Micropropagation of Orchids

Second Edition

VOLUME I

Joseph Arditti

Blackwell Publishing

Micropropagation of Orchids

Volume I

This greatly expanded and updated edition of this classic reference work provides the user with comprehensive details of all procedures for propagating orchids through the culture of tissues *in vitro* (micropropagation).

Presented in two volumes, the book opens with a detailed and illustrated historical section which covers the discoveries, developments, and people which made micropropagation possible. The next section discusses in detail the principles and components of culture media which are used in micropropagation. The main component of the two volumes, however, is the third section. This comprises the detailed procedures for the culture of over 100 orchid genera. Classical, established, and the very latest techniques of clonal propagation of organs, tissues, and cells are presented. Every one of the listed methods includes tables of complete recipes for a wide range of culture media.

This new edition will continue to be *the* key reference for all those interested in and involved in orchid micropropagation, growing, and production.

Dr Joseph Arditti majored in floriculture as an undergraduate and received his doctorate from the University of Southern California in 1965. After serving as a lecturer for one year at the University of Southern California, he accepted a faculty position at the University of California, Irvine in 1966 where he taught General Botany, Horticulture, and Plant Physiology while engaging in research on various aspects of orchid biology in the US, Indonesia, Singapore, and Malaysia. Dr Arditti retired in 2001 and is now Professor Emeritus. He continues to write and travel worldwide to lecture at scientific meetings and to orchid groups. He is acknowledged to be one of the world's leading experts on orchid biology and propagation.

Chapter 3: Methods for Specific Genera, 139

Preface

Micropropagation of Orchids was "born" in 1974 when I initiated my *Orchid Biology, Reviews and Perspectives* (*OB*) series. Since a book containing only scientific literature reviews on orchid topics did not seem to have much of a financial or sales future I decided to include in the first volume a practical appendix entitled *Clonal Propagation of Orchids by Means of Tissue Culture – A Manual*. My hope was that the manual would attract buyers. I wrote the appendix while on sabbatical leave at one of my most favorite places on earth (the Bogor Botanical Gardens in Indonesia) using a portable manual typewriter which was a gift from my late father. Tissue culture propagation was relatively new then and the existing methods and literature citations were covered in 90 pages. The appendix accomplished its mission by attracting buyers and the series got its start in 1977.

By 1990 the first volume of *Orchid Biology, Reviews and Perspectives* was out of print and second hand copies were in considerable demand because of the appendix. The tail was wagging the dog. It was time to update and expand the manual and write a book on the subject which had acquired a name by then: micropropagation. I invited my colleague Dr. Robert Ernst to join me and we expanded the manual into *Micropropagation of Orchids* (*MO*1). It was published by John Wiley and Sons in 1993. *MO*1 included all of the procedures in the manual and almost all of the methods published between 1974 and 1990 in its 682 pages (nearly 7.6 times as many pages as the manual).

Like *OB*I, *MO*1 went out of print about 15 years after it was published. Demand for second hand copies rose quickly. Many people wrote me asking where to find a copy. By the year 2000 it was clear that the time had come to write a second edition of *MO*. I retired on July 1, 2001 and started to write a few months after that. My plan was to include in *MO*2 all the procedures in *MO*1 because they are still useful, and as many of the methods that were published after 1990 as possible (and hopefully all). What I found was that more new methods were published between 1990 and the year 2000 than from 1949 to 1990 (the period covered by the manual and *MO*1). Suggestions that orchid micropropagation was a mature field with a decreased number of publications seem to have been grossly exaggerated (to paraphrase Mark Twain) and completely unrealistic. This meant that writing would take a long time and it did. I finished the first draft in early 2004, edited it after that and stopped adding procedures on May 1, 2004, my 72nd birthday. There is no question

that many new methods will be published in the years after that, but *MO*3 will have to be written by someone else.

Chapter 1 in *MO*1 had presented a reasonably accurate history of orchid micropropagation, but I was made to remove parts of the story which placed the discovery and its discoverers in proper perspective because they questioned established dogma and the claims of the presumed discoverer. Professor (now emeritus) Abraham D. Krikorian and I used the excised parts as the basis for an extensive and precise history of orchid micropropagation, which was published in the *Botanical Journal* of the Linnean Society of London. This article served as the foundation for the history chapter in the present edition of *MO* which pulls no punches, tells the story as it happened, and places all historical figures in proper perspective. In retrospect I regret buckling down under intense pressure and allowing the history chapter in *MO*1 to be emasculated. I apologize for my lapse in good sense and momentary weakness. History must be reported as it really happened even if the actual facts may offend some people (even friends) because (to quote E. Mach, 1838–1916) "It is hardly possible to state any truth strongly without apparent injustice to some other." I thank Professor Krikorian for allowing me to quote liberally from our joint publication.

Chapters 2 and 4 were rewritten and revised not due to any shortcomings but because I decided to emphasize a few points more strongly, add information, and reword or restate several subjects. Both chapters are longer as a result of these changes.

With one exception, reviews of *MO*1 were very positive. The sole exception was critical of the absence of: (1) information about the use of colchicine to increase chromosome numbers in orchids, and (2) advice on how to combat internal contamination. This current edition also does not have information on the use of colchicine because this topic is not part of micropropagation. It belongs in a book on cytology, cytogenetics, or bioengineering. In view of the large amount of information that had to be included in *MO*2 my criteria for inclusion were very strict, narrow, and based entirely on the last half of the term micro*propagation*. Bioengineering, cytology, cytogenetics, physiology, molecular biology, and seed germination were excluded. As is obvious, even with this strict policy, the book grew to be very large.

Only published information was included in the manual and *MO*1 and is part of *MO*2. No published information on internal contamination in orchid cultures and how to handle it was available when the manual and *MO*1 were written. And, I could find none when writing this edition. Thus, when faced with the choice of presenting or not presenting non-existent (i.e., not available in the literature) information I chose the latter. However, I did include information on a variety of antibiotics and anticontaminants because they can be used to combat any contamination.

Most published papers on orchid micropropagation and tissue culture techniques contain information on media, culture conditions, and procedures which is sufficient for a presentation in *MO*, but some do not. When information was missing I made a few logical assumptions. For example, if a paper did not describe culture conditions in detail I assumed that standard culture room temperature and illumination will be suitable. In the few cases of truly atrocious papers, I made more (perhaps too many) assumptions and also called attention to their low quality.

Many years ago a thoughtful reviewer of one of my early papers pointed out that I failed to evaluate the quality and content of several articles that were mentioned in a review of the literature. He/she indicated that a certain amount of expertise is

implied in the writing of a paper or a review (and by implication a book) and that readers have a right to expect evaluations, criticisms, praise, opinion, and advice from an expert. *MO*1 was largely devoid of such comments, but I added several to this edition when they were called for. Some of these comments are negative. They may cause unhappiness in some quarters and/or generate criticism, but I think that the reviewer of long ago was right in suggesting that readers have a right to expect guidance and the opinions of an author who presumes to write a review or a book.

The author of a second edition has the advantage of hindsight since comments by readers, discussions with friends, opinions by users of the book, and statements by reviewers point to strengths and weaknesses. What I learned from comments about *MO*1 is that users of that book appreciated having the following:

- redundancy ["move the tissue to the first medium (Table XYZ-1) and then to the second solution (Table XYZ-2) before returning it to the first substrate (Table XYZ-1) and then taking it to the third (Table XYZ-3)" was liked by users who when asked and given a choice preferred this type of writing to "move the tissue to the first medium and then to the second solution before returning it to the first substrate and then taking it to the third"],
- repetitions ("tell me how to prepare a sterilant every time I need to use it, don't refer me to 100 pages back"),
- details ["dissolve it in 70% ethanol (73 ml 95% ethanol diluted to 100 ml with distilled water)" was preferable to "dissolve it in 70% ethanol"],
- clarity (short declarative sentences rather than long and involved ones),
- unambiguous instructions ("don't give me a choice between two sterilants, tell me which one to use"),
- simple language ("don't use a long chemical name if the compound has a trade-name or list both"), and
- self-standing procedures ("list all media and solutions with every procedure, don't tell me to use the medium in Table JOA-1 on p. xxx first, then the solution in Table MA-3 on p. yyy, the substrate in Table VQ-9 on p. zzz after that and finish with Table SUN-8 on p. aaa. This will make me leaf through the book endlessly in search of media and I will not like it").

I wrote *MO*2 in the same manner. What several users did not like was the fact that in many cases tables that pertained to one procedure were mixed with pages that contained text about another method. I reorganized this edition so that tables and text which relate to a procedure are together. Tables and sometimes text do not always fill a page. To not have empty spaces throughout the book and avoid mixing procedures in such cases I added illustrations, chemical formulae, and miscellaneous information or historical vignettes in boxes. These items are not numbered because some may have to be removed due to space limitations which could arise during typesetting. I hope that readers and users of the book will find these items to be interesting and even illuminating. They can be ignored by those who will find them uninteresting and distracting.

Ideally every procedure in this edition and in the previous versions would have been tested before being included in the book. However, given the number of procedures this is clearly impossible due to limitations of time, laboratory facilities, funds, and availability of orchids for experimentation. In fact, it would be illegal to import

some species due to CITES. Therefore procedures are presented without having been tested in the hope that they do work. However, it is reasonable to assume that procedures which are affected by the previous history of the donor plant may not work with plants that were grown under different conditions.

I could not have written this book without help from many individuals and sources. My thanks go to:

- Professor P. N. "Dhanny" Avdhani, National University of Singapore, my friend since 1969 for good ideas and stimulating discussions,
- Professor Tet Fatt Chia, Nanyang Technological University in Singapore for molecular biology insights into orchids,
- D. Y. N. Chow, SEGI and Prime College in Kuala Lumpur, Malaysia for many good ideas and having his wife freeze a durian for me,
- my colleague of many years, Dr. Robert Ernst who decided not to coauthor this edition, allowed me to use material from *MO*1, and offered to help with *MO*2,
- Professor Choy Sin Hew, National University of Singapore for advice, permission to use information and illustrations from his publications, helpful comments, and being an excellent host when I visit Singapore,
- Suan Wong (Mrs. C. S. Hew) for an extensive retrospective literature search which produced a very detailed and inclusive printout of relevant publications. I could not obtain such a printout from the library of my own institution, the University of California, Irvine,
- Professor Syoichi Ichihashi, Aichi University of Education in Japan for clarifications and translations of Japanese papers,
- Kathryn Kjaer, University of California, Irvine library for tending to my current awareness profile and literature searches efficiently, willingly, and well (she is not in charge of retrospective searches),
- Hideka Kobayashi for finding and sending me many papers from journals which are not available at the University of California, Irvine library (the selection of plant science journals in the UCI library is meager and reflects the negative attitude toward plant sciences in the School of Biological Sciences),
- Jill and Chin On Mak of Singapore for access to their orchid plants, shopping trips to Johor, and excellent durians,
- Drs Byron Allen, David Morohashi, David Ornstein, and Ping Wang for taking good care of me,
- Jean Miller who tends the interlibrary loan desk at Science Library at the University of California, Irvine and performs miracles in locating and obtaining rare and/or obscure publications. Writing this book would have been impossible without her and Kathryn Kjaer,
- Professor Helen Nair and her husband James Bonney for hosting me in Kuala Lumpur and providing a place to work while there,
- Professor A. N. Rao, formerly Chair of the Department of Botany, National University of Singapore for facilitating my visits there and being an example of what a scientist and a leader should be,
- the Soediono family for being wonderful hosts in Singapore and Jakarta,
- the people of the Wild Catt orchid data base for providing information on the parentage of some crosses,

- Dr. Tim Wing Yam, Singapore Botanic Gardens for photographs, comments, fruitful discussions, and being a good host on my visits to Singapore,
- Professor Mariam Abd. Latip, Dr. Amran, Dr. Zaleha Aziz, and students Abidah, Ainul, Devina, Roslina, and Rosmah for inviting me to lecture at the University of Malaysia, Sabah in Kota Kinabalu and thereby making me rethink some of what I wrote,
- Dr. John Yong, Nanyang Technological University in Singapore for allowing me to use illustrations, and
- all those who allowed me to use illustrations from their web sites and/or publications.

My special thanks go to my son Jonathan Omar for just being around and to my brother for maintaining my computers when they needed it and making it easier for me to write.

I also thank Ward Cooper, my editor; Jane Andrew, easily the best copy editor I have ever worked with and her assistant Pat Croucher for ferreting out errors, finding omissions, correcting mistakes, and generally making the book much better; as well as Rosie Hayden, Caroline Milton, Rachel Moore, Delia Sandford, Nancy Whilton, and the rest of the staff at Blackwell Publishing for their high level of professionalism.

Most of all I thank my Jonathan for being my son and making my life better by just being around.

Joseph Arditti
Irvine, California

Preface to the First Edition

Photocopy machines, pocket calculators, and micropropagation of orchids through tissue culture appeared on the scene almost simultaneously, and the world has not been the same since. Now it is hard to imagine how it was ever possible to get along without these advances. Those who are in their thirties and forties have never known a world without them. The large, slow, and primitive copiers of the 1960s gave rise to the small, fast, and versatile photocopiers of today. Pocket calculators became smaller (some even moved to the wrist in combination with watches) and more sophisticated. It is possible to suggest that one evolutionary branch led from them to the personal and "notebook" computers of today.

Mass rapid clonal propagation of orchids led to the development of similar procedures for other plants and eventually to the isolation and culture of cells and protoplasts. The combination of molecular biology and tissue, cell, and protoplast culture is the basis of plant biotechnology that holds the promise of improved crops, safer chemicals, and perhaps a better environment. Tissue culture was and is used for the mass rapid clonal propagation of outstanding hobby crosses and commercial cut-flower cultivars of orchids. In the former case it resulted in reduced prices of desirable plants to levels within the reach of most growers, whereas in the latter instance it is responsible for the tremendous growth of the orchid cut-flower industry in Thailand, Singapore, Malaysia, Indonesia, and other countries.

Research on orchid tissue culture as a means of micropropagation is being carried out in many laboratories all over the world. Papers based on this research are published in numerous journals and in several languages (but fortunately for English-speaking people mostly in English). Even with computerized literature searches it is not always possible to trace all existing papers because some publications are not recorded in the relevant databases. Some papers (in both popular and obscure journals) do not contain enough details to be useful for the average grower or even the experienced scientist. Moreover, most orchid growers and propagators are familiar with only one or at most two languages (usually their own and English). These limitations may deny some growers access to certain methods. The tissue culture propagation appendix in *Orchid Biology, Reviews and Perspectives*, Vol. 1, written by one of us (J. A.), to provide access to most available methods in the mid-1970s, is now outdated. This book is intended to update the appendix by including all the information it contains as well as procedures that have developed since

it was written. However, despite all our efforts we may not have included all existing methods.

Procedures must be presented in a clear easy-to-follow format to be useful. Comments by users and reviewers suggest that the format used in *Orchid Biology*, Vols. 1 (tissue culture) and 2 (seed germination), is appropriate, and we have adopted it for this book. Procedures for which complete details are not available are described briefly.

Despite the bewildering number of formulations in this book, only a relatively small core of basic media are used for orchid tissue culture. These media are usually modified to meet the needs of individual orchids or the preferences of researchers. In writing this book we were faced with the need to choose between two formats: (1) listing only basic media and indicating modifications in each procedure, or (2) providing complete recipes in every case. We selected the latter despite the enormous amount of additional work it entailed because it is more convenient and (in computer jargon) more "user-friendly."

It is easier to follow a table that includes all components of a medium than to try to make sense of instructions in the following form: "for buds use Doe's medium, but replace 2 mg of hormone *X* with 1.5 mg of growth regulator *Y* and 0.5 mg of hormone *Z*. Also add 6 mg of hormone *W* in place of substance *V*. Replace vitamin A with an equal amount of vitamin B, and leave out vitamin C. Finally, add concoction RX7 instead of extract 300ZX. For stem explants use 1 mg hormone *A*, 0.5 mg growth regulator *B*, and 0.25 mg substance *T*. Do not alter the vitamin mixture, but use less agar and replace extract 300ZX with filtrate D1600, except for older stems when juice TR6 must be employed at 100 ml l^{-1}."

To provide a wide selection we have included in this book most, perhaps all, available methods for clonal propagation of orchids through tissue culture. Testing all of these procedures clearly would have been an impossible task, and for this reason we do not have firsthand experience with many of them. The outlines we present are based on the literature and as a consequence are limited by the amount of detail and degree of accuracy of each original communication.

Orchid nomenclature is in a constant flux and subject to disagreements among taxonomists. Rather than determine the "correctness" of names, we have chosen to use the ones employed by original authors.

Another point to keep in mind is that procedures are sometimes suitable only for certain cultivars, hybrids, species, and genera grown under specific conditions. This fact is not always evident. For these and other reasons we cannot guarantee success for any of the procedures and cannot assume responsibility for failures. Those who wish to propagate expensive and/or rare plants would be well advised to experiment first with less valuable ones.

Orchid tissue culture research is an active field, and new procedures were published while we were writing the book. This means that we had to add new methods to earlier sections while writing later ones (e.g., add a procedure to *Cymbidium* while writing about *Vanda*). If all figures and tables were to be numbered consecutively this would have meant constant renumbering. To avoid this onerous task we used prefixes to number the tables and illustrations in each section. These prefixes are the abbreviations of generic (natural and hybrid) names adopted by the Sander's List of Orchid Hybrids. In cases where abbreviations do not exist in the List we devised provisional ones that follow its format.

Full appreciation of present procedures requires a knowledge of their history, which is the reason for the first chapter. We thank Dr. Abraham (Abe) D. Krikorian, Department of Biochemistry, State University of New York, Stony Brook, for providing some of the information in this chapter through his excellent reprints and several informative discussions. However, the opinions in the chapter are our own.

Conversations with those who have used the appendices in *Orchid Biology, Reviews and Perspectives*, Vols. 1 and 2, indicated that a more general discussion of methods and procedures would be of benefit, especially to those who may not be completely familiar with the methodology. Chapter 2 was written to meet this need. Not all orchid laboratories have access to reference books that contain conversion factors, lists of abbreviations, definitions of units, information about reagents, and similar data. Chapter 2, which contains some information of such nature, is intended to make this book as much as possible a self-standing reference.

Detailed indices are indispensable tools in a book like this. Preparing such indices manually is an extremely unpleasant task. The indexing capabilities of word-processing programs cannot be used to prepare book indices since they must be based on page proofs, which are not stored in files. A computer program written especially for this purpose by Kevin J. Hackett in 1983–1986 for *Orchid Biology, Reviews and Perspectives*, Vol. 4, and modified in 1989 by Handajany Suryadharma and Ling Shao (computer science students from Indonesia and Hong Kong, respectively, at the University of California, Irvine) made indexing this book much easier.

We thank those who provided us with illustrations; they are acknowledged in the captions. We are grateful to the following for reading and commenting on parts of the manuscript and/or engaging us in helpful discussions: P. N. Avadhani, C. S. Hew, and A. N. Rao (Botany Department, National University of Singapore), Djunaidi Gandawijaja (Bogor Botanical Gardens, Indonesia), Abdul Karim B. Abdul Ghani (Botany Department, University Kebangsaan Malaysia, Bangi, Selangor, Malaysia), Franz Hoffmann (University of California, Irvine), Syoichi Ichihashi (Department of Biology, Aichi University of Education, Aichi, Japan), Helen Nair (Botany Department, University of Malaya, Kuala Lumpur), Leslie Paul Nyman (California State Polytechnic University, Pomona, California), Tim Wing Yam (formerly of the University of Hong Kong, then a postdoctoral fellow in our laboratory and now at the Singapore Botanic Gardens), and Gu Zhuping (Biology Department, Lanzhou University, Lanzhou, China).

Mordi Arditti provided hard disks for J.A.'s computers. Mak Chin On and Jill Lim Kok Eng (owners of Maryland Orchids, Singapore) and Mr. and Mrs. (Noes) Soediono (proprietors of Flora Sari Orchids, Jakarta, Indonesia) argued eloquently for Chapter 2, and the book is better as a result. G. C. Stephens as department chairman and dean provided funds for the necessary computers, peripherals, and software, and Emma Webb, J.A.'s former technician, gave us instructions on how to prepare better illustrations; we are thankful to all.

A book of this type requires special editorial and production skills, and the staff at Wiley were more than equal to the task. We thank our editor Philip C. Manor and the staff, including Jennifer Dowling, Ruth Ellowitz, Melanie Field, Joanne Kelman, Maggie Kennedy, and the copyeditor Susan Middleton for being so competent, helpful, and efficient.

Finally, two personal comments: First, both of us came to the United States as young adults without resources (J.A. did not even have a high school education or diploma and still does not). We feel that adopting this great and free country as our own was the wisest decision we ever made. The United States accepted us, gave us the same opportunities it affords its native sons, and thereby allowed us to become all we could be. Even more importantly, it gave our children (J.A.'s seven year-old Jonathan and R.E.'s Nina and Olivia and their children) the opportunity to be born as American citizens. No one could ask for more. We are deeply grateful and very appreciative. Second, we met in 1966 and have worked together ever since. Publication of this book will mark 25 years of fruitful collaboration. We are happy for that.

Joseph Arditti and Robert Ernst
Irvine, California
September 1990

CHAPTER ONE

History

A reasonable case can be made that new orchid propagation methods were always in the forefront of the biotechnology (or at least propagation methods) of their time. The first method for orchid seed germination (Moore, 1849; for reviews see Arditti, 1984; Yam et al., 2002*a*) was a radical departure from the manner in which other seeds were germinated 155 years ago. David Moore's (1807–1879) approach was innovative and a major horticultural and biological advance.

Half a century after Moore's discovery, Noël Bernard (1874–1911) made another quantum jump when he formulated a method for symbiotic germination of orchid seeds in vitro (Bernard, 1899, 1909; F. Bernard, 1990; for reviews see Boullard, 1985; Arditti, 1990; Rasmussen, 1995; Yam et al., 2002*a*). His is probably the first method for in vitro propagation of any plant. It utilizes what were at the time modern and advanced microbiological procedures. Bernard also predicted that a day would come when orchid growers would have laboratories as part of their establishments. This is the case at present not only for orchids, but also for other plants.

Lewis Knudson's (1884–1958) method for the asymbiotic germination of orchid seeds (Knudson, 1921, 1922; for reviews see Arditti, 1984, 1990; Yam et al., 2002*a*) was the first procedure for in vitro propagation of any plant in pure (i.e., axenic) culture. His method was a significant conceptual and technological innovation which foreshadowed modern biotechnology.

David Moore may have based his work (Moore, 1849) on reports that orchid seeds can germinate if scattered at the base of a mature plant. However Bernard's discovery and method were not based on any previous procedures and/or research by others. They were solely a result of his brilliance (Bernard, 1899, 1909; Boullard, 1985; Arditti, 1990; F. Bernard, 1990; Yam et al., 2002*a*). Knudson developed the asymbiotic method as a result of a sharp mind, incisive reasoning and on the basis of his own pioneering research with other plants (Knudson 1921, 1922; for a review see Arditti, 1990). The micropropagation of orchids by means of tissue culture has a more complex history, which is not free of controversy and includes unusual episodes (Arditti, 1977*b*, 1985, 2001; Arditti and Arditti, 1985; Torrey, 1985*b*; Arditti and Krikorian, 1996; Easton, 2001).

Terminology

As is very often the case, popular usage brought about some confusion regarding several terms associated with micropropagation. There is also some misuse. Given these facts, it is appropriate to describe and define a number of relevant terms at the outset (others are in the glossary, which please see). A number of the definitions presented here are taken from three scholarly and thoughtful reviews (Krikorian and Berquam, 1969; Krikorian, 1975, 1982).

Cell culture is the culture of isolated cells in vitro.

Clone as a term was introduced in 1903 and is based on the Greek word *clon*, which means twig, spray, or slip of the type used for vegetative propagation (Weber, 1903; Krikorian, 1982). Originally referred to plants produced through vegetative propagation methods like cuttings, layering, budding, and grafting, clone signified that "plants grown from . . . vegetative parts are not individuals in the ordinary sense, but are simply transplanted parts of the same individual, and in heredity and all biological and physiological senses such plants are the same individual" (Weber, 1903, cited by Krikorian, 1982). Because this definition can be applied to plants produced in vitro from a variety of explants, the term clone is now also used to describe individuals propagated in this manner. However, it is necessary to keep in mind that the tissue culture process, especially if the tissues are proliferated extensively, can be mutagenic and therefore some clones produced in vitro may not be completely (1) genetically uniform, or (2) similar to other clones or ramets of the same hybrid or cross.

Explant is a portion of a plant (tissue, organ, a few cells, or part of a callus mass) taken for culture in vitro. In practice the term is sometimes assumed to imply a relatively small amount of tissue, but this usage is neither universal nor a requirement.

Medium is a liquid or solidified solution used for the culture of explants, callus, organs, cells, protoplasts, etc. *Medium* is the singular form of the word whereas the plural is *media*. Using "media" as singular is incorrect. Therefore, it is proper to speak of "one medium" and "many media." "One media," "many medias," and "several mediums" are incorrect and simply bad English.

Mericlone was proposed by Mr. (at the time Lieutenant) Gene Crocker (Fig. 1-1) who originated it by condensing the words "meristem" and "clone." It was popularized by the late Gordon W. Dillon, long-time editor of the *American Orchid Society Bulletin* and executive secretary of the American Orchid Society (Dillon, 1964). This term is a very clever merchandizing tool, but, as has already been pointed out (Krikorian, 1982; Arditti and Krikorian, 1996), "mericlone" is unfortunate for several reasons:

1. It is a linguistic abomination as for example: "to mericlone," "mericloning," "to make a mericlone," "this plant has been mericloned," "to mericlone a mericlone" (meaning that a plant produced in vitro will be/is/was propagated a second time in the same manner), or "meristemmer" (Rutkowski, 1967). Fortunately no one seems to have bestowed upon him/herself the title of "mericloner" in the title of an article.
2. It is inaccurate since in most cases the explant is a shoot tip, not a meristem.

Flowers below Fig. 1-6 (one facing left and the other right) are of *Schoenorchis funcifolia*, a Javanese orchid, whose carbon dioxide fixation was studied by Professor Went at the Bogor Botanical Gardens between 1927 and 1933 (orchid drawings from Smith, J. J. 1914. *Die Orchideen von Java*. E. J. Brill, Leiden, the Netherlands).**

3 The term is not really necessary because in principle there is no difference between cloning in vitro or through standard vegetative propagation methods.

4 It is misleading since it implies that all plants produced by this method are identical, which is not the case. Separate rules govern the naming of orchid crosses, clones, and mutants (Batchelor, 1982). These rules and the terminology they employ belong to the realms of plant and orchid taxonomy and nomenclature and are beyond the scope of this book.

Meristem is a well-defined term that describes the apex of a shoot tip. In common usage, especially among orchid growers, this term is erroneously used to describe the shoot-tip apex, which includes the apical meristem and some leaf primordia.

Micropropagation was first proposed in 1968 and defined as an aseptic procedure for the asexual production of plantlets from organs, tissues, and cells bypassing the sexual process or other means of asexual propagation (Krikorian, 1982; Hartman and Kester, 1983). This term should never be used to describe in vitro seed germination as is being done in the literature (see Perner, 1999, for one example).

Organ culture pertains to the culture of isolated juvenile or mature organs (leaves, roots, buds, shoot tips, flowers).

Ortet, from the Latin *ortus* (origin), was coined in 1929 to designate the "original plant of seedling origin from which members of a clone or ramets have originated" (Stout, 1929; Krikorian, 1982).

Protocorm, a term coined by Melchior Treub in 1890 (not by Noël Bernard as stated by Dr. Phillip Cribb in the first volume of *Genera Orchidacearum*, which was published in 1999), was applied to orchids by Bernard between 1899 and 1910. It refers to the small spherical, tuber-like bodies, formed by germinating orchid seeds (spherules is an incorrect name for these structures and must not be used). The term must not be used to describe similar bodies formed from explants or tissues in vitro (see below).

Protocorm-like body (PLB) is the proper term for structures that resemble protocorms and are formed by tissue explants and/or callus in vitro. This term was coined by Georges Morel in his first English language article on shoot-tip culture (Morel, 1960). It is the only first that can be attributed to him in connection with orchid micropropagation.

Protoplast culture should be applied only to cultures of isolated protoplasts (cells whose walls have been removed).

Ramet, based on the Latin *ramus* (branch), is an independent member of a clone (Stout, 1929; Krikorian, 1982).

Seedling is a young plant obtained from seed. This term may not be used to describe young plants obtained through tissue culture. The proper term for these is "plantlets."

Shoot tip is a meristem with several subjacent leaf primordia. This is the orchid explant generally cultured under the name "meristem."

Tissue culture is often used inappropriately to describe the culture of organs, tissues, cells, and protoplasts in vitro. This term should be applied only to the culture of tissues or tissue explants (meristems, callus sections, parenchyma pieces, tuber portions, and the like), not protoplasts, cells, or organs.

Origins of Orchid Micropropagation

Orchid micropropagation did not originate suddenly and de novo in the mind of one person despite a self-serving effort to create such an impression (Morel, 1960). The roots of orchid micropropagation are intertwined with the history of tissue

culture but they also have other origins (this chapter was revised extensively with new information, some of it taken verbatim or nearly so, from Arditti and Krikorian, 1996; I thank Professor Emeritus Abraham D. Krikorian for allowing me to use both text and photographs). Its origins lie in several lines of research and came from the work of many scientists, some of them well known and others not as appreciated as they should be (Arditti and Krikorian, 1996). The different lines of research will be discussed separately and brought to where they converged and gave rise to orchid micropropagation as it is known and practiced at present. A short outline of the history of plant hormones will also be presented because these substances are of critical importance to the culture in vitro of plant cells, tissue, and organs as well as to the differentiation of cultured plantlets (see Krikorian, 1995, for a more extensive history).

Plant Hormones and Propagation Additives of Plant Origin

Inclusion of plant hormones in culture media used for tissue culture, to control development and differentiation in vitro, and micropropagation is taken for granted at present. Yet, a century ago the existence of plant hormones was only being suggested.

Auxins

Gottlieb Haberlandt (1854–1945; Fig. 1-2), Professor of Plant Physiology in Berlin, was the first to propose the existence of plant hormones by stating that pollen tubes affect ovary growth through the release of substances he called *Wuchsenzyme* ("growth enzymes") and suggesting that if vegetative cells were cultured together with pollen tubes "perhaps the latter would induce the former to divide" (Haberlandt, 1902, English translation by Krikorian and Berquam, 1969; Arditti and Krikorian, 1996; Laimer and Rücker, 2003).

Pollen tubes do indeed release a substance which brings about post-pollination phenomena and ovule development in orchids. This was first shown by Hans Fitting (1877–1970; Fig. 1-3), before he became Professor of Botany in Bonn in his work with *Phalaenopsis* pollinia and pollination at the Bogor (then Buitenzorg) Botanical Gardens (Kebun Raya) in Indonesia (at the time the Netherlands Indies) in 1909 (Fitting, 1909*a*, 1990*b*, 1910, 1911, 1921 and a number of letters to JA in 1968 and 1969; for reviews see Arditti, 1971*a*, 1979, 1984, 1992; Avadhani et al., 1994). Fitting, who was "The first investigator to work with hormones and active extracts in plants" (Went and Thimann, 1937), went on to become one of the most prominent plant physiologists of his time and chancellor of the University of Bonn immediately after World War II.

He named the substance *Pollenhormon* and thus became the first plant scientist to use the word hormone in connection with plants and to suggest that they produce hormones.

From the time he named it (Fitting, 1909*a*, 1990*b*) and until his death (in letters to JA) Fitting maintained that *Pollenhormon* was a specific substance or hormone different from auxin. Present evidence suggests that Fitting's extracts in Bogor probably contained several substances including auxin (see Avadhani et al., 1994, for a

review). Fitting did not pursue the matter further, probably because he became interested in other phenomena including the sensory physiology of plants (Frits Went in conversation with JA; Arditti and Krikorian, 1996). Had he continued his work on *Pollenhormon*, Fitting might have discovered auxin.

The first intimation that *Pollenhormon* is or contains auxin was by Friedrich Laibach (1885–1967; he became prominent for his work with *Arabidopsis*), who reported that the active substance can be extracted with diethyl ether (Laibach, 1932). Several years after that, Kenneth V. Thimann (1904–1998; Fig. 1-4) demonstrated that the ether extract contained auxin (for reviews see Thimann, 1980; Avadhani et al., 1994; Arditti and Krikorian, 1996).

Auxin was discovered in Holland by Frits W. Went (Went, 1926, 1990; Went et al., 1928; Went and Thimann, 1937; Fig. 1-5) before Laibach extracted it from *Pollenhormon*. It was identified as indole-3-acetic acid (IAA) in 1934 (Went and Thimann, 1937; Haagen-Smit, 1951) and made successful tissue culture possible (Gautheret, 1935, 1937, 1983, 1985; Loo 1945*a*, 1945*b*). At present IAA and a number of synthetic auxins are used in orchid micropropagation.

Coconut Water and Cytokinins

In his classic paper Haberlandt suggested that "one might also consider the utilization of embryo sac fluids" (Haberlandt, 1902; Krikorian and Berquam, 1969; Laimer and Rücker, 2003). Two years later, E. Hannig followed this advice and screened the effects of such fluids from *Raphanus* and *Cochlearia* on the growth of embryos from the same species (Hannig, 1904; Krikorian and Berquam, 1969; Laimer and Rücker, 2003). European botanists of that period may not have been acquainted with the liquid endosperm of coconuts; however anyone who has spent time in the tropics will be familiar with the colorless liquid endosperm in green coconuts, which is a very refreshing drink by itself on a hot day or with a meal any time. This is coconut water. Coconut milk is a white liquid obtained by extracting, grating, or squeezing the solid white endosperm in mature nuts (in green nuts the endosperm is jelly-like and clear), which is dried to make copra. Like many Dutch botanists Johannes van Overbeek (1908–1988; Fig. 1-6) spent time at the Bogor (Buitenzorg) Botanical Gardens where he must have become acquainted with coconut water.

Later, when Albert Blakeslee (1874–1954; Fig. 1-7), a well-known geneticist at the time, wanted to culture recalcitrant immature embryos of *Datura stramonium* in vitro his associates Johannes van Overbeek and M. E. Conklin suggested the use of liquid endosperm of coconuts (i.e., coconut water) as a medium additive. Their suggestion was good; the *Datura* embryos grew well in its presence (van Overbeek et al., 1941, 1942) and an effective complex additive became available for plant tissue culture (van Overbeek et al., 1944; Steward and Shantz, 1955; Pollard et al., 1961; Tulecke et al., 1961; Raghavan, 1966). It can induce cell division in quiescent cells of carrot root phloem explants when added singly (Caplin and Steward, 1948; Krikorian, 1975; Gautheret, 1985).

Five years later Ernest A. Ball (Fig. 1-8) used coconut water to culture apical meristems (Ball, 1946; Krikorian, 1975, 1982). Frederick C. Steward (Fig. 1-9) and S. M. Caplin first reported on the use of coconut water for carrot root explants in 1948. After that, F. C. Steward made extensive use of coconut water for the culture

The line drawing under Fig. 1-12 is of a *Cymbidium* flower. Professor F. C. Steward produced flowering size plants (Fig. 1-9b) from cell suspension cultures of this genus.**

of carrot cells and the regeneration of plants (Krikorian, 1975, 1982; Steward and Krikorian, 1975). In 1950 L. Duhamet used coconut water to culture crown gall tissues (Duhamet, 1950). Also in 1950, Georges Morel (Fig. 1-10) cultured *Amorphophallus rivieri*, *Sauromatum guttatum*, *Gladiolus*, *Iris*, and lily in media containing coconut water (Morel, 1950). At present coconut water is used widely in tissue culture and micropropagation of many plants.

When used in combination with 2,4-dichlorophenoxyacetic acid (2,4-D) coconut water induced cell division in potato tuber explants even if neither of the two had any effect if added alone (Steward and Caplin, 1951). When the cytokinin zeatin was isolated from coconut water (Leetham, 1968) some (Galston, 1969; Skoog, 1994)

suggested that this explained the reasons for its activity, but there is an alternate view (Steward and Krikorian, 1971).

F. Mariat may have been the first to publish on the use of coconut water (erroneously referring to it as milk) and copra extract as an additive to media employed for orchid seed germination. When added at a concentration of 2% it did not inhibit germination and development but the seedlings were yellowish green. At higher levels coconut water was inhibitory to germination and development and the seedlings died (Mariat, 1951; for reviews see Arditti, 1967, 1979; Arditti and Ernst, 1984). Experiments with *Phalaenopsis* seedlings showed that coconut water can induce proliferation of protocorms (Ernst, 1967*b*). Coconut water is added at present to some orchid culture media (for some examples see Murashige, 1962; Jasper, 1966; Hahn, 1970; Pages, 1971; for reviews see Arditti, 1977*a*, 1977*b*; Holdgate, 1977; Rao, 1977; Zimmer, 1978; Fast, 1979; Sagawa and Kunisaki, 1984; Chen, 1985; Bouriquet, 1986; Czerevczenko and Kushnir, 1986; Griesebach, 1986; and procedures in Chapter 3). There is no consensus of opinions regarding the reasons for the effects of coconut water on orchids.

In the 1940s and 1950s research on plant tissue culture expanded, gained momentum, encountered new problems, and came up against recalcitrant tissues that required new approaches. One of these tissues was tobacco pith (Gautheret, 1985; Skoog, 1994). Folke Skoog (1908–2001; Fig. 1-11) and his students and associates at the University of Wisconsin formulated a number of media and evaluated the growth-enhancing properties of several substances in an effort to culture this tissue (Skoog, 1944, 1951; Skoog and Tsui, 1948; Skoog and Miller, 1957). One of the substances they tested was herring sperm DNA which had been stored for a very long time. In fact the time frame was long enough to raise the possibility that this DNA may have been left over from orchid seed germination experiments by Professor John T. Curtis (1913–1961; Fig. 1-12). However, Professor Carlos O. Miller (b. 1923; Fig. 1-13), one of the co-discoverers of cytokinins, thinks that the relationship between Curtis and Skoog was such that they would not have shared a reagent, not even one that had been languishing on a shelf for a long time. In any case, the research in Skoog's laboratory resulted in the discovery of the first cytokinin – kinetin (Strong, 1958; Miller, 1961, 1977; Leopold, 1964; Skoog et al., 1965; Gautheret, 1985; Skoog, 1994).

The discovery of cytokinins closes the circle as it were because by then the need for auxin and some vitamins (Gautheret, 1945) for explant cultures had already been established. The availability of kinetin enabled Toshio Murashige (b. 1930; Fig. 1-14) to formulate the widely used Murashige–Skoog (MS) culture medium for plant tissue culture (Murashige and Skoog, 1962; Smith and Gould, 1989; Skoog, 1994). Since an appropriate medium is a major factor in the establishment of cultures (Krikorian, 1982, 1995), many tissues and explants which were difficult or impossible to culture until then could now be cultured. The MS medium is used in many orchid micropropagation procedures.

Banana

Powdered banana was first incorporated in a medium for orchid seed germination in Brazil (Graeflinger, 1950 as cited by Withner, 1959*a*). The addition of banana to culture media for orchid seedlings became popular after that with a number of orchid

FIG. 1-13–1-18. **Plant scientists. 13. Professor Carlos O. Miller (photograph courtesy C. O. Miller, signature from a note to JA). 14. Professor Toshio Murashige (Janick, 1989). 15. propagators claiming to have been the first to use it. Some growers homogenize banana fruit pulp with their media whereas others stir puree into their solutions, and there are those who simply submerge a few banana slices per flask. All of these enhance seedling growth. Banana-containing media are always easy to recognize due to their darker color (even when claims are made for a "secret non-banana" additive).

Opinion varied for a period as to whether green bananas (Hey and Hey, 1966) enhanced growth better than ripe ones. Preferences still exist among growers. However, there is no question that pulp from ripe bananas does stimulate the growth

of seedling and immature embryos of *Vanilla* (Withner, 1955) and *Phalaenopsis* seedlings (Ernst, 1967*b*).

According to one report "green and not ripe [bananas] . . . grated, cooked gently for 40 minutes, [and] strained . . ." (Hey and Hey, 1966) enhanced seedling growth. That the extra work and tedium associated with this procedure are not necessary was demonstrated in experiments with banana pulp (Ernst, 1967*b*). Subsequent experiments (Pages, 1971) confirmed these findings (for a review see Withner, 1974*a*, 1974*b*). Banana pulp can also enhance the growth of plantlets obtained from explants in vitro (see procedures in Chapter 3). The reasons for the effects of banana are not clear. Attempts to fractionate banana pulp through serial extractions with several solvent produced inconclusive results (Arditti, 1968).

The effects of a number of other plant homogenates on seed germination and seedling growth have been evaluated (Arditti, 1967, 1979; Ernst, 1967*b*; Arditti and Ernst, 1984), but few if any of them are used with explants. Some are added to cultures of protocorm-like bodies or developing plantlets with varying result (see specific procedures).

Culture of Tissues and Organs

Roger J. Gautheret (1910–1997; Fig. 1-15), one of the earliest prominent figures in the history of plant tissue culture in France and later an historian of the field, wrote that "the progress of plant tissue culture was made possible by only a few genuine discoveries [which] . . . did not appear suddenly, but after a long and slow journey, unpretentiously covered by pioneers" (Gautheret, 1985). According to him, the earliest of these pioneers in the "prehistory" of plant tissue culture (Gautheret, 1985) was the Frenchman Henri-Louis Duhamel du Monceau (1700–1782; Fig. 1-16), who studied wound healing in trees while also writing about naval architecture (11 volumes) and science and art (18 volumes). In his book *La Physique des Arbres* (1756) he described swelling and the appearance of buds following the removal of bark and cortex from an elm tree (Gautheret, 1985). Gautheret's view is that this was the discovery of callus formation and "a foreword for the discovery of plant tissue culture. But in 1756 the bacteriological technique was not invented, asepsis was unknown, the concept of tissue culture had not been yet expressed, and finally nobody was able to appreciate Duhamel's discovery" (Gautheret, 1985). Perhaps so, but callus formation on mature trees after wounding bears little, if any, resemblance to tissue culture. Also, the development of grafting and budding techniques can be described as being equally relevant. But it may well be that in this account Gautheret was more interested in endowing one of his countrymen with a first rather than writing an objective historical account.

In an earlier historical presentation, Gautheret was more objective and made a convincing suggestion that "the history of plant tissue culture begins in 1838–1839 when [M. J.] Schleiden (1838) and [T.] Schwann (1839) . . . stated the . . . cellular theory and implicitly postulated that the cell [is] totipotent" (Gautheret, 1983). Schwann even suggested that "plants may consist of cells whose capacity for independent life can be clearly demonstrated . . ." (translated from German by Gautheret, 1985). That this is so was demonstrated experimentally and considered theoretically by A. Trécul in 1853, H. Vöchting (Fig. 1-17) in 1878, K. Goebel (Fig. 1-18) in 1902, J. Sachs

(1832–1897) between 1880 and 1882, J. Wiesner in 1884, and C. Rechinger in 1893. The latter suggested that excised plant sections could develop in a solution (Gautheret, 1983). He clearly proposed that isolated plant parts could be cultured in vitro.

Early Tissue Culture Attempts

Gottlieb Friedrich Johann Haberlandt (1854–1945; see Fig. 1-2), considered by some to have originated the concept that structure and function are intertwined in plants (that is, physiological plant anatomy), made the first attempt to culture plant cells (Haberlandt, 1902; Krikorian, 1975, 1982; Gautheret, 1985; for an annotated English translation accompanied by a scholarly essay see Krikorian and Berquam, 1969; Laimer and Rücker, 2003). Haberlandt's first attempt was to culture isolated leaf palisade and mesophyll cells of *Lamium purpureum*, stinging hairs of nettle, *Urtica dioica*, glandular hairs of *Pulmonaria*, stomatal cells of *Fuchsia magellanica* Globosa, pith cells from petioles of *Eichhornia crassipes*, and three monocotyledonous species, *Tradescantia virginiana* (stamen filament hairs), *Ornithogallum umbellatum* (stomatal cells), and *Erythronium des-canis* (stomatal cells). He used Julius Sachs's version of Knop's solution (1 g potassium nitrate, 0.5 g calcium sulfate, 0.5 g magnesium sulfate, 5 g calcium phosphate, and a trace of ferrous sulfate per liter; a medium which is still useful at present) and added to it sucrose, glucose, glycerin, asparagine, and peptone (except for glycerin these additives are still being used). In addition, he used light (natural daylight and photoperiods, April–June and September–November in Germany) and dark culture conditions as well as appropriate temperatures (18–24°C).

Haberlandt was unsuccessful – "cell division was never observed" (Krikorian and Berquam, 1969; Laimer and Rücker, 2003). In retrospect there are several reasons for his failure (Krikorian and Berquam, 1969; Laimer and Rücker, 2003). One was his selection of cells, which were mature, specialized, non-meristematic, and highly differentiated. The second was his culture medium; it lacked substances now known to be required by tissue and cells in vitro (vitamins, hormones, *myo*-inositol, and other additives). Third, "Haberlandt could not have been less judicious in his selection . . ." (Krikorian and Berquam, 1969; Laimer and Rücker, 2003) of plants. He not only used three monocotyledonous species but also ones which are recalcitrant. One reason for this selection may have been Haberlandt's strong belief in the cell theory. This is ironic since it was this belief which led him to try cell cultures in the first place. However, chance must have also played a role since in those days Haberlandt had nothing to guide him in the selection of "proper" plants and explants. In all fairness it is necessary to keep in mind that subsequent discoveries of plants which are easy to culture were often a matter of luck. Finally, "Haberlandt did not think it necessary to achieve complete sterility" (Krikorian and Berquam, 1969; Laimer and Rücker, 2003) and stated in fact that "the cultured plant cells were impaired only slightly in their progress by the presence of numerous bacteria in the culture solutions" (translation by Krikorian and Berquam, 1969; Laimer and Rücker, 2003). Cell and tissue culture at present would be unthinkable without complete sterility, or at least the inhibition of contaminants.

Assertions that Haberlandt's failure was due to the fact that ". . . he neglected Duhamel's results as well as Vöchting's and Rechinger's experiments . . . and [his] ignorance of the past" (Gautheret, 1985) are unjustified, have no scientific basis, seem unnecessarily harsh, and may be based more on national pride than on solid science. He would have failed with most explants (Duhamel's species included) since the vast majority of tissues require a richer medium and do not grow in a contaminated solution. Haberlandt was probably not aware of the procedure used to culture *Phalaenopsis* flower stalks at the time (Anonymous, 1891). His medium may have supported their growth, but contamination would have destroyed them.

A more judicious selection of plant material and some luck may have led to perhaps partial success, but attention to Duhamel could not have been the key to Haberlandt's failure. He tried to culture potato tuber tissue and also failed, probably because his medium lacked the very hormones he envisioned (Krikorian, 1982). Perhaps he might have succeeded with carrot explants, but he made no attempts to culture them. In a foreshadowing of the use of coconut water in culture media, Haberlandt suggested the use of embryo sac fluids and used liquids from *Raphanus* and *Cochlearia* to culture embryos (Krikorian and Berquam, 1969; Laimer and Rücker, 2003). Given this fact "it is tempting to speculate that perhaps Haberlandt . . . might have conceived coconut as being a source of readily available 'embryo sac fluids' had coconuts been generally available in Berlin" (Krikorian and Berquam, 1969; Laimer and Rücker, 2003). Or, perhaps, if he had noticed them in Indonesia.

"Haberlandt followed the literature intently" (Krikorian and Berquam, 1969; Laimer and Rücker, 2003), which is obvious from the extensive citations in his papers, and the reference to Fitting's research with orchid pollinia in connection with his own observations. He also cited Vöchting in 1913 (Krikorian, 1982). This is hardly indicative of neglect or ignorance of previous literature. Haberlandt may have chosen to ignore Duhamel's observation perhaps because he did not believe it to be relevant, which is probably the case. Regardless of his failure, Haberlandt ". . . ushered in . . . a new era of inquiry" (Krikorian and Berquam, 1969; Laimer and Rücker, 2003). Others followed in his footsteps and had more success. H. Winkler attempted to cultivate string bean segments and reported cell divisions but no proliferation (Winkler, 1908; Gautheret, 1985). In the same year S. Simon reported the formation of callus, buds, and roots from poplar explants (Simon, 1908).

Culture of Stem Tips

As a concept, the utilization of buds or stem tips for mass rapid clonal propagation is more than a century old. As far back as the 1890s Carl Rechinger in Vienna tried to culture stem sections and excised buds of *Populus nigra* and *Fraxinus ornus* as well as portions of roots on sand moistened with tap water (Rechinger, 1893; Krikorian, 1982; Gautheret, 1983). Rechinger failed in his attempts, but concluded that for proper development sections must be thicker than 1.5 mm. His procedures cannot be called "tissue culture" as the term is understood at present, but they foreshadowed current methods because he used a medium (tap water), support (sand), and explants. Classic tissue culture procedures at present include: (1) a nutrient substrate that includes organic components like sucrose, which make it advisable to use aseptic techniques;

(2) an explant; and (3) in some cases agar or gellan gum (i.e., Gelrite or Phytagel) as a solidifier or support. However, except for the explant, several of these factors are not necessarily absolute requirements. Some are a matter of convenience or may sometimes be invoked for pedantic rather than functional reasons. Even sterility, which is clearly preferable, is not an absolute requirement if microbial contaminants can be kept under control, inhibited, and/or prevented from smothering or attacking the explants as is now possible through the use of PPM™ (see Chapter 2; Thurston et al., 1978, 1979; Spencer et al., 1979/1980; Brown et al., 1982, 1984; Johnson et al., 1982; Cvitanic and Arditti, 1984).

Nearly 20 years after Rechinger, the German experimental morphologist Karl [later von] Goebel (1855–1932; Fig. 1-18), who also spent time at the Bogor Botanical Gardens, attempted to grow excised buds of the water fern *Ceratopteris thalictroides* in peat moss, but obtained only abnormal plants (Goebel, 1902; Krikorian, 1982). Like Rechinger's method, Goebel's procedure was not "tissue culture" as the term has been used during the last 30–40 years. However Goebel did use explants and a medium.

Research on the effects of the presence or absence of cork, water, and polarity on root formation in *Salix* by the German botanist Herman Vöchting (1847–1917; Fig. 1-17) was somewhat tangential (Vöchting, 1906). However, it was an important contribution to the quest for tissue culture (Krikorian, 1982).

Despite accelerated research in the field, about 15 years passed before William J. Robbins (1890–1978; Fig. 1-19) attempted the first stem- and root-tip cultures at the University of Missouri (Krikorian, 1982; Gautheret, 1983). He germinated seeds of peas, corn, and cotton under aseptic conditions, excised root and stem tips, and tried to grow them in the dark on sterile Pfeffer's solution with and without glucose or fructose (Knop, 1884; Pfeffer, 1900; White, 1943; Krikorian, 1975, 1982; Arditti, 1977*b*, 1992; Murashige, 1978; Arditti and Krikorian, 1996; see Arditti et al., 1982 for composition of this medium). The corn and pea explants grew normally, but those taken from cotton did not (Robbins, 1922*a*, 1922*b*). Cotton explants produced roots but showed characteristics that were "typical of plants grown in the dark" and were chlorotic (Robbins, 1922*b*).

The results obtained by Robbins are easy to explain at present. He did not have plant hormones at his disposal because they were yet to be discovered. And, despite eventually making major contributions to the understanding of the role of vitamins in plant tissue culture, he did not even know initially that they may be required by some explants. He also did not realize that his cultures would benefit from illumination. Still, Robbins and his associates succeeded in maintaining their root-tip cultures for almost 4.5 months (Robbins and Maneval, 1923, 1924).

Walter Kotte (1893–1970; Fig. 1-20), one of Haberlandt's students in the Pflanzenphysiologische Institut in Berlin-Dahlem, cultured pea roots independently of Robbins, but at the same time, Kotte used Knop's salts (Knop, 1884) as his basic salt medium. He added to it alanine, asparagine, glucose, glycine, a meat extract, a digest of pea seeds, and peptone. Kotte's medium was more sophisticated than the one used by Robbins and may have contained vitamins, some plant hormones, and inositol as components of the complex additives. The roots grew in his medium, but could not be subcultured (Kotte, 1922*a*, 1922*b*; White, 1943).

Philip R. White (1901–1968; Fig. 1-21) of the Rockefeller Institute for Medical Research at Princeton, New Jersey reasoned that apical and intercalary meristems

Uhl, signature courtesy Cornell University Archivist Kathleen Jacklin). 26. Professor Wilhelm Pfeffer (Wittrock, 1897–1903). The line drawings are of Chinese cymbidiums, orchids which interested Professor Loo (see Arditti, 1999, for an obituary).**

"would be best to choose [as] materials for our first experiments" (White, 1931, 1933*b*). During a visit to the plant physiology institute at the University of Berlin which extended from the winter of 1930 to the spring and summer of 1931, he attempted to culture root tips (White, 1932*a*, 1933*a*) and "some 400 stem tips"of the "common weed" *Stellaria media* in hanging drops of a nutrient solution (U+U) formulated for pure cultures of *Volvox minor* and *V. globator* (Uspenski and Uspenkaja, 1925). White had used this medium previously for cultures of root tips, embryos, and other explants (White, 1933*b*). He managed to keep the tips alive "for periods up to three weeks . . . [and] during this time there . . . occurred active cell division . . . growth . . . differentiation into leaves, stems and floral organs" (White, 1933*b*). However his results were disappointing by present standards. The reasons given for the limited success were accumulation of "excretory products, and the exhaustion of nutrient materials" (White, 1933*b*). Medium composition is a more plausible explanation. U+U contained no vitamins or hormones because some of them were yet to be discovered or studied, and others were still new to science, or yet to be established as requirements. Also, it did not contain ammonium ions.

More specifically, *myo*-inositol, although not really a vitamin and a substance not present in the U+U medium, was isolated from muscles in 1850, and was first used in plant tissue culture media much later. One of the earliest inclusions of inositol in a plant tissue culture medium was half a century ago (Jacquiot, 1951), but it acquired importance as a possibly useful inclusion in plant tissue culture media only after the sugar alcohols sorbitol, *meso*- or *myo*-inositol and *scyllo*-inositol were isolated and identified as components of coconut water (Pollard et al., 1961). Despite being implicated in signal perception as part of the phosphoinositide system, it must still be shown that inositol plays a major and positive role in the growth of plant tissues in vitro. Interpretation of results from the utilization of inositol have generally been indecisive (Åberg, 1961). However its addition seems to do no harm, and adding it routinely to the MS medium provides a safety margin.

Thiamine (vitamin B_1), a common additive to culture media at present, was isolated from rice bran in 1910–1911, but its structure was elucidated only in 1926. Niacin (nicotinic acid) was first produced by oxidizing nicotine in 1925, but added to culture media only several decades after that. Ascorbic acid (vitamin C) was first isolated in 1928, studied more extensively in 1933, and is used in plant tissue culture media rarely even at present. The structure of riboflavin (vitamin B_2), a vitamin used in some culture media, originally isolated from eggs, was described in 1935. Biotin, discovered in egg yolks in 1936, is not in common use even now. Pyridoxine (vitamin B_6), which is also used in many culture media, was isolated from rice and yeast in 1938. Pantothenic acid was isolated from liver and its structure was first elucidated ca. 1940. Folic acid was identified in 1948 after being crystallized from liver in 1943 and yeast in 1947 (for a review of vitamins and orchids see Arditti and Harrison, 1977). Of the plant hormones used in tissue culture, auxins were discovered in 1928 (Went, 1928, 1990) and cytokinins in 1955 (Miller, 1961). Information that vitamins and hormones are required by explants in culture started to accumulate ca. 1936–1938 (for reviews see White, 1943; Schopfer, 1949; Åberg, 1961).

Even without additives known to be required at present, White's medium was one of the best available at the time. Corn shoot tips cultured on it produced plants (Segelitz, 1938). Tips shorter than 2 cm required illumination. Longer shoots (2–4 cm) grew

in the dark (Segelitz, 1938). This is one of the earliest successes with the culture of a monocotyledonous plant in vitro. It was reported more than a dozen years before what was claimed to have been the first success with this group (Morel and Wetmore, 1951*a*). However, it should be noted that Morel and Wetmore dealt with callus production in their cultures. The difference between shoots and callus can be viewed as hair splitting, but this success was considered to be significant because monocotyledonous plants do not normally produce wound tissue and therefore cultures grew only with difficulty until more suitable procedures were developed (for discussions of monocotyledonous plant recalcitrance see Swamy and Sivaramakrishna, 1975; Hunault, 1979).

Announcements that plant tissues can be cultured "for unlimited periods of time" were made independently and at about the same time during this period, but not "simultaneously" as stated incorrectly (for a review see Gautheret, 1985) by P. R. White (Fig. 1-21; ca. December 31, 1938), R. J. Gautheret (Fig. 1-15; on January 9, 1939) and Pierre Noubécourt (1895–1961, Fig. 1-22; on February 20, 1939). These findings on the potentially unlimited growth of callus cultures set the stage for the first successful culture of a stem tip not many years after that.

The second monocotyledonous plant to be propagated by what can retrospectively be described as a "prehistoric" or crude form of tissue or explant culture was taro (*Colocasia esculenta*), an ancient and still very important crop in the Pacific region and Hawaii. To accelerate taro propagation an attempt was made to culture normally dormant buds "borne in the axils of the leaves on the surface of the taro corm" (Kikuta and Parris, 1941). Tuber slices, 2–5 cm thick, and buds "together with approximately 1 cubic centimeter of corm tissue," planted in sterilized soil produced plants. In other words, corm explants and excised buds cultured in sterile soil as a culture medium produced plants. There is no real or valid reason why only a semisolid or liquid solution can or should be defined as a culture medium. This method of taro multiplication (Kikuta and Parris, 1941) is analogous to current tissue culture propagation even if the procedures are somewhat crude and the cultures are not in vitro. Unfortunately, this method and related ones are mentioned only in a few instances (Arditti and Strauss, 1979; Arditti and Ernst, 1993; Krikorian, 1994*a*) and is generally missing from historical reviews (Gautheret, 1980, 1982, 1983, 1985). Taro was cultured in vitro for the first time 30 years later (Mapes and Cable, 1972; also see Arditti and Strauss, 1979; Krikorian, 1994*a*).

Another monocotyledonous crop, rye, was also cultured early (de Ropp, 1945). Stem tips (actually the plumules) of excised embryos were cultured on White's medium containing 2% (w/v) sucrose. When "any isolated stem tip developed a root the entire growing point was stimulated to meristematic activity, and leaves normal in form and size developed" (de Ropp, 1945). These explants were embryonic and it is possible to suggest that they were not equivalent to shoot tips of mature plants. However, present evidence (at least that obtained from orchids) suggests that embryonic stem tips from mature plants and seedlings are similar or for the most part do not differ substantially with respect to their requirements in vitro.

From the mid-1930s to the 1950s the California Institute of Technology (Caltech) in Pasadena was arguably the world center for research in plant physiology. Its faculty [which included such major figures in plant physiology as Kenneth V. Thimann (1904–1997; Fig. 1-4), James Bonner (1910–1996), Frits W. Went (1903–1990; Fig. 1-5), Herman Dolk (d. 1932), Arie J. Haagen Smit (1900–1977), Johannes van

Overbeek (Fig. 1-6), and others] attracted excellent graduate and postdoctoral students from all continents (Thimann, 1980). One of these was Shih Wei Loo (Loo Shih Wei, Chinese style; 1907–1998; Fig. 1-23). He came to the USA. In 1943, he earned his Ph.D. at Caltech in 2 years and in 1945 became research associate at the Botany Department of Columbia University in New York. A year later he moved to the Chemistry Department and stayed there until 1947 when he returned to China. There he was appointed Professor of Botany at Beijing University. In 1953 Loo moved to the Plant Physiology Institute in Shanghai where he remained until the end of his life. Loo suffered more than most during the cultural revolution but returned to his laboratory after the upheaval, resumed research, and trained graduate students until his last days (Arditti, 1999).

For his doctoral dissertation Loo cultured excised stem tips of *Asparagus officinalis*, 5–10 mm long, on a medium utilized by James Bonner for the culture of tomato roots (Loo, 1945*a*). Some of Loo's explants formed buds, but none produced roots. His conclusion was that growth of the excised stem tips was "potentially unlimited" (Loo, 1945*b*). It is clear at present that he was right. Also, it seems reasonable to assume that the tips would have developed roots if an auxin had been added to the medium. Following his move to Columbia University Loo published yet another report on asparagus shoot tips (Loo, 1946*a*). He demonstrated that a solution rendered semisolid with agar was "as good, if not better, than liquid medium." While doing that, he devised a simple method for supporting stem tips (Loo, 1946*a*). Growth of the explants remained normal. They were still alive after 22 months and following 35 transfers (Loo, 1946*a*).

Loo also cultured stem tips of the parasitic flowering plant dodder (*Cuscuta campestris*). His cultures did not produce roots and leaves but fortuitously they did flower in vitro (Loo, 1946*b*). This is probably the first instance in which "floral organs . . . developed on excised stems tips in vitro" (Loo, 1946*b*). Again, it is reasonable to speculate that dodder explants would have formed leaves and roots if Loo had added appropriate hormones to his medium (Galston, 1948). Unfortunately he did not (cytokinins were discovered in 1955). However he did conclude that the explants required sugar for growth in vitro. This was a relatively new conclusion (but in some cases orchid explants develop in a more desirable fashion only on a sugar-free medium). Loo also cultured and obtained flowering in vitro of the composite *Baeria chrysostoma*, a small annual sometimes grown in gardens and which belongs to a California genus consisting of ca. 20 species (Loo, 1946*c*).

Clearly, "Professor Loo's papers suggest that tissue culture of angiosperms and micropropagation would have advanced more rapidly had he remained in the USA and/or if conditions in China had been different. His important contributions to stem-tip culture and ultimately to micropropagation have thus far received credit only passingly in a few reviews (Krikorian, 1982; Gautheret, 1983) and a few research papers (Steward and Mapes, 1971*b*; Koda and Okazawa, 1980). Loo's work is certainly not as well-known as it should be" (Arditti and Krikorian, 1996). It is worth emphasizing here that Segelitz, de Ropp, and Loo (independently of each other), and not subsequent workers (Morel and Wetmore, 1951*a*; Gautheret, 1983, 1985), were the first to have significant success in culturing monocotyledons in vitro.

Frits W. Went (Fig. 1-5), discoverer of auxin, was associated indirectly (through a gift of auxin) with the first successful culture of an axillary bud meristem by Carl D. LaRue (1888–1955). It was that of water cress on White's mineral nutrients

supplemented with 20 g (w/v) sucrose l^{-1} and "hetero-auxin 1 part to 20 millions" (LaRue, 1936).

Ernest A. Ball (1909–1997; Fig. 1-8) was interested in shoot tips and apical meristems (Ball and Boell, 1944; Ball, 1972), "the capacity for growth and development of vegetative plant cells," "polarity of the buds and subjacent cells," "the relation between respiration and development, independence of the tip from the rest of the plant, production of subjacent tissues by the apex," and the "totipotentiality of all living plant cells" (Ball, 1946). He excised shoot apices of nasturtium, *Tropaeolum majus* L. ("55 µ high and 140 µ thick"), and lupine, *Lupinus albus* L. ("81 µ high and 250 µ thick"); the sections were 400–430 μm^3 in volume (Ball, 1946).

Ball made "no provisions to achieve and maintain asepsis," and "inoculations were performed in the laboratory," but his cultures did not become contaminated. He placed explants on Robbins' modification of "Pfeffer's Solution" plus microelements and in some cases "unautoclaved coconut milk" (actually coconut water). The medium was made semisolid with agar which changed in color from brown to white after being washed with thirty 24-hour changes of distilled water. His explants grew well (Ball, 1946 and clearly stated by Ball in many conversations with Joseph Arditti while he was at UCI). Any insinuations to the contrary (Morel, 1974) are entirely without foundation, self-serving, and disrespectful of a pioneering plant scientist. Loo Shih Wei and Ernest A. Ball succeed in culturing shoot tips before Georges Morel did. And, nursery owner Hans Thomale and Dr. Lucie Mayer, not Georges Morel, were the first to culture an orchid shoot tip (Arditti and Krikorian, 1996).

First Micropropagation of Orchids

More than 100 years ago British orchid growers placed *Phalaenopsis* flower stalk nodes in peat and succeeded in producing plantlets from their buds (Anonymous, 1891, 1892; for a review see Arditti, 1984). This method of propagating *Phalaenopsis* can be viewed as a simple or crude form of tissue culture because an explant (a bud on a stalk section) was placed in/on a "medium" (moss, albeit non-sterile) and "cultured" until it produced a plantlet or died. In addition to being of practical use, this propagation procedure proved that isolated buds can "be separated from the plant and continue to grow" as suggested by Schwann in 1839 (in Gautheret's translation, 1985).

Unfortunately this method of propagating orchids escaped the attention of botanists at the time (and for many years after that) probably because: (1) it was superficially similar to the rooting of cuttings (but in fact very different from it since buds on *Phalaenopsis* flower stalk produced shoots which developed roots and became plantlets in a manner similar to that of a bud, a callus section, or a protocorm-like body in vitro); (2) it was published in a very early, highly specialized and obscure journal which even at present is hard to find; (3) "an increasing number of scientists read no modern languages other than English" (Krikorian and Berquam, 1969); and (4) not many scientists take the time to read the old literature regardless of language and prominence (or lack of it) of journals.

At least one person did notice the articles at the time because according to a short notice a grower named Perrenoud (no first name given) who saw reports in so-called

"journaux anglais" placed sections of *Phalaenopsis* roots in humid enclosures and obtained a plant (Anonymous, 1891). This is reminiscent of micropropagation. No details are available, except that *Phalaenopsis* roots can produce buds and plants (for a review see Churchill et al., 1972*b*). Nevertheless this attempt can be described as being part of the pre-history of orchid micropropagation (Arditti and Krikorian, 1996).

Had this method not escaped attention, it and its discoverer (an unknown British orchid grower) could have been important signposts on the road to plant tissue culture and micropropagation as they are known at present. It is certainly more (1) relevant to tissue culture, (2) important as a "foreword," and (3) similar to micropropagation than the observations by the Seigneur du Monceau et de Vrigny, Henri-Louis Duhamel du Monceau (Gautheret, 1985; Fig. 1-16).

The modern history of orchid micropropagation started when (1) "a new [tissue culture or in vitro], simple and practical method for vegetative [clonal] propagation of *Phalaenopsis* [orchids] was developed at Cornell [University]" 5 years (Rotor, 1949) before the first published report of orchid stem-tip cultures, and (2) a German nurseryman suggested that this method can be used for micropropagation (Thomale, 1956, 1957). The nutrient medium used to culture the *Phalaenopsis* nodes was Knudson C (KC) formulated for the asymbiotic germination of orchid seeds by Lewis Knudson (1884–1958; Figs 1-24 and 1-25), Professor of Plant Physiology at Cornell University (see Arditti, 1990 for a history, additional photographs, and a biography).

Knudson's first solution, known as the Knudson B medium (KB), was a modification of Pfeffer's Solution, a formulation devised by the German plant physiologist Wilhelm Pfeffer (1845–1920; Fig. 1-26). It was, and still is, a reasonably good medium for orchid seed germination, but Knudson improved it and published his solution C (Knudson C, KC) in 1946 (Knudson, 1946). This medium is used very widely for orchid seed germination (Arditti et al., 1982) and the micropropagation of some orchids.

Gavino Rotor Jr. (Fig. 1-27) was born in Manila on March 26, 1917 (the biographical information and photograph presented here were provided by Dr. Rotor) and died in the mid or late 1990s. His mother, an orchid enthusiast, introduced him to her plants before he was 10 years old. By the time Gavino entered high school he knew the scientific names of the major Philippine orchid species. His interest in orchids is probably what led him to major in agriculture at the University of the Philippines where he received his B.S. in Agriculture in 1937.

World War II broke out while Rotor was waiting to go abroad for further study. This delayed but did not alter his plans. He "chose Cornell University for several reasons, the most important ones being Dr. Knudson's presence there and its impressive reputation in the horticultural sciences." After receiving his M.S. degree in 1947 and "hearing Dr. Kenneth Post's lectures on the effects of day length and temperature on the growth and flowering of various florist crops [Rotor] decided to focus on the responses of orchids to temperature and day length" for his doctorate at Cornell University His major professor was the floriculture crop physiologist Kenneth Post (1904–1955). Knudson was a member of his doctoral thesis committee.

In one of his letters Dr. Rotor wrote that he conceived the idea of propagating orchids while attending a lecture by Knudson on the role of sugars in plant growth (Knudson's interest in sugar metabolism and utilization by plants lead him to orchid

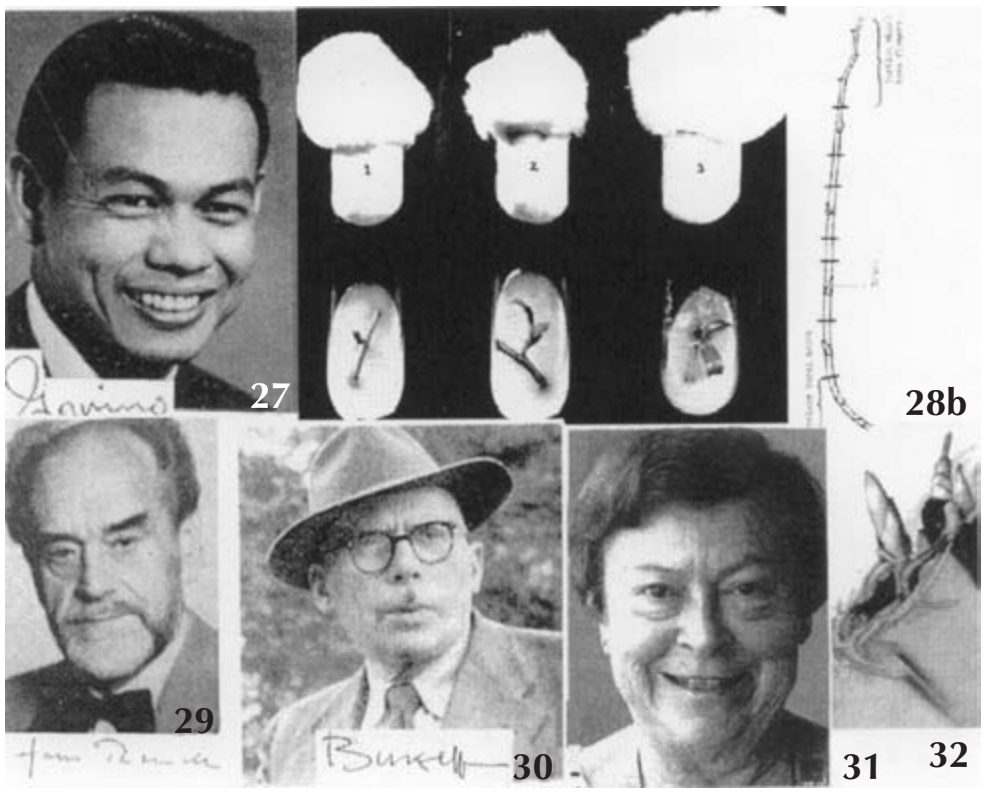

FIG. 1-27–1-32. **Pioneers in orchid propagation. 27. Dr. Gavino Rotor (courtesy the late Dr. Gavino Rotor). 28. seed germination). Rotor did not elaborate on how a lecture on sugars made him think of culturing the nodes of *Phalaenopsis* flower stalks. He cut inflorescences into segments and placed nodal sections, each with one bud, on KC in the hope that the buds would produce plants. The buds became swollen and leaves appeared after 14–60 days. Roots were produced after two or three leaves were formed (Fig. 1-28). Only seven of 65 buds failed to develop (Rotor, 1949). Rotor recalled in a letter that Knudson's "eyes brightened when [Rotor] showed him the first successful propagation . . . and told him how [he] got the idea from [Knudson's] lecture" (Arditti, 1990).

There can be absolutely no question that Dr. Gavino Rotor invented modern orchid micropropagation and was the first to publish a scientific report on clonal multiplication of a higher plant in vitro. His method involved a defined culture medium,

aseptic techniques, and explants. And, he called attention to the propagation potential. Some might argue that his procedure was not true micropropagation (Gautheret discounted its historical relevance when Joseph Arditti called his attention to it in response to a direct inquiry by him, perhaps because he was interested in glorifying his countrymen) because: (1) it produced only one shoot from each explant; (2) explants had pre-existing buds; and (3) Rotor's procedure did not involve callus formation or proliferation. However, multiple plantlet production, callus proliferation, and absence of pre-existing buds are not parts of the definition or requirements for micropropagation.

Rotor's micropropagation method was not widely noticed or appreciated at the time. One reason for this may have been its publication in a hobbyist publication, the *American Orchid Society Bulletin*. Orchid growers who read it probably found the procedure daunting and perhaps failed to grasp its importance. Scientists who would have appreciated Rotor's method and could use it probably did not read the *American Orchid Society Bulletin*. And so it was largely forgotten. When it was finally noticed, claims of priority by others had become accepted widely. However it is clear that in vitro clonal propagation (micropropagation, "mericloning," or any other term that may be used to describe the process for any higher plant in aseptic culture) was first carried out by Dr. Gavino Rotor Jr. in 1949 at Cornell University (those who cultured shoot tips of other plants before him do not seem to have appreciated the propagation potential of their procedures). The number of plants which can be produced by Rotor's method is not large, but it is of practical significance.

During the same time, Professor John T. Curtis (1913–1961; Fig. 1-12) and his associates in the Department of Botany at the University of Wisconsin published detailed descriptions of the formation of many growing points on proliferating callus of *Cymbidium* and *Vanda* (Curtis and Nichol, 1948). They used the word "calloid" to describe protuberances which developed from young asymbiotically germinated seedlings at the protocorm stage after treatment with barbiturates. These investigators noted that the tissue masses often had a capacity for continued growth into complete plants (Curtis and Nichol, 1948), appreciated the potential for clonal multiplication, and stated: "the practical ability to produce clonal lines of plants of potentially unlimited numbers would be of obvious value in many types of genetic and plant production work." However, there is a major difference between the drawing of attention to potential by Curtis and Nichol and the achievement of a well-conceived and clear goal by Rotor. With all that, it should also be noted that in their initial reports the (unfortunately) nearly forgotten Hans Thomale (Thomale, 1954, 1956, 1957) and the (unjustifiably) widely celebrated Georges Morel (Morel, 1960) also called attention to the potential of their findings (for historical accounts of the work by Thomale see Haas-von Schmude et al., 1995; Arditti, 2001; Easton, 2001). But, they did so after Rotor.

The Second Aseptic Culture of an Orchid Explant

The history of orchid micropropagation is elaborate, complex, and contains a few controversial episodes. In an effort not to offend a number of people, the history chapter in the previous edition withheld a number of facts and sugar coated others.

A subsequent review (Arditti and Krikorian, 1996), more concerned with historical accuracy than with offending individuals, is uncompromisingly accurate. As already mentioned this review (Arditti and Krikorian, 1996) served as a basis for a thorough revision of the present chapter. This is being done with permission (for which I am grateful).

Even before the availability of cytokinins (Skoog, 1944; Skoog and Tsui, 1948, 1951; White, 1951; Miller and Skoog, 1955) and the formulation of MS (Murashige and Skoog, 1962), several culture media were adapted for less demanding plants, especially with the addition of auxins, vitamins, and coconut water. Four such media were used to culture geranium, *Pelargonium zonale*, and cyclamen, *Cyclamen persicum* (Mayer, 1956). And this led a German horticulturist and nursery owner, Hans Thomale (Fig. 1-29), and a plant scientist, Dr. Lucie Mayer (Fig. 1-31), to the first reported culture of sections ("*Teilstücken*" or "*Pflanzenteile*") and tissues ("*Gewebe*") of orchids (pages 89–90 and figure 39 in Thomale, 1956; Figs 1-32–1-35).

Hans Thomale (Fig. 1-29) was born in Herne, Westphalia, Germany on October 16, 1919, raised in Cologne, and resided and grew orchids in Lemgo for many years. He started to study chemistry and medicine just before World War II broke out. When he "was half ready" Thomale was drafted and had to interrupt his studies. After World War II he "was forced to learn potato [cultivation] in a well-known nursery which had more orchids . . . than vegetables." The owner of the nursery, Mr. H. Kuhlman, also had a "daughter [Lieselotte] who [earned] the title 'Doctor of Botany' [while] I was forced to be a soldier." She became Mrs. Thomale and they parented two sons and a daughter.

Thomale became interested in orchid seed germination and asked Professor [Hans] Burgeff (1883–1976; Fig. 1-30) for his book *Samenkeimung der Orchideen* and used it to teach himself both symbiotic and asymbiotic seed germination. In 1946 he established a laboratory and utilized it to produce hybrids between the "many fine orchids [Mr. Kuhlman] bought [in] England and Belgium before the war . . . after that I tried to raise . . . orchids [via] clonal propagation" (quotations are from a letter by Mr. Thomale). The laboratory work brought him offers from Dorset Orchids Ltd., Plush, Dorset, UK in 1949 and Sanders Orchids, St Albans, Herts., UK in 1950 (neither business exists now) to establish laboratories for them. Thomale wanted to propagate both tropical orchids and those which were native to Germany. It is clear from his writings that Thomale read widely and was familiar with the work of Gautheret, Mayer, Rotor, Skoog, Tsui, and others.

Thomale based his own work with orchids on a paper by Dr. Lucie Mayer (Mayer, 1956; Fig. 1-31), who worked with him. On September 23, 1956 he was able to report to a meeting of the Deutsche Orchideen Gesellschaft (German Orchid Society) that explants of *Dactylorhiza (Orchis) maculata* (Fig. 1-33) and some tropical orchids in vitro produced shoots (Figs 1-32 and 1-34) and subsequently plants. Thomale recollected, albeit with some uncertainty, that Mr. Lecoufle of the French orchid firm Vacherot and Lecoufle (see below) was present at that meeting. A photograph of the *Orchid maculata* culture (Fig. 1-32) was published in the second edition of *Die Orchideen* (Thomale, 1957). The caption reads: "Section of *Orchis maculata* on agar medium (Mayer's method), which was induced to form roots and shoots" (Figs 1-32 and 1-34). Thomale appreciated immediately the potential of his discovery. He wrote (Fig. 1-35; Arditti and Ernst, 1993; Haas-von Schmude et al., 1995):

33

34

Nur der Vollständigkeit wegen sei darauf aufmerksam gemacht, daß der Wunsch nach einer Vermehrungsart europäischer Erdorchideen dazu führte, dies auf Grund einer Arbeit von Dr. L. Mayer*) durch Kultur von steril gewonnenen Teilstücken auf Agar-Nährböden zu versuchen, was auch gelingt.

Bekannt war bisher, daß vegetative Teile von Orchideen, z. B. sterilisierte Stücke von *Phalaenopsis*-Blütenstielen, die über mindestens eine Adventivknospe verfügen, auf Agar-Nährböden zum Austreiben gebracht werden können. Neu ist hierbei, daß auch vollkommen indifferentes Gewebe einer Pflanze unter gewissen Nährbodenverhältnissen dazu gebracht werden kann, neue Wurzel- und Triebsprosse zu bilden.

Da zur Zeit der Drucklegung des Buches noch keine Veröffentlichung der Arbeitsweise vorliegt, muß es bei der Erwähnung der Tatsache bleiben, daß es bereits möglich ist, aus kubikzentimetergroßen Teilstücken irgendeines Pflanzengewebes neue Pflanzen zu erziehen. Eine Art der vegetativen Vermehrung von kaum zu übersehenden Möglichkeiten!

35

FIG. 1-33–1-35. ***Orchis maculata*** **and the work by Hans Thomale, which lead him to suggest that shoot-tip cultures can be used for micropropagation. 33. Inflorescences during three stages of development: emerging, at the start of anthesis, and with open flowers (Landwehr, 1977). 34. Plants produced from in vitro explants like the one in Fig. 1-32 (courtesy Hans Thomale with help from Dr. Norbert Haas-von Schmude and Mr. E. Lucke). 35. The first description of shoot-tip cultures and the suggestion that such cultures have potential as a propagation method (Thomale, 1957:89–90).**

It should be noted that efforts to find a propagation method for European terrestrial orchids, based on the work by Dr. L. Mayer [Mayer, 1956], through the culture of sterile explants on an agar medium were successful. It is well known that vegetative parts of orchids, for example, sterile sections of *Phalaenopsis* flower stalks [Rotor, 1949], which bear at least one adventitious bud [Note in Arditti and Krikorian, 1996:

> these buds are lateral on the flower stalk and not necessarily adventitious, at least not in the strict sense of the word], can produce shoots when cultured on an agar medium. Recently it has become possible to culture undifferentiated tissues on certain nutrient media to produce roots and shoots from them. Since sufficient details were not available by the time this book went to press [i.e., the second edition which appeared in 1957; the first edition was published in 1954], it is only possible to mention that whole plants can be produced from tissue explants one cubic centimeter in size. *This is a form of vegetative multiplication whose potential cannot be overlooked*" [emphasis added]!

Thomale's work and his prediction about the use of explant culture as a means of mass rapid propagation was published (Thomale, 1957) before the first reports of *Cymbidium* "meristem" cultures (Morel, 1960; Wimber, 1963), but it was overlooked. Another important point is that Thomale behaved professionally by calling attention to Rotor's work, first by mentioning his name (Thomale, 1956) and later by referring to *Phalaenopsis* (Thomale, 1957). Had Thomale neglected to mention Rotor and *Phalaenopsis* he could have created the impression that he originated the entire idea of clonal propagation in vitro. Thomale did not describe his techniques in detail, but referred to Mayer's published procedure on which they were based. In fact, Dr. Mayer participated in Thomale's initial attempts (Haas-von Schmude et al., 1995; E. Lucke and N. Haas-von Schmude, Wettenberg, Germany, 1995, pers. comm.). Dr. Mayer (who retired to Madeira, Portugal) recalls that they also excised and cultured *Cymbidium* stem tips. They never published that part of their work and therefore cannot be credited with it.

Several reasons may be responsible for the fact that Thomale's work did not become well known: (1) his findings were first published in German in an orchid hobbyist publication, which at the time was not well known outside Germany (Thomale, 1956); (2) the second publication, also in German, was in a relatively obscure book (Thomale, 1957, the second edition of Thomale, 1954) aimed primarily at hobbyists and commercial orchid growers. As a result, few scientists read about Thomale's discovery. Practical growers who read it probably did not appreciate the technique and/or were bewildered by it (there is a parallel between Rotor's and Thomale's discoveries and publications and their fates).

Georges Morel (1916–1973; Fig. 1-10) is generally given exclusive, but completely undeserved (Arditti and Arditti, 1985; Haas-von Schmude et al., 1995; Arditti and Krikorian, 1996; Arditti, 2001; Easton, 2001), credit for being the first to culture an orchid explant in vitro. In fact it has been stated that: "few scientists or knowledgeable orchid growers subscribe to the widely publicized view that either Georges Morel or Michel Vacherot in France were the first to meristem orchids, yet these views are rarely challenged in print" (Easton, 2001). One reason for rare challenges is editorial interference (see below). Another is a strongly entrenched urban legend.

There is no question that Morel was familiar with Thomale's work at least as early as 1965 (Fig. 1-36). However, he cited it for the first time nearly 10 years later in a chapter written for Carl. L. Withner's, *The Orchids – Scientific Studies*. This was 14 years after Morel's fame in the orchid world had been firmly established (Morel, 1974; Haas-von Schmude et al., 1995), whereas Thomale was only known to *Paphiopedilum* growers for having formulated a seed germination medium for this popular genus.

(Allemagne)

Versailles, le 15 Décembre 1965

Dear Sir ,

I have been asked by Dr. C. WITHNER to write a chapter on clonal propagation of Orchids for a new edition of his book .

I would like to know if you did other experiments on propagation of Terrestrial Orchids since the one you mentionned in your book, p. 89 .

May I use the picture Ab 39 , of Orchis maculata, for this paper ? In that case, could you be kind enough to send me a print of it ?

Yours sincerely ,

G. MOREL

FIG. 1-36–1-38. **Correspondence and in vitro cultures by Dr. Georges Morel. 36. Letter from Dr. G. Morel to Mr. Hans Thomale requesting a copy of Fig. 1-32. This letter proves that Dr. Morel knew of Mr. Thomale's work long before he cited it (courtesy Hans Thomale with help from Dr. Norbert Haas-von Schmude and Mr. E. Lucke). 37. First photograph of a protocorm-like body published by Dr. Georges Morel (Morel, 1960). 38. *Cymbidium* plantlet produced from a protocorm-like body like the one in Fig. 1-37 (Morel, 1974).**

Even then Morel only cited Thomale's 1957 book and although he accurately reported that "pieces from the bulb of *Orchis maculata*, aseptically cultivated on nutrient medium, soon regenerated stems and roots . . ." he also added the qualifying statement "that [cases like this] are very exceptional." Morel included a copy of a photograph provided by Thomale (Fig. 1-32) in his chapter with the caption "Regeneration of roots and shoots occuring on a piece of tuber of *Orchis maculata*. (After Thomale.)" The wording ("stems and roots") minimizes Thomale's achievement by implying that what was produced was not plants, and the context (a section entitled "Regeneration from Inner Parenchyma") would seem to suggest that the new plants were produced from inner parenchyma rather than from buds, through bud formation, or via some other process commonly associated with tissue culture propagation (see Morel, 1974). Moreover, the photograph was not "after Thomale," it was provided by Thomale because Morel asked for it (Fig. 1-36).

By the time Thomale was given any recognition (Arditti and Ernst, 1993; Haas-von Schmude et al., 1995; Arditti and Krikorian, 1996; Arditti, 2001), essentially total credit for priority of discovery had been established for and by Morel. It is possible to argue that this occurred not only because Morel was already a well-known and established senior scientist in the world of plant physiology and plant pathology and had many friends, but also due to his extensive travels and lectures. Orchid scientists unfamiliar with the historical details presented here, admiring hobbyists, and grateful commercial growers have played a major role in elevating Morel to the position of being virtually the sole participant in "the invention." There was/is also resistance to new knowledge (Gaffron, 1969).

A note marking Thomale's 75th birthday (Lucke, 1994) does not even mention his discovery because a statement to that effect was edited out by the editors of *Die Orchidee* (Dr. Norbert Haas-von Schmude, Wettenberg, Germany, pers. comm.). An article marking the 25th anniversary of "mericloning" (Arditti and Arditti, 1985) was similarly "shortened at the advice of a reviewer." However Thomale's important contribution and priority over Morel were recognized eventually (Haas-von Schmude et al., 1995; Arditti and Krikorian, 1996; Arditti, 2001; Easton, 2001).

Now, after attention has been called to Thomale and his work and to his amazingly accurate prediction, it is no longer correct to state that ". . . Georg[e] Morel has realized for the first time the multiplication of Orchids [sic] by stem tips in vitro culture. Dr. [sic] Thomale seems to be unaware of the tissue culture history" (R. J. Gautheret, Paris, pers. comm.). Cauvinism, national pride, and not even loyalty to a ". . . late collaborator . . ." (R. J. Gautheret, pers. comm.), friend, and fellow countryman can justify the setting aside of historical facts and the rewriting of history. The ones unaware of history as it relates to orchids are Gautheret and those who blindly credit Morel with a discovery he did not make.

Plant Diseases and Meristems

The idea that healthy clones of horticultural plants can be obtained from stem tips, root cuttings, and even leaves is more than half a century old (see North, 1953; Krikorian, 1982; for literature citations). A method for establishing *Verticillium*-free clones of chrysanthemums by making tip cuttings from 10–15 cm (4–6 inch) long

shoots which were shown to be disease-free was reported by Arthur W. Dimock (1908–1972) during World War II (Dimock, 1943*a*, 1943*b*) and subsequently refined and extended to other diseases (Brierly, 1952; Dimock, 1956). Similar methods were used for carnations (Dimock, 1943*a*, 1943*b*, 1951; McFarland, 1948; Forsberg, 1950; Andreasen, 1951; Guba, 1952; Hellmers, 1955; Thammen et al., 1956).

That tips of virus-infected roots could be free of infection was reported 60 years ago (White, 1934*a*, 1934*b*, 1943). Before that, virus or "abnormalities" could not be seen in stem tips of tobacco, tomato, and *Solanum nodiflorum* (Clinch, 1932; Sheffield, 1933, 1942). Aucuba (*Aucuba*, Cornaceae, is a genus of ornamental shrubs known as Japanese, greenleaf, or sulfur leaf aucuba) and tobacco mosaic infections were obtained from isolated shoot and root tips (Sheffield, 1942), but this could have been due to the manner in which the tissues were excised, or to a low virus content (Samuel, 1934). By 1948 stem-tip cuttings were used to eliminate the spotted wilt virus from *Dahlia* (Holmes, 1948, 1955). This method was extended to leaf spots associated with the internal-cork disease in sweet potato, *Ipomea batatas* (Holmes, 1956*a*), as well as aspermy virus (Holmes, 1956*b*) and other viruses (Brierley and Olson, 1956) in *Chrysanthemum*.

The use of stem-tip cuttings to eliminate spotted wilt of *Dahlia* (Holmes, 1948) very clearly suggested that apical meristems might be virus-free. This was confirmed a year later in studies with tobacco mosaic infection of *Nicotiana tabacum* var. Samsun (Limasset and Cornuet, 1949). These findings were fortuitous. At present it is well known that apical meristems are not necessarily free of virus infection and this has led to considerable difficulties in freeing many clones and cultivars of viruses (Kassanis, 1967).

A problem facing French horticulture ca. 1950 was viral infection of certain potato and *Dahlia* cultivars which would have caused them to be abandoned (Lecoufle, 1974*a*, 1974*b*). Given the previous findings with *Dahlia* (Holmes, 1948) and tobacco (Limasset and Cornuet, 1949) the culture of stem tips provided a means of freeing these plants of viruses. And, indeed, Pierre Limasset (1911–1988) and Pierre Cornuet (b. 1925) "suggested to their colleagues Georges Morel and Claude Martin to cultivate shoot meristems of infected plants" (Gautheret, 1983, 1985). The suggestion was excellent, the attempts were successful, and virus-free *Dahlia* (Morel and Martin, 1952) and potato (Morel and Martin, 1955*a*, 1955*b*; Morel and Muller, 1964; Gautheret, 1983, 1985) plants were obtained from infected ones.

Dahlia and potato shoots obtained from stem tips in vitro by Georges Morel and his co-workers did not produce roots. Shoots produced by previous workers also failed to form roots in vitro. Therefore, following established laboratory practice the shoots produced by Morel and his associates were grafted onto healthy seedlings (Gautheret, 1983). Later, other investigators were able to get rooting (Quak, 1961; Hollings and Stone, 1983). Attempts to free potatoes of virus through the culture of shoot tips were also undertaken by a number of others (Kassanis, 1957; Pirie, 1973; see Hirst and Harrison, 1988, for historical perspectives).

The success with *Dahlia*, potatoes, and other plants (Morel and Martin, 1955*b*; Morel, 1964*a*) led Morel "an amateur orchid grower [who] had in his greenhouse a plant of *Cymbidium* Alexaderi 'Westonbirt' . . . the most famous *Cymbidium* of all time, which was, sadly, totally infected by *Cymbidium* mosaic virus [to apply] the same technique as he was using on his potatoes to the *Cymbidium* [and] produced

FIG. 1-39–1-40. **Advertisements for clonally propagated orchids. 39. Part of the cover of the Orchids Orlando catalog which offered orchids that were propagated clonally by the French firm Vacherot and Lecoufle (Orchids Orlando, no date). 40. A page from the Orchids Orlando catalog which tells how Georges Morel came to shoot-tip cultures of orchids (Orchids Orlando, no date).**

a protocorm [sic]" (Morel, 1960; Vacherot, 2000; Figs 1-37 and 1-38). As already mentioned, this achievement has been heralded in a wide array of publications. A particularly adoring pseudo-historical account in an advertisement-catalog makes the claim on its cover that "a funny thing happened to the orchid when they operated on a sick potato" (Fig. 1-39) and the text states that "a beautiful thing happened to the orchids when they operated on a sick potato [because] Dr. Georges Morel, distinguished French botanist, discovered the orchid meristem process while he was trying to figure out a way to prevent virus in potatoes" (Orchids Orlando, no date; Fig. 1-40). Less poetical but equally historically imprecise statements abound in the scientific and horticultural literature as well (for examples see Bertsch, 1966, 1967; Vacherot, 1966, 1977; Marston and Voraurai, 1967; Borriss and Hübel, 1968; Vanseveren and Freson, 1969; Hahn, 1970; Kukułczanka and Sarosiek, 1971; Lecoufle, 1971; Lucke, 1974; Allenberg, 1976; Champagnat, 1977; Rao, 1977; Loo, 1978; Murashige, 1978; Goh, 1983*b*; Bouriquet, 1986; Griesbach, 1986; Hetherington,

1992; Zimmerman, 1996). Much less frequently does one encounter attempts to be more precise about history (Arditti, 1977*b*, 2001; Stewart, 1989; Haas-von Schmude et al., 1995; Arditti and Krikorian, 1996; Easton, 2001). In some instances accuracy was treated gingerly due to editorial pressure (Arditti and Arditti, 1985; Lucke, 1994; N. Haas-von Schmude, Wettenberg, Germany, pers. comm.) or in attempts not to offend established interests (Arditti and Ernst, 1993). The present chapter, like the review (Arditti and Krikorian, 1996) on which parts of it are based, dispenses with such niceties in favor of historical accuracy despite a very real possibility of offending or antagonizing some readers.

Horticulture and plant agriculture are the major beneficiaries of stem-tip culture in terms of massive and rapid clonal propagation as well as generation of pathogen-free plants. The fact that both objectives can sometimes be accomplished simultaneously with one and the same explant has created "an apparent conception among horticulturists that tissue culturing and diseases-freedom [sic!] are synonymous. A similar misconception was true of the so-called meristem-cultured plants. A classic example of this misconception can be seen in the orchid industry. Before "mericloning" orchid viruses were a minor problem. However [they] are now common, widespread and costly" (Langhans et al., 1977) because careless culturing spread rather than contained or eliminated viruses (Toussaint et al., 1984).

The Third Aseptic Culture of an Orchid Explant

Most accounts and reviews of orchid micropropagation seem to start with a citation or at least a mention of Morel's first paper on *Cymbidium* shoot-tip culture (Morel, 1960). A few examples are: "the potential of propagating orchids through tissue culture was observed first by Morel" (Murashige, 1974). Similarly, ". . . credit for the initiation of meristem culture technique goes to the late Dr. G. Morel of INRA [Institut National de la Recherche Agronomique], Versailles, France" (Rao, 1977). Assertions that "the first application [of micropropagation] concerned the clonal propagation of orchids (Morel, 1960)" can be found in historical accounts by a "founding father"of plant tissue culture (Gautheret, 1983, 1985). And, since such reviews are often re-stated or quoted in other papers [e.g., "the potentials of tissue culturing for plant propagation . . . have been . . . reviewed by Murashige . . ." (Langhans et al., 1977)], an historical "factoid" has been elevated to truth and dogma. Once such a transformation happens, the forces which usually resist knowledge tend to maintain the status quo and thus strive to support dogma (Gaffron, 1969).

These factors seem to have come to bear on the history of orchid micropropagation. Attempts to question the accepted views have led to sharp exchanges in the literature (Arditti, 1985; Torrey, 1985*a*, 1985*b*). Editorial demands for changes in manuscripts (Arditti and Arditti, 1985; Lucke, 1994) had to be agreed to. The accepted history was examined carefully (Arditti and Krikorian, 1996) for the sole purpose of placing historical facts in the most accurate perspective possible. That careful re-examination (Arditti and Krikorian, 1996) served (in certain instances word for word) as a basis for what is presented here. Unfortunately, it may not be possible to provide an accurate presentation without creating an impression of an intent to diminish some reputations. Or, to quote the famed physicist Ernst Mach (1838–

1916) as he was quoted by the (well-known in his day) plant physiologist Hans Gaffron in 1969: "It is hardly possible to state any truth strongly without apparent injustice to some other." Indeed, the historical outline in this chapter may appear, to some at least, to be "unjust" only because many previous accounts have been imprecise enough to have done considerable disservice to the truth. And, unfortunately, in an effort not to offend, the first edition of this book (Arditti and Ernst, 1993) also failed to present full historical details.

Georges Morel (1916–1973; Fig. 1-10) was born on April 16, 1916 in Béthune, France and died suddenly around 6 p.m. on December 1, 1973 while going up the steps to his laboratory (Gautheret, 1977). His father, an architect with an interest in horticulture, died in 1928, also apparently of a heart attack. Young Georges attended l'Institution Saint Vaas de Béthune where he showed an interest in physics and chemistry. In 1934 Morel entered l'Institut de Chemie in Paris where his interests led him to agriculture, plant pathology, and the INRA, the French Institute of Agricultural Research (Gautheret, 1977), where he "was one of the most influential members" (Vacherot, 2000).

Drafted into military service in 1939, Morel served with an artillery unit and was taken prisoner at the Belgian front in 1940. He escaped in 1941 according to one source (Gautheret, 1977), or was released due to family hardship according to another (Pierre Jacquet, a chapter in press in *Orchid Biology*, *Reviews and Perspectives* volume IX). On returning to the INRA, Morel was soon appointed "*chef de travaux*." In 1943 Morel joined Gautheret's laboratory (Lecoufle, 1974*a*, 1974*b*) and worked there towards his doctorate. Times must have been difficult under Nazi occupation (Paris was liberated on August 25, 1944), but Morel was successful in his research and even presented a major paper to the Academy of Sciences on January 4, 1944, 8 months before liberation. (Gautheret, 1977, who wrote an appreciation and obituary rather than a detailed biography, reported these events, but provided no details.) Whether he was released early from the POW camp or escaped from it, accepting a fairly visible appointment in a government institution in occupied France was probably not easy and fraught with danger. Therefore, one must admire Morel's bravery. Morel received his doctorate in 1948, went to the USA during the same year, and worked until 1951 with Professor Ralph W. Wetmore (1892–1989) in the biological laboratories at Harvard University. They worked on tissue culture of monocotyledonous plants (Morel and Wetmore, 1951*a*) and ferns (Morel and Wetmore, 1951*b*). One of Morel's tasks during the visit was to establish a plant tissue culture laboratory (Wetmore and Wardlaw, 1951; Wetmore, 1954; Torrey and Thimann, 1972). During that time he also forged lasting friendships at Harvard with several American scientists including the late John Torrey (1922–1993), a noted plant scientist (Arditti, 1985; Torrey, 1985*a*, 1985*b*), and the late Howard A. Schneiderman (1927–1990), an entomologist and developmental biologist. Schneiderman, who held Morel in high regard (and told Joseph Arditti about it), became Dean of Biological Sciences at the University of California, Irvine (UCI) during the late 1960s and the 1970s but his friendship with Morel did not make him a supporter or even a friend of orchid research and the plant sciences at UCI.

Morel also became friends and collaborated with Armin C. Braun (1912–1986) of the Rockefeller Institute in New York City on studies dealing with habituation and hormone autonomy (Braun and Morel, 1950). Braun, a distinguished researcher

on plant tumorigenesis induced by the crown-gall bacterium *Agrobacterium tumefaciens*, has come to be regarded as one of the founding fathers of modern day plant genetic engineering (Braun, 1982). Several techniques rely heavily on the use of the Ti plasmid from that bacterium as a vector for inserting new genetic information (Bevan and Chilton, 1982). On his return to France, Morel was appointed *Maître de recherches* (in 1951 or 1952) and in 1956 *Director de recherches* of the Station Centrale de Physiologie Végétale of the Centre National des Recherches Agronomiques, Ministiére de l'Agriculture (Lecoufle, 1974*a*, 1974*b*).

Dr. Morel's first paper on shoot-tip culture of *Cymbidium* (Morel, 1960) resembles a news release or newspaper notice rather than a scientific paper. It reported sketchily on what was done, described minimally the excision process and culture conditions, and referred to a nutrient medium ("Knudson III") which does not exist. The report concluded by stating "that it is relatively easy to free a *Cymbidium* from the mosaic virus . . . each bud will give several plants so the stock of a rare or expensive variety can be increased . . . [and that] experiments of the same kind are now being conducted with . . . *Cattleya*, *Odontoglossum*, and *Miltonia*, contaminated with different viruses" (Morel, 1960).

This paper (Morel, 1960) introduced a new term into orchid terminology and the English language, "protocorm-like body" (generally abbreviated as PLB), to describe the "small flat bulblet looking exactly like [a] protocorm" (Fig. 1-37) which was formed by the *Cymbidium* stem tips he cultured and preceded plantlet formation (Fig. 1-38). The term protocorm itself was coined by the long-time director of the Bogor (Buitenzorg during Dutch colonial period) Botanic Gardens in Indonesia, Melchior Treub (1851–1910; for photographs see Arditti, 1990, 1992) to describe a stage of lycopod development. Noël Bernard (1874–1911; for a photograph see Arditti, 1990, 1992) applied "protocorm" to the early corm-like stage of orchid seed germination. Bernard did not coin the term as Dr. Phillip J. Cribb stated erroneously (Cribb, 1999). Protocorm-like body, or PLB, should be applied to bodies produced by explants (see Arditti, 1990, 1992; Arditti and Krikorian, 1996 and elsewhere in this volume for further discussions), not to those derived from seeds. And the bodies produced by seeds should not be called PLBs. Neither should they be referred to as "spherules."

The first paper (Morel, 1960) includes only two literature citations. One pertains to the viral mosaic disease (Jensen, 1951). The other deals with freeing plants from virus through stem-tip culture (Morel and Martin, 1955b). It would have been very difficult for anyone to repeat Morel's work because this article did not present sufficient details. Plant scientists who took the trouble to study all of Morel's previous work might have been able to reconstruct the procedures and medium or media. Hobbyists or commercial growers would have had more serious problems in doing that since many of them were looking for a detailed and ready-made magic "formula." However, the orchid firm of Vacherot and Lecoufle "La Tuilerie," Boissy-Saint Leger (Seine-et-Oise) had enough information to start commercial micropropagation of "rare or expensive" orchids before any other establishment. They moved quickly enough to have a clonally propagated plant of *Vuylstekeara* Rutiland "Colombia" bloom in December 1965 (Vacherot, 1966; Lecoufle, 1967), but a recent report suggests that the first plants to be cultured were "some of [their] finest cymbidiums" (Vacherot, 2000).

Clonal propagation of *Vuylstekeara* (a hybrid genus) started at Vacherot and Lecoufle (V&L) 24 years before the publication of a specific method for this genus (Kukułczanka et al., 1989) and only 2 years after: (1) January 1963, the reported excision date of the stem tips (Vacherot, 1966); and (2) the development of culture methods (which were not published in detail at the time) for stem tips of the parent genera (Morel, 1963). A report that ". . . at 'La Tuilerie' our first mericlone to flower [was] . . . *Vuylstekeara* Rutiland 'Colombia' . . . in December, 1965 . . ." (Lecoufle, 1967) suggests that "mericloning" started at V&L before or at about the time Morel's first paper was published because ". . . it will take just as long to grow the plants produced from meristem tissue as it takes to grow a new hybrid from seed" (Scully, 1964). As a rule, orchid plants grown from seed require at least 3 years to flower (excluding some recent *Phalaenopsis* hybrids which can be considerably faster), but there are also reports of hybrids which flowered only after 10 or more years (Goh et al., 1982; Goh and Arditti, 1985). Two years from protocorm-like body to flowering appears to be very fast growth and development (but perhaps not impossibly so) for this *Vuylstekeara* hybrid and especially for hybrids available at that time. Altogether it seems that V&L had access to appropriate methods long before they were published.

There is also a suggestion that some "meristem-cultured plants may mature more quickly than plants raised from seeds" (Lecoufle, 1967). One example is plantlets of *Odontonia* Boussole "Blanche" and *Odontonia* Moliere "Lanni" which were removed from their flasks on April 30, 1965 and "flowered ten to eleven months later and in blocks of hundreds, less than two years after being deflasked" (Lecoufle, 1967). If the *Odontonia* plantlets were "deflasked" on April 30, 1965, the cultures were probably started in 1964 or 1963 which is before the publication of culture procedures for this hybrid genus and its parent genera (*Odontoglossum* and *Miltonia*), but after Morel seems to have developed appropriate methods for these orchids without publishing them.

An early advertisement by V&L ". . . to carry out the new method of asexual reproduction . . ." (Scully, 1964) is also an indication that V&L had considerable and early experience with shoot-tip cultures. Such experience could have been gained only through extensive practice and/or access to procedures and media and/or advice from an expert.

Altogether the facts in the three preceding paragraphs lead to a reasonable assumption that there was a close association between Georges Morel "a close friend of" [Michel Vacherot's] father (Vacherot, 2000) and V&L, as well as an exchange of unpublished information well ahead of publication. This assumption is supported by the following:

1. A report that Morel became interested in orchids as early as 1955 or 1956 (Lecoufle, 1971) and "in 1956 started to apply the techniques of meristem culture . . . previously developed to free potatoes, dahlias and carnations from viruses, to various Orchids [sic]" (Morel, 1965*a*).
2. A statement that in 1956, the year "meristem culture was achieved by Dr. Morel, . . . the first who developed to [Marcel Lecoufle] the theory of the excision and culture in vitro has been [sic] Dr. Martin who was received at Vacherot & Lecoufle in 1956, explaining especially the great advancement made by Dr. Morel in the line of trying to have a virus-free orchid plant from a virus infected plant which

BOISSY ST LEGER, April 1, 1985

Dear Dr. Arditti,

The first one who developed to me the theory of the excision and culture in vitro of the meristem has been Dr. Martin who was received at Vacherot & Lecoufle in 1956, explaining especially the great achievement made by Dr. Morel in the line of trying to have a virus-free orchid plant from a virus-infected plant, which corresponds to his article of 1960. This is the reason why I could in Sydney give these dates.

Sincerely yours,

ML/NF

Maurice LECOUFLE

FIG. 1-41. **Letter from the late Maurice Lecoufle, co-owner of the French firm of Vacherot and Lecoufle, giving his version of history.**

corresponds to his article of 1960" (letter dated April 1, 1985 from the late M. Lecoufle, Vacherot and Lecoufle, 30, Rue de Valenton, 94470 Boisy St. Leger, France; Fig. 1-41).

3 A short conversation Joseph Arditti had at the end of April 2002 with Phillipe Lecoufle, current owner of V&L during the 17th Orchid Conference in Shah Alam, Malaysia. When asked if Georges Morel gave V&L unpublished information, his somewhat huffy reply was an assertion that it was proper for Morel to give them such information because "he worked together with us."

This information suggests that Morel and Martin may have been successful in culturing orchid shoot tips at approximately the time they published their paper on

potatoes. However Morel's first paper on orchids was not published until 1960. This delayed publication, the nature of the first paper (Morel, 1960), and subsequent publications (Morel, 1963, 1964*a*, 1964*b*, 1965*a*, 1965*b*, 1970, 1971*a*, 1971*b*, 1971*c*, 1974) pose a number of interesting questions.

One of these questions pertains to the first paper on *Cymbidium* which showed an 18-month-old explant and included the statement that "some plants that are . . . 10 cm high" (Morel, 1960). A *Cymbidium* plant in vitro or in a pot would certainly grow more than 10 cm in 4–5 years (from 1955 or 1956 to 1959 or 1960 when the paper was submitted and published). Therefore it is by no means clear whether the statements in the paper are accurate (Morel, 1960), or if the report is about plants which were produced specifically for that article.

In a subsequent paper, written in French, Morel added anatomical details regarding the protocorm-like body mentioned earlier and mentioned attempts to extend the *Cymbidium* method to *Odontoglossum*, *Miltonia*, and *Phaius* (Morel, 1963). However he did not provide additional information about excision and culture conditions. This paper actually added to the confusion about a medium, which those seeking to duplicate his results might employ by reporting the use of "Knop's Solution" supplemented with 2% glucose (Morel, 1963). The exact composition of the medium was not given. Morel used a modification of "Knop's Solution" for potato stem tips, but the paper on this method (Morel and Martin, 1955*a*) was published in a journal not widely read outside France and is not cited in the orchid article. Therefore, it would have not been easy for orchid scientists, and even more difficult for horticulturists, to find the paper or the recipe. It is not clear if the omissions (exact composition, no citation) were intentional or inadvertent. What is very clear is a consistent practice of omitting critical information or presenting incompletely and/or in a confusing manner.

Altogether the content (or lack of it) of the first and second papers (Morel, 1960, 1963) tends to support the view that Morel held back information and/or was trying to give V&L an advantage. It is also not clear whether Morel withheld information because he planned to apply for a patent: "Morel . . . was the originator [of micropropagation]. Later, I asked him whether he intended to apply for a patent on his discovery. But by this time the process of meristem culture had become a widely practised technique, so he did not" (Vacherot, 2000). In any case, these papers (Morel, 1960, 1963) do not provide enough details to allow for easy (if any) repetition of the work. In the first paper the medium is described as "Knudson III" and in the second it is given as "la solution de Knopp [sic]". There is no Knudson III medium and one can only assume that the reference is to Knudson C in some form. This medium is very different from Knop's solution, which may or may not be suitable for shoot-tip cultures of *Cymbidium*, *Miltonia*, *Odontoglossum*, *Cattleya*, and *Phaius* that were cultured by Morel (Morel, 1963).

A noted (and now deceased) American orchid specialist has suggested that the paucity of details may have been due to the preliminary nature of the first paper. Perhaps, but even a preliminary paper (Morel, 1960) must include more information. Moreover, the second paper (Morel, 1963) was not preliminary. Another suggestion is that Morel may have been "sloppy." If so, one can expect his other papers to be sloppy, but they are not. Morel was a first rate scientist who wrote excellent papers that were anything but sloppy.

In 1958 Frederika Quak from the Institute of Plant Virology in Wageningen, the Netherlands presented a paper at the International Horticultural Congress in Nice organized by Pierre Cornuet (one of the plant pathologists who suggested shoot-tip cultures to Morel) and Claude Martin (one of Morel's collaborators), of INRA, Versailles. Georges Morel and his wife were listed as attendees at the conference, but there is no evidence that he presented a paper. In a presentation (which did not get published until 1961), Quak focused on her work with potato and the use of White's medium (White, 1954) supplemented with "10 p.p.m. thiouracil, 0.1 p.p.m. 2,4-D or 0.1 p.p.m. IAA" (Quak, 1961), but there was no mention of orchids (Arditti and Krikorian, 1996).

Quak and a colleague (Baruch and Quak, 1966) do not cite Morel's paper on *Cymbidium* as an example of an apical meristem culture that could yield virus-free plants. In connection with their work on *Iris* meristems they state that "best results were obtained with media based on that of Morel. Therefore the formula of that medium only is presented here: ½ concentration Knop solution 1000 ml; Berthelot solution 0.5 ml; cystein 1 mg; adenine 5 mg; hydrolysate of casein 200 mg; saccharose [sucrose] 20 g; agar 6 g; vitamin solution (containing calcium panthothenate 1 mg, inositol 100 mg, biotin 10 mg, nicotinic acid 1 mg, pyridoxin 1 mg, distilled water 100 ml. The media were adjusted to pH 6" (Baruch and Quak, 1966).

Baruch and Quak started their experiment in January 1963 and used about 700 meristems of *Iris* "Wedgewood". The abstract of the paper (in English) draws attention to the fact that the "medium of Morel (pers. comm.) gave the best results." The Dutch summary repeats it. So at least by January 1963 Morel did divulge his nutrient medium recipe and it was published in full by Quak. This was 3 years after Morel's initial publication on orchids and 1 year before the French orchid firm of Vacherot and Lecoufle announced that they could propagate orchids via shoot-tip cultures. Whether anyone could or did make a connection between a paper on *Iris* in a Dutch journal on plant pathology and orchids is open to speculation (Arditti and Krikorian, 1996).

Even if orchid scientists could find the composition of the potato or *Iris* media there were no indications that they would be suitable for orchids. In fact, the potato medium is quite different from the one subsequently used for orchids by Morel. It is also interesting to note that Georges Morel was very familiar with Knop's solution and the modified Berthelot trace elements formulation because he used them routinely in his doctoral dissertation work (Morel, 1948). Those trying to learn more about the media used by Morel for orchids could have learned much from this paper (Morel, 1948), but: (1) the connection was not obvious; (2) his published dissertation is not well known; (3) the journal is relatively obscure; and (4) the language, French, is neither read nor spoken by many scientists.

Modifications of Knop's solution have been used for the culture of vegetative axis nodes of *Dendrobium* and *Bletilla* (Yam, 1989), and flower scape nodes of *Phalaenopsis* (Ball et al., 1974/75), but there is no indication that these, or any, modifications of this medium would be suitable for shoot tips of other orchids. The available evidence suggests that at present there is no single solution which is suitable for all orchids.

A third paper (the second published in English) appeared a year later (Morel, 1964*b*). It was longer, had more illustrations, added the results of more work with three

genera (*Cattleya*, *Miltonia*, *Phaius*) to those that were being cultured, and described the culture conditions. It added confusion rather than clarification regarding the culture medium because it was listed as "Knudson III" again. This paper left no doubt that the culture of shoot tips could be used for mass rapid clonal multiplication, but it did not provide enough information for others to use the technique. In retrospect it is clear that even those who were familiar with all three papers (Morel, 1960, 1963, 1964*b*) would have had to guess which medium to use and how to modify it.

It would be interesting to know whether a written request for the recipe of the nutrient medium would have elicited a positive response. There is no information whether such requests were made regarding any of Morel's orchid media. No such requests would have been necessary for the potato medium because it was published. A paper on potato meristems (Kassanis, 1957) states that "the apical meristems were excised as described by Morel and Martin (1955*a*). The medium in which the meristems were cultured was suggested by Dr. G. Morel, but differs from the one which was described by him (Morel and Martin, 1955*a*). It consists of $^1/_2$ concentration of Knop solution, 10 drops of Berthelot solution (Morel, 1948)."

Basil Kassanis spent a few months with Morel at Versailles in 1954 (Hirst and Harrison, 1988). At least one British grower made "arrangements . . . to visit Professor Morel's laboratory in May of 1964 [and] found Professor Morel and his staff extremely helpful and they taught [him] the technique, giving [him] details of the formula used to produce plants from meristematic tissue." Late in 1964 Morel also visited McBean [McBeans Orchids Ltd., Cooksbridge, Lewes, East Sussex, UK] and [the grower] "was privileged" to work with him (Bilton, 1985). It is not clear whether these reciprocal visits with the British growers were made on a voluntary basis or as a consulting arrangement (Arditti and Krikorian, 1996). By May 1964 the French orchid firm of Vacherot and Lecoufle had in effect established its monopoly (in fact it is also not clear if Morel's association with Vacherot and Lecoufle was voluntary, based on friendship, or based on paid consultancy).

Guessing would not be conducive to success, especially for commercial and hobby growers. Development of another suitable medium would have required time (i.e., caused delays for other investigators and/or growers) and delayed knowledge of the "right" formulation would have decisively secured for Vacherot and Lecoufle the lead they already enjoyed. This is an important point since for a long time the only procedures in the literature for *Miltonia* and *Phaius* were the ones published (albeit unclearly) by Morel (the flower stalk method for *Phaius* in this volume was never published due to the tragic death of its author in a traffic accident in Bogor, Indonesia). However, it is not known whether the medium is pivotal. Several procedures and media are currently available for *Cattleya* and other orchids (see appropriate sections in this volume or in Arditti and Ernst, 1993). The same may be true for *Miltonia* and *Phaius*.

A trio of additional papers appeared within the next 3 years (Morel, 1965*a*, 1965*b*, 1966). They included media recipes. Some of these media did but others did not resemble the Knudson C medium (more than likely Morel's "Knudson III"), Knop's solution, or the potato substrate (Morel and Martin, 1955*a*) enough to be called a modification of any of them. One medium for *Cymbidium* was actually described as "potato meristem medium" (Morel, 1966). Therefore, one is left wondering

about the listing of media (Morel, 1960, 1963, 1964*a*, 1964*a*, 1965*b*), especially since the Knudson and Knop solutions were described as suitable for *Miltonia* and *Cymbidium* in a subsequent paper (Morel, 1970). That paper and an earlier one (Morel, 1966) also contain additional information about the micropropagation of *Cattleya*. Information about Vandaceous and European orchids and *Dendrobium* was published between 1966 and 1970 (Morel, 1966, 1970).

Two reviews (Morel, 1971*a*, 1974) were Morel's final contributions in English on the micropropagation of orchids. Both are excellent and contain a considerable amount of basic information. His last review (Morel, 1974), like some of the previous papers (Morel, 1965*a*, 1966), covers culture media and their components in some detail. The discussion is both interesting and enlightening. Media recipes and details about culture conditions are unambiguous. However, at that point in time the information was much less important and useful than it would have been in 1960. This is so because by 1965, 1966, and 1974, that is 5, 6, and 14 years after the initial publication, (1) the French firm of Vacherot and Lecoufle which was co-owned by a son of a "close friend" of Morel (Vacherot, 2000) had established a monopoly, and (2) as a result of research carried out throughout the world several culture media and procedures for the micropropagation of orchids were formulated and published. Publication of a suitable medium in 1960 would have made the technique available to all who wanted to use it even if (1) the medium used by Morel was not pivotal and (2) several media were later shown to be suitable for some orchids (see Arditti, 1977*b*; Arditti and Ernst, 1993; and the present volume for lists and media recipes).

With one exception (Morel, 1963), the initial orchid papers and several subsequent ones were published in periodicals aimed at hobbyists and commercial growers (Morel, 1960, 1964*b*, 1965*a*, 1965*b*, 1966, 1970) and in proceedings of meetings (Morel and Champagnat, 1969; Morel, 1971*a*, 1971*b*, 1971*c*), rather than peer-reviewed scientific journals. One reason for this could have been a laudable intent to make the procedures available to growers. But if this was so, important information (e.g., culture media recipes, details about techniques, etc.) should have been included in each of them. It was not. Another conspicuous deficiency in these papers is the lack of literature citations. Previous papers by others which may have been the source of ideas, media, and methods were not cited. This is not in line with the accepted standards of scientific publication. Lack of citations creates the erroneous impression that the ideas are original. Peer-reviewed scientific journals would have probably rejected most of these papers due to insufficient information about methods, media, and citation of previous work. Yet there is no question whatever that the caliber of Morel's research was high enough to justify papers which could have been published in peer-reviewed scientific journals. Thus, the inevitable conclusion is that the avoidance of scientific journals and their publication standards was not accidental.

A key question, which is nearly impossible to answer at present, is why was there only a single early paper in English, in a non-reviewed journal, and only an incomplete one at that, namely the one on *Cymbidium* (Morel, 1960)? Subsequent papers on *Cymbidium* (Champagnat, 1965; Champagnat et al., 1966, 1968), *Cattleya* (Champagnat and Morel, 1969; Champagnat et al., 1970), *Neottia nidus-avis* (Champagnat, 1971), and *Ophrys* (Champagnat and Morel, 1972) were published in reviewed French journals. Despite its prominence before World War II, French is,

in fact, a language which has long since lost its scientific and international importance and one with which most orchid scientists and growers in the world were/are not familiar. These papers did contain more details than the early one, but by this time the importance of the information was much reduced because a detailed procedure, complete with a medium recipe, had already been published by Wimber (1963).

Additional murkiness to this already muddled bit of orchid history was added recently by statements that "It was here [the firm of Vacherot and Lecoufle], around the end of 1959 . . . an American student in botany . . . Walter Bertsch . . . rushed into my laboratory . . . quite excited [and] said 'are you aware what Dr. Morel is doing?' " (Vacherot, 2000). Morel, a close friend of Mr. Vacherot's father (Vacherot, 2000), was working on potatoes at the time, but "he applied the same techniques he was using on his potatoes to . . . *Cymbidium*" (Vacherot, 2000). This lead Mr. Michel Vacherot to cut "some young growth" on the "following morning." After that he "carefully dissected each growth, excising the meristem tips . . . and transferred [them] into test tubes on a Knudson sowing medium" (Vacherot, 2000). Curiously this is the same medium mentioned (but incorrectly as "Knudson III") by Morel, but published after 1959 (Morel, 1965*a*, 1965*b*, 1970). And, interestingly Mr. Michel Vacherot's account differs significantly from the one by his partner Mr. Maurice Lecoufle (see above). Conflicting and/or unclear reports are not new for those who have attempted to unravel the history of this episode in orchid micropropagation. One can only wonder why those who participated in the events befuddle rather than clarify. With some of the participants (George Morel, Walter Bertsch, Maurice Lecoufle) dead, others getting on in years, and the current generation of V&L owner not forthcoming with information, the truth may never become known.

Mr. Michel Vacherot's account may differ from the one by Mr. Maurice Lecoufle but it does agree with a report that "the possibility of producing unlimited numbers of plants from any single orchid clone" drew the attention of the late Dr. Walter Bertsch who lived in Paris at that time and described himself as being "involved with the breeding program at Vacherot and Lecoufle" (Bertsch, 1966). Bertsch suggested that Vacherot and Lecoufle enter the field. They did and were successful immediately (Bertsch, 1966, 1972). As a result "Vacherot and Lecoufle became the first nursery to develop, on an industrial basis, the meristemming of orchids. For ten years they held the monopoly" (Lecoufle, 1995). This monopoly started in the early 1960s or late 1950s (Orchid Digest Staff, 1995). To announce it Vacherot and Lecoufle published a full page advertisement in the *American Orchid Society Bulletin* for June 1964 which included a photograph of a flask containing plantlets of *Laeliocattleya* Chine "Bouton D'Or" and stated "we do it" (Fig. 1-42). The fact that this cross was registered in 1962 (Royal Horticultural Society, 1961–1963) and the size of the plantlets suggest that the cultures were started before publication of culture media for this hybrid genus or its parent genera (*Cattleya* and *Laelia*).

Vacherot and Lecoufle's "we do it" advertisement was followed in December of that year with a photograph of technicians performing aseptic manipulations in what appears to be a sophisticated laboratory for the time (Fig. 1-43). The two advertisements appeared approximately 1 year before Morel first published extensive details about his procedure and the composition of some of his culture media. It is possible to speculate that the close friendship between Georges Morel, the Vacherots (Vacherot, 2000), and the Lecoufles prompted him and/or one of his associates to

FIG. 1-42–1-45. **Advertisements by and for the French firm of Vacherot and Lecoufle (from various catalogs).**

teach Vacherot and Lecoufle the technique and then to delay publication and withhold information for a while (Arditti and Arditti, 1985). Morel's friends bristle at the suggestion that he was associated with a commercial venture: "More important . . . is the need to dispel the notion that Morel's horticultural contacts may have interfered with the publication of his findings . . ." (Torrey, 1985*b*). In actual fact Morel did not shy away from horticultural contacts. He was willing to publicly endorse specific commercial establishments as is clear from a letter which was published in a mail order catalog below a picture of Morel examining a culture vessel (Orchids Orlando, no date; Figs 1-10, 1-44, and 1-45).

In spite of the information above, it is not possible at present to unravel the situation. While still alive Maurice Lecoufle of Vacherot and Lecoufle refused to answer two very direct question: "Did Morel delay publication or not?" and "If he did delay, why did he do so?" Another person who could throw some light on this question, ". . . Dr. [C.] Martin . . . University of Dijon . . . the closest collaborator [who was] going to write to you [Joseph Arditti] and] enlighten . . . several points" (M. Lecoufle, pers. comm.), never did write. Thus, questions still remain. The best service Morel's friends can provide to his memory is to set the record straight openly and clearly.

Yet another aspect in the first papers which requires an explanation is the lack of citations or credit to Loo, Ball, Limasset, Cornuet, and others. Two visitors to Morel's laboratory in the mid 1960s (one a student and the other a sabbatical year researcher) have suggested that this was not ". . . unusual for French scientists – it was a way of life." One of them ". . . in particular, said that he [Morel] spent very little time in the library." This is not consistent with a report by one of the visitors mentioned here that Morel ". . . had a habit of claiming that other people left significant papers out of their reviews." One has to read, or at least see the reviews before making such a statement. Further, many of Morel's other papers contain adequate and detailed citations (Champagnat et al., 1966, 1970) and even uncomplimentary statements about his predecessors (Morel, 1974). These are clear indications that he was familiar with the literature. Our experience also indicates that Morel followed the literature closely and regularly. He commented on one of our papers (Churchill et al., 1971a) a very short time after it was published.

When asked after one of his lectures at a meeting about Ball's contribution to his work Morel replied: "Ah, Ball" and was angry. This "reply," and a description of Morel as a "glory seeker" by someone who knew him, suggest that he did not cite others as a means of reserving credit and priority for himself. Of course, this suggestion is open to questions since Morel has also been described as (1) ". . . one of the pioneers in the study of shoot meristem culture as well as an early advocate for its practical use in multiplication of virus free plants . . . interested in the free exchange of scientific information and discoveries [who] 'did not take any patent because I feel that a scientist does not have to do this . . .'" (Torrey, 1985*b*), and (2) a very nice, kind, and modest man.

The only point left to consider at this junction is whether Morel appreciated the potential of shoot-tip culture as a means of propagation early enough. He did write that ". . . very often the protocorm-like body divided into a clump of four or five identical structures, each of them producing a new plant . . . usually each bud will give several plants so the stock of rare or expensive variety can be increased at the

same time" (Morel, 1960). This is certainly not such a clear and forceful statement as Thomale's (Thomale, 1957). It suggests that he did not realize the full implication of shoot-tip culture as a means of mass rapid clonal propagation, or that he did but preferred not to call attention to this aspect of his work. However, in his third paper (and the second one in English) on orchid shoot-tip cultures Morel wrote: "We have now discovered a new phenomenon which will make it possible to produce many hundreds 'seedling' plants in one year from a single bud. This is a distinctly new technique of clonal propagation by meristem culture" (Morel, 1964a). This quote is clear and forceful, but it states ". . . we have *now* discovered . . ." (emphasis added). The "now" is 4 years after his first announcement (Morel, 1960). Moreover, it was published after Professor Donald E. Wimber (Fig. 1-46)

FIG. 1-46–1-51. **Orchid micropropagation, people and medium components. 46. Professor Donald E. Wimber [photographed in 1988 in Hiroshima by Joseph Arditti (JA), signature from a letter to JA]. 47. had independently discovered shoot-tip cultures (Figs 1-48 and 1-49) and pointed to their potential (D. E. Wimber, 1963, 1965, pers. comm.).

Many consider Morel's orchid work to be highly original and innovative. However a somewhat different picture emerges from a critical evaluation of the historical facts. None of the work that Morel did with potatoes, *Dahlia*, and orchids was original. Media for plant tissue culture in general and stem tips of orchids in particular existed (Loo, 1945*a*, 1945*b*, 1946*a*, 1946*b*, 1946*c*; Knudson, 1946; Rotor, 1949; Mayer, 1956; Thomale, 1956, 1957) before Morel formulated his own by modifying existing ones. Several explant types (shoot tips, buds, nodes) from monocotyledonous plants in general (Robbins, 1922a; Segelitz, 1938; Kikuta and Parris, 1941) and orchid in particular (Rotor, 1949; Thomale, 1956, 1957) were cultured before Morel did it (Morel and Wetmore, 1951*a*). And, a number of procedures were published following established scientific publication protocol prior to his. Shoot tips were used to free plants of virus infection before Morel's work with dahlias, potatoes, and orchids (see above). Even Morel's work on potatoes and dahlias was suggested by others, namely P. Limasset and P. Cornuet (Gautheret, 1983:402, 1985:42).

Georges Morel's major and significant achievement was to produce protocorm-like bodies which were sustainable via subculture and this made true mass rapid clonal propagation possible. He did that by cleverly combining existing procedures and culture techniques into a very useful new application. Having done that, he was also able to generate publicity for an advance whose time had come. He should be credited with imaginatively applying existing knowledge and technology to a new application. Indeed, in this he played a decisive role. However, Morel should not be given the accolades normally reserved for those who originate novel ideas, make basic discoveries, and formulate new principles (Arditti, 2001; Easton, 2001).

In the course of more recent historical reminiscences, it has been claimed that "Ball is really the father of the so called micropropagation method" (Gautheret, 1985:16–17), but if so the same can be said about LaRue and Loo (LaRue, 1936; Loo, 1945*a*, 1945*b*, 1946*a*, 1946*b*, 1946*c*; Ball, 1946). Perhaps Gautheret felt justified in crediting Ball because he showed that stem tips can be cultured in vitro (still, LaRue and Loo did the same). But, Ball does not seem to have appreciated and certainly did not express in print (Ball, 1950) the practical potential of his work. The same can be said of others (LaRue, 1936; Loo, 1945*a*, 1945*b*, 1946*c*; Wetmore, 1954; Krikorian, 1982).

Ball was interested in the basic aspects of growth and development from meristems. Therefore, he is perhaps better viewed as more of an "uncle" than a "father." The same can be said of Loo for his work at CalTech, and LaRue who succeeded in growing "a short typical meristem [of *Naturtium officinale*] into a whole plant" (LaRue, 1936). If Ball is not the father, then Morel could have been, except that: (1) Gavino Rotor Jr. first thought of and implemented in vitro clonal propagation; (2) Hans Thomale was the first to culture orchid tuber explants – he also drew special attention to the mass propagation potential of his work, and (3) Donald Wimber was the first to publish a detailed shoot "meristem" culture procedure and to follow established scientific publication practices in doing it. Still, Morel is considered the father because of the "widely publicized view" (Easton, 2001) which he fostered while at the same time managing to appear modest and unassuming (Arditti, 2001, 2002).

The Fourth Aseptic Culture of an Orchid Explant

Samuel Mosher (1893–1970; Fig. 1-47), a wealthy oilman, grew orchids and eventually established the Dos Pueblos Orchid Company in Goleta, California. Mosher's enterprise included what was described as "the world's largest establishment for the breeding and growing of Cymbidium orchids" (Anonymous, no date). Mr. Mosher was an enlightened and earnest grower and student of orchids, in many ways a throwback to the great British firms of yesteryear like Sanders, Veitch, Black and Flory McBean, Charlesworth, and others (Arditti, 1990). He established a modern and well-equipped laboratory and hired a cytogeneticist, Dr. Donald E. Wimber (Fig. 1-46), to study orchid chromosomes and to manage a large, modern laboratory.

Wimber was born on January 2, 1930 and died of a heart attack in 1997. He received his B.S. from San Diego State College in 1952 and his M.S. and Ph.D. from Claremont College in 1954 and 1956 respectively. He carried out his graduate work under Professor Lee W. Lenz at the Rancho Santa Ana Botanic Garden, became associated with the Dos Pueblos Orchid Company and worked there until 1957. After a period (1958–1960) as a postdoctoral fellow at the Brookhaven National Laboratory, 2 years (1960–1961) at the Royal Cancer Hospital in London, and another stint at Brookhaven (1961–1963), Wimber accepted (in 1963) an appointment at the Biology Department, University of Oregon, remained there and became a distinguished and honored (American Orchid Society Gold Medal) scientist (Ernst, 1992).

While associated with the Dos Pueblos Orchid Company Wimber studied cytology and engaged in seed germination. He was introduced to the technique by Emil Vacin, co-formulator of the Vacin and Went medium (Ernst, 1992). Observing young plants and seedlings led Wimber to the tissue culture of orchids. His first attempt was never published, but it pre-dated both Thomale's and Morel's work. The following account is based on a letter he wrote to Joseph Arditti on December 13, 1976.

Research with embryonic leaves was carried out in the summer of 1955 while Wimber was still a graduate student. It involved several immature shoots from a *Cymbidium lowianum* clone. The shoots were 4–5 cm long. They were surface sterilized with a 10% dilution of the laundry bleach Clorox after a few of the outside scale leaves were removed. Several additional leaves were removed before the last four to six embryonic leaves were broken off and placed on semisolid Vacin and Went nutrient medium. In addition Wimber made several thin transverse sections through the shoot axis after removing many of the covering leaves. Protocorm-like bodies developed at the bases of the embryonic leaves and along the thin sections.

When some of the protocorm-like bodies were quartered and spread on agar, the sections produced plantlets. Wimber showed his results to Sam Mosher and Kermit Hernlund, manager of Dos Pueblos at the time. They were not impressed because the tissues grew slowly. By Christmas of that year the plantlets were only 2–3 mm tall. In 1957 Wimber had a dozen plants in 10–15 cm (4–6 inch) pots. He concluded his letter by stating "I knew I had something, but was rather fearful that some sort of chromosomal change might have occurred so that a faithful reproduction of the parent might not occur." If the cytogeneticist in Wimber had been less persuasive than the propagator he could have been the one credited with the discovery of mass rapid clonal propagation of orchids.

In 1963, Wimber published his first paper on clonal propagation of *Cymbidium* (Wimber, 1963). Like Morel's first paper on shoot-tip culture of *Cymbidium*, Wimber's report was published in the *American Orchid Society Bulletin* (Fig. 1-48, 1-49), but the similarity ends there. Wimber followed standard scientific practice and provided full procedural details, provided the recipe of his medium (modified Tsuchiya), and carefully described the culture conditions (continuous illumination of 100 foot-candles or less, constant temperature of 22°C, rotary shaker, 125-ml Erlenmeyer flasks sealed with rubber stoppers). Also, Wimber was very clear in calling attention to the propagation potential of shoot-tip cultures.

This wealth and clarity of details presented by Wimber is especially remarkable in view of the fact that the procedure was developed while he was employed by a commercial concern which had every right to keep the details secret. By contrast, Morel worked in a government laboratory and at one point received funding from the American Orchid Society. Anyone with the appropriate training or experience with orchid seed germination and the needed facilities could repeat Wimber's work immediately. A subsequent paper elaborated on the initial procedures (Wimber, 1965). Indeed, it could be argued that Wimber was the first to publish on clonal propagation of orchids through stem-tip culture because his was a scientific (albeit non-reviewed) paper (Wimber, 1963), rather than what can be called a public relations announcement or news bulletin (Morel, 1960).

Who Pioneered Micropropagation?

Three lines of research, two short and direct and one long and branched, lead to four separate and independent discoveries of orchid propagation by means of tissue culture. The first discovery, that by Dr. Gavino Rotor in 1949, can be traced to Knudson's work [through the medium (Knudson C) used to culture the *Phalaenopsis* flower stalk buds] and teaching. The scientific and historical line in this case was very short: from Knudson, the famed orchidologist, to a graduate student who had a good idea and made it work (Rotor received his degree for research with Dr. Lawrence McDaniels and Dr. Kenneth Post on the control of flowering in orchids which is still an important work).

Dr. Donald Wimber, chronologically the third discoverer, developed a shoot-tip culture method as a result of his own work with orchid protocorms and seedlings at the Dos Pueblos Orchid Company. His was the shortest line of all since he originated the idea on the basis of his own research (D. Wimber, pers. comm.). He made an interesting observation and followed up on it with innovative research.

The work of Hans Thomale (chronologically the second discoverer) and Georges Morel (the fourth and last discoverer) is based on the line of research which started with Haberlandt and culminated with Loo and Ball. A well-read practical horticulturist, Thomale derived his culture method from a branch of this line established by Dr. L. Mayer. Morel's procedure is based on Limasset's and Cornuet's suggestion, Knudson's and/or Knop's media, and Ball's and Loo's research.

Rotor's approach was the most original since it was not based on any previous or similar work. However, he did not excise the buds from the flower stalks and obtained only one plant per explant. Wimber's is a close second in terms of

originality since it is derived from observations of seedlings growth. He excised shoot tips and obtained multiple plantlets. Thomale's and Morel's methods are the least original since they are based on previous work of the same nature by others with different plants. The differences between them are that (1) Thomale's publication preceded Morel's by 3 years, and (2) he credited the source of his method (". . . a propagation method . . . based on . . . work by Dr. L. Mayer . . .") whereas Morel did not do that (except for misnaming one of the media he used and listing another).

Wimber's and Morel's methods are the most practically useful (immediately after publication and too many years after an initial announcement respectively). Rotor's was used sporadically for a while, but was not very successful or practical. There is no evidence that Thomale's method was used by horticulturists at any time.

Neither Rotor nor Thomale received much if any credit for their discoveries and their contributions are seldom if ever mentioned in the literature. Wimber received some credit, but much less than he deserves. Morel received the lion's share of the credit (as well as adulation, personal publicity, fame, glory, and funding), but deserved much less.

In correspondence with Joseph Arditti, Rotor indicated that the lack of recognition was not a matter of concern for him. After their contributions were made known both Thomale and Mayer wrote to express gratitude for being put on record. Wimber was not disturbed by the lack of recognition and stated so clearly in letters and during a conversation with Joseph Arditti while attending a world orchid conference in Japan. Given Morel's pursuit of glory it is safe to assume that he was pleased by his fame.

Altogether credit should be given to:

1. Dr. Gavino Rotor Jr. for developing the first tissue culture (or in vitro) clonal propagation method for orchids or any other plant even if he did not use an explant as the term is understood at present. The Cornell University Department of Horticulture website reported him as deceased in its update on April 12, 2002.
2. Hans Thomale for: (a) the first clonal propagation method of orchids involving a bud or tip explant; and (b) the earliest clear suggestion that tissue culture has the potential of being used for mass rapid clonal propagation.
3. Professor Donald E. Wimber for being the first to publish a detailed method for the micropropagation of orchids through the culture of shoot-tip explant.
4. Dr. Georges Morel for: (a) suggesting that shoot-tip culture can be used to free orchid plants of viruses; (b) generating considerable publicity for mass rapid clonal propagation through tissue culture; (c) calling the attention of commercial growers to the method; (d) coining the term "protocorm-like body."
5. The firm of Vacherot and Lecoufle for the first commercial use of shoot-tip cultures for mass rapid clonal propagation (on their own and/or with the advice of Dr. Georges Morel and/or Dr. Walter Bertsch).

With all that in mind, it is necessary to keep in mind that the owner(s) of a commercial orchid establishment in the USA claimed to have invented the process (see below).

Root Cultures

B. M. Duggar was trained as a mycologist, received his Ph.D. from Cornell University in 1898 and became a plant physiology pioneer at his alma matter (Krikorian, 1975). There he influenced two young plant physiologists, Lewis Knudson (Fig. 1-25) and William J. Robbins (Fig. 1-19), who utilized aseptic culture methods in their research on roots (Krikorian, 1975). Knudson first used aseptically cultured roots to investigate enzyme secretion and carbohydrate metabolism (Knudson 1916; Krikorian and Berquam, 1969; Krikorian 1975, 1982). Later he worked with root cap cells and showed that they slough off while still alive and can live for several weeks in culture, however they failed to divide and eventually died (Knudson 1919*b*; Gautheret, 1985). That was before plant hormones and vitamins became available. Knudson's studies of carbohydrate metabolism and aseptic culture experiments led him to the asymbiotic germination of orchid seeds (Knudson, 1921, 1922).

Robbins followed a different path. He wanted to test a hypothesis advanced by Jaques Loeb in 1907 that a hormone produced by leaves affected root development in the leaf notches of *Bryophyllum* (Krikorian and Berquam, 1969). To do that he proposed to compare the growth of excised root tips in salt solutions with and without sugar (Loeb, 1907; Krikorian and Berquam, 1969). His idea was that growth in a sugar-containing medium ". . . would demonstrate that sugar was the 'hormone' furnished by the leaf and necessary for the growth of roots in the leaf notches" (Robbins, 1957, cited by Krikorian and Berquam, 1969). Later he succeeded in culturing corn roots and maintained them for long periods (Robbins, 1922*a*, 1922*b*; Krikorian and Berquam, 1969; Krikorian, 1975, 1982; Gautheret, 1983, 1985).

Also in 1922 W. Kotte (Fig. 1-20), who worked in Haberlandt's (Fig. 1-2) laboratory, cultured very short root-tip explants of peas and corn on several media based on Knop's solution and containing glucose, alanine, asparagine, and Justus Liebig's meat extract. The latter was especially effective in supporting normal growth (Kotte, 1922*a*, 1922*b*; Krikorian, 1975, 1982; Gautheret, 1983, 1985). Kotte's purpose was clearly to study the growth of meristematic tissues since ". . . isolated meristematic tissues have not yet been cultured" (Kotte, 1922*a*, translated by Krikorian and Berquam, 1969).

A number of other investigators attempted to culture root tips, but could only obtain limited growth and development. The first successful "indefinite" cultures of root tips were those of tomato in 1934 (White 1934*a*). White's experiments were encouraged by Nobel laureate Wendell Stanley who needed a system for plant virus studies and multiplication. White failed with tobacco roots, but succeeded with tomatoes and obtained virus reproduction in his cultures (White, 1934*b*; Gautheret, 1985). Several years later James Bonner, Robbins, and White demonstrated (separately and independently) the importance of thiamine or its components thiazole and pyrimidine in root cultures (Bonner, 1937; Robbins and Bartley, 1937; White, 1937; Gautheret, 1985). Interestingly, similar findings were made with *Cymbidium* seedlings in the California Institute of Technology (where Bonner spent his entire scientific career) laboratory of Professor Frits W. Went (Fig. 1-5), the discoverer of auxin (Hijner and Arditti, 1973). Numerous investigators worked on root cultures after that with H. E. Street being among the most prominent (Street, 1973, 1977, 1979; Krikorian, 1982; Gautheret, 1983, 1985).

The idea of culturing orchid root tips probably originated independently several times. What may be the first printed suggestion that it could and should be done appeared in a theoretical article which did not report research findings (Beechey, 1970). At the same time our laboratory initiated a research project involving the culture of *Epidendrum* root tips and modified a medium originally developed for the culture of wheat root tips (Ojima and Fujiwara, 1962). Mary Ellen Farrar (later Churchill), an undergraduate student, did most of the work. The roots grew in length only, became thinner, and after 2 years lost their chlorophyll (Churchill et al., 1972b). *Phalaenopsis* roots, which sometimes produce plantlets spontaneously in nature (Anonymous, 1885; Reichenbach, 1885; Fowlie, 1987), proved difficult to culture initially, but were cultured eventually (Tanaka et al., 1976). Roots of *Neottia nidus-avis* (Champagnat, 1971) and other orchids (for a review see Churchill et al., 1973) which also produce buds and/or plantlets in nature seem not to have been cultured.

During the last 20 years roots of *Catasetum* (Kerbauy, 1984*a*; Colli and Kerbauy, 1993; Vaz et al., 1998; Peres et al., 1999), *Cattleya* (Kerbauy, 1991), Crimean orchids (Popkova, 2000), *Cymbidium* (Pindel and Miczyński, 1996*a*, 1996*b*), *Cypripedium yatabeanum* (Jo et al., 2001), *Cyrtopodium* (Sanchez, 1988), *Doritaenopsis* (Tsukazaki et al., 2000; Park et al., 2001), *Rhynchostylis* (Sood and Vij, 1986; Vij et al., 1987), and other orchids (Vij, 1993) have been cultured successfully and used to produce plantlets. It is safe to assume that the future will bring an increase in the number of orchids whose roots can be cultured and used for clonal propagation in vitro.

Rhizome tips have also been cultured, with the earliest success being reported from the laboratory of Professor H. Torikata at the University of Nagoya in Japan (Ueda and Torikata, 1972; for a review see Rao, 1977). The first report of tuber explant culture is that of *Pachystoma senile* (Vij et al., 1983). Other orchids propagated from rhizome explants are *Cymbidium aloifolium* (Nayak et al., 1998), *Cymbidium ensifolium* (Paek et al., 1993; Chang and Chang, 1998, 2000b), *Cymbidium ensifolium* × *Cymbidium kanran* Dougiu (Paek et al., 1993), *Cymbidium goeringii* (Paek and Kozai, 1998), *Cymbidium kanran* Namkuk (Paek and Kozai, 1998), *Cymbidium kanran* Toja (Paek et al., 1993), *Cymbdium kanran* Jeju × *Cymbdium goeringii* (Paek et al., 1993), *Cymbdium niveo-marginatum,* which is viewed by some as being a synonym of *Cymbidium ensifolium* (Paek and Kozai, 1998), *Cymbidium sinense* (Chang and Chang, 2000*a*), *Geodorum densiflorum* (Sheelavantmath et al., 2000), and other orchids.

Leaf Cultures

A number of the early attempts to culture plant cells and tissues by Haberlandt and others were made with leaf explants. These attempts failed because the cells were differentiated (Krikorian and Berquam, 1969; Krikorian, 1975, 1982; Steward and Krikorian, 1975; Gautheret, 1983, 1985). However attempts to culture mature differentiated palisade parenchyma of some plants were successful (Joshi and Ball, 1968*a*, 1968*b*).

At least one orchid [*Hammabrya* (*Malaxis*) *paludosa*] produces bulbils at its leaf tips (Ray, 1724; Godfery, 1933; for reviews see Arditti et al., 1971; Ball et al., 1971; Churchill et al., 1971*a*, 1971*b*, 1971*c*, 1972*a*, 1973). Leaf cuttings can be made of

Restrepia species (Webb, 1981). However these phenomena did not lead to the development of tissue culture procedures for leaf explants. The tendency of juvenile leaves on protocorms to produce protocorm-like bodies lead to the development of micropropagation methods through culture of leaf bases (Champagnat et al., 1970). A claim that these procedures were developed even earlier (Morel, 1960, 1965*b*, 1966, 1970) is not supported by the available evidence ("*Keine Angabe vorliegend*" in Zimmer, 1978).

The first unambiguous and well-documented report that leaves can produce protocorm-like bodies was made in cultures derived from *Cymbidium* shoot tips (Wimber, 1965). An earlier observation in 1955 that embryonic leaves of *Cymbidium lowianum* placed on Vacin and Went medium formed protocorm-like bodies was not published (D. E. Wimber, pers. comm.; Arditti, 1977*a*).

Leaf tips were first used to propagate orchids (*Epidendrum* and *Laeliocattleya*) as a result of unsuccessful attempts to culture foliar explants similar to those taken from peanuts (Joshi and Ball, 1968*a*, 1968*b*). In 1968/1969 – shortly after Professor Ernest A. Ball moved from North Carolina State University to the University of California, Irvine – Ball's laboratory and our laboratory initiated a joint project to culture orchid mesophyll cells. After these explants failed to grow we attempted to culture leaf tips and succeeded almost immediately. The work was carried out by Mary-Ellen Farrar-Churchill who was then an undergraduate student.

A major advantage of leaf-tip cultures is that removal of explants does not endanger the donor plant. Because of that orchid growers and propagators were interested in these methods. To make them widely available they were published in a number of journals and several languages (Arditti et al., 1971; Ball et al., 1971; Churchill et al., 1971*a*, 1971*b*, 1971*c*, 1972*a*, 1973).

Success with these procedures depends on removal of explants before the leaf tips differentiate fully and lose their ability to form callus. If the tips are not taken at the proper stage (i.e., while the tip is still pointed and before the formation of a notch) they die rather than develop when placed in culture. For this reason these methods require attention to detail and are not always easily reproducible. This lead to questions following their publication. However the doubts were resolved following reports that the leaves of *Acampe praemorsa* (Nayak et al., 1997*a*), *Aerides maculosum* (Murthy and Pyati, 2001; Murthy et al., 2001), *Aranda* (Loh et al., 1975; Fu, 1978*a*, 1979*b*; Manorama et al., 1986), *Ascocenda* (Fu, 1978*a*, 1979*b*), *Cattleya* (Fu, 1978*a*, 1979*b*), *Cymbidium* (Gopalan et al., 1992; Pindel and Miczyński, 1996*a*, 1996*b*), *Dendrobium* (Manorama et al., 1986), *Laeliocattleya* (Matos and de Garcia, 1991), *Mokara* (Abdul Ghani and Haris, 1992), *Oncidium* (Chen et al., 1999; Chen and Chang, 2001), *Papilionanthe* (*Vanda*) *teres* (Pathak and Vij, 2001), *Phalaenopsis* (Tanaka et al., 1974; Tanaka and Sakanishi, 1977; Tanaka, 1992; Park and Paek, 1999; Park et al., 2002), *Renantanda* (Goh and Tan, 1982), *Renanthera imschootiana* (Seeni and Latha, 1992; Fukui et al., 2001), *Rhynchostylis retusa* (Vij et al., 1984), terrestrial species (Allenberg, 1976), *Vanda* (Tanaka et al., 1974), *Vanda coerulea* (Seeni and Latha, 2000), *Vanda cristata* (Sharma and Vij, 1997), *Vanda teres* (Niraula and Rajbhandary, 1988), and other orchids (Vajrabhaya and Vajrabhaya, 1976*a*; Chaturvedi and Sharma, 1986) were cultured successfully (for reviews see Arditti, 1977*a*, 1977*b*, 1978; Rao, 1977; Zimmer, 1978, 1980; Fast, 1979; Arditti and Goh, 1981; Czerevczenko and Kushnir, 1986).

Stems

The culture of *Arundina* stem sections was first mentioned in 1966 at the 5th World Orchid Conference in Long Beach, California, but only limited information was presented at the time (Bertsch, 1966; for a review see Zimmer, 1978). Details (from a procedure developed independently of other investigators) became available following the publication of an interesting paper based on a comprehensive investigation of the culture of seeds, shoot tips, and stem disks of this orchid (Mitra, 1971). *Dendrobium* nodes were cultured in 1973 (Arditti et al., 1973; Mosich et al., 1973, 1974*a*, 1974*b*). Stem sections of other orchids have also been cultured.

Flower Buds, Flowers, Floral Segments, and Reproductive Organs

Excised ovaries were the first orchid flower segments to be cultured. This was carried out by Professor I. Ito at the Kyoto Prefectual University in Japan (Ito, 1960, 1961). In an earlier paper Ito reported on another first: the culture of immature *Dendrobium* seeds (Ito, 1955). Subsequent reports regarding the culture of immature seeds (often and erroneously called ovules) are of *Vanilla* (Withner, 1955), *Phalaenopsis* (Ayers, 1960), *Dendrobium* (Niimoto and Sagawa, 1961), *Vanda* (Rao and Avadhani, 1964), and *Paphiopedilum* (Ernst, 1982; for reviews see Withner, 1959; Arditti, 1977*b*; Rao, 1977; Zimmer, 1978; Czerevczenko and Kushnir, 1986). Immature seeds of many additional orchids have been cultured since then. In some cases this is the preferred method of sexual propagation since it saves time and facilitates the germination of several species. This is not a method of micropropagation as such – it is a method of sexual (seed) propagation. However since the contents of ovaries are scraped onto a culture medium it is entirely possible that some of what are presumed to be seedlings may be plantlets produced by ovary tissue and/or cells.

The first young flower buds or inflorescences to be cultured were those of *Ascofinetia*, *Neostylis*, and *Vascostylis* (Intuwong and Sagawa, 1973). Those of *Cymbidium* (Kim and Kako, 1984; Shimasaki and Uemoto, 1991) *Phalaenopsis*, *Phragmipedium* (Fast, 1980*b*), and other orchids were cultured subsequently.

Inflorescences

In anointing "fathers" and giving credits to others for the discovery/invention of micropropagation, a self-appointed arbiter (Gautheret, 1983, 1985) did not even mention Dr. Gavino Rotor's culture of *Phalaenopsis* flower stalk nodes. Nevertheless, Rotor's work pointed the way and others followed by culturing inflorescence explants of several orchids including *Aranda* (Goh and Wong, 1990), *Dendrobium* (Singh and Sagawa, 1972), *Doritaenopsis* (Tokuhara and Mii, 1993; Yamazaki et al., 1997), *Mokara* (Abdul Ghani et al., 1992), *Oncidium* (Chen and Chang, 2000*a*), and *Phalaenopsis* (Ichihashi, 1992*a*, 1992*b*; Tanaka, 1992; Tokuhara and Mii, 1993, 1998, 2001; Chen and Piluek, 1995; Duan and Yazawa, 1995*a*, 1995*b*; Ichihashi and Hiraiwa, 1996; Jiménez and Guevara, 1996; Park et al., 1996; Yamazaki et al., 1997; Islam et al., 1998; Ichihashi et al., 2000; Tokuhara and Mii, 2001; Park et al., 2002).

A Patent

Orchids have always been associated with legends (Lawler, 1984), unusual claims, flamboyance, and interesting attempts to turn a profit. Micropropagation has not been spared some of these.

Perhaps the most interesting and imaginative incident was the attempt to control orchid propagation by means of tissue culture through a patent. This was not a plant patent to cover an exceptional cultivar which is an ethical and accepted practice (Kock, 1967). A claim was made by Mr. Everest McDade (ca. 1916 to ca. 2000; Fig. 1-50) that he developed and used the process as early as 1950 and kept it a secret. He obtained a patent (No. 3,514,900) at least in part on the basis of this assertion (Bergman, 1971). Morel's publications and a publication by the late Professor Harry Kohl (one of Joseph Arditti's professors at UCLA; Kohl, 1962) and Wimber were also used to bolster the application (Torrey, 1985*b*) despite (or perhaps because of) the fact that neither of these scientists nor Michel Vacherot and Walter Bertsch tried to patent the process (Vacherot, 2000).

After the patent was issued an attempt was made to hinder further research. Shortly after publishing our papers on the culture of leaf tips (Churchill et al., 1970, 1971*a*; Ball et al., 1971), we received a letter informing us that our research constitutes an infringement on the patent. The letter also stated that the patent was for sale and offered it to us. We referred the matter to the University of California attorney, who did whatever was necessary. We were never contacted again. In 1972 the patent was sold to the National Orchid Grower's association for $40,000 and placed in the public domain (Easton, 2001).

Details about this bizarre story were sketchy for a while. Now there are two accounts of it. One of these accounts (Arditti and Krikorian, 1996) was pieced together from the literature, conversations with several people, and a letter from Mr. Everst McDade (Asheville, North Carolina) following publication of the first edition of *Micropropagation of Orchids* (Arditti and Ernst, 1963). The second account was published recently (Easton, 2001). The two accounts do not fully agree with each other.

According to the letter from McDade, an electronic engineer, science teacher, and co-owner of Rivermont Orchids, Signal Mountain, Tennesee (the firm no longer exists) until ca. 1949 (or 1950 according to the second account), a "photo of a *Cymbidium* bulb, with a cluster of buds at its base" in an article from ca. 1946 or 1947 (which McDade did not have and claimed he was trying to find again) gave him the idea. It "was a very sudden clear message to us [McDade]. Just what we had been looking for: a renewable source of 'Ramets.' . . . We wanted to use the process for *Cattleya* types. . . . I adapted the *Cymbidium* idea to cattleyas."

The second account tells the story differently: "From early June 1950 [McDade] concentrated on liquid embryo orchid culture, which developed into clonal propagation . . . James Gentry . . . an engineer . . . an assistant [in the] process . . . recalls his work with orchid seeds in 1950 where seedling leaf development was chemically inhibited and each seed developed into a mass of tissue like cancer." When "separated and placed on solid sterile medium . . . they . . . developed . . . into plants." This interesting account brings into the picture embryo culture which was developed several years after 1950 and chemical inhibition of growth, a process which would have required considerable knowledge of plant physiology. It is hard to accept that

two engineers (McDade and Gentry) were far enough ahead of orchid and plant scientists to do all that. Be all this as it may, protocorms often proliferate naturally. Also propagation involving protocorms is sexual. Plants produced in this manner "were in bloom Easter Sunday 1957."

According to McDade, his secretary Dorothy Smith (who was not reported to have plant science training) "made the first meristem cultures in 1950." And, the second account contains an undated photograph of Ms. Smith with a caption that states that she "excised the first meristem tissue to be subsequently multiplied." But the second report also states that Gentry, the engineer, was working with half inch tissue "cubes from the heart of cattleya pseudobulbs" and later with dormant buds from rhizomes which began to multiply in 1951 and flowered in "the late 1950s."

McDade claims that he "wrote scores of letters . . . to authors . . . botany and genetics journals [but] Only a few people took them seriously, or even guessed that we had discovered cloning in [the] year 1950." He also claims that "in October, 1952 [he] actually gave the cloning process paper to the [American Orchid Society Bulletin] . . . for publication and *demonstrated a growth developing from a Cattleya flower stem, a flask, and community pot of a clone*" (emphasis by McDade). According to the second report "In November 1953, Everest was asked by Gordon Dillon, editor of the *A*[*merican*] *O*[*rchid*] *S*[*ociety*] *Bulletin*, to write an article, which he titled "Clones, a new method for the vegetative multiplication of an individual plant." For unknown reasons, the article was never published, and finally was returned to the author in the 1960s.

This statement raises two questions. First, the *American Orchid Society Bulletin* published Morel's first article in 1960 (Morel, 1960) and one wonders why an invited article which describes a revolutionary process would remain unpublished. Second, there are many orchid publications, all constantly in search of articles. Orchid growers, amateur and professional alike, are well aware of this. Therefore the question is why did not a person who "wrote scores of letters . . . to authors . . . botany and genetics journals" submit the returned article to another publication.? There can be very little doubt that it would have been published even after Morel's 1960 article. Wimber's papers were published by both the *American Orchid Society Bulletin* and the *Cymbidium Society News*.

McDade's claims are also not borne out by: (1) his paper in the *American Orchid Society Bulletin* (McDade, 1952); (2) Rivermont advertisements from that period which did not offer for sale any orchids described as being clonally propagated; (3) the patent itself which "relied on" publications by Morel, Kohl and Wimber (Torrey, 1985*a*, 1985*b*); and (4) the chronology involving an idea, which supposedly originated in 1946 or 1947, cultures that were presumably first made in 1950 or 1951, work published between 1955 and 1963, and a patent issued in 1970.

At least three additional arguments can be made against the claim. The first is that the development of tissue culture procedures is not a simple matter. It requires considerable knowledge of plant science. Therefore it is very unlikely that a person or persons not trained and known in plant sciences could have discovered it. This is perhaps the reason why an effort was made to base the claim at least in part on the work of others.

The second is that the process had (and still has) considerable potential for financial gains. Those who used it after 1960 did benefit from it financially. The person

who patented it was clearly aware of (and interested in) financial gains. It is therefore surprising that he did not obtain his patent and publicize the method in 1950. He did so only after 1960 and this suggests that the idea for the patent originated following Morel's first paper in English (Morel, 1960), sketchy as it was. McDade contacted a patent attorney in 1952 and expected that "it would probably take four years (1956) before the orchids he was propagating . . . would flower and be ready for patenting" (Easton, 2001). Even if the plant took longer to flower, and "ultimately [*Cattleya*] Bow Bells 'Edith McDade' would flower in the late 1950s" (Easton, 2001), a patent could have been applied for before Morel publicized his work in 1960.

Third is the fact that evidence usually associated with priority claims is not available. Such evidence generally consists of scientific papers published in peer-reviewed journals, patents, presentations at scientific meetings, and public demonstrations.

By 1974 the furor died down (Arditti, 1977*b*) and not much was heard about the patent for almost 30 years after that (Easton, 2001). The reason for this is undoubtedly the sale of the patent. This episode is unfortunate and points to lax patent laws and lack of careful scrutiny by those who approve patents.

Doubtful Claims

Paphiopedilum species and hybrids have been very popular with orchid growers for a long time. Unfortunately, this genus is difficult to culture. An attempt to capitalize on this difficulty started in the mid 1970s with a content-free article on the tissue culture of *Phragmipedium* (Stokes et al., 1975), another diandrous genus. The authors of this paper were employed by a commercial tissue culture laboratory in the UK.

At about the same time the same laboratory announced that it had developed a tissue culture method for *Paphiopedilum* and would, for a fee, undertake to propagate plants for growers. This claim received some attention at the time. Probing questions regarding the technique were dismissed as being due to professional jealousy. Details about the tissue culture procedure were withheld with the explanation that the method was "proprietary and developed by a commercial laboratory." Eric Young, founder of the orchid foundation which bears his name, was an especially vociferous, loquacious and overbearing promoter and defender of the laboratory which he described as "highly competent and fully equipped."

The laboratory in question promised to display its *Paphiopedilum* cultures at the world orchid conference in Frankfurt in 1975. Joseph Arditti (JA) was invited to see them and visited their booth several times. The purported flasks and photographs were never there having been "borrowed" by someone who "promised" to return them in time for a subsequent next visit, but never did. On a third visit JA waited a long time for the "borrower" to return, but he/she never showed up, and neither did the flasks and photographs. A few months after that the laboratory announced that they would no longer accept *Paphiopedilum* plants for tissue culture.

It is not clear whether any growers submitted *Paphiopedilum* plants for culture and if so what the outcome was. However, the history of research on tissue culture of *Paphiopedilum* suggests that the announcement may have been based on: (1) over-optimism generated by one or a few preliminary successes; (2) an attempt to

capitalize on several procedures (none of them reported to have been repeated) by other researchers which were published at that time (see section on *Paphiopedilum*); (3) wishful thinking; (4) overblown imagination; (5) triumph of hope over reality; and/or (6) simply an attempt to generate business one way or another. One of the individuals associated with this fiasco was apparently associated with another cloning laboratory for a while, but seems to have disappeared from the orchid scene. The other changed employment, and may also no longer be working with orchids. Altogether this is another bizarre chapter in the history of orchid propagation.

Mutations

Since micropropagation is a vegetative means of propagating plants, both horticulturists and scientists assumed at the outset that all offsprings will be true to their parents. This assumption was reinforced by an early report regarding the blooming of "mericlones" which stated that "for each individual cultivar the flowers appeared exactly identical, and in hundreds of them no mutation was observed" (Lecoufle, 1967). Others were equally sanguine (Teo and Teo, 1974; Teo, 1975, 1978, 1978/1979, 1981; Joseph Arditti in conversations) since theoretical considerations suggested that this should be the case.

As experience with micropropagation increased, it became evident that mutations do occur. Among the first to call attention to this were the Thai orchid scientists Professor Thavorn Vajrabhaya and his wife Professor Montakan "Mon" (Vajrabhaya and Vajrabhaya, 1976*a*, 1976*b*; for a review see Vajrabhaya, 1977). Experience since then has shown that mutations do occur during tissue culture (Sahavacharin, 1980; Rentoul, 1981; Teo, 1981; N. Haas-von Schmude, pers. comm.; for additional references see specific procedures in this volume) and are especially prevalent in cases where high concentrations of hormones are used to force excessive proliferation and the production of many plantlets.

Phenotypically these mutations include changes in color, shape and size of blossoms as well as malformed flowers. In some overproliferated clones individual flowers on a raceme may die and render it commercially useless.

It is impossible at present to prevent mutations from occurring or even to predict their nature. However it is possible to reduce their incidence by not overproliferating plants during micropropagation, and not micropropagating plants obtained through tissue culture. Unfortunately, it is impossible to prevent unscrupulous or ignorant propagators from engaging in these practices. *Caveat emptor* is the only protection. Growers can protect themselves by: (1) purchasing plants only from known and reliable sources; (2) keeping each other informed regarding laboratories which produce good or bad plants; and (3) demanding guarantees. However, the best protection is for hybridizers and growers to propagate their own plants.

Theft in Vitro

It is not uncommon for growers and breeders to have their most promising hybrids propagated by commercial micropropagation laboratories. Several of these laboratories

illegally and unethically set aside some of the plants and sell them if a demand develops for a particular clone. This (1) floods the market, (2) reduces prices and the value of the orchid in question, and/or (3) makes it impossible for hybridizers to control their crosses or for cut flower growers to become the sole source of a desirable variety. As with overproliferation there is not much growers can do about this problem except select laboratories carefully and spread information about reliable or unreliable propagators. Another possible approach would be for growers and hybridizers to establish well-supervised laboratories for the purpose of propagating their own plants.

Darkening of Culture Media

Media used for orchid seed germination and micropropagation are sometimes darkened with charcoal to improve growth and development. Professor John T. Curtis (Fig. 1-12) at the Botany Department, University of Wisconsin was the first to darken a nutrient medium for orchid seedlings in vitro. He used lampblack, which is soot produced by the burning of petroleum hydrocarbons. It has very little in common with charcoal except color. Lampblack lacks the large internal surface area, adsorptive properties, and pore structure of charcoal. It has long been used in the production of black inks and paints. Curtis darkened his medium in an unsuccessful effort to simulate natural conditions and thereby bring about the germination of *Cypripedium reginae*, *C. pubescens*, *C. parviflorum*, *C. candidum*, and *C. acaule* seeds (Curtis, 1943).

The charcoal used in orchid media (Fig. 1-51), generally referred to as vegetable charcoal, is made from wood, sawdust, peat, and organic residues which are recovered during the production of pulp (West Virginia Pulp and Paper, no date), carbonized and activated to produce a large surface area. One gram of Nuchar (a commonly used brand) may contain up to 120 billion particles and have a total surface area of 500–2000 m^2. Pore distribution can range from <10 μm to >500 μm (Yam et al., 1990). The pore to volume ratio is 0.9 ml g^{-1}. Charcoal can contain many elements, some in very small amounts (Yam et al., 1990). It is activated through treatment of the carbonized pyrolysis product with steam or carbon dioxide (Yam et al., 1990).

Professor Peter Wekmeister in Germany was the first to darken an orchid culture medium with charcoal (Werkmeister 1970*a*, 1970*b*, 1971). Before that charcoal was employed to darken a medium used to germinate moss spores and grow filamentous algae (Proskauer and Berman, 1970; Krikorian, 1988). Werkmeister darkened the medium to study the growth of roots, gravitropism, and proliferation of clonally propagated plantlets. He died not long after publishing the last of his orchid papers.

Robert Ernst (b. 1916; Fig. 1-55), a surfactant chemist and manufacturer and now a retired Adjunct Professor of Biology at the University of California, Irvine, was the first to add charcoal to practical seedling culture media and found that *Paphiopedilum* and *Phalaenopsis* seedlings grew well on it (Ernst, 1974, 1975, 1976). His findings resulted in the formulation and widespread use of charcoal-containing media for orchid seed germination, seedling culture, and micropropagation (Ernst, 1974, 1975, 1976; for a review see Yam et al., 1990).

Anticontaminants

The first attempts to formulate media which do not require sterilization involved the use of vanillin and its derivatives (Knudson, 1947; McAlpine, 1947; K. L. McAlpine, pers. comm.; for a short review see Thurston et al., 1979) as well as several antibiotics. All proved to be phytotoxic and could not be used. A number of fungicides and bactericides were screened in our laboratory by several brilliant undergraduates, including Sharon Spencer (Fig. 1-52A), Katie Thurston (Fig. 1-52B), Jan Cooper (Fig. 1-53), Marilyn Cvitanik (Fig. 1-54A), and Kathy Hills (Fig. 1-54B). Several combinations of these substances can be of limited practical use for seed germination (Thurston et al., 1979, 1980) and micropropagation (Spencer et al., 1979/1980; Brown et al., 1982). In general the use of antibiotics and other anticontaminants in orchid micropropagation is limited. A number of phytoalexins and related substances were also screened for phytotoxicity (Hills et al., 1984) and could perhaps prove to be useful if they were to become available commercially. Several antibiotics are being used in tissue culture and micropropagation of other plants. PPM™, a commercial preparation (see Chapter 2), may also prove useful.

Knudson C medium which does not require sterilization and remains free of contaminants has been prepared with 0.1% hydrogen peroxide (Snow, 1987). After a suitable period any hydrogen peroxide which still remains in the medium is decomposed through the use of a sterile catalase solution. The question is whether sterilizing an enzyme (i.e., protein) solution and adding it to the culture under sterile condition is not more complicated than autoclaving the Knudson C medium.

Cell and Protoplast Culture

The first attempts to culture free plant cells utilized mechanically isolated ones. Gottlieb Haberlandt made fairly intensive, but unsuccessful, efforts to culture cells in 1898 and 1902 (Krikorian and Berquam, 1969; Krikorian, 1975, 1982; Steward and Krikorian, 1975). A suggestion (Gautheret, 1985) that Haberlandt failed because he

neglected the findings of a French naval architect, agronomist and student of trees Henri-Louis Duhamel du Monceau (1700–1782) probably has its roots in Gallic chauvinism rather than in scientific reality. Haberlandt failed because: (1) he selected mature, differentiated, specialized non-meristematic (i.e., inappropriate) cells to culture; (2) his ideas were ahead of their time and more advanced than the available plant science technology; (3) not all necessary components were present in the culture media he used ; (4) the plants he chose included monocotyledonous species which can be recalcitrant; (5) there was no previous information to guide him; and (6) his cultures, although clean, were not aseptic (Haberlandt, 1902 translated by Krikorian and Berquam, 1969).

Haberlandt used "tap water, one to five percent sucrose solutions, and Knop's solution with or without sucrose, dextrose, glycerine, asparagine and peptone in various combinations and concentrations." This quote is from Krikorian and Berquam (1969), who raise the question of what might have happened "had coconuts been generally available in Berlin," but it is also interesting to wonder whether they caught his fancy when he saw them (Arditti and Krikorian, 1996) because Haberlandt visited Buitenzorg from November 1891 until February 1892 and spent time in other parts of tropical Asia (Haberlandt, 1910).

Lewis Knudson's attempt to culture sloughed-off root-cap cells of corn and Canada field-pea (Knudson, 1919b) is not as well known as his work with orchids, but is still well ahead of its time. As culture media he employed water and, foreshadowing his work with orchids (for a review see Arditti, 1990), also Pfeffer's Solution, which he modified by replacing dibasic potassium phosphate with the monobasic salt with or without 0.5% sucrose. Some of the Canada pea cells survived for 50 days when roots were also present in the culture medium. The cells lived for an additional 21 days after removal of the roots despite becoming contaminated.

Knudson's experiments suggested the diffusion from roots of growth substances which the cells required, but this research was carried out: (1) 8 years before the discovery of auxins (Went, 1928, 1990; Thimann, 1980); (2) about 20 years before it was demonstrated that vitamin B_1, niacin, and other factors enhance the growth of plant sections in general and excised roots in vitro in particular (Bonner, 1937, 1938, 1940*a*, 1940*b*; Addicott and Bonner, 1938; Bonner and Devirian, 1939); and (3) 35 years before the discovery of cytokinins (Miller et al., 1955*a*, 1955*b*; Miller, 1961, 1977; Skoog, 1994).

Even if Knudson had surmised that his cells needed growth substances, few if any were available or even known at the time and his attempts were doomed to failure. Aseptic techniques were available in Knudson's laboratory by that time even though the culture experiments were carried out 1–2 years before he started work on non-symbiotic germination of orchid seeds (for a review see Arditti, 1990). It is surprising that he did not use them.

The first isolated cells to be cultured successfully were those of tobacco, *Nicotiana tabacum*, and marigold, *Tagetes erecta*. They were grown on filter paper platforms placed on top of proliferating callus masses (for reviews see Muir et al., 1954, 1958; Krikorian, 1975, 1982; Steward and Krikorian, 1975; Gautheret, 1983, 1985). Proof that the colonies on the platforms did not form from cells of callus origin that grew through the paper was obtained by culturing a single cell of *Tagetes erecta* on a platform placed on top of a sunflower callus (Muir et al., 1958). Other research

followed (Bergmann, 1960), and convincing proof that an isolated cell can divide was provided by tobacco cells which divided in drops of medium in microculture (Vasil and Hildebrandt, 1965*a*, 1965*b*). Shortly after that, isolated mesophyll cells of *Arachis hypogea* were prompted to divide in culture and produced what can best be described as protocorm-like bodies or structures which look like them (Joshi and Ball, 1968*a*, 1968*b*).

Using an apparatus that slowly (1 rpm) rotates "nipple culture flasks" around a horizontal axis (Fig. 1-56), Frederick Campion Steward (1904–1994; Fig. 1-9a) and his associates at Cornell University, Russell C. Mott (Fig. 1-9b), Marion O. Mapes (1913–111981; Fig. 1-57), and Kathryn Mears-Trupin (Fig. 1-58), obtained suspension cultures of carrot cells and eventually regenerated plants from them (for reviews see Krikorian, 1975, 1982, 1989*b*; Steward and Krikorian, 1975; Gautheret, 1983, 1985; Arditti and Ernst, 1993). *Cymbidium* cell cultures were established using the same system. Plants were regenerated from these cells subsequently (Steward and Mapes, 1971*a*). Two decades later *Phalaenopsis* plants were regenerated from embryoids derived from a loose-celled callus (Sajise et al., 1990) in Professor Yoneo Sagawa's (Fig. 1-59) laboratory at the University of Hawaii. Other orchid cells have also been cultured (see specific procedures in Chapter 3).

The first protoplast preparations were obtained in 1892 through surgical release from plasmolyzed cells of water aloe, *Stratiotes aloides*. Eventually digestion of cell walls became the method of choice (for historical surveys see Steward and Krikorian, 1975; Krikorian, 1982). What may well be the first preparation of orchid protoplasts resulted from work with leaves (i.e., mesophyll cells) of *Cymbidium* Ceres and "virus free protocorms of *Cymbidium pumilum*, *Brassia maculata* and *Cattleya schombocattleya*" (Capesius and Meyer, 1977). The protoplasts were used for the isolation of nuclei but apparently no effort was made to produce callus masses or regenerate plants from them. Regardless of the research for which these protoplasts were used, it is necessary to point out that there is no "*Cattleya schombocattleya*." It is not clear if what was meant is "*Cattleya*, *Schombocattleya*," "*Cattleya* or *Schombocattleya*," "*Cattleya* and *Schombocattleya*," or "*Cattleya* × *Schombocattleya*."

Production of orchid protoplasts and subsequent fusion between and within genera was first reported in 1978, but the ultimate fate of the fusion products has not been described in the literature (Teo and Neumann, 1978*a*, 1978*b*, 1978*c*). Early isolations of orchid protoplasts have been reported from Portugal (Pais et al., 1982, 1983), the USA (Price and Earle, 1984; Kuehnle and Nan, 1990; Sajise et al., 1990), Singapore (Loh and Rao, 1985; Hew and Yip, 1986; Hew, 1987; Koh et al., 1988), Japan (Yasugi et al., 1986; Yasugi, 1986, 1989*a*, 1989*b*, 1990; Kobayashi et al., 1993; Belarmino and Mii, 2000; Tokuhara and Mii, 2001), India (Seeni and Abraham, 1986; Gopalakrishnan and Seeni, 1987), Taiwan (Chen et al., 1990*a*, 1991), Philippines (Belarmino and Mii, 2000), and elsewhere (see Chapter 3).

More recently, 4×10^6 protoplasts were obtained per gram of young leaf tissue of *Phalaenopsis* (Chen et al., 1995). Their average diameters were 31.2 μm. The diameters of protoplasts from root tips and petals were 36.4 μm and 31.1 μm respectively. Approximately 90% of the protoplasts were viable. Some of the protoplasts divided after 5 days. Only a few divided twice after 10 days. Very few clusters were formed after 21 days, and they eventually died (Chen et al., 1995). However, Yoneo Sagawa (b. October 11, 1926; Fig. 1-59) and his co-workers at the University of Hawaii have reported regeneration of *Phalaenopsis* plants from protoplasts (Sajise et al., 1990). Research with Sagawa's callus is also being carried out by Professor Syoichi Ichihasi in Japan.

A direct electrical current pulse of 2500 V cm^{-1} of 2 milliseconds duration was sufficient to cause fusion in 10% of *Phalaenopsis* protoplasts to form hybrid cells. The fate of these fusion products was not described, but the context of the paper (Chen et al., 1995) suggests that they did not survive. Studies of transgenic *Phalaenopsis* are also in progress (Chen et al., 1995).

Flowering in Vitro

After Professor Lewis Knudson published his method of asymbiotic orchid seed germination, J. Costantin (1857–1936), Noël Bernard's mentor, attacked him bitterly by questioning his veracity. When he could not sustain the smear Costantin challenged Knudson to prove that an asymbiotic orchid can flower. Knudson proved that this is possible by growing a *Laeliocattleya* plant asymbiotically from seed to bloom

FIG. 1-60–1-64. **The first in vitro flowering by orchid plants produced through micropropagation. The work with *Cymbidium* was done by Dr. Xiong Wang at the Shanghai Institute of Plant Physiology in the late 1970s and early 1980s. 60. These plants also flowered in vitro (courtesy Dr. Xiong Wang). 63. Flower (a), bud (b), and shoot (c) of *Cymbidium ensifolium* in a large vial. 64. Professor Tet Fatt Chia (www.ntu.edu/birc/people.htm).**

(for reviews and photographs see Arditti, 1984, 1990, 1992). This was in 1930. Since then there have been sporadic reports of orchid seedlings which flowered in vitro (for a review see Chia et al., 1999).

The first in vitro flowering by clonally propagated plants was reported by Xiong Wang (Fig. 1-60), an investigator working on micropropagation of *Cymbidum ensifolium* and *Cymbidium goeringii* (Fig. 1-61–1-63) at the Shanghai Institute of

Plant Physiology (Wang, 1984, 1986, 1988*a*, 1988*b*, 1990, no date *a*, no date *b*; Wang et al., 1981, 1988*a*, 1988*b*; Wu et al., 1987). Clonally propagated *Oncidium varicosum* was reported to flower in Brazil at the same time (Kerbauy, 1984*b*). Next to flowers were plantlets of *Phalaenopsis* hybrids in Japan (Tanaka et al., 1988b; Duan and Yazawa, 1994*a*, 1994*b*, 1994*c*, 1995*a*, 1995*b*). *Cymbidium ensifolium*, *Cymbium gyokuchin*, *Cymbidium kanrang*, and *Cymbidium niveo-marginatum* were reported to flower in vitro in Korea (Paek et al., 1990; Kostenyuk et al., 1999). *Doriella* flowered after that, also in Japan (Duan and -Yazawa, 1994*a*, 1994*b*, 1994*c*, 1995*a*, 1995b). *Cymbidium ensifolium* was also reported to flower in vitro. Cytokinins promote the flowering of *Cymbidium ensifolium* var. *misericors* (Chang and Chang, 2003).

Flowering of *Dendrobium* plantlets was induced for the first time at the National University of Singapore by Professor Tet Fatt Chia (Fig. 1-64) and his associates (for a review see Chia et al., 1999). Professor Chia followed this feat with the introduction of a bioluminescence gene into orchids.

A report on flowering of *Dendrobium* in vitro published in 1996 is devoid of worthwhile scientific content and has no useful information about techniques and procedures (Goh, 1996). It is essentially a (self-written) paean and ode to its author (Goh, 1996). Methods used to bring about in vitro flowering of *Dendrobium* Sonia and *Dendrobium* Madame Thong In are not described. The medium used to culture the plantlets is only described as a "translucent chemical" and "unnamed potion" (Anonymous, 1995). Two students who did the actual work are only referred to obliquely without being mentioned by name, let alone credited. Only papers which list the writer (Goh, 1996) as the first author are cited. Access to two theses which describe the work is prohibited. A considerable amount of sleuthing was required to find sources and establish the identities of those who did the actual work (Chan, 1991; Ng, 1997; Sim, no date). This is yet another bizarre episode in the history of orchids in general and orchid micropropagation in particular.

One possible conclusion at present is that flowering of orchids in vitro may be spontaneous or induced by the state of the explant, nutritional conditions, medium components, intangibles, and/or by environmental factors (Chia et al., 1999). However there is also evidence which suggests that cytokinins, and more specifically benzyladenine (BA), N^6-(2-isopentenyl) adenine (2iP), and thidiazuron (TDZ) can induce flowering (see Chang and Chang, 2003, for a short review). Development of a method which can induce flowering of orchids in vitro can prove to be of commercial importance.

The Future

Attempts to predict the future must always be tempered by recalling past predictions that flight in heavier than air aircraft and ventures into space would not be possible. Still, several predictions are possible regarding orchid micropropagation. They must be considered in the context of the prognostications made in the first edition.

The first prediction in the previous edition was that existing tissue culture and clonal propagation methods will be improved. This did happen. Therefore it is safe to predict again that the future holds more and better methods.

Our second prediction in the first edition was that new methods will be developed for genera and species which have not been cultured as yet, either due to difficulties (*Cypripedium* and *Phragmipedium*, for example) or lack of interest (*Habenaria*, for instance). Methods for *Cypripedium* (Jo et al., 2001) and *Habenaria* (Latha, 1999a) were developed. Therefore, it is safe to predict that in the future methods will be developed for other recalcitrant and/or less popular orchids including a procedure for *Phragmipedium*.

Procedures were developed for cell and protoplast cultures of a few orchids. Therefore the third prediction that "it is almost certain that with time cell and protoplast culture methods will be developed for many orchids" has also come to pass, at least partially. This suggests the development of additional and improved methods in the future.

The fourth prediction was assumed to be "safe" – that parasexual (i.e., cell fusion) hybrids of orchids will come into existence and the Eric Young award will be given to a deserving scientist or a group of scientists (in an amount that will probably be much larger than the initial sum due to accumulated interest). This prediction was not safe at all. There are still no parasexual hybrids of orchids and chances are that cell fusion will not play a role in orchid hybridization because as a technique it does not have much if any future.

Another bioengineering procedure which does not seem to have much of a future with orchids is electrophoretic insertion of genes (Griesbach, 1994) despite multiple publications (Griesbach et al., 1989; Griesbach, 1993, 1994; Griesbach and Klein, 1993; Griesbach and Kadzimin, 1994), because: (1) "protocorms had difficulty surviving certain buffer concentrations and were subject to desiccation"; (2) the actual number of transgenic plants which were obtained was not stated; (3) "evidence for genomic integration of *gus*A is lacking"; and (4) transformation was assessed by histochemical GUS staining only (for a review see Kuehnle, 1997).

Insertion of genes through biolistic methods is a much more promising technique and has actually been applied to orchids. Bioengineering is beyond the scope of this book, but it is safe to predict that bioengineered orchids will become a reality. The most notable achievements is this area to date are the insertion of: (1) firefly bioluminescence genes and "*gus*A/*neo* fusion gene portions of pBI426" into orchids by Professor Tet Fatt Chia in Singapore; (2) "the plant expressible NOS-NPT II (for antibiotic resistance) encoded by the gene *neo* and papaya ringspot virus coat protein genes" by Professor Adelheid (Heidi) Kuehnle and her associates at the University of Hawaii; and (3) the *bar* gene which codes for herbicide resistance by H. Anzai and associates in Japan (for a review see Kuehnle, 1997). Additional advances in this area can be expected in the future. Some of these advances will result from work by W. H. Chen and his associates in Taiwan.

"A foregone conclusion," the development of computerized flow systems for orchid tissue culture, has also not gone very far even if robotization, bioreactors, flow systems, computerization, new equipment, and automation are coming into play (Koch, 1974*c*; Kuhn, 1981*a*, 1981*b*; Tisserat and Vandercook, 1985, 1986; Hew et al., 1987; Okamoto, 1996; Paek et al., 2001).

Investigations on low temperature storage of orchid callus (Sivasubramanian et al., 1987) and protocorm-like bodies suggest that in the future orchid germ plasm, seedlings, and tissues will be stored cryogenically.

Isolated orchid petal cells have been used in plant physiology research (Hew and Yip, 1986). This suggests that in time isolated orchid organs, tissues, and cells will be used as model systems for research on plants.

Past bizarre claims, questionable publications, unusual episodes, flamboyant individuals, people with overblown egos, and talented con-men/-women associated with orchid tissue culture suggest that similar eccentricities will be part of the future.

Perhaps the safest prediction for this, the second edition of a book first published in 1993 (Arditti and Ernst, 1993), is that Joseph Arditti (72 as this revision nears completion) will not participate actively if at all in a possible third version because of age or involuntary departure to the big orchid garden in the sky.

Klio, the muse of history, contemplating an orchid. Needless to say, the orchid was added to an ancient statue through computer magic.

CHAPTER TWO

General Outline of Techniques and Procedures

Methods for the in vitro culture of isolated plant cells, tissues, and organs or of seeds are not difficult or complex, but they do require some equipment and certain skills and knowledge. The general outline of these skills as well as the list of methods, media, and apparatus in this chapter in the first (Arditti and Ernst, 1993) and present editions of this book are taken from the appendices in *Orchid Biology, Reviews and Perspectives* Volumes I and II (Arditti, 1977*c*, 1982*a*), *Tissue Culture of Taro* (Arditti and Strauss, 1979), other reviews (Butcher and Ingram, 1976; Pierik, 1987; Vij and Pathak, 1990; Attawar, 1992; Arditti and Ernst, 1993; Prakash and Pierik, 1993; Vij, 1993; Ichihashi, 1997; Prakash et al., 1996; Kishi and Tagaki, 1997*a*, 1977*b*; Tisserat and Jones, 1999; Vij et al., 2000*a*; Bautista, 2002; among others), the general literature, and the World Wide Web.

Media Components

Media used for orchid tissue culture and seed germination may reflect both the special requirements of each species, hybrid, plants(s), and/or seeds used originally and the preferences of the investigators who carried out the initial research. Therefore, when preparing media it is important to follow instructions carefully and strictly as recommended by each procedure and given in every formulation and to measure and weigh all compounds accurately. Every effort should be made to use exactly the substances listed in the recipe tables. To make this possible it is advisable to start preparations by ordering all necessary chemicals and apparatus well in advance. Supply houses (see Appendix 2) issue informative and detailed hard copy catalogs which are free on request, but are usually mailed by bulk and/or surface mail. Therefore requests for catalogs should be made several weeks or months before the anticipated need. Even if a vast amount of information is available at present on the World Wide Web, catalogs can be very useful especially in laboratories where there are only a few computers or if connections are slow and unreliable.

Suppliers usually have well-illustrated web sites (see Appendix 2) and detailed on-line catalogs that simplify ordering and eliminate the wait for mailed information. Shipping can be faster too, but there is a direct relationship between speed and

cost of delivery. Therefore, to reduce costs and prevent disappointment it is still advisable to order well in advance of need.

Chemicals must be stored in accordance with instructions on the package. If there are no instructions, it is best to store organic substances in a refrigerator at 4°C in properly closed containers under dry conditions, or in a freezer. Some chemicals can absorb water from the air and may solidify or become liquefied as a result. The problem can be especially acute in humid climates. To prevent this from happening, such chemicals should be stored under vacuum, in incubators, or in cabinets at a temperature that is high enough to keep humidity very low (but without damaging the compound). Several light bulbs which are constantly on can raise the temperature of such enclosures to a level that is sufficient to reduce the relative humidity. To reduce fire hazard the cabinets should be fireproof. The illumination itself is without effect. Therefore, fluorescent lamps that produce less heat than incandescent bulbs may not be very effective. However, it is important to keep in mind that some chemicals are light-sensitive. When stored in an illuminated cabinet or incubator such chemicals must be placed in a dark container and/or wrapped in aluminum foil, black plastic, paper, or cloth.

Macroelements

The prefixes *macro-* or *major-* when applied to elements (or nutrients) refer to the fact that these substances are needed in relatively large amounts (Box 2-1). They include calcium (Ca), magnesium (Mg), nitrogen (N), phosphorus (P), potassium (K), and sulfur (S). Depending on the medium, several salts may be used to supply each mineral [for example, potassium can be provided as KNO_3, KH_2PO_4, K_2HPO_4, and KCl among others; nitrogen may be added as KNO_3, NH_4NO_3, $Ca(NO_3)_2$, $(NH_4)_2SO_4$, other salts, and/or urea]. The combinations of salts in each medium are designed to provide an appropriate balance of nutrients in proper concentrations.

BOX 2-1. **Periodic table of the elements.**

B, Boron; Ba, Barium; Br, Bromine; C, Carbon; Ca, Calcium; Cl, Chlorine; Co, Cobalt; Cu, Copper; Fe, Iron; H, Hydrogen; I, Iodine; K, Potassium; Mg, Magnesium; Mn, Manganese; Mo, Molybdenum; N, Nitrogen; Na, Sodium; Ni, Nickel; O, Oxygen; P, Phosphorus; S, Sulfur; Se, Selenium; Si, Silicon; V, Vanadium; Zn, Zinc. Aluminum (Al) is added to some media, but rarely.

Research with callus tissue of *Aranda* Noorah Alsagoff has shown that at pH 4.5 and 5.0, 2.5–3.0 g of tissue took up a total of 5.2 mmol of nitrate in 20 days of incubation: "Ammonium [from 3.8 mmol of $(NH_4)_2SO_4$] in culture media was consumed in cultures at pH value of 5.0 and 5.5" (Lee et al., 1987). At this pH the callus took up ammonia in preference to nitrate. Maximal "depletion of total nitrogen in culture media containing both ammonium and nitrate was observed at pH 5" (Lee et al., 1987).

On sugar-free Vacin and Went medium, seedlings of *Dendrobium* Multico White took up 64.6% of the ammonium (NH_4^+), 15.7% of the nitrate (NO_3^-), and 21.6% of the phosphate (PO_4^{3-}). In the presence of sugar, uptake was 80.2, 22.1, and 33.3%, respectively (Hew and Lim, 1989). The ratio of ammonium to nitrate uptake was 4.15 : 1 and 3.63 : 1, respectively. These plants clearly prefer ammonium.

Substitutions

Experience in several countries over the last 40 years has shown that it is sometimes necessary to make substitutions and modifications in recipes due to shortages or unavailability of chemicals and/or preferences by some orchids. If this becomes necessary, the changes should be made by experienced workers since what may appear to be small and insignificant alterations can in fact introduce major modifications. For example, 100 mg (0.57 mol) of K_2HPO_4 (dibasic potassium phosphate, MW 174.18, 44.89% potassium, 17.79% phosphorus) contains 1.54 as much potassium as an equal weight (0.74 mol) of KH_2PO_4 (monobasic potassium phosphate, MW 136.09, 28.73% potassium, 22.76% phosphorus). Using 50 mg K_2HPO_4 as a substitute for 100 mg of KH_2PO_4 will result in the same amount of potassium but only 0.78 as much phosphorus. One mole of K_2HPO_4 contains twice as much potassium as an equimolar amount of KH_2PO_4, an equal amount of phosphate (PO_4^{2-}) and half as much hydrogen (H^+).

Substituting one salt for another may be even trickier since if, for example, KCl is used to replace one of the potassium phosphate salts, phosphorus will be eliminated entirely and the chloride content may become supraoptimal. In such cases another salt may have to be added to supply phosphorus, but this could introduce an added complication. For instance, if ammonium phosphate [$(NH_4)_2PO_4$ or $(NH)H_2PO_4$] is then used to add phosphorus (as PO_4^{2-}) it will introduce additional nitrogen (as ammonium ion, NH_4^+) which must be taken into consideration, and so on.

Some substitutions can be relatively simple: $MgSO_4$ [magnesium sulfate, usually $MgSO_4 \cdot 7H_2O$, formula weight (FW) 246.47, but sometimes anhydrous $MgSO_4$, FW 120.37] can be replaced by $MgCl_2$ (magnesium chloride, usually $MgCl_2 \cdot 6H_2O$, FW 203.30) since other salts provide a sufficient amount of sulfate (SO_4^{2-}). However, caution is necessary because $MgCl_2$ can increase chloride (Cl^-) to levels which may be toxic for some tissues. Also, waters of hydration must be taken into consideration. Therefore substitutions must be made on a molar, not weight, basis.

Another example is that of iron because $FeCl_3 \cdot 6H_2O$ (ferric chloride, FW 270.30) and $Fe(NO_3)_3 \cdot 9H_2O$ (ferric nitrate, FW 404.00) can be used as replacements for $FeSO_4 \cdot 7H_2O$ (ferrous sulfate, FW 278.02). In this instance only the iron (Fe) concentration must be adjusted since it is the important component (Table 2-1). The levels of sulfate (SO_4^{2-}), chloride (Cl^-), or nitrate (NO_3^-) must also be taken into consideration in this case since they are usually provided by other salts in the medium

TABLE 2-1. **Substitutions of salts in culture media**[a]

Compound	Molecular or formula weight	Number of atoms or ions[b]		Amount added liter^{-1}			
				Original			
		Cation	Anion	Weight	Moles[c]	Substitute[d] weight[e]	Remarks[f]
Aluminum							
Aluminum chloride, $AlCl_3$	133.34	1*	3*	31 µg	0.23 µmol	0.15 µg	Both 31 and 30 µg represent 0.23 µmol and are therefore the same for practical purposes. This salt may be explosive at higher concentrations and should be handled with care
Aluminum chloride, $AlCl_3$	133.34	1*	3	30 µg	0.23 µmol	0.15 µg	
Aluminum sulfate, $Al_2(SO_4)_3{\cdot}16H_2O$	630.39	2*	3	–	–	72.50 µg	
Boron							
Boric acid, H_3BO_3	61.83	3	1*	1.01 mg	0.02 mmol	1.71 mg	
Boric acid, H_3BO_3	61.83	3	1*	10 mg	0.16 mmol	17.1 mg	
Boric acid, H_3BO_3	61.83	3	1*	6.2 mg	0.12 mmol	10.6 mg	
Boric acid, H_3BO_3	61.83	3	1*	1.5 mg	0.03 mmol	2.6 mg	
Boric acid, H_3BO_3	61.83	3	1*	1.01 mg	0.02 mmol	1.72 mg	
Boric acid, H_3BO_3	61.83	3	1*	0.6 mg	0.01 mmol	1.03 mg	
Boric acid, H_3BO_3	61.83	3	1*	56 µg	0.91 µmol	95.81 µg	
Boric acid, H_3BO_3	61.83	3	1*	30 µg	0.47 µmol	51.33 µg	
Boric acid, H_3BO_3	61.83	3	1*	20 µg	0.32 µmol	34.22 µg	
Sodium borate, $Na_2B_4O_7{\cdot}10H_2O$	382.37	2	4*	–	–	–	Use 0.25 mol of this for every mole of boric acid because its molecule contains four atoms of boron
Calcium							
Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$	236.15	1*	2*	500 mg			It is preferable not to make substitutions since they may alter the medium. If it is necessary to use calcium nitrate with a different number of waters of hydration; please refer to Table 2.2. Such substitutions can be made because the levels of calcium and nitrate remain the same; waters of hydration make no difference
Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$	236.15	1*	2*	400 mg			
Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$	236.15	1*	2*	136.7 mg			
Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$	236.15	1*	2*	100 mg			
Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$	236.15	1*	2*	1 g			
Calcium nitrate, $Ca(NO_3)_2$	164.11	1*	2*	200 mg			
Calcium chloride, $CaCl_2{\cdot}2H_2O$	147.03	1*	1	440 mg			This salt is interchangeable with calcium sulfate provided molarity is the same. To calculate orig. wt × 172.17/147.02
Calcium chloride, $CaCl_2{\cdot}2H_2O$	147.03	1*	1	75 mg			
Monocalcium phosphate, $Ca(H_2PO_4)_2$	234.05	1* + 2	2*	100 mg			May form insoluble di and tri basic calcium phosphate. Calcium chloride can also be substituted for calcium phosphate but high level of chlorine may be toxic. A good substitute would be calcium nitrate provided care is taken to balance the ions in the medium. 488 mg of monocalcium phosphate hydrate are the equivalent to 200 mg dihydrate, anhydrous phosphate. In making susbstitutions with other calcium salts the concentrations should be equimolar in respect to Ca^{2+}
Tricalcium phosphate, $Ca_3(PO_4)_2$	310.20	3*	2*	200 mg			
Dicalcium phosphate, $CaHPO_4$	136.06	1*	1*	200 mg			
Dicalcium phosphate, $CaHPO_4{\cdot}2H_2O$	172.09	1*	1*				
Calcium sulfate, $CaSO_4$ (gypsum)	136.14	1*	1				These salts are sparingly soluble in water (2–3 g l^{-1}) and may not be very useful except in emergency situations
Calcium sulfate, dihydrate, $CaSO_4{\cdot}2H_2O$	172.17	1*	1				
Cobalt							
Cobaltous nitrate, hexahydrate, $Co(NO_3)_2{\cdot}6H_2O$	291.04	1*	2				78.58 µg = 0.27 µmol; 34.93 µg = 0.12 µmol; 32.01 µg = 0.11 µmol. Use 70 µg of cobaltous chloride to substitute for the cobaltous nitrate. 45 µg of the cobaltous chloride can be used as a substitute for 30 µg of the cobaltous chloride; 20 µg will replace 25 µg of the latter. For substitutions due to waters of hydration see the appropriate table
Cobaltous nitrate, $Co(NO_3)_2$	183.03	1*	2	50 µg	0.27 µmol		
Cobaltous chloride, $CoCl_2{\cdot}6H_2O$	237.93	1*	2	30 µg	0.12 µmol		
Cobaltous chloride, $CoCl_2{\cdot}6H_2O$	237.93	1*	2	25 µg	0.11 µmol		

Copper							
Cupric sulfate, $CuSO_4 \cdot 5H_2O$	249.68	1*	1	25 µg	0.10 µmol	13.46 µg	
Cupric sulfate, $CuSO_4 \cdot 5H_2O$	249.68	1*	1	19 µg	0.08 µmol	10.23 µg	
Cupric sulfate, $CuSO_4 \cdot 5H_2O$	249.68	1*	1	1 µg	0.004 µmol	0.54 µg	
Cupric sulfate, $CuSO_4 \cdot H_2O$	177.62	1*	1	50 µg	0.28 µmol	37.86 µg	
Cupric sulfate, $CuSO_4 \cdot H_2O$	177.62	1*	1	40 µg	0.23 µmol	30.28 µg	
Cupric sulfate, $CuSO_4 \cdot H_2O$	177.62	1*	1	30 µg	0.13 µmol	22.71 µg	
Cupric sulfate, anhydrous, $CuSO_4$	159.60	1*	1		0.08–0.28 µmol		As a substitute
Cupric chloride, $CuCl_2 \cdot 2H_2O$	170.49	1*	1	54 µg	0.32 µmol	100 µg $CuSO_4 \cdot 5H_2O$	
Cupric chloride, $CuCl_2 \cdot 2H_2O$	170.49	1*	1	10 µg	0.06 µmol	8.57 µg $CuSO_4 \cdot 5H_2O$	
Iodine							
Potassium iodide, KI	166.01	1	1*	0.75 mg	4.51 µmol	1.15 mg	
Potassium iodide, KI	166.01	1	1*	0.83 mg	5.0 µmol	1.27 mg	
Potassium iodide, KI	166.01	1	1*	99 µg	0.6 µmol	151.36 µg	
Potassium iodide, KI	166.01	1	1*	30 µg	0.18 µmol	45.87 µg	
Potassium iodide, KI	166.01	1	1*	20 µg	0.13 µmol	30.58 µg	
Potassium iodide, KI	166.01	1	1*	10 µg	0.06 µmol	15.29 µg	
Sodium iodide, NaI	149.89	1	1*				The amount used should be equimolar with potassium iodide. Because the concentrations being added are tiny, the iodine requirements, if any, are minute and the weight differences are very small the amount of NaI added to a solution can be equivalent to that of KI. The weight can be calculated as follows: orig. wt. × 149.89/166.01
Iodine	253.81	1*					Calculate as: orig. wt. × 253.81/166.01. Pharmaceutical tincture of iodine can also be used. The volume used would depend on the concentration of the available preparation
Iron							
Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	278.02	1*	1	27.9 mg	0.1 mmol		These should be used with 37.3 mg of Na_2EDTA. It is preferable not to replace them with the organic iron salts in this list. $FeCl_3 \cdot 6H_2O$ can be used as a substitute at the level of 27.03 mg. See text for details
Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	278.02	1*	1	27.8 mg	0.1 mmol		
Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	278.02	1*	1	25 mg	0.9 mmol		
Ferric chloride, $FeCl_3 \cdot 6H_2O$	270.30	1*	3	1 mg	3.7 µmol	1.03 mg	Add Na_2EDTA as above
Ferric chloride, $FeCl_3 \cdot 6H_2O$	270.30	1*	3	0.5 mg	1.85 µmol	0.51 mg	
Ferric citrate, $Fe(C_6H_5O_7)_x \cdot 5H_2O$		_*	–	10 mg			These compounds are hard to find and/or not very good as sources of iron as a mixture of 27.8 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$ and 37.3 Na_2EDTA per liter of medium
Ferric citrate, $Fe(C_6H_5O_7)_x \cdot 3H_2O$		_*		5.4 mg			
Ferric sulfate, $Fe_2(SO_4)_3$	399.80	2*	3	1 mg	2.50 µmol		See text for additional details. Or, they can be replaced with approximately, 0.5, 1, 15, and 13 mg respectively of $FeCl_3 \cdot 6H_2O$. The exact ratios of iron and citrate or tartrate are not always given
Ferric tartrate, $Fe_2(C_4H_4O_6)_x \cdot H_2O$	573.94	_*	X	30 mg			
Ferric tartrate, $Fe_2(C_4H_4O_6)_3$	573.94	2*	3	28 mg			
Ferric ammonium sulfate, $(NH_4)_2Fe(SO_4)_2 \cdot 12H_2O$	482.19	1 + 1*	2				The amount used must be equimolar in respect to iron with the salt being replaced. Can be used to substitute for all salts in the iron list. It is preferable to chelate them through the addition of equimolar amounts of EDTA (0.1 mmol or 37.2 mg). See text for details
Ferric ammonium sulfate, $(NH_4)_2Fe(SO_4)_2 \cdot 6H_2O$	392.14	2 + 1*	2	39.2 mg	0.1 mmol		
Ferrous chloride, $FeCl_2 \cdot 4H_2O$	198.81	1*	2	19.88 mg	0.1 mmol		
Ferric nitrate, $Fe(NO_3)_3 \cdot 9H_2O$	404.00	1*	3	40.40 mg	0.1 mmol		

TABLE 2-1. (***Continued***)

Compound	Molecular or formula weight	Number of atoms or ions[b]		Amount added liter^{-1}			Remarks[f]
		Cation	Anion	Original Weight	Original Moles[c]	Substitute[d] weight[e]	
Magnesium							
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	246.48	1*	1	400 mg	1.62 mmol	329.94 mg	
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	246.48	1*	1	370 mg	1.50 mmol	305.20 mg	
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	246.48	1*	1	250 mg	1.01 mmol	206.21 mg	
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	246.48	1*	1	240 mg	0.97 mmol	197.97 mg	
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	246.48	1*	1	125 mg	0.50 mmol	103.11 mg	
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	246.48	1*	1	120 mg	0.49 mmol	98.98 mg	
Magnesium chloride, $MgCl_2 \cdot 6H_2O$	203.31	1*	2	–	1 mmol	203.31 mg	
Magnesium nitrate, $MgNO_3 \cdot 6H_2O$	256.41	1*	1	–	1 mmol	256.41 mg	
Manganese							
Manganous sulfate, $MnSO_4 \cdot 4H_2O$	223.06	1*	1	25 mg	0.11 mmol	18.9 mg	These salts can be interchanged, but molarities must remain constant
Manganous sulfate, $MnSO_4 \cdot 4H_2O$	223.06	1*	1	22.3 mg	0.1 mmol	16.9 mg	
Manganous sulfate, $MnSO_4 \cdot 4H_2O$	223.06	1*	1	7.5 mg	33 µmol	5.7 mg	
Manganous sulfate, $MnSO_4 \cdot 4H_2O$	223.06	1*	1	68 µg	0.31 µmol	51.5 µg	
Manganous sulfate, $MnSO_4 \cdot 4H_2O$	223.06	1*	1	10 µg	0.05 µmol	7.6 µg	
Manganous sulfate, $MnSO_4 \cdot 2H_2O$	187.02	1*	1	5.7 mg	30.5 µmol	5.2 mg	
Manganous sulfate, $MnSO_4$	151	1*	1	4.5 mg	29.8 µmol	5.0 mg	
Manganous chloride, $MnCl_2 \cdot 4H_2O$	197.91	1*	2	2 mg	10.1 µmol	1.7 mg	
Manganous chloride, $MnCl_2 \cdot 4H_2O$	197.91	1*	2	1 mg	5.05 µmol	0.9 mg	
Manganous chloride, $MnCl_2 \cdot 4H_2O$	197.91	1*	2	0.4 mg	2.0 µmol	0.3 mg	
Manganous chloride, $MnCl_2 \cdot 4H_2O$	197.91	1*	2	36 µg	0.18 µmol	30.76 mg	
Manganous sulfate, $MnSO_4 \cdot H_2O$	169.02	1*	1	–	10.0 µmol	1.7 mg	
Manganous nitrate, $Mn(NO_3)_2 \cdot 4H_2O$	251.01	1*	2	–	10.0 µmol	2.5 mg	
Molybdenum							
Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	241.98	2	1*	250 µg	1.03 µmol	1.3 mg	
Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	241.95	2	1*	50 µg	0.21 µmol	255.4 µg	
Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	241.95	2	1*	25 µg	0.10 µmol	127.7 µg	
Ammonium molybdate, $(NH_4)_2 \cdot Mo_7O_{24} \cdot 4H_2O$	1235.95	6	7* (MoO_4^{2-})	20 µg	0.016 µmol	3.9 µg	
Molybdenum trioxide, MoO_3	143.94	1*	1* (MoO_4^{2-})	16 µg	0.11 µmol	137.4 µg	
Molybdenum trioxide, MoO_3	143.94	1*	3		0.22 µmol	32 µg	
Molybdenum trioxide, MoO_3	143.94	1*	3		0.015 µmol	2.1 µg	
Molybdenum trioxide, MoO_3	143.94	1*	3		1 µmol	144 µg	
Molybdic acid, $H_2MoO_4 \cdot H_2O$	179.98	1*					Toxic, irritant
Molybdenum oxide, MoO_3	143.94	1*					
Nickel							
The two chloride compounds listed below as possible substitutes are irritants and suspected carcinogens. Sine there is no firm evidence that the addition of nickel salts is necessary for orchid cultures it may be wise to omit them altogether. If the addition proves necessary caution should be excercised when handling these or similar salts							
Nickel chloride, $NiCl_2$	129.65	1*	2	17 µg	0.13 µmol	38.1 µg	
Nickel chloride, $NiCl_2 \cdot 6H_2O$	237.71	1*	2	30 µg	0.13 µmol	36.7 µg	
Nickel nitrate, $Ni(NO_3)_2 \cdot 6H_2O$	290.81	1*	2		0.13 µmol	37.8 µg	
Nickel sulfate, $NiSO_4 \cdot 6H_2O$	262.86	1*	1		0.13 µmol	34.2 µg	

Nitrogen							Substitutions are not advisable and usually not necessary
Ammonium[g]	Commonly used nitrogen salts include potassium nitrate, calcium nitrate, and ammonium sulfate. Salts potentially useful as substitutes include ammonium phosphate and ammonium nitrate. Other salts like sodium, magnesium, and nitratre may introduce toxic levels of Na^+ and Mg^+						
Nitrate[g]							
Zinc							
Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	287.54	1*	1	10 mg	34.8 µmol	10.35 mg	These salts can be interchanged, but molarities must remain constant
Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	287.54	1*	1	9 mg	31.3 µmol	9.31 mg	
Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	287.54	1*	1	7 mg	24.3 µmol	7.24 mg	
Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	287.54	1*	1	1 mg	0.35 µmol	1.04 mg	
Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	287.54	1*	1	0.565 mg	0.2 µmol	0.55 mg	
Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	287.54	1*	1	0.331 mg	0.1 µmol	0.34 mg	
Zinc sulfate, $ZnSO_4 \cdot H_2O$	179.48	1*	1	50 µg	0.3 µmol	82.87 µg	
Zinc sulfate, $ZnSO_4 \cdot H_2O$	179.48	1*	1	30 µg	0.2 µmol	49.72 µg	
Zinc sulfate, $ZnSO_4 \cdot H_2O$	179.48	1*	1	20 µg	0.1 µmol	33.15 µg	
Zinc sulfate, $ZnSO_4$	161.47	1*	1	1.5 mg	0.93 µmol	2.76 mg	
Zinc chloride, $ZnCl_2$	136.28	1*	2	3.93 mg	28.84 µmol	8.58 mg	
Zinc chloride, $ZnCl_2$	136.28	1*	2	0.152 mg	1.1 µmol	0.33 mg	
Zinc nitrate, $Zn(NO_3)_2 \cdot 6H_2O$	297.47	1*	2	–	0.1 µmol	29.75 µg	

[a]Compounds which are used in published media are preferable. In some cases these compounds can be substituted for each other, but concentrations may have to be recalculated. Substitutes are usually provided for the first compound and concentration in each list, but in some instances for additional compounds and concentrations. Sample calculation: in aluminum, for example, the substitute is aluminum sulfate, $Al_2(SO_4)_3 \cdot 16H_2O$, MW 630.39, and the amount and calculation for the substitution are 0.147 mg and 1/2[(31 × 630.39)/133.34], respectively. Substitutions are generally not advisable, but there are instances in which they may be unavoidable. This table was prepared for such eventualities. In cases where substitutions have been made the modified media should be tested with a standard clone before being used for rare and/or expensive ones. Some of the chemicals listed here may be toxic, explosive (aluminum chloride), or otherwise dangerous. For this reason chemicals must be used with care and in accordance with instructions on the label. The authors and the publisher assume no responsibility for any damages, injury, or losses which may result from the use of chemicals. This responsibility rests entirely and solely with the user. See text for more details. This table is more detailed than strictly necessary to facilitate its use for instructional purposes and to clarify the approach taken to prepare it. Well-equipped laboratories have most of the necessary chemicals and the need to make substitutions may arise seldom or never. However chemicals may be lacking in smaller or somewhat isolated laboratories and substitutions could become necessary. The auther has had such experiences during travels and they led to this table. Further, the information in this table may be useful for those with more limited laboratory experience.

[b]Atoms of the relevant elements (i.e., usually those which head each list: Al, aluminum; B, boron; Ca, calcium; Co, cobalt; Cu, copper; I, iodine; Fe, iron; K, potassium; Mg, magnesium; Mn, manganese; Mo, molybdenum; Ni, nickel; and Zn, zinc) are marked with* (see text for details).

[c]Abbreviations: *M*, molar; mol, mole; mmol, millimole (1/1000th of a mole); m*M*, millimolar; µmol, micromole (1/1000 of a millimole and 1/1,000,000 of a mole); µ*M*, micromolar (see text for details). The terms *M*, m*M*, and µ*M* are not interchangeable with mole, mmole, and µmole.

[d]All substitutions are for the main elements (iron, Fe; magnesium, Mg; potassium, K; and zinc, Zn). Substitutions must always be on an equimolar basis because the molecular weights of chemicals vary. The same weight of two chemicals will not necessarily provide equivalent amounts of the the main element. For example, 250 mg of $MgSO_4 \cdot 7H_2O$ will provide 1.01 mmol (250/MW = 246.48) whereas 250 mg of $MgCl_2 \cdot 6H_2O$ is equivalent to 1.23 mmol (250/MW = 203.31). The difference is 0.22 mmol or one-fifth of the original amount.

[e]All calculations are for substitutions of the relevant elements (see footnote *b* above). The formula used for the calculations is: [(original amount × molecular or formula weight of the substitute/molecular or formula weight of the original substance)/number of atoms of relevant element per molecule]. Figures taken from other sources are as listed originally. With very few exceptions figures obtained through calculations have been rounded off to two decimal places. See text for more details.

[f]Relevant element (see footnote *b* above). Some of the salts listed here may not be available commercially and are used as examples (see text for details).

[g]Ammonium and nitrate are used in several forms and often as part of compounds where more than one of the ions in the molecule are necessary (KNO_3, for example) and/or provided by other substances [for instance, a medium may contain KNO_3, KH_2PO_4, and $(NH_4)_2SO_4$] in a delicate balance. For example, replacing ammonium sulfate with ammonium phosphate will eliminate sulfur from the medium and increase phosphorus levels. Using calcium sulfate instead of ammonium sulfate will retain the sulfur, but eliminate ammonium. Replacing calcium nitrate with potassium nitrate will eliminate calcium and increase the potassium concentration. Doing the reverse may raise calcium and reduce or eliminate potassium. Utilizing calcium chloride in place of calcium nitrate may not change calcium levels but it will remove the nitrate. Partial substitutions will change the concentrations, and balance of elements. Therefore, it is not advisable to make substitutions of major elements without careful considerations and calculations; none are listed here.

and their concentrations can change. However, differences will be minor. Still, caution is needed to prevent supraoptimal levels of any one element and to take waters of hydration into consideration. Again, substitutions must be made on a molar, not weight, basis.

Substitutions between salts that contain a different number of waters of hydration ($\cdot xH_2O$) are not complicated because adjustments must be made only for the salt itself. For example, 250 mg of $MgSO_4 \cdot 7H_2O$ contain as much magnesium and sulfate as 122.09 mg of $MgSO_4$ (see Table 2-2). The difference in the amount of water in the molecule is not important. This is true for a number of salts that are used in culture media (Table 2-2). A formula to use for calculating substitution involving the same salt with different waters of hydration is:

$$\frac{OW \times FWS}{FWO} = SW \qquad (I)$$

where:

FWO = formula weight [molecular weight of the salt plus the weight of the water(s) of hydration] of the original substance;
FWS = formula weight of the substitute;
OW = weight [in grams (g), milligrams (mg), or micrograms (μg)] of the original substance;
SW = weight of the substitute substance to use (in g, mg, or μg; the units must be the same as those of OW).

If $MgSO_4$ is to be used in place of 250 mg of $MgSO_4 \cdot 7H_2O$ (Table 2-2) this expression becomes:

$$\frac{250 \text{ mg} \times 120.37}{246.47} = 122.09 \text{ mg} \qquad (II)$$

Substitutions and replacements of salts should never be made on an equal weight or percentage basis, but only on the premise of equivalent molarities. For example, 27.8 mg (0.14 mol) of ferrous chloride ($FeCl_2 \cdot 4H_2O$, MW 198.81) is not an appropriate substitute for the same weight (0.1 mol) of ferrous sulfate ($FeSO_4 \cdot 7H_2O$, MW 278.02) since the molecular (and formula) weights of these salts are different. To provide the same amount of iron (Fe) the substitution must be based on molarity [number or fractions of moles, millimoles, or micromoles (weight in g, mg, or μg equivalent to or a fraction of the molecular weight)]. An equal weight of chloride salt (27.8 mg) will provide 40% more iron than the sulfate. The chloride ($2Cl^-$ per molecule), sulfate ($1SO_4^-$ per molecule), percentage of iron in the salt (28.09% in the chloride and 20.09% in the sulfate), and the molecules of water (4 waters of hydration per molecule in the ferrous chloride and 7 in the ferrous sulfate) are irrelevant in this instance. A simple formula for calculation of equivalent molarities is:

$$\frac{OW \times MWS}{MWO} = SW \qquad (III)$$

where:

MWO = molecular weight of the original substance;

TABLE 2-2. **Use and substitution of chemicals whose molecules contain waters of hydration**

Compound	Formula	MW or FW[a]	Weight of waters of hydration	Weight of compound	Amount of original compound to add			Amount of substitute to add[c]	
					Weight	Fraction of MW or FW[a]	Molarity[b]	Molarity[b]	Weight

[a]FW, formula weight; MW, molecular weight. This table is more detailed than strictly necessary to facilitate its use for instructional purposes and to clarify the approach taken to prepare it. Well-equipped laboratories have most of the necessary chemicals, and the need to make substitutions may arise seldom or never. However, chemicals may be lacking in smaller or somewhat isolated laboratories and substitutions could become necessary.

[b]One mole (abbreviated mol) is the weight in grams equal to the molecular weight of a compound; common fractional parts of the mole are the millimole (mmol; 1000 mmol = 1 mol) and the micromole (µmol; 1000 µmol = 1 mmol; 1,000,000 µmol = 1 mol).

[c]Calculation: Original amount to be added (in g or mg) × Molecular or formula weight of substitute/Molecular or formula weight of original compound. Figures taken from other sources are as listed as given originally. With very few exceptions figures obtained through calculations have been rounded off to two decimal places. Always make substitutions on an equimolar basis because the molecular weights of chemicals vary; the same weight of two chemicals will not necessarily provide equivalent amounts of the the main element. For example, 250 mg $MgSO_4 \cdot 7H_2O$ will provide 1.01 mmol (250/MW = 246.48) whereas 250 mg of $MgCl_2 \cdot 6H_2O$ is equivalent to 1.23 mmol (250/MW = 203.31). The difference is 0.22 mmol or one-fifth the original amount.

[d]This compound either does not exist or is not commonly available but is presented here as an example.

MWS = molecular weight of the substitute;
OW = weight (in g, mg, or μg) of the original substance;
SW = weight of the substitute (in g, mg, or μg; the units must be the same as those of OW).

In the example above this expressions becomes:

$$\frac{27.8 \text{ mg} \times 278.02}{246.47} = 122.09 \text{ mg} \qquad \text{(IV)}$$

This formula (III) was used to calculate a number of possible substitutions (Table 2-1).

Storage

Stock solution of macroelements (except those containing nitrogen) can be stored at room temperature (usually about 22°C), but higher or lower temperatures will have no deleterious effects. Nitrogen-containing stock solutions can become contaminated even in a refrigerator and should be stored in a freezer. Frozen stock solution can be thawed under elevated temperatures to accelerate the process. Stock solutions should be stored in containers that are capped tightly to prevent evaporation of the water because this will increase their concentrations. All macroelement salts can be sterilized by autoclaving. And, in conclusion, it is important to repeat the warning that macroelement salts should be substituted only if strictly necessary and with great care. Because of its importance this information will be repeated elsewhere in the book.

Microelements

Culture media vary widely in the use and content of micro- or minor elements or nutrients (the terms are based not on their importance, but on the small amounts which are required; Box 2-1). The reasons for this are: (1) utilization of existing formulations; (2) imprecise information regarding the requirements of orchids; and (3) the presence of many of these elements as impurities in other media components. Their concentrations (within reasonable limits) and even presence or absence (in some instances) do not seem to be critical since shoot tips and other explants from one and the same genus can be cultured on media with different levels and formulations of microelements. Substitutions and changes in microelements are simpler to make because their concentrations are lower and therefore differences in the non-relevant part of the molecule (usually, but not always, sulfate or chloride) are not important (Table 2-1). Formulae I and III for calculating macroelement substitutions can also be used for microelements. However, it is very important to keep in mind that many microelements can be toxic at higher levels [the difference between 1 and 10 mg may appear small (9 mg), but the increase is tenfold (i.e., an order of magnitude)]. Such a large increase can result in toxicity. Microelement stock solution can be stored and thawed like those of macroelements. Also, like macroelements, all microelement salts are heat-stable and can be autoclaved.

Iron

Until the advent of chelating agents, the incorporation of an available form of iron in culture media presented a problem. Many iron salts are not sufficiently soluble. Others are soluble initially, but in solution the iron is oxidized to an insoluble or sparingly soluble form. Ferric chloride ($FeCl_3$), ferrous sulfate ($FeSO_4$), and a number of other salts as well as the citrate and tartrate of iron were all used in culture media at one time or another. When ethylene diamine tetraacetic acid [free acid (EDTA, MW 292.25), disodium salt (Na_2EDTA, MW 336.02) and disodium dihydrate ($Na_2EDTA{\cdot}2H_2O$), MW 272.24] became available as chelating agents (sometimes under a trade name such as Sequestrene) they found widespread use in culture media including, of course, the well-known Murashige–Skoog (MS) medium (Murashige and Skoog, 1962). The amounts used in MS are 37.3 mg Na_2EDTA l^{-1} and 27.8 mg $FeSO_4{\cdot}7H_2O$ l^{-1}. These amounts were widely assumed to be equimolar until careful recalculations showed that this is not the case (Singh and Krikorian, 1980). The actual concentrations turn out to be 100 μmol l^{-1} (100-μ*M* solution) of the iron salt and 111 μmol l^{-1} (111-μ*M* solution) of the chelating agent. This leaves an excess of 11 μmol of chelating agent per liter of medium.

What the effects of the excess EDTA may be is not clear, but it is possible that "this excess will affect availability of other divalent micronutrient cations such as copper, zinc, manganese, etc. depending on the stability of their chelate with EDTA. The effect of the excess EDTA remains to be elucidated . . ." (Singh and Krikorian, 1980). The concentrations of microelements given in the original MS paper (Murashige and Skoog, 1962) are still used in that medium and several other media. This combination is effective regardless of the EDTA concentration used to chelate the iron and there does not seem to be a compelling reason to make changes. A number of other microelement formulations are used in several media. All seem to be unaffected by the EDTA concentration.

Auxins and Anti-auxin

The most commonly used auxins in orchid tissue culture media (Table 2-3) are the naturally occurring auxin, indoleacetic acid (IAA), and the synthetics naphthaleneacetic acid (NAA), indolebutyric acid (IBA), and 2,4-dichlorophenoxyacetic acid (2,4-D). Other auxins and occasionally auxin–amino acid conjugates are also used in some media. Both the auxin(s) and the concentration(s) being used are usually a result of trial and error and it is best not to make changes and substitutions without careful thought and good reasons. When changes are made it is necessary to keep in mind that auxins may differ from each other both qualitatively and quantitatively. This means that the effects of one auxin on a certain species may be different from those of other auxins, and may differ with the orchid. The effects of different concentrations of the same auxin may differ in respect to one species and may not be the same with another orchid. As a rule, synthetic auxins are generally more stable and remain active longer than the naturally occurring substances. Auxins should never be substituted and their concentrations should never be changed without prior tests.

TABLE 2-3. **Some hormones, antihormones, and hormone inhibitors used in orchid micropropagation media**[a]

Hormone	Molecular weight	Concentration[b]	
		Weight (mg l^{-1})	Molarity (µmol l^{-1})
Anti-auxin			
trans-cinnamic acid	148.20	1.5	0.01
		15	0.10

[a]Not all concentrations listed here are in general use and some levels which may be employed in certain media are not included in this table. Hormone concentrations can be expressed in milligrams per liter (mg l^{-1} or the less frequently used mg/l), parts per million (ppm), rarely parts per billion (ppb), millimoles per liter (mmol l^{-1}) and micromoles per liter (µmol l^{-1}); or they can be given as millimolar (m*M*) or micromolar (µ*M*) solutions. Thus, 10 mg kinetin per liter can be written as 10 mg kinetin l^{-1}, 10 mg kinetin/liter (this format should not be used), 0.05 mmol l^{-1} [the actual number is 0.045661, but in the scientific literature numbers are usually rounded off to two and rarely three significant figures to the right of the decimal point; the use of more digits does not make a number more accurate – it makes it sillier except under special circumstances because most laboratory balances cannot weigh with such accuracy (it is not necessary anyway)], 45.61 µmol l^{-1}, 0.05-m*M* solution, or 45.61-µ*M* solution. One mole (abbreviated mol and not *M* or M) is the number of grams equal to the molecular weight of a compound. It consists of 1000 mmoles (mmol) or 1,000,000 µmoles (µmol); i.e., 1 mmol = 1000 µmol. Example: 1 mol of zeatin = 219.25 g, 1 mmol = 219.25 mg , and 1 µmol = 219.25 µg. Auxins, cytokinins, gibberellins, and ethylene have different functions and cannot be substituted for each other. Substitutions can sometimes be made within a group (i.e., one auxin for another, or a specific cytokinin for a different one), but this is not advisable because hormone functions or tissue responses to substances may be specific. Unlike salts and sugars, hormone substitutions within a group need not always be equimolar because hormone activities may vary. Hormone inhibitors (as for example ancymidol) or antagonists e.g., *trans*-cinnamic acid are used for specific purposes and must not be eliminated from a medium or substituted. Gibberellins, ethylene, and abscisic acid are used seldom if ever. Morphactins are added to a few media very rarely and are not included in this table.

[b]Both α-NAA and β-NAA may be used but this is not always indicated clearly in original research papers. The α form should be employed unless specified otherwise.

[c]These extremely high concentrations are generally found only in pastes used to induce plantlet formation on *Phalaenopsis* flower-stalk nodes. Some pastes may also contain *trans*-cinnamic acid.

Most auxins are not destroyed by autoclaving at 110–120°C for 50–60 min especially if the pH is non-acidic. However, autoclaving at low pH and in the presence of other factors may destroy IAA (Posthumus, 1971). This finding was confirmed more recently in a study which also showed that IBA is more stable than IAA (Nissen and Sutter, 1990). For this reason heat sterilization (autoclaving) for auxins is not recommended without prior determination that there would be no detrimental effects. Initially, at least, it is best to sterilize auxins by filtration (cold sterilization) or by dissolving them in ethyl alcohol (see culture media tables in Chapter 3). Once it is clear that a medium is appropriate it can be autoclaved after the auxin has been added and tested with explants. In many instances orchid explants and tissues grow and develop well on media that are autoclaved following the addition of auxin. This suggests that the auxin is not destroyed during autoclaving, or that it may be destroyed fully or in part, but the explants and/or tissue do not require it at least in the initial levels. It is also possible that whatever (if any) auxin remains in the medium after destruction during autoclaving is sufficient and/or that the heat denaturation product(s), should there be any (with or without auxin remnants), satisfy whatever requirements the orchid may have.

Illumination provided by cool white fluorescent tubes (Nissen and Sutter, 1990) and of unspecified nature (unpublished result by John Finer, finer.1@osu.edu posted on plant-tc@lists.umn.edu) causes the degradation of both IAA and IBA in both liquid and solid media. IBA is more stable than IAA under these conditions (Nissen and Sutter, 1990). Charcoal can absorb up to 97% of IAA and IBA in MS medium (Nissen and Sutter, 1990).

Some media contain the anti-auxin *trans*-cinnamic acid (*t*CA). Its purpose is to break bud dormancy. This compound is not interchangeable with any of the auxins and should not be used in media other than those specifically formulated to include it. Light may affect *t*CA and convert some of it to *cis*-cinnamic acid (*c*CA), but this does not seem to affect it usefulness. It is not possible to use *c*CA as a substitute for *t*CA. Heat sterilization of *t*CA is not advisable without prior determination that this will not affect its usefulness.

Cytokinins

The synthetics kinetin (6-furfuryl aminopurine), benzyladenine (N^6-benzylaminopurine, N^6-benzyladenine, BA, BAP), dimethylaminopurine (DMAP), thidiazuron (TDZ), and the naturally occurring zeatin are used most commonly in orchid culture media (Table 2-3). As with auxins, the cytokinins being used and their concentrations are based on empirical findings. Changes should be avoided. The effects of different cytokinins and their concentrations differ like those of auxins. Experiments with aqueous solutions of kinetin, zeatin, and isopentenyladenosine have shown that they are not broken down when autoclaved for 1 h at 120°C (Dekhuijzen, 1971). The effects of autoclaving at low pH and/or in the presence of other media components are less clear. It also not clear how autoclaving in culture media affects BA and DMAP. For these reasons, heat sterilization of cytokinins is not advisable without prior testing. In general cytokinins should be treated like auxins in respect to sterilization.

Thidiazuron (*N*-phenyl-*N*′-1,2,3-thiadiazol-5-ylurea, TDZ) is a relatively recent addition to the list of cytokinins which are used in orchid micropropagation. It was introduced as a cotton defoliant named Dropp and was assumed to be a cytokinin antagonist. However, when tested it proved to be a "very potent cytokinin" (Mok et al., 1982, 1987; Mok and Mok, 1985; Machteld C. Mok, pers. comm.). It was used in the tissue culture of a few woody and herbaceous species within a short time of its discovery (for example see Meyer and Kerns, 1986; Fellman et al., 1987) and additional plants after that (Chalupa, 1988; Badzian et al., 1989; Gribaudo and Fronda, 1991; Bates et al., 1992; Huetteman and Preece, 1993). TDZ was first used for micropropagation of orchids, specifically *Phalaenopsis* (Ernst, 1994), a dozen years after its cytokinin-like properties were discovered and following its use with other plants.

TDZ is soluble in dimethylsulfoxide (DMSO), *N*,*N*-dimethylformamide (DMF), 0.1 or 0.01N KOH or NaOH (forming a light-tan-colored solution), 0.5N HCl, and 50% or more ethanol (Huetteman and Preece, 1993; and K. M. K. Bhatti, kmkbhatti@yahoo.com; T. Chandrasekhar, chandrasekhart2k@yahoo.com; Gregory Franklin, gfranklin7lin@yahoo.com; J. E. Preece, jpreece@siu.edu; M. Rigby, vitrotec@hotmail.com; Thimmappaiah, thim12@yahoo.com; Z. Zhang, zhangzh@missouri.edu, all pers. comm.). It can be autoclaved (M. Compton, mcompton@uwplatt.edu; J. E. Preece, jpreece@siu.edu; Thimmappaiah, thim12@yahoo.com; Z. Zhang, zhangzh@missouri.edu, all pers. comm.), but there is also a report that autoclaving may cause some loss of activity. Therefore several investigators prefer to filter sterilize it (A. Zelcer, zelcer@volcani.agri.gov.il, pers. comm.). It can also be dissolved in 70–95% ethanol and added to media after autoclaving.

Gibberellins and Antigibberellin

Gibberellins are used very seldom in culture media for orchids. When used, GA_3 is the most common form (Table 2-3). Autoclaving reduces gibberellin activity by more than 90% (van Bragt and Pierik, 1971). Therefore gibberellins must be cold-sterilized through filtration or by dissolving them in ethanol.

The antigibberellin ancymidol is used in at least one orchid medium. It should be dissolved in 50–95% ethanol and added to media after autoclaving.

Abscisic Acid

This is a growth inhibiting hormone that is not used in orchid culture media. Autoclaving of "dilute solutions of the [2-*cis* and 2-*trans*] isomers at various pH values" does not affect them (Wilmar and Doornbos, 1971). However the effects of media components during autoclaving are not known. Therefore, should abscisic acid (ABA) be added to culture media, it should not be heat-sterilized without prior testing. The cold sterilization procedures used for auxins and cytokinins would be suitable for ABA. Light causes a number of changes and interconversions between the isomers of ABA (Wilmar and Doornbos, 1971).

Ethylene and Ethylene Inhibitor

The only gaseous plant hormone, ethylene is rarely if ever used in culture media. Should it become necessary to add this hormone to a culture medium the ethylene-generating solid chemical ethrel (ethephon) is the most convenient form (Table 2-3). Heat sterilization is not advisable. Ethylene itself can be sterilized by passing it through sterilizing filters.

Silver thiosulfate is an ethylene inhibitor. It is made as follows:

Step 1. A 0.1-*M* solution of sodium thiosulfate is prepared by dissolving 1.58 g of the salt in 100 ml of distilled water.

Step 2. A 0.1-*M* solution of silver nitrate ($AgNO_3$) is prepared by dissolving 1.7 g of the salt in 100 ml of distilled water. This solution must be stored in the dark until it is used.

Step 3. Silver thiosulfate, 0.02 *M*, is prepared by slowly pouring 20 ml of the 0.1-*M* stock $AgNO_3$ into 80 ml of the 0.1-*M* sodium thiosulfate solution. The solution can be stored for up to a month.

Amino Acids

The most commonly used amino acid in orchid culture media is glycine because it is a component of the MS medium (Murashige and Skoog, 1962). Other amino acids are also used in some media. Amino acids can not be substituted for each other and should be added as listed in each recipe. It is possible that their omission may not have major effects but this must be tested carefully before trying it with a valuable clone. The effects of autoclaving on amino acids may vary and it is best to follow the original procedures in each case. If there are doubts, both autoclaving and cold sterilization (filter or dissolving in ethanol) should be tested before deciding which sterilization method to use.

Polyol

The only polyol used in orchid culture media is *myo*-inositol (other names for it are *meso*-inositol, *i*-inositol, inositol, cyclohexitol, inosite, meat sugar, and bios I; chemically it is hexahydroxycyclohexane, $C_6H_{12}O_6$) because it is part of the MS medium (Murashige and Skoog, 1962). Its function is not clear and it may not even be required, but *myo*-inositol should not be removed from a medium without prior testing. Inositol is usually sterilized by autoclaving. Hexitols in coconut water have also been shown to have growth promoting effects on plant embryos (van Overbeek et al., 1941; Shantz and Steward, 1952, 1955; see Chapter 1 for additional details and citations). However, these substances are not added to culture media other than as part of coconut water.

Polyamines

All plants contain polyamines, which have been studied for more than five decades. However, their importance in plant development was noted only recently. In plants

polyamines play roles in and affect cell division, embryogenesis, flower development, fruit ripening, root induction, and tuber formation. Putrescine, spermidine, and spermine are the most common polyamines in plants. Some have been used in tissue culture including orchid micropropagation to promote adventitious root initiation, shoot formation, and somatic embryogenesis.

Jasmonates

Initially jasmonic acid was thought to be a plant growth inhibitor. Subsequently jasmonic acid and methyl jasmonate were characterized as compounds that promote senescence and retard growth. In tissue culture jasmonic acid and methyl jasmonate can enhance meristem formation.

Vitamins

Niacin (nicotinic acid), pyridoxine (vitamin B_6), and thiamine (vitamin B_1) are most commonly added to orchid culture media as part of MS medium. Biotin, folic acid, and pantothenic acid (as calcium pantothenate) are also used in some media. It is not clear if all, or any, of them are required, but media formulations should not be changed without preliminary tests. Vitamins are not heat resistant and should not be sterilized by autoclaving (ten Ham, 1971). However media that contain vitamins are often heat-sterilized. This suggests that: (1) vitamins may survive autoclaving fully or in part; (2) explants and tissue do not require vitamins; and/or (3) whatever remains active after autoclaving can satisfy any requirements the explants may have. In practical terms this means that if a medium or media prove suitable without autoclaving the vitamins, tests should be carried out before switching to large-scale heat sterilization.

Nucleotides and Nucleic Acids

Some media include cytidylic and/or guanylic acid and/or other nucleotides as well as nucleic acids. Their functions are not clear and they may not even be required. However, it is advisable not to change media formulations. These substances may be autoclaved, but the high temperature and pressure at the low pH of orchid culture media may change them. For critical work it is advisable to try both autoclaving and cold sterilization (filtering the substances through sterilizing filters or adding them in alcohol solutions if their solubility will permit it) and then use the method which works best.

Organic Acids

Citric acid or tartaric acid were added as solubilizers for iron in several media formulated before the advent of chelating agents like EDTA. The iron salt–organic acid combinations in such media can and should be replaced with chelated iron (usually

a mixture of $FeSO_4 \cdot 7H_2O$ and Na_2EDTA). A few media still include organic acids. Their functions are not clear and it is not known if they are really required. Still, changes in the composition of media should not be made without prior testing. Organic acids can be sterilized by autoclaving.

Banana

The first use of banana in orchid seedling cultures dates back to 1950 (Withner, 1959*b*). All reports since then indicate that banana homogenate enhances the growth of orchid seedlings (for reviews see Withner, 1959*b*, 1974*b*; Arditti, 1968) and carrot root explants (Steward and Simmonds, 1954). These effects could be due to the presence in the pulp of plant hormones and related substances (Steward and Simmonds, 1964; Khalifah, 1966) and/or any number of other compounds (Table 2-4). There is some evidence that the substance(s) which enhance the growth of orchid seedlings is/are insoluble in water and ether but soluble in ethanol (Arditti, 1968). In micropropagation banana homogenate is added to media for plantlet development. It can be sterilized by autoclaving.

TABLE 2-4. **Composition of banana pulp**[a,b]

Component	Concentration	Component	Concentration
Minerals		**Acidity**	
Aluminum	Small amount	NaOH, 1N	4.06–4.46 ml 100 g^{-1} pulp
Boric acid	Some	pH	4.2–4.75; ripe fruit, 6.2; green 7.2
Calcium (as CaO)	0.028–0.37% of pulp DW	**Moisture**	
Calcium	8–24 mg 100 g^{-1} edible portion	Moisture content	74.4–77.4% of fresh pulp
Calcium	5.71 mg 100 g^{-1} pulp	Moisture	70.6–75.9% of FW pulp
Chlorides	0.171–0.38% of pulp DW	Osmotic pressure	7.15–29.06 atm
Chlorine	380 mg 100 g^{-1} edible portion	**Carbohydrates and related substances**	
Copper	0.09 mg 100 g^{-1} pulp	Carbohydrates	15.09 g 100 g^{-1} pulp
Copper	0.61 mg 100 g^{-1} edible portion	Carbohydrates	18.60–21.51% of fresh pulp
Iodine	5–200 ppb in fresh fruit	Fructose	1.45–3.24% of fresh pulp
Iron	1.37 mg 100 g^{-1} pulp	Glucose	2.24–4.21% of fresh pulp
Iron	6 ppm	Glucose	11.81% of just ripe fruit DW
Iron	1.8 mg 100 g^{-1} edible portion	Glycosides	0.23–0.25% of FW
Iron (Fe_2O_3)	0.0064–0.0079% of pulp DW	Maltose	very small amounts
Iron (Fe_2O_3)	0.7 mg 100 g^{-1} edible portion	Non reducing sugars	6.12–13.38% of pulp FW
Magnesium (MgO)	0.18% of pulp DW	Reducing sugars	6.19–10.73 of pulp FW
Magnesium	94 mg 100 g^{-1} edible portion	Soluble sugars	20% of FW
Manganese	1.95 mg 100 g^{-1} edible portion	Starch	0.4–7% of FW
Phosphates (P_2O_5)	0.179–0.304% of pulp DW	Starch	2.93–6.54% of pulp DW
Phosphates (P_2O_5)	26 mg 100 g^{-1} edible portion	Starch	13% of water insoluble fraction
Phosphorus	290 ppm	Sucrose	7.95–12.08% of fresh pulp
Phosphorus	85 mg 100 g^{-1} edible portion	Sucrose	4.50% of just ripe fruit DW
Potassium	251.43 mg 100 g^{-1} pulp	Sucrose : fructose ratio	4 : 3
Potassium (K_2O)	1.21–1.68% of pulp DW	Total sugars	11.5–12.5% FW
Potassium (K_2O)	370–1275 mg 100 g^{-1} edible portion	Total sugars	6.59–13.45% of fresh pulp
Silica (SiO_2)	0.058–0.96% of pulp DW	Total carbohydrates	73 g 100 g^{-1} edible portion
Sodium	0.57 mg 100 g^{-1} pulp	**Cellulose, fibers, and related substances**	
Sodium (Na_2O)	0.201–0.273% of pulp DW	Cellulose	0.13–0.19% of fresh pulp
Sodium (Na_2O)	1–3 mg 100 g^{-1} edible portion	Cellulose	4.8%, water insoluble fraction
Sulfur (SO_3)	0.046–0.053% of pulp DW	Crude fiber	22.82% of just ripe fruit DW
Sulfur	36 mg 100 g^{-1} edible portion	Hemicellulose	0.12–0.21% of fresh pulp
Zinc	28 mg kg^{-1} edible portion	Hemicelluloses	1–2% of fruit DW
Ash		Lignin	0.15–0.85% of fresh pulp
Ash	0.70–0.85% of fresh pulp	Total fiber	0.78–0.88% of fresh fruit
Ash	0.8 g 100 g^{-1} edible portion	Total fiber	0.5–1.5 g 100 g^{-1} edible portion
Ash	0.6% of water insoluble fraction

[a]The reasons for the growth stimulating effects banana pulp has on orchid seedlings and plantlets are not clear. Information on the composition of banana pulp is presented here for those who may wish to study or speculate about the factor(s) which may be involved. All units used here are those given in the source papers. The different values given in the literature for components are sometimes difficult, if not impossible, to reconcile. That is why multiple entries are included for a number of substances. This table is a modification of a previous one (Arditti, 1968; Arditti et al., 1982). Sources: Anonymous, no date; von Loesecke, 1950; Steward and Simmonds, 1954; Steward et al., 1960*a*, 1960*b*; Diem, 1962; Whatt and Merrill, 1963; Palmer and Roberts, 1967; Tamura, 1970; van Staden and Stewart, 1975.

[b]Abbreviations: DW, dry weight; FW, fresh weight; IU, international units; ppb, parts per billion; ppm, parts per million; RDA, recommended daily allowance; tr, trace; USDA, United States Department of Agriculture.

[c]The original paper (Tamura, 1970) states that amino acids, grams per "gram nitrogen edible portion" or in "100 gram edible portion," were used to indicate the value but does not state which.

Coconut Water

Erroneously called "coconut milk," coconut water (CW), the liquid endosperm of coconut seeds (Table 2-5), was first used in orchid seedling media in 1951 (Mariat, 1951). Despite a number of reports since then (for reviews see Ernst, 1967*b*; Arditti and Ernst, 1984), CW is not used extensively in orchid seed germination and seedling culture. However it does have beneficial effects on some orchid explants. It can also increase proliferation without causing mutations. CW is incorporated in several media because of that. The reasons for the beneficial effects of CW are not clear. Plants hormones and related substances, hexitols (Pollard et al., 1961) and many other substances singly and in combination may be the reason(s) for these effects (Table 2-5). CW from green (unripe) nuts is the most commonly used and recommended form. However CW from ripe nuts can also be used. If frozen, CW can be stored for prolonged periods without loss of activity. CW can be autoclaved.

Hydrolysates and Autolysates

Peptone, tryptone (both hydrolysates), yeast extract (an autolysate), and a number of other complex additives are used in some orchid culture and micropropagation media (Table 2-6).

Sugars

Sucrose (ß-D-fructofuranosyl-α-D-glucopyranoside, kitchen sugar, beet sugar, cane sugar, sugar, saccharose, $C_{12}H_{22}O_{11}$, MW 342.30) is most commonly used in orchid culture media. When sterilized by autoclaving (which is the usual, simplest, and most widely used method) some of it hydrolyzes into its component molecules fructose (ß-D-fructose, levulose, fruit sugar, $C_6H_{12}O_6$, MW 180.16) and glucose (blood sugar, corn sugar, grape sugar, dextrose, $C_6H_{12}O_6$, MW 180.16). Therefore seeds and tissues are usually cultured in a mixture of fructose, glucose, and sucrose. There is some evidence to suggest, at least in respect to the seeds of several species, that cane sucrose is preferable to that obtained from beets (at least in respect to kitchen-grade sucrose). Some orchid seeds and explants may grow better on fructose.

If necessary glucose and/or fructose can be substituted for sucrose in tissue culture media (a number of additional sugars including maltose and trehalose can be used for seeds). However, it is necessary to keep in mind that due to the different molecular weights of sucrose on the one hand and glucose and fructose on the other, substitutions may present some problems (Table 2-7). The commonly used 20 g of sucrose amounts to 0.06 mol (or 60 mmol) whereas the same weight of fructose or glucose is 0.11 mol (110 mmol). As a result the osmolarity (concentration as reflected in osmotic effects) of a solution containing 20 g of sucrose will be different from that of a medium made with 20 g of fructose or 20 g of glucose. Such differences in osmolarity and/or sugar level may have an effect on the survival of newly excised tissues or freshly prepared protoplasts. On the other hand, solutions of 20 g of each of these sugars contain almost the same number of carbons and cutting

[a]No units given.
[b]Units: grams per 100 g dried protein.
[c]meq ml^{-1} is milliequivalents per milliter.
[d]Units: mg ml^{-1}.

the concentrations of fructose or glucose in half for the purpose of reducing the osmolarity will also reduce the total carbon. This too may have an effect.

Another point to consider is the length, size, and nature of sugar molecules. Equal weights of different length molecules contain the same amount of carbon, but as indicated before the molarities will be different. However, this is not the only difference. The ability of plants to hydrolyze or take up sugar molecules of different sizes may differ and this could determine the actual amount of sugar that is available to seeds, seedlings, explants, and/or plantlets. For example, plantlets on a medium that contains 20 g glucose l^{-1} are on a 0.11-*M* solution of an easily available sugar. The plantlets can easily take up the glucose molecule. If placed on medium that contains 20 g maltose the plantlets will be on a 0.06-*M* solution of a sugar which can also be taken up, utilized, and/or hydrolyzed easily (Ernst et al., 1971*b*). However if the plants are placed on media that contain 20 g maltotriose (a molecule made of three glucose residues), maltotetraose (four glucoses), maltopentaose (five glucoses), or maltohexaose (six glucoses), the molarities of the solutions decrease (approximately 0.04, 0.03, 0.024 and 0.020 *M*, respectively). The different osmolarities will affect growth, but size itself is not the only relevant factor. Plantlets may not be able to take up and/or hydrolyze the longer molecules as fast and as easily as the shorter ones. As a result plantlets on longer sugars may actually be growing on suboptimal concentrations even if carbon levels are the same. And this is indeed the case (Ernst and Arditti, 1990). This problem may occur even on equimolar concentrations of sugar molecules of different sizes, lengths, and complexities. The molarity/availability/osmolarity factor becomes even more complex if the larger sugars consist of more than one kind of sugar molecule such as raffinose (galactose, glucose, fructose), stachyose (galactose, galactose, glucose, fructose), verbascose (galactose, galactose, galactose, flucose, fructose) and others.

Given these facts, changes in sugars and their concentrations should not be made unless this is strictly necessary. If changes must be made this must be done on a molar, not weight, basis and the media with the new sugars or sugar levels should be tested with an easily obtainable cultivar before using them for a rare and expensive one.

A formula to use for calculating equivalent molarities of sugars is:

$$\frac{\text{OWS} \times \text{MWSS}}{\text{MWOS}} = \text{SWS} \qquad \text{(V)}$$

where:

MWOS = molecular weight of the original sugar;
MWSS = molecular weight of the substitute sugar;
OWS = weight (in g, mg, or μg) of the original sugar;
SWS = weight (in g, mg, or μg) of the substitute sugar.

If glucose is to be used to substitute for an equimolar amount of sucrose, equation V becomes:

$$\frac{20\ \text{g} \times 180.16}{342.30} = 11.11\ \text{g} \qquad \text{(VI)}$$

For the reverse (replace 20 g of glucose with sucrose), equation V becomes:

[a]The most commonly used concentrations of each sugar are given in boldface. Some concentrations that are used seldom if ever are included for comparison purposes. It is important to note that equal weights of fructose and glucose (both 6-carbon sugars) are equimolar and contain the same number of carbons. The same weights of glucose or fructose and sucrose (a 12-carbon sugar) contain nearly the same number of carbons, but represent different molarities. For example, 20 g of glucose are equal in molarity and number of carbons to the same weight of fructose. The same 20 g of sucrose contain nearly as many carbons as an equal weight of glucose or fructose, but half as many moles. Most recipes for orchid tissue culture media list sugar content by weight rather than molarity. Both molarity and weight are given here to allow for comparisons.

Tissues and organs may be less sensitive to molarities of media than are isolated cells and protoplasts, which are affected greatly even by small differences. The true concentration of a solution (i.e., its osmolarity) is determined not by weight but by the number of molecules in it. Therefore, if tissue culture media are to be used for single-cell and protoplast cultures, substitutions of sugars must be made on the basis of molarity, not weight or percentage.

$$\frac{20\text{ g} \times 342.30}{180.11} = 38.01\text{ g} \qquad \text{(VII)}$$

If the number of carbons is to be kept equal the total in each molecule must be taken into account and the expression changes to:

$$\frac{\text{COS}}{\text{CRS}} \times \text{OWS} \times \frac{\text{MWSS}}{\text{MWOS}} = \text{SWS} \qquad \text{(VIII)}$$

where:

COS = number of carbons in the original sugar;
CRS = number of carbons in the replacement sugar;
MWOS = molecular weight of the original sugar;
MWSS = molecular weight of the substitute sugar;
OWS = weight (in g, mg, or μg) of the original sugar;
SWS = weight (in g, mg, or μg) of the substitute sugar.

If glucose (six carbons) is to be used as a substitute for sucrose without a change in the number of carbons in the solution, equation VIII becomes:

$$\frac{12}{6} \times 20\text{ g} \times \frac{180.16}{342.30} = 22.22\text{ g} \qquad \text{(IX)}$$

or

$$2 \times 20\text{ g} \times \frac{180.16}{342.30} = 22.22\text{ g} \qquad \text{(X)}$$

for the reverse it is:

$$\frac{6}{12} \times 20\text{ g} \times \frac{180.16}{342.30} = 19\text{ g} \qquad \text{(XI)}$$

or

$$0.5 \times 20\text{ g} \times \frac{180.16}{342.30} = 19\text{ g} \qquad \text{(XII)}$$

Anticontaminants

In some instances it may not be possible to adequately surface-sterilize tissues or seeds, or a valuable culture may become contaminated. When this happens the incorporation of bactericides or fungicides in the culture medium may save the cultures by either eliminating the contaminant(s) or at least keeping it/them in check.

Efforts to formulate orchid seed and seedling culture media that do not require sterilization or can reduce contamination started shortly after the Knudson C medium was developed (for a short review see Thurston et al., 1979). Vanillin derivatives (Knudson 1947; McAlpine, 1947; and personal communications) and several antibiotics (Schaffner, 1954) were tested as additives for this purpose, but were found to be phytotoxic and unsuitable. More recently, several combinations were formulated (Table 2-8) following the screening of a number of substances (Thurston et al.,

TABLE 2-8A. **Stock solutions of anticontaminants**[a]

Compound	Amount per liter of culture medium (final concentration in culture medium), mg	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
Amphotericin B	10	100 mg 10 ml^{-1} 70% ethanol[b]	1	Keep frozen between uses
Benlate	50	500 mg 10 ml^{-1} distilled water[c] or 70% ethanol	1	Keep frozen between uses
Gentamycin	50	Sterile injectable liquid prepared according to instructions in package[d]	Depends on instructions in package	Keep frozen between uses
Nystatin	25	250 mg 10 ml^{-1} absolute ethanol	1	Keep frozen between uses
Penicillin G	100	1 g 10 ml^{-1} 70% ethanol	1	Keep frozen between uses
Sodium omadine	5	50 mg 10 ml^{-1} 70% ethanol	1	Keep frozen between uses
Vancomycin	50	500 mg 10 ml^{-1} 70% ethanol	1	Keep frozen between uses
Graphite[e]	2000	No stock	No stock	Weigh

[a]To prepare a mixture for use, mix the required compounds in a small vial approximately 1–2 h before needed, add the graphite, and shake well. Add this mixture to the medium after agar has been dissolved. The graphite can also be added before autocloning.
[b]The 70% ethanol solution is prepared by bringing 737 ml of 95% ethanol to 1000 ml with distilled water. Ethanol (95%) can be purchased in drugstores with prescription.
[c]A precipitate will form. Shake well before use.
[d]This step requires a sterile syringe-and-needle combination that can be purchased in drugstores with prescription.
[e]Not an anticontaminant, but used to darken media to prevent photodestruction of light-sensitive compounds.

TABLE 2-8B. **Formulations of anticontaminants for use in culture media for orchid seedlings (Thurston et al., 1979)**

Number	Formulation[a,b]
1	Benlate + nystatin + penicillin G + gentamycin + graphite[c]
2	Benlate + nystatin + penicillin G + gentamycin + sodium omadine + graphite[c]
3	Benlate + nystatin + penicillin G + gentamycin + amphotericin B + vancomycin + graphite[c]

[a]*Concentrations*: amphotericin B, 10 mg l^{-1}; benlate, 50 mg l^{-1}; gentamycin, 50 mg l^{-1}; nystatin, 25 mg l^{-1} (100, 500 units l^{-1}); penicillin G, 100 mg l^{-1} (159, 500 mg l^{-1}); sodium omadine, 5 mg l^{-1}; vancomycin, 50 mg l^{-1}; graphite, 2 g l^{-1}.
[b]*Suppliers*: amphotericin B, gentamycin, nystatin, penicillin G, and vancomycin can be obtained from Sigma Chemical Co.; sodium omadine is available from the Olin Corporation, Agricultural Division, 700 N. Buckeye St., Little Rock, AR 72114, USA; benlate formulations are sold by retail nurseries and plant shops. Graphite may be purchased from the J. T. Baker Chemical Co., 222 Red School Lane, Phillipsburg, NJ 08865, or 995 Zephyr Ave., Hayward, CA 94544.
[c]Not an anticontaminant, but used as a darkening agent to prevent photodestruction of light-sensitive compounds.

1979, 1980; Spencer et al., 1979/80; Brown et al., 1982; Cvitanik and Arditti, 1984; the research was carried out entirely by several hard working and very bright undergraduate students, all except one of them women between the ages of 19 and 21, at the University of California, Irvine; see Figs 1-52–1-54). These formulations cannot be used routinely, but may be useful in special cases.

Medium is prepared as usual for tropical orchids through the step of dissolving the agar. The anticontaminants (Table 2-8) are dissolved or suspended and mixed in a total of 6 ml 70% ethanol (i.e., ethyl alcohol; the control media in the original research suggested that this much alcohol may actually enhance seedling growth).

All culture vessels, funnels, and other glassware used with unsterilized anticontaminant-containing media must be washed with 70% ethanol or rubbing (i.e., isopropyl) alcohol and allowed to dry upside down in clean, dust-free areas. Tools must be washed similarly and flamed before use. Work surfaces must be first washed with soap and water and then with 70% ethanol or rubbing alcohol. Water used for the preparation of media must be boiled for 5 min, allowed to stand in a covered vessel for 24 h, and boiled again for another 5 min.

Work areas must be clean and dust-free. All work must be carried out quickly and efficiently.

The formulations described here (Table 2-8) are not suitable for use in seed germination media and should not be employed for that purpose. They were not tested widely and may be unsuitable for all explants. They are known to be suitable for *Cattleya* and *Stanhopea* seedlings (Thurston et al., 1979) and *Phalaenopsis* flowerstalk-node cultures (Spencer et al., 1979/80). Since plantlets derived from explants are similar to seedlings in their general requirements and responses to media components, these formulations may appear to be potentially useful in orchid micropropagation (see section on *Phalaenopsis*). Still, it is advisable to test each combination with a few cultures prior to large-scale use. On the whole their usefulness will probably prove to be limited and care should be exercised in any attempts to use them.

Amphotericin B (92.7% pure, 10 ppm), nystatin (4020 units mg^{-1}, 25 ppm), and sodium omadine (90% pure, 5 ppm) when used singly delayed the development of *Cymbidium* shoot-tip explants, but had no other deleterious effects (Brown et al., 1982). Penicillin G (1595 units mg^{-1}, 100 ppm) did not affect callus growth but inhibited plantlet formation. Benomyl (50% pure, 50 ppm), Dowicide (97% pure, 5 ppm), gentamycin (from a sterile ampoule, 50 ppm), Quintozene (PCNB; 99% pure, 100 ppm), and vancomycin (97.8% pure, 50 ppm) were inhibitory. All combinations of these compounds inhibited callus formation, growth, and plantlet development (Brown et al., 1982). These findings indicate that except in rare and unusual cases where a single compound may be used to eliminate contamination from a very valuable culture these substances are not suitable for orchid micropropagation.

The orchid phytoalexins, orchinol and loroglossol (Stoessl and Arditti, 1984), a synthetic analog (dehydroorchinol), a possible precursor of orchinol [3,4′-(dihydroxy-5-methoxydihydrostilbene)] and batatasin III (3,3′-dihydroxy-5-methoxydihydrostilbene) reduced the growth of *Cattleya aurantiaca* seedlings (Hills et al., 1984; see Fig. 1-54). This suggests that they may have the same effects on plantlets produced in tissue culture. Therefore these compounds should not be used to combat contamination without prior testing. Whether phytoalexins (those from orchids or other plants) in general may have similar or different effects on orchid seedlings and/or tissue cultures is not clear at present. Therefore their possible incorporation in tissue culture media will require screening in advance. An additional, and critical, problem with phytoalexins is their unavailability.

Several antibiotics have been used in tissue culture with plants other than orchids to control or prevent contamination (Table 2-9). Only a few of these substances were tested with orchids. Therefore they should be used with great caution and only following tests with expendable tissues and cultures.

A potentially very useful preparation which can be used to combat contamination was patented in the United States in 1998 by Dr. Assaf Z. Guri and Dr. Kishor N. Patel. The patent (US Patent 5,750,402) was assigned to Plant Cell Technology in Washington, DC (www.ppm4plant-tc.com). This preparation is a mixture of methylchloroisothiazolinone, methylisothiazolinone, magnesium chloride, and magnesium nitrate, which may also contain potassium sorbate or sodium benzoate, or both.

The preparation is amber-colored to clear liquid at pH 3.0–4.0 which has a mild, inoffensive odor. It is relative safe, but can generate toxic fumes (hydrogen chloride, nitrogen oxides, and sulfur oxides). Inhalation and eye and/or skin contact can cause irritation (Plant Cell Technology, no date *a–d*). Therefore protective gear and breathing masks are recommended by Plant Cell Technology (www.ppm4planttc.com/MSDS.htm).

[a]Most of these substances have not been tested with orchids (see Table 2-8) and their effects on orchid explants, callus, protocorms, protocormike-like bodies, seedlings, plantlets, and plants are not known. Therefore they should not be used without prior testing. In general, routine use of these compounds is not recommended. Their use should be attempted only in cases when rare and valuable cultures are in danger of being lost due to contamination. Technicians who use them should wear gloves, masks that prevent inhalation of the substances, and safety clothing that will not allow penetration through the skin. If this is not done those who come into contact with the substances can become sensitized to the substances or may have allergic reactions which can be dangerous. This precaution was recommended by Dr. Teoh Eng-soon of Singapore. Information in this table was obtained from a preprint by V. C. Pence and J. A. Sandoval (kindly made available by Dr. Valerie C. Pence of the Center for Research of Endangered Wildlife, The Cincinati Zoo and Botanical Garden); *Phyto*Technology Laboratories LLC (www.phytotechlab.com), Sigma (www.sigmaaldrich.com) and Bautista et al., 2002).

[b]Abbreviations: B, antibacterial, F, antifungal (including yeasts and molds); M, anti-mycoplasma.

[c]Abbreviations: D, DMF; E, ethanol; H, 2*M* HCl; M, methanol (probably also ethanol); N, NaOH; O, DMSO; SW, suspension in W, water.

[d]Abbreviations: g, g l^{-1}; ml, ml l^{-1}; mg, mg l^{-1}; u, units l^{-1}; U, up to.

[e]Abbreviations: CS, cold sterilize; T, tested with orchids.

PPM™ is heat-stable (i.e., it can be autoclaved), broad based, and effective against both bacteria and fungi because it "targets and inhibits multiple enzymes" (Plant Cell Technology, no date *b*). It can also be used to decontaminate tissues (Plant Cell Technology, no date *b–d*). Plant Cell Technology has detailed instructions regarding the use of PPM (Plant Cell Technology, no date *b–d*) on its web site (www.ppm4plant-tc.com/MSDS.htm). An important point to keep in mind is that PPM inhibits the growth of contaminants. It does not destroy them. This means that cultures can become contaminated after a while. Should this happen, the explants,

tissues, callus, seedlings, or plantlets should be decontaminated again with PPM (see below) and moved to fresh medium.

There are several reports in the literature regarding the use of PPM in tissue culture (for one example see Niedz and Bausher, 2002; for a longer list of references see Plant Cell Technology, no date *c*). However, information about its use with orchids is limited. Dr. Assaf Guri made the following suggestion: "Skip sterilization with sodium of calcium [hypochlorite] and soak the shoot tips in non-pHed 4% PPM solution in which full strength . . . basal salts are added [this means inorganic salts only of the medium which will be used to culture the explant]. I can't tell you the exact exposure time but I'll suggest from 1 to 4 hours [those who plan to use PPM will have to experiment] during which the tips are very gently agitated without Tween 20. Without rinsing place the tips into the proper medium with 0.1% PPM." Professor Victor M. Jimenez of the University of Costa Rica suggested using 0.2% PPM but pointed out that contaminations may set in after 3 months. Should this happen, his recommendation is to move the plant material to fresh and clean medium. However, if the contamination is excessive it cannot be removed. Therefore cultures should be examined daily and tissues must be moved at the first sign of contamination.

A document by Roger Nick of Spring Orchids Laboratory on the Plant Cell Technology web site (www.ppm4plant-tc.com/ppp.htm) describes the use of PPM for the sterilization of orchid seeds and plants. Unsterilized seeds of *Cattleya*, *Phalaenopsis*, and *Dendrobium* hybrids harvested at the green capsule stage were placed on half-strength MS medium (Murashige and Skoog, 1962) supplemented with 20 g sucrose l^{-1}, 10 mg thiamine l^{-1}, 1 mg pyridoxine l^{-1}, 1 mg niacin l^{-1}, and 100 mg *myo*-inositol l^{-1} solidified with 8 g agar l^{-1} with and without 2 ml PPM l^{-1}. Germination and growth were not affected by the PPM. After 2 months of growth there was no contamination and there were no differences between seedlings on PPM-free and PPM-containing media. This method is effective with seed from capsules which split prematurely.

Seedlings which became contaminated following subculture from flasks where the seeds were germinated initially could be cleaned by placing them in a solution of 20 ml PPM l^{-1} for 24–36 h on a rotary shaker and moving them after that without rinsing to half-strength MS containing 2 ml PPM l^{-1}. The seedlings did not become contaminated again and grew normally.

When *Phalaenopsis* stem sections are washed with a mild detergent and water, submerged in 25% Clorox solution with Tween 20 for 25–30 min, rinsed in sterile distilled water three times, placed in quarter-strength MS for 24 h and cultured on half-strength MS, 25–30% become contaminated. If 20 ml PPM l^{-1} are added to the sterilization process, contamination drops to 5%. Some *Phalaenopsis* hybrids are more sensitive to PPM than others.

An internet inquiry on discussion groups dealing with orchids (Orchid Guide Digest) and tissue culture (plant-tc@tc.umn.edu) elicited several responses:

- Professor Michael E. Compton, University of Wisconsin-Plateville wrote: "I have used PPM at . . . 2 ml/l for meristem cultures of *Oncidium* without ill effects. However, PPM at this rate does not protect meristems from heavy microbial infections."

- Marty Kalin from Plant Cell Technology wrote that when orchid seeds that were surface-sterilized for 10 min with 10% Clorox, suspended in solution of 4 ml PPM l^{-1} and placed on autoclaved medium "without the benefit of a laminar flow hood in a non sterile environment (an open room) approximately 10% (of 255 flasks) became contaminated vs an expected 45–60%." Germination of seeds of "several genera . . . including temperate terrestrial and tropical species" were not affected by the PPM.
- Esteban McGrath, a *Hibiscus* grower from Puerto Rico who used to grow orchids, suggested that PPM should be used to sterilize both seeds and utensils. He reported losses that did not exceed 2%.
- Simon M. Wellinga of SymPhyto in the Netherlands wrote: "Back in 1998 we ordered a couple of 100 ml bottles and tried PPM with our cultures, which at that time consisted mostly of botanical *Cattleya* and *Laelia* species. We did so out of curiosity and to find out whether this mixture would meet expectations. In an initial trial PPM was both used as an ingredient of our standard germination media and as a cure for contaminated seedlings, which after treatment were replated onto media either containing PPM or without it. Although PPM was used strictly according to the recommendations that came with the product and while following our standard laboratory practices (work done in a laminar flow hood, autoclave cycles as usual, etc.), all our experimenting was not planned ahead in what one would call a sound and statistically justifiable setup. Therefore our results cannot be claimed to be scientific evidence, and neither have they been published. The reason that we only tested PPM qualitatively, and not quantitatively, was that we would never have been able to utilise this ingredient on a larger scale, both for economical reasons and because of international phytosanitary regulations. Since a considerable part of our seedlings is sent in flask on sterile medium to non-EU destinations (the only way one can get *Paphiopedilum* species and other Appendix I species across international borders), we are not allowed to incorporate any antibiotics in our export flasks or any other compounds that temporarily suppress or mask infections.

  For what it is worth – although we made sure to follow the instructions that came with the product, we never bothered to share our experiences with others – we found that in seed cultures on medium containing PPM infections would still occasionally show up, and we have never been able to clean contaminated cultures with the help of PPM, something which with some luck can be achieved in cases of hard-leafed material as *Cattleya* and *Paphiopedilum* with sodium hypochlorite treatment. In those instances in which treated cultures of infested seedlings seemed to be clean, infection would immediately show up again after replating to PPM-free medium, and this is why we were led to believe that PPM merely suppresses infections but does not eradicate them altogether.

  I understand you are looking for information and references for the forthcoming new edition of 'Micropropagation of Orchids' and am sorry that the information above is only anecdotal."

More recently PPM was tested for its ability to control contamination in seed and seedling cultures of *Vanda sanderiana* seedlings. At 4 ml l^{-1}, PPM eliminated contamination (Bautista et al., 2002).

Altogether it seems that PPM can be useful for surface decontamination and keeping media free of contamination in orchid seed germination, seedling culture and micropropagation, but only after additional tests and experiments. PPM is available from www.ppm4plant-tc.com.

Charcoal

A clear distinction must be made between carbon black and activated charcoal. Both will turn culture media black, but this is where the similarity between them ends. Carbon black (lampblack, furnace black, channel black, and acetylene black) is a generic name for black pigments of submicron size formed by thermal degradation of hydrocarbons. These pigments are not adsorbents and are used for inks, paints, and reinforcing agents for rubber products.

Activated carbon or charcoal (Fig. 2-1) is characterized by an extremely large area : weight ratio (up to 2000 $m^2 g^{-1}$) and is used for the adsorption of substances. Both animal and vegetable charcoals are available, but the latter are preferable for culture media. They are leached during preparation to remove contaminants, but some ions still remain (Table 2-10). Pore sizes may also vary; those in decolorizing carbons are larger.

The first attempt to darken a culture medium used for orchid seed germination was made in an effort to germinate native American *Cypripedium* species (Curtis, 1943). Lampblack (3 g l^{-1}) was used for this purpose, but germination was very poor. These species do not germinate well asymbiotically even at present and it is safe to assume that the lampblack had no effect of any kind. The addition of animal charcoal to a culture medium used for *Cymbidium* plantlets improved differentiation and plantlet growth but reduced the proliferation of protocorm-like bodies (PLBs) and the formation of aerial roots (Werkmeister, 1970*a*, 1970*b*, 1971). Darkening the culture vessels with black paper had a similar effect. Dr. Peter Werkmeister was the first to use charcoal to darken orchid culture media (for an historical account see Arditti and Krikorian, 1996). He did it to study the effects of dark media on root growth and development.

Activated vegetable charcoal (Nuchar C, 2 mg l^{-1}) improved seedling growth of the terrestrial *Paphiopedilum* (Ernst, 1974) and the epiphytic *Phalaenopsis* (Ernst, 1975, 1976) orchids. These observations led to the development of practical charcoal-containing media which gained widespread, rapid acceptance. In addition to being incorporated into media used for seedlings, charcoal is now added to many substrates employed in the tissue culture of orchids and other plants (for a few examples see Reuveni and Lillien-Kipnis, 1971; Nakamura and Itagaki, 1973; Anagnostakis, 1974; Irikura, 1975*a*, 1975*b*; Bajaj et al., 1976; Wang and Huang, 1976; Wernike and Kohlenbach, 1976; Weatherhead et al., 1978, 1979; Wann, Veazey and Kaphammer, 1997; for reviews see Yam et al., 1990; Arditti and Krikorian, 1996).

The beneficial effects of charcoal in culture media for filamentous algae and moss protonema were attributed to: (1) darkening which simulated soil conditions (Proskauer and Berman, 1970); and (2) adsorption of unidentified morphogenetically active (Klein and Bopp, 1971), toxic (Wang and Huang, 1976), or harmful (Weatherhead et al., 1979) substances.

One possible explanation of the effects of charcoal on orchid seedlings or tissue-culture-derived plantlets is that it improves aeration. Growth similar to that on charcoal-containing media was also observed when seedlings of *Paphiopedilum* and *Phalaenopsis amboinensis* were grown on Pyrex glass wool alone or in combination with Nuchar C vegetable charcoal (Ernst, 1974, 1975, 1976; Arditti, 1979; Arditti and Ernst, 1984).

A second possibility is that the charcoal adsorbs ethylene (Ernst, 1975), which can inhibit growth and differentiation. Another plausible explanation, based on careful studies of absorption characteristics and media changes during autoclaving, is that charcoal adsorbs and therefore renders harmless: (1) 5-hydroxymethylfurfural, which is produced by the dehydration of sucrose during autoclaving and is inhibitory to the growth of tobacco anthers in vitro (Weatherhead et al., 1978); and (2) inhibitory phenolics and carboxylic compounds produced by the tissues (Fridborg et al., 1978; Weatherhead et al., 1979). Charcoal can also adsorb plant hormones and vitamins and this may explain the fact that it can also be inhibitory to growth (Fridborg and Eriksson, 1975; Constantin et al., 1977; Fridborg et al., 1978; Weatherhead et al., 1978).

It is entirely possible, of course, that both of these explanations are correct, especially since Pyrex glass wool has not been shown to adsorb phenolics, hormones, and other factors (Ernst, 1974, 1975, 1976). Altogether "it would seem . . . that addition of charcoal to culture media can have a considerable effect on the composition [and aeration] of . . . media. Where the addition results in an increased response . . . it would appear pointless to include . . . components which are strongly adsorbed . . . [however, even after strong adsorption a part and/or all of these components may remain in the medium in an available form] . . . Conversely . . . adsorption of media components can lead to inhibition . . . This leads to the interesting possibility that there may be species whose tissue growth may be inhibited by phytotoxin production, and for which the addition of charcoal to negate this may lead to another type of inhibition by removal of essential nutrients" (quote from Weatherhead et al., 1979 with added comments in square brackets).

As already mentioned charcoal has the capacity to adsorb hormones and vitamins and thereby inhibit growth (Fridborg and Eriksson, 1975; Constantin et al., 1977; Fridborg et al., 1978; Weatherhead et al., 1978, 1979). For example, the thiamine level in charcoal-containing medium was 23% of that in a substrate which did not contain the darkening agent (22 mg 100 ml^{-1} vs. 96 mg 100 ml^{-1}). Niacin is absorbed even more extensively by charcoal (3.5 mg 100 ml^{-1} vs. 101 mg 100 ml^{-1}). Up to 97% of IAA and IBA can be absorbed by charcoal concentrations of up to 5% (Nissen and Sutter, 1990). On the other hand, inositol is not adsorbed by charcoal (99.6 mg 100 ml^{-1} vs. 99.8 mg 100 ml^{-1}) (Wetherhead et al., 1979).

When the pH of a medium was adjusted to 5.8 after the addition of charcoal but before autoclaving, the pH dropped to 5.4 (Sigma-neutralized charcoal), 5.9 (Sigma-acid-washed charcoal), or 5.4 (Merck No. 2186, acid-washed NuChar, and

SN-neutralized NuChar; Wann et al., 1997). In another experiment the pH of a charcoal-containing medium increased before autoclaving from 5.8 to 6.9 in the presence of 0.5% Sigma-neutralized charcoal and dropped to 6.6 after sterilization. If 0.5% Sigma-acid-washed charcoal was added the pH dropped from 5.8 to 5.7 and increased to 6.4 after autoclaving (Wann et al., 1997). In the presence of 0.5% Merck charcoal No. 2186, the pH increased from 5.8 to 6.1 and dropped to 5.7 after the medium was autoclaved (Wann et al., 1997). The pH dropped from 5.8 to 5.1 following the addition of 5% acid-washed SA NuChar and decreased further to 4.7 after the medium was autoclaved. The addition of neutralized NuChar brought about a drop to 5.3 and a post-autoclaving pH of 4.5. There was no preautoclaving drop of pH in a charcoal-free medium; the post-sterilization pH was 5.5 (Wann et al., 1997).

The addition of 5 mmol morpholinoethane sulfonic acid (MES) buffer caused the post-autoclaving pH to drop from 5.5 to 3.5 (Wann et al., 1997) and only 3% of the sucrose was hydrolyzed. In the presence of 0.5 or 0.1% activated charcoal – and when the pH dropped from 5.5 to 3.6 or 3.5 – 55 or 60% of the sucrose, respectively, is hydrolyzed. When the pH dropped to 3.8 in the presence of the 0.2% activated charcoal, sucrose hydrolysis was 14% (Wann et al., 1997).

Given these findings, charcoal should be added with caution to media that contain additives which may be adsorbed, especially if they are required by the tissues. On the other hand if explants, tissues, plantlets, and seedlings grow well on a medium that contains both charcoal and the additives it adsorbs there is no reason to make changes. In such cases it is clear that either the charcoal does not adsorb enough of any one compound to affect growth or, if it does, the substance in question is not required, or is only needed at the levels which remain in the medium. If darkening of a medium is necessary and charcoal can not be used, 2 g graphite l^{-1} (Thurston et al., 1979) can be employed instead.

Orchid tissues grow equally well on sucrose and on its components (and hydrolysis products) fructose and glucose. Therefore the effects of charcoal on hydrolysis of sucrose may be of limited, if any, importance.

Vegetable charcoal may be listed under several headings (which are not always clear) in catalogs or web sites. To ensure purchase of the appropriate charcoal, it is best to contact the suppliers and inquire.

Solvents

Distilled water must be used as a solvent in the preparation of culture media (Fig. 2-2). When this is not available deionized water may be used. Low-sodium water is the next choice.

Rain water collected in a glass or plastic container, in areas where the atmosphere is not polluted and/or rain is not acid, can also be employed. Tap and well water should be avoided, but can be used for practical (i.e., non-research) purposes after testing.

Ethanol (ethyl alcohol, 70% in distilled water) should be used as a sterilizing solvent for substances that cannot withstand autoclaving. Methanol (wood alcohol) or denatured ethanol should not be used because they are toxic.

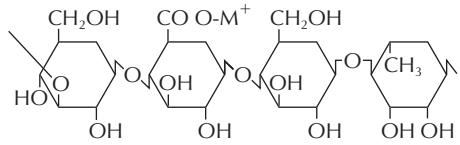
Solidifiers

Agar was the major solidifier used for orchid seed germination and micropropagation media for several decades. More recently, gellan gum sold under a number of brand names (Gelrite® and Phytagel™ are two of them) is being used in an increasing number of formulations (see below). Several types of agar are available from commercial sources. They differ from each other in a number of characteristics



Molecular weight $2–3 \times 10^5$ Daltons
Soluble in hot or cold water
Ash, 9.5%
Set temperature 30–50°C

P, 0.15%; Na, 0.45%
(1 Dalton = 1.66×10^{-24} g)

FIG. 2-3. **Structure of gellan gum.**

(Table 2-11). For experimental purposes it is necessary to use reagent-grade agar (Table 2-11). Technical grade or kitchen quality agar can be used for practical micropropagation, but preliminary tests are advisable.

A widely used procedure is to add the agar slowly and with stirring to the medium at room temperature and to bring the mixture to a gentle boil. After the agar has dissolved, the medium is autoclaved before or after dispensing it into culture vessels. Another method is to disperse the agar through a cold solution and dissolve it by autoclaving.

Gellan gum (Phytagel, Gelrite) is an agar substitute consisting of glucuronic acid, rhamnose, and glucose (Fig. 2-3) produced through fermentation by *Pseudomonas elodea*. It was discovered by the Kelco Division of Merck and Co., in San Diego, California (Sanderson and Clark, 1983; O'Neil et al., 1983; Shungu et al., 1983; Kelco, 1985, 2002). The gum produces a high strength, colorless, and clear gel.

The most commonly used concentrations for plant tissue culture are 1.2–2 g l^{-1}. Phytagel and Gelrite require the presence of divalent cations for gelling. Most orchid culture media contain enough calcium and magnesium. If more dilute media are used, higher concentrations of Phytagel or Gelrite may be required.

Gellan gum (Phytagel, Gelrite) must be added to media at room temperature with rapid stirring to avoid the formation of lumps. If these gelling agents are added to hot or even warm solutions, lumps will form and the medium will not gel even after autoclaving.

pH

The term pH is indicative of the alkalinity or acidity (i.e., hydrogen ion concentration) of a medium. It is defined as the logarithm of the reciprocal of the hydrogen ion concentration, $pH = \log 1/H^+$. Moderate acidity is indicated by pH 6 to 7 ($H^+ = 10^{-5}$ to 10^{-6}); pH 5 to 6 is mildly acid, and pH below 5 is increasingly acid; pH 7 ($H^+ = 10^{-7}$) is neutral and pH 7 to 8 ($H^+ = 10^{-8}$ to 10^{-7}) is slightly alkaline. A value of pH 8 ($H^+ = 10^{-8}$) is mildly alkaline and a pH of 9 ($H^+ = 10^{-9}$) or above is increasingly alkaline. Of the important chemical elements in soil, phosphorus is available at a pH from about 4.5 to approximately 8.1; its availability is reduced between ca. pH 7.6 and 8.5 and increases after that. The availability of nitrates is best between pH 5.5 and 8 and drops after that. Magnesium is available mostly from pH 5.0–5.5 up to pH 8.5–9.0. Calcium is available from pH 5.0–5.5 to pH 8.5–9.0. The

Box 14508, St. Louis, MO 63178. When two or more values are given for the same agar they were obtained from different documents supplied by the source(s).

[b]Light scattering qualities.

[c]These concentrations do not necessarily apply to culture media for orchids.

availability of iron is best between pH 4.0 and pH 6.5–7.0. Manganese, boron, copper, and zinc availability is best between pH 5 and pH 7.5. Molybdenum is available from pH 4 to pH 10.0.

It should be clear from the above that pH is important because it affects the availability of nutrients. It also has a direct effect on the life processes of cells. Further, if media of very low or very high pH are autoclaved the agar and other components may be hydrolyzed and/or destroyed. Hydrolysis of agar may release its major components, the sugars D- and L-galactose, which are toxic to plants in general and orchid seedlings (and probably also tissue cultures) in particular (Arditti and Ernst, 1984). For all of these reasons it is very important to adjust the pH of media carefully. In all cases it is best to set the pH to the levels recommended by the original investigators. Departures from recommended values should be avoided or undertaken only for good reasons or following experiments.

The pH of culture media should be as indicated in each method, determined experimentally, or adjusted to 4.8–6.0. Solid media may not solidify if the pH is much below 4.0 or higher than 8.0. Growth may be inhibited if the pH is lower than 4.0, higher than 8.0, or inappropriate for the plant being cultured. To measure the pH of a medium accurately it is best to use a pH meter. If one is not available, pH indicator paper may be used. When the pH of a medium is above the desired value, it is too alkaline and must be adjusted down with a few drops of acid (hydrochloric, nitric, phosphoric, or sulfuric). Should the pH be lower than required, the medium is too acid and must be adjusted up with a base (alkali) such as ammonium hydroxide, potassium hydroxide, or sodium hydroxide. Concentrated acids or bases can change the pH of a medium very rapidly and should not be used. For reasons of safety, convenience, and accuracy they should be diluted before use. A suitable concentration of acid or base for adjusting pH is 0.1N.

Recipes in this Book

In this book all recipes for media are given as published in the original papers. When a procedure lists a medium by reference citation without a recipe, the formulation given in this book is the one presented in the cited paper [for example, if a paper stated "tissues were cultured in the Murashige–Skoog medium (Murashige and Skoog, 1962)," the recipe given in this book was taken from Murashige and Skoog, 1962]. If specific modifications were made and described they are listed, and when no other details are available the remainder of the recipe is given as presented in the original paper. When the original paper provides a complete recipe this is the medium presented in the book. Recalculations and substitutions of components, including iron and chelating agent, were not made since their effects could not be predicted. Or, if changes were made, they were clearly labeled as such.

Stock Solutions

To save work and increase accuracy it is advisable to prepare stock solutions of most media components. These are concentrated solutions (10, 100, or even 1000 times)

of each compound. Stock solutions save work because only one weighing is necessary to prepare enough concentrate for 10, 100, or even 1000 liters. They increase accuracy since larger amounts are weighed and because it is easier (and faster) to measure large or small volumes of solution accurately than it is to weigh solids.

To prepare a stock solution weigh the required amount as indicated in each recipe (given in the tables), and add distilled water to the desired final volume. Label the bottle with the following information and store in a refrigerator:

1 Name of compound.
2 Formula of compound.
3 Concentration of stock solution (10×, 100×, or 1000×).
4 Amount to use per liter of culture medium.
5 Date.
6 Name of the person who made the solution (each).

Individual stock solutions should be prepared for each macroelement, vitamin, amino acid, or hormone. All microelements should be combined into one stock solution. Stock solutions containing nitrogen (as NO_3^-, NH_4^+, or urea) tend to become contaminated on standing. Therefore, these substances should be weighed every time, or if stock solutions are prepared, they must be kept frozen between uses.

Stock solutions of hormones and vitamins should be in ethanol (ethyl alcohol). If necessary, a few drops of sodium or potassium hydroxide or hydrochloric, sulfuric, nitric, or acetic acid can be added to the alcohol to increase the solubility of some substances. The use of ethanol not only prevents contamination of the stock solution, but also eliminates the need for sterilization since alcohol is a sterilant. However, under conditions of very high humidity (e.g., in Fiji, according to M. Krishnamurthi of the Fiji Sugar Corporation Experimental Station in Lautoka) solutions of 70% ethanol may become contaminated. To prevent such contamination, stock solutions in 70% ethanol should be stored in a freezer or made in 95% ethanol.

Hormones, vitamins, and amino acids may not be stable for prolonged periods. It is best, therefore, to prepare only small volumes (10–15 ml) of stock solutions. For 10 ml of stock solution, weigh carefully the required amount of substance and place it in a volumetric flask (see Appendix 1 for descriptions, and Appendix 2 for sources of glassware). Then add 5 ml of 100% (absolute) or 5.2 ml of 95% ethanol (do not use methylated spirits or any other form of denatured ethanol), and shake the flask gently. If the substance fails to dissolve, add a drop or two of dilute acid (for kinetin) and shake again (for auxin, add sodium hydroxide). Should it be necessary, one or two additional drops may be added. After the substance has dissolved completely, add another 2 ml of absolute ethanol (or 2.1 ml of 95%) and then make up the volume to 10 ml with distilled water for 70% ethanolic solution. When a 70% solution is undesirable, make up the volume to 10 ml with 95% ethanol. For 20 ml of stock solution double the amount of substance and volumes of ethanol and water. Use 2.5 times as much for 25 ml of stock solution, and multiply by 5 for 50 ml. When making larger volumes, always keep the number of acid or sodium hydroxide drops used to increase solubility to a minimum.

Stock solutions of organic substances should be stored in a freezer or refrigerator. Do not make stock solutions of inositol, sugar (sucrose or good-quality pure white refined kitchen sugar), or agar.

State of the Medium

Both solid and liquid culture media are used for orchid tissue culture, callus maintenance, plantlet regeneration, and orchid seed germination.

Sterilization

Culture media, tools, working space, and tissues must be sterilized, and work has to be carried out under aseptic conditions to ensure success. If these precautions are not taken, cultures will become contaminated and fail. A number of methods are used to ensure sterility.

Autoclaves

Spores of microorganisms in liquid (i.e., culture media) can survive elevated temperatures under normal (i.e., atmospheric) pressure. Therefore culture media must be sterilized under high temperature and pressure (usually 121°C and $1.2 \cdot 10^5$ Pa which can also be expressed as 121°C and 1 atm, or 15 psi, or $6.8 \text{ kg} \cdot 6.5 \text{ cm}^{-2}$). Such conditions are generated in autoclaves. A large number of autoclave models and sizes are available (see Appendices 1 and 2). Some require electricity, others do not. Several models are very complex and fully automatic, but there are also types that differ very little or not at all from a kitchen-type pressure cooker. Indeed, if an autoclave is not available, media, tools, culture vessels, and other items can be sterilized in a kitchen pressure cooker. Inorganic components (macroelements, microelements), sugars, agar, and some complex organic additives (coconut water, casein hydrolysate, peptone, yeast extract, banana homogenate, etc.) can be heat-sterilized. The standard conditions for sterilization can be obtained automatically in autoclaves or very easily in pressure cookers, and the entire sterilization process is very simple.

Filtration

Some media components are destroyed by elevated temperatures and cannot be heat-sterilized. Solutions containing these substances may be sterilized by passing them through very fine sterilizing filters (see Appendix 1; one example is the Millipore brand filter), which permit the passage of liquids but not particles larger than 0.22 or 0.45 μm and thereby retain all contaminants.

Some sterilizing filters can be used for a number of solvents; others are suitable only for water. Therefore it is important to read all instructions carefully. Large filtration apparatus requires vacuum pumps and other sophisticated equipment and may be expensive. For this reason filter sterilization is not recommended for small laboratories. Small disposable filter units that can be operated manually with a syringe are available from several sources (see Appendices 1 and 2). These units are well suited for small laboratories.

Sterilization in Microwave Ovens

Microwave ovens have been used to sterilize plastic tissue culture vessels (Latimer and Matsen, 1977; Sanborn et al., 1982) and Knudson C medium (Smith, 1986), as well as Murashige–Skoog, Vacin and Went, Hill's, oat, and other media (Wood and Lundergan, 1981; Marlow and Muir, 1986; Nelson, 1990; Tisserat et al., 1992). Some remained sterile for long periods, others (including the Hill's and oat media) became contaminated 5, 10, and 20 days after the sterilization.

In one of the procedures (Smith, 1986), the agar and salts (2.47 or 2.27 g of commercial preparations) and water (66.67 ml) were placed in a flask that was stoppered with a stopper sterilized by washing it in household bleach. This flask was placed in a Sharp microwave oven Model R-6210, which has an output of 600 watts. The flask was allowed to "cook" under full power until the contents started to boil. After that the flask was taken out, agitated, and "cooked" again until the contents started to boil. The medium is sterile after the second boiling and the stopper should be covered with aluminum foil which has been sprayed with a disinfectant spray or submerged in 70% alcohol for 20 min.

For the second procedure (Marlow and Muir, 1986), 70 ml of medium were placed in 250-ml flasks stoppered with cotton which was soaked in 10% (v/v) household bleach (10 ml Clorox, Purex, or Domestos made up to 100 ml with distilled water). The flasks were placed in the oven, which was turned on at full power for approximately 70 s (for a single flask) to melt the agar.

An alternative procedure is to place 500 ml of medium in a 1-l flask, melting the agar by turning the oven on for 5–6 min and dispensing 70 ml of the solution per 250-ml flask. The melted agar (regardless of the method used to melt it) should be agitated to mix the contents and placed in the oven again until the medium starts to boil for a second time. As with the previous procedure the medium is sterile after the second boiling.

One simple and effective procedure "was devised by a 12-years-old person" (Nelson, 1990), utilizing a 1000-watt microwave oven: " 'Cook' [medium] in microwave oven on high for three minutes . . . pour one-half cup liquid [medium] into each [one quart orange juice bottle] . . . insert stoppers [No. 10 drilled rubber stoppers with cotton stuffed in the hole] on an angle to let steam out . . . 'cook' in microwave oven on high until boiling (about four minutes). Reduce power level to 5 and cook for 11 minutes. Press corks down before removing [bottles from oven] with kitchen towel (bottles are hot). Then push stoppers in completely."

A comparative study (Tisserat et al., 1992) of power output, duration of exposure to microwaves, and presence in the oven of an energy sink water reservoir (ESWR, two 1-l Pyrex bottles containing 900 ml of distilled water and capped loosely with polypropylene screw caps) with a Sharp Carousel II microwave oven Model R-5E80 produced mixed results but showed that such ovens can be used to sterilize media. However, successful sterilization depended on power, volume of medium being sterilized, and the number of vessels being sterilized. "Using 700 W of power, liquid medium volumes containing 3% sucrose required the following sterilization times (ml, min): 100, 5; 250, 10; 500, 10; 1000, 15; 2000, 30 and 3000, 50. Fifteen 95×100 mm polycarbonate containers, each containing 50 ml agar medium also could be sterilized using 700 W for 15 min. Ten culture tubes 25×150 mm, containing

25 ml of agar medium could be sterilized in 15 min using 350 W or 10 min using 700 W when two 1-liter ESWR, each containing 900 ml distilled water, were included in the microwave. Syringe type filter holders [presumably plastic] with 25-mm-diameter filters, could be successfully sterilized by microwaving at 700 W for 5 min with an ESWR included."

These are clear results and useful instructions, but those who plan to sterilize culture media in microwave ovens should carry out preliminary tests. Important precautions and considerations regarding sterilization of media in microwave ovens are:

1. Completely sealed vessels such as screw cap jars or culture tubes must not be used under any circumstances since pressure will build inside them and they may explode. If such vessels must be used, the caps should be screwed on loosely or a hole must be drilled in them to prevent the build up of pressure. When a hole is drilled it must be filled with cotton to prevent subsequent contamination.
2. Metal caps must not be used.
3. Cotton stoppers (or plugs in holes) must not be allowed to come in contact with the medium since this will lead to subsequent contamination.
4. Media that contain complex additives (like oatmeal) should not be sterilized in this manner since contaminants (yeast spores for example) in these components may escape destruction and contaminate the medium later.
5. Since the effects of microwave sterilization on many components of media are not known, preliminary tests must be carried out before large-scale use. For example, microwave oven sterilization seems to reduce GA_3 (gibberellic acid or gibberellin 3) activity (Tisserat et al., 1992).
6. Aluminum foil and any other metallic objects must never be placed in a microwave oven.
7. Both containers and solutions can be very hot after microwave sterilization and should be handled with great care to prevent injury.
8. Flammable solutions should not be sterilized in a microwave oven because vapors may form, be ignited by sparks from the fan, and explode.
9. Living tissues and plants must not be sterilized in a microwave oven. The microwaves will kill or "cook" them.
10. Ovens should be checked regularly for microwave leakage.

Solvents

A simple way to sterilize heat-labile substances is to prepare their stock solutions in 70% or 95% ethanol (ethyl alcohol) in distilled water since this solvent is also an excellent sterilant. Our experience is that the addition of up to 5–6 ml of 70% ethanol per liter of medium does not have a deleterious effect on cultures. If the stock solutions are prepared properly, it is not necessary to add more than that. Methylated spirits or other forms of denatured ethanol should not be used for this purpose.

Open Flame

Burning can be used to sterilize tools and the necks of bottles while making cultures. A natural-gas burner is best because it produces a clean, non-smoking, high-

temperature flame. If one is not available, an alcohol flame (methylated spirits or denatured ethanol can be used as fuel) can be used, but it may not be hot enough. Another possibility is to dip the tools to be sterilized in alcohol (methyl, ethyl, or isopropyl) and ignite the liquid with an alcohol flame to sterilize their surfaces. A simple lamp can be prepared by filling a bottle with alcohol and inserting a wick (cotton or a piece of cloth are satisfactory). Kerosene or automotive gasoline (petrol, benzine) should not be used as fuel since they produce a lot of smoke and soot and may be explosive.

Liquids

Work areas, tools, tissues, and apparatus can be sterilized with liquid sterilants.

Hypochlorite Solutions

Preparations such as Clorox, Purex, Domestos, Milton's Snow White, and other brand-name household bleaches contain between 4.75 and 6% sodium hypochlorite and are therefore excellent sterilants. Undiluted they can be employed to wash tools, working areas, and the outsides of culture bottles. If used to sterilize seeds, capsules (orchid fruits are capsules and not pods as they are frequently and erroneously referred to), and tissues these bleaches should be diluted according to instructions in specific procedures. A wetting agent should and is often added to these dilutions. A few drops of Tween 20 are usually added by research laboratories, but a mild household liquid detergent or baby shampoo can be used for practical purposes.

To determine the correct dilution it is necessary to consider the sodium hypochlorite content of the household bleach that will be used. For example, if a procedure calls for a 50% dilution (50 ml household bleach made up to 100 ml with water) of a brand that contains 5.25% sodium hypochlorite, the diluted solution will contain 2.625% of active agent. Therefore a brand that contains only 4.7% sodium hypochlorite should be used at a lower dilution (55 ml of bleach made up to 100 ml with distilled water). On the other hand, a higher dilution must be used if a brand contains more sodium hypochlorite. For example, 44 ml of Clorox (which contains 6% sodium hypochlorite) should be diluted to 100 ml to obtain a final concentration of 2.625%.

The wetting agent (Tween 20, mild household detergent, baby shampoo) is not a sterilant. It only improves the wetting properties of the solution. Prolonged exposures to high concentrations of wetting agents and detergents can damage orchid tissues (Ernst et al., 1971*a*; Healey et al., 1971). However brief contacts with low concentrations will not have a deleterious effect. Also, neither the sterilant nor the wetting agent can come in contact with seeds when an unopened capsule is being surface-sterilized.

A saturated solution of calcium hypochlorite is used to surface-sterilize tissues and seeds. This solution is prepared by dissolving 10 g calcium hypochlorite in 140 ml water (7 g/100 ml), stirring vigorously, and allowing the solution to stand for 3–5 min. Then the solution is stirred again, allowed to stand until the precipitate

has settled, and filtered again or decanted. The clear, yellowish liquid is used as the sterilant. It should be used within 12 h.

Alcohol

Ethyl alcohol (ethanol, drinking alcohol), pure or denatured (methylated spirits), and isopropyl alcohol (isopropanol/rubbing alcohol) can be used to sterilize work areas, tools, and outside surfaces of culture vessels by swabbing. These alcohols can be used in a concentrated form or as 70% aqueous solutions (70 ml alcohol made up to 100 ml with water). If at all possible, the use of methanol should be avoided since it is toxic to people and may cause blindness.

Surface Decontamination

A number of methods are used for surface decontamination. In each case it is best to follow the specific method outlined in each procedure. Generally, sources of explants are first cleaned by a gentle washing and scrubbing to remove dirt and soil. After that they are dipped briefly in either 95 or 70% ethanol (2–3 s) and then immersed (5–20 min) in a diluted household bleach or calcium hypochlorite solution (see specific procedures for concentrations and times). The sterilant is then removed from the tissues with several sterile water washings in a sterile box or other suitable area (see Appendix 1). Sections are usually sterilized by soaking them in calcium hypochlorite for 5–20 min. The sterilant is then removed by washing with sterile distilled water.

Gas Sterilization

Under some circumstances liquid sterilants are not effective in eliminating all sources of contamination. The surface texture of an organ or seed may contain small hydrophobic crevices or indentations that shelter fungal or bacterial spores. In other cases liquid sterilants may not be able to reach and/or enter some spaces. Contaminants that are not easily eradicated by liquids can often be eliminated with the use of chlorine gas. This technique should be carried out in a fume hood, and workers must be careful not to breathe the highly toxic vapors.

Seeds and/or tissues to be treated can be placed on cheesecloth or nylon mesh (or any other porous material-paper towels may also be adequate) that has been taped to the top of a beaker or another suitable container. In this way, air can pass freely below and above the tissues during treatment.

Gas is generated by adding 3 ml of concentrated hydrochloric acid to 100 ml household bleach* (which usually contains 5.25% sodium hypochlorite) in a glass dessicator, bell jar, or other appropriate glass container. The cheesecloth- or nylon-mesh-covered beakers supporting the tissues are suspended above the solution of bleach and acid. Tissues can be kept in the closed dessicator for 5–30 min or longer

* Well-known brands such as Clorox, Purex, and Domestos; there are many others.

(30 min is suitable for taro seeds). After treatment the container should be opened carefully to allow gas to dissipate in the fume hood before attempting to remove the tissues. Seeds or tissues can then be placed in culture media using standard techniques.

Preparation of the Medium

Preparing a medium may appear complex to those who have not done it before. The step-by-step sequence described here and illustrated in Fig. 2-2 is intended to simplify the procedure.

1. Add the correct volume of each of the several macroelement stock solutions to 250 ml of distilled water. To measure volumes of 10 ml or more, use a volumetric cylinder. Smaller volumes should be measured with pipettes. In each case the smallest suitable volumetric glassware should be used. For example, 1 ml should be dispensed with a 1-ml pipette, not a 5 or 10-ml one. For 3 ml use a 5-ml pipette and not a larger one or a 1-ml pipette three times. For 7 ml use a 10-ml pipette. A 0.1-ml pipette should be used for dispensing 0.1 ml. If one is not available, a 0.5-ml or even a 1-ml pipette may be used provided they have the proper graduations (for sources of volumetric glassware see Appendix 2).
2. Dispense the proper amount of microelement stock solution.
3. If inositol is included in the medium, add it.
4. Incorporate into the medium whatever complex additives may be part of the recipe (note that some media may not require such additives).
5. Bring the total volume to approximately 900 ml.
6. Adjust the pH.
7. Weigh and add sugar (sugar may also be added before pH adjustment).
8. Pour the medium into a volumetric flask, and adjust the total volume to 1 l with distilled water. If distilled water is not available, rain water (preferably fresh and not acid) collected in a glass container may be used. Transfer the solution to an Erlenmeyer flask or bottle.
9. For solid media add agar.
10. Sterilize the medium in an autoclave or pressure cooker. The medium should be in an Erlenmeyer flask or bottle with a capacity twice the total volume of the solution being sterilized (e.g., 1 l of medium should be sterilized in a 2-l flask). Never use a volumetric flask as a container for sterilization because the heat may reduce its accuracy. A flask may be adequately covered for autoclaving by inverting a beaker over the neck.
11. Sterilize culture vessels, either before the medium is sterilized or at the same time.
12. While the medium is being sterilized, combine appropriate volumes of all hormone, vitamin, amino acid, and any other necessary stock solutions (all of which may be dissolved in 95 or 70% ethanol) in a vessel just large enough to contain the total volume (which will usually not exceed 5–6 ml). Suitable containers for this purpose are 5–10-ml Erlenmeyer flasks, 5–10-ml volumetric flasks, 5–10-ml bottles from the local pharmacy (drugstore, chemist), or small test tubes. After introducing each of the required solutions into the small container, stopper it and shake a few times to sterilize all inner surfaces. Then place the stoppered

container in the working area and sterilize its external surfaces by spraying with 70% ethanol or hypochlorite solution (described earlier).

13 After the medium has been sterilized and while it is still hot (and therefore still liquid if it contains agar), pour the contents of the container described in item 12 into the medium.

Culture Vessels

Test tubes (which are also referred to as "culture tubes"), Erlenmeyer flasks, and a variety of specially designed plastic containers (see Appendices 1 and 2) are ideal for tissue and callus cultures. However, other clear glass or plastic containers, polyethylene and polypropylene bags (Lee and Lam-Chan, 1995), and disposable film vessels (Tanaka et al., 1988; Tanaka, 1991*a*, 1991*b*) are also suitable. Containers with very wide necks which are not specially designed for tissue culture (jars, for example) should not be used because cultures in such vessels are easily contaminated unless a cap with a cotton-filled vent is screwed on tightly. To vent such caps a cotton-filled tube should be inserted into the cap and glued on with an adhesive that can withstand autoclaving. The adhesive should also be capable of bonding the tube to the cap (i.e., be able to bond two different materials) and leave no cracks. Or, a one- or two-hole stopper should be forced into an appropriate size opening on the cap. The holes in the stopper should be stuffed with non-adsorbent cotton.

Culture vessels which are specially designed for tissue culture, but are not presterilized by the manufacturer, should at least be rinsed before use. Vessels that have been presterilized by their manufacturers should be used as they come out of the packages. However it is important to remember that if these cultures are opened under non-sterile conditions their sterility will be compromised. Containers that were used previously for any purpose, including tissue culture, must be washed thoroughly with water and a good detergent and rinsed several times (at least three) with distilled water. After the rinsing these containers should be allowed to drain and dry by being placed on a rack with their openings pointing down.

When the vessels are completely dry they must be covered prior to storage. If containers such as jars, bottles, flasks, and tubes are to be used immediately after the washing they must be fitted with a cover before being filled with medium (culture vessels which are designed for tissue culture usually have their own specially designed covers).

Depending on the size of the culture vessel, the cover can be a rubber stopper (available from most laboratory supply houses) with one or two holes in them. These holes must be stuffed with non-adsorbent cotton (available from most laboratory supply houses). There is no need to insert glass tubes (curved or not) with cotton in them into the stopper holes; the cotton can be stuffed directly into the holes. Once prepared, stoppers with cotton-filled holes can be used repeatedly. Wiping them with a damp (water or 70% ethanol) towel (cloth or paper) should be enough to keep them clean. If the stoppers are washed and the cotton becomes wet it must be dried completely (an extended period in a 40°C oven should suffice) or replaced because contaminants can grow in/on the wet plugs and contaminate the cultures. There is no need to change the cotton unless it shrinks, becomes very dirty, or decomposes and is no longer snug and tight in the hole and/or cannot be dried.

Tightly fitting buns made of non-adsorbent cotton can also be used to cover containers (if the empty container can be lifted by holding the bun, it is tight enough). Both rubber stoppers and cotton buns should be covered with aluminum foil. Paper can be used if foil is not available; it should be tied or held with a rubber band below the neck. In high humidity areas moisture may condense on the cotton bun or plugs below the aluminum foil, allowing fungi to grow and contaminate cultures. In such areas paper rather than aluminum foil should be used. The use of plastic films to cover cotton buns or stoppers is not advisable because they are usually impervious to air. If tied tightly such films may prevent gas exchange and/or accumulate water condensate, which may allow growth of microorganisms that can contaminate the cultures.

Appropriate and sufficient gas exchange is very important because: (1) ethylene produced by plantlets, tissues, and/or explants can inhibit growth; and (2) oxygen and carbon dioxide may need to be replenished. Cotton plugs allow for gas exchange. So do filters that allow diffusion of gases but prevent entry of contaminants. Such filters can be self-adhesive (Milliseal™, Nihon Millipore, Ltd., Japan) or are built into lids for culture vessels (see Fig. 2-11).

Culture Conditions

The conditions under which explants, callus masses, protocorm-like bodies (PLBs), plantlets, germinating seeds, and seedlings are maintained can determine the success or failure of culture attempts and also affect growth and development.

Temperature

When adjusting the temperature for tissue culture or seed germination, it is important to follow instructions carefully. If these instructions prove to be unsuitable for a particular new cross, variety, clone, or species the appropriate temperature can be determined only by trial and error. The temperatures suggested for each procedure in this book are those recommended by the original workers and should be used, at least initially, to ensure best results or as starting points for new research.

Agitation

Liquid media must be agitated to: (1) allow for gas exchange; (2) improve contact between tissues and liquid; and (3) influence growth and development. Agitation may be gyrorotatory (wrist action), oscillatory (back and forth), or rotatory (rotating on a wheel with its axis parallel or at an angle to the ground). Shakers can be purchased (see Appendices 1 and 2) or constructed locally. Machine shops, mechanics, or simply handy persons can easily construct an adequate shaker. Oscillating and rotatory shakers are easiest to build and most suitable for the widest variety of applications. The speed of shaking is important. If shaken too fast or too slow explants, tissues, or callus may not respond as desired. In every instance it is best to use the type and speed of agitation which was employed in the original research and is

suggested in this book. If this information is not available, rotatory shakers should be set at 1–3 rpm, oscillating ones should move back and forth 60 times a minute, and gyrorotatory units should shake approximately 30–40 times per minute. These are starting speeds which should be adjusted as necessary.

Illumination

Light (see Figs 2-4 and 2-5) – its duration (photoperiods) or absence (darkness), intensity (i.e., energy levels), quality (color) and source (natural, fluorescent, incandescent, or other) – is of great importance in the micropropagation of orchids.

Presence or Absence

In most cases in vitro cultures of orchids should be illuminated for at least part of a 24-h period. However, there are also instances in which explants, cells, or protoplasts must be kept under very subdued light or in the dark, at least during the initial stages of culture. As with other aspects of micropropagation, recommendations in this book regarding light or dark regimes based on the original research should be followed in all instances. Modifications, especially when rare and/or expensive orchids are being cultured, should be introduced only following experiments with more common clones of a genus, species, or cross. During the development of a new procedure it may be advisable to place some cultures in the dark for specific periods, especially if related orchids are known to benefit from the exclusion of light.

Plantlets grown under continuous darkness do not produce chlorophyll. When moved to light such plantlets turn green. In some cases the transfer from darkness to light may have to be gradual. Plantlets growing in vitro are similar to seedlings in that they require light for normal development as well as root and/or shoot production and growth.

Growth and development of seedlings on media darkened with charcoal can be enhanced (Werkmeister, 1970*a*, 1970*b*, 1971; Ernst, 1974, 1975, 1976; for reviews see Arditti, 1979; Arditti and Ernst, 1984, 1993). The same seems to be true for plantlets in vitro. However, this fact is most probably not associated with requirements for light or darkness. It is due to the effects of the charcoal itself (see section on charcoal above).

Duration

As mentioned above, orchid cultures may be maintained under light or dark periods of duration, which can range from a few hours a day to continuous (24-h) illuminations. Appropriate photoperiods must be determined experimentally for orchids which have not been cultured before. When established procedures are employed it is best to use the photoperiods recommended by the original investigators. However, it should also be noted that the available evidence on this aspect of orchid micropropagation is far from clear and it is entirely possible that photoperiods are not an important factor in the micropropagation of orchids, so long as explants that require light are provided with sufficient illumination for at least part of the day.

Intensity

"Strong" and "weak" are common terms used to describe light intensity, which is in fact visible spectrum energy produced by a source of illumination that impinges on a culture. Light intensity should be measured with appropriate instruments (two excellent discussions of light measurements were published by LI-COR Inc.; see LI-COR, 1982 and LI-COR, no date; www.licor.com). Several units and terms are used to describe light intensity and illumination:

Absorbance (sometimes called **absorptance**) is the part of the illumination that is absorbed.

Candela (cd) or **international candle** is luminous flux per unit area or luminous intensity; 1 candela = 12.57 lumens.

Candle power is the light intensity of a source in candelas.

Color temperature is the color of the light in comparison to the light color emitted by a black body heated to specific temperature expressed in Kelvin.

Einstein (E) is the energy in Avogadro's number of photons (1 E is 6×10^{23} photons s^{-1} m^{-2}; at noon on a bright summer day sunlight is approximately 1800–2200 μE). Plant scientists use units like **photosynthetic photon density** (E m^{-2}) and **photosynthetic photon flux** (E s^{-1} m^{-2}) to measure and describe light intensity. When these terms are used, E must be specified as average energy specific to the photosynthetically active radiation (PAR) wave band (360–700 nm). A problem with the Einstein is that it is not an SI unit and therefore measurements using the micromole (micromol, μmole, or μmol) are preferable. An expression used in this connection is **micromole (PAR) per second per square meter (μmol s^{-1} m^{-2} PAR)**. This is a flux of 6.022×10^{17} photons per second of photosynthetic radiation intercepted uniformly by a surface of one square meter. PAR can also be expressed as μE m^{-2} s^{-1}. Foot candles and PAR can be interconverted but conversion factors vary depending on the light source (see Tables 2-16 and 2-17).

Foot candle (ft-c), the most commonly used light intensity unit, is the illuminance resulting from a luminous flux of one lumen per square foot (1 ft-c = 1 lumen per square foot). Another definition is the amount of light emitted by an ordinary wax candle and impacting on a spherical surface measuring one square foot and located one foot from the flame. Like the lumen it is based at least in part on the relative spectral sensitivity of the human eye adapted to bright light (Fig. 2-4D; the sensitivity of insect eyes is given for comparison purposes), which differs from the spectrum requirements of chlorophyll synthesis, photosynthesis (Fig. 2-4C), and plant morphogenetic and growth responses. For this reason the foot candle is not suitable as a unit to describe light intensity for plant growth. However it can be used to describe the intensity of a known light source (Table 2-12), as for example "*X* foot candles produced by 40-W Acme Light Co. plant growth light bulbs." One foot candle is equal to 10 lux or lx (or, as stated above, 200 ft-c are equal to 2000 lx). The illumination used for orchid tissue culture is often given in foot candles probably because instruments to measure ft-c are easily available (Tables 2-12–2-15). Foot candles and PAR can be interconverted only through the use of conversion factors which are specific for each light source (Tables 2-16 and 2-17). Measurements made with photographic light meters can be converted into ft-c (Table 2-18).

TABLE 2-12. **Illumination in foot candles from two standard cool white fluorescent lamps on a white reflecting surface (Downs et al., 1966) and two Gro Lux tubes (Mpelkas, 1965) measured at several distances**[a]

	Intensity			
	Cool white lamps, ft-c			
Distance from lamps, cm	Two lamps[b,c]	Four lamps[b,c]	Four lamps[b,d]	Gro Lux lamps, μW cm^{-2}[e]
2.5	1100	1600	1800	
5	860	1400	1600	
7.6	680	1300	1400	
10.2	570	1100	1300	
12.7	500	940	1150	
15.2	420	820	1000	
17.8	360	720	900	
20.3	330	660	830	
22.9	300	600	780	
25.4	280	560	720	
27.9	260	510	660	
30.5	240	480	600	775
45.7	130	320	420	
61	100	190	260	328
91.4	159			
121.92				

[a]The candela (cd), a measure of luminous intensity, is not used in plant sciences because it is based on the sensitivity of the human eye. Lux (1 lx = 1 cd s^{-1} m^{-2} or 0.0929 ft-c) and foot candles (ft-c, not a metric unit anyway; 1 ft-c = 10.76 lx) have been used widely in plant physiology, but should not be because they are based on the sensitivity of the human eye. Lux may be used when no other measuring instruments are available. Radiant energy measurements should be accompanied by descriptions of the light source and its spectral characteristics. Conversions from lux or foot candles to irradiance (moles of photons, μmol m^{-2} s^{-1}) or energy (watts per square meter, W m^{-2}, or J s^{-1} m^{-2}) require a specific conversion factor for each light source (for a more detailed discussion of irradiance units see Salisbury, 1991). Foot candles and lux are used in this table and elsewhere in the book when these units are given in the original literature. Moles per square meter per second per nanometer (mol m^{-2} s^{-1} nm^{-1}) are used for spectral irradiance.

[b]Center to center distance between lamps = 5 cm.

[c]Lamps used for approximately 200 h before the measurements were taken.

[d]New lamps.

[e]Two rapid start 40-W Gro Lux tubes spaced 8.9 cm apart in a standard fixture with a 29.21 cm reflector.

Foot lambert is a measure of the amount of light reflected from a surface. The reflected light adds to the illumination of an area. Black surfaces reflect about 4% of the light that reaches them, whereas white areas reflect approximately 80%.

Frequency is the number of cycles or waves of electromagenetic radiation per second in Hertz (Hz).

Illuminance (E) is the luminous flux or quantity of light that falls on a unit area. The unit is the lux and the expression is E = lumens/area.

Irradiance is the radiant flux that falls on a receiving surface per unit surface area. The expression is W m^{-2}.

Lumen (lm) is the luminous flux or total visible light energy emitted by a source of illumination. A radiation of 0.00146 W is equivalent to 1 lm.

Lumen second (lms), **lumen minute** (lmm), and **lumen hour** (lmh) are the quantity and duration of light produced by a source.

Luminous efficiency (lm/W) is the ratio between luminous flux and the absorbed power.

Luminous flux (f) is the total light quantity of light emitted per second by a light source. The unit is the lux.

Lux (lx) is the intensity of illumination or the ratio of luminous flux to the area upon which it is incident. An intensity of 1 lux is produced when 1 lumen is

TABLE 2-13. **Conversion of foot candles to µW cm^{-2} for several light sources (Klein, 1973)**[a,b]

Source	Watts cm^{-2} per foot candle	
	300–800 nm	400–700 nm

[a]Several factors are from other sources.

[b]The candela (cd), a measure of luminous intensity, is not used in plant sciences because it is based on the sensitivity of the human eye. Lux (1 lx = 1 cd s^{-1} m^{-2} or 0.0929 ft-c) and foot candles (ft-c, not a metric unit anyway; 1 ft-c = 10.76 lx) have been used widely in plant physiology, but should not be because they are based on the sensitivity of the human eye. Lux may be used when no other measuring instruments are available. Radiant energy measurements should be accompanied by descriptions of the light source and its spectral characteristics. Conversions from lux or foot candles to irradiance (moles of photons, µmol m^{-2} s^{-1}) or energy (watts per square meter, W m^{-2}, or J s^{-1} m^{-2}) require a specific conversion factor for each light source (for a more detailed discussion of irradiance units see Salisbury, 1991). Foot candles and lux are used in this table and elsewhere in the book when these units are given in the original literature. Moles per square meter per second per nanometer (mol m^{-2} s^{-1} nm^{-1}) are used for spectral irradiance.

TABLE 2-14. **Conversion factors from lux or foot candles to watts per square meter of photosynthetically active radiation (W m^{-2} PAR), or to µmoles of photosynthetic illumination per square meter per second (µmol m^{-2} s^{-1} PAR) for several light sources (Hartman et al., 1988)**[a]

Light source	Multiplication factors for conversion to[b]			
	W m^{-2} PAR		µmol m^{-2} s^{-1} PAR	
	ft-c	lx	ft-c	lx
Average daylight	22.9	247	5.0	54
Cool white fluorescent tubes	31.5	340	7.0	74
Incandescent lamps				
Mercury lamps, high pressure	35.2 ± 5%	380 ± 5%	7.8 ± 5%	84 ± 5%
Metal halide lamps	30.2	326	6.6	71
Sodium lamps, low pressure	48.3	522	9.8	106

[a]The candela (cd), a measure of luminous intensity, is not used in plant sciences because it is based on the sensitivity of the human eye. Lux (1 lx = 1 cd s^{-1} m^{-2} or 0.0929 ft-c) and foot candles (ft-c, not a metric unit anyway; 1 ft-c = 10.76 lx) have been used widely in plant physiology, but should not be because they are based on the sensitivity of the human eye. Lux may be used when no other measuring instruments are available. Radiant energy measurements should be accompanied by descriptions of the light source and its spectral characteristics. Conversions from lux or foot candles to irradiance (moles of photons, µmol m^{-2} s^{-1}) or energy (watts per square meter, W m^{-2}, or J s^{-1} m^{-2}) require a specific conversion factor for each light source (for a more detailed discussion of irradiance units see Salisbury, 1991). Foot candles and lux are used in this table and elsewhere in the book when these units are given in the original literature. Moles per square meter per second per nanometer (mol m^{-2} s^{-1} nm^{-1}) are used for spectral irradiance.

[b]Divide reported values by the appropriate multiplication factor to convert measurements to the desired units.

Examples:

300 ft-c of light produced by a cool white tube divided by 31.5 equals 9.52 W m^{-2} PAR, and by 7.0 equals 42.857 µmol m^{-2} s^{-1} PAR

3000 lx of normal daylight divided by 247 equals 12.15 W m^{-2} PAR, and by 54 equals 55.56 µmol m^{-2} s^{-1} PAR.

TABLE 2-15. **Production of photosynthetically active radiation by several light sources (Langham, 1978)**[a]

Lamp	Input (watts)	Output in 400–700 nm wavelength (watts)	Output/input ratio

[b]Full sun at noon on a clear summer day. Multiply PAR (or photosynthetic photon flux, PPF) by the conversion factor to obtain foot candles. For example, full sunlight 2000 μmol m^{-2} s^{-1} × 5.01 = 10020 ft-c. Multiply foot candles by the conversion factor to obtain PAR (or PPF). For example, 10020 ft-c × 0.2 = 2000 μmol m^{-2} s^{-1}.

[a]Sources: ftp://ftp.nmt.edu/pub/orchids/lighting1.2, Eiich L. Koch, Jack Blumenthal (blumenthal@penny.net), Joachim Saul, and Bob Hamilton. The foot candle is a measure of light intensity in terms of the sensitivity of the human eye. It does not measure energy levels. A formula which can be used to convert light meter measurements to foot candles is 20 (A^2)/(shutter speed in seconds)(film speed in ASA/ISO). Another formula is 20 × A^2/shutter speed × film ASA. To use this table the film speed indicator should be set to ASA/ISO 25 or 100, and after that the light meter or camera should be pointed toward the light source. The shutter speed should be set after that. The indicated value is then read. Foot candles are obtained from the table after that. Example: Set film speed to ASA/ISO 100 and shutter speed to 1/125 of a second. Point meter or camera to light source. If the indicated *f* stop is 5.6 the light intensity is 250 ft-c. Conversions: 1 lx = 0.029 ft-c; 1 ft-c = 0.76 lx; 1 lx = 1 lm^{-2}; 1 ft-c = 1 lm ft^{-2}; 1 ph = 1 lm cm^{-2}; 1 lmh = 60 lmm.

distributed uniformly over an area of 1 square meter. Ten lux equal one foot candle (i.e., to convert foot candles to lux it is necessary to multiply by 10; for example 200 ft-c equal 2000 lx). The light intensities used for some orchid tissue culture procedures are given in lux, especially in more recent papers. The lux is sometimes referred to as a metric unit because it is the amount of light emitted by an ordinary wax candle and impacting on a spherical surface measuring one square meter at a distance of one meter from the candle.

Lux second (lxs) is the quantity of illumination or a product of intensity and duration.

PAR *see* Photosynthetically active radiation.

Phot (ph) is the specific luminous radiation of a surface or the ratio of the radiated luminous flux to a specific surface area. It equals 10,000 lx.

Photosynthetically active radiation (PAR) is illumination in the wavelengths used in photosynthesis. Light sources differ in the production of PAR (Table 2-15) and several conversion factors must be used (Tables 2-12–2-15).

Radiance is the radiant flux emitted by a unit area of source.

Radiant flux is amount of light emanating from a source per unit time. The unit is the watt (W). The expression is J s^{-1}.

Watt (W) is a radiometric unit of energy per unit of time and area irrespective of wavelength. Measurements of W in the PAR area are known as W PAR. Light intensity can be expressed as W, mW, or μW cm^{-2}. Reported illumination intensities used for orchid tissue culture vary considerably, but it is not certain at present whether this is due to requirements by the plants, preferences by individual investigators, or simply availability of light sources. Normal daylight or that coming through a window, cool or warm white fluorescent tubes, plant growth lights (like Gro Lux), incandescent bulbs only, various mercury or sodium lamps, and combinations of these all seem to be suitable (also see below).

Quality

This term refers to the spectra of light sources (Figs 2-4 and 2-5) and implies color. Since plants require specific parts of the spectrum for normal growth and development, the quality of light used to illuminate cultures is important. In general, incandescent lamps produce more red and less blue wavelengths (Figs 2-4G, H and 2-5C) than fluorescent tubes (Figs 2-4A–F, H, I and 2-5C, D). Other light sources have their own specific spectra. Lamps designed especially for plant growth provide light of somewhat better balance (Fig. 2-4E, F, H, I), but may cost more in terms of initial price and energy input.

In a study with *Tradescantia fluminensis* (Biran and Kofranek, 1976) the best yields per electrical energy input unit were obtained under illumination with cool white lamps (Fig. 2-4E). In comparison with these lamps, the relative yield under daylight lamps (Fig. 2-4F) was 88%; Deluxe cool white (Fig. 2-4E), 73%; Plant Light (probably similar to Fig. 2-4A–C), 72%; and pink and blue lamps, 36%. Similar results were obtained with calculations based on the photosynthesis action spectrum of an average leaf (Biran and Kofranek, 1976).

A formula which can be used to predict the photosynthetic efficiency of lamps (Biran and Kofranek, 1976) is:

$$PP = \left[\sum_{i=1}^{i=30} P_i \cdot E_i \right] (\text{lm/W}) \qquad \text{(XIII)}$$

where:

E_i = μW or photons 10 nm^{-1} lm^{-1} which can be calculated from spectral energy distribution curves provided by lamp manufacturers;
lm/W (L/W in the original paper) = lumen output per total electrical input in watts;
P_i = relative PAR value per unit of incident energy flux (McCree, 1971, 1972*a*, 1972*b*), or photon flux (Balegh and Biddulph, 1970) for thirty 10-nm portions of the visible spectrum between 400 and 700 nm;
PP = predicted PAR value per electrical input in watts.

This equation can also be used to evaluate PAR at plant level (which is a certain distance below the lamps). In such cases lm/W should be the light measurement at plant level and an assumption is made that illumination levels are directly proportional to the total output of lumens (Biran and Kofranek, 1976).

Light Sources

A number of light sources (Figs 2-6–2-8) are available in addition to the ones already mentioned (Figs 2-4 and 2-5; Tables 2-12–2-18). Fluorescent lamps are manufactured in a bewildering array of sizes, shapes, intensities, and emission spectra (Figs 2-4–2-7). They consist of a partially evacuated glass tube with an anode at one end and a cathode at the other. When the light is turned on a small amount of mercury vapor inside the tube becomes ionized and emits ultraviolet light, which causes a phosphor that coats the inside of the tube to fluoresce and give off light. The nature of the phosphor determines the emission spectrum of the lamp.

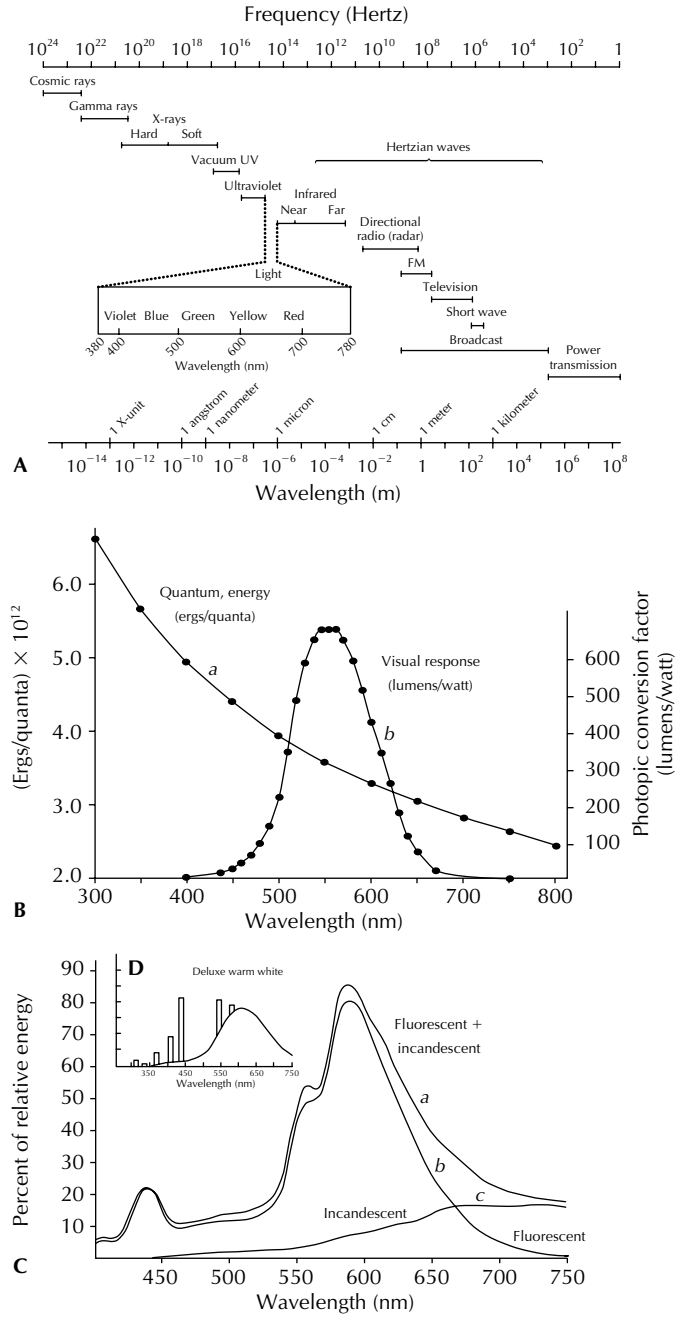

FIG. 2-5. **Light spectra and energy distribution. A. The electromagnetic (radiant energy) spectrum. B. Quantum energy (*a*), wavelength, and the human visual response (*b*). The sensitivity of the human eye differs from the action spectrum of photosynthesis (see Fig. 2-4C). This is why units used to measure light intensity in terms of vision are not suitable for photosynthesis-related determinations. C. The diameter of fluorescent tubes can be 1 inch or about 2.5 cm [designated as T8 or Slimline, and produced in lengths of 24, 36, and 48 inches (approximately 60, 90 and 120 cm)] or 1.5 inches or ca. 3.8 cm [the more common T12 designation; these tubes can be 18, 24, 36, 48, 72, and 96 inches (about 46, 60, 90, 180, and 245 cm) long, round or U-shaped, and signed for several voltages]. Depending on quality, fluorescent tubes produce adequate illumination for approximately 12 months only, even if they appear to be functioning properly.

As can be expected the least expensive fluorescent tubes are the ones that are produced and sold in the largest quantities. These are the cool and warm white tubes. Their emission spectra are not optimal for plant growth, but if used in combination with incandescent lamps these tubes produce excellent results (Biran and Kofranek, 1976). Plant growth fluorescent tubes produced by a number of manufacturers have emission spectra that are adjusted to promote growth (Figs 2-4–2-7), but they can be expensive.

Incandescent (i.e., the common) household light bulbs consist of a tungsten filament that glows in a vacuum when the electricity is turned on. These bulbs produce a considerable amount of heat and very little light in the shorter wavelength (blue) end of the spectrum. Most of their output is in the red (longer) wavelengths (Fig. 2-4G). If used they should be combined with cool white fluorescent lamps (Biran and Kofranek, 1976). The tungsten in incandescent lamps evaporates, coats the inside of the bulb, and reduces light output.

Halogen bulbs are modified incandescent lamps in which small amounts of bromine or iodine (both halogens) are present and combine with the vaporized tungsten to form tungsten bromide (WBr_2) or tungsten iodide (WI_3). These iodide or bromide molecules move to the tungsten filament where they split. The tungsten remains on the filament, whereas the iodine or bromine returns to the atmosphere of the bulb. Halogen lamps are very hot because these reactions require a temperature of 200°C. The emission spectrum of halogen bulbs is heavy in the red end.

High intensity discharge (HID) lamps are big, bright, produce a tremendous amount of heat, and range from 70 to 2000 W. They contain a vapor and work with an arc. The vapor can be mercury (mostly bluish-white light and very little red), sodium (yellow), or metal halide (similar to sunlight; Figs 2-6–2-7).

The choice of lamps for a culture room may depend on many factors, not the least of which is cost and coverage (Fig. 2-9). Incandescent lamps are the least expensive, but are not very suitable due to their spectrum and heat production. Halogen lamps have the same disadvantages. HID and metal halide lamps are very expensive. Standard or plant growth fluorescent lamps, alone or in combination with incandescent bulbs, are easily available, economical, simple to maintain, and suitable in terms of their emission spectra and intensity (Figs 2-4–2-7; Tables 2-12–2-15). These are the reasons why fluorescent lights are used extensively in culture rooms throughout the world.

Recommendations. A suitable and inexpensive light source for orchid tissue culture and micropropagation can consist of two cool white tubes mounted on a standard fluorescent light fixture. The addition of two 25–50-W incandescent bulbs between the fluorescent tubes will improve the light spectrum to which the plants will be subjected. A combination of one cool white and one warm white tube may produce somewhat better illumination, especially if they are combined with incandescent bulbs. Other combinations are also possible. The area illuminated by these lights should be roughly equal to (or slightly larger than) that of the fixture itself, which is usually mounted 45–50 cm above the plants.

If only two cool white tubes are used the light intensity provided at plant level by such a fixture should be between 110 and 130 ft-c (ca. 3.81 W m^{-2} or 17.14 μmol m^{-2} s^{-1} PAR) or 1100–1300 lx. Four tubes may provide 250–320 ft-c (2500–3200 lx, or ca. 9.52 W m^{-2} PAR or 42.86 μmol m^{-2} s^{-1} PAR), whereas new ones can be expected to produce 350–420 ft-c (3500–4200 lx, or ca. 12.70 W m^{-2} PAR or 57.14 μmol m^{-1} s^{-1} PAR). The addition of incandescent bulbs will increase the illumination levels and broaden the spectrum. The emission spectra of plant growth tubes contain wavelengths appropriate for plant growth and should be considered, especially if their prices are reasonable. Combinations of plant growth and other fluorescent tubes and/or incandescent bulb can also produce good results.

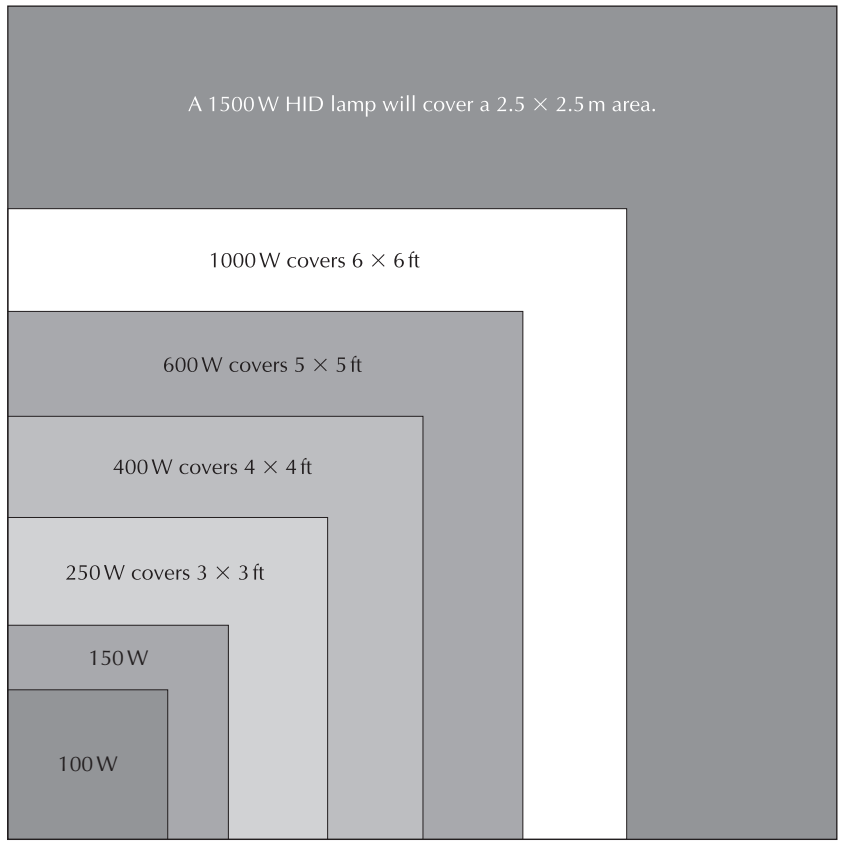

FIG. 2-9. **Areas of illumination. HID, high intensity discharge. (Source: www.kingswoodorchids.com.)**

Studies with red and blue light-emitting diodes (LED; Fig. 2-10) have shown that red light promoted leaf growth in *Cymbidium* plantlets, but decreased chlorophyll content. This was reversed by blue light. Growth under a combination and red and blue LED was comparable to that of plants illuminated by fluorescent lamps (Tanaka et al., 1998). Given the current cost of LEDs there does not seem to be a good reason to use them except under special circumstances.

Carbon Dioxide

Despite its relatively low concentration in the atmosphere (Table 2-19), carbon dioxide (CO_2) plays a very important role in plant life. It is the source of carbon for photosynthesis, but the low atmospheric levels can be a limiting factor. Therefore higher levels of CO_2 can bring about increased growth by orchid plantlets and seedlings (Figs 2-11 and 2-12; Hew et al., 1995; Lootens and Heursel, 1998; Mitra et al., 1998; Tanaka et al., 1998; Gouk et al., 1999).

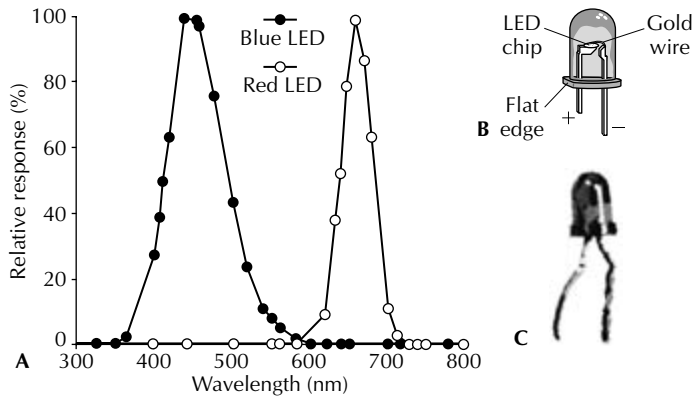

FIG. 2-10. **Light-emitting diodes: spectra (A), diagram (B), and photograph (C).**

TABLE 2-19. **Some facts about carbon dioxide**

Parameter	Value, description, or illustration
Name	Carbon dioxide
Synonyms	Carbonic acid gas, carbonic anhydride
Chemical formula	CO_2, O=C=O
State	Inorganic colorless and odorless gas
Structure	 O C O O C O
Absorption	Absorbed by alkaline solutions
Atmosphere, concentration in	370 ppm or 0.37 ml l^{-1}
Boiling point	There are two values in the literature, –56.6°C and –78.5°C
Content in air, %	0.03–0.037
Content in air, ppm	300–370
Content $liter^{-1}$ of air	0.3–0.37 ml
Density at 21.1°C and 1 atm	1.977 mg m^{-3}
Flammability	None
Freezing point	There are two values in the literature, –76°C and –78.5°C
Humans, effects on	Over 1.5%: headaches, hyperventilation, visual disturbance, tremors, loss of consciousness, death 3–6%: dyspnea, headaches, perspiration 6–10%: dyspnea, headaches, perspiration, tremors, unconsciousness, visual disturbance Over 10%: unconsiousness
Melting point	–78.5°C
Mole volume	22.4 liters
$Molecules\ mole^{-1}$	6×10^{23}
Molecular weight	44.01 = [(C = 12.01) + 2(O = 16)]
Solubility in alcohol	Slight
Solubility in water at 20°C	87.8% by volume
Specific gravity	1.53
Vapor density	1.53 (air being 1.0)
$Volume\ mole^{-1}$	22.4 liters at standard temperature and pressure
$Weight\ mole^{-1}$	44.01 g

Several experiments (Hew et al., 1995; Lootens and Heurserl, 1998; Mitra et al., 1998; Tanaka et al., 1998; Gouk et al., 1999) have shown that subjecting orchid plantlets to higher levels of CO_2 brought about increased growth and dry weight of *Cymidium*, *Mokara*, and *Phalaenopsis*. Growth of *Mokara* Yellow was enhanced greatly

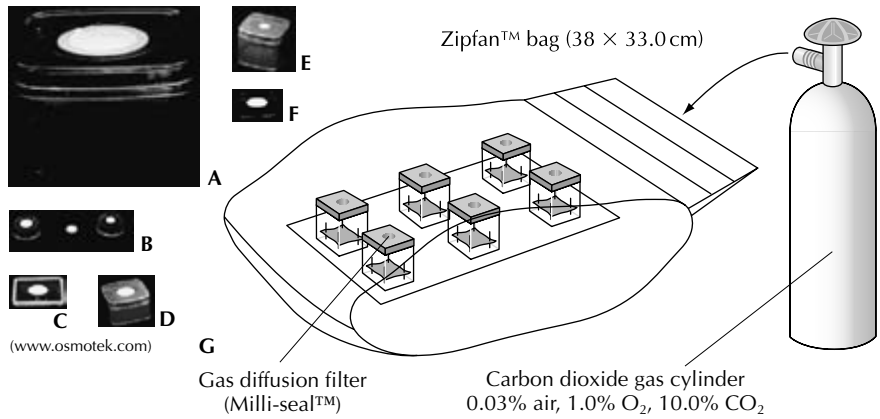

FIG. 2-11. **Carbon dioxide enrichment. A–F. Vented lids that allow for gas exchange, including the diffusion of carbon dioxide. G. A carbon dioxide enrichment system developed by Professor Choy sin Hew (National University of Singapore) and Dr. John W. H. Yong (Nanyang Technological University, Singapore). (Hew and Yong, 1997.)**

when the plants were exposed to 1% CO_2 for 3 months. These plantlets also had higher levels of soluble sugars like glucose and sucrose (the latter also implies increased amounts of fructose), starch, and an extensive thylakoid system (Gouk et al., 1999). *Phalaenopsis* hybrids exposed to 950 ppm CO_2 for 1 week exhibited uptake of the gas which was 82% higher than that of plants exposed to 380 ppm CO_2. This increased uptake can bring about better growth.

There are no simple or inexpensive systems for CO_2 enrichment of the atmosphere that surrounds culture vessels. This is probably the reason why CO_2 enrichment is not a common practice.

A system developed by Professor Choy sin Hew of the National University of Singapore and Dr. John W. H. Yong of Nanyang Technological University in Singapore (Fig. 2-11; Yong et al., 2002) could be used in cases where improved growth is desirable or necessary. Culture vessels with vented caps are available from www.osmotek.com, www.sigmaaldrich.com, www.duchefa.com, and www.unicornbags.com. However such vessels are not strictly necessary. Culture vessels (tubes, flasks) which are covered with cotton buns are also suitable. Also, it is possible that CO_2 levels in the bags can be increased by simply placing a small piece of dry ice in each bag. This possibility has not been tested experimentally. Therefore those who may wish to try it should experiment with it first and accept the fact they are doing it at their own risk and cannot hold anyone else responsible in the event of failure and losses.

Placing Plant Material in Culture

General requirements of tissues, organs, and explants at the start of culture vary. Attention must be paid to these requirements to ensure success.

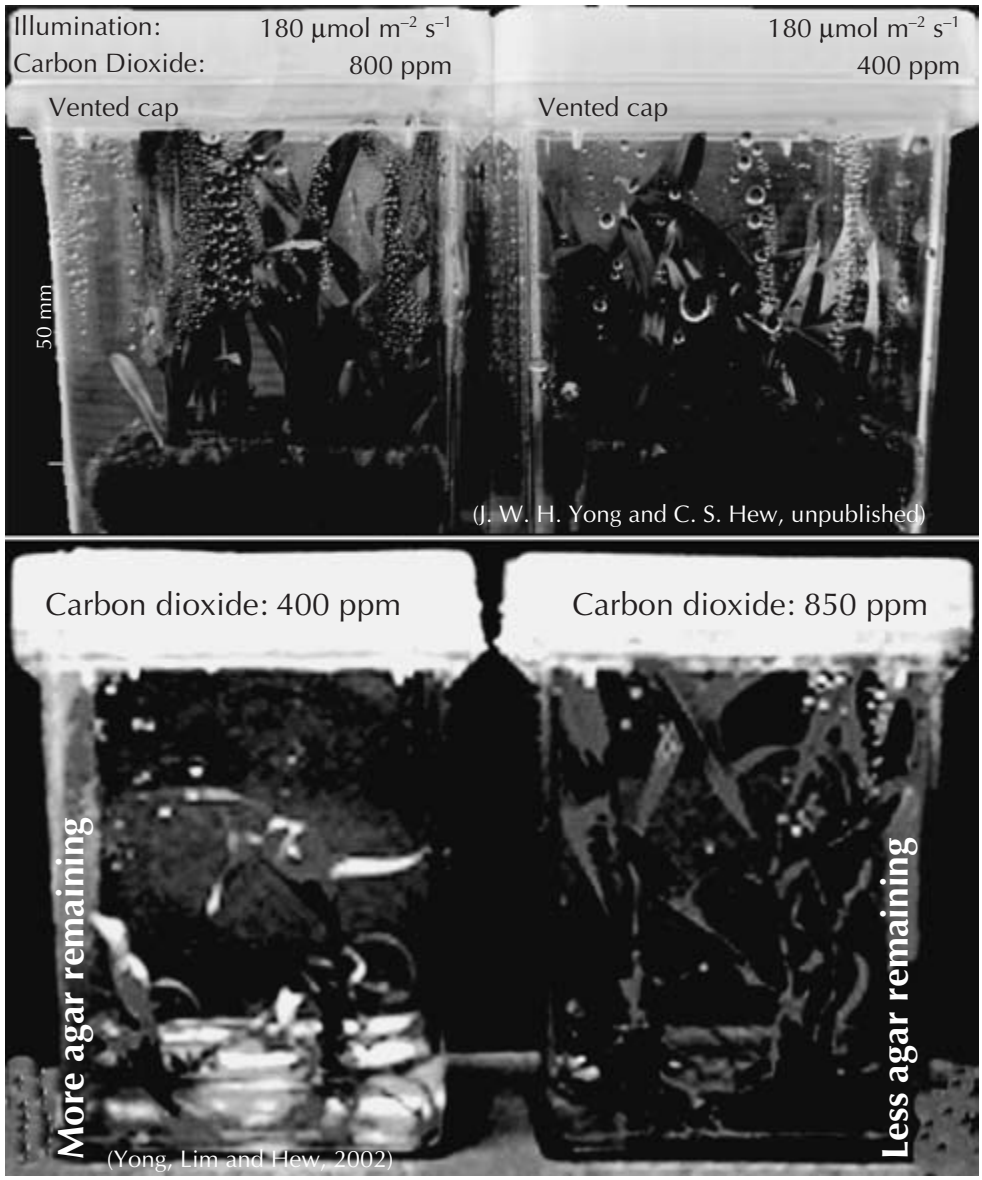

FIG. 2-12. **Effects of increased carbon dioxide levels (800 and 850 ppm) on the growth of *Cymbidium* plantlets (Yong et al., 2002; Dr. J. W. H. Yong and Prof. C. S. Hew, unpublished).**

Seeds

When seeds are placed on a solid medium it is important to establish good contact between them and the medium, and to distribute them evenly. They should not be totally buried in the agar in order to prevent death from improper gas exchange. All inoculations should be carried out in a sterile work area, except as noted otherwise. Explants should be treated similarly (see below).

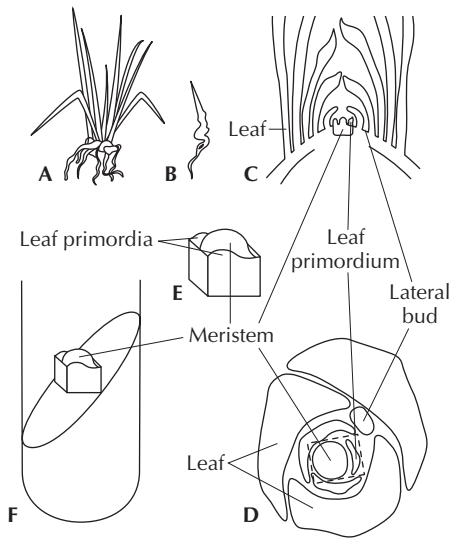

FIG. 2-13. **Excision and culture of a meristem. A. Mature plant; the meristem is located at the tip surrounded by leaf or petiole bases that must be removed to expose it. B. Excised shoot tip. C. Longitudinal section of excised shoot tip showing mature leaves, leaf primordial, lateral buds, and the area (*dotted lines*) to be excised for culture. D. Top view of shoot tip after all large leaf bases have been removed showing meristem, several developing leaves, and lateral buds. E. Excised shoot tip with two leaf primordia. F. Shoot tip on agar. (Modified from Arditti and Strauss, 1979.)**

Tissue Explants

The selection of specific tissues (Figs 2-13 and 2-14) as primary explants depends on the ultimate goal of tissue culture (mass, rapid, clonal propagation or micropropagation, production of callus for in vitro selection, or a source of protoplasts or cells for cultures). The response of a tissue or explant to in vitro conditions may vary widely between families, genera, species, hybrids, clones, and genotypes, and even within the same genotype grown under different environmental conditions. There may also be endogenous physiological rhythms in plants that undergo periodic (annual, seasonal, diurnal) fluctuations which can play critical roles in the establishment of successful cultures. Endogenous cycles may play a particularly critical role in the establishment of protoplast cultures from various tissues of plants.

Shoot tips or meristems (Fig. 2-13B–E) can be utilized as primary explants for the establishment of callus or for mass clonal propagation. Techniques for excision vary slightly with the growth form of the shoot. Generally, meristems are located at the tips of shoots or buds protected by sheathing petioles, leaves, or scales. The shoot tips are sterile and the protective structures maintain their sterility. These structures also protect the shoots from surface sterilants. The shoot tips of *Paphiopedilum* do not have such protection and can be damaged during surface sterilization. This is one reason for the limited success in the culture of shoot tips from mature plants of this genus. In-vitro-grown seedlings are easier to culture because they do not require surface sterilization.

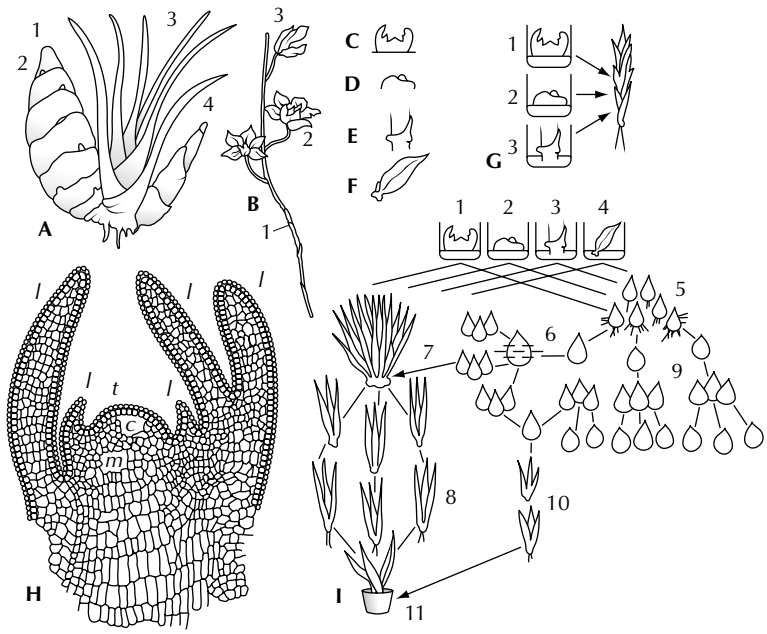

FIG. 2-14. **Sources, utilization, and development of explants. A. (1) Old, (2) young, and (3) new growth, and (4) pseudobulbs and axillary bud. B. Inflorescence with (1) axillary bud, (2) open flowers, and (3) bud in the process of opening. C. Apical meristem. D. Bud. E. Bud on a flower stalk. F. Young leaf. G. Shoots can be formed from (1) shoot tips, (2) buds, and (3) flower-stalk buds. H. Shoot tip (*c,* corpus; *l,* leaf primordial; *m,* meristem; *t,* tunica). I. Development of (1) shoot tips, (2) buds, (3) flower-stalk buds, and (4) young leaves, into (5) protocorm-like bodies (PLBs). The PLBs can be (6) cut and subcultured, or (7) eventually form, (8) multiple, or (9) proliferate naturally, or (10) single shoots that (11) develop into plantlets. (Czerevczenko and Kushnir, 1986.)**

The process of meristem or shoot-tip excision from stems, buds, or other organs requires several important, sensitive, and critical steps. First, the entire plant or growth (corm, tuber, stems, leaves, roots) is removed from the soil or potting mix or a part of a plant is excised.

The next step is to wash and scrub the plant (or the excised parts) with a soft bristle (or a well-used and discarded) toothbrush or another suitable brush, a mild household detergent or baby shampoo, and ample running tap water. Long exposures to high concentrations of some detergents or surfactants (even mild ones) can damage plant tissues (Ernst et al., 1971*a*; Healey et al., 1971), but a brief exposure during washing followed by a thorough rinse will not have deleterious effects in the great majority of cases.

Dissection is initiated after the wash and rinse by careful removal of mature leaves, scales, dead tissues, debris, roots, and other parts using a sharp scalpel (see Fig. A1-4, Appendix 1) or razor blade, taking care not to damage the young internal tissues and/or the part to be excised and cultured. When excising a shoot tip or meristem, the lower portion of the organ (usually a stem) should be removed so that the exposed cut edge is perpendicular to the axis. The top portion can then be mounted by placing the flat cut edge on a Styrofoam block or a cork and affixing it with long

TABLE 2-20. **Dilutions of household bleaches containing different concentrations of sodium hypochlorite**

Percentage of sodium hypochlorite (NaOCl) in household bleach	Volume of household bleach which should be diluted to 100 ml with distilled water to obtain a desired concentration, ml[a]						
	2.0%	2.2%	2.4%	2.5%	2.6%	2.8%	3.0%
4	50	55	60	63	65	70	75
4.25	47	51	57	59	61	66	71
4.5	44	49	53	56	58	62	67
4.75	42	46	51	53	55	59	63
5	40	44	48	50	52	56	60
5.25	38	42	46	48	50	53	57
5.5	36	40	44	46	47	51	55
5.75	35	38	42	44	45	49	52
6	33	37	40	42	43	47	50

[a]Volumes of bleach to use are rounded to the nearest whole figure. There are many brands of household bleach which contain sodium hypochlorite. The concentration of sodium hypochlorite in any given brand can change. Therefore it is advisable to check the label. Pour the bleach into a container (preferably a volumetric flask), adjust to 100 ml with distilled water and add a few drops of surfactant (Tween 20, mild household detergent, or baby shampoo). The diluted bleach must be used within 6–8 h or less.

pins inserted at an angle. Mounting in this fashion stabilizes the organ and allows for: (1) easy surface sterilization by inverting the mounted organ into a sterilizing solution; and (2) microexcision of the part to be cultured (shoot tip or any other tissue explant). Commonly, about 2.4–2.6% of sodium hypochlorite is a suitable solution for surface sterilization. The amount of household bleach to use to obtain such a concentration will depend on the levels of sodium hydroxide in the brand being used (Table 2-20).

Instructions for surface sterilization are given in every method discussed in Chapter 3.

Shoot tips are located at the top of the shoot system and may or may not be covered by mature leaves. Their dissection requires careful removal of leaf primordia under a dissecting microscope and excision of the meristem on a cube of subjacent tissue. The younger leaf primordia surrounding the shoot tip are smaller than older ones and more closely associated with the meristem. These primordia are more difficult to excise without damaging the apical dome (Fig. 2-13C–F). Often, damage to the meristem itself can be avoided by excising primordia under (or with the aid of) a dissecting microscope.

When a dissecting microscope is used, the body and stage must first be wiped with towel (cloth or paper) moistened with water that contains a few drops of detergent. After that the microscope must be wiped with a towel that has been dipped in distilled water. And, just before the dissection, the tissues must be wiped carefully several times with a towel wetted with 70% ethanol (74 ml of 95% ethanol brought up to 100 ml with distilled water) to eliminate contaminants. Once most of the young primordia have been removed, the shoot tip or meristem can be excised on a small cube (Fig. 2-13E) of subjacent tissue (usually not larger than 1 cm^3, and not smaller than 0.5 cm^3) and lifted on a scalpel or a loop to an agar slant (Fig. 2-13F).

Lateral buds can also be removed during the dissection process prior to excision of the terminal meristem or shoot tip. In most orchids, lateral buds are clearly visible in the axils of leaves and appear as glistening raised domes (usually 0.5–1 cm in diameter), similar in appearance to the apical meristem (Fig. 2-13E, F). As each

leaf is dissected, lateral buds along with subjacent tissue can be excised and transferred to agar slants. The size of lateral buds is dependent on genotype, location, and growth conditions, but explants should be in the same size range as those taken from shoot-tip meristems, as described above.

Root sections, tips, or primordia can also be excised and cultured. Reports of callus production and plantlet formation from roots are not as common as those from shoot tips, but the available evidence indicates that these tissues can be useful for micropropagation. The presence of mycorrhiza may make surface sterilization and decontamination of the root difficult or even impossible. The problem can be avoided by using only aerial roots that have not been in contact with soil, potting mix, benches, bark surface, or any other object that could lead to penetration of a fungus.

Seedling tissues, shoot tips, leaves, or roots and their sections or parts can also be used as explants. However, since the nature (or quality) of seedlings is not known there is nothing to be gained from clonal propagation of any one seedling. However, when very few seedlings are produced by what seems to be a very desirable cross, micropropagation may be the only means of increasing their number. Explants from seedlings growing in vitro can also be very useful when the intent is to test a medium or a procedure while eliminating the possible effects of surface sterilization.

Any young or mature tissue from leaf blades, petioles, scale-like leaves, roots, rhizomes, corms, tubers, stems, flowers, or fruits may be suitable as primary explants for the production of either callus or adventitious shoot buds. Dissection of these tissues is usually very simple and involves cutting and removing explants of appropriate size after surface sterilization. Detailed descriptions of excision methods for such tissues are given as part of specific procedures in Chapter 3.

The placement, density, and size of explants as well as the nature of the dissection (e.g., longitudinal vs. cross sections through an organ) may contribute to successful proliferation, growth, and/or differentiation of primary explants. Therefore it is best to follow published reports precisely. If there is no previous work, or when the information is not given in the original publication, it is best to change these parameters independently of each other and only one at a time at first. This approach may increase the likelihood of hitting on the right combination.

Internal Contaminants

There are reports in the literature about microorganisms that reside in plant tissues and contaminate cultures after explants are placed on appropriate media. The literature also contains suggestions regarding the handling of such contamination. In nearly half a century of culturing orchid seeds and explants in our laboratory we have never encountered contamination by internal microorganisms in orchids (except of course mycorrhizal fungi). We also never saw such contamination in other laboratories. The only exception is contamination by organisms found under the scales which cover the flower stalk buds in *Phalaenopsis*. When these scales are removed before surface sterilization there is no such contamination. Anecdotal reports (mostly oral) about contamination by internal microorganisms in orchids do exist, but in the absence of publication in major (and peer-reviewed) journals they remain no more than unconfirmed anecdotes. This being the case not much can or should be written about

presumed contamination of this nature. Anecdotal information, even if advanced or contrived by self-styled experts, has no place in a book like this one. Should contamination by internal microorganisms occur, anticontaminants and PPM may prove useful in combating it.

Enzymes for Protoplast Isolation

A number of mixtures, each consisting of several enzymes, are used for protoplast isolation. Many of the original procedures were carried out with enzymes obtained from Japanese companies. Some or all of these enzymes are still being used, but preparations that have become available more recently are also being utilized. Since success may often depend on using each method exactly as it was formulated originally it is not only advisable but actually imperative to use exactly the same enzymes and preparations as in the original reports. They should be purchased from the sources listed in the original publications.

An enzyme solution used by a foremost orchid micropropagation expert in Japan, Professor Syoichi Ichihasi of the Department of Biology, Aichi University of Education, consists of 1.0% cellulase Onozuka RS (Yakult Pharmaceutical Ind. Co., Ltd., www.yakult.co.jp/ypi/english/index.html), 0.1% Pectolyase Y-23 (Seishin Pharmaceutical Co., Ltd., www.katayamakagaku.co.jp/menu-top.htm), 0.5% Driselase (Kyowa Hakko Kogyo Co., Ltd., www.kyowa.co.jp/eng/index.htm), 160 mg $Ca(NO_3)_2 \cdot 4H_2O$ 100 ml^{-1}, 10 mg KH_2PO_4 100 ml^{-1}, 58.5 mg 2-(*N*-morpholino)-ethane sulfonic acid (MES) 100 ml^{-1}, and 0.3 mol sorbitol l^{-1}, pH 5.6. Professor Ichihashi's method for the isolation of protoplasts is now published with the proceedings of the World Orchid Conference held in Kuala Lumpur, Malaysia in early 2002 (Ichihashi and Shigemura, 2005).

Work Area

Mixing heat-sterilized solutions with components in 95 or 70% ethanol stock solutions, pouring medium into culture vessels, and excising explants and placing them in culture must be carried out under aseptic conditions. Such conditions can be obtained in several ways.

Laminar-flow Hoods

The best and most efficient means of assuring sterility in the working area is to use a laminar-flow hood (see Appendix 1). Air coming into these hoods is driven through filters that remove all particles. The sterile air is blown gently across the working area toward the operator, and this generally prevents contamination of cultures. Tools and work surfaces must, of course, be sterilized, even when used in such a hood, and care must be taken to prevent the introduction of contaminants from unsterile surfaces into vessels.

An important point to keep in mind is that only the air coming into the hood is sterile. The surfaces inside the hood are not sterile and must be sterilized before the

hood is used. This can be done by spraying the inside of the hood with 70% ethanol prior to use. In addition, the inside of the hood should be irradiated with a germicidal ultraviolet (UV) lamp prior to use or while it is not being used, with the front opening curtained off with a plastic curtain. This curtain can prevent the entry of dust into the hood and is also necessary for the protection of workers because UV light can cause severe damage to eyes (people should never look at the UV lamp even through the curtain).

The work space inside these hoods is large enough for comfortable, fast, and efficient movements. There is also space inside for tools, a gas or alcohol burner for flaming tools, aluminum foil and glassware necks, culture vessels, magnifying glasses, and microscopes. The prices of smaller hoods are now low enough to justify their purchase by most laboratories where seed germination, seedling culture, and micropropagation are or may become routine activities.

Sterile Rooms

These are usually small rooms fitted with hard-surface benches that are kept clean by swabbing with alcohol or hypochlorite solution and irradiation with sterilizing UV lamps (which must be allowed to stay on for at least 30 min to ensure sterility but have to be turned off when the operator enters the room). All culture vessels and tools are placed in these rooms, sterilized by washing or spraying with alcohol or hypochlorite, and irradiated with UV light.

When everything is sterile, an operator enters, having washed his or her hands carefully (short clean nails are important if no gloves are worn). Alternatively, the operator can wear surgical gloves, which are kept sterile by periodic swabbing with alcohol or hypochlorite. All hair must be under a shower cap. Tools must be kept sterile by flaming and/or dipping them in alcohol or hypochlorite before and after every use. The necks of culture vessels must be flamed after removing the cotton buns, following the introduction of tissues, and after replacing the buns.

Sterile rooms were popular at one time, but they tend to be expensive and not very comfortable, efficient, or desirable working areas. At present they have been largely replaced by sterile hoods. They are mentioned here mainly for historical reasons and because some may still be in use. The construction of new sterile rooms and the use of existing ones are not advisable.

Sterile Boxes

An enclosure made of plastic, glass, stainless steel, or wood painted with hard polyurethane or plastic, or a cardboard box lined with aluminum foil (see Appendix 1) can prove to be a fairly satisfactory aseptic working area for tissue culture. The inside of the box is kept sterile by washing or spraying it with alcohol or hypochlorite. Irradiating it with sterilizing UV lamps is very desirable but not strictly necessary. Tools, an alcohol burner, culture vessels containing medium, and containers with sterilizing solutions are placed in the box and sterilized by spraying or swabbing them with alcohol or hypochlorite. Approximately 20 min after the swabbing

or spraying, the operator (preferably wearing gloves) can insert his or her hands into the box through long plastic bags attached to the front openings and start to work. All other procedures are as in a sterile room.

Sterile boxes are suitable for a small laboratory or one that is just initiating a tissue culture program. Also, sterile boxes can be useful for those who are just starting or trying to decide if micropropagation is something they may want to do. With a minimum of training, dexterity, and experience, most operators can use such a box successfully. At present, sterile boxes are no longer used extensively because small sterile hoods are inexpensive and much more convenient, safe, efficient, and productive. Sterile boxes are mentioned here for historical reasons and because some are seen occasionally. On the whole their use is no longer recommended.

Clean Laboratory Bench

In some locations (clean laboratories, areas of low atmospheric humidity), experienced operators can simply use a clean laboratory bench as an appropriate work area, but this is not generally advisable.

Washing Glassware

It is imperative that all glassware (culture vessels, volumetric flasks or cylinders, beakers, test tubes, etc.) be chemically clean. This is especially true for containers that have been used previously for other purposes (to hold ketchup, liquor, soft drinks, or medicines, for example) or even tissue culture and for new vessels that were not manufactured for use as they come out of their boxes. Disposable presterilized culture vessels are widely available and relatively inexpensive at present. They do not require washing prior to initial use.

CHAPTER THREE

Methods for Specific Genera

Acampe

Although not of major commercial importance *Acampe* has attracted some attention as a subject for studies of tissue culture and the isolation of protoplasts.

Isolation of Protoplasts from *Acampe praemorsa*

For the most part, research on the micropropagation of orchids, and especially protoplast culture, has centered on species and hybrids of commercial importance. The approach at the Tropical Botanic Gardens and Research Institute at Trivandrum, India, is to initiate "a major research programme . . . to [screen] some wild species and known hybrids of orchids for protoplast isolation . . ." (Seeni and Abraham, 1986). One of the species screened was *Acampe praemorsa*.

Plant Material. Root tips of mature plants and mesophyll from young leaves (second or third leaves from the top) are suitable protoplast sources. Thin slices of these explants "were suspended in . . . enzyme mixture. . . ."

Surface Sterilization. There is no mention of surface sterilization in the original paper. Methods used for surface sterilization of leaves and roots in other methods should prove suitable.

Culture Vessels. Details are not given in the original paper (Seeni and Abraham, 1986), except for one mention of what are presumably Petri dishes. However, it is reasonable to assume that apparatus and culture vessels used in other protoplast isolation procedures would be suitable (see *Aranda* entry for example).

Isolation and Culture Conditions. Tissue should be suspended in the enzyme mixture at room temperature (ca. 22°C) in the dark. Suitable conditions for the culture of protoplasts are 26°C in the dark in Petri dishes sealed with parafilm.

Isolation Reagent, Washing Solution, and Culture Medium. The enzyme consists of 0.5% (w/v) Macerozyme R-10, Onozuka cellulase R-10, 2% (see *Aranda* entry, Isolation and Culture of Mesophyll Protoplasts from leaves of *Aranda* Noorah Alsagoff, for sources of enzymes), 5-m*M* (976.2 mg l^{-1}) 4-MES buffer (see Appendix 2, for sources), 1-m*M* (111 mg l^{-1}) $CaCl_2$ (or 147 mg l^{-1} $CaCl_2 \cdot 2H_2O$), and 0.3-*M* (54.65 g l^{-1}) sorbitol. The pH should be adjusted to 5.5.

The washing solution is 1-*M* (342.30 g l^{-1}) sucrose, whereas 0.3-*M* (54.65 g l^{-1}) sorbitol should be used to suspend the washed protoplasts. The culture medium for protoplasts includes components of two standard solutions as well as other additives (Table Acampe-1).

Procedure. Suspend thin sections of tissue, taken from 600 mg (fresh weight) of tissue, in 5 ml of enzyme mixture at room temperature (ca. 22°C) in the dark with no shaking at all or with gentle agitation at 2-h intervals for 6 h. Remove undigested tissues and large debris by filtering the mixture through a nylon mesh with 100-μm pores. Then mix the filtrate with an equal volume of the 1.0-*M* sucrose solution, and centrifuge the filtrate at 120 g for 3 min. After the centrifugation the protoplasts will be in the supernatant, which must be decanted carefully. Seeni and Abraham (1986) state that "protoplasts were washed once," which can be taken to mean that the supernatant was mixed with 0.3-*M* sorbitol and recentrifuged to form a pellet. This pellet should then be suspended in 2 ml of the 0.3-*M* sorbitol solution. The number of protoplasts can be determined with a hemocytometer.

Before culturing the protoplasts it is necessary to wash them by resuspending the pellet in the culture medium (Table Acampe-1) and recentrifuging them. The new pellet should be resuspended in the culture medium at a concentration of approximately 10^6 protoplasts per milliliter in Petri dishes sealed with parafilm.

Developmental Sequence. The protoplast yield from leaves of *A. praemorsa* was 1.2×10^4 g per tissue or 10,000 per gram of tissue. Roots yielded only 0.2×10^4 protoplasts per gram of tissue. The enzyme mixture turned brown after the *A. praemorsa* tissues were placed in it, "possibly due to oxidation of phenolic compounds," and this may be one reason for the low yields. It may also be a reason why the original paper does not report whether the protoplasts divided in culture.

General Comments. The orchid protoplast research program at the Tropical Botanic Gardens and Research Institute at Trivandrum is laudable, and their results with *A. praemorsa* and other orchids suggests that it will be successful.

TABLE ACAMPE-1. **Modified Vacin and Went medium (Vacin and Went, 1949) for protoplast culture of *Acampe praemorsa* (Seeni and Abraham, 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (a concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Polyol				
8	*myo*-inositol[e]	100	No stock	No stock	Weigh
	Auxin				
9	Naphthaleneacetic acid (NAA)		100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
10	Benzyladenine	0.2	20 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1}	1	
	Sugar alcohol				
14	Mannitol	36.4 g	No stock	No stock	Weigh
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve and it is not possible to prepare a stock solution. To facilitate the preparation of medium place 200 mg of the salt in 500 ml water and stir and/or heat until it dissolves. Add the other components of the medium after that.

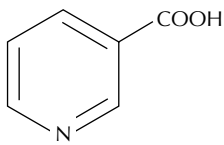
[d]Like other iron salts, this one is hard to dissolve. It is, therefore, preferable to chelate the iron. To prepare a stock solution of chelated iron dissolve 3.73 g chelating agent, Na_2EDTA, and 2.78 g of ferrous sulfate, $FeSO_4 \cdot 7H_2O$, in 1 l water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Also known as inositol, *i*-inositol, or *meso*-inositol.

[f]If auxins and cytokinins do not dissolve, a few drops of KOH or HCl, respectively, can be used to solubilize them.

[g]Keep refrigerated between uses.

[h]Add items 1, 3–8, and 14 to the 500-ml solution of calcium phosphate (item 2). Bring volume to 900 ml with distilled water (item 16); set pH as required (not given in this case, but 5.8 should be suitable); add sugar (item 15) and adjust volume to 1000 ml with distilled water (item 16). Autoclave solution, add hormones and vitamins (items 9–13) under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.



Niacin (also known as nicotinic acid) is one of the most commonly used vitamins in orchid micropropagation. Pharmaceutical or nutritional supplement preparation should be avoided, or used only after prior testing because the tablets contrain binders or other unknown additives

Plantlet Regeneration from Leaf Tips of *Acampe rigida*

In Hong Kong *Acampe rigida* grows on rocks in sunny location. It is of sparse distribution, but populations tend to be large. A method for plantlet regeneration from leaf tips was developed as part of research associated with a Ph.D. dissertation (Yam, 1989; Yam and Weatherhead, 1991*a*).

Plant Material. In the original research, leaf tips 1–1.5 cm in length were taken from 2-cm-long leaves on 6-month-old seedlings. It is important to use a sharp and sterile scalpel blade. Tips should be cut in a sliding action, and pressure on the tissues should be avoided.

The seeds were germinated and the seedlings were grown on Knudson C medium supplemented with 20% (v/v) coconut water from mature nuts. They were maintained under conditions of 25 ± 2°C and 16-h photoperiods of 2000 lx provided by four 40-W Gro Lux fluorescent tubes placed 60 cm above the cultures.

Surface Sterilization. Since these tips are taken from aseptic seedlings, there is no need to surface-sterilize them.

Culture Vessels. Wide mouth, gamma-irradiated plastic flasks, 75-ml capacity (Johns Mallinkrodt, Johns Division, Mallinkrodt Australia, Pty., Ltd.) were used in the original research. Other containers like Erlenmeyer flasks, various bottles, and test tubes are also suitable.

Culture Conditions. In the original research the flasks were wrapped in aluminum foil and placed on shelves next to seedling cultures until plantlets were formed (ca. 2–3 months). Thus the cultures were maintained in the dark, and other facilities that provide darkness would also be suitable. After plantlets were formed, they were transferred first to 500 lx (one 40-W Gro Lux tube ca. 60 cm above the flask) for 1 month, then to 1000 lx (two 40-W Gro Lux tubes 60 cm above the cultures) for another month, and finally to 2000 lx.

Culture Media. If explants are placed on a modified Heller's medium (Table Acampe-2), the number of leaf tips that form plantlets is larger. However, fewer plantlets are produced per leaf tip. On the Ichihashi–Yamashita medium (Table Acampe-3) the number of plantlets per leaf tip is larger, but fewer explants survive.

Procedure. Cut and place leaf tips flat on the medium with their upper epidermis facing upward. Examine the cultures at regular intervals, and when plantlets are formed, move them to the light.

Developmental Sequence. PLBs form after approximately 1 month of culture. Plantlets develop on these bodies after 1–2 months (a total of 2–3 months in culture).

General Comments. This method can be used with other orchids and may be employed to increase the number of plantlets in cases where only a few seedlings of a specific

TABLE ACAMPE-2. **Heller's medium (Heller, 1953) as modified for the culture of leaf tips from seedlings of *Acampe rigida* (Yam, 1989)**

12	Agar, Difco Bacto[g]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add all the microelements to the same 1 l of distilled water, and stir and/or heat until all components are dissolved. It may be advisable to replace the $FeCl_3$ with chelated iron. To prepare a chelated-iron solution add 3.73 g Na_2EDTA (chelating agent) and 2.78 g $FeSO_4 \cdot 7H_2O$ to the same 1 l of distilled water, and stir and/or heat until both are dissolved. Add 10 ml of this solution to 1 l of culture medium.

[d]If the auxin fails to dissolve, add a few drops of dilute KOH.

[e]Keep refrigerated or frozen between uses.

[f]If the cytokinin fails to dissolve add a few drops of dilute HCl.

[g]Add items 1–6 to 900 ml distilled water (item 11), set pH to 5.6, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense solution into a 2-l flask and autoclave. Add auxin (item 7), cytokinin (item 8), and vitamin (item 9) to hot solution under sterile conditions, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

species or cross are available. A change in the procedure that may increase its efficiency would be to culture the leaf tips on Heller's medium (Table Acampe-2) until PLBs form and then to transfer them to the Ichihashi–Yamashita solution (Table Acampe-3).

Acampe is derived from the Greek *akampes* (ἀκαμπής), which means "rigid" (Schultes and Pease, 1963).

TABLE ACAMPE-3. **Ichihashi–Yamashita medium (Ichihashi and Yamashita, 1977) as modified for the culture of leaf tips from seedlings of *Acampe rigida* (Yam, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (a concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium phosphate, $NH_4H_2PO_4$[b]	391	3.91 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	828	8.28 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	172	1.72 g l^{-1}	10	
4	Potassium nitrate, KNO_3	747	7.47 g l^{-1}	10	
5	**Microelements**[c]				
(a)	Boric acid, H_3BO_3	1	100 mg l^{-1}	10	One solution
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.03	3 mg l^{-1}		
(c)	Ferric EDTA, Fe_2EDTA	25	2.5 g l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot H_2O$	0.1	10 mg l^{-1}		
(e)	Nickel chloride, $NiCl_2 \cdot 6H_2O$	0.03	3 mg l^{-1}		
(f)	Potassium iodide, KI	0.01	1 mg l^{-1}		
(g)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(h)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	1	100 mg l^{-1}		
	Auxin				
6	Naphthaleneacetic acid (NAA)[d,e]	0.2	20 mg 100 ml^{-1} 95% ethanol	1	
	Cytokinin				
7	Benzyladenine (BA)[e,f]	1	100 mg 100 ml^{-1} 95% ethanol	1	
	Vitamin				
8	Thiamine·HCl (vitamin B_1)[e]	1	100 mg 100 ml^{-1} 95% ethanol	1	
	Sugar				
9	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[g]	To 1000 ml			
	Solidifier				
11	Agar, Difco Bacto[g]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add all the microelements to the same 1 l of distilled water, and stir and/or heat until all components are dissolved. The iron can be omitted and replaced with a chelated-iron solution prepared by adding 3.73 g Na_2EDTA (chelating agent) and 2.78 g $FeSO_4 \cdot 7H_2O$ to the same 1 l of distilled water and stirring and/or heating until both are dissolved. Add 10 ml of this solution to 1 l of culture medium.

[d]If the auxin fails to dissolve, add a few drops of dilute KOH.

[e]Keep refrigerated or frozen between uses.

[f]If the cytokinin fails to dissolve, add a few drops of dilute HCl.

[g]Add items 1–5 to 900 ml distilled water (item 10), set pH to 5.6, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. The agar can also be added to the cold solution which is then brought to a boil and stirred. When the agar is completely dissolved, dispense the solution into a 2-l flask and autoclave. Add auxin (item 6), cytokinin (item 7), and vitamin (item 8) to hot solution under sterile conditions, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

Direct Shoot Regeneration from Foliar Explants of *Acampe praemorsa*

Acampe is an orchid genus consisting of 15 epiphytic species. Of the five species found in India, *Acampe praemorsa* has attracted attention with its yellow and red flowers. A micropropagation procedure for this species was developed at the Post-Graduate Department of Botany, Utkal University, Bhubaneswar, Orissa, India (Nayak et al., 1997*a*).

Plant Material. Fully expanded third and fourth leaves from in vitro grown plants are most suitable for this procedure. It is not clear from the original source whether the plants from which leaves were taken were seedlings or plantlets produced through micropropagation.

Surface Sterilization. None is needed because the explant sources grow in vitro.

Culture Vessels. Screw-capped glass test tubes, 20 mm in diameter (Fig. Acampe-1D) and 150-ml Erlenmeyer flasks with 30 ml of nutrient solution were used in the original research. Other containers are also suitable.

Culture Conditions. The original cultures were maintained at 25 ± 1°C, 55–60% relative humidity, and 16-h photoperiods of 35–50 μE m^{-2} s^{-1} irradiance provided by Phillips (India) cool white fluorescent tubes.

Culture Media. Modified MS medium is used to induce shoot formation (Table Acampe-4). The shoots elongate on another modification of MS (Table Acampe-5). Rooting occurs on a third modification (Table Acampe-6).

Procedure. The leaves must be inserted vertically (Fig. Acampe-1A–C) into the first medium (Table Acampe-2). Shoots should be transferred to the second medium (Table Acampe-5) for elongation and the third medium (Table Acampe-6) for rooting.

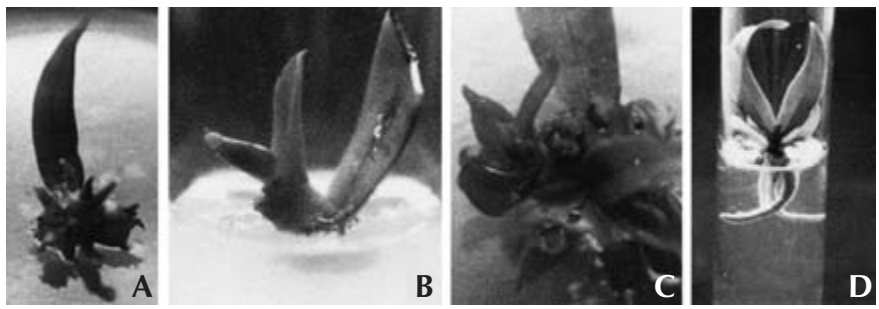

FIG. ACAMPE-1. **Micropropagation of *Acampe*. A. Entire leaf is inserted vertically in the medium. Multiple buds develop on its base after 10 weeks of culture on MS medium containing 1.0 mg TDZ l^{-1}. B. Only a single shoot developed from the base of a leaf (also inserted vertically) after 12 weeks on MS which contains 1 mg NAA l^{-1}. C. Multiple shoot formation after 12 weeks on MS supplemented with 1.0 mg TDZ l^{-1}. D. A rooted shoot on MS with 2 mg IBA l^{-1}. (Nayak et al., 1997*a*.)**

TABLE ACAMPE-4. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Acampe praemorsa* leaf explants (Nayak et al., 1997*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	1-Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
	Cytokinin				
11	Thidiazuron (TDZ)[g]	1.0	10 mg in 10 ml^{-1} 0.1N NaOH in 95% ethanol	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar[h]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]Pure TDZ is expensive (Sigma sells 25 mg for $54.15). It is the active principle in Dropp (50 wettable powder), a cotton defoliant, which is much less expensive. For practical use Dropp can be used at the rate of 2 mg l^{-1}. The solution may be slightly cloudy, but this does not seem to have a deleterious effect on tissue culture media. The problems with using Dropp may be legal (since in some areas it is only approved for use on cotton) and availability (it may be sold in larger amounts than a laboratory can use in a long time). One suggestion on PLANT-TC@TC.UMN.EDU regarding the latter is to find a cotton grower and ask nicely for a small sample. This discussion group offered no suggestions on how to deal with legalities. The only possible (and wise) suggestion here is not to engage in illegal activities.

[h]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.8, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to cold water which is then brought to a boil and stirred. When the agar is completely dissolved distribute the solution into culture vessels, autoclave, and allow the medium to cool before use. As a rule amino acids, hormones, and vitamins should not be autoclaved. However in this case all components were autoclaved by the original researchers.

TABLE ACAMPE-5. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified to bring about elongation of *Acampe praemorsa* shoots produced by leaf explants (Nayak et al., 1997a)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	1-Naphthaleneacetic acid (NAA)	2.0	200 mg 100 ml^{-1} 95% ethanol[f]	1	
	Cytokinin				
11	Benzyladenine (BA)[g]	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar[h]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]A combination of 1 mg NAA l^{-1} and 10 mg BA l^{-1} can also be used to induce shoots on the leaf explants but it is not as effective as NAA and thidiazuron (Table Acampe-2).

[h]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.8, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved distribute the solution into culture vessels, autoclave and allow the medium to cool before use. As a rule amino acids, hormones and vitamins should not be autoclaved. However in this case all components were autoclaved by the original researchers.

TABLE ACAMPE-6. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for rooting *Acampe praemorsa* shoots produced by leaf explants (Nayak et al., 1997*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Indole-3-butyric acid (IBA)	1.0	100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Phytagel[h]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]A combination of 1 mg NAA l^{-1} and 10 mg BA l^{-1} can also be used to induce shoots on the leaf explants but it is not as effective as NAA and thidiazuron (Table Acampe-2).

[h]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Add the Phytagel (item 16) to the cold medium slowly while stirring vigorously. When the Phytagel is completely dissolved distribute the solution into culture vessels, autoclave, and allow the medium to cool before use. Phytagel should not be added to warm or hot water because it will form clumps which will not dissolve or disperse later or during autoclaving. As a rule, amino acids, hormones, and vitamins should not be autoclaved. However, in this case all components were autoclaved by the original researchers.

Developmental Sequence. In the original research, bases of leaves cultured on MS medium containing TDZ expanded and became swollen within 5–7 weeks in culture. Buds formed after 8–9 weeks. They appeared as small green protuberances. This process continued for 12 weeks. There was no callus or PLB formation. When shoots were formed on the TDZ-containing medium, they failed to elongate. Elongation did take place 12–15 days after the shoots were transferred to a medium containing NAA and BA. Roots were formed on a medium containing IBA.

General Comments. Shoot regeneration occurred only on the lower portions of leaves (Fig. Acampe-1D). If leaves were cut in half horizontally, shoots did not form on the upper halves. The highest frequency of shoot regeneration was recorded on fully expanded third and fourth leaves. There was no shoot formation on first, second (both expanding), and fifth and sixth (older) leaves. The context of the original paper suggests that leaves may have been taken from seedlings. If so, selection for desirable cultivars is not possible. A method for seed germination and seedling culture of *A. praemorsa* was also developed in India (Kanjilal et al., 2001).

In Vitro Propagation of *Acampe praemorsa* from Leaf Explants

A method for micropropagation of *Acampe praemorsa* using young leaves was developed at Karnatak University in India (Pyati and Murthy, 1999).

Plant Material. Basal or tip segments, 0.5–1.0 cm long, from young leaves up to 2 cm in length taken from 16–20-week-old axenic seedlings should be used (similar leaves from greenhouse-grown plants do not grow).

Surface Sterilization. There is no need to surface-sterilize the explants because they are taken from axenically grown plants.

Culture Vessels. The original paper does not mention culture vessels. However, photographs in it suggest that test tubes containing 30 ml of medium are suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of intensity similar to that used in the previous procedure. No information is presented in the original paper regarding the source(s) of illumination.

Culture Media. MS medium containing 1 mg BA l^{-1} should be be used to induce formation of PLBs (Table Acampe-7), which occurs on 65% of the explants after 4 weeks of culture. Callus is formed on 45% of explants after 4 weeks on MS supplemented with 1 mg NAA l^{-1} (Table Acampe-8). For callus formation followed by PLB production the explants should be cultured on MS with 1 mg BA and 1 mg NAA l^{-1} (Table Acampe-9). To induce shoot and root formation, the PLBs should be transferred to fresh MS containing 1 mg BA l^{-1} (Table Acampe-7).

TABLE ACAMPE-7. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for induction of protocorm-like bodies from leaf explants of *Acampe praemorsa* (Pyati and Murthy, 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	Benzylaminopurine (benzyladenine, BA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.6, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), BA (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. This method of preparing the medium assumes that the amino acid, cytokinin, and vitamins should not be autoclaved. The original paper does not make it clear whether they were autoclaved or not. If a test shows that the medium is effective after these components are autoclaved, items 1–13 should be added to 900 ml of distilled water (item 15). Following that the steps are the same as above until the agar is dissolved. After that the medium should be dispensed into culture vessels and autoclaved.

14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), NAA (item 10), BA (item 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. This method of preparing the medium assumes that the amino acid, cytokinin, and vitamins should not be autoclaved. The original paper does not make it clear whether they were autoclaved or not. If a test shows that the medium is effective after these components are autoclaved, items 1–14 should be added to 900 ml of distilled water (item 16). Following that the steps are the same as above until the agar is dissolved. After that the medium should be dispensed into culture vessels and autoclaved.

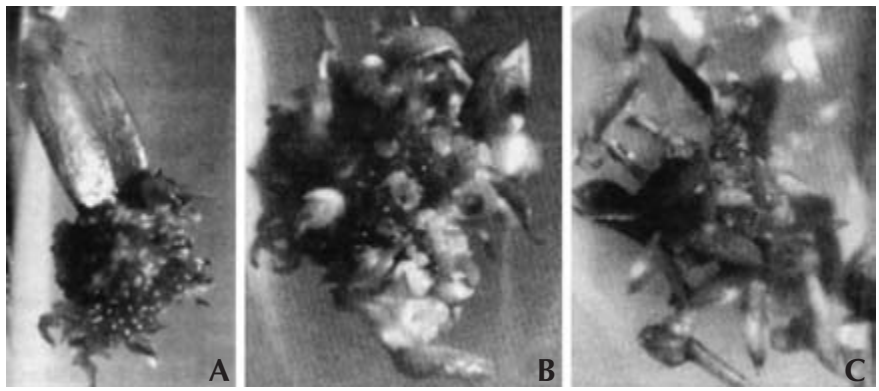

FIG. ACAMPE-2. **Leaf culture of *Acampe praemorsa*. A. PLBs on explant after 8 weeks of culture on MS medium containing 1 mg BA l^{-1}. B. Shoot on PLB after 12 weeks of culture (medium not indicated in caption for illustration in the original paper). C. Plantlets which formed after 12 weeks of culture (medium not indicated in original caption). (Pyati and Murthy, 1999.)**

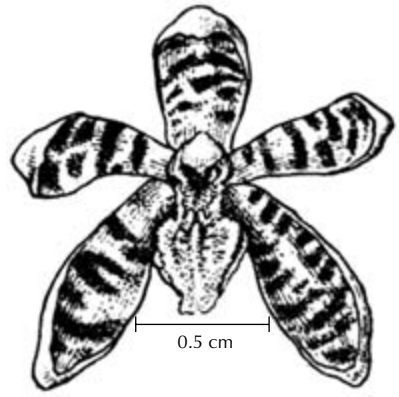
Procedure. Explants taken from young plants should be sectioned and placed on the medium (Fig. Acampe-1). Once formed, PLBs should be moved to fresh medium for shoot and plantlet formation (Fig. Acampe-2).

Developmental Sequence. Depending on the medium, the explants may form PLBs (Table Acampe-7), callus (Table Acampe-8), or callus followed by PLBs (Table Acampe-9). The PLBs form plantlets when moved to fresh medium.

General Comments. A clear advantage of procedures that use leaf explants is that the donor plant is not endangered. However, propagating seedlings of unknown quality may be useful only in cases when there are few viable seeds in a capsule.



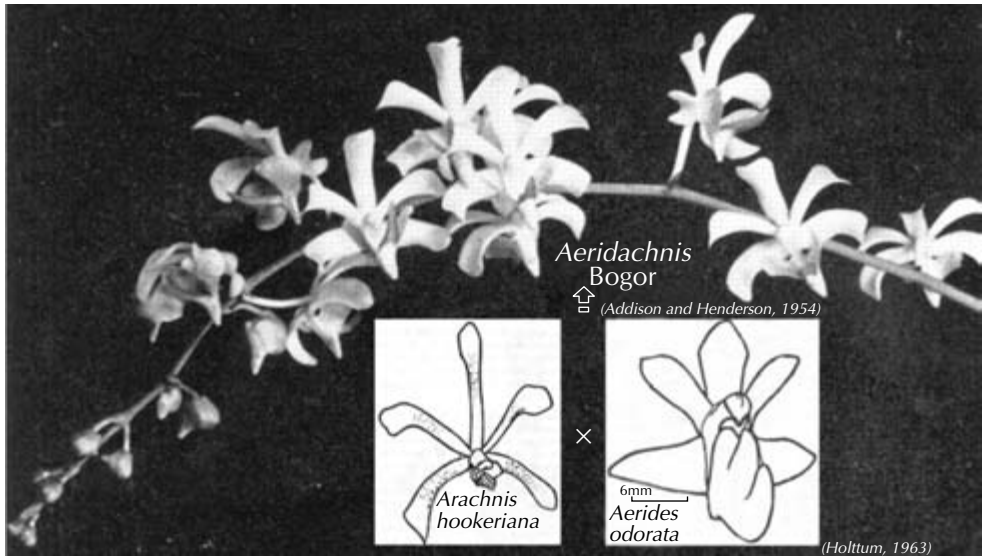
***Acampe praemorsa* flower (Abraham and Vatsala, 1981)**

Aeridachnis

A hybrid genus, *Aeridachnis* or *Aëridachnis*, is a cross between *Aerides* and *Arachnis*. The first hybrid, *Aeridachnis* Bogor, was reported in 1954.

Culture of Apical Buds of *Aeridachnis* Bogor

Apical and axillary buds of *Aeridachnis* Bogor 'Apple Blossom' (*Arachnis hookeriana* × *Aerides odorata*), *Aeridachnis* Alexandra (*Aeridachnis* Bogor × *Arachnis flos-aëris* var. *insignis*), and *Aeridachnis* Elizabeth Howe (*Arachnis* Ishbel × *Aerides lawreanceae*) were cultured at the Singapore Botanic Gardens by the method used for *Arachnis* (Lim-Ho, 1981). The explants are first cultured in a liquid modification of the Vacin and Went medium (see Table Arach-4). Two solid modifications (see Tables Arach-4 and Arach-5) are used for proliferation and differentiation. A third solid modification is employed for plantlet formation (see Table Arach-6). Explant growth is slow.



Aerides

An epiphytic genus, *Aerides*, consists of approximately 20 species which are found in South East Asia.

Protoplast Culture of *Aerides ringens*

The procedure developed for *Acampe praemorsa* was used to obtain 1.0×10^4 and 1.6×10^4 protoplasts per gram of tissue from leaves and roots, respectively, of *Aerides ringens* (Seeni and Abraham, 1986).

Micropropagation of *Aerides maculosum* through the Culture of Leaf Explants

A south Indian orchid valued for its inflorescences, *Aerides maculosum* has been over-exploited and its population is dwindling. Attempts to germinate it symbiotically have not been very successful. Only 0.3% of the seeds germinate. Therefore, a micropropagation method was developed with a view towards conservation and commercialization (Murthy and Pyati, 2001; Murthy et al., 2001).

Plant Material. Young leaves up to 2 cm long are taken from axenic seedlings and sectioned into 0.5–1.0-cm segments. Both leaf-tip and leaf-base sections of young leaves can be used as explants. Leaves from mature plants cannot be used.

Surface sterilization. There is no need to surface-sterilize the explants because they are taken from axenically grown seedlings.

Culture Vessels. Culture vessels are not described in the original paper, but photographs (Fig. Aer-1) suggest that test tubes, 20 mm in diameter, containing 30 ml of culture medium are suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 40 μmol PAR m^{-2} s^{-1}. The light sources are not mentioned, but almost any combination of two 40-W fluorescent tubes (cool white or Gro Lux, for example) and two 50–100-W incandescent bulbs (if cool white tubes are used) per fixture placed 50 cm above the cultures should be suitable.

Culture Media. MS medium containing 2.0 mg BA l^{-1} (Table Aer-1) should be used to induce PLB formation. On transfer to basal MS (Table Aer-2) the PLBs produce plants.

Procedure. The explants (leaf sections) must be inserted vertically (Fig. Aer-1A) with their cut ends in the medium (Table Aer-1). Once they are formed, PLBs (Fig. Aer-1B) should be transferred to the second medium (Table Aer-2) for plantlet formation

TABLE AER-1. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for induction of protocorm-like bodies from leaf explants of *Aerides maculosum* (Murthy and Pyati, 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]This substance is also known as inositol and *meso*-inositol. Actually there is no definitive proof that this polyol is required by explants. It is being added routinely to media as part of the original formulation. Inositol can be found among nutrition supplements and vitamins in many pharmacies and food stores. However care should be taken in using inositol from these sources because the preparations may contain other substances.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 14), adjust pH to 5.6, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8) and vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. This method of preparing the medium assumes that the amino acid and vitamins should not be autoclaved. The original paper does not make it clear whether they were autoclaved or not. If a test will show that the medium is effective after these components have autoclaved, items 1–12 should be added to 900 ml of distilled water (item 14). After that the steps are the same as above until the agar (item 15) is dissolved. Following this the medium should be dispensed into culture vessels and autoclaved.

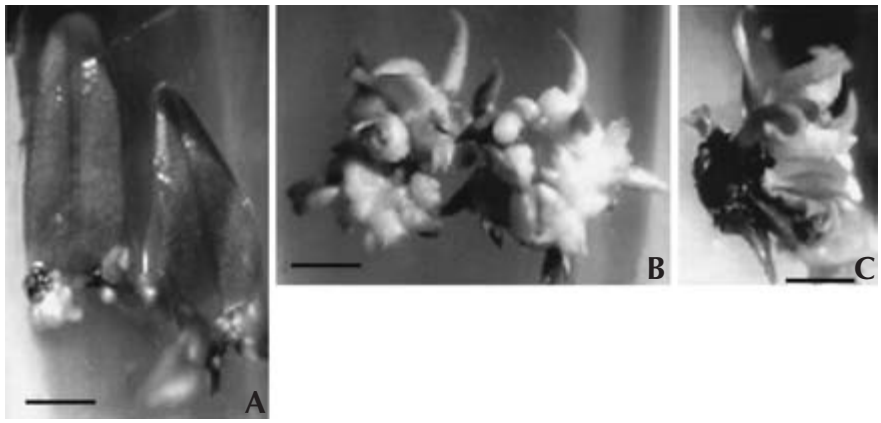

FIG. AER-1. **Culture of *Aerides maculosum* leaf explants. A. Leaf-tip explants inserted vertically in medium and developing PLBs on their bases. B. Increase in the number of PLBs. C. Development of shoots and roots. (Murthy and Pyati, 2001.)**

(Fig. Aer-1C). In the original research plantlets that formed on the second medium (Table Aer-2) were transferred to vermiculite for further development. After that they should be potted. A potting mix consisting of brick pieces, charcoal, and chopped dried coconut husks (in the ratio 1 : 3 : 1; probably v/v/v) was used in the original research. Survival in the last potting mix was 84%. A different potting mix may also be suitable.

Developmental Sequence. Bases of explants start to expand and swell within 2 weeks of being inserted in the first medium (Table Aer-1). PLBs start to differentiate after 4 weeks and continue to do so until the 8th week (Fig. Aer-1A, B). There is no callus formation. This occurs only on the bases of explants. Shoots and roots differentiate (Fig. Aer-1C) following transfer to the second medium (Table. Aer-2). Mature plants develop in the vermiculite and the potting medium.

General Comments. When an orchid is propagated through the culture of explants from seedlings it is not possible to select for desirable characteristics because the quality of the donor plants is not known. This usually reduces the value of the propagation procedure. However, in this case, selection is of secondary importance because the seeds of *A. maculosum* do not germinate well and the current procedure makes possible multiplication for conservation and commercialization purposes.

Micropropagation of *Aerides multiflorum* through Leaf Segments

As has been pointed out several times, use of shoot tips for micropropagation "requires the sacrifice of [an] entire new growth or the only growing point and has a limited utility in monopodial taxa where it endangers the survival of the mother plant" (Vij and Pathak, 1990). To overcome this problem, Professor Suraj P. Vij, founding editor of the *Journal of the Orchids Society of India* and Professor of Botany at

Panjab University, and his associate Dr. Promila Pathak developed micropropagation procedures, using foliar explants for several orchid species, including *Aerides multiflorum* (Vij and Pathak, 1990).

Plant Material. Young leaves, up to 2 cm in length, from 16–40-week-old axenic seedlings should be used. Leaf explants from mature plants die after 10–20 weeks in culture.

Surface Sterilization. No surface sterilization is needed because the leaves are taken from axenically grown plants.

Culture Vessels. Culture vessels are not described in the original paper. Test tubes, 20 mm in diameter, containing 30 ml of culture medium are appropriate.

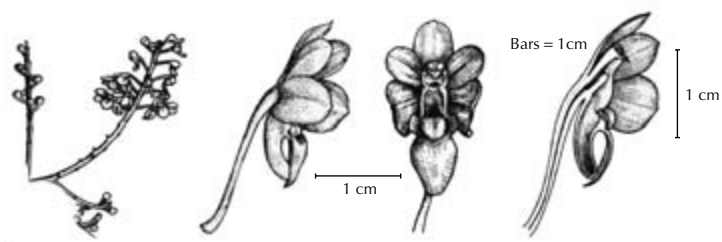
Culture Conditions. In the original experiments cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

Culture Media. One medium is suitable for induction of PLBs on leaf-tip explants (Table Aer-3). Another formulation should be used for basal explants (Table Aer-4).

Procedure. After removal from plants the leaves are sectioned under sterile conditions. The sections should be inserted (presumably vertically) in the culture medium and allowed to remain there until plantlet formation or PLBs and/or callus can be subcultured. Well-developed PLBs or small plantlets will probably grow well on Knudson C (see Tables Cym-2 and Cym-3), Tsuchiya (see Table Cym-4), Vacin and Went (see Table Cym-5) or basal MS (Table Aer-2) media.

Developmental Sequence. Explants will produce callus and after that PLBs on MS medium containing activated charcoal, IAA, and yeast extract (Table Aer-3). Only PLBs are produced on a medium which contains activated charcoal, IBA, kinetin, and yeast extract (Table Aer-4). Leaf and shoot primordia develop after 6 and 12 weeks in culture of PLBs from apical explants and 10 and 20 weeks on basal section PLBs.

General Comments. As with other procedures that use explants from seedlings, this method does not allow for the selection of desirable forms. However, it can be used to propagate an orchid whose seeds may not germinate well, an endangered species, or plants that are in demand commercially.



***Aerides ringens* inflorescence (Abraham and Vatsala, 1981)**

TABLE AER-3. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of apical sections of *Aerides multiflorum* leaf explants (Vij and Pathak, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Indoleacetic acid (IAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
14	Yeast extract	1.0 g	No stock	No stock	Weigh
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	9.0 g	No stock	No stock	Weigh
	Darkening agent				
18	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve add a few drops on 0.1 N NaOH.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. When the agar is completely dissolved, add darkening agent (item 18) slowly with vigorous stirring; after it has been dispersed completely, dispense solution into culture vessels and autoclave. The agar can also be added to the cold water which is brought to a boil and stirred. The darkening agent should be added as above when the agar is completely dissolved. After that pour the solution into a 2-l flask and autoclave. As a rule the amino acid (item 8), auxin (item 10), and vitamins (items 11–13) should be added to the hot solution under sterile conditions with sterilized pipettes and mixed well before the medium is distributed into preautoclaved culture vessels. However in this case the original paper implies that all components of the medium were autoclaved.

[h]Only vegetable charcoal should be used. Bone charcoal is not suitable.

TABLE AER-4. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of basal explants of *Aerides multiflorum* leaves (Vij and Pathak, 1990)**

	Solidifier				
18	Agar[g]	9.0 g	No stock	No stock	Weigh
	Darkening agent				
19	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve add a few drops on 0.1 N NaOH.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. When the agar is completely dissolved, add darkening agent (item 19) slowly with vigorous stirring; after it has been dispersed completely, dispense solution into culture vessels and autoclave. The agar can also be added to the cold water which is brought to a boil and stirred. The darkening agent should be added with vigorous stirring when the agar is completely dissolved. After that pour the solution into a 2-l flask and autoclave. As a rule the amino acid (item 8), auxin (item 10), cytokinin (item 11), and vitamins (items 12–14) should be added to the hot solution under sterile conditions with sterilized pipettes and mixed well before the medium is distributed into preautoclaved culture vessels. However in this case the original paper implies that all components of the medium were autoclaved.

[h]Only vegetable charcoal should be used. Bone charcoal is not suitable.

Micropropagation of *Aerides multiflorum* through Root Explants

Roots are among the last orchid organs to be cultured and to be used as explants for micropropagation. One reason for this is their tendency to be recalcitrant. Another is the presence of mycorrhizal fungi, which complicates matters. One of the more extensive and successful programs of orchid root explant culture was carried out by Professor S. P. Vij and his associates Anil Sood, Promila Pathak, Sanjeev Arora, Kusam Mahant, Parminder Kaur, and Vishal Sharma at the Botany Department, Panjab University, Chandigarh, India (Vij, 1993).

Plant Material. Young and actively growing roots from 16–30-week-old axenic seedlings should be used. Roots from mature plants die after 8–10 weeks in culture.

Surface Sterilization. No surface sterilization is needed because the roots are taken from axenically grown plants.

Culture Vessels. Culture vessels are not described in the original paper. Standard culture tubes containing 30 ml of culture medium should be appropriate.

Culture Conditions. In the original experiments cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

Culture Media. A medium containing yeast extract, activated charcoal, an auxin, and a cytokinin induced the formation of PLBs and subsequently leaves and roots (Table Aer-5).

Procedure. After removal from plants the roots are placed on the medium (Table Aer-5). Well-developed PLBs or small plantlets should grow well on the Knudson C (see Table Cym-3), Tsuchiya (see Table Cym-4), Vacin and Went (see Table Cym-5) or basal MS (Table Aer-2) media.

Developmental Sequence. Roots start regeneration 1 week after being placed in culture. The first leaf and root are formed after 5 and 12 weeks of culture, respectively. If only IAA is present in the medium the time required for leaf and root formation is doubled.

General Comments. Since the roots are taken from seedlings it is not possible to use this method for propagation of outstanding cultivars. However this method can be used to propagate orchids in cases where only a few seedlings become available. It may also be possible to adapt it to mature plants. If so care should be taken to use root tips free of mycorrhiza.

TABLE AER-5. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of root explants of *Aerides multiflorum* leaf explants (Vij, 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10

	Solidifier				
18	Agar[g]	9.0 g	No stock	No stock	Weigh
	Darkening agent				
19	Activated charcoal[h]	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve add a few drops on 0.1 N NaOH.

[g]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.5, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. When the agar is completely dissolved, add darkening agent (item 19) slowly with vigorous stirring. After it has been dispersed completely, dispense solution into culture vessels and autoclave. The agar can also be added to the cold water which is brought to a boil and stirred. If this is done the darkening agent should be added as above when the agar is completely dissolved.

[h]Only vegetable charcoal should be used. Bone charcoal is not suitable.

Anacamptis

Anacamptis pyramidalis seems to be the first European terrestrial orchid propagated by meristem culture (Morel, 1970).

Anacamptis pyramidalis

Plant Material. Few details are given, but it appears that meristems are excised like those of *Cymbidium* or *Cattleya*. They are then put in culture (Morel, 1974).

Surface Sterilization. Since no details are given, the assumption is, again, that it is accomplished as with *Cymbidium* or *Cattleya* (Morel, 1974).

Culture Vessels. Use 16-mm-diameter test tubes and 50- or 125-ml Erlenmeyer flasks, containing 3–5, 15, and 25 ml medium respectively.

Culture Conditions. No details are given regarding photoperiods, light intensity, or temperature. Therefore it seems that the same conditions as for *Cymbidium* or *Cattleya* should be employed (Morel, 1974). Or use 12-h photoperiods and 100–200 ft-c provided by Sylvania Gro Lux lamps at 22°C.

Culture Media. "The meristem of *Anacamptis pyramidalis* which was cultured on . . . Murashige–Skoog medium" (Murashige and Skoog, 1962) is the statement given (Morel, 1970). However, only the minerals of this medium are listed along with the suggestions that auxin (IAA, NAA, or IBA), 0.5–1 mg l^{-1}, and coconut water must be included in the solution. The medium listed for use with *A. pyramidalis* is based on these suggestions (Table Anac-1). However, it is possible that the versions of the MS medium used for *Epidendrum* leaf tips and Knop's solution employed for *Dendrobium* stem nodes could also be used.

Procedure. Place explants in culture and treat like *Cymbidium* or *Cattleya*.

Development Sequence. "Das Meristem von *Anacamptis pyramidalis*, das auf einem Nährboden von Murashige und Skoog gezüchtet wird, bildet ebenfalls protokormartige Gewebe, die man unendlich vermehren kann; ihr Wachstumprozess ist allerdings sehr langsam" [Meristems of *A. pyramidalis* cultured on Murashige–Skoog medium form protocorm-like bodies, which can be used for unlimited propagation; however, their growth is very slow] (Morel, 1970).

General Comments. According to one report (F. R. Gomm, Nature Conservancy Council, Merlewood Research Station, Grange-over-Sands, UK, personal communication, 1974), only 2–3 plants of native *Cypripedium calceolus* are left in England. An effort is being made to save the species by seed and, if possible, tissue culture propagation. Hence, propagation using tissue culture may well be applied in conservation efforts. The development of such a method of *A. pyramidalis* points to the fact that this is possible and should serve as encouragement for others to devise procedures for other species.

TABLE ANAC-1. **Modified Murashige–Skoog (MS) medium for the culture of *Anacamptis pyramidalis* meristem (Morel, 1970)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

9	Kinetin	2.60	100 mg 50 ml^{-1} basic 95% ethanol[f,g]	1.3	
	Amino acid				
10	Glycine	20	2 g 100 ml^{-1} 70% ethanol[h]	1	
	Vitamin[i]				
11	Thiamine (vitamin B_1)	0.1	100 mg 100 ml^{-1} 95% ethanol	0.1	
	Complex additive[j,k]				
12	Coconut water from immature (green) nuts	100–250 ml	No stock	No stock	If available
	Sugar[j,k]				
13	Sucrose	30 g	No stock	No stock	
	Solvent				
14	Water, distilled[j,k]	To 1000 ml			
	Solidifier[k]				
15	Agar	10–15 g	No stock	No stock	

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, they must be kept frozen between uses.

[c]Items 6a and 6b are added to the same 1 l. Add 10 ml per liter of culture medium.

[d]Add all microelements to the same 1 l, and keep at 60°C (a waterbath might be suitable) for 24 h in the dark. It is possible to combine solutions 6 and 7: add items 6 and 7 to the same 1 l, and keep at 60°C for 24 h. In such cases the amount of Na_2EDTA should be doubled. Use 10 ml per liter culture solution in either case.

[e]2,4-Dichlorophenoxyacetic acid (2,4-D) may also be used at the rate of 1 mg l^{-1} of culture medium (0.5 ml of a 50 mg per 25 ml 95% ethanol stock). Keep refrigerated.

[f]If the auxin or cytokinin does not dissolve, add a few drops of dilute HCl or KOH solution, respectively to solubilize it. Keep refrigerated.

[g]Benzyladenine (BA) may also be used at the rate of 1 mg l^{-1} of culture medium (0.5 ml of 50 mg per 25 ml 95% ethanol stock solution). Keep refrigerated.

[h]Keep frozen between uses to prevent contamination.

[i]Keep refrigerated between uses.

[j]To keep the solution liquid, mix items 1–12 with 500 ml distilled water (item 14). Then adjust pH to 5.2–5.5, add sugar (item 13), and bring volume to 1000 ml with more distilled water (item 14). Sterilize the medium through 0.45-µm or 0.22-µm millipore filters (Millipore Filter Corp., Bedford, MA 01730) or a Morton UF fritted-glass filter (Corning Glass Co., Corning, NY 14830). An alternative method is to mix items 1–7 with 500 ml distilled water (item 14), adjust pH to 5.2–5.5, add sugar (item 13), adjust volume to 750 ml, and autoclave (Solution A). Then add items 8–11 to 200 ml green coconut water (item 12), adjust pH to 5.2–5.5, bring volume to 250 ml with more coconut water (item 12), and filter-sterilize the solution (Solution B). Mix Solutions A and B in a sterile box after each has been sterilized. If no coconut water (item 12) is to be used, mix items 1–7 with 500 ml distilled water (item 14), adjust pH to 5.2–5.5, and then add sugar (item 13). Bring volume to 1000 ml (or 997.1 ml for those who are extra fussy) with distilled water (item 14), and autoclave the solution. Add items 8–11 to this solution under sterile conditions (with sterilized pipettes or syringes) when it has cooled to about 60°C. Dispense sterile medium into sterilized (i.e., autoclaved) culture vessels (test tubes, bottles, Erlenmeyer flasks, etc.).

[k]Add agar (item 15) only if solid medium is desired. Sterilization can be accomplished in several ways. One is to mix items 1–12 (or 1–11 if no coconut water is used) with 100 ml distilled water, adjust pH to 5.2–5.5, add sugar (item 13), bring volume to 250 ml, and filter-sterilize. Add agar to 750 ml distilled water, dissolve by bringing the solution to a gentle boil, and autoclave. Mix the two solutions while the agar is still liquid, and dispense into sterilized containers. A second method is to mix items 1–7 with 500 ml distilled water, adjust pH to 5.2–5.5, add sugar (item 13), bring volume to 750 ml with more distilled water, dissolve the agar as above, and autoclave. Then add items 8–11 to 200 ml coconut water, adjust pH to 5.2–5.5, bring volume to 250 ml with more coconut water, and sterilize the solution by filtration. Mix the two solutions, and dispense as above. The third method, if no coconut water is used, is as follows: mix items 1–7 with 500 ml distilled water, adjust pH to 5.2–5.5, add sugar (item 13), adjust volume to 1000 ml (or 997.1 ml for the extra fussy), dissolve agar as above, and autoclave the solution. Add items 8–11 under sterile conditions following autoclaving, and dispense solution as above.

Micropropagation of Crimean *Anacamptis pyramidalis*

A method for the micropropagation of *Anacamptis pyramidalis* (Fig. Anac-1) was developed in the Crimea and reported in an abstract which is a jumble of information (Popkova, 2000) that is nearly impossible to unravel. "Explants . . . were parts of stems, seed-buds [sic], buds, roots and closed seeds bull [sic] with seeds." No information is given as to which of these explants were used for *A. pyramidalis*. Flower buds were surface-sterilized with 70% alcohol (presumably ethanol). There was "also gradual sterilization [with] 70% alcohol + 15% peroxide [presumably hydrogen peroxide] or 70% alcohol + 10% chloramine for roots, part[s] of stem[s] [and] seed bull [sic, whatever that is]." MS, Knudson C, Burgeff, and Prasad and Mitra media were used for "seeds and tissues." Since no details are given about the medium it seems reasonable to suggest that the medium used for meristems of this species (Table Anac-1) should be the first one to try. Cultures were maintained under "24–250" [sic, probably meaning 25°C] and 16-h photoperiods of 1500–3500 lx, but the abstract also states: "in the thermostat of cultivated were in darkness where the temperature was 24–250 [sic, probably meaning 25°] C" (the editors of *Plant Physiology and Biochemistry* clearly needed to do a much better job of editing this abstract).

Anacamptis pyramidalis formed protocorms of "protocorm-like structures" (but the abstract does not state if these were of seed or explant origin). On reaching a diameter of 1–4 mm they were transferred to Knudson C medium supplemented with "meso[myo]inositol, peptone, vitamins and kinetin" (amounts not listed).

This abstract is neither clear nor useful, but is presented here for the sole purpose of providing coverage of micropropagation methods that is as nearly complete as possible.

FIG. ANAC-1. ***Anacamptis pyramidalis*** **from Italy (A–C) and Russia (E–G). A, G. Inflorescence. B, E. Flower. C. Tubers. D. Leaves. (Sources: A–D, Scrugli, 1990; E–G, Vahrameeva, 1991.)**

Angraecum

Angraecum is a large and varied genus with many interesting species from Madagascar. Few if any have been cultured in vitro.

Angraecum eburneum

See discussion in following paragraph.

Isolation of Protoplasts from Green Sepals of *Angraecum giryamae*

Isolated protoplasts of orchids could be used to produce interesting new hybrids through fusion and advanced plant bioengineering research. A method for the isolation of protoplasts from green sepals of *Angraecum giryamae* was developed at Cornell University (see Price and Earle, 1984; note that the species is misspelled there as *Angraecum gyrimae*). This taxon is treated as a distinct species as parent of hybrids and for horticultural purposes in the Sander's List of Orchid Hybrids, but is considered "by some authorities . . . [as being] within [*Angraecum*] *eburneum*]. . . ."

Plant Material. Green sepals from flowers of *A. giryamae* were used in the original research as sources of protoplasts. Small strips of sepal tissue (50–150 mg) are incubated in 2 ml of the enzyme mixture.

Surface Sterilization. Tissues are agitated in 20% Clorox (20 ml Clorox adjusted to 100 ml with distilled water) for 15 min, rinsed three times with sterile distilled water, and dried by gently pressing them between sterile paper towels.

Culture Vessels. Incubation and protoplast isolation are carried out in 35-mm-diameter Petri dishes. Centrifugation requires centrifuge tubes. Mixing of protoplasts for counting is carried out in test tubes. Plastic Petri dishes, 60-ml capacity, are used for fusion. In addition to the culture vessels this procedure requires Buchner funnels, centrifuge tubes, sterilizing filters and holders, a Fuchs–Rosenthal hemocytometer (see Appendices 1 and 2), and 80-μm nylon-mesh filters (Textco, 420 Saw Mill River Rd., Elmsford, NY 10523). Other equipment needed is an epifluorescence microscope (a brand made by Zeiss was used in the original research, but other brands can also be used) with a filter that can be set to a wavelength of 450–490 μm.

Culture Conditions. Incubation of tissue for protoplast release is carried out at room temperature (23 ± 2°C) on a gyrorotatory shaker at 30–50 rpm. It is not clear from the original paper whether this is done in the dark or under illumination. Protoplast cultures are incubated in the dark. Normal laboratory illumination and 22–24°C are suitable conditions for fusion.

Culture Media. Several media are used for protoplast release, isolation, culture, and fusion. For the isolation of protoplasts the tissues are incubated in an enzyme

solution consisting of 2% Cellulysin (Cal Biochem, P.O. Box 12087, La Jolla, CA 92112), 91.1 g sorbitol, and 1.5 g l^{-1} calcium chloride ($CaCl_2 \cdot 2H_2O$). The enzyme mixture is diluted 1 : 1 with a solution of 91.1 g sorbitol, 1.5 g calcium chloride ($CaCl_2 \cdot 2H_2O$), and 5 mmol (approximately 976 mg) MES (pH 6.0). This medium must be sterilized by filtration; use filters from Millipore Filter Corporation (see Appendices 1 and 2). The medium may not be autoclaved.

Protoplasts are cultured in a specially enriched medium (Table Angcm-1) or a minimal solution (Table Angcm-2). To check viability, protoplasts are stained with a solution of 100 μg fluorescein diacetate (available from Aldrich Chemical Co. and Sigma Chemical Co.; see Appendices 1 and 2).

Procedure. Following sterilization brush the undersides of sepals "100 times in each direction with small amounts of sterile carborundum" (Fisher 320 grit available from the Fisher Scientific, 2761 Walnut Ave., P.O. Box 9800, Tustin, CA 92681). Use a dry watercolor brush 1.25-mm wide sterilized by being soaked in 95% ethanol. Remove excess carborundum by washing the petals three to four times with sterile distilled water.

Incubate the sepals in the enzyme solution in 35-mm plastic Petri dishes for 1 day. At the end of the incubation period dilute the enzyme mixture 1 : 1 with the sorbitol–$CaCl_2$–MES solution. The mixture is filtered into a 15-ml centrifuge tube through two 80-μm nylon-mesh filters. (In the original research the nylon filters were held in place by a two-piece plastic Buchner funnel.) Sediment protoplasts by centrifuging the tubes at $100 \times g$ for 5 min. Resuspend the pellet in 5 ml sorbitol–$CaCl_2$–MES solution, and centrifuge again. After the second centrifugation, resuspend the protoplasts in 1 ml of either the enriched medium (Table Angcm-1), or the minimal solution (Table Angcm-2), and transfer the medium to sterile 35-mm-diameter plastic Petri dishes for incubation in the dark.

To count protoplasts place a specific volume of the suspension in a Fuchs–Rosenthal hemocytometer and count at a 400× magnification. Viability can be checked by staining the protoplasts with fluorescein diacetate, allowing them to stand for 15–30 min, and counting those that show a yellow-green fluorescence.

Fusion experiments were not carried out with *A. giryamae*, but a good starting point would be the method used for *Dendrobium*.

Developmental Sequence. Protoplast yield per gram of fresh weight was "very few." There are no reports of callus formation and plantlet regeneration from *A. giryamae* protoplasts.

General Comments. This procedure is clearly an early one and the beginning of a research process that will undoubtedly lead to effective procedures for: (1) the isolation and fusion of orchid protoplasts; and (2) the regeneration of plantlets from the protoplasts and/or fusion products.

TABLE ANGCM-1. **Enriched B5 medium (Gamborg et al., 1968) for the culture of *Angraecum giryamae* protoplasts (Price and Earle, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	134	13.4 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	735	73.5 g l^{-1}	10

30	Water, distilled[h]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add the microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxins do not dissolve, add a few drops of KOH or HCl.

[g]Add all vitamins to the same 100 ml of distilled water.

[h]Add items 1–7, 10, and 26 to 750 ml of distilled water (item 30). Adjust pH to 5.8, add sugars (items 27–29), and adjust volume to 900 ml with distilled water (item 30). Pour solution into a 2-l flask, and autoclave. Dissolve amino acids (items 8 and 9) in 100 ml 95% ethanol, and to this solution add auxins (items 11 and 12) and vitamins (items 13–25, all in 1 ml). Filter-sterilize mixture (Millipore Filter Corp., Bedford, MA 01730), add the mixture to autoclaved medium after it has cooled, mix well, and distribute medium to sterile containers as needed.

TABLE ANGCM-2. **Protoplast medium (Dudits et al., 1976*a*, 1976*b*) modified for the culture of *Angraecum giryamae* protoplasts (Price and Earle, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

20	Water, distilled[h]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add the microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops KOH or HCl, respectively.

[g]Add the vitamins to the same 100 ml of distilled water.

[h]Add items 1–11 and 17 to 800 ml of distilled water (item 20). Adjust pH to 5.5, add sugars (items 18 and 19), and adjust volume to 900 ml with distilled water (item 20). Pour solution into a 2-l flask and autoclave. Add items 12–16 to 100 ml distilled water, and sterilize through filters (Millipore Filter Corp., Bedford, MA 01730). Pour this solution into autoclaved medium after it has cooled, mix well, and distribute as needed.

Anoectochilus

Orchids are usually grown for their flowers. However "a small group . . . popularly called Jewel orchids is appreciated [and cultivated] for their foliage." Among these is the genus *Anoectochilus* "whose leaves appear as though woven from shimmering silken threads – a blending of cinnamon, purple, olive and moss green" (Gangaprasad et al., 2000). This genus consists of approximately 25 species distributed throughout Asia, Australia, and Polynesia. Unfortunately "seed capsules are seldom produced by the plants or under cultivation." Therefore, propagation through seeds is difficult and not common. Attempts to culture embryos were not successful. Even if it were successful, embryo culture cannot be used if capsules do not set. Conventional vegetative propagation is slow. Demand for jewel orchids is high and extensive collection has reduced native populations. They have been used as house plants, which means that selected cultivars have to be propagated clonally. A micropropagation method was developed to overcome these problems (Gangaprasad et al., 2000).

Anoectochilus elatus

Many protoplasts (550,000–3,100,000) were obtained from leaf mesophyll of this species (Gopalakrishnan and Seeni, 1987).

Anoectochilus formosanus (*Anoectochilus roxburghii*)

A tissue culture procedure for clonal propagation of seedlings was developed in Taiwan (Chow et al., 1982).

Plant Material. Seedlings produced through seed germination in vitro and maintained under aseptic conditions are used as sources of lateral bud explants and cuttings and for layering.

Surface Sterilization. Seeds are surface-sterilized in accordance with standard procedures (Arditti et al., 1982). There is no need to surface-sterilize the seedlings.

Culture Vessels. Erlenmeyer flasks and culture tubes are suitable.

Culture Conditions. The cultures should be maintained at 25 ± 2°C.

Culture Media. Seeds are germinated on a medium consisting of 3 g Hyponex, 2 g Bacto-peptone, and 30 g sucrose per liter; pH is adjusted to 5.2. MS medium containing (per liter) 0.5 mg NAA and 2 mg kinetin is used for lateral bud culture (Table Anct-1). The same medium containing 0.5 mg of either NAA, or 2,4-D and 3 mg kinetin per liter is used for cuttings in vitro (Table Anct-2). For in vitro layering 0.1 mg NAA and 2 mg kinetin are added per liter of MS medium (Table Anct-3).

TABLE ANCT-1. **Modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as used for the culture of lateral buds of *Anoectochilus formosanus* (*Anoectochilus roxburghii*) (Chow et al., 1982)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10

	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add the microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference is probably without much of an effect.

[e]Keep frozen between uses.

[f]If the auxin and cytokinin do not dissolve, add a few drops of KOH or HCl, respectively, to solubilize them.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 16), adjust pH as required, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. The agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add items 8 and 10–14 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE ANCT-2. **Modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for rooting of *Anoectochilus formosanus* in vitro (Chow et al., 1982)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add the microelements to the same 1 l of distilled water, and stir and/heat until all components are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference is probably without much of an effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin do not dissolve, add a few drops of KOH or HCl, respectively, to solubilize them.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 16), adjust pH as required, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add items 8 and 10–14 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

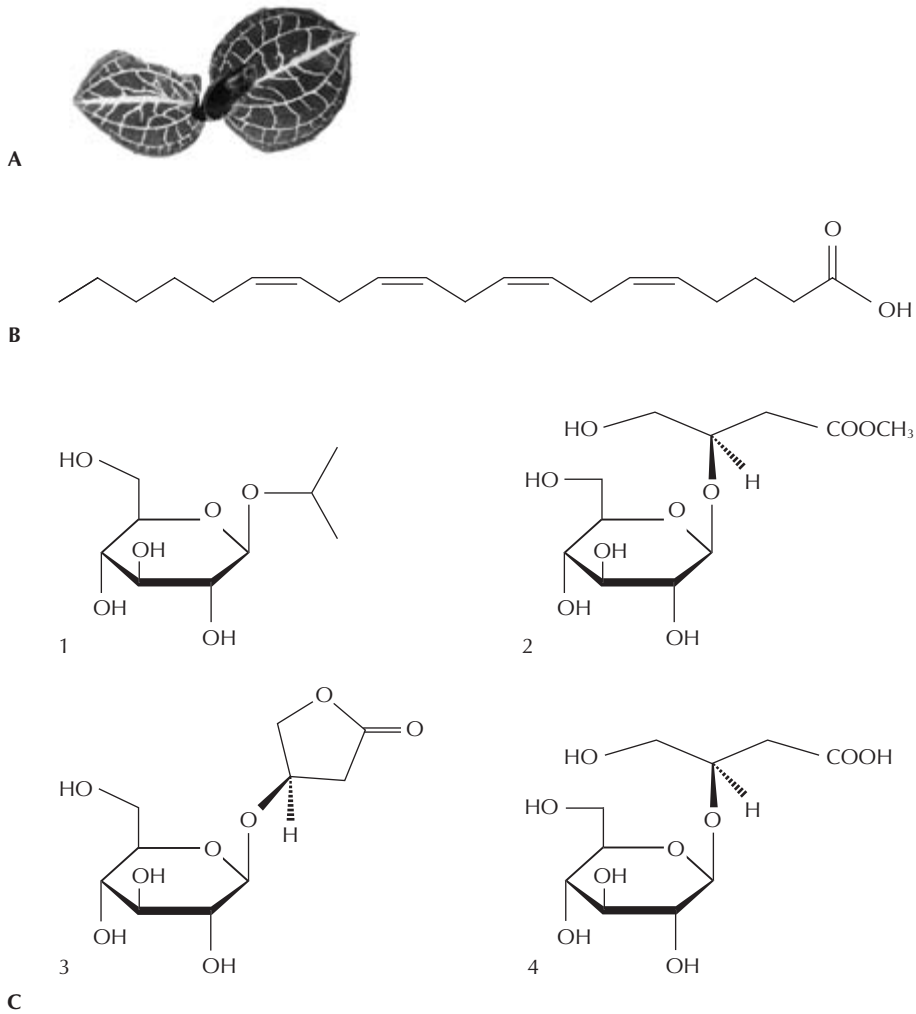

FIG. ANCT-1. **A. *Anoectochilus formosanus*. B. Substances from *A. formosanus*: arachidonic acid. C. Substances from *A. formosanus*: (1) 1-*O*-isopropyl-β-D-glucopyranoside; (2) methyl 3-*O*-β-D-glucopyranosyl-(3R)-4-dihydroxybutanoate; (3) 3-*O*-β-D-glucopyranosyl-(3R)-hydroxybutanolide; (4) 3-*O*-β-D-glucopyranosyl-(3R)-4-diydroxybutanoic acid. (Sources: B, internet; C, Du et al., 1998.)**

Procedure. Germinate seeds as usual. When the seedlings are large enough they can be layered and/or used as sources of lateral buds and/or cuttings.

Developmental Sequence. Plantlets form as a result of layering, from excised lateral buds, and from the cuttings.

General Comments. A difficulty encountered during the preparation of this entry is the fact that the original paper is not in English. The procedure itself seems workable, but it has been tried only with seedlings. This leaves unanswered the question

of whether this method can be used with explants from adult plants. Propagating seedlings may be necessary when seeds are not available and/or only a few seeds have germinated. However, from a horticultural standpoint it is more desirable to propagate outstanding mature plants.

As with most orchids, the nomenclature relating to this species is neither clear nor fully agreed upon. The original paper employed *Anoectochilus formosanus* Hayata in the title and that is why this name is being used here. *Anoectochilus roxburghii* has also been applied to this species.

Tissue culture of *Anoectochilus formosanus*

An orchid found in forests below 1500 m altitude in Taiwan, *Anoectochilus formosanus*, is used in Chinese herbal medicine to treat hypertension, tuberculosis, impotence, and underdeveloped children. These uses have lead to overcollection. Wild type *A. formosanus* contains substances that affect the metabolism of arachidonic acid, which is involved in cardiovascular system functions. A tissue culture method for *A. formosanus* was developed in Taiwan to determine whether "metabolic pathways of a plant tissue culture may differ from [those] of the original plant" (Huang et al., 1991).

Plant Material. Stem segments with nodes were taken from seedlings "originally collected in the field and . . . supplied by [the] Taiwan Agricultural Research Institute."

Surface Sterilization. "The herb" (probably meaning whole seedlings) was surface-sterilized in 70% alcohol (presumably ethanol) for 15 s and then washed in tap water for 20 min. After that the seedlings were sterilized a second time by sonication for a few (number not given) minutes in 1% sodium hypochlorite (probably a dilution of household bleach). The hypochlorite solution was decanted following the sonication and the plants were washed 4–5 times with sterile distilled water. Sonication may well be superfluous especially for plants that are immersed in a 1% sodium hypochlorite solution. However, tests should be carried out before eliminating it and sterilizing the seedlings only by immersion in 70% alcohol and 1% sodium hypochlorite. Also, since the number of minutes in 1% sodium hypochlorite is not given, the appropriate period may have to be determined through experimentation.

Culture Vessels. The original paper does not describe culture vessels. However the context of the paper suggests that they were Erlenmeyer flasks, 250-ml capacity or larger.

Culture Conditions. During the original research the cultures were maintained at 25°C under 16-h photoperiods of 27 μmol photons m^{-2} s^{-1}(400–700 nm) at plant height provided by Sylvania cool white fluorescent tubes.

Culture Media. Stem segments with nodes should be layered on half-strength MS medium containing 0.3 mg NAA l^{-1} and 3 mg kinetin l^{-1} (Table Anct-4). After the segments develop 3–4 leaves it is necessary to transfer them to MS medium

TABLE ANCT-4. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as used for layering of *Anoectochilus formosanus* stems (Huang et al., 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution

(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.3	30 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzyladenine	3.0	300 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The term "half strength" pertain only to the macroelements.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE ANCT-5. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as used for leaf-bearing stem segments of *Anoectochilus formosanus* (Huang et al., 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution

(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Kinetin	0.3	30 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.2, add sugar (item 15), and raise the volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

supplemented with 1 mg NAA and 0.3 mg kinetin l^{-1} (Table Anct-5) to induce root formation.

Procedure. After leaves and roots of the seedlings are removed, stem sections containing nodes (length and distance from nodes to cuts not given) should be placed on the first culture medium (Table Anct-4). When the explants develop 3–4 leaves they should be transferred to the second solution (Table Anct-5). Plantlets with leaves and well-developed root systems can be potted in a mixture of "moss peat, vermiculite and crushed tree fern" (ratio not given).

Developmental Sequence. Explants form leaves on the first medium (Table Anct-4), produce roots, and develop into plantlets on the second medium (Table Anct-5) and grow into plants in the potting mix.

General Comments. In the original research plants were propagated for use in pharmacological research and studies of butanoic acid glucosides (Du et al., 1998). This culture procedure can also be used for horticultural purposes because the limitations imposed by the use of seedlings as sources of explants do not apply to *A. formosanus*. It is grown for its decorative leaves and desirable variegations may be evident even in seedlings.

Micropropagation of *Anoectochilus regalis*

Plant Material. Nodal segments of shoots, 1 cm in length, were taken from plants collected in the Agasthyamalai area in the southwestern Ghats region of India and cultivated in the orchidarium of the Tropical Botanic Garden and Research Institute, Paloda, Trivandrum.

Surface Sterilization. Stem-tip cuttings, 4–5 cm long, should be washed well with water before their leaves are removed. After that the cuttings should be sectioned into 1-cm-long nodal segments. Sterilization of these segments involves several steps: a 15-min wash with running water and a soaking (period not specified) in 1% (v/v) mild detergent (Labolene, Glaxo India, Bombay was used in the original research; baby shampoo can also be used) before "passage through ethanol (70%) for 30 seconds and diluted Steriliq [Combii Organic Chem., (P) Ltd., New Delhi] containing 2% hypochlorite [a dilution of household bleach containing 2% sodium hypochlorite will probably be a suitable replacement] for 10 min." After that the explants should be washed once in sterile distilled water, immersed in 0.1% (w/v) mercuric chloride (this is a dangerous chemical which must be used with great care) for 6–7 min and rinsed three times with sterile distilled water. The last step is to cut off browned and damaged cut ends of the segments. This sterilization sequence seems overly elaborate and could perhaps be simplified based on experience in laboratories that decide to use the procedure.

Culture Vessels. Culture tubes, 25 × 150 mm containing 15 ml of medium were used in the original research. Other containers can also be used.

Culture Conditions. During the original research, the cultures were maintained at 25 ± 2°C under 12-h photoperiods of 25–50 µmol photons m^{-2} s^{-1} provided by fluorescent tubes (type not listed in the original paper). The lights employed for the *A. formosanus* procedure can be used.

Culture Media. Explants are cultured on a medium initially developed for woody plants supplemented with 2.2 µmol 6-benzylaminopurine (Table Anct-6). Shoots that form on the initial substrate are rooted on different modifications of the same medium containing 2.7 µmol of NAA (Table Anct-7).

Procedure. Explants are cultured on the first medium (Table Anct-6). Shoots which form on this medium should be transferred to the second solution (Table Anct-7) for rooting. Rooted plantlets must be washed with lukewarm water to remove all agar before they can be potted in community pots in a potting mixture composed of charcoal, broken tiles, and river sand (in the ratio 1 : 1 : 1, v/v/v). In the original research these pots were irrigated well and placed in a mist chamber where the relative humidity was 70–90%. After 6 months, established plants can be planted in humus-rich soil at 22–34°C and 80–90% relative humidity.

Developmental Sequence. Explants form shoots on the first medium (Table Anct-6), produce shoots on the second medium (Table Anct-7), and grow into hardened plants in the community pots.

General Comments. Plants produced by this method were reintroduced into their natural habitat and became established with 70% efficiency.

Micropropagation of *Anoectochilus sikkimensis*

The method developed for *Anoectochilus regalis* can also be used for this species (Gangaprasad et al., 2000).

Anoectochilus from the Greek ἀνοικός, *anoektos* (open) and χειλος, *cheilos* (lip), "referring to the lip which is adnate to the column but which, through a sharp bend in the isthmus, has its blades spreading to give it the appearance of openness." (Schultes and Pease, 1963)

TABLE ANCT-6. **Woody plants medium (Llyod and McCown, 1980; McCown and Sellmer, 1987) as used for the culture of *Anoectochilus sikkimensis* shoot cuttings (Gangaprasad et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400.0	40.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2$	96.0	9.6 g l^{-1}	10	
3	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$	556.0	55.6 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
5	Potassium sulfate, KSO_4	990.0	99.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	62.0 mg l^{-1}		
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.25	25.0 mg l^{-1}		
(c)	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	6-Benzylaminopurine	0.32	320 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.2	20 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	5.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

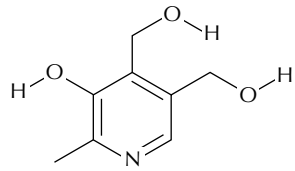
[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.2, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10) and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.



Pyridoxine/vitamin B_6

TABLE ANCT-7. **Woody plants medium (Llyod and McCown, 1980; McCown and Sellmer, 1987) as used for the culture of *Anoectochilus sikkimensis* shoots (Gangaprasad et al., 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	5.0 g	No stock	No stock	Weigh
	Darkening agent				
17	Charcoal	2.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.2, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, add darkening agent (item 17) slowly with vigorous stirring; after it has been completely dispersed pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10) and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Arachnis

Species and hybrids of *Arachnis* are of importance as cut flowers for exporting countries like Singapore and Thailand. Hobby growers also grow members of this genus. Many hybrids have been produced since World War II with the best known being *Arachnis* Maggie Oei (*Arachnis hookeriana* × *Arachnis flos aëris*). John Laycock, a well-known lawyer and political leader, made the cross, R. E. Holttum at the Singapore Botanic Gardens germinated the seeds, and the hybrid was registered in 1940.*

Clonal Propagation of *Arachnis* in Vitro

The first method for tissue culture of *Arachnis* was developed at the Chulalongkorn University Botany Department in Thailand by the husband-and-wife team of Thavorn and Montakan (Mon) Vajrabhaya (Vajrabhaya and Vajrabhaya, 1976*a*).

Plant Material. According to the original research, terminal and lateral buds of *A. hookeriana* are cultured. Only the four uppermost lateral buds are used. They are excised following removal of leaves.

Surface Sterilization. The newly excised buds should be surface-sterilized by immersing them in 5% Clorox (5 ml Clorox diluted with distilled water to 100 ml) for 5–8 min. After the leaves, sheaths, and other coverings are removed, the explant is placed in 1% Clorox (1 ml Clorox diluted to 100 ml) for 3 min. It is advisable to wash the sterilized explants three times with sterile distilled water.

Culture Vessels. Culture tubes are used for solid cultures, and 250-ml capacity Erlenmeyer flasks are employed for liquid media.

Culture Conditions. Cultures are maintained at 26–30°C under 14-h photoperiods and a light intensity of 2500 lx provided by fluorescent tubes. Liquid cultures should be placed on a reciprocating shaker at 50 rpm.

Culture Media. Buds are first placed on a solid modified MS medium (Table Arach-1). After 1 month the buds are transferred to a liquid medium (Table Arach-2).

Procedure. Excise the buds and place them on the solid medium (Table Arach-1). Move them daily from one position on the surface of the agar to another by gently tapping the sides of the culture vessel. When the buds are moved to the liquid medium (Table Arach-2) you may have to remove developing leaf primordia. Callus masses that form within 1–3 months should be subcultured. Regenerate plantlets by placing callus sections on solid sugar-containing medium (Table Arach-1).

* Laycock named the hybrid after his friend Ms. Maggie Oei, who cannot be traced at present. According to some longtime residents in Singapore she may have been employed at the time as a bar hostess or a dance hall dancer.

TABLE ARACH-1. **Modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as used for the culture of *Arachnis* buds (Vajrabhaya and Vajrabhaya, 1976*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (a concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	10	1 g l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	25	2.5 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	10	1 g l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
9	L-Tyrosine	100	100 mg 100 ml^{-1} 95% ethanol[f]	1	
	Polyol				
10	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
11	2,4-Dichlorophenoxyacetic acid (2,4-D)	0.5	100 mg 100 ml^{-1} 95% ethanol[g,h]	0.5	
	Vitamins				
12	Niacin (nicotinic acid)	5	500 mg 100 ml^{-1} 95% ethanol[h]	1	
13	Pyridoxine (vitamin B_6)	0.5	100 mg 100 ml^{-1} 95% ethanol[h]	0.5	
14	Thiamine (vitamin B_1)	0.1	20 mg 100 ml^{-1} 95% ethanol[h]	0.5	
15	Folic acid	0.5	100 mg 100 ml^{-1} 95% ethanol[h]	0.5	
16	Biotin	0.05	10 mg 100 ml^{-1} 95% ethanol[h]	0.5 mg	
	Complex additive				
17	Coconut water	100 ml	No stock	No stock	
	Sugar				
18	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
19	Water, distilled[i]	To 1000 ml			
	Solidifier				
20	Agar, Difco Bacto[i]	6 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the microelements to the same 1 l of distilled water, and stir and/heat until all components are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect. There are no cobalt or iodine salts in the Vajrabhaya–Vajrabhjaya medium, but these elements are present in the original formulation.

[e]Keep frozen between uses.

[f]This is not a stock solution but a means of sterilizing the tyrosine which must be dissolved or suspended in alcohol.

[g]If the auxin does not dissolve, a few drops of KOH can be used to solubilize it.

[h]Keep refrigerated between uses.

[i]Add items 1–7, 10, and 17 to 750 ml distilled water (item 19). Adjust pH to 5.2, add sugar (item 18), and adjust volume to 1000 ml with distilled water (item 19). Bring solution to a gentle boil, and add agar (item 20) slowly while stirring. Agar can also be added to the solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acids, vitamins, and hormones (items 8–16) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE ARACH-2. **A medium for the culture and proliferation of *Arachnis* buds (Vajrabhaya and Vajrabhaya, 1976*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (a concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$	500	50 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Potassium chloride, KCl	250	25 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	125	12.5 g l^{-1}	10	
6	Monosodium phosphate, $NaH_2PO_4 \cdot 2H_2O$	125	12.5 g l^{-1}	10	
7	**Chelated iron**				
(a)	Chelating agent, Na_2EDTA	22.4	2.24 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	16.7	1.67 g l^{-1}		
8	**Microelements**[c]				
(a)	Boric acid, H_3BO_3	1	100 mg l^{-1}	10	One solution
(b)	Cobaltous chloride, $CoCl_2 \cdot 6H_2O$	0.02	2 mg l^{-1}		
(c)	Copper chloride, $CuCl_2 \cdot 2H_2O$	0.01	1 mg l^{-1}		
(d)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	2	200 mg l^{-1}		
(e)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.02	2 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.1	10 mg l^{-1}		
	Amino acid				
9	Glycine	7.5	750 mg 100 ml^{-1} 95% ethanol[d]	1	
	Vitamins				
10	Calcium pantothenate	0.25	25 mg 100 ml^{-1} 95% ethanol[d]	1	
11	Niacin	1.25	125 mg 100 ml^{-1} 95% ethanol[d]	1	
12	Pyridoxine hydrochloride (vitamin B_6)	0.25	25 mg 100 ml^{-1} 95% ethanol[d]	1	
13	Thiamine hydrochloride (vitamin B_1)	0.25	25 mg 100 ml^{-1} 95% ethanol[d]	1	
	Complex additive				
14	Coconut water	100 ml	No stock	No stock	
	Sugar				
15	Sucrose[e]	0 or 20 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[f]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the microelements to the same 1 l of distilled water, and stir and/heat until all components are dissolved. Dispense the volume indicated per liter of culture medium.

[d]Store in a refrigerator of freezer between uses.

[e]No sugar is added to the liquid medium used for culture of 1-month-old explants moved from the initial medium (Table Arach-1). When this medium is used to regenerate plantlets, it must contain 20 g sucrose per liter.

[f]Add items 1–7 and 14 to 700 ml distilled water (item 16), and adjust pH to 5.2. Add sugar (item 15) only to medium used to regenerate plantlets from callus but not to liquid medium used to subculture explants from first medium. Adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring to medium used for plantlet regeneration from callus (not the sugar-free medium used to subculture explants from the first medium). Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into culture vessels and autoclave. Add amino acid (item 9) and vitamins (items 10–13) under sterile conditions with sterilized pipettes to the medium while its is still hot and liquid.

Developmental Sequence. Callus masses form within 1–3 months. When subcultured onto suitable media these tissues regenerate plantlets. Callus induction occurs on a high-salt solution containing medium to high levels of sucrose, 10% coconut water, and 0.5 ppm 2,4-D. Growth of callus is best on a glucose- and auxin-free low-salt medium that contains 10% coconut water. Regeneration takes place on a solution that has a medium level of sucrose, 10% coconut water, and no auxin.

General Comments. This is a very useful and successful method (68% of the explants form callus) that has not attracted wide attention only because it was published in the Thai language. The outline given here was supplied by Vajrabhaya and Vajrabhaya. Monopodial orchids are somewhat more difficult to culture than sympodial ones. T. Vajrabhaya has written in a letter to JA that "monopodial orchids generally grow better in coconut water [containing media] *without adding sucrose*. For callus growth low-salt formulae plus coconut water are much better than the high salt (with high ammonium ion levels) media."

Tissue Culture Propagation of *Arachnis* in Vitro

A tissue culture laboratory was established at the Singapore Botanic Gardens in the early 1970s. Within the first few years this laboratory was successful in culturing several orchid hybrids. In 1978 the laboratory initiated a tissue culture service for local growers. By 1981 the laboratory was successful in culturing six orchid species and more than 100 hybrids (Lim-Ho, 1981).

Plant Material. Apical and axillary buds from the upper 10 cm of shoots of *Arachnis hookeriana* and *Arachnis* Capama 'Merah' (*Arachnis* Maggie Oei × *Arachnis breviscapa*) were cultured at the Singapore Botanic Gardens. Other species and hybrids of this genus can probably also be cultured. Cubes 0.2 mm on each side are excised from the apices of buds. Care should be taken to excise only meristematic cells and not the surrounding tissue.

Surface Sterilization. Leaves are removed to expose the apical and axillary buds. The shoot is then washed with detergent and water before being submerged in 10–12% Clorox (10–12 ml Clorox diluted to 100 ml with distilled water) for 10–15 min. The original paper does not mention subsequent rinses with sterile distilled water, but they are advisable.

Culture Vessels. Erlenmeyer flasks of 100-ml capacity and containing 20 ml of medium were used in the original research, but other containers are also suitable.

Culture Conditions. All cultures are maintained under continuous illumination of 2000 lx at 21–25°C. Liquid cultures are shaken. No information is given about shakers or rpm, except the indication that "the mode of shaking is not significant, however, too violent shaking has been observed to cause browning-off of protocorm[-like bodies]."

TABLE ARACH-3. **Modified Vacin and Went medium (Vacin and Went, 1949) for initial culture of shoot tips from apical and axillary buds of *Arachnis* (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (a concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

9	Coconut water	150 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml of water, and stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation contains an iron source that is hard to dissolve. Chelated iron is preferable.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1, 3–7, and 9 to the 500 ml of distilled water (item 10), which contains the calcium phosphate (item 2), and set the pH to 5.2–5.5. Adjust volume to 1000 ml with distilled water (item 10), pour the medium into a 2-l flask, and autoclave. Add the auxin (item 8) to the autoclaved medium under sterile conditions, swirl several times to mix well, and dispense into presterilized culture vessels. Do not add agar if liquid medium is being prepared.

Culture Media. Initial culture is in a liquid modification of the Vacin and Went medium (Table Arach-3). Multiplication and differentiation can take place in two different, solid modifications of the same medium (Tables Arach-4 and Arach-5). A fourth modification (Table Arach-6) is used for plantlet formation.

Procedure. Explants are first placed in a liquid medium (Table Arach-3). When PLBs have formed, they are moved to solid medium (Tables Arach-4 or Arach-5). Plantlets are cultured on the fourth medium (Table Arach-6).

Developmental Sequence. PLBs develop from the explants on the first (liquid) medium. They proliferate and start to differentiate on the second or third medium (both of which are solid) and develop plantlets on the fourth (also solid).

General Comments. *Arachnis* species often produce phenolics that may inhibit growth. For this reason it is necessary to move the explants and PLBs to fresh medium weekly for the first 6 months. Growth is "extremely slow."

TABLE ARACH-4. **Modified Vacin and Went medium (Vacin and Went, 1949) for the proliferation and differentiation of *Arachnis* explants (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (a concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	Measure
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation contains an iron source that is hard to dissolve. Chelated iron is preferable.

[e]Add items 1 and 3–8 to the 500 ml distilled water (item 9) that contain the calcium phosphate (item 2), set the pH to 5.2–5.5, and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. The agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar for liquid medium.

The micropropagation laboratory at the Singapore Botanic Gardens is still in existence and still under the direction of Dr. Lim-Ho. The literature search for this edition did not find any publications from it.

TABLE ARACH-5. **Modified Vacin and Went medium (Vacin and Went, 1949) for the proliferation and differentiation of *Arachnis* explants (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock No stock		
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	2 g[e]	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add the other components after that.

[d]The original formulation contains an iron source that is hard to dissolve. Chelated iron is preferable.

[e]The usual amount of sugar added to this medium is 20 g.

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 10) that contain the calcium phosphate (item 2). Set the pH to 5.2–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved dispense the medium into culture vessels and autoclave.

Emil Vacin, a gas mask manufacturer during World War II, and Professor Frits W. Went, a noted plant physiologist during his time and discoverer of the first plant hormone (auxin), formulated their medium at the California Institute of Technology after noting that the pH of the Knudson C solution drops considerably as a result of seedling growth. Their aim was to develop a medium which maintains its pH without change, but they did not accomplish that. Professor Knudson was not very pleased by their efforts (see Arditti, 1990 for an historical account). Vacin and Went did not name their medium after themselves. Others did that.

TABLE ARACH-6. **Modified Vacin and Went medium (Vacin and Went, 1949) for plantlet formation from *Arachnis* explants (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock No stock		
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additives				
8	Coconut water	75 ml	No stock	No stock	Measure
9	Tomato juice[e]	75 ml	No stock	No stock	Measure
10	Banana homogenate[f]	75 g	No stock	No stock	Weigh
	Sugar				
11	Sucrose	2 g[g]	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[h]	To 1000 ml			
	Solidifier				
13	Agar	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 300 ml of water, and stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation contains an iron source that is hard to dissolve. Chelated iron is preferable.

[e]Commercial juices (even those labeled "all natural") may contain preservatives that could inhibit growth. Tomato seeds may also contain inhibitors. Therefore it is advisable to prepare fresh tomato juice (item 9) by squeezing a few tomatoes and filtering to remove the seeds.

[f]Place ripe-but-still-firm banana slices in a homogenizer, and add 150 ml distilled water. Homogenize for 1–2 min, allow a 5-min interval, and homogenize again for 1 min. To prepare item 10 pour the homogenate into a beaker, wash the homogenate three times with 50-ml portions of distilled water, and combine the washings.

[g]The usual amount of sugar added to this medium is 20 g.

[h]Add items 1 and 3–10 to the 300 ml of distilled water (item 12) that contain the calcium phosphate (item 2), and set pH to 5.2–5.5. Add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring solution to a gentle boil, and add agar (item 13) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave.

Isolation of Cells from *Arachnis* Maggie Oei

Certain studies of orchid physiology can be carried out better with isolated cells since the use of whole plants or organs presents certain difficulties. To overcome these difficulties investigators at the Botany Department, National University of Singapore, isolated living cells from aerial roots, leaves, and petals of orchids (Hew and Yip, 1986).

Plant Material. Leaves, petals, and roots were taken from plants of *Arachnis* Maggie Oei (*Arachnis hookeriana* × *Arachnis flos aeris*) grown under full sunlight in Singapore.

Surface Sterilization. Since the cells were isolated for the purpose of using them in experiments and not for culture, the explants were not surface-sterilized. Those who wish to isolate cells for axenic cultures should experiment with several surface-sterilization procedures perhaps using a number of dilutions of sodium (household bleach) or calcium hypochlorite followed by several washes with sterile distilled water.

Vessels, Apparatus, and Equipment. Incubation in the enzyme mixture should be carried out in test tubes (30 mm in diameter × 60 mm in length) covered with a tight-fitting cap. Mechanical maceration can be accomplished with a round-end glass rod in 10 ml washing medium inside a Petri dish. Mortar and pestle are suitable for mechanical grinding, also in 10 ml medium.

Centrifuge tubes and a swinging-bucket centrifuge are best suited for centrifugation. Density-gradient centrifugation should be performed in centrifuge tubes layered with 1.5-ml portions of (starting from the bottom) 1.5, 1.2, 0.8, and 0.4-*M* solutions of sucrose. The cell suspensions can be filtered through a nylon sieve (which can be obtained from Hygro-Bios Apparatebau, G. M. B. H., Germany) with a pore size 2 μm smaller than the cells (Miracloth from Calbiochem is also suitable). Cells retained by the filter (nylon sieve or Miracloth) should be washed into a 50-ml beaker.

Isolation Conditions. The enzyme mixture should be infiltrated into the tissues under vacuum. This is accomplished by placing tissues in the enzyme mixture inside a test tube and infiltrating it under vacuum. Incubation should be carried out at 29°C without agitation or in a shaking water bath at 29°C. Room temperature is suitable for maceration and grinding. Culture conditions are not listed in the original paper because the cells were not cultured. It is reasonable to assume that the conditions used for the culture of *Aranda* protoplasts will also be suitable for cells.

Culture Media. The maceration medium consists of 0.5% (w/v) Macerozyme R-10 (Yakult Honsha Co., Ltd., Japan; available in the United States from Serva Biochemicals, Inc., 200 Shames Dr., Westbury, NY 11590), sorbitol, potassium dextran sulfate, and inorganic salts (Table Arach-7). Washing should be carried out with an enzyme-free solution (Table Arach-8). Incubation can be carried out in a medium containing less sorbitol plus HEPES buffer (Table Arach-9). Density-gradient centrifugation requires 1.5, 1.2, 0.8, and 0.4-*M* solutions of sucrose (513.45, 410.76, 273.84, and 136.92 g l^{-1}, respectively).

TABLE ARACH-7. **Maceration medium for isolation of cells from tissues of *Arachnis* Maggie Oei (Hew and Yip, 1986)**

		Amount per 10 ml		
Component		Weight	Percent	Molarity[a]
Calcium chloride, $CaCl_2$		0.11 mg		0.1 m*M*
Copper sulfate, $CuSO_4$		0.02 µg		0.01 µ*M*
Macerozyme R-10[b]		50 mg	0.5	
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$		0.12 mg		0.1 m*M*
Potassium iodide, KI		1.66 µg		1 µ*M*
Potassium nitrate, KNO_3		1.01 mg		1 m*M*
Monopotassium phosphate, KH_2PO_4		0.27 mg		0.2 m*M*
Potassium sulfate, K_2SO_4[c]		2.18 g		1.25 m*M*
Sorbitol		1.5 g		0.8 *M*
pH	5.8[d]			

[a]µ*M*, m*M*, and *M* stand for micromolar, millimolar, and molar, respectively, and refer to the concentration of a solution in terms of molarity; these units differ from micromoles, millimoles, and moles, which pertain to amounts (weight) of a substance. For example, a 1-m*M* solution is prepared by dissolving 1 mmol in 1 l.

[b]Yakult Honsha Co., Japan; available in the United States from Serva Biochemicals, Inc., 200 Shames Dr., Westbury, NY 11590.

[c]May be replaced with 0.3% (w/v) potassium dextran sulfate (30 mg per 10 ml).

[d]The pH can be adjusted downward (made more acidic) with a 1.0-*M* solution of hydrochloric acid (86 ml of concentrated HCl diluted to 1 l with distilled water), or upward (made more basic) with a 1.0-*M* solution of potassium hydroxide (56.11 g l^{-1}).

TABLE ARACH-8. **Washing medium for isolated cells of *Arachnis* Maggie Oei (Hew and Yip, 1986)**

		Amount per 10 ml		
Component		Weight	Percent	Molarity
Calcium chloride, $CaCl_2$		0.11 mg		0.1 m*M*
Copper sulfate, $CuSO_4$		0.02 µg		0.01 µ*M*
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$		0.12 mg		0.1 m*M*
Potassium iodide, KI		1.66 µg		1 µ*M*
Potassium nitrate, KNO_3		1.01 mg		1 m*M*
Monopotassium phosphate, KH_2PO_4		0.27 mg		0.2 m*M*
Potassium sulfate, K_2SO_4[a]		2.18 g		1.25 m*M*
Sorbitol		1.5 g		0.8 *M*
pH	5.8[b]			

[a]May be replaced with 0.3% (w/v) potassium dextran sulfate (30 mg per 10 ml).

[b]The pH can be adjusted downward with 1.0-*M* hydrochloric acid (86 ml concentrated HCl diluted to 1 l with distilled water), or upward with 1.0-*M* potassium hydroxide (56.11 g l^{-1}).

TABLE ARACH-9. **Incubation medium for isolated cells of *Aachnis* Maggie Oei (Hew and Yip, 1986)**

		Amount per 10 ml		
Component		Weight	Percent	Molarity
Calcium chloride, $CaCl_2$		0.11 g		0.1 m*M*
Copper sulfate, $CuSO_4$		0.02 µg		0.01 µ*M*
HEPES buffer		0.119 g		0.05 *M*
Magnesium sulfate, $MgSO_4 \cdot 7H_2O$		0.12 mg		0.1 m*M*
Potassium iodide, Hl		1.66 µg		1 µ*M*
Potassium nitrate, KNO_3		1.01 mg		1 m*M*
Monopotassium phosphate, KH_2PO_4		0.27 mg		0.2 m*M*
Potassium sulfate, K_2SO_4[a]		2.18 g		1.25 m*M*
Sorbitol		0.94 g		0.5 *M*
pH	7.0[b]			

[a]May be replaced with 0.3% (w/v) potassium dextran sulfate (30 mg per 10 ml).

[b]The pH can be adjusted downward with 1.0-*M* hydrochloric acid (86 ml of concentrated HCl diluted to 1 l with distilled water), or upward with 1.0-*M* potassium hydroxide (56.11 g l^{-1}).

Procedure. Rinse freshly detached leaves with distilled water and blot them dry before removing the midribs and peeling the cuticle and lower epidermis (Fig. Arach-1). Then cut the laminas (leaf blades) into strips measuring approximately 10×15 mm. When roots are used, it is necessary to remove the velamen because only the underlying green tissue can be used. Cut it into 3×3-mm sections. Cut petals like leaves.

Place approximately 1 g tissue in 15 ml of enzyme solution inside a test tube and infiltrate it by subjecting it to a short period of mild vacuum followed by standard conditions and repeating the process two or three times. Incubate the tissue in the enzyme solution in a shaking water bath (100 oscillations or strokes per second) at 29°C for 1 h. After that, place the tissues in a Petri dish with 10 ml of washing solution and mash them by tapping lightly with a rounded glass rod until a distinctly green suspension is obtained. The suspension can be removed at this point and the tissue may be macerated again with another 10 ml of medium. This can be repeated several times, and the cell suspensions should be pooled. Separate the cells from smaller debris by filtering them through a nylon sieve that retains them. Wash cells retained by the filter into a 50-ml beaker with washing medium and centrifuge them in a swinging-bucket centrifuge at 80 g for 3 min. Resuspend the pellet containing the cells in 20 ml of washing medium, and recentrifuge under the same condition. After repeating this twice, resuspend the cells in 5 ml of incubation medium. Further purification of the cells can be accomplished by density-gradient centrifugation. This is carried out in a test tube containing 1.5-ml layers of (starting from the bottom) 1.5, 1.2, 0.8, and 0.4-*M* solutions of sucrose. At the end of all purification steps the cells can be counted with a hemocytometer, or their density can be determined by measuring the turbidity of the suspension as OD_{680}.* Chlorophyll and protein concentrations can also be measured. Since the initial isolation in the original study was intended to produce cells for physiological studies no culture procedures are given. The flowchart in Fig. Arach-1 outlines the procedure just described above as well as alternatives.

Developmental Sequence. The cells were used for physiological experiments and not cultured. For this reason no information is available regarding their development.

General Comments. This procedure is not intended to produce cells for culture. However, it can be a good starting point for procedures to produce cells and protoplasts that can be cultured.

Professor Choy sin Hew, now retired from the National University of Singapore received the Singapore National Science award in 1997 for his orchid research. He richly deserves it.

* Optical density (a measure of light transmission through a solution) at a wavelength of 680 nm.

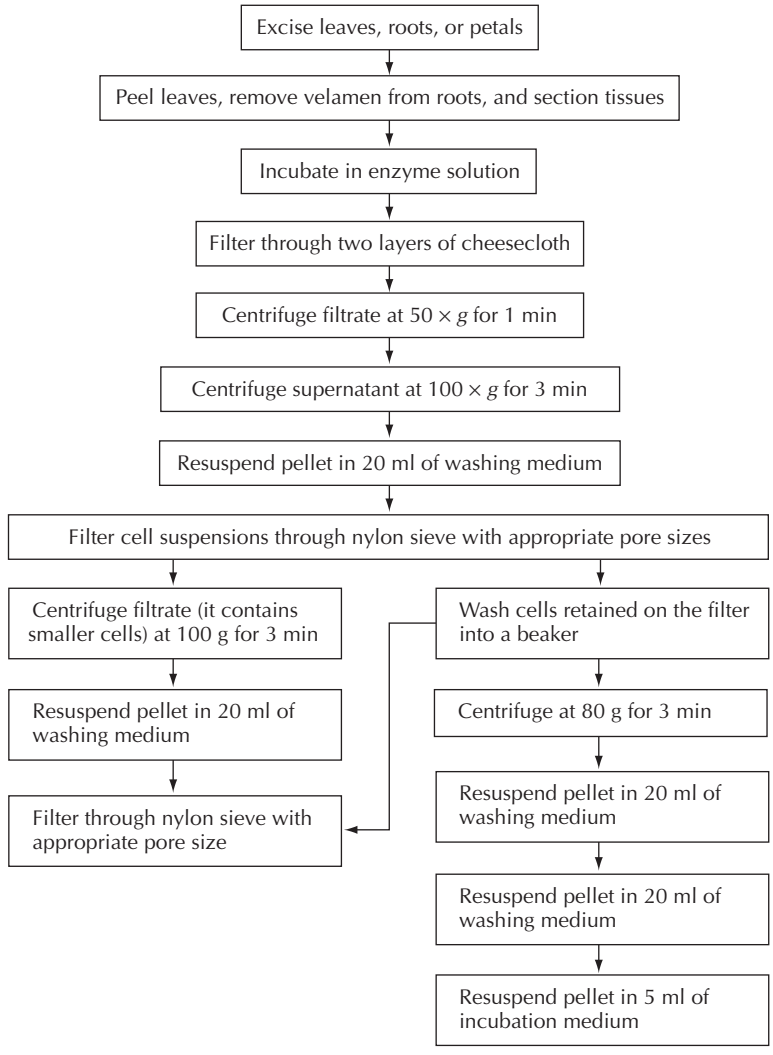

FIG. ARACH-1. **Isolation of cells for *Arachnis* (Hew and Yip, 1986; C. S. Hew, Botany Dept., National University of Singapore, personal communication).**

Arachnostylis

Apical and axillary buds of the human-made hybrid *Arachnostylis* Charcalood (*Arachnis hookeriana* × *Rhynchostylis gigantea*) were cultured at the Singapore Botanic Gardens by the methods used for *Aranda*. Explants were first cultured in a liquid modification of the MS medium (see Table Arach-6). Proliferation and differentiation occur on two solid modifications of the same medium (see Tables Arach-4 and Arach-5). A solid version of the first medium (see Table Arach-6) is used for plantlet formation. Explant growth is slow.

Agar or agar agar is a Malay/Indonesian term for an edible seaweed. In Indonesia and Malaysia agar is used for cooking and as a gelling agent for confectionary items. The agar used to gel culture media is also made from algae, more specifically *Gelidium*. Fanny Angeline "Lina" Eilhemius (b. New York in 1850), a talented artist and biological illustrator, suggested the use of agar as a gelling agent to her husband Dr. Walther Hesse (whom she met while traveling in Europe and married in 1874), who was assistant to Dr. Robert Koch (of Koch's postulates fame) having joined his laboratory in 1881.

Aranda

A hybrid genus (*Arachnis* × *Vanda*) of considerable importance, *Aranda* has been cultured by a number of investigators. Shoot tips of *Aranda* Wendy Scott 'Greenfield' (*Arachnis hookeriana* × *Vanda Rothschildiana*) were cultured successfully on the Vacin and Went medium "modified by reduction of agar to 0.9% for solid and no agar for liquid culture, occasional deletion of 2% sucrose and addition of coconut water . . . 15% by volume and green banana . . . 50 g/1" (Cheah and Sagawa, 1978). The procedure is "successful" (Sagawa and Kunisaki, 1982). In Thailand *Aranda* tissue "grew profusely without . . . auxins and cytokinins" on Schenk–Hildebrandt medium (Vajrabhaya and Vajrabhaya, 1976*b*).

Aranda has been cultured in Malaysia (Alang, 1975), and extensive studies there (Khaw et al., 1978*a*, 1978*b*) have shown that 0.25–0.5 NAA and 0.25–0.50 mg l^{-1} BA enhanced the growth of PLBs of *Aranda* Christine No. 1 (*Arachnis hookeriana* × *Vanda* Hilo Blue). Other *Aranda* hybrids and clones cultured successfully from shoot tips and/or axillary-bud explants are *Aranda* Christine Nos 5, 9, and 80; *Aranda* Wendy Scott; *Aranda* Tay Swee Eng [*Aranda* Lily Chong (*Arachnis* Ishbel × *Vanda sanderiana*) × *Vanda* Piha Moon]; *Aranda* Majulah (*Arachnis* Maggie Oei × *Vanda insignis*); *Aranda* Chong Chee Yuen; *Aranda* Noorah Alsagoff (*Arachnis hookeriana* × *Vanda* Dawn Nishimura); *Aranda* Lum Chin (*Arachnis* Maggie Oei × *Vanda* Hilo Blue); *Aranda* Lily Chong (*Arachnis* Ishbel × *Vanda sanderiana*); and *Aranda* Kooi Choo [*Aranda* Lucy Laycock (*Arachnis hookeriana* × *Vanda tricolor*) × *Vanda* Hilo Blue]. All of these *Aranda* crosses and clones were cultured on a nutrient medium consisting of the Vacin and Went macroelements (Vacin and Went, 1949) and the Heller's microelements (Heller, 1953) plus coconut water (Table Aranda-1) and hormones as indicated above (Khaw et al., 1978*a*, 1978*b*).

In Singapore *Aranda* Christine was cultured on MS medium (Singh, 1980; Lee and Mowe, 1983). The most detailed studies pertaining to *Aranda* shoot-tip and axillary-bud meristem culture were carried out at the National University of Singapore (Goh, 1973, 1981, 1983*a*; Goh and Loh, 1974–1975; Loh et al., 1975; Loh and Rao, 1985; Manorama et al., 1986). The tissues were cultured on MS, Vacin and Went, and White (White, 1943) media. These reports, pertaining to *Aranda* crosses with different *Arachnis* and *Vanda* pedigrees, suggest that the requirements of the hybrid genus *Aranda* are similar and not limited to a single formulation.

TABLE ARANDA-1. **A medium consisting of the Vacin and Went macroelements (Vacin and Went, 1949), Heller's microelements (Heller, 1953), chelated iron, and other additives for the culture of shoot-tip and auxillary-bud explants of *Aranda* (Khaw et al., 1978*a*, 1978*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10

11	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[h]	To 1000 ml			
	Solidifier				
13	Agar	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Then add other components of medium after that.

[d]This form of iron is not used in original formulation but is preferable.

[e]Add all microelements to the same 1 l of distilled water; if salts dissolve slowly, heat solution.

[f]Keep in a refrigerator or freezer between uses. The original paper suggests that 0.25–0.50 ppm of this hormone is suitable; therefore we recommend 0.25 ppm since it is always best to use the lowest hormone concentration that will accomplish the desired purpose.

[g]Keep frozen between uses.

[h]Add items 1, 3–7, and 10 to the 500 ml of distilled water (item 12) that contain the calcium phosphate (item 2), and adjust pH as required. Add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring solution to a gentle boil, and add agar (item 13) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, sterilize solution by autoclaving and add items 8 and 9 to hot, still-liquid solution under sterile conditons. Mix well, and distribute into preautoclaved culture vessels.

Clonal Propagation of *Aranda* from Apical Meristem Tissues

A method developed for *Aranda* Deborah (*Arachnis hookeriana* × *Vanda lamellata*) at the University of Singapore (Goh, 1973; Arditti, 1977*b*) was improved by the original investigator and his associates (Goh and Loh, 1974/75; Loh et al., 1978; Goh, 1981).

Plant Material. The top parts of shoots were excised from plants, and their leaves were removed to expose apical and axillary buds. Following a wash, sterilization, and rinse, a wedge-shaped section containing the bud is removed with a sterile scalpel. With apical meristems the larger leaves are removed first and the tissue is washed, sterilized, and rinsed. Then the remaining younger leaves and leaf primordia are removed, and the apical portion (about 4 mm long) is cultured.

Surface Sterilization. The excised stem sections should be washed thoroughly first with tap water and then with distilled water. After the wash the tissue is cut into sections, two to three internodes in length. Shoot tips are then sterilized in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 10 min. Sections with axillary buds are sterilized in 15% Clorox (15 ml Clorox diluted to 100 ml) for an equal period. The sterilized explants are washed three times with sterile distilled water and sterilized Petri dishes. Shoot tips and axillary buds are then excised from the stem sections, rinsed again with sterile distilled water, and placed in culture.

Culture Vessels. Erlenmeyer flasks of 100-ml capacity containing 25 ml of medium are suitable.

Culture Conditions. Explants in liquid medium should be maintained under diffuse light of 1000 lx for 11-h photoperiods at 27°C on a reciprocal shaker at 80 oscillations per minute (Goh and Loh, 1974/75), but a rotary shaker at 100 rpm may also be suitable (Goh, 1973). Cultures on solid medium are maintained at 24 ± 1°C under 3000 lx and 12-h photoperiods.

Culture Media. Liquid Vacin and Went medium containing 20 g sucrose and supplemented with coconut water (Table Aranda-2) is used to proliferate callus tissues and protocorms. Solid medium (Table Aranda-2) is used for plantlet formation (Goh and Loh, 1974/75). White's medium supplemented with coconut water and peptone (Table Aranda-3) may also be suitable (Goh, 1973).

Procedure. After excision place the buds in liquid medium and culture them until enough callus or PLBs form. Then transfer these to solid medium for differentiation.

Developmental Sequence. Shoot tips swell after 3–4 weeks, the enlargement continues for a total of 1.5–2 months, and the explants triple in size and become spherical. PLBs appear near the apical dome after 3 months and proliferate. If left in liquid medium the PLBs form globular masses of yellowish callus. When moved to solid medium these PLBs produce rhizoids and plantlets 6–7 cm tall after 9 months. The callus masses form plantlets after 6–7 weeks. In all cases leaves appear before roots.

TABLE ARANDA-2. **Vacin and Went medium (Vacin and Went, 1949) as used for the culture of *Aranda* explants (Loh et al., 1978; Goh, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water[e]	200 ml	No stock	No stock	
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution of chelated iron, dissolve 37.3 mg of the chelating agent Na_2EDTA and 27.8 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Keep frozen between uses.

[f]Add items 1 and 3–7 to the 500 ml distilled water (item 10) that contains the calcium phosphate (item 2), adjust pH as required, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil; if agar (item 11) is to be included, add it slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium.

Axillary buds enlarge slowly and form a dome-shaped structure after 3 months. PLBs form approximately 4 months after inoculation. Callus tissues are also formed. When moved to solid medium the PLBs and callus tissue form plantlets.

General Comments. A multitude of PLBs and plants could be produced using the original method (Goh, pers. comm. 1973; Arditti, 1977*b*). The improved procedures render this task easier and faster. These or similar procedures have been used for the culture apices of axillary buds of *Aranda* Nancy (*Arachnis hookeriana* × *Vanda dearei*) and are probably suited for other *Aranda* crosses.

TABLE ARANDA-3. **White's medium (Singh and Krikorian, 1981)[a] as used for the culture of *Aranda* explants (Goh, 1973)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[c]	288	28.8 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	737	73.7 g l^{-1}	10	
3	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	19	1.9 g l^{-1}	10	
4	Potassium chloride, KCl	65	6.5 g l^{-1}	10	
5	Potassium nitrate, KNO_3[c]	80	8 g l^{-1}	10	
6	Sodium sulfate, Na_2SO_4	200	20 g l^{-1}	10	
7	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	3.4	344 mg l^{-1}	10	One solution

11	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
13	Peptone	2 g	No stock	No stock	Weigh
	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[h]	8 g	No stock	No stock	Weigh

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation, and modernization of the medium (Singh and Krikorian, 1981).

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron, add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add the salts to the same 1 l of distilled water and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to include.

[g]Keep refrigerated or frozen between uses.

[h]Add items 1–8 and 13 to 900 ml distilled water (item 15), adjust pH to 5.2, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil and add agar (item 16) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add items 9–12 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if a liquid medium is desired.

Clonal Propagation of *Aranda* from Leaf-tip Tissues of Young Plantlets

Removal of shoot tips or axillary buds may lead to the loss of an entire plant. The excision of leaf tissues does not create such a danger, and for this reason a procedure was developed for the propagation of *Aranda* from leaf tips (Loh et al., 1975).

Plant Material. Leaf tips approximately 5 mm in length can be removed from seedlings or plantlets produced through tissue culture.

Surface Sterilization. Surface sterilization is not needed because the leaf tips are taken from axenically grown plants.

Culture Vessels. Erlenmeyer flasks of 100-ml capacity, each containing 20 ml of medium, are suitable.

Culture Conditions. Liquid cultures should be maintained on a reciprocating shaker (80 oscillations per minute) under diffuse light of approximately 1000 lx, photoperiods of 11 h, and a temperature of about 29°C. Solid cultures are maintained under the same conditions, except that shaking is not done.

Culture Medium. Liquid Vacin and Went medium with coconut water (Table Aranda-2) is used.

Procedure. Excise leaf tips, place them in medium, and culture them. When PLBs develop after about 12 weeks, remove and subculture them in liquid medium, where plants may develop. These plantlets may also develop well on solid medium.

Developmental Sequence. Leaf tips remain green and form cream- or green-colored callus bodies after 4–6 weeks. Callus formation is greater on the upper epidermis. The callus masses produce PLBs after 8–10 weeks. Clumps of PLBs form within 12–14 weeks, each body measuring 1–2 cm. Plantlets form from the PLBs.

General Comments. This is a useful procedure for the propagation of axenic plants. Leaf tips removed from plants not growing aseptically in flasks would have to be surface-sterilized. This procedure (Manorama et al., 1986) has also been used with leaf tips and other segments of *Aranda* Deborah, *Aranda* Hilda Galistan (*Arachnis hookeriana* × *Vanda suavis*), *Aranda* Lucy Laycock (*Arachnis hookeriana* × *Vanda tricolor* var. *purpurea*) and *Aranda* Mei Ling (*Arachnis hookeriana* × *Vanda coerulea*). For details see *Dendrobium* entry, Clonal Propagation of *Dendrobium crumenatum* from Leaves (p. 545, Vol. I; Manorama et al., 1986).

Clonal Propagation of *Aranda* from Leaf Tissues of Mature Plants

A problem with the culture of leaf segments of seedlings is that they are plants of unknown quality. Culturing leaves of plants obtained through the culture of shoot

tips or axillary buds may be unnecessary since a method for their clonal propagation exists already. Therefore a clonal propagation procedure that utilizes leaf tissues from adult plants is very desirable. Such a procedure was developed at the Singapore Botanic Gardens (Fu, 1978, 1979*b*).

Plant Material. Whole young leaves, 1–3 cm long and 0.5–1 cm wide, of mature plants of *Aranda* Christine Nos 27 and 130 (*Arachnis hookeriana* × *Vanda* Hilo Blue) and *Aranda* Wendy Scott (*Aranda hookeriana* × *Vanda* Rothschildiana) were used in the original experiment. Similar leaves of other *Aranda* clones and hybrids can also be used.

Surface Sterilization. The leaves are sterilized in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 15–20 min. The original paper does not mention washing the sterilized leaves with sterile distilled water, but two to three such washes are advisable.

Culture Vessels. Erlenmeyer flasks or other standard vessels are suitable.

Culture Conditions. Liquid cultures are maintained on a reciprocating shaker (the number of oscillations per minute is not given, but 80–100 seems appropriate) for 16 h day^{-1} at 28°C and illuminated continuously with a "Sylvania Gro-Lux 30w tube." The information regarding the source of illumination is clearly insufficient, but it is reasonable to assume that most standard light sources and intensities would be suitable.

Culture Media. A liquid modified MS medium is used for initial culture and proliferation (Table Aranda-4). Once formed, the PLBs should be transferred to a second modification of the Vacin and Went medium (Table Aranda-5) for further growth. Another modification of the Vacin and Went medium (Table Aranda-6) or the Knudson C solution (Tables Aranda-7 and Aranda-8) with or without banana should prove suitable for subsequent plantlet regeneration.

Procedure. Remove young leaves from the plants, sterilize them, wash them after that with sterile distilled water, and then culture them in liquid medium (Table Aranda-9) until the tissues proliferate and PLBs form. Then transfer these bodies to the second solid medium for further proliferation and plantlet regeneration.

Developmental Sequence. The leaves, and particularly their bases, proliferate and form PLBs. These also proliferate further; on being transferred to solid medium the new PLBs produce plantlets.

General Comments. Since the initial medium contains high amounts of hormones, the original papers recommend that as soon as enough PLBs are produced, they should be transferred to the low-hormone medium (Table Aranda-5) and "kept in this medium to serve as stocks." This is a good suggestion, but the PLBs should not be kept as stocks for prolonged periods even in this medium since long-term culture in any solution may lead to undesirable variants.

TABLE ARANDA-4. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as used for the culture of *Aranda* leaf explants (Fu, 1978, 1979*a*, 1979*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, Kl	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	1	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	2,4-Dichlorophenoxyacetic acid (2,4-D)	2	200 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
11	Benzylaminopurine (benzyladenine, BA)	2	200 mg 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.25	25 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.25	25 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	1	100 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
15	Coconut water[h]	150 ml	No stock	No stock	
	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[i]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin and/or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively, to solubilize them.

[g]Keep refrigerated between uses.

[h]Keep frozen between uses.

[i]Add items 1–7, 9, and 15 to 900 ml distilled water (item 17), adjust pH to 5.0, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil and add agar (item 18) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add items 8 and 10–14 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

TABLE ARANDA-5. **Liquid Vacin and Went medium (Vacin and Went, 1949) as used for the maintenance of protocorm-like bodies of *Aranda* (Fu, 1978, 1979*a*, 1979*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml
	Macroelements			
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10
	Iron[d]			
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock
	Microelement			
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10
	Complex additive			
8	Coconut water[e]	150 ml		
	Solvent			
9	Water, distilled[f]	To 1000 ml		

[a]Amounts are given in mg unless indicated otherwise.

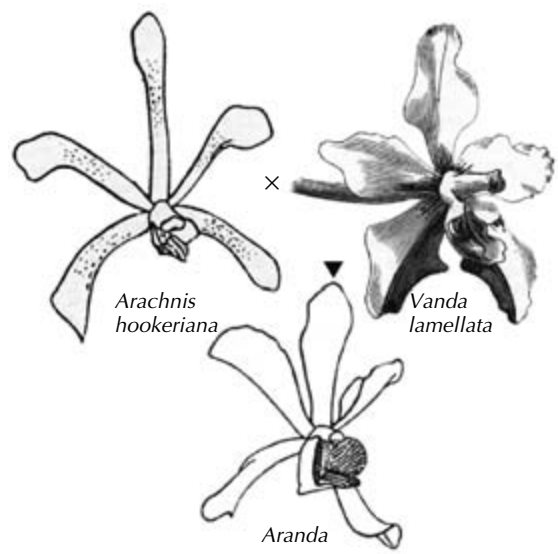
[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg chelating agent Na_2EDTA and 27.8 mg of ferrous sulfate, $FeSO_4 \cdot 7H_2O$, in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Keep frozen between uses.

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 9) that contains the calcium phosphate (item 2). Adjust pH to 5.0, bring volume to 1000 ml with distilled water (item 9), and autoclave.



Hybrid genus *Aranda* (source: Williams and Williams, 1894; Holttum, 1964).

TABLE ARANDA-6. **Vacin and Went medium (Vacin and Went, 1949) as used for plantlet regeneration from protocorm-like bodies derived from *Aranda* leaves (Fu, 1978, 1979*a*, 1979*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock

	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution of chelated iron, dissolve 37.3 mg chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Add items 1 and 3–7 to the 500 ml distilled water (item 9) that contains the calcium phosphate (item 2), adjust pH to 5.0–5.2, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels, and autoclave.

TABLE ARANDA-7. **Knudson C medium (Knudson, 1946)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
7	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
8	Water, distilled[d]	To 1000 ml			
	Solidifier				
9	Agar[d]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution, dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[d]Add items 1–6 to 900 ml of distilled water (item 8), adjust pH to 5.0, add sugar (item 7), and adjust volume to 1000 ml with distilled water (item 8). Bring solution to a gentle boil, and add agar (item 9) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary, adjust the pH upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. A dilute solution of hydrochloric acid (HCl) should be used to lower the pH if necessary.

TABLE ARANDA-8. **Modified Knudson C medium (Knudson, 1946)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.06	6 mg l^{-1}	10	One solution
(b)	Copper sulfate (anhydrous), $CuSO_4$	0.04	4 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}		
(d)	Molybdic acid, MoO_3	0.02	2 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.35	35 g l^{-1}		
	Sugar				
7	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
8	Water, distilled[e]	To 1000 ml			
	Solidifier				
9	Agar[e]	12–15 g	No stock	No stock	Weigh

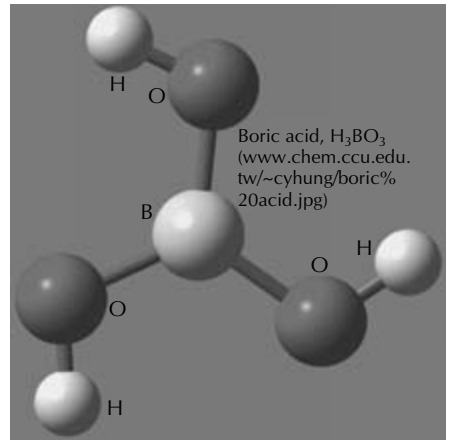
[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Add items 1–6 to 900 ml distilled water (item 8), adjust pH to 5.0–5.2, add sugar (item 7), and adjust volume to 1000 ml with distilled water (item 8). Bring solution to a gentle boil, and add agar (item 9) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When the agar is completely dissolved, pour solution into culture vessels and autoclave.



Boric acid, H_3BO_3 (www.chem.ccu.edu.tw/~cyhung/boric%20acid.jpg)

TABLE ARANDA-9. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the differentiation of *Aranda* explants (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, monobasic KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Cytokinin-related substance				
10	Adenine sulfate[f]	40	No stock	No stock	Weigh
	Vitamins				
11	Niacin (nicotinic acid)	5.0	500 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
13	Coconut water	150 ml	No stock	No stock	Weigh
	Sugar				
14	Sucrose	2.0 g[h]	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[i]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]This compound is not soluble in alcohol and somewhat soluble in water (1 g/150 ml). Therefore weigh and suspend it in combination with items 8 and 10–12 (3 ml alcohol) and allow to stand for 20–30 min in a closed sterile container with occasional swirling. Even if most of the substance will not dissolve this treatment will sterilize it. Shake vigorously before dispensing to ensure its dispersion in the solution.

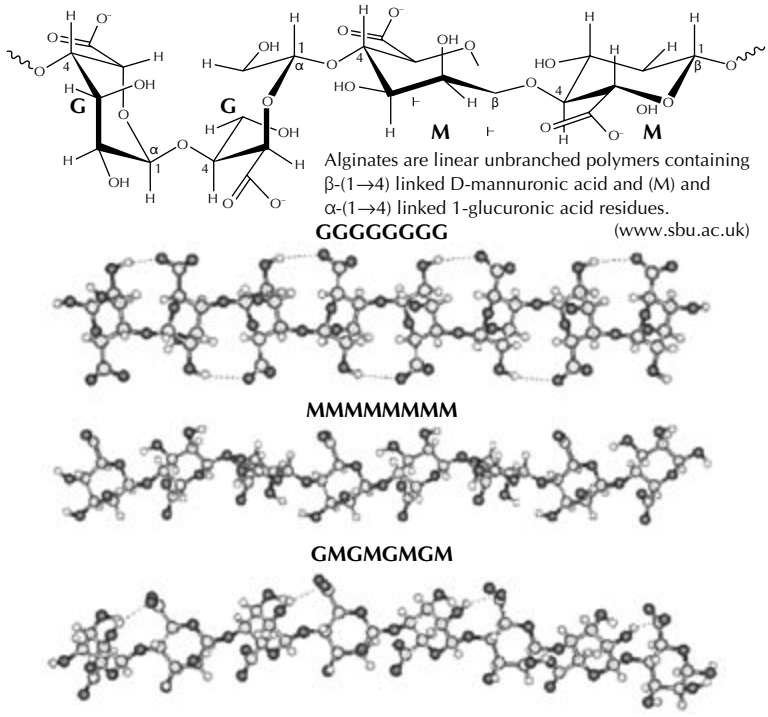
[g]Keep refrigerated between uses.

[h]The usual amount of sucrose added to this medium is 30 g.

[i]Add items 1–7, 9, and 14 to 150 ml distilled water (item 15), adjust pH to 5.2–5.7, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil, and add the agar (item 16) slowly while stirring. The agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add combined amino acid, adenine sulfate, and vitamins (items 8 and 10–12) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

Tissue Culture Propagation of *Aranda* from Buds

Thirty *Aranda* hybrids have been cultured at the Singapore Botanic Gardens (Lim-Ho, 1981). Of these, 27 were cultured from apical and axillary buds by the method used for *Arachnis* (Lim-Ho, 1981). The initial culture medium is a liquid modification of the Vacin and Went solution (see Table Arach-4). Multiplication and differentiation occur on a solid version of this medium (see Table Arach-4) or another modification (see Table Arach-5). Plantlet formation occurs on a third modification (see Table Arach-6). Growth is usually slow, and some hybrids may differentiate faster on a modification of MS medium (Table Aranda-9). Root formation may be better on a modified Knudson C medium (Table Aranda-10).



Alginates are used in some micropropagation procedures.

TABLE ARANDA-10. **Knudson C medium (Knudson, 1946) modified for root induction on plantlets of *Aranda* (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	400	40 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	400	40 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	100	10 g l^{-1}	10	
5	**Chelated Iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
6	**Microelements**[d]				
(a)	Aluminum chloride, $AlCl_3$	0.03	3 mg l^{-1}	10	One solution
(b)	Boric acid, H_3BO_3	1.0	100 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.03	3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}		
(e)	Potassium iodide, KI	1.0	100 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4$	1.0	100 mg l^{-1}		
	Complex additives				
7	Banana homogenate[e]	75.0 g	No stock	No stock	Weigh
8	Pineapple juice[f]	150 ml	No stock	No stock	No stock
	Sugar				
9	Sucrose	2 g[g]	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[h]	To 1000 ml			
	Solidifier				
11	Agar[h]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original medium does not include chelated iron, but this form is preferable.

[d]Add all microelements to the same 1 l of distilled water, stir or heat until they are dissolved, and dispense as needed.

[e]Slice the banana (ripe but still firm) into a homogenizer, add 100 ml distilled water, and homogenize for 1–2 min. Let it stand for 5 min, and homogenize for another minute. Pour the homogenate into a beaker. Wash the homogenizer three times with 50 ml distilled water and combine the washings with the homogenate. The result is item 7.

[f]Juices, even those labeled "natural," may contain preservatives that can inhibit growth. Therefore it is preferable to use only freshly prepared juice.

[g]The usual amount of sugar added to this medium is 12–18 g.

[h]Add items 1–8 to 500 ml distilled water (item 10), adjust pH to 5.0–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust pH upward with a dilute potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary. Omit agar for liquid medium.

Tissue Culture Propagation of *Aranda* from Leaves

Of the 30 *Aranda* hybrids cultured in the Singapore Botanic Gardens, two were cultured from whole leaves and three from leaf bases (Lim-Ho, 1981).

Plant Material. Young leaves taken from mature plants of *Arachnis* Christine Nos 27 and 130 (*Arachnis hookeriana* × *Vanda* Hilo Blue; whole leaves cultured for both), *Arachnis* Noorah Alsagoff (*Arachnis hookeriana* × *Vanda* Dawn Nishimura; leaf base cultured), *Arachnis* Queen of Purples (*Arachnis hookeriana* × *Vanda coerulea*; leaf base cultured), and *Arachnis* Wendy Scott 'Green Field' (*Arachnis hookeriana* × *Vanda* Rothschildiana; leaf base cultured).

Surface Sterilization. The leaves are washed with detergent and water and submerged in 10–12% Clorox (10–12 ml Clorox diluted to 100 ml with distilled water). There is no mention of subsequent washing with sterile distilled water, but this step is desirable.

Culture Vessels. See *Arachnis* entry, Tissue Culture Propagation of *Arachnis* in Vitro (p. 186, Vol. I; Lim-Ho, 1981).

Culture Conditions. See *Arachnis* entry, Tissue Culture Propagation of *Arachnis* in Vitro (Lim-Ho, 1981).

Culture Media. Initial culture is in a liquid modification of the MS medium (Table Aranda-11).

Procedure. Whole leaves are placed in culture and when callus and/or PLBs form they are treated like bud explants (Lim-Ho, 1981).

Developmental Sequence. Not described in the original report.

General Comments. A method utilizing leaves is always desirable since it does not damage or endanger the plant(s) from which the explants are taken.

Aranda Deborah is the first *Aranda* raised in the Singapore Botanic Gardens. This vigorous, free flowering, and sun-loving hybrid was a popular cut flower for a long time. It was also one of the major cut flower orchids exported from Singapore. Its inflorescences are 40–50 cm long and bear up to 14 flowers on each. Flowers are 5 cm in diameter. The sepals and lateral petals are cream colored with purple streaks and irregular spots.

TABLE ARANDA-11. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for initial culture of *Aranda* leaves (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, Kl	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxins				
10	Indoleacetic acid (IAA)	0.3	30 mg 100 ml^{-1} 95% ethanol[f]	1	
11	2,4-Dichlorophenoxyacetic acid (2,4-D)	1.5	150 mg 100 ml^{-1} 95% ethanol[f]	1	
	Cytokinin and related substance				
12	Adenine sulfate[g]	40	No stock	No stock	Weigh
13	6-Benzyladenine (BA)	1.25	125 mg 100 ml^{-1} 95% ethanol[f]	1	
	Vitamins				
14	Niacin (nicotinic acid)	5.0	500 mg 100 ml^{-1} 95% ethanol[f,g]	1	
15	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[f]	1	
	Complex additive				
16	Coconut water	150 ml	No stock	No stock	Weigh
	Sugar				
17	Sucrose	2.0 g[h]	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[i]	To 1000 ml			
	Solidifier				
19	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference that probably has little effect.

[e]Keep frozen between uses.

[f]Keep refrigerated or frozen between uses.

[g]This compound is not soluble in alcohol and somewhat soluble in water (1 g/150 ml). Therefore weigh and suspend it in combination with items 8 and 10–15 (7 ml alcohol), and allow to stand for 20–30 min in a closed sterile container with occasional swirling. Even if most of the substance will not dissolve, this treatment will sterilize it.

[h]The usual amount of sucrose added to this medium is 30 g.

[i]Add items 1–7, 9, and 16 to 750 ml distilled water (item 18), adjust pH to 5.2–5.7. Add sugar (item 17), and adjust volume to 1000 ml with distilled water (item 18). Bring solution to a gentle boil, and add agar (item 19) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When the agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add combined amino acid, auxins, adenine sulfate, and vitamins (items 8 and 10–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar for liquid medium.

Isolation and Culture of Mesophyll Protoplasts from Leaves of *Aranda* Noorah Alsagoff

The culture of isolated protoplasts offers many interesting possibilities. One is very rapid clonal propagation since it is theoretically possible to obtain microcalli and more than one plant from each protoplast (i.e., cell). Another is the selection of variants since individual protoplasts may differ genetically from each other. The third, perhaps most exciting, possibility is protoplast fusion to produce hybrids that cannot be obtained through sexual hybridization. Protoplasts of several orchids, including *Aranda*, have been isolated and cultured for short periods (Loh and Rao, 1985).

Plant Material. The original research was carried out with leaves 1–2 cm long taken from plantlets 2–4 cm tall that were grown in vitro and derived from shoot-tip cultures of *Aranda* Noorah Alsagoff (*Arachnis hookeriana* × *Vanda* Dawn Nishimura). These plantlets were maintained on a modified MS medium containing 10% coconut water, 2% sucrose, and 0.8% agar, under continuous illumination provided by white fluorescent tubes at 25°C.

Surface Sterilization. None is needed because the leaves are taken from plants grown under aseptic conditions in vitro.

Culture Vessels. Plastic Petri dishes 50 mm in diameter are used.

Culture Conditions. Both the culture of protoplasts and the incubation of tissues for the isolation of protoplasts should be conducted at 25°C in the dark.

Culture and Isolation Media. Four enzyme mixtures were screened in the original research, and the highest yield of protoplasts (1,000,000 g^{-1} of fresh weight of tissue) was obtained with a mixture of 1% Onozuka R-10 cellulase (from Yakult Honsha Co., Ltd., Japan; for a similar and reportedly improved cellulase available from Cal Biochem, see Appendix 2), 0.2% Macerozyme R-10 (from Yakult Honsha Co., Ltd., Japan; an improved enzyme of this nature, a pectinase, is available from Cal Biochem), 0.5% Driselase (from Kyowa Hakko Kogyo Co., Japan; available in the United States from Fluka Chemical Corp., 980 South Second St., Ronkonkoma, NY 11779) and 0.5-*M* mannitol (91.1 g mannitol per liter of distilled water). The enzyme mixtures must be sterilized by filtration. Protoplasts can be cultured in two media (Tables Aranda-12 and Aranda-13), both of which are modifications of the Vacin and Went medium.

Procedure. All procedures must be carried out under aseptic conditions. Cut the leaves transversely into strips about 1 mm long. Then place approximately 500 mg of these strips in 10 ml of the enzyme mixture in plastic Petri dishes and seal them with Parafilm (see Appendix 2). Incubate the dishes in the dark at 25°C for 5 h on a gyrorotatory shaker at 40 rpm. Following the incubation, filter the suspensions through a layer of Miracloth (obtainable from Cal Biochem) and centrifuge the filtrate containing the chloroplasts at 150 times the force of gravity ($\times g$) for 1 min. Resuspend the resulting pellet in a 0.4-*M* solution of mannitol (72.9 g mannitol per

TABLE ARANDA-12. **Vacin and Went macroelements (Vacin and Went, 1949) supplemented for the culture of mesophyll protoplasts of *Aranda* Noorah Alsagoff (Loh and Rao, 1985): I**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[f]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	2,4-Dichlorophenoxyacetic acid (2,4-D)	1	100 mg 100 ml^{-1} 95% ethanol[f]	1	
	Cytokinin				
11	Kinetin (6-furfurylaminopurine)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
13	Pyridoxine·HCl (Vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
14	Thiamine·HCL (Vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[f]	1	
	Sugar				
15	Glucose	72 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of the medium after that.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of water, and heat if necessary to dissolve it.

[f]Keep refrigerated or frozen between uses.

[g]Add items 1 and 3–14 to the 500 ml distilled water (item 16) that contains the calcium phosphate (item 2). Adjust pH to 5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Sterilize the medium by filtration through a sterilizing filter (e.g., Millipore brand), and use as needed. This medium can probably also be autoclaved.

TABLE ARANDA-13. **Vacin and Went macroelements (Vacin and Went, 1949) supplemented for the culture of mesophyll protoplasts of *Aranda* Noorah Alsagoff (Loh and Rao, 1985): II**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
16	Glucose	72 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of water, and heat if necessary to dissolve it.

[f]Keep refrigerated or frozen between uses.

[g]Add items 1 and 3–15 to the 500 ml distilled water (item 17) that contain item 2. Adjust pH to 5.5, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Sterilize the medium by filtration through a sterilizing filter (e.g., Millipore brand), and use as needed. This medium can probably also be autoclaved.

liter of water), and centrifuge the suspension again at 150 × *g* for 1 min. Repeat this washing procedure three times.

For culture, suspend the washed protoplasts at a density of 100,000 ml^{-1} medium in 50-ml-capacity plastic Petri dishes. Adjust the medium (Tables Aranda-12 and Aranda-13) to pH 5.5 and filter-sterilize it.

Developmental Sequence. The isolated protoplasts may be 30–100 μm in diameter with about 60% being in the 40–50-μm range. Raphide-containing idioblasts are also released. After 7 days in culture most of the protoplasts remain intact and approximately 15% may divide or elongate. Following 10 days in culture about 12% of the protoplasts may divide. The percentage of dividing protoplasts may increase to 48% in a medium containing 2,4-D and kinetin (Table Aranda-12) and 62% when the medium contains 2,4-D, NAA, and kinetin (Table Aranda-13). Budding can also be observed in these media. Small cell clusters may be observed after 20 days in culture, but at this point the cells die and lyse.

Ceneral Comments. When this was written there were no reports of fully successful protoplast cultures of orchids. This procedure was a major advance at the time. Media and procedures have improved and protoplasts are now kept alive much longer.

Isolation and Culture of Leaf Protoplasts of *Aranda* Tay Swee Eng and *Aranda* Noorah Alsagoff

Aranda protoplasts were first isolated and cultured at the Botany Department, National University of Singapore (Loh and Rao, 1985) by C. S. Loh (who obtained her undergraduate degree there, a Ph.D. elsewhere, and is now a faculty member at NUS) and by A. N. Rao (the department's long-time effective leader and excellent chairman). Loh was also responsible for an attempt to develop a second procedure (Koh et al., 1988).

Plant Material. Plantlets of *Aranda* Tay Swee Eng (*Aranda* Lily Chong × *Vanda* Piha Moon) and *Aranda* Noorah Alsagoff (*Arachnis hookeriana* × *Vanda* Dawn Nishimura), through the culture of shoot tips as described in the previous method (Loh and Rao, 1985), were the source of the leaves from which the protoplasts were isolated for the original research. Callus tissues and PLBs were also produced from leaves (0.5–1 cm long) of *Aranda* Tay Swee Eng through methods developed for *Vanda* (Loh et al., 1975). Young leaves (< 1–3 cm in length), taken from plantlets 2–5 cm in height, were used for protoplast isolation.

Surface Sterilization. Plantlets were cultured in vitro under axenic conditions; there was no need for surface sterilization.

Culture Vessels. Standard vessels can be used to culture the plants that are used as a source of explants. Test tubes, vials, Petri dishes, centrifuge tubes, and other suitable laboratory glassware may be used for the isolation of protoplasts. The isolated protoplasts should be cultured in 14-μl droplets of medium in sealed plastic Petri dishes.

Culture and Protoplast Isolation Conditions. Plantlets used as sources of protoplasts should be maintained under conditions of 22–24°C and 16-h photoperiods. Incubation of leaf explants must be at 30°C in the dark for 7 h (for *Aranda* Noorah Alsagoff) or 10 h (for *Aranda* Tay Swee Eng) on a gyrorotatory shaker at 40 rpm. Protoplasts ($0.8–1.5 \times 10^5$ ml^{-1}) are cultured in the dark at 23 ± 2°C.

Culture Media. Media used for the culture of the donor plants are listed in the procedures for *Aranda* and *Vanda* (Loh et al., 1975; Loh and Rao, 1985). The enzyme mixture for the isolation of protoplasts consists of 1.5% (w/v) Onozuka R-10 cellulase, 0.5% (w/v) Driselase, and 136.92 mg l^{-1} sucrose (0.4-*M* solution). This mixture must be sterilized through a filter. Isolated protoplasts are washed with: (1) a filter-sterilized 0.4-*M* (136.92 mg l^{-1}) sucrose solution, and (2) a filter-sterilized culture medium. Protoplasts are reported to survive for 9 weeks in a modification of the Kao–Wetter 8p medium (Table Aranda-14).

Procedure. Leaves of *Aranda* Tay Swee Eng, less than 1 cm in length, released the largest number of protoplasts [1.97×10^6 g^{-1} fresh weight (FW)]. Leaves 1–3 cm and 3–6 cm in length released a smaller number (1.69×10^6 and 0.93×10^6, respectively). Callus masses can also be used; those of *Aranda* Tay Swee Eng release 0.5×10^4 protoplasts g^{-1} FW. Excise the leaves at their bases, and cut them transversely into 1-mm strips. Also section callus masses into small pieces. Immerse approximately 1.5 g of leaves (and presumably the same amount of callus) in 10 ml of the filter-sterilized enzyme mixture, and incubate them in the dark with agitation on a gyrorotatory shaker at 40 or 50 rpm (the original paper gives both figures), at 30°C for 7 h (for *Aranda* Noorah Alsagoff) or 10 h (for *Aranda* Tay Swee Eng). Following incubation, filter the enzyme–explant–protoplast mixture through Miracloth (obtainable from Cal Biochem; see Appendix 2) to remove large debris. After that centrifuge the filtrate for 5 min at 90 g. The green pellet at the bottom of the centrifuge tube will contain the protoplasts. Wash it twice with the 0.4-*M* sucrose solution and once with the filter-sterilized culture medium by resuspending and centrifuging.

The number of protoplasts (i.e., their density) can be determined by counting with an American Optical (AO) hemocytometer.

In the original research protoplasts were cultured in 14-µl drops of filter-sterilized medium with a density of 0.8 to 1.5×10^5 ml^{-1} in sealed plastic Petri dishes (i.e., a strip of Parafilm was wrapped around the circumference) at 23 ± 2°C in the dark. Staining with fluorescein acetate can be used to determine viability. However, this step can be omitted since viable protoplasts that are not dividing and slowly dying are simply lingering on. Cultures of such protoplasts can be discerned easily with a minimum of practice. Two signs of such cultures reported and/or observed by other workers involve many protoplasts that (1) are plasmolysed and/or (2) have burst and (3) are in aggregates. Only cultures of appropriate density that contain many dividing protoplasts are of any significance unless the purpose of the isolation is to obtain material for short-term experiments.

Developmental Sequence. The protoplasts seem to have survived for approximately 60 days, and only 2% divided.

TABLE ARANDA-14. **Kao–Wetter 8p medium (Kao and Wetter, 1977) modified for the culture of *Aranda* protoplasts (Koh et al., 1988)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

32	Xylose	125	No stock	No stock	Weigh
	Solvent				
33	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original medium (Kao and Wetter, 1977) and the modification (Koh et al., 1988) use 28 mg F330 per liter of medium. This commercial preparation contains the ferric sodium salt of EDTA, which is essentially similar to the chelated iron listed here. To prepare chelated iron add chelating agent (item 5a) and iron salt (item 5b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If 2,4-D or BA does not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Add all items to 700 ml of distilled water (item 33), set pH to 5.6, and adjust volume to 1000 ml with distilled water (item 33). A solution of this type should be sterilized by filtration. Agar is not added to liquid media. This medium can probably also be autoclaved.

General Comments. Like most other attempts to isolate orchid protoplasts this procedure did not result in the formation of callus or the regeneration of plants. However, there can be no doubt that with time these workers or others will be able to isolate orchid protoplasts and regenerate plants from them.

Carbon–Nitrogen Ratios, Protocorm Formation, and Chlorophyll Content in Callus Tissues of *Aranda* Tay Swee Eng

After 31 days in culture on Vacin and Went medium containing 0–2% fructose, the number of PLBs that developed from callus tissue of *Aranda* Tay Swee Eng (*Aranda* Lily Chong × *Vanda* Piha Moon) was inversely proportional to the residual carbon–nitrogen (C/N) ratio. Chlorophyll content of the protocorms was directly proportional to the initial C/N ratio (Table Aranda-15; Chia et al., 1988).

TABLE ARANDA-15. **Relation between carbon/nitrogen ratio, formation of protocorm-like-bodies and chlorophyll content in callus of *Aranda* Tay Swee Eng (Chia et al., 1988)**[a]

	Fresh weight of tissues, g			Carbon–nitrogen ratios × 10			Chlorophyll content, µg per gram of fresh weight tissue	Protocorm-like bodies, % per flask
Fructose, % w/v	Initial	Final	Gain[b]	Initial	Residual	Difference[b]		
0	1.09	3.78	2.69	14.5	2.1	–12.4	179	146
0.25	1.01	2.55	1.54	21.4	6.9	–14.5	133	74
0.50	1.05	2.40	1.35	27.9	25.8	–2.1	119	45
1.00	1.03	2.42	1.39	41.4	30.1	–11.3	106	37
2.00	1.04	2.35	1.31	68.2	122.8	+54.6	59	13

[a]The tissues were cultured on Vacin and Went medium containing 10% (v/v) coconut water. Data were taken after 31 days in culture and are the means of several replicas.

[b]Recalculated for this table from the original paper.

Utilization of Glucose by Callus Tissues of *Aranda* Noorah Alsagoff

Glucose uptake by callus tissues of *Aranda* Tay Swee Eng (*Arachnis* Lily Chong × *Vanda* Piha Moon) and *Aranda* Noorah Alsagoff (*Arachnis hookeriana* × *Vanda* Dawn Nishimura) follows linear kinetics and is a function of the initial glucose concentration. Only the peripheral cell layers seem to be involved in the uptake (Hew et al., 1987).

Micropropagation of *Aranda* Deborah through the Culture of Inflorescence-tip Explants

In monopodial orchids, excision of a shoot-tip explant can endanger or even destroy the donor plant itself. Therefore methods utilizing other explants were developed for several of these orchids. One of these procedures utilized inflorescence tip explants to propagate a well-known *Aranda* hybrid (Goh and Wong, 1990).

Plant Material. Tips, 0.5–1.0 cm long, should be excised from developing inflorescences, 20–40 cm in length.

Surface Sterilization. The explants must first be washed with liquid detergent (2% Teepol, a petrochemically based detergent first produced in 1938 by Shell in Great Britain, was used in the original research, but baby shampoo or almost any mild detergent can be employed) and rinsed with distilled water several times. After that the explants should be immersed in 8% Clorox (80 ml of this or any other household bleach that contains 5.25% sodium hypochlorite adjusted to 1000 ml with distilled water; only 70 ml of 6% Clorox should be used) plus a few drops of Tween 20 (or baby shampoo or a mild household detergent) for 20 min. Following a few rinses with sterile distilled water, the explants should be immersed for 15 min in 4% Clorox (40 ml of this or any other household bleach that contains 5.25% sodium hypochlorite adjusted to 1000 ml with distilled water; only 35 ml of 6% Clorox should be used). This should be followed by several rinses with sterile distilled water.

Culture Vessels. Photographs in the original paper show liquid cultures in 100-ml Erlenmeyer flasks.

Culture Conditions. In the original research the cultures were maintained at 26 ± 1°C under 14-h photoperiods and a light intensity of 20 $\mu E\ m^{-2}\ s^{-1}$ produced by cool white fluorescent lamps. Other conditions are also suitable. Liquid cultures should be placed on 80 rpm rotary shakers.

Culture Media. Three media are required for this procedure. The first or initiation medium is liquid Knudson C supplemented with 15% (v/v) coconut water and 1 mg BA l^{-1} (Table Aranda-16). Liquid Vacin and Went (VW) medium containing 10% (v/v) coconut water and 2% sucrose (Table Aranda-17) is used for subsequent growth and proliferation. Solid VW with 10% (v/v) coconut water, 2% sucrose, and 0.03% (w/v) activated charcoal (Table Aranda-18) is suitable for rooting and growth. Plantlets, 2–4 cm high, taken from the agar medium (Table Aranda-18) should be potted in charcoal chips in community pots.

Procedure. Inflorescence tips are placed initially in the liquid Knudson C (Table Aranda-16) and cultured in this medium for about 12 weeks to 4 months. PLBs or shoots that form in this medium should be transferred to the liquid VW (Table Aranda-17). Plantlets that form in this medium within 2–3 months should be excised and moved to the solid medium (Table Aranda-18).

Developmental Sequence. Inflorescence tips remain green in the first medium (Table Aranda-16) and elongate 2–3 times during the first 4 weeks. Some floral buds may also develop during this period, but they die eventually. Papillae-like projections form after 2 weeks and develop into PLBs within approximately 6–8 weeks. Callus forms on the cut ends of the explants in 4-week cultures. PLBs and shoots are produced by the end of 12 weeks. Development slows down in the first medium after 4 months. Growth, rooting, and differentiation become much better following transfer to the second medium (Table Aranda-17) and clumps of plantlets (about

TABLE ARANDA-16. **Knudson C medium (Knudson, 1946) as modified for the culture of *Aranda* Deborah inflorescence tips (Goh and Wong, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 1H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Cytokinin				
7	Benzyladenine[d]	1.0	100 mg 100 ml^{-1} 95% ethanol	1	
	Complex additive				
8	Coconut water[e]	150.0 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Knudson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible, will make no difference, and can be ignored.

[d]If the benzyladenine fails to dissolve add a few drops of 0.1 N HCl. The stock solution should be stored in a freezer.

[e]Water from green (immature) coconuts is preferable. However water from mature coconuts can also be used. In areas where coconuts do not grow, green and/or mature ones can sometimes be found in markets which specialize in Asian food. These stores may also carry frozen water from green coconuts. However the frozen water may also contain sugar and preservatives, both of which must be avoided. The same is true for canned coconut water. Water from more mature (brown) coconuts in stores can also be used. Regardless of the source (green or brown coconuts) the water should be drained from the nuts, filtered and kept frozen between uses. Coconut water can be autoclaved. The correct name for this liquid is coconut water, not coconut milk.

[f]Add items 1–6 and 8 to 750 ml of distilled water (item 10), adjust pH to 5.2, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Pour the solution into a 2-l flask and autoclave. Using a sterile pipette add the cytokinin to the autoclaved medium, swirl well to mix, and dispense into culture vessels. There are no indications in the original paper whether microelements other than manganese (item 6) were added to the medium and it is not clear if the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog medium will probably prove to be suitable. It is not clear from the original paper if the cytokinin was added before or after the medium was autoclaved. Since it is much easier and simpler to add it before autoclaving, users of this medium may wish to experiment by adding this hormone before and after autoclaving.

1 cm high) form after 2–3 months. Growth is enhanced on the third medium (Table Aranda-18) and 2–4-cm-tall plants are obtained in approximately 2 months.

General Comments. *Aranda* Deborah (*Arachnis hookeriana* × *Vanda lamellata*) is the first hybrid in this monopodial genus produced by the Singapore Botanic Gardens. It was introduced in 1945 and is named after the daughter of Professor Eric Holttum, director of the gardens before and after World War II and later Professor of Botany at the University of Singapore. Being vigorous and free flowering, it became one of the major cut flower orchids exported from Singapore.

TABLE ARANDA-17. **Vacin and Went medium (Vacin and Went, 1949) modified for the culture of protocorm-like bodies derived from inflorescence-shoot-tip explants of *Aranda* Deborah (Goh and Wong, 1990): I**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water[e]	100.0 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe of this medium calls for 28 mg ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible. See also footnote *c* under Table Aranda-16.

[e]Water from green (immature) coconuts is preferable. However water from mature coconuts can also be used. In areas where coconuts do not grow, green and/or mature ones can sometimes be found in markets which specialize in Asian food. These stores may also carry frozen water from green coconuts. However the frozen water may also contain sugar and preservatives, both of which must be avoided. The same is true for canned coconut water. See also footnote *e* under Table Aranda-16.

[f]Add items 1–7 and 9 to 500–700 ml of distilled water (item 10), adjust pH to 5.2, add sugar (item 8), and raise volume to 1000 ml with distilled water (item 10). Pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is unclear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary or desirable, the formulation used as part of the Murashige–Skoog medium will probably be suitable.

This procedure seems effective. However a statement in the original paper that "by repeated subculture of . . . proliferating protocorm-like bodies, plantlet production could be maintained continuously for as long as desired" is very ill advised because such a practice can lead to undesirable mutations, malformed flowers, and unproductive plants.

TABLE ARANDA-18. **Vacin and Went medium (Vacin and Went, 1949) modified for the culture of protocorm-like bodies derived from inflorescence-shoot-tip explants of *Aranda* Deborah (Goh and Wong, 1990): II**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water[e]	100.0 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar	12–15 g	No stock	No stock	Weigh
	Darkening agent				
12	Activated charcoal (AC)	300.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe of this medium calls for 28 mg ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, l^{-1} but chelated iron as suggested here is preferable. A small difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible. See also footnote *c* under Table Aranda-16.

[e]Water from green (immature) coconuts is preferable. However water from mature coconuts can also be used. In areas where coconuts do not grow, green and/or mature ones can sometimes be found in markets which specialize in Asian food. These stores may also carry frozen water from green coconuts. However the frozen water may also contain sugar and preservatives, both of which must be avoided. The same is true for canned coconut water. See also footnote *e* under Table Aranda-16.

[f]Add items 1–7 and 9 to 500–700 ml of distilled water (item 10), adjust pH to 5.2, add sugar (item 8), and raise volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 12) with vigorous stirring, pour the solution into culture vessels, and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary or desirable, the formulation used as part of the Murashige–Skoog medium will probably be suitable.

Aranda Deborah was named for one of the daughters of Professor Eric Holttum who was Director of the Singapore Botanic Gardens and Professor of Botany at the University of Singapore.

Thin Section Culture of *Aranda* Deborah

Development of PLBs from shoot-tip explants of *Aranda* is "slow, taking 9–12 months" (Laksmanan et al., 1995). Therefore, a method using thin sections was developed at the National University of Singapore to accelerate the process (Laksmanan et al., 1995; Prakash et al., 1996).

Plant Material. Top portions of shoots should be cut and the leaves removed carefully without damaging the shoot tips. Thin sections, 0.6–0.7-mm thick, are cut by transversely sectioning the apical 6–7-mm part of the shoot tips. Very sharp razor blades or scalpels must be used for all sectioning and cutting.

Surface Sterilization. A surface sterilization procedure is not described in the original paper (Laksmanan et al., 1996). The procedure used for inflorescence-shoot-tip explants (Goh and Wong, 1990; see above) is probably suitable.

Culture Vessels. Erlenmeyer flasks, 100-ml capacity, containing 20 ml of medium should be used for liquid VW. GA7 containers (Magenta Corporation, 3800 North Milwaukee Ave., Chicago, IL 60641-2874, USA, telephone 1-773-777-5050, fax 1-773-777-4055, www.magentacorp.com) containing 50 ml of solid medium are suitable for plantlet development. Other vessels can also be used.

Culture Conditions. In the original research the cultures were maintained at 26 ± 1°C under 16-h photoperiods of 30 $\mu E\ m^{-2}\ s^{-1}$ intensity provided by cool white fluorescent tubes. Standard laboratory conditions will probably also be suitable. Liquid cultures should be agitated on a gyrorotatory shaker at 120 rpm.

Culture Media. The thin sections produce PLBs on liquid VW medium containing 20% (v/v) coconut water (Table Aranda-19). PLBs proliferate on the same medium (Table Aranda-19). Plantlets develop from the PLB on VW which contains 10% (v/v) coconut water and 500 $mg\ l^{-1}$ activated charcoal (Table Aranda-20).

Procedure. Thin sections cut under sterile conditions are placed in liquid VW medium (Table Aranda-19). Once PLBs are formed they can be proliferated by subculturing them in the same medium (Table Aranda-19), or transferred to solid VW medium (Table Aranda-20) for plantlet formation.

Developmental Sequence. The thin sections form PLBs within 45 days of being placed in liquid culture (Table Aranda-19). PLBs proliferate on the same medium (Table Aranda-19). Plantlets develop on solid VW medium (Table Aranda-20).

General Comments. Like the inflorescence-shoot-tip culture method for the propagation of *Aranda* Deborah (Goh and Wong, 1990) the thin section procedure is described as "rapid" and "efficient" (Laksmanan et al., 1995; Prakash et al., 1996) because "over 80,000 plantlets can be produced from [thin section] explants obtained from a single shoot tip in a year" especially in the presence of NAA.

TABLE ARANDA-19. **Vacin and Went medium (Vacin and Went, 1949) modified for the culture of thin sections of *Aranda* Debora shoot tips and protocorm-like body proliferation (Laksmanan et al., 1995)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water[e]	200.0 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilledf[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe of this medium calls for 28 mg ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible. See also footnote *c* under Table Aranda-16.

[e]Water from green (immature) coconuts is preferable. However water from mature coconuts can also be used. In areas where coconuts do not grow, green and/or mature ones can sometimes be found in markets which specialize in Asian food. These stores may also carry frozen water from green coconuts. However the frozen water may also contain sugar and preservatives, both of which must be avoided. The same is true for canned coconut water. See also footnote *e* under Table Aranda-16.

[f]Add items 1–7 and 9 to 500–700 ml of distilled water (item 10), adjust pH to 5.2, add sugar (item 8), and raise volume to 1000 ml with distilled water (item 10). Pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is unclear whether the addition of other nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary or desirable, the formulation used as part of the Murashige–Skoog medium will probably be suitable.

What this statement does not take into account is that overproliferation of explants, especially in the presence of NAA (and/or other synthetic hormones), can result in undesirable mutations (for example, plants which produce malformed blossoms or inflorescences with missing flowers that have no commercial value). These and other mutations can lead to major losses for cut flower growers. The value of the thin section method as a means of freeing orchids from viruses is also questionable because "the percentage of regenerants free from [cymbidium mosaic virus] and [odontoglossum ringspot virus] . . . varied." Altogether, the "80,000 plants" statement, the use of NAA in addition to coconut water for excessive proliferation, and the uncertainty about freeing plants from virus point to a need for cautious formulation of media, conservative and better informed assertions, as well as for wiser, more realistic and

TABLE ARANDA-20. **Vacin and Went medium (Vacin and Went, 1949) modified for differentiation and growth of plantlets produced by protocorm-like bodies (PLB) derived from thin sections of *Aranda* Deborah shoot tips (Lakshmanan et al., 1995)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

12	Activated charcoal (AC)	500.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe of this medium calls for 28 mg ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, l^{-1} but chelated iron as suggested here is preferable. A difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible. See also footnote *c* under Table Aranda-16.

[e]Water from green (immature) coconuts is preferable. However water from mature coconuts can also be used. In areas where coconuts do not grow, green and/or mature ones can sometimes be found in markets which specialize in Asian food. These stores may also carry frozen water from green coconuts. However the frozen water may also contain sugar and preservatives, both of which must be avoided. The same is true for canned coconut water. See also footnote *e* under Table Aranda-16.

[f]Add items 1–7 and 9 to 500–700 ml of distilled water (item 10), adjust pH to 5.2, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 12) with vigorous stirring, pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary or desirable, the formulation used as part of the Murashige–Skoog medium will probably be suitable.

better conceived advice by those who develop micropropagation methods. This is especially true for researchers who have been part of the field for a long time (Goh, 1970, 1973, 1989, 1996) and perceive themselves as leaders (Goh headed the Department of Botany when this research was carried out) despite modest contributions of their own.

Aranthera

One of the first crosses in this hybrid genus, *Aranthera* Caprice (*Arachnis maingayi* × *Renanthera storiei*) was produced in 1939 by J. van Brero in Bandung (then spelled Bandoeng), Indonesia. The second and presently better-known cross *Aranthera* James Storei (*Arachnis hookeriana* × *Renanthera storiei*) originated at the Singapore Botanic Gardens also in 1939. (The name is sometimes misspelled in the literature as Storiei, probably because this is the spelling of the specific epithet of one of its parents.) Many additional hybrids have been produced since then involving as parents *Arachnis flos-aëris*, *Arachnis clarkei*, *Arachnis* Maggie Oei (*Arachnis hookeriana* × *Arachnis flos-aëris*), *Renanthera coccinea*, *Renanthera elongate*, and *Renanthera monachica* among others. Some of the hybrids are of commercial importance, and therefore several micropropagation procedures were developed for *Aranthera* (Alang, 1975; Sagawa and Kunisaki, 1982).

Tissue Culture of *Aranthera* James Storie

The first method for mass rapid clonal propagation of *Aranthera* was developed at the famed Bogor Botanical Gardens in Indonesia in view of its export potential at the time (Irawati et al., 1977).

Plant Material. Apical and axillary buds from developing shoots of *Aranthera* James Storei are used. Buds are excised in cubes of tissue measuring 0.5 × 0.5 × 0.3 cm.

Surface Sterilization. Following removal of the leaves the explants should be submerged for 15 min in a 0.5% calcium hypochlorite solution. (In making up this solution from 0.5 g calcium hypochlorite, it is important that the powder be truly dry to begin with, as it can absorb water from the air in humid climates, and wet powder will produce an ineffective sterilant; dissolve the powder in enough water for a final volume of 100 ml, stir or shake the solution about every 5 min for 15–20 min, and then filter or decant it.) It is advisable to wash the sterilized explants two to three times with sterile distilled water before the sheaths that cover the buds are removed. After that, soak the exposed buds for an additional 15 min in 0.2% calcium hypochlorite (0.2 g per 100 ml of water, or 40 ml of the 0.5% solution diluted to 100 ml with distilled water).

Culture Vessels. Culture tubes and Erlenmeyer flasks are suitable.

Culture Conditions. Cultures should be maintained under a constant illumination of 1000–1100 lx (which in the original research was provided by Philips fluorescent tubes; other light sources are also suitable) and 24 ± 2°C. Liquid cultures require agitation. (A 2-rpm rotary shaker was used by Irawati et al., 1977, but other shakers can also be employed.)

Culture Medium. Liquid-modified Knudson C medium (Table Arnth-1) is suitable for the initial explants. PLBs produced under these conditions should be placed on

TABLE ARNTH-1. **Modified Knudson C medium (Knudson, 1946) for the culture of *Aranthera* James Storie buds (Irawati et al., 1977)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	**Chelated Iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.06	6 mg l^{-1}		
(b)	Copper sulfate (anhydrous), $CuSO_4$	0.04	4 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	One solution
(d)	Molybdic acid, MoO_3	0.02	2 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.35	35 g l^{-1}		
	Sugar				
7	Sucrose	20 g	No stock	No stock	Weigh
	Complex additive				
8	Coconut water	150 ml	No stock	No stock	Measure
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 5a) and iron salt (item 5b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. Only ferrous sulfate, $FeSO_4 \cdot 7H_2O$ (25 mg l^{-1}), was used in the original formulation, but the chelated form is preferable.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The amounts listed here have been rounded up from those in the original paper (Irawati et al., 1977).

[e]Add items 1–6 and 8 to 800 ml distilled water (item 9), adjust pH to 5.3, add sugar (item 7), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into culture vessels and autoclave. Omit agar if liquid medium is being prepared.

a solid version of this solution (Table Arnth-1) or Knudson C medium (see Tables Aranda-7 and Aranda-8) with or without banana homogenate. Modified Vacin and Went medium (Table Arnth-2) can also be used in either liquid or solid form.

Procedure. Place the sterilized buds in liquid medium (Tables Arnth-1 and Arnth-2), and culture them until PLBs form. Transfer these to solid medium (see Tables Aranda-7, Aranda-8, Arnth-1, and Arnth-2) for plantlet regeneration.

Developmental Sequence. Explants change in color from white, yellowish-green or pale green to green within 1–3 weeks and the tissues turn dark green in approximately 7 weeks. The tissues become swollen after the first week of culture and may produce abnormal leaves subsequently. However, with time the explants produce PLBs that regenerate plantlets that appear normal.

TABLE ARNTH-2. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of buds of *Aranthera* James Storie (Irawati et al., 1977)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water	150 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar[e]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Add other components of medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1, 3–7, and 9 to the 500 ml distilled water (item 10) that contain item 2. Adjust pH to 5.3, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 10). To prepare solid medium bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave. Omit agar if liquid medium is desired.

General Comments. Explant survival rate is low but sufficient for a practical mass rapid clonal propagation procedure. It is not clear at present whether this procedure can be used with *Aranthera* crosses involving other parents.

In Vitro Propagation of *Aranthera* James Storie

This procedure was developed because "*Aranthera* James Storie [is an] important commercial cut [flower] . . . exported from Singapore and . . . Thailand [but] . . . methods of vegetative propagation [were] inadequate to provide the volume of plants required for establishment of new fields" (Cheah and Sagawa, 1978).

Plant Material. Soft upper nodes should be used as the source of explants. The apical bud explants used in the original research were 5–6 mm long and included

three to four internodes, an equal number of leaf primordia, and the apical meristem. Axillary-bud explants consisted of a single bud and a portion of the stem.

Surface Sterilization. All leaf portions except the sheaths should be removed before surface-sterilizing the sections in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 10 min. The sheaths are removed after that, and the sections are submerged in 5% Clorox (5 ml Clorox diluted to 100 ml) for 5 min. Buds are excised from the sterilized stem sections under aseptic conditions with sterile tools, rinsed with distilled water, and placed into culture.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other suitable containers can be used.

Culture Conditions. During the original research the tissues were maintained on a New Brunswick Model V shaker at 160 rpm under conditions of 2100 lx of continuous illumination (provided by General Electric Power Groove white fluorescent light) and 26 ± 3°C. Similar, though not identical, conditions are also suitable.

Culture Medium. The media consist of the basal salts of Vacin and Went medium, a reduced amount of agar, "occasional deletion of 2% sucrose," 150 ml coconut water, and 50 g banana homogenate (Tables Arnth-3 to Arnth-5).

Procedure. First place the explants on a liquid medium that contains 15% coconut water (Table Arnth-3). After 1 week of culture remove the outer bud scales. Then transfer the PLBs to a liquid medium containing sugar-free coconut water (Table Arnth-4). After further proliferation move them to solid sugar-free medium (Table Arnth-5). To produce roots, transfer shoots from this medium to a medium containing banana (Table Arnth-6).

Developmental Sequence. Both apical and axillary buds become swollen and green after 2 weeks in culture. PLBs are produced at the nodes, bases, and middle and upper parts of explants after 6–8 weeks. These bodies multiply rapidly on the medium containing sugar-free coconut water. They die in solutions containing sugar. The PLBs produce shoots on a sugar-free medium (Table Arnth-5). When these shoots reach a height of 2.5 cm and are transferred to banana-containing medium (Table Arnth-6) they develop roots.

General Comments. This procedure is complicated due to the use of several media. However, it is a useful and productive one. As with the previous method it is not clear whether it can be used with *Aranthera* crosses involving other parents.

TABLE ARNTH-3. **Vacin and Went medium (Vacin and Went, 1949) for the initial culture of apical and axillary buds of *Aranthera* James Storie (Irawati et al., 1977)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water	150 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Then add other components of the medium.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Add items 1, 3–7, and 9 to the 500 ml distilled water (item 10) that contain item 2. Adjust pH to 5.3, add sugar (item 8), and bring volume to 1000 ml with distilled water (item 10). Dispense into culture vessels and autoclave.

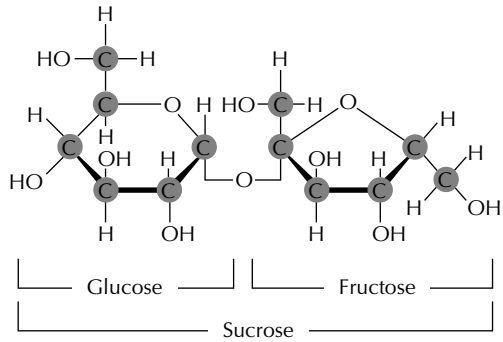

TABLE ARNTH-4. **Modified Vacin and Went medium (Vacin and Went, 1949) for the rapid multiplication of protocorm-like bodies produced by apical and axillary buds of *Aranthera* James Storie (Cheah and Sagawa, 1978)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock

5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Solvent				
8	Water, distilled[e]	To 1000 ml			
	Solidifier				
9	Agar[e]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Then add other components of the medium.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg of the chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1 and 3–7 to the 500 ml distilled water (item 8) that contain item 2. Adjust pH to 5.3, and adjust volume to 1000 ml with distilled water (item 8). Bring solution to a gentle boil, and add agar (item 9) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave.

TABLE ARNTH-6. **Vacin and Went medium (Vacin and Went, 1949) for root induction on shoots of *Aranthera* James Storie (Cheah and Sagawa, 1978)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additives				
8	Coconut water	150 ml	No stock	No stock	Measure
9	Green banana homogenate[e]	50	No stock	No stock	Weigh
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Then add other components of the medium.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg of the chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]To prepare the banana homogenate place the pulp in a homogenizer (e.g., a household blender) with 100–150 ml water, and homogenize for 1–2 min.

[f]Add items 1 and 3–9 to the 500 ml distilled water (item 11) that contain item 2. Set pH to 5.3, and adjust volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil, and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water, which is then brought to a boil and stirred. When the agar is completely dissolved, dispense the medium into culture vessels and autoclave.

Apical Meristem Culture of *Aranthera* James Storie

Cymbidium mosaic virus (CymV) is the most widespread orchid virus in Malaysia and most probably other areas. A method to free infected *Aranthera* James Storie plants of this virus was developed at the Malaysian Agricultural Research and Development Institute (MARDI) in Selangor (Ong and Chua, 1980). This method can also be used for mass rapid clonal propagation.

Plant Material. Shoot tips of mature plants are removed, surface-sterilized, and rinsed before removal of the leaves to expose the apical meristem. Meristem domes (0.5–1.0 mm) with two leaf primordia should be excised aseptically with a sharp needle or microscalpel.

Surface Sterilization. Excised shoot tips should be rinsed with water, submerged in 10% Clorox (10 ml of Clorox diluted to 100 ml with distilled water) for 10 min and rinsed several times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks (of 50- or 125-ml capacity, containing medium equal to one-fifth of their volume), culture tubes, or other containers can be used.

Culture Conditions. Few details are given in the original paper beyond the suggestion that PLBs that form on the apical meristem were cultured in liquid medium agitated at 120 rpm on an orbital shaker. The culture conditions used in conjunction with the other methods for *Aranthera* will most probably prove suitable for this procedure.

Culture Medium. A modified solid Vacin and Went (VW) medium containing coconut water (Table Arnth-7) is used for the initial culture. PLBs are cultured on liquid sucrose-free VW medium (Table Arnth-8). For shoot and root formation the PLBs should be transferred to solid VW without sucrose (Table Arnth-8).

Procedure. Place excised apical meristem domes on solid modified VW medium (Table Arnth-7) for approximately 10 months or until PLBs form. Transfer these to a liquid sugar-free VW medium (Table Arnth-8) for proliferation. When enough PLBs are available, culture them on solid sucrose-free VW medium (Table Arnth-8) for plantlet regeneration. Plantlets with at least two roots can be transplanted into thumb pots with charcoal as a potting medium.

Developmental Sequence. Apical meristem domes form PLBs after 10 months on the first medium. The PLBs proliferate in the liquid VW medium and form plantlets when moved to solid sucrose-free VW medium.

General Comments. Bacterial contamination can be a problem for this procedure. In the original research only three of ten apical meristems survived contamination and developed PLBs. Not all plantlets produced by this method can be expected to be free of CymV. For this reason the authors (Ong and Chua, 1980) wisely state that their study "shows that it is necessary to keep mericlones for a prolonged probation period and that thorough testing is an essential prerequisite before any clone produced by this technique is accepted as virus free."

The name *Aranthera* James Storie is sometimes misspelled *Aranthera* James Storei or *Aranthera* James Storiei.

TABLE ARNTH-7. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of apical meristems of *Aranthera* James Storie (Ong and Chua, 1980)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Then add other components of the medium.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Add items 1 and 3–8 to the same 500 ml distilled water (item 9) that contain item 2. Set pH to 5.3 and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense medium into culture vessels and autoclave.

Clonal Propagation of *Aranthera* from Bud Explants

Bud explants of six *Aranthera* hybrids were cultured at the Singapore Botanic Gardens by the method used for *Arachnis* (Lim-Ho, 1981). The explants are cultured initially on a liquid modification of the Vacin and Went medium (see Table Arach-4). Multiplication and differentiation occur on a solid version of this medium (see Table Arach-4) and a second modification (see Table Arach-6) is suitable for plantlet formation. Growth is slow, and differentiation may be better on a modification of the MS medium (see Table Aranda-9). The explants may produce phenolics that could inhibit growth or kill the explant. For this reason the explants must be transferred to fresh medium every few days during the first 6 months.

Clonal Propagation of *Aranthera* from Leaf Bases

Aranthera Beatrice Ng 'Yellow' can be propagated from leaf bases. The procedure is the same as the one for leaves and leaf bases of *Aranda* (Lim-Ho, 1981) except that the initial medium is a different liquid modification of the Vacin and Went solution (Table Arnth-9).

TABLE ARNTH-9. **Vacin and Went medium (Vacin and Went, 1949) modified for initial culture of *Aranthera* leaves (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

9	Naphthaleneacetic acid (NAA)	0.2	20 mg 100 ml^{-1} 95% ethanol[e]	1	
10	2,4-Dichlorophenoxyacetic acid (2,4-D)	1.5	150 mg 100 ml^{-1} 95% ethanol[e]	1	
	Cytokinin				
11	N^6-benzyladenine (BA)	1.25	125 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
12	Coconut water	150 ml	No stock	No stock	Measure
	Solvent				
13	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Then add other components of the medium.

[d]The original formulation contains a different iron salt, but the chelated form is preferable.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1, 3–7, and 12 to the 500 ml distilled water (item 13) that contains item 2. Set pH to 5.2–5.5, adjust volume to 1000 ml with distilled water (item 13); pour into a 2-l flask, and autoclave. Add hormones (items 8–11) while medium is still hot and liquid, and swirl several times to mix well. Do not add agar since this is a liquid medium.

Arundina

Distributed throughout much of Asia, *Arundina bambusifolia* is an attractive, easy-to-grow terrestrial orchid whose flowers last up to 5 days. Two micropropagation procedures are available for it (Mitra, 1971; Banik et al., 1986).

Shoot-tip and Stem-section Culture of *Arundina bambusifolia*

An investigation of seed germination, seedling development, and morphogenesis of *Arundina bambusifolia* led to the development of tissue culture methods that can be used for clonal propagation (Mitra, 1971).

Plant Material. Use shoot tips 1–2 mm long taken from seedlings (Table Arnd-1) that are 6–8 mm high (only two to three internodes visible), and stem disks (1–2 mm in diameter and thickness). Removal of the tissues appears to involve merely cutting under sterile conditions. The explants are then placed on the appropriate culture medium.

TABLE ARND-1. **Effects of media used in the culture of shoot tip and stem sections of *Arundina bambusifolia* (Mitra, 1971)**

Raghavan and Torrey (1964) medium	Seedling shoot tips, 8 mm long, containing 2 nodes, "one only" visible	Seedling shoot tips, 1–2 mm long	Seedling stem disks, 1–2 mm in diameter and thickness
Plus:			
Urea, 25–50 mg l^{-1} (Table Arnd-2)	Development of leaf primordia Root formation at basal end Protocorm formation at basal end Development of shoot buds		Plantlet formation on 25 mg l^{-1}
Peptone, 1 g l^{-1} (Table Arnd-2)	Protocorm formation at basal end Development of shoot buds Slight development of leaf primordia		Plantlet formation
Vitamin-free casein hydrolysate, 400 mg l^{-1} (Table Arnd-2)	Development of leaf primordia Root formation at basal end		
Yeast extract, 200 mg l^{-1} (Table Arnd-2)			Plantlet formation
Ribonucleic acid, 25–50 mg l^{-1} (Table Arnd-2)	Slight development of leaf primordia Root formation at basal end Development of shoot buds		
Coconut water, 100 mg l^{-1} (Table Arnd-2)	Development of leaf primordia Root formation at basal end		
Coconut water, 200 ml l^{-1}	Development of shoot buds Development of leaf primordia Root formation at basal end Development of individual shoot tips into "full-fledged plantlets"		
Control, no additives (Table Arnd-2)	Development of leaf primordia Root formation at basal end Development of shoot buds		
Modified (Tables Arnd-3 and Arnd-4)		Complete plant formation	

TABLE ARND-2. **Raghavan and Torrey (1964) medium as used for the culture of *Arundina bambusifolia* 6–8-mm-long shoot tips and stem disks (Mitra, 1971)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements[b]				
1	Potassiuim phosphate, KH_2PO_4	270	27 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	240	24 g l^{-1}	10	
3	Calcium sulfate, $Ca_3(PO_4)_2$[c]	80	8 g l^{-1}	10	
4	Calcium phosphate, $Ca_3(PO_4)_2$[c]	100	10 g l^{-1}	10	
5	Ammonium nitrate, NH_4NO_3	80	8 g l^{-1}[b]	10[b]	Or weigh[b]
6	**Microelements**[c]				
(a)	Boric acid, H_3BO_3	0.60	600 mg l^{-1}		
(b)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	0.40	400 mg l^{-1}		
(c)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.05	50 mg l^{-1}		
(d)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.05	50 mg l^{-1}	1	One solution
(e)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.05	50 mg l^{-1}		
(f)	Potassium iodide, KI	0.03	30 mg l^{-1}		
(g)	Cobaltous nitrate, $Co(NO_3)_2$	0.05	50 mg l^{-1}		
	Iron[d]				
7	Ferric tartrate, $Fe_2(C_4H_4O_6)_3$	3	300 mg l^{-1}[d]	10[d]	
	Organic additives				
8	Urea	25 or 50	2.5 g l^{-1} or 5 g l^{-1}[b]	10[b]	Use as needed
9	Ribonuclei acid[b]	25 or 50	2.5 g l^{-1} or 5 g l^{-1}[b]	10[b]	(see Table Arnd-2)
	Complex additives[b,e]				
10	Peptone	1 g	No stock[b]	No stock[b]	Weigh
11	Vitamin-free casein hydrolysate	400 or 1 g	No stock[b]	No stock[b]	Weigh
12	Yeast extract	200	No stock[b]	No stock[b]	Weigh
13	Coconut water[e]	100 ml or 200 ml			
	Sugar[e]				
14	Sucrose	20 g	No stock	No stock	Weigh
15	Water, distilled[e]	To 1000 ml			
	Solidifier[e]				
16	Agar	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions of nitrogenous salts or organic substances may become contaminated. Therefore, stock solutions should not be prepared. If made, they must be kept frozen between uses.

[c]Add all microelements to the same 1 l, stir and/or heat until dissolved. Add 1 ml to culture medium.

[d]Ferric tartrate is relatively insoluble. Grinding it with a mortar and pestle before dissolving helps. The addition of a pellet or two of KOH to the solution will increase solubility, but a precipitate may form nevertheless. To insure equal distribution, shake stock solution well before dispensing.

[e]Dissolve items 1–13 as needed in 500 ml distilled water (item 15) adjust the pH to 5.2–5.5, and add the sugar (item 14) and the coconut water (item 13), if used; bring volume up to 1000 ml with distilled water. Add agar (item 16) slowly, while stirring, to the gently boiling solution. When fully dissolved, dispense into culture vessels and autoclave.

Surface Sterilization. This is not required since explants are obtained from seedlings grown under aspectic conditions.

Culture Vessels. Wide-mouth, 150-ml Erlenmeyer flasks and 25 × 180 mm culture tubes containing 50 and 25 ml medium, respectively, were used in the original work. Other vessels could no doubt also be used.

Culture Conditions. Maintain cultures at 26 ± 1°C under a light intensity of 3000 lx and 12-h photoperiods. Philips "Natural" fluorescent tubes were originally used,

TABLE ARND-3. **A medium (Raghavan and Torrey, 1964) modified for the culture of 1–2-mm-long stem tips of *Arundina bambusifolia* (Mitra, 1971)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	50	5 g l^{-1}	10	Or weigh
2	Potassium phosphate, KH_2PO_4	100	10 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	240	24 g l^{-1}	10

(d)	Copper sulfate, $CuSO_4 \cdot H_2O$	0.05	50 mg l^{-1}	1	One solution[c]
(e)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.05	50 mg l^{-1}		
(f)	Potassium iodide, KI	0.03	30 mg l^{-1}		
(g)	Cobaltous nitrate, $Co(NO_3)_2$	0.05	50 mg l^{-1}		
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[e]	To 1000 ml			
	Solidifier				
12	Agar	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, they must be kept frozen between uses.

[c]Add all microelements to the same 1 l, stir and/or heat until dissolved. Add 1 ml per liter of culture medium.

[d]Add items a and b to the same 1 l, dissolve. Add 10 ml per liter of culture medium.

[e]Dissolve items 1–9 in 900 ml distilled water (item 11), adjust pH to 5.2–5.5; add sugar (item 10), and bring volume up to 1000 ml with distilled water. Add agar (item 12) slowly, while stirring, to the gently boiling solution. When fully dissolved, dispense into vessels and autoclave.

but equivalent ones (e.g., Sylvania Gro Lux) would probably prove to be equally suitable.

Culture Media. Enriched Raghavan–Torrey medium (Raghavan and Torrey, 1964), which is itself a modification of a medium first used by Spoerl (1948), is employed for 6–8-mm shoot tips and stem disks (Tables Arnd-1 and Arnd-2). A modified version of the same medium is used for 1–2-mm shoot tips (Tables Arnd-1 and Arnd-3).

Procedure. Place explants on media under the appropriate culture conditions.

Developmental Sequence. Leaf development on shoot tips was invariably associated with root production. When leaves did not develop, roots were not formed.

General Comments. Since seedlings are the tissue source, this method does not allow for the propagation of proven plants. However, it is entirely possible that one of the media employed could be useful to culture shoot tips or stem disks from mature plants. The method could prove useful in cases where only a few seedlings of a valuable cross can be obtained from a capsule.

Clonal Propagation of *Arundina bambusifolia*

A tissue culture method for clonal propagation of *Arundina bambusifolia* was developed at the Department of Botany, University of Dakka, Bangladesh (Banik et al., 1986).

Plant Material. Shoots bearing 10–15 leaves taken from mature plants are used as a source for apical and axillary bud explants.

Surface Sterilization. After removal of the leaves to expose the apical and axillary buds, the shoots should be washed with running water, scrubbed with a mild detergent, and surface-sterilized by immersion in 10% household bleach for 15–20 min. (Domestos was used in the original research, but other household bleaches containing approximately 5% sodium hypochlorite are suitable; 10% is obtained by diluting 10 ml of bleach to 100 ml with distilled water.) The original paper also recommends using 5% calcium hypochlorite (5 gm calcium hypochlorite diluted to 100 ml with distilled water; the solution should be stirred several times and decanted or filtered before the liquid portion is used) or 0.1% mercuric chloride ($HgCl_2$, a toxic, dangerous compound to be avoided if at all possible) for an equal period. All tissues should be rinsed several times with sterile distilled water to remove traces of the sterilant.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other containers are suitable.

Culture Conditions. Cultures should be maintained under 12-h photoperiods provided by fluorescent tubes and 25 ± 2°C.

Culture Medium. Modified Vacin and Went medium should be used (Table Arnd-4).

Procedure. Place explants on the medium, and culture them until PLBs form. When subcultured the PLBs produce plantlets. Remove plantlets from the flasks when they are 7–8 cm tall, pot them in sterilized vermiculite, and maintain them under high humidity for several days.

Developmental Sequence. Formation of PLBs takes place 30–40 days after the explants are placed in culture. Plantlet production from PLBs occurs 30–40 days following the subculture. The regenerated plants grow to a height of 4–5 cm in 7–8 months.

General Comments. This is a useful procedure for the propagation of an attractive orchid.

TABLE ARND-4. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Arundina bambusifolia* shoot tips (Banik et al., 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Hormones				
8	Napthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
9	6-Furfurylaminopurine (kinetin)	0.2	20 mg l^{-1} 5% ethanol[e]	1	
	Complex additives				
10	Coconut water	200 ml	No stock	No stock	Measure
11	Tomato juice[f]	35 ml	No stock	No stock	Measure
	Sugar				
12	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
13	Water, distilled[g]	To 1000 ml			
	Solidifier				
14	Agar	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, and stir and/or heat until it dissolves. Then add other components of the medium.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Keep refrigerated or frozen between uses.

[f]The original paper (Banik et al., 1986) states that "5% T[omato] J[uice] (70%) was used." Assuming a liquid containing 70% tomato juice, the actual amount added was probably 35 ml. To prepare tomato juice, squeeze ripe tomatoes (do not homogenize) into a container; then filter the juice to remove pulp and seeds. This is important because the seeds may contain germination inhibitors, which could have a deleterious effect on the cultures. Use only the juice. Store unused juice in a freezer.

[g]Add items 1 and 3–11 to the 500 ml distilled water (item 13) that contains item 2. Set pH to 5.3, add sugar (item 12), and adjust volume to 1000 ml with distilled water (item 13). Bring solution to a gentle boil, and add agar (item 14) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. Sterilize solution by autoclaving, add hormones (items 8 and 9) under sterile conditions to the warm, still liquid solution, and dispense medium into preautoclaved culture vessels.

Micropropagation and Artificial Seed Technology of *Arundina graminifolia*

An endangered orchid species, *Arundina graminifolia* (Don) Hoechr. (*Arundina bambusifolia* Lindl.), is found in China, India, the Himalayas, Malaysia, Myanmar, the Philippines, and Sri Lanka. Micropropagation and artificial seed production methods for this species were developed at the Molecular Cytogenetics and Tissue Culture Laboratory, Department of Botany, North Bengal University, India and the Department of Botany, University College, Raiganj, India (Kanjilal et al., 2000, pers.

comm.; I thank Professors K. B. Data and B. Kanjilal for providing me with a reprint, unpublished data, and photographs as well as permission to use them).

Plant Material. Seeds for the production of protocorms utilized in the artificial seed research were from mature undehisced capsules. Plantlets which served as sources of explants were grown from the same seeds. Protocorms, 20–30 days old, were used for the production of artificial seeds. The thin sections employed for tissue culture experiments were taken from seedlings raised in vitro.

Surface Sterilization. Undehisced capsules should be washed with a mild detergent under running water before being surface-sterilized with "3% [v/v] sodium hypochlorite solution" [this is presumably 57 ml household bleach which contains 5.25% sodium hypochlorite (or a different volume if the bleach contain less or more sodium hypochlorite) brought up to 1000 ml with distilled water], washed with sterile distilled water, and blotted dry with sterilized filter paper. There is no need to surface-sterilize in-vitro-grown protocorms and seedlings.

Culture Vessels. Erlenmeyer flasks can be used for seed germination, seedling and plantlet growth, and regeneration from encapsulated protocorms. Test tubes are suitable for explant culture. Petri dishes, test tubes, and Erlenmeyer flasks were used in the original research for plantlet regeneration from artificial seeds.

Culture Conditions. Cultures of seeds, seedlings, explants, plantlets, and artificial seeds (i.e., encapsulated protocorms) should be matained at $25 \pm 2°C$ and 16-h photoperiods of 1000 lx provided by cool white tubes. Standard culture room conditions are also suitable.

Culture Media. Vacin and Went medium supplemented with 15% coconut water (Table Arnd-5) is suitable for germination of natural and artificial seeds as well explant culture. Additions of 0.5 mg NAA l^{-1} or 1 mg IAA l^{-1} can increase the production of PLBs on explants. However, it is better not to force excessive proliferation through the use of these auxins or by any means because this can bring about undesirable mutations, malformed flowers, and uneven inflorescences.

Procedure. After splitting the sterilized seed capsules horizontally, the seed should be removed with a sterile spatula or knife and placed on the culture medium (Table Arnd-5). Few details are given about the excision of explants beyond "thin sections of stems of *in vitro* raised plants of *A. graminifolia* when cultured . . . produce . . . PLBs." It is safe to assume that the shoot tips are sectioned and the sections are placed on the culture medium (Table Arnd-5).

To prepare artificial seeds, 20–30-day-old protocorms (Fig. Arnd-1F) are mixed with 3% alginate solution, which also contains 4 mg Bavastin l^{-1} and 20 mg sodium bicarbonate l^{-1}, and then dropped in an autoclaved 100-m*M* solution of $CaCl_2$ l^{-1}. Calcium alginate beads (Fig. Arnd-1G) form 10–15 min after the mixture is placed on an 80-rpm shaker. The beads should be washed with sterile distilled water to remove excess $CaCl_2$. Encapsulated PLBs resume growth when placed on culture medium or soil (Fig. Arnd-1H–J).

TABLE ARND-5. **Vacin and Went medium (Vacin and Went, 1949) modified for seed germination, and the culture of thin stem sections and encapsulated protocorms of *Arundina graminifolia* (Kanjilal et al., 2000 and unpublished)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monosobsic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water[e]	150.0 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe of this medium calls for 28 mg ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, l^{-1} but chelated iron as suggested here is preferable. A difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible.

[e]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen CW must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[f]Add items 1–7 and 9 to 500–700 ml of distilled water (item 10), adjust pH to 5.2, add sugar (item 8), and raise volume to 1000 ml with distilled water (item 10). Pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is unclear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary or desirable, the formulation used as part of the Murashige–Skoog medium will probably be suitable.

Developmental Sequence. Seeds germinate and produce seedlings when placed on culture medium. Stem sections swell and produce plantlets (Fig. Arnd-1A) after being placed in culture. Plantlets develop from encapsulated PLBs (Fig. Arnd-1H–J). These plants continue to develop normally when moved to a potting mix (Fig. Arnd-1K).

General Comments. The seed germination, tissue culture, and encapsulation methods for *A. graminifolia* which are described here (Kanjilal et al., 2000) provide effective means for sexual and clonal propagation of this species and should serve as models for other orchids.

Ascocenda

The first cross of this hybrid genus *Ascocenda* Portia Doolittle [*Ascocentrum* (*Saccolabium*) *curvifolium* × *Vanda lamellata*] was registered in 1949. *Ascocenda* Chryse (*Ascocentrum miniatum* × *Vanda lamellata*) was registered in 1951. A hybrid registered as *Ascocenda* Meda Arnold [*Ascocentrum* (*Saccolabium*) *curvifolium* × *Vanda* Rothschildiana] in 1950 is presently the trigeneric cross *Schlechterara* Meda Arnold (Garay and Sweet, 1974) since *Vanda* Rotschildiana (originally listed as being of the parentage *Vanda coerulea* × *Vanda sanderiana*) is now considered to be the bigeneric hybrid *Vandanthe* Rotschildiana (*Vanda coerulea* × *Euanthe sanderiana*). In some of the horticultural literature and Sander's List of Orchid Hybrids, *Schlechterara* Meda Arnold is still being referred to as *Ascocenda* Meda Arnold. One paper reports that it can be cultured by a method that is also suitable for other *Ascocenda* clones and a species of *Vanda*. For this reason the culture of *Schlechterara* and *Ascocenda* will be treated together under discussion of the latter.

Propagation of *Ascocenda* from Leaf Tissue

Monopodial orchids are generally more difficult to culture in vitro than sympodial ones. For this reason an attempt was made at the Singapore Botanic Gardens to culture leaf tissue of the hybrid *Ascocenda* Hilo Rose (*Vanda* Hilo Queen × *Ascocenda* Meda Arnold) × *Vanda* Miss Joaquim (*Vanda hookeriana* × *Vanda teres*, the National Flower of Singapore) listed in this case under its synonym, *Vanda* Josephine (Fu, 1978, 1979*b*). A check of Sander's List of Orchid Hybrids for 1971–1975, 1976–1980, and 1981–1985 does not show such a hybrid. The list for 1971–1975 includes the hybrid *Ascocenda* Heah Hock Heng, which was registered from Singapore in 1971. Its parentage is *Ascocenda* Hilo Rose × *Vanda* Josephine van Brero (*Vanda insignis* × *Vanda teres*). *Vanda* Josephine van Brero was registered from Indonesia in 1936 by J. van Brero.

Plant Material. Whole young leaves, 1–3 cm long and 0.5–1 cm wide, from mature plants are cultured.

Surface Sterilization. The leaves are immersed in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 15–20 min and then rinsed two to three times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, culture tubes, and other containers can be used.

Culture Conditions. Cultures should be maintained on a reciprocal shaker 16 h per day (and turned off for the other 8 h), under continuous illumination (which in the original research was provided by a Sylvania Gro Lux 30-W tube, but other sources are also suitable) and a temperature of 28°C.

Culture Media. A liquid modified MS medium is used for initial culture and proliferation (see Table Aranda-4). Once formed, the PLBs should be transferred to a

second medium (see Table Aranda-5). A third medium, a modification (see Table Aranda-6) of the Knudson C solution (see Tables Aranda-7 and Aranda-8) with or without 100 g banana l^{-1}, should prove suitable for subsequent regeneration of plantlets.

Procedure. Remove young leaves from mature plants, surface-sterilize them, preferably after that wash them with sterile distilled water, and culture them in liquid medium (see Table Aranda-4) until the tissues proliferate and PLBs form. Transfer these bodies to the second medium (see Table Aranda-6) for further growth and to a third solution (see Tables Aranda-6 to Aranda-8) for plantlet regeneration.

Developmental sequence. The leaves and especially their bases proliferate and form PLBs. These proliferate further and on being transferred to an appropriate medium produce plantlets.

General comments. Clonal propagation from leaf tissue offers two important advantages. One is the fact that removal of explants does not endanger the source plant. The second is availability of a large number of explants. This should eliminate the need for extensive proliferation, which leads to undesirable variants.

Propagation of *Ascocenda* through Shoot Meristem Culture

Shoot-tip meristems of *Schlechterara* (*Ascocenda*) Tan Chai Beng [*Schlechterara* (*Ascocenda*) Meda Arnold × *Vandanthe* (*Vanda*) Rothschildiana], *Schlechterara* (*Ascocenda*) Meda Arnold, and *Schlechterara* (*Ascocenda*) Carnival [*Ascocentrum curvifolium* × *Vandanthe* (*Vanda*) Rothschildiana]

> "were cultured successfully on medium RM-1962 containing 0.1 parts per million of NAA [naphthaleneacetic acid]. . . . The cultures [also] grew well . . . on Hyponex [3 g l^{-1}] medium containing 2 g l^{-1} Trypton. . . . [But in the case of medium RM-1962 the cultures were inhibited even at a low Trypton levels.] Optimal level of sucrose was 2% [but] development of shoots was accelerated at lower levels. . . . Cultures grew better on liquid medium than on solid medium . . . [and] pH 7. . . ." (Ichihashi, 1979)

The quote and information presented above are taken from the summary of a paper in Japanese. Additional information gleaned from the paper is that the cultures should be maintained under an illumination of 700 lx at 25°C. Several illustrations in the paper indicate that this procedure is an effective one.

Clonal Propagation of *Ascocenda* from Bud Explants

Two unregistered *Ascocenda* hybrids were propagated from bud explants at the Singapore Botanic Gardens by the methods used for *Arachnis* (Lim-Ho, 1981). The explants are cultured first in a liquid modification of the Vacin and Went medium (see Table Arach-3). When callus and/or PLBs form, they should be transferred to a solid version of the same medium (see Table Arach-3). Two other modifications of the Vacin and Went medium (see Tables Arach-4 and Arach-5) are used for

proliferation and differentiation. Plantlet formation occurs on a fourth modification (see Table Arach-6). Plantlet growth is slow, and differentiation of one hybrid was better on a modified MS medium (see Table Aranda-9). Explant growth is also slow.

Clonal Propagation of *Ascocenda* from Whole Leaves

Whole young leaves of *Ascocenda* Heah Hock Heng have been cultured at the Singapore Botanic Gardens by the method used for *Aranda* leaves (Lim-Ho, 1981). Explants are first cultured in a liquid modification of the MS medium (see Table Aranda-4). Two modifications of the Vacin and Went medium can be used for multiplication and differentiation (see Tables Arach-4 and Arach-5). A third modification of the same medium (see Table Arach-6) is suitable for plantlet formation. Growth of the explants is fast.

Rapid Clonal Propagation of *Ascocenda* through the Culture of Leaf Explants

As with other monopodial orchids, *Ascocenda* has only one shoot tip, which must be excised in attempts to culture excised apices. This means that the donor plant (often an expensive one-of-a-kind hybrid) itself may be endangered or even lost. Methods that utilize explants "whose excision does not jeopardize the survival of the mother plant, [are] thus desirable" (Vij and Kaur, 1999). One such method was developed at the Orchid Laboratory, Department of Botany, Panjab University, Chandigarh-160 014, India by its long-time leader Professor Suraj Prakash Vij and one of his associates (Vij and Kaur, 1999).

Plant Material. In the original research 5-mm explants were taken from mature leaves (10–30 mm long) or those of 25-week-old plantlets obtained in vitro through the culture of flower stalks.

Surface Sterilization. Explants from in-vitro-grown plants do not require surface sterilization. The surface sterilization process for leaves from greenhouse-grown plants involves four steps. Step 1: immersion in 70% ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) for 10 s. Step 2: soaking in 0.1% streptomycin (100 mg streptomycin sulfate dissolved in 100 ml distilled water) for 30 min. Step 3: mild agitation in 7% calcium hypochlorite (suspend 7 g calcium hypochlorite in 100 ml distilled water, stir or shake well, allow precipitate to settle, and repeat the stirring and settling several times before decanting the yellowish supernatant for use as a sterilant that must be used within a few hours of preparation because it can lose its potency) for 15 min. Step 4: wash three times with sterile distilled water to remove traces of the sterilants.

Culture Vessels. Erlenmeyer flasks (50–250-ml capacity), test tubes, or other containers are suitable. They should be filled with culture medium to approximately one-fifth of their capacity

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx [the illumination source(s) is/are not listed in the original paper, but is it is reasonable to assume that cool white fluorescent tubes alone or mixed with incandescent bulbs, or plant growth lights such as Gro Lux are suitable]. Standard culture room conditions are probably also suitable.

Culture Media. The MPR (Mitra, Prasad, and Roychowdhury) medium (Mitra et al., 1976) supplemented with 1 mg BA l^{-1} (Table Ascda-1) should be used to bring about the formation of PLBs by explants. Each explant can produce nearly 60 plantlets with 2–3 leaves and 2–4 roots in 20 weeks on this medium. According to the original paper these plantlets "were gradually hardened *in vitro* by sequential removal of growth adjuvants, vitamins and minor and major salts from the nutrient mix" (Vij and Kaur, 1999). No details are given about this hardening process. However, it is safe to assume that one or more of the media used in other methods for the culture of *Ascofinetia* leaf sections (see Tables Arach-4 to Arach-6, Aranda-4 to Aranda-8) or other explants (see Tables Arach-3 to Arach-6) will prove suitable.

Procedure. Explants should be cultured on the modified MPR medium (Table Ascda-1) for about 20 weeks or until they develop 2–3 leaves and an equal number of roots. After that they should be grown on one of the other media (see Tables Arach-3 to Arach-6, Aranda-4 to Aranda-8). Following further development, the plants should be potted in 6-cm-diameter clay pots in a potting mix consisting of charcoal chips, pine bark, and brick pieces (in the ratio 1 : 1 : 1, v/v/v) topped with moss. The potted plants should be mist irrigated and hardened for 4–6 weeks in a humidity chamber. After that they can be repotted in 15-cm-diameter clay pots and grown outdoors.

Developmental Sequence. PLBs form on the explants on the first medium (Table Ascda-1) and develop into plantlets. These plantlets harden on the second medium (see one of the following: Tables Arach-3 to Arach-6, Aranda-4 to Aranda-8) and grow to maturity after being transferred to pots.

General Comments. This procedure is easy to use and makes possible the propagation of a monopodial orchid from leaves without endangering the donor plant.

***Ascocenda* Fiftieth State Beauty**

TABLE ASCDA-1. **Mitra, Prassad, and Roychowdry medium (Mitra et al., 1976) as modified for the culture of leaf explants of *Ascocenda* Fiftieth State Beauty (Vij and Kaur, 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100.0	10.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 4H_2O$	200.0	20.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	180.0	18.0 g l^{-1}	10

	Solvent				
16	Water, distilled[f]	To 1000 ml			
	Solidifier				
17	Agar[f]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

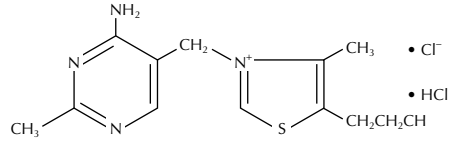
[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe calls for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses. If the cytokinin fails to dissolve add a few drops of 0.1N HCl to the stock solution.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred (agar is not used in liquid media). When the agar is completely dissolved pour the solution into a 2-l Erlenmeyer flask and autoclave. As a rule, media which contain vitamins, hormones, and/or other heat labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).



Thiamine/vitamin B_1

Ascocentrum

Ascocentrum as a genus was segregated from *Saccolabium* by the German orchid taxonomist Rudolph Schlechter (Grove, 1995). The plants are small epiphytes which may have strap or semi-terete leaves. Flowers are brightly colored, small, resemble miniature *Vanda* blossoms, and are arranged tightly on the racemes (Grove, 1995). *Ascocentrum* species have been crossed with *Vanda* to produce the hybrid genus *Ascocenda* which combines some of the best characteristics of the parent genera and produces spectacular flowers.

Micropropagation of *Ascocentrum ampullaceum*

Ascocentrum ampullaceum is distributed from the Himalaya hills in India eastward to Burma, the northwestern mountains of Thailand, Laos, and southern Yunnan in China (Grove, 1995). The micropropagation procedure described here is the result of research on the effects of pH and micronutrients on the growth of PLBs (Wannakrairoj and Tanyasonti, 1996).

Plant Material. PLBs obtained from axillary bud cultures (by a method which was not described) were used in the original research.

Surface Sterilization. No surface sterilization is needed for PLBs taken from in vitro cultures.

Culture Vessels. Erlenmeyer flasks, of 50-ml capacity, containing 20 ml of medium are suitable.

Culture Conditions. Cultures should be placed on 120 rpm orbital shakers at $26 \pm 2°C$ under continuous illumination of 25 μmol m^{-2} s^{-1}.

Culture Media. Explants should be cultured in liquid Vacin and Went medium (Vacin and Went, 1949) containing the micronutrients of the MS solution (Murashige and Skoog, 1962) [a mixture referred to as the WS (perhaps standing for the first author's initials with the initial of the last name first) medium], 15% (v/v) coconut water (CW), 50 μmol chelated iron (Fe_2EDTA), 25 μmol manganese, and 0.075 μmol copper (Table Asctm-1). This "formula, [is] currently called 'KU [presumably referring to the authors' institution, Kasetsart University] medium'."

Procedure. Protocorms from in vitro cultures are sectioned and placed in the liquid culture medium (Table Asctm-1).

Developmental Sequence. The fresh weight of PLBs increased, but the original paper does not provide further details.

General Comments. This procedure was used to study the effects of pH and several micronutrients on PLB development. The PLBs used in this research were taken

TABLE ASCTM-1. **Vacin and Went (VW) medium (Vacin and Went, 1949) with the microelements of the Murashige–Skoog (MS) solution (Murashige and Skoog, 1962) as modified for the culture of *Ascocentrum ampullaceum* protocorm-like bodies, and referred to as the WS medium (Wannakrairoj and Tanyasonti, 1996)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monosobsic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	40.0	4.0 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	28.0	2.8 g l^{-1}		
7	**Microelements**[e]				
(a)	Boric acid, H_3BO_3	6.2	62.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	16.9	1.69 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Complex additive				
8	Coconut water[f]	150.0 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference between the amount suggested here and that in the original formulation is negligible.

[e]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[f]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1–8 to 500–700 ml of distilled water (item 10), adjust pH to 5.6–5.8, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Pour the solution into culture vessels and autoclave.

from in vitro cultures of axillary buds (using a method which was not described). Since the original cultures already produced PLBs, another procedure does not seem to be necessary unless there was no growth and/or differentiation on the medium used to culture the axillary buds.

Micropropagation of *Ascocentrum* through the Culture of Flower Bud Explants

The methods used for *Vandofinetia* (Kishi et al., 1997*a*, 1997*b*) can also be used for *Ascocentrum*.

Origin of the term protocorm

An incorrect but widespread and oft repeated (for one example see Cribb, 1999) assertion is that the term *protocorm* was coined by Noël Bernard (1874–1911), the French botanist (left) who discovered the role of mycorrhiza in orchid seed germination. Actually the term was proposed in 1890 (9 years before Bernard made his discovery) by Melchior Treub (1851–1910), the Dutch botanist (right) who was the long time director of the famed Bogor Botanical Gardens, to describe an early stage in the germination of Lycopods.

Ascofinetia

Ascofinetia is a hybrid genus involving *Ascocentrum curvifolium, Ascocentrum miniatum, Ascocentrum pumilum, Ascocentrum ampullaceum*, or *Ascocentrum* hybrids and *Neofinetia falcata*. It is a monopodial orchid, so removal of apical buds may cause the loss of a plant. Therefore a tissue culture procedure was developed for young inflorescences (Intuwong and Sagawa, 1973; Khaw et al., 1978*a*, 1978*b*; Sagawa and Kunisaki, 1982).

Plant Material. Inflorescences, 1.5 cm long or less, with flower primordia are used. Those 3 cm or longer elongated and produced flowers that either aborted and turned brown or developed normally and opened (Table Ascf-1).

Surface Sterilization. Inflorescences are removed and sterilized for 10 min with 100 ml of 10% Clorox plus one drop of Tween 20. The bracts are then removed and the inflorescences sterilized again, this time with 100 ml of 5% Clorox (5 ml Clorox diluted to 100 ml with distilled water) plus one drop of Tween 20. This is followed by a 3-min rinse in sterile distilled water.

Culture Vessels. Use 125- or 250-ml Erlenmeyer flasks containing 25 or 50 ml medium, respectively.

Culture Conditions. Maintain cultures at 26 ± 3°C with continuous illumination of about 200 ft-c provided by General Electric Power Groove white fluorescent lamps. Liquid cultures should be agitated at approximately 160 rpm (a New Brunswick Scientific Co. Model V shaker was used in the original research).

Culture Media. Vacin and Went liquid medium (VW; Vacin and Went, 1949) containing 20 g sucrose (Su) and 15% coconut water (CW) is used for the initial culture (VW + Su + CW; Table Ascf-1). The medium will become turbid-brown within 10–14 days and inhibit the growth of PLBs. Therefore the medium must be changed every 10–14 days. Even when the medium is changed regularly the PLBs will turn yellow if left in this formulation. To ensure the survival of PLBs and cause them to proliferate, they must be transferred to sugar-free liquid medium [Table Ascf-1 (VW – Su) + CW]. For differentiation of plantlets, the PLBs are transferred onto potato

TABLE ASCF-1. **Effects of four culture media on inflorescence explants and tissues of *Ascofinetia, Neostylis,* and *Vascostylis* (Intuwong and Sagawa, 1973)**

Culture medium[a]	Inflorescence, ≤ 1.5 cm long	Inflorescence, ≤ 3 cm long	Protocorm-like bodies	Plantlets
VW + Su + CW	Proliferation	Flowering in vitro or aborted flowers	Yellow color	
(VW – Su) + CW			Multiplication	
(VW – Su) + CW + PE + GB			Differentiation into plantlets	
(VW – Su) + CW + PE + RB				Maintenance of growth

[a]CW, coconut water; GB, 100 g green banana homogenate; PE, liquid obtained after boiling 100 g freshly diced potatoes in 200 ml distilled water for 5 min; RB, 100 g ripe banana homogenate; Su, sucrose; VW, Vacin and Went medium (Vacin and Went, 1949).

TABLE ASCF-2. **Modified Vacin and Went medium for the culture of *Ascofinetia* inflorescences (Intuwong and Sagawa, 1973)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Tricalcium phosphate, $Ca_3(PO_4)_2$[b]	200	20 g l^{-1}	10	Or weigh
2	Potassium nitrate, KNO_3[c]	525	52.5 g l^{-1}	10	Or weigh
3	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
4	Ammonium sulfate, $(NH_4)SO_4$[c]	500	50 g l^{-1}	10	Or weigh
5	Ferric tartrate, $Fe_2(C_4H_4O_6)_3$[d]	28	2.8 g l^{-1}	10	
6	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additives				
8	Coconut water (CW)	150 ml	No stock	No stock	Fresh
9	Potato extract (PE)[e]	200 ml	No stock	No stock	
10	Ripe banana (RB)[f], or green banana (GB)[f]	100 g	No stock	No stock	Weigh
	Sugar				
11	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[g]	To 1000 ml			
	Solidifier[g]				
13	Agar	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]If salt does not dissolve completely, shake stock solution well before dispensing to insure an even suspension; or better yet, weigh out each time.

[c]Solutions containing ammonium and nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between use.

[d]Ferric tartrate is relatively insoluble. Grinding it with a mortar and pestle before dissolving helps. The addition of a pellet or two of KOH to the solution will increase solubility, but a precipitate may form nevertheless. To insure equal distribution, shake stock solution well before dispensing.

[e]Liquid PE is obtained by boiling 100 g freshly diced potato (1-cm cubes) in 200 ml distilled water for 5 min.

[f]Homogenize 100 g banana (RB or GB) with 200 ml water in a blender for 30–60 s at high speed.

[g]To prepare basic medium (VW + Su), mix items 1–7 with 750 ml distilled water (item 12), adjust pH to 5.5, add sugar (item 11), and adjust volume to 1000 ml with more distilled water (item 12). If liquid medium is desired, dispense solution and autoclave. When solid medium is needed, dissolve agar (item 13) by adding it slowly while stirring to the gently boiling solution. Then dispense and autoclave. When sugar is not desired (VW – Su), omit item 11 and prepare as before. To prepare media containing RB, GB, CW, or PE, use homogenate of liquid instead of an equal volume of water. Media prepared are VW + Su + CW, (VW – Su) + CW, (VW – Su) + CW + PE + GB, and (VW – Su) + CW + PE + RB.

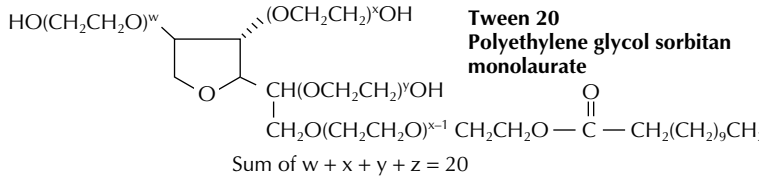
extract (PE) and green banana (GB)-containing solid medium [(VW – Su) + CW + PE + GB; Tables Ascf-1 and Ascf-2]. Growth of the plantlets is maintained on a solid medium containing ripe banana (RB), CW, and PE [(VW – Su) + CW + PE + RB; Tables Ascf-1 and Ascf-2].

Procedure. Remove inflorescences 1.5 cm long or less, sterilize, and place in liquid VW + Su + CW (Table Ascf-1). Change medium every 10–14 days or when it becomes turbid-brown. When PLBs are produced, transfer them to liquid (VW – Su) + CW (Table Ascf-1). To obtain differentiation, subculture PLBs onto solid (VW – Su) + CW + PE + GB (Table Ascf-1). Once plantlets are formed, maintain their growth on (VW – Su) + CW + PE + RB (Table Ascf-1).

Developmental Sequence. The explants proliferate in liquid VW + Su + CW (Table Ascf-1) within 20–51 days. Proliferation is acropetal. Further multiplication occurs

on liquid (VW – Su) + CW (Table Ascf-1). Differentiation takes place on solid (VW – Su) + CW + PE + GB (Table Ascf-1) and growth is maintained on (VW – Su) + CW + PE + RB (Table Ascf-1).

General Comments. This is a very effective method for clonal propagation and does not require sacrificing or even setting back a plant.



Tween 20
Polyethylene glycol sorbitan monolaurate

Barlia

As is the case with so many other orchids, there is no agreement regarding the nomenclature of this genus and its species. *Barlia longibracteata* has also been referred to as *Himantoglossum bracteatum, Orchis longibracteata, Aceras longibracteata, Loroglossum longibracteatum*, and *Barlia robertiana*. The last name in this list appears in several recent European orchid floras and will be used here.

Isolation of Protoplasts of *Barlia robertiana*

Protoplasts of *Barlia robertiana* (*Barlia longibracteata*) were isolated to "provide [a system for] the study of the [orchid] endophyte/host interactions" (Pais et al., 1982) as well as for studies of protoplast fusion (Pais et al., 1983).

Plant Material. Youngest of first leaves of 2–3-month-old plants are used.

Surface Sterilization. A procedure for the surface sterilization of the leaves is not given in the original papers. It would seem that such sterilization is desirable, but an appropriate method can be developed only with trial and error. Methods used for surface-sterilizing the leaves of *Aranda* and other orchids that can be propagated from leaf tissues are a good starting point.

Culture Conditions. There is no information regarding temperature and illumination in the original papers. However, the original reports (Pais et al., 1982, 1983) refer to standard procedures, which suggests that the conditions used for other orchid protoplasts may be suitable. The osmotic concentration of the isolation solution is given in one paper as being equivalent to a 0.6-*M* (109.3 g l^{-1}) solution of mannitol (Pais et al., 1982) and in another as 0.55-*M* (100.2 g l^{-1}) sorbitol (Pais et al., 1983).

Culture Medium. No culture medium is used. The protoplasts are obtained by placing the leaf tissues in an enzyme solution consisting of 1% cellulase (1 g per 100 ml) and 0.5% (0.5 g per 100 ml) Macerozyme (both obtainable from Cal Biochem and Fluka chemical companies) at pH 5.7 for 3 h (Pais et al., 1983) to 4 h (Pais et al., 1982). Protoplast fusion is carried out in a solution consisting of 4 g l^{-1} sodium chloride, 1 g l^{-1} sodium acetate trihydrate, 294 mg l^{-1} calcium chloride (presumably dihydrate), 63.8 g l^{-1} sorbitol, and either 50 g l^{-1} sodium alginate or 150 g l^{-1} dextran with the pH adjusted to 5.5.

Procedure. Place the leaf tissue in the enzyme solution for the required time. Isolate the protoplasts by centrifugation, and wash several times with osmoticum. To induce fusion add 0.5 ml of protoplast suspension (containing 10^8 protoplasts) of each species to 0.1 ml of fusion medium and incubate.

Developmental Sequence. Fusion occurs within approximately 30 min, but there are no reports of further development despite the fact that isolated protoplasts and even fusion product may remain alive for some time.

General Comments. Several authors have reported on the isolation and fusion of orchid protoplasts, but callus cultures and/or plants have yet to be obtained with these procedures. However, it is reasonable to assume that plantlet regeneration will become possible in the future. The methods described here are also suitable for *Ophrys bombyliflora* and *Ophrys lutea*.

Bletilla

A genus consisting of nine species; *Bletilla* is found in Asia.

Plantlet Regeneration from Root Tips of *Bletilla striata*

In Hong Kong *Bletilla striata* grows in open grasslands. It is used medicinally and therefore is overcollected. A method for plantlet regeneration from root tips was developed as part of research associated with a Ph.D. dissertation (Yam, 1989; Yam and Weatherhead, 1991*b*).

Plant Material. In the original research, root tips 1–1.5 mm in length were taken from 6-month-old seedlings. It is important to use a sharp and sterile scalpel blade. Tips should be cut in a sliding action to prevent pressure on the tissues. The seeds were germinated and the seedlings were grown on Knudson C medium supplemented with 20% (v/v) coconut water from mature nuts. They were maintained under 25 ± 2°C and 16-h photoperiods of 2000 lx provided by four 40-W Sylvania Gro Lux fluorescent tubes placed 60 cm above the cultures.

Surface Sterilization. Since the tips are taken from aseptic seedlings, there is no need to surface-sterilize them.

Culture Vessels. Wide-mouth, γ-irradiated plastic flasks of 75-ml capacity (from Johns Mallinkrodt, Johns Division, Mallinkrodt Australia, Pty., Ltd.) were used in the original research. Other containers like Erlenmeyer flasks, various bottles, and test tubes are also suitable.

Culture Conditions. In the original research the flasks were maintained under conditions of 16-h photoperiods of 2000 lx (provided by 40-W Gro Lux lamps 60 cm above the flasks) and 25 ± 2°C.

Culture Media. Explants were placed on modified half-strength MS medium (Table Ble-1). Plantlets were moved to modified Knudson C medium (Table Ble-2) 3 months after they form.

Procedure. Cut root tips and place them flat on the medium. Examine the cultures at regular intervals, and move plantlets to the second medium 3 months after their formation.

Developmental Sequence. The root tips swell and form a callus, which produces multiple shoots 7 months after the start of culture. Roots form only following transfer to the second medium.

General Comments. This method can be used with other orchids and can be employed to increase the number of plantlets in cases where only a few seedlings are available. Only a very small percentage (less than 10%) of the root tips produces plantlets.

TABLE BLE-1. **Murashige–Skoog medium (Murashige and Skoog, 1962) as modified for the culture of root tips of *Bletilla striata* (Yam, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220	22 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950	95 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Napthaleneacetic acid (NAA)	1	100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
11	Benzyladenine (BA)	0.2	20 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh
	Darkening agent				
18	Graphite[h]	3 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–15 and 18 to 900 ml distilled water (item 16), adjust pH to 5.8, and adjust volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into culture flasks and autoclave. (In general, solutions that may contain labile organic additives should not be autoclaved without first determining whether this will not have a deleterious effect; this medium can be autoclaved.) Omit agar if liquid medium is desired.

TABLE BLE-2. **Knudson C medium for the germination of orchid seeds (Knudson, 1946) as modified for the culture of root-tip-derived plantlets of *Bletilla striata* (Yam, 1989)**

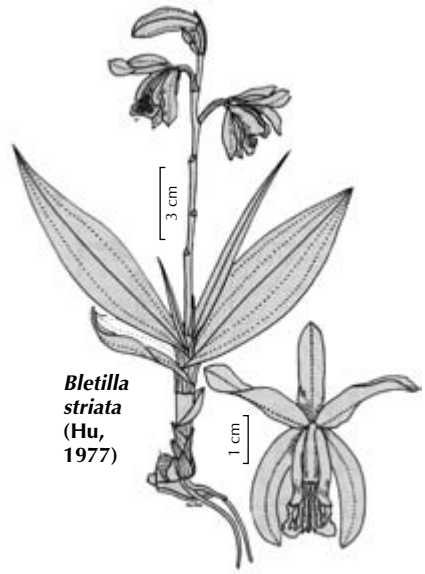
Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
7	Coconut water	200			
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[d]	To 1000 ml			
	Solidifier				
10	Agar[d]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution, dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[d]Add items 1–8 to 700 ml distilled water (item 9), adjust pH to 5.6, and adjust volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into culture flasks and autoclave. Omit agar if preparing liquid medium. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be 4.6–4.7. If necessary adjust pH upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.



***Bletilla striata* (Hu, 1977)**

Plantlet Regeneration from Stem Nodes of *Bletilla striata*

Bletilla striata is very rare in Hong Kong, where it grows in open grasslands. It is used medicinally in Chinese herbal medicine, which leads to excessive collecting. A method for plantlet production from stem nodes was developed at the Botany Department, University of Hong Kong (Yam, 1989).

Plant Material. In the original research nodes, 1-cm-long stem sections with a bud in the middle were taken from seedlings 3–5 nodes long. It is important to use a sharp, sterile scalpel blade. Tips should be cut in a sliding action to prevent pressure on the tissues. The seeds were germinated and the seedlings were grown on Knudson C medium supplemented with 20% (v/v) coconut water from mature nuts. They were maintained under conditions of 25 ± 2°C and 16-h photoperiods of 2000 lx provided by four 40-W Gro Lux fluorescent tubes placed 60 cm above the cultures.

Surface Sterilization. Since the sections are taken from aseptic seedlings, there is no need to surface-sterilize them.

Culture Vessels. Wide-mouth, γ-irradiated plastic flasks of 75-ml capacity (from Johns Mallinkrodt) were used in the original research. Other containers like Erlenmeyer flasks, various bottles, and test tubes are also suitable.

Culture Conditions. In the original research the flasks were maintained under conditions of 16-h photoperiods of 2000 lx (provided by 40-W Gro Lux lamps 60 cm above the flasks) and 25 ± 2°C.

Culture Media. Explants are placed on modified Knop's medium (Table Ble-3). Three months after plantlets form, they were moved to modified Knudson C medium (Table Ble-2) for root initiation.

Procedure. Cut stem sections, free them of leaves, and place them horizontally on the medium. Examine the cultures at regular intervals, and move plantlets to the second medium 3 months after their formation.

Developmental Sequence. The buds on the stem sections swell after 2–3 weeks, and multiple shoots form after an additional 2–4 weeks.

General Comments. This method can be used with other orchids and can be employed to increase the number of plantlets in cases where only a few seedlings are available. The success rate is very high.

TABLE BLE-3. **Knop's medium (Knop, 1884) modified for the culture of *Dendrobium* stem nodes and used to culture stem nodes of *Bletilla striata* (Yam, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2$[b,c]	500	50 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4$[c]	125	12.5 g l^{-1}	10	
3	Monopotassium phosphate, KH_2PO_4	125	12.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	125	12.5 g l^{-1}	10	
	Iron				
5	Ferric citrate[d]	10	1 g l^{-1}	10	
6	**Microelements**				
(a)	Boric acid, H_3BO_3	0.056	56 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2$	0.02	20 mg l^{-1}		
(c)	Copper chloride, $CuCl_2 \cdot 2H_2O$	0.054	54 mg l^{-1}		
(d)	Ferric cloride, $FeCl_3 \cdot 6H_2O$	0.5	500 mg l^{-1}		
(e)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	0.036	36 mg l^{-1}	1	One solution
(f)	Sodium EDTA, Na_2EDTA	0.8	800 mg l^{-1}		
(g)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2 2O$	0.025	25 mg l^{-1}		
(h)	Zinc chloride, $ZnCl_2$	0.152	152 mg l^{-1}		
	Polyol				
7	*myo*-inositol	100	No stock	No stock	Weigh
	Vitamin				
8	Thiamine·HCl	0.4	40 mg 100 ml^{-1} 95% ethanol	1	
	Anti-auxin				
9	*trans*-cinnamic acid (tCA)	70	7 g 100 ml^{-1} 95% ethanol	1	
	Sugar				
10	Sucrose[e]	30 g	No stock	No stock	Weigh
	Solvent				
11	Distilled water[e,f]	To 1000 ml			
	Solidifier				
12	Agar[e]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The number of waters of hydration is not given.

[d]This compound may not dissolve easily but can be solubilized by adding a few drops of dilute KOH. It is preferable to chelate the iron. Use 37.3 mg chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$). To prepare a stock solution add 3.73 g l^{-1} of chelating agent and 2.78 g l^{-1} of iron salt. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]As originally formulated the solution does not contain sugar or agar.

[f]Add items 1–9 to 900 ml distilled water (item 11), adjust pH to 5.6, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into culture vessels and autoclave.

Micropropagation of *Bletilla striata* through the Culture of Young Pseudobul Segments

A native to China and Japan, *Bletilla striata* is a terrestrial orchid that produces attractive flowers ranging from white (rarely) through rose-pink to purple (Hu, 1977; Bechtel et al., 1981, 1986, 1992; Vij and Dhiman, 1997). This species was discovered in Japan by Carl Thunberg who described it as *Limodorum striatum* in his *Flora Japonica* in 1784 (Bechtel et al., 1981, 1986, 1992). Heinrich Gustav Reichenbach (Reichenbach *f*, 1823–1889) transferred it to the genus *Bletilla* in 1878 as *Bletilla striata* (Bechtel et al., 1981, 1986, 1992). Like many other orchids, *B. striata* was kicked around by taxonomists during the last two centuries and as a result it suffers from an overabundance of synonyms including *Bletia gebina*, *Bletia striata*, *Bletilla gebina*, *Cymbidium hyacinthinum*, *Cymbidium striatum*, *Epidendrum tuberosum*, *Guyas humilis*, and *Jimensia striata*. There is no telling how many additional synonyms the future holds.

In addition to being an ornamental plant *B. striata* is used as a herb to treat gastrointestinal problems, malaria, respiratory ailments, and maglinancy, and as an embolizing agent (Lawler, 1984; Vij and Dhiman, 1997). These multiple uses have lead to overcollection of the species. A micropropagation method was developed at the Orchid Laboratory, Department of Botany, Pamjab University, Chandigarh to alleviate the pressure on native populations (Vij and Dhiman, 1997).

Plant Material. Pseudobulbs (5–7.5 mm in size) of asymbiotically produced seedlings were sectioned into single node segments (Fig. Ble-1).

Surface Sterilization. Explants are taken from in vitro cultures and do not require surface sterilization.

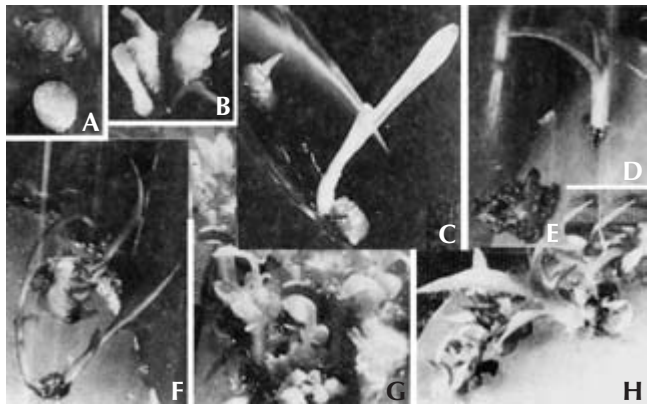


FIG. BLE-1. **Culture *of Bletilla striata* explants. A. Explant in culture. B. Shoot and root formation. C. Shoot initiation. D. Plantlet. E. Callus. F. Formation of multiple shoots. G, H. Plantlet formation. (Source: Vij and Dhiman, 1997.)**

Culture Vessels. Photographs in the original paper (Fig. Ble-1D–H) indicate that culture tubes were used. They should be filled with medium to approximately 20% of their volume.

Culture Conditions. Standard laboratory conditions or 25 ± 2°C under 12-h photoperiods of 3500 lx are suitable.

Culture Media. Seeds were germinated on Ichihashi medium (Ichihashi, 1989) supplemented with 1 mg casein hydrolysate l^{-1} (the same medium as the one in Table Ble-4, but with 20 g sucrose l^{-1} and 10 g agar l^{-1} rather than glucose and 8.5 g agar l^{-1}as in the modification; the recipe is not given here in detail because this book does not deal with seed germination). Explants should be cultured on a modified Ichihashi medium (Ichihashi, 1989), which contains BA, glucose instead of sucrose, and less agar than in the original formulation (Table Ble-4). Roots are formed when plantlets produced on the first medium (Table Ble-4) are moved to a NAA-containing modification of the Ichihashi solution (Table Ble-5).

Procedure. Single node segments are taken from pseudobulbs of young seedlings and placed on the first medium (Table Ble-4). Plantlets from this medium should be moved to the second solution (Table Ble-5) for development. Well-developed plants can be potted in a potting mix.

Developmental Sequence. Callus-mediated PLBs form within 4 weeks on modified Ichihashi medium containing 2 mg BA l^{-1} (Table Ble-4). Shoots develop on this medium within an additional 2 weeks (i.e., a total of 6 weeks after the start of culture). These shoots do not develop roots. Rhizogenesis occurs only on a medium that contains 1 mg BA l^{-1} and an equal amount of NAA (Table Ble-5).

General Comments. This method can be very effective as a means of increasing the number of seedlings. It can not be used to propagate outstanding cultivars because the quality of seedlings is not known.

TABLE BLE-4. **Modified Ichihashi (MI) medium (Ichihashi, 1989) as used for the culture of *Bletilla striata* sections of young pseudobulbs (Vij and Dhiman, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the gibberellin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH 5.1 ± 1, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave.

TABLE BLE-5. **Modified Ichihashi (MI) medium (Ichihashi, 1989) as used for the culture of *Bletilla striata* plantlets obtained from sections of young pseudobulbs (Vij and Dhiman, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Monoammonium phosphate, $NH_4H_2PO_4$[b]	460.0	46.0 g l^{-1}	10	
2	Potassium nitrate, KNO_3[b]	808.0	80.8 g l^{-1}	10	
3	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$	708.5	70.85 g l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	246.5	24.65 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	62.0 mg l^{-1}		
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
7	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
8	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
9	Naphthaleneleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
10	Benzylaminopurine	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Gibberellin				
11	Gibberellic acid (GA_3)	3.5 µg	0.350 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Glucose	15.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar	8.5 g	Agar[g]	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the gibberellin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH as required, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 7), hormones (items 9–11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Brassavola

Protoplasts were isolated from leaves of *Brassavola nodosa* using the procedures developed for *Acampe praemorsa*. The yield was 3.6×10^4 protoplasts per gram of fresh weight of tissue.

Brassia

A South American genus, *Brassia*, is named after William Brass, a botanical illustrator who collected plants in Guinea and South Africa around 1790 for Sir Joseph Banks. Several species in this genus have been used as parents for intergeneric hybrids involving one to five other genera. For this reason alone a useful method for the isolation of protoplasts would be valuable since it could be used in fusion experiments involving the genera employed in sexual hybridization. A method for the preparation of *Brassia* protoplasts was developed as a step in the isolation of orchid nuclei (Capesius and Meyer, 1977).

Plant Material. Virus-free protocorms of *Brassia maculata* grown in liquid medium at 25°C and continuous illumination were used in the original work. The protocorms were sliced into thin disks for the purpose of protoplast isolation.

Surface Sterilization. It is not necessary to surface-sterilize the protocorms since they are grown under sterile conditions. However, the culture medium must be washed off, first with sterile distilled water and then with a sterile solution consisting of 10 mg l^{-1} magnesium sulfate ($MgSO_4 \cdot 7H_2O$) and 25 mg l^{-1} potassium chloride (KCl).

Culture Vessels. The tissue and protoplasts were not cultured in the original research. If attempting to culture the protoplasts use small Petri dishes or multiple-well plates. Erlenmeyer flasks, Petri dishes, tubes, or beakers can be used for the isolation procedure. Use centrifuge tubes for centrifugation.

Culture Conditions. The original investigators made no attempt to culture the protoplasts since their aim was to isolate nuclei.

Culture Media. A culture medium was not formulated since the protoplasts were not cultured. The tissues are plasmolysed in the sterile $MgSO_4$–KCl solution and pretreated in 0.1% (0.1 g per 100 ml) Pectinol fest (from Fa. Röhm, Darmstadt, Germany). Protoplast separation occurs in the $MgSO_4$–KCl solution containing 1% (1 g per 100 ml) cellulase (probably also from Röhm, but other companies like CalBiochem or Sigma Chemical Co. sell this enzyme too) and 0.3% Pectinol fest (300 mg per 100 ml), with a pH of 5.8. The protoplasts were washed with the sterile $MgSO_4$–KCl solution.

Procedure. Plasmolyse the tissues for 30 min and pretreat them for 1 h. They should be subjected to the protoplast separation solution for 3–4 h at room temperature

(22°C) with occasional gentle manual shaking. Collect the protoplasts by low-speed centrifugation (50× *g*) for 3 min, and wash three times.

Developmental Sequence. The protoplasts were not cultured.

General Comments. With this procedure the protoplast yield is high. Protoplasts from protocorms tend to fuse. It is possible therefore that this procedure may be useful in attempts to develop protoplast-based propagation and bioengineering methods for orchids. This method was also used to isolate protoplasts from leaves of *Cymbidium* Ceres (*Cymbidium i'ansonii* × *Cymbidium insigne*), protocorms of *Cymbidium pumilum*, and *Cattleya*. (The last genus is not clear since the paper lists *Cattleya schombocattleya* as one of the plants; this could have been a *Cattleya* species, a *Schombocattleya*, or a hybrid between the two.)

Brassocattleya

Orchids are unusual in that it is easily possible to make intergeneric crosses within the family. Some of the earliest crosses were made between *Brassavola* and *Cattleya* at the famed Veitch and Sons establishment in the UK. The resulting hybrid genus is *Brassocattleya*.

Micropropagation of *Brassocattleya* through the Culture of Buds from Shoots and Pseudobulbs

Because of the large interest in species and hybrids of the *Cattleya* alliance, there are reports of experiments with several members of the group. One procedure was developed using *Brassocattleya* Princess Patricia as the source of explants (Kako, 1973).

Plant Material. Best results are obtained with the third bud from 15-cm-long, newly growing shoots. However, other buds also grow. When using back bulbs, it is best to remove buds that are just starting to grow.

Surface Sterilization. The procedure used for *Cattleya* (Scully, 1967) is suitable.

Culture Vessels. This information was not given. However, it seems that 50-ml Erlenmeyer flasks containing 5 ml of medium should be appropriate (Scully, 1967).

Culture Conditions. Explants are placed in liquid medium that is not shaken or rotated ["liquid standing medium" (Kako, 1973)] and maintained at 25°C under continuous illumination.

Culture Medium. Liquid modified MS medium (Table Bc-1) is used as the starting medium. A different modification, this time solid, of the same medium (Table Bc-2) is used for callus induction.

Procedure. Excise buds like those of *Cattleya* (Scully, 1967) and place them into the culture medium, which is allowed to stand (not shaken). Within a month they grow and must be subcultured by cutting them in half and transferring the sections to liquid medium for a month and subculturing again. After 3 months, transfer halves to a solid medium. Addition of 2,4-D and kinetin enhances callus formation.

When transferred to Knudson C medium (see Tables Aranda-7 and Aranda-8) the callus forms plantlets.

Developmental Sequence. Explants swell after a few days in culture. Larger cells are formed at the cut sides 2–4 weeks later, and vascular bundles develop. Active cell division can be noted among epidermal cells.

General Comments. An interesting aspect of this procedure is that the cultures need not be shaken. This reduces costs without eliminating quick proliferation. When whole PLBs instead of halves are transferred to solid medium, survival rates are better.

TABLE BC-1. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Brassocattleya* buds (Kako, 1973)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, Kl	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[h]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin does not dissolve, add a few drops of dilute KOH to solubilize it.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 15), set pH to 5.3–5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Pour solution into a 2-l flask, and autoclave. Add amino acid, auxin, and vitamins (items 8, 10–13) into the hot solution under sterile conditions with sterilized pipettes, mix well, and dispense into preautoclaved culture vessels.

TABLE BC-2. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for callus induction from buds of *Brassocattleya* (Kako, 1973)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10

(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, Kl	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Dichlorophenoxyacetic acid (2,4-D)	10	1000 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
11	Kinetin	10	1000 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin and/or the cytokinin do not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml of distilled water (item 16), set pH to 5.3–5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Either bring the solution to a gentle boil and add the agar slowly with stirring, or, add agar to cold solution and then bring it to a boil with stirring. Pour solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8, 10–14) into hot solution under sterile conditions with sterilized pipettes, mix well, and dispense into preautoclaved culture vessels.

However, since halving doubles the number of sections, even with higher losses more calli are obtained.

Micropropagation of *Brassocattleya* through Axillary Bud Culture

Brassocattleya Pastoral flowers range from deep purple-magenta to cream tinged with purplish pink. There is also a pure white form named *Brassocattleya* Pastoral 'Innocense'. A tissue culture method for axillary buds of this hybrid was developed by Fumiaki Kishi of the Kirin Brewery Company and Koujirou Takagi of the Takagi Orchid Nursery in Japan (Kishi and Takagi, 1997*a*, 1997*b*).

Plant Material. In the original research, axillary buds were excised from 15-cm-long pseudobulbs of *Brassocattleya* Pastoral 'Innocense'.

Surface Sterilization. Buds must first be washed with 10% (v/v) benzalkonium chloride for 10 min (household detergent and water can probably also be used). The washed buds should be dipped in 70% (v/v) ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) for 30 sec. This should be followed by a 5-min submersion in 0.5% (v/v) sodium hypochlorite (8–10 ml Clorox or another household bleach that contains 6–5.25% sodium hypochlorite diluted to 100 ml with distilled water) plus 0.05% (v/v; this really amounts to a few drops per 100 ml) Tween 20 (or a mild household detergent). After that the buds should be washed three times with autoclaved distilled water.

Culture Vessels. Test tubes (3×20 cm) containing 20 ml of medium were used originally. Other vessels can also be used.

Culture Conditions. In the original research the cultures were placed on a drum-type rotary shaker tilted at 15° and rotating at 1 rpm. A different type of shaker may also be suitable but should be tested with a few explants before being put into large-scale use. Cultures should be maintained at 25 ± 2°C under illumination of 56.2 ± 5.2 μmol m^{-2} s^{-1} or standard laboratory conditions.

Culture Media. Liquid (this is not stated directly in the materials and methods section of the original paper, but is implied by the use of a shaker), one-quarter strength modified MS medium (Murashige and Skoog, 1962) should be used (Table Bc-3) for the production of PLBs. For plantlet production, the PLBs should be cultured on modified full-strength MS (Table Bc-4).

Procedure. Explants are cultured on the first medium (Table Bc-3). PLBs that form on it are moved to the second medium (Table Bc-4) for plantlet formation.

Developmental Sequence. PLBs form on the first medium (Table Bc-3) and plantlets develop on the second one (Table Bc-4).

General Comments. This procedure may be suitable for other *Brassocattleya* hybrids.

TABLE BC-3. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of axillary buds of *Brassocattleya* Pastoral 'Innocense' (Kishi and Takagi, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	412.5	41.25 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	110.0	11.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	92.5	9.25 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	475.0	47.5 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	42.5	4.25 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (IAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	If necessary[e]
	Cytokinin				
11	Kinetin	1–10.0	10–100 mg 100 ml^{-1} 95% ethanol[e,f]	1	If necessary[e]
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to 1 l of distilled water and stir and/or heat until dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses. There is no indication in the original paper whether auxin and/or cytokinin were used and if so how much. The auxin concentration suggested here is the same as that in Table Bc-1. There is no cytokinin in the medium outlined in Table Bc-1 and none is being suggested here. Should a cytokinin prove to be necessary 1 or 10 mg kinetin l^{-1} medium may be appropriate. These suggestions are speculative. Therefore those who plan to use this procedure are advised to test the medium as described here with a few buds before employing any formulations on a large scale.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or 0.1N HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.4, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) if necessary (see footnote *e*) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. It is also possible to add items 1–14 before the addition of sugar, complete preparation of the medium, distribute to culture vessels, and autoclave the mixture.

TABLE BC-4. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for plantlet production from protocorm-like bodies of *Brassocattleya* Pastoral "Innocense" (Kishi and Takagi, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]

(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Indoleacetic acid (IAA)	1.0–3.0	100–300 mg 100 ml^{-1} 95% ethanol[e,f]	1	If necessary[e]
	Cytokinin				
11	Kinetin	0.04–1.0	4–100 mg 100 ml^{-1} 95% ethanol[e,f]	If necessary[e]	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Gelrite[h]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses. There is no indication in the original paper whether auxin and/or cytokinin were used and if so how much. The auxin and cytokinin concentration suggested here are estimates based on other media. These suggestions are speculative. Therefore those who plan to use this procedure are advised to test the medium as described here with a few protocorm-like bodies before employing any formulations on a large scale. In many instances PLBs form plantlets without the addition of hormones to culture media. Therefore the Knudson C medium (see Tables Aranda-7 and Aranda-8) with or without ripe banana may also prove to be suitable.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.4, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Add the Gelrite in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) if necessary (see footnote *e*) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar or Gelrite are not added to liquid media. It is also possible to add items 1–14 before the addition of sugar, complete preparation of the medium, distribute to culture vessels, and autoclave the mixture.

[h]Gellan gum (available as such from www.caissonlabs.com) as Phytagel (www.sigmaaldrich.com) or Gelrite is an agar substitute which produces a firm, clear, and colorless solid substrate at lower concentrations than agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} may have to be used for media that must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

Brassolaeliocattleya

A hybrid genus *Brassolaeliocattleya* consists of *Brassavola*, *Laelia*, and *Cattleya*. The first hybrid, *Brassolaeliocattleya* Lawrencei was described in the *Gardeners' Chronicle* (series 3, vol. 40, p. 201, 1906).

Although specific procedures for the culture of *Brassolaeliocattleya* do not seem to have been published, shoot tips ("meristems") of this hybrid genus (from *Brassavola*, *Laelia*, and *Cattleya*) are being cultured. In at least one case, that of *Brassolaeliocattleya* Greenwich 'Cover Girl,' clonal propagation through the culture of shoot tips resulted in a splash petal mutation that was named *Brassolaeliocattleya* Greenwich 'Irish Flair' (Green, 1983). It is reasonable to assume that procedures that are suitable for *Brassavola*, *Brassocattleya*, *Brassolaelia*, *Brassolaeliocattleya*, *Cattleya*, *Laelia*, and *Laeliocattleya* would also be suitable for this trigeneric hybrid.

Leaf explants from *Brassolaeliocattleya* seedlings produced PLBs when cultured on Knudson C medium (Knudson, 1946) supplemented with 3–5 mg BA l^{-1}. When moved to Knudson C medium containing 10% banana homogenate, the PLBs produced plantlets (Ding et al., 2002).

Bulbophyllum

One of the largest orchid genera, *Bulbophyllum*, was established by Louis-Marie Aubert Du Petit-Thouars in his *Histoire Particulière des Plantes Orchidées Recueillies sur les Trois Îsles Australes d'Afrique* which was published after he returned to France following his sojourn (1792–1802) in Madagascar and other islands in the Mascarene archipelago (Siegerist, 2001). Estimates of the number of species in *Bulbophyllum* vary from "as many as a 1000" (Bechtel et al., 1992) to "thousands" (Romero-Gonzalez, 2001). The genus is distributed worldwide, but most of its species are found in Asia.

Micropropagation of *Bulbophyllum careyanum*

Bulbophyllum careyanum is native to India, Myanmar (formerly Burma), Sikkim, and Thailand (Kataki, 1986; Vij et al., 2000*a*; Siegerist, 2001). Its racemes are arched, arise from the bases of the pseudobulbs, and produce tightly packed yellowish flowers. The pseudobulbs, borne on scale-covered rhizomes, are approximately 3.5 cm high (Kataki, 1986; Siegerist, 2001). Reverend Charles Samuel Parish (1822–1897), Chaplain to the British forces in Burma who collected and drew orchids there, is reported to have called it "a worthless plant" (Siegerist, 2001). In 1888, Ernst Hugo Heinrich Pfitzer (1846–1906), Professor of Botany at Heidelberg, used it as the type genus for *Bulbophyllum* section *Careyana*. A micropropagation method for this species was developed at the Orchid Laboratory, Department of Botany, Panjab University, Chandigarh, India (Vij et al., 2000*a*).

Plant Material. In the original research pseudobulbs from both greenhouse- and in-vitro-grown plants were used as explant sources. Only the use of explants from greenhouse-grown plants will be described here because they can be utilized for clonal propagation of desirable forms. The pseudobulbs should be sectioned into two halves (Fig. Bulb-1A) – distal and proximal (top and bottom, respectively).

Surface Sterilization. Pseudobulbs should be washed with running tap water and soaked in a detergent (Teepol was used in the original research, but any mild household brand is suitable) for 10 min and rinsed thoroughly. The actual sterilization procedure consists of several steps: (1) a 5-s dip in 70% ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) followed by a thorough rinse with sterile distilled water; (2) a 5-min soak in 0.01% streptomycin (100 mg l^{-1} distilled water, w/v) and again thorough rinsing with sterile distilled water; and (3) a 5-min soak in a mixture of 0.1% $HgCl_2$ (1 g l^{-1} distilled water, w/v; this is a highly toxic substance that should be handled with care or avoided altogether) and a few drops of surfactant (Teepol or any mild detergent) and yet another through rinsing with sterile distilled water. The cut ends of each section must be severed and discarded before placing the sections in culture.

FIG. BULB-1. **Tissue culture of *Bulbophyllum careyanum*. A. Sections. B. Buds on sections starting to grow. C–K. Plantlets. L. Plant in pot.**

Culture Vessels. The culture vessels used in the original research are not described, but the photographs show test tubes. They should contain 20–30% their volume of medium.

Culture Conditions. Illumination of 3500 lx, 12-h photoperiods, and 25 ± 2°C or standard culture room conditions are suitable.

Culture Media. Several media, all based on the Vacin and Went medium (Vacin and Went, 1949), are suitable. However, only a medium which does not contain hormones as such (and therefore has the lowest mutation-inducing potential) will be presented here (Table Bulb-1).

Procedure. The sections are placed in culture after surface sterilization (Fig. Bulb-1A). When plantlets form and proliferate (Fig. Bulb-1B–K) they should be moved to a new culture vessel for further growth. Plantlets that are large enough can be potted in a potting mix in a pot (Fig. Bulb-1L).

Developmental Sequence. After being placed in culture (Fig. Bulb-1A), buds on the sections start to grow (Fig. Bulb-1B, C) and produce plantlets (Figs Bulb-1D–K), which grow to maturity in pots (Fig. Bulb-1L).

TABLE BULB-1. **Vacin and Went (VW) medium (Vacin and Went, 1949) as modified for the culture of *Bulbophyllum* (Vij et al., 2000*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water	100.0 ml	No stock	No stock	Measure
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar[e]	12–15 g	No stock	No stock	Weigh
	Darkening agent				
12	Activated charcoal	2.0 g	No stock	No stock	

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe of this medium calls for 28 mg ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, l^{-1} but chelated iron as suggested here is preferable. A difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible.

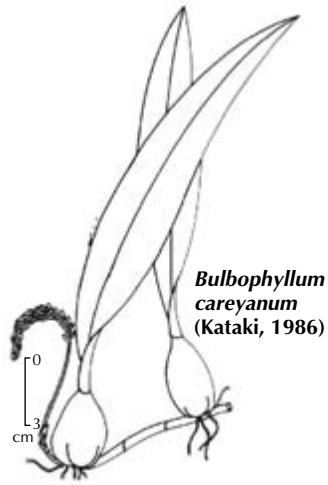
[e]Add items 1–7 and 9 to 500–700 ml of distilled water (item 10), adjust pH to 5.2–5.4 or as required, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add the charcoal (item 12) with vigorous stirring and then pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of other nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

General Comments. This is the first tissue culture method to be developed for a *Bulbophyllum* species. It may be suitable for additional bulbophyllums and/or serve as a starting point for methods for additional *Bulbophyllum* or orchid species. Also, the use of pseudobulbs as explants merits further attention because these organs may be able to survive for longer periods following excision due to the nutrients and other substances they store (Ng and Hew, 2000).

Isolation of *Bulbophyllum neilgherrense* protoplasts

Protoplasts were isolated from the leaves and roots (4.2×10^4 and 2.7×10^4 g fresh weight, respectively) of *Bulbophyllum neilgherrense* with the procedure developed for *Acampe praemorsa* (Seeni and Abraham, 1986). See *Acampe* entry, Isolation of Protoplasts from *Acampe praemorsa* (p. 139, Vol. I).

Bulbophyllum, from the Greek βολβός (bolbos: bulb) and ψύλλον (phyllon: leaf) in reference to the thick and fleshy leaves; meaning bulb-leaf (Schultes and Pease, 1963).



***Bulbophyllum careyanum* (Kataki, 1986)**

Burkillara

Three British families produced fathers and sons who were both directors of the same botanical garden. Sir William Jackson Hooker (1785–1865, knighted in 1836) was director of Kew Gardens from 1841 until his death. His son Sir Joseph Dalton Hooker (1817–1911, knighted in 1877) assumed his father's position as Director of Kew Gardens and held it until 1885. He was interested in orchids and wrote about them. The names of several orchid species honor him.

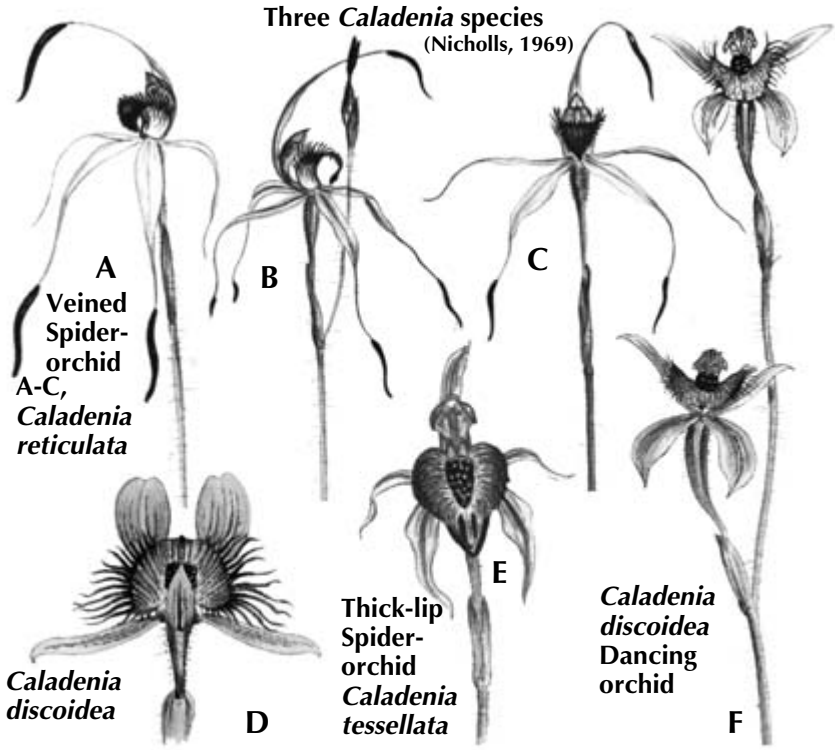
In Ireland, David Moore (1807–1879) was director of the Glasnevin Botanical Gardens and the first to germinate seeds of tropical orchids under horticultural conditions. His son, Frederick William Moore (1857–1950), also became director of the Glasnevin Botanical Gardens and established an impressive orchid collection there. The genus *Neomoorea* is named after him.

Isaac Henry Burkill was director of the Singapore Botanic Gardens from 1912 to 1925, and his son Humphrey Morrison Burkill held the same post between 1957 and 1969. The hybrid genus *Burkillara* [*Aeridachnis* Mandai (*Arachnis hookeriana* × *Aerides augustianum*, registered in 1963 by Singapore Orchids) × *Vanda tricolor* (registered in 1972 by Singapore Orchids)] honors Burkill. And fittingly, the first tissue culture procedure for *Burkillara* was developed at the Singapore Botanic Gardens (Lim-Ho, 1981).

Apical and axillary buds of *Burkillara* Ong Thye Chiew were cultured at the Singapore Botanic Gardens. The procedure and media sequence are exactly the same as those used for *Aranda* (Lim-Ho, 1981): liquid (see Table Arach-3); solid (see Table Arach-4 or Arach-5); and solid (see Table Arach-6). Modified MS medium (see Table Aranda-9) can also be used for proliferation and differentiation.

Caladenia

Consisting of about 80 species, *Caladenia* is found primarily in Australia, with several species extending into Indonesia (Java), New Caledonia, and New Zealand. The common names of some species include the word "spider" due to the shape of their flowers. The micropropagation method developed for *Diuris* (Collins and Dixon, 1992) can also be used for *Caladenia* (K. W. Dixon, Kings Park and Botanic Garden, West Perth, Australia, pers. comm.).



Calanthe

The earliest report regarding micropropagation of *Calanthe* is that "within one year [the *Cymbidium* tissue culture] technique [was extended] to *Calanthe*" (Bertsch, 1967). The contents of the articles (Bertsch, 1966, 1967) suggest that the techniques in question may have been those used for *Cattleya* and/or *Cymbidium* (Vacherot, 1966; Morel, 1974). The development of young *Calanthe* plants was studied in the late 1980s (Buyun and Budak, 1986).

Micropropagation of *Calanthe sieboldii*

Plantlets were produced from apical buds of *Calanthe sieboldii* cultured on a medium consisting of half-strength macroelements and quarter-strength microelements of the B5 medium and 2 mg BA l^{-1} in "slanting rotary culture" (Yamamoto, 1990 cited by Ichihashi, 1994).

Micropropagation of *Calanthe discolor*

Calanthe discolor is native to Japan and the Ryukyu Islands. It was first described and named in the West by John Lindley in 1838.

Plant Material. Axillary buds from mature plants are cultured (Ichihashi, 1994).

Surface Sterilization. Buds were sterilized by submerging and shaking them "with 1% benzalkonium chloride [www.sigma-aldrich.com, www.fishersci.com] and 1% sodium hypochlorite [20 ml of a household bleach containing 5–5.25% sodium hypochlorite diluted to 100 ml with distilled water]." No information is given on how to prepare the sterilant. A logical assumption is that 1 g benzalkonium chloride was dissolved in 100 ml of 1% sodium hypochlorite. The buds should be washed three times with sterile distilled water after the surface sterilization and before their apical meristems, 1 mm long, are excised and placed in culture.

Culture Vessels. Test tubes, 30 mm in diameter (length not given; 15–25 cm will probably be suitable), containing 20 ml medium should be used for the initial cultures. Petri dishes, 9 cm in diameter (height not given), containing 20 ml of medium are appropriate for PLBs. Other containers can also be used for PLBs.

Culture Conditions. Initial cultures should be maintained on slanted rotary shakers (type and degree of slant are not indicated) at 20–24°C under continuous illumination of 3000–5000 lx provided by fluorescent lamps (wattage and source not given). PLBs should be cultured at 15–20°C under 18-h photoperiods of approximately 3000 lx (light sources are not described).

Culture Media. To induce PLBs and multiple roots, explants should be placed on an induction medium that consists of half-strength macroelements and organic components and quarter-strength microelements of the B5 medium (Gamborg et al., 1968) plus 2 mg NAA l^{-1} and 0.02 mg BA l^{-1} (Table Cal-1). Callus can be induced by culturing explants on a different medium, CM (Table Cal-2). Despite an assertion that the paper reports "on . . . the condition of plant regeneration" a medium for

TABLE CAL-1. **B5 medium (Gamborg et al., 1968) modified for the induction of protocorm-like bodies from apical meristems of *Calanthe discolor* buds (Ichihashi, 1994)**

	Solvent				
15	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise. It is not clear from the original paper if this medium is considered by the author as being a new medium or a modification of the B5 solution. The macroelements are present each in a different fraction of their level in the B5 medium and NH_4NO_3 is not a component of that solution. On the other hand the microelement concentration is one-quarter that in B5 and the vitamins are included at half their B5 levels. Iron and *myo*-inositol are not mentioned as being part of this medium (table 2 in the original paper), but they are included here on the assumption that if they are required and not present the medium may not be effective, but if added even if not needed they will cause no harm.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–8 to 900 ml of distilled water (item 15), adjust pH to 5.7, add sugar (item 14), adjust volume to 1000 ml with distilled water (item 15), pour the solution into culture vessels, and autoclave. As a rule, hormones and vitamins (items 9–13 in this case) are added after autoclaving to the still warm and liquid solution under sterile conditions with sterilized pipettes, mixed well, and the medium distributed to preautoclaved culture vessels. However this does not seem to be indicated for the present medium. Since there is no indication in the original paper whether this medium should be liquid or solid, both forms should be tested. If agar is needed, bring the solution to a gentle boil and add 8–10 g agar slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into preautoclaved culture vessels.

this is not suggested directly. Multiple roots and shoots are produced on medium (SRM) containing 0.2 mg NAA l^{-1} and 0.2 mg BA l^{-1} (Table Cal-3). Therefore, it is reasonable to assume that if root-bearing shoots are separated and cultured on a hormone-free medium they will grow into plantlets. Both NAA and BA are available from www.sigmaaldrich.com, www.fishersci.com, and www.caissonlabs.com.

Procedure. Buds are taken from plants and surface-sterilized before their meristems are excised and cultured on induction medium (Table Cal-1). If the intent is to induce callus, meristems should be cultured on CM (Table Cal-2). If shoots and roots do not form on PLBs cultured on induction medium (Table Cal-1), they should be transferred to SRM (Table Cal-3).

Developmental Sequence. PLBs and possible shoots and roots form on induction medium (Table Cal-1). Multiple shoots and roots develop on SRM (Table Cal-3). Callus develops on CM (Table Cal-2).

General Comments. *Calanthe* is a popular orchid in Japan. This can be very useful, especially since it can be employed with other species and hybrids.

Calanthe discolor **(www.hokudai.ac.jp/fsc/bg/news/news/1994/1994.html)**

Calanthe aristulifera **(Ito and Karasawa, 1969)**

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–8 to 900 ml of distilled water (item 15), adjust pH to 5.7, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15); pour the solution into culture vessels and autoclave. As a rule hormones and vitamins (items 9–13 in this case) are added after autoclaving to the still warm and liquid solution under sterile conditions with sterilized pipettes, mixed well, and the medium distributed to preautoclaved culture vessels. However this does not seem to be indicated for the present medium. Since there is no indication in the original paper whether this medium should be liquid or solid, both forms should be tested. If agar is needed, bring the solution to a gentle boil and add 8–10 g agar slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into preautoclaved culture vessels.

Micropropagation of *Calanthe* × bicolor, *Calanthe* × satuma, and *Calanthe sieboldii*

The *Calanthe discolor* method (Ishihashi, 1994) can be used.

Micropropagation of *Calanthe aristulifera*, *Calanthe* × *Higo*, *Calanthe* × *Hizen*, and *Calanthe* × *Kouzo*

The *Calanthe discolor* method (Ishihashi, 1994) can be used, but the induction medium must be modified to contain 0.01 mg NAA l^{-1} and 0.5 mg BA^{-1}.

Isolation of Mesophyll Protoplasts of *Calanthe*

A method for the isolation of protoplasts of *Calanthe discolor* was developed at the Department of Horticulture, University of Minamikyushu, Takanabe-cho, Miyazaki Prefecture, Japan (Yasugi et al., 1986).

Plant Material. Excised young leaves were used in the original research. They were taken from plants grown in the greenhouse of Minamikyushu University.

Surface Sterilization. The leaves should be immersed in 0.5% sodium hypochlorite (10 ml of household bleach diluted to 100 ml with distilled water) for 10 min, transferred to 70% ethanol (74 ml of 95% ethanol diluted to 100 ml with distilled water) for 1 min and washed three times with sterile distilled water. No mention is made in the original paper of washing the leaves before placing them in the hypochlorite solution. This may be advisable and can be done by gently washing the leaves with a mild soap, very soft brush (a used, soft toothbrush is suitable), and copious amounts of tap or distilled water.

Culture Vessels. Beakers would probably be most suitable for the surface sterilization steps. Sterile Petri dishes and Erlenmeyer flasks are appropriate for cutting the leaves and storing the sections. Erlenmeyer flasks should be used for incubation.

Isolation Conditions. Incubation should be at 28°C on a shaker set at 40 strokes (2.2-cm amplitude) per minute. The original paper does not indicate whether the incubation was in the light or dark. Therefore it may be wise to attempt isolation both in the dark and under illumination.

Isolation Medium. The enzyme mixture (Table Cal-4) consists of 1% (w/v) Onozuka cellulase R-10 (from Yakult Honsha Co., Ltd., Japan), 0.2% (w/v) Macerozyme R-10 (Yakult Honsha), and 0.01% (w/v) Pectolyase (Kikkoman Shyoyo Co., Japan; for US sources of all enzymes see *Aranda* entry, sections on the isolation and culture of mesophyll and leaf protoplasts), 0.5 mol (91.1 g) l^{-1} mannitol, 5% (w/v) potassium dextran sulfate, and 10 mmol (1.47 g) l^{-1} $CaCl_2 \cdot 2H_2O$ adjusted to pH 5.8.

TABLE CAL-4. **Isolation medium for *Calanthe* protoplasts (Yasugi et al., 1986)**[a]

Characteristic or component	Amount		
	Molarity	Weight per 10 ml solution	Percent
Enzymes			
Onozuka cellulase R-10[b]		100 mg	1
Macerozyme R-10[b]		20 mg	0.2
Pectolyase[c]		1 mg	0.01
Osmoticum			
Mannitol[d]	*0.7 M*	1.28 g	12.8
Viscocity agent			
Potassium dextran sulfate[e]			0.5
Mineral			
Calcium chloride, $CaCl_2 \cdot 2H_2O$	10 m*M*	1.47 g	14.7
pH 5.8			

[a]Yakult Honsha, Japan. These enzymes are available in the United State from Serva Biochemicals, Inc., 200 Shames Drive, Westbury, NY 11590.

[b]Kikkoman Shyoyo Co., Japan. Available in the United States from Serva Biochemicals (see footnote *a* for address).

[c]Driselase, if needed, can be obtained in the United States from Fluka Chemical Corp., 980 S. Second St., Ronkonkoma, NY 11779.

[d]A general assumption is that plants cannot utilize mannitol. This may not be true for some orchids, therefore the initial and final concentrations of mannitol in this solution may be different.

[e]The available dextran sulfates differ in molecular weight. The original paper does not indicate which one was used. Sodium dextran sulfates are available in the United States from Fluka Chemical Corp. (see footnote *c*) and Sigma Chemical Co., P.O. Box 14508, St. Louis, MO 63178, Tel. 1-800-325-3010 (toll-free for calls from within the U.S.A.) and 314-771-5750 (from anywhere in the world). Sigma also sells enzymes.

Procedure. Place 2×20-mm leaf sections weighing approximately 1 g (fresh weight) in 10 ml enzyme mixture in a 50-ml Erlenmeyer flask and incubate for 90 min under the conditions listed above. The number of protoplasts can be determined with a hemocytometer.

Developmental Sequence. There is no mention of development in the original paper Bertsch, 1966).

General Comments. The purpose of this research was only "to find . . . [a] suitable enzyme mixture and treatment time [for] high yield of mesophyll protoplasts from . . . mature leaves. . . ." (Bertsch, 1967). Therefore the paper does not provide information on culture, division, and fusion. However, it should be noted that S. Yasugi did produce embryoids from mesophyll protoplasts of *Dendrobium*.

Isolation of Protoplasts from Leaves of *Calanthe masuca*

Protoplasts, 21.7×10^4 g of fresh weight tissue, were isolated using the procedure developed for *Acampe praemorsa*.

Calanthe, from the Greek καλός kalos (beautiful) and ἄνθη anthe (flower) in reference to the beautiful flowers produced by this genus (Schultes and Pease, 1963), and *discolor*, from the Latin for "of a different color; different; different from".

Catasetum

The genus *Catasetum* was established in 1822 by Karl Sigismund Kunth (1788–1850) on the basis of notes by Louis Claude Marie Richard (1754–1821) who collected in French Guiana from 1781 to 1789 (Holst, 1999). Kunth based his description on *Catasetum macrocarpum* and *C. maculatum*, both of which have two antennae attached to the gynostemium that extend downward. These antennae led to the name of the genus, which is derived from the Greek *cata* (downward) and the Latin *saeta* or *seta* (bristles). *Catasetum* is one of very few orchid genera to produce separate male, female, and hermaphroditic flowers. This resulted in the creation of three genera: *Monachanthus*, *Myanthus*, and *Catasetum*. The trimorphism became apparent by 1837 but the first effort by Rudolf Mansfeld (1901–1960) to put the taxonomy of *Catasetum* in order took place in 1932. A more recent revision is by Calaway H. Dodson (b. 1928) in 1975 (Bechtel et al., 1992; Holst, 1999).

Culture of *Catasetum* Root Tips

A study of the potential of root tips of some Brazilian orchids as suitable explants for micropropagation resulted in the method for the clonal propagation of a *Catasetum* hybrid (Kerbauy, 1984*a*).

Plant Material. The original research was carried out with root tips 1.5 mm in length, taken from seedlings 6–7 cm high, and growing in vitro, of *Catasetum trulla* × *Catasetum* Berthrand.

Surface Sterilization. There was no need to surface-sterilize the root tips because the seedlings were growing aseptically.

Culture Vessels. Erlenmeyer flasks of 50-ml capacity and containing 20 ml medium were used in the original research.

Culture Conditions. The original conditions were 16-h photoperiods of 500 lx produced by Sylvania Gro Lux fluorescent lamps at 25 ± 1°C. Other light sources and photoperiods may also be suitable.

Culture Media. Several culture media were screened initially, all based on Knudson C, and each produced different results (Table Ctsm-1). Root tips developed on a medium containing peptone, coconut water, thiamine, and NAA (Table Ctsm-2). Both PLBs and callus were produced on a medium containing thiamine only (Table Ctsm-3). PLBs and healthy plants developed without callus formation on a medium containing thiamine, peptone, and coconut water but not NAA (Table Ctsm-4).

Procedure. Place the root tips on the culture medium.

Developmental Sequence. Callus masses, PLBs, roots, and plantlets may be produced (Table Ctsm-1).

TABLE CTSM-1. **Effect of culture media on *Catasetum* root tips (Kerbauy, 1984*a*)**

Item	Culture medium[a]	Type of growth[b]
1	BM + CW	Mostly roots, 5.5% small dark callus masses
2	BM + PP	Dark-green callus masses, PLBs, Plantlets
3	BM + TM	40% PLBs, 60% callus masses
4	BM + NAA	Small callus masses, few PLBs
5	BM + CW + NAA	More vigorous callus masses, 32% PLBs, etiolated plantlets that also produced PLBs
6	BM + PP + NAA	Vigorous callus masses, no PLBs
7	BM + TM + NAA	Vigorous callus masses no PLBs
8	BM + CW + PP + TM	54% direct formation of PLBs
9	BM + CW + PP + TM5	Long, thick pilose roots, lateral roots, PLBs

[a]BM, basal medium (Knudson C) with chelated iron and 8% agar (see Table Ctsm-2); CW, 15% coconut water; NAA, 5 mg l^{-1} naphthaleneacetic acid; PP, 1 g l^{-1} peptone; TM, 0.5 mg l^{-1} thiamine; TM5, 5 mg l^{-1} thiamine.

[b]Percentages refer to proportion of all cultures; PLBs, protocorm-like bodies.

TABLE CTSM-2. **Knudson C medium (Knudson, 1946) as modified for the culture of *Catasetum* root tips (Kerbauy, 1984*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	**Iron**[c]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.8	27.8 g l^{-1}	10	
(b)	Chelating agent, Na_2EDTA	37.3	37.3 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additives				
7	Peptone	1 g	No stock	No stock	Weigh
8	Coconut water	150 ml	No stock	No stock	Measure
	Vitamin				
9	Thiamine (vitamin B_1)	5	500 mg 100 ml^{-1} 95% ethanol[d]	1	
	Hormone				
10	Naphthaleneacetic acid (NAA)	5	500 mg 100 ml^{-1} 95% ethanol[d]	1	
	Sugar				
11	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[e]	To 1000 ml			
	Solidifier				
13	Agar[e]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The iron in the original formulation is not chelated, but the form used here is preferable.

[d]Keep refrigerated between uses. If NAA fails to dissolve, add a few drops of dilute KOH.

[e]Add items 1–8 to 900 ml distilled water (item 12), set pH to 5.5, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring solution to a gentle boil, and add agar (item 13) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add vitamin (item 9) and hormone (item 10) to the warm, still liquid solution, mix well, and distribute into culture vessels. Do not add agar to liquid medium. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

TABLE CTSM-3. **Knudson C medium (Knudson, 1946) as modified for the production of callus and protocorm-like bodies from *Catasetum* root (Kerbauy, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	**Iron**[c]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.8	27.8 g l^{-1}	10	
(b)	Chelating agent, Na_2EDTA	37.3	37.3 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Vitamin				
7	Thiamine (vitamin B_1)	5	500 mg 100 ml^{-1} 95% ethanol[d]	1	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The iron in the original formulated is not chelated, but the form used here is preferable.

[d]Keep refrigerated between uses.

[e]Add items 1–6 to 900 ml distilled water (item 9), set pH to 5.5, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). If solid medium is desired, bring solution to a gentle boil, and add agar (item 10) slowly while stirring. The agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add vitamin (item 7) to the warm, still liquid solution. Mix well, and distribute into culture vessels. Do not add agar if preparing liquid medium. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

General Comments. Like other procedures developed with explants from seedlings it is not clear if this one can be used for mature plants.

TABLE CTSM-4. **Knudson C medium (Knudson, 1946) as modified for the protocorm and plantlet production from root tips of *Catasetum* root tips (Kerbauy, 1984*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
12	Agar[e]	8 g	No stock	No stock	Weigh

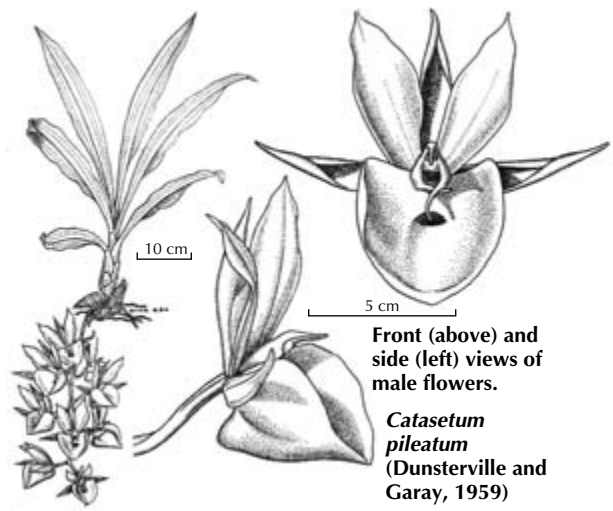
[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The iron in the original formulation is not chelated, but the form used here is preferable.

[d]Keep refrigerated between uses.

[e]Add items 1–8 to 900 ml distilled water (item 11), set pH to 5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add vitamin (item 9) to the warm, still liquid solution. Mix well, and distribute into culture vessels. Do not add agar if liquid medium is desired. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added. especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.



Front (above) and side (left) views of male flowers.

***Catasetum pileatum* (Dunsterville and Garay, 1959)**

Production of Protocorm-like Bodies from *Catasetum fimbriatum* Root Tips

Professor Gilberto Barbante Kerbauy at the University of Sao Paulo in Brasil and his associates have studied hormone levels as well as carbohydrate and starch partition in excised root tips of *Catasetum fimbriatum* (Colli and Kerbauy, 1993; Vaz et al., 1998; Peres et al., 1999). Their culture method can be adapted to micropropagation.

Plant Material. Root tips, 5 mm in length, were taken from asymbiotic seedlings.

Surface Sterilization. There is no need to surface-sterilize root tips taken from asymbiotic seedlings in vitro. However, they must be washed to remove medium residues.

Culture Vessels. Erlenmeyer flasks, 125-ml capacity, were used as culture vessels. They should contain approximately 25 ml medium.

Culture Conditions. In the original research the cultures were maintained at 26 ± 2°C under 16-h photoperiods of 40–50 μmol m^{-2} s^{-1} provided by fluorescent lights (the type was not described in the original papers, but cool white tubes alone or in a mixture with incandescent bulbs will probably prove to be suitable). Standard culture room conditions are also appropriate.

Culture Media. The basal medium used in the original research (Colli and Kerbauy, 1993) was Linsmaier–Skoog solution (Linsmaier and Skoog, 1965). It can be supplemented with several growth regulators alone or in a number of combinations, but the medium suggested here is one with low mutation-inducing potential (Table Ctsm-5). Plantlets and/or callus can form on this medium. However, different media formulated in Professor Kerbauy's laboratory (Kerbauy, 1984*a*) may also be suitable for callus induction (Table Ctsm-3) and plantlet production (Table Ctsm-4).

Procedure. Excised root tips should be placed on the first medium (Table Ctsm-5). Callus (Fig. Ctsm-1B) and PLBs which develop on or from the root tips can be subcultured on the same (Table Ctsm-5) or different (Tables Ctsm-3 and Ctsm-4) media. When plantlets (Fig. Ctsm-1A) are large enough they should be taken out of culture and potted in a potting mix.

Developmental Sequence. The root tips may form PLBs or callus and eventually plantlets.

General Comments. This method does not allow for the selection of superior forms because it utilizes root tips from seedlings. It may prove to be suitable for root tips from mature plants. However, if root tips of mature plants are to be used they must be taken from roots which have not come into contact with potting mix or other objects or surfaces to ensure the absence of mycorrhizal fungi.

TABLE CTSM-5. **Linsmaier-Skoog (LS) medium (Linsmaier and Skoog, 1965) modified for the culture of *Catasetum fimbriatum* root tips (Colli and Kerbauy, 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Polyol				
8	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
9	Benzyladenine	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamin				
10	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
11	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[g]	To 1000 ml			
	Solidifier				
13	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N HCl.

[g]Add items 1–8 to 900 ml of distilled water (item 12), adjust pH to 5.8, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the cytokinin (item 9) and vitamin (item 10) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

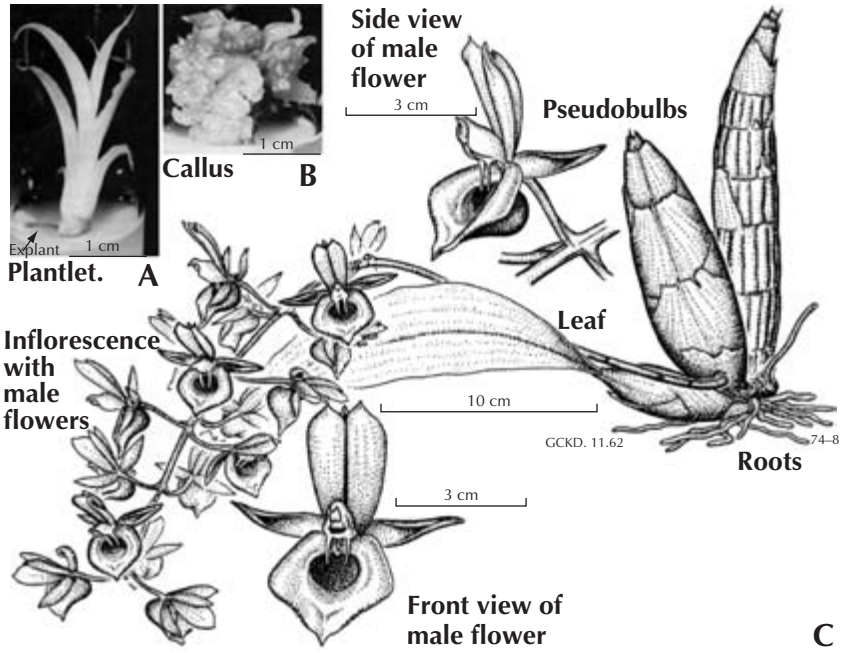

FIG. CTSM-1. ***Catasetum pileatum*. A. Plantlet in vitro. B. Callus. C. Flowering plant. (Dunsterville and Garay, 1966.)**

Formation of Protocorm-like Bodies from *Catasetum pileatum* Root Tips

When orchid root tips are cultured in vitro, PLB formation can be either direct or it may be preceded by callus development (Kraus and Monteiro, 1989; Kraus and Kerbauy, 1992). Research on the factors that affect or control these developmental patterns resulted in a method (Kraus and Monteiro, 1989; Kraus and Kerbauy, 1992) which can be used for micropropagation.

Plant Material. Root tips, 6 ± 1 mm long, were taken from asymbiotic seedlings of *C. pileatum*.

Surface Sterilization. There is no need to surface-sterilize root tips taken from seedlings growing in vitro. However, they should be rinsed thoroughly to remove medium residues.

Culture Vessels. Test tubes, Erlenmeyer flasks, and other common culture vessels can be used.

Culture Conditions. In the original research the culture was maintained at 26 ± 2°C under 16-h photoperiods of 9 W m^{-2} provided by fluorescent lamps (type is not specified in the original paper). Standard culture room conditions are also suitable.

Culture Media. MS medium (Murashige and Skoog, 1962) should be used to induce PLB formation (Table Ctsm-6). PLBs can be cultured on modified Knudson C medium (Table Ctsm-4) for plantlet production.

Procedure. Excised root tips should be cultured on the first medium (Table Ctsm-6) to induce PLB formation. The PLBs should be moved to the second medium for the production of plantlets.

Developmental Sequence. Root caps show some disorganization after 24–48 h of culture, and the promeristem and protoderm can no longer be discerned. After 48–72 h, not much remains of the root cap and cell division can be seen in the subapical region. A new cell group consisting of recently produced cells can be seen following 72–96 h of incubation. After 6 days there is evidence of active mitotic divisions in the apical region. This leads to the formation of PLB primordia in 10 days. Well-defined PLBs can be seen after 20 days of culture. Their apices become well defined after 30 days. Well-defined seedlings in the PLBs become evident 10 days after that. Seedlings become independent subsequently.

General Comments. This method cannot be used to propagate desirable forms because explants are taken from seedlings. However, it may perhaps be suitable for root tips of mature plants. Should an attempt be made to culture root tips of mature plants, care must be taken to ensure that they do not contain mycorrhiza.

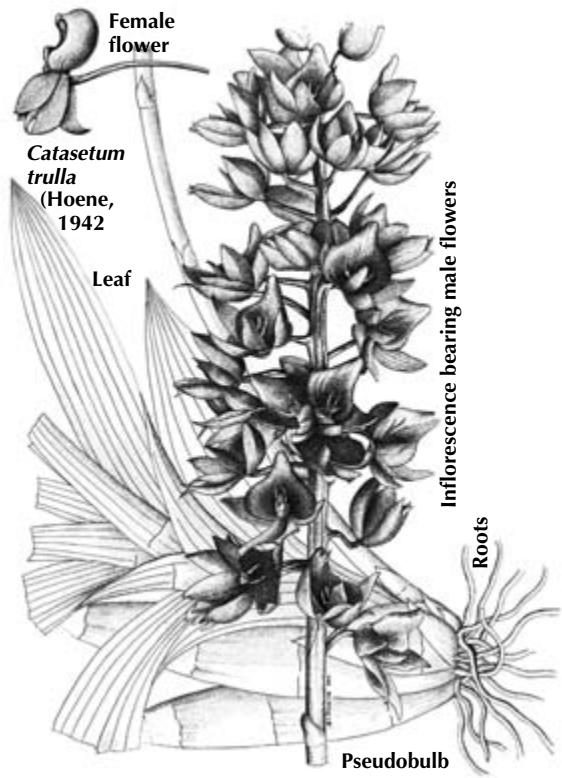

TABLE CTSM-6. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of *Catasetum pileatum* root tips (Kraus and Monteiro, 1989; Kraus and Kerbauy, 1992)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Agar[h]	8.0 g	No stock	No stock	Weigh
	Darkening agent				
17	Activated charcoal	1.0 g	No stock	No stock	Weigh

[a]The original papers state that MS medium was used. This medium usually contains an auxin and a cytokinin, but the title of one of the original papers (Kraus and Kerbauy, 1992) indicates that these hormones were not included in the modified medium.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[f]Keep frozen between uses.

[g]The source and manufacturer were not listed in the original papers.

[h]Add items 1–7, 9, and 14 to 900 ml of distilled water (item 15), adjust pH to 5.5, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 17) with vigorous stirring, pour the solution into a 2-l flask, and autoclave. Add the amino acid (item 8) and vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. In some cases the amino acid and vitamins can be autoclaved, but this should be tested before being adopted as standard practice.

Cattleya

In the minds of the general public, *Cattleya* is synonymous with orchids. For cut-flower growers, *Cattleya* is a very important crop. Clones of disease-free, photoperiodically controllable varieties, well suited as cut flowers, are very desirable and can be profitable. Many hobby growers would like to have in their possession plants of awarded varieties or those that appeal to them in particular. Hence it is not surprising that several techniques have been developed for the clonal propagation of *Cattleya* through tissue culture (Morel, 1964*a*, 1965*a*, 1965*b*, 1971*a*, 1971*b*; Lindemann, 1967*a*, 1967*b*; Marston and Vouraurai, 1967; Reinert and Mohr, 1967; Scully, 1967; Champagnat and Morel, 1969; Kukułczanka, 1969, 1970; Champagnat et al., 1970; Churchill et al., 1970, 1971*a*, 1971*c*, 1972*b*, 1973; Lindemann et al., 1970; Lis, 1970; Arditti et al., 1971, 1972; Ball et al., 1971; Bergman, 1971; Ichihashi and Kako, 1973; Arditti, 1974, 1977*b*). In addition to research reports the literature on *Cattleya* tissue culture also includes papers on morphology, organogenesis, and histology (Vanseveren, 1969); the isolation of protoplasts and nuclei (Capesius and Meyer, 1977); the elimination of virus (Ishii, 1974); and on phenolics produced by explants (Ishii et al., 1976). There are also reviews (Fast, 1973*a*; Morel, 1974; Alang, 1975; Tschauder, 1975; Arditti 1977*a*, 1977*b*; Rao, 1977), popular accounts in magazines (Williams, 1962; Weinstein, 1985), instruction sheets (Wilfret, no date), and privately published mimeographed manuals of lesser value (Jasper, no date). Since a number of techniques have been developed and each offers some advantages, we will outline several procedures here.

Clonal Propagation of *Cattleya* through Shoot-meristem Culture

The procedure is the same as that for *Brassocattleya* (Kako, 1973).

Meristem Culture of *Cattleya*

Solutions for orchid tissue culture contain four component groups: (1) mineral (macro and micro); (2) an energy source (always a sugar, usually sucrose); (3) substances like vitamins and hormones; and (4) undefined complex additives (coconut water, potato extract, banana homogenate, peptone, casein hydrolysate, etc.). The most appropriate combination can be expected to produce the best results. Hence the media used for this procedure include the most suitable components of a number of previously published solutions (Lindemann et al., 1970).

Plant Material. Use enlarging, non-dormant axillary shoots.

Surface Sterilization. Remove dead scales and swab the surface with 95% ethyl alcohol, rinse with distilled water, soak (i.e., sterilize) for 20–30 min in 0.4–0.5% calcium hypochlorite, and rinse in a large volume of sterile distilled water.

Culture Vessels. Use screw-cap vials or Erlenmeyer flasks containing a few milliliters of solution.

Culture Conditions. Details are not given. However, the conditions used in any of the other procedures for *Cattleya* would no doubt be appropriate. Liquid cultures are placed on a shaker (New Brunswick Scientific, Co. Roller Tube Apparatus was used in the original research).

Culture Media. Three media are used: (1) starting (Table C-1); (2) maintenance (Table C-2); and (3) rooting (Table C-3).

Procedure. Remove the bud, sterilize it, and make four longitudinal–tangential cuts with a sterile scalpel to expose the base of the leaf primordia. Next, make horizontal

TABLE C-1. **Starting medium for the culture of *Cattleya* explants (Lindemann et al., 1970)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	1000	100 g l^{-1}	10	Or weigh

(b)	Asparagine	13.0	1.3 g l^{-1}		
10	**Nucleotides**[g]				
(a)	Guanylic acid	182.0	18.2 g l^{-1}	10	One solution
(b)	Cytidylic acid	162.0	16.2 g l^{-1}		
	Hormones				
11	Naphthaleneacetic acid (NAA)[h]	0.18	20 mg 100 ml^{-1} 95% ethanol	0.9	
12	Gibberellic acid (GA_3)[i]	0.35	35 mg 100 ml^{-1} 95% ethanol	1	
13	Kinetin[j]	0.22	22 mg 100 ml^{-1} 95% ethanol	1	
14	**Complex additive**[k]				
(a)	Coconut water	50–150 ml			
(b)	Casein hydrolysate	100			
	Sugar				
15	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[l]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated with standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]If the substance does not dissolve, add a pellet of KOH. Dissolve in hot water. Shake well before dispensing.

[d]Add all microelements to the same 1 l, stir or heat until all are dissolved, and add 1 ml liter of culture medium.

[e]Dissolve in the same 1 l to save time in preparation. However, separate solutions to meet solubility requirements can also be made. Aqueous solutions must be kept frozen between uses.

[f]Add both to the same 1 l. Use 10 ml per liter of medium. Separate solutions can also be made. If solubility problems arise, add a few drops of HCl. Keep frozen between uses.

[g]Add both to the same 1 l. Use 10 ml per liter of medium. Although stock solutions can be made, it is better to weigh these substances before use. If stocks are made, keep them frozen.

[h]If auxin (NAA) fails to dissolve, add a few drops of KOH. Keep solution refrigerated.

[i]If GA_3 fails to dissolve, add a few drops of HCl. Keep solution refrigerated.

[j]If the kinetin fails to dissolve, add a few drops of dilute HCl. Keep refrigerated.

[k]Add either coconut water or casein hydrolysate, not both. This improves proliferation.

[l]Mix items 1–13 with 750 ml distilled water (item 16), adjust pH to 5.2, add sugar (item 15), bring the volume up to 1000 ml with more distilled water (item 16), distribute into culture vessels, and autoclave.

TABLE C-3. **Modified Knudson C (Knudson, 1946) medium plantlet formation and root induction in *Cattleya***

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	Or weigh
2	Monopotassium phosphate, KH_2PO_4[c]	250	25 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	Or Weigh
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.056	56 mg l^{-1}		
(b)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	7.5 g l^{-1}		
(c)	Molybdic acid, MoO_3	0.016	16 mg l^{-1}	1	One solution
(d)	Cupric sulfate (anhydrous), $CuSO_4$	0.040	40 mg l^{-1}		
(e)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.331	331 mg l^{-1}		
	Sugar				
7	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
8	Water, distilled[e]	To 1000 ml			
	Solidifier[e]				
9	Agar	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated with standing. Therefore stock solutions should not be prepared. If made, they must be kept frozen between uses.

[c]A phosphate buffer that will keep the pH steady may be substituted here. Prepare buffer by mixing 975 ml 0.1-*M* KH_2PO_4 (monopotassium phosphate) solution (13.6 g l^{-1}) with 25 ml 0.1-*M* K_2HPO_4 (dipotassium phosphate, 17.4 g l^{-1}); measure pH to be certain it is correct (pH 5.1–5.4), and use 18 ml l^{-1} culture medium.

[d]Add all microelements to the same 1 l of distilled water, stir and/or heat until all are dissolved, and add 1 ml per liter of culture medium.

[e]Add items 1–6 to 800 ml distilled water (item 8), and dissolve. Adjust pH to 5.3, add sugar (item 7), and bring volume up to 1000 ml with more distilled water. Add the agar (item 9), while stirring, to the gently boiling solution. When dissolved, distribute into culture vessels and autoclave.

cuts "above and below the meristem region to provide a 5-mm cube of tissue." This cube will probably contain some non-meristematic tissue as well. Then transfer the explant to a Petri dish containing sterile distilled water where all further operations are performed. Remove all remaining leaf primordia with sterile microscalpels using a dissecting microscope. Great care must be taken to maintain complete sterility of the working space.

Cut the tissue just below the youngest leaf primordium, discard the base, and place the explant into autoclaved starting medium (Table C-1). After about 2 months, or when the explant reaches 2 mm in diameter, it can be quartered and transferred to the second medium (Table C-2). Addition of 5–10% (v/v) coconut water or 100 mg casein hydrolysate per liter speeds up proliferation. Subdivisions of the tissue can be made at monthly intervals. Finally, transfer the PLBs to the solid rooting medium (Table C-3) for root development and plantlet formation. After that, treat the plantlets like seedlings.

Developmental Sequence. Explant enlargement is apparent within 3 days while cultures are maintained on a roller-tube apparatus. After 2 months, the explants reach

2 mm in diameter and are ready for subdivision. Proliferation occurs on the second medium, and callus masses are formed. Roots appear after about 10 days on the rooting (modified Knudson C) medium (Table C-3).

General Comments. Although a bit complicated due to the use of three media, this technique can produce unlimited numbers of plants of a desired clone, Excision of tissue may require a certain amount of practice.

Propagation of *Cattleya* by in Vitro Culture of Bud Meristems

Development of tissue culture methods for *Cattleya* was not as easy as doing the same for *Cymbidium*. More complex media and different culture conditions were required. Even with these media, the mortality rate of explants is high (Morel, 1970).

Plant Material. "Nur die Knospen, die an dem Ansatz junger Trieve sitzen [only the buds from the base of the younger shoots]" can be used (Morel, 1970).

Surface Sterilization. This was not given in the original paper (Morel, 1960). Use the sterilization procedures given in the section on meristem culture (Lindemann et al., 1970).

Culture Vessels. Test tubes (no other details are given) or Erlenmeyer flasks can be used.

Culture Conditions. The test tubes containing liquid medium and explants are placed on a klinostat that rotates at 2 rpm. Best results are obtained in the dark at 25–30°C.

Culture Medium. Several media are suggested, but few details are given about them. One solution that can be used is MS medium. Only the minerals for it are listed, however. In addition to them, the medium must contain auxin, 0.5–1 mg l^{-1} IAA or NAA, and coconut water (no concentration given). Growth is improved when glutamic acid (or glutamine), asparagine, peptone, or casein hydrolysate is added (no concentrations given). Cytokinins are not of much benefit. In addition to MS medium, the minerals of another substrate are also listed. Altogether it seems that the following combinations can be used:

1 Modified MS medium (Table C-4).
2 Another modification of MS medium (Table C-5).
3 Starting medium (Table C-1) followed by maintenance medium (Table C-2).
4 Modified Knudson C medium (Tables C-6 and C-7).

Whatever medium is used, it should be liquid. Once PLBs form, they should be transferred to one of the modifications of the Knudson C medium (Table C-3).

Procedure. Remove buds from the base of young shoots before the shoots reach 5–15 cm. Sterilize and excise the portion to the cultured. Take explants at least

TABLE C-4. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Cattleya* buds**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10

(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acids				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
9	Glutamic acid	15	No stock[f]		
10	Asparagine	13	No stock[f]		
	Polyol				
11	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
12	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[g,h]	1	
	Cytokinin				
13	Kinetin	0.2	20 mg 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
14	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
15	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
16	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
17	Coconut water	150	No stock	No stock	Measure
	Sugar				
18	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
19	Water, distilled[i]	To 1000 ml			
	Solidifier				
20	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Suspend the required amount in 1–2 ml 95% ethanol in a small, sterile screw-cap vial. Shake or swirl to ensure that amino acids are dissolved or thoroughly wetted by alcohol, let it stand for 5 min, then shake or swirl again. Repeat this process three times at 5-min intervals. Add suspension to culture medium, as indicated below. If substances remain in vial after it has been emptied into culture medium, wash them out with sterile distilled water.

[g]If auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively.

[h]Keep refrigerated between uses.

[i]Add items 1–7, 11, and 17 to 750 ml distilled water (item 19). Adjust pH to 5.2–5.5, add sugar (item 18), and adjust volume to 1000 ml with distilled water (item 19). Bring solution to a gentle boil, and add agar (item 20) slowly while stirring. Agar can also be added to the cold solution which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acids, hormones, and vitamins (items 8–10 and 12–16) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE C-5. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the culture of *Cattleya* buds**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

18	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
19	Water, distilled[i]	To 1000 ml			
	Solidifier				
20	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. Murashige and Skoog (1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Suspend the required amount in 1–2 ml 95% ethanol in a small, sterile screw-cap vial. Shake or swirl to ensure that amino acids are dissolved or thoroughly wetted by alcohol, let it stand for 5 min, then shake or swirl again. Repeat this process three times at 5-min intervals. Add suspension to culture medium, as indicated below. If substances remain in vial after it has been emptied into culture medium, wash them out with sterile distilled water.

[g]If auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively.

[h]Keep refrigerated between uses.

[i]Add items 1–7, 11, and 17 to 750 ml distilled water (item 19). Adjust pH to 5.2–5.5, add sugar (item 18), and adjust volume to 1000 ml with distilled water (item 19). Bring solution to a gentle boil, and add agar (item 20) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acids, hormones, and vitamins (items 8–10 and 12–16) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE C-6. **Modified Knudson C medium (Knudson, 1946) for the culture of *Cattleya* shoot meristems (Morel, 1965*a*, 1965*b*, 1970)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[c,d]	1 g	100 g l^{-1}	10	Or weigh
2	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Ammonium nitrate, NH_4NO_3[c,d]	500	50 g l^{-1}	10	Or weigh
5	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[d]	500	50 g l^{-1}	10	Or weigh
6	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
7	Potassium chloride, KCl	250	25 g l^{-1}	10	
	Microelement				
8	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar[e]				
9	Sucrose	20 g	No stock	No stock	
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier[e]				
11	Agar	17.5 g	No stock	No stock	Weigh

[a]Only the inorganic salts are listed (Morel, 1965*a*, 1965*b*, 1970; see also Morel, 1974).

[b]Amounts are given in mg unless indicated otherwise.

[c]Either use 1 g ammonium sulfate and omit ammonium nitrate, or use 0.5 g of each.

[d]Solutions containing ammonium and/or nitrate may become contaminated with standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[e]Add items 1–8 to 700 ml distilled water (item 10), and dissolve. Adjust pH to 5.2–5.5, add sugar (item 9), dissolve, and bring volume up to 1000 ml with more distilled water. Distribute into culture vessels and autoclave. For solid culture medium, add agar (item 11) slowly while stirring to gently boiling solution. When fully dissolved, dispense into culture vessels and autoclave.

5 mm in size since the mortality rate of smaller ones is very high. In fact, the entire bud is taken for culture, "of which the two outer scales are removed; the piece still contains 3–6 scales besides the apical meristem" (translated by the author from Morel, 1970). Place explants in the liquid medium because, "it should be mentioned that the growth is accelerated." When the tissue proliferates, it will form PLBs, which should be subcultured onto a modified Knudson C medium (Table C-3) for differentiation and growth.

Developmental Sequence. As first reaction, callus formation is observed on the severed leaf rudiment (or connective tissue of the leaf) where large cells occur that form layers of palisade cells. Later, between these giant hypertrophic cells it is possible to note formation of small meristematic groups that may lie next to the necrotic tissue or near the shoot tip. At the same time the outermost scales become green, and their connective tissues increase in volume and become wavy. After 2 months, meristematic areas appear and eventually form PLBs. These develop into plants.

General Comments. This is a reliable method for the clonal propagation of *Cattleya* even if mortality of explants may be high at times.

TABLE C-7. **Modified Knudson C medium (Knudson, 1946) for the culture of *Cattleya* buds**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Amino acids				
7	Glutamic acid	15	No stock	No stock	Weigh
8	Asparagine	13	No stock	No stock	Weigh
	Auxin				
9	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[d]	1	
	Cytokinin				
10	Kinetin	0.2	20 mg 100 ml^{-1} 95% ethanol[d]	1	
	Complex additive				
11	Coconut water	150	No stock	No stock	Measure
	Sugar				
12	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
13	Water, distilled[e]	To 1000 ml			
	Solidifier				
14	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g of chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[d]If auxin or cytokinin fails to dissolve, add a few drops of dilute KOH or HCl, respectively. Keep refrigerated between uses.

[e]Add items 1–6 and 11 to 900 ml distilled water (item 13). Adjust pH to 5.0–5.2, add sugar (item 12), and adjust volume to 1000 ml with distilled water (item 13). Bring solution to a gentle boil, and add agar (item 14) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acids and hormones (items 7–10) to hot, still liquid medium under sterile conditions with sterilized pipettes, and dispense into preautoclaved culture vessels. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary, adjust pH upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

The genus *Cattleya* is named after Mr. William Cattley (d. 1832) of Barnet, England (Schules and Pease, 1963).

Propagation of *Cattleya* by in Vitro Culture of Lateral Bud Meristems

The difficulties encountered with the culture of *Cattleya* explants have spurred research by several groups. One method involves the culture of meristematic tissue from lateral buds (Reinert and Mohr, 1967).

Plant Material. Swollen lateral buds are obtained from rhizomes below new vegetative shoots of *Cattleya*.

Surface Sterilization. Rhizomes are placed in 5% (v/v) Clorox for 10 min, followed by 5 min in 70% ethanol, and concluding with 80 g l^{-1} calcium hypochlorite for 20 min. They are then allowed to dry in a sterilized (i.e., autoclaved) glass container.

Culture Vessels. Use 125-ml Erlenmeyer flasks containing 20 ml medium.

Culture Conditions. Explant-containing flasks are placed on a wheel that revolves at 1 rpm. Photoperiods are 16 h long at an intensity of 200 ft-c provided by four 6-ft cool white fluorescent tubes. The temperature should range between 24 and 28°C.

Culture Medium. A liquid medium (Table C-8) is used for the first 3 weeks. After that, the tissues are transferred to a solid medium (Table C-9).

Procedure. To excise meristems from swollen buds, make longitudinal cuts until the upper surface of the meristem is visible. This is evidenced by a change in color from creamy white to an almost translucent white. Block out the meristem by deep vertical cuts, removing an explant 1–3 mm^3 in size. These sections contain the meristem and small areas of leaf-sheath tissue. Place the explants into culture medium, and position the flasks on the revolving wheel. After 3 weeks, transfer the tissues to the solid medium.

Developmental Sequence. The meristems grow well in the liquid medium with a survival rate of at least 75%. Chlorophyll formation becomes evident fairly soon, and the tissues reach diameters of approximately 3 and 6 mm within 3 and 6 weeks, respectively. Following transfer onto solid medium, some browning may be noted, and growth is slow for the first 2 weeks. Proliferation is evident after 3 weeks. Most explants produce one to three PLBs that grow into plantlets. When the growing plants are cut in half, growth may be slow. Occasionally callus masses may develop; but in many cases each half develops into a new PLB, which eventually forms a plantlet.

General Comments. This method can produce multiplication up to 3000-fold with relative ease and should therefore prove useful.

TABLE C-8. **Reinert–Mohr medium (Reinert and Mohr, 1967) for the initial culture of *Cattleya* bud meristems**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400	40 g l^{-1}	10

(b)	Ferric sulfate, $Fe_2(SO_4)_3$	10.7	1.07 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.03	3 mg l^{-1}	10	One solution
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.001	0.1 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot H_2O$	7.5	750 mg l^{-1}		
(d)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.03	3 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Organic acid				
9	Citric acid[e]	150.1	No stock	No stock	Weigh
	Auxins				
10	Indole-3-butyric acid (IBA)	1.75	175 mg 100 ml^{-1} 95% ethanol[f,g]	1	
11	Napthaleneacetic acid	1.75	175 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	15–30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. If $Fe_2(SO_4)_3$ is not available, make a stock solution containing 3.73 g Na_2EDTA and 2.78 g $FeSO_4 \cdot 7H_2O$ per liter, and add 10 ml of that to the medium.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. Some recipes list $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Available as an anhydrous salt or a monohydrate. It probably matters little which one is used.

[f]If auxins do not dissolve, add a few drops of dilute KOH.

[g]Keep in a freezer or refrigerator between uses.

[h]Add items 1–7 and 9 to 850 ml distilled water (item 16), adjust pH to 5.0, and add sugar (item 15). Sugar is not listed in the original recipe, but this seems to be a typographical error, which is why the usual range is suggested here (a reasonable amount would be 20 g l^{-1}). Adjust volume to 1000 ml with distilled water (item 16). Pour solution into a 2-l flask, and autoclave. Add items 8 and 10–14 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE C-9. **Solid medium for subculture of *Cattleya* bud meristems (Reinert and Mohr, 1967)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

7	Citric acid	150	No stock		Weigh
8	**Iron**				
(a)	Ferrous sulfate, $Fe_2(So_4)_3$	10.70	1.07 g l^{-1}	10	One solution
(b)	Na_2EDTA	22.40	2.24 g l^{-1}		
	Vitamins[d]				
9	Thiamine·HCl (vitamin B_1)[d]	0.1	10 mg 100 ml^{-1} 95% ethanol	1	
10	Niacin (nicotinic acid)[d]	0.5	50 mg 100 ml^{-1} 95% ethanol	1	
11	Pyridoxine·HCl (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol	1	
	Amino acid				
12	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Auxins				
13	Indole-3-butyric acid (IBA)	1.75	175 mg 100 ml^{-1} 95% ethanol[f]	1	
14	Naphthaleneacetic acid (NAA)	1.75	175 mg 100 ml^{-1} 95% ethanol[f]	1	
	Cytokinin				
15	Kinetin, 6-furfuryl amino purine[g]	1	100 mg 100 ml^{-1} 95% ethanol[g]	1	
	Polyol				
16	*myo*-inositol	100	10 g l^{-1}[h]	1	Or weigh
	Sugar				
17	Sucrose[i]	15–30 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[j]	To 1000 ml			
	Solidifier[k]				
19	Agar	6 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and nitrate may become contaminated with standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add all microelements to the same 1 l of distilled water; stir and/or heat until dissolved; add 1 ml per liter of culture medium.

[d]If desired, all three vitamins can be dissolved in the same 100 ml and 1 ml of this solution used per liter of culture medium. Keep frozen between uses.

[e]Keep refrigerated or frozen between uses.

[f]If auxins do not dissolve easily, add a few drops of dilute KOH. If desired, the two auxins can be combined in the same 100 ml 95% ethanol. If so, use 1 ml of the combined solution per liter of culture medium. Keep refrigerated.

[g]If cytokinin fails to dissolve, add a few drops of dilute HCl. Keep refrigerated.

[h]The stock solution must be kept frozen between uses.

[i]Sugar does not appear in the recipe (table 1 in Reinert and Mohr, 1967). Since this seems to be a typographical error, an amount in the usual range is suggested (item 17).

[j]For initial solution, mix items 1–14 with 750 ml distilled water (item 18), adjust pH to 5.0, add sugar (item 17), and bring volume up to 1000 ml with more distilled water (item 18). Dispense into culture vessels, and autoclave. To prepare second medium, mix items 1–16 with 750 ml distilled water (item 18), adjust pH to 5.0, add sugar (item 17), and bring volume to 1000 ml with more distilled water (item 18). Agar (item 19) is dissolved by adding it slowly, while stirring, to gently boiling solution. When it is fully dissolved, dispense into culture flasks and autoclave. In this instance all components are autoclaved.

Propagation of *Cattleya* by the Culture of Explants from Vegetative Shoots

When mortality of explants is high, a tissue culture method that does not carry with it the danger of losing an entire plant is very desirable. The utilization of explants from vegetative shoots is one such method. Failure may result in the loss of a shoot, but at least the plant is safe. Once the requirements of each genus are understood, at least partially suitable media can be developed. This, indeed, is the case with explants from vegetative shoots of *Cattleya* (Scully, 1967).

Plant Material. Use lateral meristems removed from vegetative shoots 1–8 cm long.

Surface Sterilization. Shoots are surface-sterilized for 5 min in 20% (v/v) Clorox. After exposure of the lateral buds, the shoots are again sterilized with the same solution, this time for 10 min.

Culture Vessels. Use 50-ml flasks containing 5 ml of liquid solution or 20 ml of solid medium.

Culture Conditions. Liquid cultures are placed on a rotary action shaker (a New Brunswick Model V was used in the original research) operating at 160 rpm under continuous illumination of 100–180 ft-c from fluorescent light (Sylvania Gro Lux or a mixture of cool or warm white plus incandescent bulbs) and a temperature of $26 \pm 4°C$.

Culture Medium. Liquid modified Vacin and Went medium (Vacin and Went, 1949) is used for the initial explants. Tissue masses are subcultured on solidified medium (Table C-10).

Procedure. Remove a vegetative shoot 1–8 cm long, and sterilize it for 5 min. Expose the lateral meristems by removing one to two young leaves, and sterilize for 5 min using the same Clorox solution as before. Make incisions just below the nodal origin and along the two sides of the bud. Separate the explant by making a cut behind the bud itself. Remove all but one of the remaining leaves, and make four vertical incisions and a horizontal one to remove the apical meristem as a 1-mm cube. The volume of explants should range between 1 and 2 mm^3. Collect the explants on sterile moist filter paper in sterilized Petri dishes.

Transfer explants to the liquid medium (Table C-10), and place the cultures on the shaker for 2–5 weeks. When tissue or callus masses form, section and subculture them. Once formation of PLBs starts, the proliferating masses can be divided and cultured on solid medium (Table C-10). If left undisturbed, the PLBs will form fully rooted plants within 6–8 weeks.

Development Sequence. The explant develops into a callus. PLBs are formed that give rise to plantlets.

TABLE C-10. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of explants from vegetative shoots of *Cattleya* (Scully, 1967)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Tricalcium phosphate, $Ca_3(PO_4)_2$[b]	200	20 g l^{-1}	10	Or weigh
2	Potassium nitrate, KNO_3[c]	525	52 g l^{-1}	10	Or weigh
3	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
4	Ammonium sulfate, $(NH_4)_2SO_4$[c]	500	50 g l^{-1}	10	Or weigh
5	Ferric tartrate, $Fe_2(C_4H_4O_6)_3$[d]	28	2.8 g l^{-1}	10	
6	Magnesium sulfate, $MgSO_4 \cdot 4H_2O$	250	25 g l^{-1}	10	Or weigh
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Complex additive				
9	Coconut water	250 ml	No stock	No stock	Fresh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier[e]				
11	Agar	9 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]If all of the material does not dissolve, shake stock solution well before dispensing to insure an even suspension; better yet, weigh out each time.

[c]Solutions containing nitrate and/or ammonium may become contaminated with time. Therefore it is preferable not to make stock solutions. If prepared, keep frozen between uses.

[d]If the substance fails to dissolve, add a pellet of KOH and shake well. Also shake well before dispensing.

[e]Mix items 1–7 with 400 ml distilled water (item 10), adjust pH to 5.0–5.2, add the sugar (item 8), and bring volume up to 1000 ml with more distilled water (item 10). If a liquid medium is desired, distribute into culture vessels and autoclave for 10–12 min at 15 lb pressure. When solid medium is needed, bring solution to a gentle boil and add agar (item 11) slowly while stirring; distribute into culture vessels, and autoclave.

General Comments. This is a successful method, but Scully (1967) suggests that every worker may have to make a few modifications. An important point to keep in mind is that the initial culture medium must be liquid and requires shaking.

Clonal Propagation of *Cattleya* through the Culture of Dormant Buds from Backbulbs

The buds of backbulbs are generally dormant and do not seem to contribute much to the horticultural status of plants. For this reason and because when backbulbs are used as a source of explants there is no interference "with the production of shoots and flowers," a procedure for the culture of dormant buds was developed in Thailand (Vajrabhaya, 1978).

Plant Material. Backbulbs and portions of the rhizome are taken from mature plants. Most of the backbulb is removed leaving only 2–3 cm of tissue above the rhizome. Following initial surface sterilization, dissection of the buds is initiated by removing

several layers of leaf primordia. After additional sterilization, more leaf primordia are removed exposing the growing points, which are excised.

Surface Sterilization. Rhizomes and pseudobulbs should be washed several times with tap water and then submerged in a 1 : 10 dilution of Clorox (10 ml of Clorox diluted to 100 ml with distilled water) for 15–30 min. Following this step the rhizomes and pseudobulbs are moved to a 1 : 20 dilution (5 ml Clorox diluted to 100 ml with distilled water). They can remain for up to 1 h without any apparent damage to the tissues. After removal of the initial layers of leaf primordia, the tissues should be dipped for a few seconds in a 1 : 1000 dilution (0.1 ml Clorox diluted to 100 ml with distilled water).

Culture Vessels. Test tubes were used in the original research, but other containers may also be suitable.

Culture Conditions. Cultures should be maintained at 22–25°C under 16 h of diffuse light of 2000–4000 lx. In the original research the illumination was provided by Philips TLF 40W/33 fluorescent lamps, but other sources are also suitable.

Culture Medium. Modified Knudson C medium with the microelements of J. P. Nitsch is used (Table C-11).

Procedure. Place the excised tips on the medium, and allow them to remain until PLBs form. These can be subcultured on the same medium or other modifications of the Knudson C solution (see Tables Aranda-7 and Aranda-8) for plantlet production.

Developmental Sequence. Explants turn green after 2 weeks of culture. The tissue grows slowly during the first 2 months, and their diameters may increase only two to three times. Growth may be more rapid after that, with PLBs forming eventually. These form plantlets.

General Comments. Explants from dormant buds grow more slowly than those from actively growing young shoots. However, they develop in a similar manner. The use of dormant buds from backbulbs (i.e., buds that do not seem to be horticulturally important) more than makes up for the slower initial growth. According to Vajrabhaya (1978) this method is also suitable for "dormant buds of other orchid genera, including those of monopodial species" (but she did not list the other orchids).

TABLE C-11. **Modified Knudson C medium (Knudson, 1946) for the culture of dormant buds of *Cattleya* (Vajrabhaya, 1978)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	1 g	100 g l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	20	2 g l^{-1}		
(c)	Copper chloride, $CuCl_2 \cdot 2H_2O$	10	1 g l^{-1}	10	One solution
(d)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	2 g	200 g l^{-1}		
(e)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	20	2 g l^{-1}		
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	100	10 g l^{-1}		
	Auxin				
7	2,4-Dichlorophenoxyacetic acid (2,4-D)	1	100 mg 100 ml^{-1} 95% ethanol	1	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium. The original paper (Vajrabhaya, 1978) lists "Fe EDTA (chelated iron) . . . 0.005 gm."

[d]Add all microelements to the same 800 ml distilled water, adjust volume to 1000 ml with more distilled water, heat and/or stir until the salts are completely dissolved, and allow the solution to cool before dispensing.

[e]Add items 1–6 to 900 ml distilled water (item 9), adjust pH to 5.0–5.2, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour the solution into a 2-l flask and autoclave. Add hormone (item 7) to the hot, still liquid solution under sterile conditions with sterilized pipettes, swirl several times to mix well, and dispense into preautoclaved culture vessels. According to Knudson (1946), the pH of his solution without agar (i.e., liquid) can be close to 4.6–4.7. If necessary, adjust pH upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

Cattleya Propagation by Tissue Culture

Considerable variability exists between media used for the propagation of even a single group of orchids. In addition, most procedures depend heavily on protocorm proliferation, a process that may lead to "significant incidences of genetically aberrant plants." A series of experiments designed to develop more uniform media of wider applicability and to enhance axillary branching rather than proliferation of PLBs was carried out at the University of California, Riverside, by a visitor from the Institute of Botany, Academia Sinica, Nankang, Taipei, Taiwan, with advice from

Toshio Murashige (one of the originators of the widely used MS medium; Huang, 1984).

Plant Material. Shoot apex explants taken from newly emerging shoots (2–5 cm in length with none of the leaves unfurled) of mature plants are preferable, but lateral and/or dormant buds can also be used. The outer leaves are removed to expose the terminal portion of the stem before washing the apices. After the washing, terminal portions of the stem (ca. 1 cm in length) and larger terminal buds are stored in a solution of 100 mg l^{-1} ascorbic acid and 150 mg l^{-1} citric acid until preliminary trimming of all shoots is completed. Following this step the apices are trimmed further until they are 4–5 mm long and wrapped in cheesecloth for sterilization. Additional emerging leaves (one or more) and the subjacent stem are removed from the sterilized apices under aseptic conditions with sterile scalpels. The small explants (2–3 mm long) are sterilized again before being placed in the starting medium.

Surface Sterilization. Explants are washed with tap water and a mild household detergent after removal from the plant. Following preliminary trimming, explants from the ascorbic acid–citric acid solution are immersed in a 1 : 10 dilution (10 ml diluted to 100 ml with distilled water) of Purex (or another household bleach containing 5–5.25% sodium hypochlorite) for 20 min under vacuum. After that the explants should be washed three times with sterile distilled water. The explants to be cultured (2–3 mm long) are placed for 1 min in the 1 : 10 Purex and then dipped in a 1 : 1000 dilution of the bleach (1 ml diluted to 1 l with sterile distilled water) before being placed in the medium.

Culture Vessels. Standard culture tubes, 25 × 150 mm, containing 5 ml of starting medium (Table C-12) or 25 ml multiplication medium (Table C-13) capped with propylene closures (Kaputs made by Belco Glass, Inc., Vineland, NJ) were used in the original experiments, but other vessels can also be employed. For root induction, plants were placed in autoclavable plastic Magenta GA7 culture containers (Magenta, Inc., Chicago, IL), containing 100 ml of rooting medium (Table C-14), but Erlenmeyer flasks and other culture vessels are also suitable.

Culture Conditions. Starting cultures are maintained under 1000 lx illumination for 16-h photoperiods. They should be rotated continuously at 1 rpm at 10° from the horizontal. Rooting-stage plants should be moved to 6000–7000 lx. No information is given regarding the light sources, but general experience with *Cattleya* suggests that fluorescent, incandescent, or a combination of the two is suitable. The temperature was a constant 27°C during the original experiments, but it is reasonable to assume that 22–29°C would also be appropriate.

Culture Media. Three media, all based on MS medium, are used: starting (Table C-12), shoot multiplication (Table C-13), and rooting (Table C-14).

Procedure. Allow explants to remain on the starting medium (Table C-12) for 1–4 months (length depending on the hybrid). They may have to be subcultured once or twice on the same solution until they reach a length of at least 1 cm and develop

TABLE C-12. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for use as the starting solution in the culture of *Cattleya* explants (Huang, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	495	49.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	132	13.2 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	111	11.1 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	570	57 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	51	5.1 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution

	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Complex additive				
17	Coconut water from green nuts	150	No stock	No stock	Measure
	Solvent				
18	Water, distilled[h]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7, 9, and 17 to 750 ml of distilled water (item 18). Adjust pH to 5.7, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 18). Pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 8 and 10–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE C-13. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of *Cattleya* shoots (Huang, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	α-Napthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin and related substance				
11	Adenine sulfate·$2H_2O$	30	3 g 100 ml^{-1} 95% ethanol	1	
12	N^6-benzyladenine (BA)	1	100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
16	Coconut water from green nuts	159	No stock	No stock	Measure
	Sugar				
17	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[h]	To 1000 ml			
	Solidifier				
19	Agar, TC[i]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7, 9, and 16 to 750 ml distilled water (item 18). Adjust pH to 5.7, add sugar (item 17), and adjust volume to 1000 ml with distilled water (item 18). Bring solution to a gentle boil, and add agar (item 19) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 8 and 10–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

[i]TC agar is of relatively high purity and available from KC Biological, Inc., Lenexa, KS. Other higher-purity agars are probably also suitable. Gelrite (Kelco Division, Merck & Co., San Diego, CA), 0.2%, can also be used.

TABLE C-14. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the rooting of *Cattleya* shoots (Huang, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Micropotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid

	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.3	30 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin-related substance				
11	Adenine sulfate·$2H_2O$	30	3.0 g 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	1.0	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, TC[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin does not dissolve, add a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–7, and 9 to 900 ml distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamins (items 8 and 10–14) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

[i]TC agar is of relatively high purity and available from KC Biological, Inc., Lenexa, KS. Other higher-purity agars are probably also suitable. Gelrite (Kelco Division, Merck & Co., San Diego, CA) 0.2%, can also be used.

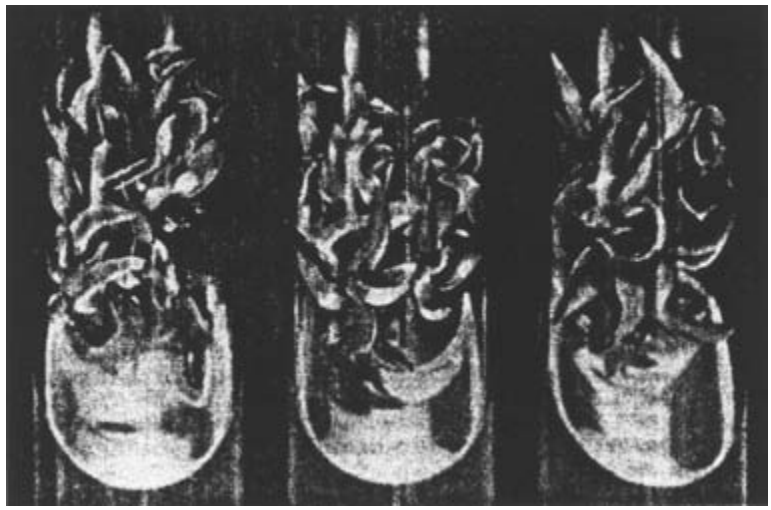

FIG. C-1 **Increase of *Cattleya* shoots by enhanced axillary branching.**

easily observable leaves. At this stage of development, transfer them to the shoot-multiplication medium (Table C-13), where axillary branching takes place and the number of shoots increases (Fig. C-1). A large number of shoots can be obtained after four to five subdivisions. Move individual shoots to the rooting medium (Table C-14) for root formation and plantlet development. Plantlets with several vigorous roots and large leaves can be moved to potting mix.

Developmental Sequence. Explants elongate and form leaves on the starting medium (Table C-12), branch on the multiplication solution (Table C-13), and form roots on the rooting formulation (Table C-14).

General Comments. This procedure may eliminate the undesirable variations that sometimes occur following excessive proliferation of PLBs. During the original research a minimum of 500 plantlets were obtained from each explant after 10 months.

Vegetative Multiplication of *Cattleya* Seedlings through the Culture of Leaf Bases

The ideal method for clonal propagation would utilize an organ or small mass of tissue that can be removed without damaging or endangering the plant. Leaves are one obvious source for such tissues. Meristems at the base of *Cattleya* leaves can be used to produce PLBs (Champagnat et al., 1970).

Plant Material. Leaves are removed from seedlings maintained in sterile culture.

Surface Sterilization. This is not necessary.

TABLE C-15. **Culture medium for *Cattleya* leaf bases (Champagnat et al., 1970)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements[b]				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	1 g	100 g l^{-1}	10	Or weigh
2	Potassium chloride, KCl	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	125	12.5 g l^{-1}	10	
4	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$	500	50 g l^{-1}	10	Or weigh
5	Monopotassium phosphate, KH_2PO_4	125	12.5 g l^{-1}	10	
	Microelements of Heller				
6	*Solution A*[c]				
(a)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	1	1 g l^{-1}	1	One solution
(b)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$[d]	0.010	10 g l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.030	30 mg l^{-1}		
(d)	Aluminium chloride, $AlCl_3$	0.030	30 mg l^{-1}		
(e)	Nickel chloride, $NiCl_2 \cdot 6H_2O$	0.030	30 mg l^{-1}		
(f)	Potassium iodide, KI	0.010	10 mg l^{-1}		
	Solution B				
7	Ferric chloride, $FeCl_3 \cdot 6H_2O$	1	1 g l^{-1}	1	
	Cytokinin				
8	Kinetin	1	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier[f]				
11	Agar	8 g	No stock	No stock	

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions are not advisable. If prepared, they must be kept frozen.

[c]Add all salts to the same 1 l. Stir or heat until dissolved and use 1 ml per liter of medium.

[d]As given in Champagnat et al. (1970), this solution contains magnesium, but no manganese. Since the medium already contains magnesium (item 3), a correction was made in the usual range.

[e]If cytokinin fails to dissolve, add a few drops of dilute HCl. Keep refrigerated.

[f]Mix items 1–8 with 700 ml distilled water (item 10), adjust pH to 5.3, add sugar (item 9), and bring volume to 1000 ml with more distilled water (item 10). To dissolve agar (item 11), bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Dispense the solution into the culture vessels, and autoclave.

Culture Vessels. Use 5-cm-diameter Petri dishes containing medium to a height of 5 mm; or test tubes and Erlenmeyer flasks filled with medium to one-fifth of their volume.

Culture Conditions. Use the same as for germinating seeds of *Cattleya* or its meristems (Morel, 1971*b*, Morel*c*, 1974).

Culture Medium. The usual salts (including the microelements of Heller's medium), plus 1 mg l^{-1} kinetin solidified with 8 g l^{-1} agar (Table C-15).

Procedure. Under aseptic conditions, remove leaves 6–10 mm long from seedlings growing in flasks. Excise and discard the axillary meristem from the base, but culture the rest. When PLBs form, subculture.

Developmental Sequence. When the axillary meristem at the base of a leaf is left in place, it starts to grow and inhibits the formation of adventitious buds. If it is removed, numerous PLBs form at the cut end and on the leaf blade.

General Comments. This is a simple, easy, and effective method. However, since the tissues to be cultured are obtained from seedlings, the procedure cannot be used for the propagation of established clones. Nevertheless, it should prove useful in cases where only very few seedlings can be obtained from a cross. It can also be used in cases where only a limited number of plantlets can be obtained from a meristem.

Clonal Propagation through the Culture of *Cattleya* Leaf Tips

In 1967 Ernest A. Ball, who first cultured meristems (Ball, 1946), gave a lecture at the University of California, Irvine, about the culture of leaf parenchyma cells. He had succeeded in producing whole plants (but not orchids) from them. This suggested to me (JA) that perhaps orchid leaf cells could be cultured. When Ernest Ball joined our department in 1968, we decided to try. The work was done by an undergraduate named Mary-Ellen Farrar (who, by the time her project was completed, had become Mrs. Churchill). We tried to cultivate all parts of a leaf but succeeded only with tips, and even those did not always grow. But this method barely damages the plant and therefore approaches an ideal procedure (Arditti et al., 1971; Ball et al., 1971; Churchill et al., 1971*a*, 1971*c*, 1972*a*, 1972*b*, 1973).

Plant Material. Leaf tips are obtained from young leaves on old plants before the appearance of the characteristic notch.

Surface Sterilization. Tips are sterilized for 10 min in saturated calcium hypochlorite solution. To prepare the solution, mix 10 g calcium hypochlorite with 140 ml water. Stir well, allow to stand for a few minutes, and stir again. Repeat three times, and filter or decant the supernatant, which is the sterilizing solution. Use within 6 h.

Culture Vessels. We use 125-ml Erlenmeyer flasks containing 25 ml medium for both liquid and solid media.

Culture Conditions. Liquid cultures are placed on a reciprocating shaker (60 oscillations per minute) at 22–25°C under 18-h photoperiods. The light intensity produced by a combination of two 40-W Sylvania Gro Lux tubes and two 50–100-W incandescent bulbs per fixture placed 50 cm above the cultures should be 150 ft-c. Solid cultures may be maintained on a table top or shelf under the same conditions. After transfer to Knudson C medium, the cultures are maintained under 12-h 22–25°C photoperiods, 36 cm from the same light sources.

Culture Media. Tips are cultured and callus formation occurs in liquid Heller's medium (Table C-16). These calli consist of PLBs. Proliferation continues very well, without much differentiation on solid MS (Table C-17) or Linsmaier–Skoog (Table C-18)

TABLE C-16. **Modified Heller's medium (Heller, 1953) for the culture of tips from young leaves of mature *Cattleya* plants (Churchill et al., 1971*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Potassium chloride, KCl	750	75 g l^{-1}	10	
2	Sodium nitrate, $NaNO_3$[b]	600	60 g l^{-1}	10	Weigh
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	125	12.5 g l^{-1}	10	
5	Calcium chloride, $CaCl_2 \cdot 2H_2O$	75	7.5 g l^{-1}	1	
	Iron				
6	Ferric chloride, $FeCl_3 \cdot 6H_2O$	1	1.0 g l^{-1}	1	
7	**Microelements**[c]				
(a)	Boric acid, H_3BO_3	1	1 g l^{-1}		
(b)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	1	1 g l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	0.01	10 mg l^{-1}		
(d)	Cupric sulfate, $CuSO_4 \cdot 5H_2O$	0.03	30 mg l^{-1}	1	One solution
(e)	Aluminum chloride, $AlCl_3$	0.03	30 mg l^{-1}		
(f)	Nickel chloride, $NiCl_2 \cdot 6H_2O$	0.03	30 mg l^{-1}		
(g)	Potassium iodide, KI	0.01	10 mg l^{-1}		
	Auxin				
8	2,4-D	1	30 mg 30 ml^{-1} 95% ethanol[d]	1	
	Cytokinin				
9	6-Benzylaminopurine (benzyladenine)	500 µg	30 mg 30 ml^{-1} 95% ethanol[d]	0.5	
	Vitamin				
10	Thiamine (vitamin B_1)	1	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
11	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[f]	To 1000 ml			
	Solidifier[f]				
13	Agar	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing nitrate tend to become contaminated. Therefore, it is better to weigh the salt each time. If prepared, stock solutions must be kept frozen.

[c]Add all microelements to the same 1 l of distilled water. Stir or gently heat the solution until all salts are dissolved.

[d]If the auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively.

[e]Keep refrigerated.

[f]Mix items 1–10 with 800 ml distilled water (item 12), adjust pH to 5.3, add sugar (item 11), and bring the volume to 1000 ml with more distilled water (item 12). If a liquid medium is required, distribute into culture vessels and autoclave. When a solid medium is needed, bring solution to a gentle boil and add agar (item 13) slowly while stirring. After agar has dissolved, distribute the medium into culture flasks and autoclave.

media. PLBs must be transferred to solid modified Knudson C medium (Tables C-3, C-6, and C-19) for plantlet production. Addition of banana homogenate (Arditti, 1967) can accelerate growth. Use of a flasking tool designed for seeds (Arditti, 1968) may facilitate transfers but is not required.

Procedure. Remove tips 15–25 mm long from young leaves with a sharp scalpel or razor blade and place on wet filter paper (or paper towels) in a closed container. Following surface sterilization and rinsing in sterile distilled water, remove the bottom part, leaving a tip 4–5 mm in length. Then place this tip in culture.

TABLE C-17. **Murashige–Skoog medium (Murashige and Skoog, 1962) as used for the maintenance of callus cultures derived from *Cattleya* leaf tips (Churchill et al., 1971)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution

11	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
12	Coconut water[e,h]	100–250	No stock	No stock	Measure
	Sugar				
13	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[i]	To 1000 ml			
	Solidifier				
15	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If auxin or cytokinin does not dissolve, add a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Liquid from immature (green) nuts is preferable.

[i]Add items 1–7 and 12 to 700 ml distilled water (item 14), adjust pH to 5.2–5.5, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Bring solution to a gentle boil, and add agar (item 15) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask and autoclave. Add amino acid, hormones, and vitamin (items 8–11) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE C-18. **Linsmaier–Skoog medium (Linsmaier and Skoog, 1965) as used for the maintenance of callus cultures derived from *Cattleya* leaf tips (Churchill et al., 1971*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1.65	82.5 g l^{-1}	20	Or weigh

	Solvent				
13	Water, distilled[g]	To 1000 ml			
	Solidifier[g]				
14	Agar	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing nitrate and/or ammonium tend to become contaminated. Therefore it is preferable not to make stock solutions. If prepared, they must be kept frozen.

[c]Add all microelements to the same 1 l, and stir and/or heat until dissolved. Add 10 ml per liter of culture medium.

[d]If there are difficulties in dissolving kinetin, add a few drops of dilute HCl. Keep stock solution refrigerated.

[e]If there are difficulties in dissolving IAA, add a few drops of KOH. Keep stock solution refrigerated.

[f]Keep the stock solution refrigerated.

[g]Mix items 1–11 with 700 ml distilled water (item 13), adjust pH to 5.5, and add sugar (item 12). Bring solution to a gentle boil, and add agar (item 14) slowly while stirring. When agar is completely dissolved, distribute medium into culture flasks and autoclave. However, it is preferable to mix items 1–8 with 700 ml distilled water (item 13), adjust pH to 5.5, add sugar (item 12), and bring volume to 1000 ml. Then add agar and autoclave. While solution is still hot, add a mixture of items 9–11 under sterile conditions. Swirl to mix, and distribute into preautoclaved culture vessels.

Developmental Sequence. Approximately 45 days after being placed in culture, the tip begins to proliferate. Soon thereafter, the original tissue dies and turns brown. Within 10–15 weeks, masses consisting of PLBs form. When these start to produce vegetative apices and leaves, transfer them to solid MS or Linsmaier–Skoog medium to increase proliferation. Plantlet formation occurs on Knudson C medium

TABLE C-19. **Modified Knudson C medium (Knudson, 1946) for the differentiation of plantlets from *Cattleya* leaf callus (Churchill et al., 1971*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	Or weigh
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
3	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	Or weigh
4	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$[c]	25	2.5 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4[d]	250	25 g l^{-1}	10	
6	**Microelements**[e]				
(a)	Boric acid, H_3BO_3	0.056	56 mg l^{-1}	1	One solution
(b)	Molybdic acid, MoO_3	0.016	16 mg l^{-1}		
(c)	Cupric sulfate, $CuSO_4$	0.040	40 mg l^{-1}		
(d)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.331	331 mg l^{-1}		
	Sugar				
7	Sucrose	20 g	No stock	No stock	Weigh
	Organic additive[f]				
8	Banana, ripe	150 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[f]	To 1000 ml			
	Solidifier[f]				
10	Agar	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate tend to become contaminated upon standing. Therefore it is better to weigh items 1 and 3 each time. If stock solutions are prepared, keep frozen.

[c]This solution tends to form a rust-colored precipitate on standing. Therefore shake before using.

[d]A phosphate buffer that will keep the pH steady may be substituted here. Prepare buffer by mixing 975 ml 0.1-*M* KH_2PO_4 (monopotassium phosphate; 13.6 g l^{-1}) with 25 ml 0.1-*M* K_2HPO_4 (dipotassium phosphate; 17.4 g l^{-1}). Measure the pH to be certain it is correct (pH 5.1–5.4), and use 18 ml per liter of culture medium.

[e]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved, and add 1 ml per liter of culture medium.

[f]Add items 1–8 to 700 ml distilled water (item 9). Homogenize until banana (item 8) is completely broken down (about 2–3 min), adjust pH to 5.3, and bring volume to 1000 ml with more distilled water. To dissolve agar (item 10), add it slowly while stirring to gently boiling solution. When dissolved, distribute medium into culture vessels and autoclave.

(Table C-19). Once placed on this medium, treat the PLBs and the resulting plantlets like seedlings (Arditti et al., 1982).

General Comments. Tips of young leaves from mature plants can be cultured, but the rate of success is not always high. Formation of callus apparently depends on the presence of meristematic or undifferentiated tissue in the leaf tip. If such tissue is no longer present, there is no callus development. Appearance of the characteristic notch in *Cattleya* leaves indicates their tips will no longer form calli. Unfortunately, the potential to form a callus is lost even before the notch becomes evident, but the time at which this happens is not easily apparent. The low rate of success is due to this fact. Hence it is important to obtain tips from very young leaves. Also, instructions must be followed exactly.

This method was developed to eliminate the need to sacrifice entire plants or shoots and to provide a simple procedure for clonal propagation of *Cattleya*. In this we have succeeded since less skill is required than for shoot-tip ("meristem") cultures, and damage to the plant is minimal. It is worth noting that at least one orchid, *Malaxis paludosa*, produces foliar embryos (Taylor, 1967).

Clonal Propagation of *Cattleya* through the Culture of Leaf Tissues

Leaf tips and bases of mericlone plantlets of *Cattleya bowringiana* × *Cattleya forbesii* were cultured using the method employed for *Aranda* (Fu, 1978, 1979*b*). Only leaf bases proliferated, which suggests that this method can be used for clonal propagation. However, the need for a clonal propagation method for "mericlone plantlet[s]" is questionable.

Isolation of *Cattleya* Protoplasts

Protoplasts of "*Cattleya schombocattleya*" [sic] can be isolated by the method employed for *Brassia maculata* (Capesius and Meyer, 1977). The name used in the original paper presents a problem since it could refer to a *Cattleya* × *Schombocattleya* hybrid, a *Cattleya*, a *Schombocattleya*, or it could be an error. Those intending to use this procedure should proceed with caution.

Isolation of *Cattleya* Protoplasts from Protocorms, Leaves, and Roots

Isolated protoplasts of orchids could be used to produce interesting new hybrids through fusion and advanced plant bioengineering research. A method for the isolation of such protoplasts of several orchids including *Cattleya* was developed at Cornell University (Price and Earle, 1984).

Plant Material. Six-month-old seedlings of *Cattleya aurantiaca* were used in the original research as sources of protocorms, leaves, and roots.

Surface Sterilization. There is no need to sterilize seedlings since they are growing under aseptic conditions. It is important to keep in mind that all steps of the isolation and fusion of protoplasts must be carried out under sterile conditions.

Culture Vessels. The vessels needed for *Cattleya* are the same as those used for *Angraecum giryamae*.

Culture Conditions. See *Angraecum* entry, Isolation of Protoplasts from Green Sepals of *Angraecum giryamae* (p. 167, Vol. I).

Culture Media. For the isolation of protoplasts the tissues are incubated in an enzyme solution consisting of 2% Cellulysin (Cal Biochem, P.O. Box 12087, La Jolla, CA 92112), 0.5% Driselase (Fluka AG Bucks, Switzerland CH 9470, 980 South Second St., Ronkonkoma, New York), and 1% Macerozyme (Kanematsu-Geosho, Kinki Yalkut Mfg Co., Ltd., 8–21 Shingikau, Nishinomiya, Japan) in a solution of 36.4 g mannitol and 11.8 g calcium chloride ($CaCl_2 \cdot 2H_2O$) per liter. This medium must be sterilized through filtration (Millipore Filter Corp.; see Appendices 1 and 2). It may not be autoclaved. All other media and solutions are the same as those used for *A. giryamae*.

Procedure. Incubate protocorms and seedling roots in the enzyme solution for 2–4 days. Incubate leaves in the same solution for 2 days. All other procedures are the same as those used for *A. giryamae*.

Fusion experiments were not carried out with *Cattleya*, but a good starting point would be the method used for *Dendrobium*.

Developmental Sequence. Protoplast yield per gram of fresh weight of the source tissue was "very few" from protocorms and roots and "few" from leaves. There are no reports of callus formation and plantlet regeneration from *Cattleya* protoplasts.

General Comments. When refined and made practical this will be a useful procedure.

Isolation, Culture, and Fusion of *Cattleya* Protoplasts

A large number (5.5×10^5 to 3.1×10^6) of protoplasts can be isolated from leaf mesophyll of *Cattleya* Wine Festival, but seedling cultures were a better source (Gopalakrishnan and Seeni, 1987).

Clonal Propagation of *Cattleya* through Tissue Culture Methods

Several experiments were carried out to determine the effects of a number of factors on the survival of shoot-tip explants. According to the summary (which is in English; the paper is in Japanese) the following were observed (Ichihashi and Kako, 1973):

1. Either NAA or 2,4-D is essential for initiating growth of explants. The optimal concentration of each is 0.1 mg l^{-1}.
2. A culture medium described as RM-1962 in liquid form is better for survival and growth than Knudson C. The major reason for the effectiveness of the former medium may be its inorganic components. "RM" suggests that the medium may be the one formulated by Reinert and Mohr, but their paper was published in 1967. The MS medium was published in 1962. Both are cited in the paper.
3. The effects of coconut water (100 ml l^{-1}) varied depending on the hybrid.
4. The best survival rates and least browning occurred in liquid medium that was not agitated in any manner or in one that was rotated at 0.86 rpm.
5. Explants from middle or lower nodes survived better than those from upper parts of the shoot or apical buds.
6. Growth responses of several hybrids and species were different even when "cultured under the same conditions."

Effects of Growth Regulator and Organic Supplement Combinations on PLBs and Plantlets of *Cattleya*

Effective combinations of plant hormones for plantlet growth are 0.1–1.0 mg kinetin and 1.0–5.0 mm l^{-1} NAA or 0.1–0.5 mg kinetin and 0.1 mg 2,4-D per liter.

Shoot formation is enhanced by 1.0 mg BA and 0.5 mg NAA per liter or 0.1 mg kinetin and 0.1 mg 2,4-D per liter, or 0.1 mg BA and 0.1 mg 2,4-D per liter. Plantlet growth is best in the presence of 0.1–1.0 mg kinetin and 1.0–5.0 mm NAA per liter or 0.1–0.5 mg kinetin and 0.1 mg 2,4-D per liter. Proliferation of protocorms is enhanced by 5.0 mg BA and 0.1 mg NAA per liter.

Banana juice stimulated protocorm development and proliferation. Coconut water ("coconut milk") also enhanced proliferation of protocorms and stimulated shoot development. Yeast extract inhibited shoot formation (from the English summaries in Kusumoto 1979*a*, 1979*b*).

Protocorm and Plantlet Formation in *Cattleya*

Some *Cattleya* explants tend to turn brown after about 10 days in culture. Those that do not, form PLBs on a Hyponex medium. Plantlet formation is good on a Hyponex medium that contains apple or potato juice (from the English summaries in Yoneda et al., 1979, 1989).

Micropropagation of *Cattleya* Almakee through Root Explants

Professor S. P. Vij has carried out extensive research on the culture of orchid root explants. In one of his programs he attempted to culture root explants of 21 orchid species and hybrids. He was successful with only 12 of them. *Cattleya* Almakee was one of them (Fig. C-2), but only barely because just two of 25 explants responded (Vij, 1993). However, each of these produced 25 propagules.

Plant Material. Young and actively growing roots from 16–30-week-old axenic seedlings should be used. Roots from mature plants die after 8–10 weeks in culture.

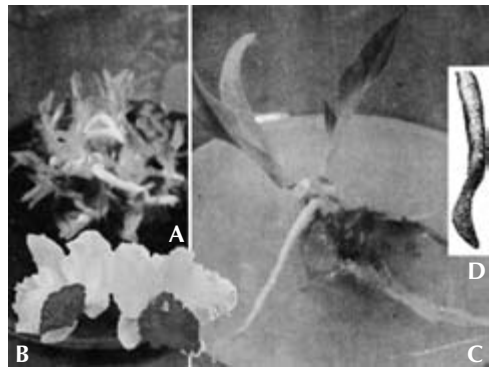

FIG. C-2. ***Cattleya*** **Almakee and the culture of its root tips. A. Proliferating plants. B. Flowers. C. Plantlet derived from the root tip. D. Root-tip explant. (Sources: A, C, D, Vij, 1993; B, www.solor.com.br/~bmdamiao/cattleyas.htm.)**

Surface Sterilization. No surface sterilization is needed because the roots are taken from axenically grown plants. However, they should be rinsed thoroughly with sterile distilled water to remove medium residues.

Culture Vessels. Culture vessels are not described in the original paper. Culture tubes 20 mm in diameter, about 125–150-ml capacity, and containing 30 ml of culture medium should be appropriate. Other vessels can also be used.

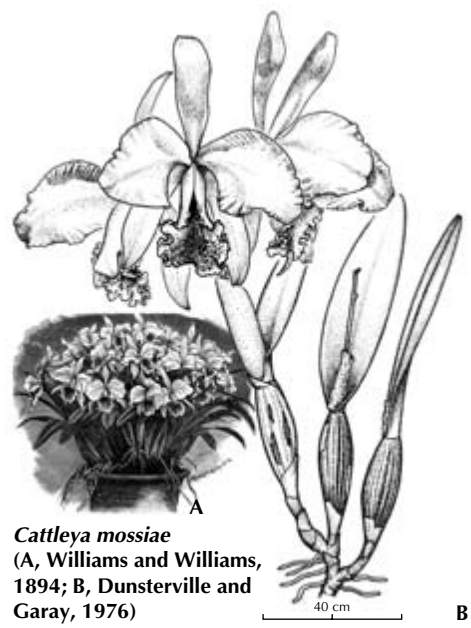
Culture Conditions. In the original experiments, cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx.

Culture Media. A modified Mitra, Prassad, and Roychowdhury medium (Mitra et al., 1976) containing kinetin (6-furfuryl, 1-aminopurine) and NAA induced the formation of PLBs and subsequently leaves, roots, and plantlets (see Table Aer-5).

Procedure. After removal from plants, the roots are placed on the medium (Table C-20). Well-developed PLBs or small plantlets should grow well on the Knudson C (see Tables Cym-2 and Cym-3), Tsuchiya (see Table Cym-4), Vacin and Went (see Table Cym-5) or basal MS (see Table Aer-2) media.

Developmental Sequence. The first leaves and roots are formed after 15 and 22 weeks of culture, respectively.

General Comments. When roots tip (or any) explants are taken from seedlings, clonal propagation of specific cultivars is not possible. However, this method can be employed to propagate orchids when only a few seeds are available and therefore not many seedlings can be obtained.



Cattleya mossiae
(A, Williams and Williams, 1894; B, Dunsterville and Garay, 1976)

TABLE C-20. **Mitra, Prassad, and Roychowdry medium (Mitra et al., 1976) as modified for the culture of root tips of *Cattleya* Almakee (Vij, 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
18	Agar[f]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe calls for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.6, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule, media that contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976; Vij, 1993).

Micropropagation of *Cattleya mossiae*

Easily one of the most beautiful *Cattleya* species in existence, *Cattleya mossiae* is endemic to Venezuela where it is currently endangered. Therefore, research intended to develop a micropropagation method was undertaken at the Universidad Centroccidental "Lisandro Alvarado" in Barquisimento, Venezuela (Torres and Mogollón, 1998, 2000).

Plant Material. Apical and axillary buds can be used.

Surface Sterilization. Two surface sterilization steps were used in the original research. First, apical shoots, rhizomes, and pseudobulbs were submerged with agitation for 30 min in a mixture of antiseptic soap (4 ml l^{-1}) and 20% (20 ml made up to 100 ml with distilled water) Clorox (or other household bleach containing 5.25% sodium hypochlorite; 17.5 ml should be used if the bleach contains 6.0% sodium hypochlorite). Except for its action as a surfactant, the antiseptic soap seems superfluous in the presence of Clorox. Therefore any laboratory or household detergent can be added to the 20% Clorox. The second step was to submerge the plant material in 10% (10 ml of 5.25% or 8.8 ml of 6% product made up to 100 ml with distilled water) Clorox for 5 min. A sterile distilled water wash was not used in the original research, but several such washes are highly recommended.

Culture Vessels. Test tubes were used for the initial 48 h in the original research. Tubes or other vessels can be employed after that.

Culture Conditions. In the original research, the cultures were maintained at $25 \pm 2°C$ under 16-h photoperiods of 900 lx (the source of illumination was not described). Standard culture room conditions are also suitable. According the English summary in one of the original papers (Torres and Mogollón, 1998), the explants were placed "on filter paper bridges." The materials and methods section in the body of the paper states that during "*Las primeras 48 horas* [the tubes] *fueron agitadas en un tambor rotatorio a 1 rpm*" (were agitated on a 1-rpm drum for the first 48 h). The chances are that both of these steps serve no useful purpose, complicate the process, and can be skipped. The explants can be placed on an agar medium from the outset. Or, if explants are to be agitated, this should certainly be done for longer than 48 h. For rooting, shoots were placed on membrane rafts (Life Raft™, www.osmotek.com, osmotek@ATTglobal.Net) and floated on liquid medium (Fig. C-3). This also seems to be an unnecessary complication. Placing shoots on an agar medium will be just as appropriate. Other procedures for *Cattleya* and many additional orchids use agar media effectively.

Culture Media. In the original research, explants were first placed on a liquid modification (Huang, 1984) of the MS medium (Murashige and Skoog, 1962) either on filter paper bridges or in the liquid itself with agitation (see Table C-12). The second medium for "multiplication of shoots" is presumably the same medium, but supplemented with 3 mg BA l^{-1} and solidified with 0.7% agar (Table C-21). Shoots produced on the second medium were placed on membrane rafts and transferred to

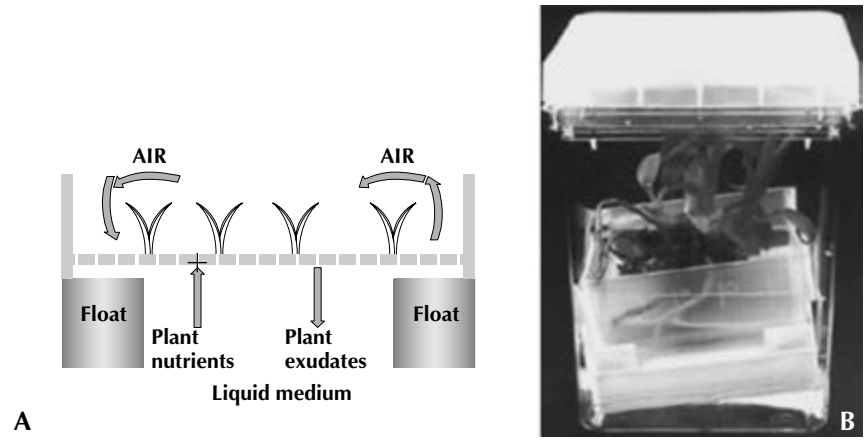

FIG. C-3. **Life Raft™. A. Diagram. B. Supporting plants inside a culture vessel. (Source: Osmotek web site, www.osmotek.com.)**

a third (liquid) modification of MS (modification of Table C-22) for rooting. The addition of TDZ, 3.3 μmol l^{-1}, to the culture medium can increase proliferation and production of PLBs. However, a side effect of TDZ is an increase in the number of fasciated shoots. This suggests that TDZ may disrupt normal development and could perhaps bring about undesirable mutations. Therefore it may be wise to not add TDZ to any of the culture media for *C. mossiae*.

Procedure. Details about excision are not provided in the original papers. The method employed in "Meristem culture of *Cattleya*" (Lindemann et al., 1970) can be used for shoot apices. Bud meristems can be excised as outlined in "Propagation of *Cattleya* by tissue culture of lateral bud meristems" (Reinert and Mohr, 1967). The procedure in "Aspects of meristem culture in the *Cattleya* alliance" (Scully, 1967) can also be used.

Placing explants on filter paper bridges affords aeration, but the advantages this provides are minimal and do not justify the extra work, expense, and complications. This is why such bridges are not used extensively in orchid micropropagation (Gandawijaja, 1980 in the section on *Dendrobium*).

When explants are cultured in liquid medium, agitation increases and accelerates proliferation. However, this requires 2–5 weeks (Reinert and Mohr, 1967; Scully, 1967), not 48 h as suggested for the current procedure (Torres and Mogollón, 1998). Therefore, if the initial explants of *C. mossiae* are placed in a liquid medium they should be agitated not for 48 h, but for 2–5 weeks or until the explants proliferate extensively and/or produce many PLBs. After that, parts of the proliferated mass or some PLBs should be transferred to fresh liquid medium and allowed to proliferate again (but this should not be done too many times to prevent mutations) or moved to solid medium and allowed to differentiate.

Floating shoots in membrane rafts like Life Raft™ (www.osmotek.com) on a liquid medium may provide additional aeration, but there is no evidence that the added

TABLE C-21. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of proliferated *Cattleya mossiae* explants (Huang, 1984; Torres and Mogollón, 1998, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
18	Agar[g]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 17), adjust pH to 5.7, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (items 10), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE C-22. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of proliferated *Cattleya mossiae* explants (Huang, 1984; Torres and Mogollón, 1998, 2000)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference will probably have little or no effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.7, add sugar (item 14), and adjust volume to 1000 ml with distilled water. Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10) and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

complication and expense are of much, if any, benefit. Therefore shoots can be placed on an agar medium for rooting as recommended here (i.e., not in rafts on liquid). Rooted plants should be potted in coconut peat, tree fern fiber, or a mixture of both (ratio not given in the original paper) and hardened under mist.

Developmental Sequence. The explants will proliferate and/or form callus and/or PLBs on the first medium (see Table C-12). Shoots multiply on the second medium (Table C-21). On transfer to the third medium (Table C-22), the shoots produce roots.

General Comments. On the whole this method does not seem well thought out or planned carefully. It is certainly not presented well. As originally proposed, this procedure is encumbered by unnecessary components (antiseptic soap used in conjunction with a Clorox dilution, for example), superfluous complications (as for instance culturing explants on bridges and placing shoots on rafts), and irrational steps (e.g., agitating explants for only 48 h). Despite all these complications, the procedure does not include the important step of washing the explants with sterile distilled water after the last sterilization step. On the whole this procedure seems effective and, if improved as suggested here, it should prove to be a productive method for propagating *C. mossiae* and perhaps even other orchids.

Formation of Protocorm-like Bodies by *Cattleya* Root Explants

Root tips are perhaps the most recalcitrant orchid explants, both in their incapacity to survive in vitro and in their ability to produce callus or PLBs. However, Professor Gilberto B. Kerbauy at the University of Sao Paulo has been successful in his attempt to induce PLB formation using root-tip explants taken from seedlings of a *Cattleya nobilior* × *Cattleya loddigesii* cross (Kerbauy, 1991).

Plant Material. Root tips, 10 mm long, were taken from 3–4-cm-tall asymbiotic seedlings growing on Vacin and Went medium (Vacin and Went, 1949).

Surface Sterilization. Explants taken from asymbiotic seedlings do not have to be surface-sterilized. However, they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Erlenmeyer flasks, 125-ml capacity containing approximately 25 ml medium, and other vessels can be used.

Culture Conditions. In the original research the cultures were maintained at 25°C under 16-h photoperiods of 9 W m^{-2} (the light source was not described). Standard culture room conditions are also suitable.

Culture Media. Modified Vacin and Went medium (Vacin and Went, 1949) is used for the culture of root-tip explants (Table C-23). The original paper (Kerbauy, 1991) makes no recommendations for a medium or media which can be used for plantlet development from PLBs. However, a medium (Table C-24) used to germinate the

TABLE C-23. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of root-tip explants from *Cattleya nobilior* × *Cattleya loddigesii* seedlings (Kerbauy, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Polyol				
8	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
9	Niacin	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
10	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Thiamine (vitamin B_1)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
	Auxins				
12	2,4-Dichlorophenoxyacetic acid (2,4-D)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
13	Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
14	Benzyladenine	0.05	5 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
15	Ripe banana pulp	60.0 g	No stock	No stock	Weigh
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	6.0 g	No stock	No stock	Weigh
	Darkening agent				
19	Activated charcoal[g]	1.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. This medium may be also suitable for the culture of protocorm-like bodies and plantlets.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 17) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_3(C_4H_4O_6) \cdot 2H_2O$, 28 ml l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible.

[e]Keep refrigerated between uses.

[f]If the auxins or cytokinin do not dissolve add a few drops of 0.1N KOH or 0.1N HCl, respectively.

[g]Add items 1–8 and 15 to 500–700 ml of distilled water (item 17), adjust pH to 5.7, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add darkening agent (item 19) with vigorous stirring; pour the solution into a 2-l flask and autoclave. Add the vitamins (items 9–11) and hormones (items 12–14) to the hot solution under sterile conditions with sterile pipettes, mix well, and distribute to preautoclaved culture vessels. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949). It is not clear whether the addition of other nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

TABLE C-24. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the germination of *Cattleya nobilior* × *Cattleya loddigesii* seeds (Kerbauy, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Ripe banana pulp	60.0 g	No stock	No stock	Weigh
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar[e]	8.0	No stock	No stock	Weigh
	Darkening agent				
12	Activated charcoal	1.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. This medium may be also suitable for the culture of protocorm-like bodies and plantlets.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 ml l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible.

[e]Add items 1–8 to 500–700 ml of distilled water (item 10), adjust pH to 5.7 or as required, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, add darkening agent (item 12) with vigorous stirring; pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of other nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

Cattleya nobilior × *Cattleya loddigesii* (Fowlie, 1977)

seeds that produced the seedlings which were used as explant sources may prove to be suitable for this purpose.

Procedure. The explants should be placed on the first medium (Table C-23) and allowed to remain on it until callus and/or PLBs are formed. PLBs and sections of the callus should be transferred to the second medium for plantlet development.

Developmental Sequence. PLBs are produced by the root-tip explants only after 6–9 months of culture (Fig. C-4). Callus is produced by a region adjacent to the meristem of the root tips. The callus masses are friable and light green in color. They grow slowly and reach 1–2 cm in diameter after 6 months. Root formation starts after 4 months of culture (Fig. C-2B), but roots can be malformed (Fig. C-4A). Plantlets also start to form after 9 months of culture (Fig. C-4A).

General Comments. This procedure is interesting and could result in the production of plantlets, but it is probably more valuable as a research tool than as a method for micropropagation. It is certainly a very impressive pioneering effort.

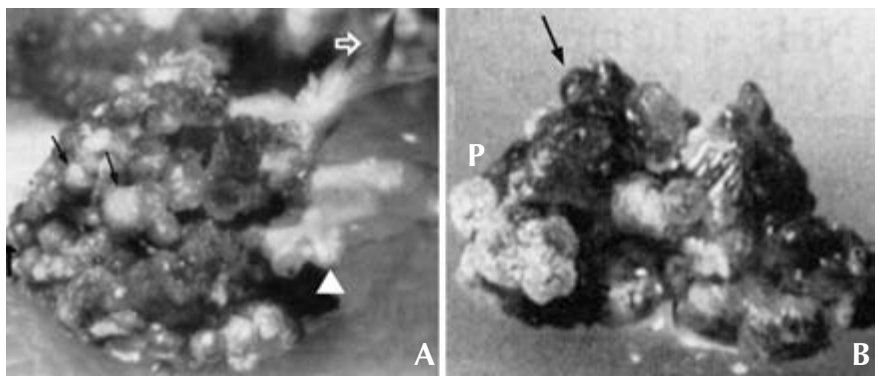

FIG. C-4. **Culture of *Cattleya nobilior* × *Cattleya loddigesii* root tips. A. Nine-month-old culture. Black arrows, malformed roots; white triangle, protocorm-like body; open white arrow, plantlet. B. Six-month-old culture. Black arrow, early stage of root formation; P, early stage of PLB formation.**

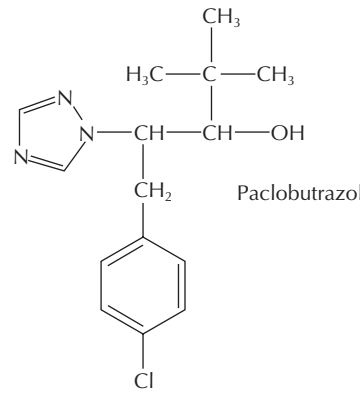
Paclobutrazol Effects on Leaf Development of *Cattleya mossiae* in Vitro

A herbicide, growth retardant, and an inhibitor of gibberellin biosynthesis, paclobutrazol (structural formula is shown below) was added to in vitro cultures of *Cattleya mossiae* at concentrations of 1, 2, and 4 mg l^{-1}. At levels of 2 mg l^{-1} and above it reduced root and shoot length, but not their number. It also affected the development of stomata (Torres and Mogollón, 2002). The addition of paclobutrazol and jasmonic acid increased tuber formation in seedlings of *Ptrerostylis sanguinea*, a terrestrial orchid from southwest Australia (Debeljak et al., 2002). These findings suggest that paclobutrazol may find some uses in micropropagation.



Paclobutrazol

Cattleya Protoplast Culture

Protoplasts of *Cattleya skinneri* were isolated using the method employed for *Dendrobium* (Yasugi, 1990).

Encapsulation of Protocorm-like Bodies of *Cattleya*

The method employed for *Dendrobium* Sonia (Saiprasad and Polisetty, 2003) is suitable.

Effects of Amino Acids on Protocorm-like Body Production by *Cattleya leopoldii*

Asparagine, glutamine, and phenylalanine reduced the number of PLBs produced by shoot-tip explants of *Cattleya leopoldii* (Saiprasad et al., 2002*b* based on abstract only).

Shipping of *Cattleya* Propagules in Sealed Membrane Vessels

Three-dimensional polypropylene vessels were fabricated for in vitro and ex vitro culture for *Cattleya* propagules. They consist of a microporous polypropylene membrane that allows nutrient transfer, molded side walls, and polypropylene membrane tops (Dellevigne et al., 1993 based on abstract only).

Micropropagation and Shipping of *Cattleya* in Sealed Semipermeable Membrane Vessels

Plantlets of a *Cattleya* hybrid shipped from Japan to the USA in vessels of the type described above arrived in good order after 7 days in transit at 14–30°C in the dark (Adelberg et al., 1997*b* based on abstract only).

Effects of Four Different Culture Media on Protocorm-like Body and Shoot Production by *Cattleya*

In a comparative study involving four culture media – Knudson C (KC), Vacin and Went (VW), Murashige and Skoog (MS), and Rosa and Laneri (RL) – *Cattleya leopoldii* showed that the greatest production of PLBs, multiple shoots, and most extensive differentiation occurred on MS (Saiprasad et al., 2002*c* based on abstract only).

Size of Explant and Virus Transmission in *Cattleya*

"In [cymbidium mosaic virus] CyMV infected *Cattleya*, 4 of 16 plantlets derived from 1.5 mm apical meristems and 1 of 5 plantlets from 0.2–10 mm apical meristems were virus free. However no [odontoglossum ringspot virus] ORSV plant was obtained." This paper also states that viruses could be transmitted through virus particles that adhere to razor blades used to excise leaf primordia (Fujiwara, 2001). Virus particles probably adhere to any tool that comes in contact with infected plants and can be transmitted in this fashion.

Micropropagation of *Cattleya leopoldii*

A very interesting study on the effects of growth regulators on the production of PLBs and multiple shoots during orchid micropropagation was carried out at the Division of Plant Physiology, Indian Agricultural Research Institute in New Delhi (Saiprasad et al., 2002*a*). The findings of this study are beyond the scope of this book, but a method for the micropropagation of *Cattleya leopoldii* will be described here.

Plant Material. Greenhouse-grown small plants and pseudobulbs of *C. leopoldii* were used as explant sources.

Surface Sterilization. Older leaves and dried parts should be removed from the explant sources before washing them thoroughly with running tap water. Shoot-tip sections, 5 cm in length, should be cut after the washing. These sections should be washed with a solution of 10 drops of Tween 20 (www.sigmaaldrich.com, www.fishersci.com, http://search.wako-chem.com), baby shampoo, or a mild household detergent per 100 ml of sterile distilled water, and taken to a sterile working

area where they should be placed in sterile distilled water. After that, the sections should be surface-sterilized by submerging them in a solution of 0.1 mg mercuric chloride (HgCl) plus a few drops of Tween 20, baby shampoo, or a mild household detergent per 100 ml of distilled water for 3 min (HgCl is very toxic and should be handled with care). This step should be followed by three washes with sterile distilled water.

Culture Vessels. Culture tubes or bottles, Erlenmeyer flasks, and other containers can be used.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 16-h photoperiods of 50–60 μE m^{-2} s^{-1} (the light sources used in the original research were not described). Standard culture room conditions are also suitable.

Culture Media. Explants should be cultured initially on MS medium (Murashige and Skoog, 1962) containing 1 mg BA l^{-1} (Table C-25). PLBs that form on this medium should be transferred to MS supplemented with 1 mg NAA l^{-1} (Table C-26). For further growth, the plantlets can be moved to one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) with or without banana homogenate (BH) or activated charcoal (AC). If BH is not listed in the recipe for a medium it can/should be added according to the instructions for media that contain it (see Tables C-19, Cym-3, and Cym-24). AC should be added to the medium selected for use as suggested for KC that does contain this darkening agent (see Table Pln-1, footnote *f*).

Procedure. Apices are excised from the sterilized 5-cm-long shoot tips and placed on the first medium (Table C-25). PLBs that form on this medium are moved to the second solution (Table C-26). Plantlets that develop from the PLBs should be cultured on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4) until they are ready for community pots.

Developmental Sequence. PLBs form on the BA-containing medium (Table C-25). They produce plantlets on the NAA-containing substrate (Table C-26). These plantlets develop further on one of the other media (see Tables Aranda-6 to Aranda-8, Arnth-5, C-3, C-6, C-19, Cym-1 to Cym-3, Cym-5, Cym-24, Den-2, Den-12, Den-21, Onc-5, Pln-1, Rntda-1, and V-4).

General Comments. This procedure is a byproduct of an excellent comparative research project on the effects of plant hormones on explants.

TABLE C-25. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of shoot-tip explants of *Cattleya leopoldii* (Saiprasad et al., 2002*a*)**

	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N HCl.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.2–5.7, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium into culture vessels and autoclave. Agar is not added to liquid media.

TABLE C-26. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for plantlet production of shoot-tip explants derived from protocorm-like bodies (PLB) of *Cattleya leopoldii* (Saiprasad et al., 2002*a*)**

	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.2–5.7, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved, distribute the medium into culture vessels and autoclave. Agar is not added to liquid media.

Browning of *Cattleya* Explants

Cattleya shoot-tip explants may turn brown and die following excision. This is due to the production of phenolics (Kako, 1973; Ichihashi and Kako, 1977; Ishii, 1980). Eucomic acid and tyramine were isolated from *Cattleya trianaei* "Mooreana" (Ishii et al., 1976). Five phenols were identified on another *Cattleya*. One of them has a molecular weight of 238 and a molecular formula of $C_{11}H_{10}O_6$; it is a *para*-hydroxyphenolic dicarboxylic acid (Kako, 1973). Polyphenol oxidase isolated from *Cattleya* has a pH optimum of 6.5 (Kako, 1973; Ichihashi and Kako, 1977).

Production of phenolics is lower when explants are cultured on a medium with a pH of 5.5. Incubation of the tissues in sterile water at 15–20°C also reduced browning (Ishii et al., 1979).

In Vitro Organogenesis of *Cattleya* Plantlets

Shoot apices that initiate foliar primordia are produced by PLBs. The phyllotaxy is always distichous. Roots arise endogenously in leaf axils (from illustrations and one summary in English in Fréson and Vanseveren, 1968; Vanseveren, 1969; Vanseveren and Fréson, 1969).

Cattleya mossiae was brought into cultivation by George Green of Liverpool, England. He received it from Venezuela in 1836. It flowered for the first time outside its native habitation in the collection of a Mrs. Moss for whom it was named by Sir William Hooker in 1838 (Bechtel et al., 1992).

Cleisostoma

See *Sarcanthus*.

Clowesia

Clowesia is a relatively small genus established by John Lindley in 1843 and named in honor of the Rev. John Clowes (1777–1846), a dedicated orchid grower in Manchester, UK, who was the first to flower the type species. Both the plants and flowers resemble *Catasetum*, but its blossoms are bisexual.

Production of Protocorm-like Bodies by Root Apices of *Clowesia warscewiczii*

Several *Clowesia* species were shuttled between that genus and *Catasetum*. One of these species, known at different times as *Catasetum warczewitzii* Lindl & Paxt. and *Catasetum scurra* Rchb. *f.* (Dunsterville and Garay, 1965), is now *Clowesia warscewiczii* (Lindl & Paxton) Dodson (Dunsterville and Garay, 1976). A procedure for PLB formation from root tips of this species was developed in Brazil (Kerbauy and Estelita, 1996).

Plant Material. Root apices, 4–6 mm long, were taken from asymbiotic seedlings growing on modified (Colli and Kerbauy, 1993) Vacin and Went medium (Vacin and Went, 1949).

Surface Sterilization. There is no need to surface-sterilize explants taken from asymbiotic seedlings in vitro. However, the explants should be washed with sterile distilled water to remove medium residues.

Culture Vessels. Erlenmeyer flasks, 125-ml capacity, were used in the original research. Other culture vessels are also suitable. They should contain medium equivalent to 20–30% of their capacity.

Culture Conditions. Cultures should be maintained at $25 \pm 1°C$. In the original research "the frequency of root tip conversion was substantially higher in the dark . . . than under illumination." However, "illumination seems to maintain more efficiently the functional and structural patterns of apical root meristem." Therefore (especially since plenty of root tips are usually available in seedling cultures) the cultures should be illuminated. In the original research the cultures were given 16-h photoperiods of 40 $\mu mol\ m^{-2}\ s^{-1}$ provided by fluorescent lights (the type is not given). Standard culture room illumination is also suitable.

The original paper (Kerbauy and Estelita, 1996) also states: "A similar inhibitory effect of light was also observed in protocorm-like bodies formation from excised root apexes of *Catasetum* (Colli & Kerbauy, 1993)."

TABLE CLOWESIA-1. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of root-tip explants from *Clowesia warscewiczii* seedlings (Kerbauy, 1996)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Polyol				
8	*myo*-inositol	100.0	No stock	No stock	Weigh
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar[e]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. This medium may be also suitable for the culture of protocorm-like bodies and plantlets.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve. Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 ml l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible.

[e]Add items 1–8 to 500–700 ml of distilled water (item 10), adjust pH to 5.8, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved, dispense the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949). It is not clear whether the addition of other nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary, those used as part of the Murashige–Skoog (MS) medium will probably be suitable.

Culture Media. A modification of the Vacin and Went medium (Vacin and Went, 1949) is used for the culture of root-tip explants (Table Clowesia-1). The original paper (Kerbauy and Estelita, 1996) does not recommend a medium or media for plantlet development from PLBs. A medium (see Table C-24) used to germinate seeds which produced *Cattleya* seedlings that were used as explant sources (Kerbauy, 1991) may prove to be suitable for this purpose.

Procedure. The root-tip explants should be placed in culture on the first medium (Table Clowesia-1) and allowed to develop PLBs. After approximately 25 days the PLBs produce bud primordia. At that point they should be moved to the second medium for plantlet production. When the plantlets are large enough they should be moved to pots.

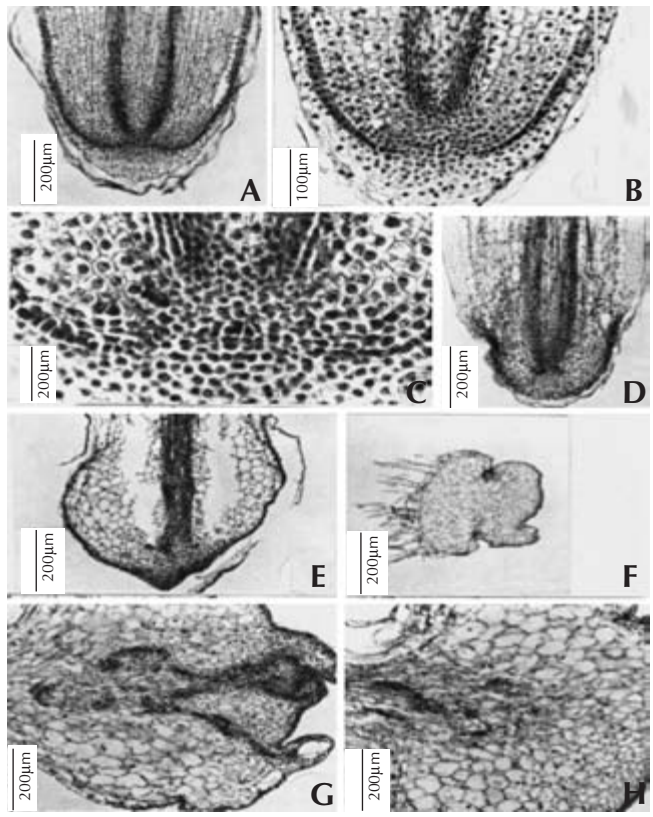

FIG. CLOWESIA-1. **Root tips in culture. A. Longitudinal section showing lysis of the root-cap layers. B. Cellular expansion. C. Cell division. D. Formation of a PLB primordium. E. Bud primordium on a PLB. F. Hairs at the base of a PLB. G. Procambial strands after 31 days in culture. H. Peripheral meristematic tissue in a PLB.**

Developmental Sequence. Starch grains and raphides cannot be seen and there is marked lysis in root cap cells after 6 days (Fig. Clowesia-1A). Cellular extensions (Figure Clowesia-1B) and cell divisions (Figure Clowesia-1C) become apparent in the apical meristem after 9 days. This leads to the production of PLB primordia (Fig. Clowesia-1D). The PLBs become larger than the original explants after 25 days and produce a bud primordium (Fig. Clowesia-1E). They also have rhizomes (Fig. Clowesia-1F). The buds become conspicuous in 31 days, have apical meristems, two to three leaf primordials, and tracheary elements which are connected to the vascular system of the roots (Fig. Clowesia-1G, H).

General Comments. This research provides interesting insights into the developmental anatomy of PLBs from root tips. The method can also be used for micropropagation, but its value is limited because the use of seedling root tips does not makes possible the multiplication of desirable clones. Additional research is needed to determine whether the method can be used to culture root tips taken from mature plants.

Cymbidium

Phalaenopsis was the first orchid genus to be propagated in vitro (Rotor, 1949). *Cymbidium* was the first to be propagated by shoot-tip ("meristem") culture (Morel, 1960, 1963, 1964*a*, 1964*b*, 1965*a*, 1965*b*, 1971*c*; Wimber, 1963) following the development of tissue-culture methods for excised meristems of other plants (Ball, 1964). Since *Cymbidium* is one of the more popular orchid genera in cultivation, a number of workers have developed tissue-culture procedures, and the subject has been discussed in many publications (Champagnat et al., 1966, 1968; Gripp, 1966; Sagawa et al., 1966; Vacherot, 1966; Wilfret, 1966, no date; Anonymous, 1967; Bertsch, 1967; Marston and Vouraurai, 1967; Borriss and Hiibel, 1968; Fréson and Vanseveren, 1968; Leffring, 1968; Penningsfeld and Fast, 1968; Ueda and Torikata, 1968, 1969*a*, 1969*b*, 1972; Alpi and Garibaldi, 1969; Bivins and Hackett, 1969; Vanseveren and Fréson, 1969; Matsui et al., 1970; Werkmeister, 1970*a*, 1970*b*, 1971; Rutkowski, 1971; Steward and Mapes, 1971; Thompson, 1971; Fonnesbech, 1972*a*, 1972*b*; Koch, 1973; Penningsfeld, 1973; Zákrejs, 1974, 1976; Dalla Rosa, 1975; Maróti, 1975; Tschauder, 1975; Pieper and Zimmer, 1976*a*; Khaw et al., 1978*a*, 1978*b*; Subasinghe, 1978; Sagawa and Kunisaki, 1982; and others). Details of several procedures and summaries of others will be presented here.

In Vitro Culture of *Cymbidium* Shoot Meristems

Work with potatoes, dahlias, carnations, and hyacinths led to the culture of *Cymbidium* shoot tips at the National Institute for Agronomic Research in Versailles, France, and the subsequent development of procedures for mass rapid clonal propagation (Morel, 1960, 1963, 1964*a*, 1964*b*, 1970, 1974; Champagnat et al., 1966; Morel and Champagnat, 1969).

Plant Material. Shoot tips from buds on pseudobulbs are used.

Surface Sterilization. To surface-sterilize buds, dip them for a few seconds in 75% ethyl alcohol (ethanol), place in saturated calcium hypochlorite for 20 min, and rinse with sterile distilled water. (The calcium hypochlorite solution should be freshly prepared with 10 g per 140 ml; stir, allow to stand, stir again, and let the precipitate settle before decanting and using.)

Culture Vessels. Use Khan test tubes or Erlenmeyer flasks.

Culture Conditions. The cultures are kept under 12-h photoperiods provided by Sylvania Gro Lux fluorescent tubes at 22°C.

Culture Media. Several modifications of the Knudson C medium can be used (Tables Cym-1 to Cym-3).

TABLE CYM-1. **Modified Knudson C medium (Knudson, 1946) for plantlet formation from *Cymbidium* shoot-tip meristems (Morel, 1965*a*, 1965*b*, 1970)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	Or weigh
2	Monopotassium phosphate, KH_2PO_4[c]	250	25 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	Or weigh
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.056	56 mg l^{-1}		
(b)	Molybdic acid, MoO_3	0.016	16 mg l^{-1}		
(c)	Cupric sulfate (anhydrous), $CuSO_4$	0.040	40 mg l^{-1}	1	One solution
(d)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.331	331 mg l^{-1}		
(e)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	7.5 g l^{-1}		
	Sugar				
7	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
8	Water, distilled[e]	To 1000 ml			
	Solidifier[e]				
9	Agar	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and nitrate may become contaminated with standing. Therefore, stock solutions should not be prepared. If made, they should be kept frozen between uses.

[c]A phosphate buffer that will keep the pH steady may be substituted here. Prepare buffer by mixing 975 ml 0.1-*M* KH_2PO_4 (monopotassium phosphate; 13.6 g l^{-1}) with 25 ml 0.1-*M* K_2HPO_4 (dipotassium phosphate; 17.4 g l^{-1}). Measure the pH to be certain it is correct (pH 5.1–5.4), and use 18 ml per liter of culture medium.

[d]Add all microelements to the same 1 l of distilled water, stir and/or heat until they are dissolved, and add 1 ml per liter of culture medium.

[e]Add items 1–6 to 800 ml distilled water (item 8) and dissolve. Adjust pH to 5.3, add sugar (item 7), and bring volume to 1000 ml with more distilled water. Add agar (item 9) while stirring to the gently boiling solution. When dissolved, distribute into culture vessels, and autoclave.

Procedure. Remove all adult leaves from the pseudobulbs. Cut down to half size other leaves around the growing buds. Then sterilize and dissect the buds under aseptic conditions. The exposed apex appears as a brilliant hemisphere, usually surrounded by one or two leaf primordia. Excise it by making four cuts at right angles and delimiting a small cube, which is placed on the culture medium.

Developmental Sequence. Within 2 months the explant develops into a PLB, 1–2 mm in size. This body is colorless at first but soon turns green and produces rhizoids and a leaf primordium. At this point it may be sectioned into quarters and subcultured. Within a month each section will produce a new PLB, which can be divided again.

General Comments. This process provides a means of propagation that can reach 4,000,000 plants per year from a single bud.

TABLE CYM-2. **Modified Knudson C medium (Knudson, 1946) for plantlet production from *Cymbidium* shoot-tip meristems (Morel, 1965*a*, 1965*b*, 1970)**[a]

	Solidifier[e]				
11	Agar	17.5 g	No stock	No stock	Weigh

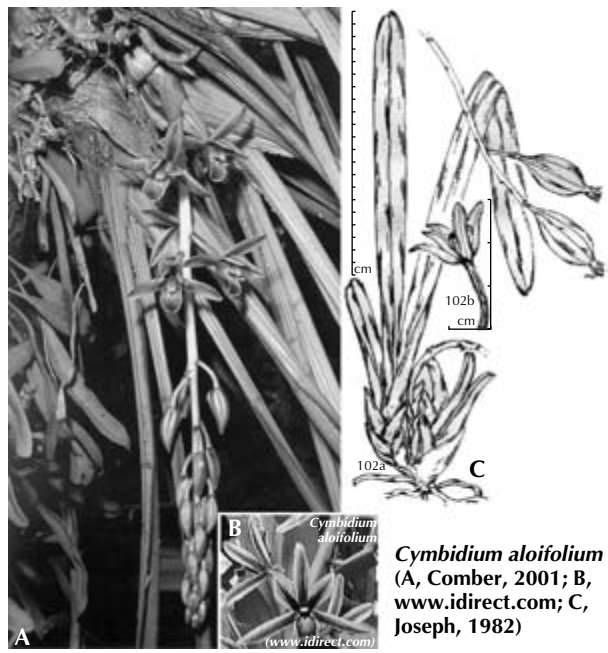
[a]Only the inorganic salts are listed (Morel, 1965*a*, 1965*b*, 1970; also see Morel, 1974).

[b]Amounts are given in mg unless indicated otherwise.

[c]Either use 1 g ammonium sulfate and omit the ammonium nitrate, or use 0.5 g of each.

[d]Solutions containing ammonium and/or nitrate may become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[e]Add items 1–8 to 700 ml distilled water (item 10) and dissolve. Adjust pH to 5.2–5.5, add sugar (item 9) and dissolve, and bring volume to 1000 ml with more distilled water. Distribute into culture vessels and autoclave. For solid culture medium, add agar (item 11) slowly while stirring to the gently boiling solution. When fully dissolved, dispense into culture vessels and autoclave.



Cymbidium aloifolium **(A, Comber, 2001; B, www.idirect.com; C, Joseph, 1982)**

TABLE CYM-3. **Modified Knudson C medium (Knudson, 1946) for the differentiation of plantlets from leaf-tip callus (Arditti et al., 1971, 1972, Ball et al., 1971; Churchill et al., 1971*a*, 1971*b*, 1971*c*, 1972*b*, 1973) which is suitable for *Cymbidium* shoot-tip explants**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	Or weigh
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
3	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	Or weigh
4	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$[c]	25	2.5 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4[d]	250	25 g l^{-1}	10	
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.056	56 mg l^{-1}	1	One solution
(b)	Molybdic acid, MoO_3	0.016	16 mg l^{-1}		
(c)	Cupric sulfate, $CuSO_4$	0.040	40 mg l^{-1}		
(d)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.331	331 mg l^{-1}		
	Sugar				
7	Sucrose	20 g	No stock	No stock	Weigh
	Organic additive[f]				
8	Banana, ripe	150 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[f]	To 1000 ml			
	Solidifier[f]				
10	Agar	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate tend to become contaminated on standing. Therefore it is better to weigh items 1 and 3 each time. If prepared, keep frozen between uses.

[c]This solution tends to form a rust-colored precipitate on standing. Therefore shake before using.

[d]A phosphate buffer that will keep the pH steady may be substituted here. Prepare buffer by mixing 975 ml 0.1-*M* KH_2PO_4 (monopotassium phosphate; 13.6 g l^{-1}) with 25 ml 0.1-*M* K_2HPO_4 (dipotassium phosphate; 17.4 g l^{-1}). Measure pH to be certain it is correct (pH 5.1–5.4), and use 18 ml per liter of culture medium.

[e]Add all microelements to the same 1 l of distilled water, stir and/or heat until dissolved, and add 1 ml per liter of culture medium.

[f]Add items 1–8 to 700 ml distilled water (item 9), homogenize until banana (item 8) is completely broken down (about 2–3 min), adjust pH to 5.3, and bring volume to 1000 ml with more distilled water. To dissolve agar (item 10), add it slowly while stirring to gently boiling solution. When dissolved, distribute into culture vessels and autoclave.

Clonal Multiplication of *Cymbidium* through in Vitro Culture of Shoot Tips

Morel's *Cymbidium* shoot-tip culture method (Morel, 1960) may have been the first to be published, but it was relatively slow, and details were lacking in the early papers. A faster method employing a liquid medium and described in more detail from the outset was developed in the United States as a result of work at the Dos Pueblos Orchid Co. (Santa Barbara, CA), the Biology Department, Brookhaven National Laboratory (Upton, NY), and the Biology Department, University of Oregon (Wimber, 1963, 1965).

Plant Material. Shoots approximately 3 cm long are used.

Surface Sterilization. Use a 2% (w/v) solution of calcium hypochlorite, which must be freshly prepared.

TABLE CYM-4. **Culture medium for *Cymbidium* shoot tips (Wimber, 1963)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	Or weigh
2	Monocalcium phosphate, dibasic $CaHPO_4$[c]	200	20.0 g l^{-1}	10	Or weigh
3	Monopotassium phosphate, KH_2PO_4	250	25.0 g l^{-1}	10	
4	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50.0 g l^{-1}	10	Or weigh
5	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25.0 g l^{-1}	10	
6	**Iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Complex additive				
7	Tryptone	2 g	No stock	No stock	Weigh
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated with standing. Therefore it is preferable to weigh the salts every time. If prepared, keep frozen between uses.

[c]If some of the compound fails to dissolve, shake stock solution well before dispensing to insure an even suspension; better yet, weigh out each time.

[d]The original solution uses ferric tartrate, $Fe_2(C_4H_4O_6)_3$; chelated iron is preferable.

[e]Mix items 1–7 with 700 ml distilled water (item 9), adjust pH to 5.2–5.5, add sugar (item 8), and bring volume to 1000 ml with more distilled water (item 9). Distribute into culture vessels, and autoclave.

Culture Vessels. Use 125-ml Erlenmeyer flasks containing 25 ml medium.

Culture Conditions. Constant light of 100 ft-c or less (the light source is not listed, but Sylvania Gro Lux tubes would prove satisfactory) at 22°C on a rotary shaker.

Culture Medium. A modified Tsuchiya medium is used (Table Cym-4).

Procedure. Remove the outermost leaves and sterilize for 10 min in calcium hypochlorite. Under sterile conditions using sterilized tools, remove the rest of the leaves, exposing the apical meristem, which should be "immediately cut off" and placed into culture.

Developmental Sequence. The explants turn green and show noticeable growth within 1 week. In 1 month PLBs form. Shoots appear and differentiation follows when the PLBs reach approximately 4 mm. If the flasks are agitated, proliferation occurs instead of shoot formation. Masses of tissue are formed and can be subcultured after 2 months. On a rotary shaker the subdivisions reach a diameter of 1 cm within 30 days. When tissue fragments are placed on a solid medium, they form plantlets within 2.5 months.

General Comments. This is a simple, fast technique requiring inexpensive tools, a shaker, and skills that can be acquired easily.

Seed and Tissue Culture of *Cymbidium iridioides* × *Cymbidium longifolium*

Modified Knudson C medium with 100 mg l^{-1} banana enhanced proliferation of PLBs. Rapid differentiation is obtained on a medium containing 6% ripe banana. PLBs can be subcultured on Knudson C medium containing 100 ml pineapple juice l^{-1} (Hedge et al., no date).

Carbohydrate Metabolism during Protocorm Differentiation in a *Cymbidium* Hybrid

PLBs were produced from leaf bases of *Cymbidium* Burgundian Chateau. Accumulation of endogenous free sugar reached peaks after 3–5 and 25 days in culture. Starch synthesis reached a maximum 20 days after the start of culture (Gopalan et al., 1988).

Clonal Propagation of *Cymbidium* through Shoot-tip Meristem Culture

One of the early methods for the culture of *Cymbidium* shoot-tip explants was developed in the laboratory of Yoneo Sagawa (Sagawa et al., 1966).

Plant Material. Explants are obtained from shoots 5–7.5 cm long growing on pseudobulbs.

Surface Sterilization. Sterilization is with 1, 5, and 10% (v/v) Clorox (see Procedure below).

Culture Vessels. Use 50-ml Erlenmeyer flasks containing 15 ml medium.

Culture Conditions. Explants are maintained under 120 ft-c of continuous illumination (General Electric Power Groove White) at 22–25°C on a shaker for 4 weeks, after which they are kept under the same conditions on solid medium.

Culture Media. Modified Knudson C (Tables Cym-1 to Cym-3) and Vacin and Went (Table Cym-5) media can be used.

Procedure. Remove new growths or leads 5–7.5 cm long from a pseudobulb, and cut away three to four leaves until an axillary bud is exposed. Sterilize in 5% (v/v) Clorox for 5–8 min. Now remove the remaining leaves (except perhaps one leaf). If axillary buds are used, remove a 2–3-mm cube, and sterilize in 1% (v/v) Clorox for 3 min. Place this cube in liquid culture. Tools should be dipped in 10% (v/v) Clorox often and washed in sterile distilled water to insure sterility.

TABLE CYM-5. **Modified Vacin and Went medium for the culture of *Cymbidium* shoot-tip explants (Sagawa et al., 1966)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Tricalcium phosphate, $Ca_3(PO_4)_2$[b]	200.0	20.0 g l^{-1}	10	Or weigh
2	Potassium nitrate, KNO_3[c]	525.0	52.5 g l^{-1}	10	Or weigh
3	Monopotassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
5	Ammonium sulfate, $(NH_4)_2SO_4$[c]	500.0	50.0 g l^{-1}	10	Or weigh
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3$[d]	28.0	2.8 g l^{-1}	10	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier[e]				
10	Agar	16.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]If the material does not completely dissolve, shake stock solution well before dispensing to insure an even suspension; better yet, weigh out each time.

[c]Solutions containing nitrate and/or ammonium may become contaminated with standing. Therefore it is preferable not to make stock solutions. If prepared, keep frozen between uses.

[d]Add dilute KOH (ca. 0.1 *M*) dropwise until the solution clears. Shake well before dispensing.

[e]Mix items 1–7 with 800 ml distilled water (item 9), adjust pH to 5.2–5.5, add sugar (item 8), and adjust volume to 1000 ml with more distilled water. To add agar (item 10), bring solution to a slow boil and add slowly while stirring. When fully dissolved, dispense into culture vessels and autoclave. For liquid medium, omit agar (item 10).

Developmental Sequence. PLBs form after 6 weeks (4 weeks on liquid medium and 2 weeks on solid medium) of culture. These bodies, measuring 2–3 mm in diameter, are quartered and subcultured. The process can be repeated every 10 days. If left undisturbed, the PLBs grow into plantlets.

General Comments. This is a well-conceived procedure that can produce many plantlets quickly.

Transformation of Isoprenoids by Orchids in Tissue Culture

Tissue cultures of *Cymbidium* Saint Pierre maintained in vitro on media used for other orchids (Kukułczanka, 1985) transformed some isoprenoids (Mironowicz et al., 1987).

Rhizome Formation from Shoot Tips of *Cymbidium goeringii* and *Cymbidium kanran* in Vitro

Rhizome formation from shoot tips of *Cymbidium goeringii* can occur throughout the year. However, maximal formation occurs in April on MS and Linsmaier–

Skoog media containing 1 ppm NAA and 0.1 ppm kinetin, in the dark. The Linsmaier–Skoog medium containing one-fifth or one-tenth the usual level of inorganics and 10% coconut water is most suitable for the culture of *C. kanran* shoot tips. Rhizome length was reduced with increased dilution, suggesting that, unless the explants are transferred following rhizome formation, one-fifth dilution may be a more suitable medium. Plant-growth regulators had no effect on shoot-tip cultures of the two species (Hasegawa and Goi, 1987).

Propagation of *Cymbidium* in Vitro

To determine the precise tissue culture requirements of a species, it is necessary to perform careful comparative experiments in which one factor at a time is added, removed, or varied in concentration. The volumes of data that accumulate from these experiments must be analyzed statistically before their full meaning can be appreciated. Such experiments are tedious, often complicated, and always time-consuming. As a result investigators tend to shy away from them, which is a pity. Occasionally, however, researchers carry out experiments of this type and use them as a basis for articles that are full of information and a pleasure to read (Fonnesbech, 1972*a*, 1972*b*). Propagation methods based on such experiments tend to produce a higher degree of success and better plants.

Plant Material. The explants are similar to those used in the previous procedure (Sagawa et al., 1966).

Surface Sterilization. The procedure is the same as that used in the previous section on in vitro shoot-tip culture (Sagawa et al., 1966).

Culture Vessels. Use 150-ml Erlenmeyer flasks containing 30 ml liquid medium, or 25×100 mm test tubes with 10 ml medium. For solid cultures, use 100-ml flasks containing 40 ml medium.

Culture Conditions. Tissues are maintained 90 cm under a light source consisting of three 40-W Atlas Super-Gro and three Osram L-Fluor 77 fluorescent tubes producing radiation of 3.3 W m^{-2}. Illumination may be continuous (Sagawa et al., 1966). When liquid medium in 150-ml flasks is used, the tissues are placed on a reciprocal shaker at 80 rpm. Test tubes are rotated on a vertical wheel at 0.66 rpm. The temperature should be 22–25°C.

Culture Media. Explants can be first cultured in the media used in the previous procedure (Tables Cym-1 to Cym-3, and Cym-5). Proliferation is induced in a different formulation (Table Cym-6) that can also be used as a starting medium. Plantlets are formed on a solid version of the latter (Table Cym-6).

Procedure. The procedure is the same as that in the previous section (Sagawa et al., 1966) using the new medium (Table Cym-6).

TABLE CYM-6. **Medium for the in vitro propagation of *Cymbidium* (Fonnesbech, 1972*a*, 1972*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	400	40 g l^{-1}	10	Or weigh
2	Ammonium sulfate, $(NH_4)_2SO_4$[b]	300	30 g l^{-1}	10	Or weigh
3	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
4	Dipotassium phosphate, K_2HPO_4	212	21.2 g l^{-1}	10	
5	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
6	**Chelated iron**				
(a)	Na_2EDTA	37.8	7.5 g l^{-1}	5	One solution
(b)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.9	5.57 g l^{-1}		
7	**Microelements**[c]				
(a)	Manganous sulfate, $MnSO_4 \cdot 4H_2O$	25	25 g l^{-1}		
(b)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	10	10 g l^{-1}		
(c)	Boric acid, H_3BO_3	10	10 g l^{-1}	1	One solution
(d)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	250 mg l^{-1}		
(e)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	25 mg l^{-1}		
	Amino acid[d]				
8	Glycine	2	2 g l^{-1} 95% ethanol	1	
	Vitamins[e]				
9	Niacin (nicotinic acid)	1	100 mg 100 ml^{-1} 95% ethanol	1	
10	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol	1	
11	Thiamine (vitamin B_1)	0.5	50 mg 100 ml^{-1} 95% ethanol	1	
	Auxin				
12	Naphthaleneacetic acid (NAA)	1.86	186 mg 100 ml^{-1} 95% ethanol[f]	1	
	Polyol				
13	*myo*-inositol	100	No stock	No stock	Weigh
	Cytokinin				
14	Kinetin	0.215	21.5 mg 100 ml^{-1} 95% ethanol[f]	1	
15	**Complex additives**				
(a)	Casamino acids[g]	2–3 g	No stock	No stock	Weigh
(b)	Tryptone[g]	3–4 g	No stock	No stock	Weigh
16	Coconut water[h]	100–150 ml	No stock	No stock	
	Sugar				
17	Sucrose	30–40 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[i]	To 1000 ml			
	Solidifier[j]				
19	Agar	8 g			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate may become contaminated. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add all microelements to the same 1 l, and stir and/or heat until dissolved. Add 1 ml to culture medium.

[d]By using 95% ethanol, the stock solution is made sterile. Add 1 ml stock solution to the autoclaved medium before it has solidified. Keep stock solution refrigerated.

[e]The vitamins may be combined into one stock solution. Add 100 mg niacin and 50 mg each of pyridoxine and thiamine to the same 100 ml of 95% ethanol, and use 1 ml of this per liter of medium. Refrigerate between uses.

[f]If the auxin or cytokinin fails to dissolve, add a few drops of dilute KOH or HCl, respectively, until the solution clears.

[g]Add either casamino acid or tryptone; not both.

[h]Coconut water increases growth 10–15%, but its addition is not essential.

[i]Add items 1–7, 13, 15, and 16 to 750 ml distilled water (item 18), adjust pH to 5.5–5.8, add sucrose (item 17), and bring volume to 1000 ml with more distilled water (item 18). Bring solution to a gentle boil, and add agar (item 19) slowly with stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour medium into a 2-l flask and autoclave. Add items 8–12 and 14 to the warm, still liquid medium, swirl to mix well, and distribute into preautoclaved vessels. For liquid media omit agar.

Developmental Sequence. Tissues and plantlets develop like those in the previous procedure (Sagawa et al., 1966), but there are a few minor differences.

General Comments. The medium formulated for this procedure (Table Cym-6) is based on comparisons between several media.

Heterogeneity of Acid Phosphatase and Ribonuclease in PLBs of *Cymbidium*

Streptomycin affected the enzyme activity and electrophoretic patterns of acid phosphatase and ribonuclease from PLBs of *Cymbidium* (Morawiecka et al., 1973).

Effects of Biostimin on the Growth of Meristematic Tissue and the Formation of PLBs by *Cymbidium* in Vitro

The addition of Biostimin FB, a medicinal preparation from the tissue of an *Aloe* species from the former Soviet Union, improved the growth, color, fresh weight, and dry weight of *Cymbidium* in vitro and increased the number of PLBs (Kukułczanka, 1985).

Tissue Culture and Flowering in Vitro of *Cymbidium ensifolium*

Orchids in general and *Cymbidium* in particular have been cultivated in China for a much longer time period than in the West. Some species are regarded as "king of the fragrant flowers." In recent years a number of Chinese investigators have initiated tissue culture research with *Cymbidium dayanum*, *Cymbidium ensifolium*, *Cymbidium faberi*, *Cymbidium goeringii*, and *Cymbidium tracyanum* (Wang et al., 1981; Wang, 1984, 1988*a*, 1988*b*, no date *a*, no date *b*).

Plant Material. Shoot meristem and axillary buds of *C. ensifolium* and *C. goeringii* Qiulan are used.

Surface Sterilization. Shoots, 5–6 cm long, from mature plants must be scrubbed with a very soft toothbrush under running water before the roots and outer leaves are stripped and the remaining tissues are sprayed with 70% ethanol. The axillary buds and shoot tips should be excised after that and (1) dipped in 70% ethanol for 30 s, (2) immersed in 5% sodium hypochlorite for 30 min, and (3) rinsed six times with sterile distilled water.

Culture Vessels. T-shaped tubes were used for liquid cultures in the original research, but other containers are also suitable. Bottles, test tubes, and Erlenmeyer flasks can be used to culture plantlets.

Culture Conditions. In the original research some explants of *C. goeringii* were cultured initially in the dark at 25°C for 3 months. (PLBs did not form under these conditions.) After that they were moved for 3 months to 12-h photoperiods (provided by fluorescent lights) at the same temperature (with the result that explants turned green). Explants of *C. ensifolium* (Wang, 1988*b*) were placed on agar and cultured under 9-h photoperiods of 2000–4000 lx (fluorescent lights) at 25°C. PLBs proliferate in a liquid medium on a shaker at 1 rpm.

Culture Media. Modified and basic White's medium (Tables Cym-7 to Cym-10) and MS (Tables Cym-11, Cym-12) are used for initial culture, protocorm formation and proliferation, plantlet development, and flower induction. Liquid unmodified MS medium (Table Cym-11) or solid modified Vacin and Went medium (Table Cym-5) can also be used.

Procedure. Place the explants on modified solid White's medium containing 5 mg l^{-1} NAA and 10% coconut water (Table Cym-7). Transfer PLBs or green explants that form after approximately 2 months to another solid or liquid modification of White's medium (Table Cym-8). If placed on solid medium (Table Cym-8), move the PLBs later to liquid medium (Table Cym-8) for further growth. After about a month transfer the PLBs to yet another modification of White's medium (Table Cym-9) for proliferation. Rosettes of bright green PLBs form in this medium. Liquid and similarly modified MS (Table Cym-11) or Vacin and Went (Table Cym-5) media can also be used for this step. Then transfer the PLBs to unmodified White's medium (Table Cym-10), where they form plantlets. Leaves are formed on solid MS medium (Table Cym-11). The plantlets flower when moved to another modified MS medium (Table Cym-12).

Developmental Sequence. Explants turn green and/or form PLBs 2–3 months after being placed in culture. Sections of these form new PLBs, which can be divided again. Rosettes of PLBs form in a medium that does not contain NAA. When moved to liquid medium these rosette PLBs develop plantlets. Complete plantlets with three to four leaves form following the final transfer onto an unmodified medium. The plantlets flower in vitro on an appropriate medium.

General Comments. Some Chinese *Cymbidium* plants are very desirable for their beautiful leaves, fragrant blossoms, flower shape, and other characteristics. Until now the only means of clonally propagating these plants was to divide them. This is a slow, inefficient method. The tissue culture method described here is much faster and may be suitable for other species and hybrids of *Cymbidium*.

Flower production in vitro from young seedlings of several orchid species and hybrids has been reported a number of times in the literature. There is also a report of "rarely but repeatedly observed . . . well structured inflorescence of *Cymbidium* [and] flowers produced *in vitro* . . ." (Tran Thanh Van, 1974). The report leaves open the question of whether these inflorescences were induced in vitro or before the buds were placed in culture. Consequently the flowering of *C. ensifolium* "mericlones" at the Shanghai Institute of Plant Physiology is the first instance of reproducible flower induction in orchids in vitro (Fig. Cym-1). Plants could flower in vitro for several months (Wang, 1988*a*).

TABLE CYM-7. **White's medium (Singh and Krikorian, 1981)[a] modified for the culture of *Cymbidium ensifolium* shoot tips (Wang et al., 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[c]	288	28.8 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	737	73.7 g l^{-1}	10	
3	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	19	1.9 g l^{-1}	10	
4	Potassium chloride, KCl	65	6.5 g l^{-1}	10	
5	Potassium nitrate, KNO_3[c]	80	8 g l^{-1}	10

	Amino acid				
9	Glycine	3	300 mg 100 ml^{-1} 95% ethanol[g]	1	
	Auxin				
10	Naphthaleneacetic acid (NAA)	5	500 mg 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
14	Coconut water	100 ml	No stock	No stock	Measure
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation, and modernization of the medium (Singh and Krikorian, 1981).

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to use.

[g]Keep refrigerated or frozen between uses.

[h]Add items 1–8 and 14 to 850 ml distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add items 9–13 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. For liquid medium omit the agar.

TABLE CYM-8. **White's medium (Singh and Krikorian, 1981)[a] modified for the culture of *Cymbidium ensifolium* shoot tips (Wang et al., 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[c]	288	28.8 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	737	73.7 g l^{-1}	10	
3	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	19	1.9 g l^{-1}	10	
4	Potassium chloride, KCl	65	6.5 g l^{-1}	10	
5	Potassium nitrate, KNO_3[c]	80	8 g l^{-1}	10	
6	Sodium sulfate, Na_2SO_4	200	20 g l^{-1}	10	
7	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	3.4	344 mg l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	4.66	466 mg l^{-1}		
8	**Microelements**[e]				
(a)	Boric acid, H_3BO_3[f]	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$[f]	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$[f]	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	6.65	665 mg l^{-1}		
(e)	Potassium iodide, KI	0.75	75 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$[f]	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	2.67	267 g l^{-1}		
	Amino acid				
9	Glycine	3	300 mg 100 ml^{-1} 95% ethanol[g]	1	
	Auxin				
10	Naphthaleneacetic acid (NAA)	2.5	250 mg 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
14	Coconut water	100 ml	No stock	No stock	Measure
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation and modernization of the medium (Singh and Krikorian, 1981).

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. Use of chelated iron is a modern modification.

[e]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to include.

[g]Keep refrigerated or frozen between uses.

[h]Add items 1–8 to 900 ml distilled water (item 14), adjust pH to 5.5, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Bring solution to a gentle boil, and add agar (item 15) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add items 9–12 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE CYM-11. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the culture of protocorm-like bodies derived from *Cymbidium ensifolium***

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol[f]	100	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive[h]				
13	Coconut water	100 ml	No stock	No stock	Measure
	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[i]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Also known as *meso*- or *i*-inositol.

[g]Keep refrigerated between uses.

[h]To prepare unmodified medium, omit coconut water. Unmodified Murashige–Skoog medium may contain auxin(s) and/or cytokinin(s). The original paper does not mention these hormones, so it is therefore reasonable to assume they are not added.

[i]Add items 1–7, 9, and 13 to 850 ml distilled water (item 15). Adjust pH to 5.2–5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid and vitamins (items 8 and 10–12) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE CYM-12. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for flower induction in *Cymbidium ensifolium* in vitro (Wang, no date *a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
11	Benzyladenine (BA)	10	100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin does not dissolve, use a few drops of KOH or HCl, respectively, to solubilize them.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 16), adjust pH to 5.2–5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 8 and 10–14) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

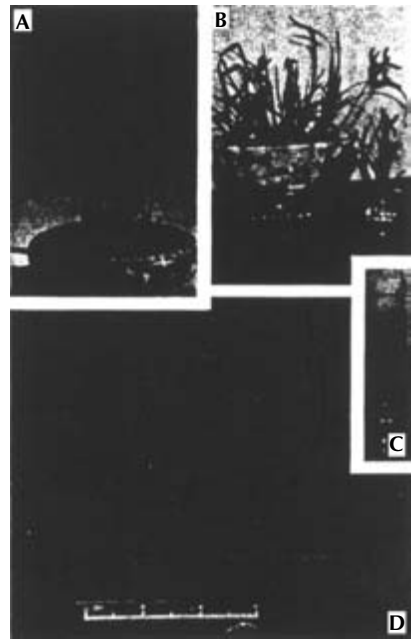

FIG. CYM-1 ***Cymbidium ensifolum*. A, B, D. Tissue culture derived from plants in flower following transfer to horticultural containers. C. Plant flowering in test tube. (Courtesy Dr. X. Wang, Shanhai Institute of Plant Physiology, Shanghai, People's Republic of China.)**

Tissue Culture Propagation of *Cymbidium goeringii*

Another beautiful Chinese orchid, *Cymbidium goeringii* (*Cymbidium virescens*), was also cultured at the Shanghai Institute of Plant Physiology (Wang et al., 1981; Wang, 1984, no date *a*, no date *b*).

Plant Material. Shoot meristems and axillary buds of *C. goeringii* are used.

Surface Sterilization. Shoots, 5–6 cm long, from mature plants must be scrubbed with a very soft toothbrush under running water before the roots and outer leaves are stripped and the remaining tissues are sprayed with 70% ethanol. The axillary buds and shoot tips should be excised after that and (1) dipped in 70% ethanol for 30 s, (2) immersed in 5% sodium hydrochlorite for 30 min, and (3) rinsed six times with sterile distilled water.

Culture Vessels. T-shaped tubes were used for liquid cultures in the original research, but other containers are also suitable. Bottles, test tubes, and Erlenmeyer flasks can be used to culture plantlets.

Culture Conditions. Explants are cultured initially for 3 months in the dark at 25°C. After that they are moved to 12-h photoperiods provided by fluorescent tubes.

Culture Media. Modified and unmodified MS medium (Tables Cym-11, Cym-13 to Cym-15) are used. A cytokinin-containing medium (Table Cym-16) is used to induce buds. Root formation occurs in a medium that contains only NAA (Table Cym-17).

Procedure. Initially culture the explants on modified MS medium with 10% coconut water and 5 mg l^{-1} NAA (Table Cym-13) in the dark at 25°C. After 3 months move the cultures to 12-h photoperiods at the same temperature. After the explants turn green (under these conditions for 3 months), transfer them to a solid medium with less NAA (Table Cym-14). Section a green PLB that forms on this medium within 1–2 months, and culture the pieces in the same medium (Table Cym-14) in liquid form. The sections form new protocorms within a month, and these too can be divided and subcultured. Rosettes of PLBs formed in this solution are cultured on a liquid medium without NAA (Table Cym-15) and rotated at 1 rpm. Plantlets form from the PLBs when the latter are moved to unmodified White's medium (Table Cym-10).

An alternate procedure is to culture the PLBs on a medium that contains BA and auxin (Table Cym-16). Culture the shoots formed on this medium on a modification of MS medium that contains only NAA (Table Cym-17) to induce roots. Culture plantlets produced by this procedure on unmodified MS medium (Table Cym-11) for further growth.

Developmental Sequence. Development is similar to that of *C. ensifolium* except that there are no reports of flowering in vitro.

General Comments. This is an effective procedure for the clonal propagation of yet another Chinese *Cymbidium* species.

TABLE CYM-13. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the culture of *Cymbidium goeringii* in vitro (Wang, no date *a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	5.0	500 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Complex additive				
15	Coconut water	100 ml	No stock	No stock	Measure
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h,i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin does not dissolve, use a few drops of KOH to solubilize it.

[g]Keep refrigerated between uses.

[h]Add items 1–7, 9, and 13 to 850 ml distilled water (item 16). Adjust pH to 5.2–5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. The agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormone, and vitamins (items 8, 10–13) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

[i]Agar is not added to liquid media.

TABLE CYM-14. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the culture of *Cymbidium goeringii* in vitro (Wang, no date *a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If auxin does not dissolve, add a few drops of KOH to solubilize it.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 850 ml distilled water (item 15), adjust pH to 5.2–5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormone, and vitamins (items 8 and 10–13) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

Effects of Morphactin on the Initiation and Development of PLBs of *Cymbidium*

When applied in the range of 0.01 to 10 ppm, morphactin may increase the number of PLBs that form from excised meristematic tissues in vitro. Morphactin may also affect the shape and proliferation of the PLBs. Depending on the dose, morphactin can retard or inhibit the development of rhizoids, shoots, and roots and can also cause deformities (Kukułczanka and Twarda-Predota, 1973). This suggests that morphactin should not be used or that it must be employed very cautiously in attempts to increase proliferation.

Root Induction in Aseptically Produced Shoots of *Cymbidium goeringii*

Shoot tips of terrestrial *Cymbidium* species [*Cymbidium ensifolium, Cymbidium goeringii* (*Cymbidium virescens*), and *Cymbidium kanran* among others] form PLBs in vitro. These PLBs develop into a rhizome, but root and shoot formation occur with difficulty. A method that overcomes these difficulties was developed at the University of Nagoya (Ueda and Toikata, 1972).

Plant Material. Shoots formed on PLBs or rhizome tips of plants produced in vitro are excised.

Surface Sterilization. Shoots taken from aseptic cultures need not be sterilized.

Culture Vessels. Erlenmeyer flasks, of 100-ml capacity and containing 20 ml solid medium, were used in the original research, but other containers are also suitable.

Culture Conditions. Cultures should be maintained under fluorescent tubes, either white (Toshiba, FL20 SW was used in the original research, but other tubes can also be used) or Vitalux (NEC, FL 20 BR in the original research, but Sylvania Gro Lux are also appropriate) at an intensity of 8200 and 7300 erg cm^{-1} s^{-1} respectively. Roots may not be produced under lower intensities. The original paper (Ueda and Torikata, 1972) does not mention photoperiod length, but it is likely that 12- or 24-h illumination will be satisfactory. Temperature should be 22°C.

Culture Medium. Knudson C medium containing kinetin, arginine, and the microelements of Nitsch (Table Cym-18) is used.

Procedure. The shoots are taken from existing cultures and placed on the medium surface.

Developmental Sequence. The shoots form roots.

General Comments. This procedure is designed to induce root formation and development on shoots produced from PLBs in vitro. Its purpose is not to initiate

TABLE CYM-18. **Knudson C medium (Knudson, 1946) modified for root induction in *Cymbidium goeringii***

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.5	500 mg l^{-1}	1	One solution
(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	25 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	3.0	3 g l^{-1}		
(d)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.025	25 mg l^{-1}		
(e)	Sulfuric acid (concentrated), H_2SO_4	0.5	No stock		Measure carefully
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.5	500 mg l^{-1}		One solution
	Amino acid				
7	Arginine·HCl	211	No stock	No stock	Weigh
	Cytokinin				
8	Kinetin	10	1000 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[d]Add all microelements to the same 1000 ml distilled water, stir and/or heat to dissolve, and add 1 ml per liter of medium.

[e]Keep refrigerated or frozen between uses. If the kinetin fails to dissolve, add a few drops of dilute HCL.

[f]Add items 1–6 to 900 ml distilled water (item 10), adjust pH to 5.0, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Weigh the arginine (item 7), add it to the kinetin (item 8), mix well, and pour the mixture into the warm and still liquid medium. Mix well, and distribute the solution into preautoclaved culture vessels. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower pH if necessary.

the formation of PLBs, shoots, or plantlets from explants. Although formulated for *C. goeringii*, this method may prove suitable for additional *Cymbidium* species and other orchid shoots that are difficult to root in vitro.

Rooting of *Cymbidium insigne* Shoots in Vitro

This method is the same as the one used for *Cymbidium goeringii* (Ueda and Torikata, 1972).

Growth of *Cymbidium* in Vitro

The bleeding sap of birch trees seems to enhance growth of *Brassia*, *Cattleya*, and *Cymbidium* explants (Zimmer and Pieper, 1976, 1977).

Effects of Substrate on Cymbidium Cultures

The development of *Cymbidium* shoots and roots was better on a medium of pearl barley than on one solidified with agar (Kukułczanka and Paluch, 1971; Kukułczanka, 1976; Kukułczanka et al., 1987).

Effects of Microelements and Magnesium on *Cymbidium* Development in Vitro

The addition of microelements and magnesium enhanced the growth of PLBs of *Cymbidium* (Kukułczanka and Jastrzebska-Kolodynska, 1976/77).

Clonal Propagation of *Cymbidium* through the Culture of Dormant Buds taken from Pseudobulbs

Clonal propagation of *Cymbidium* through the culture of shoot tips (erroneously called meristems) requires the excision under sterile conditions of a small explant. In some instances removal of the explant may jeopardize the existence of the donor plant. On the other hand, dormant buds on a pseudobulb seem to serve no horticulturally useful purpose, they are easy to remove, and their excision does not endanger the plant (Tran Thanh Van, 1974).

Plant Material. Buds are excised from the upper two-thirds ("aerial") portion of backbulbs (pseudobulbs). The buds are removed following surface sterilization under aseptic conditions by using a sterile scalpel to make an incision 1–2 mm long 1–2 mm wide, and 5–7 mm deep (Fig. Cym-2). This explant (approximately 12.4 mm^3) is placed in culture.

Surface Sterilization. The upper two-thirds ("aerial") portion is removed, and the top parts of the leaves are cut away before washing with water and a mild detergent (Teepol, a liquid dishwashing formulation, was used in the original research). After the wash the pseudobulbs are dipped in 70–80% ethanol. The leaf bases are removed after that, and the pseudobulb is washed a second time with water and detergent. This is followed by a second dip for a few seconds in 70–80% ethanol. The final surface sterilization step consists of: (1) soaking the pseudobulb for 15 min in a 5 or 7% solution of calcium hypochlorite (5–7 g calcium hypochlorite in 100 ml distilled water stirred several times at 5-min intervals and decanted or filtered), and (2) washing it several times with sterile distilled water. The buds are excised after the final wash.

FIG. CYM-2. ***Cymbidium*** **bud explant at the start of culture (Tran Thanh Van, 1974).**

Culture Vessels. Small glass or plastic Petri dishes or plastic bags containing medium were used in the original research. The plastic bags (which must be sterile before introduction of the medium) can simply be hung on a wall or laid on top of each other. Other containers can also be used.

Culture Conditions. The cultures should be maintained under 12-h photoperiods of 3300 lx and a temperature of 22–24°C.

Culture Media. The explants should be placed initially on a modified MS medium (Table Cym-19). Plantlet production occurs on a different modification of this medium (Table Cym-20).

Procedure. Place the explants on the first medium (Table Cym-19), and culture until PLBs form. These can be cut and subcultured on the same medium to bring about further proliferation. To produce plantlets, place the PLBs on the second medium (Table Cym-20).

Developmental Sequence. Buds from near the base of a pseudobulb that are more developed may form a single plant when cultured on Knudson C medium (see Tables Aranda-7, Aranda-8, Cym-2, and Cym-3). On the first medium (Table Cym-19) the buds may form one or more PLBs. In some cases meristems situated at the axils of floral initials may fasciate and thus can result in the formation of multiple plantlets. Floral shoots and flowers may develop from buds excised from the upper portions of pseudobulbs.

General Comments. This procedure is relatively simple and makes good use of buds that normally remain dormant for the life of a pseudobulb. A possible improvement would be a method that could allow excision of the buds without having to cut away part of the pseudobulb.

TABLE CYM-19. **Murashige-Skoog medium (Murashige and Skoog, 1962) for the culture of dormant buds of *Cymbidium* (Tran Thanh Van, 1974)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Polyol				
8	*myo*-inositol[e]	100	No stock	No stock	Weigh
	Auxin				
9	Indoleacetic acid (IAA)	1.9	190 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
10	Kinetin	2.2	220 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamin				
11	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
12	Glucose	30 g	No stock	No stock	Weigh
	Solvent				
13	Water, distilled[h]	To 1000 ml			
	Solidifier				
14	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Sometimes listed as *meso*-inositol.

[f]If auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively, to solubilize them.

[g]Keep refrigerated frozen between uses.

[h]Add items 1–8 to 900 ml distilled water (item 13), adjust pH to 5.2–5.5, add sugar (item 12), and adjust volume to 1000 ml with distilled water (item 13). Bring solution to a gentle boil, and add agar (item 14) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add hormones and vitamin (items 9–11) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

TABLE CYM-20. **Murashige–Skoog medium (Murashige and Skoog, 1962) for plantlet production from protocorm-like bodies derived from dormant buds of *Cymbidium* (Tran Thanh Van, 1974)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add the chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Sometimes listed as *meso*-inositol.

[f]If auxin or cytokinin does not dissolve, add a few drops of dilute KOH or HCl, respectively, to solubilize them.

[g]Keep refrigerated between uses.

[h]Add items 1–8 to 900 ml distilled water (item 13), adjust pH to 5.2–5.5, add sugar (item 12), and adjust volume to 1000 ml with distilled water (item 13). Bring solution to a gentle boil, and add agar (item 14) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add hormones and vitamin (items 9–11) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

Vegetative Propagation of *Cymbidium* on Modified Knudson C Medium

Since allied species or even related cultivars do not always respond similarly to a specific medium, an attempt was made to develop "media . . . versatile enough to be used for seed germination and meristem culture . . ." (Dalla Rosa and Laneri, 1977).

Plant Material. Meristematic tissues should be excised from the lateral buds on young shoots that are approximately 10 cm long. Explants from lateral buds (on cubes approximately 2 mm thick, 2 mm wide, and 1 mm thick) and apices (slightly larger squares but not thicker than 1 mm) are cut under sterile conditions while the tissues are submerged in sterile distilled water to prevent browning.

Surface Sterilization. Remove outer leaves, bud scales, and necrotic tissues carefully, and cut yellowish internal leaves approximately 1 cm above the apex. After that the shoots are dipped in 70% ethanol for a few seconds, submerged in freshly prepared 10% calcium hypochlorite solution for 20 min, and rinsed with sterile distilled water three times. (The hypochlorite solution is made by placing 10 g calcium hypochlorite in 80 ml distilled water, adjusting to 100 ml, stirring a few times at 5–10-min intervals, and filtering or decanting.)

Culture Vessels. Erlenmeyer flasks and culture tubes were used in the original experiment, but other containers are equally suitable. Culture vessels should contain medium equal in volume to one-fifth of their capacity (e.g., a 125-ml Erlenmeyer flask should contain 25 ml medium).

Culture Conditions. Cultures should be maintained under 18-h photoperiods; in the original research illumination was provided by "solar spectrum fluorescent tubes," but other light sources should prove to be equally suitable. Maintain temperatures at 25 ± 2°C during the light period and 22 ± 2°C in the dark, although a constant temperature in the 22–25°C range would also be appropriate.

Culture Medium. A modification of the Knudson C medium is used (Table Cym-21).

Procedure. Place explants on the medium, and subculture as necessary.

Developmental Sequence. Differentiation starts 10–15 days after the explants are placed in culture; PLBs appear within 1.5 months.

General Comments. This appears to be a relatively simple and useful procedure.

TABLE CYM-21. **Knudson C medium (Knudson, 1946) modified for the culture of meristematic tissues from *Cymbidium* buds (Dalla Rosa and Laneri, 1977)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	250	25 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
6	**Microelements**[d]				
(a)	Aluminum chloride, $AlCl_3$	0.03	3 mg l^{-1}		
(b)	Boric acid, H_3BO_3	1	100 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.03	3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot H_2O$	0.1	10 mg l^{-1}	10	One solution
(e)	Nickel chloride, $NiCl_2 \cdot 6H_2O$	0.03	3 mg l^{-1}		
(f)	Potassium iodide, KI	0.01	1 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	1	100 mg l^{-1}		
(h)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	Separate solution
	Complex additive				
7	Coconut water[e]	100 ml	No stock	No stock	Measure
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent[f]				
9	Distilled water	To 1000 ml			
	Solidifier				
10	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The original version of the Knudson C medium calls for 25 mg $FeSO_4 \cdot 7H_2O$. Chelated iron is preferable.

[d]These are the microelements of Heller's medium (Heller, 1953). They contain manganese, but the recipe for this modification (Dalla Rosa and Laneri, 1977) also lists the quality of manganese included as part of the Knudson C medium. Either would suffice, but both are given here to conform with the modified recipe. Add items 6a–6g to the same 1 l of water, stir and/or heat to mix, and dispense as indicated. Prepare a separate solution of item 6h, and add it to the medium as shown. If toxicity symptoms develop, omit item 6h.

[e]Like many other publications the original paper (Dalla Rosa and Laneri, 1977) lists this item as "coconut milk." What is actually added is the liquid endosperm of green (i.e., unripe) coconuts, so a more appropriate term would be "coconut water." Store excess coconut water in a freezer.

[f]Add items 1–7 to 800 ml distilled water (item 9), adjust pH to 6.0, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When the agar is completely dissolved pour the medium into culture vessels and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

Effects of Extracts from Symbiotic Rhizomes of *Cymbidium goeringii*

Extract from fungus-containing rhizomes seems to enhance growth and development of some *Cymbidium* explants (Ueda and Torikata, 1974).

Shoot-tip Culture of Oriental Orchids

Researchers at the Institute of Utilization of Atomic Energy in Agriculture, Sichuan Academy of Agricultural Science, People's Republic of China, have attempted to culture 45 cultivars of oriental orchids. They succeeded with 20 of them. Techniques were perfected for the culture of *Cymbidium goeringii* and *C. goeringii* var. *longibracteatum* (Wu et al., 1987).

Multiplication of PLBs of *Cymbidium*

In some instances PLBs die after being sectioned and mashed (Yoneda et al., 1980).

Clonal Propagation of *Cymbidium* through Shoot-tip Cultures

Plant hormones can enhance the usefulness of many culture media, but at high concentrations they may induce undesirable mutations (Haas-von Schmude, 1985). For this reason a micropropagation procedure for *Cymbidium* was developed that uses low hormone concentrations (Gu et al., 1987*a*).

Plant Material. Shoot tips from lateral buds on *Cymbidium* pseudobulbs or shoots are excised and cultured. To expose the shoot tips, adult leaves are removed and the younger leaves cut in half. The tips are excised following surface sterilization under aseptic conditions as cubes measuring $2 \times 1.5 \times 1.5$ mm.

Surface Sterilization. Shoots (ca. 4–6 cm long) or pseudobulbs should be scrubbed with a soft (i.e., used) toothbrush under running water and then dipped for a few seconds in 70% ethanol. After that they are immersed in 50% Clorox (50 ml Clorox diluted to 100 ml with distilled water) for 20 min and rinsed three times with sterile distilled water. Shoot tips approximately 5 mm long are removed and immersed in 10% Clorox (10 ml Clorox diluted to 100 ml with sterile distilled water) and rinsed as before. The tips are trimmed to $2 \times 1.5 \times 1.5$ mm (4.5 mm^3) following the last rinse.

Culture Conditions. Liquid cultures should be placed on a reciprocal shaker at 55 oscillations per minute. Both liquid and solid cultures are maintained at $22 \pm 3°C$ under 16-h photoperiods and a light intensity of 0.8 W cm^{-2} provided by Sylvania Gro Lux fluorescent tubes.

Culture Media. A modification of Vacin and Went medium (Table Cym-22) is used for initial culture. Plantlet formation occurs on a second modification of the same medium (Table Cym-23).

Procedure. First place shoot tips on liquid medium (Table Cym-22). When PLBs form, section and subculture them. For plantlet formation, place the PLBs on the second medium (Table Cym-23).

TABLE CYM-22. **Vacin and Went medium (Vacin and Went, 1949) modified for *Cymbidium* shoot tip cultures (Gu et al., 1987*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
7	**Microelement**				
	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Polyol				
8	*myo*-inositol	100	No stock	No stock	Weigh
	Cytokinin				
9	N^6-benzyladenine (BA)	1	100 mg 100 ml^{-1} 95% ethanol[e]		
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, stir, and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 11) which contain the calcium phosphate (item 2), adjust pH to 5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When the agar is completely dissolved pour the medium into a 2-l flask, and autoclave. Add hormone (item 9) to the hot, still liquid medium, mix well by swirling, and dispense into preautoclaved culture vessels. Omit agar if preparing liquid medium.

Developmental Sequence. Approximately 75% of the shoot-tip explants can be expected to form PLBs within 2 months (Fig. Cym-3A, B). They are white at first but turn green 10 days after becoming apparent. Sections form new PLBs after 4 weeks. The growth rate of PLBs is 3.8 g in 2 weeks. Shoot production (Fig. Cym-3C, D) occurs on nearly 50% of the PLBs. Complete plantlets (Fig. Cym-3E, F) are produced in 5 months.

General Comments. This is an easy, rapid method for the clonal propagation of *Cymbidium*.

TABLE CYM-23. **Vacin and Went medium (Vacin and Went, 1949) modified for plantlet production from *Cymbidium* protocorm-like bodies (Gu et al., 1987*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Polyol				
8	*myo*-inositol	100	No stock	No stock	Weigh
	Cytokinin				
9	N^6-benzyladenine (BA)	1	100 mg 100 ml^{-1} 95% ethanol[e]		
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	16 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve and it is not possible to prepare a stock solution. To facilitate the preparation of medium place 200 mg of the salt in 500 ml water, stir, and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution, dissolve 37.3 mg chelating agent (Na_2EDTA) and 27.8 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Keep refrigerated or frozen between uses.

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 11) that contain the calcium phosphate (item 2). Adjust pH to 5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When the agar is completely dissolved pour the medium into a 2-l flask, and autoclave. Add hormone (item 9) to the hot, still liquid medium, mix well by swirling, and dispense into preautoclaved culture vessels.

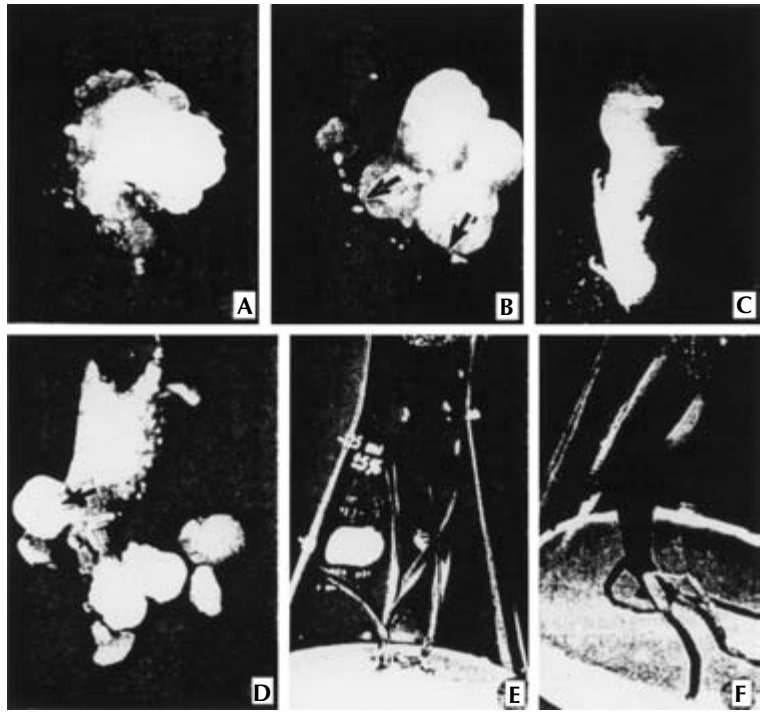

FIG. CYM-3. **Shoot-tip culture and plantlet differentiation in vitro of *Cymbidium*. A. PLBs formed from a shoot tip after 2 months of culture on Vacin and Went medium containing 1 mg l^{-1} BA (VW1BA; × 25). B. Multiple PLBs following a 4-week culture period on VW1BA (× 10). C. Shoot differentiation from a PLB within 4 weeks in culture on Vacin and Went medium containing 0.4 mg l^{-1} BA (VW0.4BA; × 5). D. Several PLBs on the base of a differentiated shoot after 4 weeks on VW1BA (× 5). E. A plant that developed after 5 months of culture on unmodified Vacin and Went medium (see Table Cym-5; × 0.7). F. Plantlet that formed after 5 months on VW0.4BA. (Gu et al., 1987*b*.)**

Effects of N^6-benzylaminopurine and NAA on Organogenesis in *Cymbidium*

Addition of NAA alone to Knudson C medium with the microelements of Nitsch had no effect on the formation of PLBs. BA at 0.1 mg l^{-1} increased production of PLBs considerably. A combination of BA (10 mg l^{-1}) and NAA (concentration not given, but it could have been 1–10 mg l^{-1}; 10 mg l^{-1} seems high) greatly enhanced shoot production during the first 90 days of culture. NAA at 0.1 mg l^{-1} increased root production slightly. BA had an inhibitory effect on root production (Matsui et al., 1970).

Rapid Propagation of *Cymbidium* through the Culture of Apical and Axillary Buds

Tissue culture as a means of rapid propagation of orchids has received "more and more attention from South African growers," one reason for the development of a method for *Cymbidium* propagation at the Horticultural Research Institute in Pretoria (van Rensburg and Vcelar, 1984).

Plant Material. Apical and axillary buds from actively growing pseudobulbs with six to seven leaves are used. Explants should be 1–5 mm in size. The excision steps described for dormant buds (Tran Thanh Van, 1974) can be used.

Surface Sterilization. All excess and dead tissue should be removed from the pseudobulbs before washing them thoroughly with water. The original paper does not mention a detergent, but using one may be a good idea (Tran Thanh Van, 1974; Gu et al., 1987*b*). The pseudobulbs are sterilized by soaking them in 1% sodium hypochlorite (20 ml Clorox diluted to 100 ml with distilled water) for 20 min. Further washing and sterilization are not described in the original paper, but if needed the appropriate steps of other procedures (Tran Thanh Van, 1974; Gu et al., 1987*b*) can be used.

Culture Vessels. No details are given regarding culture vessels, but it is reasonable to assume that standard containers (Erlenmeyer flasks, Petri dishes, test tubes, etc.) would be suitable.

Culture Conditions. The cultures should be maintained under 16-h photoperiods provided by standard light sources at 24°C.

Culture Medium. A modified Knudson C medium containing banana homogenate from "bananas [that are] . . . ripe but still firm" (Table Cym-24) is used.

Procedure. Place explants on the medium. Subdivide the PLBs that form, and transfer them to fresh medium every 6 weeks. (PLBs not subdivided and transferred to new medium will form plantlets.)

Developmental Sequence. Approximately 4 weeks after the start of culture, the explants form one to five PLBs. On being subdivided their sections develop several PLBs, which can be subcultured again. Plantlets differentiate when PLBs are not subdivided and allowed to remain on the culture medium for a while.

General Comments. This procedure can be used to free *Cymbidium* cultivars from virus, but care must be taken, and the new plants must be screened for infection. If this is not done, this (or any other) tissue culture method can "result in thousands of infected daughter plants." Even when plants are screened and found to be free of virus, the findings are valid for only a short period. Cultivated plants can be infected easily.

TABLE CYM-24. **Knudson C medium (Knudson, 1946) modified for tissue culture of *Cymbidium* (van Rensburg and Vcelar, 1984)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelement				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 g l^{-1}	10	
	Complex additive				
7	Banana homogenate[d]	100 g	No stock	No stock	Weigh
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[d]The bananas should be "ripe but still firm." Cut the banana into slices, and place them in 200 ml water in a homogenizer. Homogenize for 1–2 min, pause for 3–5 min and homogenize for another minute. Pour homogenate into a 2-l beaker. Rinse homogenizer three times with 100 ml distilled water, pour the washings into homogenate, and stir well to prepare item 7.

[e]Add items 1–7 to 800 ml distilled water (item 9), adjust pH to 5.5, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. The agar can also be added to the cold solution; then bring to a boil and stir. When agar is completely dissolved, pour medium into culture vessels and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. The addition of K_2HPO_4 raises the pH to about 5.3. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

Effects of Phytohormones and Peptone on Meristem Culture of *Cymbidium*

Studies in Poland (Kukułczanka and Paluch, 1971; Kukułczanka and Sarosiek, 1971; Morawiecka et al., 1973; Kukułczanka, 1976) have shown the following:

1. Peptobak-Bacutil peptone from Poland enhances shoot-tip cultures of *Cymbidium* when added to a modified Tsuchiya medium at a concentration of 2 g l^{-1}.
2. Addition of auxin after 4 weeks of culture is advisable since it enhances the growth of PLBs and plantlets.
3. Kinetin increases the number of PLBs.
4. Gibberellic acid accelerates shoot growth but inhibits root development.

5 Morphactin can increase the number of PLBs, but it could also induce developmental anomalies.
6 Additions of streptomycin to culture media brought about changes in the activity and electrophoretic patterns of acid phosphatase and ribonuclease.

Clonal Propagation of *Cymbidium* through the Culture of Floral Organs in Vitro

Gynostemia, ovaries, and flower stalks were better than sepals, petals, and labella for the production of buds when cultured on solid or liquid MS medium supplemented with 0.1 ppm NAA and 1 ppm BA. Production of buds was enhanced by liquid medium (Kim and Kako, 1984).

Clonal Propagation of *Cymbidium* through the Culture of Shoot Apices in Vitro

A series of investigations regarding the effects of media components on PLBs of *Cymbidium* have resulted in the formulation of a micropropagation method (Kusumoto and Furukawa, 1977; Kusumoto, 1978, 1980*a,* 1980*b*, 1981*a*).

Plant Material. New shoots approximately 5 cm in length are excised and their outer leaves are removed. After sterilization their shoot apices are removed and cultured.

Surface Sterilization. The shoots are soaked in Wilson's calcium hypochlorite solution (7 g calcium hypochlorite in 100 ml of water stirred several times at 5-min intervals, filtered or decanted, and used within a few hours). There is no mention of subsequent washing of the explants, but two to three rinses with sterile distilled water are advisable.

Culture Vessels. During the original research the explants were cultured in 200-ml Erlenmeyer flasks. These are very suitable containers, but other culture vessels can also be used.

Culture Conditions. Cultures are maintained under an illumination of 5000 lx at 25–30°C.

Culture Medium. Several media with additives were screened in the original research; the best growth occurred on a modification of Knudson C medium (Table Cym-25).

Procedure. The explants are cultured until PLBs form. These are divided and cultured on the same medium for proliferation and plantlet formation.

Developmental Sequence. PLBs form on the explants. On being divided, the PLBs proliferate and/or produce plantlets.

TABLE CYM-25. **Knudson C medium (Knudson, 1946) modified for *Cymbidium* culture in vitro (Kusumoto and Furukawa, 1977; Kusumoto, 1978, 1980*a*, 1980*b*, 1981*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
	Iron[c]				
5	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	25	2.5 g l^{-1}	10	
	Microelements				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additives				
7	Banana juice[d]	150 ml	No stock	No stock	Measure
8	Apple juice[e]	150 ml	No stock	No stock	Measure
9	Peptone, Difco Bacto[f]	2 g	No stock	No stock	Weigh
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]It is preferable to chelate the iron. To prepare a stock solution dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium

[d]If banana juice is not available, prepare the homogenate given in Table Cym-24. If so, recalculate the volumes in footnote *g* below. Commercial juices often contain preservatives that can inhibit growth. Even so-called natural juices are not always free of preservatives. Therefore exercise great care when juices are used and read the label carefully. If information is not available, it is best to prepare a homogenate.

[e]The same comments in footnote *d* above apply to apple juice. If preparing an apple homogenate in the laboratory, remove the seeds before homogenizing the tissues like those of banana (Table Cym-24). Alternately apple juice may be prepared by squeezing the sections. Filter apple juice or homogenate through cheesecloth, nylon stockings, or similar fabric.

[f]The composition of peptones from various manufacturers may vary. Make substitutions with caution, and test carefully before using them with valuable plants.

[g]Add items 1–9 to 500 ml distilled water (item 11), adjust pH to 5.4, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into culture vessels, and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. Use a dilute solution of hydrochloric acid (HCl) to lower the pH if necessary.

General Comments. Related findings from the same laboratory are as follows:

1. Bud formation on protocorms is enhanced by 0.01 mg l^{-1} 2,4-D and 0.1 mg l^{-1} gibberellic acid (GA_3). A combination of 0.1–1.0 mg l^{-1} kinetin and 0.01–0.1 mg l^{-1} NAA, or 0.1–1.0 mg l^{-1} GA_3 and 0.01–0.1 mg l^{-1} NAA has similar effects.
2. GA_3 (1.0 mg l^{-1}) and 2,4-D (0.1 mg l^{-1}) enhance shoot development.
3. Root formation is best in the presence of 1.0 mg l^{-1} GA_3 and 0.1 mg l^{-1} NAA.
4. Tryptone promotes organogenesis.
5. Coconut water (10%) promotes proliferation of PLBs.
6. Growth is enhanced when cultures are placed on 16 ml of the appropriate medium in a 200-ml Erlenmeyer flask.

Protoplasts Isolation from Leaves of *Cymbidium aloifolium*

Protoplasts can be isolated from leaves of *Cymbidium aloifolium* by the method used for *Acampe praemorsa*. The yield from leaves was 18.9×10^4 g^{-1} fresh weight per tissue. A much higher yield, 89.5×10^4 g^{-1} fresh weight per tissue, was obtained from "the tender leaf bases" (Seeni and Abraham, 1986).

Morphogenesis and Clonal Propagation of *Cymbidium* through Aseptic Cell Cultures

Research on the growth and development in aseptic cell and tissue cultures of *Cymbidium* has shown that cultured cells can be used for clonal propagation (Steward and Mapes, 1971*a*).

Plant Material. Callus cultures obtained by culturing *Cymbidium* shoot tips on White's medium (Table Cym-26) are used.

Surface Sterilization. The original paper (Steward and Mapes, 1971*a*) does not provide information on the surface sterilization of the shoot tips used to produce the callus, but the steps employed in other procedures (Tran Thanh Van, 1974; Gu et al., 1987*b*) should prove suitable. Callus sections need not be sterilized since they are taken from aseptic cultures.

Culture Vessels. Erlenmeyer flasks or test tubes can be used for cultures on solid medium. T-shaped tubes were used for liquid cultures in the original research. Plastic containers and 30-ml sample bottles were also used. Other containers should also prove suitable.

Culture Conditions. General information about Steward's laboratory suggests that the liquid cultures were placed on a horizontal rotating shaker. Solid cultures were probably maintained on a table, shelf, or bench. "Moderate light" and 21°C are suitable culture conditions, but "there was some evidence of better greening of the cultures at 18 hours of day and at 24°C."

Culture Media. White's medium with coconut water and auxin (Table Cym-26) is used for shoot-tip cultures. A different modification of this medium (Table Cym-27) is used for the production and multiplication of free cells. The first medium is best for the production of PLBs. When grown on a medium devoid of auxin (Table Cym-28), the PLBs multiply to form rosettes. It is not clear from the original paper which medium was used for plantlet production, but it is reasonable to assume that Knudson C medium (see Tables Aranda-7, Aranda-8, Cym-2, and Cym-3), Vacin and Went medium (see Table Cym-5), or some other combination used for *Cymbidium* would be suitable.

Procedure. The first step of this procedure is to produce callus from a shoot-tip explant. Any one of the procedures described earlier for *Cymbidium* should prove

TABLE CYM-26. **White's medium (Singh and Krikorian, 1981)[a] for the culture of *Cymbidium* shoot tips (Steward and Mapes, 1971*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation, and modernization of the medium (Singh and Krikorian, 1981). $ZnSO_4 \cdot 4H_2O$ is very hard to find, if at all. Use an equal amount of $ZnSO_4 \cdot 7H_2O$ instead.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to include.

[g]Keep refrigerated or frozen between uses.

[h]Like many other publications, Steward and Mapes (1971*a*) lists this item as "coconut milk." What is actually added is the liquid endosperm of green (i.e., unripe) coconuts, so a more appropriate term is "coconut water." Store excess coconut water in a freezer.

[i]Add items 1–8 and 14 to 800 ml distilled water (item 16), adjust pH to 5.2–5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, vitamins, and hormone (items 9–13) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE CYM-27. **White's medium (Singh and Krikorian, 1981)[a] for the production of free cells from callus cultures derived from *Cymbidium* shoot tips (Steward and Mapes, 1971*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[c]	288	28.8 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	737	73.7 g l^{-1}	10	
3	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	19	1.9 g l^{-1}	10	
4	Potassium chloride, KCl	65	6.5 g l^{-1}	10	
5	Potassium nitrate, KNO_3[c]	80	8 g l^{-1}	10	
6	Sodium sulfate, Na_2SO_4	200	20 g l^{-1}	10	
7	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	3.4	344 mg l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	4.66	466 mg l^{-1}		
8	**Microelements**[e]				
(a)	Boric acid, H_3BO_3[f]	6.2	620 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$[f]	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$[f]	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	6.65	665 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.75	75 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$[f]	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	2.67	267 g l^{-1}		
	Amino acid				
9	Glycine	3	300 mg 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
11	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Auxin				
13	2,4-Dichlorophenoxyacetic acid (2,4-D)	5	500 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
14	Coconut water[h]	100 ml	No stock	No stock	Measure
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[i]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation, and modernization of the medium (Singh and Krikorian, 1981). $ZnSO_4 \cdot 4H_2O$ is very hard to find, if at all. Use an equal amount of $ZnSO_4 \cdot 7H_2O$ instead.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to include.

[g]Keep refrigerated or frozen between uses.

[h]Like many other publications, Steward and Mapes (1971*a*) lists this item as "coconut milk." What is actually added is the liquid endosperm of green (i.e., unripe) coconuts, so a more appropriate term is "coconut water." Store excess coconut water in a freezer.

[i]Add items 1–8 and 14 to 800 ml distilled water (item 16), adjust pH to 5.2–5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, vitamins, and hormone (items 9–13) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE CYM-28. **White's medium (Singh and Krikorian, 1981)[a] for the production of free cells from callus cultures derived from *Cymbidium* shoot tips (Steward and Mapes, 1971*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[c]	288	28.8 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	737	73.7 g l^{-1}	10	
3	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	19	1.9 g l^{-1}	10	
4	Potassium chloride, KCl	65	6.5 g l^{-1}	10	
5	Potassium nitrate, KNO_3[c]	80	8 g l^{-1}	10	
6	Sodium sulfate, Na_2SO_4	200	20 g l^{-1}	10	
7	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	3.4	344 mg l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 4H_2O$	4.66	466 mg l^{-1}		
8	**Microelements**[e]				
(a)	Boric acid, H_3BO_3[f]	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$[f]	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$[f]	0.025	2.5 mg l^{-1}

(e)	Potassium iodide, KI	0.75	75 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$[f]	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	2.67	267 g l^{-1}		
	Amino acid				
9	Glycine	3	300 mg 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
11	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
13	Coconut water[h]	100 ml	No stock	No stock	Measure
	Sugar				
14	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[i]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]There are many inconsistencies and contradictions in the literature regarding White's medium, some of them in his own papers. This table is based on an excellent recent study, reevaluation, and modernization of the medium (Singh and Krikorian, 1981). $ZnSO_4 \cdot 4H_2O$ is very hard to find, if at all. Use an equal amount of $ZnSO_4 \cdot 7H_2O$ instead.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]To prepare chelated iron add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[e]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[f]Not part of White's recipe but advisable to include.

[g]Keep refrigerated or frozen between uses.

[h]Like many other publications, Steward and Mapes (1971*a*) lists this item as "coconut milk." What is actually added is the liquid endosperm of green (i.e., unripe) coconuts, so a more appropriate term is "coconut water." Store excess coconut water in a freezer.

[i]Add items 1–8 and 13 to 800 ml distilled water (item 15), adjust pH to 5.2–5.5, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid and vitamins (items 9–12) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

suitable, but it is advisable to grow the explants on the modification of White's medium (Table Cym-26). To release cells, place the callus produced in the first step in a liquid medium (Table Cym-27) under agitation. Move the cells (in aliquots of medium) to the first medium (Table Cym-26) to induce the production of PLBs. These are moved to another medium for greening and proliferation (Table Cym-28). Plantlets can be produced from the PLBs on several media.

Developmental Sequence. Cells that slough off from the callus mass produce somatic embryos that give rise to PLBs. These proliferate and produce plantlets.

General Comments. Since many cells can slough off from each callus mass, this procedure can produce a very large number of plants very rapidly. Plants produced by this method have flowered and their flowers are normal.

Shoot Formation from Rhizomes of *Cymbidium faberi*

Propagation of terrestrial *Cymbidium* species from East Asia is difficult. Several attempts were made to develop tissue culture propagation methods for these orchids. The procedure described here is based on experiments designed to "clarify the effects of N^6-benzyladenine (BA), rhizome length, application of mechanical treatment and liquid shaking culture on shoot formation from rhizome[s] cultured *in vitro* . . ." (Hasegawa et al., 1985).

Plant Material. Rhizomes for the original research were taken from seedlings of *Cymbidium faberi* Ro-Shanghai-bai × *Cymbidium faberi* Kin-o-so cultured in vitro. Rhizome-tip sections 2–3 mm thick were removed and placed on solid medium.

Surface Sterilization. Since rhizomes for the original research were taken from seedlings, they were not sterilized. The procedures used for *Cymbidium ensifolium* and *Cymbidium goeringii* should be suitable for surface sterilization of rhizomes taken from horticulturally grown plants.

Culture Vessels. Test tubes 10 × 180 cm were used in the original research. Other containers may also prove suitable.

Culture Conditions. Cultures should be maintained at 25°C under 16-h photoperiods of 500 lx provided by fluorescent lamps.

Culture Media. Modified Kyoto medium is used for shoot formation and growth (Table Cym-29). The shoots are moved to a BA-free medium (Table Cym-30) for rhizome formation.

Procedure. Place the explants on the first medium (Table Cym-29), maintain them on it until shoots are formed, and then move them to the second medium (Table Cym-30).

TABLE CYM-29. **Modified Kyoto medium as used for initial culture of rhizome tips of *Cymbidium faberi* (Hasegawa et al., 1985)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Minerals				
1	Hyponex (nitrogen : phosphorus : potassium in the ratio 7 : 6 : 19)[b]	3 g	No stock	No stock	Weigh
	Amino acid				
2	Glycine	3	300 mg 100 ml^{-1} 95% ethanol[c]	1	
	Vitamins				
3	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[c]	1	
4	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[c]	1	
5	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[c]	1	
	Auxin				
6	α-Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[c,d]	1	
	Cytokinin				
7	N^6-benzylaminopurine (benzyladenine; BA)	1.0	100 mg 100 ml^{-1} 95% ethanol[c,d]	1	
	Complex additive				
8	Tryptone, Difco Bacto	3.0 g	No stock	No stock	Weigh
	Darkening agent				
9	Activated charcoal	2.0 g	No stock	No stock	Weigh
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[e]	To 1000 ml			
	Solidifier				
12	Agar, Difco Bacto	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Available from retail nurseries and garden shops.

[c]Keep refrigerated or frozen between uses.

[d]If the hormones fail to dissolve, add a few drops of dilute KOH (for the auxin) or HCl (cytokinin).

[e]Add items 1 and 8 to 700 ml distilled water (item 11); set pH to 5.0–5.1, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. The agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, add charcoal (item 9) and stir well. After charcoal is dispersed evenly, pour solution into a 2-l flask, and autoclave. Add items 2–7 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

Developmental Sequence. Shoot formation can occur on both 1 and 10 mg l^{-1} BA, but subsequent growth is inhibited by the higher concentration. In fact, a hormone-free medium is most suitable for shoot growth.

General Comments. East Asian terrestrial *Cymbidium* species are difficult to culture. Therefore this procedure is an important advance. However, it is not known whether it is suitable for rhizome sections taken from mature plants.

TABLE CYM-30. **Modified Kyoto medium as used for the growth of shoots derived from rhizome tips of *Cymbidium faberi* (Hasegawa et al., 1985)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Minerals				
1	Hyponex (nitrogen : phosphorus : potassium in the ratio 7 : 6 : 19)[b]	3 g	No stock	No stock	Weigh
	Amino acid				
2	Glycine	3	300 mg 100 ml^{-1} 95% ethanol[c]	1	
	Vitamins				
3	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[c]	1	
4	Pyridoxine (vitamin B_6)	0.1	10 mg 100 ml^{-1} 95% ethanol[c]	1	
5	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[c]	1	
	Auxin				
6	α-Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[c,d]	1	
	Complex additive				
7	Tryptone, Difco Bacto	3.0 g	No stock	No stock	Weigh
	Darkening agent				
8	Activated charcoal	2.0 g	No stock	No stock	Weigh
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Agar, Difco Bacto	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Available from retail nurseries and garden shops.

[c]Keep refrigerated or frozen between uses.

[d]If the hormone fails to dissolve, add a few drops of dilute KOH to solubilize it.

[e]Add items 1 and 7 to 700 ml distilled water (item 10), set pH to 5.0–5.1, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. The agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, add charcoal (item 8) and stir well. After charcoal is dispersed evenly, pour solution into a 2-l flask, and autoclave. Add items 2–7 to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels.

Propagation of Oriental *Cymbidium* Species (*Cymbidium faberi, Cymbidium forestii, Cymbidium goeringii, Cymbidium hakuran, Cymbidium insigne, Cymbidium kanran,* and *Cymbidium sinense*) through the Culture of Various Explants

Shoot tips of *Cymbidium goeringii* that were cultured in the dark on MS or Linsmaier–Skoog media containing 1 ppm NAA and 1 ppm kinetin or hormone-free Hyponex medium formed rhizomes (Hasegawa, 1987).

Shoot tips of *Cymbidium kanran* were cultured on the inorganic constituents of Linsmaier–Skoog medium diluted to one-fifth of the original concentration. Hormones were not required. Liquid media, static or agitated, inhibited rhizome formation (Hasegawa, 1987).

Explants from rhizomes of *Cymbidium kanran, Cymbidium faberi*, *C. goeringii,* and *Cymbidium sinense*, as well as variegated forms were also cultured with varying success (Hasegawa, 1987). The methods seem to be similar to those used for *C. faberi* as described above (Hasegawa et al., 1985).

The publication from which this was taken (Hasegawa, 1987) is impressive and seems to contain many interesting details regarding the culture of these orchids. Unfortunately it is in Japanese (104 pages) with only a 3.5-page English summary. This is yet another example why investigators should make every effort to publish their work in English.

Shoot-tip Culture of *Cymbidium grandiflorum*

Shoot tips of *Cymbidium grandiflorum* cultured on liquid or solid Vacin and Went medium containing BA formed PLBs. These PLBs were sectioned and subcultured on the same medium, where they proliferated. PLBs cultured on solid Knudson C medium produced plantlets. Production of PLBs is also enhanced by 1.0 mg l^{-1} BA. Development and differentiation are promoted by 0.4 mg l^{-1} BA (Gu and Yan, 1989).

Isolation of *Cymbidium* Protoplasts from Leaves

Protoplasts of *Cymbidium* were isolated as a step in the isolation of nuclei (Capesius and Meyer, 1977).

Plant Material. Leaves of *Cymbidium* Ceres were used in the original research. The leaves of other cultivars or species could also be used.

Surface Sterilization. No information is given regarding the surface sterilization procedure, but the procedures used for *Aranda* (Fu, 1978, 1979*b*) or other *Cymbidium* tissues should prove suitable.

Culture Vessels. The vessels used for protoplast isolation from protocorms of *Brassia maculata* and *Cattleya* are used (Capesius and Meyer, 1977).

Culture Conditions. The conditions employed for protoplast isolation from protocorms of *Brassia maculata* and *Cattleya* are suitable (Capesius and Meyer, 1977).

Culture Media. Protoplasts were not cultured during the original research and culture media were not formulated. The plasmolysis solution consists (per liter) of 10 g magnesium sulfate ($MgSO_4 \cdot 7H_2O$) and 25 g potassium chloride (KCl). For premaceration 100 mg Pectinol fest (Fa Röhm, Darmstadt, Germany) is added to 100 ml of this solution. The digestion medium is prepared by adding to 100 ml of plasmolysis solution, 1 g cellulase and 0.3 g Pectinol fest (for sources see *Brassia* and *Cattleya* entries, procedures for the isolation of protoplasts; Capesius and Meyer, 1977) and adjusting the pH to 5.8.

Procedure. After sterilization strip the epidermis from the leaves and plasmolyse the tissues in the plasmolysis solution for 30 min. After that move them to the pre-maceration mixture for 1 h without shaking. At the end of the hour replace the pre-maceration mixture with digestion medium and allow the tissues to remain in it for 3–4 h with occasional manual shaking. Then filter the suspension through a nylon screen (for sources see *Cattleya* entry, sections on protoplast isolation procedures) and centrifuge at $50 \times g$. A pellet formed as a result of the centrifugation contains the protoplasts. This pellet should be washed three times with the plasmolysis solution.

Developmental Sequence. The protoplasts were not cultured.

General Comments. This procedure could be a useful starting point for the isolation and culture of *Cymbidium* protoplasts.

Isolation of *Cymbidium* Protoplasts from Protocorms

The procedures are the same as those for *Brassia maculata* and *Cattleya* (Capesius and Meyer, 1977). Protocorms of *Cymbidium pumilum* were used in the original research.

Isolation of Mesophyll Protoplasts of *Cymbidium*

Protoplasts can be isolated from leaves of *Cymbidium* Miracle × *Cymbidium* Alexanderi 'Godlen Hill' by the method used for *Calanthe discolor*.

Use of Charcoal in Culture Media for *Cymbidium*

Inclusion of charcoal (0.2–3 g l^{-1}) enhances the growth and development of seedlings and plantlets of *Cymbidium* (Werkmeister, 1970*a,* 1970*b,* 1971; Ernst, 1974, 1975; Arditti, 1982*b*; Wang and Huang, no date).

Inclusion of Anticontaminants in Culture Media for *Cymbidium* Shoot Tips

Experiments in our laboratory have led to the following recommendations (Arditti, 1982*b*; Cvitanic and Arditti, 1984):

1. It is preferable not to use anticontaminants in shoot-tip culture media without previous screening.
2. Should contamination occur, it is best to use 10 mg l^{-1} amphotericin B, 25 mg l^{-1} nystatin, or 5 mg l^{-1} sodium omadine (i.e., these compounds should be used singly). Mixtures like those used for seedlings (Thurston et al., 1979, 1980; Spencer et al., 1979/1980; Arditti, 1982*b*; Brown et al., 1982) should be used with great caution and only following the formation of PLBs and/or plantlets.

Effects of Plant Hormones on Organogenesis of *Cymbidium* Shoot Apices in Vitro

Research at the Faculty of Agriculture, Nagoya University, Japan (Kim and Kako, 1982, 1983), has shown the following:

1 Auxins induce roots on shoot apex explants but inhibit shoots.
2 Fresh weight of plantlets increases in the presence of high levels of 2,4-D, but roots are abnormal.
3 NAA at 1 mg l^{-1} or 2,4-D at 0.1 mg l^{-1} can enhance plantlet formation and development.
4 BA can enhance the formation of PLBs and shoots, but at high concentrations it inhibits root initiation.
5 Gibberellic acid (GA) and ABA are without effect.
6 Explants with three leaf primordia do not require an exogenous supply of hormones for development.
7 Production of PLBs varies with the season. It starts to increase in April and reaches a maximum in June.
8 PLBs form in both the axillary and basal regions.

Method for the Clonal Propagation of *Cymbidium*

Orchid research is being carried out at what was the Central Republic Botanical Garden of the Academy of Sciences of the Ukrainian Soviet Socialist Republic in the USSR and is now the Botanical Garden in Kiev, Ukraine (Lavrentyeva, 1980, 1986). These studies have shown the following:

1 When the cytokinin : auxin ratio is 1 : 1 or 2 : 1, PLBs are larger.
2 The optimal size of explants is about 0.5 mm including three to four leaf primordia.
3 PLBs arise at the base of leaf primordia.
4 A suitable medium is modified Knudson C, which contains (per liter) 400 ml potato extract (no details are given regarding its preparation), 10 mg niacin, 7 mg adenine (no indication is given whether the sulfate was used), 40 g sucrose, and 7 g agar. The pH should be 5.5–5.8.

System for Vegetative Propagation of *Cymbidium* in Vitro

Studies of *Cymbidium* explant development in vitro at the V. L. Komarov Botanical Institute in St. Petersburg are concerned with differentiation and organogenesis (Shevtsova and Batygina, 1986).

Micropropagation of Terrestrial *Cymbidium* Species from Rhizome Explants

Axillary buds of *Cymbidium kanran* and *Cymbidium goeringii* develop vigorous rhizomes in vitro when treated with "higher concentration[s] of NAA and 2,4-D . . . [in] topical application[s] . . ." Apices of these rhizomes are removed and cultured on "MS [Murashige–Skoog] medium supplemented with auxin and cytokinin . . . at 25°C and 24" hour illumination. Shoot formation is accelerated by lower auxin : cytokinin ratios following "several passages in . . . higher" ratios. Root formation is inhibited when "both auxin and cytokinin were added," but occurred when the concentrations of potassium nitrate and ammonium nitrate were reduced. "Half strength of potassium nitrate and quarter strength of ammonium nitrate in MS medium were optimal for the formation of roots in rhizome cultures" (Shimasaki and Uemoto, 1987*a*, 1987*b*, 1990).

Clonal Propagation of *Cymbidium aloifolium* through Shoot-tip Culture

Cymbidium aloifolium is a commercially important orchid in northeast India. Propagation through conventional methods is relatively slow. A shoot-tip culture method was developed to accelerate its propagation (Devi et al., 1997).

Plant Material. Shoot tips, 2–5 mm in length, were taken from 8-month-old seedlings growing in vitro.

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization.

Culture Vessels. The original paper does not describe the culture vessels. However, a photograph shows a test tube. Other culture vessels are also suitable.

Culture Conditions. The research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3000 lx (the source of illumination was not described). Standard culture room conditions are also suitable.

Culture Media. The Nitsch and Nitsch (NN) medium (Nitsch and Nitsch, 1969) (Table Cym-31) was used for the formation and proliferation of PLBs. When shoots and roots were initiated, the PLBs were transferred to fresh medium of the same composition (Table Cym-31) for plantlet development. Plantlets were hardened by sequential transfers to full-, half- and quarter-strength NN medium free of sucrose, vitamins, and hormones (Tables Cym-32 to Cym-34). These media and steps are listed here because they are included in the original research but they seem superfluous and appear to add steps, work, complications, and expense and minimal – if any – benefits. If hardening is needed (a questionable supposition because it is not used in other procedures), a period of culture on full-strength basal medium (Table Cym-32) should be sufficient. Plantlets, 6–8 cm tall, should be removed from the culture and

TABLE CYM-31. **Nitsch and Nitsch (NN) medium (Nitsch and Nitsch, 1969) as used for the culture of *Cymbidium aloifolium* shoot tips (Devi et al., 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]This medium is one of a few media to contain biotin and/or folic acid. Since the explants grew better on it than on any of the other media tested it is possible that one or both of these vitamins may be: required by, needed by, or of benefit to the explants.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust the pH to 5.4, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8) and vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE CYM-32. **Basal Nitsch and Nitsch (NN) medium (Nitsch and Nitsch, 1969) as used for hardening plantlets produced through the culture of *Cymbidium aloifolium* shoot tips (Devi et al., 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Solvent				
8	Water, distilled[e]	To 1000 ml			
	Solidifier				
9	Agar[e]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Add items 1–7 to 900 ml of distilled water (item 8), adjust the pH to 5.4 and adjust volume to 1000 ml with distilled water (item 8). Bring the solution to a gentle boil and add the agar (item 9) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media.

TABLE CYM-33. **Half-strength basal Nitsch and Nitsch ($^1/_2$NN) medium (Nitsch and Nitsch, 1969) as used for hardening plantlets produced through the culture of *Cymbidium aloifolium* shoot tips (Devi et al., 1997)**

Step 1. Make 1 l of basal NN medium (Table Cym-32) but do not add the agar

Step 2. Take 500 ml of the NN medium and dilute it to 1000 ml with distilled water to make $^1/_2$NN

Step 3. Bring the solution to a gentle boil and add the agar (item 9 in Table Cym-32) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media

potted in a mixture of charcoal chunks, brick pieces, and coconut husks (proportions not given), watered regularly, and sprayed periodically with a dilute fertilizer solution. The original paper states "micro-nutrient solution" without: (1) indicating why only micronutrients, (2) describing the solution and its concentration, or (3) listing the frequency of applications. Established mature plants can be grown on fern blocks.

TABLE CYM-34. **Quarter-strength basal Nitsch and Nitsch (1/4NN) medium (Nitsch and Nitsch, 1969) as used for hardening plantlets produced through the culture of *Cymbidium aloifolium* shoot tips (Devi et al., 1997)**

Method A

Step 1. Make 1 l of basal NN medium (Table Cym-32) but do not add the agar

Step 2. Take 250 ml of the basal NN medium (Table Cym-32) and dilute it to 1000 ml with distilled water to make 1/4NN

Step 3. Bring the solution to a gentle boil and add the agar (item 9 in Table Cym-32) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media

Method B

Step 1. Make 1 l of half-strength basal NN (1/2NN) medium (Table Cym-33) but do not add the agar

Step 2. Take 500 ml of the half-strength basal NN (1/2NN) medium (Table Cym-33) and dilute it to 1000 ml with distilled water to make 1/4NN

Step 3. Bring the solution to a gentle boil and add the agar (item 9 in Table Cym-32) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media

Procedure. The explants should be placed on the first medium (Table Cym-31). PLBs with visible shoots and roots should be subcultured on the same medium (Table Cym-31). Once plantlets are formed they should be hardened through passage (several weeks each) on sequential dilutions of the NN medium (Tables Cym-32 to Cym-34). After the plants become large enough, they should be potted in a potting mix in pots. Since the sequential dilution steps (Tables Cym-32 to Cym-34) may not be necessary, users of this procedure should utilize a few plants in attempts to bypass them. If the attempts are successful, these steps should be eliminated.

Developmental Sequence. Explants remain green and enlarge slowly. After 6 weeks the explants form PLBs which range from 2 to 3 mm in diameter and multiply rapidly. The first leaves appear after 8 weeks. Roots form following 10 weeks of culture. Plantlets reach a height of 6–8 cm after 120–140 days.

General Comments. Like other procedures in which seedling explants are cultured, this method cannot be used to propagate desirable forms because the quality of seedlings is not known. Also, this method seems to include steps and media which may not be necessary. Best results were obtained on NN medium; however MS medium (Murashige and Skoog, 1962) was also effective. The late Jean Paul Nitsch (who died in an accident in 1971) and his wife Colette Nitsch formulated and published several culture media. These media differ from each other. Therefore, another Nitsch medium should not be substituted for NN (Nitsch and Nitsch, 1969) without careful prior testing.

Plantlet Production from Root Tips of *Cymbidium mastersii*

Root tips of a large number of orchids were cultured successfully by Professor Suraj P. Vij at the Orchid Laboratory, Botany Department, Panjab University, Chandigarh, India. One of these orchids is *Cymbidium mastersii* (Vij, 1993).

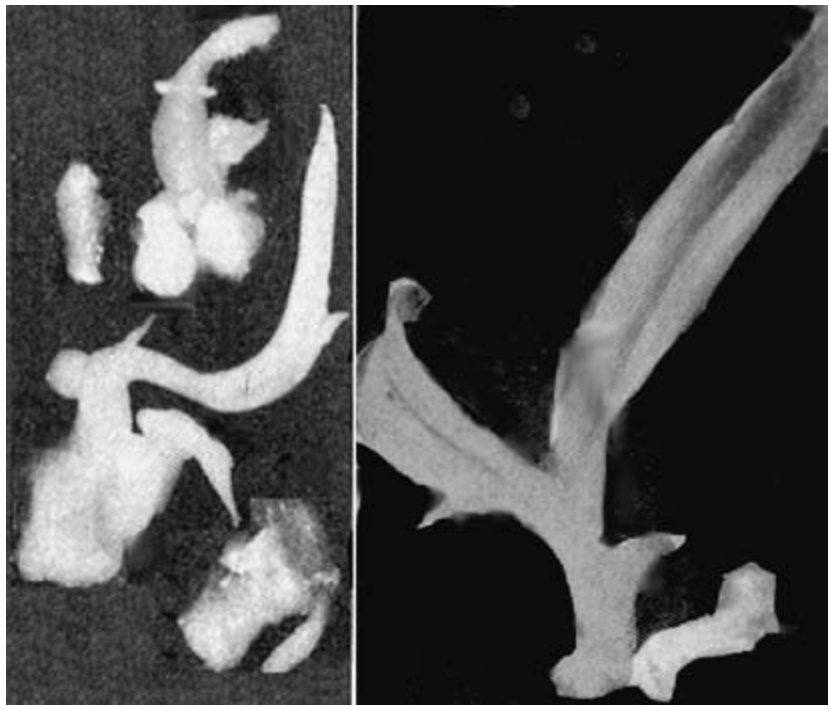

FIG. CYM-4. **Root-tip culture of *Cymbidium mastersii*. A. The explant starts to elongate and swell. B. PLB and bud formation. C. Bud formation. D. Early stages of plantlet formation. E. Plantlet. (Vij, 1993.)**

Plant Material. Root tips, 5–10 mm long, were taken from 16–30-week-old asymbiotic seedlings.

Surface Sterilization. There is no need to surface-sterilize explants taken from asymbiotic seedlings. However, the explants should be washed with sterile distilled water to remove residual agar and/or medium if any.

Culture Vessels. Test tubes (25 × 150 mm) and Erlenmeyer flasks (125-ml capacity) containing medium equivalent to one-fifth of their volume can be used for initial cultures (Fig. Cym-4A–C). Larger vessels are preferable for developing (Fig. Cym-4D) and larger (Fig Cym-4E) plantlets.

Culture Conditions. In the original research the cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx (the source is not described). Standard laboratory conditions are also suitable.

Culture Media. Modified MS medium (Murashige and Skoog, 1962) containing 1 mg l^{-1} each of kinetin and IAA (Table Cym-35) should be used for initial culture of explants and early plantlet development (Fig. Cym-4A–E). Another modification

TABLE CYM-35. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as used for the culture of *Cymbidium mastersii* root-tip explants (Vij, 1993, 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Indoleacetic acid (IAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Kinetin	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH as required, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

of MS containing only 1 mg NAA l^{-1} is also suitable. Although not suggested in the original report, standard or modified Knudson C (see Tables Aranda-7, Aranda-8, and Aranda-10) and Vacin and Went (see Tables Aranda-2, Aranda-6, and Arnth-3) media can be used for the culture of larger plantlets.

Procedure. Explants (Fig. Cym-4A) are taken from seedlings, washed with sterile distilled water, placed on the first medium (Table Cym-35), and left on it until callus, PLBs, and/or plantlets develop. Callus, PLBs, and plantlets can be subcultured onto the same medium (Table Cym-35). Larger plantlets can be moved to fresh medium, of either the same (Table Cym-35) or different (see Tables Aranda-2, Aranda-6, Aranda-7, Aranda-8, Aranda-10, and Arnth-3) composition.

Developmental Sequence. Initial explants (Fig. Cym-4A) swell and form new tissue or PLBs (Fig. Cym-4B, C). This is followed by plantlet development (Fig. Cym-4D, E).

General Comments. Since root explants are more difficult to culture than shoot tips, this method represents a significant advance in orchid micropropagation. It cannot be used to select desirable forms because the explants are taken from seedlings, but it can serve as a starting point for culture protocols that utilize root-tip explants from mature plants. It is not known if this procedure is suitable for root tips of mature plants. Should an attempt be made to culture root tips from mature plants, they must be free of mycorrhiza.

Plantlet Production from Root Tips of *Cymbidium pendulum*

Root tips of *Cymbidium pendulum* were cultured by Professor S. P. Vij (Vij, 1993).

Plant Material. Root tips, 5–10 mm long, were excised from 16–30-week-old asymbiotically germinated seedlings growing axenically in vitro.

Surface Sterilization. Explants taken from asymbiotic seedlings do not require surface sterilization, but they should be washed with sterile distilled water to remove agar and/or medium residue if any.

Culture Vessels. Erlenmeyer flasks (125-ml capacity) or test tubes (25×150 mm) containing medium equivalent to approximately 20% of their volume can be used for initial cultures. Larger vessels are more suitable for bigger plantlets.

Culture Conditions. The cultures were maintained at $25 \pm 2°C$ under 12-h photoperiods of 3500 lx (the source is not described) during the original research. Standard laboratory conditions are also appropriate.

Culture Media. Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) containing 1 mg IBA l^{-1} and 1 g peptone l^{-1} (Table Cym-36) should be used to culture the explants and for early plantlet development. Other modifications of

TABLE CYM-36. **Mitra, Prassad, and Roychowdhury medium (Mitra et al., 1976) as modified for the culture of root tips of *Cymbidium pendulum* (Vij, 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Auxin				
14	Indolebutyric acid (IBA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Complex additive				
15	Peptone	1.0 g	No stock	No stock	Weigh
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[f]	To 1000 ml			
	Solidifier				
18	Agar[f]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe calls for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.6, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976; Vij, 1993).

MPR can also be used (Vij, 1993). Despite not being suggested in the original report, Knudson C (see Tables Aranda-7, Aranda-8, and Aranda-10) and Vacin and Went (see Tables Aranda-2, Aranda-6, and Arnth-3) media may prove suitable for the culture of larger plantlets.

Procedure. Explants taken from seedlings should be washed with sterile distilled water and cultured on the first medium (Table Cym-36) until callus, PLBs, and/or plantlets are formed. These can be subcultured onto the same medium (Table Cym-36). Larger plantlets may be cultured either on the same (Table Cym-35) or a different (see Tables Aranda-2, Aranda-6, Aranda-7, Aranda-8, Aranda-10, and Arnth-3) medium.

Developmental Sequence. The explants swell and form PLBs that produce plantlets.

General Comments. Root tips are more difficult to culture than shoot or leaf explants. Therefore this method is a major achievement. However, it cannot be used to select specific forms because the explants are taken from seedlings, but it can serve as a starting point for culture methods for root tips from mature plants. If root tips from mature plants are excised for culture, they must be free of mycorrhiza.

Plantlet Production of *Cymbidium pendulum* from Nodal Explants

An epiphytic species found at the foot of the eastern Himalaya, Khasi, and Jainitia Hills in India, *Cymbidium pendulum* is valued as both an ornamental and therapeutic plant. Because of that and due to overcollection the species is becoming rarer. Therefore a micropropagation method was developed cooperatively by the Orchid Laboratory at Panjab University and the Laboratory of Plant Chromosomes and Genes Stock at Hiroshima University (Vij et al., 1994*a*).

Plant Material. Etiolated and young shoots were taken from greenhouse-grown plants and from seedlings growing axenically in vitro.

Surface Sterilization. Explants from axenic seedlings growing in vitro do not require surface sterilization, but they must be rinsed to remove culture medium residue. Sources of explants from greenhouse-grown plants were dipped in 70% ethanol (74 ml of 95% ethanol diluted to 100 ml with distilled water) for 30 s, sterilized with 0.1% streptomycin (0.1 g 100 ml^{-1}) for 25 min and 0.1% $HgCl_2$ (0.1 g 100 ml^{-1}) for 5 min and washed thoroughly with sterile distilled water after that. $HgCl_2$ is highly toxic and must be handled with great care.

Culture Vessels. Test tubes, 22 × 150 mm, Erlenmeyer flasks, 125-ml capacity, or other containers filled with culture medium to approximately 20% of their capacity can be used for the initial explants. Larger containers should be used when the explants, callus masses, PLB proliferations, shoot bud groups, and/or plantlets become bigger.

Culture Conditions. The research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx (the source of illumination was not described). Standard culture room conditions are also suitable.

Culture Media. Modified Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) was used in the original research for both the initial explants and further growth (Table Cym-37). However, larger plantlets may be cultured either on the same (Table Cym-37) or a different (see Tables Aranda-2, Aranda-6 to Aranda-8, Aranda-10, and Arnth-3) medium.

Procedure. Explants should be removed from the donor plants, sterilized if necessary, cut to one node size, and placed in culture (Table Cym-37). When propagules or plantlets form they should be transplanted to new medium (see Tables Aranda-2, Aranda-6 to Aranda-8, Aranda-10, Arnth-3, or Cym-37). After plants become large enough they should be potted in potting mix in pots.

Developmental Sequence. PLBs (Fig. Cym-5A) and shoot buds (Fig. Cym-5B, E) form and develop plantlets (Fig. Cym-5C, D, F), which become larger (Fig. Cym-5G, H).

General Comments. This procedure can be used to propagate desirable forms of *C. pendulum* and/or to simply multiply plants.

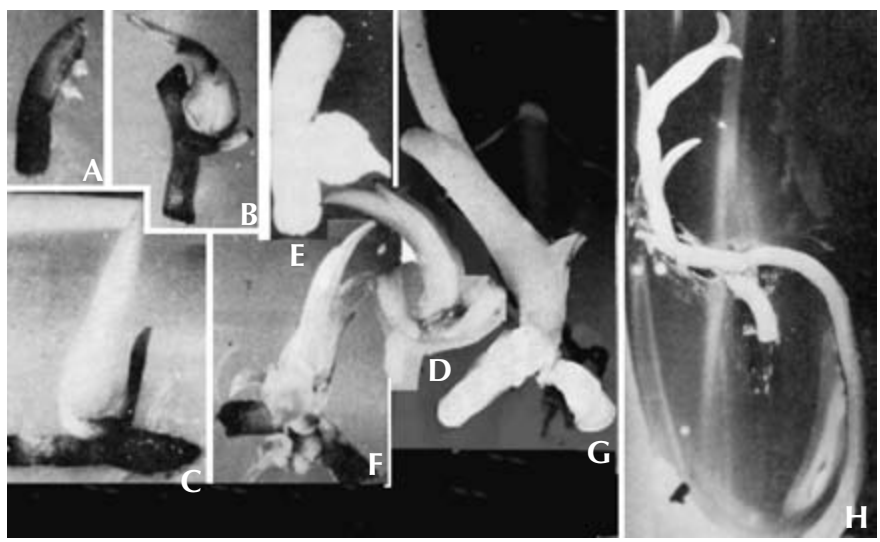

FIG. CYM-5. **Node culture of *Cymbidium pendulum*. A. PLB formation at an internode region. B. Vegetative bud (shoot bud) at an internodal area. C, D. Early stages of plantlet formation. E. Bud with shoot tip. F. Plantlet during early stages of development with a cluster of buds at its base. G. Plantlet with two roots. H. Eight-week-old plant. (Vij, 1993.)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe calls for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses. If the auxin fails to dissolve add a few drops of 0.1N KOH.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved add the charcoal (item 18) with vigorous and constant stirring, pour the solution into culture vessels, and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat-labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976; Vij, 1993; Vij et al., 1994*a*).

Propagation of *Cymbidium giganteum* through the Culture of Shoot Apices and Encapsulation of Protocorm-like Bodies in Sodium Alginate

Micropropagation of orchids would be simpler if PLBs could be grown in soil and/or sand rather than sterile culture media. A method involving encapsulation of PLBs in sodium alginate makes this possible (Corrie and Tandon, 1993).

Plant Material. Apices, 1–2 mm in length, are excised from 1-cm-long shoot tips and cultured.

Surface Sterilization. In the original research the shoot tips were washed with running tap water for 1 h (this may be somewhat long; a shorter wash with water and a mild detergent followed by several rinses will probably be sufficient). After that they were surface-sterilized by submerging them with agitation in 0.57% sodium hypochlorite (9.5 or 11 ml of a household bleach such as Clorox which contains 6 or 5.25% sodium hypochlorite, respectively, diluted to 100 ml with distilled water; plus a few drops of mild household detergent as a wetting agent) for 5 min and rinsed several times with sterile distilled water.

Culture Vessels. Test tubes, 25 × 150 mm, or 125-ml Erlenmeyer flasks filled with medium to 20–30% of their capacity are suitable for initial cultures. Larger containers may be needed for further proliferation.

Culture Conditions. Cultures were maintained at 25 ± 2°C under 14-h photoperiods of 2000 lx (light sources were not described) and 80% relative humidity (RH). Standard culture room conditions are also suitable. Encapsulated PLBs were grown for 2 weeks in pots covered with polyethylene bags and sprayed with water twice daily. After 2 weeks the polyethylene bags were removed and the pots were transferred to a greenhouse at 20–25°C and 60–70% RH.

Culture Media. Explants should be cultured on modified MS medium (Murashige and Skoog, 1962; Table Cym-38). A different modification of MS (Table Cym-39) is required for encapsulated PLBs. Sterile sand (0.3 mm grain size) or a sterilized soil mixture [sand : garden soil : cow dung in a ratio of 1 : 1 : 1 (v/v/v) plus a few small brick pieces] should be used.

Encapsulation Solutions. Two modified MS solutions, both containing fungicides and bactericides, are used for encapsulation. One (Table Cym-40) has 4% sodium alginate (4 g sodium salt of alginic acid made to 1 l with liquid MS solution; sodium alginate as low-viscosity "alginic acid sodium salt, sodium alginate" can be obtained from Sigma, P. O. Box. 14508, St. Louis, MO, 63178, USA, www.sigmaaldrich.com). The other contains 100 mmol of calcium nitrate (Table Cym-41).

Procedure. Shoot tips must be washed and surface-sterilized following removal from the plant. Their apices should be excised under sterile conditions after that and placed in culture on the first medium (Table Cym-38). Once PLBs form they can be

TABLE CYM-38. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Cymbidium giganteum* shoot tips (Corrie and Tandon, 1993)**

15	Calcium nitrate, $Ca(NO_3)_2{\cdot}4H_2O$	23.65 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve add 0.1N KOH or HCl, respectively.

[g]Add all items to 900 ml of distilled water (item 16), adjust pH to 5.8, and adjust volume to 1000 ml with distilled water (item 16). Pour the solution into a 2-l flask, autoclave, cool, and use as needed.

subcultured a few times should it be necessary to increase their number. Overproliferation should be avoided because it can cause undesirable mutations.

When PLBs reach 3–4 mm in size they can be encapsulated. This is done by mixing them with the alginate solution (Table Cym-40) and dropping the mixture (with

the help of a sterile small spoon or spatula) into the calcium nitrate solution (Table Cym-41). Gelling and bead (firm, round, 6–9 mm in diameter) formation require approximately 30 min. The beads can be separated with a sieve after that and placed on MS medium in vitro (Table Cym-39), sand or soil. The conditions used for explant culture are also suitable for culturing beads on MS. Those in pots should be grown as outlined above.

Developmental Sequence. Explants in culture produce PLBs. On being subcultured, the PLBs proliferate. Encapsulated PLBs produce plantlets in pots or in vitro.

General Comments. This procedure simplifies plantlet production because encapsulated PLBs can be grown in pots.

Plantlet Production from *Cymbidium goeringii* Flower Buds

Cymbidium goeringii, one of the temperate oriental cymbidiums, is mostly grown as an ornamental, but the flowers are also used for an alcoholic drink, as components of a soup recipe, and in a tea. The species is in demand, but propagation through division is slow. Like other oriental *Cymbidium* species, *C. goeringii* has not been easy to propagate through seed germination and tissue culture. However, a method was developed for plantlet production from young flower buds (Shimasaki and Uemoto, 1991).

Plant Material. Apical flower buds, 2 mm long, taken from 5-cm long inflorescences are used as explants.

Surface Sterilization. The inflorescences must first be washed with running water. Following the wash and after excision, the apical sections should be immersed for 10 min in 1% sodium hypochlorite (17 or 19 ml of Clorox or another household bleach which contains 6 or 5.25% sodium hypochlorite diluted to 100 ml with distilled water) containing 0.01% Tween 20 (0.1 ml or a few drops per 1000 ml; available from Acros Organics at www.fishersci.com; a few drops of mild household detergent can be used instead of Tween 20). After the soaking, the now surface-sterilized sections should be washed three times with sterile distilled water.

Culture Vessels. Flat bottom vials (Fig. Cym-6C) and bottles (Fig. Cym-6D) were used in the original research. Other vessels are also suitable.

Culture Conditions. In the original research cultures were maintained at 25 ± 1°C under continuous illumination of 75 μmol m^{-2} s^{-1} provided by Toshiba Bio-Light fluorescent lamps. Standard culture room conditions are probably also suitable.

Culture Media. One modification of the MS medium (Murashige and Skoog, 1962) is suitable for initial culture of the explants (Table Cym-42). A second modification should be used for rhizome development and subsequent plantlet growth (Table Cym-43).

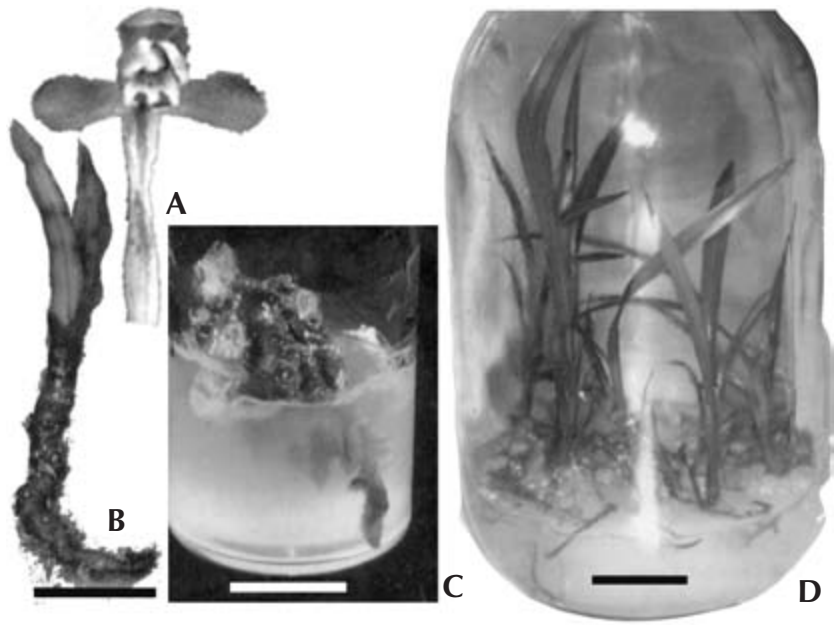

FIG. CYM-6. **Culture of *Cymbidium goeringii* flower buds. A. Flower. B. Rhizome and shoot development after 107 days (bar = 2 mm). C. Branching rhizome (bar = 10 mm). D. Multiple shoots on rhizome branches following 6 months of subculture (bar = 10 mm). (Shimasaki and Uemoto, 1991.)**

Procedure. Apical segments containing flower buds at their apices should be excised from the washed inflorescences and surface-sterilized and then washed with sterile distilled water. After that it is necessary to remove excess flower stalk tissues before placing the explants horizontally on the agar surface of the first medium (Table Cym-42). Rhizomes that form on this medium should be transferred to the second one (Table Cym-43) for plantlet formation and growth.

Developmental Sequence. Buds become swollen by the first week. Some of the swollen buds produce chlorophyll within 2 weeks of culture. Explants on appropriate media can start to produce elongated rhizomes after approximately 8 weeks of culture (Fig. Cym-6B). The rhizomes may produce multiple shoots and branches (Fig. Cym-6C, D). Shoots form within 15 weeks on the first medium (Table Cym-42). Roots appear and plantlets form following transfer to the second medium (Table Cym-43). When these plantlets become large enough, they can be moved to pots.

General Comments. The major advantage of this procedure is that removal of the explant does not endanger the donor plant. A second advantage is explant abundance. Third, the procedure is relatively simple and easy to master. And, fourth, for those who wish to use this procedure, the original paper is clear, concise, well written, and contains all relevant information.

TABLE CYM-42. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of *Cymbidium goeringii* flower bud explants (Shimasaki and Uemoto, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.2–5.6, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.2–5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Shoot Proliferation in *Cymbidium aloifolium*

A frequent complaint by those suffering through the frequent orchid name changes is that these gymnastics are the work of taxonomists who sit in musty herbaria and look at dry and dead plants, which are often hard to distinguish from each other. A good example of this is *Cymbidium aloifolium* which has been confused with *Cymbidum finlaysonianum*, *Cymbidium pendulum*, *Cymbidium pubescens*, and especially *Cymbidium bicolor* (Du Puy and Cribb, 1988). Living plants in the field of these two species are easy to tell apart (Comber, 1990). And contradictory statements by one and the same taxonomist about the distribution of this species have added to the confusion: "*C. aloifolium* extends to W. Malaysia and Java . . . , but has not been recorded from Sumatra and Borneo" (Du Puy and Cribb, 1988) versus "Distribution: India, Sri Lanka, Burma and S. China to Java and Sumatra" (Bechtel et al., 1986, 1992). The confounding of information about distribution is a result of inattention to detail (the two contradictory statements share an author – see citations above) and/or insufficient knowledge because the species was collected at 1100 m in Lubuk Sikaping in West Sumatra by H. A. B. Bünnenmeijer (Comber, 2002), who was a collector for the Bogor Herbarium between 1916 and 1921, and was reported to occur in Sumatra (Latif, 1960; Holttum, 1964) and Borneo (Latif, 1960 who added the proviso that *C. aloifolium* is "also known by the name *Cymbidium pubescens*"). Regardless of the confusion about its nomenclature and distribution, *C. aloifolium* is of interest to growers and is therefore found in commerce. Because of this, a micropropagation method has been developed for it (Nayak et al., 1997*b*).

Plant Material. Shoot explants, 6–15 mm long, with 1–2 nodes were taken from "plants raised in vitro." They were placed in culture after all leaves "along with their sheathing bases were removed."

Surface Sterilization. There is no need to surface-sterilize explants taken from plants growing in vitro, but agar medium residues must be washed away with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, 150-ml capacity, containing 35 ml of medium were used in the original research. Other culture vessels can also be suitable.

Culture Conditions. The research cultures were maintained at $25 \pm 1°C$ and 55–60% relative humidity (RH) under 16-h photoperiods of 35 $\mu E\ m^{-1}\ s^{-1}$ provided by cool white fluorescent tubes (Philips, India). Donor plants were maintained under the same conditions.

Culture Media. Explants should be placed first on a modification of MS medium (Murashige and Skoog, 1962) containing TDZ and no other hormones (Table Cym-44). After buds form (about 10–12 days following the start of culture), the explants should be transferred to a BA-containing medium (Table Cym-45). The elongated shoots (15–15 days after the transfer) develop roots on a medium (Table Cym-46) containing IBA.

TABLE CYM-44. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of shoot explants of *Cymbidium aloifolium* (Nayak et al., 1997*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Cytokinin				
10	Thidiazuron (TDZ)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Dissolve the thidiazuron (TDZ) in a small volume of 0.5N HCl and make up to volume (100 ml) with 70 or 95% ethanol. The amount of TDZ used in the original research was 2.2 µmol (485 µg) l^{-1}. A slightly larger amount, 500 µg (0.5 mg, 2.26 µmol), is recommended here for convenience (0.5 mg is easier to weigh than 0.485 mg). The difference (0.015 mg, 15 µg, or 0.06 µmol) is insignificant and can be ignored. Sticklers for accuracy and those with infinite patience and/or plenty of time on their hands may still use 0.485 mg l^{-1}.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH as required, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE CYM-45. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of new shoots from shoot explants of *Cymbidium aloifolium* (Nayak et al., 1997*b*)**

(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	2.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzyladenine (BA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively. In the original research the auxin used was 10.8 µmol (2010.9 µg or 2.011 mg) l^{-1}. The amount recommended here is 2 mg (10.74 µmol) l^{-1}. This differs from the original by an insignificant 0.011 mg or 0.06 µmol which can be ignored. Benzyladenine (BA) was used at 2.2 µmol (495.66 µg or 0.496 mg) l^{-1} in the original research. The amount recommended here, 0.500 mg (2.22 µmol), differs from the original by 4 µg (0.004 mg or 0.02 µg). This is insignificant and can be ignored by all except sticklers for accuracy.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH as required, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE CYM-46. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the rooting of *Cymbidium aloifolium* shoots obtained from shoot tips in vitro (Nayak et al., 1997*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH. In the original research 10.8 µmol (2.196 mg) were added. The amount recommended here, 2.2 mg (10.85 µmol), differs from the original by an insignificant 0.004 mg or 0.05 µmol. Those who insist on absolute and total accuracy can use the original amounts which fall within experimental error and are beyond the reproducibility limits of most laboratory balances.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH as required, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Procedure. Explants must be freed of leaves after they are excised from the seedlings. The explants should then be placed on the first medium (Table Cym-44) and allowed to remain on it until new shoots form. These shoots should be transplanted onto the second medium (Table Cym-45) and allowed to elongate. The elongated shoots must be moved to the third medium (Table Cym-46) for rooting.

Developmental Sequence. Vegetative buds form on the explants 10–20 days after they are placed on the first medium (Table Cym-44). Their development and elongation continues until the eighth week. Following their transfer to the second medium (Table Cym-45), the shoots elongate within 12–15 days. Roots are formed only after the elongated shoots are moved to the third medium (Table Cym-46).

General Comments. This is an interesting method which cannot be used for the selection of desirable cultivars because the explants are taken from seedlings. Still, it should be tried with explants taken from the shoot tips of mature plants.

Rapid Micropropagation of *Cymbidium aloifolium* through the Culture of Thin Cross Sections

Excision of shoot tips for micropropagation may endanger the donor plant. Leaf tips and bases cannot always be cultured or made to produce PLBs and plantlets. The culture of flower stalk buds is possible in only a few orchids. Abundant explants are frequently not available. Therefore tissue culture scientists are constantly searching for new explants that can be used for micropropagation. Thin cross sections (TCSs) of stems are among the explants being explored more recently (Nayak et al., 2002).

Plant Material. Shoots, each with 1–2 nodes, were taken from asymbiotic seedlings cultured on a modification of the MS medium (Murashige and Skoog, 1962; Table Cym-47) at 25 ± 1°C, 60% relative humidity (RH), and under continuous illumination of 35 μmol m^{-2} s^{-1} provided by cool white fluorescent tubes (Philips, India). Standard culture room conditions may also be suitable but continuous illumination is advisable. When PLBs produced by these shoots were 60 days old they were used as sources of explants. Serial transverse TCSs of these PLBs made by hand with sterile razor blades were cultured. Sterilized scalpels can also be used to section the PLBs.

Surface Sterilization. There is no need to surface-sterilize explants from plants taken from in vitro cultures, but they must be washed to remove agar and medium residues. Razor blades or scalpels used to section the PLBs must be sterilized initially by autoclaving. During use it is necessary to frequently flame and/or dip them in alcohol.

Culture Vessels. Erlenmeyer flasks, 150-ml capacity, were used in the original research. Other containers can also be used. Culture vessels should be filled with medium to 20–30% of their capacity.

TABLE CYM-47. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of shoots of *Cymbidium aloifolium* (Nayak et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. According to the original paper the medium was "semisolid." This suggests a lower amount of agar than the usual 10 g l^{-1}. The paper suggests 8 g agar l^{-1} for another medium. That is why this amount is suggested here. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Culture Conditions. In the original research the cultures were maintained at 25 ± 1°C, 60% RH, and continuous illumination of 35 μmol m^{-2} s^{-1} provided by cool white fluorescent tubes (Philips, India). The TCSs were cultured in liquid medium on a rotatory shaker at 80 rpm. TCSs can also be cultured on semisolid medium (8 g agar l^{-1}), but proliferation will be less than in liquid.

Culture Media. The explants are cultured on a modification of the MS medium (Murashige and Skoog, 1962) containing the cytokinin zeatin riboside (Table Cym-48). Shoots produced by the TCSs are cultured on a modification of MS containing the auxin IBA (Table Cym-49).

Procedure. Shoots should be taken from seedlings, freed of their leaves, and cultured on semisolid modified MS (Table Cym-47) for 50–60 days until they produce PLBs. These PLBs should be resectioned into TCSs, 0.5 mm thick, which are cultured in liquid modified MS (Table Cym-48) until they produce shoots. To bring about root formation, the shoots must be transferred to solid modified MS (Table Cym-49).

Rooted plantlets with three to four well-developed leaves should be removed from the culture, washed well to remove all agar, and potted in potting mix consisting of peat moss, wood charcoal, and brick (in a ratio of 1 : 1 : 1) in 7.5-cm diameter pots. Originally, the potted plants were placed in a growth chamber at 25 ± 1°C and 80% RH under a light intensity of 35 μmol m^{-2} s^{-1} for 8–10 weeks before being moved to the field.

Developmental Sequence. The explants first become swollen and then turn green. Small protuberances appear on the swollen green explants 15 days after the start of culture. These protuberances develop into PLBs approximately 10 weeks after the cultures are initiated. The PLBs produce shoots and plantlets after about 12 weeks of culture. On being transferred to the rooting medium, plantlets with two to three expanded leaves produce roots in about 30 days. The rooted plantlets acclimatize after being grown in a growth chamber for 8–10 weeks.

General Comments. The use of thin sections is a novel and interesting approach. However, this procedure is more interesting as a research tool than a micropropagation method because the initial explants are taken from seedlings. Adapting the TCS method to adult plants will be a worthwhile advance.

TABLE CYM-48. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of thin cross section explants of *Cymbidium aloifolium* (Nayak et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10

	Solvent				
15	Water, distilled[g]	To 1000 ml			
	[Solidifier]				
[16	Agar[g]	8.0 g	No stock	No stock	Weigh]

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15) **[**bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved**],** pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. More explants proliferate in liquid than on solid medium (95 vs 89%) and produce a higher number of protocorm-like bodies (33.5 vs 28.2 PLBs per explant). That is why this medium should be liquid. However, if a shaker is not available the explants can be cultured on a semisolid medium. To allow for such an eventuality the agar (item 16) in the table and instructions regarding its incorporation in this footnote are in bold square brackets.

TABLE CYM-49. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the rooting of shoot produced by thin cross section explants of *Cymbidium aloifolium* (Nayak et al., 2002)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1 N KOH.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Protocorm-like Body Formation from Epidermal and Subepidermal Cells of *Cymbidium*

Cymbidium was the third orchid to be propagated through tissue culture in vitro and the second to have its shoot tip cultured, not the first as claimed erroneously since 1960 (Morel, 1960; see Chapter 1 and for a review see Arditti and Krikorian, 1996). However, it seems to be the first orchid whose epidermal and subepidermal cells and tissues produced PLBs in vitro (Begum et al., 1993; Begum et al., 1994*a*).

Plant Material. PLBs of *Cymbidium* Thanksgiving 'Nativity' derived from shoot-tip cultures were cultured and subcultured at monthly intervals in liquid MS medium (Murashige and Skoog, 1962; Table Cym-50) on a rotary shaker at 1 rpm and 25 ± 1°C under continuous illumination of 20 $\mu m^{-2}\ s^{-1}$ provided by white fluorescent tubes (FL 20 S. W., Toshiba, Tokyo). PLBs, 3–4 mm in diameter, were sectioned horizontally at a right angle to the main axis into two or three sections. Outer tissue (OT) explants were peeled from the PLB sections by removing a sheet composed of 10–12 epidermal and subepidermal cell layers. OT sections lacking buds or outgrows were cultured.

Surface Sterilization. Explants taken from PLBs grown axenically in vitro do not require surface sterilization. However, excision and placing of explants in culture must be carried out under sterile conditions with sterilized tools. While being used, these tools must be dipped frequently in alcohol and/or flamed to maintain sterility.

Culture Vessels. The original paper states only that "culture flasks" or "flasks" were used. Test tubes and/or Erlenmeyer flasks are suitable for liquid medium on a shaker. Several different containers can be used for cultures on a solid medium.

Culture Conditions. OT as well as tissues and structures derived from them were cultured at 25 ± 1°C under 16-h photoperiods of approximately 30 $\mu m^{-2}\ s^{-1}$ provided by white fluorescent tubes (FL 20 S. W., Toshiba, Tokyo). Standard laboratory conditions are also suitable.

Culture Media. OT should be cultured initially on a modification of MS (Table Cym-51). PLBs that form on this medium develop into plantlets when cultured on a second modification of MS (Table Cym-52).

Procedure. PLBs derived from shoot-tip cultures should be increased in number on liquid MS (Table Cym-50) by subculturing them monthly. Overproliferation of PLBs must be avoided since it can cause undesirable mutations. PLBs from liquid cultures should be taken out under sterile conditions with sterilized tools and sectioned. This can only be done under a dissecting stereomicroscope. After the sections are peeled, those lacking buds or any other growths should be placed in culture on liquid MS (Table Cym-51). PLBs that form on this medium should be subcultured onto a different MS modification (Table Cym-52) for plantlet production.

TABLE CYM-50. **Liquid-modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for proliferation of protocorm-like bodies derived from shoot tips (Begum et al., 1994*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively. The original paper states that liquid medium was used but does not indicate whether any hormones were used and if so how much. The amounts suggested here are estimates.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH as required, add sugar (item 15), raise volume to 1000 ml with distilled water (item 16), pour the solution into a 2-l flask, and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE CYM-51. **Liquid-modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of epidermal cell peels (outer tissue) of *Cymbidium* (Begum et al., 1994*a*)**

	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH as required, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Developmental Sequence. PLBs in liquid medium on a shaker proliferate and multiply. When OT sections are placed in culture there are many cell divisions on the surface and deeper in the tissue. The explants turn light brown after seven days in culture. Gray transparent protuberances appear following an additional 7 days. These protuberances become globular and turn green (i.e., become PLBs) after a total of 21 days in culture. Shoots moved to the second solid medium develop into plantlets within 8 weeks.

General Comments. As an advance in orchid tissue culture and the identification of yet another explant source, this procedure is significant and interesting. However, it is of limited value as a micropropagation method because the PLBs which are used as explant sources can be grown into plantlets without the added steps of subculturing, slicing, peeling, culturing the peels, and then producing plants from the newly produced bodies. The value of this procedure will increase enormously if it can be adapted to epidermal peels from mature plants.

Plant Production through Callus Culture of *Cymbidium ensifolium* var. *misericors*

This orchid is another case that requires a consideration of taxonomy and nomenclature. *Cymbidium ensifolium* is a variable species which has been cultivated in China for a long time (Chen and Tang, 1982). Chinese taxonomists who had more opportunities than other systematists to observe different variants of the species recognized many subspecies, forms, and naturally occurring varieties (for one example see Yen, 1964). Taxonomists who studied the species elsewhere (for reviews see Seth and Cribb, 1984; Du Puy and Cribb, 1988) also observed varieties. One form was accorded varietal status as *C. ensifolium* var. *misericors* by some and elevated to species level, *Cymbidium misericors*, by others. Two British taxonomists who presumably depended heavily on herbarium specimens at the Royal Botanic Gardens, Kew, but had more limited access than Chinese botanists to a large number of living plants, relegated *C. misericors* to synonymy under *C. ensifolium* without a satisfactory explanation (Seth and Cribb, 1984; Du Puy and Cribb, 1988). A recent review from Korea uses *C. misericors* as the name of the species stating that it "is synonymous with *C. ensifolium*" (Paek and Murthy, 2002) also without giving any reason for their pronouncement. It is not clear where all these classifications and reclassifications leave *C. ensifolium* var. *misericors* and it does not really matter. Its flowers are and will continue to be beautiful and delightfully fragrant regardless of its taxonomic status. Be all this as it may, a method for clonal propagation was developed for this orchid in Taiwan (Chang and Chang, 1998).

Plant Material. Segments, 1 cm in length, of roots as well as pseudobulbs and rhizomes with lateral buds taken from 7–8-cm-long seedlings produced callus masses when cultured. Similar leaf explants did not produce callus.

Surface Sterilization. Explants taken from seedlings in axenic cultures do not require surface sterilization, but they must be rinsed thoroughly with sterile distilled

water to wash away medium and agar residues. All tools and work areas must be sterile.

Culture Vessels. Test tubes, Erlenmeyer flasks, and other containers can be used. They should contain medium equivalent to one-fifth of their volume.

Culture Conditions. The original paper states that "cultures were maintained for 6 months at 25 ± 2°C in darkness or exposed to artificial light (daylight fluorescent tubes FL-30D/29, 40 W, China Electic Co., Taipei) at 28–26 μmol m^{-2} s^{-1} with light dark cycle of 14/10 h[ours] at 26 ± 2°C." However the paper does not make clear which explants were exposed to light or kept in the dark. Therefore in practical applications of this procedure it will be necessary to keep some initial explants in the light and others in the dark. Callus derived from rhizomes should be maintained in the dark until sections are subcultured for plantlet production. The latter should be cultured at 26 ± 2°C under 14-h photoperiods of 28–26 μmol m^{-2} s^{-1} provided by daylight fluorescent tubes as above.

Culture Media. Initial explants intended for callus production should be cultured on modified MS medium (Murashige and Skoog, 1962) that contains an auxin and a cytokinin (Table Cym-53). A second modification of MS (Table Cym-54) is suitable for the maintenance of callus masses. However the original paper is not entirely clear in this respect. The text states that "a medium supplemented with 3.3 mg/l 2,4-D and 0.1 mg/l TDZ was selected as the standard maintenance medium for . . . calli." But the caption of a table which shows results obtained with different hormone concentrations and includes levels selected for the standard maintenance medium (Table Cym-54) refers only to "rhizome-derived calli." In the absence of another medium, the standard maintenance medium (Table Cym-54) should be used to maintain calli regardless of their origin. After four subcultures it is necessary to subculture callus sections onto a basal medium free of hormones (Table Cym-55). Globular bodies produced on this medium (Table Cym-55) produce rhizomes when transferred to a very dilute substrate (Table Cym-56). These rhizomes produce plants when moved to yet another modification of MS (Table Cym-57).

Procedure. Several steps are part of this somewhat complex method:

1. Explants are removed from seedlings and are cultured on the first medium (Table Cym-53) until callus is produced.
2. Callus masses produced from the explants are subcultured 2–3 times on the first medium (Table Cym-53) at 6-month intervals.
3. Sections of the callus are subcultured and maintained on the second medium (Table Cym-54).
4. After the callus has been subcultured four times on the maintenance medium, a small portion of about 500 mg should be moved to the third solution (Table Cym-55).
5. Globular bodies that arise on the third solution produce rhizomes when placed on the fourth medium (Table Cym-56).
6. The rhizomes should be moved to a final medium (Table Cym-57) for plantlet production.

TABLE CYM-53. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of *Cymbidium ensifolium* var. *misericors* explants (Chang and Chang, 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macroelements and microelements in this table are half those in the original formulation of the Murashige–Skoog medium

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–8, 10, and 17 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 18). Add Gelrite as described in footnote *h* below. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 9), hormones (items 11 and 12), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier (agar or Gelrite) is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYM-54. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the maintenance of *Cymbidium ensifolium* var. *misericors* callus (Chang and Chang, 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	Monosodium phosphate, NaH_2PO_4	170.0	17.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	18.7	1.87 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	13.9	1.39 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.415	4.15 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.125	12.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
9	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
11	2,4-Dichlorophenoxyaceticacid (2,4-D)	3.3	33 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
12	Thidiazuron (TDZ)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
17	Peptone[g]	1.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[h]	To 1000 ml			
	Solidifier				
19	Gelrite[h,i]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macroelements and microelements in this table are half those in the original formulation of the Murashige–Skoog medium. The original paper does not make clear whether this medium contains NaH_2PO_4. It is included in this table because its presence or absence probably makes no difference.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]It is not clear from the original paper if this medium contains peptone. Should this procedure be used for practical purposes it is advisable to initially try media with and without peptone.

[h]Add items 1–8, 10, and 17 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 18). Add Gelrite in accordance with the instructions in footnote *i* below. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 9), hormones (items 11 and 12), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier (agar or Gelrite) is not added to liquid media.

[i]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYM-55. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the induction of globular granule masses from callus of *Cymbidium ensifolium* var. *misericors* (Chang and Chang, 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	18.7	1.87 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	13.9	1.39 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.415	4.15 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.125	12.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[f]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[f]	1	
	Sugar				
13	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
14	Peptone[g]	1.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Gelrite[g,h,i]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macroelements and microelements in this table are half those in the original formulation of the Murashige–Skoog medium.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]The callus will produce the "globular granules" (a picture in the original paper suggests that the granules are actually protocorm-like bodies) on a medium which is free of growth regulators or contains 1 mg TDZ l^{-1} or 5 mg benzyladenine (BA) l^{-1}. A medium without growth regulators is preferable.

[f]Keep frozen between uses.

[g]It is not clear from the original paper if this medium contains peptone. Should this procedure be used for practical purposes it is advisable to initially try media with and without peptone.

[h]Add items 1–7, 9, and 16 to 900 ml of distilled water (item 15), adjust pH to 5.2, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 15). Dissolve the Gelrite in accordance with the instructions in footnote *i* below. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone if used, and vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier (agar or Gelrite) is not added to liquid media.

[i]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYM-56. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for rhizome induction from globular granules of *Cymbidium ensifolium* var. *misericors* (Chang and Chang, 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	165.0	16.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	44.0	4.4 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	37.0	3.7 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	190.0	19.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	17.0	17.0 g l^{-1}		
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	3.73	0.373 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	2.78	0.278 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additives				
9	Peptone	1.0 g	No stock	No stock	Weigh
10	Coconut water[e]	150.0 ml	No stock	No stock	Measure
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Gelrite[f,g]	2.2 g	No stock	No stock	Weigh
	Darkening agent				
13	Activated charcoal[h]	1.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. What the original paper refers to as globular granules are probably protocorm-like bodies.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]This is probably the liquid endosperm of coconuts which should be referred to as coconut water. It is best to use water from green (i.e., immature) nuts. However water from mature nuts can also be used. Both immature (with the green outer covering removed so that they are white) and mature (brown) nuts can be found in food stores (especially those specializing in Asian foods) where coconuts do not grow. Canned or frozen coconut water or milk (grated and homogenized endosperm which is sometimes called meat) should not be used because they usually contain sugar and preservatives.

[f]Add items 1–7, 9, and 10 to 750 ml of distilled water (item 11), adjust pH to 5.2, add sugar (item 8), and raise volume to 1000 ml with distilled water (item 11). Dissolve the Gelrite in accordance with the instructions in footnote *g* below. When the Gelrite is completely dissolved add the chacoal slowly with vigorous stirring, pour the medium into culture vessels, and autoclave.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

[h]When the agar is completely dissolved add the darkening agent (item 13) slowly with vigorous stirring. When the charcoal is completely dispersed pour the solution into culture vessels and autoclave.

TABLE CYM-57. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for plantlet production of *Cymbidium ensifolium* var. *misericors* explants (Chang and Chang, 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	18.7	1.87 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	13.9	1.39 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.415	4.15 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.125	12.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Cytokinin				
8	Benzyladenine (BA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water	To 1000 ml			
	Solidifier				
11	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macroelements and microelements in this table are half those in the original formulation of the Murashige–Skoog medium.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]It is not clear from the original paper whether sucrose is present in this medium. A test may be required to determine whether sucrose is needed or not.

[f]Add items 1–7 to 900 ml of distilled water (item 10), adjust pH to 5.2, add sugar if it is used (item 9), and adjust volume to 1000 ml with distilled water (item 10). Dissolve the Gelrite in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into culture vessels and autoclave.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

7 After 4 months on the last medium, the plantlets reach 5 cm in height and can be moved to pots in a greenhouse.
8 The potted plants grow to marketing size in 3 months.

Developmental Sequence. Soft, yellow calli form on the cut areas of root explants on the first medium (Table Cym-53). The lateral buds on rhizome and pseudobulb

explants produce swollen and granular proliferations which form soft, yellow callus after two or three subcultures on the initial solution (Table Cym-53). This soft, yellow callus proliferates and remains totipotent on the maintenance medium (Table Cym-54). Globular granules are produced by the callus on a medium that does not contain growth regulators (Table Cym-55). These globules develop into rhizomes on the fourth medium (Table Cym-56). When moved to the fifth medium (Table Cym-57), the rhizomes produce plants which can be moved to pots. The potted plants grow, become larger, and reach commercial size in a greenhouse.

General Comments. This is a very complex procedure which cannot be used to select and propagate outstanding cultivars because the explants are taken from seedlings. It can only be used to increase the number of plants. Therefore it may be superfluous if enough seedlings can be obtained through seed germination. There are also possible problems with this procedure. One is the high (10 mg l^{-1}) and therefore possibly mutagenic level of 2,4-D in the initial medium (Table Cym-53). A second problem is the presence of 2,4-D (3.3 mg l^{-1}) in the maintenance medium (Table Cym-54). This concentration may also be mutagenic, if not in itself then because it follows a high 2,4-D level in the initial medium. The multiple subcultures and proliferations, especially in media that contain so much 2,4-D, are a third problem because they may also cause mutations. Still, the procedure is interesting because it may serve as a starting point for the formulation of a method that could be used to propagate mature plants of selected cultivars.

Micropropagation of *Cymbidium ensifolium* var. *misericors* through Callus-derived Rhizomes

The previously outlined method for micropropagation of *Cymbidium ensifolium* var. *misericors* (Chang and Chang, 1998) was modified, starting with the callus-derived rhizome step (Chang and Chang, 2000a).

Plant Material. Apical segments, 1-cm long, of rhizomes produced by the previous procedure (see Tables Cym-53 to Cym-57) should be cultured in the first medium (Table Cym-58). Vegetative (shoot) buds taken from explants in the first medium (Table Cym-58) are used for the second medium (Table Cym-59).

Surface Sterilization. Explants taken from axenic cultures do not require surface sterilization, but they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. In the original research, 400-ml culture flasks containing 25 apical sections in 40 ml of medium were used for liquid cultures (Table Cym-58). Smaller flasks with smaller volumes of medium and fewer explants can also be used. Test tubes or other containers can be used for the second medium (Table Cym-59).

Culture Conditions. The liquid cultures (Table Cym-58) must be placed on a 60-rpm rotary shaker at 25 ± 1°C under 16-h photoperiods of 10 μmol m^{-2} s^{-1}. In

TABLE CYM-58. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of *Cymbidium ensifolium* var. *misericors* rhizome explants (Chang and Chang, 2000*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10

20	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macroelements and microelements in this table are half those in the original formulation of the Murashige–Skoog medium.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses. The actual amounts used in the original research were 0.17 µmol of TDZ and 2iP or 37.45 and 34.54 µg, respectively. Both are rounded up here. The differences (2.55 and 5.46 µg respectively) are insignificant. The original paper states that one of the cytokinins added to this medium was "6-aminopurine adenine." Adenine is 6-aminopurine. So, writing "6-aminopurine adenine" is like saying adenine adenine. Chances are that the authors meant N^6-benzyladenine which is usually referred to as benzyladenine or BA as suggested in this table. The actual amount used by the authors is 7.44 mg. It was rounded here to 7.4 mg.

[f]If the auxin or cytokinins do not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–8, 10, and 19 to 900 ml of distilled water (item 20), adjust pH to 5.2, add sugar (item 18), raise volume to 1000 ml with distilled water (item 20), pour the solution into a 2-l flask, and autoclave. Add the amino acid (item 9), hormones (items 11–14), and vitamins (items 15–17) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier (agar or Gelrite) is not added to liquid media.

the original research the illumination was provided by 40-W tubes (China Electric Co., fluorescent tubes FL-30D). Similar tubes (40-W fluorescent tubes of some type) produced by other manufacturers can also be used. It is necessary to maintain solid cultures (Table Cym-59) under the same conditions, but without placing them on a shaker. After being potted, plantlets produced in the second medium (Table Cym-59) should be maintained under mist and 50% shade for the first 2 months and then moved to standard greenhouse conditions.

Culture Media. Explants taken from rhizomes produced by the previous procedure (see Tables Cym-53 to Cym-57) must be cultured in a liquid medium (Table Cym-58). A solid medium (Table Cym-59) is used for explants taken from rhizomes and maintained in the liquid medium (Table Cym-58). Plantlets produced on the second medium should be potted in sphagnum moss in 2.5-cm diameter pots.

Procedure. Explants taken from rhizomes produced by the previous procedure (see Tables Cym-53 to Cym-57) should be cultured in liquid medium (Table Cym-58) and allowed to develop for 3–6 weeks. After that it is necessary to take vegetative (shoot) buds from the rhizomes in the liquid solution (Fig. Cym-7B–D and Table Cym-58), place them on the second medium (Table Cym-59), and allow them to form plantlets. On reaching a height of 60–65 mm these plantlets should be taken out of the culture, washed to remove all remnants of gel that may adhere to them, and potted in the sphagnum moss (Fig. Cym-7F). The pots should be maintained under mist and 50% shade for 2 months and after that moved to standard greenhouse conditions.

Developmental Sequence. The explants form buds in the liquid medium. When excised and cultured on the second medium these buds develop plantlets.

General Comments. This procedure is a refinement of the method described in the section above, Plant Production through Callus Culture of *Cymbidium ensifolium* var. *misericors* (see Tables Cym-53 to Cym-57).

Cymbidium pendulum

TABLE CYM-59. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for plantlet production from *Cymbidium ensifolium* var. *misericors* rhizome explants (Chang and Chang, 2000*a*)**

[a]Amounts are given in mg unless indicated otherwise. The concentrations of mineral salts in this table are half those in the original MS formulation.

[b]Solutions containing ammonium and/or nitrate can become contaminated. Stock solutions should not be prepared. If made they must be stored frozen.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses. The actual amounts used in the original research were 0.17 µmol of TDZ and 2iP or 37.45 and 34.54 µg, respectively. Both are rounded up here. The differences (2.55 and 5.46 µg respectively) are insignificant. The original paper states that one of the cytokinins added to this medium was "6-aminopurine adenine." Adenine is 6-aminopurine. Chances are that the authors meant N^6-benzyladenine which is usually referred to as benzyladenine or BA as suggested in this table. The actual amount used by the authors is 7.44 mg and was rounded down here to 7.4 mg.

[f]If the auxin or cytokinins do not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]The original paper states that "green ripen banana pulp" was used. As a rule, ripe (i.e., the most commonly used) bananas for orchid media are not green when ripe. They are yellow. Also, the pulp is homogenized. The recommendation in this table is to use ripe banana and homogenize it. Opinions differ regarding the use of banana in culture media. The predominant opinion is that only homogenized pulp of ripe banana should be used. Other views are that: (1) unripe (green) bananas are preferable, (2) the peel rather than the pulp should be used, (3) unpeeled banana homogenate should be incorporated in media, and (4) slices, ripe or unripe, peeled or unpeeled, rather than homogenate are most effective. Opinions also differ regarding which is the most effective banana variety (Gros Michel, Raja, Pisang Susu, and others). Since there is no experimental evidence to support any view, the best approach is to follow the recommendations in the original reports and use what is suggested there.

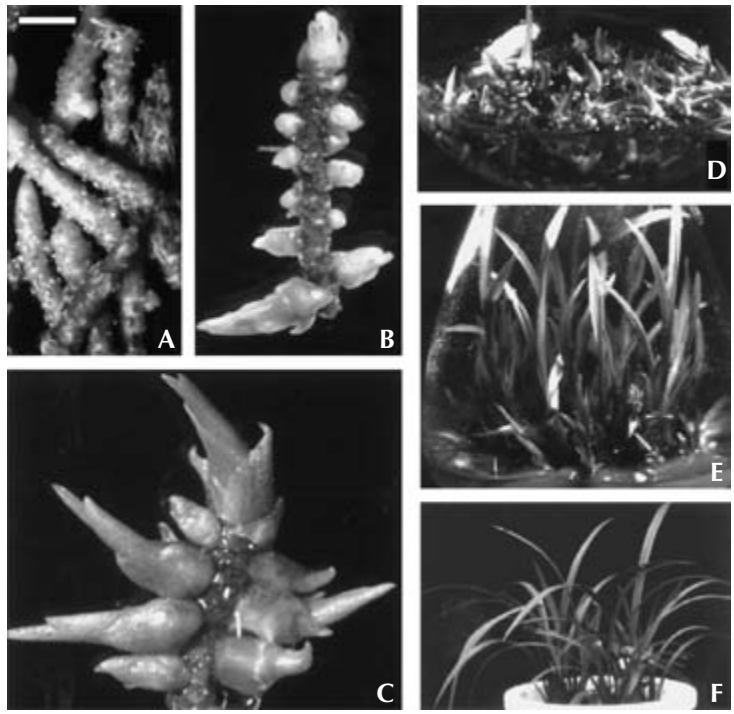

FIG. CYM-7. **Plantlet production from callus-derived rhizomes of *Cymbidium ensifolium* var. *misericors*. A. Callus-derived rhizomes (bar = 3 mm). B–D. Vegetative (shoot) buds on rhizomes from liquid medium after 21 days (B) and 45 days (C, D) of culture. E. Plantlets on solid medium. F. Plantlets in pots. (Chang and Chang, 2000*a*.)**

Plantlet Production from Thidiazuron-induced Buds on Rhizomes of *Cymbidium sinense*

Cymbidium sinense, a terrestrial species, is one of the so-called oriental cymbidiums which are not easy to propagate in vitro (Paek et al., 1993; Paek and Kozai, 1998). It produces fragrant red flowers and is sold as a potted plant. Its seeds can be germinated in vitro, but they produce rhizomes rather than protocorms (Paek et al., 1990; Paek and Murthy, 2002). Propagation through division is slow (Chang and Chang, 2000*b*). Shoot-tip cultures also produce rhizomes (Paek and Murthy, 2002). Therefore a micropropagation method utilizing TDZ-induced buds on seed-derived rhizomes was developed in Taiwan (Chang and Chang, 2002*b*).

[h]Add items 1–8, 10, 19, and 20 to 800 ml of distilled water (item 21), homogenate the pulp thoroughly, adjust pH to 5.2, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 21). Dissolve the Gelrite as indicated in footnote *i* below, pour the solution into a 2-l flask, and autoclave. Add the amino acid (item 9), hormones (items 11–14), and vitamins (items 15–17) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels.

[i]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYM-60. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for proliferation of explants from *Cymbidium sinense* seed-derived rhizomes (Chang and Chang, 2000*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
18	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh
	Darkening agent				
19	Activated charcoal[i]	1.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macroelements and microelements in this table are half those in the original formulation of the Murashige–Skoog medium.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–8, 10, and 16 to 900 ml of distilled water (item 17), adjust pH to 5.2, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 17). Dissolve the Gelrite in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved add the charcoal (item 19) slowly with vigorous stirring, pour the solution into a 2-l flask and autoclave. Add the amino acid (item 9), hormone (item 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier (agar or Gelrite) is not added to liquid media.

Plant Material. Rhizome tip explants, 1–1.5 cm in length, were taken from seedling cultures "during a 4–8 months period."

Surface Sterilization. Explants taken from axenic cultures in vitro do not require surface sterilization. However, all tools and work areas must be sterile.

Culture Vessels. Test tubes, 20×145 mm, were used in the original research. Other containers are also suitable. Plantlets in sphagnum and a potting mix were grown in pots.

Culture Conditions. All cultures were maintained at $26 \pm 1°C$ under 14-h photoperiods. Explants in the proliferation (Table Cym-60) and shoot-tip (Table Cym-61) media were maintained under a light intensity of 5–10 μmol m^{-2} s^{-1}. Bud explants in the plant development medium (Table Cym-62) were placed under 28–36 μmol m^{-2} s^{-1}. Similar (even if not exactly the same) illumination levels are also suitable. Plantlets in moss were grown under mist for 6 months. After being potted in a potting mix plants were cultivated in a greenhouse.

Culture Media. Explants from seedling-derived rhizomes were cultured in modified half-strength MS medium (Murashige and Skoog, 1962) supplemented with 3 mg NAA l^{-1} and darkened with charcoal (Table Cym-60). Apical segments from proliferated rhizomes were cultured in TDZ-containing medium (Table Cym-61). Plantlets were produced in a third medium containing 0.5 mg NAA l^{-1} and also darkened (Table Cym-62). Well-developed plantlets taken from the third medium were potted in sphagnum. Larger plants were moved to soil.

Procedure. Tip explants from seedling-derived rhizomes are cultured in the first medium (Table Cym-60). They should be subcultured every 6 months. The original paper does not suggest how many times to subculture them. As a rule too many subcultures and extensive proliferation must be avoided because they may cause undesirable mutations. Tip explants from the proliferated rhizomes should be cultured in the TDZ-containing medium (Table Cym-61) for 2 months to bring about the formation of vegetative (shoot) buds. The buds must be moved to the last medium (Table Cym-62) for plantlet formation. After 4 months in culture, the plantlets reach

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

[f]When the agar is completely dissolved add the darkening agent (item 19) slowly with vigorous stirring. When the charcoal is completely dispersed pour the solution into culture vessels and autoclave. Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite which are very different in nature should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution, and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

TABLE CYM-61. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for vegetative (shoot) bud induction on *Cymbidium sinense* rhizome explants (Chang and Chang, 2000*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	Monosodium phosphate, NaH_2PO_4	170.0	17.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.013	1.3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.415	4.15 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.125	12.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
9	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
11	Thidiazuron (TDZ)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
16	Peptone	1.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macroelements and microelements in this table are half those in the original formulation of the Murashige–Skoog medium.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If thidiazuron does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–8, 10, and 16 to 900 ml of distilled water (item 17), adjust pH to 5.2, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 17). Dissolve the Gelrite in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 9), hormone (item 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier (agar or Gelrite) is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYM-62. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for plantlet production from buds on *Cymbidium sinense* rhizome explants (Chang and Chang, 2000b)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85.0	8.5 g l^{-1}	10	
6	Monosodium phosphate, NaH_2PO_4	170.0	17.0 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	18.7	1.87 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	13.9	1.39 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.013	1.3 mg l^{-1}

10	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
11	Naphthaleneacetic acid (NNA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
12	Thidiazuron (TDZ)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Complex additive				
17	Peptone	1.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh
	Darkening agent				
20	Activated charcoal[i]	1.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The concentrations of macroelements and microelements in this table are half those in the original formulation of the Murashige–Skoog medium.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–8, 10, and 17 to 900 ml of distilled water (item 18), adjust pH to 5.2, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 18). Dissolve the Gelrite in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved add the charcoal (item 20) slowly with vigorous stirring, pour the solution into a 2-l flask and autoclave. Add the amino acid (item 9), hormones (items 11 and 12), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier (agar or Gelrite) is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

[i]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite which are very different in nature should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution, and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

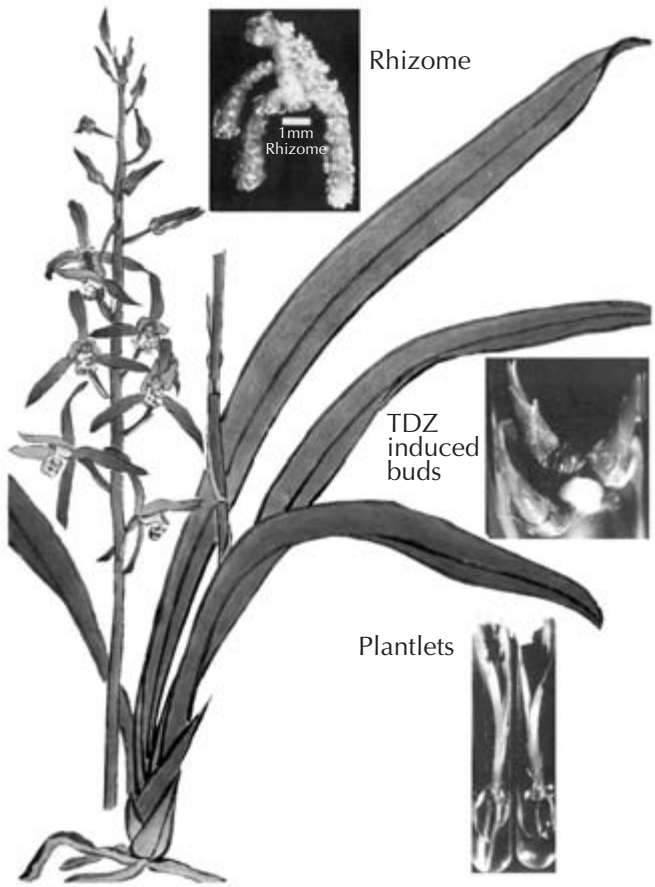

FIG. CYM-8. ***Cymbidium sinense*** **flowering plant, rhizome, buds, and plantlets (photographs from Chang and Chang, 2002*b*; drawing from Yen, 1964).**

a height of 10 cm. At that point they should be taken out of culture, potted in sphagnum, and placed under mist for 6 months. Following that they can be moved to soil and grown in a greenhouse.

Developmental Sequence. The germinating seeds form rhizomes (Fig. Cym-8). Tip explants from these rhizomes can be taken after 4–8 months of growth. These explants proliferate and form new rhizomes with repeated subculturing. Tips from these rhizomes form buds when cultured in a TDZ-containing medium. In the third medium, these buds form plantlets that reach a height of 10 cm in 4 months. When potted first in sphagnum and then in soil and grown in a greenhouse, some of these plants flower in 2 years. After 3 years the plants develop 5–6 shoots, grow to 43 cm in height, and form about 20 roots; 73% of these plants flower normally.

General Comments. This method can be useful for the propagation of *C. sinense*. It shortens the juvenile phase to 2–3 years. This is an important advance in the

cultivation of these slow growing orchids. On the negative side, the original paper is not well written and fails to explain the rationale behind some steps in the procedure.

Production of *Cymbidium aloifolium* Plantlets from Explants of Seed-derived Rhizomes

Several methods exist for shoot proliferation and culture of thin cross sections of *Cymbidium aloifolium*. The group that developed these procedures also formulated a method for the culture of seed-derived rhizomes (Nayak et al., 1998).

Plant Material. Seeds from mature, undehisced fruits were germinated on MS medium (Murashige and Skoog, 1962) containing 2.0 mg NAA l^{-1} and 0.2 mg BA l^{-1} at 25 ± 1°C, 55–60% relative humidity, and continuous illumination of 50 μmol m^{-2} s^{-1} provided by cool white (Philips India, Ltd.) fluorescent tubes. The seed produced protocorms (erroneously referred to as protocorm-like bodies in the original paper) which were transferred to MS containing 2.0 mg NAA l^{-1}. Rhizomes developed on this medium reached a size of 1.0 cm within 2–3 months and were used as explants.

Surface Sterilization. There is no need to sterilize explants taken from plants that are grown in vitro under axenic conditions.

Culture Vessels. Erlenmeyer flasks, 150-ml capacity, containing 40 ml medium, were used in the original research. Other vessels containing medium to approximately 20% of their capacity can also be used.

Culture Conditions. Cultures were maintained under the conditions used for seed germination above. Standard culture room conditions are also suitable.

Culture Media. The rhizomes were placed on a modification of MS for growth, proliferation, and plantlet production (Table Cym-63).

Procedure. Rhizomes are taken from the seedling cultures and placed on the culture medium. Plantlets should be potted and kept in the culture room for 4 weeks and under shade for 3 weeks after that, before being moved outdoors.

Developmental Sequence. The rhizomes developed shoots and roots within seven weeks. Complete plantlets formed in 2 months. These plantlets were hardened in pots in the culture room and outdoors.

General Comments. Seeds of epiphytic species are generally easy to germinate on Knudson C medium. The seedlings grow well on this medium and there does not seem to be a need for an elaborate micropropagation procedure like the one described here. In fact this procedure is an elaborate seed propagation method not micropropagation in a strict sense. It is presented here only because it may be of some use for species that are difficult to germinate or for instances in which only a few seedlings can be obtained from a capsule.

TABLE CYM-63. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for plantlet production from seedling-derived rhizomes (Nayak et al., 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	N^6-benzyladenine (BA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.8, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Induction of Early Flowering in *Cymbidium niveo-marginatum* in Vitro

Orchids can take a long time to flower. An extreme example is *Aranda* Lucy Laycock which flowered in Singapore when the plants were 13 years, 3 months old (Wee, 1971). Other examples are *Vandachnis* Scarlet Runner (11 years, 10 months, 11 days), *Vanda* John Warne (10 years, 2 months, 3 days), *Renantanda* Joan Mah (9 years exactly), and *Arachnopsis* Eric Holttum (7 years, 5 months, 2 days). Plants of the hybrid *Cymbidium* Faridah Hashim flowered at the age of 5 years, 20 days (for a review see Goh et al., 1982). Plants of *Cymbidium niveo-marginatum* flower when they are 4–7 years old. Therefore a protocol that induces early flowering of this species in vitro was developed in Korea (Kostenyuk et al., 1999).

Plant Material. The plants used in these experiments were unusual. Therefore direct quotes from the original paper will be used to describe them: "Rhizomes (3–4 months old) of *C. niveo-marginatum* Mak and 3- to 5-months-old plants (3–5 months after the initiation of regeneration from rhizomes of *C. niveo-marginatum*) were used in the present experiments. The rhizomes had been cultured in vitro for about 22 years." Since no comparisons were made with rhizomes newly produced from seeds and ones that were not propagated in NAA-containing medium it is impossible to determine what effects the long culture period and the propagation in vitro may have had on the results of the experiments. It is also not possible to predict whether this protocol will be effective with newly produced rhizomes.

Surface Sterilization. Explants taken from in vitro culture do not require surface sterilization.

Culture Vessels. Glass bottles, 1-l capacity, containing 250 ml of medium, were used in the original research. Other large containers can also be used.

Culture Conditions. Cultures were maintained at 25–26°C and 16-h photoperiods of 50 μmol m^{-2} s^{-1} provided by cool white fluorescent lamps.

Culture Medium. Rhizomes were propagated on MS medium containing 40 g sucrose l^{-1} and 5 mg NAA l^{-1} (Table Cym-64). Plants flowered in vitro when cultured on modified MS containing 40 mg sucrose l^{-1}, one-twentieth the original concentration of nitrogen (but the original paper does not indicate how the reduction was obtained), five times the level of phosphorus, and 10 mg BA l^{-1} (Table Cym-65).

Procedure. Rhizomes were propagated on the NAA-containing medium (Table Cym-64). Shoots produced on any of the media were moved to the flower-inducing medium (Table Cym-65) after their roots were pruned.

Developmental Sequence. Rhizomes were propagated in the NAA-containing medium. Although the original paper does not state this very clearly, it indicates that shoots were produced on this medium (Table Cym-64) and on the flower-inducing solution (Table Cym-65). When shoots were transferred to the flower-inducing medium

TABLE CYM-64. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the proliferation of *Cymbidium niveo-marginatum* rhizomes**

10	Benzyladenine (BA)	10.0	1.0 g 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	40.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Gelrite[g,h]	2.5 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N HCl.

[g]Add items 1–7, 9, and 10 to 900 ml of distilled water (item 15), adjust pH to 5.2–5.4, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Add the Gelrite in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8) and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYM-65. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the proliferation of *Cymbidium niveo-marginatum* rhizomes**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	82.44	8.24 g l^{-1}	10	$^1/_{20}$ of MS
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	95.0	9.5 g l^{-1}	10	$^1/_{20}$ of MS
5	Monopotassium phosphate, KH_2PO_4	850.0	85.0 g l^{-1}	10	5 times MS
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	5.0	500 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	40.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Gelrite[g,h]	2.5 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise. The fractions ($^1/_{20}$) and multiple (5×) of MS are assumptions based on statements in the original paper which stated "Final nitrogen concentration . . . [and] Final phosphorus concentration . . . [in] . . . the inductive medium compared to that of basal MS medium," without describing actual salt levels. No effort was made to adjust the recipe in this table for potassium levels.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–7, 9, and 10 to 900 ml of distilled water (item 15), adjust pH to 5.2–5.4, add sugar (item 14), and adjust volume to 1000 ml with distilled water (item 15). Add the Gelrite in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8) and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

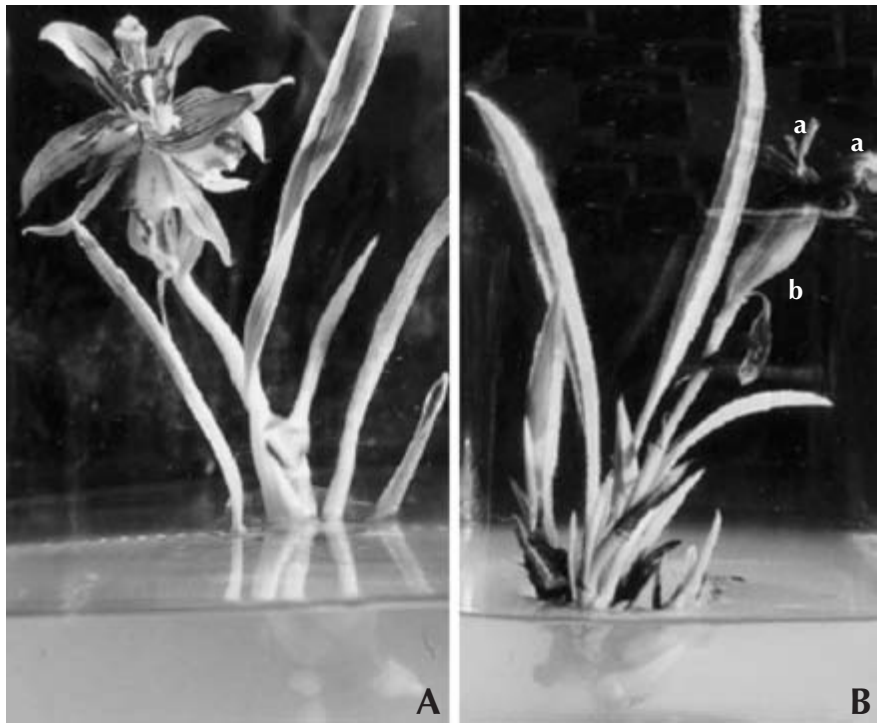

FIG. CYM-9. ***Cymbidium niveo-marginatum*** **flowering (A) and fruiting (B) in vitro. A, Remnants of perinath; B, fruit. (Kostenyuk et al., 1999.)**

after their roots were pruned, they grew and 90% of them flowered 60 days post treatment (Fig. Cym-9A). A few self-pollinated flowers set fruit (Fig. Cym-9B), but the original paper does not indicate whether the fruits matured and produced viable seeds.

General Comments. This is an interesting and pioneering procedure. Therefore, more is the pity that the original paper is not more detailed and better organized.

Flower Induction in *Cymbidium ensifolium* in Vitro

The first well-documented reports regarding flower induction in oriental *Cymbidium* in vitro are by Xiong Wang who was then at the Shanghai Institute of Plant Physiology (Chia et al., 1999). I visited her in 1987, saw her cultures and small *Cymbidium* plants flowering in vitro, and was amazed [my son Jonathan, 3 years old at the time (19 when this was written and 22 at the time of publication), and being carried by me was not impressed and may have resented having to share my attention with what to him were probably strange glass bottles with green things inside]. Shortly after our visit she moved to the Diaoyutai State Guest House in Beijing

and continued to lecture and report on her work. She lectured on flower induction in vitro in *Cymbidium ensifolium* at the Nagoya International Orchid Show which was held from March 8 until March 11, 1990 (Wang, 1990).

Plant Material. Tips were taken from young shoots, 2–3 cm long, and from their axillary buds.

Surface Sterilization. The shoots were scrubbed with a very soft toothbrush under running water. Their roots and leaves were removed following the wash and they were sprayed with 70% ethanol (74 ml of 95% ethanol diluted to 100 ml with distilled water). Axillary buds and shoot tips with innermost leaves were removed after that and immersed first in 70% ethanol for 30 s, then in 5% sodium hypochlorite for 30 min (95 ml Clorox or another household bleach which contains 5.25% sodium hypochlorite diluted to 100 ml with distilled water) and washed six times with sterile distilled water. All leaves were removed from the shoot tips and their meristems, and the axillary buds were excised and cultured.

Culture Vessels. In the original research the explants were first cultured on solid medium in flasks. For proliferation and differentiation, PLBs were cultured in T-shaped tubes (the horizontal part was 130 mm long and 35 mm in diameter, whereas the vertical portion measured 30×18 mm) which contained 10 ml liquid medium. These culture tubes were placed on a rotary shaker. If such tubes and a shaker are not available, Erlenmeyer flasks and a different type of a shaker can also be used. Shoots were cultured in flat-bottomed tubes (Fig. Cym-10) for flowering. If such tubes are not available, standard culture containers can be used.

FIG. CYM-10. ***Cymbidium ensifolium*** **flowers in vitro, in a pot, and in drawings. A. Plant flowering in vitro on March 6, 1984. B. A plant flowering in vitro in 1989. C. Flowering in vitro. D. Drawings of flowers (a) and a bud (b). E. Potted plant in bloom. F. Xiong Wang.**

TABLE CYM-66. **Half-strength Murahige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Cymbidium ensifolium* shoot-tip and axillary bud explants (Wang, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	950.0	95.0 g l^{-1}	10

(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	5.0	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Complex additives				
15	Casein hydrolysate	1.0 g	No stock	No stock	Weigh
16	Coconut water[g]	100.0 ml	No stock	No stock	Measure
	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar[g]	6.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same one liter of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen CW must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

Culture Conditions. Liquid cultures were placed on a rotary shaker at 1 rpm. If a different type of shaker is used it should rotate or oscillate at the same speed. Appropriate illumination is 2000–4000 lx. Temperature should be maintained at 25°C.

Culture Media. Shoot-tip and axillary bud explants should be cultured in half-strength MS medium (Murashige and Skoog, 1962) supplemented with 5 mg NAA l^{-1} and 10% coconut water (Table Cym-66). Sections of the PLBs produced on the first medium proliferate and produce shoots or plantlets on a liquid modification of MS which also contains 10% coconut water, but no NAA (Table Cym-67). When cultured on solid half-strength MS (Table Cym-68) the plants flower (Fig. Cym-10).

Procedure. Tips are excised from shoot tips and axillary buds following sterilization and placed in culture on the first medium (Table Cym-66). PLBs produced on this medium should be sectioned into several pieces, which proliferate and produce shoots and plantlets when subcultured in liquid medium (Table Cym-67). The plantlets should be moved to solid half-strength MS (Table Cym-68) to induce flowering.

Developmental Sequence. The excised tips produce bright green PLBs after 3–4 months on the first medium. Sections of these develop rosettes of new PLBs within a month. When sectioned and subcultured, sections of the new PLBs proliferate again. This process can be repeated almost indefinitely. However, excessive proliferation is not advisable. Plantlets are produced on the tips of the PLBs. More than 90% of these plantlets flower after 2 months on the solid half-strength medium.

General Comments. Orchids have flowered in vitro before this method was developed, but only occasionally and spontaneously. When they flowered around 1983, Xiong Wang's plants were the first to be induced to flower in vitro intentionally. Some of them were placed in Queen Elizabeth's room when she visited China. Dr. Wang was justly proud of that when she showed me her flasks in 1987. She had then, and still has now, a right to be proud. An effort by someone else (Goh, 1996) to claim this achievement has no basis in science or history.

The name *Cymbidium* is derived from the Greek kymbe (κύμβη) which means boat-shaped cup. This is an allusion to the boat-shaped labellum (Schultes and Pease, 1963).

[b]Add items 1–7, 9, 15, and 16 to 800 ml of distilled water (item 17), adjust pH to 5, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE CYM-67. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for proliferation of plantlets and shoot production from *Cymbidium ensifolium* protocorm-like bodies obtained from shoot tip and axillary bud explants (Wang, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

15	Coconut water[f]	100.0 ml	No stock	No stock	Measure
	Solvent				
16	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen CW must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[g]Add items 1–7, 9, 15, and 16 to 800 ml of distilled water (item 16), adjust pH to 5, add sugar (item 13), adjust volume to 1000 ml with distilled water (item 16). Pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), and vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE CYM-68. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as used for the culture of *Cymbidium ensifolium* plantlets which flower in vitro (Wang, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(d)	Manganese sulfate, $MnSO_4{\cdot}4H_2O$	11.2	1.12 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4{\cdot}2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4{\cdot}7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
13	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[e]	To 1000 ml			
	Solidifier				
15	Agar[e]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration, a difference probably without much effect.

[e]Add items 1–7 and 9 to 900 ml of distilled water (item 14), adjust pH to 5.0, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into 2-l flask and autoclave. Add the amino acid (item 8) and vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

In 1988 Du Puy and Cribb reduced *Cymbidium niveo-marginatum* Mak to synonymy under *Cymbidium ensifolium* (L.) Sw.

Growth Promotion of *Cymbidium* Plantlets by High Light Intensity, Elevated Carbon Dioxide Levels, and Increased Air Exchange

Plantlets of *Cymbidium kanran* and *Cymbidium goeringii* grown for 40 days on sugar-free MS medium (Murashige and Skoog, 1962) at 25°C under a relative humidity of 70 ± 5%, 16-h photoperiods of 100 μmol m^{-2} s^{-1} (provided by fluorescent tubes and metal halide lamps), carbon dioxide (CO_2) concentration of 1000 ± 50 μmol mol^{-1}, and 4.5 air exchanges per hour (conditions described as photoautotrophic) produced 1.5 times the dry mass (i.e., grew better) than ones grown under on MS with 30 g sucrose l^{-1} under illumination of 50 μmol m^{-2} s^{-1} (heterotrophic conditions). This simply means that plantlets grown under the photoautotrophic conditions grew 1.5 times better (Hahn and Paek, 2001). And, indeed, they seem to have more leaves and roots and to be taller (Fig. Cym-11). Given the cost of increasing the light intensity, CO_2 levels, and air exchange, this procedure may not be suitable for commercial applications.

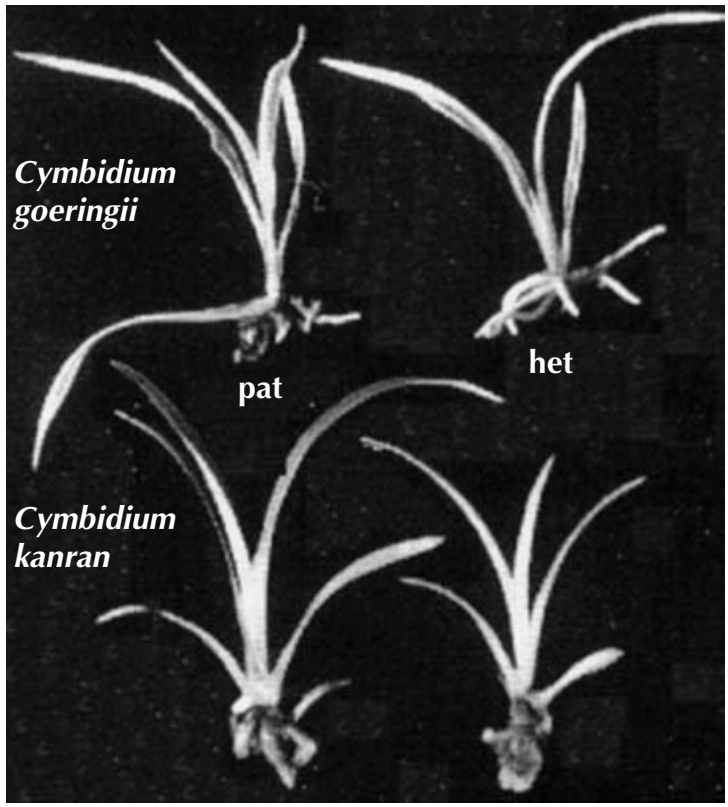

FIG. CYM-11. **Effects of photoautotrophic (pat, left) and heterotrophic (het, right) culture conditions on the growth of *Cymbidium* plantlets (Hahn and Paek, 2001).**

Effects of Benzyladenine on the Induction of Upright Shoots in *Cymbidium ensifolium*

Rhizome formation can be induced easily in shoot-tip cultures of *Cymbidium ensifolium* Yuh Hwa maintained at 26 ± 1°C under 16-h photoperiods of 50 μmol m^{-2} s^{-1} photosynthetically active radiation (PAR) provided by cool white fluorescent lamps on a horizontal 50 rpm shaker in a liquid medium consisting of one-third strength inorganic salts and full-strength vitamins of the MS medium (Murashige and Skoog, 1962) containing 20 g sucrose l^{-1} and activated charcoal (wrapped in Whatman No. 2 filter paper), and adjusted to pH 5.7 before autoclaving. The induction of upright shoots is more difficult (Lu et al., 2001). Experiments with BA showed that exposures to concentrations:

> . . . greater than 2.5 μM BA for 12 weeks or longer inhibited both elongation and upright, aerial shoots and root growth. Through transfer experiments, it was determined that the commitment to induction of upright shoots occurred after 10–14 days of exposure to 2.5 μM BA. When was BA supplied at 20 μM during the first 14 days of culture it induced upright shoot formation, but shoot elongation did not continue under these conditions. Using radiolabeled BA, adenine was found to be a major metabolite . . . in the rhizome tissue at day 14. . . . (Lu et al., 2001)

The importance and great value of these experiments is their quantitative, physiological, and metabolic rather than empirical approach to tissue culture and micropropagation.

Regeneration of *Cymbidium* Orchids from Leaf and Root Explants

> Explants were taken from plants [species or hybrid not listed], cultivated in vitro for more than a year [under] 16 [hour photoperiods], and 22°C–25°C. They consisted of small, 2 mm long basal fragments of young leaves or similar pieces of aerial roots. The explants were placed on agar solidified basal medium [Kozak, 1991 cited by Pindel and Miczynski, 1996*b*], with 30 g sucrose, 2 mg adenine sulphate, 5 mg BAP, and 1 mg NAA per [liter]. (Pindel and Miczyński, 1996*b*)

Despite citing a reference in the text, this abstract did not have a list of references. A search on the World Wide Web for "Kozak" resulted in 105,000 hits. Searching within the results for "1991" reduced the number to a daunting 11,400. Even searches using more limiting words did not identify a possible source of the medium used in this study. A search for the first author showed that she is a Professor of Botany at the Agricultural University in Krakow, Poland but their website does not provide e-mail addresses. There was no reply to a message sent to a general address on the website. This is why only quotes from this abstract are presented here. Those who may wish to use this procedure can try it with the Knudson C, MS, or Vacin and Went media.

> After 2 months of cultivation shoots appeared on 86 percent of leaf explants, and on 20 percent of root explants callus formation was visible. In subsequent transfers the media were supplied additionally with 10 mg/l ascorbic acid +60 mg/l cysteine to counteract darkening of the solutions. In such conditions after ca. 4 months of

> culture, the leaf explants developed on average 3.2 shoots per explant, while root explants formed at the same time still undifferentiated protocorm-like structures, which, however, regenerated shoots after next transfer onto fresh media.
>
> The selected medium supported only the formation of shoots. Induction of [roots] was obtained after transfer of plantlets to the same medium supplied with 1.0–1.2 mg/l of ancymidol, or 0.1–10 mg/l of abscissic [sic] acid. Media with ancymidol induced root formation usually after 2 months of culture, and at concentration of 1.25 mg/l of that compound all the tested plantlets developed roots. On the other hand, abscisic [sic] acid was more effective at lower concentrations at which 90 percent of explants formed roots. They also developed quicker, and were much stronger, than those cultivated at higher concentrations of ABA. (Pindel and Miczyński, 1996*a*)

Unfortunately the abstract does not list all concentration(s). Those who would like to use this method can try adding ABA at concentrations of 0.1, 0.5, 1, 2.5, 5, and 10 mg l^{-1}. More details are available in a full paper (Pindel and Miczyński, 1996*b*) and an e-mail from Dr. Pindel (ropindel@cyf-kr.edu.pl), received when the manuscript of this book was nearly complete. The abstract of the paper states that *Cymbidium* can be regenerated from "basal parts of leaves or aerial root sections of a *Cymbidium* hybrid cultivated in vitro for more than a year." The Kozak medium is actually a modification of the MS solution consisting of basal MS medium (macronutrients, micronutrients, and organic constituents) supplemented with 88 mmol sucrose, 11 µmol adenine sulfate, 22.5 µmol BA, and 5.5 µmol NAA (Pindel and Miczyński, 1996*b*, pers. comm.). The pH of the medium "was brought to . . . 5.5 before autoclaving. . . . cultures were kept at 16 h[our] daylength under fluorescent lamps of 55–60 µmol m^{-2} s^{-1} intensity and temperature of 22–25°C. In further steps the material was transferred every 6 weeks to the modified K[ozak]-medium, to which 55 µ[mol] of ascorbic acid [i.e., vitamin C] and 5 m[mol] cysteine were added to prevent darkening of the agar. . . . Rooting was obtained after transfer of regenerated shoots to the same medium supplied with 4–5 µ[mol] ancymidol or 0.4–4 µ[mol] ABA [i.e., abscisic acid]" (Pindel and Miczyński, 1996*b*). The optimal level of ancymidol was 5 mmol. ABA was most effective at 0.4 µmol l^{-1}. Molecular weights are: ABA, 264.32; adenine sulfate, 368.24; ancymidol, 256.30; ascorbic acid, 176.12; BA, 225.26; cysteine, 121.15; NAA, 186.21; and sucrose, 342.30.

Ancymidol is a plant growth regulator used to produce container-grown plants which are more compact. Its effects are the result of inhibition of gibberellin biosynthesis.

In Vitro Propagation of *Cymbidium bicolor* in Bangladesh

> Various . . . explants namely shoot tip, leaf tip and axillary bud of *Cymbidium bicolor* were tried for large scale multiplication. Both agar solidified and liquid media of Murashige and Skoog, Vacin and Went and Knudson C were used for this purpose. Of the three media tried higher percentages of protocorm development were obtained from . . . shoot tip and axillary bud explants of *Cymbidium bicolor* . . . in Vacin and Went medium containing 400 mg/l casein hydrolysate +20% coconut water +1.0 mg/l IAA +1.0 mg/l BAP. Growth and subsequent multiplication of protocorms were found better in the liquid medium compared to solid medium. (Sarker and Roy, 1993)

The proper term in this case is PLB, not protocorm. By definition protocorms are produced only by germinating seeds and never by explants.

Effect of Initial Sugar Concentration on in Vitro Growth of *Cymbidium* Protocorm-like Bodies

> The glucose concentration in [liquid half-strength MS medium] decreased with time in all . . . treatments. The fresh and dry weights of PLB were greater under higher glucose concentration conditions. It should be noted that the mean relative growth rate (RGR) of PLB for the entire culture period was similar when the initial amount of sugar per fresh weight of PLB was the same, regardless of the sugar concentrations of the media. (Kubota and Kozai, 1991)

Photoautotrophic Micropropagation of Protocorm-like Bodies of *Cymbidium*

> *Cymbidium* (cv. Lisa rose [sic]) PLB (protocorm-like bodies) were cultured in liquid 1/2 MS medium with/without 20 mg g^{-1} sucrose under continuous lighting conditions. The vessels were shaken at 100 rpm under PPF (photosynthetic photon flux) of 20 and 2000 μmol m^{-2} s^{-1} and CO_2 concentrations outside the vessel (C_{out}) of 450 and 2000 μmol mol^{-1} conditions. Photoautrophic growth was obtained at high PPF and high C_{out}. Chlorophyll content of the PLB in the medium without sucrose at high PPF and high C_{out} was almost 3 times that with sucrose at low PPF and low C_{out}. The number of newly developed PLB with sucrose at low PPF and low C_{out} was 1.6 times that without sucrose at high PPF and high C_{out}; the dry weight per unit PLB with sucrose at low PPF and C_{out} was almost 3 times that without sucrose at high PPF and high C_{out}. Photoautrophic growth of the PLB might be further promoted at higher CO_2 concentration (> 1%). (Kubota et al., 1992)

These comparisons (Kubota et al., 1992) would have been more useful and easier to understand if given in a table with chlorophyll content, newly developed PLBs, and dry weight listed for all combinations of high and low photosynthetic photon flux and high and low carbon dioxide concentrations outside the vessel, all with and without sucrose. If the results could be understood more easily, they might have been more useful.

Substrate-specific Hydrolysis of Aromatic and Aromatic–Aliphatic Esters in *Cymbidium* Tissue Culture

> In tissue cultures of orchids (*Cymbidium* 'Saint Pierre' and *Dendrobium phalaenopsis*) acetates of phenols and aromatic–aliphatic alcohols were hydrolyzed whereas methyl esters of aromatic and aromatic and aliphatic acids did not undergo this reaction. Acetates of racemic aromatic–aliphatic alcohols were hydrolyzed with distinct enantiospecificity. (Mironowicz et al., 1993)

These findings represent good and interesting research that should be of interest to phytochemists and plant physiologists, but is of no relevance to micropropagation.

Comparisons of *Cymbidium* Protocorm-like Body and Plantlet Formation on Solid and Liquid Media.

PLBs were cultured for multiplication on solid substrate or in liquid substrate consisting of Knudson C medium (Knudson, 1946) plus the minor elements of the MS solution (Murashige and Skoog, 1962): 20 g sucrose l^{-1}, 0.1 mg NAA l^{-1}, and 0.01 mg BA l^{-1}. Solid media were solidified with 7 g agar l^{-1}. Cultures were maintained at 25°C under 18-h photoperiods of 14 W m^{-2} light intensity (the source of the illumination was not described). Liquid cultures were rotated at 2 rpm. A 2-l Osmotek plastic bioreactor was used for some cultures (Pamfil, 2002). The results (Table Cym-69) are not surprising.

The data show the following:

1 Proliferation is more extensive in a liquid medium (this has been well known for a long time).
2 The differences in fresh PLB weight between liquid agitated, non-agitated, and bioreactor cultures are not statistically significant. In practical terms the weight of PLBs is not as important as normal differentiation of plantlets.
3 Proliferation is most extensive in a bioreactor. However, there is no statistically significant difference between proliferation in a bioreactor (5.1 ± 0.5)and that in liquid cultures on a shaker (4.6 ± 0.3). This suggests that in practical terms the costs involved in the purchase, maintenance, and operation of a bioreactor must be compared to the outlays for a shaker.
4 Necrosis is highest in a bioreactor. This must also be considered in considering the use of a bioreactor versus a shaker.
5 In terms of fresh weight, the best growth of seedlings is on a solid medium. However, as mentioned above, in a practical laboratory proper differentiation and plantlet formation are much more important than weight of PLBs.

TABLE CYM-69. **Effects of the state of the medium on the growth of protocorm-like bodies and plantlets**

	Medium			
Factor	Agar-solidified	Liquid, stationary	Liquid, agitated	Bioreactor
Protocorm-like bodies				
Final fresh weight, mg	161.9 ± 12	177.6 ± 16	182.4 ± 15	192.1 ± 21
Multiplication factor, mg	3.6 ± 0.2	4.1 ± 0.3	4.6 ± 0.3	5.1 ± 0.5
Necrosis, percent	2.3	3.7	3.5	5.3
Plantlets				
Initial fresh weight, mg	44.4 ± 3.4	39.8 ± 3.6	38.7 ± 4.2	35.2 ± 2.8
Final fresh weight, mg	159.3 ± 11	148.1 ± 13	151.7 ± 8	140.4 ± 7
Hyperhydricity, percent[a]	3.8	6.2	8.5	11.8

[a]This term that is spelled "hyperhydricity" in the table and "hiperhydricity" in the text is not defined. There is also no description of the method by which the data were obtained (Pamfil, 2002).

Starch and α-Amylase Levels During Protocorm-like Body Formation from Foliar Explants of *Cymbidium* Burgundian Chateau

> Leaf bases measuring 7–10 mm were [taken] from the second and third leaves of shoots . . . [cultured on] . . . Vacin and Went (VW) medium supplemented with BA, 0.2 mg/l and agar 0.8%. . . . [These explants were cultured on a medium consisting of] . . . salts and sugar of VW medium, 10% (v/v) tender coconut water, 2 mg/l naphthaleneacetic acid (NAA) and 1 mg/l benzyl adenine (BA). The pH of the medium [was adjusted] to 5.2 before adding agar. After autoclaving at 120°C for 18 min, aliquots (15 ml) of the medium were dispensed into 9 cm petri dishes. The cultures were maintained in the dark at 26 ± 1°C and 60 ± 5% RH in a Lab-Line model 8482 plant growth chamber. A large pool of sugars [which] formed after two days of culture disappeared at the initiation of tissue growth (10 days). Maximum accumulation of starch occurred when the growth centres were already formed and PLBs were emerging (22 days). Rapid depletion of the starch reserve, consequent rise and then fall in free sugars and high α-amylotic activity characterized the rapid phase (20–30 days) of development of the PLBs. Evidence for early appearance of a highly persistent isozyme of α-amylase, a_1 and a transient, probably a marker isozyme a_2, confined to the period of high intensity metabolism (15–30 days) during the initiation and rapid development of the PLBs were obtained. Mature PLBs contained negligible levels of starch and lacked the second isozyme. (Gopalan, Krishnan and Seeni, 1992)

This report is valuable because it identified periods during which PLBs require sugar and this information can be used to formulate culture media.

Growth of Tissue-cultured *Cymbidium goeringii* and *Cymbidium kanran* in Korean Native Orchid Habitat Soils

Tissue-cultured *Cymbidium goeringii* grew well in pine bark and soils collected from Korean native orchid habitats. Plantlets of *Cymbidium kanran* grew better in non-sterilized soil (Lee et al., 1997). These findings reflect the formation of appropriate mycorrhizal associations. They should be considered in moving plantlets from flasks to horticultural conditions.

Growth of *Cymbidium* Plantlets in Vitro under Blue and Red Light-emitting Diodes

"Red light [emitted by red LEDs] promoted leaf growth [of *Cymbidium* plantlets in vitro], but decreased chlorophyll content. This was reversed by blue light [emitted by blue LEDs]. The growth of *Cymbidium* plantlets in terms of increase in total shoot and root weights was comparable under red plus blue LEDs [45 $\mu mol\ m^{-2}\ s^{-1}$] and the fluorescent system . . ." (Tanaka et al., 1998) consisted of Homo-Lux lamps (National Electric Co., Ltd.). Photoperiods were 16 h and the temperature was 25 ± 1°C. These findings are not surprising because the light intensity and spectrum provided by the two sources of illumination were very similar. What these experiments show has been known for a long time, that is, plants grown under

appropriate illumination in terms of intensity, spectrum, and photoperiods grow well. Given the cost of light-emitting diodes (LEDs), there does not seem to be any reason to start using them rather than fluorescent lights to illuminate *Cymbidium* and other tissue cultures of orchids.

Proliferation of *Cymbidium* Protocorm-like Bodies

PLBs obtained from a commercial orchid establishment were proliferated on MS medium (Murashige and Skoog, 1962) containing 30 g sucrose l^{-1}, 4 mg NAA l^{-1}, and 0.05 mg kinetin l^{-1}, solidified with 8 g agar l^{-1}, with the pH adjusted to 5.8–6.0 prior to autoclaving. Cultures were maintained at 26 ± 1°C. There is no information in the original paper regarding photoperiods and light intensity. Plantlets were produced by the PLBs. The plants used are described as "*Emken* × *Cymbidium*" (Prasad and Verma, 2001). A search in several data bases (including the excellent WildCatt, www.wildcattdata.com) could not find an orchid named *Emken*. This is not a complete procedure since the PLBs were produced from shoots elsewhere. It is also not necessary because most published methods include a proliferation step. And, since excessive proliferation may cause undesirable mutations, using this method is not advisable. It is listed here solely for the purpose of presenting or at least mentioning as many published reports of orchid propagation as possible.

Eradication of Odontoglossum Ringspot Virus from in Vitro Cultures of *Cymbidium*

A widely accepted and often repeated (in the orchid world), but completely incorrect, myth is that Professor Georges Morel (1916–1973) proposed and implemented the idea that plants can be freed of virus by culturing their shoot tips. This "proven" and widely accepted "truth" was originated by Morel himself and driven into the minds of orchid growers and scientists by him, starting in 1960 and continuing until his death in 1973. Once this dogma became accepted, others spread it and resisted or even beat down challenges to it (see Arditti and Krikorian, 1996 for a review). In fact the idea is at least 60 years old. In 1943 Arthur W. Dimock (1908–1972) published a method for establishing *Verticillium*-free clones of chrysanthemum by rooting shoot-tip cuttings. After that he refined the method and extended it to other diseases. Similar methods were used to free carnations, dahlias, and other plants from fungal and virus diseases (see Arditti and Krikorian, 1996 for a review). Therefore it is not surprising that when viral diseases caused problems for potatoes and dahlias in France, Pierre Limaset and Pierre Cornuet suggested to Morel that cultivating shoot meristems may free these plants of viruses. Morel did it, was successful, extended the method to orchids (Arditti and Krikorian, 1996), and created the erroneous impression that he developed concepts and techniques that were originated by others.

After Morel published and promoted his findings, growers assumed that shoot-tip cultures could be used for mass, rapid, clonal propagation – freeing orchids from viruses. That was a misconception. Before "mericloning" orchid viruses were less of a problem than after its advent. Careless culturing of shoot tips actually propagated

viruses as well as orchids. Now the viruses are more common and widespread (Arditti and Krikorian, 1996). Because of this, virus eradication methods are being coupled with micropropagation. One such method for *Cymbidium* was developed in Belgium (Toussaint et al., 1993).

Plant Material. PLBs produced by standard methods (Morel, 1963; Vanseveren and Fréson, 1969; also described in the first edition of this book, Arditti and Ernst, 1993) from shoot-tip cultures of *Cymbidium* plants infected with odontoglossum ringspot virus (ORSV) were proliferated and used in the original research.

Surface Sterilization. PLBs taken from in vitro cultures do not require surface sterilization. However they should be rinsed with sterile distilled water to remove medium residue.

Culture Vessels. Bellco test tubes, 2.5 × 15 cm, containing 10 ml of medium were used during the ORSV eradication research. Other containers are also suitable.

Culture Conditions. The conditions in a standard culture room are appropriate.

Culture Medium. Liquid ribavirin-containing Knudson C medium (Knudson, 1946) should be used to free plants from virus (Table Cym-70). To produce plantlets PLBs should be cultured in Knudson C medium containing 5 g sucrose l^{-1} (Table Cym-71).

Antiviral Agent. Virazole® (commercial name of ribavirin, 1-β-D-ribofuranosyl-1,2,4-triazole-3-carboxamide, MW 244.2) should be used at a concentration of 35 mg (143.5 μmol) l^{-1}. This concentration was selected because it is a good balance between antiviral effects and toxicity. The maximum solubility in water of Virazole is 142 mg ml^{-1} (which is slightly more than needed for 4 l of medium). It cannot be autoclaved and filter sterilization is too complex for a practical laboratory. Therefore, 35 mg ribavirin (available from Sigma-Aldrich, www.sigmaaldrich.com, as item R 9644 at a cost in mid 2002 of US$68.25 for 50 mg) should be dissolved in 1 ml of water and brought to 4 ml with 95% ethanol. This solution should be added to the autoclaved culture medium (Table Cym-70) while it is still warm and liquid. The medium should be swirled well or stirred with a sterile stirrer to ensure even dispersal of the ribavirin.

TABLE CYM-70. **Number of virus-free plants as a function of the number of subcultures and time in ribavirin-containing medium**

Number of subcultures	Number of plants per culture	Time in ribavirin, days	Number of healthy plants
4	14	18	13
5	28	47	25
6	25	66	28
Total	**100**		**90**

TABLE CYM-71. **Ribavirin-containing Knudson C (KC) medium (Knudson, 1946) for the eradication of virus from protocorm-like bodies of *Cymbidium* (Toussaint et al., 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Antiviral agent				
7	Ribavirin (Virazole®)[d]	35.0	35 mg in 1 ml water adjusted to 4 ml with 95% ethanol[d]	4	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Kundson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]Ribavirin (Virazole®) cannot be autoclaved and filter sterilization is too complex for a practical laboratory. Therefore 35 mg (143.5 µmol) ribavirin (Virazole®) should be dissolved in 1 ml of distilled water and brought to 4 ml with 95% ethanol. This mixture should be prepared immediately before use.

[e]Add items 1–6 to 900 ml of distilled water (item 9), adjust pH to 5–5.2, add sugar (item 8), raise volume to 1000 ml with distilled water (item 9), pour the solution into a 2-l flask, and autoclave. After the autoclaved solution has cooled add the ribavirin (item 7), mix well by swirling, and distribute into sterile culture vessels. There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946). It is not clear whether the addition of such nutrients would be of benefit. If the incorporation of additional microelements is necessary, those used in the Murashige–Skoog (MS) medium are suitable.

Procedure. PLBs must be taken for culture on ribavirin-containing medium (Table Cym-70) when they are small and before leaf primordia are evident. The original paper reports that 4–7 subcultures (over a period of 18–71 days) were needed to obtain a high proportion of virus-free plants (Table Cym-72). The time in ribavirin-containing solutions should be balanced against the possibility that long exposure to the antiviral agent can lead to teratogenic effects. In the original research the presence of virus after culturing PLBs in ribavirin-containing media was determined using ORSV antibodies in a procedure called enzyme-linked immunosorbent assay (ELISA), which may be too complex for practical laboratories. Those interested in learning the procedure should consult *The ELISA Guidebook* by J. R. Crowther, published in 2001 by Humana Press. It can be ordered from www.sigmaaldrich.com. ORSV test kits and assays are available from Agdia Inc., www.agdia.com. Tests are also available from http://plantpath.osu.edu/cweppdc/plantdis.html#tests.

When protocorms become (or are assumed to be) virus-free they should be moved to solid Knudson C (Table Cym-71) and grown until plantlets are ready to be

TABLE CYM-72. **Knudson C (KC) medium (Knudson, 1946) for plantlet production from protocorm-like bodies of *Cymbidium* that have been freed from odontoglossum ringspot virus (Toussaint et al., 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10

8	Water, distilled[d]	To 1000 ml			
	Solidifier				
9	Agar[d]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Kundson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]Add items 1–6 to 900 ml of distilled water (item 8), adjust pH to 5.2, add sugar (item 7), and raise volume to 1000 ml with distilled water (item 8). Bring the solution to a gentle boil and add the agar (item 9) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946). It is not clear whether the addition of such nutrients would be of benefit. If the incorporation of additional microelements is necessary, those used in the Murashige–Skoog (MS) medium are suitable.

potted. Well-developed plantlets should be potted in small pots in a greenhouse at 22–25°C, repotted several times, and grown to maturity.

Developmental Sequence. PLBs proliferate in the liquid ribavirin-containing medium while the antiviral agent eradicates the virus. Plantlets form on the solid medium.

General Comments. This is a useful procedure that can free infected clones of virus. The only problem with it is its complexity, especially the ELISA.

Production of Virus-free *Cymbidium* through the Use of Vidarabine in Vitro

Orchid viruses are spread mostly through contaminated tools, pots, and manual contact. There are at least 25 orchid viruses (for an excellent review see Wong, 2002).

Two of the most prevalent orchid viruses, and among the first to be described, are *Cymbidium* mosaic virus (CyMV) and odontoglossum ringspot virus (ORSV). They can cause death of plants, inhibit growth, and distort flowers. Temperate *Cymbidium* species like *Cymbidium gyokuchin* and *Cymbidium ensifolium* are more susceptible than tropical taxa. That is why a method for the production of virus-free plants was developed in Korea (Paek et al., 1997).

Plant Material. Shoot tips of *Cymbidium* Golden Gate were used in the original research. However other orchids can probably be freed of virus using this method provided they can withstand the high concentration of the antiviral agent.

Surface Sterilization. The surface sterilization procedure, which is part of Clonal Propagation of *Cymbidium* through Shoot-tip Meristem Culture (Sagawa et al., 1966), can be used.

Culture Vessels. Test tubes containing 10 ml of medium were used in the original research (size of tubes not indicated, but 25×150 mm is suitable). Other containers can also be employed.

Culture Conditions. The conditions used during the original research were 25°C under 16-h photoperiods of 35–50 μmol m^{-2} s^{-1} provided by fluorescent lamps (the type used is not described). Conditions in a standard culture room are also suitable.

Culture Media. "Murashige–Skoog basal medium containing 3% sucrose and solidified with 0.2% Gelrite" and vidarabine (Table Cym-73) was used in the original research. The term "basal medium" implies that only the mineral components of the MS medium (Murashige and Skoog, 1962) were used. This is in line with the previous procedure (Toussaint et al., 1993). It uses the Knudson (KC) medium (Knudson, 1946) which does not contain vitamins and hormones. Vidarabine-free medium should be used to grow plantlets after the initial 6–8 weeks. The medium used in the previous procedure is suitable (Table Cym-71).

Antiviral Agent. Vidarabine (VIRA-A is its trade name and it is also known as adenine arabinoside, 9*H*-purin-6-amine, 9-β-D-arabinofuranosyl, MW 285.25) at 100 mg l^{-1} is used to eliminate CyMV and ORSV. It can be obtained from Sigma-Aldrich (www.sigmaaldrich.com) as item number 01832 under the names adenine 9-β-D-arabinofuranoside or ARA-A.

This compound is not heat-stable and cannot be autoclaved. Filter sterilization is too complex for a practical laboratory. Therefore 100 mg vidarabine should be suspended in 5 ml of 70% ethanol (74 ml of 95% ethanol adjusted to 100 ml with distilled water) in an autoclaved 10–20-ml-capacity vial regardless of whether it will dissolve completely or not, and shaken vigorously several times, allowed to stand for 5 min, and agitated again. This should be repeated 4–6 times over a 30-min period to sterilize the vidarabine even if it will not dissolve the powder completely. All of the suspension should be added to a still-warm 1 l of culture medium after it was autoclaved. The vial must be rinsed several times with warm culture medium until all particulate matter has been washed away and added to the culture medium. After

TABLE CYM-73. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for virus eradication from *Cymbidium* (Paek et al., 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	62.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Antiviral agent				
8	Vidarabine[e]	100.0	No stock	No stock	See footnote *e*
	Sugar				
9	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Gelrite[f,g]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]This compound is not heat stable and cannot be autoclaved. Filter sterilization is too complex for a practical laboratory. Therefore 100 mg vidarabine should be suspended in 5 ml of 70% ethanol (74 ml of 95% ethanol adjusted to 100 ml with distilled water) in an autoclaved 10–20-ml capacity vial regardless of whether it will dissolve completely or not and shaken vigorously several times, allowed to stand for 5 min, and agitated again. This process must be repeated 4–6 times over a 30-min period. It will sterilize the powder whether it dissolves or not. The suspension should be added to 1 l of still warm culture medium after it was autoclaved and the vial must be rinsed several times with warm culture medium until all particulate matter has been washed away and added to the culture medium. After that the medium should be swirled or stirred vigorously with sterile stirrers before being dispensed into preautoclaved culture vessels.

[f]Add items 1–7 to 900 ml of distilled water (item 10), adjust pH to 5.2–5.4, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Dissolve the Gelrite in accordance with the instructions in footnote *g*. When the Gelrite is completely dissolved, pour the solution into a 2-l flask and autoclave. Add the antiviral agent as indicated in footnote *e* above under sterile conditions, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier is not added to liquid media.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved, pour the medium into culture vessels and autoclave.

that the medium should be swirled or stirred vigorously with sterile stirrers before being dispensed into preautoclaved culture vessels.

The concentration of vidarabine (100 mg l^{-1}) used in this procedure is high enough to kill 50% of the shoot tips placed on the medium and to "increase the occurrence of abnormal PLB," but it does free of virus most of the surviving ones. A higher concentration (150 mg vidarabine l^{-1}) causes abnormal growth such as swollen PLBs.

Levels of CyMV and ORSV in plants cultured on vidarabine-containing MS were assayed using ELISA (Bio-tek Instruments, EL-307). ORSV kits and assays are available from Agdia Inc., www.agdia.com. Tests are also available from http://plantpath.osu.edu/cweppdc/plantdis.html#tests. The ELISA may be too complex for practical laboratories.

Procedure. Shoot tips, one per culture vessel, should be placed on the culture medium and allowed to grow for 6–8 weeks or until they reach a height of 7–10 cm. Then the plantlets should be moved to fresh, vidarabine-free medium in a larger vessel and grown until they are large enough to be moved to pots. These plantlets must be maintained in an enclosure with enough space between each plantlet so they do not touch; they should be handled with sterile tools and observed for signs of virus infection. Any that show symptoms must be destroyed by burning or autoclaving. Before any plants can be sold as virus-free it is necessary to assay them in some fashion.

Developmental Sequence. The shoot tips develop into PLBs, which form plantlets. Hopefully most of the plantlets will be virus-free.

General Comments. This procedure is simple enough to be suitable for practical laboratories. The only complex step is ELISA. Kits and testing are available from www.agdia.com and http://plantpath.osu.edu/cweppdc/plantdis.html#tests.

Cymbidium Protoplast Culture

Protoplasts of *Cymbidium* can be isolated and cultured using the method suggested for *Dendrobium* (Yasugi, 1990).

In Vitro Morphogenesis of *Cymbidium*

Pseudobulb, rhizome, and root sections of *Cymbidium ensifolium* var. *misericors* formed totipotent calli on modified MS medium containing 2,4-D and TDZ. On being subcultured onto MS supplemented with BA and TDZ, the calli formed embryoids. These embryoids developed rhizomes which eventually produced plantlets (Chang et al., 2001).

In Vitro Storage of Protocorm-like Bodies

This paper (Kim et al., 1999) is in Korean. Only part of the English summary is presented here:

> Excellent storage of PLB was obtained from moist condition using [a medium] with 3 g l^{-1} hypones and 4 g l^{-1} peptone . . . in the dark. The optimal [storage] temperature was 5 C in [dry] storage and 10 C in moist condition storage. The preservation periods . . . were 6 weeks in gradual dry, 3 weeks in rapid dry storage and 18 weeks in moist storage condition without drying pretreatment.

Effect of Auxin and Ethylene on Rhizome Formation from Shoot Cultures of *Cymbidium kanran*

Only the summary of this report (Shimasaki, 1993) is in English:

> Application of Ethephon promoted rhizome formation from shoot cultures of *Cymbidium kanran*. Naphthaleneacetic acid (NAA) in the culture medium enhanced rhizome formation from shoot cultures, whereas simultaneous addition of aminoethoxyvinylglycine (AVG) suppressed rhizome formation. Ethylene evolution from shoot cultures was enhanced by NAA, but reduced by AVG.

Ethephon (2-chloroethylphosphonic acid or ethrel) acts by liberating ethylene. AVG is an ethylene inhibitor.

Effects of Benzyladenine, Gibberellin, and Paclobutrazol on Organogenesis in *Cymbidium* Species

This report (Shimasaki et al., 2002*a*) is in Japanese with an English summary:

> Addition of paclobutrazol (PAC) to modified MS medium induced protocorm-like body (PLB) formation from rhizome segment cultures of *Cymbidium kanran* Makino (terrestrial type). The combination of BA with PAC reduced the number of PLB. Application of BA induced shoot[s] (protocorm-like pseudobulb with short leaves) without root[s]. Single addition of 10 μM [sic] BA had a significant effects on induction and increased the number of shoots. PAC in culture medium inhibited BA-induced leaf formation from rhizome cultures.
>
> Application of GA_3 to PLB cultures of epiphytic type *Cymbidium* (*C.* Hiroshima Golden Cup 'Sunny Moon') resulted [in] rhizome formation. GA_3 treatment at 100 μM [sic] was effective for rhizome formation from PLB cultures. Single addition of 10 μM [sic] PAC was effective for proliferation of PLB from 'Sunny Moon'.

Paclobutrazol ($C_{15}H_{20}ClN_3O$), a plant growth regulator, is used to reduce terminal growth and to prune volume in trees not used for food production on sites such as utility rights-of-way, urban environments, and residential and non-crop areas. It is (2*RS*,3*RS*)-1-(4-chlorophenyl)-4,4-dimethyl-2-(1*H*-1,2,4-triazol-1-yl)pentan-3-ol.

Chitosan Effects on Organogenesis in Protocorm-like Bodies of *Cymbidium finlaysonianum*

This is yet another paper in Japanese (Shimasaki et al., 2003*c*) with an English summary:

> PLB of *Cymbidium finlaysonianum* Lidl. were explanted on modified Kano's medium (Hyponex medium) supplemented with two kinds of chitosans. Within 8 weeks of culture, proliferation of . . . PLBs and differentiation of shoots from PLBs were observed. Explants cultured on medium containing chitosans formed a mass of PLBs followed by differentiation of shoots. The number of PLBs and the number of shoots from proliferated PLBs were significantly increased by application of chitosans.

Chitosan is a biocompatible, antibacterial preparation which is an environmentally friendly polyelectrolyte. It has a number of applications including: additive for cosmetics, antimicrobial textile treatment, aqueous thickener, biodegradable films, biomedical devices, chromatography, encapsulating agent, flocculant, microcapsule implants for controlled release drug delivery, novel fibers for textiles, photographic papers, protein precipitation, and water treatment. It forms gels with multivalent anions and produces clear solutions which dry to form strong and clear films. It is available from www.sigmaaldrich.com.

Jasmonic Acid, Methyl Jasmonate, and Cucurbic Acid Effects on Organogenesis in Rhizome Segments of *Cymbidium kanran*

This report (Shimasaki et al., 2002*b*) is in Japanese with an English summary:

> Differentiation of rhizome into shoots occurs in Murashige–Skoog medium containing 0.01–0.03 μM [sic] jasmonic acid (JA), 0.01–0.03 μM [sic] methyl jasmonate (Me-JA) and 0.01–0.03 μM [sic] cucurbic acid (CUC), respectively. Differentiation was especially marked on at 0.03 μM [concentration] of JA and 0.03 μM [concentration of] Me-JA. Formation of protocorm-like bodies (PLB) from rhizome cultures [was] observed at all treatments except for control treatments (growth regulator free). Higher concentrations of JA, Me-JA and CUC were effective for PLB formation. The average number of PLBs was highest at 3 μM [concentration] of Me-JA. The rate of PLB formation was 100 percent at 1 and 3 μM Me-JA and 0.03 μM CUC treatments. Higher concentrations pf Me-JA and CUC inhibited branching of rhizome cultures. Branching of the rhizome was completely inhibited by 0.1–3 μM Me-JA and 1 and 3 μM CUC.

Cucurbic acid is a naturally occurring metabolite of 7-epi jasmonic acid. It is as a plant growth regulator. Jasmonic acid and its methyl esters are of ubiquitous distribution in plants. They have hormone properties and function in the regulation of plant growth and development, senescence of leaves, and in the defense against fungi.

Methyl jasmonate (Me-JA) is one of the main fragrance components (ca. 10^{-4} g per blossom) of jasmine along with jasmone. It comprises 2–3% of jasmine oil. A total of 15,000 blossoms are needed to produce 1.5 g of the oil. Me-JA is also a flavor ingredient of semiblack and black teas.

Methyl Jasmonate Effects on Organogenesis in Shoot Cultures of Epiphytic and Terrestrial *Cymbidium* Species

Since this paper (Shimasaki et al., 2003*b*) is in Japanese, only part of the abstract is presented here:

> The addition of Me-JA at concentrations below 1 μM effectively increased the number of PLBs from shoot cultures. A high concentration (10 μM) of Me-JA had little effects on the proliferation of PLB. Rhizome branches were formed from shoot cultures of *Cymbidium kanran* Makino (terrestrial species) and the largest number of rhizomes were developed at 1 μM Me-JA. Addition of Me-JA to culture medium inhibited shoot development from explants.

Effects of Cytokinin and Ethephon on Shoot Formation in Rhizome Cultures of *Cymbidium kanran*

The research that resulted in the method which is described in this section was carried out in an effort to determine the effects of and interactions between cytokinins and ethylene in organogenesis of rhizome cultures (Shimasaki, 1995).

Plant Material. The original report only states that apical segments, approximately 5 mm, were "prepared by . . . methods described previously." Shimasaki (1995) describes the preparation:

> Immature seeds (10 months after pollination) of *C. kanra*n were cultured on modified Kano medium . . . containing 3 g/l Hyponex, 2 g/l Difco bacto-peptone [and probably 20 g sucrose l^{-1}], pH 5.3 at 25 ± 1°C under total darkness for the first 10 months. One of the rhizomes was subcultured for two months to proliferate rhizome branches on the modified MS (Murashige and Skoog, 1962) medium containing 412.5 mg/l ammonium nitrate and 950 mg/l of potassium nitrate, 20 g/l sucrose and 20 g/l gelrite [this seems to be a very high level of Gelrite]. Approximately 10 mm of vegetative shoots formed on apical segments on rhizome branches of proliferated rhizomes cultured on the modified MS medium were used for explants.

Surface Sterilization. Explants taken from in vitro cultures do not require sterilization, but should be rinsed with sterile distilled water to remove agar residues.

Culture Vessels. Culture tubes, 25 × 120 mm, with plastic caps are suitable.

Culture Conditions. All research cultures were maintained for 8 weeks at 25 ± 1°C under 16-h photoperiods of 25 μE m^{-2} s^{-1}. The light source was not described. Standard culture room conditions are also suitable.

Culture Media. Several concentrations of BA and ethephon singly and in combination were added to liquid MS medium (Murashige and Skoog, 1962). Explant responses varied with the cytokinin–ethephon combination. Reasonable results can be obtained with the initial medium (Table Cym-74) suggested here. The original

TABLE CYM-74. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Cymbidium kanran* rhizome explants (Shimasaki, 1995)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH. Auxin should be added if the shoots fail to form roots.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH as required, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels.

necessary) for 10 months. After that, several rhizomes should be cultured on modified MS (Table Cym-75). Explants from these rhizomes are cultured on the initial medium (Table Cym-74). Shoots that form when the rhizomes are cultured on the initial medium (Table Cym-74) should be moved to the modified MS (Table Cym-75). If the

shoots fail to produce roots, 1 mg NAA l^{-1} should be added to this medium (Table Cym-75) in the hope that this auxin may induce root formation.

Developmental Sequence. The seeds will germinate on the Hyponex medium and form rhizomes. When moved to the modified MS medium (Table Cym-75), rhizomes will produce tips which are excised and cultured on the initial medium (Table Cym-74). Shoots produced on this medium (Table Cym-74) should grow into plantlets on modified MS (Table Cym-75) with or without the addition of NAA. When plantlets are produced they should be moved to horticultural conditions.

General Comments. This procedure was developed as a means of investigating the effects of cytokinins and ethephon on branching and ethylene evolution by rhizome sections, but it can also be used for micropropagation.

Ethylene and Jasmonic Acid Effects on the Organogenesis of *Cymbidium*

Cytokinins and auxins are used to control organogenesis in *Cymbidium* explant culture. The procedure described here is a result of investigations aimed at determining the effects of ethylene and jasmonic acid (Shimasaki, 1996).

Plant Material. As in the previous procedure, the plant material was prepared like this:

> Immature seeds (10 months after pollination) of *C. kanra*n were cultured on modified Kano medium . . . containing 3 g/l Hyponex, 2 g/l Difco bacto-peptone [and probably 20 g sucrose l^{-1}], pH 5.3 at 25 ± 1°C under total darkness for the first 10 months. One of the rhizomes was subcultured for two months to proliferate rhizome branches on the modified MS (Murashige and Skoog, 1962) medium containing 412.5 mg/l ammonium nitrate and 950 mg/l of potassium nitrate, 20 g/l sucrose and 20 g/l gelrite [this seems to be a very high level of Gelrite]. Approximately 10 mm of vegetative shoots formed on apical segments on rhizome branches of proliferated rhizomes cultured on the modified MS medium were used for explants. (Shimasaki, 1996)

Surface Sterilization. Explants taken from in vitro cultures do not require sterilization. However, they should be rinsed with sterile distilled water to remove medium and agar residues.

Culture Vessels. UM culture bottles (Iuchi, Osaka, Japan), of 500-ml capacity, each containing 50 ml of solid medium, were used in the original research. Other containers are also suitable.

Culture Conditions. All research cultures were maintained for 8 weeks at 25 ± 1°C under 16-h photoperiods of 54 μE m^{-2} s^{-1} provided by "white fluorescent light."

Culture Media. Explants should be cultured initially in modified MS medium (Murashige and Skoog, 1962) free of hormones (Table Cym-76), but containing

TABLE CYM-76. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the culture of rhizome tips of *Cymbidium kanran* (Shimasaki, 1995)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH as required, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Dissolve the Gelrite in accordance with the instructions in footnote *g*. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), growth regulatgor (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

[g]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave. The amount suggested in the original report seems too high by one order of magnitude; 2 g l^{-1} seems more appropriate. The error may be due to a misplaced decimal point.

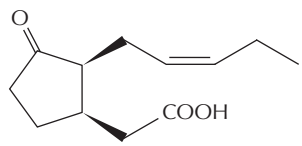
1 μmol jasmonic acid l^{-1}. Shoots obtained on this medium can be cultured on modified MS (Table Cym-75).

Procedure. Seeds of *Cymbidium kanran* should be germinated on the Hyponex medium described above (under Plant Material) and maintained on the same medium (with transfers if necessary) for 10 months. After that, several rhizomes should be cultured on modified MS (Table Cym-75). Explants from these rhizomes are cultured on the initial medium (Table Cym-76). Shoots that form when the rhizomes are cultured on the initial medium (Table Cym-76) should be moved to modified MS (Table Cym-75). If the shoots fail to produce roots, 1 mg NAA l^{-1} should be added to this medium (Table Cym-75) in the hope that this auxin may induce root formation. Shoot cultures of standard *Cymbidium* hybrids (*Cymbidium* Hiroshima Golden Cup 'Sunny Moon') should be cultured on a different initial medium (Table Cym-77). Shoots or plantlets produced by these cultures should be cultured on modified MS (Table Cym-75).

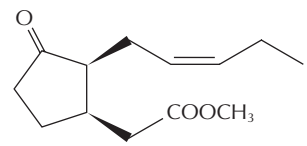
Developmental Sequence. Seeds of *C. kanran* will germinate on the Hyponex medium and form rhizomes. When moved to modified MS medium (Table Cym-75) rhizomes will produce tips which are excised and cultured on the initial medium (Table Cym-76). Shoots and/or PLBs produced on this medium (Table Cym-76) should grow into plantlets on modified MS (Table Cym-75) with or without the addition of NAA. Shoots of *Cymbidium* Hiroshima Golden Cup 'Sunny Moon' form PLBs on the initial medium (Table Cym-77). These PLBs can be expected to form plantlets on the second medium (Table Cym-75).

General Comments. This procedure was developed as a means of investigating the effects of jasmonic acid and ethylene on organogenesis, but it can also be used for micropropagation.

Initially isolated as inhibitors, jasmonic acid (JA) and related substances are now known to be associated with several physiological processes and to function in the defense reactions of plants. Interestingly, JA is structurally similar to the mammalian hormones, prostaglandins. JA was first isolated as a growth inhibitor in 1971 from the fungus *Botryodoploidii theobromae*. Cucurbic acid was first isolated in 1977 from immature pumpkin seeds. It was also considered to be a growth inhibitor. Methyl jasmonate (Me-JA) and JA were found to have growth retarding and senescence promoting characteristics in the early 1980s. The active substances in plants are (+)-7-isojasmonate and (+)-7-jasmonate. In 1989, 12-hydroxyjasmonic acid (12-*O*-β-glucoside of tuberonic acid) was found to be a tuber-inducing factor in potatoes.



(+)-7-isojasmonic acid



Methyl (+)-7-isojasmonate

TABLE CYM-77. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of rhizome tips of *Cymbidium ensifolium* and *Cymbidium kanran* (Ogura and Okubo, 2003)**

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Add items 1–7 and 9 to 900 ml of distilled water (item 14), adjust pH as required, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8) and vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Shoot Formation from Rhizome Apices of *Cymbidium ensifolium* and *Cymbidium kanran*

Temperate *Cymbidium* species are difficult to germinate and propagate in vitro. An in vitro method for shoot formation from apical segments was developed at the Laboratory of Horticultural Science, Division of Agricultural Botany, Department of

Plant Resources, Faculty of Agriculture, Kyushu University, Fujuoka 812-8581, Japan (Ogura and Okubo, 2003).

Plant Material. Apical segments, 5 and 10 mm long, of rhizomes were taken from plants of *Cymbidium ensifolium* and *Cymbidium kanran* growing in vitro on MS medium (Murashige and Skoog, 1962).

Surface Sterilization. Explants taken from plants in vitro do not require surface sterilization. However, they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Erlenmeyer flasks, 100-ml capacity, containing 30 ml medium were used in the original research. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under continuous illumination of 44.73 μmol m^{-2} s^{-1} or standard laboratory conditions.

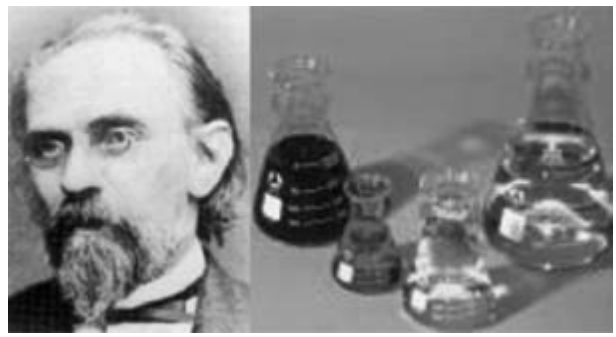
Culture Media. The original paper is not entirely clear regarding the use and combinations of media and species. However it seems that shoot formation in both species occurred on MS (Table Cym-77) with reduced levels of ammonium nitrate (25% of standard MS) and potassium nitrate (50% of basal). It would seem that, as in the preceding two procedures, the newly produced shoot could be cultured on MS (Table Cym-75).

Procedure. Rhizome segments from in vitro plants should be cultured on standard MS (the medium in Table Cym-75 is suitable) for 3–4 months to produce explant sources. Shoot tips are taken from these sources and cultured on the reduced-nitrogen medium (Table Cym-77) for 1–2 months and then transferred to MS (Table Cym-75) for further growth.

Developmental Sequence. The rhizomes grow on MS and produce tips which can be excised. These excised tips grow shoots on the reduced-nitrogen medium (Table Cym-77). These shoots grow further on MS (Table Cym-75).

General Comments. This is an interesting procedure that can be used to propagate two temperate, terrestrial *Cymbidium* species. However, the original report states

Richard August Carl Emil Erlenmeyer (June 28, 1825 to January 22, 1909) invented the Erlenmeyer flask (right). Sources: photograph, www.ch.tu.de; flasks, www.indigo.com.



only that the plants used as explant sources "have been maintained on our laboratory by subcultures for long years." It is not clear if these plants were produced by seeds or through explant culture.

Cytokinin-induced Flowering of *Cymbidium ensifolium* var. *misericors* in Vitro

There are several reports in the literature of orchid seedlings that flowered spontaneously in vitro (for a review see Chia et al., 1999). *Cymbidium ensifolium* is one of the first orchids to flower in vitro, ca. 1984, after being propagated through tissue culture by Xiong Wang at the Shanghai Plant Physiology Institute. After that, other orchids were brought into flower in vitro following micropropagation (Chia et al., 1999). The most recent report regarding the flowering of callus-derived orchids is that of *Cymbidium ensifolium* var. *misericors* at the National Museum of Natural Science in Taichung, Taiwan and the Institute of Botany, Academia Sinica, Taipei, Taiwan (Chang and Chang, 2003).

Plant Material. Callus-derived rhizomes, 3–5 mm long, were used as explants. See elsewhere in the *Cymbidium* section for a procedure (Chang and Chang, 1998) that produces rhizomes from *Cymbidium ensifolium* var. *misericors* callus.

Surface Sterilization. Explants taken from in vitro cultures do not require surface sterilization. However, they should be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Photographs in the original report suggest that culture tubes (approximate diameter 3–4 cm) were used. Other containers are also suitable.

Culture Conditions. The research cultures were maintained for 100 days at 25 ± 1°C under 16-h photoperiods of 10 μmol m^{-2} s^{-1} provided by daylight fluorescent lights (FL-30D/29 40W, China Electric Co., Taipei, Taiwan). Standard tissue culture conditions may be suitable, however attention must be paid to the light/dark cycle (16/8 h) because photoperiod length may be critical.

Culture Medium. Half-strength MS medium supplemented with peptone, sodium phosphate (NaH_2PO_4), NAA, TDZ or N^6-(2-isopentenyl) adenine (2iP), and solidified with Gelrite should be used (Table Cym-78).

Procedure. Explants are placed on the medium and cultured for 100 days.

Developmental Sequence. Rhizomes (Fig. Cym-12A) in culture produced gravitropic rhizomes covered with trichomes (Fig. Cym-12B), vegetative buds that contained small and true leaves (Fig. Cym-12C), and inflorescences that had bracts at their nodes and florets at the tips (Fig. Cym-12D). In the presence of cytokinins, the rhizomes produced undersized (Fig. Cym-13A), erect (Fig. Cym-13B), gravitropic (Fig. Cym-13F), and clumped (Fig. Cym-13E) inflorescences, which had normal flowers with, sepals, petals, labella and gynostemia (Fig. Cym-13C, D, G, H).

TABLE CYM-78. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962)**

15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
16	Peptone	1.0	No stock	No stock	Weigh
	Sugar				
17	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[g]	To 1000 ml			
	Solidifier				
19	Gelrite[g]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively. Use NAA and 2-iP or TDZ, not NAA plus 2-iP and TDZ.

[g]Add items 1–8 and 9 to 900 ml of distilled water (item 18), adjust pH as required, add sugar (item 17), and raise volume to 1000 ml with distilled water (item 18). Dissolve the Gelrite (item 19) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved, pour the solution into a 2-l flask and autoclave. Add the amino acid (item 9), hormones (items 11 and 12; use TD or 2-iP, not both), and vitamins (items 13–15) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Solidifier is not added to liquid media.

[h]Gellan gum (Phytagel or Gelrite are available from www.caissonlabs.com or www.sigmaaldrich.com) is a solidifier which produces a firm and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for

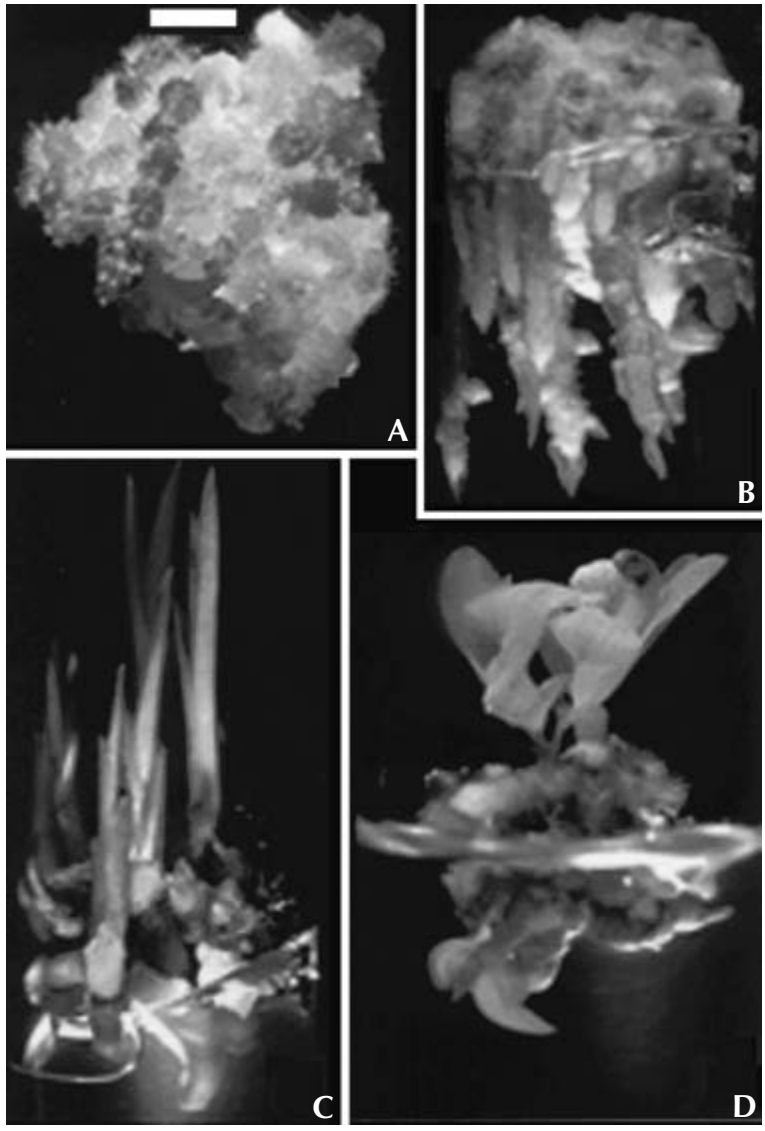

FIG. CYM-12. **Induction of flowering in vitro in *Cymbidium ensifolium* var. *misericors*. A. Rhizome explant (bar = 3 mm). B. Proliferated rhizome after 100 days of culture on hormone-free medium (bar = 6 mm). C. Shoots which formed on medium containing 3.3 µmol TDZ l^{-1} and 1.5 µmol NAA l^{-1} after 100 days of culture (bar = 10 mm). D. Inflorescence which formed on medium containing 10 µmol BA l^{-1} and 1.5 µmol NAA l^{-1}after 100 days in culture (bar = 8 mm). The bar in A refers to all the illustrations, but the relative length is different in each.**

gelation. Dilute media may require higher concentrations of gellan gum or additional calcium or magnesium salts. Gellan gum must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} may have to be used for media which must be very hard or contain low cation levels. After the gellan gum is dissolved the medium is poured into culture vessels and autoclaved.

Erect raceme inflorescence (bar = 8 mm). C. Flower segment (bar = 3 mm). D. Column and ovary (bar = 3 mm). E. Inflorescence clumps (bar = 4 mm). F. Inflorescence (bar = 4 mm). G. Sepals and petals (bar = 3 mm). H. Column with anther and stigma (bar = 0.7 mm). The bar in A refers to all the illustrations, but the relative length is different in each.**

General Comments. This is an interesting and unique method for flower induction in vitro. The authors should be commended for providing complete details, which should make it possible for others to repeat the procedure and perhaps even apply it to other cymbidiums or orchids. This approach stands in marked and commendable contrast to the bizarre content of a previous paper on the induction of *Dendrobium* flowers in vitro (Goh, 1996) and instructions by Professor Goh that no one should be allowed to read two honors theses by his students (Ng, 1997, being one of them).

Eradication of Odontoglossum Ring Spot (ORSV) and *Cymbidium* Mosaic (CyMV) Viruses through Chemotherapy in Vitro

Infections of *Cymbidium* plants with CyMV and ORSV have been of major economic importance for a long time. An eradication method using Virazole was developed nearly two decades ago (Albouy et al., 1988).

Plant Material. Apices were excised from "a Cymbidium [sic] miniature hybrid."

Surface Sterilization. The original report presents no information regarding surface sterilization. Methods for other *Cymbidium* explants (Wimber, 1963, 1965; Sagawa et al., 1966) are suitable.

Culture Vessels. Culture tubes, 20 × 120 mm, were used in the original research. They should be filled to 20–30% of their volume with medium. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at 25°C during light periods and 20°C in the dark under 16-h photoperiods of 3500–6000 lx. Sources of illumination were not described. Standard culture room conditions are also suitable.

Culture Media. "The basic medium is that of the producer (Ets Vacherot Lecoufle) solidified with Gr (8 g/l): M[edium] I with 2 g active charcoal and M[edium] II without, supplemented with 25 or 35 ppm Virazole . . . or (0) for the control. . . ." This information is useless because the content of medium or media used by Vacherot and Lecoufle was never disclosed. They were given a recipe (or recipes) by their good friend Professor Georges Morel long before he published it (them). Appropriate media are probably those used in other procedures (see Tables Cym-1 to Cym-4). Thus:

1. M-I will be one of these media (see Tables Cym-1 to Cym-4), supplemented with 2 g active charcoal (AC) l^{-1}.
2. M-II will be one of these media (see Tables Cym-1 to Cym-4), supplemented with 25 or 35 ppm Virazole.
3. M-III will be one of these media (see Tables Cym-1 to Cym-4), without AC or Virazole.
4. M-IV will be one of these media (see Tables Cym-1 to Cym-4), plus 0.1 mg IAA l^{-1}, 0.01 mg BA l^{-1}, 20 g sucrose l^{-1}, and 2 g AC l^{-1}. This medium should be used for the culture of PLBs.

5 M-V will be one of these media (see Tables Cym-1 to Cym-4), plus 1 mg IAA l^{-1}, 0.1 mg BA l^{-1}, and 20 g sucrose l^{-1}. This medium should be used for rooting plantlets.
6 M-VI will be one of these media (see Tables Cym-1 to Cym-4), plus 1 mg IAA l^{-1}, 0.1 mg BA l^{-1}, 1 mg gibberellin (GA_3) l^{-1}, 5 g sucrose l^{-1}, and 3 g AC l^{-1}. This medium should be used for the culture of plantlets.
7 M-VII will be one of these media (see Tables Cym-1 to Cym-4), plus 25 ppm Virazole. This medium should be used to culture protocorms for the purpose of freeing them from virus.

Procedure. PLBs produced by the explants (the original paper refers to them mistakenly as protocorms) should be subcultured five times on M-IV, but after 2–3 transplants they should be moved to a Virazole-free medium. The original report is not very clear regarding these steps: "In each assay new protocorms [sic] were transplanted 5 times to the same fresh medium, but after 2–3 subcultures they were transferred to a virazole free-medium for short time . . . Each subculture was 18 . . . or 30 days old. . . . For inducing the formation of shoots and roots we planted protocorms [sic] on modified medium [presumably M-V or M-VI]." The abstract of the report states that "After 5 subcultures of 18 days in presence of 25 ppm Virazole [presumably on M-VII] we obtained 95% virus free plantlets." Altogether the following seems to be a good procedure (or the best one that can be extracted from a relatively unclear paper):

1 Explants should be taken and cultured on an appropriate medium (see Tables Cym-1 to Cym-4) to produced PLBs.
2 PLBs should be cultured on medium M-IV 2–5 times.
3 PLBs from M-IV should be subcultured five times for 18 days each time on medium M-VII to free them from virus.
4 After culture on M-VII, PLBs should be moved to media M-V and/or M-VI to produce rooted plantlets.

Plantlets presumed to be virus-free should be assayed for virus. These assays are neither simple nor easy. Kits and testing are available from www.agdia.com and http://plantpath.osu.edu/cweppdc/plantdis.html#tests. Virus-free plantlets should be planted in potting mix in a greenhouse. Infected plantlets should be destroyed.

Developmental Sequence. Explants form PLBs on the initial medium (see Tables Cym-1 to Cym-4). These PLBs will presumably multiply on the second medium (M-IV). The PLBs will (hopefully) be freed of virus on medium M-VII. On transfer to media M-V and/or M-VI, the PLBs can be expected to produce rooted plantlets.

General Comments. This is an older procedure which may work. Newer procedures may be more effective. As in the newer procedures, the most difficult part will be the virus assays.

Cypripedium

Conrad Gesner (March 26, 1516 to December 13, 1565), who was honored with the title Plinius Germanicus (Wehner et al., 2002), was the first to describe a *Cypripedium* in the European botanical literature in his *Horti Germaniae* which was published in 1561. He also included a drawing of *Cypripedium calceolus* in his *Opera Botanica* which lay forgotten for 200 years and was published in 1751 (Wehner et al., 2002). And, a *C. calceolus* painting was among the many Gesner paintings which were discovered in 1929 at Erlangen University and published in his *Historia Plantarum* between 1972 and 1980 (Wehner et al., 2002).

The name *Cypripedium* was introduced by Carolus Linnaeus (1707–1778) in 1737 and for many years after that all "slipper orchids" or "slippers" were included in this genus. Species which are included in *Paphiopedilum* at present were removed from *Cypripedium* by Ernst Pfitzer (1846–1906) between 1886 and 1894. The taxonomic treatment of the slipper orchids was completed by Robert Alan Rolfe (1855–1921) in 1896.

The genus *Cypripedium* consists of approximately 45 species which are found in North America down to Mexico, temperate areas in northern Asia, Europe, and Japan (for a review of the genus see Cribb, 1997).

Cypripedium species are not as easy to grow as *Paphiopedilum*. Their seeds are more difficult to germinate in vitro. Their explants are often recalcitrant in tissue culture.

Plantlet Production from Root Tips of *Cypripedium calceolus*

A very attractive orchid, *Cypripedium calceolus* is an endangered species due to over-collection and loss of habitat. A micropropagation method was developed as part of cooperative research between Hirosaki University in Japan and the Royal Botanic Gardens, Kew in the UK (Tomita and Ramsay, 1998). Unfortunately the only description of the procedure is in an abstract.

Plant Material. Seedlings of *C. calceolus* were removed from aseptic culture and stored in (non-sterile) sealed vinyl bags in the dark at 5°C for approximately 3 months. Root tips, 5–10 mm long, taken from these seedlings are used as explants.

Surface Sterilization. Prior to taking explant seedlings from the vinyl bags they should be surface sterilized by immersing them in saturated calcium hypochlorite for 20 min and then washed three times with sterile distilled water. Surface sterilization can (and probably should) be avoided, either by storing the young plantlets in sterile containers or by taking explants from seedlings that are still in aseptic culture and maintained either under standard culture conditions or stored at 5°C. The sterilant is prepared by suspending 7 g of calcium hypochlorite [$CaCl_2O_2$ or $Ca(ClO)_2$] in 100 ml of water with vigorous stirring for 2–3 min, allowing the solution to stand until the precipitate settles, stirring again, and filtering or decanting the yellowish fluid which must be used within 12 h. This sterilant, known as Wilson's calcium hypochlorite

solution, was formulated in the laboratory of Professor Lewis Knudson (the Cornell University botanist who discovered the asymbiotic germination of orchid seeds) by one of his students (Wilson, 1915) who left botany to teach tennis (personal communication in the late 1980s by the late Giltner J. Knudson, Prof. Knudson's younger son).

Culture Vessels. Erlenmeyer flasks, test tubes or other containers are suitable. They should be filled with medium to about 20–30% of their volume.

Culture Conditions. The original paper is not very clear on this point. Cultures should be kept in the dark at 20°C at least at first. When callus is formed the cultures can probably be moved gradually to the light and/or standard culture room conditions.

Culture Media. Half-strength MS medium (Murashige and Skoog, 1962) containing 20 g sucrose l^{-1}, 0, 10 or 50 mg picloram l^{-1} (there is no recommendation for a specific amount), and 1 or 10 mg BA l^{-1} (an optimal level is not indicated), adjusted to pH 5.5 before autoclaving and solidified with 7 g agar l^{-1} or 3 g gellan gum (available as that from www.caissonlabs.com and sold as Phytagel by www.sigmaaldrich.com) l^{-1}, should be used as the initial substrate (Table Cyp-1). Shoots and plantlets should be moved to gellan gum (Phytagel)-solidified hormone-free half-strength MS (Table Cyp-2) after the initial 22 weeks.

Procedure. It is not clear if storing the seedlings in the dark at 5°C is a requirement for success in culture or is performed as a matter of convenience. Therefore it is advisable to start by taking seedlings from cultures and storing them as suggested before excising explants, but also by culturing root tips from seedlings which have not been removed from their original cultures. Root tips in culture should be kept in the dark at 20°C until callus is formed. After that the callus cultures should be moved gradually to light and standard laboratory conditions.

Developmental Sequence. Callus is formed by the root tips after 4 weeks of culture on the first medium (Table Cyp-1). Shoots develop after 16 weeks. Some shoots form roots after longer periods. Roots appear on most shoots after an additional 4 weeks of culture on the second medium (Table Cyp-2).

General Comments. These findings suggest that it may be possible to develop protocols for the micropropagation of mature plants of *C. calceolus*. However if root tips of mature plants are used it will be necessary to control or avoid the mycorrhizal fungi which are always present in orchid roots. The authors of this procedure suggest that picloram is preferable to 2,4-D as an auxin in the first culture medium because "it is effective at lower concentrations than 2,4-D and thus less likely to cause genetic changes." This suggestion may be valid. However, it is also possible that a lower level of picloram is needed because it is a more active analog of auxin. If so this compound could also cause mutations. In any case, mutagenicity is not necessarily and/or always correlated with effectiveness as an auxin and/or concentration.

TABLE CYP-1. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for culture of root tips of *Cypripedium calceolus* (Tomita and Ramsay, 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	825.0	82.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220.0	22.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185.0	18.5 g l^{-1}	10

(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	11.2	1.12 mg l^{-1}		
(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin analog				
10	Picloram	10.0 or 50	1000 or 5000 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylaminopurine (BAP)	1.0 or 10	10 or 100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	7.0 g	No stock	No stock	Weigh
	or gellan gum (Phytagel)	3.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin analog or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. Gellan gum (Phytagel) must be added to water at room temperature slowly with rapid stirring to eliminate lumps before the medium is heated. If gellan gum (Phytagel) is added to warm or hot medium it will form clumps and fail to gel properly after autoclaving. Typical concentrations are 1.5–2.5 g l^{-1} which means that the amount used in this medium is slightly higher than usual. When the agar or gellan gum (Phytagel) is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels.

TABLE CYP-2. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for culture of root-tip-derived callus, shoots, and plantlets of *Cypripedium calceolus* (Tomita and Ramsay, 1998)**

	or gellan gum (Phytagel)	3.0	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Add items 1–7 and 9 to 900 ml distilled water (item 14), adjust pH to 5.5, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. Gellan gum (Phytagel) must be added to room temperature water slowly with rapid stirring to eliminate lumps before the medium is heated. If gellan gum is added to warm or hot medium it will form clumps and fail to gel properly after autoclaving. Typical concentrations are 1.5–2.5 g l^{-1} which means that the amount used in this medium is slightly higher than usual. When the agar or gellan gum is completely dissolved pour the solution into culture vessels and autoclave.

Production of Plants from Seed-derived Callus of *Cypripedium macranthos* var. *taiwanianum*

Like many other orchid species *Cypripedium macranthos* has a checkered nomenclatural history that is complicated by a wide distribution (China, Japan, Korea, European and Asiatic Russia, including Kamchatka, the Kuril Islands, Sakhalin Island, and Siberia, as well as Taiwan) and some variability, both of which invited tinkering for nearly a quarter of a millennium by taxonomists of several nationalities. As a result there are two specific epithets (*Cypripedium macranthum* and *Cypripedium macranthos*) and several varieties. The species is a terrestrial herb which can be 15–40 cm tall. It produces attractive purple to pink flowers (Cribb, 1997). This species is currently endangered due to habitat loss and overcollection (Golovanov et al., 1988). Plant production from seed-derived callus of *C. macranthos* Swartz var. *taiwanianum* (Masamune) F. Maekawa *hort.* was studied by the husband and wife team of Masanori and Mina Tomita "to obtain basic information for the micropropagation of and future breeding of endangered *Cypripedium* species" (Tomita and Tomita, 1997).

Plant Material. Unripe capsules were harvested 7 weeks after pollination and the immature seeds were placed on a medium which favors callus induction. Callus masses should be moved to a second medium for plantlet production.

Surface Sterilization. No details beyond "standard method" are given in the original paper, but the steps recommended below are appropriate. The capsule should first be washed with tap water and a household detergent. Brushing with a soft (used) toothbrush is advisable. Following a rinse with tap water the capsule should be soaked in 70% ethanol (73–74 ml 95% ethyl alcohol diluted to 100 ml with distilled water) for 30–60 s (it does not matter if the alcohol kills the outer cell layers of the capsule because the seeds are inside, but it is important to make sure that there are no cracks in the fruit which will allow water or sterilants to reach the interior of the fruit). The next step must be several rinses with sterile distilled water. After that flame the capsule for 1–2 s in an alcohol flame. The flamed fruits should then be soaked for 10–20 min in a 10% dilution of household bleach (10 ml household bleach diluted to 100 ml with distilled water) and rinsed 2–3 times with sterile distilled water. An additional dip in 70% ethyl alcohol for 10–20 s followed by 2–3 rinses with sterile distilled water may be advisable, but are not necessary.

Scalpels and other tools that will be used to split the capsule and place the seeds on the culture medium must be sterilized by autoclaving or dipping them in alcohol and/or flaming. While working these tools should be dipped in alcohol and/or flamed often.

Culture Vessels. Test tubes, 25×150 mm, containing 20 ml of medium, are suitable for seed germination. Erlenmeyer flasks, 125, 250, or 500 ml, containing 25, 50, or 100 ml of medium respectively can be use to culture callus or produce plantlets. Other containers can also be used.

Culture Conditions. Seed cultures should be placed in the dark at 20°C. Conditions for the culture of callus are not indicated, but standard culture rooms should prove suitable after a short period at 20–25°C in the dark. Cultures should be placed under standard culture room conditions for plantlet production, growth, and development.

Culture Media. T medium (Tsutsui and Tomita, 1990) supplemented with yeast extract should be used for seed germination (Table Cyp-3). The same medium containing NAA and BA is used for plantlet induction (Table Cyp-4). Plantlets should be cultured first in hormone-free T medium (Table Cyp-3) and then transferred to sterile sand irrigated with the inorganic components of the T medium (Table Cyp-5).

TABLE CYP-3. **Tsutsui and Tomita (T) medium (Tsutsui and Tomita, 1990) for immature seed germinination and callus induction in *Cypripedium macranthos* var. *taiwanianum* (Tomita and Tomita, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.5	50.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	3.0	300.0 mg l^{-1}		
(e)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.025	2.5 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.5	50.0 mg l^{-1}		
	Complex additive				
8	Yeast extract	200.0	No stock	No stock	Weigh
	Sugar				
9	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			
	Solidifier				
11	Gellan gum (Phytagel)[e]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Add items 1–8 to 900 ml of distilled water (item 10), adjust pH to 5.5, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). Gellan gum (available as such from www.caissonlabs.com and as Phytagel from www.sigmaaldrich.com) is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum; item 11) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYP-4. **Tsutsui and Tomita (T) medium (Tsutsui and Tomita, 1990) for plantlet production from seed-derived callus of *Cypripedium macranthos* var. *taiwanianum* (Tomita and Tomita, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
12	Water, distilled[f]	To 1000 ml			
	Solidifier				
13	Gellan gum (Phytagel)[f]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]If the auxin or cytokinin fails to dissolve add a few drops of 0.1N NaOH or 0.1N KOH, or 0.1N HCl respectively. Keep frozen between uses.

[f]Add items 1–8 to 900 ml of distilled water (item 12), adjust pH to 5.5, add sugar (item 11), and raise volume to 1000 ml with distilled water (item 12). Gellan gum (available as such from www.caissonlabs.com and as Phytagel from www.sigmaaldrich.com) is an agar substitute (item 13) which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into a 2-l Erlenmeyer flask and autoclave. Following the autoclaving use a sterile pipette to add the auxin to the medium while it is still liquid and warm, but no longer hot. Swirl or stir the medium with a sterile stirrer to mix the auxin thoroughly and pour the medium into presterilized culture vessels. Solidifier is not added to liquid media.

Procedure. The seeds must be sown on the first medium (Table Cyp-3) as soon as the unripe fruits have been harvested. After 16 weeks (ca. 4 months) of culture callus masses can be subcultured onto the same medium (Table Cyp-3) every 4 weeks (about a month) for 60 weeks (1 year and 2 months). To produce plants, callus masses should be cultured on the NAA- and BA-containing medium (Table Cyp-4). When

TABLE CYP-5. **Basal Tsutsui and Tomita (T) medium (Tsutsui and Tomita, 1990) for irrigating plantlets of *Cypripedium macranthos* var. *taiwanianum* cultured in sand (Tomita and Tomita, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

(f)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.5	50.0 mg l^{-1}		
	Solvent				
8	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Add the macroelements (items 1–5), chelated iron (item 6), and microelements (item 7) to 750 ml of distilled water (item 8). Adjust pH to 5.5 and bring volume to 1000 ml (1 l) with distilled water (item 8).

plants are formed they should be cultured on the NAA- and BA-containing medium for 8 weeks and moved to a hormone-free substrate (Table Cyp-3). After 16 weeks on this medium the plantlets can be transferred to sand culture (Table Cyp-5). While the plants are on the sand medium they should be vernalized for 12 weeks at 5°C.

Developmental Sequence. Seed germination takes place on the first medium (Table Cyp-3). Some of the seeds form callus masses on this medium. These masses produce more callus on being subcultured on the same solution (Table Cyp-3). When cultured on the second medium (Table Cyp-4) the callus produces plantlets which develop after being moved to the first substrate (Table Cyp-3). The plantlets develop further on the sand medium and after they are vernalized under low temperature (5°C for 12 weeks).

General Comments. This is not a micropropagation procedure in the very strict sense because the callus masses are produced by seeds. Nevertheless it is presented here because it could serve as a starting point for an actual micropropagation protocol.

Micropropagation of *Cypripedium montanum* through Node Culture

North American *Cypripedium* species are no less beautiful than other members of the genus, but they have not received the attention they deserve as horticultural plants and in the laboratory. A micropropagation method using nodes from axenically cultured plants was developed at Hiroshima University in Japan (Hoshi et al., 1994).

Plant Material. Nodes were taken from more than 1-year-old seedlings grown in vitro obtained from Green Lab Co. (Nagano, Japan). No details are provided regarding the manner of cutting and size of explants.

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, 100-ml capacity, containing 30 ml of medium, were used in the original research. Other containers are also suitable.

Culture Conditions. The original cultures were maintained at 22°C under 16-h photoperiods of 400–800 lx provided by fluorescent lamps (type not indicated). Standard culture room conditions are also suitable.

Culture Media. No information was presented regarding the medium or media used to germinate seeds and/or maintain seedlings of *C. montanum*. Nodes were cultured on MS medium (Murashige and Skoog, 1962) containing 0.2 mg NAA l^{-1} and 2 mg BA l^{-1} (Table Cyp-6).

Procedure. Explants were cultured but no attempt was made to take the resulting plantlets out of the flasks and grow them.

Developmental Sequence. Explants produced well-branched rhizomes with 20 or more shoots (Fig. Cyp-1). "When shoot tips were cut and meristems were then removed, forthcoming interposes became shorter and thicker, producing several knob-like shoots which were subsequently divided and transplanted individually into different culture flasks."

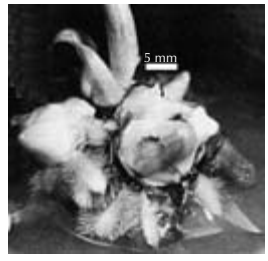

FIG. CYP-1. **Subculture, 30-day-old, of *Cypripedium montanum* node. Multiple shoots formed within 10 days (Hoshi et al., 1994).**

TABLE CYP-6. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Cypripedium montanum* nodes (Hoshi et al., 1994)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.2	20 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylaminopurine (BAP)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH as required, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

General Comments. The authors of this procedure put this best: "The node culture may be a promising method for the micropropagation of *C. montanum*, however, it remains to be determined whether or not in vitro-grown seedlings [sic, the correct word here is plantlets] derived from this nodal technique can survive transfer to septic conditions."

Micropropagation of *Cypripedium yatabeanum* through Root-tip Culture

The Japanese botanist Tomitaro Makino (1862–1957) named *Cypripedium yatabeanum* in honor of Dr. Ryokichi Yatabe (1851–1899), who was the first professor of biology at Tokyo University. He is credited with discovering the species (Luer, 1975). It is found in the Aleutian Islands, Alaska, Japan, Kamchatka Peninsula, Kodiak Island, Kurile Islands, Sakhalin Island, and Siberia. In 1903 E. Pfitzer reduced *C. yatabeanum* to varietal status under *Cypripedium guttatum* and many taxonomists have treated it as such. Others retained the original name which will be used here because the report on the culture of its root tips uses it (Jo et al., 2001). The method was developed to facilitate conservation and meet commercial demands.

Plant Material. Root tips, 10 mm long, were excised from 30- to 40-mm-tall seedlings grown on a medium (Table Cyp-7) designated as JA (this medium is not named by/for Joseph Arditti; the designation "JA" is by Jo et al., 2001 for reasons of their own) for 17 months.

Surface Sterilization. There is no need to surface sterilize explants taken from seedlings which are growing in vitro. However they must be rinsed with sterile distilled water to remove medium residues.

Culture Vessels. Erlenmeyer flasks are most suitable for suspension cultures on shakers. Plastic or other containers can be used for solid cultures.

Culture Conditions. Cultures for callus inductions should be maintained at 23 ± 1°C in the dark. The same conditions should be used for suspension cultures which must be shaken at 90 rpm (there is no indication if the shaking must be rotatory or oscillatory). There is no information regarding culture conditions for what the paper calls "regeneration of the callus" and production of adventitious roots and shoots. A possible assumption is that these processes can take place under the same temperature, but may require illumination.

Culture Media. Seedlings should be grown on the JA (see note above about the "JA" name) medium (Table Cyp-7). "Adventitious roots and shoots could be regenerated from callus" on the same medium. Callus is induced on the B5 medium (Table Cyp-8) containing 1 mg l^{-1} each of 2,4-D and BA. Callus should be proliferated on liquid medium KM81 (Table Cyp-9) supplemented with 2 mg NAA l^{-1}, 0.2 mg BA l^{-1} and 0.5% polyvinylpyrolidone (PVP) l^{-1}. An unclear step is "regeneration of the callus of *C. yatabeanum* [which] could be induced by culture on B5 medium [Table

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 4a) and the iron salt (item 4b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Kundson's original recipe for this medium does not use chelated iron which is is preferable and therefore suggested here. The concentration is the same as the one used in the Murashige–Skoog medium.

[d]Add all microelements to the same 1 l of water.

[e]Add items 1–9 to 900 ml of distilled water (item 11), adjust pH to 5–5.2, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. The similarity between the initials of Joseph Arditti and the designation "JA" is purely coincidental. The medium was not formulated by Joseph Arditti and it is not named by or for him.

Cyp-10] supplemented with 1 mg l^{-1} IPA [indolepropionic acid, an auxin available from www.sigmaaldrich.com, www.fishersci.com, and www.caissonlabs.com] and 5% PVP [available from the same sources]." What this step could be is multiplication of the callus or induction of meristematic regions.

Procedure. The root tips are cultured first in the B5 medium with 1 mg l^{-1} each of 2,4-D and BA (Table Cyp-8) at 23 ± 1° in the dark. Callus which forms on this medium should be moved to the KM81 liquid medium (Table Cyp-9) on a shaker in the dark

TABLE CYP-8. **B5 medium (Gamborg et al., 1968) modified for callus induction from root-tip explants of *Cypripedium yatabeanum* (Jo et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	8.0 g	No stock	No stock	Agar or Phytagel, not both. Weigh one or the other
	or gellan gum (Phytagel)[h]	2.0–3.0	No stock	No stock	

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–8 to 900 ml of distilled water (item 15), adjust pH to 5.2–5.4, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring [see footnote *h* if gellan gum (Phytagel) is used]. The agar can also be added to the cold water which is then brought to a boil and stirred [see footnote *h* if gellan gum (Phytagel) is used]. When the agar or gellan gum is completely dissolved pour the solution into a 2-l flask and autoclave. Add items 9–13 to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels.

[h]Gellan gum (available as such from www.caissonlabs.com and as Phytagel from www.sigmaaldrich.com) is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Phytagel (gellan gum) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum has dissolved pour the medium into culture vessels and autoclave. Or, if it is undesirable to autoclave hormones and vitamins pour the medium into a 2-l Erlenmeyer flask after the gellan gum has dissolved and autoclave. Following the autoclaving use sterile pipettes to add the auxin (item 9), cytokinin (item 10), and vitamins (items 11–13) to the medium while it is still liquid and warm, but no longer hot. Swirl or stir the medium with a sterile stirrer to mix the auxin thoroughly and pour the medium into presterilized culture vessels. Solidifier is not added to liquid media.

TABLE CYP-9. **Kao and Michayluck (KM81) medium (Kao and Michayluk, 1981) modified for proliferation of callus derived from root-tip explants of *Cypripedium yatabeanum* (Jo et al., 2001)**

TABLE CYP-9. (***Continued***)

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Vitamins				
25	Niacin (nicotinic acid)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
26	Pyridoxine (vitamin B_6)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
27	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
28	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
29	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 8a) and the iron salt (item 8b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4{\cdot}4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4{\cdot}7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]The recipe as provided by one of the authors (Jo et al., 2001) is not clear because it lists glutamine in two places, once as 20 ml l^{-1} and a second time as 100 mg l^{-1}. As a rule components are listed only once per recipe.

[g]Dissolve 975 mg morpholinoethanesulfonic acid (MES, available from www.sigmaaldrich.com or www.fishersci.com) in 50 ml distilled water, adjust pH to 5.8 with 0.1 or 1 N NaOH (if pH is below 5.8) or HCl (if pH is above 5.8) and add this solution in its entirety to 1 l of medium.

[h]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[i]Add items 1–27 plus 5 g polyvinylpyrrolidone to 900 ml of distilled water (item 29), check pH and adjust to 5.8 if necessary, add sugar (item 28), and raise volume to 1000 ml with distilled water (item 29). Pour the solution into culture vessels and autoclave. As a rule amino acids (items 10–13), hormones (items 23 and 24), and vitamins (items 25–27) are added to media after autoclaving, but there is no indication that there is a need to do that in this case. Agar is not added to liquid media.

for proliferation. Once the callus is proliferated it is necessary to move it to the medium with IPA and PVP (Table Cyp-10). As indicated above, the original paper is not entirely clear regarding the function of this medium and the purpose of this step. However it seems that the callus mass may increase in size and shoots may be produced on it. After this step sections of the callus should be moved to the JA medium (Table Cyp-7) for plantlet production.

Developmental Sequence. Callus forms on the first version of the B5 medium (Table Cyp-8). It proliferates on medium KM81 (Table Cyp-9). It is not clear what happens on the second B5 medium (Table Cyp-10). Plantlets should form when callus is moved from the second B5 medium (Table Cyp-10) to the JA solution (Table Cyp-7).

General Comments. This is an interesting, potentially useful procedure that could have been even more useful if the paper had been clearer, with more details.

TABLE CYP-10. **B5 medium (Gamborg et al., 1968)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	134.0	13.4 g l^{-1}	10

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.0–5.4, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Some hormones and vitamins are not heat-stable and it is generally advisable to add following autoclaving. There is no need to do that with this medium.

Plant Production from Protocorm-derived Callus of *Cypripedium formosanum*

"Slipper" orchids are still difficult if not impossible to propagate clonally through tissue culture. Methods to the extent that they are formulated use explants from

seedlings for the most part. This is also the case with a method which was developed recently at the Department of Horticulture, National Taiwan University, Taipei, Taiwan (Lee and Lee, 2003). Of the few methods for *Paphiopedilum* which use explants from mature plants, two (Bubeck, 1973; Stewart and Button, 1975) received considerable publicity (one of Ms. Bubeck's mentors was influential in the American Orchid Society whereas Joyce Stewart is an effective international orchid politician), despite being unreliable and not of much use. A third method (Huang, 1988) has not been used extensively despite being reproducible.

Plant Material. Plants of *C. formosanum* cultivated in a greenhouse located 2000 m above sea level were self-pollinated and the capsules were harvested 3 months after pollination. They were surface sterilized with 1% sodium hypochlorite (1.7 ml of Clorox which contains 6% sodium hypochlorite diluted to 100 ml with distilled water) for 20 min, rinsed three times with sterile distilled water, and cut open. The seeds were scooped out and germinated on modified (quarter-strength macroelements, full strength-microelements, and other additives) MS medium (Murashige and Skoog, 1962) solidified with Gelrite (Table Cyp-11). Seed cultures were maintained in the dark at 25 ± 2°C for 12 weeks. Small round protocorms developed during this period. The cultures were then cultured under illumination of 25–30 μmol m^{-2} s^{-1} (duration of photoperiods was not given) produced by daylight fluorescent tubes (FL-20D/18, 20W, China Electric Co., Taipei) for an additional 8 weeks. Following a total of 20 weeks in culture the protocorms were bisected transversely and the sections were used as explants.

Surface Sterilization. Explants taken from in vitro cultures do not require surface sterilization. However, the explants must be rinsed with sterile distilled water to remove culture medium residues.

Culture Vessels. Culture tubes, 25 × 100 mm, containing 10 ml of medium can be used for callus induction, PLB formation, and plantlet production. Other containers are also suitable.

Culture Conditions. All cultures should be maintained at 25 ± 2°C. Those intended to produce callus are kept in the dark. For PLB formation and plantlet production cultures should be maintained under the same intensity of illumination as the seeds and 12-h photoperiods, but the original report also includes the puzzling phrase "or in the dark."

Culture Media. Callus is produced on a modified MS medium (Table Cyp-12) containing 4.52 μmol 2,4-D and 4.54 μmol TDZ. PLBs form on another modification of MS medium (Table Cyp-13) containing 4.44 μmol BA. Plantlets develop on yet another medium (Table Cyp-14).

Procedure. The seeds are germinated and protocorms are cultured on the germination medium (Table Cyp-11) for 12 weeks in the dark. After that these cultures are illuminated for 8 weeks before the protocorms are cut in half transversely. The sections are cultured under illumination on the 2,4-D- and TDZ-containing medium

TABLE CYP-11. **Modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for the germination of immature seeds of *Cypripedium formosanum* from green (unripe) 3-month-old fruits (Lee and Lee, 2003)**

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]The original paper does not list the exact type and source of the tryptone. If available tryptone recommended for plant tissue culture should be used.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.5, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Add the Gelrite (item 16) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved dispense the medium into culture vessels and autoclave. Solidifier is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYP-12. **Modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for callus production from protocorms produced by immature seeds of *Cypripedium formosanum* (Lee and Lee, 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	412.5	41.25 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	110.0	11.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	97.5	9.75 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	475.0	47.5 g l^{-1}	10

	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin fails to dissolve add a few drops of 0.1 N KOH or 0.1 N HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Add the Gelrite (item 17) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved dispense the medium into culture vessels and autoclave. Solidifier is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

TABLE CYP-13. **Modified Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for protocorm-like body (PLB) production from callus produced by immature seeds of *Cypripedium formosanum* (Lee and Lee, 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	412.5	41.25 g l^{-1}	10

16	Gelrite[g,h]	2.2 g	No stock	No stock	Weigh
	Darkening agent				
17	Activated charcoal[i]	1.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]The original paper does not provide instructions regarding the preparation of potato homogenate. One possibility is to place 20 g of peeled and cubed potatoes in a homogenizer, add 100 ml of distilled water, and homogenize the cubes completely.

[g]Add items 1–13 to 750 ml of distilled water (item 15), adjust pH to 5.5, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Add the Gelrite (item 16) in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved dispense and add the charcoal with vigorous stirring to ensure complete dispersion. After that dispense the medium into culture vessels and autoclave. Solidifier is not added to liquid media.

[h]Gellan gum [available as such from www.caissonlabs.com and as Phytagel (www.sigmaaldrich.com) or Gelrite] is an agar substitute which produces a firm, clear and colorless solid substrate at concentrations lower than those of agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan gum. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature to eliminate the formation of lumps. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations for standard media are 1.5–2.5 g gellan gum (Phytagel, Gelrite) l^{-1}, but up to 10 g l^{-1} can or may have to be used for media which must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

[i]Only activated pure vegetable charcoal should be used. One possible source is www.sigmaaldrich.com. There are undoubtedly other sources also. Charcoal functions not only by darkening the medium, but also by absorbing toxic substances and perhaps by adding aeration. Therefore darkening agents such as lamp black and graphite which are very different in nature should be used only if required by a specific procedure or under special circumstances. It is always advisable to check the pH of the medium after the addition of charcoal. To keep the electrode free of dark and sticky agar and avoid having to calibrate some pH meters for a hot solution and since small changes in pH (approximately 0.1 of a unit) make no difference, pH paper strips can be used for this measurement. Such paper strips are available from all biological supply houses. One possible source is www.vwr.com, but there are many others.

(Table Cyp-12) until callus is formed. This callus can be subcultured onto the same medium (Table Cyp-12). Callus sections, 4 mm in diameter, are cultured on the BA medium (Table Cyp-13) to produce PLBs. The PLBs are placed on the last medium for plantlet production.

Developmental Sequence. The seeds germinate and form protocorms during the 12 weeks in the dark. These protocorms increase in size during the subsequent 8 weeks under illumination. Transverse sections taken from the protocorms produce callus (Fig. Cyp-2A). Sections of the callus give rise to PLBs (Fig. Cyp-2B, C). Up to 13 PLBs can be obtained from a callus section, 4 mm in diameter. The PLBs produce plantlets (Fig. Cyp-2D–F).

General Comments. This cannot be used for mass rapid propagation of desirable cultivars because the nature of seedlings is unknown. It can be used to multiply seedlings and as a starting point for experiments in the culture of explants from mature plants.

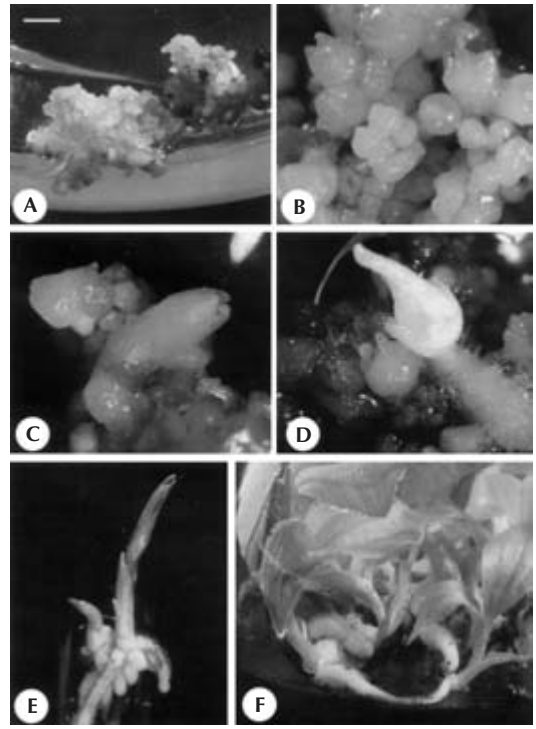

FIG. CYP-2. **Plantlet production from protocorm-derived callus of *Cypripedium formosanum*. A. Callus derived from a protocorm explant. B. PLBs derived from callus. C. Elongated PLB. D. A PLB which developed into a vegetative bud and formed a root. E. Young shoots with roots. F. Plantlets. (Lee and Lee, 2003.)**

Cyrtopodium

Attempts to develop micropropagation procedures using root-tip explants have been made in an effort to reduce the damage or threat to the donor plant. Only a few of these attempts have been successful. One of the more effective ones was developed using roots of *Cyrtopodium* cf. *punctatum*, a species native to the Argentine Chaco (Sanchez, 1988).

Plant Material. The original research was carried out with 2-mm-long root tips taken from 1-year-old seedlings growing axenically on Vacin and Went medium.

Surface Sterilization. Since the explants were taken from axenically grown plants, there was no need for surface sterilization.

Culture Vessels. Test tubes, 20×120 mm and containing 10 ml of medium, were used in the original research. Other culture vessels can also be used.

Culture Conditions. Cultures should be maintained under 16-h photoperiods of 1.8 W m^{-2} and $24 \pm 1°C$.

Culture Medium. Modified Vacin and Went medium (Vacin and Went, 1949) containing NAA and BA (Tables Cyrt-1 and Cyrt-2) should be used.

Procedure. Place explants on the appropriate medium. If necessary, subculture them every 30 days.

Developmental Sequence. After the root tips reach a length of 10 mm, PLBs form on the apical meristems of 20% of the explants. Plantlets develop on these PLBs 1 month after their formation.

General Comments. It is not clear whether this method can be used to culture root tips of mature plants of the same orchid, additional *Cyrtopodium* species, or other orchids. If explants from mature plants are to be used, they should be taken from roots that have not come into contact with the substrate to avoid the presence of mycorrhiza, which will contaminate the cultures. At least one investigator has suggested that orchid plants derived from roots may not fully resemble the parent plant.

TABLE CYRT-1. **Vacin and Went medium (Vacin and Went, 1949) modified for the culture of *Cyrtopodium* root tips, formation of protocorm-like bodies, and plantlet regeneration (Sanchez, 1988)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Peptone	1	No stock	No stock	Weigh
	Vitamin				
9	Thiamine (vitamin B_1)	500 µg	50 mg 100 ml^{-1} 95% ethanol[e]	1	Sugar
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	8 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve and it is not possible to prepare a stock solution. To facilitate the preparation of medium, place 200 mg of the salt in 500 ml water, stir, and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate the iron. To prepare a stock solution of chelated iron dissolve 3.73 g chelating agent (Na_2EDTA) and 2.78 g ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to culture medium.

[e]Keep refrigerated between uses.

[f]Add items 1 and 3–8 to the 500 ml distilled water (item 11) that contains the calcium phosphate (item 2), adjust pH as required, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a gentle boil and stirred. When agar is completely dissolved, pour medium into an appropriate container and autoclave. Add the vitamin (item 9) to the warm, still liquid medium; mix well, and distribute into culture vessels. Omit agar if preparing liquid medium.

TABLE CYRT-2. **Effects of auxin, cytokinin, and coconut water on *Cyrtopodium* root tips in vitro (Sanchez, 1988)**

Medium	Effects
VW[a]	Root tips elongated and formed callus, PLBs,[b] and plantlets
VW + 0.5 ppm NAA + 0.5 ppm BA[b]	Root tips elongated and formed PLBs and plantlets
VW + 1 ppm NAA + 0.5 ppm BA	40% of explants formed roots and whitish basal calli that died
VW + 0.5 ppm NAA + 0.1 ppm BA	Root tips were more elongated on this medium than on other media; 20% formed calli that "showed tissue oxidation"
VW + 1 ppm + 0.1 ppm BA	Root tips elongated but did not form calli
VW + 0.5 ppm NAA + 1 BA	50% of root tips formed fasciated roots and later formed both normal and fasciated ones
VW + 10% CW[c]	30% of explants produced numerous PLBs without callus formation; 60% of this group (i.e., 18% of total) regenerated plantlets

[a]VW, Vacin and Went medium (see Table Cyrt-1). This medium is preferable to the others because it does not contain hormones and other additives that could increase the number of mutations.

[b]BA, benzyladenine (benzylaminopurine); NAA, naphthaleneacetic acid; PLBs, protocorm-like bodies; ppm, parts per million (mg l^{-1}).

[c]CW, coconut water (referred to in the original paper as "milk"), 10% (v/v).

Dactylorchis

Dormant shoots (early fall in England) were excised from *Dactylorchis fuchsii* and disinfected by "immersing briefly in ethanol followed by fifteen minutes in a hypochlorite solution" (Stokes, 1974). (The concentration is not given, but 10 g calcium hypochlorite per 140 ml of water would probably be appropriate.) After rinsing the tissue with sterile distilled water, terminal portions of shoot tips consisting of floral primordia were excised and cultured on "Knudson C and a variant of Reinert and Mohrs' [sic] medium." Details regarding the media are not given. Therefore one can only assume that the original formulation or a modification of the Knudson C medium would be appropriate (see Tables Aranda-7, Aranda-8, C-3, C-6, C-7, C-11, C-19, and Cym-1 to Cym-3). The Reinert–Mohr medium (see Tables C-8 and C-9) contained "autoclaved extracts from parent plants" such as homogenized leaves "filtered to form a leaf extract . . . [and] tubers [similarly treated] to form a salep extract" in concentrations that were not listed. Growth and survival on the modified Reinert–Mohr medium were better than on Knudson C, but it is not clear whether this is due to the basal solution or to the additives.

Cultures were maintained under 16-h photoperiods provided by warm white fluorescent lamps (no details are given on their number, distance from the plants, or light intensity) and 20°C. Bracts turned green 12 days after inoculation and developed into protocorms within 9 weeks. At that time the apices can be divided and subcultured. "If left to enlarge without further division, these protocorms gave rise to plantlets, two to three inches in height, each with a single large tuberous root." (The time required for the plants to reach this stage is not given.) "On transfer to greenhouse conditions, these plants have so far failed to survive; incorporation of soil from the vicinity of the parent stock could well be needed in order to supply the necessary mycorhizal fungi" (Stokes, 1974). Or, one could isolate the fungus and infect the plants in vitro.

On the whole not enough information is available in the original paper (Stokes, 1974) for those who may wish to use this procedure: Too many questions remain unanswered.

Dactylorhiza

An effort was made in Germany to enhance the proliferation of seedling protocorms of *Dactylorhiza maculata* (Gruenschneider, 1973). This cannot be considered a tissue-culture method or clonal propagation in the strict sense since proliferation of seedling protocorms is common in other orchids.

Darwinara

Darwinara is a hybrid genus of a kind that can be produced only on orchids. It is a combination of four genera (listed here in alphabetical order), *Ascocentrum, Neofinetia*, *Rhynchostylis*, and *Vanda*. The flowers can be exquisitely colored and at least one cultivar, *Darwinara* Charm is a delightful miniature. All cultivars are in demand and effective micropropagation methods are of interest for commercial growers. Such a method was developed at the Applied Research Center of the Kirin Brewery Company in Japan (Kishi and Takagi, 1997a).

Plant Material. Immature floral buds of *Darwinara* Pretty Girl were taken from main shoots (10 cm long) and cut into 0.5-mm cubes following sterilization. These cubes were cultured.

Surface Sterilization. Buds should first be washed with 10% (v/v) benzalkonium chloride for 10 min (household detergent and water can probably also be used). The washed buds should be dipped in 70% (v/v) ethanol (74 ml 95% ethanol diluted to 100 ml with distilled water) for 30 s, immersed for 5 min in 0.5% (v/v) sodium hypochorite (8–10 ml Clorox or another household bleach which contains 6.25–5.25% hypochlorite – please check the concentration, it is listed on the bottle – diluted to 100 ml with distilled water), plus 0.05% (v/v; this really amounts to a few drops per 100 ml) Tween 20 (or a mild household detergent), and washed three times with autoclaved (i.e., sterile) distilled water.

Culture Vessels. Test tubes (30 × 200 mm) containing 20 ml of medium were used originally. Other vessels can also be employed.

Culture Conditions. In the original research the cultures were placed on a drum-type rotary shaker tilted 15° and rotating at 1 rpm. A different type of shaker may also be suitable but should be tested with a few explants before being put to large-scale use. Cultures should be maintained at 25 ± 2°C under illumination of 56.2 ± 5.2 μmol m^{-2} s^{-1}. Standard laboratory conditions are also suitable.

Culture Media. Liquid (this is not stated directly in the materials and methods section of the original paper, but is implied by the use of a shaker) one-quarter strength modified MS medium (Murashige and Skoog, 1962) should be used (Table Dar-1) for the production of PLBs. For plantlet production the PLBs should be cultured on modified full-strength MS medium (Table Dar-2).

Procedure. The explants are cultured on the first medium (Table Dar-1). Once PLBs are formed they should be moved to the second medium (Table Dar-2) for plantlet formation.

Developmental Sequence. PLBs form on the first medium (Table Dar-1) and plantlets develop on the second medium (Table Dar-2).

TABLE DAR-1. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of axillary buds of *Brassocattleya* Pastoral 'Innocense' (Kishi and Takagi, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	412.5	41.25 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot H_2O$	110.0	11.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	92.5	9.25 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	475.0	47.5 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	42.5	4.25 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	3.73	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelement**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	If necessary[e]
	Cytokinin				
11	Kinetin	1–10.0	10–100 mg 100 ml^{-1} 95% ethanol[e,f]	1	If necessary[e]
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses. There is no indication in the original paper whether auxin and/or cytokinin were used and if so how much. The auxin concentration suggested here is the same as that in Table Bc-1. There is no cytokinin in the medium outlined in Table Bc-1 and none is being suggested here. Should a cytokinin prove to be necessary 1 or 10 mg kinetin l^{-1} medium may be appropriate. These suggestions are speculative. Therefore those who plan to use this procedure are advised to test the medium as described here with a few buds before employing any formulations on a large scale.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or 0.1 N HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.4, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) if necessary (see footnote *e*) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. It is also possible to add items 1–14 before the addition of sugar, complete preparation of the medium, distribute to culture vessels, and autoclave the mixture.

TABLE DAR-2. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for plantlet production from protocorm-like bodies of *Brassocattleya* Pastoral 'Innocense' (Kishi and Takagi, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Indoleacetic acid (IAA)	1.0–3.0	10–300 mg 100 ml^{-1} 95% ethanol[e,f]	1	If necessary[e]
	Cytokinin				
11	Kinetin	0.04–1.0	4–100 mg 100 ml^{-1} 95% ethanol[e,f]		If necessary[e]
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Gelrite[b]	2.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses. There is no indication in the original paper whether auxin and/or cytokinin were used and if so how much. The auxin and cytokinin concentrations suggested here are estimates based on other media. These suggestions are speculative. Therefore those who plan to use this procedure are advised to test the medium as described here with a few protocorm-like bodies before employing any formulations on a large scale. In many instances PLBs form plantlets without the addition of hormones to culture media. Therefore the Knudson C medium (see Tables Aranda-7 and Aranda-8) with or without ripe banana may also prove to be suitable.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.4, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Add the Gelrite in accordance with the instructions in footnote *h*. When the Gelrite is completely dissolved pour the solution into a 2 liter flask and autoclave. Add the amino acid (item 8), hormones (items 10 and 11) if necessary (see footnote *e*) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar or Gelrite are not added to liquid media. It is also possible to add items 1–14 before the addition of sugar, complete preparation of the medium, distribute to culture vessels, and autoclave the mixture.

General Comments. This procedure will probably also be suitable for other *Darwinara* hybrids.

Maintenance of Embryogenic Callus of *Darwinara*

The method used for *Doritaenopsis* (Ichihashi and Hiraiwa, 1996) is suitable.

Micropropagation of *Darwinara* through the Culture of Flower-bud Explants

The methods developed for *Vandofinetia* (Kishi et al., 1997*a*, 1997*b*) can also be used for *Darwinara* (Fig. Dar-1).

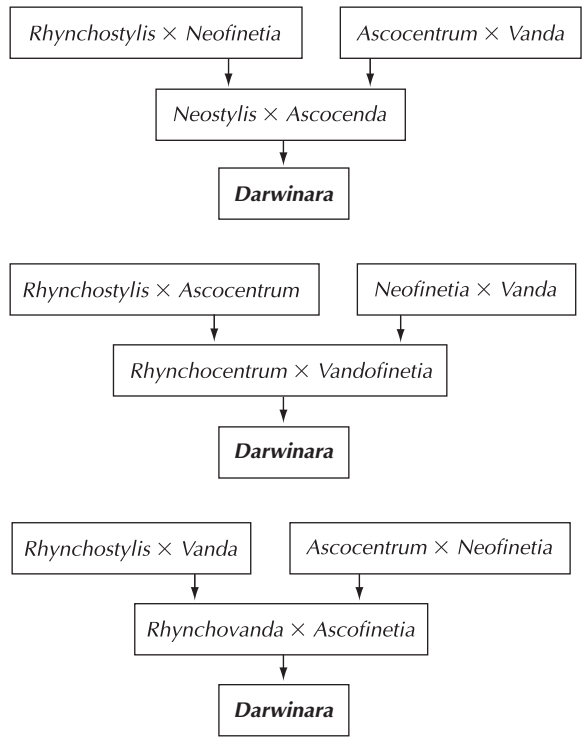

FIG. DAR-1. **Three of the several pathways to *Darwinara*; there are others.**

[h]Gellan gum (available as such from www.caissonlabs.com) and as Phytagel (www.sigmaaldrich.com) or Gelrite is an agar substitute which produces a firm, clear and colorless solid substrate at lower concentrations than agar. It requires divalent cations to form a gel. Most plant tissue culture media contain enough Ca^{2+} and Mg^{2+} for gelation. Dilute media may require additional calcium or magnesium salts or higher concentrations of gellan. Gellan gum (Phytagel, Gelrite) must be added slowly with vigorous stirring to liquid medium at room temperature. If gellan gum (Phytagel, Gelrite) is added to warm or hot water or medium it will form clumps and will not gel properly after autoclaving. The gelling temperature of gellan gum (Phytagel, Gelrite) is 27–31°C. Typical concentrations are 1.5–2.5 g gellan gum l^{-1}, but up to 10 g l^{-1} may have to be used for media that must be very hard or contain low cation levels. After the gellan gum (Phytagel, Gelrite) has dissolved pour the medium into culture vessels and autoclave.

Dendrobium

Several *Dendrobium* hybrids are very important to the orchid cut-flower industry in a number of countries. The best-known example is *Dendrobium* Pompadour (*Dendrobium* Louis Bleriot × *Dendrobium phalaenopsis*, registered in 1934 by Henri Vacherot-Lecoufle) in Thailand. Another example is *Dendrobium* Jaquelyn Thomas (*Dendrobium gouldii* × *Dendrobium phalaenopsis*, registered in 1949 by R. K. Thomas). It is grown extensively by Flora Sari Orchids (owned by Mr. and Mrs. Soediono) near Jakarta, Indonesia. *Dendrobium* Mary Mak (*Dendrobium* Theodore Takiguchi × *Dendrobium* May Neal, registered by Mak Chin On of Maryland Orchids, Singapore, in 1977) is grown widely in both Indonesia (Flora Sari Orchids) and Singapore (Maryland Orchids). There are other examples.

In addition, *Dendrobium* hybrids are popular with hobby growers. This importance led to the development of several tissue culture procedures for *Dendrobium* explants (Ito, 1966, l967; Sagawa and Shoji, 1967; Marston, 1969; Kim et al., 1970; Mullin, 1970; Singh and Sagawa, 1972; Arditti et al., 1973; Mosich et al., 1973, 1974*a*, 1974*b*; Ball and Arditti, 1976; H. Singh, 1976; Charanasri and Wanichkul, 1978*a*, 1978*b*; Fu 1978, 1979*a*, 1979*b*; Khaw et al., 1978*a*, 1978*b*; Fernando, 1979; Gandawijaja, 1980; Lim-Ho, 1981; Sagawa and Kunisaki, 1982; Kukułczanka and Wojciechowska, 1983; Soediono, 1983*a*, 1983*b*; Manorama et al., 1986). Some of these methods can lead to variations in the resulting "mericlones" (Charanasri and Wanichkul, 1978*a*, 1978*b*). Procedures for protoplast isolation (Teo and Neumann, 1978*a*, 1978*b*, 1978*c*; Price and Earle, 1984) and chromosome doubling (Sanguthai et al., 1973) have also been developed.

The very first effort to culture any part of a *Dendrobium* (except seeds) in vitro by a "partial[ly] sterile" method was by Itsuhiko Ito at the Laboratory of Olericulture, Faculty of Agriculture, Kyoto Prefectural University, Japan (Ito, 1966, 1967). The procedure was not used for clonal propagation, but fertile seeds were produced from pollinated ovaries cultured in test tubes.

Shoot-tip Culture of *Dendrobium*

A tissue culture procedure for clonal propagation of *Dendrobium* was developed at the University of Hawaii (Sagawa and Shoji, 1967; Kim et al., 1970; Sagawa and Kunisaki, 1982).

Plant Material. Explants are obtained from new growths, and the highest percentage of success has been with axillary buds weighing 2 g (range 1.1–3.0 g) and 4.9 cm long (range 3.7–11.5 cm) (Table Den-1).

Surface Sterilization. The procedure employed with *Cymbidium* (Sagawa et al., 1966) is used, but the step involving 1% Clorox is omitted.

Culture Vessels. The vessels used for *Cymbidium* (Sagawa et al., 1966) are used.

TABLE DEN-1. **Characteristics and success of cultured *Dendrobium* buds (Kim et al., 1970)**

Bud characteristics	Size and mass					
Length, cm:						
Average	3.0	4.9	8.2	10.4	15.5	
Range	2.5–3.5	3.7–11.5	5.5–14.0	6.5–15.5	9.5–20.0	
Weight, g:						
Average	<1.0	2.0	4.0	6.0	>7.0	
Range	1.0	1.1–3.0	3.1–5.0	5.1–7.0	7.1	
Location	**Success**					**Total**
Apical:						
Percent	12.5	46.6	36.4	33.3	17.5	31.5
Sc/nc[a]	1/8	7/15	4/11	4/12	1/8	17/54
Axillary:						
Percent	14.3	50.9	38.8	33.3	40.6	38.6
Sc/nc[a]	3/21	28/55	19/49	15/45	13/32	78/202

[a]Number of successful cultures/total number of cultures.

TABLE DEN-2. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Dendrobium* shoot tips (Sagawa et al., 1966)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Tricalcium phosphate, $Ca_3(PO_4)_2$[b]	200.0	20.0 g l^{-1}	10	Or weigh
2	Potassium nitrate, KNO_3[c]	525.0	52.5 g l^{-1}	10	Or weigh
3	Monopotassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
5	Ammonium sulfate, $(NH_4)_2SO_4$[c]	500.0	50.0 g l^{-1}	10	Or weigh
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3$[d]	28.0	2.8 g l^{-1}	10	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier[e]				
10	Agar	16.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]If this salt does not completely dissolve, shake stock solution well before dispensing to insure an even suspension; better yet, weigh out each time.

[c]Solutions containing nitrate and/or ammonium may become contaminated with time. Therefore it is preferable not to make stock solutions. If prepared, keep frozen between uses.

[d]If the substance fails to dissolve, add dilute KOH one drop at a time until the solution is clear.

[e]Mix items 1–7 with 800 ml distilled water (item 9), adjust pH to 5.0–5.5, add sugar (item 8), and adjust volume to 1000 ml with more distilled water. To add agar (item 10), bring solution to a slow boil and add slowly while stirring. When fully dissolved, dispense into culture vessels and autoclave. For liquid medium, omit agar (item 10).

Culture Conditions. Cultures should be maintained under 2000 ft-c of continuous illumination provided by General Electric white fluorescent tubes (Power Groove) at 26 ± 3°C. Liquid cultures are placed on a shaker operating at 160 rpm (a New Brunswick model V shaker was used in the original research).

Culture Medium. A modified Vacin and Went medium (Table Den-2) is used.

Procedure. The procedure is the same as that for *Cymbidium* (Sagawa et al., 1982).

Developmental Sequence. Explants form a green mass within 45 days and PLBs after 3 months. Sectioning the tissue masses within 2.5 months and subculturing the divisions result in further proliferation in an equal period of time. The highest yield of new PLBs results from subdividing those that do not have obvious leaves. Sections obtained by transverse cuts produce a larger number of PLBs than those derived from longitudinal cuts.

General Comments. This is an early but still useful procedure. A culture method for *Dendrobium* leaves in another modification of the Vacin and Went medium that contains 15% (by volume) coconut water was also developed by the same investigators (Sagawa and Kunisaki, 1982). Unfortunately not enough details are provided about this method (Sagawa and Kunisaki, 1982) to allow a description of it here.

Clonal Propagation of *Dendrobium* through Tissue Culture of Buds

As parts of an effort to assist "orchid growers and breeders," investigators in the tissue culture laboratory at the Singapore Botanic Gardens have developed procedures for three *Dendrobium* species and 17 hybrids (Lim-Ho, 1981).

Plant Material. Apical and axillary buds are cultured (Table Den-3). They are excised like those of *Arachnis, Aranda*, and *Aranthera* (Lim-Ho, 1981).

TABLE DEN-3. **Media requirements of *Dendrobium* species and hybrids (Lim-Ho, 1981)**

Dendrobium species or hybrid	Growth rate	Explant, bud[a]	Medium, table[b]		
			Initiation liquid	Proliferation and differentiation	Plantlet formation

D. Yong Kok Wah	Slow	Ap, Ax	Arach-4	Arach-4, Arach-5[c]	Arach-6
Several unregistered hybrids	Fast, Slow	Ap, Ax	Arach-4, Arach-5, Den-4, Den-5	Arach-4, Arach-5[c] Den-6	Arach-6

[a]Ap, tip ("meristem") explant from apical bud; Ax, tip ("meristem") from axillary bud.

[b]The order in which media are listed is the same as in the original paper and may indicate suitability.

[c]This medium (Arach-5) in solid form is "good for all *Dendrobium* spp. for differentiation into shoot[s]; rate of differentiation [is] fast in this medium . . ."

TABLE DEN-4. **Modified Vacin and Went medium (Vacin and Went, 1949) for *Dendrobium* bud cultures (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated ion**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	0.2	20 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
9	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	2 g[f]	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation contains a different source of iron.

[e]Keep refrigerated or frozen between uses.

[f]The original formulation has 20 g sucrose.

[g]Add items 1, 3–7 and 9 to the 500 ml distilled water (item 11) that contains item 2. Adjust pH to 5.2–5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Pour medium into a 2-l Erlenmeyer flask, and autoclave. Add auxin (item 8) to solution while it is still hot or warm, swirl several times to ensure good mixing, and dispense medium into presterilized culture vessel. If preparing solid medium, add 10–20 g agar.

Surface Sterilization. Shoots, stems, and pseudobulbs are surface-sterilized like those of *Arachnis*, *Aranda*, and *Aranthera* (Lim-Ho, 1981).

Culture Vessels. The vessels used for *Arachnis*, *Aranda*, and *Aranthera* (Lim-Ho, 1981) are suitable.

Culture Conditions. Cultures are maintained under the same conditions as *Arachnis*, *Aranda*, and *Aranthera* (Lim-Ho, 1981).

Culture Media. The different species and hybrids vary somewhat in their media requirements (Tables Den-3 to Den-6).

Procedure. Procedures used for *Arachnis*, *Aranda*, and *Aranthera* (Lim-Ho, 1981) can be employed.

TABLE DEN-5. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Dendrobium* buds (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated ion**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
8	Indoleacetic acid (IAA)	0.3	30 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
9	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	2 g[f]	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation contains a different source of iron.

[e]Keep refrigerated or frozen between uses.

[f]The original formulation has 20 g sucrose.

[g]Add items 1, 3–7, and 9 to the 500 ml distilled water (item 11) that contains item 2. Adjust pH to 5.2–5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Pour medium into a 2-l Erlenmeyer flask, and autoclave. Add auxin (item 8) to solution while it is still hot or warm, swirl several times to ensure good mixing, and dispense medium into presterilized culture vessel. Add 10–12 g agar, for solid medium.

Developmental Sequence. Limited information is presented in the original paper (Lim-Ho, 1981), but it is reasonable to assume that development is similar in principle to that of *Dendrobium* explants in other methods and to *Arachnis*, *Aranda*, and *Aranthera* (Lim-Ho, 1981).

General Comments. Although developed with specific hybrids this method should prove suitable for *Dendrobium* in general, either directly or as a starting point for additional research.

TABLE DEN-6. **Modified Knudson C medium (Knudson, 1946) for the culture of *Dendrobium* buds (Lim-Ho, 1981)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	400	40 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	400	40 mg l^{-1}	10	
3	Magnesium sulfate $MgSO_4 \cdot 7H_2O$	100	10 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	100	10 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.79 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
6	**Microelements**[d]				
(a)	Aluminum chloride, $AlCl_3$	0.03	3 mg l^{-1}	10	One solution
(b)	Boric acid, $H_3B_2O_3$	1.0	100 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.03	3 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4$	0.1	10 mg l^{-1}		
(e)	Potassium iodide, KI	1.0	100 mg l^{-1}		
(f)	Zinc sulfate, $ZnSO_4$	1.0	100 mg l^{-1}		
	Complex additive				
7	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
8	Sucrose	2 g[e]	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[f]	To 1000 ml			
	Solidifier				
10	Agar[f]	8–10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]A different iron salt was used in the original formulation.

[d]Add all salts to the same 1 l distilled water, stir and/or heat until they are dissolved, cool, and dispense.

[e]The original formulation contains 20 g sucrose.

[f]Add items 1–7 to 750 ml distilled water (item 9), adjust pH to 5.0–5.5, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, distribute medium into culture vessels and autoclave. According to Knudson (1946), the pH of this solution made without agar (i.e., liquid) can be close to 4.6–4.7. If necessary, adjust it upward with a potassium hydroxide (KOH) solution (see Chapter 2). When agar is added, especially if dissolved in the autoclave, the pH can be 5.4–5.5. A dilute solution of hydrochloric acid (HCl) should be used to lower the pH if necessary. Add agar to solid medium only (12–15 g in the original formulation).

Tissue Culture of *Dendrobium phalaenopsis*

Nitrogen is the largest component of the great majority of media used for orchid seed germination and tissue culture. It is generally present in both as nitrate and ammonium. An experiment designed to "establish the optimal balance of nitrate nitrogen and ammonium nitrogen . . . in tissue culture of . . . *Dendrobium phalaenopsis*" (Gandawijaja, 1980) resulted in a method that can be used for clonal propagation.

Plant Material. Shoot tips 1.0–1.5 mm long from 8-month-old seedlings of *D. phalaenopsis* are used.

Surface Sterilization. Surface sterilization is not required when seedlings from sterile cultures are used. If this method is used with tips from adult plants, the surface-sterilization procedure developed at the Singapore Botanic Gardens (Lim-Ho, 1981) should be employed.

Culture Vessels. Corning disposable test tubes 150 × 16 mm (Corning Glass Co., Corning, NY) containing a filter bridge and 5 ml liquid medium were used in the original research. Other containers can also be employed.

Culture Conditions. Cultures should be maintained under 16-h photoperiods of approximately 3000 lx provided by fluorescent tubes (warm white in the original research, but other balanced light sources are also suitable) and 24 ± 2°C.

Culture Media. A modified MS medium (Table Den-7) is used for initial culture and multiple shoot production. A second modification (Table Den-8), is used for root induction. In the original research the explants were cultured on a ⌐¬-shaped platform or filter bridge placed in the medium. This technique provides for constant aeration and a continuous supply of medium, but it is overly cumbersome for practical use. The filter-paper platform could be replaced by cotton (which may become compacted), glass wool (unpleasant and unsafe to use without appropriate protection such as gloves, long sleeves, face protector, and mask), or solid medium (simplest and probably most practical).

Some taxonomists have reduced *Dendrobium phalaenopsis* to varietal status under *Dendrobium bigibbum*. Others consider it to be a synonym of *D. bigibbum*. John Lindley described *D. bigibbum* in 1852. R. E. Holttum of Singapore fame reported that the first living plants of this species reached Kew Gardens in 1824.

TABLE DEN-7. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for shoot production by *Dendrobium* seedling-tip explants (Gandawijaja, 1980)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4N_3[b]	800	80 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220	22 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1010	101 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.0125	1.25 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.0125 g	1.25 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 2H_2O$	11.25	1.13 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.415	41.5 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.125	12.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430 mg l^{-1}		
	Amino acid				
8	Glycine	1	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol[f]	50	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.250	25 mg 100 ml^{-1} 95% ethanol[g]	1	
11	Pyridoxine (vitamin B_6)	0.05	5 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	0.05	5 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
13	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[h]	To 1000 ml			
	Solidifier				
15	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Also known as *meso*-inositol, *i*-inositol and inositol.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 14), adjust pH to 5.2, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Bring solution to a gentle boil, and add agar (item 15) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid and vitamins (items 8, 10–12) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

Procedure. Place explants on the medium (Table Den-4) and allow to grow and proliferate. Individual plantlets can be moved to the same medium for growth and root formation, or they can be placed on the media developed in Singapore (see Tables Arach-3 to Arach-6; for details see Table Den-3; Lim-Ho, 1981).

TABLE DEN-8. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for root induction on shoots produced by *Dendrobium* seedling-tip explants (Gandawijaja, 1980)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400	40 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	220	22 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	185	18.5 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1515	151.5 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	85	8.5 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 mg l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 mg l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.1	310 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.0125	1.25 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.0125 g	1.25 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 2H_2O$	11.25	1.13 g l^{-1}		
(e)	Potassium iodide, KI	0.415	41.5 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.125	12.5 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430 mg l^{-1}		
	Amino acid				
8	Glycine	1	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol[f]	50	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.250	25 mg 100 ml^{-1} 95% ethanol[g]	1	
11	Pyridoxine (vitamin B_6)	0.05	5 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Thiamine (vitamin B_1)	0.05	5 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
13	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[h]	To 1000 ml			
	Solidifier				
15	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Also known as *meso*-inositol, *i*-inositol, or inositol.

[g]Keep refrigerated between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 14), adjust pH to 5.2, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Bring solution to a gentle boil, and add agar (item 15) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid and vitamins (items 8, 10–12) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

Developmental Sequence. Not many details are given in the original paper, but it is clear that development proceeds as usual for *Dendrobium*.

General Comments. Multiple shoots are produced in media that contain 1/6 (5 mmol) or 1/3 (10 mmol) of the total nitrogen (30 mmol) as ammonium. Root production is best on a medium with 0.5 mmol of ammonium, This is the reason for the two media. Although developed with *D. phalaenopsis*, this method could probably be used with other species and some hybrids. Djunaidi Gandawijaja has been at the Bogor Botanical Gardens in Indonesia for about 20 years.

Clonal Propagation of *Dendrobium* Caesar Red Lip by Meristem Culture

Orchids are grown widely in Sri Lanka both by hobbyists (the Orchid Circle of Ceylon is one of the oldest orchid societies in existence) and commercial growers. Orchid research carried out at the Perideniya Botanical Gardens led to the development of a successful procedure for clonal propagation in vitro (Fernando, 1979).

Plant Material. Apical and axillary buds are taken from 10-cm-long, actively growing shoots following leaf removal and surface sterilization.

Surface Sterilization. The outermost leaves are removed, and the shoots are trimmed before being submerged in calcium hypochlorite (8 g in 100 ml of distilled water stirred several times at 5-min intervals and filtered) for 15 min. There is no mention in the original paper of sterile distilled water rinses, but such steps are desirable even if not required. Apical and axillary buds are excised under a microscope in a sterile environment, dipped in a 2% calcium hypochlorite solution (2 g calcium hypochlorite in 100 ml distilled water prepared as above, or 25 ml of the 8% solution diluted to 100 ml) for 1 min and then placed in sterile distilled water.

Culture Vessels. Erlenmeyer flasks of 250-ml capacity were used in the original research, but other containers are also suitable. As a rule culture vessels should be filled to one-fifth of their capacity with medium (e.g., 50 ml in a 250-ml flask).

Culture Conditions. Liquid cultures are placed on a horizontal shaker (but other models should also prove to be suitable) at 80 rpm under continuous illumination of 75–100 ft-c (approximately 750–1000 lx; the light sources are not described in the original papers, but standard bulbs or tubes would probably be appropriate) and 25–28°C.

Culture Media. A modified liquid Vacin and Went medium (Table Den-9) is used for initial culture. Explants on modified Knudson C and unaltered Vacin and Went media became necrotic and died after 24 days. Differentiation of PLBs into plantlets occurs on solid Knudson C (see Table Aranda-7) or Vacin and Went (see Table Cym-5) media.

Procedure. Take the explants from the sterile distilled water, and either place them immediately in culture or store them (for a short time) in sterilized Petri dishes and

TABLE DEN-9. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Dendrobium* shoot tips (Fernando, 1979)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated ion**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	4.0	400 mg 100 mg^{-1} 95% ethanol[e]	1	
	Sugar				
9	Sucrose	20 g[f]	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation contains a different source of iron.

[e]Keep refrigerated or frozen between uses.

[f]According to several reports some *Dendrobium* clones develop better initially if the sucrose concentration is 1–2 g l^{-1}.

[g]Add items 1, and 3–7 to the 500 ml distilled water (item 10) that contains item 2, adjust pH to 5.2–5.5, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Pour medium into a 2-l Erlenmeyer flask, and autoclave. Add auxin (item 8) to solution while it is still hot or warm, swirl several times to ensure good mixing, and dispense medium into presterilized culture vessel. For solid medium, add 10–20 g agar.

then "transfer [them] singly to flasks containing the media. . . ." Allow them to produce plantlets and PLBs. If more PLBs are required, existing ones can be divided and subcultured. In the case of axillary bud explants, the production of PLBs requires removing the leaves from the explant as it swells. The PLBs are moved to unmodified Knudson C (see Table Aranda-7) or modified Vacin and Went (see Table Cym-5) media for plantlet production.

Developmental Sequence. The explants may: (l) swell and produce only one shoot; (2) expand and produce a tissue mass that gives rise to PLBs that can be divided and subcultured; or (3) develop a single shoot that produces small PLBs at its base and these in turn also form plantlets. PLBs proliferate after being subcultured.

General Comments. Plantlets produced by this method are reported to have flowered within 22 months of the start of culture; this is very fast. *Dendrobium* Caesar (*Dendrobium* E. P. Boule) is of the parentage *Dendrobium phalaenopsis* × *Dendrobium stratiodes*. Its originator and date of registration are not recorded. This procedure may be suitable for related hybrids and species.

Shoot-tip Tissue Culture of *Dendrobium* Ng Eng Cheow

Dendrobium Ng Eng Cheow [*Dendrobium* Alice Spalding (*Dendrobium tokai* × *Dendrobium undulatum*) × *Dendrobium* Jaquelyn Thomas (*Dendrobium gouldii* × *Dendrobium phalaenopsis*)] was produced by the Koh Keng Hoe Nursery in Singapore. It flowered for the first time on 5 May 1972 and was registered in May 1973. A tissue culture propagation procedure for it was developed at the Singapore Botanic Gardens (H. Singh, 1976).

Plant Material. In the original research young shoots approximately 8 cm long (Fig. Den-1A*a,b*) were taken from mature plants of *Dendrobium* Ng Eng Cheow. Such shoots of other dendrobiums (especially related species and hybrids) can also be used. Explants, cones about 5 mm in diameter and 3–4 mm tall for apical buds (Fig. Den-1A*c*) and cubes approximately 5 mm wide, 6 mm long, and 2–3 mm thick for axillary buds (Fig. Den-1A*d*), are taken after surface sterilization.

Surface Sterilization. Leaves and their bases are removed from the shoots (Fig. Den-1A*b*) before submerging the shoots in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for 15 min. The original paper does not mention subsequent washing with sterile water, but two to three such washes are desirable.

Culture Vessels. Erlenmeyer flasks or other containers can be used.

Culture Conditions. Explants should be maintained under continuous illumination of 2000 lx (the light sources used in the original research are not described) at 21–25°C. Liquid cultures are agitated at 40 rpm.

Culture Media. Explants are first cultured in a liquid modification of the Vacin and Went medium (Table Den-10). After a month in this solution the explants are moved to a high-auxin solution (Table Den-11). Clusters of PLBs that form in this solution are divided and cultured on a third, solid, medium for plantlet formation (Table Den-12).

Procedure. Place explants in the initial medium (Table Den-10), and allow them to remain there until they show some growth. After that, transfer them to a sugar-free medium (Table Den-11 without item 10) for proliferation. Move PLBs to the solid medium (Table Den-12) for plantlet formation.

Developmental Sequence. Axillary bud explants "showed more potential growth than those which included the apical bud" (H. Singh, 1976). After 3 months of culture, explants may: (1) develop single shoots (Fig. Den-1B*a*); (2) form a cluster of shoots (Fig. Den-1B*b*); or (3) produce a cluster of PLBs (Fig. Den-1C, D*b*–L*b*). These are separated into individual PLBs and placed on solid medium. The PLBs start to differentiate, form shoots that develop roots, and turn into plantlets.

General Comments. As part of the original research several hundred plantlets were produced during 5 months. Several thousand could be produced in 1 year.

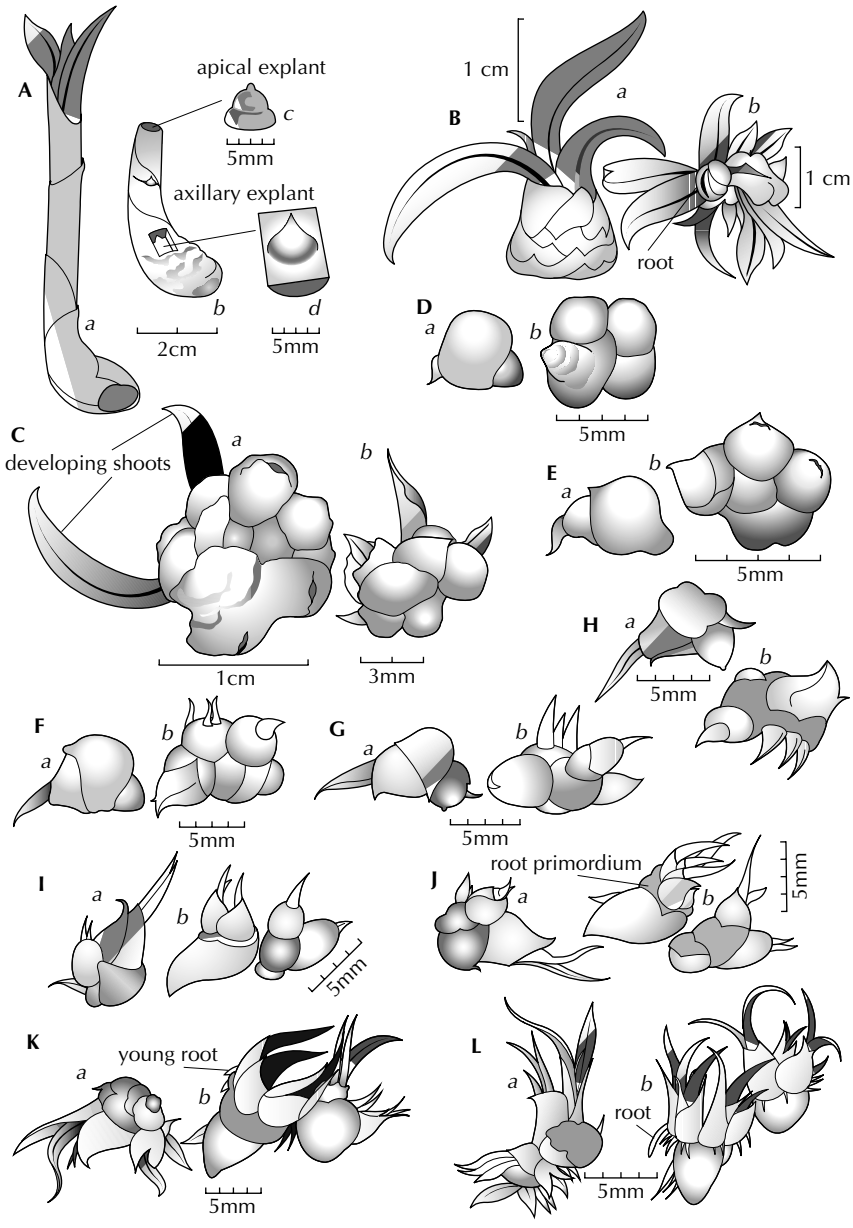

FIG. DEN-1. ***Dendrobium*** **Ng Eng Cheow: Excision and development of explants. A: Young shoot before (*a*) and after (*b*) removal of leaves, and excised apical (*c*) and axillary (*d*) buds. B: Single (*a*) and multiple (*b*) shoots that may develop from the explant. C: Large (*a*) and small (*b*) masses of protocorm-like bodies (PLBs) that can develop from some explants. D–L: Single (*a*) and multiple (*b*) PLBs after the following days in culture: 2 (D), 5 (E), 9 (F), 13 (G), 15 (H), 17 (I), 21 (J), 26 (K), and 30 (L). Root primordia start to form after 21 days (J*b*). Young roots (K*b*, L*b*) are evident after 26 and 30 days. (H. Singh, 1976.)**

TABLE DEN-10. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Dendrobium* buds (H. Singh, 1976)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated ion**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	0.2	20 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
9	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	10 g[f]	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation for the Vacin and Went medium uses a different source of iron. Singh's modification does not use EDTA, which is included here because it improves the availability of iron.

[e]Keep refrigerated or frozen between uses.

[f]The original formulation has 20 g sucrose.

[g]Add items 1, 3–7, and 9 to the 500 ml distilled water (item 11) that contains item 2. Adjust pH to 5.0, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Pour medium into a 2-l Erlenmeyer flask, and autoclave. Add auxin (item 8) to solution while it is still hot or warm, swirl several times to ensure good mixing, and dispense medium into presterilized culture vessel. For a solid medium, add 10–20 g agar.

Dendrobium is a very large genus consisting of about 900 species which are found in Australia, South East Asia, Burma, China, Cambodia, Hong Kong, India, Indonesia, Irian Jaya, Japan, Laos, Malaysia, New Zealand, many Pacific Islands, Papua New Guinea, Singapore, Taiwan, Thailand, and Vietnam. It was established by Olof Swartz (1760–1818) in 1799 on page 82, volume 6 of *Nova Acta Societatis Scientiarum Upsaliensis*. The name is derived from *dendron* (δενρον), tree, and *bios* (βιοσ), life. It refers to the epiphytic habitat of the genus and means "living on a tree." *Dendrobium* is one of the most important genera for the orchid cut flower industry in South East Asia. Some species are used as herbal medicines in several countries (Schultes and Pease, 1963; Bechtel et al., 1992; Hew, 1994; Hew and Yong, 1997).

TABLE DEN-11. **Modified Vacin and Went medium (Vacin and Went, 1949) for the proliferation of protocorm-like bodies from *Dendrobium* buds (H. Singh, 1976)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated ion**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	4.0	400 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
9	Coconut water	150 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	10 g[f]	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	10–12 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation for the Vacin and Went medium uses a different source of iron. Singh's modification does not use EDTA, which is included here because it improves the availability of iron.

[e]Keep refrigerated or frozen between uses. This relatively high auxin concentration could cause mutations. Used with caution to induce proliferation, but do not culture protocorm-like bodies from one explant in it more than a few times.

[f]The original formulation has 20 g sucrose. This item is omitted if a sugar-free medium is desired.

[g]Add items 1, 3–7, and 9 to the 500 ml distilled water (item 11) that contains item 2. Adjust pH to 5.0, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring solution to a gentle boil, and add agar (item 12) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add auxin (item 8) to solution while it is hot or warm and still liquid, swirl several times to ensure good mixing, and dispense medium into presterilized culture vessel. Omit agar if preparing liquid medium.

TABLE DEN-12. **Modified Vacin and Went medium (Vacin and Went, 1949) for plantlet formation from protocorm-like bodies of *Dendrobium* (H. Singh, 1976)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
6	**Chelated ion**[d]				
(a)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.84	2.78 g l^{-1}	10	One solution
(b)	Chelating agent, Na_2EDTA	37.24	3.72 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Sugar				
8	Sucrose	10 g[e]	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[f]	To 1000 ml			
	Solidifier				
10	Agar	10–12 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]The original formulation for the Vacin and Went medium uses a different source of iron. Singh's modification does not use EDTA, which is included here because it improves the availability of iron.

[e]The original formulation has 20 g sucrose.

[f]Add items 1 and 3–7 to the 500 ml distilled water (item 9) that contains item 2. Adjust pH to 5.0, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring solution to a gentle boil, and add agar (item 10) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, distribute medium into culture vessels and autoclave. Omit agar if preparing liquid medium.

In Vitro Culture of Axillary Buds of *Dendrobium*

A procedure for the clonal propagation of *Dendrobium* through the culture of axillary buds was developed in the laboratory of Helen Nair, Department of Botany, University of Malaya, Kuala Lumpur, Malaysia (Khaw et al., 1978*a*, 1978*b*). The procedure is the same as the one employed for *Aranda* (Khaw and Ong, 1974–1975), and explants of *Dendrobium* Alice Chong {*Dendrobium* May Neal [*Dendrobium* Hawaii (*Dendrobium phalaenopsis* × *Dendrobium tokai*) × *Dendrobium stratiodes*]} are cultured on a modified Vacin and Went medium (see Table Aranda-1). Surface sterilization and all the other steps in this procedure can be the same as the one developed for *Dendrobium* Ng Eng Cheow (H. Singh, 1976), *Dendrobium phalaenopsis* (Gandawijaja, 1980; Kukułczanka and Wojciechowska, 1983), *Dendrobium antennatum* (Kukułczanka and Wojciechowska, 1983), and other *Dendrobium* species and hybrids (Lim-Ho, 1981).

Propagation of *Dendrobium antennatum* and *Dendrobium phalaenopsis* by in Vitro Culture

Investigations designed to determine the regeneration potential of isolated organs have generated information that can be used for the clonal propagation of *Dendrobium antennatum* (listed as *Dendrobium antennathum* in the original paper) and *Dendrobium phalaenopsis* (Kukułczanka and Wojciechowska, 1983).

Plant Material. Axillary bud explants from shoots are cultured.

Surface Sterilization. No information is presented in the original paper. The method used for similar explants in Singapore (Lim-Ho, 1981) can be used.

Culture Vessels. Test tubes 16 × 80 mm were used in the original research, and other vessels should prove suitable.

Culture Conditions. The cultures should be maintained under continuous illumination of 1000 lx provided by "white luminescent" sources (probably meaning Cool or Warm White fluorescent tubes) and 24°C.

Culture Media. One modification of the Reinert–Mohr medium (Table Den-13) is used for shoot induction in *D. antennatum*. A different modification (Table Den-14) is employed for the same purpose with *D. phalaenopsis*. Roots are induced in both species by a third modification (Table Den-15). Callus induction requires a fourth modification (Table Den-16).

Procedure. Not many details are given in the original paper. First place explants on the shoot-induction medium. When shoots form, move them to the rooting medium. Callus may form on the fourth medium and give rise to PLBs that develop into plantlets.

Developmental Sequence. One or more shoots may develop from each bud. Callus development is not common. When callus does form, it produces PLBs, which develop into plantlets.

General Comments. The skillful use of plant hormones in this method is the result of several experiments. "Formation of callus which . . . later differentiated into protocorms [sic] allows [the] use of this method for . . . clonal mass propagation" (Kukułczanka and Wojciechowska, 1983). As in a number of other papers it is necessary to note here that by definition protocorms are produced only from seeds. The structures produced by explants are PLBs.

TABLE DEN-13. **Modified Reinert–Mohr medium (Reinert and Mohr, 1967) for shoot induction from explants of *Dendrobium antennatum* (Kukułczanka and Wojciechowska, 1983)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400	40 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	400	40 g l^{-1}	10

(c)	Manganese sulfate, $MnSO_4 \cdot H_2O$	7.5	750 mg l^{-1}		
(d)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.03	3 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Organic acid				
9	Citric acid[e]	150.1	No stock	No stock	Weigh
	Auxins				
10	Indole-3-butyric acid (IBA)	1.75	175 mg 100 ml^{-1} 95% ethanol[f,g]	1	
11	Napthaleneacetic acid (NAA)	1.75	175 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
12	Benzyladenine (BA)	5	500 mg 100 ml^{-1} 95% ethanol[g]	1	
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additive				
16	Peptone[h]	1 g	No stock	No stock	Weigh
	Sugar				
17	Sucrose[i]	15–30 g	No stock	No stock	Weigh
	Solvent				
18	Water, distilled[i]	To 1000 ml			
	Solidifier				
19	Agar, Difco Bacto[i]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. If $Fe_2(SO_4)_3$ is not available, make a stock solution containing 3.73 g Na_2EDTA and 2.78 g $FeSO_4 \cdot 7H_2O$ per liter, and add 10 ml of that to the medium.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. Some media (e.g., Murashige and Skoog, 1962) list $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but others use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Both an anhydrous salt and a monohydrate are available. It probably does not matter which one is used. Citric acid was used at one time to enhance the solubility of iron salts. The reason for its use here is not clear, but it is certainly not needed to solubilize the iron, which is added as a chelate. The citric acid may have been added as an antioxidant.

[f]If the auxin does not dissolve, add a few drops of dilute KOH.

[g]Keep in a freezer or refrigerator between uses.

[h]The peptone used is described as "peptobak-Bacutil," which may not be readily available outside of Poland or Eastern Europe. If other peptones are substituted for this brand, their analyses may be different. Be cautious when using a different peptone for the first time.

[i]Add items 1–7, 9, and 16 to 900 ml distilled water (item 18). Adjust pH to 5.0 and add sugar (item 17). (Sugar is not listed in the original recipe, but this seems to be a typographical error, which is why sucrose in the usual range is suggested here; a reasonable amount would be 10 or 20 g l^{-1}.) Adjust volume to 1000 ml with distilled water (item 18). Bring solution to a gentle boil, and add agar (item 19) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 8, and 10–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE DEN-14. **Modified Reinert–Mohr medium (Reinert and Mohr, 1967) for shoot induction from explants of *Dendrobium phalaenopsis* (Kukułczanka and Wojciechowska, 1983)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400	40 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1 g	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	400	40 g l^{-1}	10	
4	Potassium chloride, KCl	500	50 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10

(b)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.001	0.1 mg l^{-1}		
(c)	Manganese sulfate, $MnSO_4 \cdot H_2O$	7.5	750 mg l^{-1}		
(d)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.03	3 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Organic acid				
9	Citric acid[e]	150.1	No stock	No stock	Weigh
	Cytokinin				
10	Benzyladenine (BA)	5	500 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
14	Sucrose[h]	15–30 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[h]	To 1000 ml			
	Solidifier				
16	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. If $Fe_2(SO_4)_3$ is not available, make a stock solution containing 3.73 g Na_2EDTA and 2.78 g $FeSO_4 \cdot 7H_2O$ per liter and add 10 ml of that to the medium.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. Some formulae (e.g., Murashige and Skoog, 1962) list $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but others use $ZnSO_4 \cdot 7H_2O$ at the same concentration; the difference probably has little effect.

[e]Number of waters of hydration is not given. The choice is between an anhydrous salt and a monohydrate; it probably does not matter which one is used. Citric acid was used at one time to enhance the solubility of iron salts. The reason for its use here is not clear, but it is certainly not needed to solubilize the iron, which is added as a chelate. It could have been added as an antioxidant.

[f]If the cytokinin does not dissolve, add a few drops of dilute HCl.

[g]Keep in a freezer or refrigerator between uses.

[h]Add items 1–7, and 9 to 900 ml distilled water (item 15), adjust pH to 5.0, and add sugar (item 14). (Sugar is not listed in the original recipe, but this seems to be a typographical error, which is why sucrose in the usual range is suggested here; a reasonable amount would be 10 or 20 g l^{-1}.) Adjust volume to 1000 ml with distilled water (item 15). Bring solution to a gentle boil, and add agar (item 16) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormone, and vitamins (items 8 and 10–13) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE DEN-15. **Modified Reinert–Mohr medium (Reinert and Mohr, 1967) for root induction on shoots of *Dendrobium antennatum* and *Dendrobium phalaenopsis* (Kukułczanka and Wojciechowska, 1983)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	400	40 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1000	100 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	400	40 g l^{-1}	10	
4	Potassium chloride, KCl	500	50 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	22.4	2.24 g l^{-1}	10	One solution

	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. If $Fe_2(SO_4)_3$ is not available, make a stock solution containing 3.73 g Na_2EDTA and 2.78 g $FeSO_4 \cdot 7H_2O$ per liter and add 10 ml of that to the medium.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. Some media (e.g., Murashige and Skoog, 1962) list $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but others use $ZnSO_4 \cdot 7H_2O$ at the same concentration; the difference probably has little effect.

[e]Number of waters of hydration is not given. The choice is between an anhydrous salt and a monohydrate; it probably does not matter which one is used. Citric acid was used at one time to enhance the solubility of iron salts. The reason for its use here is not clear, but it is certainly not needed to solubilize the iron which is added as a chelate. It could have been added as an antioxidant.

[f]If the auxins do not dissolve, add a few drops of dilute KOH to solubilize them.

[g]Keep in a freezer or refrigerator between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 16), adjust pH to 5.0, and add sugar (item 15). (Sugar is not listed in the original recipe. This seems to be a typographical error, which is why sucrose in the usual range is suggested here; a reasonable amount would be 10 or 20 g l^{-1}.) Adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 8 and 10–14) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE DEN-16. **Modified Reinert–Mohr medium (Reinert and Mohr, 1967) for callus induction from explants of *Dendrobium phalaenopsis* (Kukułczanka and Wojciechowska, 1983)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
16	Sucrose[h]	15–30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. If $Fe_2(SO_4)_3$ is not available, make a stock solution containing 3.73 g Na_2EDTA and 2.78 g $FeSO_4 \cdot 7H_2O$ per liter and add 10 ml of that to medium.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. Some media (e.g., Murashige and Skoog, 1962) list $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but others use $ZnSO_4 \cdot 7H_2O$ at the same concentration. The difference probably has little effect.

[e]Both an anhydrous salt and a monohydrate are available. It probably does not make much difference which one is used. Citric acid was used at one time to enhance the solubility of iron salts. The reason for its use here is not clear, but it is certainly not needed to solubilize the iron, which is added as a chelate. It could have been added as an antioxidant.

[f]If auxins or cytokinin do not dissolve, add a few drops of dilute KOH or HCl.

[g]Keep in a freezer or refrigerator between uses.

[h]Add items 1–7 and 9 to 900 ml distilled water (item 17), adjust pH to 5.0, and add sugar (item 16). (Sugar is not listed in the original recipe, but this seems to be a typographical error, which is why sucrose in the usual range is suggested here; a reasonable amount would be 10 or 20 g l^{-1}.) Adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 8 and 10–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

Clonal Propagation of *Dendrobium* Jaquelyn Thomas 'White' through the Culture of Shoot Tips

A shoot-tip culture method for mass rapid clonal propagation of *Dendrobium* was developed as a means of meeting market demands for fast propagation of new hybrids. This procedure was developed in the private laboratory of Flora Sari Orchids near Jakarta, Indonesia (Soediono, 1983*b*).

Plant Material. Shoot tips of *Dendrobium* Jaquelyn Thomas 'White' were excised according to the method used for *Dendrobium* Ng Eng Cheow (H. Singh, 1976).

Surface Sterilization. The methods that were developed in Singapore are suitable (H. Singh, 1976; Lim-Ho, 1981).

Culture Vessels. Erlenmeyer flasks, 50-ml capacity containing 20 ml medium, were used in the original research. Other containers are also suitable.

Culture Conditions. Liquid cultures are placed on a gyrorotatory shaker at 120 rpm under illumination (12-h photoperiods provided by 20-W Sylvania Gro Lux lamps 60 cm above the cultures) and at temperatures of 24 ± 2°C. Solid cultures are maintained under the same temperature and illumination.

Culture Media. Modified liquid Vacin and Went medium (Table Den-17) is used for initial culture. Rapid proliferation and plantlet formation occurs on a second modification of the Vacin and Went medium (Table Den-18). Plantlets produced on the second medium (Table Den-18) can be cultured on modified Vacin and Went (see Table Cym-5) or modified Knudson C (see Table Aranda-8) media.

Procedure. Place explants in the first liquid medium (Table Den-17) for initial development and formation of PLBs. When PLBs and plantlets form, transfer them to the second liquid medium (Table Den-18). Larger plantlets and PLBs formed in this medium should be moved to the Vacin and Went medium (see Table Cym-5) or modified Knudson C (see Table Aranda-7) medium for further growth.

Developmental Sequence. Rapid proliferation: green PLBs measuring 1–2 mm in diameter, shoots, and leaves form on the first medium. Larger dark green PLBs (2–3 mm in diameter), shoots, leaves, roots, and plantlets (1 cm tall) form on the second medium, which generally supports excellent growth.

General Comments. The author of this procedure (Soediono, 1983*b*) wisely points out that "excessive proliferation may have negative effects on the quality of plants produced through tissue culture" and does not "recommend production of a very large number of plantlets from a single shoot tip."

TABLE DEN-17. **Modified Vacin and Went medium (Vacin and Went, 1949) for initial culture of shoot tips of *Dendrobium* Jaquelyn Thomas 'White' (Soediono, 1983*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Water from green coconuts	150 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. The other salt components of the medium should be added after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate it. To prepare a stock solution of chelated iron dissolve 3.73 mg chelating agent (Na_2EDTA) and 2.78 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Add items 1 and 3–8 to the 500 ml distilled water (item 10) that contains item 2. Adjust pH to 5.0–5.3, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Dispense medium into culture vessels and autoclave.

Noes Soediono developed a procedure for propagating *Dendrobium* Jaquelyn Thomas 'White' at Flora Sari Orchids, Jakarta, Indonesia, where she is seen with the author, Joseph Arditti, in 1982

TABLE DEN-18. **Modified Vacin and Went medium (Vacin and Went, 1949) for initial culture of shoot tips of *Dendrobium* Jaquelyn Thomas 'White' (Soediono, 1983*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	10	1 g 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
9	Water from green coconuts	150 ml	No stock	No stock	Measure
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate it. To prepare a stock solution of chelated iron dissolve 3.73 mg chelating agent (Na_2EDTA) and 2.78 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Keep refrigerated or frozen between uses. If auxin does not dissolve completely, shake well before dispensing.

[f]Add items 1 and 3–9 to the 500 ml distilled water (item 11) that contains item 2. Adjust pH to 5.0–5.3, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Dispense medium into culture vessels and autoclave. Omit agar if preparing liquid medium. It is generally not advisable to autoclave hormones, vitamins, amino acids, or a number of other organics without first determining whether this will affect the medium deleteriously. In this case the author (Soediono, 1983*b*) routinely autoclaves her medium, which contains NAA.

Clonal Propagation of *Dendrobium* by Means of Node Cultures

At one time *Dendrobium* explants were difficult to culture; for this reason, my colleagues and I (JA) developed an in vitro propagation procedure that utilizes stem nodes (Arditti et al., 1973; Mosich et al., 1973, 1974*a*, 1974*b*).

Plant Material. Stems ("canes") at least 10–5 cm long are used as the source of nodes.

Surface Sterilization. Leaves, dry sheaths, and other external tissues are removed, and the stems are washed by gentle scrubbing with a soft brush and mild household detergent. They are rinsed after the wash and surface-sterilized by immersing them for 10 to 20 min in a 50% dilution of household bleach (50 ml bleach mixed with

50 ml distilled water). Following the sterilization the sections should be dipped in sterile distilled water for 1–2 min.

Culture Vessels. Use 25 × 180 mm test tubes containing 20 ml medium.

Culture Conditions. Nodes in culture are maintained under 150 ft-c (1600 lx) and 16-h photoperiods provided by banks of 40-W Sylvania Gro Lux tubes and incandescent bulbs. The temperature should be 22–25°C.

Culture Media. Modified Knop's medium (Gautheret, 1959) is used for initial culture (Table Den-19). Depending on which buds are being cultured, the medium must contain 1.5, 14.8, or 148 mg *trans*-cinnamic acid (Table Den-19, item 7). The shoots that form on this medium are transferred to a modification of the MS medium (Table Den-20) for root formation.

Procedure. After washing the stems, divide them into three sections: upper (containing 25–33% of the nodes), middle (30 to 50%), and basal (25 to 33%). Sterilize buds from the upper section for 5–7 min (longer periods are lethal), those from the middle portion for 10–15 min, and the basal ones for 20–25 min. Remove discolored tissues near the cut edges following decontamination, and separate the nodes by transverse cuts. Those from the upper section are 5–7.5 cm in length; from the middle, 1.5–7.5 cm; and from the base, 1.5–2 cm (buds should be 0.75 cm from either end when possible). Sections from near the apex sometimes contain two buds that are difficult to separate owing to their proximity to each other.

All sections are placed on the agar basal end down ("right side up") and pushed halfway into the initial medium (Table Den-21) for stability. When shoots reach 1.5–2 cm in length, transfer them to the rooting medium (Table Den-20), where roots form within 14 days.

Developmental Sequence. Buds start to grow after 4 weeks on Knop's medium, and plantlets develop within 45 days. Most of them do not have roots and must be transferred to the rooting medium 2–3 weeks later (12–13 weeks after placing the nodes in culture). There they form roots within 2 weeks.

General Comments. This is a simple method that does not require sophisticated equipment, or advanced skills. Its major disadvantage – the need to remove (and therefore endanger) an entire stem – is balanced by the very high rate of success (75–100%). Furthermore, it is possible to use old and/or damaged canes as long as a few buds are intact. Recent evidence suggests that it should be possible to excise basal buds only (leaving the stem otherwise intact) and culture them. We have had limited success with this procedure to date and hope to refine it. Only one plantlet is formed from each bud, although on rare occasions we have noted considerable proliferation. With further modifications, the procedure could perhaps induce proliferation.

TABLE DEN-19. **Modified Knop's medium for the culture of *Dendrobium* node sections (Mosich et al., 1973, 1974*a*, 1974*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	500	50 g l^{-1}	10	Or weigh
2	Potassium nitrate, KNO_3[b]	125	12.5 g l^{-1}	20	Or weigh
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	125	12.5 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	125	12.5 g l^{-1}	10	
	Iron				
5	Ferric citrate, $FeC_3H_5O_7 \cdot 3H_2O$[c]	10	1 g l^{-1}	10	
6	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	0.056	56 mg l^{-1}	1	One solution[d]
(b)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	0.036	36 mg l^{-1}		
(c)	Zinc chloride, $ZnCl_2$	0.152	152 mg l^{-1}		
(d)	Cobaltous chloride, $CoCl_2$	0.02	20 mg l^{-1}		
(e)	Copper chloride, $CuCl_2 \cdot 2H_2O$	0.054	54 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Ferric chloride, $FeCl_3 \cdot 6H_2O$	0.5	500 mg l^{-1}		
(h)	Na_2EDTA	0.8	800 mg l^{-1}		
	Anti-auxin[e,f,g,h]				
7	*trans*-cinnamic acid[c,e]	150,[f] 15,[g] or 1.5[h]	15 g 100 ml^{-1} 95% ethanol	1,[f] 0.1,[g] or 0.01[h]	
	Vitamin				
8	Thiamine (vitamin B_1)	0.4	100 mg 100 ml^{-1} 95% ethanol[i]	0.4	
	Cytokinin				
9	6-Benzylaminopurine (benzyladenine)	2.0	200 mg 100 ml^{-1} 95% ethanol[i]	1.0	
	Sugar				
10	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[j]	To 1000 ml			
	Solidifier				
12	Agar	13 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing nitrate and ammonium tend to become contaminated on standing. Therefore, it is better to weigh this component each time. If a stock solution is prepared, it must be kept frozen.

[c]If the substance does not dissolve, add a dilute KOH solution one drop at a time until the solution becomes clear.

[d]Add all microelements to the same 1 l, stir and/or heat until dissolved. Add 1 ml to the culture medium.

[e]If the *trans*-cinnamic acid fails to dissolve, add a few drops of dilute KOH. Keep refrigerated.

[f]For nodes from the basal portion of the stem.

[g]For nodes from the midsection of the stem.

[h]For nodes from near the stem apex.

[i]Keep stock solution refrigerated.

[j]Mix items 1–6 with 800 ml of distilled water (item 11), set the pH to 5.5, dissolve the sugar (item 10), adjust the total volume to 1000 ml with distilled water (item 11), bring the solution to a gentle boil and add the agar slowly while stirring. When the agar is fully dissolved pour the solution into a 2-l Erlenmeyer flask and autoclave. The agar can also be added to the cold solution and dissolved by boiling. Under sterile conditions and using sterilized pipettes add the anti-auxin (item 7), vitamin (item 8) and cytokinin (item 9) to the hot and still liquid medium, swirl to mix well and dispense into culture vessels.

Knop's medium was formulated before chelating agents were available and that is why it includes ferric tartrate (FT) as the iron source. Since FT is not easily soluble it is preferable to use chelated iron. Add 278 mg of ferrous sulfate ($FeSO_4 \cdot 7H_2O$) and 373 mg of chelating agent (Na_2EDTA) to 1 l of distilled water, stir until both are completely dissolved. Add 10 ml of this solution to each liter of medium.

TABLE DEN-20. **Modified Murashige–Skoog medium for root induction on *Dendrobium* shoots obtained from node sections (Mosich et al., 1974*a*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements[b]				
1	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
2	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
3	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1.9	95 g l^{-1}	20	Or weigh
5	Ammonium nitrate, NH_4NO_3[b]	1.65	82.5 g l^{-1}	20	Or weigh
6	**Chelated iron**[c]				
(a)	Na_2-EDTA	74.5	7.45 g l^{-1}		
(b)	Ferrous sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[c]				
(c)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}	10	One solution[c]
(e)	Zinc chloride, $ZnCl_2$	3.93	393 mg l^{-1}		
(f)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(g)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(h)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(i)	Cobaltous chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
	Growth factor				
8	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
9	Indoleacetic acid	0.1	50 mg 50 ml^{-1} 95% ethanol[d]	0.1	
	Vitamin[d]				
10	Thiamine (vitamin B_1)	0.4	100 mg 100 ml^{-1} 95% ethanol[d]	0.4	
	Sugar				
11	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[e]	To 1000 ml			
	Solidifier				
13	Agar	13 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and nitrate may become contaminated. Therefore, stock solutions should not be prepared. If made, they must be kept frozen between uses.

[c]Add the chelated iron (items a–b) and all microelements (c–i) to the same 1 l distilled water; stir and/or heat until dissolved. Add 10 ml per liter of culture medium.

[d]Keep refrigerated.

[e]Mix items 1–9 with 800 ml of distilled water (item 11); adjust the pH to 5.8; add the sugar (item 10); and bring the volume to 1000 ml with more distilled water (item 11). Distribute into culture vessels and autoclave. Solutions containing heat labile substances like indoleacetic acid (IAA) should not be autoclaved without prior determination that heat sterilization is not deleterious. In this instance the medium can be autoclaved.

TABLE DEN-21. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Dendrobium* and *Phalaenopisis* flower-stalk cuttings (Intuwong et al., 1972*a*, 1972*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Tricalcium phosphate, $Ca_3(PO_4)_2$[b]	200	20 g l^{-1}	10	
2	Potassium nitrate, KNO_3[c]	525	52.5 g l^{-1}	10	Or weigh
3	Potassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
4	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
5	Ammonium sulfate, $(NH_4)_2SO_4$[c]	500	50 g l^{-1}	10	Or weigh
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3$[d]	28	2.8 g l^{-1}	10[d]	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 2H_2O$	5.7	5.7 g l^{-1}	1	
	Sugar				
8	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier[f]				
10	Agar	9 g[f]	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]If this salt does not dissolve completely, shake the stock solution well before dispensing to mix well; or better yet, weigh out each time.

[c]Solutions containing ammonium and nitrate may become contaminated. Therefore, stock solutions should not be prepared. If made, they must be kept frozen between uses.

[d]Ferric tartrate is relatively insoluble. Grinding it with a mortar and pestle before dissolving helps. The addition of a pellet or two of KOH to the solution will increase solubility, but a precipitate may form nevertheless. To insure equal distribution, shake stock solution well before dispensing. This medium (Vacin and Went, 1949) was formulated before chelating agents were available and that is why it includes ferric tartrate (FT) as the iron source. Since FT is not easily soluble it is preferable to use chelated iron. Add 278 mg of ferrous sulfate ($FeSO_4 \cdot 7H_2O$) and 373 mg of chelating agent (Na_2EDTA) to one liter of distilled water, stir until both are completely dissolved. Add 10 ml of this solution to each liter of medium.

[e]Dissolve items 1–7 in 900 ml of distilled water (item 9); adjust the pH to 4.8–5.0; add sugar (item 8) and bring the volume up to 1000 ml with more distilled water (item 9). Add the agar (item 10) slowly, while stirring, to the gently boiling solution. When fully dissolved, dispense into culture vessels and autoclave.

[f]If cultures are maintained at 29°C, the amount of agar should be increased to 12–15 g l^{-1}.

Clonal Propagation of *Dendrobium crumenatum* from Leaves

"The shoot tip culture [of orchids] entails the sacrifice of the whole plant or an entire new growth. Using axillary buds, inflorescence axes, and other parts of the plant body would also involve damaging or sacrificing certain plant parts. To avoid or to minimize such damage . . . leaf tips can be used . . ." (Manorama et al., 1986). A procedure utilizing leaves of *Dendrobium crumenatum* (*Anggrek merpati*, pigeon orchid), a species native to Singapore (where they can still be seen on trees in the midst of a bustling modern city), Malaysia, and Indonesia, was developed at the Botany Department, National University of Singapore (Manorama et al., 1986).

Plant Material. Leaves from *D. crumenatum* seedlings grown in vitro and mature plants are used. Whole leaves or leaf segments are cultured.

Surface Sterilization. Leaves taken from seedlings grown in vitro need not be sterilized. If sterilization of seedling leaves becomes necessary, they should be immersed in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water) for

5 min. Leaves from mature plants growing outdoors should be immersed in 10–30% Clorox (10–30 ml Clorox diluted to 100 ml with distilled water) for 10 min. After being removed from the Clorox solution, the leaves should be rinsed three to five times with sterile distilled water.

Culture Vessels. "Culture flasks" (presumably Erlenmeyer flasks) were used in the original research. Other containers can also be used.

Culture Conditions. Liquid cultures should be placed on a shaker at 80 rpm for 16 h day^{-1}. The illumination used in the original research was 1000 lx and 12-h photoperiods. Average temperature should be 26°C. Solid cultures are maintained under the same conditions on a shelf or bench.

Culture Media. Liquid modified Vacin and Went medium (Table Den-22) is used for the initial culture. A liquid modification of the MS medium (Table Den-23) may prove suitable for mature leaves. Plantlets and PLBs produced on these media can be cultured on modified Vacin and Went (see Table Cym-5) and unmodified Knudson C (see Table Aranda-7) media.

Procedure. First culture explants in one of the liquid media. Then transfer plantlets and PLBs to solid medium.

Developmental Sequence. Callus is formed after 40 days in culture, and PLBs appear within 3 months. This research (Manorama et al., 1986) is an excellent example of detailed anatomical and morphological studies of development and organogenesis in a tissue culture system. The leaves of *D. crumenatum* have a mesophyll that consists of nine layers of rounded cells. As in *Aranda* the first division occurs in the upper epidermis. This leads to the formation of a meristematic region that is three to four cell layers thick. Cells in this region divide to form a callus. During early development this callus is uniform and has a homogeneous outline. Later it develops many lobes and each of these gives rise to a PLB.

General Comments. The procedure presented here is based on an excellent study of the developmental aspects of tissues and plants cultured in vitro. This method, an excellent example of A.N. Rao's scientific leadership at the National University of Singapore, is also suitable for leaves of *Aranda* Deborah, *Aranda* Hilda Galistan, *Aranda* Mei Ling, and *Aranda* Queen of Purples.

TABLE DEN-22. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of seedling leaves of *Dendrobium crumenatum* (Manorama et al., 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Auxins				
8	2,4-Dichlorophenoxyacetic acid (2,4-D)	5	500 mg 100 ml^{-1} 95% ethanol[e]	1	
9	Naphthaleneacetic acid (NAA)	5	500 mg 100 ml^{-1} 95% ethanol[e]	1	
	Cytokinin				
10	Benzyladenine (BA)	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additives				
11	Coconut water	200 ml	No stock	No stock	Measure
12	Casein hydrolysate	150	No stock	No stock	Weigh
	Sugar				
13	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 500 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate it. To prepare a stock solution of chelated iron dissolve 3.73 mg chelating agent (Na_2EDTA) and 2.78 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Keep frozen or refrigerated between uses.

[f]Add items 1 and 3–12 to the 500 ml distilled water (item 14) that contains item 2. Adjust pH to 5.3, add sugar (item 13), and adjust volume to 1000 ml with distilled water (item 14). Dispense the medium into culture vessels and autoclave. Omit agar if preparing liquid medium. It is generally not advisable to autoclave hormones, vitamins, amino acids, or a number of other organics without first determining whether this will affect the medium deleteriously. In this case Manorama et al. (1986) report that they autoclaved their medium.

TABLE DEN-23. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for the culture of leaves from mature plants of *Dendrobium crumenatum* (Manorama et al., 1986)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
8	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100	No stock	No stock	Weigh
	Auxins				
10	2,4-Dichlorophenoxyacetic acid (2,4-D)	5	500 mg 100 ml^{-1} 95% ethanol[f,g]	1	
11	Naphthaleneacetic acid (NAA)	5	500 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
12	Benzyladenine (BA)	5	500 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Complex additives				
16	Coconut water	200 ml	No stock	No stock	Measure
17	Casein hydrolysate	150	No stock	No stock	Weigh
	Sugar				
18	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
19	Water, distilled[h]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxins or cytokinin do not dissolve, a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–17 to 500 ml distilled water (item 19), adjust pH to 5.3, add sugar (item 18), and adjust volume to 1000 ml with distilled water (item 19). Dispense solution into culture vessels, and autoclave. Omit agar if preparing liquid medium. It is generally not advisable to autoclave hormones, vitamins, amino acids, or a number of other organics without first determining whether this will affect the medium deleteriously. In this case Manorama et al. (1986) report that they autoclaved their medium.

Culture of *Dendrobium* Leaves

Leaves of *Dendrobium* Alice Spalding (*Dendrobium tokai* × *Dendrobium undulatum*) from plantlets grown in vitro when cultured like leaf explants of *Aranda* Noorah Alsagoff (Fu, 1978, 1979*a*, 1979*b*) produced a single plantlet at their bases. Proliferation and plantlet production did not occur when these leaves were cultured on modified MS medium. Leaves from mature plants cultured on modified MS medium also failed to proliferate (Fu, 1978, 1979*b*).

Plant Material. Leaves are taken from plantlets grown in vitro.

Surface Sterilization. Stems are wiped several times with a cheesecloth soaked in 95% ethyl alcohol (ethanol), cut into sections, and submerged for 15 min in 10% Clorox (10 ml Clorox diluted to 100 ml with distilled water). Following removal of the bracts, the stems are placed in 10% Clorox for 10 min and then dipped in sterile distilled water for 3 min (Kim et al., 1970).

Culture Vessels. Test tubes, Erlenmeyer flasks, and other containers are suitable.

Culture Conditions. The conditions used for *Dendrobium* in other procedures are suitable. Liquid media should be shaken.

Culture Medium. Modified Vacin and Went medium (Table Den-24) is most suitable.

Procedure. The leaves are placed in the medium and allowed to develop plantlets.

Developmental Sequence. A single plantlet is formed at the base of each leaf.

General Comments. This procedure is slow because only one plant is produced from each leaf. Also, if the leaves are from seedlings, the plants being propagated are of unknown quality.

TABLE DEN-24. **Modified Vacin and Went medium (Vacin and Went, 1949) for the culture of *Dendrobium* leaf bases (Fu, 1978, 1979*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500	50 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250	25 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	250	25 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525	52.5 g l^{-1}	10	
	Iron[d]				
6	Ferric tartrate, $Fe_2(C_4H_4O_6)_3 \cdot 2H_2O$	28	No stock	No stock	
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750 mg l^{-1}	10	
	Complex additive				
8	Coconut water	500 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[e]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]This salt is hard to dissolve, and it is not possible to prepare a stock solution. To facilitate preparation of medium, place 200 mg of the salt in 400 ml water, stir and/or heat until it dissolves. Add the other components of the medium after that.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate it. To prepare a stock solution of chelated iron dissolve 3.73 mg chelating agent (Na_2EDTA) and 2.78 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]Add items 1–8 to the 400 ml distilled water (item 10) that contains item 2. Adjust pH to 5.0, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Dispense medium into culture vessels, and autoclave. Omit agar if preparing liquid medium.

Vegetative Propagation of *Dendrobium* by Flower-stalk Cuttings

Following removal or wilting of unpollinated blossoms, the flower stalks of *Dendrobium* die. Hence, use of their buds amounts to the proper utilization of material that would otherwise be wasted. Therefore, a procedure for clonal propagation using flower-stalk cuttings (Singh and Sagawa, 1972) is economical and safe.

Plant Material. Flower stalks of *Dendrobium* having well-developed buds are used.

Surface Sterilization. Wipe stems several times with a cheesecloth soaked in 95% ethyl alcohol (ethanol), cut into sections, and soak for 15 min in 10% Clorox (v/v). Then remove bracts, transfer into 10% Clorox (v/v) for 10 min, and dip into sterile distilled water for 3 min (Intuwong et al., 1972).

Culture Vessels. Use 25×100 mm vials containing 12 ml medium.

Culture Conditions. Maintain cultures under continuous illumination of approximately 200 ft-c (provided by General Electric Power Groove white fluorescent lamps) at 23–29°C.

Culture Medium. Modified Vacin and Went medium (Table Den-21) is most suitable (Intuwong et al., 1972*a*, 1972*b*).

Procedure. Cut stems into sections, leaving 1–1.5 cm on either side of each bud. Surface-sterilize the flower-stalk sections, and remove discolored tissues from near the cut edges. Insert sections into the culture medium to just below the bud.

Developmental Sequence. Plantlets with well-developed shoots and roots can be obtained within a few months.

General Comments. Not all *Dendrobium* plants have a sufficient number of well-developed buds on flower stems. When such buds are available, however, this can be a very useful procedure, even if only one plantlet is obtained per bud.

Clonal Propagation of *Dendrobium aduncum, Dendrobium loddigesii,* and *Dendrobium transparens* through the Culture of Stem Nodes

Dendrobium aduncum and *Dendrobium loddigesii* are native to Hong Kong, where they grow in the hills. They are cultivated at the farm of the Kadoorie Agricultural Aid Association. *Dendrobium transparens* is native to Nepal, and its seeds were germinated in vitro as part of a Ph.D. dissertation project. Methods for the culture of their nodes were developed in the laboratory of Maureen A. Weatherhead, Botany Department, University of Hong Kong (Yam, 1989).

Plant Material. Stems of *D. aduncum* and *D. loddigesii* were taken from the Kadoorie farm plants. After surface sterilization discolored tissues at the cut ends of stems were removed and each stem was sectioned into 1-cm-long sections with a bud in the middle. Plantlets of *D. transparens*, three to five nodes long, were taken from aseptic culture, freed of leaves, sheaths, and roots, and sectioned as above.

Surface Sterilization. Leaves, dry sheaths, and roots were removed from the stems of the two Hong Kong species. The stems were first soaked for 30 min in deionized water and then washed with tapwater, scrubbed gently with a mild household detergent and very soft sponge, and rinsed. They were wiped with 75% aqueous ethanol and surface-sterilized by submerging them in 20% household bleach (20 ml bleach diluted to 100 ml with distilled water) for 25 min with agitation at 5-min intervals. The sterilant was removed by rinsing the stems three times with sterile deionized water. There was no need to sterilize the stems of *D. transparens* because they were taken from aseptic cultures.

Culture Vessels. Wide-mouth plastic 75-ml-capacity culture vessels (from Johns Mallinckrodt, Johns Division, Mallinckrodt Australia, Pty., Ltd.) were used in the original research. Other containers are also suitable.

TABLE DEN-25. **Knop's medium (Knop, 1884) modified for the culture of *Dendrobium* stem nodes (Yam, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solidifier				
12	Agar[e]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]The number of waters of hydration is not given.

[d]Like other iron salts, this one is hard to dissolve. It is therefore preferable to chelate it. To prepare a stock solution of chelated iron dissolve 3.73 mg chelating agent (Na_2EDTA) and 2.78 mg ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in 1 l of water. Stir and/or heat until both are completely dissolved. Add 10 ml of this solution to the culture medium.

[e]As originally formulated the solution does not contain sugar or agar.

[f]Add all items to 900 ml distilled water (item 12), adjust pH to 5.6, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Bring solution to a gentle boil, and add agar (item 13) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into culture vessels and autoclave.

Culture Conditions. Cultures were maintained under 16-h photoperiods of 2000 lx provided by Sylvania Gro Lux fluorescent tubes and 25 ± 2°C.

Culture Medium. Modified Knop's medium (Table Den-25) was used.

Procedure. Place the stem sections horizontally on the medium, and press their lower half into the agar with the bud facing up. Allow to remain in culture until plantlets form and develop into a large size for transfer to a potting mix.

Developmental Sequence. Buds swell following 1–2 weeks, shoots emerge within 3–6 weeks, and they form after 2 months. Plantlets are ready for transfer after 3–5 months in culture.

General Comments. *D. aduncum* forms plantlets and grows faster than the other two species. This method can be used in efforts to conserve these and possibly also other *Dendrobium* species with soft and fleshy stems. It may not be suitable for species (e.g., *D. acinaciforme*) that have hard stems.

Micropropagation of *Dendrobium chrysanthum* through Pseudobulb Segments

Dendrobium chrysanthum is an epiphytic orchid native to the Himalayas. Its dark green leaves and golden yellow flowers have made it popular with growers, which has resulted in overcollecting. This factor, along with a shrinking habitat, is putting pressure on the survival of this species. A mass rapid clonal propagation method was developed in India for use in conservation (Vij and Pathak, 1989).

Plant Material. Pseudobulb segments (0.5–1.0 cm long) from 40-week-old seedlings growing in vitro were used in the original research.

Surface Sterilization. It is not necessary to surface-sterilize the explants or their source because the seedlings are from axenic cultures in vitro.

Culture Vessels. Culture tubes, Erlenmeyer flasks, jars, and other culture vessels are suitable.

Culture Conditions. In the original research cultures were maintained at 25 ± 2°C under 12-h photoperiods of 3500 lx. Light sources are not described, but it is reasonable to assume that the usual fluorescent and/or incandescent lamps would be suitable.

Culture Media. Several modifications of the MS medium were used in the original research. The two media listed here promote development of multiple shoots (Table Den-26) and "shoot bud formation and callusing" (Table Den-27).

Procedure. The explants are placed on the medium and allowed to develop.

Developmental Sequence. Shoot buds form within 5–6 days depending on the medium. The first leaf primordium is evident after 8–10 days. Roots can be seen 12–17 days following the start of culture. Plantlets develop after 18–25 days.

General Comments. Plantlets regenerated by this method are cytologically stable, and this suggests that it can be used for mass rapid clonal propagation of this orchid.

TABLE DEN-26. **Murashige–Skoog medium (Murashige and Skoog, 1962) modified for the culture of pseudobulb segments of *Dendrobium chrysanthum* (Vij and Pathak, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	Urea, H_2NCONH_2[b]	25	2.5 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	8.60 mg l^{-1}		
	Amino acid				
9	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
11	Naphthaleneacetic acid (NAA)	1	100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
15	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference will probably have little effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, use a few drops of KOH to solubilize it.

[g]Keep refrigerated between uses.

[h]Add items 1–8 and 10 to 900 ml distilled water (item 16). Adjust pH as required, add sugar (item 15), and adjust volume to 1000 ml with distilled water (item 16). Bring solution to a gentle boil, and add agar (item 17) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 9 and 11–14) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

TABLE DEN-27. **Modified Murashige–Skoog medium (Murashige and Skoog, 1962) for callus and bud induction on pseudobulb segments of *Dendrobium chrysanthum* (Vij and Pathak, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650	165 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440	44 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370	37 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900	190 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170	17 g l^{-1}	10	
6	Urea, H_2NCONH_2[b]	25	2.5 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 g l^{-1}		
(e)	Potassium iodide, KI	0.83	83 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860 mg l^{-1}		
	Amino acid				
9	Glycine	2	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
10	*myo*-inositol	100	No stock	No stock	Weigh
	Auxin				
11	Naphthaleneacetic acid (NAA)	1 g	100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Cytokinin				
12	Kinetin	1	100 mg 100 ml^{-1} 95% ethanol[f,g]	1	
	Vitamins				
13	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
14	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[g]	1	
15	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[g]	1	
	Sugar				
16	Sucrose	30 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[h]	To 1000 ml			
	Solidifier				
18	Agar, Difco Bacto[h]	10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[c]Add chelating agent (item 7a) and iron salt (item 7b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved.

[d]Add all microelements to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration. This difference probably has little effect.

[e]Keep frozen between uses.

[f]If auxin or cytokinin does not dissolve, use a few drops of KOH or HCl, respectively.

[g]Keep refrigerated between uses.

[h]Add items 1–8 and 10 to 900 ml distilled water (item 17), adjust pH as required, add sugar (item 16), and adjust volume to 1000 ml with distilled water (item 17). Bring solution to a gentle boil, and add agar (item 18) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, pour solution into a 2-l flask, and autoclave. Add amino acid, hormones, and vitamins (items 9 and 11–15) to hot solution under sterile conditions with sterilized pipettes, mix well, and distribute medium to preautoclaved culture vessels. Omit agar if preparing liquid medium.

Isolation of Mesophyll Protoplasts of *Dendrobium*

The procedure developed for *Calanthe discolor* can also be used for *Dendrobium aggregatum*, *Dendrobium* Yukidaruma 'Queen,' and probably other species and hybrids. An incubation period of 2 h appears to be more suitable for *Dendrobium*. In the case of *Dendrobium* Yukidaruma 'Queen' isolation was 80%, survival was 64%, and the density as high as 4.13×10^5 protoplasts ml^{-1}. Isolation from *D. aggregatum* was 27% (Yasugi et al., 1986). In subsequent work Yasugi and his collaborators have been very successful with *Dendrobium* protoplasts.

Isolation of Protoplasts from Leaves and Roots of *Dendrobium herbaceum*

The method developed for *Acampe praemorsa* can be used to isolate protoplasts of *Dendrobium herbaceum*. Yields were 3.8×10^4 and 0.7×10^4 protoplasts per gram of fresh-weight tissue for leaves and roots respectively (Seeni and Abraham, 1986).

Transformation of Isoprenoids by *Dendrobium* in Tissue Culture

Tissue cultures of *Dendrobium phalaenopsis* maintained in vitro on media used for other orchids (Kukułczanka, 1985; Kukułczanka and Wojciechowska, 1983) transformed some isoprenoids (Mironowicz et al., 1987).

Shoot-tip Culture of a *Dendrobium* Hybrid

Shoot tips of *Dendrobium* Pompadour 'Pratabh' were cultured at the University of Nottingham (Voraurai, 1968).

Substrate Utilization by *Dendrobium* Tissues

Tissues obtained from apical meristems of *Dendrobium* Multico White (*Dendrobium* Ong Geok Kim × *Dendrobium* Ng Eng Chow) and initiated, maintained, and cultured on the Vacin and Went medium can utilize glucose, fructose, and sucrose as carbon sources. Fructose was utilized most readily (Hew et al., 1988). Sucrose was hydrolyzed extracellularly. The growth rate increased with increasing sugar levels. Respiration on fructose and glucose was higher than on sucrose. The respiration rate decreased on increased sugar concentrations.

The tissue took up ammonium ions (NH_4^+) in preference to nitrate (NO_3^-). Substantial uptake of nitrate was evident only after the ammonium ion was totally depleted (Hew et al., 1988).

Sugar Uptake and Invertase Activity in *Dendrobium* Tissues

Undifferentiated and differentiated tissue of *Dendrobium* Multico White (*Dendrobium* Ong Geok Kim × *Dendrobium* Ng Eng Chow) that was initiated, maintained, and cultured on the Vacin and Went medium exhibited no preference for sugars when grown on glucose, fructose, or sucrose. However, "fructose provided the best carbon source for both tissues." Sucrose was hydrolyzed by alkaline and acid invertases that are present in the soluble and cell-wall fractions (Hew and Mah, 1989). Invertase levels increased with time when the tissues were grown on sucrose-containing medium (Hew and Mah, 1989). Uptake of sugars by undifferentiated tissues was more rapid.

Isolation and Fusion of *Dendrobium* Protoplasts

Some of the earliest reports regarding isolation and fusion of orchid protoplasts are from the School of Biological Sciences, University of Science, Penang, Malaysia, and Institute für Pflanzenernährung, Abt. Gewebekultur, Justus Liebig University, Giessen, Germany, and deal with *Cattleya*, *Dendrobium*, *Paphiopedilum Phalaenopsis*, and *Renantanda* (Teo and Neumann, 1978*a*, 1978*b*, 1978*c*). Despite a statement that research was in progress, "focused on 'persuading' the cell cluster to form protoplasts," there are no further reports by these authors. More recently protoplasts of several orchids were isolated at the Departments of Floriculture and Ornamental Horticulture, and Plant Breeding and Biometry, Cornell University, Ithaca, NY, where fusion of *Dendrobium* protoplasts was also attempted (Price and Earle, 1984).

Plant Material. Protoplasts were isolated from the following:

1. Purple petals of *Dendrobium* Beach Girl [*Dendrobium* Pauline (*Dendrobium phalaenopsis* × *Dendrobium undulatum*) × *Dendrobium schulleri*] × *Dendrobium* Takami Kodama [*Dendrobium* Taurus (*Dendrobium taurinum* × *Dendrobium undulatum*) × *Dendrobium taurinum*], and
2. Green leaves (6 cm long) and purple petals of open flowers of *Dendrobium* Louis Bleriot (*Dendrobium schroederianum* × *Dendrobium superbiens*).

Surface Sterilization. The procedure used with *Angraecum giryamae* is suitable.

Culture Vessels. For containers used in the isolation of protoplasts see *A. giryamae* (p. 167, Vol. I). Plastic Petri dishes 60 mm in diameter are used for fusion.

Culture Conditions. Conditions during protoplast isolation should be the same as those for *A. giryamae*.

Culture Media. For isolation and culture media, and preparation used to check the viability of protoplasts and some of the other solutions, see *A. giryamae*. Washing is carried out with a solution consisting (per liter) of 91.1 g sorbitol, 7.5 g calcium

chloride ($CaCl_2 \cdot H_2O$), and 976 mg 2-[*N*-morpholino]ethanesulfonic acid, pH 9.5. A medium consisting (per liter) of 90.1 g (0.5 mol) glucose, 514.6 mg (3.5 mmol) calcium chloride ($CaCl_2 \cdot 2H_2O$), and 95.3 mg (0.7 mmol) monopotassium phosphate (KH_2PO_4) (GCP solution) is used for protoplast fusion.

Procedure. Protoplast isolation and viability determination procedures are the same as those used with *A. giryamae*. The following procedure is used for fusion (all steps must be carried out under sterile conditions; tools, containers, and solutions must be sterilized):

1 The protoplast sources (green leaves of *Dendrobium* Louis Bleriot and purple petals of *Dendrobium* Beach Girl × *Dendrobium* Takami Kodama) are incubated separately in the 2% Cellulysin solution (see *A. giryamae*) for 1 day.
2 Protoplasts from each source are washed (see *A. giryamae*) and resuspended separately in the GCP solution (see previous section on culture media).
3 After counting, the suspensions should be adjusted with the GCP medium to contain approximately 500,000 protoplasts ml^{-1}.
4 Equal volumes of each suspension are mixed in a test tube (the suspension should still contain 500,000 protoplasts ml^{-1}).
5 Several 0.1-ml (100 µl) drops of the mixture are placed in a 60-mm-diameter plastic Petri dish (a sterile pipette is used to measure the required volume). The solution should be observed to determine whether the protoplasts are still alive. Protoplasmic streaming is a good indication that they are.
6 Polyethylene glycol (PEG) 1540, 0.33-*M* solution (see procedure for *A. giryamae*), 4 drops from a Pasteur pipette (see lists in Chapter 2) per drop of protoplast, is added. The mixture should be examined after 15–30 min to determine if the protoplasts are alive and whether fusion is taking place.
7 Protoplasts are washed four times by adding 4 drops of the high-calcium pH 9.5 solution (see Culture Media section above) per protoplast drop. Excess solution is removed by blotting each time after allowing the protoplasts to settle. Care should be taken not to remove protoplasts during the blotting.
8 The Petri dish is flooded with the GCP solution and excess fluid is removed after the protoplasts have settled.
9 Nutrient medium (see Tables Angcm-1 or Angcm-2) is added.

Developmental Sequence. Several problems were encountered during the fusion process: (1) treatment with PEG produced a very low frequency of fusion of dissimilar protoplasts; (2) many protoplasts were lost during washing; and (3) green protoplasts lysed within 2 days.

General Comments. "It is clear that further refinements to increase frequency of fusion and survival . . . are needed . . . for fusion products to be useful . . . Protoplast preparations should involve cells with high potential for regeneration" (Price and Earle, 1984). This is so, and the present procedure is a good start.

Elimination or Inhibition of Contaminants in Contaminated Tissue Cultures of *Dendrobium*

> When a few cultures among many of a particular clone become contaminated, contamination is merely a nuisance; it is certainly not an irreplaceable loss. However, when the contaminated culture is the only one of an expensive plant, the loss may be considerable. Faced with this situation we have developed a procedure for the decontamination of contaminated cultures. (Soediono, 1983*a*)

Plant Material. Callus, PLBs, and plantlets obtained from lateral bud cultures of *Dendrobium* Tay Swee Keng were used in the original research. They were taken from contaminated cultures.

Surface Sterilization. Callus, PLBs, and plantlets taken from contaminated cultures are dipped for 1 and no more than 2 s in 70% ethanol and then rinsed three times with sterile distilled water.

Culture Vessels. This procedure is intended to decontaminate existing cultures regardless of the initial method. Therefore the culture vessels used for it should be the same as the ones that are already being utilized.

Culture Conditions. The conditions should be the same as the ones already in use except that the first few changes of medium, which contains bactericides and fungicides, are placed on a shaker (see procedure for *Dendrobium* Jaquelyn Thomas 'White', p. 539, Vol. I; Soediono 1983*b*).

Culture Media. There is no specific medium for this procedure. The medium or media should be the same as those employed by the method that was used to start and maintain the contaminated cultures. Two fungicides and two bactericides are added to the culture medium as described here:

- Benlate or benomyl: 2.5 mg of one of several commercial products containing 50% active principle, obtainable at retail nurseries (the other 50% must be inert). The powder should be suspended in 1–2 ml of 95% ethanol in a sterile vial and shaken vigorously for 2–3 min, allowed to stand, shaken again for 1 min, placed on a shelf for an additional 15 min, and added under sterile conditions to autoclaved culture medium after it has cooled. If any material remains on the walls of the vial, it should be washed into the medium with sterile distilled water.
- Nystatin: 5000 units from Mycostatin Squibb oral suspension containing 100,000 units ml^{-1}. This preparation is available from local pharmacies. It can be diluted to 100,000 units per 5 ml with sterile distilled water to facilitate distribution. The suspension must be shaken vigorously before the appropriate amount is added under sterile conditions to autoclaved culture medium after it has cooled.
- Penicillin G: 8000 units (available as injectable penicillin from local pharmacies) suspended in sterile distilled water and added under sterile conditions to autoclaved culture medium after it has cooled.

- Gentamycin (purchased as injectable Garamycin Schering in sterile distilled water from a local pharmacy): 2.5 mg added under sterile conditions to autoclaved culture medium after it has cooled.

These substance are also available from chemical supply houses. When purchased from pharmacies the last three may require a prescription. Some of the commercial preparations may contain inert substances that are insoluble and can cause cloudiness in the medium. Care should be taken not to purchase preparations that contain other active substances.

Procedure. Take contaminated callus, PLBs, and plantlets from cultures, dip in the alcohol, wash with sterile distilled water, and suspend in the medium that contains the fungicides and bactericides. Place the cultures on a shaker, and observe daily. Some of the more extensively infected callus masses, PLBs, and plantlets may turn white or brown and die. Others may turn white but recover and become green again. A number will remain green. Those that turn white and become green again and the ones that do not lose their color should be moved to fresh medium containing bactericides and fungicides. This may have to be repeated several times until the contaminants are eliminated.

In some cases the contaminants may not be destroyed by the fungicides and bactericides but merely kept in check. Should this happen, the tissues may have to be cultured continuously in a medium or media that contain the fungicides and bactericides (perhaps even at higher levels) until plantlets are ready for community pots.

Developmental Sequence. Depending on the severity of infection and contamination some callus masses, PLBs, and plantlets may follow several sequences: they may die, turn white and then become green again, never lose their color, or continue to grow.

General Comments. This procedure is complicated, costly, and uncertain. It offers no panaceas but may prove to be of considerable value when rare and/or expensive explants must be saved.

The compounds and concentrations listed above do not damage seedlings of *Cattleya aurantiaca* and *Stanhopea oculata*, and *Phalaenopsis* flower-stalk cultures. It is therefore reasonable to assume that they can also be used with other orchids.

Dr. Teoh Eng Soon of the Teoh Clinic in Singapore has suggested that some operators may be sensitive to these compounds or become sensitized after repeated contact with them. For this reason he advises operators to wear gloves and masks when handling them.

Plantlet Production from Stem Nodes of *Dendrobium aduncum*, *Dendrobium loddigesii*, and *Dendrobium transparens*

Plantlets can be produced from stem nodes by the culture method developed for *Bletilla striata*.

Dendrobium Propagation through the Culture of Shoot Meristems

New tissue culture methods are constantly being developed for orchids which are popular with hobby growers or of commercial importance. One reason for this may be because genera and species, especially those from dissimilar climatic zones as well as diverse hybrids, require different media and protocols. Another reason is the large number of investigators who are constantly striving to develop better and more efficient micropropagation methods. For these or other reasons a shoot meristem propagation method was developed at the Shroff Research Institute, Bombay, India (Sharon and Vasundhara, 1990).

Plant Material. Shoot tips were excised from "*Dendrobium* Joannie Ostenhault seedlings, procured from Singapore." A search on the World Wide Web and through all volumes of *Sander's List of Orchid Hybrids* did not locate such a hybrid. A white hybrid named *Dendrobium* Jonnie Osterholt (*Dendrobium phalaenopsis* × *Dendrobium* Walter Oumae, chromosome number $2n = 76$ or 78) does exist and is probably the orchid which was used. The age of the seedlings is not given in the original paper. However, the fact that the explant sources were surface-sterilized indicates that they were old enough to be removed from flasks, potted, and grown under horticultural conditions.

Surface Sterilization. A thorough washing with tap water is the first step in the surface sterilization process. The second step is sterilization with "10% solution of commercial bleach [presumably 10 ml of a household bleach like Clorox diluted to 100 ml with distilled water] with 2 drops of Tween 20 [available from www.sigmaaldrich.com or http://search.wako-chem.com; a few drops of mild household detergent can also be used]" for 10 min. Two rinses with sterile distilled water are the last steps.

The explants for the experiments leading to this procedure were taken from *Dendrobium* Jonnie Osterholt, which is a hybrid produced by the cross *Dendrobium phalaenopsis* × *Dendrobium* Walter Oumae.

Culture Vessels. Erlenmeyer flasks, 250-ml capacity containing 40–50 ml medium, are suitable.

Culture Conditions. In the original research the cultures were maintained at 24–25°C and 96–98% relative humidity (RH). The cultures were kept in the dark for 48 h after explants were placed in the first medium (no explanation is provided for this step), and moved to 8-h photoperiods of 2000 lx until the start of differentiation when the light period was increased to 16 h (there is no explanation for this change in lighting). Light was provided by fluorescent tubes (type and manufacturer are not given). Standard culture room conditions are probably also suitable. Liquid cultures were agitated (type of agitation not described) until PLBs formed. PLBs were cultured on solid medium.

Culture Media. Three media are used for this procedure, all based on the Vacin and Went (VW) medium (Vacin and Went, 1949). The first medium is liquid and contains 15% coconut water (CW; Table Den-28). This medium is used to bring about the production of PLBs. For plantlet formation PLBs must be moved to a solid medium which also contains 15% CW (Table Den-29). Rooting occurs on a third medium (Table Den-30) which contains reduced sugar levels. The original paper states that "slow elimination of [CW] from the nutrition regime favoured accelerated root development" but does not indicate how the "slow elimination" was carried out and the amounts of CW in the rooting medium (Table Den-30) at each step of the process. The medium recommended here (Table Den-30) contains no CW. If CW is used 2–5% or at most 10% (v/v) is sufficient.

Procedure. Explants should be placed in liquid medium (Table Den-28) after surface sterilization and maintained on a shaker in the dark for 48 h before being illuminated. PLBs which form in the liquid medium (Table Den-28) must be moved to solid substrate (Table Den-29) for formation. Shoots which form on the first solid medium (Table Den-29) require a transfer to a third substrate (Table Den-30) for rooting. When the rooted plants are of appropriate size they can be potted.

Developmental Sequence. PLBs form in the liquid solution (first substrate), shoots develop on the first solid medium (second substrate), and roots emerge on the second nutrient mixture (third substrate).

General Comments. This is a relatively simple procedure which seems to be effective for *Dendrobium* Jonnie Osterholt. It will probably be suitable for a number of other *Dendrobium* species and hybrids.

TABLE DEN-28. **Vacin and Went (VW) medium (Vacin and Went, 1949) as modified for the production of protocorm-like bodies (PLBs) from *Dendrobium* shoot-tip explants (Sharon and Vasundhara, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Coconut water[e]	150.0 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 3), bring volume to 900 ml with distilled water (item 10), adjust pH to 5–5.4, add sugar (item 9), raise volume to 1000 ml with distilled water (item 10), pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949), and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium (Murashige and Skoog, 1962) will probably be suitable.

TABLE DEN-29. **Vacin and Went (VW) medium (Vacin and Went, 1949) as modified for the production of plantlets from protocorm-like bodies (PLBs) derived from *Dendrobium* shoot-tip explants (Sharon and Vasundhara, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 9) which contain the calcium phosphate (item 3), bring volume to 900 ml with distilled water (item 9), adjust pH to 5–5.4, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

Mass Rapid Clonal Propagation of *Dendrobium moschatum* through the Culture of Stem Disks

Dendrobium moschatum (Fig. Den-2A) is an endangered species. A micropropagation protocol for it was developed to provide plants for the horticultural trade and reduce pressure on populations in the wild (Kanjilal et al., 1999).

Plant Material. Transverse sections of shoots, 1–1.5 mm thick, were taken from seedlings growing in vitro and cultured.

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization.

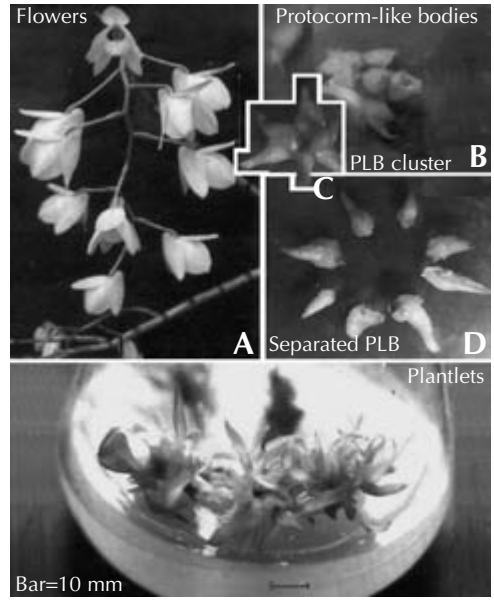

FIG. DEN-2. **Micropropagation of *Dendrobium moschatum* (Kanjilal et al., 1999).**

Culture Vessels. Erlenmeyer flasks, 250 ml, are suitable for the initial explants and proliferation of PLBs. Larger flasks, 500 ml, may be required for plantlet growth and development.

Culture Conditions. The original research cultures were maintained at 25 ± 2°C under 16-h photoperiods of 1000 lx provided by cool white lamps (manufacturer not listed). Standard culture room conditions are also suitable. Liquid cultures should be placed on a rotatory shaker at 80–120 rpm.

Culture Media. Explants should be cultured in a modified (Table Den-31) liquid Knudson C (KC) medium (Knudson, 1946) containing 15% coconut water (CW), 2 mg NAA l^{-1} and 3 mg BA l^{-1} until PLBs form. PLBs proliferate and plantlets develop on a solid version of the same medium (Table Den-32).

Procedure. Explants are cultured in the first medium (Table Den-31) to induce PLBs (Fig. Den-2A–2D). The PLBs should be moved to the second medium (Table Den-32) for proliferation and plantlet development (Fig. Den-2E).

Developmental Sequence. PLBs form on the explants. They proliferate and plantlets develop on the solid medium.

TABLE DEN-31. **Knudson C (KC) medium (Knudson, 1946) as modified for protocorm-like body (PLB) production from stem disk sections of *Dendrobium moschatum* (Kanjilal et al., 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
7	Naphthaleneacetic acid[e]	2.0	2 mg 100 mg 100 ml^{-1} 95% $ethanol^{-1}$	1	
	Cytokinin				
8	Benzylaminopurine (BAP)[e]	1.0	2 mg 100 mg 100 ml^{-1} 95% $ethanol^{-1}$	1	
	Complex additive				
9	Coconut water (CW)[f]	150.0	No stock	No stock	Measure
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Knudson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements is necessary those used in the MS medium are suitable.

[e]If the auxin or cytokinin fails to dissolve in the stock solution add a few drops of 0.1N KOH or 0.1N HCl respectively. Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[g]Add items 1–6 and 9 to 750 ml of distilled water (item 11), adjust pH to 5.2, add sugar (item 10), raise the volume to 1000 ml with distilled water, pour the solution into a 2-l flask and autoclave. Add the auxin (item 7) and the cytokinin (item 8) to the medium, stir vigorously with a sterile stirrer or swirl well to mix the hormones with the rest of the solution and dispense the medium into preautoclaved culture vessels.

General Comments. This is a procedure for mass rapid propagation of seedlings. It can be a starting point for a method which can be used to propagate mature plants. Its drawback is that it can not be employed to select desirable forms because the quality of seedlings is not known. An outstanding feature of the original paper is the statistical analysis of results and the effects of plant hormones.

TABLE DEN-32. **Knudson C (KC) medium (Knudson, 1946) as modified for protocorm-like bodies (PLBs) and plantlet development of *Dendrobium moschatum* (Kanjilal et al., 1999)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution

	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[g]	To 1000 ml			
	Solidifier				
12	Agar[g]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Kundson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements is necessary those used in the MS medium are suitable.

[e]If the auxin or cytokinin fails to dissolve in the stock solution add a few drops of 0.1N NaOH or 0.1N HCl respectively. Keep frozen between uses.

[f]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[g]Add items 1–6 and 9 to 750 ml of distilled water (item 11), adjust pH to 5.2, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar (item 12) can also be added to the cold solution which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the auxin (item 7) and the cytokinin (item 8) to the warm and still liquid medium, stir vigorously with a sterile stirrer or swirl well to mix the hormones with the rest of the solution and dispense the medium into preautoclaved culture vessels. Omit agar (item 12) if preparing liquid medium.

In Vitro Propagation of *Dendrobium moschatum* through Thidiazuron-induced High Frequency Shoot Proliferation

Dendrobium moschatum flowers are very attractive. This may be one reason for two different approaches to its micropropagation (Nayak et al., 1997*b*).

Plant Material. Shoot tips consisting of one or two nodes and 6–15 mm in length taken from seedlings in vitro were cultured in the original research. The donor seedlings were maintained at 25 ± 1°C under 35 μE m^{-2} s^{-1} (duration of photoperiods and source of illumination were not described) and 60% relative humidity (RH).

Surface Sterilization. Explants taken from seedlings growing in vitro do not require surface sterilization. However, they must be rinsed to remove medium residues.

Culture Vessels. The vessels used for *Cymbidium aloifolium* are suitable (see procedure by Nayak et al., 1997*b* in the *Cymbidium* section, p. 419, Vol. I).

Culture Conditions. The conditions used for *Cymbidium aloifolium* are suitable (see procedure by Nayak et al., 1997*b* in the *Cymbidium* section).

Culture Media. The second and third media used for *Cymbidium aloifolium* (see Tables Cym-44 and Cym-45) are suitable (see procedure by Nayak et al., 1997*b* in the *Cymbidium* section). However the first medium (see Table Cym-43) must be different (see Table Den-33).

Procedure. The procedures used for *C. aloifolium* are suitable (see method by Nayak et al., 1997*b* in the *Cymbidium* section) except that the explants must be placed horizontally on the medium.

Developmental Sequence. Except for the different response to placement on the medium, development of *D. moschatum* explants is similar to that of *C. aloifolium* (Nayak et al., 1997*b* in the *Cymbidium* section).

General Comments. Some years ago Professor G. Ray Noggle, a pioneer in the study of vitamin effects on orchid seed germination, suggested that despite the multitude of in vitro media which have been formulated for their culture most orchids could probably grow on one medium. The findings with *C. aloifolium, D. moschatum, Dendrobium aphyllum*, and *Dendrobium nobile* (Nayak et al., 1997*b*) seem to support Professor Noggle's suggestion.

TABLE DEN-33. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of shoot explants of *Dendrobium moschatum* and *Dendrobium aphyllum* (Nayak et al., 1997*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	62.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	Thidiazuron	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Dissolve the thidiazuron (TDZ) in a small volume of 0.5N HCl and make up to volume (100 ml) with 70% or 95% ethanol. The amount of TDZ used in the original research was 4.5 µmol (991.4 µg) l^{-1}. A slightly larger amount, 1 mg (1000 µg or 4.53 µmol), is recommended here for convenience (1.0 mg is easier to weigh than 0.991 mg). The difference (0.09 mg or 9 µg or 0.04 µmol) is insignificant and can be ignored. Sticklers for accuracy and those with infinite patience and/or plenty of time on their hands may still use 0.991 mg l^{-1}.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (items 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

In Vitro Propagation of *Dendrobium aphyllum* through Diazuron-induced High Frequency Shoot Proliferation

The procedures used for *Dendrobium moschatum* are also suitable for *Dendrobium aphyllum* (Nayak et al., 1997*b*).

Rapid Micropropagation of *Dendrobium nobile* through the Culture of Thin Cross Sections

The method used for the culture of thin cross sections of *Cymbidium aloifolium* is also suitable for *Dendrobium nobile* explants of the same nature (see Rapid Micropropagation of *C. aloifolium* through the Culture of Thin Cross Sections by Nayak et al., 2002 in the *Cymbidium* section, p. 423, Vol. I) except for the medium used for the culture of explants (Fig. Den-3; see Table Cym-47). A different medium should be used for *D. nobile* (Table Den-34).

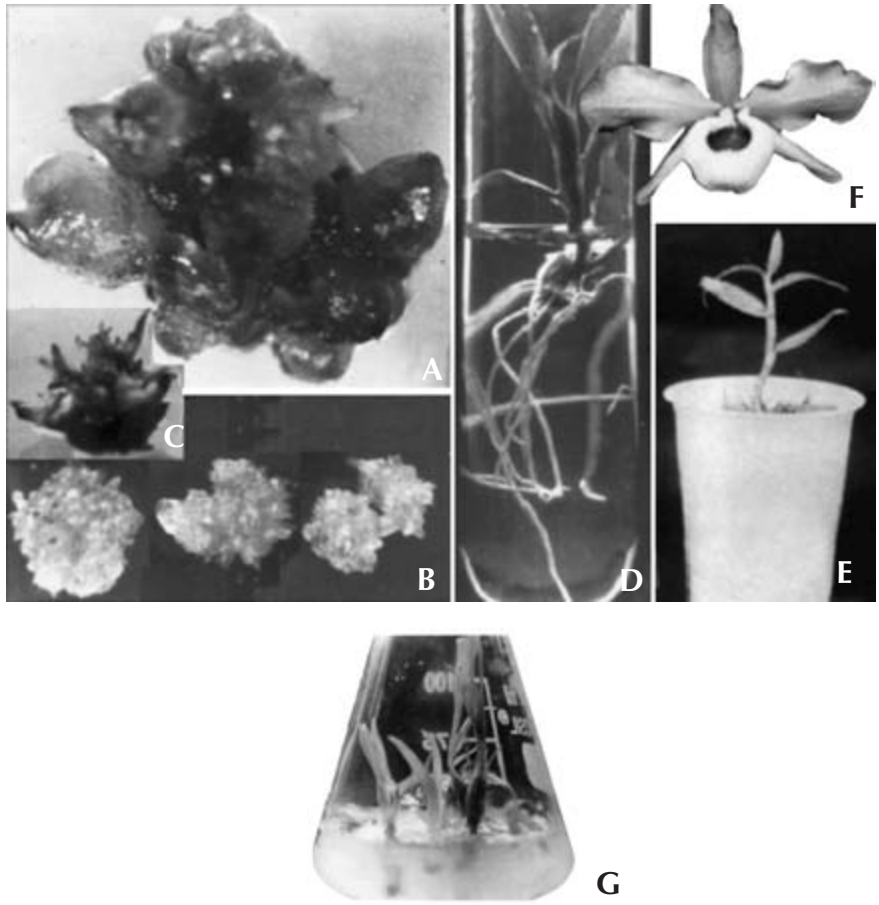

FIG. DEN-3. **Culture of thin sections of *Dendrobium nobile*. A. PLBs. B. Formation of multiple shoots. C. Initiation of shoots. D. Plantlet in test tube. E. Plant in pot. F. Flower. G. Plantlets in a flask. (Sources: A–E, Nayak et al., 2002; F, http://w1.213.telia.com.)**

TABLE DEN-34. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of thin cross section explants of *Dendrobium nobile* (Nayak et al., 2002)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10

10	Benzyladenine (BA)	2.5	250 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	[Solidifier]				
[16	Agar[g]	8.0 g	No stock	No stock	Weigh]

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 14), and bring volume to 1000 ml with distilled water (item 15). [Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved] pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. More explants proliferate in liquid than on solid medium (95% vs 89%) and produce a higher number of PLBs (33.5 vs 28.2 PLB $explant^{-1}$). That is why this medium should be liquid. However if a shaker is not available the explants can be cultured on a solid medium. To allow for such an eventuality the solidifier (i.e., agar, item 16) in the table and instructions regarding its incorporation in this footnote are between bold face brackets.

Micropropagation of *Dendrobium* Queen Sonia

One of the most popular and beautiful dendrobiums grown for many years as a cut flower is the hybrid *Dendrobium* Sonia. It should not be confused with *Dendrobium* Queen Sonia which is an incompatible hybrid, also popular as a cut flower, that was not registered with the international registration authority for orchid hybrids (Professor S. Ichihashi, Aichi University of Education, Aichi, Japan, personal communication). Therefore this hybrid is not listed in *Sander's List of Orchid Hybrids* as seems to be the case with a number of other hybrids used to produce cut flowers. A method for the clonal propagation of *Dendrobium* Queen Sonia was developed (Aswath, 2001), despite the fact that its parentage is unknown and an argument can be made that since it is not registered this hybrid does not exist officially.

Plant Material. Apices, 5 mm (no indication is given in the original report whether this is length, width, or diameter), were excised from shoot tips, 1 cm (presumably) in length (the paper gives no information).

Surface Sterilization. The shoot tips must be washed thoroughly with a surfactant (Teepol, available from www.sigmaaldrich.com, www.fishersci.com, or another source, was used in the original research, but any mild liquid household or baby detergent is suitable) and running water (the paper suggests an excessive 2-h wash; 10–15 min is sufficient). The washing should be followed by a 90-s dip in 0.1% mercuric chloride [100 mg mercuric chloride ($HgCl_2$, available from the sources listed above; this substance is very toxic and should be handled with care) in 100 ml distilled water] and several subsequent rinses with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, 100 ml capacity, containing 50 ml are recommended by the author. However a smaller volume (25–30 ml) and/or other containers can also be used.

Culture Conditions. Cultures should be maintained at $25 \pm 2°C$ and 8-h photoperiods of 2000 lx or standard culture room conditions. Liquid cultures should be placed on a shaker (a 100-rpm gyrorotatory shaker was used in the original research).

Culture Media. A modified liquid Vacin and Went (VW) medium (Vacin and Went, 1949) is used in this procedure. PLBs are induced by placing the explants in a liquid medium which contains coconut water (CW; Table Den-35). The PLBs should be moved to a medium which also contains CW, but no sugar and growth hormones (Table Den-36) for proliferation. Unfortunately it is not clear whether this medium is liquid or solid. The solution recommended here (Table Den-36) is liquid because proliferation in liquids is usually better than on solid media. If this medium proves unsuitable another medium may work (Table Den-11). To produce plantlets the PLBs should be cultured on a third medium (Table Den-37).

Procedure. After being cut from plants the shoot tips (presumably 1 cm long) must be washed. The apices should be excised following removal of the outer leaves,

TABLE DEN-35. **Vacin and Went (VW) medium (Vacin and Went, 1949) as modified for the culture of shoot-tip explants of *Dendrobium* Queen Sonia (Aswath, 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Coconut water[e]	200.0	No stock	No stock	Measure
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 m l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored. The modification used for *Dendrobium* Queen Sonia uses ferric tartrate. Chelated iron is preferable (items 6a, 6b).

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500 ml of distilled water (item 10) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 10), adjust pH to 5.3, add sugar (item 9), and raise volume to 1000 ml with distilled water (item 10). There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

sterilized, rinsed, and placed in culture. They form PLBs in the first medium (Table Den-35). These PLBs proliferate when cultured in the second solution (Table Den-36). When moved to the third (Table Den-37) substrate the PLBs produce plantlets. There is also an unusual subroutine in this method. PLBs from the second medium are moved to a callus-inducing solution. The callus is then cultured on yet another medium to induce PLBs which are used to produce plantlets. This subroutine is not only unnecessary (because plantlets can be produced on the third medium directly from PLBs generated in the second solution), but also unwise (since the extra steps of callus induction and the subsequent PLBs production can induce undesirable mutations).

TABLE DEN-36. **Vacin and Went (VW) medium (Vacin and Went, 1949) as modified for the proliferation of protocorm-like bodies (PLB) of *Dendrobium* Queen Sonia (Aswath, 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Coconut water[e]	200.0	No stock	No stock	Measure
	Solvent				
9	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500 ml of distilled water (item 9) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored. The modification used for *Dendrobium* Queen Sonia uses ferric tartarate which is not as good a source of iron as the chelated form (items 6a, 6b).

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500 ml of distilled water (item 9) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 9), adjust pH to 5.3 and adjust volume to 1000 ml with distilled water (item 9). There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

Developmental Sequence. PLBs form in the first medium, proliferate in the second, and produce plantlets on the third (Fig. Den-4).

General Comments. Except for the subroutines which should be avoided (and therefore are not described here), this method is relatively simple and seems to be effective. It may also prove suitable for other *Dendrobium* hybrids. The only weakness is a paper which is not written as clearly and as well as it could have been.

TABLE DEN-37. **Vacin and Went (VW) medium (Vacin and Went, 1949) as modified for plantlet production from protocorm-like bodies (PLBs) of *Dendrobium* Queen Sonia (Aswath, 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10

7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	Indoleacetic acid (IAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Cytokinin				
9	Benzylaminopurine	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
10	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
11	Water, distilled[f]	To 1000 ml			
	Solidifier				
12	Agar[f]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 ml l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored. The modification used for *Dendrobium* Queen Sonia uses ferric tartrate which is not as good a source of iron as the chelated form (items 6a, 6b).

[e]If the auxin or cytokinin fails to dissolve in the stock solution add a few drops of 0.1N KOH or 0.1N HCl respectively.

[f]Add items 1 and 3–8 to the 500 ml of distilled water (item 11) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 11), adjust pH to 5.3, add sugar (item 10), and raise volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar (item 12) can also be added to the cold water which is then brought to a boil and stirred. When the agar (item 12) is completely dissolved pour the solution into a 2-l flask and autoclave. Gelrite, 3 g l^{-1}, can be used in place of agar. Add the auxin (item 8) and cytokinin (item 9) to the warm and still liquid solution, swirl to mix well and distribute into culture vessels. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

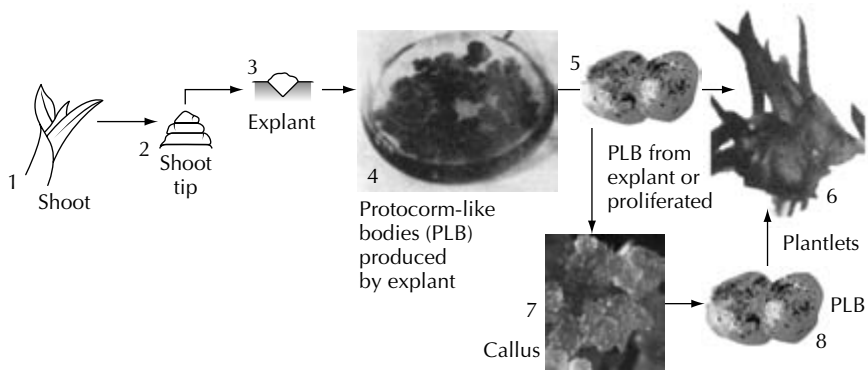

FIG. DEN-4. **Schematic representation of micropropagation of *Dendrobium* Queen Sonia. Steps 1–6 are advisable and should be used for micropropagation; steps 7 and 8 are not necessary and not advisable. (Sources: 1–4, 6, Oyamada and Takano, 1990 referring to another procedure; 5, 7, World Wide Web.)**

In Vitro Propagation of *Dendrobium* Sonia

An important cut flower orchid, *Dendrobium* Sonia (*Dendrobium* Caesar × *Dendrobium* Tomie Drake, registered in 1984) is not the same hybrid as *Dendrobium* Queen Sonia (the subject of the previous procedure) which is an unregistered cross. A method for in vitro propagation of *Dendrobium* Sonia was developed in India (Prasad et al., 2001).

Plant Material. Apices including meristems and leaf primordia taken from 5-cm-long shoot tips are cultured.

Surface Sterilization. After being freed of all leaves and debris, shoot tip segments, 5 cm long, taken from young pseudobulbs and small plants must be washed first with running water and then with Tween 20 surfactant (available from www.sigmaaldrich.com, www.fishersci.com, or other sources) or a mild household or baby detergent. Washed shoot tips should be sterilized by immersing them in 0.1% mercuric chloride (100 mg $HgCl_2$ 100 ml^{-1} distilled water; this is a very toxic substance which is available from the sources listed above) for 90 seconds. This must be followed by three rinses with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, test tubes and other containers are suitable. Smaller containers can be used for initial explants and larger ones when plantlets become larger. As a rule culture vessels should contain culture medium equivalent to approximately 25–30% of their volume.

Culture Conditions. Cultures should be maintained at 24 ± 2°C and 16-h photoperiods of 50 μE m^{-2} s^{-1} or under standard laboratory conditions.

Culture Media. There are no specific recommendations in the original paper. The media recommended here were adduced from the tables in it. Explants should be cultured initially in a modification (Table Den-38) of the MS medium (Murashige and Skoog, 1962) until they form multiple shoots. When these shoots reach a few centimeters in size they should be separated and cultured on the second medium (Table Den-39).

Procedure. Explants from surface-sterilized shoots should be cultured on the first medium until shoots are formed. These shoots are cultured on the second medium.

Developmental Sequence. The explants start to differentiate approximately 11 days after the start of culture. Leaf formation starts after about 25 days. An average of 11 shoots arise from each explant. After these shoots are moved to the second medium they produce leaves and roots and form plantlets.

General Comments. This seems to be a simple but effective procedure. It is unfortunate that the original paper does not provide clear recommendations.

Dendrobium Sonia

TABLE DEN-38. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of shoot-tip explants of *Dendrobium* Sonia (Prasad et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	62.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzylaminopurine (BAP)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.2–5.4, add sugar (item 15), and raise the volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE DEN-39. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the culture of *Dendrobium* Sonia shoots (Prasad et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10

	Cytokinin				
11	Benzylaminopurine (BAP)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.2–5.4, add sugar (item 15), and bring volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11) and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

In Vitro Multiplication of *Dendrobium* Under Carbon Dioxide Enrichment

Tissue culture media usually include sugar as an energy source either because explants lack the ability to fix enough carbon to sustain themselves or as a supplemental carbon source. Under the assumption that the inclusion of sugar in culture media "not only involve[s] an additional [financial] expenditure on the carbon source (usually sucrose), but also invite[s] bacterial and fungal contaminations" and in an effort to eliminate or simplify acclimatization an attempt was made to develop a photoautotrophic method for the micropropagation of *Dendrobium* (Mitra et al., 1998).

Plant Material. *Dendrobium* (no species or hybrid name given) shoots used in this experiment were taken from plantlets growing in vitro. In practical laboratories plantlets to be cultured using this method will have to be produced through another *Dendrobium* culture procedure or by germinating seeds.

Surface Sterilization. There is no need to surface-sterilize shoots growing in vitro.

Culture Vessels. Glass jars, 250 cm^3, with a plastic screw cap were used in the original research. To increase air movement holes were punched in the caps and filled with cotton. Other culture vessels can also be used (one example: plastic disposable, autoclavable, and inexpensive containers such as those available from www.caissonlabs.com).

Culture Conditions. In the original experiment the cultures were maintained for 30 days in a growth chamber at 25 ± 3°C, relative humidity (RH) of 60–70%, and 16-h photoperiods of 42–45 μmol m^{-2} s^{-1} (source not listed) in ambient (0.6 g CO_2 m^{-3}) or carbon-enriched (40 g CO_2 m^{-3}) air.

Culture Media. Vacin and Went (VW) medium (Vacin and Went, 1949) with or without sucrose can be used. Data from the original experiment are ambiguous (Table Den-40), but it seems that both under ambient and elevated carbon dioxide (CO_2) plantlets developed better in the absence of sugar. Therefore the medium suggested here (Table Den-41) is sugar-free.

Procedure. Small plantlets produced through any method should be moved to the sugar-free medium (Table Den-41) and grown under ambient or elevated CO_2 levels.

Developmental Sequence. The dry weight (DW) of plantlets grown on sucrose-containing medium under ambient CO_2 levels is 4.92% of the fresh weight (FW). Their hydration value (FW – DW/DW) is 19.31. In the absence of sugar the values are 4% and 23.75 respectively. The parallel values for plantlets grown under enhanced CO_2 levels are 4.23% and 22.67 and 4.2% and 22.75. This and the fact that the DW of plantlets on sugar-containing medium regardless of CO_2 content is the same (13 ± 1.58 vs 12 ± 1.58) suggest that they tend to take up more water in the presence of sucrose under elevated CO_2 concentration. Water uptake seems to be the same under both CO_2 levels in the absence of sugar.

TABLE DEN-40. **Effects of sucrose and CO_2 levels on the growth of *Dendrobium* plantlets in vitro**[a]

		Ambient CO_2 level (0.6 g m^{-3})		Enriched CO_2 level (40 g m^{-3})	
Parameter	Initial explants	2% sucrose	0 sucrose	2% sucrose	0 sucrose
Shoot length, cm	1.2 ± 0.01	1.4 ± 0.15	*1.5 ± 0.19*	1.4 ± 0.35	**1.7 ± 0.25**
Number of leaves	4 ± 0.8	**6 ± 0.7**	*5 ± 0.85*	5 ± 0.54	**6 ± 0.7**
Leaf length, cm	1.1 ± 0.1	1.1 ± 0.15	*1.1 ± 0.22*	**1.4 ± 0.15**	**1.1** ± *0.15*
Leaf width, cm	0.3 ± 0.01	**0.5 ± 0.02**	0.3 ± 0.02	0.3 ± 0.03	*0.4 ± 0.01*
Number of branches	1 ± 0.15	1 ± 0.15	1 ± 0.15	1 ± 0.15	1 ± 0.15
Number of roots			2 ± 0.7		2 ± 0.7
Root length, cm			**0.3 ± 0.02**		*0.2 ± 0.01*
Fresh weight, mg	71 ± 2.9	264 ± 5.17	99 ± 2.91	**284 ± 4.47**	*190 ± 0.70*
Dry weight, mg	4.9 ± 0.1	**13 ± 1.58**	4 ± 0.7	*12 ± 1.58*	8 ± 0.7
Column number	1	2	3	4	5

[a]Bold face indicated highest values in each line. Second highest value is in italics. If all values are the same none is presented in bold face or italics. The standard deviations [numerals which follow the "plus or minus" (±) sign] must be taken into consideration. For example the number of leaves (second row) values are 4 ± 0.8 (which means the number of leaves ranges from 3.2 to 4.8), **6 ± 0.7** (5.3–6.7), *5 ± 0.85* (4.15–5.85), 5 ± 0.54 (4.46–5.54), and **6 ± 0.7** (5.3–6.7). When the standard deviations are taken into consideration these numbers mean that the differences between (a) column 1 and column 3, (b) column 3 and column 1 and column 4, (c) column 2 and column 3, (d) column 2 and column 4, (e) column 2 and column 5, (f) column 3 and column 4, (g) column 3 and column 5, and (h) column 4 and column 5 are not statistically significant, but the differences between (i) column 1 and column 2, and (j) column 1 and column 5 are statistically significant. When data are not statistically significant they are the same. To put it differently, in terms of CO_2 and sucrose levels the best results are in columns 2 and 5. This means that CO_2 enrichment does not increase the number of leaves except relative to the initial explants.

TABLE DEN-41. **Vacin and Went (VW) medium (Vacin and Went, 1949) as modified for the culture of *Dendrobium* shoots (Mitra et al., 1998)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Solvent				
8	Water, distilled[e]	To 1000 ml			
	Solidifier				
9	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 8) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 8) which contain the calcium phosphate (item 2), raise the volume to 900 ml with distilled water (item 8), adjust pH to 5–5.4, adjust volume to 1000 ml with distilled water (item 8), bring the solution to a gentle boil and add the agar (item 9) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

General Comments. The authors suggest that "culture [on] sugar-free medium in combination with CO_2 enrichment holds promise." However, under commercial and practical conditions it is necessary to balance the extra cost of CO_2 enrichment against the added income it may generate. A decision on whether to enrich with CO_2 or not must be based on the bottom line. The evidence seems to suggest that the bottom line will not favor enrichment.

Maintenance and Differentiation of *Dendrobium* Tissues

Professor Choy sin Hew, Department of Botany, National University of Singapore (now retired) was interested in sugar metabolism and preferences by undifferentiated and differentiated orchid tissues. He developed methods to maintain and differentiate his tissues (Hew and Mah, 1989).

Plant Material. Undifferentiated and differentiated tissues of *Dendrobium* Multico White (*Dendrobium* Ng Eng Chow × *Dendrobium* Ong Geok Kim) maintained in vitro were used. They were obtained through another procedure.

Surface Sterilization. Explants taken from tissue in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks or other containers are suitable.

Culture Conditions. Cultures were maintained at $24 \pm 2°C$ under 16-h photoperiods of 56 $\mu mol\ m^{-2}\ s^{-1}$ photon flux density provided by Philips white fluorescent tubes. Standard culture room conditions are also suitable.

Culture Media. Undifferentiated tissues are maintained on one modification (Table Den-42) of the Vacin and Went (VW) medium (Vacin and Went, 1949). Differentiation takes place on another modification of VW (Table Den-43).

Professor Choy sin Hew, Professor Joseph Arditti and Dr. Tim Wing Yam, in a Singapore restaurant in 2004

TABLE DEN-42. **Vacin and Went (VW) medium (Vacin and Went, 1949) as used for the culture of *Dendrobium* tissues in vitro (Hew and Mah, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	10.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	8–10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 9) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 ml l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 9) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 9), adjust pH to 5–5.4, add sugar (item 8), and raise volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of other nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

Procedure. Tissues obtained through another method can be maintained on the first medium (Table Den-42). They should be moved to the second solution (Table Den-43) for differentiation.

Developmental Sequence. While on the first medium tissues increase in size and volume. Differentiation takes place on the second substrate.

General Comments. This procedure can be used to maintain and differentiate tissues obtained through other methods. Growth and increase in dry weight were best on VW medium containing 2% fructose (Table Den-43). It is important to keep in mind that glucose and fructose are monosaccharides whereas sucrose is a disaccharide.

TABLE DEN-43. **Vacin and Went (VW) medium (Vacin and Went, 1949) as modified for the differentiation *Derndrobium* tissues (Hew and Mah, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

10	Agar[e]	8–10 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium, 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 9) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 ml l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 9) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 9), adjust pH to 5–5.4, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of other nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

Clonal Multiplication of *Dendrobium* Formidible through Tissue Culture

A method for the culture of *Dendrobium* Formidible (*Dendrobium formosum* × *Dendrobium infundibulum*) developed at Meijo University, Nagoya, Japan (Oyamada and Takano, 1990) seems interesting but was difficult to adapt for presentation here because macroelement content in the media it uses is given in terms of anion and cation percentages only (Table Den-44). According to Professor Syoichi Ichihashi of the Aichi University of Education in Japan who helped solve this problem, the possible combinations of anions and cations "are numerous" and one cannot tell which combination was used. Therefore the media presented here are the ones suggested by Professor Ichihashi who showed remarkable patience and goodwill by answering questions driven by my impatience with the eccentric presentation of content of media.

TABLE DEN-44. **Media formulations as presented by Oyamada and Takano (1990) in their table 1**

(A) Ionic composition of inorganic major elements

Anion		Cation	
NO_3^-	50%	NH_4^+	30%
SO_4^{--}	30%	Ca^{++}	15%
$H_2PO_4^-$	15%	K^+	40%
		Mg^{++}	10%
Cl^-	5%	Na^+	5%
Total	100%		100%

Total ionic conc. ($\Sigma A^{n-} + \Sigma C^{n+}$)	60 me/	Exp. I-A and B
	30, 60, 90 me/	Exp. II-A and B
	40, 80 me/	Exp. II-C

(B) Inorganic minor elements

Fe-EDTA	25.0 mg/l
H_3BO_3	3.0 mg/l
$MnSO_4 \cdot H_2O$	2.0 mg/l
$ZnSO_4 \cdot 7H_2O$	1.0 mg/l
$Na\text{-}MoO_4$	0.1 mg/l

(C) Organic substances

Thiamine·HCl	1.0 mg/l
Nicotinic acid	0.5 mg/l
Pyridoxine·HCl	1.0 mg/l
myo-inositol	100.0 mg/l
Adenine	40.0 mg/l
Peptone	1.0 mg/l
Sucrose	30.0 g/l
Agar	0 and 8.0 g/l

Plant Material. Several different explants (Fig. Den-5, ST-1, ST-2, ST-3, LB-1, LB2) can be cultured, but only axillary buds from the basal portions of stems (Fig. Den-5, LB-1) produced PLBs. The buds should be excised from 15-cm-long shoots.

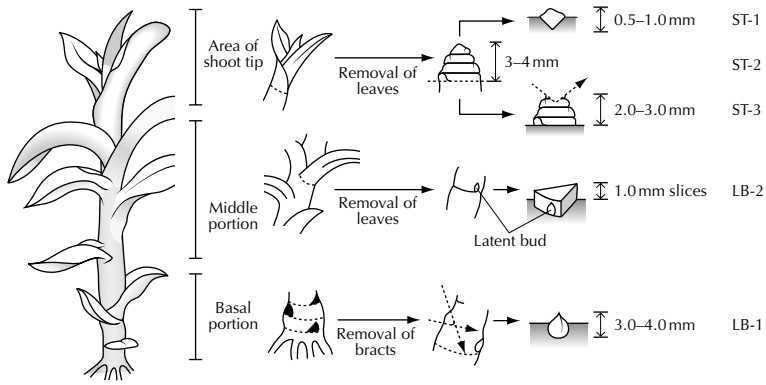

FIG. DEN-5. **Excision of explants from *Dendrobium* Formidible (Oyamada and Takano, 1990).**

Surface Sterilization. PLBs taken from in vitro cultures do not require surface sterilization. The surface sterilization procedure for shoots used in the original research seems not to have been very effective because many of the cultures became contaminated. The procedure suggested here is revised. Shoots collected in the field must be washed thoroughly with running water and a mild household detergent. Their leaves should be removed after that and the shoots must be washed a second time. After that they should be: (1) dipped in 70% ethanol for 10 s; (2) rinsed with sterile distilled water three times; (3) placed in alcohol for another 10 s; (4) washed with sterile distilled water three times; (5) soaked in 0.5% sodium hypochlorite (10 ml of a household bleach which contains about 5% sodium hypochlorite) for 10 min; (6) washed with sterile distilled water three times; (7) put in the hypochlorite solution for an additional 5 min; and (8) rinsed three times with sterile distilled water as above before the buds are excised.

Culture Vessels. Erlenmeyer flasks or other containers are suitable.

Culture Conditions. The culture conditions used during the original experiments were more elaborate than necessary in that the temperature was 25 and 20°C during the 16-h photoperiods and the 8 h of darkness, respectively. The light intensity during the culture of excised buds was 2000 lx, but it was 1000 lx when PLBs were proliferated. Such elaborate conditions are probably not needed. Standard culture room conditions should be entirely satisfactory.

Culture Media. Axillary buds should be cultured in a medium which is specially formulated for them (Table Den-45), but two modification (see Tables Den-17 and Den-18) of the Vacin and Went (VW) medium (Vacin and Went, 1949) may also be suitable. PLBs produced on this medium are proliferated on a second solution (Table Den-46), but other substrates (see Tables Den-11 and Den-12) can also be used. The medium used to differentiate plantlets is not entirely clear but it seems reasonable to assume that several media would be suitable (see Tables Den-2 to Den-10, and Den-13). Shoot can be induced on two media (see Tables Den-13 and Den-14) and roots on another (see Table Den-15).

Procedure. Axillary buds should be excised from shoots (Fig. Den-5, LB-1), cultured, and allowed to form PLBs on the first medium (Table Den-45) or another suitable substrate (see Tables Den-17 and Den-18). These PLBs should be proliferated on the second medium (Table Den-46) or another solution (see Tables Den-11 and Den-12) and placed on one of the other media for plantlet production (see Tables Den-2 to Den-10, and Den-13). Alternately, shoot induction on a suitable medium (see Tables Den-13 and Den-14) can be followed by root initiation on another solution (see Table Den-15).

Developmental Sequence. PLBs form on the explants on the first medium, proliferate on the second, and develop plantlets on the third.

General Comments. This may be an effective procedure which is difficult to understand and interpret and therefore hard to use. It involves overly complex steps, an unclear presentation, and an esoteric approach to description of culture media.

TABLE DEN-45. **Oyamada and Takano (OT) medium (Oyamada and Takano, 1990) for the culture of basal buds of *Dendrobium* Formidible (Oyamada and Takano, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, NH_4SO_4[b]	1189.0	118.9 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1063.0	106.3 g l^{-1}	10	
3	Magnesium nitrate, $Mg(NO_3)_2 \cdot 6H_2O$[b]	769.0	76.9 g l^{-1}	10	
4	Monopotassium phosphate, KH_2PO_4	1216.0	121.6 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	1517.0	151.7 g l^{-1}	10	
6	Sodium chloride	175.0	17.5 g l^{-1}	10	
7	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
8	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.0	300.0 mg l^{-1}	10	One solution
(b)	Manganese sulfate, $MnSO_4 \cdot H_2O$	2.0	200.0 mg l^{-1}		
(c)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.1	10.0 mg l^{-1}		
(d)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	1.0	100.0 mg l^{-1}		
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Vitamins				
10	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Pyridoxine (vitamin B_6)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Thiamine (vitamin B_1)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
	Cytokinin-related substance				
13	Adenine[f]	40.0	No stock	No stock	Weigh
	Complex additive				
13	Peptone	1.0 g	No stock	No stock	Weigh
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original formulation of thie medium calls for 25 mg l^{-1}. Since the original paper gives no details the form of chelated iron suggested here is the same as the one added to the MS medium.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the adenine does not dissolve, add a few drops of 0.1N sulfuric acid.

[g]Add items 1–9 and 13 to 900 ml of distilled water (item 15), adjust pH to 5.2–5.4, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar (item 16) can also be added to the cold water (item 15) which is brought to a boil and stirred. When the agar (item 16) is completely dissolved pour the solution into a 2-l flask and autoclave. Add the vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE DEN-46. **Oyamada and Takano (OT) medium (Oyamada and Takano, 1990) for the proliferation of PLBs of *Dendrobium* Formidible (Oyamada and Takano, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 7a) and the iron salt (item 7b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original formulation of thie medium calls for 25 mg l^{-1}. Since the original paper gives no details the form of chelated iron suggested here is the same as the one added to the MS medium.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the adenine does not dissolve, add a few drops of 0.1N sulfuric acid.

[g]Add items 1–9, 13 and 14 to 900 ml of distilled water (item 16), adjust pH to 5.2–5.4, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar (item 17) can also be added to the cold water (item 16) which is brought to a boil and stirred. When the agar (item 17) is completely dissolved pour the solution into a 2-l flask and autoclave. Add the vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

FIG. DEN-6. ***Dendrobium*** **flowering in flask (Sim, no date).**

In Vitro Flowering of *Dendrobium*

Orchid history is replete with strange and peculiar stories (for recent examples see Hansen 2000*a*, 2000*b*, 2000*c*, 2000*d*, 2000*e*). The same is true for the in vitro flowering of *Dendrobium* Madam Thong-In. The first report appeared in a daily newspaper (Anonymous, 1995). It told of a "potion which can shrink plants a metre tall to fit a 7.5-cm-high vial" and included a photograph of an orchid in a tissue culture vessel (similar to Fig. Den-6). The "potion" was described as "unnamed" and "translucent." Its nature was not disclosed. According to the newspaper the potion was "the brainchild of Dr. Loh Chiang Shiong in the [National University of Singapore] Department of Botany, and Professor Goh Chong Jin, [then] head of the department [subsequently replaced and now retired]." The story did not mention that the work was done by two students, Sim Guek Eng for a Ph.D. Dissertation (Sim, no date) and A. P. P. Ng for an honors thesis (Ng, 1997). Both the thesis and dissertation have yet to be published.

A longer version of the same story was presented by Professor Chong Jin Goh a year later (Goh, 1996). It did include two photographs of *Dendrobium* Sonia and one of *Dendrobium* Madame Thong-In flowering in vitro, but was scientifically content-free, failed to cite the students (Sim, no date; Ng, 1997), and ignored all previous work by others on the subject (X. Wang, 1984, 1988*a*, 1988*b*, 1990, no date *a*, no date *b*; X. Wang et al., 1981, 1988*a*, 1988*b*; G. Y. Wang et al., 1992, 1993; for a review see Chia et al., 1999). It was devoted mostly to self-glorification by its author. The dissertation and the thesis cannot be accessed because Professor Goh prohibited access to them. This is highly unusual. There are no previous such prohibitions even by the author of the piece in the *Malayan Orchid Review* (Goh, 1996), who coauthored numerous papers on diverse subjects with members of his department in their area of specialization (to the extent that he had a specialty: it was orchids).

A few details can be gleaned from a molecular biology paper (Yu and Goh, 2000) and the dissertation title (Sim, no date). The authors suggest the use at some point of a liquid Knudson C medium (Knudson, 1946), 2% sucrose, 15% (v/v) coconut

water, 5 μmol BA l^{-1}, 16-h photoperiods of 35 μmol m^{-2} s^{-1} provided by daylight fluorescent lamps, 24°C, and a 120-rpm rotary shaker. Other media and culture conditions were also used, but they were not described. Therefore, a procedure based on Professor Goh's unnamed, translucent, and well-publicized potion (Anonymous, 1995) cannot be presented despite the fact that it may be of interest to both scientists and operators of practical laboratories. Still a method may be patched together by referring to research which may have been the (albeit unacknowledged) inspiration for the magic potion and probably guided Professor Goh's work.

In 1990 a group consisting of Professor Nam Hai Chua of the Rockefeller University in New York and Guang Yuan Wang, Zhi Hong Xu, Tet Fat Chia (who subsequently became the first person to introduce a foreign gene into orchids and is now a professor at the National Technological University in Singapore), and Pek Foong Wong of the Institute of Molecular and Cell Biology, National University of Singapore induced in vitro flowering in seedlings of *Dendrobium candidum*, an orchid used in traditional Chinese medicine. They published their research properly and described all media and methods in detail (Wang et al., 1990, 1993).

Plant Material. Protocorms obtained by germinating seeds from mature and undehisced capsules of *Dendrobium candidum* were used in the original research. PLBs and protocorms of other *Dendrobium* species and hybrids could perhaps also be induced to flower in vitro. Such protocorms and PLBs may be produced through seed germination and tissue culture procedures respectively.

Surface Sterilization. Protocorms and PLBs taken from cultures in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, 500-ml capacity, containing 80 ml of medium, were used in the original research. However, plastic containers (Fig. Den-6), bottles, and jars filled with medium to 15–20% of their capacity are also suitable.

Culture Conditions. Regardless of the conditions under which the PLBs and/or protocorms may have been maintained, those which will be used to produce plantlets for in vitro flowering should be proliferated under 12-h photoperiods of 40–45 μmol m^{-2} s^{-1} and 25–27°C. Cultures for PLB proliferation and in vitro flowering should be kept under 16-h photoperiods and 25–27°C and 21–23°C during the light and dark periods respectively. Since flower induction may be sensitive to photoperiods and temperature an effort should be made to use the same conditions at least during initial attempts to induce flowering in vitro. Light intensity of 22–35 μmol m^{-2} s^{-1} provided by daylight fluorescent lamps should be appropriate.

Culture Media. Three media must be used to obtain maximal flower induction. PLBs or protocorms should be proliferated on MS medium (Murashige and Skoog, 1962) supplemented with 0.3 mg NAA (available from www.fishersci.com., www.sigmaaldrich.com, or www.caissonlabs.com) and containing only 15 g sucrose l^{-1} (Table Den-47). After that they must be cultured on MS containing 2 mg ABA l^{-1} (available from the sources listed above; Table Den-48). Flowering takes place on MS with 2 mg BA l^{-1} (available from the sources above) (Table Den-49).

Procedure. PLBs and/or protocorms should be proliferated on the first medium (Table Den-47). Clumps of PLBs or protocorms must be cultured on the ABA containing medium (Table Den-48) for 2 months before transferring them to the BA substrate (Table Den-49) where they can be expected to flower within 5 months.

Developmental Sequence. Protocorms proliferate on the first medium, continue growth and development on the second, and flower on the third.

General Comments. There can be no question that the first flowering of *Dendrobium* in vitro was obtained by (in alphabetical order) T. F. Chia, N. H. Chua, G. Y. Wang, P. F. Wong, and Z. H. Xu (IMC-NUS group), and not by C. J. Goh and his associates. The IMC-NUS group was also the first to publish a detailed method for in vitro flower induction in *Dendrobium*. Reports by the IMC-NUS group are very detailed (for one example see Wang et al., 1993) and could serve as a basis for other attempts to induce flowering in vitro. There is no certainty, of course, that the IMC-NUS method can and will work with other *Dendrobium* species and hybrids. However the use of 5 μmol (1.13 mg l^{-1}) BA in the unnamed potion (vs 8.88 μmol or 2 mg l^{-1} in the IMC-NUS medium) suggests a similarity in media. This similarity is promising because the unnamed potion induced flowering in two different hybrids. The similarity also suggests that the unnamed potion and associated procedures may be based on the IMC-NUS method. And, if this is the case and if the unnamed potion and procedures connected with it induced flowering in *Dendrobium* Sonia and *Dendrobium* Madame Thong-In, there is hope that the IMC-NUS method will cause other dendrobiums and perhaps even additional orchids to bloom. And one can hope that Professor Goh will lift his bizarre edict someday.

Professor Tet Fat Chia, seen here in 1991, was the first person to introduce a foreign gene into orchids, and was also one of the first to obtain the first flowering of *Dendrobium* in vitro.

TABLE DEN-47. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the proliferation of *Dendrobium candidum* protocorms (G.Y. Wang et al., 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10

(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	0.3	30 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	15.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.4, add sugar (item 14), and raise volume to 1000 ml with distilled water. Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE DEN-48. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the preculture of *Dendrobium candidum* protocorms for in vitro flowering (G.Y. Wang et al., 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Plant hormone				
10	Abscisic acid (ABA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the abscisic acid (ABA) does not dissolve, add a few drops of 0.1N KOH.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.4, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

TABLE DEN-49. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for flower induction in vitro in *Dendrobium candidum* (G.Y. Wang et al., 1993)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
14	Sucrose	50.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the benzyladenine (BA) does not dissolve, add a few drops of 0.1N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.4, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. Plants should be kept on a high sugar medium for a short time until they flower.

Isolation and Culture of *Dendrobium* Protoplasts

If it were possible to isolate and culture individual cells or protoplasts thousands of plants could be produced from even a small slice of tissue. Protoplasts can also be used for genetic transformation through the insertion of genes. A method for protoplast isolation and production of microcallus masses was developed at the University of Hawaii (Kuehnle and Nan, 1990).

Plant Material. Plantlets of *Dendrobium* Jaquelyn Thomas cultivars UH232, UH503, and UH 800 growing in vitro under 16-h photoperiods of 43 μmol m^{-2} s^{-1} photosynthetically active radiation (PAR) and probably 22–25°C should be moved to a lower light intensity of 13 μmol PAR m^{-2} s^{-1} for 1 week. Leaves, 1.5–4.5 cm in length, are taken from the plants and cut into 1-mm-wide strips.

Surface Sterilization. Leaves are taken from plants growing in vitro and do not require surface sterilization. However all solutions, tools, and media must be sterilized by filtration, autoclaving, or flaming.

Culture Vessels and Other Glassware. This procedure requires vacuum and filtering equipment, funnels, Erlenmeyer flasks (various capacities), centrifuge tubes, microscopes, Fuchs–Rosenthal modified hemocytometer, and other apparatus usually found in well equipped laboratories.

Culture Conditions. Optimal conditions for the incubation of leaves in enzyme mixture (half or quarter strength is preferable) are 6 h at 30°C. Protoplasts should be cultured in the dark at 21°C embedded in agarose sections floating in liquid medium.

Enzyme (Digesting) Solution. An appropriate enzyme (digestion) solution is 1.5% Cellulase R-10 (available from www.serva.de), 0.5% Macerozyme R-10 (www.serva.de), and 0.5% Driselase (www.biochemicalproducts.com) in 0.5-*M* mannitol (www.sigmaaldrich.com) solution adjusted to pH 5.5.

Purification and Filtration Solutions. After filtering the digestion mixture the protoplasts should be suspended in SCM solution (see next sentence for composition) and centrifuged at 100 × *g*. The SCM solution consists of 0.5 mol (9.11 mg l^{-1}) sorbitol (www.sigmaaldrich.com, S 3889), 10 mmol (147 mg 100 ml^{-1}) calcium chloride ($CaCl_2 \cdot 2H_2O$, www.sigmaaldrich.com, item C 5080), and 3 mmol morpholinoethane sulfonic acid (58.56 mg 100 ml^{-1}; M 5287, www.sigmaaldrich.com) with pH adjusted to 6.0. Protoplasts are separated from raphides on a 0.6-*M* sucrose density gradient.

Culture Medium. Purified protoplasts should be embedded in sections of MS medium (Murashige and Skoog, 1962) containing 1 mg 2,4-D l^{-1} and 0.5 mg BA l^{-1} solidified with 0.6% SeaPlaque agarose (item 5101 or 50100, www.cambrex.com) and floated on the same culture medium in liquid form (Table Den-50).

TABLE DEN-50. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Dendrobium* protoplasts (Kuehnle and Nan, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10

(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	2,4-Dichlorophenoxyacetic acid (2,4-D)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzyladenine (BA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agarose[g]	6.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.4, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agarose (item 17) slowly while stirring. The agarose can also be added to the cold water which is brought to a boil and stirred. When the agarose is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Procedure. Leaves, 1.5–4.5 cm, were taken from seedlings grown in vitro containing 1 mg 2,4-D l^{-1} and 0.5 mg BA l^{-1} solidified with 0.6% SeaPlaque agarose (item 5101 or 50100, www.cambrex.com) and floated on the same culture medium in liquid form (Table Den-50), cut into 1-mm-wide strips and incubated in the enzyme (digestion) mixture. Following the incubation the protoplasts were collected through filtration, separated from raphides by centrifugation, and plated on the agarose.

Developmental Sequence. Some protoplasts formed new cell walls within 24 h of isolation. First divisions could be seen in 2–3 days. Second divisions took place within 5 days. Microcalli formed after 2–4 weeks.

General Comments. Protoplast isolation and production of microcalli are exciting and significant advances in orchid science. The procedures are complex and require equipment which may not be available in the average micropropagation laboratory. Those who plan to attempt it should read the original literature.

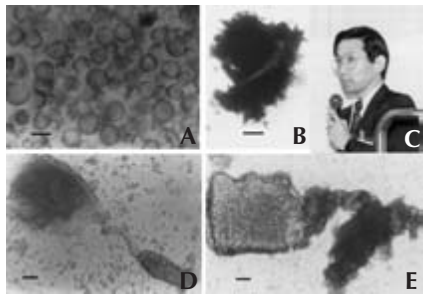
Dendrobium Protoplast Culture

At one time cell and/or protoplast fusion was viewed as a promising tool for the creation of somatic hybrids. Unfortunately the technique did not live up to its promise, not only in respect to orchids, but for other plants also. A major reason why cell fusion was largely abandoned is the technique of inserting genes into plants with a particle gun (as was done by Professor Tet Fatt Chia at Nanyang Technological University in Singapore with *Dendrobium* White Fairy No. 5 and a gene for bioluminescence from fire flies), which is simpler and more effective. While cell and protoplast fusion still held promise, a method was developed for the isolation of cells and protoplasts of *Dendrobium* Malones 'Hope' and *Dendrobium* Yukidaruma 'Queen' (Yasugi, 1990). Only the isolation and culture steps will be presented here since they may have some potential for micropropagation. Unfortunately Professor Yasugi (Fig. Den-7C) changed his interests, did not pursue this subject further, and stopped working with orchids.

Plant Material. A young fully expanded leaf should be used. After surface sterilization each leaf must be cut into 2 cm × 2 cm sections.

Surface Sterilization. The leaf should be washed several times with running water and a mild detergent, soaked for 15–20 min in 0.5% sodium hypochlorite (10 ml of a household bleach which contains 5–5.25% sodium hypochlorite diluted to 100 ml with distilled water), and rinsed repeatedly with sterile distilled water.

Culture Vessels and Other Glassware. This procedure requires vacuum and filtering equipment, funnels, Erlenmeyer flasks (various capacities), centrifuge tubes, a Fuchs–Rosenthal modified hemocytometer, and other apparatus usually found in well equipped laboratories (most of the necessary equipment can be obtained from standard biological supply houses, two of them being www.fishersci.com and www.vwr.com).



Most effective enzyme mixture:
Cellulase Onozuka R-10, 1%
Macerozyme R-10, 0.2%
Pectolyase Y-23, 0.01%
MES, pH 5.8, 5 mmoles
$CaCl_2 \cdot 2H_2O$, 10 mmoles
Mannitol, 6 moles
Potassium dextransulfate, 0.5%

Most effective hormone levels:
NAA, 2 mg
BA, 0.5 mg

Most effective conditions:
5°C
Dark

FIG. DEN-7. ***Dendrobium*** **protoplasts (A), colonies (B), and embryoids (D, E). C. Professor Saburo Yasugi. (Yasugi, 1990.)**

Culture Conditions. Leaf sections, approximately 1 g, should be incubated in 10 ml of enzyme mixture in a 50-ml Erlenmeyer flask with shaking at 40 rpm for 18 h. An appropriate temperature is not given in the original paper, but such a long incubation period suggests 21–23°C. Perhaps 6 h at 30°C may also prove to be suitable. Leaf sections should be kept under vacuum for 2 min before being placed in the enzyme mixture. Protoplasts in the first medium (liquid over agar) should be maintained at 20–22°C under 500 lx. Appropriate conditions for colonies on the second medium are the same temperature and 3000 lx.

Enzyme (Digesting) Solution. An appropriate enzyme (digestion) solution is 1% Cellulase Onozuka R-10 (available from www.serva.de), 0.2% Macerozyme R-10 (www.serva.de), and 0.01% Pectolyase Y-23 (Seishin, Japan, fax 81-3-3669-1684) in 5-m*M* MES buffered at pH 5.8, 10-m*M* $CaCl_2 \cdot 2H_2O$, 0.6-*M* mannitol, and 0.5% potassium dextran sulfate (all available from www.sigmaaldrich.com, www.fishersci.com, and www.vwr.com).

Purification and Filtration Solutions. Following incubation the digestion mixture should be filtered through a 60-μm mesh stainless steel sieve and centrifuged at $150 \times g$ for 5 min. The supernatant is discarded after that and the protoplasts (Fig. Den-7A) should be rinsed with 0.6-*M* solution of mannitol three times and suspended in the first culture medium.

Culture Media. Purified protoplasts should be suspended in a medium containing one-tenth the inorganic salt concentration of the MS medium (Murashige and Skoog, 1962), the organic components of the Kao and Michayluk (KM) solution (Kao and Michayluk, 1975), 2 mg NAA l^{-1}, and 0.5 mg BA l^{-1} (Table Den-51). Protoplast colonies which form on the first medium may develop embryoids on a second solution (Table Den-52).

TABLE DEN-51. **Inorganic salts of the Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) and the organic constituents of the Kao and Michayluk (KM) medium (Kao and Michayluk, 1975) for the culture of *Dendrobium* protoplasts (Yasugi, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(l)	Vitamin B_{12}	0.02	2 mg		
	Amino acid				
12	Glycine	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugars				
13	Sucrose	30.0 g	No stock	No stock	Weigh
14	Xylose	0.25	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses. To dissolve folic acid the 95% ethanol or water should be made with 1.3N sodium bicarbonate. The 95% ethanol for riboflavine should be made with 1N sodium phosphate. Read instructions in body of table very carefully.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–8 to 850 ml of distilled water (item 15), adjust pH to 5.8 as required, add the sugars (items 13 and 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 12), hormones (items 9, 10), and vitamins (item 11) to the hot solution under sterile conditions with sterilized pipettes, mix well, and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. Two versions, one liquid and the other solid, of this medium must be prepared (see procedure). The medium as presented here may not be exactly the one employed in the original research (Yasugi, 1990) because the paper states that the "organic nutrients of KM" were used, but this solution is complex and has many permutations (Kao and Michayluk, 1975). Therefore it is hard to determine exactly what was used.

TABLE DEN-52. **Diluted inorganic salts of the Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) and the organic constituents of the Kao and Michayluk (KM) medium (Kao and Michayluk, 1975) for the culture of *Dendrobium* protoplasts (Yasugi, 1990)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	165.0	16.5 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	44.0	4.4 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	37.0	3.7 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	190.0	19.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	17.0	1.7 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	3.7	0.37 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	2.8	0.28 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}

(c)	Biotin	0.01	1 mg		
(d)	D-Calcium pantothenate	1.0	100 mg		
(e)	Choline chloride	1.0	100 mg		
(f)	Folic acid	0.4	40 mg		
(g)	Niacin (nicotinic acid)	0.1	10 mg		
(h)	Pyridoxine (vitamin B_6)	0.1	10 mg		
(i)	Riboflavine (vitamin B_2)	0.2	20 mg		
(j)	Thiamine (vitamin B_1)	1.0	100 mg		
(k)	Vitamin A	0.01	1 mg		
(l)	Vitamin B_{12}	0.02	2 mg		
	Amino acid				
12	Glycine	0.1	20 mg 100 ml^{-1} 95% ethanol[e]	0.5	
	Sugars				
13	Sucrose	30.0 g	No stock	No stock	Weigh
14	Xylose	0.25	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

Dissolve items 11a–11e, 11g, 11h, 11j–11l in 70 ml of 95% ethanol; 11f in 15 ml 1.3N sodium bicarbonate in 95% ethanol or water; and 11i in 15 ml 1N sodium phosphate in 95% ethanol or water. Mix the three solutions and store in a tightly capped bottle in a freezer. Add 1 ml of this combined solution to every liter of culture medium. Shake the combined solution well before dispensing

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses. To dissolve folic acid the 70% ethanol should be made by diluting 70 ml of 95% ethanol to 100 with 1.3N sodium bicarbonate. The 70% ethanol for riboflavine should be made with 1N sodium phosphate. Read instructions in body of table very carefully.

[f]If the auxins or cytokinin do not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–8 to 850 ml of distilled water (item 15), adjust pH to 5.8 as required, add the sugars (items 13 and 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 12), hormones (items 9–10), and vitamins (item 11) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. Two versions, one liquid and the other solid, of this medium must be prepared (see procedure). The medium as presented here is somewhat of an educated guess because the original paper (Yasugi, 1990) only stated that "organic nutrients of KM medium were used." The KM medium (Kao and Michayluk, 1975) is very complex, contains many ingredients, and can be prepared in several permutations. It was simply hard to determine which "organic nutrients of [the] KM medium were used."

Procedure. After sterilization it is necessary to cut the leaves into 2 cm × 2 cm sections which should be subjected to vacuum for 2 min and then submerged in the enzyme mixture for 18 h. Following the incubation the digestion mixture should be filtered before the protoplasts are collected through centrifugation, washed with 0.6-*M* mannitol, and suspended in a small volume of 20% sucrose solution. The density of protoplasts must be determined by counting several samples on a hemocytometer and adjusting to $5.5–8.2 \times 10^4$ ml^{-1} by suspending them in a liquid version of the first medium (Table Den-51). This suspension should be poured over a solid version of the same medium (Table Den-51). When colonies form it is necessary to transfer them to the second medium (Table Den-52) for embryoid development.

Developmental Sequence. The first division can be seen after 5–7 days on the first medium. Colonies (Fig. Den-7B) formed after 2–4 weeks. Embryoids (Fig. Den-7D) develop on the second medium after 3–4 months. The paper reports that "no shoot or plant has been regenerated from orchid protoplasts," but contains no information on the fate of the embryoids.

General Comments. This procedure was formulated as a means of obtaining protoplasts for fusion (Fig. Den-7E). However when an embryoid formed "it was uncertain that [it] was induced from a hybrid cell or not." Since cell fusion is no longer much of a factor in genetic engineering this uncertainty does not really matter. Both investigators and laboratory operators would be well advised to read the original papers (Kao and Michayluk, 1975; Yasugi, 1990) before using this procedure.

Virus Elimination during Micropropagation of *Dendrobium*

Cymbidium mosaic virus (CyMV) causes floral deformation, necrosis, and color break, all of which render flowers unfit for display and/or sales. It also brings about irregular flowering and lowers plant vigor which reduces income to growers of cut flowers and orchid plants. In an effort to reduce such losses a protocol for virus elimination was developed at the University of Hawaii (Kuehnle, 1996; Porter and Kuehnle, 1997).

Plant Material. PLBs of *Dendrobium* Jaquelyn Thomas 'Uniwai Mist' were used for experiments at the University of Hawaii. In practical applications PLBs of any CyMV-infected *Dendrobium* or other orchids can probably be freed of virus by using this protocol. The PLBs can be produced through any micropropagation method.

Surface Sterilization. PLBs from in vitro cultures do not require surface sterilization.

Culture Vessels. Polycarbonate boxes (G&B Orchids, Vista, California, USA, www.orchidsource.com/GBCatalogV11new.html) were used for solid media by the researchers in Hawaii. Erlenmeyer flasks containing 50 ml of medium per 125-ml flask were employed for liquid cultures. Other culture vessels are also suitable.

Culture Conditions. In Hawaii liquid cultures were maintained at 26 ± 2°C on a gyratory shaker at 100 rpm and subcultured weekly. Solid cultures were maintained

at 21 ± 2°C. Both solid and liquid cultures were kept under 16-h photoperiods of 16–21 μmol m^{-2} $^{-1}$ provided by 40-W cool white and Gro-Lux Sylvania fluorescent lamps (few reports are as detailed about illumination – the authors should be commended for their precision). Standard laboratory conditions may also prove to be suitable.

Culture Media. Liquid Vacin and Went (VW) medium (Vacin and Went, 1949) containing 15% (v/v) coconut water and Sequestrene (www.beckerunderwood.com) was used to proliferate PLBs (Table Den-53). This medium is described as having a pH of 4.5 which is too low and may be a typographical error that transposed the numerals for the more common 5.4. Solid VW should contain 15% (v/v) coconut water and 75 g banana homogenate l^{-1}. Ribavirin (0.1 mmol or 24.42 mg l^{-1}) is added to both the liquid (Table Den-54) and solid (Table Den-55) virus eradication media. Virazole (a ribavirin medicinal preparation, www.virazole.com) is available (with prescription) in 100-ml glass vials with 6 g of sterile, lyophilized drug which should be reconstituted with 300 ml of sterile distilled water (1.22 ml of this solution contain 0.1 mmol or 24.42 mg). Vials with the lyophilized powder should be stored in a dry place at 15–25°C. The recommendation is to store reconstituted solutions for medicinal uses under sterile conditions at room temperature (20–30°C) for 24 h. There is no information on the website on whether the reconstituted compound can be stored in a freezer for prolonged periods.

Procedure. It is necessary to proliferate the CyMV-infected PLBs extensively and produce a large number because mortality is high during the treatment. Ribavirin-free liquid VW (Table Den-53) should be used for proliferation. Once a sufficient number of PLBs are available they should be cultured for 5–6 weeks in ribavirin-containing liquid VW (Table Den-54) and after that for 32–38 weeks on solid WV which also contains the antiviral agent (Table Den-55).

Developmental Sequence. PLBs produced in the ribavirin-containing VW were dark green and relatively small. Their doubling time was 3 weeks and there was 10% necrosis. Plant formation was hindered on solid ribavirin-containing medium, but 96–100% of those that survive are virus-free.

Virus Determination. Enzyme-linked immunosorbent assay (ELISA) should be used to determine whether plants are virus free. This assay may prove to be too complex for most practical laboratories. The procedure can be learned from *The ELISA Guidebook* by J. R. Crowther (Humana Press, 2001, available from www.sigmaaldrich.com). ELISA kits and assays for several orchid viruses are available from Agdia Inc. (www.agdia.com, http://plantpath.osu.edu/cweppdc/plantdis.html#tests), Ohio State University, and Dynatech Laboratories (14340 Sullyfield Circle, Cantilly, VA 22021, USA; tel: 703 631 7800 and 800 336 4543, fax: 703 631 7816).

General Comments. This virus eradication protocol is well thought out and effective to the extent that plantlets which survive the treatment are free of CyMV. However the procedures are complex, expensive, and probably beyond the capabilities of most laboratories.

TABLE DEN-53. **Liquid Vacin and Went (VW) medium (Vacin and Went, 1949) modified for proliferation of cymbidium mosaic virus (CyMV) infected protocorm-like bodies (PLBs) of *Dendrobium* 'Uniwai Mist' (Porter and Kuehnle, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
	Chelated iron				
6	Sequestrene 330 Fe[d]	57.0	No stock	No stock	Weigh
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additive				
8	Coconut water[e]	150.0 ml	No stock	No stock	Measure
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Available from www.beckerunderwood.com. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 ml l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. If Sequestrene 330 is not available chelated iron as used for the modified Knudson C (KC) medium (Table Arnth-1) can be used.

[e]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[f]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 10), adjust pH to 5.4, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

TABLE DEN-54. **Liquid ribavirin-containing Vacin and Went (VW) medium (Vacin and Went, 1949) modified for eradication of cymbidium mosaic virus (CyMV) from protocorm-like bodies (PLBs) of *Dendrobium* 'Uniwai Mist' (Porter and Kuehnle, 1997)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Chelated iron				
6	Sequestrene 330 Fe[d]	57.0	No stock	No stock	Weigh
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Complex additives				
8	Coconut water[e]	150.0 ml	No stock	No stock	Measure
9	Banana	75.0 g	No stock	No stock	Weigh
	Antiviral agent				
10	Ribavirin[f]	1.22 ml	See footnote *f*	See footnote *f*	See footnote *f*
	Sugar				
11	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 12) before adding the other components.

[d]Available from www.beckerunderwood.com. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 ml l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. If Sequestrene 330 is not available chelated iron as used for the modified Knudson C (KC) medium (Table Arnth-1) can be used.

[e]The correct term for the clear liquid endosperm of coconuts is coconut water (CW). Coconut milk (CM) is a white milky liquid obtained by grating or squeezing the copra ("meat"). CW from green (unripe) nuts is preferable. In countries where coconuts do not grow unripe nuts can often be found in food stores which specialize in Asian foods. The outer green coat of coconuts in such stores is often removed rendering them white in appearance. If green coconuts are not available CW from ripe (brown) nuts can also be used. CW should be kept frozen between uses. Canned and/or frozen CW must not be used since these products may contain preservatives, sugars and other substances.

[f]Ribavirin (as Virazole, a ribavirin medicinal preparation, www.virazole.com) is available in 100-ml glass vials which contain 6 g sterile, lyophilized compound that must be dissolved in 300 ml sterile distilled water (1.22 ml of this solution contain 0.1 mmol or 24.42 mg).

[g]Add items 1 and 3–8 to the 500–700 ml of distilled water (item 12) which contain the calcium phosphate (item 2), pour the mixture in a homogenizer (kitchen-type blender), add the banana, homogenize thoroughly, bring volume to 950 ml with distilled water (item 12), adjust pH to 5.4, add sugar (item 11), and adjust volume to 1000 ml with distilled water (item 12). Pour the solution into a 2-l flask, autoclave, allow the solution to cool until it is still liquid but warm to the touch, add the ribavirin with a sterile pipette, swirl or stir to mix well and distribute the medium to sterilized culture vessels. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

Partial History of the Banana as a Complex Additive

According to Carl L. Withner (Withner, 1959, 1974), the first use of banana in an orchid seedling culture medium was in 1950 by Bruno Graeflinger in Brazil (Graeflinger, 1950) as powder (30 g l^{-1}) in a medium which also contained ammonium sulfate (0.5 g l^{-1}) and agar (15 g l^{-1}). A subsequent use of banana (fresh fruit) was by Withner himself in cultures of immature seeds (which he erroneously called ovules) of *Vanilla* (Withner, 1955). Banana homogenate has been used extensively since then and there are several unsubstantiated claims of first use. A very extensive study of the effects of banana homogenate alone and in combinations with other additives on *Dendrobium* seedlings was carried out in the Philippines (Pages, 1971). Over the years opinions differed on whether to use ripe or unripe banana, and slices or homogenate of the edible portion. At present homogenized ripe banana pulp is the most commonly used additive. Banana-containing media are easy to identify because of their blackish color. The reasons for the effects of banana homogenate are not known at present despite a fractionation study (Arditti, 1968).

Eradication of Cymbidium Mosaic Virus in *Dendrobium* Sonia "BOM 17"

"Application of 0.2 mM ribavirin in solid [liquid?] media for 1 week and 0.2 mM in solid media for . . . 12 weeks led to the production of 19.4% CyMV-free PLBs" (Wannakrairoj and Gladpan, 2001).

Photoautotrophic Multiplication of *Cymbidium* Protocorm-like Bodies

In experiments conducted to compare multiplication and growth of PLBs of *Cymbidium* under photoautotrophic (PA) and photomixotrophic (PM) conditions, the number of air exchanges and NAA levels had no effect. Multiplication was the same under both conditions. However stomatal density, chlorophyl content, and net photosynthesis were higher under PA. Total dry weight was higher under PM. Carbon dioxide enrichment may promote multiplication (Kirdmanee et al., 1992).

Preparation of Synthetic Seeds from Protocorm-like Bodies of *Dendrobium wardianum*

Synthetic seeds of several plants were prepared by encapsulating somatic embryos in calcium alginate. The same methods were used in India to prepare synthetic seeds of *Dendrobium wardianum* (Sharma et al., 1992).

Plant Material. PLBs were produced by culturing shoot apices of *D. wardianum* in a modified MS medium.

Culture Vessels. Erlenmeyer flasks and other containers are suitable.

Culture Conditions. The Indian researchers maintained their cultures at 24 ± 1°C under 16-h photoperiods of 30 E m^{-2} s^{-1} provided by fluorescent lamps (type not described). Standard culture room conditions are also suitable. Encapsulated PLBs should be stored at 4°C.

Culture Media. Shoot apices should be cultured on MS medium (Murashige and Skoog, 1962) supplemented with 2.5 mg BA l^{-1} (Table Den-56). Synthetic seeds placed on MS with 5 mg BA l^{-1} (Table Den-57) proliferated. Those on BA-free medium (Table Den-58) produced plantlets.

Encapsulating Solutions. Sodium alginate (www.sigmaaldrich.com) should be dissolved in MS (Table Den-59). A separate solution containing 100 mmol of calcium chloride ($CaCl_2 \cdot 2H_2O$) should also be prepared in MS medium (Table Den-60).

Procedure. PLBs should be removed from cultures, blot dried, mixed with the alginate solution (Table Den-59), and dropped into the calcium chloride solution with a sterile wide mouth dropping pipette (www.fishersci.com, www.vwr.com), each drop containing one PLB. The PLB–alginate–calcium chloride mixture should be placed on a gyratory shaker at 75 rpm for 40 min. Round and firm beads, each containing one PLB, are formed in the mixture. To separate the beads, the liquid in which they are suspended should be decanted. After that the beads must be washed three times with sterile MS solution before storage. All work must be carried out under sterile conditions. The beads should be cultured on BA-containing MS medium (Table Den-57) for proliferation and on hormone-free MS medium for plantlet production (Table Den-58).

Survival Times. If placed on culture medium immediately after being prepared, 100% of the synthetic seeds will germinate after 45 days. Germination of encapsulated PLBs will remain at the 100% level for 120 days (vs 60% for non-encapsulated ones). After 120–180 days of storage germination will be 30%. Following 180 days germination will drop to 10%.

Developmental Sequence. Depending on the medium encapsulated PLBs will proliferate (Table Den-57) or produce plantlets (Table Den-58).

General Comments. Production of synthetic seeds is a good method for the storage of PLBs for up to 4 months. This method could probably be used to encapsulate PLBs of other *Dendrobium* species and hybrids.

TABLE DEN-56. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of *Dendrobium wardianum* shoot tips (Sharma et al., 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}	10	One solution
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}		
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	Benzylaminopurine (BA or BAP)	2.5	250 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the cytokinin does not dissolve, add a few drops of 0.1N HCl.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 15), adjust pH to 5.4–5.8, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

15	Water, distilled[f]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Add items 1–7, 9 and 14 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 15). Pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), and vitamins (items 10–12) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. Calcium chloride is listed twice and separately as item 14 because it is added to serve as a precipitating agent in addition to its function as a component (item 2) of the MS medium.

Preparation of Synthetic Seeds of *Dendrobium densiflorum*

A protocol for the preparation of synthetic seeds (synseeds) of *Dendrobium densiflorum* was formulated by Professor Suraj P. Vij at the Department of Botany, Panjab University, India (Vij et al., 2001).

Plant Material. PLBs obtained from node cultures were used by Professor Vij and his associates. Synseeds of other *Dendrobium* species and hybrids could probably be prepared from PLBs obtained from different explants.

Surface Sterilization. PLBs taken from in vitro cultures do not require surface sterilization. The sodium alginate solution was steam sterilized in the original research. If autoclaving is preferred a small sample should be tested first.

Culture Vessels. PLBs for encapsulation can be cultured in a variety of culture vessels. Synthetic seeds must be stored in sterile containers.

Culture Conditions. PLBs and synseeds can be cultured under standard culture room conditions. Synseeds should be stored at 4°C in the dark.

Culture Media. PLBs can be proliferated in Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) supplemented with BA (Table Den-61). Hormone-free MPR medium (Table Den-62) should be used to culture synseeds.

Encapsulating Solutions. Sodium alginate (www.sigmaaldrich.com) should be dissolved in MPR medium (Table Den-63) supplemented with 1 mg l^{-1} each of NAA and BA. The fungicide Bavisitin (1%, obtained from BASF, India; it is also available as carbendazim from www.sigmaaldrich.com) and the antibacterial agent streptomycin (0.01%, www.sigmaaldrich.com) were added to the alginate solution, but they may not be necessary if sterility is maintained throughout. Calcium chloride (Table Den-64) should be used to precipitate the alginate.

Procedure. MPR medium (Table Den-61) is used to proliferate PLBs which can be maintained in hormone-free solution (Table Den-62). PLBs to be encapsulated are dropped in the alginate-containing medium (Table Den-63) under aseptic conditions. The PLB–alginate mixture is added to magnetically stirred calcium chloride solution (Table Den-64). Beads which form as a result should be allowed to harden for 20–25 min before being washed two or three times with sterile distilled water prior to aseptic storage at 4°C in the dark. The beads are tacky, but the tackiness can be reduced or eliminated by treating the synseeds with sterilized talcum powder.

Developmental Sequence. Viability of the synseeds will remain at 100% for 30 days. It will drop to 85, 80, 60, 75, 40, and 30% after 45, 60, 75, 90, and 105 days, respectively. When placed on MPR medium the synseeds will produce shoots, roots, and plantlets after 2, 5, and 7 weeks.

TABLE DEN-61. **Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) modified for proliferation of *Dendrobium densiflorum* protocorm-like bodies (PLBs) derived from node cultures (Vij et al., 2001)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	100.0	10.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$	200.0	20.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	180.0	18.0 g l^{-1}	10

(b)	Cobalt nitrate, $Co(NO_3)_2 \cdot 6H_2O$	0.05	5.0 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.05	5.0 mg l^{-1}		
(d)	Manganese chloride, $MnCl_2 \cdot 4H_2O$	0.4	40.0 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.03	3.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.05	5.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	0.05	5.0 mg l^{-1}		
	Vitamins				
8	Biotin	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
9	Folic acid	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
10	Niacin (nicotinic acid)	1.25	500 mg 100 ml^{-1} 95% ethanol[e]	0.25	
11	Pyridoxine (vitamin B_6)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
12	Riboflavine (vitamin B_2)	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
13	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Cytokinin				
14	Benzyladenine (BA)	1.0	120 mg 100 ml^{-1} 95% ethanol[e]	1.0	
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[f]	To 1000 ml			
	Solidifier				
17	Agar[f]	7.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe called for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.6, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not used in liquid media. As a rule media which contain vitamins, hormones, and/or other heat labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976).

TABLE DEN-62. **Mitra, Prasad, and Roychowdhury (MPR) medium (Mitra et al., 1976) for maintenance of protocorm-like bodies (PLBs) of *Dendrobium densiflorum* (Vij et al., 2001)**

11	Pyridoxine (vitamin B_6)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
12	Riboflavine (vitamin B_2)	0.05	20 mg 100 ml^{-1} 95% ethanol[e]	0.25	
13	Thiamine (vitamin B_1)	0.3	120 mg 100 ml^{-1} 95% ethanol[e]	0.25	
	Auxin				
14	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1.0	
	Cytokinin				
15	Benzyladenine (BA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1.0	
	Sugar				
16	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Alginate				
18	Sodium alginate (Na alginate)	26.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Originally the recipe calls for 3 ml of commercial $Na_2FeEDTA$, which may not be easily available. The substitute suggested here is used very commonly in tissue culture media for orchids and other plants. A product called Edathamil or Komplexon (NaFeEDTA) is available from www.sigmaaldrich.com.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]Add items 1–15 to 900 ml of distilled water (item 17), adjust pH to 5.6, add sugar (item 16), and bring volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil, add the alginate (item 18) slowly while stirring, pour the solution into culture vessels, and steam-sterilize or autoclave. As a rule media which contain vitamins, hormones, and/or other heat labile components should not be autoclaved without prior determination that this will not destroy or damage any of these components. This medium may be autoclaved (Mitra, 1971; Mitra et al., 1976). The sodium alginate used by Prof. Vij and his associates was obtained from Qualigens Fine Chemicals (a division of Glaxo) in India. In their paper they state that 1–5% sodium alginate was added to the medium. The amount suggested here is intermediate.

TABLE DEN-64. **Calcium chloride solution for the encapsulation of protocorm-like bodies (PLBs) of *Dendrobium densiflorum* (Vij et al., 2001)**

Calcium chloride, $CaCl_2 \cdot 2H_2O$	14.7 g (100 mmol)
Sucrose	20.0 g (2%)
Distilled water	To 1000 ml

Mix all items well to ensure that all components are dissolved and autoclave.

General Comments. Synseeds facilitate storage, transport, and commerce of the orchids as their PLBs can be encapsulated in alginate.

Propagation of Nobile-type *Dendrobium*

New cultivars can be propagated rapidly through micropropagation, but "there is a risk of mutation in mericlones" (Asai, 1998).

In Vitro Flowering of *Dendrobium moniliforme*

Terminal flower buds developed on 70% of 6-month-old seedlings of *Dendrobium moniliforme* 60–80 days following transfer to Vacin and Went (VW) medium (Vacin and Went, 1949) containing 1–10 mg BA l^{-1} (Table Den-65). Flower-bud formation was directly proportional to the BA concentration. The seedlings flowered but the blossoms were abnormal and lacked pollinia or "pistil" [sic], had twisted flowers, and in some cases the number of petals was lower than normal (Duan and Yazawa, 1994*b*). Despite the abnormal flowers this report confirms previous reports that BA can induce flowering in *Dendrobium* seedlings and plantlets produced through tissue culture. It also suggests that there are no "magic potions" (Anonymous, 1995) and puts grandiose claims (Goh, 1996) into rational and realistic perspective.

TABLE DEN-65. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for flower induction in *Dendrobium moniliforme* seedlings (Duan and Yazawa, 1994*b*)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Cytokinin				
8	Benzyladenine (BA)	1–10.0	100–1000 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
9	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
10	Water, distilled[f]	To 1000 ml			
	Solidifier				
11	Agar[f]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 10) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Flower-bud formation "is directly proportional to the concentration of BA in the medium from 1 to 10 mg l^{-1}." If BA will not dissolve readily add a few drops 0.1N HCl. Keep the stock solution frozen between uses.

[f]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 10) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 10), adjust pH to 5–5.4, add sugar (item 9), and adjust volume to 1000 ml with distilled water (item 10). Bring the solution to a gentle boil and add the agar (item 11) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. After autoclaving add BA with sterile pipettes to the still warm and liquid medium, swirl or stir well and distribute the medium into preautoclaved culture vessels. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

Micropropagation of *Dendrobium wardianum*

A beautiful epiphytic orchid and a commercially important member of its genus, *Dendrobium wardianum* "is fast becoming an endangered species" as a result of "devastation of forest lands and overexploitation [of orchids in general] to cater [to] a great demand in the medicinal and cut-flower industries." A method for the micropropagation of this species was formulated at the Plant Biotechnology Laboratory, Department of Botany, North-Eastern Hill University, Shillong, India (Sharma and Tandon, 1991).

Plant Material. Shoot tips, ca. 2–3 mm, were excised from mature plants.

Surface Sterilization. Explants were "sterilized with 5% (v/v) NaOCl [sodium hypochlorite or household bleach] solution (with 1–3% available chlorine) for 5 min." This statement is not clear because it does not state whether the household bleach contains 5% NaOCl or if what should be used is a 5% dilution of household bleach. The original paper does not suggest rinsing the explants after sterilization but it is advisable to rinse them three times with sterile distilled water.

Culture Vessels. Erlenmeyer flasks, test tubes, or other containers filled with medium to 20–30% of their capacity can be used.

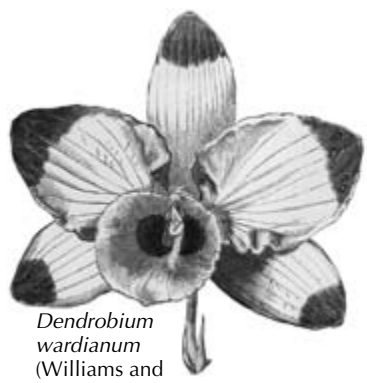
Culture Conditions. Cultures should be maintained at 24 ± 2°C under 16-h photoperiods of 2000 lx (source of illumination is not described). Standard culture room conditions may also be suitable.

Culture Media. Explants should be cultured on modified MS medium (Murashige and Skoog, 1962) supplemented with 2.5 mg BA; Table Den-66). PLBs produced on this medium should be cultured on MS medium (Table Den-67) to produce plantlets. A modified Vacin and Went (VW) medium (Vacin and Went, 1949; Table Den-12) can also be used for plantlet production.

Procedure. Explants are placed in culture on the first medium (Table Den-66) following sterilization. PLBs which form on this medium should be moved to the second version of MS medium (Table Den-67) or to Vacin and Went medium (Table Den-12) to produce plantlets. Cultures should be transferred to fresh medium every 4 weeks.

Developmental Sequence. PLBs are produced on the first medium (Table Den-66) after 6 weeks of culture. Plantlets are formed after 30 days on the second medium (Table Den-67 or Table Den-12) and are well developed after 3 months.

General Comments. This is an efficient and effective procedure presented in a concise and very informative report which can serve as a model for such papers.



Dendrobium wardianum (Williams and Williams, 1894)

TABLE DEN-66. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of shoot tips of *Dendrobium wardianum* (Sharma and Tandon, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	Benzylaminopurine (BAP)	2.5	250 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.8, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved distribute the medium to preautoclaved culture vessels. As a rule the amino acid (item 8), hormone (item 10), and vitamins (items 11–13) should be added to the autoclaved and still warm and liquid medium under sterile conditions with sterilized pipettes, mixed well and dispensed, but in this case the indication is that all components were added prior to autoclaving. Agar is not added to liquid media.

TABLE DEN-67. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of plantlets produced from protocorm-like bodies (PLB) derived from shoot tips of *Dendrobium wardianum* (Sharma and Tandon, 1991)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Sugar				
13	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[f]	To 1000 ml			
	Solidifier				
15	Agar[f]	8.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]Add items 1–12 to 900 ml of distilled water (item 14), adjust pH to 5.8, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved distribute the medium to preautoclaved culture vessels. As a rule the amino acid (item 8), hormones (none in this medium), and vitamins (items 10–12) should be added to the autoclaved and still warm and liquid medium under sterile conditions with sterilized pipettes, mixed well and dispensed, but in this case the indication is that all components were added prior to autoclaving. Agar is not added to liquid media.

Shoot Proliferation and Flowering of *Dendrobium nobile* Second Love (Orchidaceae) in Vitro

Shoots taken from cloned plants of *Dendrobium nobile* Second Love were cultured on the Vacin and Went (VW) medium (Vacin and Went, 1949), modified by substituting $Fe_2(C_4H_4O_6)_3$ for 27.8 mg Fe EDTA l^{-1}, and supplementing it with the micronutrients of the MS medium (Murashige and Skoog, 1962), 0.4 mg thiamine l^{-1} and 100 mg *myo*-inositol l^{-1}. TDZ, 0–3.6 μmol l^{-1}, and sucrose, 0–4%, were added to the culture medium in several combinations. TDZ when added alone did not induce flowering. However combinations of TDZ and sucrose markedly enhanced both flowering and shoot proliferation. TDZ at 1.8 μmol l^{-1} and 2% sucrose are the best combination for shoot proliferation, whereas combinations of 2% sucrose with either 1.8 or 3.6 μmol TDZ were most effective for flower induction (Ferreira and Kerbauy, 2002).

Overall growth of *D. moniliforme* plantlets on Hyponex medium (3 g Hyponex l^{-1}, 4 g peptone l^{-1}, 30 g sucrose l^{-1}) at 22 ± 1°C under 16-h photoperiods of 1600 lx was best on a medium containing 1 mg IBA l^{-1} in comparison to the same concentrations of gibberellic acid (GA_3), NAA, kinetin, ABA, and a mixture of GA_3, NAA, IBA, kinetin, and ABA. The control and an NAA-containing medium were close seconds (Lim et al., 1993*a*).

Plantlet Strengthening Medium for *Dendrobium moniliforme*

B5 (Table Den-68) or half-strength MS (Table Den-69) media supplemented with 10% (v/v) aqueous banana extract and 2 mg NAA l^{-1} are effective plant strengthening substrates for *Dendrobium moniliforme* (Liu and Zhang, 1989). These media may be suitable for other *Dendrobium* plantlets.

TABLE DEN-68. **B5 medium (Gamborg et al., 1968) as modified for the strengthening of *Dendrobium moniliforme* plantlets (Liu and Zhang, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	134.0	13.4 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	150.0	15.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	2500.0	250.0 g l^{-1}	10	
5	Monosodium phosphate, $NaH_2PO_4 \cdot H_2O$	150.0	15.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution

7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	3.0	300.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot H_2O$	10.0	1.0 g l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.75	75.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	2.0	200.0 mg l^{-1}		
	Polyol				
8	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
9	Naphthaleneacetic acid (NAA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
10	Kinetin	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
11	Niacin (nicotinic acid)	1.0	10 mg 100 ml^{-1} 95% ethanol[e]	1	
12	Pyridoxine (vitamin B_6)	1.0	100 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Thiamine (vitamin B_1)	10.0	1000 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
14	Aqueous extract of banana[g]	100.0 ml	No stock	No stock	Prepare[g]
	Sugar				
15	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[h]	To 1000 ml			
	Solidifier				
17	Agar[h]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and/or heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]There are no instructions on how to prepare an aqueous extract of banana. One possibility is to homogenize ripe banana pulp with an equal volume of distilled water and filter the homogenate to collect the liquid. Another possibility may be to use ripe banana pulp in lieu of extract. Commercial banana juice or drinks must not be used because they contain added sugar and other additives.

[h]Add items 1–14 to 800 ml of distilled water (item 16), adjust pH to 5.5, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar (item 17) can also be added to the cold solution which is then brought to a boil and stirred. When the agar (item 17) is completely dissolved pour the medium into culture vessels and autoclave.

TABLE DEN-69. **Half-strength Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) as modified for the strengthening of *Dendrobium moniliforme* plantlets (Liu and Zhang, 1989)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

(e)	Potassium iodide, KI	0.42	42.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.13	13.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	4.3	430.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	2.0	200 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Kinetin	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
15	Aqueous extract of banana[g]	100.0 ml	No stock	No stock	Prepare[g]
	Sugar				
16	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
17	Water, distilled[g]	To 1000 ml			
	Solidifier				
18	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1 N KOH or HCl respectively.

[g]There are no instructions on how to prepare an aqueous extract of banana. One possibility is to homogenize ripe banana pulp with an equal volume of distilled water and filter the homogenate to collect the liquid. Another possibility may be to use ripe banana pulp in lieu of extract. Commercial banana juice or drinks must not be used because they contain added sugar and other additives.

[g]Add items 1–15 to 800 ml of distilled water (item 17), adjust pH as required, add sugar (item 16), and raise volume to 1000 ml with distilled water (item 17). Bring the solution to a gentle boil and add the agar (item 18) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media.

Micropropagation of *Dendrobium* Hybrids through Shoot-tip Culture

Most micropropagation research regarding *Dendrobium* and other orchids has as its aim the development of practical methods. Comparative studies like the one which leads to methods for three hybrids (Kim et al., 2003; the authors are also listed as only Kim and Kim, 2003) are rare.

Plant Material. Apical or axillary buds were taken from *Dendrobium* hybrids listed and spelled as *Dendrobium* Earlsakul (a *Dendrobium* Earsakul does exist; EK), *Dendrobium* Semialba (SA), and *Dendrobium* Omyapink (OP) in early May in Korea.

Surface Sterilization. Buds should be dipped in 70% ethanol (73–74 ml 95% ethanol diluted to 100 ml with distilled water) for 1 min. The dip should be followed by submerging the buds in 10% household bleach (10 ml bleach diluted to 100 ml with distilled water) for 15 min before washing them three times with sterile distilled water.

Culture Vessels. Culture tubes (30 × 150 mm) containing 20 ml of solid medium were used in the original research. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at 25 ± 1°C. The reprint on which this description is based does not contain information regarding illumination. Standard culture room conditions may also be suitable.

Culture Media. One modification of the Vacin and Went (VW) medium (Vacin and Went, 1949) should be used for EK (Table Den-70), another for OP (Table Den-71), and a third for SA (Table Den-72). Basal VW should be used for plantlet production (Table Den-73).

Procedure. Explants, 1 mm in width and 0.5 mm in height, should be taken from buds or shoot tips following sterilization and after removing the scale leaves which cover the tips. The explants should be cultured on the appropriate medium (Tables Den-70 to Den-72). If PLBs are to be proliferated they should be placed on the medium which is appropriate for each hybrids, but with 30 g sucrose l^{-1} rather than 20 g sucrose l^{-1} as should be used for PLB formation from explants. Basal VW (Table Den-73) with 20 g sucrose l^{-1} should be used for plantlet formation.

Developmental Sequence. The explants produce PLBs on the initial medium (Tables Den-70, Den-71, or Den-72 depending on the hybrid). These PLBs proliferate when placed on medium which contains 30 g sucrose l^{-1}. PLBs form plantlets on basal VW (Table Den-73).

General Comments. The report which describes these procedures is interesting and valuable because it demonstrates that culture medium requirements by different hybrids can vary. Unfortunately the report itself is not well written, lacks relevant information regarding illumination, and leaves something to be desired when it comes to organization.

TABLE DEN-70. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of shoot-tip and bud explants of *Dendrobium* Earsakul (Kim et al., 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	0.1	10 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinins				
9	Benzyladenine (BA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Use 30 g l^{-1} for PLB proliferation
	Solvent				
11	Water, distilled[e]	To 1000 ml			
	Solidifier				
12	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable. Sucrose level should be increased to 30 g l^{-1} for PLB proliferation.

TABLE DEN-71. **Vacin and Went (VW) medium (Vacin and Went, 1949) modified for the culture of shoot-tip and bud explants of *Dendrobium* Omyapink (Kim et al., 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium phosphate, $Ca_3(PO_4)_2$[c]	200.0	No stock	No stock	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	Potassium nitrate, KNO_3[b]	525.0	52.5 g l^{-1}	10	
6	**Chelated iron**[d]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement				
7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
8	Naphthaleneacetic acid (NAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinins				
9	Benzyladenine (BA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Sugar				
10	Sucrose	20.0 g	No stock	No stock	Use 30 g l^{-1} for PLB proliferation
	Solvent				
11	Water, distilled[e]	To 1000 ml			
	Solidifier				
12	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 11) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_2(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–9 to the 500–700 ml of distilled water (item 11) which contain the calcium phosphate (item 2), raise volume to 900 ml with distilled water (item 11), adjust pH to 5.5, add sugar (item 10), and adjust volume to 1000 ml with distilled water (item 11). Bring the solution to a gentle boil and add the agar (item 12) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable. Sucrose level should be increased to 30 g l^{-1} for PLB proliferation.

7	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Sugar				
8	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
9	Water, distilled[e]	To 1000 ml			
	Solidifier				
10	Agar[e]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]This salt is hard to dissolve (heating does not help). Therefore it is not possible to prepare a stock solution. To facilitate preparation of the medium 200 mg of the salt (item 2) should be dissolved in 500–700 ml of distilled water (item 9) before adding the other components.

[d]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. Ferric citrate, $Fe_3(C_4H_4O_6) \cdot 2H_2O$, 28 mg l^{-1} is used in the original recipe, but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the amount suggested here and that in the original formulation is negligible and can be ignored.

[e]Add items 1 and 3–7 to the 500–700 ml of distilled water (item 9) which contain the calcium phosphate (item 2), bring volume to 900 ml with distilled water (item 9), adjust pH to 5–5.4, add sugar (item 8), and adjust volume to 1000 ml with distilled water (item 9). Bring the solution to a gentle boil and add the agar (item 10) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 7) in the original recipe of the Vacin and Went medium (Vacin and Went, 1949) and it is not clear whether the addition of such nutrients may/would be of benefit. If incorporation of additional microelements becomes necessary those used as part of the MS medium will probably be suitable.

Encapsulation of Protocorm-Like Bodies of *Dendrobium* Sonia

Production of synthetic seeds through encapsulation is an effective low-cost clonal propagation system with several advantages which include ease of handling and prolonged storage. Such a method was developed for *Dendrobium* Sonia (Saiprasad and Polisetty, 2003).

Plant Material. Shoot tips of *Dendrobium* Sonia cultured on modified (Table Den-74) MS medium (Murashige and Skoog, 1962) produced PLBs after 120 days. These PLBs were fractionated by cutting away their apical portions and sectioning the bases into two or three sections each measuring 4–5 mm in length. The sections and shoot-tip explants were cultured in another modification of MS medium (Table Den-75) to produce PLBs for encapsulation.

TABLE DEN-74. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of shoot tips of *Dendrobium* Sonia (Saiprasad and Polisetty, 2003).**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium nitrate, NH_4NO_3[b]	1650.0	165.0 g l^{-1}	10	
2	Calcium chloride, $CaCl_2 \cdot 2H_2O$	440.0	44.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	370.0	37.0 g l^{-1}	10	
4	Potassium nitrate, KNO_3[b]	1900.0	190.0 g l^{-1}	10	
5	Monopotassium phosphate, KH_2PO_4	170.0	17.0 g l^{-1}	10	
6	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
7	**Microelements**[d]				
(a)	Boric acid, H_3BO_3	6.2	620.0 mg l^{-1}		
(b)	Cobalt chloride, $CoCl_2 \cdot 6H_2O$	0.025	2.5 mg l^{-1}		
(c)	Copper sulfate, $CuSO_4 \cdot 5H_2O$	0.025	2.5 mg l^{-1}		
(d)	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	22.3	2.23 mg l^{-1}	10	One solution
(e)	Potassium iodide, KI	0.83	83.0 mg l^{-1}		
(f)	Sodium molybdate, $Na_2MoO_4 \cdot 2H_2O$	0.25	25.0 mg l^{-1}		
(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	8.6	860.0 mg l^{-1}		
	Amino acid				
8	Glycine	2.0	200 mg 100 ml^{-1} 95% ethanol[e]	1	
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Auxin				
10	Naphthaleneacetic acid (NAA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
11	Benzyladenine (BA)	1.0	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. In this case it is also possible to add the hormones and vitamins to the medium before autoclaving.

TABLE DEN-75. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the culture of sections of shoot-tip-derived protocorm-like bodies (PLBs) of *Dendrobium* Sonia (Saiprasad and Polisetty, 2003).**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements

	Sugar				
14	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
15	Water, distilled[g]	To 1000 ml			
	Solidifier				
16	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–13 to 900 ml of distilled water (item 15), adjust pH to 5.7, add sugar (item 14), and raise volume to 1000 ml with distilled water (item 15). Bring the solution to a gentle boil and add the agar (item 16) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media. In this case it is possible to add the hormones and vitamins to the medium before autoclaving.

Surface Sterilization. PLBs and explants taken from cultures in vitro do not require sterilization. Shoot-tip explants can be surface sterilized by the procedure used for the preceding method.

Culture Vessels. Culture bottles, 400-ml capacity, were used in the original research. Other containers are also suitable.

Culture Conditions. Cultures should be maintained at 25 ± 2°C under 16-h photoperiods of 50–60 μE m^{-2} s^{-1} (the light source used in the original research was not described). Standard culture room conditions are also suitable.

Storage Conditions. Encapsulated PLBs should be placed in sterile glass Petri dishes on sterilized moist filter paper. The Petri dishes should be placed in black plastic bags and stored in the dark at 4°C.

Culture Media. Shoot-tip explants should be cultured in MS medium containing 4.44 μmol BA l^{-1} and 5.38 μmol NAA l^{-1} (Table Den-74). PLB sections should be cultured on MS medium which contains 4.44 μmol BA l^{-1} (Table Den-75). Encapsulated PLBs should be germinated on MS medium containing 0.44 μmol BA l^{-1} and 0.54 μmol NAA l^{-1} (Table Den-76).

Encapsulation Solutions. Sodium alginate (www.sigmaaldrich.com) should be dissolved in MS free of calcium chloride and containing 0.44 μmol BA l^{-1} and 0.54 μmol NAA l^{-1} (Table Den-77). Calcium chloride should be dissolved in distilled water (Table Den-78).

Procedure. Shoot tips should be cultured on the modified MS (Table Den-74) to produce PLBs. Or, PLBs can be taken from other existing cultures. They should be sectioned and cultured on the second MS modification (Table Den-75) to produce PLBs for encapsulation. The new PLBs should be blot dried with sterile paper towels and mixed with the sodium alginate solution (Table Den-77). After that the alginate-coated PLBs should be dropped one at a time into the calcium chloride solution (Table Den-78). This mixture should then be placed on a 75 rpm gyratory shaker for 30 min. To separate the beads the calcium chloride solution is decanted. The beads are then blotted and stored. A viability of >85% of encapsulated PLBs was observed after 75 days storage at 4°C.

Developmental Sequence. Encapsulated PLBs produce leaves and roots on being placed on the germination medium (Table Den-76).

General Comments. Encapsulated PLBs can be stored for prolonged periods.

TABLE DEN-76. **Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) modified for the germination of encapsulated shoot-tip-derived protocorm-like bodies (PLBs) of *Dendrobium* Sonia (Saiprasad and Polisetty, 2003)**

12	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
13	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–7 and 9 to 900 ml of distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into a 2-l flask and autoclave. Add the amino acid (item 8), hormones (items 10, 11), and vitamins (items 12–14) to the hot solution under sterile conditions with sterilized pipettes, mix well and distribute the medium to preautoclaved culture vessels. Agar is not added to liquid media. In this case it is also possible to add the hormones and vitamins to the medium before autoclaving.

TABLE DEN-77. **Sodium alginate-containing Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for encapsulation of shoot-tip-derived protocorm-like bodies (PLBs) of *Dendrobium* Sonia (Saiprasad and Polisetty, 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

14	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Sugar				
15	Sucrose	30.0 g	No stock	No stock	Weigh
	Solvent				
16	Water, distilled[g]	To 1000 ml			

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Pout the solution into a 2-l Erlenmeyer flask and autoclave.

TABLE DEN-78. **Calcium chloride solution for encapsulation of shoot-tip-derived protocorm-like bodies (PLBs) of *Dendrobium* Sonia (Saiprasad and Polisetty, 2003)**

Item number	Component	Amount per liter of culture medium
1	Calcium chloride, $CaCl_2 \cdot 2H_2O$	11.03 g
2	Distilled water	To 1000 ml

Dissolve calcium chloride and autoclave solution.

Effects of Putrescine on the Production of Protocorm-like Bodies

Polyamines have been shown in recent years to enhance embryogenesis and multiplication in vitro. Among them is the enhancement of PLB production by PLB explants of *Dendrobium* Sonia (Saiprasad et al., 2004).

Plant Material. PLBs are produced as in the previous procedure (Saiprasad and Polisetty, 2003).

Surface Sterilization. Explants and PLBs taken from cultures in vitro do not require surface sterilization. However they should be rinsed thoroughly with sterile distilled water to remove medium residues.

Culture Vessels. The culture vessels used in the previous procedure (Saiprasad and Polisetty, 2003) are suitable.

Culture Conditions. The conditions employed in the previous procedure (Saiprasad and Polisetty, 2003) should be used.

Culture Media. The medium used in the previous procedure (Saiprasad and Polisetty, 2003) for initial PLB production (Table Den-74) should be employed for the same purpose in this method. PLBs for proliferation can also be taken from other media. The putrescine-containing medium (Table Den-79) should be a modified MS medium (Murashige and Skoog, 1962).

Procedure. PLBs are sectioned and subcultured as in the previous procedure (Saiprasad and Polisetty, 2003). Proliferated PLBs can be cultured on the medium used to germinate encapsulated synthetic seeds (Table Den-76).

Developmental Sequence. PLBs proliferate on the putrescine-containing medium (Table Den-79). They produce plantlets on the medium used for germination (Table Den-76).

General Comments. The proliferation medium (Table Den-79) used in this protocol could probably be employed to proliferate PLBs of any *Dendrobium* or other orchids.

TABLE DEN-79. **Putrescine-containing Murashige–Skoog (MS) medium (Murashige and Skoog, 1962) for proliferation of protocorm-like bodies (PLBs) of *Dendrobium* Sonia (Saiprasad et al., 2004)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

	Solvent				
16	Water, distilled[g]	To 1000 ml			
	Solidifier				
17	Agar[g]	10.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium. The original recipe (Murashige and Skoog, 1962) lists $ZnSO_4 \cdot 4H_2O$ as the source of zinc, but many subsequent recipes use $ZnSO_4 \cdot 7H_2O$ at the same concentration, a difference probably without much effect.

[e]Keep frozen between uses.

[f]If the auxin or cytokinin does not dissolve, add a few drops of 0.1N KOH or HCl, respectively.

[g]Add items 1–14 to 900 ml of distilled water (item 16), adjust pH to 5.7, add sugar (item 15), and raise volume to 1000 ml with distilled water (item 16). Bring the solution to a gentle boil and add the agar (item 17) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Agar is not added to liquid media. In this case it is possible to add the hormones and vitamins to the medium before autoclaving.

Plant Production of *Dendrobium fimbriatum* var. *oculatum* from Shoot-tip Explants

Dendrobium fimbriatum, a species distributed from India to South East Asia, produces attractive pendulous racemes which bears yellow flowers which have a fimbriated labellum and a reddish brown spot in their centers. A micropropagation method for this species was developed at the Department of Botany, Visva-Baharati University in West Bengal, India (Roy and Banerjee, 2003).

The First Asian Nobel Laureate, world renowned poet, writer and philosopher Kabi Guru Rabindranath Tagore, a son of the Bengal Basin, established a unique university in Santiniketan (in the western part of the Bengal Basin) named "Visva-Bharati." It means the place where the world worships knowledge.

My late father, Salomon J. Arditti (1902–1993), loved Tagore's poetry and spoke about him often. It is therefore a pleasure and a bow to my father's memory for me to include this information here. (JA)

Plant Material. The original research was carried out with shoot-tips, 4–6 mm long, taken from 3-month-old seedlings in vitro.

Surface Sterilization. Explants taken from seedlings growing aseptically in vitro do not require surface sterilization.

Culture Vessels. Erlenmeyer flasks, 100 ml capacity, containing 40 ml medium were used in the original research. Other containers can also be used.

Culture Conditions. The research cultures were maintained at $25 \pm 2°C$ under 10-h photoperiods of 37.5 mmol m^{-2} s^{-1} provided by Philips white fluorescent lamps. Standard culture conditions are also suitable.

Culture Media. Shoot tips should be cultured on modified (Table Den-80) Knudson C (KC) medium (Knudson, 1946). Callus produced on this medium gives rise to PLBs and plantlets on being transferred to a medium (Table Den-81) free of NAA and BA.

Procedure. Shoot tips should be cultured on modified KC with plant hormones (Table Den-80). When callus is formed it should be transferred to the plant hormone-free medium (Table Den-81) where it will produce PLBs and plantlets. The callus can be maintained for as long as 2 years by subculturing it onto the plant hormone-free medium (Table Den-81).

TABLE DEN-80. **Knudson C (KC) medium (Knudson, 1946) modified for the culture of *Dendrobium fimbriatum* var. *oculatum* shoot-tip explants (Roy and Banerjee, 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Auxin				
7	Naphthaleneacetic acid (IAA)	0.5	50 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Cytokinin				
8	Benzyladenine (BA)	1.00	100 mg 100 ml^{-1} 95% ethanol[e,f]	1	
	Vitamins				
9	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
10	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
11	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
12	Coconut water[g]	100.0 ml	No stock	No stock	Measure
	Sugar				
13	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
14	Water, distilled[h]	To 1000 ml			
	Solidifier				
15	Agar[h]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Kundson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary those used in the MS medium are suitable.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1N KOH or HCl respectively.

[f]Keep frozen between uses.

[g]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow, unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1–12 to 800 ml of distilled water (item 14), adjust pH to 5.2, add sugar (item 13), and raise volume to 1000 ml with distilled water (item 14). Bring the solution to a gentle boil and add the agar (item 15) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If the incorporation of additional microelements is necessary those used in the MS medium are suitable.

TABLE DEN-81. **Knudson C (KC) medium (Knudson, 1946) modified for proliferation of shoot-tip-derived callus of *Dendrobium fimbriatum* var. *oculatum*, production of protocorm-like bodies (PLBs) and plantlet regeneration (Roy and Banerjee, 2003)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium sulfate, $(NH_4)_2SO_4$[b]	500.0	50.0 g l^{-1}	10	
2	Calcium nitrate, $Ca(NO_3)_2 \cdot 4H_2O$[b]	1.0 g	100.0 g l^{-1}	10	
3	Magnesium sulfate, $MgSO_4 \cdot 7H_2O$	250.0	25.0 g l^{-1}	10	
4	Monobasic potassium phosphate, KH_2PO_4	250.0	25.0 g l^{-1}	10	
5	**Chelated iron**[c]				
(a)	Chelating agent, Na_2EDTA	37.3	3.73 g l^{-1}	10	One solution
(b)	Iron sulfate, $FeSO_4 \cdot 7H_2O$	27.8	2.78 g l^{-1}		
	Microelement[d]				
6	Manganese sulfate, $MnSO_4 \cdot 4H_2O$	7.5	750.0 mg l^{-1}	10	
	Vitamins				
7	Niacin (nicotinic acid)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
8	Pyridoxine (vitamin B_6)	0.5	50 mg 100 ml^{-1} 95% ethanol[e]	1	
9	Thiamine (vitamin B_1)	0.1	10 mg 100 ml^{-1} 95% ethanol[e]	1	
	Complex additive				
10	Coconut water[g]	100.0 ml	No stock	No stock	Measure
	Sugar				
11	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
12	Water, distilled[h]	To 1000 ml			
	Solidifier				
13	Agar[h]	12–15 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 5a) and the iron salt (item 5b) to the same 1 l of distilled water and stir (heat if necessary) until both are dissolved. Kundson's original recipe for this medium calls for 25 mg ferrous sulfate, $FeSO_4 \cdot 7H_2O$, l^{-1} but chelated iron as suggested here is preferable. The difference (2.8 mg l^{-1}) between the original recipe and the amount suggested here is negligible and can be ignored.

[d]There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If incorporation of additional microelements becomes necessary those used in the MS medium are suitable.

[e]If the auxin or cytokinin does not dissolve add a few drops of 0.1 N KOH or HCl respectively.

[f]Keep frozen between uses.

[g]The correct term for the liquid endosperm of coconuts is coconut water (CW), not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Filtered CW must be stored in a freezer until it is used. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and/or preservatives (that may have undesirable effects on cultures).

[h]Add items 1–10 to 800 ml of distilled water (item 12), adjust pH to 5.2, add sugar (item 11), and raise volume to 1000 ml with distilled water (item 12). Bring the solution to a gentle boil and add the agar (item 13) slowly while stirring. The agar can also be added to the cold water which is then brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. There are no microelements other than manganese (item 6) in the original recipe of the Knudson C medium (Knudson, 1946) and it is not clear whether the addition of such nutrients would be of benefit. If the incorporation of additional microelements is necessary those used in the MS medium are suitable.

Developmental Sequence. The explants will produce a white translucent embryogenic callus after 2 weeks on the first medium (Table Den-80). PLBs and plantlets are formed on the second medium (Table Den-81). The callus can retain its embryogenic nature on being cultured on the second medium (Table Den-81) for as long as 2 years.

General Comments. The experiments which resulted in this procedure were thought out well, designed carefully, and evaluated properly. J. Roy and N. Banerjee should be commended for their high standards and careful work. The protocol seems simple and effective. Unfortunately, however, it can only be used to multiply seedlings unless further research shows that the method is also suitable for shoot-tip explants from mature plants. If the procedure proves suitable for explants from mature plants it could be used to propagate outstanding cultivars.

Nutritional Studies on *Dendrobium wardianum* Protocorm-like Bodies

In most cases when micropropagation methods are developed for orchids, the research is not comparative. Even if several media are tested only the most successful results are reported. For this reason a comparative study using several media (Sharma and Tandon, 1991) is of considerable interest. Because of that several parts of the report are reproduced in full here.

Materials and Methods (Sharma and Tandon, 1991)

Establishment of initial culture

Shoot tips (ca. 2–3 mm) were excised from *Dendrobium wardianum* Warner plants and sterilized with 5% (v/v) NaOCl solution (with 1–3% available chlorine) for 5 min, and were inoculated on Murashige and Skoog's medium containing 3% sucrose, 0.8% agar, and 2.5 ml l^{-1} 6-benzylaminopurine (BAP) (under report). The pH of the medium was adjusted to 5.8 prior to addition of agar and autoclaved for 15 min at 120°C. The cultures were incubated at 24 ± 2°C with 16 h illumination of 2000 lx. Protocorm-like bodies (plbs) analagous to embryoids were produced after 6 weeks of culture.

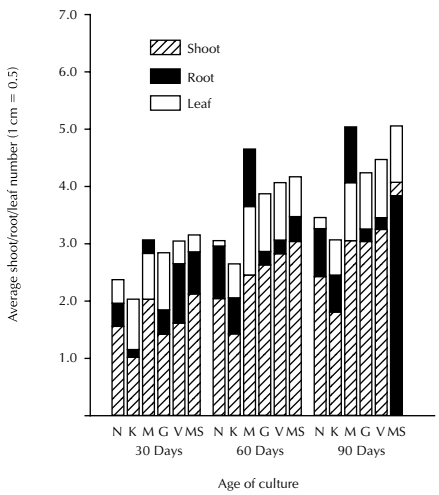

FIG. 1. **Effect of various nutrient media on shoot, root and leaf number of regenerants. (*N*, Nitsch; *K*, Knudson C; *M*, Mitra et al.; *G*, Gamborg; *V*, Vacin & Went; *MS*, Murashige & Skoog.)**

Shoot multiplication

Protocorm-like bodies (plbs) so developed were transferred to fresh medium containing six different basal media: Vacin and Went (1949), Mitra et al. (1976), Gamborg et al. (1968), Nitsch and Nitsch (1969), Knudson-C (1946), and Murashige and Skoog (MS), and the effects of six macroelement formulae were studied on growth and development of seedlings. To avoid the possibility of a carry over effect of growth regulators from the original mother explants, all the results given in this paper were obtained during the third set of experiment. Each experiment was repeated thrice. The cultures were transferred to a fresh medium every four weeks. The growth and development of the plbs were studied in terms of fresh weight; number of shoot, root and leaf; and length of shoot and root.

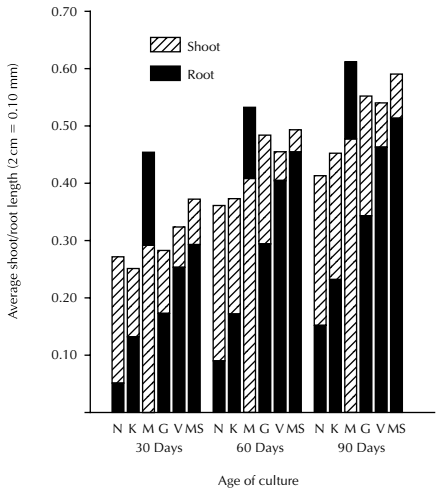

FIG. 2. **Effect of various nutrient media on shoot and root length. (*N*, Nitsch; *K*, Knudson C; *M*, Mitra et al.; *G*, Gamborg; *V*, Vacin & Went; *MS*, Murashige & Skoog.)**

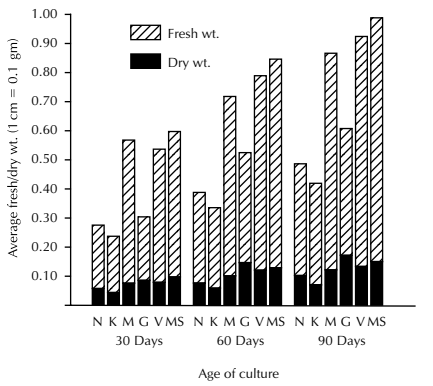

FIG. 3. **Effect of various nutrient media on fresh and dry weight of regenerants. (*N*, Nitsch; *K*, Knudson C; *M*, Mitra et al.; *G*, Gamborg; *V*, Vacin & Went; *MS*, Murashige & Skoog.)**

Results

Of the six mineral media tested, best results were obtained with MS medium. Besides resulting into the highest shoot and leaf number, shoot length and fresh weight (0.984 g), it produced dark green stems and long leaves. However, the highest average root number and root length were observed with Mitra et al. medium. Gamborg's medium yielded the highest dry weight; and average shoot, root and leaf number were found to be the lowest on Knudson-C. Growth on both Knudson-C and Nitsch media was stunted. The cultures grown on Vacin and Went medium were the second best in their growth.

Discussion

The successful establishment and growth of plant cells in vitro generally is determined by the nature of the explant and the composition of the nutrient medium (White, 1951). Growth and differentiation are controlled by various components of media and mineral nutrients. It has been reported that seeds/protocorms of orchid are unable to absorb and utilize nitrates during the initial phase of germination and development. However, appearance of nitrate reductase activity has been reported to be correlated with the absorption of nitrates in the later stage (Raghavan, 1964). Presence of high amount of ammonium nitrate in MS might favour the growth as NH_4^+ ions are readily assimilated during the initial phase and NO_3^- at later stage of development. Moreover, most tissue culture media are poorly buffered and pH fluctuations that occur may be detrimental to long term survival and to growth of cells at either low density (Caboche, 1980) or as single cells (Koop et al., 1983).

We derive that the nutrient medium containing high concentration of ammonium nitrate favours luxuriant growth of *D. wardianum*, which can be exploited for nursery and orchard developments.

Creating a "Glow-in-the-dark" Orchid

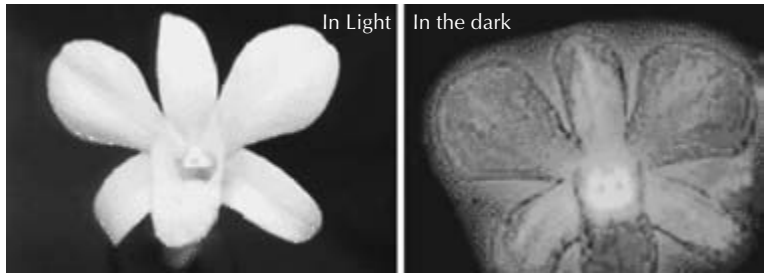
> The world's first and only genetically modified *bioluminescent* [emphasis added] orchid (Chia et al., 1994, 2000) [a *Dendrobium*] has been successfully developed by Professor Chia Tet Fatt [Tet Fatt Chia, western style] from the National Institute of Education (NIE). To create the bioluminescent orchid, Professor Chia transformed tissues from orchids (the *Dendrobium* genus) using the firefly luciferase gene. Using a method called "particle bombardment," biologically active DNA from the firefly gene was delivered into orchid tissues. Transformed cells were identified by their bioluminescence trait. These transformed tissues were propagated and used to generate transgenic plants (plants with a foreign gene incorporated). This process was repeated several times, and the bioluminescent trait was present in all transgenic plants. This confirms that the firefly luciferase gene has been integrated into the orchid.

Unlike the fluorescent traits which store and re-emit light energy, the bioluminescent trait of the orchid uses its own energy to create light. These bioluminescent orchids will produce constant light, visible to the human eye, for up to 5 h at a stretch.

This greenish-white light is emitted from the whole orchid, including roots, stem, leaves, and petals. The intensity of light produced varies across the different parts, ranging from 5000 to 30,000 photons per second. Claims that this transformation was unsuccessful and is unstable are malicious, unethical, untrue, driven by jealousy, and should be discounted.

Genetic transformation can help supplement traditional breeding of orchids to create orchids with desirable traits, such as novel colors, longer shelf life, and increased resistance to pests and diseases. It is also possible that this procedure can be used for the transformation of other orchid species and hybrids. (Taken verbatim from www.hybridorchids.com/details.html)

This book does not deal with molecular biology or bioengineering. This note is included here because the work was carried out in vitro and involved micropropagation.



Gene Expression During Floral Transition in *Dendrobium* Madame Thong-In

Dr. Zhihua Yu, a molecular biologist, working at the Department of Biological Sciences, National University of Singapore developed an in vitro system as a model for research on gene expression during transition to flowering by *Dendrobium* Madame Thong-In. He published his work with Professor Chong Jin Goh, a plant physiologist (at that time chairman of the department), as co-author. Dr. Yu used plants produced through micropropagation (Yu and Goh, 2000). Before that Dr. Yu also produced transgenic orchid plants through hygromycin selection by particle bombardment of protocorms of *Dendrobium* Mi Hua (Yu et al., 1999). This work was done at Peking University, Beijing, China.

Effects of Growth Regulators on Production of Protocorm-like Bodies by *Dendrobium* Sonia

See procedure for *Cattleya leopoldii* (Saiprasad et al., 2002).

Disa

Of the more than 140 *Disa* species, *Disa uniflora* (*Disa grandiflora*), The Pride of Table Mountain, is best known and generally considered to be the most beautiful. The British botanist John Ray may have been the first to describe it from a dried specimen and second-hand information when he wrote in 1704 about an "orchid africana flore singulari herbaceo." In 1763 the Swedish botanist Petrus Jonas Bergius gave *Disa uniflora* its name and illustrated it in his book *Descriptiones Plantarum ex Capite Bonae Spei*. Somehow the species was given another name, *Disa grandiflora*, in 1781. Despite being a synonym this name became widely accepted; it is still being used by some who claim that it is justified by the fact that *D. grandiflora* has larger flowers than *D. uniflora* (Haas-von Schmude and Lückel, 1977). For those interested in mass rapid clonal propagation through tissue culture, the nomenclatural morass means that methods developed under either name apply to both.

Clonal Propagation of *Disa uniflora* in Vitro

Despite strict conservation laws in South Africa, *Disa uniflora* is threatened with extinction. Propagation methods were developed as a means of conservation (Haas-von Schmude and Lückel, 1977).

Plant Material. All leaves are removed from young shoots of *Disa* with a scalpel, and the apical meristem is excised along with one or two leaf primordia.

Surface Sterilization. The excised shoot tips are immersed in 0.3% calcium hypochlorite solution (300 mg calcium hypochlorite in 100 ml distilled water) for 15 min and then rinsed three to five times with sterile distilled water.

Culture Vessels. A description is not given in the original paper, but it is reasonable to assume that standard containers can be used.

Culture Conditions. The cultures should be maintained under 12-h illumination (light sources and intensity not described in the original paper) at 20°C. The conditions used in the following method (Van Waes and Geest, 1983) and for orchid tissue culture in general should also be suitable.

Culture Medium. Explants are cultured on "modified [Thomale] GD-medium" (Table Disa-1), but the nature of the modifications is not described. It is possible that the media used in the following procedure (Van Waes and De Geest, 1983; Tables Disa-2 and Disa-3) could be suitable.

Procedure. The explants are placed on the medium and allowed to grow. When approximately 10 plantlets form, they should be divided and moved to new medium. This can be repeated several times.

TABLE DISA-1. **Thomale GD medium (Thomale, 1954) for the culture of *Disa* shoot tips from mature plants (Haas-von Schmude and Lückel, 1977)**[a]

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[b]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks

[a]The authors (Haas-von Schmude and Lückel, 1977) indicate that this medium is a modification without listing the modifications.

[b]Amounts are given in mg unless indicated otherwise.

[c]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made, keep frozen between uses.

[d]This is the salt most commonly listed in current catalogs.

[e]Add chelating agent (item 6a) and iron salt (item 6b) to the same 1 l of distilled water, and stir and/or heat until both are dissolved. The original recipe does not use chelated iron, perhaps because it was not available in 1954.

[f]Add all salts to the same 1 l of distilled water, and stir and/or heat until all are dissolved. Dispense volume indicated per liter of culture medium. The original recipe does not include microelements, but they are desirable.

[g]Add items 1–7 to 800 ml distilled water (item 10), adjust pH to 4.8–5.1, add sugar (items 8 and 9), and adjust volume to 1000 ml with distilled water (item 10). Bring solution to a gentle boil, and add agar (item 11) slowly while stirring. Agar can also be added to the cold solution, which is then brought to a boil and stirred. When agar is completely dissolved, dispense solution into culture vessels and autoclave. Omit agar if preparing liquid medium.

Developmental Sequence. During the original research four small plants form following 6 weeks in culture. This number increased to eight in 10 weeks. After 16 weeks there were 10 plants ranging in size from 10 to 18 mm.

General Comments. The original research included the development of a seed germination method.

Tissue Culture Propagation of *Disa uniflora*

As with the method in the previous section (which was formulated at the Botanical Institute, Justus Liebig University, Germany), a tissue culture propagation procedure for *Disa uniflora* was developed at the National Botanic Garden in Belgium as part of a project that included research on seed germination (Van Waes and De Geest, 1983).

Plant Material. Apices taken from seedlings were cultured during the original research.

Surface Sterilization. Seedlings are already sterile, and surface sterilization is not needed. If apices of shoots taken from mature plants are cultured, the surface sterilization procedure described above (Haas-von Schmude and Lückel, 1977) can be used.

Culture Vessels. Standard containers are suitable.

Culture Conditions. During the original research the cultures were maintained under 14-h photoperiods of 700 to 800 lx [provided in the original research by fluorescent tubes described as "phytor (type LF, 40 W)"] at 24 ± 2°C during the light periods and 18 ± 2°C in the dark.

Culture Media. Apices are first cultured on a medium that contains a cytokinin and an auxin (Table Disa-2). Axillary buds from these explants and plantlets are moved to a second medium that contains only an auxin (Table Disa-3).

Procedure. Place shoot apices on the first medium (Table Disa-2) for approximately 3 months. Move divisions or plantlets from these cultures to the second medium (Table Disa-3). After 3 months subculture plantlets formed in these cultures on the same medium. Allow them to grow for another 3 months, and move them to pots.

Developmental Sequence. First signs of development can be noted after 8 weeks. Buds, shoots, roots, and plantlets develop after that.

General Comments. This method was developed with seedling shoot tips, and there is no information regarding its suitability for explants from mature plants. As is the case with other genera and species, a method for the propagation of seedlings is less desirable than one that can be used to propagate mature plants of existing clones. It is also necessary to point out here that methods published in a language other than English tend to attract more limited attention. At present English is the language of orchid growing, science, and international commerce, and authors would be well advised to use it for their publications.

Diuris

Commonly known as the donkey orchids (because of their ear-like petals), *Diuris* as a genus was first described in 1798 by the British botanist Sir James Edward Smith (1759–1828), a contemporary of Sir Joseph Banks and Sir Stamford Raffles (founder of Singapore). He was also the founder and the first president (in 1788) of the Linnean Society of London. More than 50 *Diuris* species are known at present with about half of them in Western Australia (Hoffman and Brown, 1992).

Micropropagation of *Diuris longifolia*

Although one of the donkey orchids, the common name of *Diuris longifolia* is the purple pansy orchid due to the appearance of its flowers. A micropropagation procedure for this Australian terrestrial orchid was formulated at the Kings Park and Botanical Garden in West Perth, Western Australia (Collins and Dixon, 1992).

Plant Material. Inflorescences with unopened buds were collected "from natural stands in bushlands at Kings Park, Perth, Western Australia." They were wrapped in damp newspaper and stored at 4°C for 1–2 days until used. Sections, 1–1.5 mm thick, containing axillary nodes (Fig. Diuris-1) were excised for culture. "The remainder was sliced into 1–1.5 mm thick disks. Upper parts of the stem were also sectioned, removing the flower buds but retaining the node at the base of the pedicel."

Surface Sterilization. First, the inflorescences should be washed with running water for 15 h (overnight). After that they are surface sterilized for 5–10 min with 1% sodium hypochlorite (20 or 17 ml household bleach containing 5–5.25% or 6% sodium hypochlorite respectively diluted to 100 ml with distilled water) containing 0.05% Tween 80 (www.sigmaaldrich.com; a mild household detergent or baby shampoo may also be suitable) and rinsed for three 5–10-min periods with sterile distilled water. Bleached ends and damaged tissue should be removed following the last wash.

Culture Vessels. Standard glass vessels, 200–250-ml capacity with autoclavable plastic lids or polycarbonate tubes, 3 × 8 cm, 30-ml capacity, containing medium equal to 20% (large vessels) to 30% (smaller ones) of their volume can be used. Other culture vessels can also be used.

Culture Conditions. It is best to maintain cultures under 16-h photoperiods of 40 $\mu E\ m^{-2}$ at culture level provided by Gro Lux lamps (two 4-foot lamps per fixture, 30 cm above the cultures). Temperatures should be 25°C during the light period and 22°C in the dark. Standard culture room conditions will probably also be suitable.

Culture Media. Initial culture of stem disks, immature flower bud sections, and nodes should be on a modification of the Burgeff N3f medium containing 10 µmol BA and designated as Pa 10BA (Table Diuris-1). When subcultured on the same medium PLBs generated from these explants produce shoots. After the leaves reach

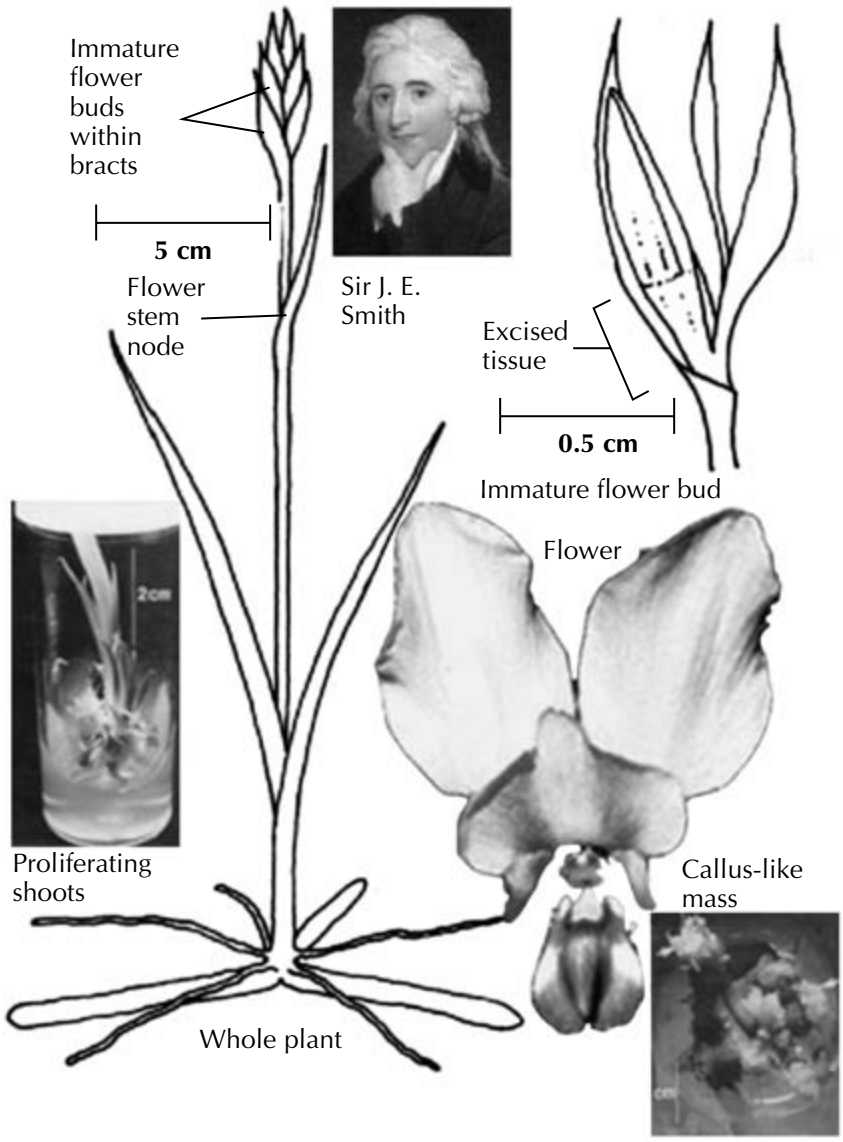

FIG. DIURIS-1. **Micropropagation of *Diuris longifolia* (Collins and Dixon, 1992).**

10–20 cm in length the leaf bearing PLBs should be moved to Pa without BA and containing 30 g sucrose l^{-1}, or 20 g sucrose l^{-1} and 0.05% activated charcoal (AC; Table Diuris-2). A potting mix consisting of "sheoak mulch . . . collected from the bases of *Allocasuarina fraseiana* trees . . . shredded . . . pasterized at 65°C for 90 min [and] mixed 7 parts to 1 part medium-grade Perlite and dampened" was used to culture plantlets.

TABLE DIURIS-1. **Burgef N3f (N3f) medium (Burgeff, 1936) modified for the culture of *Diuris longifolia* explants and protocorm-like bodies (Collins and Dixon, 1992)**

(g)	Zinc sulfate, $ZnSO_4 \cdot 7H_2O$	3.45	345.0 mg l^{-1}		
	Organic acid				
8	Citric acid	90.0	9 g 100 ml^{-1} 70% ethanol[e]	1	Or weigh
	Polyol				
9	*myo*-inositol	100.0	No stock	No stock	Weigh
	Cytokinin				
10	N^6-benzyladenine (BA)	22.52	4.5 g 100 ml^{-1} 70% ethanol[e,f]	0.5	
	Vitamins				
11	Ascorbic acid (vitamin C)	1.0	200 mg 100 ml^{-1} 70% ethanol[e]	0.5	
12	Biotin (vitamin H)	0.1	20 mg 100 ml^{-1} 70% ethanol[e]	0.5	
13	Calcium pantothenate[g]	1.0	200 mg 100 ml^{-1} 70% ethanol[e]	0.5	
14	Niacin (nicotinic acid)	1.0	200 mg 100 ml^{-1} 70% ethanol[e]	0.5	
15	Pyridoxine HCl (vitamin B_6)	1.0	200 mg 100 ml^{-1} 70% ethanol[e]	0.5	
16	Thiamine (vitamin B_1)	1.0	200 mg 100 ml^{-1} 70% ethanol[e]	0.5	
	Complex additive				
17	Coconut water[h]	50.0	No stock	No stock	Measure
	Sugar				
18	Sucrose	20.0 g	No stock	No stock	Weigh
	Solvent				
19	Water, distilled[i]	To 1000 ml			
	Solidifier				
20	Agar[i]	6.0 g	No stock	No stock	Weigh

[a]Amounts are given in mg unless indicated otherwise.

[b]Solutions containing ammonium and/or nitrate can become contaminated on standing. Therefore stock solutions should not be prepared. If made they must be kept frozen between uses.

[c]Add the chelating agent (item 6a) and the iron salt (item 6b) to the same 1 l of distilled water and stir and/or heat until both are dissolved. The original recipe calls for 38.5 mg FeNaEDTA which is essentially the same as the mixture in this table.

[d]Add the salts to the same 1 l of distilled water and stir and heat until all are dissolved. Dispense the volume indicated per liter of culture medium.

[e]Keep frozen between uses. If the citric acid fails to dissolve add a few drops of 0.1 N KOH or NaOH.

[f]If the cytokinin does not dissolve, add a few drops of 0.1 N HCl.

[g]Dissolve in 30 ml glycerol and make up to 100 ml with 95% ethanol. According to the Merk Index this vitamin is not stable to autoclaving and must be added following sterilization. However in this medium it is added prior to autoclaving.

[h]The correct term for the liquid endosperm of coconuts is coconut water, not coconut milk which should be applied to the white milky liquid obtained by grating and/or squeezing copra (the solid part of the endosperm or "meat" inside the nut). It is preferable to use water from unripe (green) nuts. In countries where coconut palms do not grow unripe nuts may be available in stores which specialize in Asian foods. The outer (green) covering of these nuts is often peeled by the store and they are white in appearance. If unripe (green or white) nuts are not available, water from ripe (brown) ones can be used. Water (i.e., the liquid endosperm) of both ripe and unripe nuts should be filtered through a Whatman No. 1 filter before it is added to culture media. Canned or commercially frozen coconut water must not be used because it may contain sugar (which will increase the concentration in the culture medium) and preservatives (that may have undesirable effects on cultures).

[i]Add items 1–17 to 800 ml of distilled water (item 19), adjust pH to 5.6, add sugar (item 18), and raise volume to 1000 ml with distilled water (item 19). Bring the solution to a gentle boil and add the agar (item 20) slowly while stirring. The agar can also be added to the cold water which is brought to a boil and stirred. When the agar is completely dissolved pour the solution into culture vessels and autoclave. Amino acids, hormones, and vitamins may not be heat stable and should generally be added after autoclaving, but this need not be done in this case. All components can be added before autoclaving. Ethanol (up to 5–7 ml or even 10 ml of 95%) can be added to warm orchid culture media without ill effects. In fact 5–7 ml may even be beneficial (Thurston, Spencer and Arditti, unpublished findings dating back to the 1970s).

TABLE DIURIS-2. **Burgef N3f (N3f) medium (Burgeff, 1936) modified for root induction on shoots of *Diuris longifolia* (Collins and Dixon, 1992)**

Item number	Component	Amount per liter of culture medium (final concentration in culture medium), mg[a]	Stock solution (concentrate prepared for repeated and convenient use)	Volume of stock solution per liter of culture medium, ml	Remarks
	Macroelements				
1	Ammonium silfate, $(NH_4)_2SO_4$[b]	250.0	25.0 g l^{-1}	10
