhamnose, and glucose. The gel it produces is clear and of high strength. To prevent clumping it should be added to solutions at room temperature with rapid stirring. The amounts which should be used are those recommended for each procedure. Typically, concentrations recommended for plant media are 1.5–2.5 g l^{-1}, but some media may require higher or lower levels. Gellan gum (Phytagel or Gelrite) requires the presence of divalent cations such as Ca^{2+} or Mg^{2+} for gelling to take place. Most micropropagation media contain sufficient amounts of these cations for gelling.

In the absence of experimental evidence, it is not clear at present if the solidifying agent makes a difference for some explants and tissues. This being the case it is best to use the solidifier recommended for each procedure. If a change is desired it is best to proceed with caution and only after preliminary tests.

A mineral inorganic product first discovered in the Hawaiian islands as part of formations created by volcanic activity, is the basis of rockwool (Fig. 4-13), a horticultural product made either from rock only or from a mixture of rocks, limestone,

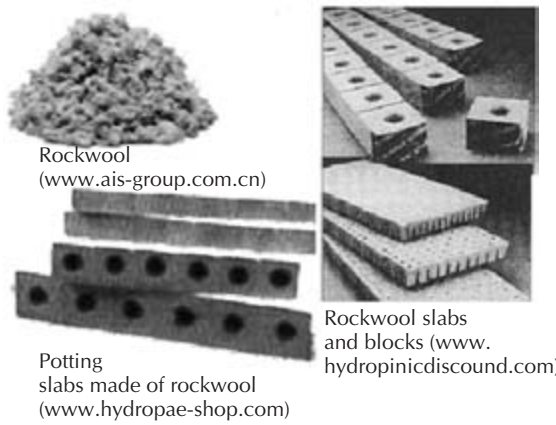

FIG. 4-13. **Rockwool.**

and coke. The components are melted at temperatures of around 1400°C (about 2500°F). This molten solution is poured over a spinning cylinder, flies away from it, elongates, and forms fibers as it cools. These fibers, called rockwool, can be granulated or pressed into sheets, cubes, or blocks. Granulated rockwool can be added to soil mixes as an amendment or used as support for older plantlets in culture (Hew and Yong, 1997).

Root growth in *Phalaenopsis* was reported to be better in rockwool than on agar for reasons which are not clear (Hew and Yong, 1997). If the plants are grown in multi-blocks, transplanting to pots is less of a shock because the roots remain intact (Hew and Yong, 1997). However "more work is needed to evaluate the suitability of rockwool as an alternative method for . . . genera such as *Dendrobium*, *Aranda* and *Mokara*" (Hew and Yong, 1997).

Aeration improved growth when seedlings, protocorms, and explants of *Cattleya*, *Cymbidium*, *Dendrobium*, *Epidendrum*, and *Laeliocattleya* were cultured on microporous polypropylene membranes (as, for example, the Osmotek Life Raft™). The use of rafts also renders subculturing easier.

As mentioned and illustrated above (see Fig. 4-1), membrane rafts are a good support for the culture of explants, tissues, PLBs, and plantlets. Excellent research done since about 1990 by Dr. Jeffrey Adelberg and his associates at Clemson University has shown that proliferation on a membrane, rather than on agar, resulted in more harvestable plants. The plants were also larger (Fig. 4-14) and flowered earlier. Also, plants on membranes did not require regular transfers to fresh medium. Instead, adding water or medium could sustain and accelerate growth. Utilization and uptake of medium by the plants, as well as evaporation, tended to reduce or eliminate contact with the membrane and required periodic additions (Adelberg et al., 1991, 1992, 1997*b*, 1998; Adelberg and Darling, 1992; Young, 1994).

Adsorbents

Polyvinylpyrrolidone (PVP) or polyvinylpolypyrrolidone resins have been suggested as additives to tissue culture media for the absorption of toxic metabolites such as polyphenol oxidates and other phenolics that may be produced by explants. Some of these substances are dark and easily visible and unsightly on agar- or gellan-gum-solidified media. Activated charcoal (AC), described in detail in Chapter 2, may also serve this purpose, among other beneficial effects. It also renders the dark spots invisible. The problem with both PVP and AC is that they can absorb culture medium components such as hormones and vitamins, thereby reducing their concentrations to subphysiological levels. Because of this, PVP and AC should be used with caution. Sometimes problems created by explant exudates can be eliminated or reduced by moving the tissues from a dark area on the medium to a clear spot. It may be necessary to do this a few times or even move explants to a new vessel before they cease to exude the offending substances.

Applications of Orchid Tissue Culture

It is not at all surprising that the culture of shoot tips, and subsequently of other explants of orchids, created considerable interest almost immediately (even if credit for the discovery went to the wrong person; see Chapter 1). The potential of these methods for mass clonal propagation and biotechnological applications was, and still is, immense. A large number of articles on the subject have been published over the years. Some researchers explained the procedures and described their background (for example, Murashige, 1962; Butcher and Ingram, 1976; Laetsch, 1967; Attawar, 1992; Ichihashi, 1997; Vij et al., 2000*a*); others have dealt with methodology (Teo, 1978; Warren, 1983; for reviews also see Arditti and Ernst, 1993; Dodds and Roberts, 1995); one embarrassingly bad pamphlet sought to exploit procedures which were novel at the time (Jasper, 1966) and was accorded the oblivion it richly deserved. There was also a self important report of an individual's personal experiences (Rutkowski, 1967). Some reviews were boastful but not very informative (Goh, 1996), not very useful (Goh, 1989), or telegraphic consisting of one (Sagawa and Kunisaki, 1982), six (Sagawa and Kunisaki, 1984; Griesbach, 1986), or seven (Tisserat and Jones, 1999) pages. Reviews have been published in Chinese and Malay (Chen, 1985), English (Morel, 1974; Arditti, 1977*b*; Holdgate, 1977; Rao, 1977; Teo, 1978; Arditti and Goh, 1981; Goh, 1983*b*; Griesbach, 1986; Hew and Yong, 1997), French (Bouriquet, 1986), German (Hahn, 1970; Fast, 1980*a*, 1980*b*), Japanese (for a review see Ichihashi, 1997), Russian (Cherevchenko et al., 1982; Cherevchenko and Kushnir, 1986), and many other languages. These and other publications have helped both amateur and professional growers to establish tissue culture laboratories, which revolutionized the industry.

Automation was introduced as the industry developed. A flow system first became available in 1982. It agitated cultures with air (Hew and Yong, 1997, 2004). This was followed by systems involving pumps and tubing (Fig. 4-15A; Tisserat and Vandercook, 1985) and computers (Hew and Yong, 1997). More elaborate systems followed (Fig. 4-15B, C; Okamoto, 1996; Adelberg et al., 1998; Paek et al., 2001). A commercial system (manufactured by Osmotek Ltd, www.osmotek.com) is also available (Fig. 4-15D). These systems can be useful for some laboratories and will undoubtedly become increasingly important, but they are not very common at present perhaps because much of the orchid micropropagation industry is in low wage countries.

Commercialization

By its very nature, micropropagation is a process well suited for commercialization. Because of that it is not surprising that commercial micropropagation laboratories exist in all parts of the world (Hew, 1994; Pamfil, 1996; Govil and Gupta, 1997, 2001; Ichihashi, 1997; Pathak et al., 2001). In 1997 the estimated global market for tissue culture was 15 billion US dollars (Govil and Gupta, 1997). Some of these laboratories are a one-person operation which started as a hobby (Parsons, 1990). The literature on commercialization of micropropagation is mostly descriptive rather than instructive.

Conservation

Very rare species can be propagated in vitro and reintroduced into their natural habitat. This approach has the obvious disadvantages of genetic pauperization (i.e., reduction of genetic diversity) and introducing into nature a single clone or a few clones and its/their possible mutant(s). However, this is preferable to extinction. Further, orchids are usually very heterozygous, and heterogeneity could be re-established after a few years or several generations through natural pollination. Conservation projects utilizing in vitro seed germination have been initiated and/or exist in Australia (Dixon et al., 1991; Dixon, 1994), Belgium (Ronse, 1989), India (Pathak et al., 2001; Decruse et al., 2003*a*, 2003*b*), the UK (Fay, 1992; Ramsay, 1997), Singapore and Hong Kong (both under the direction of Dr. Tim Wing Yam of the Singapore Botanic Gardens), and the USA (Pence et al., 1997). The procedures used to culture plants for the purpose of conservation are no different from those utilized for standard commercial or hobby micropropagation. They can be found in Chapter 3.

Patents

In the United States, at least, plants can be patented only if they have been reproduced asexually and have then flowered. Micropropagation can be used for large-scale propagation of plants that have been or will be patented (Lecoufle, 1976). Several micropropagation procedures have been patented (Zhou and Tanaka, 2000; Oh and Kostenyuk, 2001; Chang, no date), but it is hard to imagine how such patents can be enforced. There was also an anecdotal report that an attempt was contemplated or made to patent an in vitro flowering procedure in a South East Asia country, or to sell it for an astronomical amount, but nothing seems to have come out of it, which is just as well. Patents and the process of obtaining them are legal matters and beyond the scope of this book.

Plant Improvement and Biotechnology

Orchids may have been the first crop plants to be improved in vitro through the doubling of chromosomes of seedlings (Rentoul, 1981). When tissue culture procedures became available, they were also used for the same purpose (Sanguthai and Sagawa, 1973; Binnie, 1979; Kam and Kamemoto, 1980; Sahavacharin, 1980; for procedures see Tanaka and Kamemoto, 1984). This too may have been another first for orchids, not only for ploidy changes but also for what is presently called genetic engineering. Not surprisingly the subject of genetic engineering and orchids has been discussed (Khaw and Ong, 1974/75; Kerr, 1983; Miller, 1983). Mutations, induced or accidental, have also been used to select improved clones (Vajrabhaya and Vajrabhaya, 1974; Sahavacharin, 1980; Teo, 1981).

One of the most interesting and impressive (and probably the first) biotechnology feats achieved with orchids has been the insertion of a bioluminescence gene in a *Dendrobium* by Professor Tet Fatt Chia of the Nanyang Technological University

in Singapore (Chia et al., 1994, 2000). For a period the plant could be seen on a World Wide Web site and it may still be there. Under illumination its appearance is that of a normal plant, but it glows in the dark. As so often happens with orchids, excessive competitiveness, ego, and jealousy led to intrigues and the spreading of a false rumor at one of the World Orchid Conferences that Professor Chia's genetically engineered plants were not stable. The truth is that the engineered plants are stable, very stable. The spreading of such false rumors, especially by a scientist who claims a standing among orchid scientists and growers, is unethical. Fortunately plants (especially ones which glow in the dark) speak louder than words and the false rumors were relegated to the trash heap of orchid history.

Chromosome doubling and bioengineering procedures are not covered in this book and this section was not updated for two reasons. One is the simple fact that even if performed in vitro, these techniques are not actually micropropagation. Descriptions of these techniques belong in a book on biotechnology. The second reason is that this book is already large enough.

Cryopreservation

Storing pollen in a refrigerator has been a common practice among orchid growers for at least 35 years. Orchid seeds have been stored in the cold for nearly 70 years. More recently, attempts have been made to store callus tissue of *Dendrobium* Multico White at 25, 10, 0, −5, and −78°C (Sivasubramaniam et al., 1987). The results indicate that callus can be stored easily at 10°C, but "a lot more work is needed to store orchid callus tissue at . . . temperatures . . . below 10°C" (Sivasubramaniam et al., 1987). Similar work was carried out in the laboratory of Professor Katsuhiko Kondo in Japan where methods were developed for the cryopreservation of *Cattleya loddigesii* var. *harrisoniana*, *Cattleya walkeriana*, *Dendrobium* Yukidaruma (Kondo et al., 2001*a*, 2001*b*), and *Vanda pumila* (Na and Kondo, 1995, 1996).

The methods used to produce tissues for cryopreservation are alluded to in Chapter 3. However, cryopreservation itself, even if it can be used to preserve tissues produced in vitro, is not micropropagation per se and is therefore not included in this book.

Physiological Studies

Explants, callus masses, PLBs, and plantlets produced through tissue culture methods have been used for studies of the effects of initial and subsequent pH on the growth of orchid plantlets (Piriyakanjanakul and Vajrabhaya, 1980), and the optimal composition of culture media (Ichihashi and Uehara, 1987). Other phenomena and processes can also be studied conveniently in vitro or with material produced by tissue culture.

Orchid roots are ageotropic and sometimes even negatively geotropic. This phenomenon was first studied at the famed Bogor Botanical Gardens in Indonesia in the early 20th century (Tischler, 1905; Wilkins, 1966; for reviews see Churchill et al.,

1972*b*; Arditti, 1977*b*). Aerial roots can often be seen to grow upward or sideways in nature, in vitro, and under cultivation. Such roots bend down eventually due to their own weight. The roots of *Grammatophyllum speciosum* are hard, point upward, have sharp thorn-like laterals, and form nest-like masses, called "trash baskets" (Dressler, 1981) that accumulate debris. The laterals are first noticeable 4–5 cm from the tips and always grow at a right angle to the main axis. Many large plants of *G. speciosum* grow on trees along one of the avenues in the Bogor Botanical Gardens. The view is spectacular and suggests that orchid roots could be used for studies of geotropism. Roots of *Brassia*, *Epidendrum*, *Oncidium*, and *Vanda* lack statoliths (Tischler, 1905), thereby offering a unique system for the study of the role of these organelles in nature, under horticultural conditions, and in vitro.

The roots of *Phalaenopsis* seedlings grown under illumination often point upward, whereas those of *Cymbidium* plantlets on dark medium grow downward. These phenomena suggest the use of orchid roots for studies of root phototropism and the relation between light and geotropism.

The roots of *Cattleya* and *Epidendrum* (Erickson, 1957), like those of many other orchids, are green and can fix carbon. The roots of "leafless" orchids fix carbon in a unique manner (Arditti, 1992). These roots undoubtedly perform not only all the functions of roots, but also those carried out by leaves and stems. For this reason they could prove to be a valuable system for certain physiological studies in culture.

The velamen of orchid roots (Pridgeon, 1987) is of considerable developmental, physiological, and ecological interest. Some orchid roots produce anthocyanins. Phytoalexins are present in the roots of many species following the establishment of mycorrhizae (Stoessl and Arditti, 1984). Orchid seedlings (and therefore probably also plantlets derived from explants) can establish mycorrhizae in vitro (Clements, 1982), a fact that may make seedlings useful for studies of this phenomenon. Other areas in which orchid roots in vitro may be a good research system are mineral uptake, thigmotropism, chemotropism, attachment to surfaces, and branching.

Leaf explants of both crassulacean acid metabolism (CAM) and C3 orchids have been cultured and used to produce callus and/or PLBs. All three (explants, callus masses, and PLBs) can be used for physiological and developmental research (for a review of recent research see Hew and Yong, 1997, 2004).

Phalaenopsis flower-stalk nodes can produce new flower stems when placed in culture (Intuwong et al., 1972*a*, 1972*b*). Explant-derived *Cymbidium* plantlets have been induced to flower in vitro by Xiong Wang at the Shanghai Plant Physiology Institute. The bud on a flower-stalk node of *Arachnis* Maggie Oei developed in vitro when placed in liquid stationary Knudson C medium by a worker at the Bogor Botanical Gardens. Seedlings of *Oncidium* and other orchids have been reported to flower in vitro at a very young age. Thus it seems that orchid seedlings and plantlets in vitro can be used for studies of flowering (for a review of recent and older research see Chia et al., 1999).

Several other areas for which orchids are suitable for in vitro research systems are: formation of somatic embryos, protoplasts, cell wall formation, comparisons between existing sexual hybrids and the same combinations obtained through protoplast fusion, development, mineral uptake, ontogeny, and other physiological phenomena. These topics will not be updated here due to space limitations (for reviews of work carried out since the first edition of this book see Arditti, 1994; Rasmussen, 1995; Arditti

and Pridgeon, 1997; Hew and Yong, 1997; Ichihashi, 1997; Chia et al., 1999; Kull and Arditti, 2002).

Negative Aspects of Micropropagation

Since micropropagation is a vegetative means of propagating plants, both horticulturists and scientists assumed at the outset that all offspring would be true to their parents. This assumption was reinforced by an early report regarding the blooming of "mericlones" that stated that "for each individual cultivar the flowers appeared exactly identical, and in hundreds of them no mutation was observed" (Lecoufle, 1967). This could have been the case or the statement may have been an exaggeration intended to allay the fears of potential customers. But several researchers (including myself) were also sanguine (Teo and Teo, 1974; Teo, 1975; Tanaka, 1987). However, as experience with micropropagation increased, it became evident that mutations do occur. Among the first workers to call attention to this were the Thai orchidologists Thavorn and Montakan Vajrabhaya (Vajrabhaya and Vajrabhaya, 1974; for a review see Vajrabhaya, 1977). Experience since then has confirmed that mutations do occur during tissue culture (Sahavacharin, 1980; Rentoul, 1981; Teo, 1981; Ichihashi, 1997).

Mutations are especially prevalent in cases where high concentrations of hormones are used to force proliferation and the production of a large plantlet yield. Excessive proliferation of plants through tissue culture also causes mutations. To prevent mutations: (1) proliferation should be brought about through culture in liquid medium with agitation or high levels of coconut water; (2) PLBs, tissues, or plantlets produced through tissue culture should be proliferated to a limited extent only; and (3) only a small number of plants should be produced from any one explant.

Phenotypically these mutations include changes in color, shape, malformed flowers, and stunted growth. In some overproliferated clones, individual flowers on a raceme may die and render the inflorescence commercially useless.

There is no way at present to predict the nature of mutations. It is also impossible to prevent propagators from overproliferating a clone. Buyers can protect themselves by purchasing plants produced in vitro only from known and reliable sources, and by demanding guarantees.

It is not uncommon for growers to have their most promising plants propagated by commercial micropropagation laboratories. Several of these laboratories set aside some of the plants and, if the clone proves popular, sell their stock. This can flood the market and reduce prices. It essentially deprives the original plant owner of market position and just profits. Assurances that this will not be done are only as good as the person who makes them. Patents offer limited protection against this practice even if they can be proven and enforced. Propagation of valuable clones in house is one means of preventing such robbery. Another would be for growers in specific geographic areas to establish joint, well-supervised laboratories for the propagation of clones owned by members.

APPENDIX ONE

General Information on Supplies, Equipment, Terms, and Reagents

This appendix may be used by experienced workers familiar with orchids, tissue culture, and seed germination techniques. However, it may well be a major source of information for hobbyists, commercial growers, and/or investigators who have little or no such experience. In more isolated laboratories it could be the first or only source of information. Therefore, every effort has been made to include in it all necessary information. This list describes equipment and chemicals, in alphabetical order. The numbers in parentheses refer to supply sources in Appendix 2.

Agar. Agar may vary in purity, mineral content, organic substances, or the amount required to solidify a medium, depending on its source or batch. Bacto agar from Difco Laboratories (now part of Becton, Dickinson, and Company) was a commonly used brand in the United States for many years, but other brands have also been used with success. Agar purchased in food stores has been suitable or even preferable in some instances. In general, it may be wise to test agar from a new source before using it in important media. At present gellan gum (under brand names like Gelrite and Phytagel) is also used as a gelling agent. Some structural formulae and illustrations of agar and gellan gum can be found throughout Chapter 3. (Supply sources: 1, 2, 3, 7–13, 16, 19–21, 23, 24.)

Alcohol. A term that describes a large number of compounds. The alcohol recommended for use in this book is the one familiar to most people – ethanol or drinking alcohol. Ethanol must be used to make all alcohol stock solutions and should be employed as a sterilant since methyl alcohol (methanol, methylated spirits, wood alcohol) is toxic. The same is often true for denatured ethanol. In some countries ethanol, which is not taxed like an alcoholic beverage, can be purchased in pharmacies with a prescription. Special use permits may also be required for the purchase of untaxed ethanol. Isopropyl alcohol (isopropanol, rubbing alcohol) can be used as a sterilant for surfaces, but not as a solvent for components of media. (Supply sources: 1–4, 8, 11, 13, 19, 21, 23, 24.)

Amino acids. Amino acids are components of protein which are incorporated in several media; some are not heat-stable and should be filter-sterilized or dissolved in ethanol and added to media after autoclaving. However, amino acids are often added

before autoclaving to media that are still effective. This suggests that the amino acids in question are: (i) not really needed, (2) may not be destroyed (either partially or fully) by autoclaving, or (3) that the products of amino acid heat destruction may also meet the requirements of the explants. Some structural formulae can be seen in Chapter 4 (see Fig. 4-11) and through Chapter 3. (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

Anticontaminants. These are compounds which can be added to cultures to prevent or combat contamination (see Anticontaminants in Chapter 2). Not all of the compounds listed in that chapter have been tested with orchids; the untested compounds must be used with caution. (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

Ascorbic acid. This is the chemical name for vitamin C, which is sometimes used as an antioxidant. Vitamin C is not heat-stable, yet it is often added to culture media before autoclaving. (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

Autoclaves. Autoclaves are sterilizers that develop high temperature and pressure. Many types (Fig. A1-1A, E) are available, the simplest being a pressure cooker. (Supply sources: 11, 19, 21, 24.)

Auxins. The auxins are a group of plant hormones. Indoleacetic acid (IAA) occurs naturally, but a number of synthetic auxins are available and are added to culture media. These include naphthaleneacetic acid (NAA), *para*-chlorophenoxyacetic acid (*p*CPA), 2,4-dichlorophenoxyacetic acid (2,4-D), and 2,4,5-trichlorophenoxyacetic acid (2,4,5-T), among others. The structural formulae of some auxins are shown in Chapter 4 (see Fig. 4-11) and through Chapter 3. The effects of, and plant responses to, different auxins can vary for reasons that are not known. (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

Balances. Two types of balance are necessary for accurate weighing of most media components. The first is a simple swing or beam balance (Fig. A1-1G, H, J) for weighing several grams at a time. For quantities of around 1 mg, an analytical balance (Fig. A1-1K), although expensive, is necessary. If costs are prohibitive, a balance accurate to 10 mg may be used but will require making larger amounts of some stock solutions. (Supply sources: 11, 19, 21, 23.)

Beakers. Containers made of glass (Fig. A1-1B) or plastic can be used in the preparation of solutions. Glass jars, cups, or glasses can also be used. (Supply sources: 1–4, 6–12, 16, 17, 19, 21, 23.)

Blades, Cutting. *See* Microscalpels.

Bleach, Household. *See* Household Bleach.

Calcium Hypochlorite. This is used in a filtered solution of 7 g per 100 ml of water to surface-sterilize seeds or capsules. The solution must be used within a few hours.

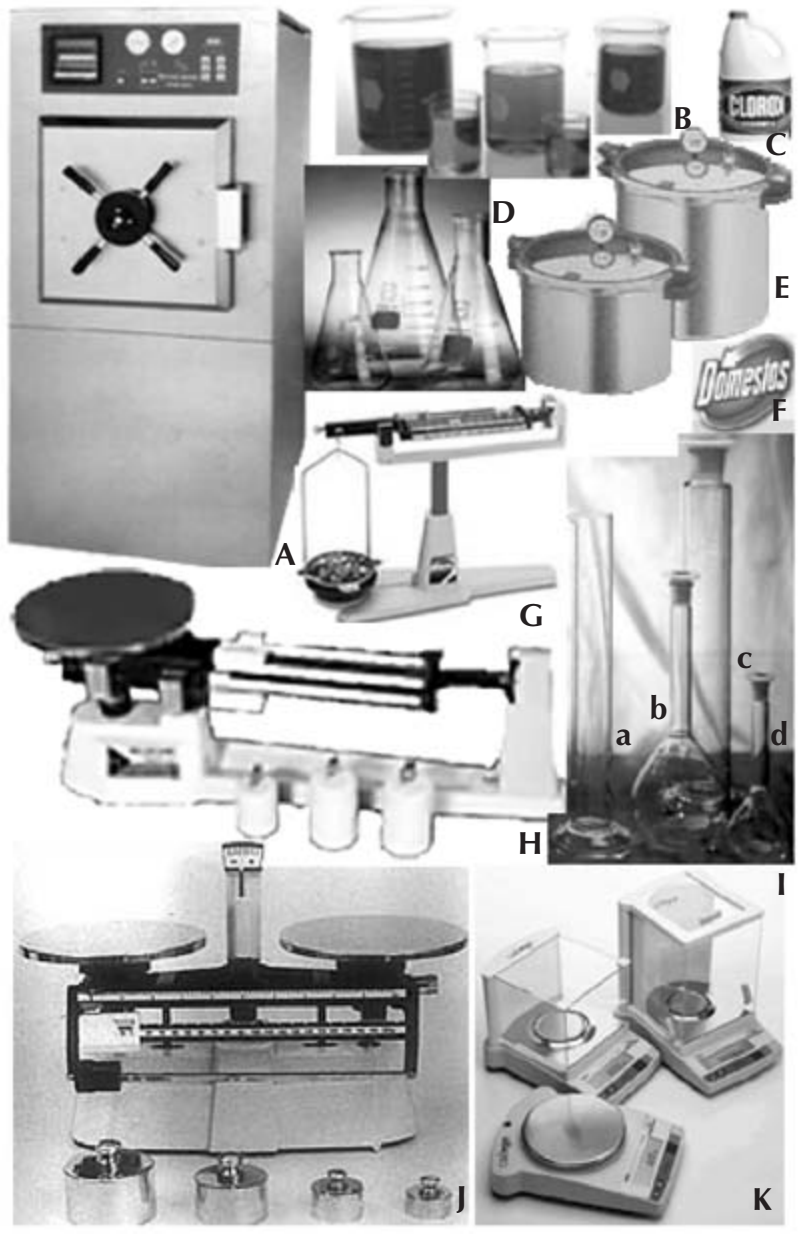

FIG. A1-1. **Laboratory equipment and glassware. A. Large autoclave. B. Beakers. C. Clorox bottle. D. Erlenmeyer flasks. E. Pressure-cooker-type autoclaves. F. Domestos. G, H, J. Swing and beam balances. I. Volumetric cylinders (a, c) and flasks (b, d). K. Analytical balances.**

A few drops of household detergent or baby shampoo should be added as a wetting agent. [Prolonged exposure to high concentrations of detergents (surfactants) can damage orchid tissues. However contact with low concentrations for short periods will not have harmful effects, especially if the tissues are rinsed with sterile distilled water after the sterilization.] (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

Casein Hydrolysate. *See* Complex Additives.

Clorox. Clorox (Fig. A1-1C) is a brand of household bleach. Another brand is Domestos (Fig. A1-1F). There are additional brands throughout the world. (Supply source: 13.)

Coconut Milk. *See* Coconut Water.

Coconut Water. This is sometimes erroneously called coconut milk. It is liquid endosperm which enhances growth of cells, tissues, organs, or seedlings in vitro. Its exact composition and reasons for its effects are not known. Water from green coconut is preferable, but we have had reasonable success with liquid removed from relatively mature nuts purchased in local food stores. Unless otherwise specified, coconut water can be autoclaved. Coconut milk is a white milky liquid obtained by grating or pressing the solid endosperm of coconut. Coconut milk is not used in culture media. (Supply sources: frozen or dried, 2, 7, 8, 10, 16, 23; fresh, 13.)

Complex Additives. These are preparations like coconut water, casein hydrolysate, banana homogenate, peptone, tryptone, or yeast extract, which are added to media but whose exact composition is unknown. (Supply sources: 1–4, 7–12, 16, 17, 19–21.)

Culture Containers. *See* Culture Vessels.

Culture Flasks. *See* Culture Vessels.

Culture Tubes. *See* Culture Vessels.

Culture Vessels. At one time Erlenmeyer flasks, culture tubes, and a variety of jars and bottles were used as culture vessels. These are still being used at present. However, a number of specially designed glass and plastic culture vessels (Fig. A1-2) are also currently being used. Some are disposable, others are not. The use of disposable culture vessels may be more economical in countries where labor costs are high. Low cost disposable plastic culture vessels are preferable when in-vitro-produced plantlets or seedlings must be shipped or sold directly to consumers. Several of the plastic culture vessels are vented through openings covered with sterilizing filters. Changeover from one type of vessel to another may require an adjustment period and retraining of laboratory personnel. (Supply sources: 6, 7, 10, 11, 15, 16, 19, 21, 23, 26.)

Cylinder, Volumetric. *See* Volumetric Cylinders.

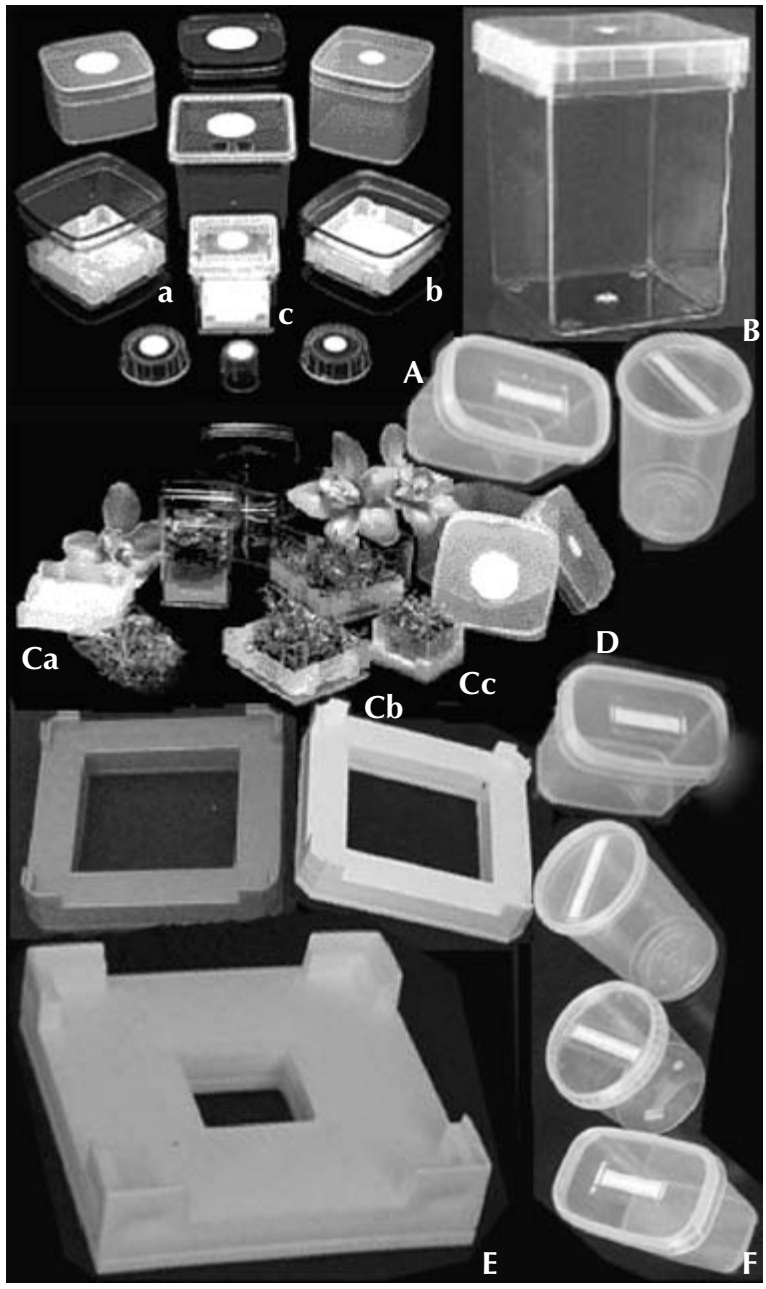

FIG. A1-2. **Culture vessels. A, C, D. Osmotek vented culture vessels, empty (A) and full (C, D). The vessels in Aa, Ab, Ac, Ca, Cb, and Cc contain lined Life Rafts™. All Osmotek culture vessels have round filter covered vents. B. Magenta culture vessels. E. Osmotek Life Rafts™. F. Duchefa culture vessels. All Duchefa culture vessels have rectangular vents.**

Cytokinins. Cytokinins are a group of hormones that regulate cell division and other plant functions. They may be used in culture media and include compounds such as benzyladenine (BA), 6-dimethyl-aminopurine (6-DMAP), kinetin, *N*-benzyl-9-(tetrahydro-2H-pyran-2-yl), an experimental compound SD 8339 (this may no longer be available), thidiazuron (TDZ), and the naturally occurring zeatin. Their formulae can be found in Chapter 4 (Fig. 4-11) and through Chapter 3. (Supply sources: 1–4, 7–12 16, 17, 19–21.)

Electrical equipment. Proper precautions should be exercised in the purchase of any electrical equipment, and the current, cycles, and voltage levels and their fluctuations should be considered. If voltage fluctuations are common and excessive, regulators are necessary. (Supply sources: 11, 13, 19, 21.)

Erlenmeyer Flasks. These are containers with relatively narrow necks and a broader base (Fig. A1-1D) that have been and still are used extensively for cultures and preparation of solutions. To withstand heating better they should be made of heat-resistant glass like Pyrex. (Supply sources: 4, 6, 7, 11, 13, 16, 19, 21, 23.)

Ethanol. *See* Alcohol.

Ethyl Alcohol. *See* Alcohol, Ethyl alcohol.

Filters, Paper. Paper filters are used to trap particles. *See also* Sterilizing Filters.

Flask, Erlenmeyer. *See* Erlenmeyer Flasks.

Flask, Volumetric. *See* Volumetric Flasks.

Graduated Cylinder. *See* Volumetric Cylinders.

Hormones (Abscisic Acid, Auxins, Cytokinins, Ethylene, Gibberellins). These substances are sparingly soluble or insoluble in water. They can be dissolved as soluble salts if they exist (e.g., potassium salts of auxins). Another approach is to dissolve them in ethyl alcohol (ethanol) plus a few drops of a dilute acid, if necessary (0.1N hydrochloric acid, for example), or a base (0.1N potassium hydroxide is suitable). Ethanolic solutions are preferable because they also sterilize the substances.

Most plant hormones are destroyed by autoclaving. Therefore they should be sterilized by filtration, a process that is somewhat complicated and may require relatively sophisticated or expensive equipment. A simpler approach is to dissolve them in ethyl alcohol (at least 70% in distilled water), which is a good sterilant as well as a suitable solvent. Stock solutions prepared for addition to media must be concentrated enough to allow for the addition of each hormone in 1 ml or less of stock solution per liter of medium. When such stock solutions are used, media are prepared as usual, but the hormones are omitted. They are added to the hot solution following autoclaving and mixed by swirling. The complete medium is then distributed into autoclaved culture vessels. Experience has shown that ethanol (up to 5 ml of 95% or 7 ml of 70% ethyl alchol per liter) will not harm orchid seedlings, explants,

or plantlets. In many cases hormones are added to media before autoclaving without any problems. (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

Household Bleach. This is usually a solution containing 4.25–6% sodium hypochlorite. It is sold under a large number of brand names all over the world. Read the label for the active agent(s) and their concentration(s) in such bleaches to determine whether they are suitable and to calculate how to dilute them. (Supply source: 13.)

Inorganic Salts. These salts provide macro- and microelements in culture media. (Supply sources: 1–4, 7, 8, 10–12, 16–21, 23, 24.)

Inositol. Inositol is a polyol which is often added to culture media with presumed beneficial effects. It is also known as *myo*-inositol, *meso*-inositol, *i*-inositol, and a number of other names. Its structural formula can be seen in Chapter 4 (see Fig. 4-11). (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

Isopropyl Alcohol (Isopropanol, Rubbing Alcohol). This is an alcohol which can be used to surface-sterilize tools and surfaces. It should not be used to dissolve media components. (Supply source: 13.)

Laminar Flow Hoods (or Cabinets). These appliances (Fig. A1-3) provide a sterile atmosphere for seed and tissue culture work. At one time they were used only by larger laboratories, and smaller laboratories used sterile boxes, some of them homemade. At present small desk-top laminar flow hoods are inexpensive enough to be within the reach of even small laboratories. (Supply sources: 5, 11, 19, 21, 25.)

Lamps, Fluorescent and Incandescent. A wide selection of lamps can be used to illuminate cultures. See the section on illumination in Chapter 2. Lamps can be ordered from many suppliers or purchased in local hardware, electrical, and lighting stores. (Supply source: 13.)

Methanol. Methanol is toxic if inhaled, ingested, or absorbed through the skin. It is best not to even have it in a laboratory. *See also* Alcohol. (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

Microfilters. *See* Sterilizing Filters.

Microscalpels. Sharp scalpels (Fig. A1-4B–F) or single-edge razor blades (Fig. A1-4A) should be used for splitting fruits or excising tissues. They may be purchased from any biological supply house or can be made from single-edge razor blades (see Fig. A1-9A). Small hypodermic needles from disposable syringes are used by some workers as substitutes for microscalpels. (Supply sources: 7, 11, 13, 16, 19, 21, 23.)

Niacin (Nicotinic Acid). This is a vitamin added to some culture media. Its structure can be seen in Chapter 4 (see Fig. 4-11). (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

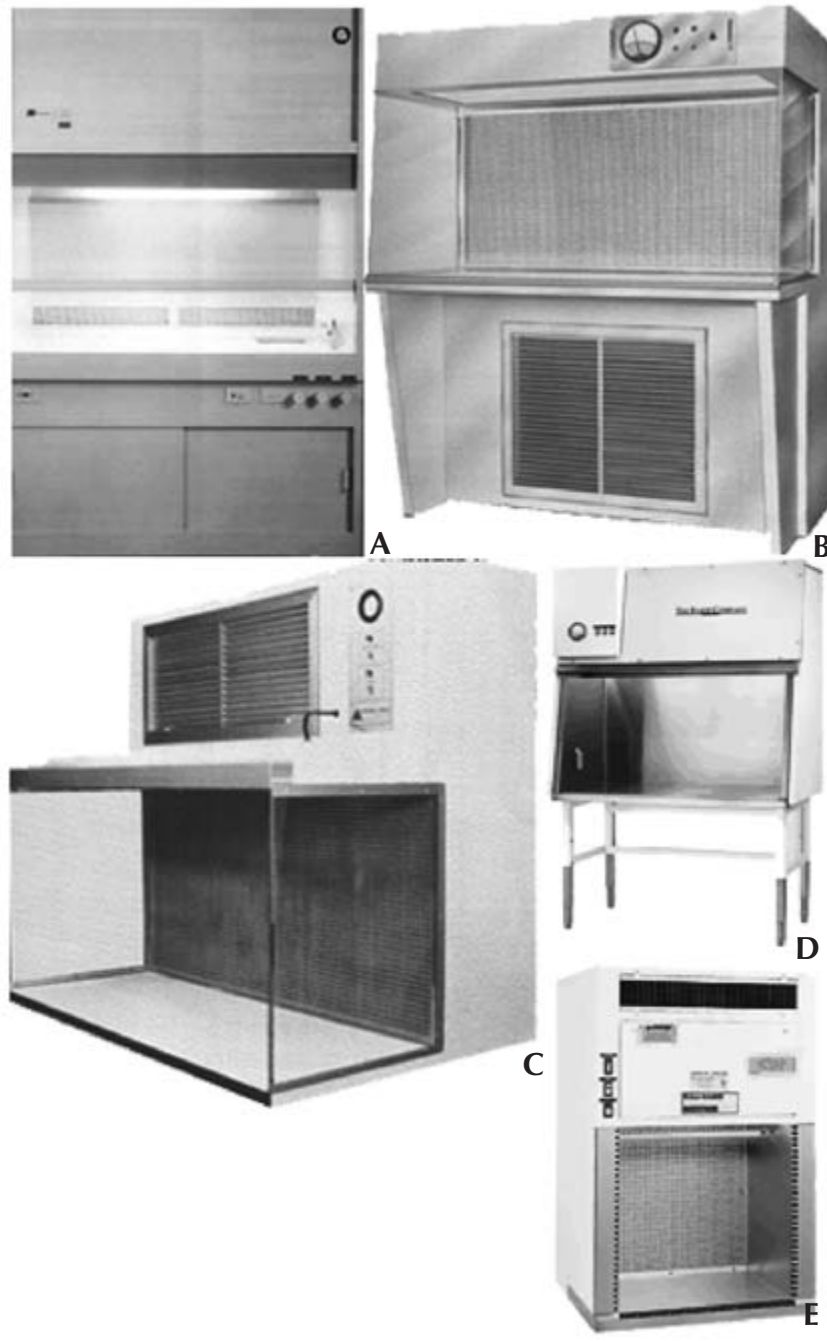

FIG. A1-3. **Laminar flow hoods. A, B, D. Stand-alone hoods. C, E. Table-top hoods. There are numerous models by many manufacturers.**

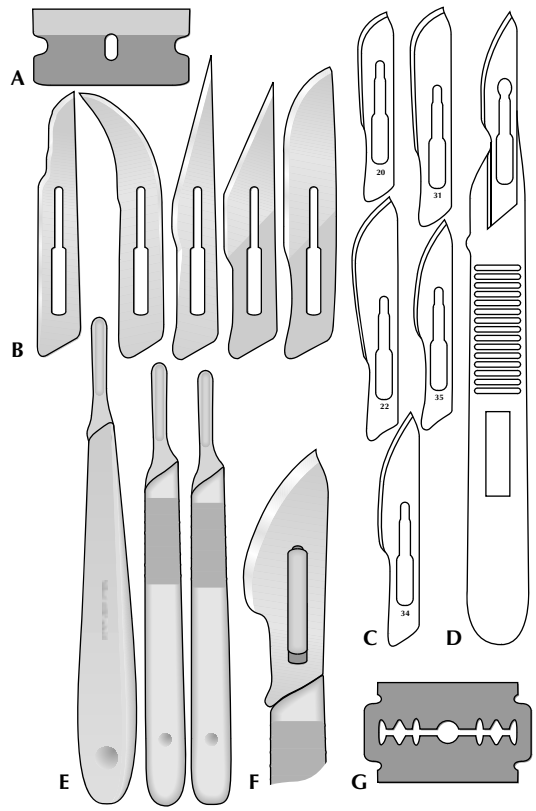

FIG. A1-4. **Cutting implements. A. One-sided razor blade. B–F. Scalpels and microscalpels. G. Two-sided razor blade.**

Nylon-mesh Filters. These are used for the filtration of protoplasts (Supply sources: www.pgcsci.com, www.marcson.com, www.coleparmer.com.)

Octadecyl-poly(ethoxy)ethanol. This is a surfactant with an average of seven ethylene oxide units, a molecular weight of 578.4, and a hydroxyl number of approximately 147. It induces proliferation when added to some culture media. This compound is not commercially available and may be hard to find. Related substances are possible substitutes. (Supply sources: 1–4, 7–12, 16, 17, 19–21, 23, 24.)

pH Meters. Such meters are electronic apparatus used to measure the reaction (basic or acidic) of a medium (Fig. A1-5). They are more accurate than pH paper. Some pH meters are portable and powered by batteries. (Supply sources: 11, 19, 21.)

pH Paper. These are strips of paper (Fig. A1-6) which can be used to measure the reaction (basic or acidic) of a medium. They are less accurate than a pH meter. (Supply sources: 11, 19, 21.)

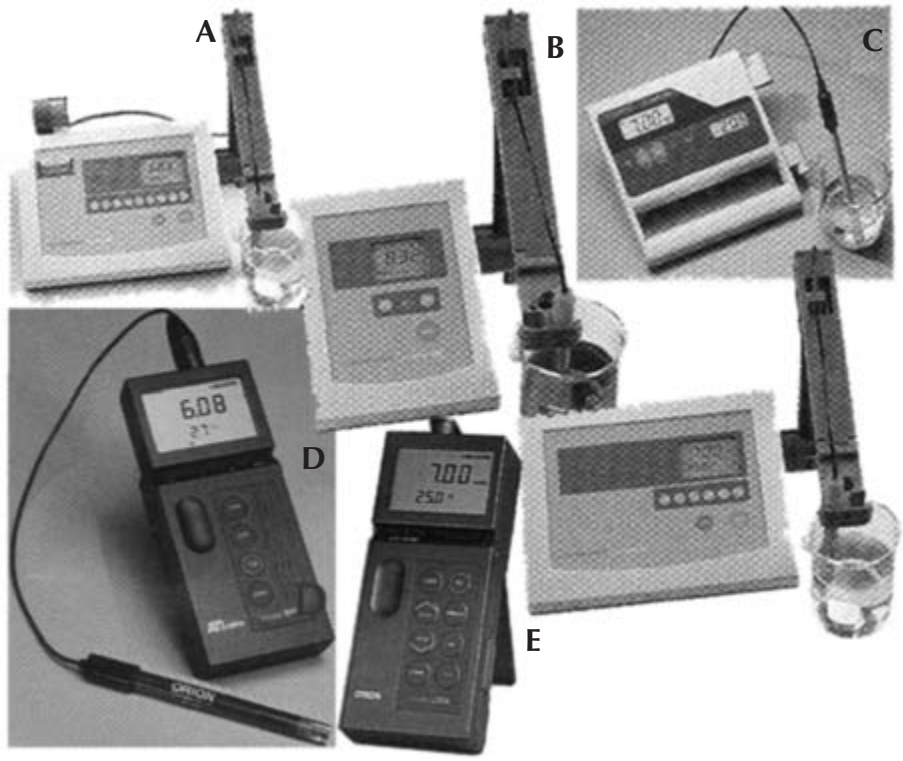

FIG. A1-5. **Desktop (A–C, F) and portable (D, E) pH meters (source: www.thomassci.com).**

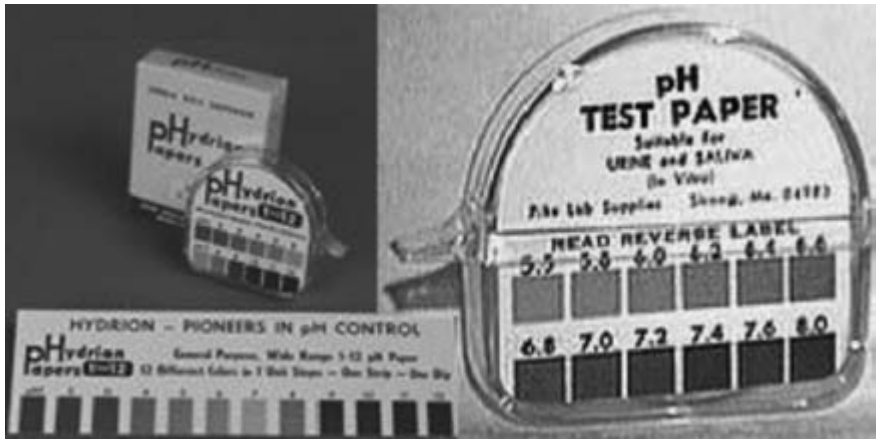

FIG. A1-6. **pH test paper.**

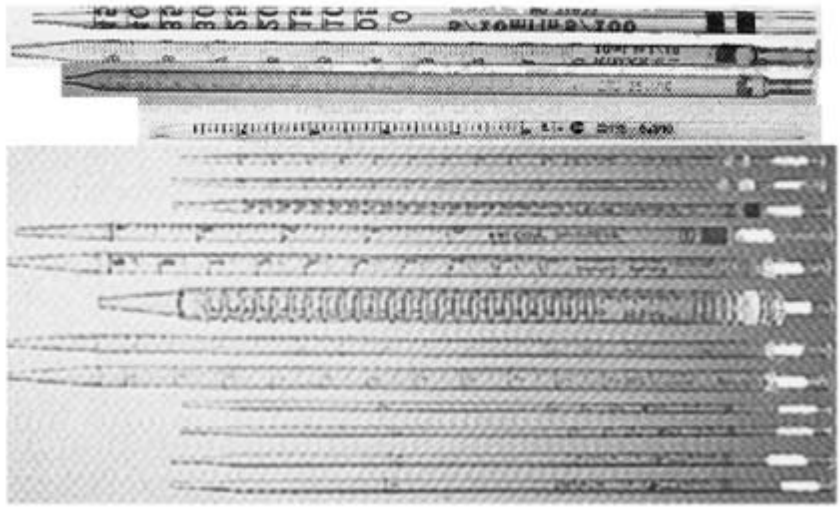

FIG. A1-7. **Pipettes.**

Pipettes. Glass or plastic pipettes (Fig. A1-7) are used to measure and dispense solutions. (Supply sources: 6, 11, 19, 21.)

Shakers. Different types of shakers (reciprocal, gyratory, and rotary) are available in a large variety of sizes (Fig. A1-8) from several suppliers. Simple shakers are also easy to construct. (Supply sources: 11, 19, 21.)

Sterile Box. A very adequate sterile enclosure (Fig. A1-9B) can be constructed from a cardboard box, Saran Wrap, and aluminum foil. Obtain a $90 \times 90 \times 90$ cm (approx $3 \times 3 \times 3$ ft, or similar) cardboard box and remove the top flaps. Draw a diagonal line along each side of the box (Fig. A1-9Ba), and cut along these lines to obtain a sloping surface (Fig. A1-9Bb). Line the inside of the box with aluminum foil and cover the top (sloping surface) with Saran Wrap. Cut two circular holes in the front (shorter) side so that a worker's hands can be inserted for work inside the box (Fig. A1-9Bc). Double-sided razor blades (see Fig. A1-4G) should not be used. (Supply sources: 7, 11, 13, 16, 17, 19, 21.)

Sterilizing Filters. Filters made of glass (Morton type) can be difficult to handle or clean, are expensive, and require a vacuum for effective filtration. Membrane filters (Millipore or other brand; Fig.A1-10A–C, E) are easier to handle and may be less expensive in the long run because the non-disposable units (Fig. A1-10C) are easier to wash and the disposable ones (Fig. 2-21E) do not have to be washed. However, membrane filters are not cheap, require vacuum pumps, and need more elaborate set ups. They may be better suited for larger and better-equipped laboratories. Disposable sterilizing filters which can be attached to syringes (Fig. A1-10D, F, G), are inexpensive, and are easily available. Metal enclosures for glass syringes are advisable to prevent injury in case of breakage, but they can be expensive. Plastic syringes

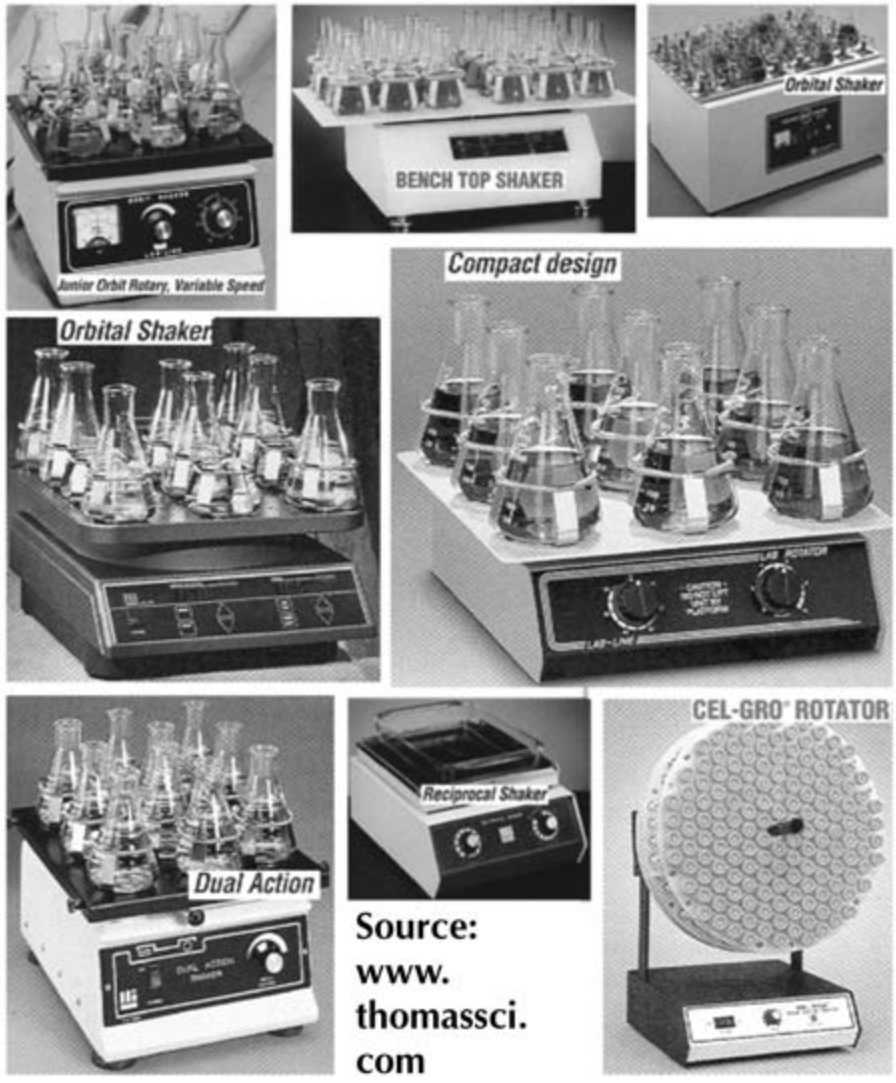

FIG. A1-8. **Shakers.**

can also be used and are preferable because they are less likely to shatter and injure the operators. (Supply sources: 11, 12, 14, 16, 19, 21, 24.)

Sterilizing Lamp. Alcohol lamps or burners (Fig. A1-11) are used to sterilize tools by flaming while working in a laminar flow hood or a sterile box. Such lamps can be purchased from supply houses or made by placing a cotton wick inside a metal container (of the kind used to hold rubber cement), through a hole made in the cover of a small jar. A small bottle can also be used. The fuel should be alcohol, and not

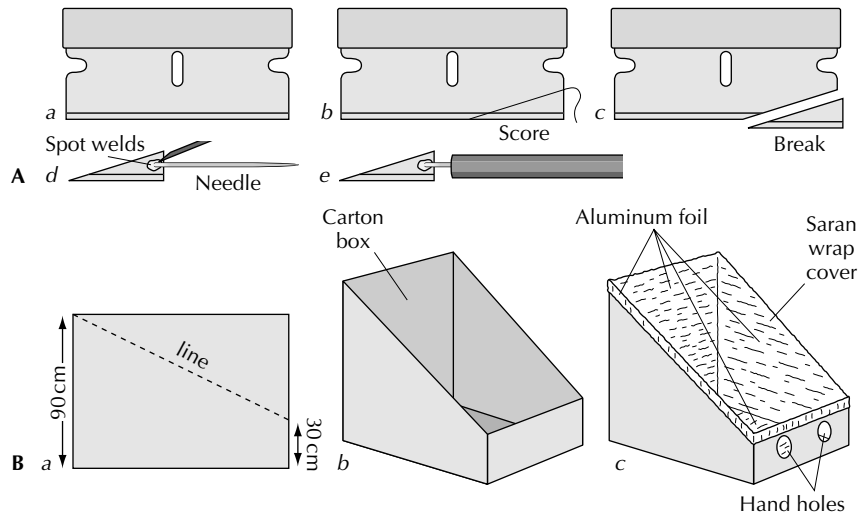

FIG. A1-9. **Making a sterile box and a simple scalpel. A. To make a microscalpel from a single-edge razor blade (a), you need a needle and a pencil, section of a branch, or piece of dowel. Score the blade (b), break off the corner with a pair of pliers (c), and weld this on to the unsharp (ear) edge of the needle (d). Then insert the entire length of the needle into the pencil, dowel, or section of branch. This simple, yet very effective, microscalpel was invented by the late Professor Ernest A. Ball, one of the first two botanists to culture a shoot tip (the other was Professor Shih wei Loo). To sterilize the scalpel while working, dip it into alcohol and a flame or dip it into household bleach. B. Construction of a sterile enclosure from a cardboard box, aluminum foil, Saran Wrap, and two plastic bags. Draw the lines as indicated (a) where the box is to be cut (b). After cutting, line the box with aluminum foil and cover with Saran Wrap. Cut two round holes in the front (c) and attach to them plastic bags whose bottoms have been cut to make them into tubes. These tubes can be used as "tunnels" for the placing of culture vessels, plant material, sterilants, and tools into the box. When working in the box, fasten the open end of the bags to the hands below the elbow to insure sterility. Sterilize the inside of the box by spraying with alcohol or domestic bleach. If the Saran Wrap becomes foggy due to condensation, wipe with paper towel. A "door" can be cut on one side of the box. Should this be done care must be taken to close the door while working in the box.**

gasoline (petrol), ether (which can cause an explosion), paraffin oil, or kerosene (because they produce dark soot). Candles also produce soot and should not be used. (Supply sources: 11, 19, 21.)

Stock Solutions. Weighing components of a medium can be time-consuming and subject to errors. Therefore more concentrated solutions of some media components are prepared in many laboratories. These are called stock solutions. For example, if a recipe calls for 1 gram per liter (1 g l^{-1}) of magnesium sulfate, a stock solution containing 10 g l^{-1} can be prepared. Then, in making the medium, 100 ml (one-tenth of a liter and therefore one-tenth of the magnesium sulfate) of the stock solution is used. If a stock solution of 100 g l^{-1} is prepared, only 10 ml of it should be used to make the medium. Using stock solutions is faster than weighing 1 g every time and also more accurate. Stock solutions should be stored under appropriate conditions.

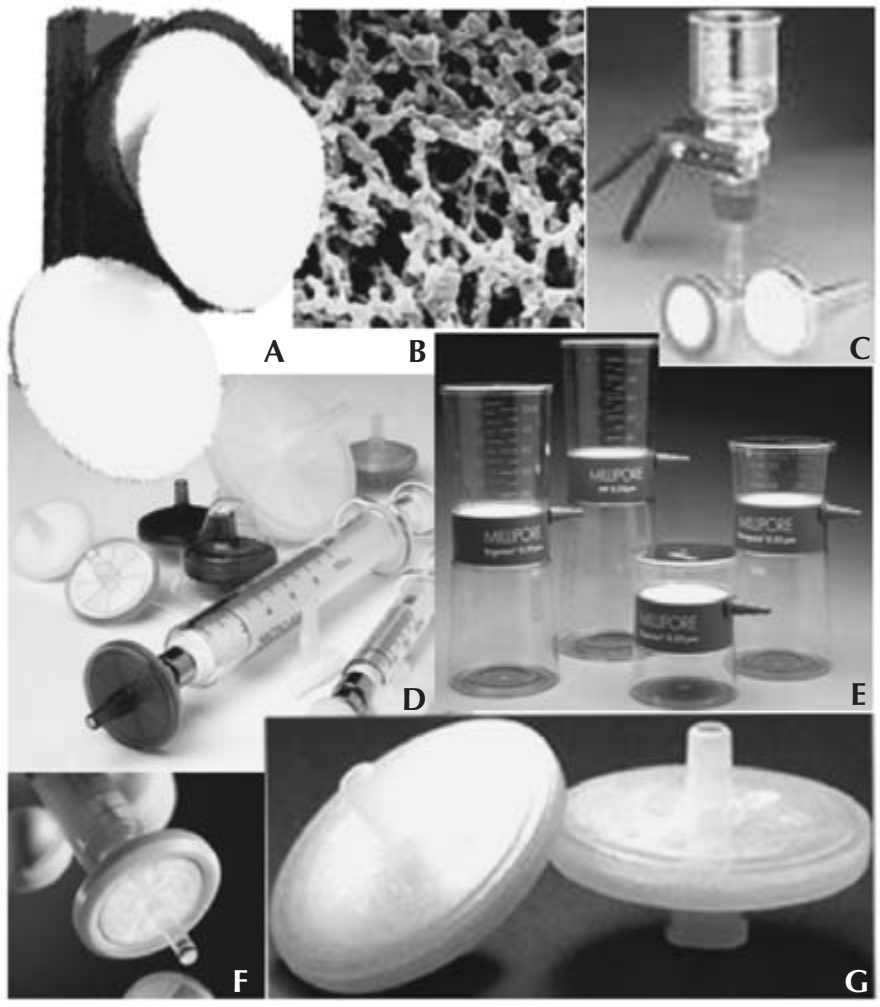

FIG. A1-10. **Sterilizing filters. A. Membrane sterilizing filters. B. Electron photograph of a sterilizing filter. C. Reusable glass filter holder and clamp. D, F, G. Plastic filter holders which attach to syringes. E. Disposable non-reusable filter holders with filters in them. These filters and the ones in (C) require a vacuum pump for suction.**

Solutions of nitrogen, even those containing inorganic salts, can become contaminated with time. Therefore it is best to prepare them fresh every few months and discard those that are no longer completely clear and/or contain a precipitate, especially one that appears to be slimy. Storage in a freezer can prolong the life of such solutions by eliminating contamination.

Solutions of organic substances in water must be kept frozen. Alcoholic solutions should also be frozen because some substances may not be stable, even in a refrigerator. Organic substances which are affected by light should be kept in the dark. Autoclaved media should not be stored for excessively long periods.

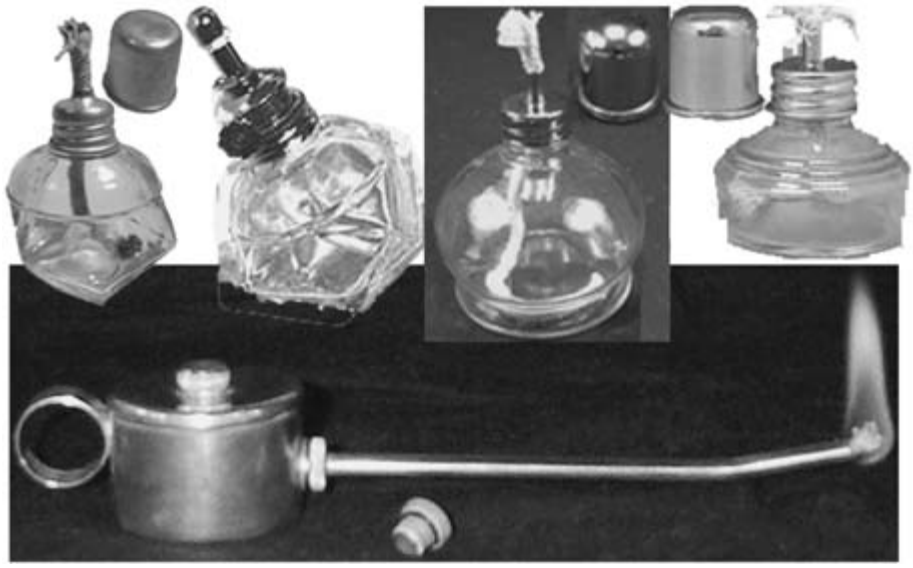

FIG. A1-11. **Alcohol lamps or burners.**

All stock solutions should be labeled with the information in the example below (self-adhesive labels can be printed in advance). A pencil or indelible ink must be used when writing on such labels. Ball point writing fluid or regular inks will smudge.

1 Name of compound: Potassium phosphate
2 Formula of compound: KH_2PO_4
3 Concentration as weight or volume per liter of stock solution: 150 g
4 Date on which the solution was made: November 23, 2003
5 Where to store stock solution: A shelf
6 Can compound be autoclaved: Yes
7 Name of the person who made the solution: Jonathan O. Arditti

If one stock solution of a substance is to be used for the preparation of several media, it is a good idea to have on the bottle a second label with a list of how much to use for each medium, as for example:

Medium A: Use 10 ml	Medium D: Use 7 ml	Medium G: Use 3 ml
Medium B: Use 10 ml	Medium E: Use 5 ml	Medium H: Use 0 ml
Medium C: Use 12 ml	Medium F: Use 8 ml	Medium I: Use 15 ml

A separate stock solution should be prepared for each macroelement. Concentrations of macroelement stock solutions should be 100 times the amount used in the medium (100×) if the solubility of the compound will allow it.

Microelements can be combined in one stock solution, usually at a 1000× concentration. Since the composition of microelements may vary with the medium, it may be necessary to prepare more than one stock solution. If this is done, the

bottle must be labeled very clearly with the name of the medium for which the stock solution is to be used.

Surfactants. These agents (surfactants, surface active agents, wetting agents, detergents, baby shampoo) are used to decrease the surface tension of liquids or solutions and increase their wetting power. Exposing orchid seedlings, tissues, and plantlets to high concentrations of these agents for long periods can cause damage. However, contrary to some overcautious advice which does not seem to have any basis in experimental evidence, short exposures to low levels of most mild household and laboratory detergents (like Tween 20 for example) or baby shampoos, followed by a rinse, will not cause any harm to tissues. (Supply sources: 1–4, 7–13, 16, 17, 19–21.)

Surgical Gloves. Lightweight surgical gloves for sterile work should be used to protect workers from alcohol, which can dry the skin, and other agents that may cause damage or be toxic. If it were not for these reasons, well-washed hands would cause no more surface contamination than gloved ones. Household gloves should not be used because they are very thick and can reduce manual dexterity. (Supply sources: 11, 13, 19, 21.)

Vials and Tubes. Various test tubes and vials can be used as culture vessels. (Supply sources: 6, 7, 11, 16, 19, 21.)

Vitamins. These substances may be heat-labile. Therefore they should generally be handled like hormones (even if their mode of action is different) in the preparation of stock solutions or the sterilization of media. They are added to culture media because some tissues and explants may require them. (Supply sources: 1–4, 7–12, 16, 17, 19–21.) *See also* Sterilization, Filtration, and Solvents.

Volumetric Cylinders. Made of glass or plastic and graduated to contain specific volumes (see Fig. A1-1Ia, c), volumetric cylinders are a necessity. Their size designation is based on the maximum volume they can contain. A seed germination or micropropagation laboratory should have volumetric cylinders in capacities of 10, 25, 50, 100, 250, 500, and 1000 ml. Always use the next largest cylinder to measure a particular volume (for example, use a 50-ml cylinder to measure 30 ml, not a 10-, 20-, or 100-ml cylinder). Plastic cylinders are less apt to break. Cylinders with stoppers can be used like volumetric flasks, whereas those with lips are for measuring and pouring; both are graduated. (Supply sources: 4, 6, 7, 11, 13, 14, 16, 19, 21, 23.)

Volumetric Flasks. Volumetric flasks are made of glass or plastic and are marked to contain specific volumes (Fig. A1-1Ib, d). They are designated by the volume they contain. A micropropagation and/or seed culture laboratory should have volumetric flasks in capacities of 5, 10, 25, 50, 100, 250, 500, and 1000 ml. To ensure accuracy, use volumetric flasks rather than beakers or flasks to make dilutions and prepare media. Volumetric flasks are expensive and should not be used as storage containers. Also, they must not be autoclaved because the high temperature and pressure may change them enough to impair their accuracy.

When using a volumetric flask to make dilutions or prepare solutions, pour the solvent into it (approximately 20–50% of its total volume), and then introduce the compound to be dissolved or solution to be diluted. Agitate by gently inverting the flask back and forth several times (after the first few inversions hold the flask with the opening pointing upward and away from individuals or equipment and gently and carefully remove the stopper to release pressure) and add solvent (water, alcohol, etc.) up to the mark. Then shake again and pour into a bottle. Follow the instructions in the tables in Chapter 3 when using a volumetric flask to prepare media. Always add acid (for example HCl, H_2SO_4 acetic) or alkali (bases like NaOH, KOH) into water (remember A comes before W) to prevent boiling, sputtering, or overheating. (Supply sources: 4, 6, 11, 13, 14, 16, 19, 21, 23.)

Wetting Agents. See Surfactants (1–4, 8, 11–13).

APPENDIX TWO

Sources of Supplies and Equipment

All chemicals and apparatus mentioned in this list are available from many suppliers in the United States and other countries (with the advent of the World Wide Web and the expansion of international trade many companies have web sites and/or branches in different parts of the world), but because an occasional item may be difficult to obtain locally, a list of suppliers is provided here. The list was compiled from a variety of sources. Listings are coded by numbers that appear in parentheses at the end of the description in each Appendix 1 entry. In addition, the general categories of laboratory equipment, reagents, chemicals, and other supplies offered by each source are summarized. There are, no doubt, other equally adequate sources in the United States and abroad; the mention of some and omission of others should not be interpreted as endorsements, approval, or criticism, or lack of them. I do not have any financial or other interest in any of the listed sources. None of the listed sources has provided me with any incentives to list them and no one has asked not to be listed.

With few or no exceptions suppliers have web sites which provide a rapid, simple, and convenient means of ordering supplies and equipment. Most suppliers are ethical, honest, and strive to serve their customers promptly, courteously, and well. However, there are exceptions and therefore caution is advisable when dealing with new or little known sources. And one should never, ever deal with suppliers who send or advertize through unsolicited faxes and e-mail messages (the much hated "spam"). Many suppliers who have web sites also issue catalogs. Those who prefer to use catalogs should request them well in advance of the time when supplies will be needed. If not ordering from a web site, orders should be sent by fax (many suppliers have in-country toll-free numbers) or by airmail from outside the United States. Airmail or shipping company (Federal Express, DHL, UPS, and similar) delivery should be requested for smaller items. In some countries the importation of equipment, apparatus, and chemicals requires special permits, which should be secured well in advance.

Some chemicals should be stored under refrigeration, and allowing them to linger in a postal warehouse may cause damage. Therefore it is advisable to alert postal authorities or delivery companies of their arrival and to make arrangements to pick them up promptly. A final word: the author and/or the publisher can neither

undertake to supply equipment, chemicals, and reagents nor act as intermediaries between suppliers and buyers.

A complaint made about this list in the first edition was that it was limited almost entirely to American companies. This was so because the authors are American who live and function in the USA, and are not familiar with suppliers elsewhere. The same is true for the author of this edition. Many American companies have branches in numerous countries. However, due to the advent of the World Wide Web this list also includes a number of foreign companies. Those who do not wish to order from American companies or their branches in other countries can easily find local suppliers.

An important point to keep in mind is that companies move, change names, are sold, go out of business, and consolidate. Therefore the accuracy of this list may change during the life of this book. At first an attempt was made to maintain a numbered alphabetical list. This proved to be impossible as new sources came to light.

1 Acrõs Organics-Fisher Scientific 2002–2003 catalog has 2448 pages which lists organics and fine chemicals. It also includes a considerable amount of helpful information. The organics catalog is also published on a CD ROM. Their address is Fisher Scientific, 2000 Park Lane Dr., Pittsburg, PA 15275-9952, USA. Telephone: orders, 800 766 7000; technical service, 800 227 6701. Fax: 800 926 1166. URLs: www.fishersci.com and www.acros.com.

2 Aldrich Chemical Co. is now part of Sigma-Aldrich, 3050 Spruce St., St. Louis, MO 63103, USA. Telephone: orders, 800 325 3010; technical service, 800 325 5832. Fax: 800 325 5052. URL: www.sigmaaldrich.com; technical service, www.sigmaaldrich.com/techinfo. E-mail: bigred@sial.com. This company carries one of the largest selections of chemicals in the world including: inorganic chemicals, organic chemicals, biochemicals, reagents, hormones, amino acids, and vitamins. Sigma-Aldrich has branches in many parts of the world. They are listed in their web site together with representatives and associated companies. Sigma and Aldrich issue separate catalogs which can be requested on their web site.

3 Anachemia is a Canadian laboratory supply house which offers chemicals and reagents. Their address is Anachemia Canada Inc., 255 Norman, Lachine, Canada H8R 1A3. Telephone: 514 489 5711. Fax: 514 363 5281. URL: www.anachemia.com. E-mail: info@anachemia.com, sales@anachemia.com, and techhelp@anachemia.com.

4 J. T. Baker Chemical Co. is now Mallinckrodt Baker, Inc., 222 Red School Lane, Phillipsburg, NJ 08865, USA. Telephone: 908 859 2151 and 800 582 2537 (1 800 JTBAKER). Fax: 908 859 6905. URL: www.jtbaker.com. E-mail: infombi@mkg.com and techservice@mkg.com. They carry a large variety of chemicals, mostly inorganics and some organic chemicals, hormones, amino acids, and vitamins. Mallinkrodt Baker has branches in many parts of the world.

5 The Baker Company, Inc., P. O. Drawer E, Sanford Airport, Sanford, ME 0407, USA manufactures and sells laminar-flow hoods. Telephone: 800 992 2537 and 207 324 8773. Fax: 207 324 3869. URL: www.bakercompany.com. E-mail: bakerco@bakerco.com.

6 The Bellco Glass Company is now part of the Schott Corporation, 3 Odell Plaza, Yonkers, NY 10701, USA. Telephone: 914 968 1400. Fax: 914 968 8585. URL: www.us.schott.com. They produce and sell a large variety of glassware as well as some laboratory equipment. Their web site lists a large number of dealers.

7 Caisson Laboratories, Inc., 5 West Center, Sugar City, ID 83440, USA or P. O. Box 337, Rexburg, ID 83440, USA produce and/or sell culture media, chemicals, containers, and equipment. Telephone: 208 656 0880 and 877 840 0500. Fax: 208 656 0888. URL: www.caissonalbs.com. E-mail: custserv@caissonlabs.com, sales@caissonlabs.com, and custserv@caissonlabs.com.

8 CalBiochem, EMD Biosciences, Inc., 10394 Pacific Center Court, San Diego, CA 9212, USA. Telephone: 800 854 3417 and 858 453 3552. Fax: 800 776 0999, 866 642 0301, and 858 450 9600. URL: www.emdbiosciences.com. E-mail: customer.service@emdbiosciences.com; technical support, technical@calbiochem.com. Their web site lists branches, dealers, and associated companies in 55 countries. CalBiochem is now a subsidiary of Merck Biosciences. They carry a wide selection of biochemicals (organic chemicals, hormones, amino acids, and vitamins), antibiotics, and other supplies.

9 Difco Laboratories was a major supplier of agar, culture media, and medium components for a long time. They are now part of BD (Becton, Dickinson, and Company), 1 Becton Dr., Franklin Lakes, NJ 07417, USA, and still carry some supplies and equipment that can be of use to orchid micropropagators, but can no longer be viewed as a major source. Telephone: technical assistance, 800 638 8663 (selection 2); customer servive, 800 675 0908; worldwide, 410 316 4000. URL: www.bd.com. E-mail: Technical_Services@bd.com

10 Duchefa Biochemie B. V., A. Hofmanweg 71, 2031 BH Haarlem, the Netherlands or P. O. Box 809, 2003 RV Haarlem, the Netherlands produces and/or sells biochemicals, plant cell and tissue culture media, and supplies and plant molecular biochemicals. Telephone: +31 (0)23 531 90 93. Fax: +31 (0)23 531 80 27. URL: www.duchefa.com. The web site lists a number of world wide locations. Their catalog is well illustrated and very informative.

11 Fisher Scientific, 2000 Park Lane Dr., Pittsburg, PA 15275-9952, USA, with branches in Canada and China, sells just about all supplies, chemicals, equipment, and apparatus a laboratory may need. The main section of their catalog consists of 1946 pages. There are also 416 pages of chemicals, several detailed indexes, and a considerable amount of valuable information. They also have a chemicals-only catalog. Telephone: 412 490 8300 and 800 766 7000. Fax: 800 926 1166. URL: www.fishersci.com.

12 Fluka Chemie AG, Industriel Strasse 25, CH-9471 Buchs, Switzerland, P. O. Box 14508, St. Louis, MO 63178-9916, USA, or P. O. Box 2060, Milwaukee, WI 53201, USA, sells laboratory chemicals, analytical reagents, and some media. Telephone: Switzerland, +41 81 755 2511; USA, 414 273 3859 and 800 558 9160. Fax: Switzerland, +41 81 756 5449; USA, 414 273 4979 and 800 962 9591; USA technical service, 800 493 7262 and 800 HYDRANAL; USA customer service, 800 358 5287; USA general service, 800 803 5832. URL: www.fluka.com (will open the Sigma-Aldrich web site). E-mail: fluka@sial.com. Fluka has worldwide branches.

13 Local stores. Many items can be purchased in local retail stores.

14 Millipore Company, 290 Concord Rd., Billerica, MA 01821, USA, sells sterilizing filters and other equipment. Telephone: 800 645 5476. URL: www.millipore.com. The web site can be accessed in several languages.

15 Osmotek Ltd., P. O. Box 550, Rehovot 76120, Israel, sells well-designed culture vessels and plant tissue culture micropropagation systems. Telephone:

+972 8 931 5556. Fax: +972 8 731 5177. URL: www.osmotek.com. E-mail: osmotek@attglobal.net. They have a free CD with excellent training movies and interesting information. This company may no longer exist.

16 Phytotechnology Laboratories, 7895 Mastin Dr., Overland Park, KS 66204-2312, USA, sells media, medium components, equipment, and supplies. Telephone and fax: 888 749 8682 and 913 341 5343. URL: phytotechlabs.com. E-mail: sales, sales@phytotechlabs.com; technical information, info@phytotechlabs.com.

17 Plant Media, www.plantmedia.com, sells culture media, chemicals, glassware, and accessories.

18 Sigma Chemical Corporation, *see* Aldrich Chemical Company (2).

19 Thomas Scientific is a 100-year-old company at 99 High Hill Rd., I-295, P. O. Box 99, Swedesboro, NJ 08085, USA. Their catalog (2000+ pages) contains everything a laboratory may need. Telephone: main number, 856 467 2000; customer service, 800 345 2100; export sales (from US telephones only), 800 524 0018. Fax: worldwide, 856 467 3087; from US only, 800 345 5232; international sales, 856 467 0512. URL: www.thomassci.com. E-mail: general, value@thomassci.com; international sales, global@thomassci.com.

20 Tissue Quick Plant Laboratories, www.tissuequickplantlabs.com, sells tissue culture and seed germination media and supplies.

21 VWR (at one time Van Waters and Rogers), 1310 Goshen Parkway, West Chester, PA 19380, USA, also has a number of global sites and web sites in several languages. Like Thomas Scientific and Fisher Scientific they sell all chemicals, supplies, apparatus, and equipment laboratories may need. Telephone: 800 932 5000 and 800 320 4357. URL: www.vwr.com. E-mail: solutions@vwr.com.

22 Whatman Inc. is a name synonymous with high quality filter and chromatography paper. Their corporate address is Whatman plc, Whatman House, St. Leonard's Road, 20/20 Maidstone, Kent ME16 0LS, UK. One US address is 9 Bridewell Place, Clifton, NJ 07014. Telephone: UK, +44 (0)1622 676670; USA main, 973 773 5800, 800 441 6555; USA customer service, 800 631 7290; USA technical service, 800 922 0361. Fax: UK, +44 (0)1622 677011; USA main, 973 472 6949. URL: www.whatman.com. E-mail: UK, information@whatman.com; USA, info@whatman.com. The web site has an interesting history of the company.

23 Austratech, 19 Blaxland Court, Mooroolbark, Victoria 3138, Australia. Telephone: +61 3 9737 1416. Fax: +61 3 9737 1418. URL: www.austratech.com.au. E-mail: sales@austratech.com.au. They carry chemicals, reagents, media components, and equipment.

24 Wako Chemicals is a Japanese company with offices in Germany and the USA. They sell a wide selection of chemicals and reagents. URL: Japan, www.wako-chem.co.jp; USA, www.wakousa.com; Germany, www.wako-chemicals.de; catalog, www.search.wako-chem.com.

25 AirClean Systems, Raleigh, NC 27604, USA, produce laminar flow hoods. Telephone: 919 255-3220 and 800 849-0472. Fax: 919 255 6120. URL: www.aircleansystems.com. E-mail: info@aircleansystems.com.

26 Unicorn Imp. & Mfg. Corporation, P. O. Box 272, Commerce, TX 75429, USA, sells plastic culture vessels. Telephone: USA, 800 888 0811; worldwide, 903 886 8282. Fax: 903 886 8878. URL: www.unicornbags.com.

APPENDIX THREE

Some Sites of Interest on the World Wide Web

An enormous amount of information on orchids and other subjects of interest is available on the World Wide Web (www). The number of web sites is very large and listing all of them is a near impossibility. Even if a list of all sites could be compiled, it would not remain accurate for long. Sites are constantly added, removed, or changed. The list below is intended as both a source of information and a starting point. Additional web sites can be found with a search engine.

- Agritech Publications, the Plant Tissue Culture Book Store, http://agritechpublications.com
- American Orchid Society, www.aos.org
- Australian Orchid Council, www.orchidsaustralia.com
- Botanical Society of America, www.botany.org
- Brazilian orchids, http://delfinadearaujo.com
- *Bulbophyllum* and *Cirrhopetalum* photographs page, www.edit.ne.jp/~kohsaka/hhtml/haru1100.htm
- Canadian Orchid Congress, www.canadianorchidcongress.ca
- Chemicals, structure, and formulae, http://chem.sis.nlm.nih.gov/chemidplus
- CITES, web page of the Secretariat for CITES, www.cites.org
- Florida native orchids, www.fl-orchid.com
- Germany, German Orchid Society, http://ourworld.compuserve.com/Homepages/rolfachim_reichart/dog.htm
- Hybrids, registration (information about registration), www.rhs.org.uk/research.registration_orchids.asp
- Index of Plant Names, www.ipni
- Indonesian orchids, www.geocities.com/RainForest/Vines/9686
- International Code of Botanical Nomenclature (St. Louis Code), with the official text in English, www.bgbm.fu-berlin.de/iapt/nomenclature/code/SaintLouis/0001ICSLContents.htm

- Units of measurement (a site which contains descriptions and conversion factors for an amazing number of units), www.unc.edu/%7Erowlett/units/index.html

I thank Wolfgang H. Bandisch, Stephen Kemp, Hideka Kobayashi (who also provided extensive lists and many copies of literature on orchid micropropagation), Jose A. Izquierdo-Rivera, and the Orchid Spring discussion board (managed by Wolfgang H. Bandisch) among others for information about some of the entries on this list.

APPENDIX FOUR

Light

Illumination is an extremely important factor in micropropagation. Light was discussed in Chapter 2 at some length. However the additional information in this appendix may be useful.

Measuring Light

Light is the source of energy for plant growth. It consists of different wavelengths (colors). The distribution and intensity of these wavelengths produced by a source of illumination is called the emission spectrum. In nature plants grow under natural sunlight. Under culture room conditions explants, seedlings, and plantlets are illuminated by artificial light sources which are designed to simulate the sun or at least emit a spectrum that approximates natural sunlight.

Light measuring instruments or sensors differ in their sensitivity to the energy spectrum. To measure light intensity in terms of the wavelengths required by plants, it is necessary to determine the photosynthetically active radiation (PAR) produced by a source. PAR light meters measure energy in the 400–700 nm range. They measure light in micromoles (or microEinsteins) per second per square meter ($\mu mol\ s^{-1}\ m^{-2}$).

Meters that measure foot candles are not appropriate because they measure light intensity in terms of human vision. Photographic light meters are also not appropriate because they measure light intensity as it affects photographic film (or digital camera sensitivity). However, it is possible to obtain approximations by using photographic light meters (stand alone or built into cameras) by making measurements with them and referring to the appropriate tables in Chapter 2. As a rule, sufficient illumination is produced by two cool white 40-W fluorescent tubes plus a pair of 25-W incandescent bulbs placed approximately 30 cm above the cultures.

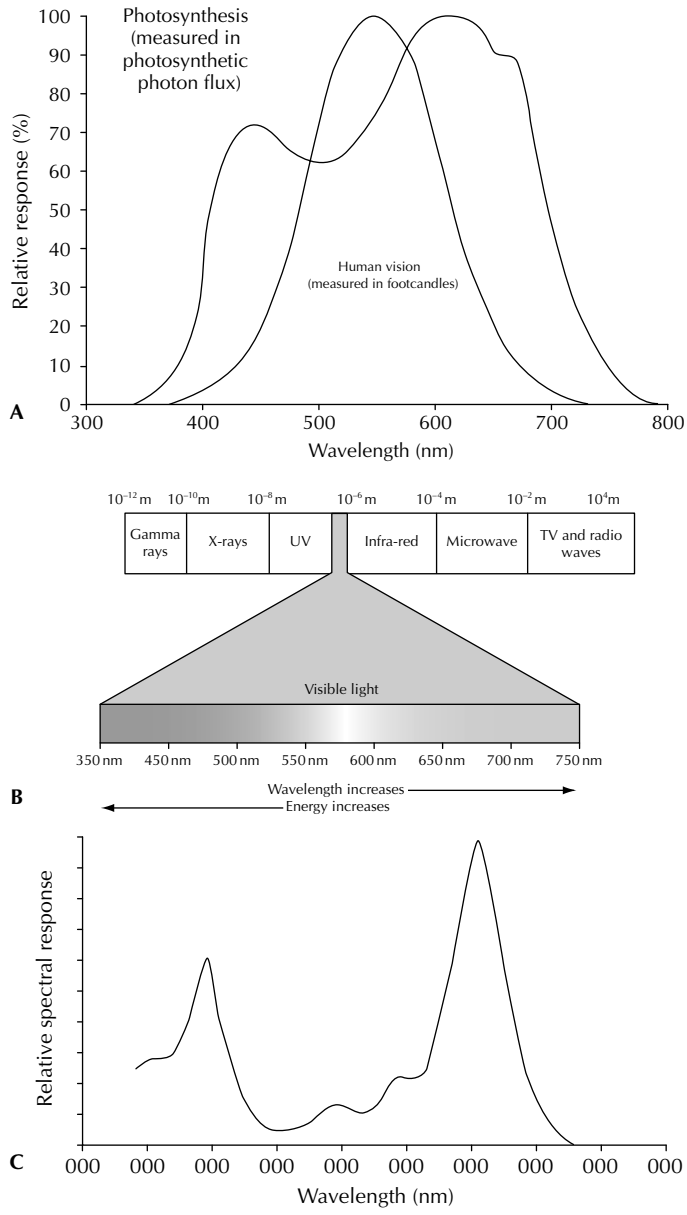

FIG. A4-1. **Light and action spectra. A. Photosynthesis and human vision. B. Electromagnetic and light spectrum. C. Action spectrum of chlorophyll synthesis.**

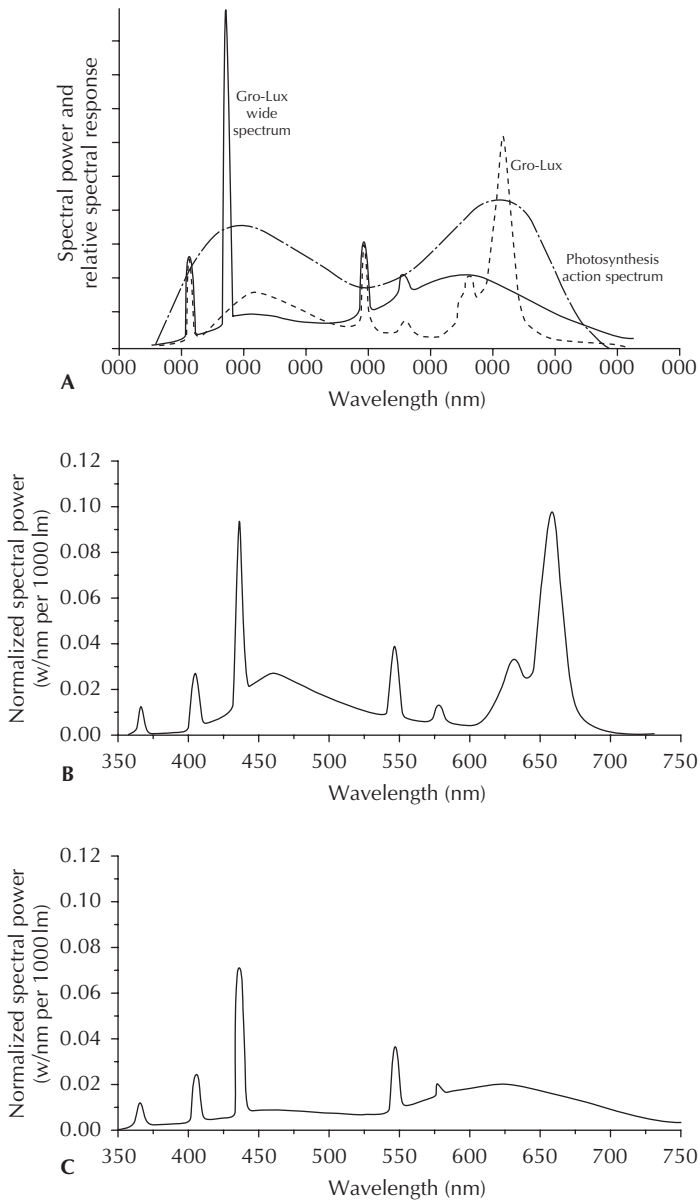

FIG. A4-2. **Emission spectra of Gro Lux lamps and photosynthesis. A. The emission spectra of Gro Lux lamps and Wide Spectrum Gro Lux lamps versus the light spectrum of photosynthesis. B. Emission spectrum of Gro Lux lamps. C. Emission spectrum of Wide Spectrum Gro Lux (GRO/WS) lamps.**

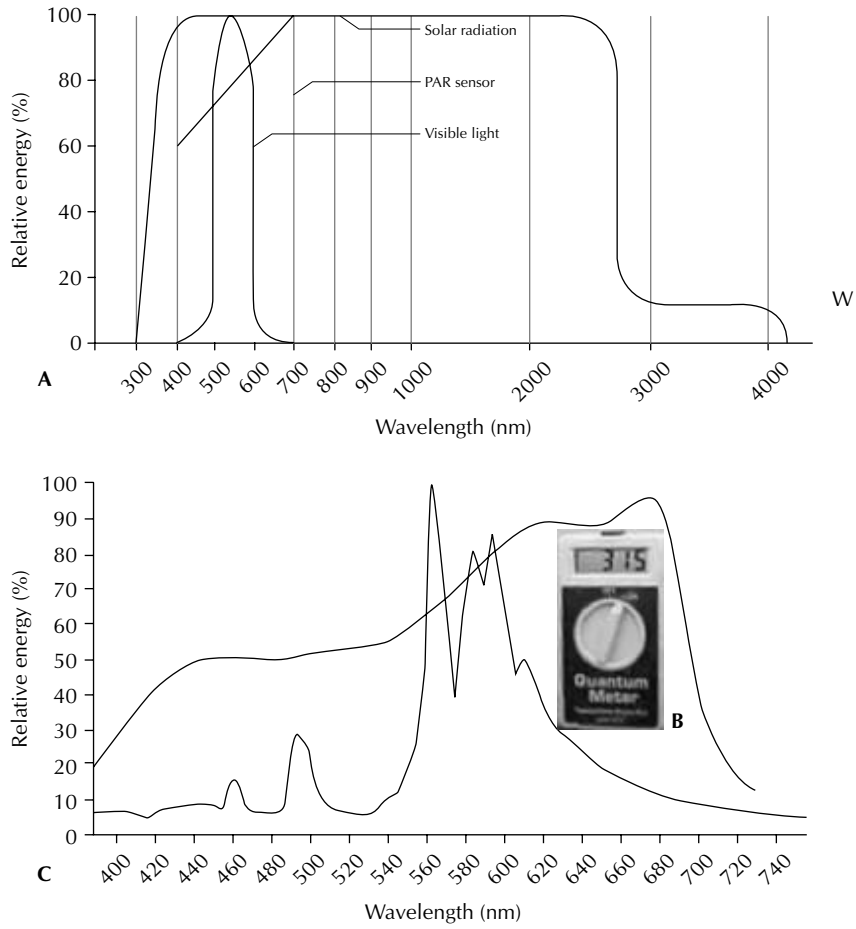

FIG. A4-3. **Light spectrum and measurements. A. Measurements of the same light source with different meters. B. A light meter that measures photosynthetically active radiation (PAR). C. Emission spectrum of a high pressure lamp versus a plant sensitivity curve.**

Wave Length and the Color of Light

TABLE A4-1. **Wave length and the color of light**[a]

Color	Wavelength, nm	
	Representative	Limits
Ultraviolet		< 400
Limit of sun UV at earth's surface		292
Visible spectrum		
Violet	410	400–424
Blue	470	424–491.2
Green	520	491.2–575
Maximum human acuity	556	
Yellow	580	575–585
Orange	600	585–647
Red	650	647–700
Infrared		> 700

[a]Plant physiologists sometimes refer to the color or spectrum of light as light quality.

Light Radiation Conversions

Plants use light energy between 400 and 700 nm. This region is called photosynthetically active radiation and is generally referred to as PAR. Illumination for plant growth, which is called "irradiance," is sometimes measured as watts of PAR per square meter ($W\ m^{-2}$). The preferred method of measuring light for plant growth utilizes the quantum flux unit in the PAR region called "photons." The units are micromoles per square meter per second ($\mu mol\ m^{-2}\ s^{-1}$), where 1 mol of photons = 6.022×1023 photons. This is an appropriate measurement because it measures directly the light energy that impacts the plants and is available for photosynthesis. Unfortunately, lamp manufacturers usually rate their products in lumens, a unit of light intensity that measures the portion of the spectrum which is visible to humans. Lighting levels are often measured or reported in lumens per square meter (lux, lx) or per square foot (foot-candles, ft-c). This is unfortunate because the spectral sensitivities of the human eye and of plants are quite different. A simple and direct method for interconverting the different units does not exist. Conversion is possible only through the evaluation of the entire range of spectral characteristics of a specific light source.

An excellent calculator and conversion table for radiation in the 400–700 nm range produced by different lamps is available on www.egc.com/illumination.html.

APPENDIX FIVE

Formulary

This formulary contains information about some chemicals and reagents which are routinely used in micropropagation laboratories.

Abscisic Acid. Abscisic is not used in orchid micropropagation. If needed it should be dissolved in 70% ethanol.

Acids and Bases. The molarities, densities, formulae, and other information for some acids and bases are given in Table A5-1.

Ammonium Hydroxide. Solutions of ammonium hydroxide can be used as a solvent and to raise pH (Table A5-2).

Auxins. Auxins can be dissolved in 0.1- or 1-*M* ammonium or potassium hydroxide as well as in 95 or 70% ethyl alcohol (ethanol, drinking alcohol). It is best to dissolve them in 70% ethanol because the alcohol is also a sterilant. Auxin solutions should be stored in a freezer between uses. Prolonged storage of solutions is not advisable.

TABLE A5-1. **Characteristics of some acids and bases: molarities, densities, formulae and other information.**

Acid or base	Molecular weight	Approximate density		Molarity of commercial product	Volume (ml) for 1000 ml of 1 normal solution (1N)[a]	Normality of concentrated reagent	Approximate percent in concentrated reagent
		g ml^{-1}	g l^{-1}				
Acids							
Hydrochloric, HCl	36.47	1.19	445	12.2	82.0	11.6	37.0
Nitric, HNO_3	63.02	1.41	989	15.7	63.8	16.0	70.0
Phosphoric, H_3PO_4	98.04	1.70	1462	14.9	22.4	44.7	85.0
Sulfuric, H_2SO_4	98.08	1.84	1742	17.8	28.2	36.0	96.0
Bases							
Ammonium hydroxide, NH_4OH	17.03 as NH_3	0.90	252	14.8	67.6	15.0	58.0 (29.0 as NH_3)
Potassium hydroxide, KOH	56.11	1.54	800	14.3	70.2		
Sodium hydroxide, NaOH	40.01	1.63	763	19.1	52.5		
Sodium hydroxide, saturated	40.01			19.1	52.5		

[a]Concentrations of commercial solutions should always be checked before use. Concentrated acids and bases are dangerous and must be used with care.

TABLE A5-2. **Preparation of ammonium hydroxide solutions**[a]

Desired molarity	Volume of reagent grade NH_4OH, ml	Distilled water to, ml[a]
15	Use as is, reagent concentration is 14.8 molar	
10	676	1000
5	338	1000
2.5	169	1000
1	67.6	1000
0.1	6.8	1000
0.01	0.7	1000

[a]Pour 500 ml of water in a 1-l volumetric flask, add the NH_4OH slowly, add 200 ml of distilled water, place stopper in opening, mix by inverting flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace stopper, and mix again several times. Store in a plastic bottle.

Benzyladenine. Benzyladenine (6-benzylaminopurine, N^6-benzylaminopurine, N^6-benzylaminopurine, BA, or BAP) can be dissolved in 0.1-*M* hydrochloric acid or 95 or 70% ethanol. It is best to dissolve it and other cytokinins in 70% ethanol because the alcohol is also a sterilant. Solutions of BA and other cytokinins should be stored in a freezer between uses. Prolonged storage of solutions is not advisable.

Buffer. *See* Potassium Phosphate Buffer.

Calcium Hypochlorite. As a saturated solution, this can be used to surface-sterilize seeds, plants, organs, and tissues. The use of this solution was formulated by J. K. Wilson, who was a student in Lewis Knudson's laboratory. Wilson published his work in the *American Journal of Botany* in 1915. According to Giltner J. Knudson, Lewis Knudson's youngest son, Wilson abandoned botany and science to become a tennis teacher and professional player. This sterilant is prepared by dissolving 10 g of calcium hypochlorite in 140 ml (or 7 g 100 ml^{-1}) of water, stirring vigorously, allowing the solution to stand for 3–5 min until the precipitate settles, stirring again, and decanting the yellowish supernatant for use. The solution must be used within 12 h. It should be discarded after that. A few drops of Tween 20, mild household detergent, or baby shampoo should be added as a wetting agent.

Clorox. Clorox is often used as surface sterilant/decontaminant for plants, organs, and tissues that serve as sources of explants, and work surfaces. Concentrations are sometimes given as percent (v/v) Clorox or levels of sodium hydroxide. Table A5-3 contains information regarding the preparation of both kinds of dilutions. In the USA, Clorox contains 6% sodium hypochlorite at present. Previously the concentration was 5.25% sodium hypochlorite. Other domestic bleaches may contain similar or slightly different levels of the active ingredient (± 0.25–1%). Small differences (0.25%) are insignificant and can be ignored. Larger differences (more than 0.25%) must be taken into consideration when dilutions are made. Clorox or other domestic bleaches should not be used to wash hands.

Cytokinins. Cytokinins are hormones which enhance bud and shoot formation and development. They include benzyladenine, dimethylaminopurine, isopentenyl adenosine, kinetin, thidiazuron, and zeatin.

TABLE A5-3. **Clorox (5.25% active principle) dilutions**[a]

Desired percentage				
	Sodium hypochlorite			
Clorox	5.25%	6.0%	Volume of Clorox, ml	Distilled water to, ml[a]
100		6.00	Use as is	None
100	5.25		Use as is	None
50	2.63	3.00	500	1000
25	1.31	1.50	250	1000
10	0.53	0.60	100	1000
5	0.27	0.30	50	1000
2.5	0.13	0.15	25	1000
1	0.05	0.06	10	1000
0.25	0.01	0.015	2.5	1000
0.1	0.005	0.006	1	1000

[a]Pour 500 ml of water in a 1-l volumetric flask, add the Clorox, add 200 ml of distilled water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace stopper, and mix again a few times. Use solutions shortly after preparation and discard unused leftovers. Tissues which are surface-sterilized with these solutions will eventually be washed with sterile distilled water. Therefore Clorox solutions can be prepared with tap or clean rain water if distilled water is in short supply, or in an emergency.

Dimethylaminopurine. This synthetic cytokinin should be dissolved in 0.01- or 0.1-*M* hydrochloric acid or sodium hydroxide in water or 70% ethanol. The latter is preferable because it is also a sterilant.

Ethyl Alcohol. Ethyl alcohol (ethanol, alcohol, drinking alcohol) is very useful in the laboratory as a solvent and sterilant. Only non-denatured ethanol should be used because the denaturing agent can be toxic to workers, tissues, and explants. Laboratory grade ethanol is available in 97 and 95% purity (the rest being water). The 97% grade is known as absolute ethanol. It is more expensive than the 95% grade and may contain a small amount of benzene. There is no reason to use it, particularly as laboratory dilutions are made with water. Also, this grade can absorb moisture from the atmosphere with time. This will reduce ethanol levels. The 95% grade is more economical in cost and preferable to absolute ethanol for most purposes. In fact the most suitable ethanol dilution for use as a solvent, as a sterilant for tissues and organs, and for swabbing surfaces is 70% in distilled water. This is more effective than higher concentrations. This solution can also be sprayed on work surfaces to ensure sterility. Instruments can be placed in it between uses or dipped and shaken to remove it and/or flamed. Table A5-4 provides instructions for making a number of dilutions. Ethanol (97 or 95%) and ethanol dilutions should be stored in glass or plastic bottles. Bottles containing 97% ethanol should be capped very tightly.

Methyl alcohol (methanol) is toxic to workers and plants and must not be used. Isopropyl (rubbing alcohol) can be used to sterilize tools and surfaces and in alcohol lamps, but it must not be employed as a solvent for compounds which may be added to culture media.

GA. *See* Gibberellins.

GA_3. *See* Giberellins.

TABLE A5-4. **Ethanol dilutions**[a]

Desired		Grade of ethanol, ml[a]		
Concentration, %	Volume, ml	97%	95%	Distilled water to, ml[b]
10	1000	103	105	1000
20	1000	206	210	1000
30	1000	309	315	1000
40	1000	412	420	1000
50	1000	515	525	1000
60	1000	618	630	1000
70	1000	721	735	1000
80	1000	824	840	1000
90	1000	927	945	1000
95	1000	Use 95% laboratory grade as is		
97	1000	Use 97% laboratory grade as is		

[a]Pour 500 ml of water in a 1-l volumetric flask, add the ethanol, add 200 ml of water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace the stopper, and mix again a few times. Store in a glass or plastic bottle.
[b]Rounded off.

Gibberellins. These are used to a very limited extent in orchid micropropagation, if at all. They can be dissolved in 0.1-*M* potassium hydroxide, 0.1-*M* sodium hydroxide, or 70% ethanol. A small amount of base can facilitate their solubility in alcohol. It is best to dissolve them in 70% ethanol because the alcohol is also a sterilant.

Hoagland's solution. Hoagland's solution is not used as a culture medium for orchid micropropagation, but there are occasional inquiries about it. There are two versions of this solution (Table A5-5).

Hydrochloric Acid. Hydrochloric acid (HCl) can be used as a solvent and to lower pH in different concentrations (Table A5-6).

Indoleacetic Acid. Indoleacetic acid (IAA), a naturally occurring auxin, should be dissolved in 70% ethanol and stored in a freezer. Prolonged storage is not advisable.

Indolebutyric Acid. Indolebutyric acid (IBA), a synthetic auxin, should be dissolved in 70% ethanol and stored in a freezer. Prolonged storage is not advisable.

Indolepropionic Acid. Indolepropionic acid (IPA), a synthetic auxin, should be dissolved in 70% ethanol and stored in a freezer. Prolonged storage is not advisable.

Kinetin. This synthetic cytokinin should be dissolved in 0.01- or 0.1-*M* hydrochloric acid or sodium hydroxide in water or 70% ethanol. The latter is preferable because it is also a sterilant.

Lanolin Pastes. Lanolin pastes can be prepared by dissolving the relevant hormone in an appropriate solvent and adding it to lanolin that has been heated to liquefaction in a water bath. It is safe to assume that 1 g of lanolin is equivalent to 1 ml of water or solvent.

TABLE A5-5. **Preparation of Hoagland's solution**[a,b]

Salt	Weight, g	Distilled water to, ml[a]	Volume of stock solution to use in preparation of nutrient, ml[b]
Version 1			
KH_2PO_4	136.09	1000	1
KNO_3	101.10	1000	5
$Ca(NO_3)_2$	164.10	1000	5
$MgSO_4$	120.39	1000	2
Version 2			
$NH_4H_2PO_4$	115.04	1000	1
KNO_3	101.10	1000	6
$Ca(NO_3)_2$	164.10	1000	4
$MgSO_4$	120.39	1000	2
Iron			
Iron tartrate[c]	5	1000	1
Micronutrients[d]			
H_3BO_3	2.86		
$MnCl_2 \cdot 4H_2O$	1.81		
$ZnSO_4 \cdot 7H_2O$	0.22	1000	1
$CuSO_4 \cdot 5H_2O$	0.08		
$H_2MoO_4 \cdot H_2O$	0.02		

[a]A separate stock solution should be prepared for each salt. Pour 500 ml of distilled water in a volumetric flask, add salt, shake to dissolve, and adjust volume to 1000 ml. Nitrogen-containing solutions can become contaminated and should be frozen.

[b]Pour 500 ml of distilled water into a volumetric flask, add the major element stock solutions, iron, and the micronutrients, shake to mix, and adjust volume to 1000 ml.

[c]This salt can be replaced with chelated iron.

[d]Add all five salts to the same 1 l of stock solution and prepare as in footnote *a* above.

TABLE A5-6. **Dilutions of hydrochloric acid**[a]

	Desired concentration, molarity[a]									
Component	0.01	0.1	1	2	2.5	4	5	6	8	10
HCl, ml	0.86	8.6	86	172	215	344	430	516	688	860
Solvent (water, ethanol, other) to, ml	1000	1000	1000	1000	1000	1000	1000	1000	1000	1000

[a]Pour 500 ml of water in a 1-l volumetric flask, add the hydrochloric acid, add 200 ml distilled water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace stopper, and mix again a few times. Store in a glass or plastic bottle.

Naphthaleneacetic Acid. Naphthaleneacetic acid (NAA) should be dissolved in 70% ethanol and stored in a freezer. Prolonged storage is not advisable.

Nitric Acid. Nitric acid (HNO_3) can be used as a solvent and to reduce pH in different dilutions (Table A5-7).

Potassium Hydroxide. Potassium hydroxide (KOH) can be used as a solvent and to raise the pH of solutions (Table A5-8).

Potassium Phosphate. Potassium phosphate solutions are prepared by dissolving the indicated amount of salt in 1 l of distilled water (Table A5-9).

TABLE A5-7. **Dilutions of nitric acid**[a]

Desired			
Molarity	Normality	Concentrated HNO_3, ml	Distilled water to, ml[a]
15	15	955	1000
10	10	637	1000
5	5	318	1000
3	3	191	1000
2	2	127.2	1000
1	1	63.6	1000
0.1	0.1	6.36	1000
0.01	0.01	0.64	1000

[a]Pour 500 ml of water in a 1-l volumetric flask, add the nitric acid, add 200 ml distilled water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace stopper, and mix again a few times. Store in a glass or plastic bottle. Always add acid to water.

TABLE A5-8. **Preparation of potassium hydroxide solutions**[a]

Desired molarity or normality	KOH, g	Distilled water to, ml[a]
0.01	0.56	1000
0.1	5.61	1000
1.0	56.11	1000
2	112.22	1000
5	280.55	1000

[a]Pour 500 ml of distilled water in a 1-l volumetric flask, drop the pellets in a few at a time, add 200 ml distilled water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace stopper, and mix again a few times. Store in a plastic bottle.

TABLE A5-9. **Preparation of potassium phosphate solutions**[a]

	Weight, g		
Desired molarity	K_2HPO_4	KH_2PO_4	Distilled water to, ml[a]
0.01	1.74	1.36	1000
0.1	17.4	13.6	1000
1.0	174	136	1000

[a]Pour 500 ml of distilled water in a 1-l volumetric flask, add the salt, add 200 ml distilled water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace stopper, and mix again a few times. Store in a glass or plastic bottle.

Potassium Phosphate Buffer. This buffer is not used extensively in micropropagation, but may become necessary under certain circumstances. The concentration of the buffer is determined by the molarity of the potassium phosphate solutions; its pH depends on the K_2HPO_4/KH_2PO_4 ratio (Table A5-10).

Sodium Hydroxide. Sodium hydroxide (NaOH) can be used as a solvent and to raise the pH of solutions (Table A5-11).

Sulfuric Acid. This can be used as a solvent and to raise the pH of solutions (Table A5-12).

TABLE A5-10. **Preparation of potassium phosphate buffers**[a]

Volume, ml			Volume, ml			Volume, ml		
K_2HPO_4	KH_2PO_4	pH of mixture	K_2HPO_4	KH_2PO_4	pH of mixture	K_2HPO_4	KH_2PO_4	pH of mixture
10.00		8.3	7.00	3.00	7.2	1.00	9.00	5.9
9.90	0.10	8.2	6.00	4.00	7.0	0.50	9.50	5.6
9.75	0.25	8.0	5.00	5.00	6.8	0.25	9.75	5.3
9.50	0.50	7.9	4.00	6.00	6.6	0.10	9.90	5.0
9.00	1.00	7.7	3.00	7.00	6.5		10.00	4.5
8.00	2.00	7.4	2.00	8.00	6.2			

[a]A separate solution should be made for each salt. Pour 500 ml of water in a 1-l volumetric flask, add the salt, add 200 ml distilled water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust to 1 l, replace stopper, and mix again a few times. Store each solution separately in a glass or plastic bottle. To make 10 ml of buffer, mix solutions as indicated in table. The German orchid expert Hans Burgeff was the first to suggest the use of K_2HPO_4/KH_2PO_4 buffer in orchid media. K_2HPO_4 contains twice as much potassium as KH_2PO_4, the same amount of PO_4, and an equal level of H.

TABLE A5-11. **Preparation of sodium hydroxide solutions**[a]

Desired molarity	NaOH, g	Distilled water to, ml[a]
0.1	4.00	1000
1.0	40.00	1000
2	80.00	1000
5	200.00	1000

[a]Pour 500 ml of distilled water in a 1-l volumetric flask, add the pellets a few at a time, add 200 ml distilled water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace stopper, and mix again a few times. Store in a plastic bottle.

TABLE A5-12. **Sulfuric acid dilutions**[a]

Desired			
Molarity	Normality	H_2SO_4, ml	Distilled water to, ml
0.01	0.02	0.56	1000
0.1	0.2	5.64	1000
1.0	2.0	56.4	1000
2	4.0	112.8	1000
5	10.0	282	1000

[a]Pour 500 ml of distilled water in a 1-l volumetric flask, add the acid slowly, add 200 ml distilled water, place stopper in opening, mix by inverting the flask a few times, remove stopper carefully to release pressure, adjust volume to 1 l, replace stopper, and mix again a few times. Store in a glass or plastic bottle. Always add acid to water (mnemonic: A comes before W in the alphabet).

APPENDIX SIX

Atomic Weights, Concentrations, Exponents, Greek and Roman Letters, Ions, Measurements, Molecular Weights, Prefixes, Valences, Units, and Solutions

A large variety of units, numbers, mathematical expressions, concentrations, designations, and other values are used in micropropagation. Some of them are listed, defined, and/or explained in this appendix.

Area

- 1 square meter (m^2) is equivalent to 10,000 square centimeters (1×10^4 cm^2) or 1,000,000 square millimeters (1×10^6 mm^2)

Circles

- Diameter × 3.14 = circumference
- Diameter^2 × 0.79 = area

Concentrations

Amounts per unit volume or weight should be written exponentially. Examples:

- 5 mg per liter or 5 mg/liter should be written as 5 mg l^{-1}
- 10 g per kg or 10 g/kg should be written as 10 g kg^{-1}
- 1 ml per liter or 1 ml/l should be written as 1 ml l^{-1}
- 3 millimoles per liter should be written as 3 mmol l^{-1} or a 3-m*M* solution (there is a difference between *M* which means molar as in "a three molar solution of

sucrose" and mole as in "dissolve 3 moles of sucrose in 500 ml of water." The term *M* (molar) refers to concentration, whereas moles should be applied to amount. It is incorrect to write "dissolve 3 *M* sucrose in 500 ml of water")
- 6 flasks per square meter or 6 flasks/m^2 should be written as 6 flasks m^{-2}

Current practice is to favor the exponential form.

Cylinder

- (Diameter$^2 \times 3.14) \times$ length = surface

Liquid Measure (not metric)

- 2 pints equal 1 quart

Energy

- 1 calorie (or calory) or gram calorie (c) is the amount of heat needed to raise the temperature of 1 g of water by 1°C, from 14.5 to 15.5°C
- 1 erg is equivalent to 10^{-7} joule (J)
- 1 joule (J) is m^2 kg s^{-2}
- 1 kilocalorie (kc) is equivalent to 1000 calories or 10^3 calories
- 1 watt (W) is J s^{-1}; it is equivalent to 1.3×10^{-3} horse power (hp)

Exponents

Very large or very small numbers can be written as exponents. Examples:

- 0.3 can be written as 3×10^{-1} and 0.000005.5 can be expressed as 5.5×10^{-6}
- 10,000 can be presented as 1×10^4

Some Greek Letters

α, alpha as in α-D-glucose (the glucose residue in starch)
β, beta as in β-D-glucose (the glucose residue in cellulose)
γ, gamma (as in gamma radiation)
Δ, δ, capital and lower case delta (Δ is used to designate difference)
μ, mu, which is used to abbreviate micro as in μmole
π, pi (3.14)
Σ, σ, capital and lower case sigma (Σ, summation of; σ, standard deviation)

Ions of Essential Elements, their Names, Weights, and Equivalent Weights

Ion	Name	Weight	Equivalent weight
Anions			
Cl^-	Chloride ion	35.46	35.46
NO_3^-	Nitrate ion	62.01	62.01
HPO_4^{2-}	Phosphate ion	97.99	48.99
$H_2PO_4^{2-}$	Phosphate ion	98.99	49.49
SO_4^{2-}	Sulfate ion	96.06	48.03
Cations			
Ca^{2+}	Calcium ion	40.08	20.04
Mg^{2+}	Magnesium ion	24.30	12.15
Na^+	Sodium ion	22.99	22.99
NH_4^+	Ammonium ion	17.03	17.03
K^+	Potassium ion	39.10	39.10

Length

- 1 centimeter (cm) consists of 10 millimeters (mm); it is 10^{-2} m and equivalent to 0.39 inches (in)
- 1 micrometer (μm) consists of 1000 (10^3) nanometers (nm); it is 1^{-6} m or 1^{-3} mm
- 1 millimeter (mm) consists of 1000 (10^3) micrometers (μm); it is 1^{-3} m and equivalent to 0.04 inches (in)
- 1 nanometer (nm) is 1^{-9} m, 1^{-6} mm, or 1^{-3} μm
- 1 angstrom (Å, no longer used) is 10^{-8} cm

Light

- The candela (cd) is a unit of luminous intensity based on the human eye. Therefore it is not an appropriate unit to measure light intensity as it relates to plant growth
- 1 foot candle (ft-c) = 10.76 lux (lx) = 10.76 meter candles = 0.0011 lumens cm^{-2}
- Irradiance (radiant energy flux received on a unit of plane surface) as energy is given in W m^{-2} or watts per square meter, which is also J s^{-1} m^{-2}, but in the case of plant growth it is important to note the light quality (color)
- Irradiance as moles of photons or moles per square meter per second is mol m^{-2} s^{-1}
- Spectral irradiance as moles per square meter per second per nanometer is mol m^{-2} s^{-1} nm^{-1}
- 1 lux is equivalent to 0.09 foot candles (ft-c). The lux is based on the human eye and therefore it is not an appropriate unit to measure light intensity as it relates to plant growth
- Photosynthetically active radiation (PAR) includes wavelengths between 400 and 700 nm. It is measured as W m^{-2}

Macro- and Microelements, their Atomic Weights and Most Common Valences

Element	Symbol	Atomic weight	Most common valences
Boron	B	10.82	3
Calcium	Ca	40.08	2
Carbon	C	12.01	–4 to +4
Chlorine	Cl	35.46	–1
Cobalt	Co	58.94	2
Copper	Cu	63.54	1, 2
Hydrogen	H	1.01	1
Iron	Fe	55.85	2, 3
Magnesium	Mg	24.31	2
Manganese	Mn	54.94	2, 4, 7
Molybdenum	Mo	95.94	3, 4, 6
Nickel	Ni	58.69	2
Nitrogen	N	14.01	3, 5
Oxygen	O	16.00	–2
Phosphorus	P	30.98	5
Potassium	K	39.10	1
Sulfur	S	32.06	4, 6
Zinc	Zn	65.37	2

Moles

- Mole, an amount in grams equal to the molecular weight of a substance (1000 millimoles)
- Millimole (1000 micromoles or 1000 μmol)
- Molar or *M*, number of moles in a solvent brought up to 1 liter (i.e., the amount of solute plus enough solvent to bring the total volume of the solution to 1 liter or 1000 ml)
- Molal, number of moles per liter (i.e., the amount of solute per 1 liter or solute plus 1000 ml of solvent)
- Moles per liter (mol l^{-1}), amount of solute expressed as moles in solvent brought up to 1 liter (i.e., the amount of solute plus enough solvent to bring the total volume of the solution to 1 liter or 1000 ml)

[b]Abbreviations:

Growth regulators: ABA, abscisic acid; Anc, ancymidol; ADS, adenine sulphate; AD, adenine; BA, 6-benzylaminopurine (also known as benzyladenine); *t*CA, *trans*-cinnamic acid; DMSO, 6-(γ, γ-dimethyallylamino)-purine; DZe, dihydro zeatin; 2,4-D, 2,4-dichlorophenoxyacetic acid; KGA, potassium salt of GA_3; GA_3, gibberellic acid; IAA, 3-indolacetic acid; IBA, 3-indolebutyric acid; KIBA, potassium salt of IBA; IPA, indole-3-propionic acid; KIN, kinetin; NAA, α-naphthaleneacetic acid; TDZ, thidiazuron; 2,4,5-T, 2,4,5-trichlorophenoxyacetic acid; ZT, zeatin; ZTR, zeatin riboside.

Solvents: 1NA, 1N NaOH; DM, dimethylsulfoxide (DMSO); Et, ethyl alcohol, usually 70 or 95%; EtHC, ethyl alcohol (ethanol), 70 or 95% with a few drops of 0.1 N or 1 N HCl; EtNa, ethyl alcohol (ethanol), 70 or 95% with a few drops of 0.1 N or 1 N NaOH or KOH; W, water.

Storage: Fr, freezer.

Sterilization: A, autoclave; S, add in ethanolic solution to still hot and liquid autoclaved medium.

Plant Growth Regulators, Molecular Weights

Name and abbreviation	Molecular weight
Abscisic acid, ABA	264.32
Adenine (anhydrous), AD	135.13
Adenine (trihydrate), ADTH	189.13

Zeatin riboside, ZTR	363.37

Prefixes

- atto = 10^{-18}
- femto = 10^{-15} (one quadrillionth), symbol is f (example: 1 femtomole is written as 1 fmol; 1 femtomolar is written f*M*)
- pico = 10^{-12} (one trillionth), symbol is p (example: 1 picomole is written as 1 pmol; 1 picomolar is written p*M*)
- nano = 10^{-9} (one billionth), symbol is n (example: 1 nanomole is written as 1 nmol; 1 nanomolar is written n*M*)
- micro = 10^{-6} (one millionth), symbol is μ (example: 1 micromole is written as 1 μmol; 1 micromolar is written μ*M*)
- milli = 10^{-3} (one thousandth), symbol is m (example: 1 millimole is written as 1 mmol; 1 millimolar is written m*M*)
- kilo = 10^{3} (one thousand), symbol is K (example: 1000 grams is 1 kilogram or 1 kg)

- mega = 10^6 (million), symbol is M
- giga = 10^9 (billion), symbol is G
- tera = 10^{12}

Pressure

- 1 atmosphere (atm) equals 1.01 bars and 1.03 kg cm^{-2}
- 1 pascal (Pa) is 1 kg s^{-2} m^{-1} and equivalent to 0.00001 atm

Roman numerals

I = 1	XX = 20	CC = 200
II = 2	XXX = 30	CCC = 300
III = 3	XL = 40	CD = 400
IV = 4	L = 50	D = 500
V = 5	LX = 60	DC = 600
VI = 6	LXX = 70	DCC = 700
VII = 7	LXXX = 80	DCCC = 800
VIII = 8	XC = 90	CM = 900
IX = 9	C = 100	M = 1000
X = 10		

Sphere

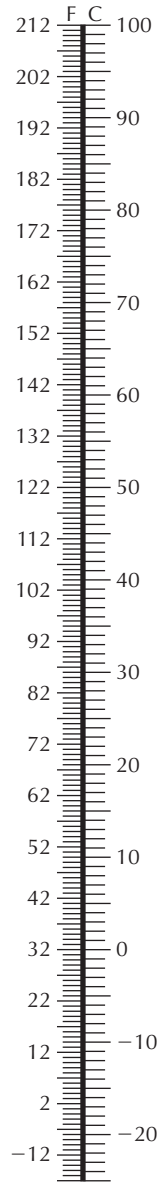
Lactose	360.31		
Leucine	131.17		

Temperature

- To convert °C to °F: $(°C \cdot {}^{9}/_{5}) + 32 = °F$
- Shortcut for °C to °F: $[(°C \cdot 2) - 10\%] + 32 = °F$
- To convert °F to °C: $(°F - 32) \cdot {}^{5}/_{9} = °C$



Volume

- 1 liter (l) is 1 cubic meter (1 m^3). It consists of 10^3 milliliters and is equivalent to 1.06 US quarts (qt)
- 1 microliter (µl) is 1^{-6} liters or 1^{-3} milliliters
- 1 milliliter (ml) is 1 cubic cm (cm^3) and consists of 1000 (10^3) microliters. It is 1^{-3} liters and equivalent to 0.03 fluid ounces (oz) or 0.06 cubic inches (in^3)

Weight

- kg, kilogram (1000 grams or 1000 g)
- g, gram (1000 miligrams or 1000 mg)
- mg, milligram (1000 micrograms or 1000 µg)
- µg, microgram (1000 nanograms or 1000 ng)

APPENDIX SEVEN

Additional Information

This appendix contains information gathered after the manuscript was copyedited. It is divided into categories for convenience.

Contamination

In some cases it may be possible to combat, inhibit or eliminate bacterial contamination through the use of plant preservative mixture, PPM (www.ppm4plant-tc.com) or Kathon (www.sigmaaldrich.com/Brands/Supelco_Home/Biocides/Kathon.html, www.rohmhaas.com/rhcis/markets_and_products/polymeremulKathon.html). A 1% solution of either PPM or Kathon in sterile distilled water can be used to decontaminate tissues. The tissue should be placed in the solution and agitated gently (or not at all if the tissue become bruised) for 24 h. After that the tissue should be cultured in a medium containing 0.2% PPM or Kathon (2 ml l^{-1} medium). The PPM or Kathon can be added before or after autoclaving. However caution is necessary because no information is available on the effects of autoclaved PPM or Kathon on humans. Timentin (www.rxlist.com/cgi/generic2/timentin.htm, www.gsk.com/products/prescription_medicines/us/timentin.htm) at 300 mg l^{-1} can also be used. It is very expensive (Eric Young, eyoung994@hotmail.com provided this information on May 5, 2003 to plant-tc@lists.umn.edu). Users of PPM and Kathon should refer to US Patent No. 5,750,402 and only follow procedures that respect it and do not violate it.

Contaminated explants and cultures can perhaps be saved through the use of a solution which consists of 5 ml PPM of Kathon in 1 l of autoclaved distilled water. The contaminated tissue should be cleaned manually as much as possible and washed with sterile distilled water. After the washing the distilled water should be discarded and replaced with the Kathon or PPM solution leaving very little (just a few milliliters) of air space at the top of the tube. The tissues should be kept in the solution for 24–36 h. Longer exposures of higher Kathon or PPM concentrations may be required in cases of severe contamination, but such treatments may damage the tissues of plants. Lower concentrations of Kathon or PPM should be used for sensitive plants or tissues. Plants or tissues so treated should be cultured a few at a time (Eric Young, eyoung994@hotmail.com provided this information on November 15, 2004 to plant-tc@lists.umn.edu). Users of PPM and Kathon should refer to US Patent No. 5,750,402 and only follow procedures that respect it and do not violate it.

For combating mites and molds see Van Epenhuijsen and Koolaard (2004*a*, 2004*b*) in the list of literature below.

Digital Cameras

Thorough reviews of digital cameras can be found at www.dpreview.com.

Freeware

Many freeware computer programs can be downloaded free of charge and completely legally from www.concisefreeware.com.

Kathon

Plant Pathology

Plant diseases are listed on www.ppath.cas.psu.edu/extention.plant_disease.

PPM

"PPM is a mixture of isothiazolone biocides (US Patent No. 5,750,402). Proclin (Supelco) is another mixture of isothiazolones, less expensive. Kathon (product number 500127, 500143, and 500135) from Supelco is a micture of the 5-chloro-2-methyl-4-isothiazolin-3-one with magnesium salts and a little copper nitrate added" (Eric Young, eyoung994@hotmail.com provided this information to plant-tc@lists.umn.edu). Supelco is part of Sigma-Aldrich, whose URL is www.sigmaaldrich.com/Brands/Supelco_Home.html.

When PPM is added to medium and autoclaved at 125°C for 15–20 min there is no substantial difference in its potency (even at concentrations of 0.05%) in comparison to being added after autoclaving if the medium does not contain any protein source. Protein seems to permanently bind the active ingredients during autoclaving. If a medium contains charcoal, the PPM concentration should be increased by 25% (Assaf Guri on the web site plant-tc@lists.umn.edu).

The following is an edited excerpt from a message by Martin Kalin (mkalin@ibek.com to plant-tc@lists.umn.edu):

> I would like you to know that we own US Patent No. 5,750,402 on the use of Kathon (and other isothiazolone equivalents) in plant tissue culture media at concentrations that reduce or prevent microbial contamination, but allow for substantially normal germination of seeds or growth or development of plants, plant organs, plant tissues or plant cells. The text of the patent is accessible on the web site of the U.S. Patent and Trademark Office, or from me upon request. We also have patents and patents pending in other countries of the world.
>
> Plant Preservative Mixture (PPM) is formulated by Plant Cell Technology specifically for plant tissue culture applications. In addition to our method claims, our patent also covers composition claims. The use of Kathon or other isothiazolone equivalents (other than PPM purchased through authorized channels) in countries where it has been patented for the prevention or reduction of microbial contamination of explants prior to placing them in media is covered under our patent. This patent also applies to instances in which remnants of the Kathon (even after washing) are still left on the explants and eventually diffuse into media and reduce or prevent microbial contamination, but allow for the substantially normal germination of seeds or growth or development of plants, plant organs, plant tissues or plant cells.
>
> To avoid patent infringement, I highly recommend you use PPM obtained from us or our distributors (PhytoTechnology Laboratories and others worldwide).
>
> PPM is also an EPA registered product for tissue culture applications and to our knowledge Plant Cell Technology, Inc. is the only EPA registered manufacturer of this chemical for this application and use (i.e., plant tissue culture media).
>
> If you or anyone else would like to discuss this issue, feel free to contact me at mkalin@ibek.com or by telephone at +1 202-778-8522, ext. 1.

Information about PPM, literature references, price lists, online store testimonials, instructions for use, contact information, a materials data safety sheet (MSDS), fax/mail

order form, testimonials, a request for input, and a list of distributors can be found at www.ppm4plant-tc.com.

APPENDIX EIGHT

Plant Preservative Mixture

Several discussions held while attending 9th Asia Pacific Orchid Conference (APOC 9) in Seoul, Korea convinced me to write this appendix on the use of plant preservative mixture (PPM) with orchids.

The following general instructions regarding the use of PPM (which have been edited only lightly) are presented here courtesy of Plant Cell Technology (PCT).* My additions and recommendations are given in square brackets.

General Instructions

Introduction

PPM™ is a heat-stable preservative/biocide which can be used to effectively prevent or reduce microbial contamination in plant tissue cultures. At optimum doses, PPM™, which stands for Plant Preservative Mixture™, is an extremely effective preservative/biocide which does not impair in vitro seed germination, callus proliferation, and regeneration.

Despite the most stringent use of sterile techniques, contamination of plant cell and plant tissue cultures remains a persistent problem which can result in losses ranging from a small number of cultures to whole batches.

PPM™ can be, and should be, used as a standard ingredient in plant tissue culture media. It is substantially less expensive and less potentially dangerous than commonly used antibiotics.

PPM™ was principally designed to inhibit contamination which airborne, waterborne and human contact induced. However, in many cases it can also be used to reduce endogenous contamination.

The principal PCT scientist involved in the development of the PPM™ application is Dr. Assaf Guri. He holds degrees in genetics, applied genetics, and plant breeding from the Hebrew University in Jerusalem and Michigan State University in the USA. Before joining PCT, he worked at the Volcani Agricultural Research Center in Israel, Michigan State University in East Lansing, Michigan and DNAP in New Jersey.

* I thank Dr. Assaf Guri for allowing me use material from the Plant Cell Technology web site.

Mechanism of Action

PPM™ is a broad-spectrum preservative and biocide, which kills bacterial and fungal cells, prevents germination of spores, and at higher concentrations, can eliminate endogenous contamination from explants. It is heat stable and therefore can be autoclaved.

Previous research has shown that the active ingredients of PPM™ penetrate the cells of the fungi or bacteria and inhibit key enzymes in central metabolic cycles such as the citric acid cycle and the electron transport chain. Our data indicate that PPM™ may also inhibit the transport of monosaccharides and amino acids from the medium into the fungal or bacterial cells.

As in any biocide, a critical ratio of PPM™ molecules per microbial cell is needed to eliminate bacteria and fungi. Keep in mind that a given volume of PPM™ dose has a constant number of PPM™ molecules while the number of spores introduced to tissue culture via endogenous contamination is highly varied. Therefore, explants should not be "squeezed" into a beaker. There should be enough volume for free movement of the solution around the explant material.

Advantages of PPM over Antibiotics

1 PPM™ is broad-based and effective against fungi.
2 PPM™ is less expensive than antibiotics, making it affordable for wide and routine use.
3 Since PPM™ targets and inhibits multiple enzymes, the formation of resistant mutants towards PPM™ is very unlikely.
4 PPM™ is heat stable and in general can be autoclaved with media.

Procedures

The procedures described below are generic. Slight modifications may be needed for your specific plant species. For assistance, contact Dr. Assaf Guri at guri1@erols.com or call +1 856 541 1141.

PPM™ significantly simplifies tissue culture working procedures for several reasons:

1 Media containing PPM™ may be dispensed outside laminar flow hoods (LFHs) under ambient conditions [however, the use of hoods is advisable for orchid laboratories]. Culture plates and vessels should be covered shortly after agar solidification. When media are dispensed with pumps, PCT recommends passing autoclaved hot water through the hoses prior to and after media dispensing.
2 Heat-sensitive or heat-stable liquid media containing PPM™ do not need to be sterilized by passing them through millipore filters or autoclaved provided they will be stored in sterile containers and that the stock solutions are not contaminated. In rich media containing 200 mg l^{-1} or more of amino acids or proteins, it is recommended to filter-sterilize the media with the PPM™ [since few orchid media are that rich this should not be necessary].

3 When working in LFHs, tools (forceps or scalpels) do not need to be flamed [for use with orchids, flaming is advisable]. They should be dipped periodically in 70% alcohol. The LFH does not need to be certified [LFHs used with orchids do not require certification anyway]. Work can be carried out outside the LFHs on a clean surface for a period not exceeding 1 h.

4 PPM™ is an acidic liquid solution (pH 3.8) which should be stored at 4°C (see safety information below). At the recommended dose of 0.05–0.2% (v/v), PPM™ is added to the medium before or after autoclavation to prevent airborne and endogenous contamination at low inoculum densities.

5 PPM™ is less effective when exposed to the high densities of bacterial or fungal spores that may be found on seed coats. For in vitro germination, seeds should be surface-sterilized conventionally with an EPA registered bleach [or other methods used for orchid seeds]. Therefore, in the presence of PPM™ (in the germination medium), the seeds can be rinsed under tap water in a non-sterile strainer and left to dry, preferably in the LFH [see below for methods to use with orchid seeds]. If the utensil ends have touched active bacteria or fungi culture or are otherwise suspected of being contaminated, they should be sterilized by autoclaving or through the use of an electric heating element.

6 General dosage levels: With the exception of endogenous contamination, the recommended dose range is 0.05–0.2%. For callus proliferation, organogenesis, and embryogenesis, the recommended range is 0.05–0.075% [different concentrations may have to be used for orchids; see below]. Add PPM to medium pre- or postautoclaving to prevent airborne and endogenous contamination at low inoculum densities or slow growing bacteria. To eliminate higher endogenous contamination densities, higher doses of PPM are needed (see point 7 below).

7 Endogenous contamination:

(a) Stir non-sterilized seeds for 8–12 h in 2–3% PPM™ solution (v/v) supplemented with full-strength basal salts of your routinely used medium. Do not add Tween-20 or pH to this solution. Subsequently, and without rinsing, transfer to germination medium supplemented with 0.05–0.1% PPM™ for herbaceous plants and with 0.2% PPM™ for woody plants. Hard-coated seeds (e.g., *Asparagus*, lupine, ornamental palm, rose, etc.) should be soaked in water for 2–4 h prior to sterilization with PPM™ [different procedures may have to be used for orchids; see below].

(b) Gently and routinely shake/stir 1-cm long explants (or shorter) for 4–12 h in 4–5% v/v PPM™ solution supplemented as above with full-strength MS basal salts [or orchid media salts] without adjusting pH and without Tween-20. Without rinsing, insert explants into a medium supplemented with 0.05–0.1% PPM™ for herbaceous plants and 0.2% PPM™ for woody plants [different procedures may have to be used with orchids; see below].

(c)* For tubers, bulbs, and scales: shake/stir the entire tuber/bulb/scale in bleach. Rinse with water (can be done under non-sterile conditions). Slice the tuber/bulb/scale into thin slices. Shake/stir for 12–24 h in 4–5% PPM™ solution supplemented with full-strength basal salts without

* Paragraphs 7(c) through 10 are intended for ornamental plants and non-North American users only.

adjusting and Tween-20. Without rinsing, insert into a medium supplemented with 0.1–0.2% PPM™ [different procedures may have to be used with orchids; see below].

8* In cases where the protocols above do not yield satisfying results (especially thick explants, highly infested explants, seeds), we recommend the following:
   (a) Shake/stir the explants in water (1 h for soft tissues and 2 h for hard tissues).
   (b) Shake/stir the explants in (50%) PPM™ supplemented with full-strength MS basal salts (without pH-ing and without Tween-20) for 5–10 min.
   (c) Without rinsing, insert the explants into the medium. In cases of fungal contamination, the addition of PPM™ to the medium is optional. However, with bacterial or mixed contamination, the addition of 0.05–0.2% PPM™ to the medium during the first month is essential. Do not discard highly oxidized explants as approximately 50% of the explants will recover within 4–6 weeks [different procedures may have to be used with orchids; see below].

9* To decontaminate contaminated cultures use the following rescue treatment (cultures should not be left visibly contaminated for longer than 1 week):
   (a) Clean the material mechanically using a soft toothbrush under a stream of tap water. Shake/stir in a 50% PPM™ solution (diluted with sterile water) for 5–15 min. For bacterial or mixed contamination we recommend lowering the solution pH to a range of 2.8–3.2 by mixing it 1 : 1 (v/v) full-strength PPM™ (100%) with 0.6 g l^{-1} citric acid solution in sterile water.
   (b) Without rinsing, insert tissues into a medium with 0.05–0.2% PPM™ for at least 1 month. Keep the culture away from high light intensities for the first 10 days. As mentioned above, do not discard oxidized explants. Wait 4–6 weeks as approximately 50% should recover.

10* In some cases the fungal or the bacterial spores are located deep within the explants beyond the reach of PPM. In such cases, and after the water-soaking period, slice the explants and then stir/shake in 50% PPM for 5–15 min [different procedures may have to be used for orchids]. For this decontamination procedure to be effective it is important to ensure that the tissues are completely and thoroughly bathed in the PPM solution.

Elimination of *Agrobacterium*

After co-cultivation, rinse the leaf discs with water. Completely dip the treated leaf discs in a 100% PPM™ solution (supplemented with full-strength basal salts) for approximately 2 min. Blot the discs between two sterile paper towels and place onto a medium supplemented with full-strength, commonly used antibiotics. After 3 weeks, transfer to a medium with PPM™ at 0.05–0.075% and no antibiotics. [This procedure may prove useful for the elimination of other bacteria from orchid cultures.]

General Notes

1 For the first transfer following sterilization with PPM™, we recommend complete insertion of the explants into a semisolid medium.

2 A 50% PPM™ solution can be reused approximately 10 times. The number of uses depends on the volume of explants treated and the inoculum density. Storing the 50% PPM™ solution at 4°C prolongs its activity. If necessary, prepare two PPM™ solutions: one to disinfect endogenous contamination and the second to disinfect in-culture contamination. The second solution should be filtered after each treatment, using 0.2-μm millipore filters. This filtration can be carried out under non-sterile conditions. A single filter can be used for the entire lifespan of the solution.

3 In cases where treatment with 50% PPM™ is still insufficient, full-strength PPM™ (100%) can be used. The treatment with 100% PPM™ is similar to the one described above for 50% PPM™, however, exposure time should not exceed 10 min.

Conclusions

PPM™ will most definitely facilitate work in any plant tissue laboratory and should significantly increase technician and laboratory productivity. However, conditions in each laboratory may vary and this could have a bearing on the effectiveness of PPM™. It is advisable for the staff to follow the guidelines above and thus maximize the effectiveness of PPM™ for a specific laboratory and particular applications. Test results show that:

- PPM™ is effective against airborne and waterborne contamination and contaminants introduced by human contact.
- If used correctly, PPM™ will free seeds or explants from endogenous contamination.
- At recommended dosages (0.5–2 ml l^{-1}), PPM™ does not impair in vitro seed germination, callus proliferation, callus regeneration, or the induction of axillary or adventitious buds.
- The formulation of certain concentrations of PPM and its use in tissue culture to prevent or eliminate microbial contamination is protected by US Patent No. 5,750,402. It is also patent pending in many countries of the world.

Safety Procedures

Safety Issues. PPM™ is non-toxic; however, inhalation and contact with skin and eyes should be avoided since it is an acid. It can be an irritant to skin, eyes, nose, and throat. As a precaution, we recommend that: (1) users wear gloves and splash goggles; (2) users avoid contact with skin and eyes; (3) users avoid inhalation; (4) proper and adequate ventilation is used; and (5) the material should not be applied by spraying it except with directed flow, positive-pressure ventilation, and protective equipment.

First Aid Measures. If swallowed, drink two glasses of water *immediately* and see a physician. Never administer anything by mouth to an unconscious person. In cases of eye and skin contact, *immediately* flush eyes with large amounts of water for at least

15 min. Wash affected skin areas thoroughly with soap and water. Remove and wash contaminated clothing thoroughly. Move subject to fresh air in cases of inhalation.

Important Information

The PPM solution as provided by PCT must/may not be concentrated for any reason.

Disposal Information

Dispose of media containing PPM™ in the same manner as that used to dispose of media without it. In an emergency, contact one of the following numbers: Dr. Assaf Guri, 1 (856) 541 1141 or Martin Kalin, 1 (202) 463-0904 ext. 134 or ext. 0 (for operator). A toxicological assessment has been performed by a qualified toxicologist. This assessment is available upon request. For more information on PPM™, or to request test results, contact: tel: 1 202 778 8522 ext. 1, fax: 1 202 429 9812.

Selected Answers from Frequently Asked Questions (FAQ) for a Previous Version of PPM™

1. PPM™ does not move as easily through plant cell walls as it does through those of fungi and bacteria. That is why explants are more tolerant to it. Plant protoplasts which are not protected by cell walls are very sensitive to PPM™.
2. It is not known if PPM™ affects anaerobic bacteria. However, since tissue cultures are usually well aerated such bacteria are not much of a problem in micropropagation.
3. Since PPM™ targets multiple enzymes it is unlikely that microorganisms can develop resistance to it.
4. In cases of high density contamination, fewer explants should be placed in a specific volume of PPM™.
5. It is possible to use PPM™ to free cultures of both contamination and endogenous contaminants.
6. PPM™ is active at a pH lower than 8.
7. At 0.5–2.0 ml l^{-1} PPM™ can be used in non-sterile media for short periods (1–7 days) without special precautions. For long-term experiments, the culture vessels must be sterile and the stock solution and water must be free of contaminants.
8. PPM™ is a liquid.
9. The effect of PPM™ may be reduced in media that contain proteins. In the presence of 1 g casein hydrolysate the concentration of PPM™ must be increased from 0.5 to 1 ml l^{-1}. Since many orchid micropropagation media contain casein hydrolysate, peptone, and/or tryptone this is an important fact to consider. Should 1 ml PPM™ l^{-1} prove to be insufficient it may be necessary to use a higher concentration, but this must be done carefully. Valuable cultures should not be subjected to high levels of PPM™ without prior testing.

10 PPM™ can be combined with antibiotics and fungicides.
11 Despite the fact that PPM™ is heat stable, autoclaving reduces its effectivity by about 10%. In protein-rich media the reduction may be as high as 90%. Therefore PPM™ must be added after autoclaving in some cases.
12 Once PPM™ has been added to an initial medium it is advisable to incorporate 0.5 ml l^{-1} in subsequent media.
13 PPM™ is a broad-spectrum biocide.

Use of PPM™ with Orchid Seeds

Report 1. Plant Cell Technology provided the following information by Roger Nick of Spring Orchid Laboratory (rn0089@msn.com) in January 2003. The report was edited to conform with style and format of this book.

- Unsterilized orchid seeds harvested at the green capsule stage were sown on half-strength Murashige and Skoog (MS) medium supplemented with 20 g sucrose, 10 mg thiamine, 1 mg pyridoxine, 1 mg niacin, and 100 mg *myo*-inositol l^{-1} and solidified with 8 g agar l^{-1}.
- Seeds from the same capsules were divided and placed on this medium without PPM™ and with 2 ml PPM™ l^{-1}. The medium was dispensed into flasks and autoclaved at 15 psi for 15 min.
- Germination was approximately 90% on both media. After 2 months of growth, no difference could be detected between plants grown on media with or without PPM™.
- The same tests were carried out with hybrid seeds *Cattleya*, *Phalaenopsis*, and *Dendrobium*. After 2 months no contamination was present in flasks containing PPM™, whereas two out of six flasks without PPM™ were contaminated.
- In the Gulf Coast region of the USA, extreme summer temperatures sometimes cause splitting of unripe capsules prior to the anticipated harvest date. Once the capsules have split, the surface can no longer be sterilized with bleach, and most of the embryos are too immature to withstand standard dry seed type sterilization with calcium hypochlorite. I have had great success with obtaining clean seedling flasks from most of the split capsules by utilizing the medium described above with the addition of 2 ml PPM™ l^{-1}, after lightly flaming the outside of the split pod over an alcohol burner. In the past, most capsules which split prematurely were lost completely.
- Occasionally I replace from "mother" flasks and get immediate contamination from what seems to be a "dormant"-type contaminant. I have been able to clean almost all of these contaminated seedlings by placing them in a solution of 20 ml PPM™ l^{-1} for a 24–36-h period on a rotary shaker. The plants are then removed and placed without rinsing on half-strength MS medium as described above with the addition of 2 ml PPM™ l^{-1}. All seedlings remained uncontaminated and grew normally for the remainder of the in-flask period.

Report 2. Marty Kalin of Plant Cell Technology (marty@mk.ibek.com) provided the following information in May 2003.

- PPM™ was incorporated into the final rinse solution used to disperse orchid seed over the surface of nutrient medium at a rate of 4 ml l^{-1}. This solution was used in 255 germination flasks containing 45 varieties of orchid seed. Flasks were sown without the benefit of a laminar flow hood in a non-sterile environment (an open room). Orchid seed was sterilized by normal procedure (10% Clorox for 10 min) then power-filtered and resuspended in PPM™ solution. Flasks were autoclaved in the usual manner and incubated at 23°C after sowing.
- Contamination rates of approximately 10% were observed after a period of 1 month (16 fungal and 5 bacterial). Since these flasks were sown quite heavily with seed and under non-sterile conditions, we consider this to be a significant reduction in the contamination rate that might normally be expected to range at around 45–60% under these conditions.
- Germination of the seed does not appear to have been affected by the presence of PPM™. Seeds of several genera were used including many temperate terrestrial and tropical species.

Report 3. Simon M. Wellinga of SymPhyto in the Netherlands (s.m.wellinga@symphyto.nl) described his findings in May 2003.

- Back in 1998 we ordered a couple of 100-ml bottles and tried PPM™ with our cultures, which at that time consisted mostly of botanical *Cattleya* and *Laelia* species. We did so out of curiosity and to find out whether this mixture would meet its expectations. In an initial trial PPM™ was both used as an ingredient of our standard germination media and as a cure of contaminated seedlings, which after treatment were replated onto media either containing PPM™ or without it. Although PPM™ was used strictly according to the recommendations that came with the product and while following our standard laboratory practices (work done in a laminar flow hood, autoclave cycles as usual, etc.), all our experiments were not planned ahead in what one would call a sound and statistically justifiable setup. Therefore our results cannot be claimed to be scientific evidence, and neither have they been published. The reason that we only tested PPM™ qualitatively, and not quantitatively, was that we would never have been able to utilize this ingredient on a larger scale, both for economical reasons and because of international phytosanitary regulations. Since a considerable proportion of our seedlings are sent in flasks on sterile medium to non-EU destinations (the only way one can get *Paphiopedilum* species and other CITES Appendix I species across international borders), we are not allowed to incorporate any antibiotics in our export flasks or any other compounds that temporarily suppress or mask infections.
- For what it is worth – although we made sure to follow the instructions that came with the product, we never bothered to share our experiences with others – we found that in seed cultures on medium containing PPM™, infections would still occasionally show up. Also, we have never been able to clean contaminated cultures with the help of PPM™, something which with some luck can be achieved in case of hard-leafed material as cattleyas and paphiopedilums with the help of a treatment with sodium hypochlorite. In those instances where treated cultures of infested seedlings seemed to be clean, infection would immediately show up again after replating to PPM™-free medium, and this is why we were led to believe that PPM™ merely suppresses infections but does not eradicate them altogether.

- I understand you are looking for information and references for the forthcoming new edition of *Micropropagation of orchids*. I am sorry that the information above is only anecdotal and that I cannot help you with more valid and statistically relevant data.

Report 4. Esteban McGrath of Loresco Tropical Plants in San Juan, Puerto Rico (lsrjm@prtc.net) wrote of his experiences in May 2003.

- I am a grower and *Hibiscus* breeder and at present no longer deal with orchid seeds. However, in my experience this product (PPM™) should be used for sterilization of not only seed, but utensils as well. I found the losses with PPM™ not to exceed 2%, whereas losses with sodium hypochlorite can be as high as 96%. The "cloro" kill rate effect was worse than its sterilization effectivity, whereas the PPM™ just simply was effective when used as proposed.
- I have used it on in vitro seeds and explants, as well as on extremely difficult to root multiplications of *Hibiscus* with good results. In-flask work was with coconut water.
- No data have been published, but as a field producer, I realize its potential for anything needing extreme pathogenic control.

Report 5. There seems to be only one published report on the use of PPM™ in orchid seed germination: Bautista, N. R., A. B. Quilang, G. B. Taylan, R. F. Madera, and C. C. Pulma. 2001. Effect of Plant Preservative Mixture™ (PPM) on contamination rate and growth of *Vanda sanderiana* Reichb. F. Seedlings (Orchidaceae) *in vitro*. Pages 121–126 *in Proceedings of the World Conference on Science and Technology: harnessing science and technology to meet global challenge* (September 13–15, 2001). Philippine Association for the Advancement of Science, Manila.

- These authors reported using a modified Knudson C medium (without describing the modification) plus 0.125, 0.25, 0.5, 1, 2, and 4 ml of PPM™ for the germination of unsterilized *Vanda sanderiana* seeds in 10 replicas. Culture conditions were 8-h photoperiods provided by fluorescent lights and 21°C.
- Contamination usually appeared 3 days after inoculation. The control and 0.125 and 0.25 ml PPM™ treatments became contaminated after a week. The contaminants were fungi. Approximate contamination percentages were:

Controls:	100%
0.125 ml PPM™:	80%
0.25 ml PPM™:	60%
0.5 ml PPM™:	50%
1 ml PPM™:	30%
2 ml PPM™:	60%
4 ml PPM™:	0%

Use of PPM in Orchid Tissue Culture

Report 1. Roger Nick of Spring Orchid Laboratory (rn0089@msn.com) also reported on the use of PPM™ in orchid micropropagation.

- I also do a considerable number of *Phalaenops*is stem propagations from our most desirable plants. In the past the stems were harvested, washed with mild detergent and water, and placed in 25% Clorox solution with Tween-20 added for a period of 25–30 min. The stems were then rinsed in sterile distilled water three times and placed in quarter-strength MS medium for a period of 24 h. They were then removed and placed in half-strength MS medium as described above with the addition of 0.5 mg naphthaleneacetic acid, 5 mg benzyladenine, and 2 ml PPM l^{-1}.
- When bleach alone was used, I averaged approximately 25–30% contamination. With bleach and PPM™ treatment (20 ml l^{-1}) the contamination rate dropped to approximately 5%. Note has been made that some *Phalaenopsis* hybrids are more sensitive to PPM™ than others. In those cases shorter exposures to 20 ml PPM™ l^{-1} solution were successful.
- To prepare replating medium for the seedlings, I supplemented the medium above with 50 g mashed white potatoes l^{-1}, 100 g mashed green bananas l^{-1}, and 0.2% activated charcoal. The addition of 2 ml PPM l^{-1} to this replating medium was done only after autoclaving.

Report 2. Dr. Victor M. Jiménez of the University of Costa Rica (vjimenez@cariari.ucr.ac.cr) reported that with 2 ml PPM™ l^{-1} contamination sets in within 3 months. If the level of this contamination is low, transfer to fresh medium. However, heavy contamination cannot be cleaned up.

Report 3. Dr. Michael E. Compton, School of Agriculture, University of Wisconsin, Plateville (compton@uwplatt.edu) used 2 ml PPM™ l^{-1} for shoot tip "cultures of *Oncidium* without ill effects. However, PPM™ at this . . . [concentration does not protect shoot tips] from heavy microbial infections."

Report 4. Dr. Asaf Guri of Plant Cell Technology and the inventor of PPM™ (guri1@erols.com) wrote the following when asked how one could use PPM™ with *Paphiopedilum* shoot tips:

> Let me suggest to you to skip sterilization with sodium or calcium hypochlorite and soak the shoot tips in non pHed 4% PPM solution in which full strength MS basal salts are added [if another basal solution is used for culture these salts should be used instead of MS]. I can't tell you the exact exposure time but I'll suggest from 1 to 4 hours exposure in which the tips are agitated very gently. Do not add Tween-20 to the solution. Without rinsing place the tips into the proper medium with 0.1% (v/v) PPM. In case the medium contains any source of peptides (as usually occurs in orchid media) the 0.1% PPM 1 minute before dispensing [some orchid media contain casein hydrolysate, peptone, and/or tryptone which could be sources of peptides]. It [the PPM] will not change the overall pH and the added PPM solution does not need to be sterilized [however the culture medium should be autoclaved regardless of when the PPM is added].

Material Safety Data Sheet

Since this is a relatively new mixture, the material safety data sheet (MSDS) should be consulted by those who will want to use PPM™. It is reproduced here courtesy of Plant Cell Technology (the company which produces and sells PPM™).

PPM™ Identification

- *Chemical name*: PPM™ (Plant Preservative Mixture).
- *Chemical family*: Proprietary.
- *CAS number*: Proprietary (several numbers).
- *Synonyms*: Not applicable.
- *DOT information*: Not corrosive (pH = 3.7).

Hazard	Rating	Scale
Oral toxicity	4	4 = insignificant/none
Eye/skin toxicity/irritation	3	3 = moderate (caution)
Fire	4	2 = high
Reactivity	4	1 = extreme/corrosive

The above rating is Plant Cell Technology's toxicity rating. It incorporates some EPA criteria.

Company identification

Plant Cell Technology, Inc.
1823 Jefferson Place NW
Washington, DC 20036, USA
+1 202 463 0904 ext. 134 (Martin Kalin)
+1 856 541 1141 (Assaf Guri)
PPM™ is a trademark of Plant Cell Technology, Inc.

Data Sheet

1. Physical Data

- *Appearance*: Clear.
- *Color*: Amber to clear.
- *State*: Liquid.
- *Odor characteristic*: Mild, inoffensive odor.
- *pH*: 3.0–4.0.
- *Solubility in water*: Completely soluble.

2. Ingredients

PPM™ is a proprietary chemical product.

3. Fire and Explosion Hazard Data

- *Flash point*:
  Auto-ignition temperature not applicable.
  Lower explosive limit not applicable.
  Upper explosive limit not applicable.
- *Unusual hazards*. Combination generates toxic fumes of the following: hydrogen chloride, nitrogen oxides, sulfur oxides.
- *Extinguishing agents*. Use extinguishing media appropriate for surrounding fire.
- *Personal protective equipment*. Wear self-contained breathing apparatus (pressure-demand MSHA/NIOSH approved or equivalent) and full protective gear.
- *Special procedures*:
  Use water spray to cool containers exposed to fire.
  Minimize exposure.
  Do not breathe fumes.
  Contain run-off.

4. Health Hazard Data

- *Inhalation*. Inhalation of vapor or mist can cause irritation to the nose and throat.
- *Eye contact*. Material can cause corrosion to eyes – permanent, irreversible eye injury.
- *Skin contact*. Skin irritation effects can be delayed for hours. Material can cause irritation to the skin and allergic contact dermatitis.
- *Ingestion*. Material is harmful if swallowed.

5. First Aid Measures

- *Inhalation*. Move subject to fresh air. Give artificial respiration if breathing has stopped.
- *Ingestion*. If swallowed, *immediately* call and see a physician. Never give anything by mouth to an unconscious person.
- *Eye and skin contact*. Flush eyes *immediately* with a large amount of water for at least 15 min. Wash affected skin areas thoroughly with soap and water. Remove and wash contaminated clothing thoroughly. Do not take clothing home to be laundered. Discard contaminated shoes, belts, and other articles made of leather. Get prompt medical attention.
- *Note to physician*. Material has a pH of 3.0–4.0. It may be advised to induce vomiting. Possible mucosa damage may contraindicate the use of gastric lavage. Measures against circulatory shock and convulsions may be necessary.

6. Reactivity Data

- This material is considered stable under specified conditions of storage, shipment, and/or use.
- Thermal decomposition may yield the following: hydrogen chloride, sulfur dioxide, or oxides of nitrogen.
- Hazardous polymerization: production will not undergo polymerization.

- Incompatibility: avoid contact with oxidizing agents, reducing agents, amines, and mercaptans.

7. Spill or Leak Procedures

Dilute with 100× water. Rinse the decontaminated solution to a chemical sewer.

8. Special Protection Information

- *Personal protection*:
  Wear compatible, chemically resistant gloves.
  Material has a pH of 3.0–4.0. If exposed to material during clean-up operations *immediately* remove all contaminated clothing and wash exposed skin areas with soap and water. See section 5 above on first aid for further information.
  Protective clothing made of the following material should be worn to avoid skin contact: butyl, rubber, or nitrite.
- *Engineering controls (ventilation)*. Use local exhaust ventilation with a minimum capture velocity of 0.75 m s^{-1} (150 ft min^{-1}) at the point of dust or mist evaluation. Refer to the current edition of *Industrial Ventilation: A Manual or Recommended Practice* published by the American Conference of Governmental Industrial Hygienists for information on the design, installation, use, and maintenance of exhaust systems.
- *Other protective equipment*. Facilities storing or utilizing this material should be equipped with an eyewash facility and a safety shower.

9. Handling and Storage

- *Storage conditions*. The maximum recommended storage temperature for this material is 55°C (131°F). The minimum recommended storage temperature for this material is 0°C (32°F). Store in a well ventilated area. Do not store this material in containers made of steel.
- *Handling procedures*. See section 8 above prior to handling. As empty containers retain product residues (vapor and/or liquid), follow all MSDS and label warnings even after containers are emptied.

10. Regulation Information

Workplace classification: this product is considered non-toxic.

11. Toxicological Information

- Oral LD_{50} (rat): 30 g kg^{-1}.
- Eye/skin irritation (rabbit): moderate irritation/insult, reversible damage.
- Sensitization data (human): allergic contact dermatitis possible.

12. Ecological Information

Not available.

13. Disposal Conditions

Dispose of PPM™-containing media as you would non-PPM™ media. Items that are contaminated with full-strength PPM™ should be rinsed liberally (100×) in water. See section 7 above.

14. Transportation Information

The US DOT hazard class is 'non-toxic'; it is classified as a skin irritant.

Disclaimer

The information contained in this appendix relates only to the specific material identified. Plant Cell Technology, Inc. (PCT) believes that such information is accurate and reliable as of the date of this material safety data sheet, but no representation, guarantee, or warranty express or implied, is made as to the accuracy, reliability, or completeness of the information. PCT urges persons receiving this information to make their own determination as to the information's suitability and completeness for their particular application.

Users of PPM™ with orchid ovules, immature seeds, unripe fruits (capsules, "pods"), seeds, protocorms, seedlings, explants, callus, protocorm-like bodies, plantlets, mature plants, leaves, roots, tubers, pseudobulbs, canes, soots, young or old growths, stems, inflorescences, flower stalks, flowers, or any other part of the plant or life cycle of orchids do so at their own risk. The author, publisher, and PCT are not responsible for any damage to humans, animals, plants, property, and equipment or any losses which may result from the use of PPM™ even if such use is in line with instructions in this appendix, this book, or the PCT web sites listed above.

Glossary

ABA, *see* Abscisic acid.

Abaxial, facing away from the axis. In a leaf the abaxial surface is the underside because it faces away from the axis of the trunk or branch.

Abscisic acid (ABA), a plant hormone which is associated with seed maturation, desiccation tolerance, suppression of vivipary, some types of seed dormancy, inhibition of seed germination, senescence, and somatic cell embryogenesis in certain plants, but despite its name does not induce abscission (even if it was originally assumed to do so). This hormone was discovered and named by F. T. Addicott and his associates at the University of California, Davis. Dormin, isolated and named by P. F. Wareing and his co-workers at the University College of Wales, Aberystwyth proved to be the same compound.

Absorption, uptake or the movement of water and/or substances across cell membranes as well as the retention of light by a pigment.

Absorption spectrum, a graph depicting the ability of a substance to absorb light of different wavelengths.

Accessory bud, a bud that occurs near an apical or axillary bud and is usually smaller than either.

Acid, a substance: (1) usually of sour taste, (2) which contains hydrogen that can be replaced by a metal or a positively charged radical (and thereby form a salt), (3) that is capable of being a proton donor, and (4) of generally low pH.

Acropetal, sequence of development or blooming, or movement of a substance or water, toward the apex (the opposite of basipetal).

Activated charcoal, charcoal treated in a manner that increases its adsorptive properties.

Active uptake, intake of substances against a concentration gradient. Such uptake requires expenditure of energy.

Adaxial, facing toward the axis. In a leaf the adaxial surface is the upper side because it faces toward the axis of the trunk or branch.

Adenine, a purine base which is a component of DNA and RNA. When added to culture media (usually as the sulfate), adenine acts as a weak cytokinin. *See also* Cytokinins.

Adhesion, attachment of different molecules to each other.

Adsorbent, a substance that adsorbs other compounds or to which other substances adhere.

Adsorption, attachment or concentration of molecules on the surface of another substance at the boundary or interface between two substances or the formation of a solid, liquid, or gas layer on a solid surface.

Adventitious, an organ or a structure arising at an unusual location or a place where it is not normally found, as for example: buds not at a leaf axil or on roots, shoots and roots on a callus, and embryos from a source other than a zygote.

Aerate, provide, supply, or introduce air.

Aerobic conditions, presence of air (opposite of anaerobic).

Agar, a substance prepared from a specific kind of red algae and used to solidify culture media.

Alba, lacking pigmentation and usually white.

Alcohol lamp, a lamp consisting of a wick dipped in alcohol. It produces a clean, smokeless, hot flame which is used to sterilize tools.

Alkali, base.

Amino acid, an acid with the structure, $NH_2–\underset{\displaystyle R}{\underset{|}{C}}–COOH$

Anaerobic, lacking air (opposite of aerobic).

Aneuploid, situation where an exact multiple of the haploid number of chromosomes is not present.

Angiosperms, plants that produce seeds that are borne within a mature ovary (*compare* Gymnosperms).

Anion, negatively charged ion often designated as A^- (*compare* Cation).

Annual, a plant that completes its life cycle (i.e., goes from seed to seed) in a year or less. There are no annual orchids.

Anther, pollen-bearing part of the stamen.

Anthesis, opening of a flower and full bloom.

Anthocyanin, water-soluble flavonoids which can be blue, mauve, pink, purple, or red and are found in vacuoles.

Antiauxin, an auxin antagonist or a substance which reverses, prevents, or inhibits the effects and/or transport of auxins. Examples are *trans*-cinnamic acid (*t*CA), 2,3,5-tri-iodobenzoic acid (TIBA), and 2,4,5-trichlorophenoxyacetic acid (TCPAA).

Antibiotic, a compound which inhibits or kills microorganisms.

Apex, tip, in roots and stems this is the part which contains the apical meristem. This part is usually excised and cultured in orchid "meristem" culture.

Apical dominance, inhibition of lateral bud growth and branching by the apical meristem.

Apical meristem, group of meristematic cells located at the apex.

Ascorbic acid, or vitamin C, one of the water-soluble vitamins, and an antioxidant.

Aseptic techniques, procedures designed and intended to prevent the introduction of unwanted agents (generally bacteria, fungi, mycoplasma, and viruses) into cultures of desirable organisms and explants (cells, tissues, and organs). These techniques may or may not eliminate internal contaminants (i.e., microorganisms which exist within explants).

Asexual embryogenesis, development of embryos from somatic (body) cells without the involvement of gametes. Asexual embryos or embryo-like structures can also develop from callus masses, cells, or explants in vitro.

Asexual propagation, reproduction which does not involve the sexual process (i.e., there is no meiosis and joining of gametes).

Autocatalytic reaction, reaction which is catalyzed by its own product; the effect of ethylene on its own production is an example.

Autoclave, a sealed or closed chamber in which apparatus, liquids, equipment, glassware, media, and other objects are heated (usually by steam) under pressure (103.4×10^3 Pa at 121°C; see Appendix 6 for definitions of units) for the purpose of sterilization. The usual period of sterilization for most media is 15 min.

Autotrophy, ability of an organism (in actuality a green plant) to manufacture its own food.

Auxin, a plant hormone, naturally occurring or synthetic, that regulates cell division, elongation, and enlargement as well as apical dominance, root initiation and growth, flowering in some instances, ethylene production, and other physiological processes in plants. Indoleacetic acid (IAA), which is used widely in orchid tissue culture and micropropagation, is a naturally occurring auxin. Other auxins used in orchid micropropagation are the synthetics naphthaleneacetic acid (NAA) and 2,4-dichlorophenoxyacetic acid (2,4-D). Auxin was the first plant hormone to be discovered. The discovery was made by F. W. Went (the co-formulator of the widely used Vacin and Went culture medium) while he was a graduate student at Utrecht University in the Netherlands.

Available substance or nutrient, a compound or substance which can be taken up and utilized by a whole plant in soil or an explant in culture.

Axenic culture, a term used to designate a culture of a single organism or one free of both external and internal contaminants.

Axillary bud, a bud located in a leaf axil. Non-adventitious lateral buds are axillary.

BA, *see* Benzyladenine.

Bacteria, plural of bacterium that is unfortunately and erroneously usually used as the singular. Bacteria are prokaryotic (they do not have a well-defined nucleus), single-celled (unicellular) microorganisms which belong to the class Schizomycetes. They can be aerobic or anaerobic, comma shaped (vibrio), corkscrew shaped (spirochaete), filamentous, rod-like (bacillus), spherical (coccus), or spiral (spirillum). Bacteria are common internal or external contaminants.

Bactericide (also bacteriocide), a substance that kills bacteria.

Bacteriostatic substance, a compound that inhibits or slows down bacterial growth and/or reproduction.

Bacterium, *see* Bacteria.

BAP, *see* Benzyladenine.

Bar, a unit used to measure pressure; 1 bar = 1 atmosphere or 10^5 pascals (see Appendix 6 for definitions of units).

Basal, a term with two meanings: (1) Located at the base. (2) Simplest formulation of a culture medium (as in basal versus enriched or supplemented medium).

Base, a term with several meanings: (1) Basal part of a structure. (2) A synonym for basal medium ("base medium"). (3) A nitrogen-containing compound that is a component of RNA and DNA (as in "base pair"). There are five such bases: adenine (A), a purine; cytosine (C), a pyrimidine; guanine (G), a purine; thymine (T), a pyrimidine which should not be confused with thiamin (vitamin B_1); and uracil (U), a pyrimidine. (4) A substance which can accept a proton (H^+), can react with an acid to form a salt, or the hydroxide of a metal.

Basipetal, sequence of development or blooming, or movement of a substance or water, toward the base (the opposite of acropetal).

Benzyladenine (6-benzylaminopurine, N^6-benzyladenine, BA, BAP), a synthetic cytokinin.

Benzylaminopurine, *see* Benzyladenine.

Binomial, the two names (genus and species) of organisms. Example: *Cattleya* (the genus) *intermedia* (the species).

Bioassay, a test (quantitative and/or qualitative) for a substance that utilizes the response(s) of an organism.

Bioreactor, a container, usually a tank, in which organisms, explants, cells, cell extracts, or enzymes carry our life processes or biological/biochemical reactions.

Biotechnology, a term with two meanings: (1) Use of organisms or biological processes in the manufacture of substances. (2) Molecular and/or genetic manipulation of organisms for the purpose of changing them and/or endowing them with new and/or different capabilities.

Biotin, one of the B vitamins. This vitamin is seldom if ever used in orchid tissue culture.

Blackening, darkening of a culture medium due to the release of phenolics by explants. Other terms are bleeding and browning.

Blade, the thin or thick, broad or narrow, flat or terete, extended part of a leaf above the petiole. Lamina is another term.

Bleach, an agent (liquid or powder) which contains free chlorine ions capable of whitening. The most common bleaches used in laboratories are calcium hypochlorite solutions (which must be prepared fresh since they lose their activity within 12 h) and commercial sodium hypochlorite products that are commonly known as domestic bleaches. Clorox, Domestos, Milton's, Snow White, and Purex are some brand names of such solutions, but there are many more. Domestic bleaches usually contain 4.75–6.0% sodium hypochlorite. They are more stable than calcium hypochlorite solutions, especially in unopened bottles, but if a bottle has been opened for a prolonged period it may be wise not to use the bleach for critical work.

Bleeding, *see* Blackening.

Bract, a modified leaf that may occur below the flowers or inflorescences.

Breeding, using sexual reproduction to produce new forms or offspring.

Browning, *see* Blackening.

Buchner flask, thick-walled, flat-bottomed, conical flask with a tube extending from its neck. The tube can be connected to a vacuum source to create suction and to accelerate filtering.

Bud, an undeveloped vegetative shoot and/or flower consisting of undifferentiated meristematic tissue as well as organs in various stages of differentiation. Buds are usually covered and protected by scales (which are modified leaves).

Buffer, a solution which can stabilize pH and resist acidity or alkalinity changes. Hans Burgeff, the German orchid expert, proposed the use of a K_2HPO_4/KH_2PO_4 buffer for the Knudson C medium to reduce acidification caused by seedlings (see Appendix 5 for the recipe). More recent work with orchid seedlings has shown that this acidification may not cause any harm.

Bulb, a modified bud consisting of a flattened, disk-shaped stem and fleshy scale leaves.

Bundle sheath, a sheath of parenchyma cells that surrounds vascular bundles.

Bunsen burner, a commonly used burner in laboratories that mixes air and gas to produce a hot, clean, smokeless flame. This burner was invented by the chemist Robert Bunsen ca. 1855 when he moved to the University of Heidelberg. As a condition for the move, Bunsen wanted a new laboratory building with gas piping. His innovation was to mix air and gas, not at the point of combustion, but before that. He (with co-author Henry Roscoe) wrote: "The principle of this burner is simply that city gas is allowed to issue under such conditions that by its own movement it carries along and mixes with itself precisely enough air so that the resulting air-bearing gas mixture is just at the limit where it has not yet acquired the ability to propagate the flame through itself." *See also* Erlenmeyer flask (which was invented at the same university).

C_3 or C3 cycle, the Calvin–Benson–Bassham pathway of carbon fixation in photosynthesis in which the three-carbon molecule, 3-phosphoglyceric acid, is the first stable product.

C_4 or C4 cycle, the Hatch and Slack pathway of carbon fixation in photosynthesis in which four-carbon molecules are the first stable products.

Callus, a term with three meanings: (1) A mass of (usually) large, thin-walled, and undifferentiated cells, which develops on a plant following wounding or infection by certain bacteria. (2) A group of cells as in meaning 1 that develops on a plant following hormone applications. (3) An undifferentiated or partially differentiated, unorganized, actively dividing mass of cells developing from an explant or individual cells in vitro.

Callus culture, the culture of a callus mass on solid medium or in liquid medium for the purpose of increasing its size or inducing organogenesis.

Calory, heat required to raise the temperature of 1 g of water by 1° from 14.5 to 15.5°C. This is also known as a gram-calory; 1 calory = 4.19 joules, 1000 calories = 1 kilocalory.

CAM, *see* Crassulacean acid metabolism.

Cambium, a one- or two-cell-thick layer of meristematic cells which gives rise to secondary tissues. Most monocotyledonous plants, orchids included, do not have cambium.

Capsule, a simple, dry, dehiscent fruit consisting of two or more carpels. Orchid fruits are capsules, not pods.

Carbohydrate, a substance composed of carbon, hydrogen, and oxygen in the ratio of 1C : 2H : 1O (CH_2O). Sugars are carbohydrates.

Carbon fixation, a reaction in which carbon from carbon dioxide is attached to a receptor and made part of an organism (essentially what occurs in photosynthesis).

Carcinogen, a substance that can cause cancer.

Carotene, a lipid-soluble, orange or orange-reddish, plastid pigment.

Carotenoid, lipid-soluble, orange, red, or orange-red pigments located in chromoplasts in fruits and flowers.

Carpel, a modified leaf (floral leaf) that bears and can enclose ovules.

Casein hydrolysate, a complex organic mixture, sometimes added to culture media, consisting of peptides and amino acids. It is produced through hydrolysis (acid or enzymatic) of casein (the proteins found in milk).

Cation, positively charged ion often designated as M^+ (*compare* Anion).

Cation exchange, replacement of one cation by another on negatively charged particles.

Cell, structural and physiological component of organisms, the smallest unit capable of carrying out life processes.

Cell culture, in vitro culture of cells isolated from multicellular organisms.

Cell cycle, stages in the life of a cell from one division to the next.

Cell differentiation, process in which cells become specialized.

Cell division, production or formation of two or more cells from an existing cell.

Cell fusion, formation of one hybrid cell through the joining of two cells.

Cell hybridization, fusion of two different cells to form a new hybrid cell.

Cell membrane, a membrane that surrounds the cytoplasm and is found just inside the cell wall.

Cell sap, aqueous solution of sugars, amino acids, organic acids, pigments, wastes, and other materials found in vacuoles.

Cell suspension, cells in culture in a liquid medium.

Cell wall, a rigid external structure that surrounds plant cells.

Cellulase, enzyme which breaks down cellulose.

Cellulose, carbohydrate found in plant cell walls. It is an unbranched chain of β-D-glucose in 1,4 linkages.

Centrifuge, laboratory apparatus that separates particles of various sizes and weights by generating gravity forces through rotation.

Chemically defined medium, a culture medium containing components which are of known and defined chemical nature.

Chlorenchyma, parenchyma tissue containing chloroplasts (and chlorophyll).

Chlorophyll, green pigment found in chloroplasts. It absorbs light energy which is used in photosynthesis.

Chloroplast, a chlorophyll-containing plastid.

Chlorosis, reduction in or loss of chlorophyll content.

Chromoplast, a plastid that contains yellow, orange, or red lipid-soluble pigments.

Cladophyll, a shoot which resembles a leaf.

Clonal propagation, multiplication of genetically identical plants.

Clone, cells or organisms (plant or animal) which are derived from a single cell or organism (plant or animal) and are genetically identical (except for possible genetic changes which can occur or may be induced by the propagation procedure).

Cloning, production of clones.

Coalescence, fusion of separate segments in a floral whorl.

Coconut milk, a white liquid obtained by grating or squeezing the solid endosperm or copra. *See* Coconut water.

Coconut water, colorless, liquid endosperm of coconuts, sometimes erroneously called coconut milk, which is added to some culture media. *See* Coconut milk.

Co-enzyme, a non-protein, low molecular weight substance which is necessary for or promotes enzyme activity.
Cohesion, union of floral parts of the same floral whorl.
Colchicine, alkaloid derived from *Colcichum autumnale*, which inhibits spindle formation during cell division, thereby preventing the separation of chromosomes and leading to cells which have multiple chromosome sets. It is used to increase (usually double) chromosome numbers in orchids and other plants.
Collenchyma, strengthening tissue consisting of thick-walled cells.
Colony, closely associated, poorly differentiated cells in culture.
Compensation point, conditions under which photosynthesis equals respiration.
Complete flower, a flower that has sepals, petals, stamens, and carpels.
Complex additive, an additive to a medium whose composition is either not fully known or very elaborate. Examples are coconut water and banana homogenate.
Conduction, movement of water and other substances through the plant.
Corm, a modified, enlarged, food-storing stem usually found underground.
Cortex, parenchymatous tissue in roots and stems located between the epidermis and pericycle or phloem, respectively.
Crassulacean acid metabolism (CAM), fixation of carbon to malic acid in the dark by succulent plants.
Cryopreservation, preservation of cells, tissue, seeds, and pollen under very low temperatures.
Cryoprotectant, a substance which prevents cell damage during freezing and thawing in cryopreservation. Examples include dextrans, dimethylsulfoxide, ethylene glycol, glycerol, hydroxyethyl starch, polyvinylpyrrolidone, and sugars.
Cultivar, plants found only in cultivation and possessing specific characteristics which distinguish them from other plants of the same kind.
Cuticle, cutin layer on the outer walls of epidermis cells. *See also* Cutin.
Cutin, a waxy substance, slightly permeable or impermeable to water vapor, liquid water, and gasses.
Cytogenetics, study of chromosomes and their role in taxonomy, genetics, variability, and other plant characteristics.
Cytokinesis, cytoplasm division in cells; it follows nuclear division (karyokinesis). *See* Meiosis, Mitosis.
Cytokinins, plant hormones, many (but not all) of which contain adenine. They control cell division and differentiation. In vitro they induce bud and shoot formation. Examples are the naturally occurring zeatin and isopentenyl adenosine as well as the synthetic benzyladenine, dimethylaminopurine, kinetin, and thidiazurone. Kinetin, the first known cytokinin was discovered and isolated ca. 1955 by Carlos Miller, Folke Skoog, and their associates in the botany department at the University of Wisconsin.
Cytology, science of cell structure and function.
Cytoplast, intact cytoplasm that remains following the removal of the nucleus.
Cytotoxic, toxic to cells.
2,4-D, *see* 2,4-Dichlorophenoxyacetic acid.

Day-neutral plant, a plant that flowers regardless of day length (*compare* Long day plant, Short day plant).

Deoxyribonucleic acid (DNA), a large helical molecule that carries hereditary information.

Development, changes in organisms, tissues, and cells, which result in the formation and appearance of features and characteristics which make possible the performance of specific and characteristic functions.

Dextrose, glucose.

2,4-Dichlorophenoxyacetic acid (2,4-D), a synthetic auxin and selective herbicide (it kills dicotyledonous plants) which is often added to tissue culture media at very low concentrations.

Dicotyledonous plant, a plant with two seed leaves (cotyledons). Also referred to as a broad leaf plant. Orchids are monocotyledonous plants, but the seeds of most species do not have a cotyledon.

Differentially permeable membrane, a membrane through which different substances move at different rates and varying ease. Some substances cannot diffuse through such membranes. Others may move freely.

Differentiation, formation of new functions, structures, organs, and specializations.

Diffusion, movement of molecules of a substance from an area of its own higher concentration to an area of it own lower concentration.

Dimethylsulfoxide (DMSO), a versatile solvent.

Diploid, presence of two sets of chromosomes, $2n$, as in body (somatic) cells. Contrast with haploid, $1n$, as in reproductive cells.

Disaccharide, a sugar consisting of two linked, simple, sugar molecules. Sucrose, which consists of one glucose molecule and one fructose molecule, is an example.

Disinfection, removal or destruction of undesirable microorganisms.

Diurnal, an event which occurs every 24 h.

DMSO, *see* Dimethylsulfoxide.

DNA, *see* Deoxyribonucleic acid.

Dormancy, state of arrested growth during which buds, seed, tubers, corms, bulbs, and other structures do not grow. Environmental cues such as cold temperature and photoperiod can break dormancy and bring about the resumption of growth.

Dorsiventral, a structure with two distinctly different upper and lower surfaces, as for example a leaf.

Dry weight (DW or D. W.), water-free weight of tissue.

EDTA, see Ethylene diamine tetraacetic acid.

Egg (ovum), female gamete.

Embryo, young sporophytic plant or immature organism before the start of rapid growth and development.

Embryo culture, the culture of embryos on a medium in vitro.

Embryo sac, female gametophyte of seed-producing plants (angiosperms).

Embryogenesis (embryogeny), development or formation of an embryo.

Embryoid, embryo-like structure, which may develop in vitro.

Emulsion, suspension in liquid of fine particles.

Endemic, an organism which is found or restricted to a specific region.

Endodermis, a single layer of thick-walled cells which forms a sheath around the vascular tissue, mostly in roots, but sometimes in stems. Cells of this layer have thickenings called Casparian strips. It is the innermost layer of the cortex.

Endogenous, from within. Opposite of exogenous.

Endosperm, nutritive tissue found in seeds. Most orchid seeds lack an endosperm.
Epidermis, the outermost layer of cells on all plant parts.
Epiphyte, an organism, often a plant, which grows on another plant. Many orchids are epiphytes.
Erlenmeyer flask, flat-bottomed conical flask with a wide or narrow neck, often used as a culture vessel, especially in research laboratories. Named after Emil Erlenmeyer, Professor of Chemistry in Heidelberg between 1863 and 1867, who designed it. *See also* Bunsen burner (which was invented at the same university).
Essential element, mineral elements required for normal plant growth and/or completion of the life cycle; also referred to as essential mineral or essential inorganic nutrient.
Ethanol, a disinfectant and solvent (ethyl alcohol, drinking alcohol).
Ethephon, a substance which breaks down to produce ethylene. It can be added to cultures, but it is almost never used in orchid micropropagation.
Ethyl alcohol, *see* Ethanol.
Ethylene, a gaseous plant hormone involved in senescence, ripening, and abscission.
Ethylene diamine tetraacetic acid (EDTA), a chelating agent used to chelate iron in culture media.
Etiolation, excessive stem elongation, abnormal development, and reduced or no chlorophyll content associated with insufficient illumination.
Eukaryote, organism with a well-defined nucleus surrounded by a membrane. Higher plants including orchids are eukaryotes.
Euploid, an organism with a chromosome number which is an exact multiple of the 1*n* number.
Ex situ conservation, conservation through the removal of a plant (or another organism) from its native habitat and maintaining it in a different location.
Exogenous, from an external source. Opposite of endogenous.
Explant, a section of tissue (usually small) or part of an organ taken from a plant and placed in a culture medium.
Exudate, produced through exudation.
Exudation, slow release or leakage of a substance.

F_1, first filial generation of a cross or mating ($P♀_1 \times P♂_1 = F_1$).
F_2, second filial generation produced by crossing or self-pollinating individuals of the F_1 generation. The offspring of the F_1 generation and "grand offspring" of the parents of the P_1 generation ($F♀_1 \times F♂_1 = F_2$). These terms are often misused by practical breeders.
Family, a group of genera. The Orchidaceae is a family.
Fertilization, a term with two meanings: (1) Addition of nutrients. (2) Fusion of two gametes.
Filter sterilization, sterilizing a liquid by passing it through a filter with holes which are small enough to retain contaminating microorganisms, but large enough to allow the passage of solute(s) and solvent(s).
Filtration, a term with two meanings: (1) Separation of particles from liquid or each other by passing a mixture through a paper or porous membrane with appropriate size pores. (2) Separation of cell clumps or aggregates from single cells in a culture.
Flavonoids, water-soluble pigments of colors ranging from yellow to blue.

Flaming, sterilizing an instrument by dipping it in alcohol, which is ignited by passing it through a flame.

Foot candle, a unit of light intensity mainly designed to measure brightness in terms of the human eye. The unit is not an appropriate measure of light energy as it applies to plants. 1 ft-c = 10.76 lux or meter candles (see section on light in Chapter 2).

Formula weight (FW), usually used to describe the molecular weight of a substance plus waters of hydration.

Freeze drying, drying cells, tissues, and organs under vacuum while they are frozen (lyophilization, cryopreservation).

Fresh weight (FW or F. W.), weight of tissues or organs including their water content.

Friable, callus which crumbles or falls apart easily.

Fungicide, a substance which can kill fungi.

FW, *see* Formula weight, Fresh weight.

Gamete, reproductive cell which can fuse with another cell of the same nature, but of the opposite sex. The result is a zygote.

Gametophyte, stage in the flowering plant life cycle that can produce gametes. This stage has 1*n* number of chromosomes. In flowering plants the pollen grain is the male gametophyte and the embryo sac is its female counterpart.

Gel, a jelly-like colloidal state.

Gellan gum, polysaccharide derived from *Pseudomonas* and used as a gelling agent. *See* Gelrite, Phytagel.

Gelrite, a proprietary trademark and brand name of a refined polysaccharide derived from *Pseudomonas* and used as a gelling agent.

Gene, unit of heredity consisting of DNA base pair sequences, which codes for RNA and protein.

Genetic engineering, manipulation of heredity and hereditary material for industrial, agricultural, medical, military, or other purposes.

Genetics, study and science of heredity.

Genome, entire genetic information in an organism or cell.

Genus, unit of classification consisting of one or more species. Several genera make up a family.

Geotropism, a term for gravitropism which is no longer used.

Germination, start of growth of a seed, spore, or pollen grain.

Gibberellins, a group of plant hormones that control or regulate elongation, flowering, fruit development, bolting, germination, vernalization, enzyme production, and other processes. These hormones were discovered by E. Kurosawa in 1926 while he was studying a rice disease in Taiwan (then called Formosa and part of the Japanese Empire).

Glucose, a six-carbon sugar. It is the most common sugar in plants, and is found in blood (hence called blood sugar). Also known as dextrose.

Glycine, an amino acid which is added to some culture media based on the Murashige–Skoog medium.

Gram molecular weight, number of grams equivalent to the molecular weight of a substance, a mole.

Gravitropism, response of plant organs to gravity.

Gro-Lux lamps, a trademark and brand name for wide spectrum fluorescent lamps which are used to illuminate plant cultures. Similar lamps are also marketed under other brand names (see section on light in Chapter 2).
Ground meristem, a meristem which produces ground tissues such as cortex and pith.
Growth, increase in size, weight, volume, and/or number of cells.
Growth factor, substance that affects growth.
Growth inhibitor, substance that inhibits growth.
Growth regulator, substance that regulates growth.
Growth retardant, substance that inhibits or retards growth.
Guard cells, two epidermal cells which surround and regulate the size of a stoma.
Gymnosperms, plants that produce seeds not in an ovary. Cone-bearing plants (conifers) are an example (*compare* Angiosperms).
Gynoecium, all of the carpels in a flower.

Hair, an outgrowth consisting of one or more cells which looks like a human hair (hence its name). Plant hairs can be adsorptive (like root hairs and rhizoids) or secretory (glandular). Despite its frequent use, the term "hair" is not favored by plant scientists who prefer the terms trichome or rhizoid except in the case of "root hairs."
Haploid, organism or life cycle phase with only a single set of chromosomes ($1n$). Contrast with diploid $2n$, as in somatic cells.
Herb, a plant lacking woody tissues; a soft, grass-like plant.
Herbaceous, adjective pertaining to herb.
Herbicide, substance which is toxic to or can kill plants. Some herbicides are hormonal in nature and if used in very low concentrations can be beneficial in tissue cultures. An example is 2,4-D.
Heterotrophic, deriving nutrients from another source.
Heterozygous, containing different alleles of the same trait, as for example, T (tall) and t (short) in the same plant (Tt). Appearance is not always indicative of the alleles that may be present in a plant.
Hormone, a substance with a very specific function which may be produced in one part of a plant and transported to another where it exerts its effects. Hormones usually are effective at very low concentrations. Synthetic analogs are available for some hormones. The first person to suggest that plants may have hormones was the German plant physiologist, Hans Fitting in 1909. He made the suggestion as a result of his work on the effects of pollen on *Phalaenopsis* flowers at the Bogor Botanical Gardens in Indonesia.
Hydrolysis, breaking down or splitting of a substance through the addition of water.
Hydroxy group, OH^-.
Hypertonic, solution of a concentration or osmotic potential relatively higher than that of another (sometimes adjacent) solution or cell. It is important to keep in mind that tonicity is determined by the molarity of a solution, not by its weight, percent, or parts per million of a solute.
Hypha, fungal filament.
Hypotonic, solution of a concentration or osmotic potential relatively lower than that of another (sometimes adjacent) solution or cell. It is important to keep in mind that tonicity is determined by the molarity of a solution, not by its weight, percent, or parts per million of a solute.

IAA, see Indoleacetic acid.
IBA, *see* Indolebutyric acid.
Illumination, providing light.
In vitro, literally "in glass," but meaning "in a culture vessel." Sometimes used (not entirely correctly) as the opposite of ex situ.
In vitro propagation, plant propagation in culture media in vessels. *See also* Micropropagation.
Indoleacetic acid (IAA), a naturally occurring auxin which is used in many culture media.
Indolebutyric acid (IBA), an auxin which is used in many culture media.
Inoculate, placing explant or cells into or on culture medium.
Inositol, hexahydroxycyclohexane, a polyol (sugar alcohol) which is added to many culture media.
Internode, area of a stem or inflorescence between two nodes.
Isodiametric, of the same diameter in all directions as in "isodiametric cell."
Isotonic, a solution of a concentration or osmotic potential equal to that of another (sometimes adjacent) solution or cell. It is important to keep in mind that tonicity is determined not by weight, percent, or parts per million of a solute, but by its molarity.

J m^{-2}, joule per square meter, a unit of light measurement (but *see* PAR). Also written as J/m^2, which is not the preferred form. *See also* Joule.
Joule (J), energy required to apply a force of 1 newton (N) over a 1-m distance.
Juvenility, early stages of development. During these stages, plants usually do not flower although in some cases very young orchid plantlets or seedlings have flowered in vitro.

Karyokinesis, division of the nucleus; it precedes cytokinesis. *See* Meiosis, Mitosis.
Karyotype, all of the chromosomes of an individual plant usually during metaphase arranged according to length, in a manner which shows their morphology and position of the centromere.
Kinetin, a synthetic cytokinin (6-furfuryl aminopurine, furfuryl adenine) which is often added to culture media. This was the first cytokinin to be isolated and identified. The work was carried out by Carlos Miller (then a graduate student) and his mentor, Folke Skoog, at the department of botany, University of Wisconsin.
Kranz anatomy, wreath-like (from the German *Kranz* meaning wreath) layers of chloroplast-rich cells which surround vascular bundles. Typical of C_4 plants.

Lactose, milk sugar; a disaccharide consisting of one galactose and one glucose molecule, and never used in orchid tissue culture media.
Lamina, *see* Blade.
Laminar flow hood, a cabinet for the preparation of cultures and other work which requires sterile conditions. Sterility of the air inside the hood is maintained by passing it through a filter. It is important to keep in mind that the work surface inside the hood as well as any equipment and apparatus inside it will not be sterile unless they are sterilized properly.

Lateral bud, a bud found on the side of a stem in the axil of a leaf (axillary bud).
Lateral meristem, a meristem that produces secondary tissues like the vascular cambium (itself a meristematic tissue).
Lateral root, a root that branches out of an older or primary root.
Leaf primordium, a lateral outgrowth on the apical meristem which develops into a leaf.
Levulose, fructose, a six-carbon sugar.
Liquid medium, a medium that does not contain a solidifier.
Log phase (log growth phase), phase during which growth or increase in number of cells is most intense or vigorous.
Long day plant, a plant that requires a light period longer than a specific critical minimum to flower.
Lux, a measure of illuminance. This is a metric unit designed to replace the foot candle (1 lx = 0.09 ft-c). Both of these units measure light intensity in terms of human vision rather than the wavelengths which support plant growth. *See also* PAR and section on light in Chapter 2.
Lyophilize, dehydration that follows rapid freezing.
Lysosome, a vacuole that contains digestive enzymes.

Macerate, breaking down tissue through cutting or digesting with enzymes to cause cell dissociation or protoplast formation.
Macroelement, an essential element which is required in relatively large amounts. A recent suggestion is that to be a macronutrient, an element must be present at a concentration higher that 0.5 mmol l^{-1}.
Mannitol, a sugar alcohol commonly used as an osmoticum in suspension solutions or media for plant protoplasts.
Media, plural of medium, which is routinely used incorrectly as the singular. *See* Medium.
Medium, a solution, formulation, or combination of nutrients and growth factors used for the culture of cells, explants, tissues, or organs.
Megaspore, the haploid ($1n$) spore in higher plants which gives rise to the female gametophyte.
Meiosis, two successive divisions of the nucleus which reduce the chromosome number from $2n$ to $1n$. Segregation of genes results from the reduction in chromosome number.
Mericloning, a practically and commercially very clever, but scientifically incorrect and linguistically abominable (especially when made into a verb), term derived by compressing "meristem" and "cloning." It was proposed by Gene Crocker, then a lieutenant and subsequently an orchid grower for Carter & Holmes Orchids (Newberry South Carolina). Gordon W. Dillon, long time editor of the *American Orchid Society Bulletin* called attention to the term in 1964 and it became popular instantaneously.
Meristem, undifferentiated and constantly young cells capable of continued division, found in tissues located at stem and root apices.
Meristem culture, culture in vitro of excised apices which contain a meristem. The most commonly cultured apices in orchids are those of shoots, but root tips are also cultured. This term is actually a misnomer because what is actually being

cultured is a shoot tip. In common usage the word meristem has been adulterated into a verb ("to meristem") and a professional description ("a meristemmer"). Both are linguistic abominations. A commonly accepted misconception is that Georges Morel of France was the first to culture a meristem. Actually, Ernest Ball (in the USA) and Loo Shih Wei (in the USA, but he returned to his native China soon after reporting his pioneering work) were the first to culture meristems (independently of each other) in 1946 and 1945–1946, respectively. The first to culture an orchid meristem was Hans Thomale in Germany in 1954. Morel reported his work in 1960 in an article which does not meet scientific standards.

MES, *see* Morpholineethane sulfonic acid.

Metabolism, chemical processes that occur in living cells and organisms.

Microelement, an essential element which is required by plants in very small amounts.

Micrometer, one millionth (10^{-6}) of a meter, or 0.001 mm; abbreviated as μm.

Micromolar, a concentration of one micromole per liter; abbreviated as μ*M*.

Micromole, one millionth of a mole; abbreviated as μmole, not μ*M*, which means micromolar.

Micron, an older, no longer used name for a micrometer; abbreviated as μ.

Micronutrient, *see* Microelement.

Micropropagation, multiplication by means of explants cultured in vitro.

Middle lamella, layer of pectic substances which cements two adjacent cells.

Milligram, one thousandth (0.001 or 10^{-3}) of a gram; abbreviated as mg.

Millimeter, one thousandth (0.001 or 10^{-3}) of a meter; abbreviated as mm.

Millimole, one thousandth (0.001 or 10^{-3}) of a mole; abbreviated as mmole, not m*M*, which means millimolar.

Mitochondrion, a small cell organelle where aerobic respiration, oxidative phosphorylation, and adenosine triphosphate (ATP) production take place.

Mitosis, division and separation of chromosomes that leads to the production of two nuclei. It is followed by cytokinesis, which results in two new cells.

Molality, number of moles added to a liter of solvent (i.e., solute in 1 l of solvent).

Molar, usually referring to concentration in terms of moles; usually abbreviated as M or *M*.

Molarity, number of moles in a solution adjusted to the total volume of one liter (i.e., the volume of the solute plus the volume of the solvent together are 1 l). The difference between molarity and molality is that in the latter, the volume of solvent is always exactly 1 l, whereas in the former the volume of solvent is 1 l minus the volume of the solute. A molal solution is prepared by mixing the solute with 1 l of solvent. Molar solutions are prepared in volumetric flasks by adding solvent to the solute until the total volume reaches 1 l. Equimolar, not equal weight, solutions must be used in comparing the effects of substance on explants.

Mole, weight of a substance in which the number of grams is equal to the molecular weight of the compound. A mole contains Avogadro's number of atoms, 6.023×10^{23}.

Molecular biology, combination of genetics and biochemistry.

Molecular weight, weight of a molecule of a substance.

Molecule, smallest unit of matter or substance which retains its chemical identity; it may consist of one or more atoms.

Monocotyledonous plant (monocotyledon, monocot), a plant whose embryo has one cotyledon (seed leaf). Orchids are considered to be monocotyledonous plants despite the fact that the seeds of most species do not have cotyledons. They have other monocot characteristics.

Monoploid, *see* Haploid.

Monosaccharide, a simple sugar, as for example the six-carbon sugar glucose, which cannot be broken into a smaller sugar molecule.

Morphogenesis, development of form and shape.

Morpholineethane sulfonic acid (MES), a compound used in the formulation of buffers.

Morphology, a term with two meanings: (1) The science and study of form and its development. (2) Generally, shape and form.

MS medium, *see* Murashige–Skoog medium.

Murashige–Skoog (MS) medium, a medium used in tissue culture.

Mutant, variant caused by sudden genetic change(s).

Mutation, process of causing a mutant.

Mutualism, the living together of two or more organisms in a mutually beneficial manner.

MW, molecular weight.

Mycelium, hyphae that make the body of a fungus.

Mycorrhiza, a mutualistic association between a fungus and the roots of a plant. The term was coined by the German botanist Albert Bernhard Frank (1839–1900). Orchids have mycorrhiza.

NAA, *see* α-Naphthaleneacetic acid.

Nanogram, one millionth (10^{-6}) of a milligram or one billionth (10^{-9}) of a gram; abbreviated as ng.

Nanometer, one millionth (10^{-6}) of a millimeter or one billionth (10^{-9}) of a meter; abbreviated as nm. Older terms are millimicron (mμ) or 10 angstrom (10 Å).

Nanomole, one millionth (10^{-6}) of a millimole or one billionth (10^{-9}) of a mole; abbreviated as nmole, not n*M*, which means nanomolar and refers to concentration.

α-Naphthaleneacetic acid (NAA), a synthetic auxin used in many culture media.

Niacin (nicotinic acid), a water-soluble vitamin often added to tissue culture media.

Nitrate, NO_3^-, a form of nitrogen which can be taken up and used directly by plants.

Nodal culture, culture of lateral buds usually with some adjacent stem tissue.

Node, location on a stem where leaves and buds arise and are located.

Nucleus, a body in a eukaryotic cell enveloped by a membrane and containing chromosomes and DNA. All plant cells except sieve tube elements have nuclei.

Nurse culture, culturing plant cells or tissue of one kind of plant on a culture of another kind of plant. The two cultures may be in direct contact or separated from each other by a membrane or filter paper.

Nutrient, a substance that provides sustenance.

Nutrient solution, a combination of macro- and microelements, a carbon (energy) source (most commonly sucrose), hormones, vitamins, sometimes amino acid(s), and a polyol, as well as complex additives (coconut water, casein, banana homogenate, etc.) used for the culture of cells, organs, tissues, and other explants.

Offshoot, a side growth from a stem often produced from the crown near soil level.
Offspring, new progeny produced by an existing organism. Both the plural and singular forms of this word are the same.
Oligosaccharide, a larger sugar molecule consisting of several linked sugar molecules.
Organ, several tissues that function together morphologically and physiologically and form a specific part of an organism.
Organ culture, culture of an entire organ in vitro.
Organelle, a specialized structure within a cell which performs a specific function, as for example chloroplast or mitochondrion.
Organic, a compound containing carbon.
Organogenesis, formation of organs.
Ortet, a term coined in 1929 to designate the "original plant of seedling origin from which members of a clone" have originated (for more extensive discussions of the term see Stout, 1929; Krikorian, 1982).
Osmosis, diffusion through a semipermeable membrane.
Ovary, enlarged basal part of the pistil; it becomes the fruit.
Ovule, a reproductive structure consisting of the embryo sac, egg cells, and integuments surrounded by the nucellus.

Palisade parenchyma, a tissue layer consisting of elongated chloroplast-rich cells positioned at a right angle to the surface and found just below the upper epidermis of a leaf.
PAR, *see* Photosynthetically active radiation.
Paradermal section, a section cut parallel to a flat surface.
Parenchyma, tissue made up of parenchyma cells. *See* Parenchyma cell.
Parenchyma cell, living, thin-walled, undifferentiated cells; the most common cell type in plants.
Parthenocarpy, development of a fruit without fertilization.
Parthenogenesis, formation of a seed without fertilization.
Parts per million (ppm), 1 mg per liter.
Pectin, a jelly-like substance which forms the middle lamella and cements cells to each other.
Pedicel, stalk of an individual flower on an inflorescence; it is located just below the ovary and is contiguous with it.
Peduncle, stalk of an inflorescence or a flower born singly.
Pentose, a five-carbon sugar.
Permeable, a membrane through which substances can diffuse.
Petal, part of the corolla (the usually colored floral segments).
Petiole, stalk of a leaf.
Petri dish, flat, round culture dish. Invented by L. Petri (1875–1946).
pH, a term or symbol which indicates the concentration of hydrogen ions (H^+) in a solution. pH 7 (the reciprocal of 1×10^{-7} which is the number of dissociated water molecules) is neutral. Values from 0 to 7 are indicative of acidity (the lower the number, the higher the H^+ level and the more acid the solution). Numbers between 7 and 14 are alkaline (the higher the number, the lower the H^+ levels and the more alkaline the solution). pH levels can be measured electronically or with indicator papers.

Phenolics, substances which have hydroxyl group(s) on benzene rings. They are produced from newly excised tissues, diffuse into the culture medium, become oxidized, and form dark colored compounds, which in addition to being unsightly may also be deleterious.

Phloem, conductive tissue in plants made of living cells called sieve elements, which transports organic substances. The sieve elements have no nuclei. They share the nuclei of adjacent companion cells.

Photon, elementary light particle; a quantum of light whose energy is proportional to its frequency and is expressed by the formula $E - h\nu$ where E is energy, h is Plank's constant or 6.62×10^{-27} erg-second, and ν is frequency.

Photoperiod, period of illumination, relative period of light, or length of day.

Photoperiodism, response of organisms to relative periods of light and dark.

Photosynthesis, synthesis of carbohydrates from carbon dioxide and water in the presence of chlorophyll, using light energy which was converted to chemical energy.

Photosynthetically active radiation (**PAR**), the wavelengths of light that are active in photosynthesis.

Phototropism, growth or bending toward light.

Phyllotaxy, phyllotaxis, arrangement of leaves on a stem.

Physiology, physical and chemical activities and functions of living organisms.

Phytagel, a proprietary trademark and brand name of a refined polysaccharide derived from *Pseudomonas* and used as a gelling agent.

Phytoalexin, a substance produced by plants to ward off attacks by fungi and bacteria. The French botanist Noël Bernard, discoverer of the role of mycorrhiza in orchid seed germination, also discovered phytoalexins while working on the interactions between orchids and their mycorrhizal fungi, just before his death. His findings were published in 1911 in a posthumous paper written by his mentor J. Costantin and his cousin J. Magrou.

Phytohormone, plant hormone, chemical regulators of plant growth and development which include abscisic acid, auxins, cytokinins, ethylene, and gibberellins. The first person to suggest the existence of plant hormones was the German plant physiologist Hans Fitting who formulated the concept as a result of his work (in the Bogor Botanical Gardens in Indonesia) on the effects of pollination on *Phalaenopsis* flowers, which was published in 1909. Auxin, the first plant hormone and the one intimated by Fitting who called it *Pollenhormon*, was discovered by Frits W. Went in 1926.

Phytokinin, an older and no longer used name for cytokinin.

Pigment, a substance which absorbs light, usually selectively.

Plantlet, a small complete (roots and shoots) plant derived from cultured cells, an explant, or a callus. It is incorrect to use "seedling" to describe such a plant.

Plasma membrane, *see* Plasmalemma.

Plasmalemma, a membrane that surrounds the cytoplasm.

Plasmolysis, shrinking of the cytoplasm and separation from the cell wall due to loss of water.

Plastid, a cytoplasmic organelle which contains lipid-soluble pigments.

PLB, *see* Protocorm-like body.

Ploidy, number of chromosome complements (sets), as for example haploid ($1n$), diploid ($2n$), triploid ($3n$), tetraploid ($4n$) to N-ploid (Nn).

Polyploid, cell, tissue, or organism with more than one complement (complete set) of chromosomes.

Polysaccharide, long chain molecule like cellulose and starch composed from monosaccharides.

Polyvinylpyrrolidone (PVP), a substance used in micropropagation media as an adsorbent, antioxidant, or osmoticum.

ppm, parts per million.

PPM, Plant Preservative Mixture, a proprietary preparation that combats contamination in cultures.

Primary growth, a growth that originates from primary meristems.

Primordium, a mass of cells which produces a specific structure like an organ.

Progeny, offspring.

Proliferation, relatively rapid increase (but not always so) brought about by constant, frequent, and repeated cell division.

Protein, a large molecule consisting of polypeptides which are made of amino acid chains. The term was coined in 1838 by the Swedish chemist Jons Jacob Berzelius (1779–1848) who also named methyl alcohol and invented modern filter paper. Despite his many achievements, Berzelius repressed the French chemist Auguste Laurent who proposed valid ideas regarding organic structures.

Protocorm, a structure produced by germinating orchid seeds. The term was coined by Mechior Treub (1851–1910), long time director of the Bogor Botanical Gardens in Indonesia, to describe the early stages of lycopod seedlings. It was not coined by Noël Bernard, as is often stated erroneously [most recently by P. J. Cribb (1999) in the first volume of the otherwise excellent *Genera Orchidacearum*]. This term should be used only for structures produced by seeds. *See* Protocorm-like body.

Protocorm-like body (PLB), a structure which resembles a protocorm but is produced by an explant or a tissue derived from an explant.

Protoplasm, living substance of cells.

Protoplast, cytoplasm surrounded by plasmalemma and freed of the cell wall.

Purine, one type of nucleotide bases (adenine and guanine) found in DNA and RNA. Adenine is a component of cytokinins.

Pyridoxin, vitamin B_6, which is often added to culture media.

Pyrimidine, a single ring nitrogenous base found in DNA and RNA such as cytosine or thymine (which should not be confused with vitamin B_1, thiamin, or thiamine).

Quantum, elemental unit of light energy whose value is hv, where h is Plank's constant, 6.62×10^{-27} erg-second and v is the vibration frequency of the light wave. *See also* Photon.

Quarantine, a term with two meanings: (1) Keeping an organism or human in isolation if there is a danger of a disease. (2) Restrictions in the shipping of organisms to prevent the spread of diseases.

Raceme, an inflorescence with an elongated main axis (rachis) which bears flowers that have pedicels (floral stalks). Most orchid inflorescences are racemes, not spikes.

Rachis, axis of an inflorescence. Traditionally the term was applied to the axis of a spike. However, at present usage has extended to the axis of most inflorescences.

Raphide, a needle-shaped crystal made of calcium oxalate and found in many cells.
Reproduction, giving rise to offspring sexually or asexually.
Respiration, biological oxidation of molecules with the release of energy.
Rhizoid, a hair-like structure.
Rhizome, a modified stem usually located underground or at ground level.
Ribose, a five-carbon sugar.
rpm, revolutions per minute.

Sap, the liquid content of phloem, vacuoles, and xylem.
Seed, a mature ovule.
Seedling, a young plant formed by a germinating seed.
Semiliquid, *see* Semisolid.
Semipermeable membrane, a partially permeable membrane; some substances can pass through it, but others cannot.
Semisolid, a medium solidified with a small amount of solidifier; semiliquid.
Senescence, an aging process in which cells and tissue lose functions, degrade, deteriorate, and eventually die.
Sheath, a term with three meanings: (1) Part of a leaf which envelops and wraps around a stem. (2) A layer of tissue which envelops or surrounds another tissue. (3) In some orchids (*Cattleya*, for example) a structure which envelops young flower buds.
Shoot, a young branch growing out of an existing stem or a young plant emerging from the soil, an explant, or a callus mass.
Shoot apex, *see* Shoot tip.
Shoot tip, terminal portion or bud of a plant (the top 0.1–1.0 mm) consisting of the apical meristem (upper 0.05–0.1 mm) and adjacent leaf primordia and stem tissues.
Short day plant, a plant that requires a dark period longer than a specific critical minimum to flower.
Sieve cell or element, a long, slender, tapering cell which is a component of the xylem.
Sieve tube, a series of sieve cells attached end to end.
Single node culture, culture of a single lateral bud with a stem section attached to it. *Phalaenopsis* flower-stalk node cultures are an example. The culture of these nodes was first reported by Dr. Gavino Rotor in 1949. This is the first instance of orchid micropropagation. It preceded Georges Morel's supposed first culture of an orchid explant by 11 years. Thus Rotor, not Morel, is the discoverer of orchid micropropagation.
Solid medium, a nutrient solution that has been solidified by a solidifier such as agar.
Solute, *see* Solution.
Solution, a mixture in which molecules of one substance (the solute) are homogeneously dispersed among the molecules of the other (the solvent).
Solvent, *see* Solution.
Species, a group of similar organisms which share many common characteristics and interbreed freely.
Spike, an inflorescence with an elongated main axis (rachis) which bears sessile flowers [i.e., flowers that do not have pedicels (floral stalks)]. Most orchid inflorescences are not spikes, they are racemes.

Starch, an insoluble polysaccharide consisting of branched or unbranched chains of α-D-glucose, which is the main food storage substance in plants.
Stele, the central vascular cylinder, located inside the cortex, in roots and stems of vascular plants.
Sterile, a term with two meanings: (1) Apparatus, condition, container, medium, tool, and other objects which do not contain microorganisms. (2) Incapable of fertilizing or being fertilized.
Sterilization, process of making sterile.
Stock solution, a concentrated solution of a medium component prepared in advance for convenient and repeated use.
Subculture, transfer of part of an existing culture to a new medium and vessel.
Substrate, a term with three meanings: (1) Substance that is changed by an enzyme. (2) Medium that supports explants or organisms in vitro. (3) Medium that supports a static organism.
Succulent, plant with fleshy stems and/or leaves which store water.
Sucrose, a disaccharide consisting of α-D-glucose and fructose.
Surfactant, surface active or wetting agent like Tween, and the components of domestic detergents and soaps.
Suspension culture, a culture of cells, explants, callus sections, protocorms, protocorm-like bodies, and other tissues growing while suspended in liquid and usually shaken.
Symbiosis, close association of two organisms. When this association is of mutual benefit it is said to be mutualistic (the phenomenon of mutualism).

TDZ, *see* Thidiazuron.
Terminal bud, bud at the tip of a stem.
Tetraploid, four complements (sets) of chromosomes ($4n$).
Thiamine, vitamin B_1, which is added to many media. Sometimes it is spelled thiamin.
Thidiazuron, *N*-phenyl-*N*′-1,2,3-thiadiazol-5-ylurea (TDZ), a compound with high cytokinin-like activity. Its cytokinin-like activity was first discovered by M. C. Mok, D. W. S. Mok, and D. J. Armstrong at the Department of Horticulture, Oregon State University, Corvalis.
Tissue, a group of similar cells.
Tissue culture, maintenance of tissue(s) and other explants on a medium in vitro, under conditions which promote growth, proliferation, and differentiation. Often used synonymously with micropropagation.
Trichome, a filament or hair.
Triose, a three-carbon sugar.
Tropism, curvature, growth, or movement in a specific direction due to an external stimulus (gravitropism, tropism induced by gravity; phototropism, tropism induced by light).
Tuber, a modified food-storing root (as in *Dahlia*) or stem (as in potato).
Turgid, swollen, crisp, or distended due to an influx of water.
Turgor pressure, internal pressure resulting from an influx of water.

Undefined component, a medium component whose composition is not known (partially or fully).

Undefined medium, medium whose composition is not known (partially or fully).
Undifferentiated, tissue or cells that lack specialization.
Unorganized growth, a tissue with few or no differentiated cells or regions and no clear, defined, or recognizable structures.

Vacuole, a cytoplasmic component consisting of a solution of various substances in water (sap) bounded by a membrane.
Vacuum, free of air or under greatly reduced atmospheric pressure.
Variegation, presence of colored and non-colored tissues.
Variety, subdivision of a species.
Vascular, pertaining to conducting tissue.
Vegetative propagation, a method of asexual propagation using parts or organs.
Venation, arrangement of veins. In most orchids, leaf venation is parallel.
Vernalization, temperature (usually low) treatment for the purpose of inducing flowering or growth.
Vessel, a term with two meanings: (1) A short cell with a lignified wall, which is a xylem component. (2) A container (bottle, Erlenmeyer flask, jar, Petri dish, or test tube) used for tissue culture.
Virus, a pathogen consisting of a protein coat or capsule that contains DNA or RNA.
Vitamin, a substance required by living organisms to maintain normal growth, development, metabolism, and physiology. The commonly used vitamins in orchid tissue culture are B_1 (thiamin or thiamine), B_6 (pyridoxin), niacin (nicotinic acid), and sometimes (rarely) biotin and C (ascorbic acid).
v/v, adding or mixing on a volume to volume basis, as for example ml/ml.
v/w, adding or mixing on a volume to weight basis, as for example ml/mg.

Water stress, lack of sufficient water.
Wet weight, weight of completely hydrated tissue. *See also* Dry weight, Fresh weight.
Wetting agent, *see* Surfactant.
w/v, adding or mixing on a weight to volume basis, as for example mg/ml.
w/w, adding or mixing on a weight to weight basis, as for example mg/mg.

Xanthophyll, a yellowish plastid pigment.
Xerophyte, resistant to drought.
Xylem, water conduction tissue in plants.

Yeast extract, an undefined or complex additive to some media consisting of substances from yeast.

Zone of elongation, part of a young root, just above the meristem, where cells are elongating.
Zygote, fusion product of two gametes.
