Contents

Foreword

The following pages are an attempt to update a situation with regard to the composition of tobacco and tobacco smoke that has existed for almost five decades. Although it is suspected that the chemical components of tobacco and tobacco smoke may have been cataloged in-house at various U.S. and foreign tobacco companies as well as by various governmental agencies, no such catalog has been published since the 1968 review by the highly competent tobacco scientist R.L. Stedman of the U.S. Department of Agriculture (3797). One article published by a tobacco company prior to that of Stedman was a 1963 referenced monograph on tobacco and tobacco smoke components by Philip Morris, Inc. (2939). Its monograph was submitted to the 1964 Advisory Committee for use in preparation of its 1964 report to the U.S. Surgeon General. The Philip Morris monograph had been preceded by the 1959 published review by Johnstone and Plimmer (1971). In subsequent years, several tobacco and tobacco smoke publications dealt with specific types or classes of components, e.g., the 1964 compilation of the polycyclic aromatic hydrocarbons (PAHs) in tobacco smoke by Elmenhorst and Reckzeh (1139), the 1969 review by Neurath on the nitrogen-containing components identified in tobacco smoke (2724), and the 1977 review by Schmeltz and Hoffmann on the nitrogen-containing components in both tobacco and tobacco smoke (3491). Several catalogs of the chemical components of only tobacco smoke have been published, e.g., the 1954 article by Kosak (2170), but the most recent one was that of Ishiguro and Sugawara (1884) in 1980. Since the 1968 Stedman article in which about 1200 tobacco and smoke components were listed, the number of identified tobacco and tobacco smoke components has increased sevenfold to almost 8600, a number that includes only about 500 of the many thousands of enzymes identified in the tobacco plant.

The references cited for a particular tobacco and/or tobacco smoke component may deal with its identification or with a variety of topics pertinent to the particular component. Such topics may include such simple items as the isolation and identification of a component, its characterization by classical chemical means such as the definition of the structure of solanesol isolated from flue-cured tobacco by Rowland et al. (3359), or the characterization of a component by spectrographic means such as UV, IR, NMR, MS, and chromatographic retention time, e.g., the identification by Snook et al. of many PAHs (3756–3758) and aza-arenes (3750) in cigarette mainstream smoke (MSS). Many references cited herein describe the search for and elucidation of the precursor in tobacco of a particular component in cigarette MSS (3616), e.g., the saturated aliphatic hydrocarbon precursors of the PAHs, including benzo[*a*]pyrene (B[*a*]P); the quantitation of the component on a per gram of tobacco basis or on its per cigarette MSS yield, particularly if the component is considered a health problem; and the improvements/developments in analytical technology to determine the per cigarette MSS and/or sidestream smoke (SSS) yield of the component. Also included in citations for a particular MSS, SSS, and environmental tobacco smoke (ETS) component are the publications of results of experimental studies on its biological activity plus discussions and/or assertions of its toxicity and/or tumorigenicity. While their number is much fewer than the opposite point of view, included are references to studies on the inhibition of adverse biological activity of a tobacco smoke component by another smoke component, e.g., the inhibition of mouse-skin tumorigenicity of B[*a*]P by *n*-hentriacontane and *n*-pentatriacontane (4314, 4336), the inhibition of *N*-nitrosodimethylamine (NDMA) mutagenicity by nicotine (2327a, 2327b), the inhibition of mouse-skin tumorigenicity of dibenz[*a,h*]anthracene (DB[*a,h*]A) by benz[*a*]anthracene (B[*a*]A) (3814), both classified as significant tobacco smoke tumorigens. Also cited are reports on the controversies over the extrapolation of the biological effect of a specific component administered individually vs. its biological effect when it is the component in a highly complex mixture such as MSS and is administered to a different species, by a different route, and at a dose level far in excess of its level in the complex mixture (1318a, 3300, 3627). Lastly, many studies are cited in which cigarette design technologies were generated to control the per cigarette MSS yield of FTC "tar" and one or more specific components of concern, e.g., reconstituted tobacco sheet, expanded tobacco, ventilated filters, filter-tip, and cigarette paper additives.

While some of the citations may seem obscure to a reader newly involved in tobacco and/or smoke research, they are included to elucidate the historical background and relationship to more recent studies, e.g., publications pertinent to 2-methyl-1,3-butadiene (isoprene), a fairly plentiful component of the vapor phase cigarette smoke. The publications include the 1913 report by Staudinger et al. (25A68) that pyrolysis of isoprene yielded a "tar." In 1918, the procedure to successfully generate tumors by animal skin painting was described (4361). Five years later, Kennaway (2073–2076) demonstrated the tumorigenicity of the pyrolysate "tar" from isoprene, and much later, Badger et al. (143) recorded the PAH content of an isoprene pyrolysate. Another example includes a series of references to the research results reported by Roffo that a tobacco "destructive distillate" was tumorigenic (3322, 3325), contained B[*a*]P (3316), and the B[*a*]P content and tumorigenicity of the "destructive distillate" were reduced by organic-solvent extraction of the tobacco prior to destructive distillation (3327).

Our goal was to present to the reader as many pertinent references that we could find for a particular component and permit the reader to decide which references to study. For some components, dozens of references are available, for other components only one or two. The multireferenced components are usually those considered to be involved in the health problems connected to tobacco smoking. Since the publication of the first edition of this book in late 2008, we have added to our Alphabetical Component Index and the appropriate major chapter tables nearly a thousand reported components of tobacco and/or tobacco smoke. References pertinent to these newly cataloged components and the earlier reported ones have been included in the Bibliography and in the appropriate major chapter tables devoted to functionality.

We express our deep appreciation to several scientific staff members of the Verband der Cigaretten-Industrie and the Beiträge zur Tabakforschung International. They reviewed the initial chapter of the draft of the first edition of our opus and made many meaningful suggestions and pointed out the need for several corrections. Most of their input was applied to that chapter and eventually extended to subsequent chapters as we wrote them. One needed correction that was described was a problem with the electronic address for a specific reference. It was found to be inaccessible at the time of the review. That was corrected, since the reference had multiple electronic addresses, the inaccessible one was replaced with an accessible and operative one. However, the finding triggered an examination of all the electronic addresses cited in the Bibliography section. Of the nearly 900 such addresses, three more were found to be inaccessible. Fortunately, each was part of a reference with multiple electronic addresses, and the inaccessible address for each was replaced with an accessible one.

We apologize to the reader for the omission not only of any tobacco or tobacco smoke component from the catalog but also any significant reference by one or more competent investigators who provided information pertinent to one or more specific components.

Acknowledgments

During the many years that this tobacco and tobacco smoke component catalog was being prepared, numerous components were discussed with colleagues, many of whom were involved either in tobacco and/or tobacco smoke research within the tobacco industry or outside of it. Much meaningful information was obtained during the many discussions, and such information has been incorporated into our effort. We greatly appreciate the input not only from those colleagues who are still with us but also from those who are not.

In the first group, we are extremely grateful to Fred W. Best, Michael F. Borgerding, N.M. Chopra, Christopher R.E. Coggins, William M. Coleman III, Lawrence C. Cook, James T. Dobbins Jr., Michael F. Dube, Curt R. Enzell, Charles R. Green, Paul Kotin, Brian M. Lawrence, Chin K. Lee, John C. Leffingwell, Robert A. Lloyd, Jr., William C. Luffman, Dwo Lynm, C.D. McGee, Alan B. Norman, Charles W. Nystrom, Michael W. Ogden, John H. Reynolds IV, Charles H. Risner, Charles E. Rix, Joseph N. Schumacher, Stephen B. Sears, Jeffery I. Seeman, Carr J. Smith, Thomas W. Stamey, Jr., David E. Townsend, and Jack L. White.

In the second group, we are grateful for the contributions of the following late colleagues: J. Gilbert Ashburn, Richard R. Baker, Stuart A. Bellin, Herbert R. Bentley, Edward Bernasek, Robert H. Cundiff, Dietrich Hoffmann, Wilbur R. Franks, James D. Fredrickson, Jesse A. Giles, Kurt Grob, Robert A. Heckman, Charles H. Keith, Philip H. Latimer, Jr., Anders H. Laurene, Jerry W. Lawson, Larry A. Lyerly, John G. Mason, Marjorie P. Newell, Thomas S. Osdene, Donald L. Roberts, Ralph L. Rowland, Murray Senkus, Alex W. Spears, William A. Rohde, Fredrick A. Thome, George P. Touey, John J. Whalen, George F Wright, Ernst L. Wynder, and George W. Young.

We also wish to express our gratitude to those who, over the years, have provided us with much information on scientific publications and presentations. They include Charles W. Nystrom, Nell W. Sizemore, and the late Frank G. Colby, William W. Menz, and John J. Whalen. Particularly meaningful over the past decade has been the information provided by the extremely diligent Helen S. Chung of the R.J. Reynolds R&D Scientific Information Division.

One of us (T.A.P.) wishes to especially thank Patricia F. Perfetti for the encouragement and faith she has showed me as my wife, best friend, faithful colleague, and my partner in many happy and productive years of scientific research.

Authors

Alan Rodgman, MA, PhD, MCIC: Most of the original text of the following biography was written in 2003 for Alan Rodgman's nomination for the Tobacco Science Research Conference Lifetime Achievement Award. He was recipient of the 2003 award. In several places, the nominator's paragraphs have been slightly modified to include additional, more recent information plus a more recent picture than the 2003 one has been provided. The author of the 2003 nomination wrote:

> For here we are not afraid to follow truth wherever it may lead, nor to tolerate any error so long as reason is left free to combat it.
>
> **Thomas Jefferson, 1820**

The words penned long ago by Jefferson epitomize the life and professional career of Alan Rodgman.

For one year short of a half century, Dr. Rodgman has been at the forefront of tobacco science. His increasingly rare combination of keen scientific intellect, unceasing productivity, sense of tobacco science history, and unfailing attention to clear, concise, timely communication make him an ideal choice for the Tobacco Science Research Conference's (TSRC's) Lifetime Achievement Award. Not only has Alan Rodgman made his own prodigious, personal scientific contributions to tobacco and smoke chemistry and their related toxicology, but his mentoring of associates and many other tobacco scientists have allowed him to amplify his contributions far beyond those capable of any one man. Dr. Rodgman's professional "family tree" reads as a "Who's Who" in tobacco science.

Alan Rodgman was born in 1924 in Aberdare, Glamorgan County, Wales, to Arch and Margaret Llewellyn Rodgman. The family moved to Toronto, Ontario, Canada, in 1928. There he was educated at the grade and collegiate level. Because of the early death of his father when Rodgman was ten years old, he worked after school and on Saturdays at the children's and adult department of a local branch of the Toronto Public Library from 1937 to 1942. In 1945, Alan Rodgman entered the University of Toronto as recipient of the two highest mathematics, physics, and chemistry scholarships awarded in competition in 1942. Because of a University of Toronto rule on retaining no more than two competitive scholarships, a third chemistry and physics scholarship awarded to Rodgman reverted to the next highest candidate. The three-year period between earning the scholarships and their implementation was spent on active duty as a volunteer in the Royal Canadian Navy during World War II, with service on the North Atlantic Ocean.

Between 1945 and 1949, at the University of Toronto, Rodgman was awarded eight additional scholarships—one in mathematics, physics, and chemistry in 1946 and seven in chemistry in 1947, 1948, and 1949. His bachelor's thesis on *N*-nitrosamines in 1949, master's thesis on kinetics of the original Diels–Alder reaction in 1951, and doctoral thesis on oxymercuration–deoxymercuration in 1953 were conducted with Dr. George F. Wright* as his advisor. Rodgman taught the laboratory aspect of analytical chemistry during the first year of his master's period. His master's and doctoral research formed part of 11 publications coauthored between 1952 and 1959 with Dr. Wright who, by the way, from 1954 to 1959, preceded Dr. Dietrich Hoffmann as Dr. Ernst L. Wynder's tobacco smoke chemistry colleague.

Rodgman married Doris Curley in June 1947. They have three sons (Eric, Paul, and Mark), three daughters-in-law (Melody, Ella, and Sara), and seven grandchildren.

While pursuing his chemistry degrees, Rodgman conducted carcinogenesis and anticarcinogenesis research from 1947 to 1953 during summers, winter evenings, and weekends with Dr. Wilbur R. Franks, cancer research professor at the Banting and Best Department of Medical Research, University of Toronto. He conducted such research full-time to mid-1954 after receiving his doctorate in June 1953. Rodgman's first three scientific publications (on anticarcinogenesis) in 1947 and 1948 preceded the receipt of his bachelor's degree in chemistry in 1949. From 1951 to mid-1954, he also taught organic and physical chemistry plus mathematics for physical chemistry in evening courses sponsored by the Chemical Institute of Canada.

In mid-1954, Rodgman joined the Research Department of the R.J. Reynolds Tobacco Company as a senior research chemist. In October 1954, he initiated its program on cigarette smoke composition, personally conducting the laboratory research until 1967 and actively directing it and environmental tobacco smoke studies thereafter until 1987. Following successive promotions from senior research chemist to section head to division manager, he became director of research in 1976, and after an R&D reorganization in

* The lack of a period after Dr. Wright's middle initial is not a typographical error.

1980, he was appointed director of fundamental research. Rodgman became an American citizen in 1961.

After more than 60 years, Rodgman is still a member of the American Chemical Society and the Chemical Institute of Canada. Until 2006, he had been a member of the New York Academy of Sciences for over 40 years and also a member of Sigma Xi. He served on the editorial board of *Tobacco Science* as member and vice chairman (1963–1967); on the editorial board of *Beiträge zur Tabakforschung International* (1976–1987); on the Industry Technical Committee, Council for Tobacco Research (1955–1960); on the CORESTA Scientific Commission (1982–1985); and on several U.S. government committees, e.g., the Tobacco Working Group of the National Cancer Institute's Smoking and Health Program on the Less Hazardous Cigarette (1976–1977) and the U.S. Technical Study Group of the Cigarette Safety Act of 1984 (1984–1987). From 1960 to 1987, Rodgman served on numerous Tobacco Chemists' Research Conference (TCRC) committees. In 1972, he was involved in various aspects of the joint CORESTA/TCRC Conference in Williamsburg, Virginia. In 1976, he persuaded his company's management to continue its CORESTA membership. In the early 1980s, when a host site for the 1982 CORESTA Symposium did not materialize, Rodgman was instrumental in arranging for his company to sponsor the symposium in Winston-Salem, North Carolina. He served as its vice chairman.

Rodgman was the chairman for the 38th TCRC symposium entitled "Design of Low-'Tar' Cigarettes" held in 1984. On the occasion of TCRC's 50th conference in 1996, he coauthored with Charles R. Green a comprehensive review and presentation entitled "The Tobacco Chemists' Research Conference: A Half Century Forum for Advances in Analytical Methodology of Tobacco and Its Products." The following year at the 51st conference, he prepared a symposium paper and presentation on "FTC 'tar' and nicotine in cigarette mainstream smoke: A retrospective." In addition, Dr. Rodgman has presented many other original research papers at the conference.

In the journal *Tobacco Science*, he has published 13 scientific papers on tobacco smoke composition. Additionally, the 1986 volume of *Tobacco Science* was dedicated to Dr. Rodgman to honor his prolific career. In addition to serving as a reviewer for manuscripts submitted to *Tobacco Science* and *Beiträge zur Tabakforschung International*, Rodgman has served as a reviewer not only for manuscripts submitted to several other journals including *Recent Advances in Tobacco Science*, *Journal of Analytical and Applied Pyrolysis*, *Food and Chemical Toxicology*, and the *Journal of Organic Chemistry* but also for the page proofs of several well-known books on tobacco-related topics.

From 1954 to retirement and from retirement to 2004, Rodgman was involved in consulting activities on the scientific aspects of litigation against R.J. Reynolds Tobacco Company. Over 13,000 pages of his contributions are available at http://tobaccodocuments.org/bliley_rjr/list. Many of the more recent contributions were the consequence of the "Master Settlement" between the states and tobacco companies. Additionally, he has been a major contributor to the scientific content of *Beiträge zur Tabakforschung International*, both through submitted papers and as a volunteer editor. Dr. Rodgman has mined the wealth of documents previously considered proprietary to clarify the intent and content of tobacco and smoke research conducted by himself, his colleagues, and other scientists. The papers authored/coauthored by Rodgman during the last two decades include publications on environmental tobacco smoke (3255a); FTC "tar" and nicotine in cigarette mainstream smoke (3258); tobacco smoke components (3260); polycyclic aromatic hydrocarbons (3262, 3306a, 3306b, 5077); phenols (3712); "smoke pH" (3261); "IARC Group 2A carcinogens" (3713) and "IARC Group 2B carcinogens" (3714) reported in cigarette mainstream smoke; the effects of additives on cigarette mainstream smoke properties (3263, 3264, 3266); the problems with lists of tumorigens (3265, 3300, 5557); various tobacco substitutes (1375a); and the effect of expansion of tobacco on cigarette mainstream smoke properties (1375b).

At the 2002 CORESTA Congress held in New Orleans, Dr. Rodgman coauthored with Charles R. Green an invited speaker symposium paper entitled "Toxic chemicals in cigarette mainstream smoke—Hazard or hoopla." In this paper, the authors critically examined the proper listing and prioritizing of toxic chemicals in cigarette mainstream smoke. Moreover, the authors pointed to a number of disconcerting chemical and biological limitations in existing knowledge, which calls into question the veracity of such listed strategies for their oft-stated purposes. This example is included in Alan Rodgman's nomination to illustrate his lifelong pursuit of the truth.

In summary, there is no question that Alan Rodgman has dedicated his professional life to the achievement of the highest standards for tobacco science. Even with this nomination and the accompanying materials, it is impossible to convey to an outsider the tremendous impact that this person has made to our knowledge of tobacco and its smoke. Although his own personal scientific accomplishments are by themselves worthy of TSRC's Lifetime Achievement Award, the amplification of his life's work through influence on many other tobacco scientists is difficult to quantify. Beyond his many professional achievements is a man who is widely respected and personally liked both within and outside the tobacco science community.

Because his philosophy on publication authorship differed substantially from that of many academic, government agency, and health organization investigators, Rodgman did not insert his name as coauthor on the many articles on tobacco and smoke composition presented at conferences and/or published in peer-reviewed journals by his staff members. If he had done what many supervisors do, his list of publications between 1960 and 1987 would be increased by almost 200. However, his contributions to many of the studies are described in the Acknowledgment section of many of his staff/colleagues' publications.

Thomas Albert Perfetti, PhD was born in 1952 in Jeannette, Pennsylvania, the second son of Ruth Peters and Bruno Massimo Perfetti. He was one of five children. Perfetti received his elementary education in several schools in the Pittsburgh area. In 1970, he entered Indiana University of Pennsylvania (IUP). He earned a bachelor of science degree in chemistry in 1974. During his stay at IUP, he conducted cell transport research with Dr. Richard Hartline and synthesized numerous radiopharmaceuticals. Perfetti's first publication was on the preferential uptake of *d*-α-amino adipate by *Alcaligens denitrificans* in 1975.

In 1974, he entered the Virginia Polytechnic Institute and State University (VPI-SU), Blacksburg, Virginia. His doctoral thesis (1977), under Dr. Michael Ogliaruso, was on the electronic effects associated with the Woodward–Hoffman Rules. While pursuing his doctoral degree in physical organic chemistry, Perfetti worked as a research fellow for NASA, taught at organic chemistry labs, and tutored undergraduates. In 1976, Perfetti won the President's Award for Distinguished Teaching at VPI-SU.

Perfetti married Patricia Ann Finley, who graduated with him from the Chemistry Department at IUP, in 1975. They have two sons, Michael and David. The family now resides in Winston-Salem, North Carolina.

In late 1977, Dr. Perfetti joined the R.J. Reynolds Research Company (RJRT) as a research chemist. There, he initiated several research programs on tobacco and smoke chemistry, cigarette design, sensory science, flavor chemistry, and analytical method development. Perfetti was promoted from senior research chemist (1979), to senior staff scientist (1984), then to master scientist (1986), and finally to principal scientist (1991). He is a recognized expert in the areas of nicotine and menthol chemistry and in the area of innovation. As principal scientist, he worked with R.J. Reynolds-Nabisco and R.J. Reynolds International on corporate program development and program management issues. He also acted as a liaison on patent acquisitions, patent applications, and consulting activities on the scientific aspects of litigation against RJRT. Much of his career was spent in the laboratory, although he served as the manager of several divisions. Dr. Perfetti retired from RJRT in 2003. In that same year, he and his wife started Perfetti & Perfetti, LLC, a scientific consulting firm in Winston-Salem, North Carolina. Their company has done quite well with numerous national and international clients.

Perfetti has served as a reviewer for *Tobacco Science,* the *Journal of Food and Chemical Toxicology*, and *Beiträge zur Tabakforschung International*. He served on several Tobacco Chemists' Research Conference committees and contributed to two of its symposia (1987, 1993), one of which he chaired (1993).

Perfetti is a member of the American Chemical Society (ACS). He has served as assistant historian to the Division of the History of Chemistry. He is a member and fellow of the American Institute of Chemists and is a certified professional chemist. He was a cofounder and past president of the North Carolina Chromatography Discussion Group and former chairman of the Education Committee of the Central North Carolina Section of the ACS. Dr. Perfetti has been cited in *Who's Who in America*, *Who's Who in Science and Technology*, in the *International Directory of Distinguished Leadership*, and *Who's Who in American Leaders in America*. In 1993, Dr. Perfetti was presented with the Distinguished Alumni Award, Indiana University of Pennsylvania. In 1995, he and several other RJRT scientists were given the George Land World-Class Innovator Award for outstanding work in instilling the principles of innovation at RJRT Research and Development.

Over the last 32 years, Perfetti has made over 60 presentations and published numerous papers in peer-reviewed journal in the areas of biochemistry, tobacco and smoke chemistry, sensory perception, mathematics, and innovation. During his career at RJRT, he prepared more than 250 formal company research reports. He has written chapters for two books and has developed and presented five courses in the areas of cigarette design and innovation. Dr. Perfetti has 38 U.S. patents and hundreds of foreign patents.

Introduction

> History balances the frustration of how far we have to go with the satisfaction of how far we have come. It teaches us tolerance for the human shortcomings and imperfections which are not uniquely of our generation, but of all time.
>
> **Lewis F. Powell, Jr. Associate Justice of the Supreme Court of the United States (1972–1987)**

INTENT OF THE WORK

Years from now, just as we were surprised how paltry was the number of identified tobacco smoke components cataloged in 1954 by Kosak (2170), others will no doubt have similar remarks concerning this catalog. We hope the reader will be satisfied rather than frustrated with the progress that has been made by tobacco scientists over the last 50+ years in furthering our knowledge base of components identified in tobacco and tobacco smoke. It should be noted the last published detailed catalog of tobacco and tobacco smoke components was that of Stedman (3797) in 1968.

CHEMICAL COMPOSITION OF TOBACCO

The Master Catalog, collected over a 50-year period, is our tabulation of all the information on the components identified in tobacco and smoke. The Master Catalog contains all of the information on components in tobacco and tobacco smoke that is contained in each chapter of this book as well as the information in the Bibliography and Alphabetical Component Index sections of this book. During the creation of this book, the information contained in the Master Catalog was searched to extract all of the components by functional group (alcohols, esters, aldehydes, etc.) to be included in the separate tables for each chapter of this book. The Bibliography was separated from the Master Catalog as a separate section of this book. An Alphabetical Components Index was created as a ready resource for readers to access particular information on each component and to locate the chapters and tables in the book chapters where that class of components is discussed. The original Master Catalog that we developed as such is not part of this book but was subdivided into numerous tables of components identified in tobacco and tobacco smoke by chemical functionality, the Bibliography, and the Alphabetical Components Index. This edition of our book catalogs nearly a thousand more tobacco and/or tobacco smoke components than were listed in the First Edition. Also, nearly a thousand more references pertinent to the newly reported components and to the previously reported ones are listed in the Bibliography.

The following, discussed in detail in Chapter 28, is a summary of the overall change in the number of components in our Index during the past 4 years, from 2008 to date:

Index Date	Tobacco Smoke	Tobacco	Tobacco and Tobacco Smoke	Subtotal	Smoke Isomers	Total
2012	6010	5595	2215	9390	192	9582
2008	5315	4994	1879	8430	192	8622

Tobacco is a fascinating organism. This plant, as all plants do, takes the simplest of molecules (carbon dioxide, nitrogen, and water), light, and a series of metals (as micronutrients) and through a sophisticated internal process converts these materials to complex molecules for plant growth regulation and maintenance. Tobacco has been called a chemical factory. It has been cultivated for the purpose of collecting nicotine for use as an insecticide and for starting material for numerous commercial chemicals such as the pyridines. More recently, it has been studied as a source of plant protein [Fraction 1 (F-1) and Fraction 2 (F-2) protein] (3974c). There are many different botanical classifications for tobacco plants. The genus *Nicotiana* has over 60 known species; each has been examined as to its genetic, physiological, botanical, and chemical characteristics (3972, 3973). Two tobacco species are grown commercially: *Nicotiana rustica* primarily for nicotine and solanesol collection; *Nicotiana tabacum* for use as in cigarette, pipe, cigar, snuff, and chewing tobaccos.

To date, nearly 5700 components have been identified in tobacco. The total appears at the end of the Alphabetical Components Index and represents an increase of more than 700 over the 4994 listed in the earlier version of our catalog [see p. 1784 in (5078)]. This number does not include the nontobacco components listed as added flavorants by Doull et al. (1053) and Baker and Bishop (172a) or the hundreds of enzyme and other proteinaceous components listed in our Master Catalog. This is a tremendous achievement compared to the number of tobacco components reported as 3044 in 1988 by Roberts (3215), reported as 2549 tobacco compounds in 1982 by Dube and Green (1067), the 200 identified compounds reported in 1960 (2338), the 199 organic compounds and 21 inorganic elements reported as identified in tobacco in 1959 (1971), and the accounting of less than 10 tobacco constituents by Frankenburg (1221) in 1946. It should be noted that in the classification by Frankenburg, the tobacco constituents listed were not individual compounds but classes of compounds such as alkaloids, proteins (soluble and insoluble fractions), nitrate-nitrogen, and amino nitrogen. It is estimated that literally tens of thousands of unidentified compounds are yet to be discovered in tobacco. This estimate is based upon

the assumptions that there has already been thousands of organic, inorganic, and organometallic compounds identified in tobacco, that each plant contains hundreds of extremely complex compounds, e.g., various types of DNA and RNA, numerous types of complex enzymes, proteins, sugar, and amino acid oligomers, needed for plant growth, regulation, and maintenance, and that numerous fragments of these complex molecules have already been reported in tobacco.

If it were not for scientists' curiosity and the tremendous advances in analytical chemistry over the last 50–60 years, the need for this revised version of our 2008 catalog of compounds in tobacco and tobacco smoke would not be critical. Over the last 50–60 years, literally tens of thousands of scientific articles on varied topics in tobacco and tobacco smoke science have been written. Our understanding of these two areas of science has advanced tremendously in the recent past. As noted by Knipling [see Preface in Tso (3974c)],

> Pioneering tobacco research was the foundation of plant science at the dawn of modern development, in such areas as light, nutrition, genetics, growth control, disorders and metabolism. Tobacco research led to current advancements in plant biotechnology. In addition, tobacco plant research contributed significantly to public health research in radioactive elements, mycotoxins, and air pollutants. However, public support for tobacco research has today greatly declined to almost total elimination because of a sense of political correctness … tobacco is one of the most valuable research tools, and is a most abundant source of scientific information. Research with tobacco plants will contribute far beyond the frontiers of agricultural science: tobacco can be a source of food supply with nutrition value similar to that of milk; tobacco can be a source of health supplies including medical chemicals and various vaccines; tobacco can be a source of biofuel. All we need is to treat tobacco with respect; the use of tobacco is only in its initial stages.

For over 50 years, our Master Catalog of components identified in tobacco and smoke has been in the process of assembly. Each component has one or more corresponding references. The tobacco literature was diligently searched for components identified in tobacco and tobacco smoke. As new components in tobacco and tobacco smoke were reported by R.J. Reynolds Tobacco (RJRT) Co. R&D personnel and in the published scientific literature, they were entered into the Master Catalog. Data on components in mainstream smoke (MSS), sidestream smoke (SSS), and environmental tobacco smoke (ETS) were collected from studies on the smokes from a variety of tobacco types and blends and numerous forms of smoking articles, e.g., cigarettes, cigars, cigarillos, pipes. Data on tobacco components were collected from studies on numerous species of *Nicotiana* (primarily *N. tabacum*). The tobacco component data were collected from studies not only on all stages of plant development (seed to harvested plant) but also from tobacco processed in various ways (aged, fermented [various degrees], steamed, cut, rolled, expanded, converted to reconstituted sheet [by various methods], treated with additives) prior to use as a smoking material.

The Master Catalog contains an enormous variety of species from nearly every class of chemical components. We have separated and combined the identified components in tobacco and tobacco smoke into classes of components, e.g., hydrocarbons, alcohols, acids, esters, aza-arenes, and each class will be discussed in a separate chapter. For the reader's information, tobacco and tobacco smoke components possessing multifunctional groups will appear in each of the appropriate chapter lists but will be only tallied once as a tobacco component and/or a tobacco smoke component. For example, 2-furancarboxylic acid (2-furoic acid) is listed in the carboxylic acid chapter and the ether chapter; 4-hydroxy-3-methoxybenzaldehyde (vanillin) is listed in each of the aldehyde, ether, and phenol chapters. Also as an amendment to the First Edition of our catalog where multifunctional components were inserted into several major chapter tables, in this edition, the multifunctional components are listed in the Index as being cited in all the major chapter tables where they occur.

The Master Catalog and the chapters on the various classes of tobacco components do contain some items not identified as tobacco components per se. They include items that (1) are not identified components of untreated tobacco and/or its smoke but are individual compounds added to the tobacco in a flavor formulation to improve consumer acceptability of commercial products,* (2) are the pesticides, herbicides, nematicides, growth control agents, etc. (or their residues), that improve the agronomic situation for tobacco cultivation or have been found on tobacco, (3) are mycotoxic products of microorganisms found on tobacco plants, e.g., aflatoxins, and (4) thermal degradation products from (1), (2), and (3) found in tobacco smoke. Many of the components in (1) were identified as added tobacco ingredients in the reports by Doull et al. (1053), Baker and Bishop (172a), and Baker et al. (174b). Many of the components in (2) are retained in the tobacco after harvesting and curing, are transferred intact to the smoke, and in some cases, are degraded to compounds not usually expected in tobacco smoke. As noted previously, the items in (1) and (3) were not included in the 4200 identified tobacco components discussed earlier. As noted previously, the items in (1) and (3) were not included in the 4200 identified tobacco components discussed earlier. Also not included in our Master Catalog are the additives comprising mixtures from naturally occurring products, e.g., alfalfa extract, basil oil, honey. These will be discussed in the chapter on tobacco additives.

During the 1920s and 1930s, plant nutrition was an active area of research and tobacco served as the model in much of that work. The results of research on nitrogen assimilation,

* Among the flavor formulation compounds listed as tobacco ingredients by Baker and Bishop (172a), Baker et al. (174b), and Doull et al. (1053) was a substantial number of compounds reported as identified components of additive-free tobacco and/or its smoke [see Tables 1, 5, and 7A in (3266)]. That number was increased recently because of the identification of several additional listed flavor formulation compounds in flue-cured tobacco by Peng et al. (2917a) and in Perique tobacco by Leffingwell and Alford (2339a).

light as a factor in nitrogen fixation, and how weather contributed to nutrient uptake contributed greatly to our understanding of plant science. All these advancements seem trivial today in light of the sophisticated work in genomics but were nonetheless initially due to the pioneering work of scientists working with tobacco (3972, 3973).

The presence of some microelements in tobacco was reported as early as 1921. Today, nearly all of the common elements including alkali, alkali earth, heavy metal, and rare elements have been reported to be present in tobacco, e.g., Al, As, Ba, B, Cs, Cr, Co, Cu, F, Au, I, Pb, Li, Mg, Mn, Hg, Mo, Ni, Pt, Po, Ra, Rb, Se, Si, Ag, Sr, S, Ta, Ti, Sn, U, V, and Zn. Many heavy metal radioactive components have been reported in tobacco including those from the uranium series, e.g., ^{234}U, ^{226}Ra, ^{228}Ra, ^{222}Rn, ^{210}Po, and others, e.g., ^{38}Cl, ^{46}Sc, ^{134}Ce, ^{59}Fe, ^{40}K. The presence of such elements in tobacco may be accidental, acquired from soil or from other sources. Scientists curious to understand the role of these assorted elements conducted research studies from the 1920s in order to understand the role of each element in plant growth and development. The effect of boron on plant growth was first noted in 1929, zinc in 1942, and copper in 1942. The concept of metals as catalysts in plant growth advanced the areas of chemical catalysis and its use in industrial fermentation (3972, 3973). The transfer of elements, particularly some of the metallic ones noted earlier, from tobacco to its smoke has been studied since the mid-1950s, e.g., Cogbill and Hobbs (769).

Elemental isotopes have also been used in tobacco research for over 50 years. Studies with single, double, and even triple labeled compounds incorporating ^{15}N, ^{3}H, and ^{14}C were reported by personnel at the U.S. Department of Agriculture (USDA) in the early 1950s in their studies on plant metabolism (3972, 3973).

Tobacco is a very labor-intensive and sensitive crop. Hundreds of agronomic and physical processing steps occur from seed planting to final use in commercial products. The type of tobacco (flue-cured, burley, MD, Oriental) as well as dark air-cured tobacco and various cigar tobaccos and how the tobacco is produced and cured affect the type and level of chemical compounds in tobacco leaf and in smoke. Among the chemicals applied to tobacco are insecticides, acaricides, miticides, nematicides, and growth control agents, e.g., sucker-control and yellowing agents. These were developed to control pests and plant growth, to reduce labor, and ultimately to produce a better, healthier, and more profitable crop. Their number and types are large. Over the years, new chemical agents were developed and commercialized as others were either banned or found to be less effective. Nonetheless, some pesticide residues remain in the soil and are often transported to the plant. All the commercial pesticides (as well as herbicides) are tested thoroughly and can be safely used (822a). As an example, today, the most widely used sucker-control agents are fatty compounds, including fatty acids, alcohols, esters, and some of their derivatives. These sucker-control agents significantly inhibit axillary growth without causing undesirable side effects to the plant or the public (3972, 3973).

The genetic makeup of tobacco includes 25,000–50,000 genes. The gene mapping of tobacco is being conducted in the Plant Pathology Department, North Carolina State University Centennial Campus, College of Agricultural and Life Sciences, Raleigh, NC, in a project known as the Tobacco Genome Initiative (TGI). Its goal is to sequence and catalog more than 90% of the genome of cultivated tobacco, *N. tabacum*. Although tobacco has been cultivated for more than 500 years and is a crop of great economic significance, relatively little information exists on its genome structure and organization.

A complete tobacco gene catalog will provide information needed to investigate the physiological and genetic processes in the plant kingdom, in general, and in *N. tabacum* specifically. Understanding the genetic processes occurring within the tobacco plant could potentially provide valuable information on ways to reduce the harm associated with cigarette smoking and also provide information on agronomic traits associated with disease and pest resistance genes for use in improving traditional and molecular breeding projects aimed at enhancing the performance of tobacco as a crop. The plants within the agriculturally important *Solanaceae* family which includes tobacco, tomato, potato, eggplant, and pepper crop plants will all benefit from gene discovery in *N. tabacum*.

Available for public use are additional databases that contain listings of enzymes, enzymatic pathways, and reaction products of metabolic and catabolic processes occurring in tobacco species. Many of these are listed as references in our chapter catalogs:

Plant scientists have long known that all organic components are dynamic in nature and change in numerous ways when present in biological systems. Chemical, catalytic, enzymatic, and bacteriological processes occur continuously during plant

growth in the field and until these biological processes are quenched at harvest and during processing. Tobacco scientists have extensively studied the metabolism and catabolism occurring in *Nicotiana* plants because the change or formation of each compound may affect its final quality and thus its usability. Organic compounds are formed, transformed, and interact during plant growth in the field, during postharvest handling processes of curing, aging, and fermentation, during manufacturing, including interaction with additives, and during blending (3972, 3973).

The chemical composition of the tobacco determines the chemical composition and yield of components in its tobacco smoke. For example, leaf protein (F-1 and F-2 protein) is abundant in tobacco and turns over and decomposes continuously to produce a vast array of protein subunits, amino acids, and amino acid oligomers (3974c).

Tobacco leaf protein by itself contributes little to smoking quality, but it is a major precursor of hundreds of tobacco smoke components, e.g., numerous nitrogenous compounds, amino acids. Similarly, other major tobacco components such as the carbohydrates, carboxylic acids, pigments, polyphenols, fatty compounds, phytosterols, and many primary or secondary compounds play a significant role in producing a myriad of tobacco smoke compounds (3972, 3973).

Tobacco has been used in one form or another in civilized society for nearly five centuries. Eventually in the late nineteenth century, investigations as to its composition began, but they were not particularly numerous. The major driving force in the escalation in the mid-twentieth century of studies on tobacco composition was the attempt to define (1) its components that contributed to the consumer acceptability of the taste and aroma of tobacco itself and its smoke and (2) the precursors in tobacco of the toxicants in its smoke.

The latter investigations were triggered by the following events: (1) The publication from 1950 to 1953 of the results from several retrospective studies on lung cancer in smokers and nonsmokers [Doll and Hill (1027), Mills and Porter (2556), McConnell et al. (2515), Sadowsky et al. (3375a), Schrek et al. (3529), Wynder and Graham (4306b)]. The results suggested an association between cigarette smoking and cancer of the lung, particularly the lung cancer tumor type defined as squamous cell carcinoma. (2) The 1953 presentation and publication by Wynder et al. (4306a) of their findings on the production of malignant tumors in a susceptible strain of mice skin painted daily with massive doses of solutions of cigarette smoke condensate (CSC) supposedly generated under conditions simulating the human smoking of a cigarette. These statistical and biological findings augmented by the results of additional similar studies led to an escalation in the research to define the composition of cigarette smoke and to determine which of its components were responsible for the observed biological response. When a particular class of components—the polycyclic aromatic hydrocarbons (PAHs)—was considered responsible, studies escalated to define the precursors in tobacco of the PAHs in its smoke.

Previous detailed reports on the composition of tobacco included those issued by Brückner in 1936 (451), Latimer in 1955 (2270), Johnstone and Plimmer in 1959 (1971), Shmuk in 1961 (3657), Stedman in 1968 (3797), Roberts et al. in 1975 (3224), Schmeltz and Hoffmann on nitrogen-containing tobacco components in 1977 (3491), and Enzell et al. on terpenoid-derived tobacco components between 1976 and the late 1980s (1149, 1150, 1156, 4089, 4090). One thing has become apparent since the mid-1950s: No other consumer product that involves a complex mixture has been defined in such detail as tobacco and/or its smoke, e.g., the number of components identified to date in tobacco is almost twice that of the number identified in coffee.

In the last 90 years, tobacco scientists have spent considerable time and effort determining and reporting on the chemical composition of tobacco. One of the first attempts at estimating the mass balance of the major and minor constituents of tobacco was that of Hobbs in 1972 (1665). Hobbs stated the following in his review:

> In order to understand; even approximately, the bearing of the various physicochemical processes on the character of the generated (*smoke*) aerosol it is essential to know in some detail the composition of the tobacco from which the aerosol is produced … It will be recognized that the use of different blending quantities of the several varieties of tobacco, or of different processing methods can markedly influence the quantitative composition of (*tobacco*), … but the differences are likely to be more quantitative than qualitative. (1665)

In his review, Hobbs included a figure illustrating the approximate chemical composition of blended cigarette tobacco. Figure 0.1 is a representation of those same data.

Table 4.1 summarizes the numbers of carboxylic acids and amino acids identified to date in tobacco and tobacco smoke. Their listing and references are presented in subsequent chapter tables (Tables 4.3 and 4.10).

The data that Hobbs used were collected over many years by scientists at Liggett and Myers Tobacco Company. Hobbs' data were subsequently reproduced by Green (1351, 1352b), in tabular form, see Table 0.1. Hobbs' original figure showed the approximate chemical composition of blended cigarette tobacco (at ~12% moisture). The data from Green (1351, 1352b) were calculated on a dry weight basis.

The data in Table 0.1 show three columns. The original data by Hobbs (1665) are in the second column. Hobbs' data included water, humectants, and flavorants on the tobacco. Column three is the same data as in column two, but the data were recalculated to remove water, the added humectants, and the applied flavorants. As can be seen in column three, the carbohydrates (sugars, celluloses, pectic substances, starch, and pentosans) represent nearly 41% of the dry weight of tobacco. Lignin accounts for about 4% of the weight. The tobacco protein and amino acids represent about 10% of the dry tobacco weight. The volatile bases and alkaloids make up about 4% of the tobacco weight. Waxes and resins (the ether extractable portion of tobacco) represent about 10% of the dry tobacco weight. Metals (6%) and inorganic ions (1.8%) make up another 7.8% of the tobacco weight. The phenolics

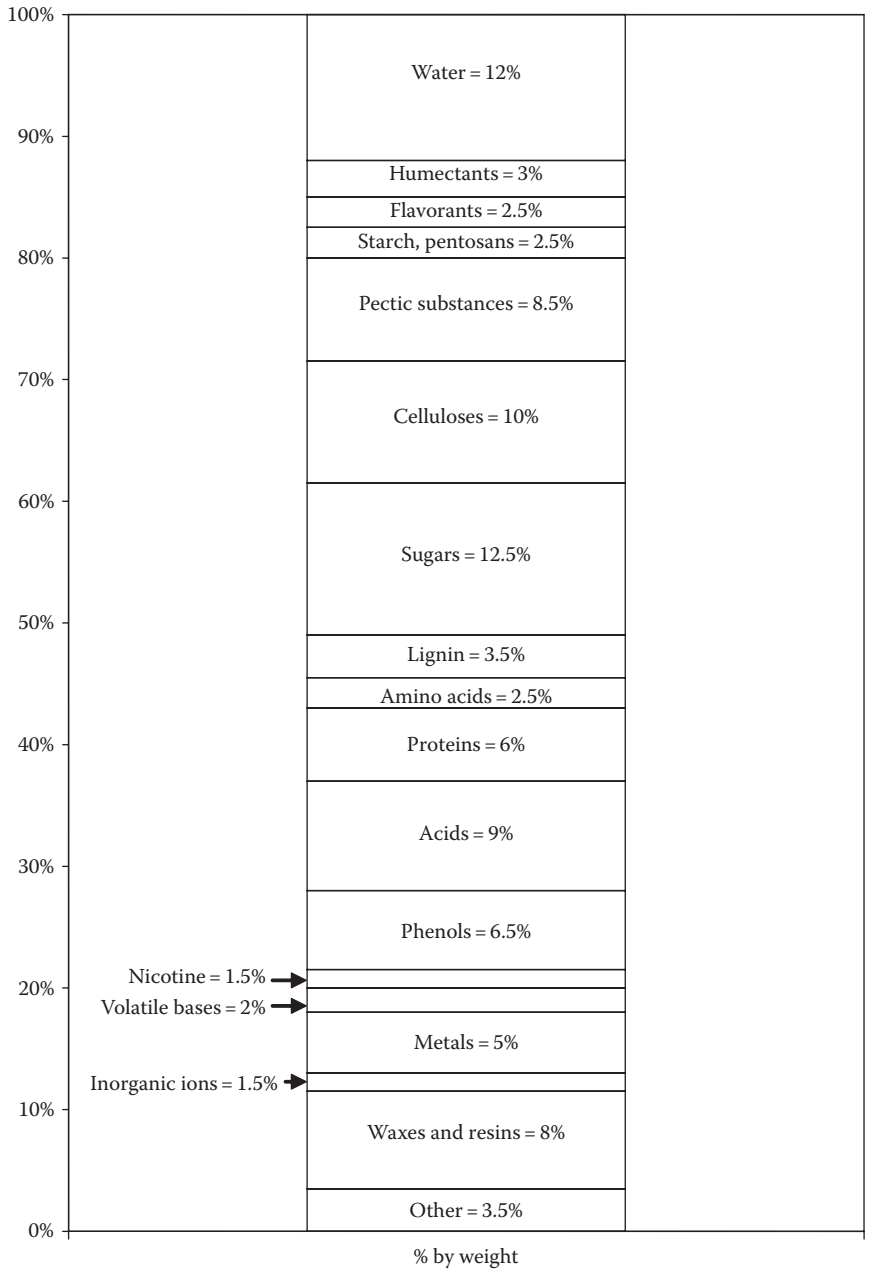

FIGURE 0.1 Approximate chemical composition of blended cigarette tobacco (1665).

and acids represent about 8% and 11% of the dry tobacco weight, respectively. Together, these tobacco constituents account for about 96% of the dry weight of tobacco. Hobbs (1665) added a category called "others" (at about 4%) which accounted for the remaining unaccounted for weight. Much of the "other" category was believed to be composed of dirt, sand, and other intractable materials.

To date, as indicated on the last page of our Alphabetical Component Index, 5596 separate components have been identified in tobacco. Table 0.2 contains three columns of information: the classification of the tobacco component(s), the average concentration of the component(s) in percent (%) dry weight of tobacco, and references to tables in the second edition of this book [Green (1351) and others that support the concentration data]. There are four broad classes of tobacco components in Table 0.2: hydrocarbons, oxygen-containing components, nitrogen-containing components, and miscellaneous components.

It must be noted that the majority of compounds found in tobacco are multifunctional. For example, polyfunctional *O*-containing compounds are counted in each functional group, e.g., propanoic acid, 2-hydroxy- (lactic acid) appears in the alcohol section and the acid section; benzoic acid, 4-hydroxy-3-methoxy- (vanillic acid) appears in the acid section, the phenol section, and the ether section. In Table 0.2, care was taken to count each tobacco isolate in only one of the component categories. Every attempt was made not to duplicate any of the 5596 tobacco compounds identified to date in tobacco. To accomplish this, a method for segregation of compounds, particularly those that were multifunctional,

TABLE 0.1
Approximate Chemical Composition of Blended Cigarette Tobacco (1665, 1351, 1352b)

Component	Wet Weight Blended Cigarette Tobacco, %	Dry Weight Tobacco (Only)[a], %

was used. The hierarchical system chosen for the segregation of the chemicals was patterned after the organization of chemical compounds in Beilstein [Heller (1990)]. That is, compounds without functional groups (i.e., the hydrocarbons) were followed by hydroxyl compounds, oxo compounds, carboxylic acids, amines, etc. As in Beilstein, the concept of parents and derivatives was followed. For example, phenol would be considered a parent. All substituted phenols were grouped with phenol as derivatives. Although, the strict rules used in Beilstein were not always applied, all of the 5596 compounds were accounted for in a logical manner.

The second column of data in Table 0.2 lists the average concentration of tobacco compounds. The values listed were obtained from several sources. Primarily, the concentration data were obtained from the present text, Rodgman and Perfetti (5078), Green (1351, 1352b), Hobbs (1665), various reports from the RJRT Company database (www.rjrtdoc.doc), Demole et al. (937–943), Dickerson et al. (965), Leffingwell (2337–2339, 2339a, 2339b, 2341), Lloyd et al. (2389), Roberts et al. (3215, 3219), Schumacher (3550, 3560, 3561), Schlotzhauer et al. (3458), Stedman (3797), Tso (3973, 3974a), Weeks (4159), and from years of personal experience (TAP) in tobacco science. In most cases, concentrations of the largest tobacco compounds (those greater than 0.05%) were obtained from literature sources. Although in a few cases, particularly those classes of compounds that had low to very low (0.001%–0.000001%) concentrations, e.g., anhydrides, quinones, oxazoles, aza-arenes, the concentrations were estimated.

Column three of Table 0.2 contains references to tables of data in this text and/or papers by Green (1351, 1352b) and others.

The chemical class of compounds in tobacco that has the largest mass is the oxygen-containing compounds (75.70%), followed by the nitrogen-containing compounds (12.98%), miscellaneous compounds (10.61%, including the category "Others" at 1.21%), and finally the hydrocarbons (0.71%). Within the oxygen-containing components, the largest single subclass of chemical components was the carbohydrates at 40.2%. There are 15.15% sugars, 12.12% celluloses, 10.36% pectins, and 3.03% starch. There are 9.8% carboxylic acids and 9.0% lipids (waxes) and resins in tobacco. In the lipids (waxes) and resins category, about 60% of the weight is lipids and 40% is resins. The lipids and resins category contain those compounds that prior to the 1950s were collected as part of the alcohol-ether-soluble fraction of tobacco. The phenolic category contains 8.3% of the dry mass of tobacco. About 2.25% of the weight of the phenolic category is lignin. The remainder of the weight from the oxygen-containing class of tobacco is composed of alcohols, phytosterols (and their derivatives), aldehydes, ketones, amino acids, esters, lactones, anhydrides, quinones, and ethers, ranging in levels from 2.0% to 0.0001% by weight of the dry mass of tobacco.

The two largest categories of compounds that contribute to the nitrogen-containing class of chemicals found in tobacco are the proteins and amino acids (6.4%) and the nitrogen heterocyclic compounds, which includes numerous types of tobacco alkaloids and related compounds (6.5%). The remainder of the weight from the nitrogen-containing class of tobacco is composed of amides, imides, *N*-nitrosamines, nitroalkanes, nitroarenes, nitrophenols, lactams, oxazoles, and aza-arenes. The mass of all of these remaining nitrogen-containing compounds represents only 0.08% of the dry weight of tobacco.

The third largest class of components found in tobacco was called "miscellaneous components" because it includes a broad range of chemical classes: sulfur-containing compounds; halogen-containing compounds; metals, nonmetals, and ions; pesticide residues; and the unknown components called "others." In the third class, the largest contributors to tobacco mass are the metals, nonmetals, and ions (7.2%). The halogen-containing compounds contribute 1.5% of the dry tobacco weight. Sulfur-containing compounds contribute 0.7% of the dry tobacco weight, and approximately 1.21% of the dry tobacco weight is compounds grouped as "others." Pesticide residues in tobacco contribute very little to the total tobacco mass (0.00001%).

The last class of components identified in tobacco is the hydrocarbons (alkanes, alkenes, alkynes, alicyclics, monocyclic aromatics, and polycyclic aromatics). The total mass of the hydrocarbons is only 0.71% of the dry weight of tobacco. The largest contributors to mass from this class of components are

Figure 0.2 illustrates the approximate chemical composition of tobacco based on the data of Table 0.2.

Table 0.3 is a comparison of the reported concentrations of chemicals found in tobacco from Hobbs (1665) compared to similar data entries in Table 0.2 of this report.

There is close agreement between the estimates of the gross compositional tobacco data reported by Hobbs (1665) in 1972 *vs*. the data of Table 0.2. The differences between the Hobbs' data and the data of Table 0.2 could be from differences in tobacco types tested or from improvements in analytical separation, detection, and quantification technologies. The differences in the subtotals for carbohydrates, proteins, and amino acids; Hobbs' classification of bases; and most of the other chemical classes are generally different by less than 1–2 weight percent. Under the classification of "Others" for the data of this report (column three), there is about 2.9% dry weight of tobacco (i.e., 4.1%–1.2% [from Table 0.2] = 2.9%) that represents hundreds of minor tobacco constituents not accounted for in the components listed in column one of this table. It is quite remarkable how qualitatively similar the data are between the Hobbs data and those from Table 0.2. As Hobbs (1665) mentioned in 1972, any "differences (*in the chemical composition of tobacco*) are likely to be more quantitative than qualitative."

Because of the excellent fractionation and identification technologies developed during the early 1950s, the compositions of tobacco and tobacco smoke, both classified as highly complex mixtures, have been defined more completely than the composition of any other highly complex commercial product such as coffee. By year-end 1953, the many years of research by scientists using classical chemical techniques to define the composition of tobacco and its smoke provided meaningful information on the nature of over 300 tobacco components and fewer than 100 tobacco smoke components. Those involved in the pre-1954 research not only provided the cornerstone of our knowledge of the two compositions but also deserve the gratitude of their successors for the early information generated on tobacco and its smoke. This article is our tribute to those researchers who generated much meaningful knowledge on the composition of tobacco and tobacco smoke prior to 1954 despite the now known fractionation and analytical limitations of the so-called classical chemical techniques. It also notes the similarity of some of the early and more recent research results obtained on the chemical and biological properties of smoke condensate and several of its components from tobacco with those obtained by Roffo in the 1930s on a destructive distillate of tobacco.

The compilation of the catalog on the more than 8400 chemical components identified in tobacco and tobacco smoke provided an excellent assessment of the caliber of the research conducted since its escalation in the mid-1950s. The classical chemical analysis used before that date to isolate and characterize a component of a complex mixture was gradually augmented post-1953 by the inclusion of many different, new, and highly efficient separation and analytical technologies. Various types of chromatography coupled with various spectral technologies such as ultraviolet, infrared, nuclear magnetic resonance, and mass provided the means to identify more complex structures of components isolated in much lesser amounts than could be done by using the classical chemical approach. For example, inclusion of such technologies resulted in the increase of the number of identified chemical components in tobacco smoke from the fewer than 100 reported by Kosak in 1954 (2170) to the more than 5200 cataloged recently by Rodgman and Perfetti (5078). The manifold scientific skills generated and employed during those more than 50 years of research obviously deserve great commendation.

In the early part of the twentieth century until the mid 1950s, there was limited interest in the relationship between the majority of identified chemicals in tobacco and tobacco smoke and the varied asserted health issues associated with smoking in general, compared to the time after the mid-1950s. This limited interest may have been due to a lack of understanding of how to interpret the chemical data collected on the complex mixtures of tobacco and tobacco smoke in relation to biological endpoint data. On the other hand, early tobacco research concentrated on a greater understanding of the alkaloids in tobacco.

In early tobacco research, nicotine and other related tobacco alkaloids were regarded as toxic constituents of

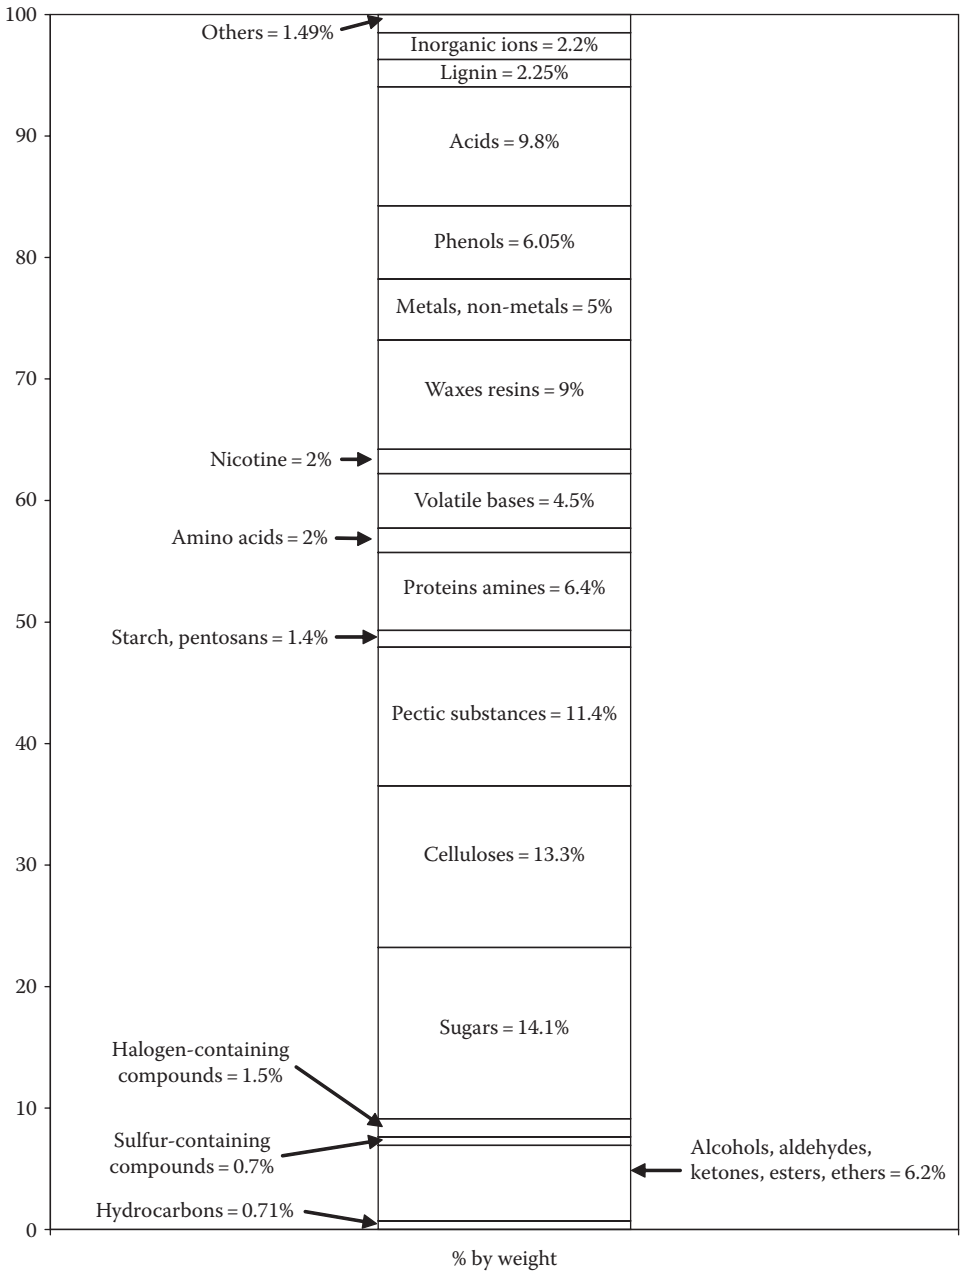

FIGURE 0.2 Approximate chemical composition of tobacco.

tobacco, and their presence in smoke was considered a health concern. Tobacco alkaloids were also important as raw materials for pesticides and as sources of raw material for the chemical industry. As a result, considerable effort was focused in the early years of tobacco research on nicotine and related tobacco alkaloids. This work included the development of new analytical determinations for tobacco alkaloids and tests to measure its toxicity and dependence of nicotine for smokers. Work in the area of breeding new tobacco lines was focused on two directions. Efforts were directed at developing low nicotine or nicotine-free tobaccos for health reasons and secondly, in the direction of tobaccos extremely high in nicotine, as a raw material for pesticides, chemicals, and pharmaceuticals.

During our cataloging of the chemical components of tobacco and tobacco smoke, it became apparent that the chemical research conducted on them from early in the 1800s to September 1953, the date of submission of the Kosak's manuscript for publication, also deserved considerable commendation. Considerable skill in classical chemical methods was used to isolate and characterize the tobacco and smoke components known by late 1953. In this article, the results of that research are summarized in an attempt to illustrate that not only should they not be minimized or disregarded but also the investigators who generated such meaningful results deserve considerable credit.

One of the stimuli cited by Kosak (2170) for the generation of his 1954 catalog of tobacco smoke components was the brief

1952 published report by Graham et al. (5202) on the induction of tumors in laboratory animals repeatedly painted with large doses of cigarette smoke tar, a report that was followed in early 1953 by a presentation at the American Association for Cancer Research (4306a) and then by a detailed publication in a peer-reviewed scientific journal in late 1953 (4306a). Wynder et al. (4306a) described many of the early studies on the effects of exposure of laboratory animals to various tars, including those derived from tobacco by smoking or extraction [E. Hoffmann et al. (1813), Helwig (1617, 5221), Bogen and Loomis (377), Cooper et al. (813), Campbell (579, 581), Schürch and Winterstein (3563), Taki (3865), Sugiura (5415), Flory (1206, 5178), and Shubik (3663)]. An early study reported in 1911 by Wacker and Schmincke (5446) preceded the development and description of the procedure to induce cancer in laboratory animals by skin painting with coal tar in 1915–1918 by Yamagiwa and Ichikawa (4361). As noted by Wynder et al. (4306a), each of the tobacco tar studies conducted after the Yamagiwa–Ichikawa reports suffered from one or more deficiencies such as a low number of daily or weekly paintings, low tar-painting dosage, inadequate smoking procedure for tar collection, and the like. However, seldom discussed is the fact that the Wynder et al. study involved a cigarette smoking procedure (35 mL puff, 2 s puff, 3 puff/min) different from the one in vogue since its elucidation (35 mL puff, 2 s puff, 1 puff/min) by Bradford et al. in 1936 (423b). Tripling the puff/min not only substantially increases the per-cigarette-tar yield but also drastically alters its composition, with substantial increases in several smoke components with known tumorigenicity to mouse skin, e.g., PAHs benzo[*a*]pyrene (B[*a*]P) and dibenz[*a,h*]anthracene (DB[*a,h*]A).

Other reports that triggered interest in the biological properties and chemical composition of CSC were the numerous publications between 1950 and 1953 on the epidemiology of lung cancer and cigarette smoking. They were presented in 1950 by Wynder and Graham (4306b), Doll and Hill (1026a), Levin et al. (2355), Mills and Porter (2556), and Schrek et al. (3529). These were followed in 1952 and 1953 by similar extensive studies conducted by Doll and Hill (1027), McConnell et al. (2515), Koulumies (4250), Lickint (5266), and Sadowsky et al. (3375a). It should be noted that the prospective method did not replace retrospective studies. Both approaches have their advantages and disadvantages. In the retrospective study, interviewers record the habits of smokers and controls; the prospective studies are better suited to survey larger groups of diseased and controls in terms of their environment, their behaviors, and specific diseases they contract.

Preceding these 1950–1953 epidemiological studies were several reported from 1912 to 1950, but in their 1950 report, Graham and Wynder (4306b) described in general several of the deficiencies of the earlier epidemiological studies, e.g., small sample size, lack of a control population, statistical procedure, tumor definition. Among the earlier studies were reports and/or comments on respiratory tract cancer by Adler (5096) in 1912, by Tylecote (5425) in 1927, by Lickint (5265) in 1935, by Arkin and Wagner (5101) in 1936, by Kennaway and Kennaway (5239, 5240) in 1936 and 1947, by Roffo (3322) in 1937, by Müller (5297) in 1939, by Ochsner and DeBakey (5316, 5317) in 1940 and 1941, and by Schairer and Schöninger (5370) in 1943.

The reports by Ochsner and DeBakey subsequently led to an interesting situation in the content of several U.S. Surgeon Generals' reports on smoking and health. From the late 1930s through the late 1960s, Ochsner, at that time one of the few eminent lung cancer surgeons in the United States, authored or coauthored over 40 articles and three books in which it was repeatedly asserted that the major cause of lung cancer was cigarette smoking. Despite his number of publications between the late 1930s and late 1963, the 1964 Advisory Committee to the U.S. Surgeon General (3999) and the 1979 (4005) and 1982 (4011) U.S. Surgeon Generals cited only one 1939 Ochsner-authored publication (5314) and one of his authored books, the 1954 edition (5315) on the relationship between lung cancer and cigarette smoking. Was the limitation of the citations of Ochsner's publications on cigarette smoking and lung cancer possibly due to either or both of the following situations?

1. Despite the repeated assertion that the major cause of lung cancer was cigarette smoking, Ochsner et al. frequently included other comments in the same articles, e.g., (a) the cause of the increasing incidence of cancer of the lung is not definite [see

p. 212 in (5317)], (b) the etiology of bronchogenic carcinoma is unknown (5320), and (c) the etiological picture (for bronchogenic carcinoma) is obscure. It is probable that there are a number of etiological factors in the production of this disease (5134).

2. Despite the repeated assertion that the major cause of lung cancer was cigarette smoking, the data on patients undergoing lung resection in the Ochsner Clinic because of lung cancer were summarized in several Ochsner et al.'s reports as follows: (a) In 129 resected cases, no factor was found which might bear a significant relationship to the occurrence of the disease. Neither occupation nor smoking habits, which some reports, including our own, have stressed as of possible etiological significance, seem of any special significance in this particular series (5318). (b) In the analysis of 147 resected cases, no etiological factor was found to bear a significant relationship to the occurrence of the disease. Both occupation and smoking, which had been particularly emphasized by some observers as possible etiological factors and which we were inclined previously to consider more seriously, were found to have no special significance in this analysis (5319).

CHEMICAL COMPONENTS OF TOBACCO AND TOBACCO SMOKE IDENTIFIED PRIOR TO 1954

Many components were identified in tobacco and/or tobacco smoke prior to the issuance of the 1954 Kosak's report (2170), the numerous epidemiological studies on tobacco smoking and respiratory cancer, and the 1953 report of tumor induction in laboratory animals by cigarette-tar painting (4306a). Most of the pre-1954 characterizations of such components were accomplished by the so-called classical chemical procedures. The components are listed in Table 0.4 with the identification and confirmation listed chronologically. If more than one study on a specific component was reported in a given year, the investigators in that year are listed alphabetically.

Examination of the data in Table 0.4 reveals the many investigators who contributed much meaningful information on tobacco and/or smoke composition prior to year-end 1953. They include the following: Brückner, Burkhard, Eulenberg, Frankenburg, Gabelya, Garner, Gottscho, Kipriyanov, Kissling, Kobel Lehmann, Molinari, Neuberg, Pfyl, Pontag, Preiss, Pyriki, Roffo, Schöller, Shmuk, Späth, Thoms, Vohl, and Wenusch. Each of them deserves much tribute for their contributions. Several of them continued to contribute to our knowledge of the composition of tobacco and/or tobacco smoke after 1953, e.g., Frankenburg, Garner, Gottscho, and Pyriki.

Compared to the fewer than 100 tobacco smoke components listed by Kosak (2170), Table 0.4 contains 325 chemical components identified and studied in tobacco prior to the publication of the Kosak's article. Included in 383 entries in Table 0.4 (as they were in the Kosak's tabulation) are several components originally assumed to be individual alkaloid-related components but subsequently were found to be known compounds or mixtures of known compounds, e.g., anodmine, gudham, lathrein, lohitam, obelin, poikiline, α-socratine, β-socratine, and γ-socratine (4208, 4209, 4210, 4211, 4213). They were not included in the count of the 325 identified tobacco components. The eventual characterization of anodmine, gudham, lathrein, lohitam, obelin, and the three socratines was described in 1955 by Kuffner et al. (2224). Their characterization of these supposedly alkaloid-related components was summarized by Johnstone and Plimmer (1971) in their 1959 review of tobacco and tobacco smoke composition. They wrote in 1959

> The constitution of these bases remained unknown until recently when investigators having access to original specimens were able to elucidate the identities of some of them by application of modern analytical techniques. γ-Socratine was found to be identical with *l*-nornicotine, and a crude mixture of α- and β-socratine (the only sample available), was shown to consist mainly of nicotyrine and 2,3′-dipyridyl with small quantities of nicotinic acid, nornicotine, and possibly anatabine (2224).

While noting that both ammonia and nicotine were previously identified as tobacco smoke components, Kosak elected not to list references to them because their number of references, in his opinion, was too numerous to list. Also the number of references to carbon dioxide and carbon monoxide was limited by Kosak (2170). Table 0.4 lists many of the pre-1954 references to ammonia, nicotine, carbon dioxide, and carbon monoxide in tobacco and/or tobacco smoke. Included in Table 0.4 are several pesticide residues, e.g., arsenic/arsenic (As) oxide, Toxaphene®, Lindane®, Parathion®, DDT, and TEPP (tetraethyl pyrophosphate), plus several pesticide residue degradation products, e.g., *o*,*p*′-DDD and *m*,*p*′-DDD, identified by Vinzant in 1951 (5439). Listed in Table 0.4 are a few compounds used as flavorants on tobacco products, most notably menthol which, however, occurs naturally in trace amounts in several tobacco types. Table 0.4 also cites numerous references to pre-1954 studies of a general nature. These include references to arsenical insecticides, alkaloids, aliphatic acids, aliphatic hydrocarbons amino acids, bases, tobacco distillates, tobacco fats, chlorophyll degradation products, enzymes (general information), hydrocarbons, hygroscopic agents, paraffins, pigments, sugars, tobacco combustion products, tobacco (general), tobacco smoke (general), and triglycerides. These items are not included in the total of 325.

Among metals, nonmetals, and ions, Kosak in his 1954 catalog listed only arsenic plus four ions as smoke components, and Kosak questioned the identification of each of the latter. Examination of Table 0.4 reveals that over 50 metals, nonmetals, and ions were identified in tobacco prior to late 1953. However, it was post-1953 when a concerted effort was made to determine the transfer of numerous metals from tobacco to tobacco smoke during the smoking process, e.g., the 1957 study by Cogbill and Hobbs (769). The references

for numerous additional studies of this type are listed by Rodgman and Perfetti [see Chapter 20 in (5078)]. Among the metals and nonmetals in tobacco smoke, the one much studied pre-1954 was of course arsenic. Between 1917 and 1951, the As level in tobacco rose from about 12 to 57 μg/g (1459). As, usually considered as As_2O_3 in tobacco, was removed from tobacco agronomy in 1952.

While our Bibliography contains numerous references on the isolation, identification, and quantitation of many of the tobacco components listed in Table 0.4, also available are literally hundreds of pre-1954 references on studies that dealt with the effect of several components in tobacco smoke, e.g., nicotine and carbon monoxide, or in chewing tobacco, e.g., nicotine and related alkaloids, on a host of human biological activities. Many such studies are cataloged in the 1961 Larson et al.'s book on experimental and clinical studies on tobacco (2264).

In Table 0.4 are listed two dozen enzymes identified in tobacco prior to 1954. This early research was done primarily to obtain an insight into the mechanism of tobacco curing, fermentation, and aging. With the subsequent escalation of technologies pertinent to the isolation and characterization of enzymes, their number in plants, including the various types of tobacco, has increased dramatically. The number of completely identified tobacco enzymes listed by Rodgman and Perfetti approximated 500, but many thousands of enzymes present in the tobaccos have been cataloged [see Chapter 22 in (5078)].

Paralleling the increase in identified chemical components in tobacco smoke from the fewer than 100 in 1954 (2170) to more than 5300 recently cataloged (5078) and to more than 6000 in this version of our book has been the increase in identified chemical components of tobacco from 325 (see Table 0.4) to the nearly 5000 recently cataloged (5078) and to almost 5600 herein cataloged.

OTHER COMPOUNDS APPLIED TO TOBACCO BUT NOT SPECIFICALLY IDENTIFIED IN TOBACCO OR TOBACCO SMOKE PRIOR TO 1954

In reviewing the tobacco and smoke literature prior to 1953, two additional sets of compounds are provided for historical purposes. These include either (1) compounds applied on tobacco prior to 1953 for the treatment of disease (molds, spores, fungi, viruses, etc.) and pests or (2) compounds applied on tobacco as flavorants, casings, and/or humectants. The listings are not complete as farmers did not always reliably report such usage for their crops and tobacco manufacturers rarely reported the composition of flavor additives, casings, and humectants used on tobacco prior to 1953. Tables 0.5 and 0.6 are primarily of historical value as the chemicals applied to tobacco for disease control and the types of additives applied to tobacco have markedly changed over time. Most of the chemicals in Tables 0.5 and 0.6 are not listed in Table 0.4 because they were not isolated and confirmed to be present on tobacco samples that were analyzed in the articles reviewed. Nonetheless, these compounds were applied to tobacco and may have been present as residues in the case of the fungicides and pesticides or at larger levels in the case of flavorants and humectants. These compounds are listed in Tables 0.5 and 0.6.

IDENTIFIED COMPONENTS OF TOBACCO AND TOBACCO SMOKE IN THE MASTER CATALOG

Many of the components identified in tobacco have also been identified in its smoke because they transfer in part from tobacco to its smoke during the smoking process. Many other identified tobacco components are not found in smoke because they decompose during the smoking process. The level of many tobacco components considered to contribute to the acceptable taste of its smoke is augmented by inclusion in various additive formulations used in the U.S. tobacco industry (1053, 3263).

Figure 0.3 illustrates the increase in number of identified components in tobacco and its smoke. Green and Rodgman (1373) discussed the contribution of improved analytical technologies to the periodic escalation in the number of identified components in each.

An enormous number of references exist pertinent to the isolation, identification, and biological studies of the great number of components in tobacco and tobacco smoke. To avoid considerable repetition, these are presented as a unified References section which contains the references cited not only in this Introduction but also in each chapter. Together with this Introduction, the References section has been issued prior to the beginning of the components catalog. It is obvious that some references have been omitted, but we assure the reader that any omission was not by design but was done unwittingly.

The references cited for a particular tobacco and/or tobacco smoke component may deal simply with its identification or with a variety of topics pertinent to the particular component. Such topics may include the following:

1. The isolation and identification of the component.
2. The characterization of the component by classical chemical means, e.g., the definition of the structure of solanesol isolated from flue-cured tobacco by Rowland et al. (3359), the characterization of a component by spectrographic means such as UV, IR, NMR, MS, and chromatographic retention time, e.g., the identification by Snook et al. of numerous PAHs (3756–3758) and aza-arenes (3750) in cigarette MSS.
3. The search for the precursor in tobacco of a particular component in cigarette MSS (3616).
4. The quantitation of the component on a per gram of tobacco basis or on its per cigarette MSS yield.
5. Improvements/developments in the analytical technology to determine the per cigarette MSS and/or SSS yield of the component, e.g., see Table 6 in (3306b).

6. Studies on the biological activity of a particular component.
7. Discussions and/or assertions of the toxicity and/or tumorigenicity of a component in MSS, SSS, or ETS.
8. Studies on the inhibition of adverse biological activity of a tobacco smoke component by another component of the smoke, e.g., the inhibition of the mouse-skin tumorigenicity of B[*a*]P by *n*-hentriacontane and *n*-pentatriacontane (4314, 4336), the inhibition of the mouse-skin tumorigenicity of DB[*a,h*]A by B[*a*]A (3814), the inhibition of the mutagenicity of *N*-nitrosodimethylamine (NDMA) by nicotine (2327a, 2327b).
9. Controversies over the extrapolation of the biological effect of a specific component administered individually *vs*. its biological effect when the component in a highly complex mixture such as MSS is administered to a different species, by a different route, and at dose level far in excess of its level in the complex mixture (1318a, 3300, 3627).
10. Description of the design technologies to control the per cigarette MSS yield of FTC "tar" and a particular component, e.g., see Table 16 in (3300).

In many instances, the references cited for a particular component may also contain additional references pertinent to the component.

The categories of chemical components in tobacco and tobacco smoke derived from our Master Catalog will be presented in the sequence shown in Table 0.7:

Each component chapter contains a major Alphabetical Component Index section. As information for the reader, Table 0.8 depicts the first page of the catalog for the alkanes (Table 0.10). A similar component catalog is present in the chapter for each component class.

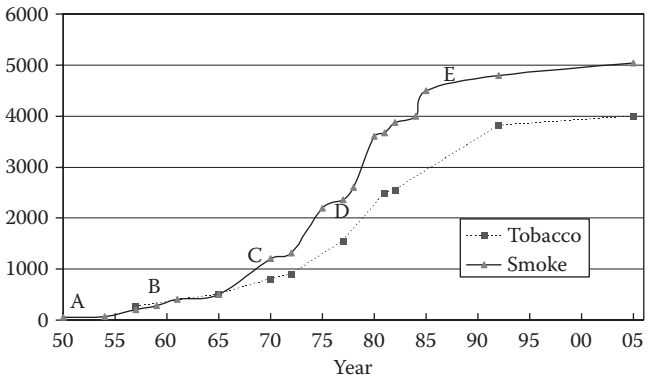

FIGURE 0.3 Number of identified tobacco and tobacco smoke components reported since 1954: accumulative by year: A, prior to 1953: "classical" chemical techniques; B, 1953–1960: column chromatography; C, 1960–1970: gas chromatography; D, 1970 to mid-1970s: glass capillary gas chromatography coupled with mass spectrometry; E, mid-1970s to date: derivatives for HRGC, HPLC, mass spectrometry.

Tobacco smoke, particularly cigarette smoke, is an aerosol comprising literally millions of liquid droplets suspended in a gaseous system [see Ingrebrethsen (1860)]. The liquid droplet portion of this smoke is defined as the particulate phase (PP), the gaseous portion as the vapor phase (VP). The PP is also described alternatively in several ways depending upon the context of the discussion; e.g., the PP collected by a variety of collection techniques such as the Cambridge filter pad, electrostatic precipitation, and jet impaction [cf. review by Dube and Green (1067)] is termed wet total particulate matter (WTPM). Correction for the water content yields total particulate matter (TPM). Subtraction of the nicotine level from TPM gives the Federal Trade Commission (FTC)-defined "tar." The reasons

	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
1.	106-97-8	Butane $H_3C\text{-}(CH_2)_2\text{-}CH_3$	85, 112, 151, 199, 238, 239, 544–546, 604, 605, 620, 621, 966, 1140, 1153, 1154, 1243, 1284, 1420, 1634, 1966, 2060, 2079, 2270, 2293, 2310, 2634, 2781, 2782, 2799a, 2804, 2857, 2909, 2939, 2940, 2942, 2946, 3059, 3308, 3583, 3584, 3769, 3797, 3876, 3882, 3901, 3939, 3940, 3950, 3973, 4052, 4056, 4162, 4249, 4319, 5811b		3901, 4052, 4056
20.	75-83-2	Butane, 2,2-dimethyl- $(H_3C)_3{\equiv}C\text{-}CH_2\text{-}CH_3$	348, 966, 1140, 2939, 3302, 3876, 4249, 5777, 5811, 5811b		
21.	78-78-4 102056-77-9	Butane, 2-methyl- {methylbutane} $(H_3C)_2{=}CH\text{-}CH_2\text{-}CH_3$	85, 112, 199, 348, 604, 605, 1140, 1153, 1154, 2060, 2767, 2781, 2782, 2804, 2946, 3226, 3308, 3557, 3769, 3797, 4249, 5811b	3973	
2.	124-18-5	Decane $H_3C\text{-}(CH_2)_8\text{-}CH_3$	142, 151, 222–224, 568b, 1445, 1634, 2387, 2543, 2570, 3308, 3365, 4570a, 5770, 5811b	151, 182, 568b, 3797, 4249, 5811b	2387
3.	61193-21-3	Decane, methyl- $C_{10}H_{21}\text{-}CH_3$	1822, 4249		
4.	6975-98-0	Decane, 2-methyl- $H_3C\text{-}CH(CH_3)\text{-}(CH_2)_7\text{-}CH_3$	3557, 4249	925	
5.	13151-34-3	Decane, 3-methyl- $H_3C\text{-}CH_2\text{-}CH(CH_3)\text{-}(CH_2)_6\text{-}CH_3$	1827, 1884, 3557, 4249		
6.	13151-35-4	Decane, 5-methyl- $H_3C\text{-}(CH_2)_4\text{-}CH(CH_3)\text{-}(CH_2)_3\text{-}CH_3$	1884, 4249		
7.	629-97-0	Docosane $H_3C\text{-}(CH_2)_{20}\text{-}CH_3$	568b, 619, 625, 727, 1360, 1375a, 1378, 1427, 1488, 1586, 2176, 2387, 2570, 2761, 2762, 2767, 2777, 2875, 3308, 3557, 3768, 3797, 4249, 5811b	182, 248, 404, 568b, 727, 840, 1488, 1978, 2339a, 3469, 3547, 3604, 3703, 3797,, 4249, 4337, 5811b	1360, 1375a, 1378, 2387
22.	1560-81-2	Docosane, 2-methyl- $(H_3C){=}CH\text{-}(CH_2)_{19}\text{-}CH_3$	1195, 1375, 4249	840, 4337, 5811b	
8.	72227-00-0	Docosane, 3-methyl- $H_3C\text{-}CH_2\text{-}CH(CH_3)\text{-}(CH_2)_{18}\text{-}CH_3$	1195, 1375, 4249	840	
9.	112-40-3	Dodecane $H_3C\text{-}(CH_2)_{10}\text{-}CH_3$	568b, 619, 1371, 1425, 1427, 1445, 1488, 1586, 2570, 2767, 3308, 3410, 3557, 3768, 3797, 4248, 4249, 4570a, 5811b	182, 404, 568b, 1488, 2339a, 2753, 2917a, 3186, 3188, 3547, 3797, 4249, 5657, 5811b	
10.	1560-97-0	Dodecane, 2-methyl- $H_3C\text{-}(CH_2)_9\text{-}CH{=}(CH_3)_2$		925	

for exclusion of nicotine and water to give the FTC "tar" value were the long-recognized nontoxicity of water plus the low toxicity of cigarette smoke nicotine as described in the 1964 report of the Advisory Committee to the U.S. Surgeon General (3999). Thus, we have the following relationships among these entities:

$$\text{WTPM} = \text{TPM} + H_2O = \text{FTC "tar"} + \text{nicotine} + H_2O.$$

The equation most frequently used in the United States since the late 1960s is the following:

$$\text{FTC "tar"} = \text{WTPM} - \text{nicotine} - H_2O$$

In many instances, collected cigarette smoke PP is called CSC.

In many countries, cigarette "tar" is determined by use of the International Organization of Standardization (ISO) method. The "tar" yield in the ISO method ISO 4387:1991 is calculated in the same manner as in the FTC method [Pillsbury et al. (2962)], i.e., by subtraction of the water and nicotine from the WTPM collected (ISO 1991). The ISO cigarette equilibration and smoking procedure differ slightly from those in the FTC procedure [see Table 1, p. 496 in Rustemeier and Piadé (3369a)]. These differences typically result in slightly lower measured yields for the ISO method *vs*. the FTC method. The measured values between FTC and

ISO methods are within the detection limits of the test. They differ by no more than 0.4 mg for "tar" and no more than 0.04 mg for nicotine for cigarettes that yield over about 10 mg of "tar." As described by Dixon and Borgerding (988a), under standard smoking regimes, the ISO and FTC methods give very similar results.

The physical nature of cigarette smoke is discussed in the following.

Periodically during the past five decades, various reviews and catalogs on the composition of tobacco smoke, with particular emphasis on cigarette MSS, have been published. These have dealt with the components of total MSS (the VP and the PP components) [Kosak (2170), Bentley and Berry (282, 283), Berry (296), Johnstone and Plimmer (1971), Izawa (1900), Philip Morris, Inc. (2939), Stedman, (3797), Ishiguro and Sugawara (1884), IARC (1871)], with MSS PP components only or with MSS VP components only [Elmenhorst and Schultz (1140)], with both MSS and SSS components [Sakuma et al. (3394, 3397, 3398), RJRT (3190), Klus (2133), Klus and Kuhn (2142)], with MSS, SSS, and ETS components [Brunnemann et al. (462), Eatough et al. (1099, 1100)], and with particular classes of smoke components, e.g., nitrogen-containing components [Neurath (2724), Schmeltz and Hoffmann (3491)] or PAHs [Elmenhorst and Reckzeh (1139)].

The majority of these reviews described the composition of smoke from cigarettes with a filler that was primarily tobacco. Although not published in the readily available scientific literature, substantial data are available from studies conducted on the smoke from cigarettes whose filler was not primarily tobacco but a "tobacco substitute" or a tobacco: "tobacco substitute" mixture. Inclusion of tobacco in the filler mixture ensures that the smoke will include the components usually found in an all-tobacco cigarette. Such data appear not only in documents from Celanese describing the composition of MSS from cigarettes containing only its Cytrel® product or in documents by Imperial Tobacco and Imperial Chemical Industries describing the MSS composition from cigarettes containing only their New Smoking Material® (NSM®) product but also in RJRT R&D reports which outline its studies on the composition of smoke from cigarettes made with Cytrel® only, NSM® only, the Sutton Smoking Material (SSM) only, or J-10 only (a tobacco substitute, comprising a puffed grain, developed in-house at RJRT). Recently, an article by Green et al. (1375a) on the effect of several tobacco substitutes on cigarette MSS composition has been published.

At RJRT, all available data on the composition of MSS from cigarettes made with various tobacco types, tobacco blends, various "tobacco substitutes," and/or celluloses have been routinely cataloged by R&D personnel, including one of the present authors (A.R.), for over five decades (2270, 2292a, 3224, 3245, 3252, 3253, 3301–3304, 3308).

Until the early 1980s, the majority of the studies on tobacco smoke composition dealt with the composition of cigarette MSS. PP composition was the major research topic throughout the 1950s with studies on VP composition receiving increased emphasis in the early 1960s when the biological response in laboratory animals could not be explained by nature and/or the level of any of the PP components acting individually or in concert.

TOBACCO SMOKE AND THE EXAMINATION OF ITS TUMORIGENICITY IN LABORATORY ANIMALS

The initial research efforts were directed at attempts to identify the components in the CSC that could be responsible for the observed biological response in the CSC-painted animals. Immediately, the class of compounds selected for intense investigation was the PAHs. Why was this class of compounds selected? Primarily, it was because of the 20 years of research effort since the initial findings in the early 1930s (194, 2078) that had shown that many PAHs were tumorigenic to mouse skin (1544), with several being classified as highly potent carcinogens to mouse skin (3306b).

After more than a century of research during which investigators attempted to induce malignant tumors in laboratory animals by administration of a variety of industrial tars, soots, oils, etc., success was finally achieved by Yamagiwa and Ichikawa (4361) who reported the first induction of tumors in laboratory animals skin-painted with coal tar solutions. Their findings, which subsequently led to extensive research on the induction of malignant tumors by skin painting of laboratory animals with various tars and oils, also led to the definition in 1923 of the terms carcinogen, carcinogenesis, and carcinogenicity: carcinogenesis was defined as the induction of a carcinoma by the treatment. In 1930, a synthetic pentacyclic PAH, dibenz[*a,h*]anthracene (DB[*a,h*]A) {I} (760, 1184), was reported to be highly carcinogenic to mouse skin by Kennaway and Hieger (2078). In the early 1930s, Cook et al. (796a, 797) isolated several PAHs from two tons of coal tar. One of the PAHs, initially unknown, was demonstrated by characterization and synthesis to be benzo[*a*]pyrene (B[*a*]P) {II}, another pentacyclic PAH structurally similar to DB[*a,h*]A (see Figure 0.4). Subsequently, it was demonstrated by Barry et al. (194) that B[*a*]P was also a potent carcinogen for the skin of susceptible mouse strains. The finding of the carcinogenicity of these two individual compounds, DB[*a,h*]A and B[*a*]P, was the stimulus for the synthesis and bioassay of literally hundreds of PAHs (and structurally similar nitrogen analogs) and their alkyl derivatives. Many of the PAHs with four or more fused rings were reported to be carcinogenic to mouse skin. A wealth of data was generated from research on attempts to correlate carcinogenic potency with PAH structure [Coulson (829), Pullman and Pullman (3003), Lacassagne et al. (2247a)]. The carcinogenic potency to mouse skin is dependent on the PAH structure and its substituents; e.g., benz[*a*]anthracene (B[*a*]A) {III} is a relatively weak carcinogen to mouse skin, whereas its 7,12-dimethyl homolog (DMBA) {IV} is an extremely potent one (983). The tricyclic PAH phenanthrene {V} is noncarcinogenic to mouse skin, but its 1,2,3,4-tetramethyl homolog {VI} is slightly carcinogenic (983).

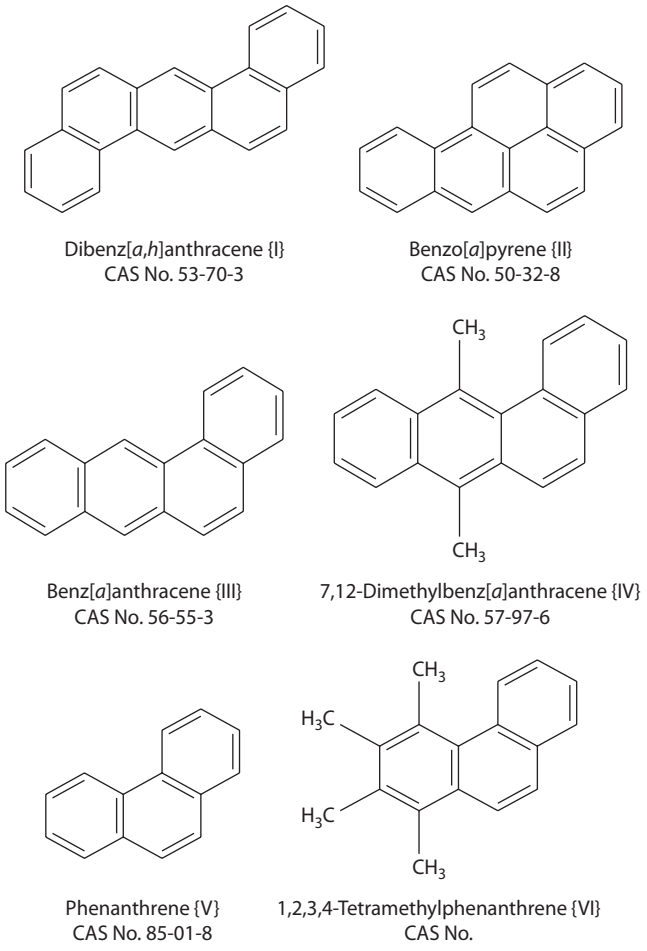

FIGURE 0.4 Polycyclic aromatic hydrocarbons.

Kennaway (2073–2076) reported that pyrolysis of a variety of organic compounds (methane, acetylene, isoprene, cholesterol) or mixtures containing organic compounds yielded pyrolysates which were tumorigenic to mouse skin. Subsequently, it was reported that a variety of carcinogenic PAHs, including B[*a*]P, were components of similar pyrolysates, e.g., the pyrolysates from the tobacco smoke components methane [Burrows and Lindsey (529a)] and isoprene [Oró et al. (2864b)], as well as the pyrolysate from the tobacco phytosterols structurally similar to cholesterol [Wynder et al. (4355), Van Duuren (4022), Schmeltz et al. (3511), Severson et al. (3616)].

For several years in the early 1950s, whether PAHs were present in tobacco smoke was a highly controversial subject. The early claims of the presence of B[*a*]P in cigarette smoke were criticized by Kosak et al. (2177) in 1956 and by Fieser (1181) in 1957 because of the failure to duplicate the reported findings when similar analytical techniques were used. Logic dictated that the PAHs, including B[*a*]P, would indeed be present since they arise pyrogenetically from organic compounds under a variety of conditions. Several of the demonstrated PAH precursors are known to be components of tobacco used in a cigarette, cigar, or pipe. The smoking process involves pyrolysis and/or combustion. The differences between the effect of pyrolysis of an individual compound *vs*. the effect of the cigarette smoking process on the same compound in the complex tobacco mixture were discussed by Rodgman et al. (3307), and their discussion will be summarized in a later chapter. However, even as late as 1957, Fieser, one of the eminent American authorities on tumorigenic PAHs, was not convinced that the presence of B[*a*]P in cigarette smoke had been demonstrated. Fieser (1181) discussed the available published data from various laboratories as follows:

> British [Cooper and Lindsey (820)] and American groups [Lefemine et al. (2335), Alvord and Cardon (55), Cardon and Alvord (593)] have claimed identification of benzpyrene following extensive chromatography of tars from cigarette smoke, but in each case the evidence of identity is correspondence of the smoke factor with the synthetic carcinogen in fluorescence spectrum, coupled with the correspondence of the two materials in one region of the ultraviolet absorption spectrum… In the absence of complete ultraviolet correspondence, the smoke-factor reported by the two groups of investigators can be described as nothing more than a benzpyrene-like substance, which may or may not be carcinogenic…
>
> Kuratsune (2237) [examined] the smoke from cigarettes of two Japanese brands and detected no benzpyrene… In my laboratory 20 g of cigarette smoke tar (from 500 cigarettes) to which 9.7 μg/g of benzpyrene was added was chromatographed… and rechromatographed… the recovery [of benzpyrene] was 7.8 μg/g of tar (80%)… In a parallel experiment with 20 g of the same tar and no additive, fractions corresponding to the positive fractions of the control were all negative… Our estimate was that benzpyrene could be present in amounts no greater than 1 part in 5 million parts of tar.
>
> Present evidence thus indicates that benzpyrene is formed in trace amounts on pyrolysis of constituents of tobacco (probably cellulosic), but that no appreciable amount passes into the smoke, and hence that this hydrocarbon is not the agent responsible for the observed carcinogenicity to mice of cigarette smoke tar [Wynder et al. (4306a)].

Fieser also reported that his colleagues Huang and Johnston failed to detect B[*a*]P in the MSS from American cigarettes even though they determined its level (80% recovery) in CSC "spiked" with B[*a*]P (1181). In Japan, Kuratsune, unable to demonstrate the presence of B[*a*]P in the CSC from Japanese cigarettes, was able to demonstrate its presence in roasted coffee beans and various other pyrolysates [Kuratsune (2237), Kuratsune and Hueper (2238)]. After subsequent studies by Orris et al. (2865) and Kiryu and Kuratsune (2099) or assessment of more complete laboratory data, Fieser (1182) and other critics reversed their earlier positions and eventually accepted that B[*a*]P was indeed present in tobacco smoke. The ultimate confirmation of the presence of B[*a*]P in cigarette smoke was its isolation in crystalline form and characterization by chemical means rather than reliance solely on the correspondence of the ultraviolet spectrum of the isolate with that of an authentic sample. Isolation of crystalline B[a]P from the MSS of a 70 mm nonfiltered cigarette was reported in 1956 by Rodgman (3240) and by Hoffmann [see Wynder and Hoffmann (4307)] in 1959 and from a filtered cigarette in 1960 by Rodgman and Cook (3273). Fieser, the

major architect of the chapter on smoke composition in the 1964 report of the Advisory Committee to the U.S. Surgeon General (3999), had access to the published data by Wynder and Hoffmann (4307) on the isolation of crystalline B[*a*]P from cigarette smoke. However, numerous proponents of the adverse effect of cigarette smoke, e.g., Wynder and Wright (4282a, 4354) and Wynder and Hoffmann (4307, 4312), asserted that the level of B[*a*]P in CSC or the levels of several tumorigenic PAHs including B[*a*]P could only account for a few percent of the biological response observed in mouse-skin-painting studies with CSC.

Since much of the post-1950 effort on MSS composition was directed to the definition of the cancer-causing agents in MSS possibly responsible for the association between lung cancer and cigarette smoke in smokers, it is a requisite that the various terms used in laboratory studies of tumor generation be understood.

In their 1990 list, Hoffmann and Hecht (1727) cataloged the tobacco and/or tobacco smoke components classified as "tumorigenic agents" and the range of the per cigarette MSS yields of each. Prior to examining the individual components on the list, an important distinction between "tumorigenicity" and "carcinogenicity" should be noted. In the 27th edition (1988) of Dorland's medical dictionary (1051b), the definition of carcinogenesis, first enunciated in 1923, is the same as that listed in the 13th edition issued in 1927 (1051b). Some investigators incorrectly use the term "carcinogenesis" for the production of any tumor type, not just for a carcinoma. The correct term, if used in this manner, is "tumorigenesis." The term "carcinogen" is often applied, again often incorrectly, to any factor that induces any type of tumor. Common in the past, but seldom used now, was the term "sarcogenesis" used to describe the production of sarcoma, the endpoint obtained in many investigations in which the mode of administration of the compound under test, e.g., a PAH, was by subcutaneous injection.

Additionally, terms such as *carcinogen*, *carcinogenicity*, and/or *carcinogenesis* or *sarcogen*, *sarcogenicity*, and/or *sarcogenesis* should not be considered as fixed properties of compounds. It should be noted that in several of their early publications, Wynder and Hoffmann (4342, 4343a, 4346) and Hoffmann and Wynder (1801) carefully differentiated among the terms *carcinogenesis*, *sarcogenesis*, and *tumorigenesis* but eventually discontinued this practice. Other investigators have done the same.

Because of the successful induction of cancer in a laboratory animal by Yamagiwa and Ichikawa (4361) and the discovery that several PAHs were tumorigenic when painted on the skin of laboratory animals (194, 797, 2078), the tumorigenicity of literally hundreds of PAHs (and structurally similar nitrogen analogs) and their alkyl derivatives was studied from 1922 to 1941. Many of the assertions made about the correlation between the laboratory findings and human experience were extremely farfetched and caused much confusion. This led to the request for Shear of the U.S. National Cancer Institute to attempt to return order to the field of carcinogenicity. The result was the classical description by Shear and Leiter (3627), a description which is still valid today.

Carcinogenicity is a variable property, depending on a number of factors. It differs from other properties of a compound that are fixed, e.g., melting point, boiling point, refractive index, specific gravity, crystalline form. As noted by Shear and Leiter (3627), by Hartwell (1544), and by many others, a substance or factor can show a range of effects from carcinogenicity to noncarcinogenicity to anticarcinogenicity, and the response will differ in the laboratory depending on the animal used (species, strain, sex, age), dose, route of administration (inhalation, ingestion, injection [subcutaneous, intravenous, intraperitoneal], skin painting, douching), mode of administration (single *vs*. multiple doses, neat, in solution, as an aerosol, as a vapor), diet supplied to the animals, and cage care.

SMOKE-FORMATION PROCESSES, DISTRIBUTION (MSS, SSS, ETS), CHEMICAL COMPOSITION, AND ANALYTICAL METHODS FOR IDENTIFICATION

Cigarette smoke composition is dependent on two major processes occurring during the smoking of tobacco: the direct transfer by vaporization of volatile tobacco components directly to the smoke and the pyrogenesis of smoke components from tobacco components. The pyrogenesis involves a variety of reactions including oxidation, reduction, aromatization, hydration, dehydration, condensation, cyclization, polymerization, depolymerization, etc.

Table 0.9, adapted from Kosak (2170), lists the fewer than 100 tobacco smoke components reported in the scientific literature to that date. Examination of his compilation reveals the following:

1. Of the approximate 80 entries, the identities of 33 (over 40%) of the components were questioned by Kosak because he did not "consider the evidence cited in the literature to be definitive proof" of their identities.
2. Two of the listed items (B[*a*]P, "condensed aromatics") were reported by Roffo (3323, 3324) whose research did *not* involve the study of tobacco smoke but involved a study of material obtained by the "destructive distillation" of tobacco.
3. Several of the alkaloid-related components (α-, β-, and γ-socratine, obelin, lohitam, anodmin, lathraein, poikiline, and gudham) first reported by Wenusch and Schöller (4210, 4211) and listed under *Alkaloids* were subsequently demonstrated to be mixtures or a component listed elsewhere in Table 0.9. For example, Kuffner et al. (2224) demonstrated that obelin was a salt of ammonia, α- and β-socratine were mixtures of nicotyrine and 2,3′-bipyridine, and γ-socratine was *l*-nornicotine. Poikiline was characterized as 4-amino-1-(3-pyridyl)-butanone. Many of these characterization corrections are described in Johnstone and Plimmer (1971).
4. Kosak listed references to phenol (1857, 4202), catechol (2107, 4202), and "phenolic acids" (3324) as tobacco smoke components. However, he failed to report the

1952 presentation by Rayburn (3089) of the unequivocal identification of phenol, guaiacol (2-methoxyphenol), *o*-cresol (2-methylphenol), and *m*-cresol (3-methylphenol) in the smokes from the four major tobacco types (flue-cured, burley, MD, Oriental).

5. Azulene, a bicyclic $C_{10}H_8$ hydrocarbon isomeric with naphthalene, was first reported as a tobacco smoke component by Ikeda (1857) and subsequently by Gilbert and Lindsey (1287, 1288), Lindsey (2365), and Lyons (2426). Despite improved analytical technology and hundreds of studies on the identification of PAHs in tobacco smoke, very few reports of its identification have appeared since those in the 1950s. This suggests the possibility that the azulene reported in tobacco smoke condensate in the 1940s and 1950s may have been formed artifactually.

In summary, Kosak's 1954 list, shown in Table 0.9, included only about 50 components, the identities of which were certain.

TABLE 0.9
Tobacco Smoke Components Listed by Kosak (2170)

Class	Component	Class	Component	Class	Component
Hydrocarbons	Hentriacontane (?)	*Ketones*	3-Pentanone	*Acids*	Formic acid
	Acetylene		4-Heptanone		Acetic acid
	"Unsaturated hydrocarbons"		17-Tritriacontanone (?)		Butyric acid
			2,3-Butanedione		Valeric acid
	Azulene phenanthrene (?)		"Higher" ketones (?)		Caproic acid
	Anthracene (?)				C_7 and C_8 aliphatic acids (?)
	Benzopyrene (?)				Succinic acid (?)
	"Condensed aromatics" (?)				Fumaric acid (?)
					Citric acid (?)
					Benzoic acid (?)
					Phenolic acids (?)
Alcohols and phenols	Methanol	*Alkaloids*	Nicotine	*Miscellaneous components*	Levoglucosan[c]
	Glycerol		Pyridyl ethyl ketone		"Phytosterol" (?)
	Diethylene glycol[a]		Myosmine		$C_{10}H_{14}O$ (a furan ?)
	Ethylene glycol[a]		Nicotyrine		"Resins" (?)
	Phenol (?)		α-Socratine[b]		"Resin acids" (?)
	Catechol (?)		β-Socratine[b]		
			γ-Socratine[b]		
			Obelin[b]		
			Lohitam[b]		
			Anodmin[b]		
			Lathraein[b]		
			Poikiline[b]		
			Gudham[b]		
Aldehydes	Formaldehyde	*Other* N-*containing components*	Pyrrole (?)	*Inorganic components*	Ammonia
	Acetaldehyde		"Pyrroles" (?)		Carbon monoxide
	Butyraldehyde acrolein (?)		"*N*-Methyl-pyrrolidines" (?)		Carbon dioxide
	Benzaldehyde				Hydrogen cyanide
	2-Furaldehyde (?)[d]		Pyridine		Hydrogen sulfide
			"Picoline" (?)		Thiocyanic acid (?)
			"Lutidine" (?)		Oxygen
			"Collidine" (?)		Arsenic[e]
			"Pyridine bases" (?)		"Acetates" (?)
			Methylamine (?)		"Chlorides" (?)
			"Chlorophyll degradation products" (?)		"Cyanides" (?)
					"Nitrates" (?)
			"Uric acids" (?)		

[a] In smoke because of transfer of an humectant added to tobacco.

[b] Subsequent study demonstrated this component was not a well-defined compound but an artifact, a mixture, or an ammonium salt [see discussion by Johnstone and Plimmer (1971)].

[c] 1,6-Anhydro-β-*D*-glucopyranose.

[d] The question mark indicates that Kosak did not consider the evidence in the literature to be definitive proof of the identity of the component.

[e] Probably present as As_2O_3.

The number of identified components in cigarette tobacco smoke has increased almost 100-fold from the 50 definitively identified tobacco smoke components listed by Kosak (2170) to the more than 5000 components identified to date and cataloged by RJRT personnel. Components were originally included in the RJRT catalog only if their identification criteria satisfy the identification criteria of classical organic chemistry. Later, identification criteria from modern analytical chemistry were employed. From 1950 to 1955—the early years of the great escalation of interest in the composition of cigarette smoke—"isolations" were often accomplished with no regard to the possibility of artifact formation. Also, "identifications" of tobacco smoke components were often based on less than complete spectral data, e.g., the PAHs and their ultraviolet spectra, R_f values, color tests, and the like. Because of the state of the art of the isolation techniques available in the early 1950s, the level in smoke of a component under investigation often precluded its isolation in quantities sufficient for application of the classical chemical techniques (melting point and mixture melting point determinations, derivative preparation, elemental analysis, etc.) used for identification.

The authors of some of the early reviews and catalogs on tobacco smoke composition listed the smoke components reported in the literature without regard to the analytical validity of their identification. This problem has progressively decreased over the years as analytical technology has increased in sophistication.

Few, if any, commercial products have experienced the analytical scrutiny that has been applied to tobacco smoke or tobacco. The composition of coffee has been examined, but the number of components identified is less than 25% of the number identified in tobacco smoke. Despite the identification of over 4700 additional smoke components since the 1954 listing by Kosak, various investigators have estimated from gas chromatographic scans that for each component identified in tobacco smoke, there are 5–20 components present at extremely low per cigarette yields that have not yet been identified. Thus, as noted by Wakeham (4103), when the identified tobacco smoke components numbered about 1350, "Gas chromatographic scans indicate there are many more, probably over ten thousand, possibly even a hundred thousand [tobacco smoke components]."

Grob (1422), one of the pioneers of the use of glass capillary gas chromatography in tobacco smoke composition studies, as well as other tobacco smoke investigators also noted that the number of peaks, each of which represented at least one component, in the chromatographic scans far exceeded the number of identified components.

In addition to the advancement in knowledge of the chemical composition of cigarette smoke was the advancement in the knowledge of its physical properties, that of an aerosol. An aerosol is defined as a colloidal system of dispersed liquid or solid material in a gaseous medium: cigarette smoke is an aerosol comprising liquid droplets in a gas.

For nearly two decades, investigators have accumulated knowledge on the conditions involved in the formation of MSS and SSS aerosols during the smoking of a cigarette and the factors contributing to or modifying their yields and composition. Theories on smoke formation in vogue in the late 1950s and early 1960s were demonstrated to be incorrect; e.g., many investigators thought that all smoke components not originally present in tobacco and thus appearing in the MSS by pyrogenesis from the tobacco were formed at or near the fire cone at temperatures in excess of 900°C. New and more nearly correct theories replaced the old ones. Advances in our knowledge of smoke formation and transport were possible because of improved technologies developed to accomplish the following tasks [cf. Townsend (3941a)]:

1. Accurately measure temperatures during puffs and during the smolder period between puffs at various sites within the burning cigarette and its fire cone.
2. Follow the formation of specific components and their subsequent passage and transport, in the case of MSS components, through the tobacco rod by puff-driven volatilization, repetitive condensations and revolatilizations, filtration by tobacco rod and filter-tip material, etc.
3. Follow the formation of specific components and their subsequent emission, in the case of SSS components, to the atmosphere.

Baker (163a, 166) has written at length on his original research and that of others on MSS and SSS aerosols and the conditions involved in the cigarette in their formation and transport. He has also periodically authored or coauthored several excellent and detailed reviews (167, 169, 170a, 171a, 171b, 174d) on this subject.

It is now known that the fire cone temperature of 900+°C measured during the puff primarily generates gaseous components such as the carbon oxides, water, ammonia, and nitric oxide. During the puff, pyrogenesis of most MSS components occurs in a 3–4 mm cylinder of the tobacco rod a few millimeters behind the fire cone–tobacco rod interface where the temperature ranges from 500°C to 650°C. During the smolder period, the fire cone temperature is 500°C–600°C, and it is at this temperature range that SSS is generated from the tobacco.

Just as profound quantitative differences exist among the chemical compositions of fresh and aged MSS, fresh and aged SSS, and ETS, there are several differences in the physical properties of these smokes. One physical property important in these various types of cigarette smoke, their inhalation, and their retention is their particle size. There are several ways to describe particle size. A frequently used one is mean mass aerodynamic diameter (MMAD).

In his review of the aerosol studies on cigarette smoke, Ingebrethsen (1860) points out that two factors are extremely important with respect to the measured particle size of an aerosol: (1) the time between aerosol generation and particle size measurement and (2) the concentration of the aerosol.

High aerosol concentration and extended time between generation and measurement result in increased coagulation

of particles and increased particle size. Freshly generated MSS and SSS have the major fraction of particle sizes, expressed as MMAD, in the range 0.3–0.4 μm [Ingebrethsen (1860c)]. Since SSS—both intra- and interpuff generated—is the major contributor, estimated at 85%–90%, to ETS, it is important to realize that its physical properties are constantly and progressively changing. These changes begin the moment it is generated and continue during its extensive dilution as it disperses through the room until it is eventually perceived as ETS. Depending on the proximity of the measuring device to the source of the SSS, it is obvious that a range of particle sizes could be found, ranging from that measured in freshly generated SSS to that found in essentially equilibrated ETS. The behavior of particles in SSS under carefully controlled conditions has been studied in detail by Ingebrethsen and Sears (1860e).

Another problem of determining the contribution of ETS to a given air space (home, office, restaurant, aircraft, etc.) is that other non-ETS contributors to VP and PP are measured at the same time as the contribution of ETS to VP and PP is measured. These include contributions from cooking oils and foods in homes and restaurants, cleaning preparations and furniture polishes, personal products (perfumes, after-shave lotions, hair sprays, deodorants, etc.), and vehicular exhausts where the air space is adjacent to much-traveled roads. Chromatographic scans of samples collected in a conference room before and after a 2 h meeting during which smoking was permitted revealed that chromatographic peaks, some representing compounds from nontobacco sources, were much larger than those known to be due to ETS (1352a). Similar findings were reported by Bayer and Black (223) who compared volatile organic contaminants (VOCs) in the offices of smokers and nonsmokers. The authors noted:

> Building materials and furnishings are the most common source of these VOCs. [The] VOC building background makes it difficult to distinguish ETS contamination from the VOCs out-gassing from other sources.

A major distinction between MSS and SSS that affects particle size is that MSS is acidic,* with a pH ranging from 6.0 to 6.6; whereas, the pH of SSS ranges from 6.7 to 7.5. The SSS from most cigarettes is alkaline with pH above 7.0. Under acidic conditions (pH < 7.0), smoke amines such as nicotine are considered to be protonated and have relatively low volatility. Under alkaline conditions (pH > 7.0), such amines are considered to be nonprotonated, i.e., "free," and are relatively more volatile.

The differences and similarities in the physical properties among MSS, SSS, and ETS are summarized in Table 0.10.

When freshly generated, MSS is inhaled during smoking; the aerosol particles in the smoke are exposed in the respiratory tract to an atmosphere whose temperature is 37°C and whose relative humidity exceeds 95%. As a result, the inhaled particles absorb water and increase in size. Those particles that are exhaled are, on average, 20%–25% larger than the inhaled particles (273, 1860b, 1860d, 1860e). When these water-saturated exhaled MSS particles (temperature at 37°C) are released into the atmosphere (temperature generally below 30°C and relative humidity below 50%), they cool and immediately undergo several evaporative processes which are completed in a few milliseconds. These processes include the following:

1. Components, usually gaseous under ambient conditions, evaporate from the particle.
2. Components with modest vapor pressures evaporate from the particle.
3. Water, incorporated into the particle either during the smoke-formation process in the tobacco rod or during its residence time in the highly humid confines of the respiratory tract, evaporates.

SSS particles behave much differently than MSS particles. Although little research has been conducted on fresh, undiluted SSS, it is reasonable to expect that the particles are physically similar to those in MSS. However, the high dilution which occurs almost immediately upon generation has the effect of preventing coagulation and promoting evaporative losses. Also, because of the alkalinity of SSS, basic components are nonprotonated and readily evaporate from the particle. Studies in 1985 by Eudy et al. (1169) on SSS and ETS, both generally alkaline (pH > 7.0), indicated that little (<5%) of the nicotine remains in the ETS particle, the bulk of it (>95%) evaporates from the particle and appears in the VP.

As a result of these various processes, the SSS and exhaled MSS particles, on their way to contribute to ETS, decrease both in particle mass and in particle size to an MMAD ranging from 0.15 to 0.20 μm for the major fraction of the particles. Experimental data for the decrease in SSS particles size were presented by Ingebrethsen and Sears (1860e, 1860f). Ten minutes after smoke generation, a major fraction of the SSS particles showed a particle size with an average MMAD of 0.198 μm.

It should be noted that these various evaporative processes involve relatively volatile smoke components. The particle size is not diminished to any appreciable degree by evaporation of nonvolatile and high-molecular-weight components such as the PAHs (B[*a*]P, DB[*a,h*]A, indeno[1,2,3-*cd*]pyrene, dibenz[*a,i*]pyrene) listed by Hoffmann and Hecht (1727) and Hoffmann and Hoffmann (1740, 1741) and other components such as solanesol, the phytosterols, α-tocopherol, and the saturated aliphatic hydrocarbons. These components remain in the particles.

In addition to the dilution that occurs when the ETS particles disperse through the room space, an additional dilution occurs by the deposition of ETS particles on the surfaces present. These processes—evaporation, dispersion, deposition—decrease the concentration of ETS particles. Ventilation, air exchanges per unit time, nature of the surfaces (fabric, plastic, wood, etc.), temperature, relative humidity, number

* The MSS from cigarettes fabricated from dark air-cured tobacco or air-cured cigar-type tobacco shows a slightly alkaline pH.

TABLE 0.10
Physical Properties[a] of MSS, SSS, and ETS

Properties	MSS	SSS	ETS
Number of identified components	Over 4300 in PP; about 1000 in VP. Some components are present in both the PP and VP, e.g., HCN, simple phenols, volatile *N*-nitrosamines	Composition assumed to be qualitatively similar to that of MSS; i.e., the number and identity of the SSS and ETS components are the same as those in MSS. Quantitative differences in component levels are substantial. The distribution of a component between PP and VP depends on the nature (acid, base, neutral) and the physical properties (vapor pressure, etc.) of the particular component. The decay (decrease) of an individual ETS component is also dependent on numerous factors such as its nature, its physical properties, and the temperature, relative humidity (RH), ventilation, and nature of surfaces (carpets, drapes, upholstered furnishings, etc.) in the smoke space	
Approximate temperature of			
• Fire cone	850°C–950°C	500°C–650°C	
• Smoke formation	500°C–600°C	500°C–600°C	
Approximate % of tobacco rod consumed[b]	30–40	50–60	
Particle size, μm	Fresh whole MSS particles have MMAD = 0.3–0.4 μm[c] and contain volatile components which readily vaporize from the particles. Because of coagulation, hydration, evaporative transfer, and other physical processes, e.g., the cloud effect, MSS particles behave as though they have a MMAD in the micron range[c]	Fresh SSS particles are about the same size as MSS particles; within a short time (<10 min) after generation, the MMAD ≫ 0.2 μm[c] for SSS particles	During dilution to ETS, exhaled MSS particles lose H2O and other volatile PP components; particle size decreases to an MMAD = 0.15–0.20 μm[c] SSS particles lose H_2O and other volatile PP components such as nicotine and amines. Thus, particle size decreases to an MMAD = 0.15–0.20 μm[c]
Particle concentration, number/cm^3	10^9–10^{10}		~1–5 × 10^5
Retention of particulate matter in respiratory tract	50%–90% Percentage retention as measured by weight loss between time of inhalation and exhalation due to mechanical trapping plus loss of volatiles from inhaled particles		10%–11% Low percentage retention as measured by weight loss is due to virtual absence of coagulation and other physical phenomenon, e.g., cloud effects, and lack of water and other volatile components which may be lost by inhaled ETS particles
Smoke pH	6.0–6.6 for cigarette MSS[d]	6.7–7.5 for cigarette SSS. Some investigators have reported SSS pH values as high as 8.0	Neutral (pH 7.0) to slightly alkaline
Inhalability of smoke into lungs	MSS inhalability favored by pH less than 7.0	Inhalability of smoke (whether cigarette SSS, pipe MSS, or cigar MSS) is progressively diminished as smoke pH increases above pH 7.0	Because of extreme dilution by air and near neutrality (pH close to 7.0), the inhalability of ETS is nearly the same as that of air
Nicotine behavior	99+% of nicotine in cigarette MSS is in the PP; because the MSS pH is much less than 7.0, amines such as nicotine are protonated; nicotine in MSS PP is presumed to be protonated by the low-molecular-weight acids present in MSS[e]	Because of alkalinity of SSS and the high concentration of SSS particles near the burning cone, nicotine (and other volatile smoke components) is distributed between the SSS PP and SSS VP; PP–VP equilibrium for these compounds is not attained adjacent to the cigarette burning cone	Because of the extremely high dilution of ETS and its pH at or slightly above 7.0, little nicotine (or other amines) is found in ETS PP; more than 95% of the nicotine in ETS is in the nonprotonated form and is found in ETS VP

TABLE 0.10 (continued)
Physical Properties[a] of MSS, SSS, and ETS

Properties	MSS	SSS	ETS
Relationship of smoke yield to cigarette design	MSS controllable by • Tobacco rod length and circumference • Filter type and dimensions • Tilter-tip additives • Tobacco blend and weight • Processed tobacco (reconstitution, expansion) • Paper and paper additives • Air dilution (paper porosity and filter perforation)	Interpuff SSS, the major contributor to total SSS, is primarily controlled by cigarette tobacco blend and weight and to a lesser degree by paper properties and additives	Since ETS comprises 85%–90% diluted and aged SSS plus 10%–15% exhaled MSS, the control of ETS resides primarily with those factors which control intrapuff SSS generation

[a] Properties listed are those for unaged and undiluted smoke.
[b] Tobacco rod not consumed during smoking estimated at 5%–8% for filtered cigarettes and 20%–25% for nonfiltered cigarettes.
[c] MMAD value listed is that for a major fraction of the smoke.
[d] The MSS from cigarettes fabricated from dark air-cured tobacco or air-cured cigar-type tobacco shows a slightly alkaline pH.
[e] Protonation of nicotine in tobacco due to long-chained acids (palmitic acid, stearic acid, etc.) and polycarboxylic acids (oxalic acid, malic acid, citric acid).

of cigarettes smoked per unit time, and number of persons present are some of the known variables that will also influence the concentration of ETS particles.

Questions are frequently raised about the particle size of MSS, SSS, and ETS and the relationship between particle size and retention in the respiratory tract of the inhaled smoke. Usually, particle size plays an important role in determining mainstream particulate retention in the lungs. Based on a comparison of particle size, one might expect ETS and MSS to be retained similarly in human lungs on a percentage basis. Empirical data demonstrate that this is not the case. In the case of MSS, other factors come into play. These drastically alter the amount of MSS particulate matter that is retained. Weight-loss measurements give values ranging from 50% to 90% for the percentage retention of inhaled MSS (1860c). The percentage retention is a characteristic of the individual smoker. The retention of inhaled MSS is much higher than would be predicted by the measured MMAD of fresh smoke, 0.3–0.4 µm. Ingebrethsen (1860c) reviewed the literature on the retention of MSS and identified five factors which might be responsible for increased MSS particle retention. These include coagulation, electrical charge, growth by water condensation, evaporative transfer, and cloud effects. Evaporative transfer and cloud effects were deemed to be the most significant factors. Recently, Moldoveanu et al. (2601b) and Moldoveanu and St. Charles (2601a) reported on the different degrees of retention by humans of 160 cigarette MSS components by comparison of their levels in smoking-machine-generated MSS *vs*. their levels in smoker-exhaled MSS.

ETS particles behave quite differently from MSS particles in terms of human retention. Unlike MSS, the retention of ETS in the lung is not affected by evaporative transfer and cloud effects. Instead, ETS retention is mainly influenced by particle size. Theoretical calculations indicate that the percentage retention of particles equivalent in size to ETS particles should vary between 10% and 20%. A value within the theoretical range was obtained: Hiller et al. from studies with human mouth-breathing volunteer nonsmokers who inhaled orally polystyrene latex spheres of particle sizes similar to those of diluted SSS (1654a) and five volunteers who inhaled a tobacco smoke defined as "sidestream smoke at a concentration similar to that encountered indoors with smokers present" (1654b), estimated the percentage retention of the smoke to be 11%.

The difference in particle retention between MSS and ETS is due largely to the high dilution which SSS particles experience almost upon formation. This dilution causes ETS particles to behave as model, nonvolatile, inert particles by preventing coagulation, obviating cloud effects, and promoting evaporation prior to inhalation.

As noted earlier (Table 0.10), numerous technologies introduced sequentially from the mid-1950s to the late 1960s were incorporated into cigarette design to control MSS yield and composition, what some have characterized as a "less hazardous" cigarette when included in cigarette design [Gori and Bock (1334b), NCI (2683), USPHS (4005, 4009)]. These technologies include

1. Tobacco blend and weight
2. Tobacco rod length and circumference
3. Filter tips (material type and additives)
4. Processed tobaccos (reconstituted tobacco sheet, expanded tobacco)
5. Paper (type and additives)
6. Air dilution (increased paper porosity, filter-tip perforations)

The chronology of introduction of these technologies in U.S. cigarette products is noted in Figure 0.5. Over the years,

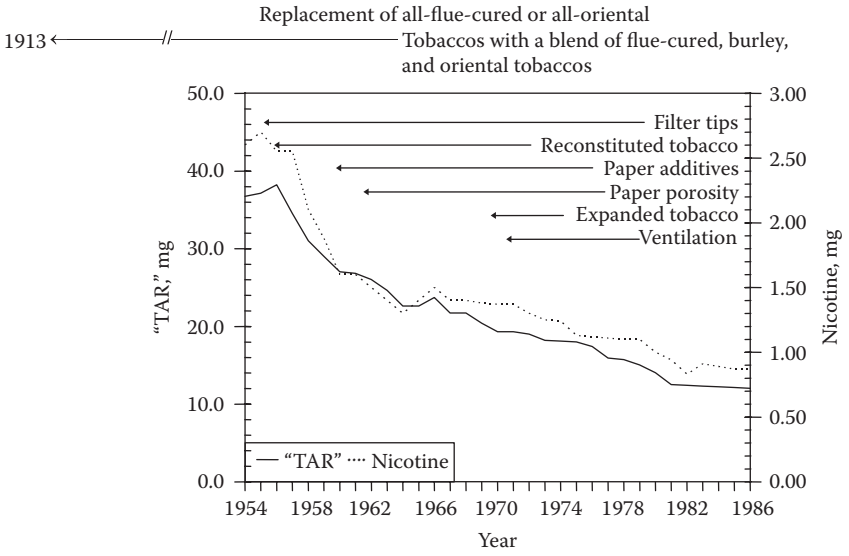

FIGURE 0.5 "Tar" and nicotine yields, sales-weighted average basis, U.S. cigarette products.

use of these technologies in concert and to various degrees in cigarette design has provided the consumer with a great variety of products whose number has increased from about a dozen in the mid-1950s to nearly 1250 in 1995 (1177c). It should be remembered that the cigarette is a system: All of these technologies used in cigarette design are interactive. That is, inclusion of or change in the level of use of any particular technology may require other adjustments in the cigarette design to maintain certain attributes acceptable to the consumer. In contrast, by current technology, SSS yield is controlled almost totally by tobacco blend and weight. The SSS is not subjected to filtration, the effect of filter-tip additives which specifically remove certain MSS components from MSS (phenols, volatile *N*-nitrosamines) or air dilution effects.

Adams et al. (31) reported data on MSS and SSS yields of 14 components in the smokes from four U.S. commercial cigarettes of different design: a nonfilter cigarette, two filtered cigarettes, and a perforated-filter cigarette. MSS and SSS yield data for TPM, nicotine, a PAH–(B[*a*]P), a phenol–catechol, a volatile *N*-nitrosamine–*N*-nitrosodimethylamine (NDMA), and a tobacco-specific *N*-nitrosamine–*N*-nitrosonornicotine (NNN) are summarized in Table 0.11.

The SSS TPM yields shown in Table 0.11 for the nonfiltered and two filter-tipped cigarettes are, on average, about 58% higher than the SSS TPM yield from the perforated-filter cigarette. Most perforated-filter cigarettes, such as Perforated Filter-D in Table 0.11, not only incorporate a perforated filter with a high percentage air dilution to reduce MSS TPM but also incorporate substantial levels (30%–50%) of expanded tobacco in the cigarette design. The inclusion of such a large percentage of expanded tobacco in the blend substantially reduces the weight of tobacco in the tobacco rod and the weight of tobacco consumed during the SS-generating smolder periods. Thus, these data show the SSS TPM yield from the perforated-filter cigarette is substantially less (37%) than the average of the SSS TPM from the other three cigarettes.

In a more recent study on the MSS and SSS yields from cigarettes classified as low tar, Chortyk and Schlotzhauer (723, 724a) provided data which differ substantially from the Adams et al.'s (31) data in Table 0.11 and from other data (3190) reported for comparable "tar"-yield cigarettes. The differences in the data for comparable FTC "tar"-yield cigarettes were found for cigarettes delivering approximately 23, 10, and 7 mg. In their MSS and SSS collection and analysis, Chortyk and Schlotzhauer (724a) used their previously reported SSS collection procedure (723) in the generation of their data. Green (1353) commented on several deficiencies in the procedures used and interpretations made by Chortyk and Schlotzhauer (724a) from their data. Examination of their data and comparison of them with the Adams et al. (31) and RJRT (3190) data (see Table 0.12) reveal an additional problem: For the three cigarette categories (23, 10, and 7 mg FTC "tar" yields), the SSS/MSS ratios for the TPMs in the Chortyk–Schlotzhauer study were between two and seven times greater than those reported in the other studies. Similarly for nicotine, the Chortyk–Schlotzhauer SSS/MSS ratios were from about 1.5 to over 7 times greater than those reported in the other studies. This strongly suggested a problem with their SSS collection procedure.

The escalation of the number of identified tobacco and tobacco smoke components is depicted in Figure 0.3. This tremendous increase in the number of identified tobacco smoke (and tobacco) components was made possible by successive advances in analytical technology, particularly the technology pertinent to the separation of components in complex mixtures.

It is realized that investigators who pioneered an emerging analytical technology were often involved with the development and/or use of the technology prior to the period indicated in Figure 0.5. No slight of their noteworthy contributions is intended. The periods indicated in Figure 0.5 are those when the analytical technology in question was sufficiently advanced and used by almost all investigators

TABLE 0.11
MSS/SSS Distribution of Selected Components Delivered by Four U.S. Commercial Cigarettes

Smoke Component, Yield/Cig	Nonfiltered A		Filtered B		Filtered C		Perforated Filter D	
	MSS	SSS	MSS	SSS	MSS	SSS	MSS	SSS

involved in the analysis of tobacco smoke and/or definition of its composition.

Prior to the early 1950s, the major part of tobacco smoke component isolation effort involved so-called classical chemical techniques, i.e., separation of the smoke condensate into neutral, acidic (acids and phenols), and basic fractions by partitioning between water-immiscible organic solvents and water, aqueous basic solutions, and/or aqueous acidic solutions, followed by crystallizations and/or distillations of the subfractions.

In the early 1950s, liquid column chromatography on column packings such as alumina, silicic acid, or Fluorosil® of the neutral, acidic, or basic fractions, as appropriate, permitted further separation of the components prior to application of the classical chemical techniques. UV and IR spectrometry was also available and used not only to combine chromatographic fractions rich in a specific component but also to assist in the identification of the component. UV absorption and fluorescence spectrophotometry were extremely useful in identification of the PAHs in tobacco smoke.

In the late 1950s/early 1960s, commercial equipment for gas chromatography became available. This technique, coupled with those mentioned previously, augmented the investigator's ability to separate, isolate, and identify smoke components. Mass spectrometry and nuclear magnetic resonance equipment and techniques were also more readily available and became additional tools that facilitated component identification. In the early days of gas chromatography, there were fewer than a dozen chromatographic column packings commercially available, and most of these did not permit satisfactory separations above 200°C. By the late

1960s, the number of available column packings increased, and the properties of newly designed column packing materials permitted separations at temperatures of approaching 350°C.

In the early 1960s, investigators such as Grob (1413) began the study on capillary gas chromatography and subsequently glass capillary gas chromatography. A major contribution by Grob was his development of methods to prepare and coat the inner wall of a capillary tube to increase its effectiveness and efficiency in separations. By the late 1960s/early 1970s, this emerging technology—glass capillary gas chromatography—had become an extremely powerful analytical tool and was used to great advantage in the study of the complex mixtures tobacco smoke [cf. Grob (1416–1419, 1422) and Grob and Völlmin (1426, 1427)] and tobacco extracts [Lloyd et al. (2389)]. The glass capillary column was usually a small-diameter (about 1 mm or so) glass or quartz tube, extremely long (50 to 300–400 m) whose interior was not packed with a solid adsorbent or an inert material mixed with a liquid adsorbent as in the previously used gas chromatographic columns. The inner wall of the narrow-bore capillary was coated with a thin layer of a liquid adsorbent. This technology not only enhanced separation capability but permitted separations to be made with extremely small samples. These advances in analytical technology were usually accompanied by a break and an increased slope in the plot of number of identified tobacco smoke components *vs.* time (see Figure 0.3). The next break in the plot and increased slope occurred in the mid-1970s when more and more investigators enhanced the effectiveness of glass capillary gas chromatography by coupling the gas chromatograph to a mass spectrometer. This permitted separation of the components of the particular tobacco smoke fraction under study and determination of the molecular weight and/or fracture pattern of each component as it exited the chromatograph and was analyzed in the mass spectrometer. Interpretation of the data thus obtained, usually in concert with findings from UV, IR, and/or NMR spectra, permitted very rapid and unequivocal identification of the components from the smoke fraction (1426, 1427). An outstanding example of the use of gas chromatography–mass spectrometry in the definition of tobacco smoke composition is the study by Snook et al. (3756–3759) on the PAHs in cigarette MSS. Over 500 individual PAHs and their homologs were detected, and many were identified unequivocally. The early to mid-1970s also saw the emergence of high-performance liquid chromatography (HPLC) (830a, 1361), a highly efficient and effective variation of liquid column chromatography.

The traditional method used to examine CSC (or a tobacco extract) usually involved its initial partition between an aqueous alcohol solution and a water-immiscible organic solvent such as hexane, cyclohexane, or diethyl ether. The organic solvent-soluble material was then separated into several neutral, acidic, and basic fractions. These, in turn, were then subjected to the various analytical techniques available at the time. Considerable success was attained in isolation and identification of the organic solvent-soluble smoke components. For many years, however, there was no satisfactory technique available to separate, isolate, and identify the many components in the aqueous alcohol fraction from the aqueous alcohol–water-immiscible organic solvent partition. Many of the aqueous alcohol-soluble components are highly polar, highly oxygenated compounds, and no chromatographic system was available to effect clean separations. In addition, many of these components—because of their structures—were highly labile at the temperatures used in gas chromatographic separation. By use of the technology known as silylation, these sometime heat-sensitive, highly polar components were converted to chromatographable stable silyl derivatives which can be readily separated by glass capillary gas chromatography and identified by mass and other spectral techniques.

By use of the latest analytical technology available at the time, the mainstream CSC from a typical cigarette was reexamined with particular emphasis on the composition of the aqueous alcohol-soluble material. The separation and identification of 1125 previously unidentified tobacco smoke components were described by Schumacher et al. (3553), Newell et al. (2769), and Heckman and Best (1587) (see Table 0.13). A striking example of the effectiveness of the improved analytical technology on tobacco smoke component identification is the following: In 1977, Schmeltz and Hoffmann (3491) cataloged about 420 nitrogen-containing components identified in MSS. They indicated that the number of identified nitrogen-containing tobacco smoke components had increased by about 200 since a previous review of nitrogen-containing tobacco smoke components by Neurath (2724). In a presentation and publication, Heckman and Best (1587) described the separation and identification of nearly 270 new nitrogen-containing smoke components, an increase of more than 60% over the number described by Schmeltz and Hoffmann (3491) in their review article.

TABLE 0.13
Number of Tobacco Smoke Components Reported (1587, 2769, 3553)

Investigators	Total Identified	Newly Identified	Confirmed Previous Identification
Heckman and Best (1587)	368	268	100
Newell et al. (2769)	643	470	173
Schumacher et al. (3553)	479	387	92
Totals	1490	1125	365

The following is another example of the impact the improved analytical technologies had on the ability to further define the composition of tobacco smoke: In the late 1950s/early 1960s, the composition of an aliphatic ester fraction isolated from flue-cured tobacco by Rowland and Latimer (3358) and from cigarette MSS by Rodgman et al. (3294) was partially defined in both cases by Rodgman et al. (3294). By saponification of the aliphatic ester fraction, followed by separation of the alcohol and acid moieties, Rodgman et al. showed that the tobacco- and tobacco-smoke-derived aliphatic ester fractions were qualitatively the same and theoretically comprised at least 272 esters formed from at least 17 aliphatic acids [myristic (C_{14}) to octacosanoic (C_{28}), oleic, linoleic, and linolenic] and 16 normal long-chained, primary aliphatic alcohols [1-dodecanol (C_{12}) to 1-heptacosanol (C_{27})]. In 1984, with improved chromatographic capability and a mass spectrometric system capable of detecting much higher molecular weights than those used by Rodgman et al. in 1961, Arrendale et al. (103) reexamined the aliphatic ester fraction from tobacco. The saponification and subsequent separation of acids and alcohols were no longer required. Arrendale et al. were able to identify unequivocally many of the individual esters by glass capillary gas chromatography and mass spectroscopic examination of the aliphatic ester fraction isolated from the tobacco. The alcohol moiety of the esters identified ranged from 1-tetradecanol (C_{14}) to 1-dotriacontanol (C_{32}); the acid moiety ranged from lauric acid (C_{12}) to *n*-dotriacontanoic acid (C_{32}) plus numerous *iso*- (from C_{13} to C_{28}) and *anteiso*- (C_{13}–C_{18} plus C_{20}) isomers of several saturated aliphatic acids. Since each ester reported by Rodgman et al. was found in tobacco and smoke (3294), logic dictates that each new tobacco ester found by Arrendale et al. is also present in smoke (103). Thus, the Arrendale et al. findings substantially increased both the number of components in tobacco and tobacco smoke.

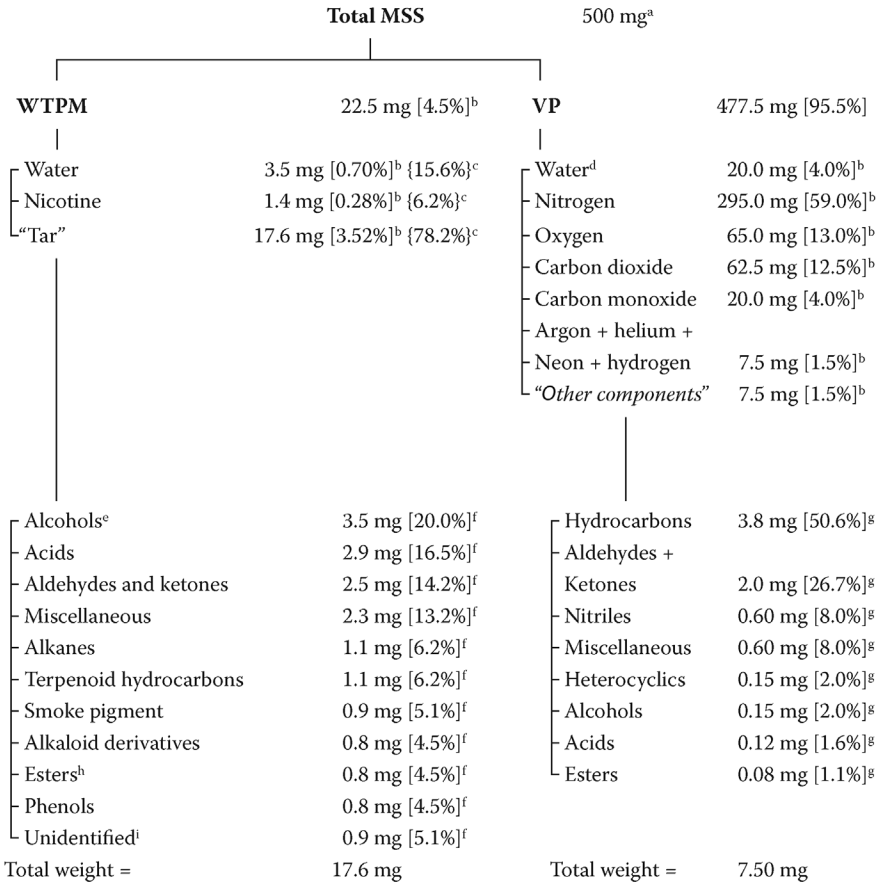
Most of the studies reported in the literature from the mid-1950s to the late 1970s/early 1980s on tobacco smoke composition dealt with the composition of the MSS from the cigarette. Gradually during the late 1970s, more and more studies were reported describing the composition of cigarette SSS [cf. Klus and Kuhn (2142)]. Presently, the major emphasis on tobacco smoke composition involves the composition of ETS, health problems reportedly associated with passive smoking, i.e., exposure to ETS, and the levels of specific components reported to be associated with these health problems [Ecobichon and Wu (1108a), Environmental Protection Agency (EPA) (1148, 1148a, 1148b), Guerin et al. (1445)]. SSS and ETS are discussed in later sections. Because of the relative efforts expended on cigarette MSS, cigarette SSS, and ETS, the numbers of identified components in each of these smokes were reported as approximately 4800, 500, and 100, respectively (3255). Given sufficient time and effort, any component identified in MSS could eventually be identified in SSS and ETS.

The approximate (and general) composition of cigarette MSS is well defined. An 85 mm cellulose acetate filter-tipped commercial cigarette (65 mm tobacco rod, 20 mm filter tip) whose filler, a typical American blend of tobaccos, weighed approximately 1000 mg was machine smoked with the FTC-prescribed smoking parameters (35 mL puff volume, 2 s puff duration, 1 puff/min, 25°C, 60% relative humidity, FTC-specified butt length) (1177b). This cigarette gave approximately 500 mg of total MSS. To separate the tobacco smoke aerosol into its two major phases—the PP and the VP—the smoke was passed through a Cambridge filter pad which retains more than 99.9% of the PP, defined as total WTPM. The VP is that portion of the smoke aerosol which passes through the Cambridge filter pad, and the major portion of its weight is due to the components of air drawn through the cigarette during the smoking process (nitrogen, oxygen, argon, etc.).

The distribution and approximate composition of the total MSS emerging from this cigarette are summarized in Figure 0.6. The data in Figure 0.6 represent a consolidation of composition data from several sources including data from RJRT R&D [Laurene (2299a)] plus data from Keith and Tesh (2068), Norman (2799a), and Browne et al. (445). To simplify the calculations throughout Figure 0.6, one value was deliberately adjusted slightly for convenience: The total MSS collected actually weighed slightly in excess of 497 mg, but the value 500 mg was used to calculate the percentages shown throughout Figure 0.6. In addition, no attempt was made with these data to define the degree of partition of some components between the PP and the VP. Because of their vapor pressure properties, significant quantities of some smoke components are found in both the PP and VP of cigarette MSS. These include hydrogen cyanide, several of the simple phenols (phenol, *o*-cresol, *m*-cresol, *p*-cresol), and several of the volatile *N*-nitrosamines.

It is obvious from the data in Figure 0.6 that the particulate matter, whether described as WTPM, TPM, or FTC "tar," comprises less than 5% (100 × 22.5/500 = 4.5%) of the total MSS emerging from the cigarette. This is true of nearly all commercial U.S. cigarettes no matter what the FTC "tar" yield. The composition of the MSS VP has been almost completely defined. It is estimated that components representing less than 1 mg of the PP (5.1% of the FTC "tar," less than 0.2% of the total MSS) remain unidentified. If the number of unidentified components is as high (as many as 100,000) as some investigators estimate (1422, 4103), then the level of each unidentified component must average in the low-nanogram range.

The extremely wide variations in the yields of components delivered in the MSS during the smoking of a cigarette have presented unique challenges to those involved in not only the identification of smoke components but also in their quantitation. Table 0.14 is a minor modification of the initial version presented in 1996 by Green and Rodgman (1373). In it, the logarithmic presentation is a more concise depiction of this wide variation in the levels of selected smoke components. For most of the components shown in Table 0.14, there obviously is a range of values, and the extent of the range for each component is dependent on the cigarette type under study (filtered, nonfiltered) and the



Note: The properties of the cigarette studied were as follows: 85 mm filtered cigarette, 68 mm, tobacco rod, 17 mm triacetin-plasticized cellulose acetate filter tip, cased commercial American blend.

[a] It is now estimated that over 5000 components have been identified in MSS from tobacco cigarettes. Some components such as water, the simple phenols, hydrogen cyanide, and the volatile *N*-nitrosamines are found in both the VP and PP of cigarette MSS. Hence, the total of the number in the two phases appears to exceed the number in the whole.

[b] Value in brackets represents percent of Total MSS weight, 500 mg.

[c] Value in parentheses represents percent of WTPM, 22.5 mg.

[d] Much of this water is contributed by the air drawn through the cigarette during puffing (35 mL puff, 1 s duration, 1 puff/min, total puffs = 10) in a laboratory whose atmosphere is controlled to the specifications proposed by the FTC, namely, temperature = 25°C, relative humidity (RH) = 60%.

[e] This class of compounds includes added humectants (glycerol, propylene glycol) transferred from the tobacco rod to the MSS. The transferred humectants constitute about 10%–12% of the FTC "tar."

[f] Value in brackets represents percent of FTC "tar" weight, 17.6 mg.

[g] Value in brackets represents percent of "Other Components" weight, 7.5 mg.

[h] This class of compounds includes transfer to smoke of some triacetin added to the filter tip plus its degradation products mono- and diacetin.

[i] There have been various estimates of the number of unidentified components present in extremely small amounts in the FTC "tar." Several investigators have estimated the number of unidentified components to range from 5 to 20 times the number of identified components, i.e., from about 20,000 to 100,000.

[a] This tobacco smoke component was included in a list published by Hoffmann and Hecht (1727) in which the component was one of 43 components defined as a "tumorigenic agent in tobacco and tobacco smoke."

[b] In a modified list of "tumorigenic agent in tobacco and tobacco smoke," Hoffmann and Hoffmann (1740) increased the number of components from 43 to 60 and included several of the "cooked food" mutagens as well as several other MSS components (1,3-butadiene, isoprene, etc.).

[c] Benz[*e*]acephenanthrylene is the currently accepted name for benzo[*b*]fluoranthene.

[d] Benzo[*rst*]pentaphene is the currently accepted name for dibenzo[*a,i*]pyrene.

weight of tobacco consumed during the smoking of the cigarette for the analysis. In general, the locations of the various components on the logarithmic plot have been adjusted for a cigarette yielding about 18–20 mg/cig of FTC "tar." If the design of the cigarette has been modified to reduce FTC "tar" yield, diminution of the yields of the other components will occur but not necessarily to the same extent as the decrease in FTC "tar" yield. Cigarette design parameters [tobacco rod length and dimensions, filter type and dimensions, filter-tip additives, tobacco blend and weight, processed tobaccos (reconstituted tobacco sheet, expanded tobacco), paper and paper additives, and air dilution (paper porosity and filter perforation)] have profound effects on cigarette MSS yield and composition. Also shown in Table 0.14 are those components listed by Hoffmann et al. (1727, 1740, 1741, 1743, 1744) as "tumorigenic components of tobacco and tobacco smoke" and cited as such by the U.S. Surgeon General (4012), the U.S. EPA (1148a), and the U.S. Occupational Safety and Health Administration (OSHA) (2825). The validity and meaning of their classification of specific tobacco smoke components as tumorigenic were recently discussed by Rodgman (3265).

Yields for the VP components range from a high of 50–60 mg/cig for carbon dioxide to lows in the nanogram range for vinyl chloride and the volatile nitrosamines such as *N*-nitrosoethylmethylamine. The major portion of the nitrogen (≫300 mg/cig) and oxygen (≫65 mg/cig) in MSS is derived from the air drawn through the cigarette during the smoking process.

The number of components identified in various tobacco types also increased substantially during the 1950s, 1960s, and 1970s both within and outside the tobacco industry. The purpose of such studies was essentially twofold: to define the tobacco components that (1) provided taste and aroma to the smoke to render it acceptable to the consumer and (2) were precursors of the smoke components asserted to be responsible for the health problems induced by tobacco smoke. Participating investigators over the years included USDA personnel initially under the leadership of Stedman in Philadelphia and subsequently by Chortyk after the move of the USDA tobacco research group from Philadelphia, PA, to Athens, GA.

The precursor research will be discussed in much greater detail in subsequent chapters dealing with those precursors in tobacco of MSS components considered adverse to the smoker, e.g., the precursors in tobacco of the PAHs, the phenols, the aldehydes and ketones, the *N*-nitrosamines, the *N*-heterocyclic amines. It is interesting to note that even the precursor studies led to differences of opinion among the scientists with views on the health problems associated with components in cigarette MSS. In 1942, Roffo (3327) proposed that the precursors of PAHs in the destructive distillate of tobacco were the tobacco phytosterols. In 1957, Fieser commented that the major precursor in tobacco of PAHs in MSS was probably cellulose (1181). Coauthors of several presentations and publications, Wynder, Wright, and Lam differed in their views on the major precursors in tobacco of PAHs in tobacco smoke. Because of his research findings from 1955 to 1959, Lam was a proponent of the concept that the long-chained aliphatic hydrocarbons were the major precursors in tobacco of the PAHs, including B[*a*]P, in MSS (2255–2258). Wynder was a proponent of the concept that the major precursors in tobacco of PAHs in MSS were the long-chained aliphatic hydrocarbons and the phytosterols (4354).* Wright, a colleague of Wynder from the early to the late 1950s, held a different view from that of Wynder and that of Lam. Wright considered the major precursors of PAHs in MSS to be the phytosterols and long-chained terpenoids

* Even though this article was coauthored by Wynder and Wright, the view held by Wright on the major precursors in tobacco of PAHs in smoke was omitted from the manuscript by Wynder.

such as solanesol (4282). Eventually, precursor studies by Rodgman and Cook (3269) in 1958 indicated that the view held by Wright was the correct one. The Rodgman and Cook 1958 findings were subsequently confirmed in the late 1970s at the USDA by Severson et al. (3616).

There were significant contributions by Rowland et al. in the early 1950s from their studies on the composition of flue-cured tobacco, studies which resulted in the isolation and identification by classical chemical means of the 45-carbon terpenoid alcohol solanesol (3359), its acetate and several other of its esters (3294, 3296, 3358), neophytadiene (3345), α-tocopherol and solanachromene (3347), the four isomeric 4-(2-butenylidene)-3,5,5-trimethyl-2-cyclohexen-1-ones (the megastigmatrienones) (3355), and several cyclotetradecanediols (3220, 3221, 3351, 3360) plus their oxabicyclo derivatives (3361). Over a decade later, with more advanced analytical technology, Lloyd et al. (2389) identified several hundred previously unidentified flue-cured tobacco components. From their early composition studies, similar to those of Rowland on flue-cured tobacco, Schumacher and Vestal isolated and identified numerous previously unidentified Oriental tobacco components (3561), including sclareolide (3533) and the first glucose tetraester (3535). Schumacher also defined numerous components in Maryland tobacco (3550). Roberts and Rohde in their study of the composition of burley tobacco identified numerous previously unidentified tobacco burley components, including several cyclotetradecanediols (3219).

As analytical methodology advanced after the 1950s, the number of identified tobacco and tobacco smoke components escalated dramatically. In addition to its study of tobacco smoke by Arnap (91–94) and Enzell et al. (1153, 1154), the R&D staff at the Swedish Tobacco Company published nearly 100 articles on the composition of tobacco, primarily Oriental tobacco. The many Swedish Tobacco Company investigators included Aasen, Almqvist, Behr, Enzell, Hlubucek, Kimland, Nishida, and Wahlberg, all of whom coauthored many tobacco composition articles (1–13, 52, 53, 84, 91–94, 227, 229–236, 1149–1157a, 1205a, 1660–1662, 2092–2095, 3315, 4083–4102). Excellent detailed summaries of their identification of hundreds of tobacco components and the generation of them from various terpenoid structures such as the noncyclic and cyclic carotenoids and the cyclotetradecane derivatives were presented and published in the late 1970s and early 1980s by Enzell (1149, 1150), Enzell and Wahlberg (1156), and Wahlberg and Enzell (4089, 4090).

In the 1960s and 1970s, the Demoles and their colleagues at Firmenich SA in Switzerland also studied the composition of flue-cured, burley, and Oriental tobaccos and characterized many previously unreported compounds in each, e.g., the studies by Demole et al. on burley tobacco composition (936–944), on flue-cured tobacco composition (945, 946, 948), and on Oriental tobacco composition (947).

As noted previously, it was estimated by Wakeham (4103) and Grob (1422) from their examination of gas chromatograms that the number of components in tobacco smoke far exceeded the number of identified components. A similar situation exists with the composition of tobaccos. As early as the mid-1970s, Dejong and Lam (922d) commented that the estimated number of enzymes in green leaves, including tobacco, ranged from 1,000 to 10,000. Our Master Catalog from which the various lists of component classes are derived comprises over 8000 components. The chapter on enzymes will list many of the tobacco enzymes but obviously will not include all of the great number of enzymes reported in tobacco.

The MSS yields for components of the PP range from that of FTC "tar" itself, shown as a yield of about 20 mg/cig in Table 0.14 (1373), to that of dibenz[*a,h*]acridine at an MSS yield of 0.1 ng/cig (100 pg/cig).* The magnitude of the range of yields for cigarette MSS components is demonstrated by the following: The ratio of the per cigarette yield of nitrogen (the most plentiful MSS component shown in Table 0.14) to that of dibenz[*a,h*]acridine (the lowest yield shown) is $\gg 3 \times 10^9$, i.e., ≫300 mg *vs.* 0.1 ng. The need for analytical methodology to determine smoke components from the high-milligram- to the low-picogram yield was one of the driving forces behind many of the developments and improvements in analytical technology for the study of complex mixtures.

ALPHABETICAL INDEX TO COMPONENTS IDENTIFIED IN TOBACCO, TOBACCO SMOKE, AND TOBACCO SUBSTITUTE SMOKE

The Index was created for two purposes. The first was to capture in one site all the basic information on the identified tobacco and tobacco smoke components discussed in the chapters of this book. The components in the Index are listed alphabetically. Secondly, the Index may permit the reader to easily retrieve or search for information on a specific tobacco and/or smoke component or class of components so that further study will be facilitated. To achieve these goals, the Index was constructed to include the following: (1) The CAS No. for many of the components; (2) an indication of the component identification in tobacco, tobacco smoke, or both; (3) the structure of many of the components; (4) the table number and chapter in which the component is not only referenced but its properties are described, particularly if they are considered adverse; and (5) for multifunctional components, several chapters and table numbers are cited. Additionally, the publishers of this book, Taylor & Francis/CRC Press of Boca Raton, Florida, have provided the Index in compact disc (read-only memory) (CD-ROM) format. Hopefully, the searchable format of the CD-ROM will aid the reader in retrieving any desired information.

The Index comprises almost 9600 components completely or partially identified in tobacco, tobacco smoke, and tobacco substitute smoke. It includes not only over 9600 identified components but also several hundred compounds

* Several new entries concerning *N*-heterocyclic amine data that were not available in 1996 for inclusion by Green and Rodgman (1373) are included in Table 5.

not identified in tobacco or tobacco smoke but reported by Doull et al. (1053) as tobacco ingredients used in the United States and by Baker et al. (172a, 174b) as tobacco ingredients used outside the United States and in a summary by Rodgman (3266) and in our Chapter 24. Because the transfer from a tobacco product to smoke of very few of the added ingredients has been examined, they primarily are listed as tobacco components. Exceptions include several humectants used in tobacco products for many years. However, it should be noted that the detailed pyrolysis study by Baker and Bishop (172a) indicated that many such added ingredients would transfer in part to MSS during the tobacco smoking process.

In some instances, the reader may wonder about the peculiar nature of the component listing. For example, a tobacco smoke component initially reported as 2-butene was later shown to be present in the smoke as *cis*- and *trans*-2-butene. Thus, three items are listed in the Index for 2-butene, namely, 2-butene (CAS No. 107-10-7), 2-butene, (*Z*)- (CAS No. 590-18-1), and 2-butene, (*E*)- (CAS No. 624-64-6). In the appropriate chapter and table, Chapter 1 and Table 1.11, references to the identification of each are provided. 2-Butenedioic acid is similarly listed in Chapter 4, Table 4.3 as 2-butenedioic acid (CAS No. 6915-18-0), 2-butenedioic acid, (*Z*)-(maleic acid) (CAS No. 110-16-7), 2-butenedioic acid, (*E*)-(fumaric acid) (CAS No. 110-17-8).

The reader will also find in the Index certain broad classifications of components, like oxidases and free radicals. These and similar examples in the Index are not there to confuse the reader, as many of the individual components in the broad classifications have specific CAS numbers. Generally, the references associated with these classes of components (found within the chapters noted in the Index) will provide the reader with information of a common nature. In nearly all cases, individual components such as ascorbate oxidase, choline oxidase, cytochrome oxidase, and glycolate oxidase follow after the broadly classified component, oxidase. Likewise, specific free radicals such as methyl-acyl radical, ethyl-acyl radical, and propyl-acyl radical {two isomers} may be found in the Index. For some components in the Index, several partially identified isomers exist, their number noted, and included in the total number of components identified in tobacco and/or smoke.

Although the number of enzymes, genes, and nucleotides listed in the Index is fewer than 500, their known number, as noted in Chapter 22, exceeds many thousands. The paltry number of enzymes, genes, and nucleotides listed in Chapter 22, Table 22.2 was never intended to represent the total biological agents operating in the plant. Those selected for inclusion were from texts, research manuscripts, and patents where active research was conducted in the past in attempts to better understand the physiology and biochemistry of tobacco. As future genetic research develops, it is envisioned that the identity and function of hundreds of thousands of additional chemicals will be published.

The authors hope that the format of the Index and accompanying CD-ROM will help the reader to reach a better understanding of the components of tobacco and tobacco smoke.

1 Hydrocarbons

1.1 ALKANES

In his catalog of tobacco smoke components reported in early 1954, Kosak (2170) listed hentriacontane as the only alkane identified in tobacco smoke. Subsequently, numerous investigations resulted in the identification of a great number of alkanes in tobacco and tobacco smoke.

Over 120 alkanes—ranging from the C_1 hydrocarbon methane to the C_{36} hydrocarbon hexatriacontane—have been identified in tobacco and tobacco smoke. Many of the higher molecular weight alkanes have been reported to be present in three isomeric forms, i.e., the *normal*, the *iso* (2-methyl), and the *anteiso* (3-methyl) isomer:

	$H_3C\text{-}CH(CH_3)\text{-}(CH_2)_{n-1}$	$H_3C\text{-}CH_2\text{-}CH(CH_3)\text{-}(CH_2)_{n-2}$
$H_3C\text{-}(CH_2)_n\text{-}CH_3$	$\text{-}CH_3$	$\text{-}CH_3$
n-alkane	*iso*-alkane	*anteiso*-alkane

In 1958, Barbezat-Debreuil (181), using column chromatography and x-ray analysis to examine the alkanes in tobacco and tobacco smoke, reported her identification of branched isomers in the alkane fraction from both sources. The next year, Carruthers and Johnstone (613) reported the results of their study on the long-chained alkanes in tobacco and the smoke from cigarettes containing it. Their analyses involved gas–liquid chromatography and mass spectroscopy. They also noted that the minor differences between the mass spectroscopic data for tobacco and smoke were not significant because, at that time, the precision of such an analysis was not high. Their findings are summarized in Tables 1.1 and 1.2.

Cuzin et al. (883) in their study of *Gauloise* cigarette mainstream smoke (MSS) reported that 1.2% of the total particulate matter (TPM) consisted of *n*-C_{25}, *n*-C_{26}, *n*-C_{28}, *n*-C_{29}, *n*-C_{30}, *n*-C_{31}, and *n*-C_{32} alkanes and 75% of this weight involved the C_{30}, C_{31}, and C_{32} compounds. They reported that their evidence indicated no *n*-alkane higher than the *n*-C_{32} alkane was present. However, in 1960, Kosak and Swinehart (2176) reported the presence in cigarette MSS of the *n*-alkanes from C_{22} to C_{36} and branched alkanes from C_{21} to C_{32}. Table 1.3 summarizes their findings. Possibly due to the status of analytical methodology at the time, Dymicky and Stedman (1081) had earlier suggested the possible presence of *n*-tetracontane ($C_{40}H_{82}$) in tobacco, but their finding has never been confirmed. In 1967, Ivanov and Ognyanov (1893b) reported the isolation of a crystalline alkane mixture, m.p. 62°C–64°C, which they proposed might contain a series of alkanes from C_{25} to C_{40}.

Carugno (619) reported the C_{31} alkanes to be the most abundant in tobacco but also noted that the C_{27}, C_{29}, C_{30}, C_{32}, and C_{33} homologs were present in appreciable amounts. Only a small portion of the alkanes in the alkane fraction from the MSS from four tobacco types and a commercial tobacco blend was found with carbon chain lengths equal to or less than C_{24}; only trace amounts of alkanes at or below *n*-hexadecane were found by Spears et al. (3768). Spears et al. also reported that nearly 48% of an alkene-free alkane fraction (0.75 mg/cig) from MSS consisted of *n*-hentriacontane (0.182 mg/cig), *n*-dotriacontane (0.108 mg/cig), and *n*-tritriacontane (0.069 mg/cig).

In their article on the pyrolysis of tobacco constituents, Badger et al. (142) reproduced a gas chromatogram provided by Reid on the alkanes in a tobacco sample. The peaks for the alkanes from C_{23} to C_{33} are readily discernible in the chromatogram. Badger et al. estimated that the tobacco alkane fraction amounted to 0.32% of the tobacco weight. Based on their pyrolysis studies, Badger et al. also proposed an elaborate mechanism for the formation of the polycyclic aromatic hydrocarbons (PAHs). It involved the degradation of the alkane to smaller fragments, followed by recombination of the fragments into substituted cyclic entities and their aromatization.

As listed in Table 1.4 adapted from Mold et al. (2595), about 25%–50% of the total alkanes in tobacco comprise nearly equal amounts of the *iso* and *anteiso* isomers of the alkanes. In the series of *normal*- and *iso*-alkanes, the homologs with odd-numbered carbons predominate with the C_{31} and C_{33} homologs being present in the largest amounts. In the *anteiso*-alkanes, the alkanes with even-numbered carbons predominate with the C_{32} homolog being present in the largest amount. The data provided by Mold et al. (2595) were reproduced by Tso in his 1990 book (3973).

As Stedman (3797) noted in his 1968 review of the composition of tobacco and smoke, it was thought at one time that *anteiso*-alkanes comprised only those homologs with even-numbered carbons, but eventually homologs with odd-numbered carbons were reported by Carugno and Rossi (625) and Chortyk et al. (727). Carugno and Rossi (625) reported the presence of both normal and branched C_{21}–C_{34} alkanes in cigarette smoke condensate (CSC).

In a later comparison of the composition of the alkane fraction in a reference tobacco (University of Kentucky 1R1) and its cigarette MSS, Chortyk et al. (727) reported that "the ratio among the constituents in leaf paraffins is almost identical [with] the ratio among the smoke paraffins." It is possible, however, that changes in agronomic practices over the years since the 1970s may have resulted in tobaccos whose contents of alkanes and distribution among the alkane homologs are substantially different from those of the tobaccos studied in the 1960s and 1970s. This, of course, would also affect the content and distribution among the alkane homologs in the tobacco smoke.

Table 1.5 summarizes the tobacco smoke alkane isomers described by Stedman (3797) and those known to be present in 1992. The number of identified alkanes in these three isomeric forms was almost doubled during the period 1968–1992.

Many of the isomeric C_8 through C_{36} alkanes have been identified in the organic solvent-soluble extracts from one or more of the major tobacco types (flue-cured, burley, Oriental, Maryland). Their presence in tobacco smoke is the result of their volatilization during the puff and smolder phases of the smoking process and subsequent direct transfer from the tobacco to its MSS and sidestream smoke (SSS). The bulk of these higher alkanes are found in the particulate phase of the smoke aerosol with traces of the lower ones (C_8–C_{12}) in the vapor phase.

The lower molecular weight alkanes (C_1 through C_7) are found predominately in the vapor phase of the MSS and SSS aerosols, and are readily separated and identified by a variety of analytical techniques.

In general, the *n*-alkanes from C_1 to C_4 are gases, those from C_5 to C_{16} are liquids, and those above C_{17} are solids. The melting points and boiling points of some of the solid alkanes in tobacco and smoke are summarized in Table 1.6.

As a result of the successful induction in the mid-1950s of carcinomas on the skin of mice painted repeatedly with concentrated

solutions of CSC (4306a), the search for the causative agent in the condensate began. The demonstration in the early 1930s of the tumorigenicity of dibenz[*a,h*]anthracene (DB[*a,h*]A) (2078) and benzo[*a*]pyrene (B[*a*]P) (796a, 797) to mouse skin triggered an enormous research effort between 1932 and 1953, excluding the World War II years, which involved the synthesis of hundreds of PAHs and their testing for tumorigenicity. Because many of them were found to be tumorigenic to mouse skin, particularly those tetracyclic and higher, the PAHs were proposed in the mid-1950s by many investigators as possible causative agents for the lung cancer type (squamous cell carcinoma) observed in cigarette smokers. This proposal led to the demonstration of the presence of numerous PAHs in CSC, determination of their levels, and studies to elucidate their precursors in the tobacco.

Despite the fact that in 1942 the phytosterols in tobacco had been proposed by Roffo (3327) as the precursors in tobacco of PAHs in a "destructive distillate" of tobacco, the tobacco phytosterols were essentially ignored in the early 1950s. Because of the research results described by Lam (2255–2258) on the pyrogenesis of PAHs from alkanes, the high-molecular-weight alkanes in tobacco were proposed as the precursors of the PAHs in tobacco smoke. Roffo's suggestion on phytosterols was discounted by Wynder and Hoffmann (4320, 4322) because his research did not involve tobacco smoke but involved the composition and specific tumorigenicity of "destructive distillates" from control and organic solvent-extracted tobacco.

Although Zeise (4406) and Kissling (2100, 2102) reported the isolation of alkane-like components from tobacco and tobacco smoke, Kosak (2170) in his catalog of smoke components classified their data as inconclusive. However, the evidence provided by Thorpe and Holmes (3914) left little doubt as to the presence of the alkanes in tobacco leaf. The Thorpe–Holmes report was followed by numerous descriptions of the isolation of alkanes from tobacco and tobacco

smoke (see Table 1.7 for a cross section of some of the published reports, particularly those issued prior to the 1980s). Also included in Table 1.7 are references to some of the studies in which the alkanes were investigated as PAH precursors by pyrolysis or by "spiking" of the tobacco filler in a cigarette.

In 1934, Chibnall et al. (701) were among the first investigators to report that the alkane fraction, comprising a mixture of several individual alkanes, melted sharply over a narrow temperature range (63.3°C–63.8°C), a melting point behavior for a mixture that was contrary to the organic chemistry teachings of the day.

From the results of studies on the pyrolysis of the "tobacco paraffins," which comprise the *n-*, *iso-*, and *anteiso*-alkanes, it was suggested by Lam (2255–2258), Wynder et al. (4356), Wynder and Hoffmann (4319, 4332), and Hoffmann and Wynder (1798) that these components were the major precursors in tobacco of the PAHs in tobacco smoke. However, in 1958, Rayburn and his colleagues (3091, 3092) challenged the proposal that the tobacco alkanes were the major precursors of the smoke PAHs, but their experimental data were not overly conclusive in support of their challenge. Nevertheless, it should be realized that in one sense Rayburn et al. were partly correct: As PAH precursors, the tobacco alkanes do contribute to the PAHs in tobacco smoke, but their contribution is much less significant than other precursors (the phytosterols and terpenoids such as solanesol) in tobacco [cf. Wright (4282), Rodgman and Cook, (3269, 3286), Severson et al. (3616)].

Table 1.8, adapted from Lam (2257), demonstrates the relationship between PAH generation and pyrolysis temperature for aliphatic tobacco hydrocarbons (the alkanes) pyrolyzed in air at several temperatures. Calculation of the yield ratios [PAH µg/g–B[*a*]P µg/g] of the other PAHs versus B[*a*]P reveals significant information: In this simple case of pyrolysis, there is little consistency between the change in ratios of PAH/B[*a*]P as the temperature is increased from 700°C to 800°C. For example, in the case of the tetracyclic hydrocarbons, the PAH/B[*a*]P ratio decreases for pyrene and chrysene but increases for fluoranthene. For the pentacyclic hydrocarbons, the ratio decreases for both perylene and benzo[*e*]pyrene. For the hexacyclic hydrocarbon dibenzo[*def,mno*]chrysene, the ratio increases. These same trends exist whether the PAH/B[*a*]P ratios are calculated in terms of molar yields or, as in Table 1.8, in terms of the absolute quantities (µg of PAH generated per gram of aliphatic tobacco hydrocarbons pyrolyzed). The significance of these data and calculations is their demonstration in 1956 that in even the simplest pyrolysis situation*, B[*a*]P is not a valid "indicator" or "marker" for the PAHs with four or more rings and/or their supposed relationship to tumorigenic activity as suggested by Wynder and Hoffmann (4317, 4320, 4332). In addition to these data by Lam, other contrary data which demonstrated the invalidity of the concept of B[*a*]P as an "indicator" or "marker" for PAHs with four or more rings and the tumorigenicity of the substrate (CSC, pyrolysate, etc.) containing them were generated not only in studies by Wynder et al. (4355, 4356) but also in studies by Campbell and Lindsey (583), Rodgman (3240), Rodgman and Cook (3269, 3286), Gori (1329, 1330, 1332, 1333), NCI (2683), and Severson et al. (3616).

When used as a solvent for B[*a*]P in mouse skin-painting tests, the C_{10}, C_{12}, or C_{16} *n*-alkanes—although noncarcinogenic per se in this bioassay—were reported by Horton et al. (1835) to accelerate the tumor-producing capability of B[*a*]P and 1,2-dihydro-3-methylbenz[*j*]aceanthrylene (3-methylcholanthrene). Horton et al. reported that *n*-octane, the C_8 alkane, did not exhibit this property. The acceleration finding of the C_{10}, C_{12}, or C_{16} *n*-alkanes was incorporated by Carruthers and Johnstone (613) into an explanation of why the % tumor-bearing animals (% TBAs) was much greater in mice painted with CSC than could be predicted by the levels of tumorigenic polycyclic hydrocarbons in the CSC: They extrapolated the finding of this property of the C_{10}, C_{12}, and C_{16} *n*-alkanes to the longer chained homologs in cigarette smoke.

In contrast, however, to the findings of Horton et al. (1835), Wynder and Hoffmann (4314, 4319, 4332) reported that the specific tumorigenicity of B[*a*]P in mouse skin-painting

* For several decades, Wynder, Hoffmann, and some other investigators asserted that the fate of a given tobacco component during inert atmosphere pyrolysis was equivalent to its fate in the oxygen-deficient (but not oxygen-free) atmosphere in the tobacco rod during the cigarette smoking process (cf. Wynder and Hoffmann (4320, 4332), Hoffmann and Wynder (1798)). At the same time, many other investigators maintained that the two processes were *not* equivalent. Hoffmann and colleagues demonstrated in 1979 with radiolabeled nicotine that the two processes were *not* equivalent, and they suggested that this nonequivalence observed for the fate of nicotine was applicable to the fate of other tobacco components (3512).

experiments was significantly "inhibited" when it was administered with the individual alkanes *n*-hentriacontane ($C_{31}H_{64}$) or *n*-pentatriacontane ($C_{35}H_{72}$) and the ratio of the alkane–B[*a*]P was either 200:1 or 100:1. These ratios are much less than those encountered in CSC. Wynder and Hoffmann also reported that increasing the level of the alkane fraction in the applied CSC from 3% to 4% (a 33% increase) resulted in a decrease (from 40% to 24%) in the % TBAs after 19 months and a decrease (from 24% to 18%) of % TBAs with malignant tumors. Surprisingly, Wynder and Hoffmann did not consider these decreases significant! These alkane–B[*a*]P data, originally presented at an AACR meeting (4314), did not appear in any journal but were included in the Wynder–Hoffmann review (4319) and book (4332) on tobacco smoke carcinogenesis.

Although they did not catalog their bioassay findings from the alkane–B[*a*]P experiments in their extensive tabulation of the induction of carcinoma in skin-painting studies with tobacco products [see pp. 330–331 in (4319) and pp. 370–371 in (4332)], Wynder and Hoffmann offered the following explanation for the result observed:

> The effect of alkanes may not be inhibitory to tumorigenicity but rather a consequence of having influenced resorption. The tumor response data of these experiments clearly express a delay of tumor appearance, a result that we believe to be due to the retarding effect of the *n*-alkanes.

Earlier, Wynder and Wright (4354) had reported that the slight tumorigenicity observed with an alkane fraction of tobacco smoke condensate in a mouse skin-painting bioassay was due not to the alkanes per se but to trace amounts of PAHs in the alkane fraction.

In later experiments with gasoline engine exhaust "tar" versus CSC, the observed tumorigenicities observed by Wynder and Hoffmann (4315) did not parallel the levels of the PAHs considered to be the major contributors to the observed skin tumors. To explain the difference (and the less than anticipated tumorigenicity of the exhaust "tar"), the authors attributed the depressed tumorigenicity of the exhaust "tar" not only to alkanes but also to nontumorigenic PAHs present in engine exhaust "tar" at levels far in excess of those of the tumorigenic PAHs such as B[*a*]P and DB[*a,h*]A (see Table 1.9). Although the ratios are not as great for CSC as for exhaust "tar," it should be noted that the levels of nontumorigenic (and antitumorigenic) PAHs in CSC far exceed those of the tumorigenic PAHs. Wynder and Hoffmann (4315) summarized their findings as follows:

> It was anticipated that the…exhaust gas "tar" and nicotine would be many times more active than tobacco smoke condensate. However,…it is only approximately twice as active. This relatively small increase in biological activity of exhaust gas "tar" raises the question of possible anticarcinogenic factors that may be more prevalent in engine exhaust "tar" … one may theorize that some of the noncarcinogenic polynuclear hydrocarbons that are present in engine exhaust gas "tar" in far greater concentrations than in tobacco smoke condensate may interfere with the resorption of the "tar." Some of the oily materials in gasoline engine exhaust "tar" and the paraffins in tobacco smoke condensate may also act as anticarcinogens.

In their comparison of the composition of the alkane fraction in a reference tobacco (University of Kentucky 1R1) and its cigarette MSS, Chortyk et al. (727) reported that "the ratio among the constituents in leaf paraffins is almost identical [with] the ratio among the smoke paraffins." They interpreted this finding as suggesting the paraffins undergo little pyrolytic degradation during the smoking process. Although octatriacontane has not been identified in either tobacco or tobacco smoke, Bass et al. (208) employed [18-^{14}C]octatriacontane to study its transfer to cigarette smoke. Their findings with this alkane agreed with those of Chortyk et al. (727) on the series of alkanes in tobacco and their transfer to smoke and with those of Jenkins et al. (1935) on the transfer of [16,17-^{14}C]dotriacontane from tobacco to smoke.

Table 1.10 lists the alkanes identified in tobacco and mainstream tobacco smoke. The citations do not necessarily include every reference to the identification or discussion

TABLE 1.9
Ratios for Individual Polycyclic Aromatic Hydrocarbons in Gasoline EET and CSC

Polycyclic Aromatic Hydrocarbon	Ratio PAH_{EET}:PAH_{CSC}	Polycyclic Aromatic Hydrocarbon	Ratio PAH_{EET}:PAH_{CSC}
Benz[*a*]anthracene	600:1	Dibenzo[*def,mno*]chrysene[a]	>440:1
Benz[*a*]anthracene, alkyl	>10:1	Benzo[*a*]pyrene	45:1
Benz[e]acephenanthrylene[b]	640:1	Benzo[*a*]pyrene, alkyl	>10:1
Benzo[*ghi*]fluoranthene	1500:1	Benzo[*e*]pyrene	4200:1
Benzo[*j*]fluoranthene	85–110:1	Fluoranthene	275–390:1
Benzo[*k*]fluoranthene	200–360:1	Fluoranthene, alkyl-	230–275:1
11*H*-Benzo[*b*]fluorene	100:1	Indeno[1,2,3-*cd*]pyrene	>80:1
Benzo[*ghi*]perylene	255–340:1	Indeno[1,2,3-*cd*]fluoranthene	>30:1
Chrysene	87–115:1	Pyrene	500–700:1
Chrysene, alkyl-[c]	33–45:1	Pyrene, alkyl-	3–4:1
Dibenz[*a,h*]anthracene	17–25:1	Triphenylene	4400:1

[a] Formerly known as anthanthrene.
[b] Formerly known as benzo[*b*]fluoranthene.
[c] Similar to 5-methylchrysene.

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke or vice versa.

of a particular alkane. Comparison of this updated list with that reported in the earlier edition indicates that very few new alkanes are included in our up-to-date Table 1.10.

1.2 ALKENES AND ALKYNES

In his summary of the identified components of tobacco smoke, Kosak (2170) listed only one unequivocally identified alkene or alkyne. It was ethyne (acetylene). Johnstone and Plimmer (1971) listed the following alkenes and alkynes identified in tobacco smoke: *cis*- and *trans*-butene, 1,3-butadiene, methyl-1,3-butadiene (isoprene), ethene, ethyne, methylethyne, propene, methylpropene, squalene and isosqualene, and several phytadienes. Less than a decade later, Stedman (3797) described and/or discussed nearly 235 acyclic alkenes and alkynes identified in tobacco smoke. This number includes the *cis* and *trans* isomers in the homologous monoalkene series discussed later.

In Table 1.11 are listed 392 acyclic alkenes and alkynes in tobacco smoke whose identifications have been reported to date. Comparison of this updated list with that reported in the earlier edition indicates that nearly 60 additional acyclic alkenes and alkynes are now included in our up-to-date Table 1.11.

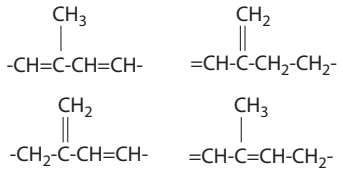
The lower molecular weight acyclic unsaturated hydrocarbons (alkenes, alkadienes, alkynes, etc.) occur primarily, if not totally, in the vapor phase of mainstream smoke (MSS). Even though some of the vapor-phase components of cigarette MSS have been shown to be significant in in vitro ciliastats, the low molecular weight hydrocarbons (alkanes, alkenes, alkynes) were not considered by Caroff et al. (604, 605) to be involved because of their low concentrations in the smoke. The smoke components (aldehyde, ketones, hydrogen cyanide, formic and acetic acids, phenol) reported to be significant in vitro ciliastats are relatively highly water soluble, whereas the low molecular weight hydrocarbons, generally considered nonciliastatic in in vitro systems, show extremely low solubility in water. Rodgman et al. (3306) and Dalhamn et al. (892, 893) described the differences in oral absorption of the tobacco smoke components isoprene (20%) *vs*. acetaldehyde (60%) or acetone (56%). It has also been noted by Wynder and Hoffmann (4332) that these compounds do not appear to play a significant role in tobacco smoke carcinogenesis: "Their [the alkenes] level in the smoke is rather low (0.01%) and they would, therefore, not be active even if they were tumor promoters."

In the National Cancer Institute study on the "less hazardous" cigarette, which involved chemical and biological (mouse skin-painting bioassay) studies on four series* (1329, 1330, 1332, 1333) of experimental cigarettes and appropriate controls, an interesting correlation was reported with the first series of cigarettes (1329): While no correlations were observed between the benzo[*a*]pyrene (B[*a*]P) content or the benz[*a*]anthracene (B[*a*]A) content of the cigarette smoke condensate (CSC) and the % tumor-bearing animals, a correlation—classified as significant—was observed between the isoprene content of the MSS and the % tumor-bearing animals. This observed isoprene—% tumor-bearing animal correlation—was heatedly discussed and debated for the following year. In the second, third, and fourth series of cigarette, the isoprene—% tumor-bearing animal correlation—was not observed, i.e., it had disappeared! It should be noted that the manipulations involved in the collection and preparation of the CSCs for the bioassay virtually preclude the presence of isoprene in the material applied to the host animals.

In its review of smoke composition and the relationship between smoke components and health, the IARC (1870) devoted very little space to the volatile acyclic hydrocarbons and just two paragraphs to the nonvolatile members of this compound group.

Among the alkenes listed as tobacco smoke components are several series of isomeric isoprenoid compounds, including the phytadienes (3247), the solanesenes (3297), and the squalenes (2175, 3297, 4033) plus several homologous series of monoalkenes (1144).

A series of phytadiene isomers with a pair of conjugated double bonds in different internal and terminal positions were identified in the MSS from cigarettes containing the American blend (3247). Similar series of phytadienes were identified in the MSSs from cigarettes containing individual tobaccos (flue cured, burley, Oriental). The evidence indicated the presence of at least the following four basic combinations of the conjugated linkages within an isoprenoid unit or between contiguous units:



The mixture of smoke phytadienes was separated into groups of phytadienes by alumina column chromatography. Because Rowland (3345) had used the Diels–Alder reaction of neophytadiene with 1,4-naphthoquinone to great advantage in its characterization, this same reaction sequence was used in the phytadiene study. Treatment of each phytadiene fraction with 1,4-naphthoquinone gave Diels–Alder adducts which were converted to anthraquinonecarboxylic acids by sequential oxidations, first to alkylanthraquinones and then to carboxylic acids. The number and positions of the carboxyl groups permitted assignment of the conjugated double bonds in the phytadiene. The phytadiene series contained 3-methylene-7,11,15-trimethyl-1-hexadecene (neophytadiene); 3,7,11,15-tetramethyl-1,3-hexadecadiene; 2,6,10,14-tetramethyl-1,3-hexadecadiene; 1,2,4-trialkyl-1,3-butadiene; and possibly as many as nine other conjugated phytadienes (excluding *cis* and *trans* isomers). No evidence was obtained to indicate that six of the possible isomeric conjugated phytadienes were present in MSS. They may have either been unreactive in the Diels–Alder reaction with 1,4-naphthoquinone or, if reactive, gave an adduct which was not oxidizable to an alkylanthraquinone.

* The four series of cigarettes involved a total of 98 test cigarettes and about 30 reference (Kentucky Reference 1R1) and standard cigarettes, divided almost equally among the four series.

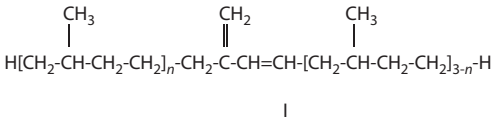
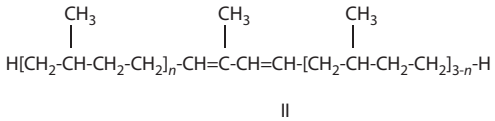
Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke or vice versa.

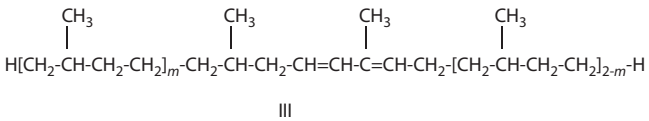
The several groups of possible conjugated phytadienes are more completely defined in structures I through VI:



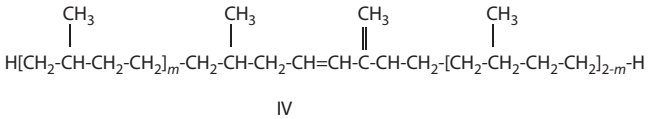
I



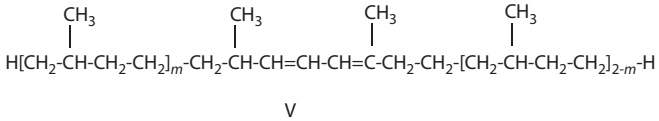
II



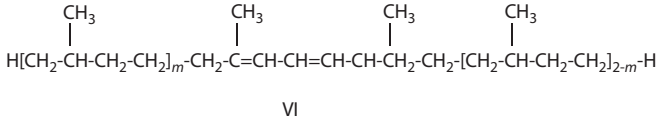
III



IV



V



VI

Phytadienes I–IV with the potential to generate anthraquinonecarboxylic acids in the reaction sequence described are shown in Figure 1.1. Phytadienes I, II ($n = 3$), and IV can exist as *cis* and *trans* isomers. The remaining phytadienes in Figure 1.1 can exist as *cis cis*, *cis trans*, *trans cis*, and *trans trans* isomers. In Figure 1.2 are shown the phytadienes (V, VI) that do not appear to form Diels–Alder adducts.

As noted previously, even if they did form the Diels–Alder adducts, they would not yield alkylanthraquinones because of the absence of hydrogen atoms at the 1 and/or

[a]Yields anthraquinone-2-carboxylic acid; [b]Yields anthraquinone-1,3-dicarboxylic acid; [c]Yields anthraquinone-1,2-dicarboxylic acid; [d]Yields anthraquinone-1,2,4-tricarboxylic acid.

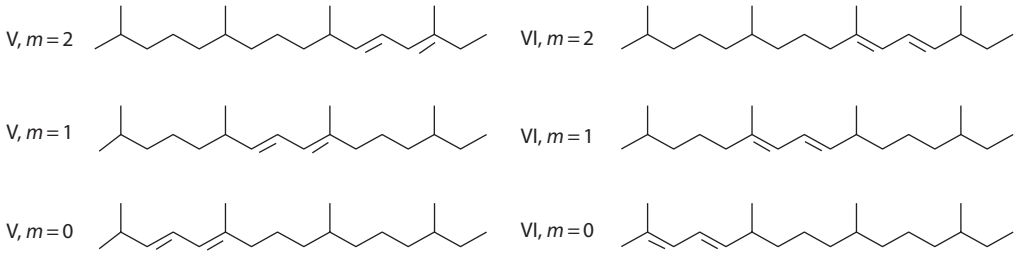


FIGURE 1.2 Phytadienes with little or no potential to form Diels–Alder adducts.

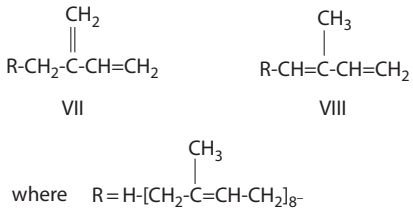
4 positions. Figure 1.1 also summarizes the various anthraquinonecarboxylic acids which could arise from the phytadienes depicted.

In their study of the smoke from British cigarettes, Johnstone and Quan (1973) reported that at least 99% of the acyclic phytadienes comprised neophytadiene. They made no comment on the presence of phytadiene isomers in the remaining 1%. Since no quantitative data were provided by Rodgman (3247) in his study of the phytadiene isomers in tobacco smoke, comparisons of the two investigations are not possible. The Johnstone–Quan study involved the study of tobacco smoke from flue-cured tobacco cigarettes, whereas the Rodgman study involved smoke from cigarettes containing a cased American blend (flue-cured, burley, Oriental, and Maryland tobaccos).

Because of the similarities among the infrared absorption spectra of the gross phytadiene fraction in cigarette MSS (3247), the mixture of phytadiene isomers described by Rowland (3345), and the mixture of phytadienes generated by heating neophytadiene (180°C, 2.5 h), Rodgman suggested that the isomeric conjugated phytadienes in tobacco smoke resulted from thermal isomerization of neophytadiene during the smoking process. However, as Lam et al. (2260) suggested, it is highly possible that the various phytadienes may be generated during the smoking process from phytol or phytyl esters in the tobacco. Vandemeent et al. (4015) reported that chlorophyll-bound phytol yielded several phytadienes when various geological materials containing chlorophylls were pyrolyzed at 610°C. Lam et al. (2260) reported the presence of at least five different phytadienes in a pyrolysate from phytol heated at 550°C. Neither Vandemeent et al. nor Lam et al. described the structures of the phytadienes they had identified.

Another series of isoprenoid hydrocarbons isolated from cigarette MSS by Rodgman et al. (3297) comprised the solanesol-related solanesenes. Dehydration of solanesol or pyrolysis of solanesyl acetate yields a mixture of solanesenes similar to that isolated from cigarette MSS. VII and VIII are the major components of the solanesene mixture in tobacco smoke.



Sodium–alcohol reduction of the mixture gave dihydrosolanesene whose infrared spectrum *vs.* that of the solanesenes was consistent with the migration of the terminal double bond to an internal position. The Diels–Alder reaction sequence used by Rowland (3345) in the characterization of neophytadiene from tobacco and the various phytadienes in cigarette MSS by Rodgman (3247) was applied to the solanesene mixture. It provided confirmatory evidence for the presence of the solanesene VII: Reaction of the isolated solanesene mixture with 1,4-naphthoquinone, followed by air oxidation of the adduct, apparently yielded a single 2-alkylanthraquinone rather than the anticipated mixture of 2-alkyl- and 1,2-dialkylanthraquinones. Only anthraquinone-2-carboxylic acid was isolated and identified as a product of the alkylanthraquinone-to-anthraquinonecarboxylic acid oxidation. The failure to demonstrate the presence of anthraquinone-1,2-dicarboxylic acid was attributed to the inertness of solanesene VIII in the Diels–Alder reaction.

Wynder and Hoffmann (4319) reported that the phytadienes did not produce hyperplasia or destroy sebaceous glands when applied to mouse skin. They also reported (4316) that removal of terpenoid hydrocarbons such as the phytadienes from a polycyclic aromatic hydrocarbon (PAH)-enriched fraction did not significantly alter its sebaceous gland suppression. From this result, they concluded that "the terpenes may not contribute significantly to the tumorigenic activity of tobacco smoke."

Entwhistle and Johnstone (1144) described six homologous series of monoalkenes isolated from tobacco smoke, including all of the possible *cis* and *trans* isomers. They reported the total delivery of these series in cigarette MSS to be about 3 µg/cigarette. These series did not appear to be present in tobacco leaf. Their precursors in tobacco have not been defined. However, Carruthers and Johnstone (614) earlier had reported that long-chained alkenes in tobacco smoke did not result from the dehydration of the corresponding alcohol during the smoking process.

Monoalkene Series	*n* =
$H_2C{=}CH\text{-}(CH_2)_n\text{-}CH_3$	7 through 25
$H_2C{=}C(CH_3)\text{-}(CH_2)_n\text{-}CH_3$	9 through 28
$CH_3\text{-}CH{=}CH\text{-}(CH_2)_n\text{-}CH_3$[a]	9 through 28
$CH_3\text{-}C(CH_3){=}CH\text{-}(CH_2)_n\text{-}CH_3$	8 through 27
$CH_3\text{-}CH{=}CH\text{-}(CH_2)_n\text{-}CH{=}(CH_3)_2$[a]	7 through 26
$CH_3\text{-}CH{=}CH\text{-}(CH_2)_n\text{-}CH(CH_3)\text{-}CH_2\text{-}CH_3$[a]	6 through 25

[a] *cis* and *trans* isomers.

Rodgman et al. (3294) described the composition of an aliphatic ester fraction isolated from MSS generated by cigarettes fabricated from an American tobacco blend, burley tobacco, or Oriental tobacco. Aliphatic ester fractions almost identical with those from the smokes were also isolated from flue-cured tobacco, burley, and Oriental tobaccos. With the analytical technology available in the early 1960s, the aliphatic ester fraction was shown to consist of a series of esters whose alcohol moiety varied from 1-dodecanol (C_{12}) to 1-heptacosanol (C_{27}), inclusive. The acid moiety ranged from tetradecanoic acid (C_{14}) to octacosanoic acid (C_{28}), inclusive, plus the C_{18} unsaturated acids, oleic, and linolenic.

More than two decades later, Arrendale et al. (103) extended the identification of the components of the aliphatic ester fraction from tobacco. The alcohol moiety ranged from 1-hexadecanol (C_{16}) to 1-tetratriacontanol (C_{34}). Esters with 1-hentriacontanol and 1-tritriacontanol as the alcohol moieties were not detected. The acid moiety ranged from dodecanoic acid (C_{12}) to dotriacontanoic acid (C_{32}). An ester with hentriacontanoic acid as the acid moiety was not detected. For a given number of carbons, the acid moiety not only included the *normal* acid but also in several cases included the *iso* and/or *anteiso* acid, e.g., esters were identified with *n*-, *iso*-, and *anteiso*-pentadecanoic acid as the acid moieties.

Even though Arrendale et al. (103) limited their study to an ester fraction isolated from tobacco, it seems logical to assume, based on the findings of Rodgman et al. (3294) on the equivalence of the aliphatic ester fractions isolated from various smokes and tobaccos, that each ester identified by Arrendale et al. would appear in tobacco smoke.

Controlled thermal degradation of higher molecular weight aliphatic esters generates an alkene and an acid (950c, 3294). Thermal degradation during the smoking process of the aliphatic esters identified in tobacco could conceivably yield some of the alkenes in the series described by Entwhistle and Johnstone (1144).

$$R\text{-}CH_2\text{-}CH_2\text{-}OOC\text{-}R_1 \rightarrow R\text{-}CH{=}CH_2 + R_1\text{-}COOH$$

2,6-Dimethyl-2,4,6-octatriene (alloöcimene) was reported by Wynder and Hoffmann (4316) as a significant tobacco smoke component (0.5% of CSC) with cocarcinogenic activity. However, Mold et al. (2597) presented contradictory data which indicated that if 2,6-dimethyl-2,4,6-octatriene were present in smoke, its level was less than 0.006%.

1.3 ALICYCLIC HYDROCARBONS

The cyclic aliphatic hydrocarbons in tobacco and tobacco smoke include compounds whose ring sizes range from cyclopropane through cyclooctane, cyclononane, cycloundecane, and cyclotetradecane. Theoretically, cyclooctatetraene could be included in the listing of monocyclic aromatic hydrocarbons. Numerous hydrocarbons with cyclopentane and cyclohexane rings were reported as tobacco and tobacco smoke components in the late 1950s through the mid-1960s (see Table 1.12). Tobacco smoke hydrocarbons with a cyclobutane ring were reported by Stedman in 1963 (3795). Three dimethylcyclopropanes were reported in 1970 by Bartle and Novotny (200). 1,3,5-Cycloheptatriene and cyclooctatetraene were reported by Enzell et al. (1154) and Mauldin (2506), respectively. A hydrocarbon with the cycloheptatriene ring had been reported previously as a tobacco smoke component in 1947 by Ikeda (1857): The bicyclic aromatic hydrocarbon azulene, an isomer of naphthalene.

Several fused-ring alicyclic hydrocarbons obviously derived from tobacco sterols were reported in 1989 in tobacco smoke by Benner et al. (273).

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke or vice versa.

In addition to a low level of cholesterol {1a}, tobacco usually contains substantial levels of several phytosterols [campesterol {Ib}, β-sitosterol {Ic}, stigmasterol {Id}, ergosterol {1e}] structurally similar to cholesterol. These phytosterols differ slightly from cholesterol in the structure of the long side chain (Figure 1.3). They are present in tobacco in both the free and bound form (as glycosides, esters, etc.), and they are transferred as such to mainstream smoke (MSS). The sterols constitute about 0.2% of the tobacco weight. As shown in Figure 1.3, pyrolysis of cholesterol {Ia} yields chrysene {III}, Diels hydrocarbon {IV}—a methylcyclopentaphenanthrene—and numerous other polycyclic aromatic hydrocarbons (PAHs). Both PAHs noted have also been identified in pyrolysates of the major tobacco phytosterols [Wynder et al. (4356); Van Duuren (4022)]. While none of the sterols {Ia–Ie} has been shown to generate the potent tumorigen 1,2-dihydro-3-methylbenz[*j*]aceanthrylene (3-methylcholanthrene) on pyrolysis, Falk et al. (1171) reported that cholesterol and cholesterol esters do generate the mouse-skin tumorigens 4-cholesten-3-one {Va} and 3,5-cholestadiene {VIa}. Veldstra (4042a) reported that the pyrolysis of cholesteryl oleate also yielded 3,5-cholestadiene {VIa}. Cholesteryl oleate was probably a component of the mixture of steryl esters described in flue-cured tobacco by Rowland and Latimer (3358) and in tobacco smoke by Rodgman et al. (3296). The steryl esters included sterols esterified with a series of saturated (palmitic, stearic, etc.) and unsaturated (oleic, linoleic, etc.) acids.

In the late 1950s/early 1960s, Rodgman proposed that the tobacco phytosterols—campesterol, β-sitosterol, stigmasterol, ergosterol—might generate compounds analogous to those generated from cholesterol, i.e., 4-campesten-3-one {Vb}, 3,5-campestadiene {VIb}, β-4-sitosten-3-one {Vc}, 3,5-sitostadiene {VIc}, 4-stigmasten-3-one {Vd}, 3,5-stigmastadiene {VId}, ergosten-3-one {Ve}, 3,5-ergostatriene {VIe}, on thermal degradation of these tobacco phytosterols or their esters during the smoking process. These campesterol-, β-sitosterol-, stigmasterol-, and ergosterol-related compounds might also be mouse-skin tumorigens as are their cholesterol counterparts. For nearly a decade, Rodgman and Cook (3286) were unsuccessful in their periodic efforts to isolate any of these steryl ketones or dienes from cigarette smoke condensate (CSC) and identify them. However, Benner et al. (273) did subsequently identify two

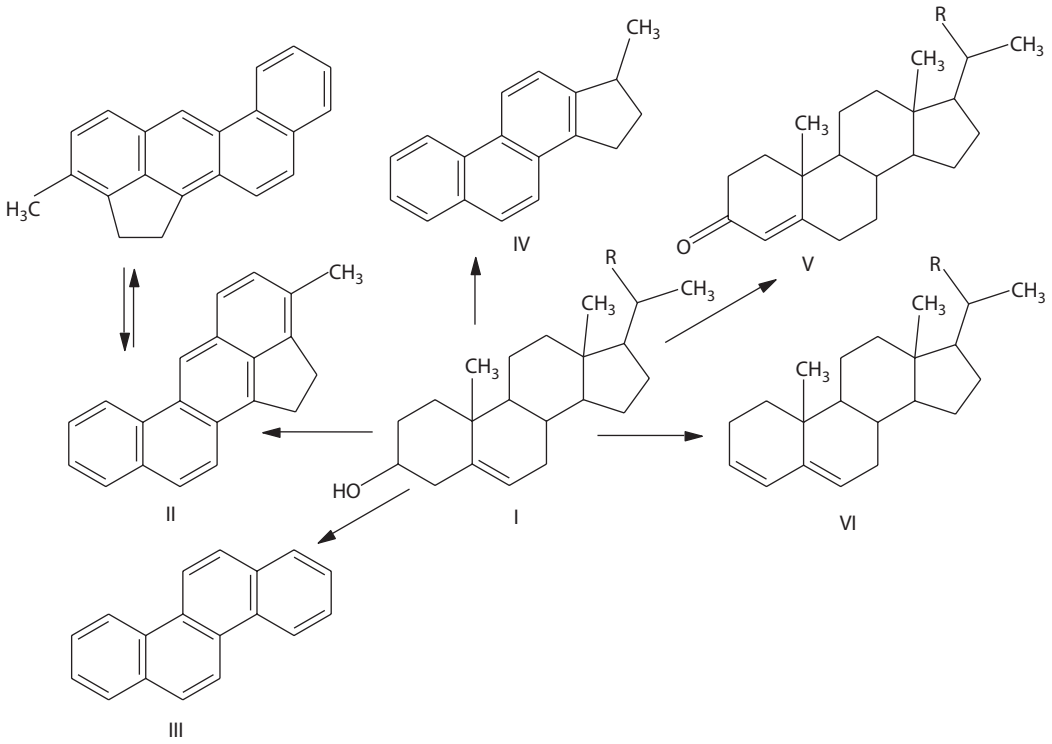

FIGURE 1.3 Possible sterol degradation products. *Sterol*, R═; Ia, cholesterol -$(CH_2)_3$-$CH(CH_3)_2$; Ib, campesterol -$(CH_2)_2$-$CH(CH_3)$-$CH(CH_3)_2$; Ic, β-sitosterol -$(CH_2)_2$-$CH(C_2H_5)$-$CH(CH_3)_2$; Id, stigmasterol -CH═CH-$CH(C_2H_5)$-$CH(CH_3)_2$; Ie, ergosterol[a] -CH═CH-$CH(CH_3)$-$CH(CH_3)_2$; II, 1,2-dihydro-3-methylbenz[*j*]aceanthrylene (3-methylcholanthrene); III, chrysene; IV, Diels hydrocarbon; Va, 4-cholesten-3-one; Vb, 4-campesten-3-one; Vc, β-4-sitosten-3-one; Vd, stigmasten-3-one; Ve, ergostadien-3-one; VIa, 3,5-cholestadiene; VIb, 3,5-campestadiene; VIc, β-3,5-sitostadiene; VId, 3,5-stigmastadiene; VIe, 3,5,7-ergostatriene. [a]Ergosterol has a double bond at the 7 position.

of these 3,5-dienes, 3,5-campestadiene {VIb} and 3,5-stigmastadiene {VId}, in tobacco smoke, see also Eatough et al. (1099,1100).

Johnstone and Quan (1973) reported that flue-cured tobacco smoke contains several hydrocarbons related to neophytadiene: an aliphatic acyclic hydrocarbon norphytene (2,6,10,14-tetramethyl-1-pentadecene) and the four alicyclic hydrocarbons {VII–X, Figure 1.4} that are dimers of neophytadiene. These dimers are identical with the major products generated when neophytadiene is heated at 190°C–200°C. The dialkylethenylcyclohexenes {IX and X} were a small proportion of the mixture. The more plentiful pair {VII and VIII} each absorbed two equivalents of hydrogen to form saturated hydrocarbons and were readily dehydrogenated to *p*- and *m*-alkylbenzene derivatives readily separable by column chromatography on alumina. Nitric acid oxidation of these benzenoid hydrocarbons generated *p*-benzenedicarboxylic (terephthalic) and *m*-benzenedicarboxylic (isophthalic) acids, respectively. Johnstone and Quan (1973) considered and rejected the possibility that the dimer mixture may have been artifactually produced during the laboratory generation, collection, and fractionation of the CSC. They noted that "At no time was the condensate subjected to temperatures above 80°C, and that only for short periods, so it is likely that the dimers were formed during the smoking process."

The isolation and identification in the late 1950s and early 1960s of several polyhydronaphthalene derivatives in tobacco

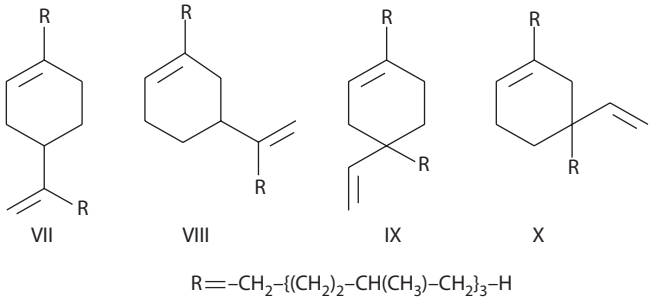

FIGURE 1.4 Phytadiene dimers.

and smoke, e.g., α- and β-levantenolide* (799, 801, 1299), α_2-levantanolide† (1290, 1300), 12α-hydroxy-13-epimanoyl oxide‡ (800, 1298, 3281), sclareolide§ (3272, 3533), and sclaral¶ (3534), subsequently led to the identification of many

* α- and β-Levantenolide are listed by Chemical Abstracts as decahydro-3,3′a,6′,6′,9′a-pentamethyl- and 3′a,4′,5′,5′a,6′,7′,8′,9′,9′a,9′b-decahydro-3,3′a,6′,6′,9′a-pentamethylspiro[furan-2(3*H*),2′(1′*H*)-naphtho[2,1-*b*]furan]-5(4*H*)-one, respectively.

† α_2-Levantanolide is listed by Chemical Abstracts as dodecahydro-3,3′a,6′,6′,9′a-pentamethylspiro[furan-2(5*H*),2′(1′*H*)-naphtho[2,1-*b*]furan]-5-one.

‡ 12α-Hydroxy-13-epimanoyl oxide is listed by Chemical Abstracts as 3-ethenyldodecahydro-3,4a,7,7,10a-pentamethyl1*H*-Naphtho[2,1-*b*]pyran-2-ol.

§ Sclareolide is listed by Chemical Abstracts as decahydro-3a,6,6,9a-tetramethylnaphtho[2,1-*b*]furan-2(1*H*)-one.

¶ Sclaral is listed by Chemical Abstracts as dodecahydro-3a,6,6,9a-tetramethylnaphtho[2,1-*b*]furan-2-ol.

more such derivatives [see Enzell and Wahlberg reviews (1156, 1157, 4089, 4090)] among which were several polyhydronaphthalenes, e.g., decahydronaphthalene (222–224), 4,7-dimethyl-1,2,3,5,6,8a-hexahydro-1-(1-methylethyl)-naphthalene, (1156, 1256, 4090), and its isomer 4,7-dimethyl-1,2,4a,5,6,8a-hexahydro-1-(1-methylethyl)-naphthalene (α-muurolene) (404), and two isomers of 1,8a-dimethyl-7-(1-methylethenyl)-1,2,3,5,6,7,8,8a-octahydronaphthalene (valencene and eremophilene) (404).

A similar situation occurred with the cyclotetradecanes. Subsequent to the isolation and identification of several hydroxy derivatives and epoxy derivatives of unsaturated cyclotetradecane from tobacco (3195, 3220, 3221, 3361) and smoke (3361), several trimethyl-(1-methylethyl)-substituted cyclotetradecatrienes and tetraenes were identified in tobacco (1149, 1149a, 3853) and/or smoke (2726).

Table 1.12 lists the alicyclic aliphatic hydrocarbons identified in tobacco and tobacco smoke. Comparison of this updated list with that reported in the earlier edition indicates that over 20 additional alicyclic hydrocarbons are now included in our up-to-date Table 1.12.

1.4 MONOCYCLIC AROMATIC HYDROCARBONS

In this section, monocyclic aromatic hydrocarbons are defined as those compounds with one or more *nonfused* aromatic rings, e.g., benzene, biphenyl, terphenyl, stilbene. Some authors might classify the aromatic hydrocarbons with two or more nonfused rings as polycyclic aromatic hydrocarbons (PAHs). Table 1.13 lists the monocyclic aromatic hydrocarbons identified in tobacco and/or tobacco smoke. None of these compounds was included in Kosak's 1954 catalog of tobacco smoke components (2170). Johnstone and Plimmer (1971) listed only five such compounds [benzene, ethenylbenzene (styrene), methylbenzene (toluene), 1,2,4-trimethylbenzene (pseudocumene), 1,3,5-trimethylbenzene (mesitylene)]. By 1964, Elmenhorst and Reckzeh (1139) listed 11 such hydrocarbons (see Table 1.13). In 1968, Stedman (3797) listed 20 monocyclic aromatic hydrocarbons. The list presented in 1980 by Ishiguro and Sugawara (1884) indicated this number had doubled. To date, over 110 monocyclic aromatic hydrocarbons have been identified in tobacco and/or its smoke. Comparison of our current Table 1.13 with that in our previous edition indicates that over a dozen monocyclic aromatic hydrocarbons have been newly reported over the past 4 years.

In its 1986 review of tobacco smoke components and their relationship to health, the IARC (1870) discussed only three monocyclic aromatic hydrocarbons, namely, benzene, methylbenzene (toluene), and ethenylbenzene (styrene):

> Tobacco smoke contains traces of other volatile compounds found to be carcinogenic in humans or in experimental animals.
>
> Benzene, a human carcinogen [IARC (1868)], has been reported in the MS of cigarettes (12-48 µg/cigarette) and in the SS of a 100-mm US filter cigarette (453 µg/cigarette) [Wynder and Hoffmann (4332); Elmenhorst and Schultz (1140); Jermini et al. (1947)]. It can be assumed that benzene is formed during the burning of tobacco either from precursors with an aromatic or cyclohexane ring or by pyrosynthesis from primary radicals such as C_6H_5… The most abundant volatile hydrocarbon in tobacco smoke is toluene [methylbenzene], which has been reported to occur at levels of up to 164 µg/cigarette in MS and 904 µg in the SS of a 100-mm US nonfilter cigarette (1140, 1947, 4332).

With regard to the carcinogenic activity (actually its leukemogenic activity) of benzene, it was noted:

> Sufficient evidence in animals with new data from US National Toxicology Program (sufficient evidence in humans).

The carcinogenicity of ethenylbenzene was described as follows:

> Limited evidence [in] animals (inadequate evidence in humans).

In 1989, Hoffmann and Hecht (1727) included benzene in their list of 43 tumorigens in tobacco and tobacco smoke. They discussed the role of exposure to benzene in tobacco smoke as follows:

> Significant amounts of benzene are found in cigarette MS (up to 50 µg/cigarette). Sufficient evidence exists that this aromatic hydrocarbon causes leukemia in humans [IARC (1868)]. On the basis of analytical data for exhaled breath, it has been calculated that a smoker inhales about 2 mg of benzene per day while a nonsmoker inhales only 0.2 mg per day [Wallace et al. (4111)]. Former epidemiological studies have not demonstrated a strong association of smoking and leukemia [IARC (1868)]. However, a recent prospective study among 248,000 U.S. veterans indicates that cigarette smokers have a significant increase in mortality from leukemia [Kinlen and Rogot (2096)].

Examination of the compendia of compounds tested for carcinogenicity [Hartwell (1543, 1544); Shubik and Hartwell (3664, 3665); Thompson et al. (3908)] reveals that benzene has not only been tested for its carcinogenicity per se to skin (mouse, rat, guinea pig, rabbit, monkey) but also has been used as the solvent for application of hundreds of compounds (PAHs, their alkyl and other derivatives, plus their nitrogen, oxygen, and sulfur analogs; quinones; aromatic aza-arenes; aromatic amines; sterols and sterol-related compounds) to the skin of a variety of laboratory animals. In many of these latter experiments, groups of "solvent control" animals were painted with benzene at the same time as other test groups were painted with benzene solutions of the compound(s) under investigation. Despite the hundreds of animals skin-painted with benzene, only in very few cases were carcinomas or other tumors observed at the painting site in the "solvent control" benzene-treated animals or in the animals treated in the benzene carcinogenicity studies.

38.	100-42-5	Benzene, ethenyl- {styrene} C_6H_5-CH═CH_2	73, 104, 111, 112, 141–143, 151, 156, 157, 174a, 174b, 174c, 174e, 299, 314, 315, 566, 568, 568b, 688, 798, 1063–1066, 1068–1074, 1139, 1140, 1153, 1154, 1168, 1217, 1262a, 1313, 1339, 1348–1350, 1354, 1365, 1374, 1375a, 1386, 1414, 1416, 1418, 1419, 1443, 1445, 1472, 1586, 1589, 1634, 1637, 1649, 1740, 1741, 1743, 1744, 1842, 1870, 1871, 1873, 1947, 1975, 1981, 2142, 2313a, 2543, 2570, 2765, 2767, 2777, 2799a, 2825, 2870, 3007, 3190, 3255, 3257, 3265, 3300, 3308, 3464, 3468, 3498, 3508, 3530, 3557, 3711, 3713, 3714, 3729, 3797, 3992, 4078, 4166, 4249, 4570a, 4998, 5012, 5034, 5049, 5512. 5554, 5770, 5811b, 5835, 5836, 5869a	568b, 984, 1983, 2260, 2339a, 2389, 2544, 2917a, 4249, 5811b	1354, 1375a, 3401
39.	27576-03-0	Benzene, ethenyl-, dimethyl-	104, 1472, 1649, 2570, 3757, 4249		
40.	28106-30-1	Benzene, ethenylethyl-	1472, 2494, 4249, 5811b		
41.	71607-81-3 77227-00-0	Benzene, ethenylethyldimethyl-	3757, 4249, 5811, 5811a, 5811b		
42.	27138-10-9 77220-33-8	Benzene, ethenylethylmethyl-	3757, 4249, 5811, 5811a, 5811b		
43.	637-69-4	Benzene, 1-ethenyl-4-methoxy-	4249, 4633		
44.		Benzene, ethenylmethyl-	1472, 5034		
45.	611-15-4	Benzene, 1-ethenyl-2-methyl-	126a, 1416, 3302, 3557, 3729, 3797, 4249, 5811b		
46.	100-80-1	Benzene, 1-ethenyl-3-methyl-	126a, 143, 568b, 1140, 1313, 1416, 3302, 3797, 4249, 5811b		
47.	622-97-9	Benzene, 1-ethenyl-4-methyl-	126a, 143, 568b, 1140, 1313, 1981, 4249, 5811, 5811a, 5811b		
48.	71607-82-4 77226-99-4	Benzene, ethenyltetramethyl-	3757, 4249, 5811, 5811a, 5811b		
49.	50976-21-1 77220-32-7	Benzene, ethenyltrimethyl-	3757, 4249, 5811, 5811a, 5811b		
50.	100-41-4	Benzene, ethyl-	37, 38, 141–143, 152, 199, 222–224, 299, 314, 315, 568b, 798, 1063–1066, 1068–1074, 1139, 1140, 1153, 1154, 1168, 1262a, 1313, 1348–1350, 1354, 1365, 1371, 1374, 1375a, 1416, 1418, 1419, 1586, 1589, 1637, 1975, 1981, 2002, 2003, 2543, 2545, 2570, 2765, 2767, 2775, 2777, 2804, 2870, 3255, 3302, 3308, 3410, 3465–3467, 3508, 3530, 3557, 3797, 4249, 4570a, 5034, 5770, 5811b, 5869a	84, 568b, 984, 2339a, 2389, 2544, 2917a, 3188, 4249, 5811b	1354, 1375a, 2244, 3401

TABLE 1.13 (continued)
Monocyclic Aromatic Hydrocarbons in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
51.	874-41-9	Benzene, 1-ethyl-2,4-dimethyl-	3557, 4249, 4570a		
52.	25550-14-5	Benzene, ethyl methyl-	1153, 1154, 4249, 4570a, 5034	1153, 4249	
53.	611-14-3	Benzene, 1-ethyl-2-methyl-	84, 568b, 1140, 1313, 1416, 1418, 1419, 2002, 2767, 3302, 3308, 3557, 3797, 4249, 5811b	84, 568b, 2339a, 4249, 5811b	
54.	620-14-4	Benzene, 1-ethyl-3-methyl-	84, 568b, 798, 1140, 1313, 1416, 1418, 1419, 2002, 2870, 3302, 3308, 3557, 3797, 4249, 5770, 5811b	84, 568b, 4249, 5811b	
55.	622-96-8	Benzene, 1-ethyl-4-methyl-	84, 568b, 798, 1140, 1313, 1416, 1418, 1419, 2870, 3302, 3308, 3557, 3797, 4249, 5811b	84, 568b, 4249, 5811b	
56.	18908-70-8	Benzene, 1-ethyl-2-(1-phenylethyl)-		2917a	
57.	18640-62-5	Benzene, 1-ethyl-4-(2-propenyl)-	2767, 4249		
58.	536-74-3	Benzene, ethynyl- {phenylacetylene}	394, 397, 568b, 1139, 2088, 2939, 3302, 3308, 3797, 4249, 5811b		3401
59.		Benzene, 1-(2-hepten-6-yl)-4-methyl-		1256, 4249	
60.	1077-16-3	Benzene, hexyl-	4249, 5811b		
61.	108-88-3	Benzene, methyl- {toluene} C_6H_5-CH_3	37, 38, 73, 104, 111, 112, 126a, 126b, 141–143, 151, 152, 156, 157, 167, 173a, 174a, 174b, 174c, 174e, 199, 222–224, 237, 239, 299, 314, 315, 402, 462, 480, 493–495, 544–546, 566, 568, 568b, 603, 605, 643, 645, 688, 892, 893, 966, 1050, 1063–1074, 1110, 1139, 1140, 1153, 1154, 1168, 1243, 1262a, 1313, 1348–1350, 1354, 1365, 1374, 1375, 1375a, 1375b, 1377, 1378, 1386, 1412–1414, 1416, 1418, 1419, 1423, 1437, 1445, 1472, 1485, 1586, 1589, 1634, 1637, 1639, 1643, 1649, 1674, 1842, 1849–1852, 1947, 1966, 1975, 1981, 2002, 2003, 2060, 2063, 2079, 2088, 2091, 2133, 2134a, 2142, 2270, 2310, 2313a, 2520, 2543, 2545, 2570, 2589, 2634, 2644, 2645, 2731, 2735, 2765, 2767, 2777, 2782, 2799a, 2800, 2804, 2822, 2857, 2870, 2939, 2942, 3007, 3059, 3105, 3106, 3190, 3254, 3255, 3257, 3265, 3300, 3302, 3308, 3370, 3373, 3418, 3464–3470, 3482, 3493, 3498, 3500, 3508, 3530, 3557, 3692, 3794, 3797, 3876, 3897, 3939, 3992, 4005–4007, 4052, 4056, 4078, 4104, 4135, 4162, 4166, 4249, 4257, 4259, 4290, 4319, 4360, 4570a, 5012, 5025, 5034, 5049, 5547, 5554, 5692a, 5770, 5811b, 5836, 5869a, 4A02	568b, 984, 1590a, 2339a, 2917a, 3186, 3188, 4249, 5811b	1354, 1375a, 1377, 1378, 2244, 3401, 3402, 4052, 4056
62.		Benzene, ^{14}C-methyl- {toluene-^{14}C-methyl}		1850	
63.	101-81-5	Benzene, 1,1′-methylenebis- {diphenylmethane} C_6H_5-CH_2-C_6H_5	151, 1508, 3757, 4249, 5811b	1256, 4249, 5811b	
64.	98-83-9	Benzene, (1-methylethenyl)- {α-methylstyrene} C_6H_5-$C(CH_3)$=CH_2	142, 143, 151, 339, 1313, 3308, 3465–3467, 3557, 4249, 4570a

TABLE 1.13 (continued)
Monocyclic Aromatic Hydrocarbons in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
65.	98-82-8	Benzene, (1-methylethyl)- {cumene} C_6H_5-CH═$(CH_3)_2$	156, 157, 339, 568b, 1063–1066, 1068–1074, 1139, 1140, 1313, 1416, 1418, 2002, 2628, 2629, 2636, 2799a, 3255, 3308, 3797, 4249, 4570a, 5770, 5811b, 5869a	568b, 984, 4249	
66.	26444-18-8	Benzene, methyl (1-methylethenyl)-	5811, 5811a, 5811b		
67.	1124-20-5	Benzene, 1-methyl-3-(1-methylethenyl)-	143, 4249		
68.	1195-32-0	Benzene, 1-methyl-4-(1-methylethenyl)- {*p*,α-dimethylstyrene}	143, 1139, 1975, 2731, 2735, 3302, 3557, 3797, 4249		
69.	535-77-3	Benzene, 1-methyl-3-(1-methylethyl)- {*m*-cymene}	143, 2767	2339a	
70.	99-87-6	Benzene, 1-methyl-4-(1-methylethyl)- {*p*-cymene}	143, 299, 568b, 798, 1140, 1313, 1365, 1419, 2767, 3224, 3255, 3266, 3308, 3557, 3797, 4249, 5811b	568b, 1053, 1157, 3266, 3370, 4082, 4249, 5811b	
71.		Benzene, methyl-propenyl-	5034		
72.	28729-54-6	Benzene, methylpropyl-	5811b		
73.	17271-70-4	Benzene, 1-methyl-3-(1-propenyl)-	2767, 2769, 3555, 3557, 4249		
74.	1074-43-7	Benzene, 1-methyl-3-propyl-	2769, 3557, 4249		
75.	1074-55-1	Benzene, 1-methyl-4-propyl-	4249		
76.	538-93-2	Benzene, (2-methylpropyl)- C_6H_5-CH_2-CH$(CH_3)_2$	2328a, 4249, 5811, 5811a, 5811b		
77.	1139-49-7	Benzene, 1-methyl-3-(2,2,6-trimethylcyclohexyl)- {toluene, *m*-(2,2,6-trimethylcyclohexyl} 	1110, 3219, 3308, 3557, 4249		
78.	16982-00-6	Benzene, 1-methyl-4-(1,2,2-trimethylcyclopentyl)-, (R)- 		1156, 1256, 4090, 4249	
79.	2189-60-8 71607-64-2	Benzene, octyl- {phenyloctane} C_6H_5-$(CH_2)_7$-CH_3	1822, 4249, 5811b		
80.	538-68-1	Benzene, pentyl- C_6H_5-$(CH_2)_4$-CH_3	37, 38	4249, 4425, 5811b	
81.	637-50-3	Benzene, 1-propenyl- C_6H_5-CH═CH-CH_3	1313, 2777, 3557, 4249, 4570a, 5811b	5811b	
82.	300-57-2	Benzene, 2-propenyl- {allyl benzene} C_6H_5-CH_2-CH═CH_2	568b, 348, 3557, 4249, 4570a, 5811b		
83.	103-65-1	Benzene, propyl- C_6H_5-$(CH_2)_2$-CH_3	152, 222–224, 299, 348, 568b, 1063–1066, 1068–1074, 1262a, 1313, 1472, 1649, 4249, 4570a, 5770, 5811b, 5869a	568b, 2339a, 4249

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke or vice versa.

Examination of the references listed for benzene provides an indication of the amount of research and discussion pertinent to the presence of benzene in tobacco smoke.

Rodgman and Green (3300) in their discussion of toxicants in tobacco and tobacco smoke noted that subsequent lists and discussions generated after that of IARC (1870) included not only benzene but also ethenylbenzene (styrene) [see Table 1.15 in (3265) and Table 1 in (3300)] and methylbenzene (toluene) [see Table 1 in (3300)].

1.5 POLYCYCLIC AROMATIC HYDROCARBONS

Classified as toxicants in many of the substances to which humans are exposed are the polycyclic aromatic hydrocarbons (PAHs). Such exposures include air pollutants from a variety of sources, foodstuffs and beverages, and tobacco smoke. Since the early 1950s, the composition of the latter has been more completely defined than that of any other consumer product. Over 5200 components have been identified in tobacco smoke and among these are over 500 PAHs either completely or partially identified.

Because of the tumorigenicity of many PAHs, much research has been conducted in attempts to define the relationship between the PAH structures and their specific tumorigenicities in laboratory animals. None of the theories to date completely answers all the questions. In 2006, Rodgman and Perfetti (3306a) cataloged the PAHs completely or partially identified in cigarette smoke as a prelude to an attempt to develop a more reasonable PAH structure–tumorigenicity relationship. Additionally, they tabulated the PAHs considered in several previous studies on structure–tumorigenicity relationships, studies that dealt primarily with all-benzenoid PAHs. The majority of the information included in Section 1.5 comes from the 2006 article from Rodgman and Perfetti (3306a).

Tobacco and tobacco products in the forms of leaf, shredded or grounded tobacco, and various forms of cigars and cigarettes have been available to individuals for ages. For centuries, people have enjoyed tobacco but have been admonished of its potential health concerns. Health concerns for cigarette smokers have increased steadily since the early 1950s due to the rapid development and advancement in separation sciences, toxicology and medicine. In his 1954 publication, Kosak (2170) was the first person to catalog compounds reported in tobacco smoke. His list contained fewer than 100 compounds, and a significant number were incorrectly characterized. Today, over 5200 compounds have been identified as components in tobacco smoke [see Figure 1, p. 140 in (1373)]. Over the past 50 years, the tobacco industry has made significant progress in both the identification of tobacco and smoke components and the development of technologies to reduce cigarette smoke yields. Significant efforts continue in government, academia, and especially the tobacco industry to understand the health effects of smoking and to develop cigarette products with reduced health risks for smokers. One class of tobacco smoke components that has been studied extensively and intensively is the PAHs due to their potential health concerns.

Periodically, tobacco researchers have reported the progress on the identification of tobacco and smoke components. Review articles by Johnstone and Plimmer (1971) and Izawa (1900) detailed the tobacco and smoke research conducted over 100 years. Izawa listed 440 identified smoke components

by 1961. Quin (3059) published a review of components found in tobacco and smoke. Herrmann (1625) reviewed phenolic compounds in tobacco smoke. In 1963, Philip Morris (2939) published a monograph on tobacco and smoke composition, a copy of which was provided the Advisory Committee on smoking and health to the U.S. Surgeon General (3999). In 1964, Elmenhorst and Reckzeh (1139) tabulated the aromatic hydrocarbons identified in tobacco smoke. Kuhn (2226) published an article on alkaloids in tobacco and smoke. In their 1967 book, Wynder and Hoffmann (4332) discussed tobacco and smoke chemistry and the results of animal studies with tobacco smoke. Elmenhorst and Schultz (1140) listed 250 low-boiling components and vapor-phase components identified in tobacco smoke. In his 1968 review, Stedman (3797) listed nearly 1200 identified tobacco and smoke components. The next year, Neurath (2724) reported on the presence of 180 nitrogen-containing compounds in smoke. With the meaningful advancements in analytical methodology, the number of tobacco and smoke components increased dramatically (1371). At R. J. Reynolds Tobacco Company (RJRT), Schumacher et al. (3553), Heckman and Best (1587), and Newell et al. (2769) identified 1490 compounds in the water-soluble and ether-soluble fractions of tobacco smoke: 365 were confirmation of previously reported components and 1125 were newly identified components. In 1977, Schmeltz and Hoffmann (3491) cataloged nearly 500 *N*-containing compounds identified in tobacco smoke, but their catalog did not include the more than 230 *N*-containing compounds newly identified in tobacco smoke by Heckman and Best (1587). Between 1974 and 1978, Snook et al. (3732, 3756–3759) published the results of their massive study of the PAHs identified in tobacco smoke, a study that was followed by an equally definitive one published in 1981 on the aza-arenes in tobacco smoke (3750). In 1980, Ishiguro and Sugawara (1884) listed 1889 identified tobacco smoke components in their monograph. However, a tally of the reported tobacco smoke components at that time exceeded 2500. No additional catalogs of the total number of identified components of cigarette mainstream smoke (MSS) have been published since the 1980 Ishiguro and Sugawara (1884) publication. Smith et al. (3712) recently reported the chemical structures of the 253 identified phenols reported in cigarette MSS.

Numerous catalogs of PAHs identified in MSS have been compiled from 1955 through 2005. Table 1.14 is a chronology of catalogs of PAHs in MSS. It contains the year of each catalog, author (and reference), and the number of PAHs listed. The catalogs prior to 2006 contain much overlap in terms of the PAHs identified. In 2006, Rodgman and Perfetti (3306a) published a report that attempted to eliminate the overlap and clearly present the 539 PAHs identified in MSS. The intent of this chapter is to present a referenced catalog of the either completely or partially characterized* PAHs in tobacco, tobacco MSS, and MSS of tobacco substitutes. The catalog to follow (Table 1.19) contains the CAS registration number, chemical name, structure, and alphabetical listing of references on PAHs.

TABLE 1.14
Chronology of Catalogs of PAHs in MSS

Year	Author	No. of PAHs Listed	Reference
1954	Kosak	4[a]	2170
1955	Latimer	10	2270
1957	Latimer and Rodgman	33	2292a
1958	Rodgman	36	3245
1959	Johnstone and Plimmer	57	1971
1960	Rodgman and Menz	68	3301
1962	Rodgman et al.	77	3303
1963	Philip Morris	61	2939
1963	Rodgman et al.	77	3304
1964	Elmenhorst and Reckzeh	70	1139
1965	Rodgman et al.	85	3302
1967	Rodgman and Woosley	85	3308
1968	Stedman	79	3797
1975	Roberts et al.	206	3224
1976	Snook et al.	252[b]	3758
1977	Snook et al.	157[b]	3756
1978	Snook et al.	438[b]	3757
1980	Ishiguro and Sugawara	191	1884
1997	Williams et al.	427[c]	4249
2005	Rodgman and Perfetti	539[d]	3306a

[a] Three of the PAHs listed were identified in a destructive distillate of tobacco, not in tobacco smoke.

[b] In the three articles on the PAH study by Snook et al. (3756–3758), some identified PAHs were listed in more than one article.

[c] In several instances, more than one isomer was reported for some monoalkyl-, dialkyl-, trialkyl-, and tetraalkyl-PAHs, but the positions of the alkyl groups were not determined. In the case of such multiple alkyl isomers, only one was listed in this report.

[d] This list includes the number of isomers of monoalkyl-, dialkyl-, trialkyl-, and tetraalkyl-PAHs reported where the positions of the alkyl groups were not determined.

The significant increase in the number of studies on tobacco smoke composition was triggered by the following events: (1) the results in the early 1950s from several retrospective epidemiology studies (1026a, 1027, 3529, 4306b) in which it was reported that an association existed between cigarette smoking and the incidence of lung cancer in smokers, (2) a 1953 report of the production of skin carcinoma in susceptible laboratory animals skin painted repeatedly with a concentrated solution of cigarette MSS condensate supposedly produced under conditions simulating the human smoking of a cigarette (4306a), (3) the realization in 1954 that very little (2170) was known about the composition of tobacco smoke to which consumers had been exposed for nearly 400 years, and (4) the incorporation of chromatography into the overall methodology of the fractionation of complex mixtures such as tobacco smoke.

Naturally, these findings raised several questions. The first dealt with the identity of the cigarette MSS component(s)

* The term "partially characterized" or "partially identified" indicates that the position of one or more alkyl substituents was not determined.

responsible for the smoking–lung cancer association in smokers and the skin tumor induction in laboratory animals. Because of extensive data generated on the specific tumorigenicity of about 25% of the hundreds of PAHs synthesized between 1929 and the early 1950s (1543, 1544), PAHs were considered the most likely tumorigenic agents in cigarette MSS even though their presence was not certain. Eventually, numerous PAHs were identified in cigarette MSS. Because of its MSS level and its high specific tumorigenicity in several bioassays, one PAH was subjected to intense scrutiny: benzo[*a*]pyrene (B[*a*]P). As a carcinogen, B[*a*]P elicited carcinomas at the painting site in the mouse-skin bioassay. As a sarcogen, B[*a*]P elicited sarcomas in rodent bioassays involving subcutaneous injection.

One class of tobacco smoke components studied extensively is the PAHs. As reported by Rodgman (3262), between 1950 and 1970, an extensive amount of research was conducted on tobacco- and cigarette smoke-related topics. The information generated led to the development of several significant cigarette design technologies that resulted in the modification of the delivery and composition of cigarette MSS.

The following is a brief chronology of the events occurring in the tobacco smoke–PAH situation: In 1939, the PAHs anthracene, phenanthrene, and B[*a*]P were reported as components of a tobacco-related material by Roffo (3323–3325) and his son (3316, 3318). In discussions of tobacco smoke, the Roffo findings are generally disregarded because the three PAHs they reported were not detected in tobacco smoke but in a destructive distillate of tobacco. However, Roffo did report another finding that led to much research both within and outside the tobacco industry. Roffo reported that comparison of the destructive distillate of tobacco with that of an ethanol-extracted tobacco indicated (3327) that the PAH content and specific tumorigenicity of the extracted tobacco destructive distillate were reduced from those of the destructive distillate from the control tobacco. Roffo speculated that the precursors of the tumorigenic PAH components of his distillates were ethanol-soluble phytosterols. Eventually, his prediction, as far as it went, was found to be true for cigarette MSS (3269, 3616). Because he was unaware of the presence in tobacco of long-chained terpenoids such as solanesol, identified in flue-cured tobacco in 1957 by Rowland et al. (3359), Roffo obviously could not include them in his 1942 precursor prediction. It should be noted that the findings by Roffo on destructive distillates of tobacco were subsequently equivalent to the effects observed in smoked tobacco, i.e., organic solvent extraction of a tobacco or tobacco blend which was then incorporated into cigarettes gave MSS with reduced PAH levels and specific tumorigenicity to mouse skin compared to the MSS from control tobacco. However, usually the reduction in specific tumorigenicity was less than the reduction in PAHs, particularly B[*a*]P.

1.5.1 Controversies over the Roffo Investigations

Because the results of a 1930 biological study reported by Roffo (25A50) on a tobacco-related material, a destructive distillate from tobacco, coincided with the demonstration of the tumorigenicity to rodent skin of the PAH DB[*a*,*h*]A in 1930 (2078) and preceded the demonstration of similar tumorigenicity of B[*a*]P in 1932 (797), questions were frequently raised about the pertinence to tobacco smoke of the subsequent Roffo findings in which the destructive distillate tar was reported not only to be tumorigenic to laboratory animal skin but also to contain the tumorigenic B[*a*]P (see Table 1.15).

In their comments on the Roffos' reports of their investigations on the chemical composition and biological properties of a destructive distillate from tobacco and the presence of B[*a*]P in the distillate (claims based on spectroscopic data), Wynder et al. (4306a) noted that Roffo had claimed to have identified B[*a*]P in the tobacco destructive distillate, but his finding was not confirmed by Cooper et al. (813). However, Wynder et al. did note that Eby (25A21), in his examination of the cigarette tar used in the Wynder et al. 1953 biological study, did not detect B[*a*]P. They made little comment about Eby's failure to identify B[*a*]P or any other tumorigenic PAH in the Wynder et al. cigarette tar or the 1957 summary by Fieser (1181) on (1) the inadequacy of the spectroscopic data purported to indicate the presence of B[*a*]P in cigarette tar or (2) the failure of Fieser's colleagues to detect B[*a*]P in cigarette tar despite their success in identifying B[*a*]P in roast coffee.

Later, in their lengthy 1964 review [see p. 259 in (4319)] and 1967 book [see p. 94 in (4332)], Wynder and Hoffmann essentially dismissed the research by Roffo on a tobacco destructive distillate by tersely noting that the preparation by Roffo of a tobacco "tar" for a carcinogenicity test involved the mere destructive distillation of tobacco, thus excluding the Roffo investigations from any discussion of tobacco smoke.

Of course, most criticisms of Roffo's research findings were based on his production of a tobacco tar by destructive distillation of tobacco, a process not considered comparable to the normal combustion of tobacco in a cigarette in the presence of air and its oxygen. It is indeed true that, during the cigarette puff, the oxygen level immediately ahead of the fire cone is depleted from the ≈21% level of air, but as Newsome and Keith (2780) demonstrated, the oxygen level is not 0% as it might be during destructive distillation. During the smoking process, the cigarette system has access to air (and its oxygen content) surrounding the cigarette both during and between puffs. Cigarette paper porosity also dictates some air flow through the cigarette paper during the puff.

In 1961, Larson et al. [see pp. 422–424 in (5260)] provided a critique of Roffo's rabbit-skin-painting studies with destructive distillates from tobaccos. Roffo succeeded in producing tumors, many of which were described as carcinomas or epitheliomas, in the treated rabbits. Because of the small number of tumors generated in the Roffo biological studies, Larson et al. considered that one must be very hesitant in placing too great weight on Roffo's reiterated description of a solitary tumor.

Roffo also claimed that his tobacco tar generated by destructive distillation was more tumorigenic than equivalent doses of coal tar, a finding at odds with those of many investigators, even those who compared the tumorigenicity in mice of various tobacco-tar preparations with that of equivalent doses of coal-tar solutions (see Table 1.15).

TABLE 1.15
Comparison of Roffo's Findings on the Destructive Distillate of Tobacco *vs.* Research Findings Reported by Others on Tobacco Smoke

Roffo and the Destructive Distillate of Tobacco and Other Related Research	Tobacco Smoke and Other Related Research
Roffo (5354) defined CO derived from tobacco as a hazard	Many investigators pre-1954 (see Table 1) and post-1953 proposed the CO in tobacco smoke as a hazard. Subsequently, because of its hazard, CO became categorized as a "Hoffmann analyte" [see Chapter 23 in (5078)]
A.E. Roffo (3316, 3318) identified several PAHs (anthracene, B[*a*]P, phenanthrene) in the destructive distillate of tobacco	In 1953, several PAHs (anthracene, pyrene) were identified in cigarette smoke by R.L. Cooper and Lindsey (818)
B[*a*]P was identified in the destructive distillate of tobacco (3323, 3325, 3326, 3327, 5360).	• E.A. Cooper et al. (813) stated that they could not confirm Roffo's finding of B[*a*]P in the destructive distillate of tobacco
Note: The Roffo's reported 1,2-benzpyrene in the tobacco destructive distillate. 1,2-Benzpyrene was the name originally assigned by Cook et al. (797) to their coal-tar isolate. Subsequently, the nomenclature 1,2-benzpyrene was changed to 3,4-benzpyrene and then to benzo[*a*]pyrene by the IUPAC	• However, it should also be noted that Eby (25A21) could not detect B[*a*]P in the "tar" used by Wynder et al. (4306a) in their noted 1953 biological study • In 1957, Fieser (1181) classified as inadequate the ultraviolet spectrographic data claimed by R.L. Cooper and Lindsey (820) and by Rand personnel (55, 593, 2335) as indicating B[*a*]P in cigarette "tar" • Fieser's colleague could not detect B[*a*]P in cigarette "tar" but identified it in roast coffee (1181) • B[*a*]P was eventually accepted universally as a cigarette smoke component after the published report in 1959 of its isolation in crystalline form from cigarette smoke by Wynder and Hoffmann (4307) • Fourteen PAHs, including benz[*a*]anthracene (B[*a*]A), B[*a*]P, and DB[*a,h*]A, had previously been isolated individually from cigarette smoke (3273), 12 in crystalline form, two as oils [see Table 1 in Rodgman(3262)]
In 1930 and 1939, Roffo reported the tumorigenicity to animal skin of the destructive distillate of tobacco (3320, 5361, 5362, 25A52)	In 1953, cigarette "tar" was reported to be tumorigenic to mouse skin in the renowned study by Wynder et al. (4306a, 5202) and subsequently reported to be tumorigenic to several other species [see Tables VII 1–3 in (4332)]
Roffo reported that the specific tumorigenicities of the destructive distillates from the different tobacco types were essentially the same (3324, 5359, 25A60)	As reported by Wynder and Hoffmann in 1963 (4317), subsequent findings with tobacco smoke did differ from those reported by Roffo (3324, 5359, 25A60). The specific tumorigenicities (mouse skin) of the cigarette "tars" from different tobacco types varied as follows: flue-cured = Oriental > Maryland > burley. The B[*a*]P levels in the CSC varied as follows: flue-cured > Oriental > Maryland > burley
Roffo (5357) claimed that the destructive distillate "tar" from tobacco showed greater specific tumorigenicity to laboratory animals than did coal tar	Later, Jaffe et al. (5233) and Hueper (5230) described findings that disagreed with those of Roffo, i.e., they reported that coal tar showed greater specific tumorigenicity to laboratory animals than did tobacco "tar"
The yields of B[*a*]P and other PAHs in the destructive distillate from organic solvent-extracted tobacco were less than those in the destructive distillate from the control (unextracted) tobacco (3327)	The per cigarette yields of B[*a*]P and other PAHs were less in the "tar" (CSC) from organic solvent-extracted tobacco than those in the CSC from control (unextracted) tobacco (116, 3241, 3246, 4353, 4354) [see Table 3 in Rodgman (3262)]
The destructive distillate from the organic solvent-extracted tobacco showed less tumorigenicity than the destructive distillate from the control (unextracted) tobacco (3327)	The CSC from organic solvent-extracted tobacco showed lower specific tumorigenicity than CSC from control tobacco but the % decrease in specific tumorigenicity was less than the % decrease in the B[*a*]P content (4353, 4354) of the CSC
Roffo proposed that the precursor in tobacco of the PAHs in the destructive distillate from tobacco (3327) was phytosterol. *Note*: In 1939 and 1941, cholesterol was not a known component of tobacco. Also, high molecular weight terpenoids such as solanesol, neophytadiene, and the cyclotetradecane derivatives had not yet been identified as tobacco components. Each cyclotetradecane derivative had a 14-carbon structure similar to that in anthracene or phenanthrene. Subsequently, the high molecular weight terpenoids and derivatives (solanesyl esters) were identified in tobacco (and tobacco smoke) as were cyclotetradecane derivatives plus numerous phytosterols and their long-chained aliphatic esters plus cholesterol, its glycoside, and many long-chained aliphatic cholesteryl esters	• Subsequently, identified in tobacco were several phytosterols [stigmasterol (1433), sitosterol (1080), campesterol (1082), ergosterol (1080)] and cholesterol (1434, 5152) and their long-chained aliphatic esters (3296). All were also identified in tobacco smoke components (612, 1434, 2178) • The saturated aliphatic hydrocarbons,[a] the phytosterols,[b] and terpenoids[c] (such as solanesol and its long-chained aliphatic esters) in tobacco, were demonstrated to be major precursors of PAHs in CSC in a 1979 study by Severson et al. (3616) of the USDA and in a 1958 study in which the levels of each category in the cigarette tobacco were doubled and tripled (3269) • In 1963 and 1964, Rowland et al. (3361) described the conversion of a cyclotetradecane derivative to a phenanthrene derivative

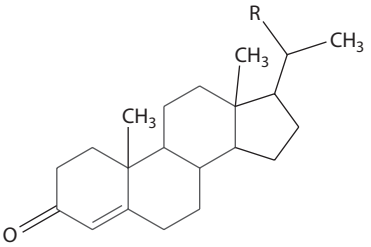
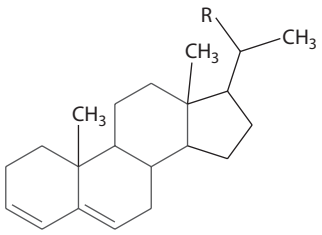
TABLE 1.15 (continued)
Comparison of Roffo's Findings on the Destructive Distillate of Tobacco *vs.* Research Findings Reported by Others on Tobacco Smoke

Roffo and the Destructive Distillate of Tobacco and Other Related Research	Tobacco Smoke and Other Related Research
In 1939, Roffo demonstrated that the pyrolysate from cholesterol was tumorigenic (4A03, 25A58), a confirmation of the 1928 findings of Kennaway and Sampson (2080) and a prelude to the 1949 findings of Falk et al. (1171).	A cholesterol pyrolysate was demonstrated to be tumorigenic in 1928 by Kennaway and Sampson (2080), in 1945 by Beck et al. (5125), and again in 1949 by Falk et al. (1171)
Note: In 1939 and 1941, cholesterol was not a known component of tobacco	
Roffo reported that the tumorigenicity of his cholesterol pyrolysate was due to derivatives of phenanthrene (4A03)	• Pyrolysis of cholesterol and cholesteryl esters yielded two tumorigenic compounds, 4-cholesten-3-one and 3,5-cholestadiene (1171, 4042a), both of which may be considered as phenanthrene derivatives

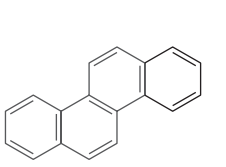


4-Cholesten-3-one

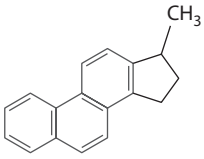


3,5-Cholestadiene

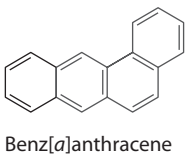
- In the 1935 report on his pyrolysis of cholesterol, Cohen et al. (5151) described the generation of phenanthrene derivatives, the so-called Diels hydrocarbon (17-methyl-17*H*-cyclopenta[*a*]phenanthrene) and chrysene. At one time, chrysene was classified as a carcinogen by the IARC (1868a), but subsequently, the IARC canceled its carcinogen classification
- By 1951, many phenanthrene derivatives had been reported as tumorigenic, e.g., 1,2,3,4-tetramethylphenanthrene (1544)
- Also, chrysene, the Diels hydrocarbon, and several tumorigenic PAHs such as benz[*a*]anthracene B[*a*]A, DB[*a,h*]A, and B[*a*]P are obviously related structurally to phenanthrene since each has one or more additional benzene rings fused to a phenanthrene structure



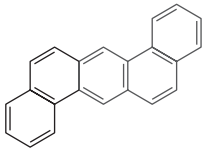
Chrysene

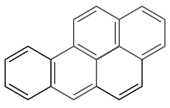


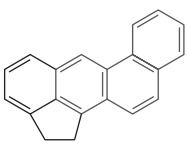
Diels hydrocarbons



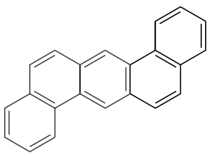
Benz[*a*]anthracene



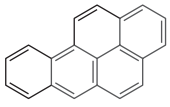




Cholanthrene



Dibenz[*a,h*]anthracene



Benzo[*a*]pyrene

TABLE 1.15 (continued)
Comparison of Roffo's Findings on the Destructive Distillate of Tobacco *vs.* Research Findings Reported by Others on Tobacco Smoke

Roffo and the Destructive Distillate of Tobacco and Other Related Research	Tobacco Smoke and Other Related Research
In 1939, Roffo reported the tumorigenicity to laboratory animals of heated/oxidized "fat" (25A53, 25A55)	• Subsequent studies on heated fats essentially confirmed the findings of Roffo, e.g., Peacock and Beck (5327), Lane et al. (5257), but a study by Morris et al. (5292) did not • Fat components such as saturated hydrocarbons were shown to yield tumorigens on heating, e.g., (142, 2257) • Fat components such as high molecular weight aliphatic esters and triglycerides yield tumorigens on heating (1646, 2111a, 5212)
Duplicating his tobacco destructive distillate procedure, Roffo reported in 1940 that the destructive distillate from tea was tumorigenic (5356) as was the destructive distillate of Yerba mate (5358) *Note*: Yerba mate is a tea like substance containing xanthines and used for drink preparations, including toasted Yerba mate used in drink preparation	• In the late 1950s, tumorigenic PAHs were reported in tea and coffee by Kuratsune (2237) and Kuratsune and Hueper (2236) • In his 1988 review, Maga (2438) summarized the identification of numerous tumorigenic PAHs in foodstuffs and beverages, including tea and coffee
In 1939, Roffo reported that the destructive distillate from coffee was tumorigenic to laboratory animals (5355)	• In 1939, Widmark (5466) reported that an extract of roasted coffee was tumorigenic to laboratory animals • With improved analytical technology available in the mid-1950s, B[*a*]P was identified in roast coffee by Fieser's colleagues (1181, 2236, 2237), but no B[*a*]P was identified by them in cigarette "tar"

[a] Considered a major precursor of PAHs by Lam and by Wynder; demonstrated to be significant but less significant than phytosterols and terpenoids such as solanesol.
[b] Considered a major precursor of PAHs by Wynder and Wright (4353); demonstrated to be major by Rodgman and Cook (3260) and by Severson et al. (3616).
[c] Considered a major precursor of PAHs by Wright; demonstrated to be major by Rodgman and Cook (3269) and Severson et al. (3616).

Despite the numerous criticisms of the information provided by Roffo in his numerous publications issued in the 1930s and early 1940s on the destructive distillate from tobacco because of the purported lack of pertinence of such information to that derived from studies on tobacco-derived smoke, it is interesting to compare the results reported by Roffo on the chemical and biological properties of the tobacco destructive distillate with those obtained post-1953 with tobacco smoke, particularly cigarette smoke. Also interesting is the comparison of the findings of Roffo on the pyrolysis of several tobacco components with reports by other investigators. Such comparisons are also presented in Table 1.15.

Although many of the findings reported by Roffo on the tobacco destructive distillate differ in degree from findings reported for tobacco smoke, many of the tobacco destructive distillate and tobacco smoke findings do parallel each other generally. As indicated in Table 1.15, two Roffo findings do differ substantially from those reported by other investigators: (1) the relationship between the tumorigenicity of tobacco destructive distillate *vs.* coal-tar tumorigenicity and (2) the similarity of the tumorigenicities of the destructive distillates from different tobacco types reported by Roffo (3324, 5359, 25A60) *vs.* the difference in tumorigenicities of the MSS "tars" from various tobacco types reported by Wynder and Hoffmann (4317). Recently, Proctor (5341) summarized the contributions of Roffo to our tobacco-pertinent knowledge and noted several of the investigators who were either supportive of or critical of his findings.

The generation in the early 1950s of carcinomas in laboratory animals (mice) skin painted with a solution of the mainstream "tar" from commercial cigarettes (4306a) led to numerous studies to identify the possible causative agent(s) in the "tar." Since much more tumorigenicity data and knowledge were available on PAHs than on any other class of compounds, most of the effort was concentrated on identifying PAHs in cigarette smoke condensate (CSC) as the possible cause of the tumorigenicity. Because of its demonstrated potency as an initiator of carcinomas on skin painting and the wealth of information on it, B[*a*]P became the target of much research on CSC. In 1951, Hartwell (1544) listed nearly 350 studies on the tumorigenicity of B[*a*]P administered in various ways to various species. The other previously studied PAHs were dibenz[*a,h*]anthracene (DB[*a,h*]A) and 1,2-dihydro-3-methylbenz[*j*]aceanthrylene (3-methylcholanthrene) with 240 and 303 reported biological studies, respectively. Benz[*a*]anthracene (B[*a*]A) and 7,12-dimethylbenz[*a*]anthracene (DMB[*a*]A) were listed with 20 and 32 studies, respectively. In the 20 studies reported by Hartwell (1544), a malignant tumor was noted in only one instance with B[*a*]A.

Although B[*a*]P was reported as a CSC component in the mid-1950s by several American (55–57, 592–594) and British investigators (820) on the basis of spectral evidence, Fieser, as late as 1957 (1181), considered the published evidence to be

inadequate as proof of the presence of B[*a*]P in CSC. Obviously, in 1957, Fieser was unaware of the report by Rodgman in 1956 (3240) on the isolation of crystalline B[*a*]P from MSS or the reports by Falk and Kotin in 1955 and 1956 (1172) on the determination of the per cigarette yields of B[*a*]P (plus B[*a*]A and dibenzo[*def,p*]chrysene) in MSS and sidestream smoke (SSS). Shortly thereafter, in 1959, Wynder and Hoffmann reported the isolation of B[*a*]P in crystalline form from CSC (4307), thus ending the controversy about its presence in cigarette smoke.

In 1954, knowledge of cigarette MSS composition was extremely limited. As mentioned earlier, Kosak (2170) listed fewer than 100 components reported in tobacco smoke, and many of those listed were incorrect. Some of the early research on cigarette MSS composition, particularly the PAHs, was conducted at RJRT.* Complete details of the experimental procedures and findings are available on the Internet at www.rjrtdocs.com.

The initial RJRT PAH investigation involved 11 PAHs in the MSS from nonfiltered cigarettes (3240, 3244) [see Table 1 in (3262)]. Naphthalene, anthracene, pyrene, fluoranthene, and B[*a*]P, isolated in crystalline form, were characterized by UV absorption spectral data as well as by classical chemical means (mixture melting point, IR spectra, derivatization, and derivative properties). The other six PAHs were identified on the basis of agreement of their UV absorption spectra with those of authentic samples or with published UV data.

The second RJRT investigation involved the MSS from filter-tipped cigarettes (3249, 3273, 5077) [see Table 1.15 in (3262)]. In that study, 43 PAHs, including the 11 PAHs found in the initial study, were identified (3240, 3244). Of the 43 PAHs, 14 were isolated (12 in crystalline form and 2 as liquids) and characterized by both UV spectral and classical chemical means [see Table 1 in (3262)]. B[*a*]P, B[*a*]A, DB[*a,h*]A, and several other PAHs were also isolated in crystalline form from the CSC (3240, 3244, 3273). The other 29 were identified from the agreement of their UV absorption spectra with those of authentic samples or with published spectra. B[*a*]P, B[*a*]A, and DB[*a,h*]A had been reported to be tumorigenic to mouse skin, although the bioassay data for B[*a*]A were contradictory (983, 1543, 1544).

Although much of the early research at RJRT R&D on the identification of PAHs in MSS and the effect of various tobacco blends and/or treatments on their MSS yields was summarized in several recent publications (3262, 3307), other members of the U.S. tobacco industry were also much involved in similar research in the 1960s and 1970s. The following paragraphs provide a few examples of their early efforts:

At Philip Morris in 1963, Robb et al. (3191) described the identification of 14 PAHs (naphthalene, fluorene, anthracene, 9-methylanthracene, phenanthrene, fluoranthene, pyrene, 1-methylpyrene, B[*a*]P, B[*e*]P), DB[*a,h*]A, benz[*e*]acephenanthrylene, perylene, benzo[*ghi*]perylene), biphenyl, and the aza-arene, carbazole, in cigarette MSS. Almost all the details in this 1963 Philip Morris in-house report were subsequently presented at the 1964 CORESTA meeting and published in 1965 (3191). Also at Philip Morris, Carpenter (606a) in 1964 described the per cigarette B[*a*]P yields from several commercial cigarettes; Oakley (2817a) in 1965 reported the per cigarette B[*a*]P yields from cigarettes fabricated from different tobacco types (flue-cured, burley, Oriental); Segura (3579a) in 1966 reported the contribution of cigarette paper to the per cigarette B[*a*]P yield; Johnson (1962b) in 1965 described the effect of a tobacco additive, aluminum chloride, on the MSS B[*a*]P yield; and Oakley (2817b) in 1966 determined the difference in per cigarette B[*a*]P yield in MSS and SSS.

At British American Tobacco Company (BAT) in 1966, Chakraborty and Thornton (646a) studied the effect of various additives on MSS PAHs. The changes in the per cigarette yields of a variety of PAHs were determined. They included anthracene, B[*a*]A, benzo[*ghi*]fluoranthene, benzo[*k*]fluoranthene, B[*a*]P, B[*e*]P, chrysene, fluoranthene, fluorene, methylfluorene, phenanthrene, several alkylphenanthrenes, dimethylphenanthrene, pyrene, and several benzofluorenes.†

Although studies on PAHs in MSS were conducted at RJRT and L&M in the 1960s, publications only dealt with analytical techniques. For example, in 1963, Mold et al. (2596a) at Liggett and Myers Tobacco Company (L&M) described the use of a compound, tetramethyluric acid, that complexes with polycyclic compounds. It was a procedure reminiscent of the finding of the water-soluble purine–PAH complex defined by Weil-Malherbe (4161a), a finding subsequently developed into an alternative analytical method for the determination of PAHs and aza-arenes in tobacco smoke and other media by Rothwell and Whiteheart (3337–3340). Although the study was not described as relating to tobacco smoke, Cundiff and Markunas (869) at RJRT in 1963 reported a titrimetric analysis of the nitro groups in numerous PAH–2,4,7-trinitrofluorenone complexes as a means to define the molecular weight of the PAH. All but one of the PAH–2,4,7-trinitrofluorenone complexes could be obtained from the PAH fraction of cigarette MSS. Of course, there were also methods developed for the in-house determination of specific PAHs, particularly B[*a*]P by Bell (239a) at Lorillard, Oakley and Stahr (2820a) at Philip Morris, and Walker (4110) and Stamey et al. (3787, 3789) at RJRT.

These and many other in-house reports on PAHs demonstrate that the early PAH research was not limited to academic or governmental laboratories or to laboratories at private institutions such as the Sloan-Kettering Institute,

* Numerous formal in-house reports and memoranda authored by RJRT R&D personnel are cited herein. Many have been published totally or in part in peer-reviewed journals and/or presented totally or in part at scientific conferences (Tobacco Chemists' Research Conferences, American Chemical Society Symposia on Tobacco and Smoke, CORESTA Conferences, etc.). Whether published, presented, or neither, copies of all RJRT reports cited are stored in various repositories such as the one in Minnesota. Their contents are available on the Internet address indicated. Experimental procedures used, data collected, and interpretations summarized here are described in detail in the reports cited.

† At the Internet address, http://legacy.library.ucsf.edu/cgi, by inserting the topic "aromatic polycyclic hydrocarbons," one may access over 20 BAT and Brown and Williamson (B&W) memoranda by Chakraborty, Thornton, and others on PAHs in tobacco smoke.

American Health Foundation, or Roswell Park Memorial Institute. Many of the previously mentioned tobacco industry reports on PAHs may now be accessed at the Internet addresses cited in the references.

Additional PAHs—both tumorigenic and nontumorigenic—were subsequently identified in CSC, but the level of B[*a*]P in CSC could account for very little (1056, 3310, 3311, 4354) or less than 2% of the observed skin-painting effect (4312, 4354) and the contribution of all the known tumorigenic PAHs in CSC could account for not much more than 3% of the observed effect. These findings led to the proposal by Wynder and Wright (4354) that CSC contained a PAH that either possessed the same specific tumorigenicity as B[*a*]P but was present at about 50 times the B[*a*]P level or present in MSS was an unknown PAH that was "supercarcinogenic" compared to B[*a*]P, i.e., its specific tumorigenicity to mouse skin was 40–50 times that of B[*a*]P. After an 18-month search, Wright, a colleague of Wynder from the early to the late 1950s, concluded that neither type PAH was present in CSC. Subsequently, the absence of a "supercarcinogen" in CSC was confirmed by the identification of hundreds of PAHs in the PAH fraction of CSC by Snook et al. (3756–3759). Detailed examination of their lists does not reveal the presence of a PAH structurally different from any of those previously classified with regard to their specific tumorigenicity on mouse-skin painting.

No other CSC fraction possessed specific tumorigenicity to mouse skin comparable to the PAH fraction. In the mid-1950s, the tumorigenicity of the *N*-nitrosamines in CSC was not an issue for several reasons: (1) the tumorigenicity of an *N*-nitrosamine was first defined in 1956 (2441a), (2) the presence of *N*-nitrosamines in MSS was not suggested until the early 1960s (422, 423, 1057), and (3) of more than 300 *N*-nitrosamines tested for tumorigenicity, only one type not found in tobacco smoke—the *N*-nitrosoalkylureas—was found to be tumorigenic to mouse skin [e.g., see Appendixes A through D in (2991)].

Consideration of all the tumorigenic PAHs and their levels in CSC could account for no more than 3% of the observed biological activity in mouse-skin-painting studies. In 1961, Wynder and Hoffmann (4312) stated:

> The polynuclear aromatic hydrocarbons are mainly formed during the combustion of tobacco. The tobacco of our standard cigarettes contains only very minute quantities of benzo(a)pyrene [*sic*] (0.02 ppm). A bioassay indicates that these polycyclic hydrocarbons of the condensate by themselves, however, can account for not more than 3 per cent of the total biological activity.

In 1967, they reiterated their 1961 comment (4340):

> Without belaboring the point as to whether B*a*P as such contributes to the carcinogenicity of tobacco smoke condensate, we can certainly agree that the concentration of B*a*P may be regarded as an 'indicator' of carcinogenic PAH in tobacco smoke condensate… While B*a*P and other carcinogenic PAH can by themselves account for only a small portion of the total tumorigenic activity of cigarette smoke condensate, probably less than 2%, they are, nevertheless, of obligatory importance as tumor initiators.

Hoffmann and Wynder (1800) reported that the major carcinogenicity of CSC resided in the CSC fraction containing the bulk of the PAHs. However, the levels in CSC of the nonalkylated carcinogenic PAHs could explain no more than 1%–3% of the observed activity. They also reported that the artificial doubling and tripling of the levels of the 17 known tumorigenic PAHs in CSC significantly increased the tumorigenicity of the CSC. However, their biological findings were contradicted by those of Roe (3310, 3311) and Lazar et al. (2320) who reported that increasing the level of B[*a*]P in CSC by a factor of 10 or 30, respectively, produced no increase in the specific carcinogenicity of the CSC. Roe (3310, 3311) also noted that the CSC level of B[*a*]P, despite its known tumorigenic potency, accounted for very little of the observed specific tumorigenicity of CSC to mouse skin. The opposite of these observations were the findings that potently tumorigenic PAHs such as DB[*a*,*h*]A on subcutaneous injection [Dobrovolskaia-Zavadskaia (1021)] and B[*a*]P on mouse-skin painting [Poel et al. (2970a)] exhibited a threshold value. Wynder et al. (4303) reported that mice skin painted with the equivalent of the B[*a*]P content of the CSC from over 500 current cigarettes developed no carcinomas. Rabbits were found to be even more resistant to higher dose levels of B[*a*]P.

Paralleling the research on the presence or absence of PAHs in cigarette MSS, their precursors in tobacco, their mechanism of formation, their contribution to laboratory animal tumorigenesis, and their possible involvement in the smoking-health issue was extensive research on ways to generate a "less hazardous" cigarette by removal of PAHs from or reduction of their per cigarette yields in MSS. To successfully resolve these questions, much pioneering research and development were initiated in late 1954 (3262). When the question of the presence of PAHs in MSS was resolved, with many PAHs identified, and their per cigarette MSS yields determined, much effort was expended to develop technologies to reduce their MSS yield, particularly the yields of those PAHs reported to be tumorigenic to CSC-painted mouse skin. In the early 1960s, a "less hazardous" cigarette was defined on the basis of three criteria [see p. iii in (1329); p. 372 in (4319); pp. 503, 531 in (4332)]: (1) the per cigarette yield of a specific toxicant has been lowered, (2) the ratio of the specific toxicant to MSS "tar" has been lowered, and (3) the specific tumorigenicity of the MSS "tar" as measured in the mouse-skin-painting bioassay has been lowered. With the advent of meaningful tests for mutagenicity and genotoxicity, criterion 3 has been modified to include them.

The tobacco industry and nonindustry scientists investigated many additional approaches in the attempt to design a "less hazardous" cigarette [see Table 5 in (3262), Table 14 in (3300)]. Two examples of technologies that appeared to be promising but presented other toxicant problems were (1) the organic solvent extraction of tobacco and (2) the use of oxidative additives.

The extraction concept was patterned after the findings of Roffo (3327) with one addition: the hexane extract of the tobacco was partitioned between hexane and aqueous ethanol to separate the flavorful compounds from those considered to be the PAH precursors, i.e., the phytosterols, the aliphatic hydrocarbons, and the long-chained terpenoids

(116, 121, 3189). When the extracted tobacco was smoked in cigarette form, its CSC showed much lower PAH levels than the control tobacco CSC (3241, 3246, 4356) and reduced tumorigenicity (4356). The flavorful components, when returned to the extracted tobacco and smoked in cigarette form, contributed little to the total PAHs or B[*a*]P in the MSS [see Figure 1, Table 3, and accompanying text in (3262)]. The solvent extraction removed from the tobacco not only many of the PAH precursors but also much of several potent anticarcinogens to such tumorigens as B[*a*]P and DB[*a,h*]A, e.g., long-chained aliphatic hydrocarbons, *d*-limonene, α-tocopherol, α- and β-1,5,9-trimethyl-12-(1-methylethyl)-4,8,13-cyclodecatriene-1,3-diol [see Table 11 in (3300)]. Thus, because of their removal from the tobacco, the anticarcinogens obviously could not be transferred to MSS during smoking. Before some of the problems were discovered, the investigation of the benefits supposedly derived from the organic solvent extraction of tobacco led to several patents on the technology (121, 2713, 2717, 3189). The earliest major nontobacco industry proponents of the contribution of the extraction technology to a "less hazardous" cigarette eventually dismissed it with the comment that the technology was "impractical both technically and economically" (4311) and "of academic interest only" (4306d). Most of the findings on tobacco components that were, and tobacco components that were not, significant precursors of MSS PAHs in this early study were confirmed some years later by Severson et al. (3616). The problems arising from the organic solvent extraction included the increased levels of nitrate and the biopolymers cellulose, starch, and pectin in the solvent-extracted tobacco. These consequences increased the yields of nitric oxide, *N*-nitrosamines, and phenols (3277) in the MSS.

Although nitrate addition reduced the per cigarette yields of FTC "tar," MSS PAHs, phenols, and CSC tumorigenicity to mouse skin (1797), it was subsequently shown, as predicted (1798), to significantly increase the yields of MSS *N*-nitrosamines and nitrogen oxides (480). Thus, the recommendation to add nitrate to tobacco to reduce MSS PAHs was eventually replaced by the recommendation to use low-nitrate tobacco in the cigarette blend and/or remove nitrate from the tobacco (480). This reversal of recommendations was paralleled by another concerning the level of long-chained hydrocarbons such as *n*-hentriacontane in tobacco: Originally, it was proposed to reduce MSS PAHs by selection of tobaccos with low levels of such components or remove the PAH precursors by organic solvent extraction. This was replaced by a proposal to select tobaccos with high levels of such components (480).

By the early 1960s, several cigarette design technologies developed by the tobacco industry and used in commercial products were categorized as significant in their contribution to the "less hazardous" cigarette (4310). Ultimately, the initial four design technologies (tobacco blend, effective and efficient filtration, reconstituted tobacco sheet (RTS), air dilution via cigarette paper porosity) were increased to eight (tobacco blend, filter tip, filter tip additives, RTS, paper additives, expanded tobacco, air dilution (paper porosity), air dilution (filter tip perforation)). Their significance was recognized in "less hazardous" cigarette design by the National Cancer Institute (NCI) (2683)* and the U.S. Surgeon General [see Table 6 in (3262), Table 15 in (3300)] (3999, 4005, 4009, 4010). It should be noted that the first two technologies considered significant were used before 1954. Tobacco or tobacco blend selection had been used since 1913, even before the first tumors were induced in a laboratory animal by skin painting with a solution of coal tar (4361). RTS was introduced into cigarette blends in 1953 when little was known about the chemical composition or biological properties of tobacco smoke (2170) or the effect of RTS inclusion in the blend on them. When knowledge of tumor induction with CSC and the presence of PAHs including B[*a*]P became available, it was shown that use of these two technologies resulted in a cigarette whose MSS was in compliance with that in the definition of a "less hazardous" cigarette (3300).

Of course, the initial thrust of this across-the-board reduction was aimed at reducing the MSS "tar" delivery because of extrapolation by Wynder et al. (4351) of their 1957 mouse-skin bioassay findings:

> Although it is difficult to estimate a comparable exposure level for man, the human data in line with the animal data indicate that a reduction in total tar exposure will be followed by a decrease in tumor formation. For this reason, measures directed toward this reduction are of utmost importance… The minimum dose of tar capable of producing papillomas in mice is about one third, of producing cancer one half, that of the optimum dose…The practical implications of these data and their relationship to the human cancer problem have been emphasized.

In his 1957 testimony during the filter-tipped cigarette hearings, Wynder reiterated this opinion that reducing "tar" exposure dose by 40%–50% would substantially reduce lung-cancer induction in smokers (4296):

Examination of the sales-weighted average "tar" delivery for U.S. commercial cigarettes reveals that the 40%–50% reduction in MSS "tar" delivery considered vital by Wynder in 1957 was achieved in the late 1960s, i.e., a reduction from 38–39 to 19–20 mg/cig. Further examination reveals that by the early 1980s, the sales-weighted average "tar" was reduced to about 12 mg/cig, i.e., an additional 40% reduction had been achieved [see Figure 3 in (3262)]. Corresponding reductions in the per cigarette yields of total PAHs in general, B[*a*]P in particular (4158), and nicotine were also observed. These reductions were also accompanied by a reduction in the specific tumorigenicity (mouse-skin painting) of the MSS CSC (4005).

* All eight cigarette design technologies eventually classified as significant by NCI, several U.S. Surgeons General, and other investigators on the basis of the 10-year NCI Smoking and Health Program on the "less hazardous" cigarette had been incorporated into one or more U.S. commercial cigarette products prior to the first meeting of the Tobacco Working Group formed in 1968 for the NCI program. In other words, from 1968 to 1978, no new design technology was generated in the NCI Smoking and Health Program on the "less hazardous" cigarette.

By year-end 1963, 91 of the 97 PAHs identified in MSS were reported in the published literature. Six PAHs, identified in MSS by Rodgman and Cook (3273), had not been reported publicly at that time. However, by 1970, identification in MSS of all but one (cholanthrene) of the 97 had been reported. Despite the availability of such information, only 18 MSS PAHs were discussed by the Advisory Committee in its 1964 Report to the U.S. Surgeon General, 13 as mainstream CSC components and five as carbon black components (3999). The detailed discussion of so few MSS PAHs and citation of so few publications were done despite the fact the committee had been provided with a detailed Philip Morris monograph on tobacco and smoke composition, a monograph that listed 61 PAHs identified in tobacco smoke plus many pertinent published references to them (2939, 3262). The Advisory Committee did note, however, that 27 other nontumorigenic PAHs—none specifically named—had been identified in tobacco smoke. The 27 unnamed PAHs had to include several of those PAHs, e.g., naphthalene, anthracene, phenanthrene, fluoranthene, and pyrene, which had been reported to significantly inhibit the action of potently tumorigenic PAHs such as B[*a*]P and DB[*a*,*h*]A in laboratory animal studies. Of the 97 PAHs known to him, Rodgman (3262) discussed the 43 PAHs identified at RJRT plus 34 other PAHs reported in the literature in numerous reports between 1954 and 1964 and in a summary 1964 report on 10-year research on cigarette MSS (3251). Interestingly, Chapter 6, in the Advisory Committee's report on cigarette smoke chemistry and the tumorigenic PAHs, was primarily authored by Fieser, one of the two eminent American PAH authorities at that time.

For over half a century, numerous theories have been advanced in attempts to explain the relationship between the tumorigenicity of PAHs in treated laboratory animals and a variety of their structural properties, including such properties as their K, L, and bay regions, electron distribution, bond orders, bond strengths, resonance, octanol–water partitioning, and the like (Figure 1.5).

Such studies were triggered by the discovery that certain PAHs when administered to laboratory animals via skin painting or subcutaneous injection induced carcinomas or sarcomas, respectively. DB[*a*,*h*]A, synthesized independently by Clar (760) and Fieser and Dietz (1184) in 1929, was shown to be a potent tumorigen to laboratory animals by Kennaway and Hieger (2078). Shortly thereafter, Cook et al. (797) isolated several PAHs from coal tar, characterized one of them as the previously unknown benzo[*a*]pyrene (B[*a*]P), and demonstrated that it too was a potent tumorigen to laboratory animals (194). Over the next two decades, the first demonstrations of the carcinogenicity of two pure compounds, DB[*a*,*h*]A and B[*a*]P, led to the synthesis and subsequent testing for tumorigenicity in laboratory animals of literally hundreds of PAHs and their alkyl derivatives plus other derivatives.

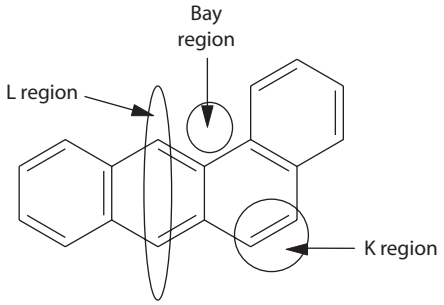


FIGURE 1.5 The L region, K region, and bay region of benz[*a*]anthracene.

During this time, the variation in biological responses observed with laboratory animals to individual PAHs eventually led to numerous unacceptable extrapolations of the results to PAH-exposed humans. To put the laboratory animal-to-human extrapolation in perspective, Shear and Leiter (3627) in 1941 issued a list of pertinent factors to be considered in such an extrapolation. Despite a diminution in PAH synthesis and tumorigenicity research during the World War II, the wealth of experimental data available in the late 1940s–early 1950s on the high-to-slight tumorigenic potency of some PAHs and the nontumorigenicity of other PAHs induced investigators to seek reasons for the observed differences in tumorigenicity and to attempt to develop explanations for them. Among those involved in the generation of the major early theories on the relationship between PAH structural properties and PAH tumorigenicity or lack of it were Coulson (829); Pullman and Pullman (3003); Daudel and Daudel (906a); Fieser et al. (1180a) and Fieser (1180b); and Lacassagne et al. (2247a). Much meaningful input to these theories was provided by other investigators such as Pauling (2910a) in the United States; Boyland, Weigert, and Mottram (423a) in the United Kingdom; and Buu-Hoï in France [see more than 30 Buu-Hoï references listed in (2247a)]. More recent studies include those by Herndon et al. (1623a, 2435a), Rubin (3365), Trosko (3966a), Zhang et al. (4410c), and Zhang, a graduate student under Herndon (4410d).

Because it was issued at the beginning of the extensive research on the composition of tobacco smoke with particular emphasis on the nature and levels of the PAHs in it, it is interesting to examine the lengthy 1955 review by Pullman and Pullman (3003) on the relationship between electronic structure and the tumorigenicity of a number of benzenoid hydrocarbons. Their publication was a detailed update of the 1953 review by Coulson (829) and included much data generated in the interim. The Pullmans used calculations based on three theoretical indexes of the K and L regions of the aromatic hydrocarbons. The indexes included Carbon Localization Energy (CLE), Bond Localization Energy (BLE), and *Para* Localization Energy (PLE) [see Table 1 in (3003)]. The Pullmans, by use of their CLE, BLE, and PLE calculations pertinent to the K and L regions in the PAHs, also attempted to relate the structures of various PAHs and their alkylated derivatives not only to their tumorigenicity but also to their rate of reaction in certain well-known reactions, e.g., Diels–Alder reaction with maleic anhydride, reaction with osmium tetroxide, reaction with lead tetraacetate, and photooxidation. Table 1.16 lists the hydrocarbons discussed by the Pullmans in

TABLE 1.16
Benzenoid Hydrocarbons Discussed by Pullman and Pullman (3003)

Aromatic Hydrocarbon Discussed	CAS No.	No. in Pullman and Pullman (3003)	Considered Tumorigenic[a] in 1955
Monocyclic			
Benzene[b]	71-43-2	I	No
Bicyclic			
Naphthalene	91-20-3	II	No
Tricyclic

[a] Tumorigenic in mouse-skin-painting study.
[b] Benzene was reported as a component of the vapor phase of tobacco smoke in 1955 by Resnik and Holmes (3106) and Laurene (2293).
[c] A dimethylchrysene was subsequently reported in tobacco smoke, but the positions of the methyl groups were not defined.
[d] At least two methylB[*a*]Ps were subsequently reported in tobacco smoke, but the position of the methyl group in each case was not defined.
[e] This PAH is not totally benzenoid; its structure includes a cyclopentanoid ring.
[f] In 1955, the tumorigenicity of benzo[*rst*]pentaphene had not been determined; later, it was reported to be tumorigenic.
[g] Although no calculation was made on this PAH, Pullman and Pullman (3003) predicted it would be tumorigenic.

1955 with an indication of those, 34 in all, which were identified in tobacco smoke before and after 1955.

The Pullmans did introduce into their discussion various PAH metabolites, their diols and phenols, but not the epoxides which were unknown at that time. Even though it had been known since 1951 (3814), no explanation was offered for the inhibition of the activity of a potently tumorigenic PAH by coadministration of a weakly tumorigenic or nontumorigenic PAH. Lastly, of course, neither the Pullmans nor Coulson discussed the fact that a bioassay finding with a highly susceptible strain or species of laboratory animal administered an individual PAH in an excessive dose has little relationship to the situation where a human is exposed by a different administration route to a mixture of PAHs with various degrees of tumorigenicity plus other known antitumorigenic compounds.

By year-end 1955, very few of the PAHs considered by the Pullmans had been reported as tobacco smoke components. More had been identified in other sources such as air pollution. In the following discussion, the comments in the early 1950s about the inadequacy of the evidence indicating the presence of B[*a*]P in tobacco smoke (1181) are disregarded. Table 1.17 lists the PAHs reported in tobacco smoke at that time.

Of the 14 PAHs reported, only eight were included by the Pullmans in their assessment: naphthalene, anthracene, phenanthrene, B[*a*]A, B[*a*]P, B[*e*]P, dibenzo[*def,mno*]chrysene, and pyrene. Of course, only one of the eight, B[*a*]P, was considered at that time a significant and potent tumorigen to mouse skin. At that time, the tumorigenicity of B[*a*]A was questioned, and still was questioned in the mid-1980s (983).

As noted previously, Pullman and Pullman not only updated the electronic structure–tumorigenicity information generated after the Coulson 1953 review but also attempted to extend the theory to alkyl-PAHs. Examination of their review reveals that they discussed, in addition to 1,2-dihydro-3-methylbenz[*j*]aceanthrylene, a total of 12 alkyl-PAHs (see Table 1.16). It is obvious from their discussion that the prediction of tumorigenicity for most of these 12 PAHs was not calculated but derived from published biological data. However, examination of the biological data in Hartwell (1543, 1544) and Shubik and Hartwell (3664, 3665) indicates that at least

[a] Molecule has a cyclopentanoid ring; thus, it was not considered by Pullman and Pullman (3003).
[b] Molecule does not possess a benzenoid structure.

64 totally benzenoid alkyl-PAHs had been tested for tumorigenicity by 1955. Several 1,2-dihydromethylbenz[*j*]aceanthrylenes had been tested for tumorigenicity by 1955, but they were not included in our count of 64. This raises the question: Why was the prediction not calculated for more of the 64 alkyl-PAHs, the tumorigenicity of which was known at that time (1543, 1544, 3664, 3665)? Pullman and Pullman noted: "It must be acknowledged that the extension of the theory to substituted derivatives of polycyclic hydrocarbons is at present far from having achieved a completely consistent and satisfactory form."

Many of the more recent theories on the relationship between PAH structural properties and tumorigenicity suffer somewhat from this and other deficiencies [cf. Herndon et al. (1623a, 2435a), Rubin (3365), Trosko (3966a), Zhang et al. (4410c), and Zhang (4410d)]. Much studied in recent years has been the application of the quantitative structure–activity relationship (QSAR) method to PAHs.

Although many theories have involved the relationships between observed laboratory-derived biological data on individually administered PAHs and their structural elements, do they speak to the exposure situation experienced by humans? Whether the exposure is by inhalation of air pollutants or tobacco smoke, by ingestion of foodstuffs or beverages, by dermal contact, or by a combination of the exposures, very few of any human exposures involve exposure to a single PAH similar to the exposure of laboratory animals treated with a single PAH by skin painting or subcutaneous injection. One such example of human exposure to a single PAH was the past use of naphthalene as the major ingredient in mothballs.

Numerous PAHs have been either completely of partially characterized in many air pollutants, foodstuffs, beverages, and contact tars and dusts. Of all the products to which humans are exposed, none has been characterized to the extent of tobacco smoke. Over 5200 components have been identified in it, nearly twice as many as in the next consumer product, coffee, subjected to detailed compositional analysis. Of the identified tobacco smoke components, about 11% were either completely or partially identified as PAHs. It should also be noted that in the detailed examination of tobacco smoke, over 5200 identified components account for over 98% of the weight of cigarette MSS. It has been estimated, based on detailed gas chromatograms, that the number of actual components in cigarette MSS may be 12–20 times the number of identified ones (4103).

Of the more than 500 PAHs either completely or partially identified in cigarette MSS, relatively few PAHs, originally 13 in all, were repeatedly defined as significant tumorigens (1727, 1808, 1871). Eventually, the International Agency for Research on Cancer (IARC) redefined the tumorigenicity of chrysene. Thus, it was deleted from all subsequent lists (1740, 1741, 1743, 1744, 2825) except one (1217). MSS is not the only source of most of the 12 PAHs still considered as significant tumorigens in cigarette MSS. Except for 5-methylchrysene, most have also been identified as significant PAH components of gasoline and diesel engine exhaust gases (1406a, 4315) and many common foodstuffs and beverages (1345, 2438).

When one is dealing with a complex mixture, which in turn contains an assortment of PAHs ranging from bicyclic to decacyclic, one cannot extrapolate the biological effect observed by administration of an individual PAH to the biological effect of that PAH in such a complex mixture. It has long been known from laboratory studies that certain nontumorigenic or slightly tumorigenic PAHs when administered by skin painting or subcutaneous injection in an equimolar dose level with a highly tumorigenic PAH partially or totally inhibit its tumorigenicity. Few studies have been done to determine the effect of a non- or low-tumorigenic PAH on the tumorigenicity of a highly tumorigenic PAH when its level greatly exceeds that of the potent tumorigen. Also, there are differences in the classification of the potency of the tumorigenicity of some PAHs. For example, B[*a*]A is classified by some as a potent or significant tumorigen (1871) but by others as only slightly tumorigenic (983).

The list of either totally or partially identified PAHs in CSC gradually increased, but in the mid-1970s, the massive definitive PAH study by U.S. Department of Agriculture (USDA) personnel in Athens, GA, increased the number of known PAHs in CSC to well over 500 (3732, 3756–3759).

Although not isolated individually, their identifications, whether total or partial, have generally been accepted across the board.

Numerous authors, including Hoffmann and Hecht (1727), listed the PAH dibenzo[*a*,*l*]pyrene as a significant tumorigen in tobacco smoke. However, Hecht eventually stated (1557) that "the presence in cigarette smoke of dibenzo[*a*,*l*]pyrene, a highly carcinogenic PAH, had not been confirmed." One should weigh the comment by Hecht against the current status of defined MSS composition. Since the appreciable decline in detailed tobacco smoke composition studies after the late 1970s, no individual investigator or no research group has reported the confirmation of the identities of many of the PAHs (3756–3759), aza-arenes (3750, cf. 3414), nitrogen-containing components (1587), or ether- (2769) and water-soluble components (3553) reported in cigarette MSS in the 1970s. While many components have been confirmed by other investigators at the same institution as the authors, examination of the post-1980 literature indicates that the identities of nearly half the new components described in the previously mentioned studies have not been confirmed by investigators at other institutions. Because of such a situation, would Hecht also discount their presence in cigarette MSS in the same way as he discounted the presence of dibenzo[*a,l*]pyrene?

Although most of the past theories have attempted to define the relationship between structural properties of the PAHs and their specific tumorigenicity as measured individually in skin-painting studies, little has been done to explain the behavior of a PAH when it is present in a complex mixture which includes a host of PAHs, some of which are known antitumorigens as well as numerous known non-PAH antitumorigens (1174).

It has been known for over 60 years that coadministration of a potently tumorigenic PAH with an equimolar quantity of a nontumorigenic PAH often results in substantial reduction in % tumor-bearing animals (%TBA).

In 1953, Coulson noted [see p. 51 in (829)]:

> The action of inhibitors may be thought of as a competition between the carcinogenic and noncarcinogenic compounds for available sites on the enzyme. If sufficient noncarcinogenic molecules are able to occupy suitable sites, then the irreversible mutation cannot occur. We can see that inhibitors, in order to compete with the carcinogenic compounds, should themselves possess a K-region.

Some of the PAHs that substantially reduce or totally inhibit the tumorigenicity of several of the most potent tumorigens known are listed in Table 1.18. Obviously, neither naphthalene nor anthracene has a K region, a requirement proposed by Coulson for the inhibitory property.

Although many of the inhibition studies were conducted with the tumorigenic and inhibiting PAHs administered in equimolar quantities, it should be remembered that this is not the case in the PAH mixture in CSC. Table 1.19 is derived from CSC PAH data presented by Hoffmann and Wynder (1788, 1798) and Rodgman (3273). The per cigarette yield data in Table 1.19 were the averages of the data generated from two different commercial American cigarettes. One was unfiltered and yielded 36.8 mg/cig of total particulate matter (TPM) (1788); the other was a filtered cigarette that yielded 37.5 mg/cig of TPM (3273). The disparity between the relative yields in each category was less than 5%.

TABLE 1.18
Inhibition of Tumorigenicity of Potently Tumorigenic PAHs by Nontumorigenic or Weakly Tumorigenic PAHs

PAH[a]	CAS No.	Effective against	References
Naphthalene	91-20-3	B[*a*]P, DB[*a,h*]A	844
Anthracene	120-12-7	B[*a*]P, DB[*a,h*]A	844

Benzo[*e*] pyrene	192-97-2	B[*a*]P, DB[*a,h*]A, DMB[*a*]A	976, 3685, 3686
Benzo[*b*] triphenylene	215-58-7	MC[b], DB[*a,h*]A, DMB[*a*]A	976, 3683, 3686

[a] Each PAH listed is a component of cigarette MSS.
[b] MC = 3-methylcholanthrene = 1,2-dihydro-3-methylbenz[*j*]aceanthrylene.

In the early structure–biological activity studies, PAHs with a pentacyclic ring were not included in the discussion of most theories, but pentacyclic compounds in which the pentacycle contained nitrogen were, i.e., benzacridines (829, 2247a). In the discussion of his theory, Coulson (829) did mention several cyclopentanoid compounds: six benzacridines and two PAHs, 2,3-dihydro-1*H*-benzo[*a*]cyclopent[*h*]anthracene, and 10,11-dihydro-9*H*-benzo[*a*]cyclopent[*i*]anthracene.

In her 1996 thesis, Zhang (4410d) noted the numerous sources of PAHs to which humans are exposed, e.g., air pollutants, foodstuffs and beverages, effluents from factories, vehicles, and heat and power sources. Zhang particularly stressed tobacco smoke, its complexity, and some of the PAHs contained therein:

> Tobacco smoke is a complex mixture which is estimated to contain at least 150 compounds in the gas phase and more than 2000 compounds have been identified in the particulate phase. Table 1* lists some PAHs that exist in the particulate phase of cigarette smoke.

Unfortunately, the inconsistent use of PAH nomenclature sometimes makes it difficult to follow the phases of the study by Zhang [cf. Table 7 and Appendix A in (4410d)].

* In her Table 1, Zhang (4410d) listed 19 MSS PAHs reported in 1978 by Hoffmann et al. (1781).

TABLE 1.19
Levels of PAH Classes in Cigarette MSS

PAH Category	Assumed Approximate mol. wt.	Mainstream Smoke Yield[a]		
		Yield, ng/cig	Approximate Nanomoles[b]	Nanomolar Ratio, PAH:B[*a*]P
Bicyclic	128[c]	4140 (77.1)[d]	32.3	293
Tricyclic	178[e]	720 (13.4)	4.0	36
Tetracyclic	228	420 (7.9)	1.8	16
Pentacyclic	278	72 (1.3)	0.26	2.4
B[*a*]P	252	27 (0.49)[f]	0.11	1.0
Non-B[*a*]P pentacyclic	278	45 (0.81)[f]	0.16	1.5
Hexacyclic	328	14 (0.3)	0.04	0.36
Totals		5366 (100.0)		

[a] Data reported by Hoffmann and Wynder (1788,1798) from a nonfiltered cigarette, TPM = 36.8 mg/cig, were averaged with data reported by Rodgman and Cook (3273) for a filtered commercial cigarette, TPM = 37.5 mg/cig.
[b] Nanomoles calculated with the approximate molecular weights in column 2.
[c] The molecular weight of naphthalene = 128, that of indene = 116. It is realized that the average molecular weight of the bicyclic PAH mixture will differ slightly from those of the parent PAH because of the presence of numerous homologs (methylnaphthalenes, dimethylnaphthalenes, etc.).
[d] Values in parentheses represent the fraction % of the PAH category in the total PAH fraction.
[e] The presence of tricyclic PAH homologs results in molecular weight slightly different from 178.
[f] The sum of the fraction % of B[*a*]P and the fraction % of non-B[*a*]P pentacyclic PAHs equals 1.3%.

Another study, recently initiated by Martin et al. (2479), involved an attempt to develop a meaningful relationship between PAH structure, chemical properties, and biological properties, specifically the effect of PAHs on specific tumorigenicity in skin painting. Reported for naphthalene- and pyrene-related PAHs were the following molecular parameters: the measured and calculated log of the octanol–water partition coefficient (MlogP, ClogP), molecular volume (MgVol), calculated molar refractivity (CMR), and the number of valence electrons (NVE). The second phase of the study involved similar data for anthracenes, phenanthrenes, and indenes (3300a). All PAHs in the first two phases of this study (2479, 3300a) are reported components of cigarette MSS. The ultimate goal is to use these data to facilitate a QSAR on MSS PAHs. If such a meaningful relationship can be derived for the more than 500 MSS PAHs, then it probably can be applied to any PAH from any source.

As a prelude to this attempt to develop a possibly reasonable explanation for the PAH structure–tumorigenicity relationship, the PAHs completely or partially identified in cigarette smoke have been cataloged. For each PAH, the nomenclature used in Tables 1.14, 1.17, and 1.18 is the most recent proposed by the International Union of Pure and Applied Chemistry (IUPAC).

The tobacco smoke–PAH references cited in Table 1.20 are not necessarily all that are available, particularly for those PAHs such as B[*a*]P and DB[*a,h*]A, which have been the subject of much research and discussion for over half a century. In most cases, included is a reference to the publication or presentation by the investigator(s) who first reported a particular PAH in MSS. References of articles and/or presentations on specific PAHs that contained evidence later criticized are included plus references to the misinterpretations or errors. The criticism by Fieser (1181) in 1957 of the shortcomings of the evidence (55–57, 592–594, 820) supposedly indicating the presence of B[*a*]P in cigarette smoke has already been mentioned. Two other notable situations involved 1,2-dihydrobenz[*j*]aceanthrylene (cholanthrene) and dibenzo[*def,p*]chrysene (formerly named dibenzo[*a,l*]pyrene, initially 1,2,3,4-dibenzopyrene). These two PAH identifications, based solely on UV spectral data, were found to be incorrect. In their study, Rodgman and Cook (3273) incorrectly defined a PAH as 1,2-dihydrobenz[*j*]aceanthrylene (cholanthrene). In the massive study by USDA personnel on the identification of MSS PAHs, 1,2-dihydrobenz[*j*]aceanthrylene was not among the several benzocyclopentanthracenes reported (3756,3759). The other incorrectly characterized PAH was dibenzo[*def,p*]chrysene. For its identification, not only Rodgman and Cook (3273) but also Bonnet and Neukomm (397), Lyons and Johnson (2430), Lyons (2427), Wynder and Wright (4354), and Pyriki (3033) relied on published UV spectral data purportedly those of synthetic dibenzo[*def,p*]chrysene (dibenzo[*a,l*]pyrene). However, in 1966, Lavit-Lamy and Buu-Hoï (2314) determined that the published UV spectral data were not those of dibenzo[*a,l*]pyrene but of the isomeric dibenz[*a,e*]aceanthrylene (dibenzo[*a,e*]fluoranthene), generated during the supposed synthesis of dibenzo[*a,l*]pyrene. The authentic dibenzo[*def,p*]chrysene (dibenzo[*a,l*]pyrene) was identified in MSS in 1977 (3756), but its MSS level was not reported.

Some authorities insist that the B[*a*]P and 4-(methylnitrosoamino)-1-(3-pyridinyl)-1-butanone (NNK)

TABLE 1.20

PAHs in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

	CAS No.	Name (per CA Collective Index)	References: Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
312.	767-60-2	1*H*-Indene, 3-methyl-	1650, 1652, 2767, 3557, 3618, 3732, 3757–3759, 4249, 5811b		
313.	2471-84-3	1*H*-Indene, 1-methylene-	3557, 4249		
314.	6596-86-7	2*H*-Indene, 2-methylene- {benzofulvene} 	3557		
315.		1*H*-Indene, 4-methyl-2-(2′-methylphenyl)-	245		
316.		1*H*-Indene, 5-methyl-2-(4-methylphenyl)-	245		
317.		1*H*-Indene, 6-methyl-2-(4-methylphenyl)-	245		
318.		1*H*-Indene, 7-methyl-2-(2′-methylphenyl)-	245		
319.		1*H*-Indene, 7-(4′-methylphenyl)-	245		
320.	71278-09-6	1*H*-Indene, pentamethyl-	3732, 3757, 4249, 5811b		
321.	38638-41-4	1*H*-Indene, phenyl-	1800, 3732, 3757, 4249, 5811b		
322.		1*H*-Indene, 2-phenyl-	278		
323.		1*H*-Indene, phenyltrimethyl-	245		
324.	27135-78-0	1*H*-Indene, tetramethyl- {at least four isomers present in MSS}	104, 1650, 1652, 2731, 2735, 3732, 3757, 4249, 5811b		
325.	60826-61-1	1*H*-Indene, trimethyl- {at least three isomers present in MSS}	104, 1650, 1652, 2506, 2507, 2731, 2735, 3618–3620, 3732, 3757–3759, 4249, 5811b		2506, 2507
326.	668-30-4	Indeno[1,2,3,4-*defg*]chrysene {also reported as indeno[3,2,1,7-*defg*]chrysene; dibenzo[*b,mno*]fluoranthene; naphtho[1,2,3,4-*ghi*]fluoranthene} 	2328, 4249		
327.	71277-94-6	Indeno[1,2,3,4-*defg*]chrysene, methyl- {indeno[3,2,1,7-*defg*]chrysene, methyl-; dibenzo[*b,mno*]fluoranthene, methyl-; naphtho[1,2,3,4-*ghi*]fluoranthene, methyl-}	2328		
328.	193-43-1	Indeno[1,2,3-*cd*]fluoranthene 	128, 142, 143, 1099, 1100, 1139, 1217, 1409, 1445, 1727, 1740, 1741, 1743, 1744, 1773, 1788, 1798, 1808, 1870, 1871, 2825, 3262, 3265, 3714, 3756, 3797, 4005, 4009, 4010, 4249, 4315, 4319, 4332, 5077, 5512		
329.	41699-07-4	Indeno[1,2,3-*cd*]fluoranthene, methyl-	2328, 4249		
330.	98791-41-4	1*H*-Indeno[1,7-*ab*]fluorene	5811, 5811a, 5811b		
331.	98791-42-5	1*H*-Indeno[1,7-*ab*]fluorene 2,11-dihydro-	5811, 5811a, 5811b		
332.	220-97-3	11*H*-Indeno[2,1-*a*]phenanthrene{11*H*-naphtho[2,1-*a*]fluorene} 	39, 1139, 2037a, 2939, 3262, 3302, 3308, 3337, 3339, 3797, 4249, 5077, 5811b

	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
333.	72254-06-9	Indenopyrene 	5811, 5811a		
334.	193-39-5	Indeno[1,2,3-*cd*]pyrene {*o*-phenylenepyrene} 	104, 126a, 128, 141, 142, 151, 239, 290, 291, 603, 1099, 1139, 1217, 1397, 1405, 1406, 1408, 1409, 1445, 1557, 1727, 1740, 1741, 1743, 1744, 1773, 1781, 1788, 1798, 1800, 1802, 1808, 1870, 1871, 2013, 2134, 2438, 2479, 2524a, 2601b, 2799a, 2825, 3176, 3255, 3257, 3262, 3265, 3300, 3302, 3308, 3370, 3616, 3714, 3756, 3758–3759, 3797, 4005, 4010, 4011, 4249, 4311, 4315, 4317, 4319, 4324, 4325, 4332, 5010, 5077, 5512, 5539, 5811b, 5869a	5567	
335.	64158-99-2	Indeno[1,2,3-*cd*]pyrene, dimethyl- {at least two isomers present in MSS}	3615, 3756, 4249, 5811b		
336.	64158-98-1	Indeno[1,2,3-*cd*]pyrene, methyl- {at least two isomers present in MSS}	2328, 3756, 4249, 5811b		
337.		Indeno[1,2,3-*cd*]pyrene, trimethyl- {at least two isomers present in MSS}	3756		
338.	92-24-0	Naphthacene 	624, 658, 798, 1139, 1211, 2113, 2114, 2249, 2550, 2799a, 2963, 3003, 3191, 3262, 3797, 4249, 5077, 5811b		
339.	5385-22-8	Naphth[1,2-*e*]acephenanthrylene {dibenzo[*b,j*] fluoranthene} 	3615, 3756, 4249, 5811b		
340.	91-20-3	Naphthalene 	84, 104, 141–144, 147, 151, 156, 157, 167, 172, 174e, 239, 291, 299, 329, 394, 397, 568b, 603, 624, 710, 746a, 798, 869, 966, 1094, 1099, 1100, 1135, 1139, 1287, 1288, 1313, 1360, 1371, 1375, 1375a, 1375b, 1377, 1378, 1427, 1435a, 1437, 1442, 1445, 1447, 1462, 1472, 1485, 1649, 1650, 1652, 1760, 1767, 1781, 1842, 1959, 1972, 1981, 2013, 2079, 2113, 2114, 2133, 2134, 2142, 2195, 2255, 2270, 2313a, 2428, 2438, 2479, 2506, 2507, 2508, 2543, 2545, 2557, 2570, 2722, 2731, 2735, 2761, 2762, 2765–2767, 2773, 2777, 2784, 2939, 2961, 2962, 3003, 3081, 3082, 3176, 3191, 3240, 3241, 3249, 3251, 3255, 3257, 3262, 3263, 3265, 3269, 3273, 3286, 3292, 3300, 3302, 3307, 3308, 3370, 3397, 3410, 3441a, 3452, 3464–3470, 3472, 3492, 3498, 3509, 3557, 3559, 3578, 3616, 3618–3620, 3647, 3729, 3732, 3741, 3757–3759, 3787, 3797, 3847, 4009, 4010, 4249, 4282, 4319, 4325, 4342, 4355, 4570a, 4966, 5010, 5034, 5077, 5539, 5811b, 5869a	84, 172, 568b, 2339a, 2784, 4249, 5533, 5567, 5636, 5811b	1360, 1375a, 1377, 1378, 2506, 2507, 3401, 3402

TABLE 1.20 (continued)
PAHs in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
341.		Naphthalene, alkyl-	2508, 2570, 3262, 3452, 3465–3470, 4319, 4325, 5077		
342.	31831-35-3	Naphthalene, diethyl-		84, 4249	
343.	29828-28-2	Naphthalene, dihydro-	2479, 2767, 4249		
344.	72692-88-7	Naphthalene, dihydrodimethyl- {at least four isomers in MSS}	1375, 1375b, 2570, 2767, 2777, 3557, 4249		
345.	39292-53-0	Naphthalene, dihydromethyl- {at least three isomers in MSS}	1360, 1375, 1375a, 1375b, 2570, 2761, 2762, 2765–2767, 3557, 4249, 5811b		1360, 1375a
346.	2717-44-4	Naphthalene, 1,2-dihydro-3-methyl-	2479, 5811b		
347.	4373-13-1	Naphthalene, 1,2-dihydro-4-methyl-	1378, 3251, 3262, 3273, 3286, 3302, 5077		1378
348.	67494-22-8	Naphthalene,1,2-dihydro-5-methyl-3-(1-methylethenyl)-		946, 1156, 4090, 4249	
349.	2717-47-7	Naphthalene, 1,2-dihydro-6-methyl-	5811, 5811a, 5811b		
350.		Naphthalene, dihydrotrimethyl- {at least two isomers in MSS}	3557	3547	
351.	30364-38-6	Naphthalene, 1,2-dihydro-1,1,6-trimethyl- 	1110, 2479, 3219, 3308, 4249	909, 1149, 1149a, 2093, 2248, 2917a, 4249, 4564, 5811b	
352.	4506-36-9	Naphthalene, 1,2-dihydro-1,5,8-trimethyl-	1375, 1375b, 2479, 2769, 3557, 4249	984, 2389, 2544, 4249, 5811b	
353.	28804-88-8	Naphthalene, dimethyl-	1360, 1375, 1375a, 1375b, 1427, 2438, 2479, 2543, 2570, 2731, 2735, 2761, 2762, 2765–2767, 2773, 2777, 3492, 3509, 3618, 4249, 5034	2339a	1360, 1375a
354.	573-98-8	Naphthalene, 1,2-dimethyl-	104, 291, 568b, 1135, 1650, 1652, 2479, 2767, 2784, 3616, 3732, 3757, 4249, 5811b	84, 568b, 2784, 4249, 4564, 5811b	
355.	575-41-7	Naphthalene, 1,3-dimethyl-	84, 104, 291, 568b, 1135, 1650, 1652, 2479, 2767, 2784, 3557, 3616, 3618–3620, 3732, 3757–3759, 4249, 5811b	84, 568b, 2784, 4249, 5811b	
356.	571-58-4	Naphthalene, 1,4-dimethyl-	104, 568b, 1135, 1650, 1652, 2479, 2784, 3492, 3616, 3618–3620, 3732, 3757–3759, 4249, 5811b	84, 568b, 2784, 4249, 5811b	
357.	571-61-9	Naphthalene, 1,5-dimethyl-	104, 1133, 1650, 1652, 2479, 2784, 3492, 3616, 3618–3620, 3732, 3757–3759, 5811b	84, 2784, 4249, 5811b	
358.	575-43-9	Naphthalene, 1,6-dimethyl-	84, 104, 568b, 798, 1135, 1139, 1375, 1375b, 1378, 1426, 1427, 1650, 1652, 1972, 2479, 2722, 2767, 2784, 3255, 3262, 3302, 3308, 3557, 3616, 3618–3620, 3732, 3757–3759, 3797, 4249, 5077, 5811b	84, 568b, 2784, 3547, 4249, 5811b	1378

387.	31032-94-7	Naphthalene, 2-ethyl-3-methyl-	1135, 2479, 2784	2784, 4249	
388.	17179-41-8	Naphthalene, 2-ethyl-4-methyl- {= naphthalene, 3-ethyl-1-methyl-}	1135, 2784	2784, 4249	
389.	17059-53-9	Naphthalene, 2-ethyl-5-methyl- {= naphthalene, 6-ethyl-1-methyl-}	1135, 2784	2784, 4249	
390.	7372-86-3	Naphthalene, 2-ethyl-6-methyl-	1135, 2479, 2784	2784, 4249	
391.	17059-55-1	Naphthalene, 2-ethyl-7-methyl-	1135, 1375, 1375b, 1650, 1652, 2479, 2769, 2784, 4249	2784, 5811b	
392.	77242-78-5	Naphthalene, hexamethyl-	1650, 1652, 3732, 3757, 5811b		
393.	1321-94-4	Naphthalene, methyl-	222–224, 1649, 2438, 2506, 2507, 2767, 2777, 2799a, 3470, 3472, 4249, 5034, 5811b	3547	2506, 2507, 3401
394.	90-12-0	Naphthalene, 1-methyl-	84, 104, 141–143, 151, 291, 568b, 798, 1094, 1139, 1313, 1360, 1371, 1375, 1375a, 1375b, 1378, 1426, 1427, 1650, 1652, 1959, 1972, 2134, 2142, 2313a, 2479, 2722, 2731, 2735, 2761, 2762, 2765–2767, 2773, 2777, 2784, 3240, 3251, 3255, 3262, 3273, 3286, 3292, 3300, 3302, 3307, 3308, 3410, 3492, 3509, 3557, 3559, 3616, 3618–3620, 3647, 3729, 3732, 3757–3759, 3787, 3797, 4010, 4011, 4249, 4570a, 5010, 5077, 5539, 5811b	84, 568b, 2339a, 2784, 4249, 5811b	1360, 1375a, 1378, 3402
395.	91-57-6	Naphthalene, 2-methyl-	84, 104, 141–143, 151, 291, 568b, 798, 820, 1094, 1139, 1287, 1288, 1313, 1360, 1371, 1375, 1375a, 1375b, 1377, 1378, 1426, 1427, 1650, 1652, 1822, 1959, 1972, 2079, 2134, 2142, 2313a, 2479, 2543, 2545, 2722, 2731, 2735, 2761, 2762, 2765–2767, 2773, 2777, 2784, 2939, 3251, 3255, 3262, 3273, 3286, 3292, 3300, 3302, 3307, 3308, 3410, 3492, 3509, 3557, 3559, 3616, 3618–3620, 3647, 3729, 3732, 3741, 3757–3759, 3787, 3797, 4010, 4011, 4249, 4570a, 5010, 5077, 5539, 5811b	84, 568b, 1256, 2339a, 2784, 3186, 3188, 4249	1360, 1375a, 1377, 1378
396.	29253-36-9	Naphthalene, (1-methylethyl)-	104, 1650, 1652, 2479, 3226, 3732, 3757, 4249, 5811b	84	
397.	2027-17-0	Naphthalene, 2 (1-methylethyl)-		2339a, 5811b	
398.		Naphthalene, methylphenyl-	4249		
399.	71607-61-9	Naphthalene, methyl-2-phenyl-	1650, 1652, 2479, 3732, 3757, 4249, 5811b		
400.	34540-66-4	Naphthalene, methylpropyl-	4810a, 4249	84	
401.	1680-58-6	Naphthalene, 1-(1-methylpropyl)-	1135, 2479, 2767, 2769, 4249	84, 4249, 5811b	
402.	16727-91-6	Naphthalene, 1-(2-methylpropyl)-	1135, 2479		
403.	71607-57-3	Naphthalene, methyltetrahydro- {at least three isomers in MSS}	2761, 2762, 2765–2767, 3557, 4249		
404.	31291-71-1	Naphthalene, methyl-1,2,3,4-tetrahydro-	1822, 2479, 2767, 3557, 4249		
405.	1559-81-5	Naphthalene, 1-methyl-1,2,3,4-tetrahydro-	1884, 2485, 5811b

TABLE 1.20 (continued)
PAHs in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
406.	3877-19-8	Naphthalene, 2-methyl-1,2,3,4-tetrahydro-	299, 2479, 2742, 2743, 4249, 5811b		
407.	2809-64-5	Naphthalene, 5-methyl-1,2,3,4-tetrahydro-	5811b	84, 4249, 5811b	
408.	1680-51-9	Naphthalene, 6-methyl-1,2,3,4-tetrahydro- = {naphthalene, 2-methyl-5,6,7,8-tetrahydro-}	39, 2742, 2743, 3618, 3758–3759, 4249	84, 4249	
409.	56908-81-7	Naphthalene, pentamethyl-	104, 1650, 1652, 2479, 3732, 3757, 4249, 5811b		
410.	605-02-7	Naphthalene, 1-phenyl-	39, 2037a, 2113, 2479, 3286, 3757, 4249, 5811b		
411.	612-94-2	Naphthalene, 2-phenyl-	143, 147, 151, 1650, 1652, 2037a, 2113, 2479, 3251, 3262, 3273, 3292, 3302, 3514, 3732, 3757, 3952, 4249, 5077, 5811b		
412.	71697-04-6	Naphthalene, phenyl-, monomethyl derivative	1508, 2479, 3797		
413.	27378-74-1	Naphthalene, propyl-		84	
414.	2765-18-6	Naphthalene, 1-propyl-	1135, 2479	1135, 4249	
415.	2027-19-2	Naphthalene, 2-propyl-	1135, 2479	1135, 4249	
416.	119-64-2	Naphthalene, 1,2,3,4-tetrahydro- {tetralin}	84, 142, 143, 151, 568b, 1426, 1427, 1959, 2479, 2743, 3219, 3308, 4249, 5811b	84, 568b, 4249, 5811b	
417.	121214-18-4	Naphthalene, tetrahydrotrimethyl- {at least three isomers in MSS}	1375, 1375b, 1650, 1652, 2570, 3557, 4249		
418.		Naphthalene, 1,2,3,4-tetrahydro-4,5,8-trimethyl-	568b, 4249		
419.		Naphthalene, 1,2,3,4-tetrahydro-4,5,8-trimethyl- (isomer)	568b, 4249		
420.	72843-02-8	Naphthalene, 1,2,3,4-tetrahydrotrimethyl-	4249		
421.	475-03-6	Naphthalene, 1,2,3,4-tetrahydro-1,1,6-trimethyl- {α-ionene}	1110, 2767, 3308, 3219, 3557, 3647, 3797, 4249, 5811b	2339a, 2917a	
422.	21693-51-6	Naphthalene, 1,2,3,4-tetrahydro-1,5,8-trimethyl-		2917a	
423.	30316-36-0	Naphthalene, 1,2,3,4-tetrahydro-1,6,8-trimethyl-		2917a	
424.	28652-74-6	Naphthalene, tetramethyl- {at least four isomers in MSS}	104, 1375, 1375b, 2479, 2570, 2731, 2735, 2767, 2769, 3618, 3732, 3757–3759, 4249, 5811b	84, 2784, 4249	
425.	28652-77-9	Naphthalene, trimethyl- {at least 10 isomers in MSS}	104, 1135, 1360, 1375, 1375a, 1375b, 1650, 1652, 2438, 2543, 2570, 2731, 2735, 2761, 2762, 2765–2767, 2769, 2773, 2777, 3492, 3509, 3618–3620, 3732, 3757–3759, 4249, 5811b	84, 2339a, 3547, 4249, 5811b	1360, 1375a
426.	2717-42-2	Naphthalene, 1,2,4-trimethyl-	1135, 1375, 1375b, 2479, 2769, 2784, 3557, 4249	2784	
427.	3031-05-8	Naphthalene, 1,2,6-trimethyl-	1135, 2479, 2784, 4249	2784	
428.	486-34-0	Naphthalene, 1,2,7-trimethyl-	1135, 2784	2784, 4249	
429.	2131-39-7	Naphthalene, 1,3,5-trimethyl-	1135, 2479, 2784	2784, 4249	
430.	3031-08-1	Naphthalene, 1,3,6-trimethyl-	798, 1135, 1139, 1375, 1375b, 1972, 2722, 2784, 3262, 3302, 3308, 3557, 3797, 4249, 5077, 5811b	2784	
431.	2131-41-1	Naphthalene, 1,4,5-trimethyl-	2767, 2769, 3557, 4249		
432.	2131-42-2	Naphthalene, 1,4,6-trimethyl-	1135, 2784	2784, 3547, 4249	
433.	2245-38-7	Naphthalene, 1,6,7-trimethyl- {= naphthalene, 2,3,5-trimethyl-}	1135, 1378, 4249, 5811b	2784	1378
434.	829-26-5	Naphthalene, 2,3,6-trimethyl-	1135, 2479, 2784, 3402a, 3741, 4249, 5811b	2784	
435.	192-65-4	Naphtho[1,2,3,4-*def*]chrysene {dibenzo[*a,e*]pyrene} 	142, 151, 290, 291, 1741, 1743, 1744, 1870, 1871, 1873, 2037a, 2825, 3257, 3262, 3265, 3300, 3308, 3714, 3756, 3787, 3788, 4249, 5512, 5869a

462.	3674-69-9	Phenanthrene, 4,5-dimethyl-	2191, 3302, 4249		
463.	110053-52-6	Phenanthrene, dimethylene-	3756, 3758, 3759		
464.	71607-65-3	Phenanthrene, dimethylethyl-	3757, 4249, 5811b		
465.	30997-38-7	Phenanthrene, ethyl-	4249, 4249, 5811b		
466.	71607-66-4	Phenanthrene, ethylmethyl-	3757, 4249, 5811b		
467.	71607-67-5	Phenanthrene, hexamethyl-	3757, 4249, 5811b		
468.	31711-53-2	Phenanthrene, methyl-	104, 143, 1378, 1644, 1645, 1647–1649, 2134, 2195, 2438, 2543, 2570, 2773, 2777, 2799a, 3262, 3308, 3410, 3437, 3470, 3473, 3514, 3557, 3741, 4248, 4249, 5077, 5811b	1127a, 3547, 4249	1378
469.	832-69-9	Phenanthrene, 1-methyl-	50, 819, 1471, 1652, 1870, 1871, 1873, 2767, 3410, 3514, 3557, 3616, 3618–3620, 3732, 3757–3759, 3797, 4249, 5811b		50
470.	2531-84-2	Phenanthrene, 2-methyl-	50, 1471, 1652, 2210, 2767, 3557, 3616, 3618, 3732, 3757–3759, 4249, 5811b		50, 2210
471.	832-71-3	Phenanthrene, 3-methyl-	49, 50, 1471, 1652, 2767, 3514, 3616, 3618, 3732, 3757–3759, 4249, 5811b		50
472.	832-64-4	Phenanthrene, 4-methyl-	244, 3616, 3618–3620, 3758, 3759, 4249, 5811b		
473.	883-20-5	Phenanthrene, 9-methyl-	39, 392, 394, 1471, 1652, 2710, 2939, 3251, 3262, 3273, 3286, 3292, 3302, 3616, 3618–3620, 3732, 3757–3759, 3797, 4249, 5077, 5811b		
474.		Phenanthrene, 1-methyl-5-(1-methylethyl)-		4249, 4723	
475.	71607-68-6	Phenanthrene, pentamethyl-	1652, 2328, 3732, 3757, 4249, 5811b		
476.	71607-69-7	Phenanthrene, propyl-	2328, 4249		
477.	71607-70-0	Phenanthrene, tetramethyl- {at least five isomers in MSS}	1652, 3225, 3300, 3732, 3757, 4249, 5811b		
478.	30232-26-9	Phenanthrene, trimethyl- {at least three isomers in MSS}	642, 1652, 2570, 3615, 3618–3620, 3732, 3757–3759, 4249, 5811b		
479.	213-46-7	Picene {benzo[*a*]chrysene} 	142, 143, 726, 2037a, 2195, 2200, 3003, 3219, 3307, 3308, 3756, 3787, 3788, 4249, 5811b		
480.	30283-95-5	Picene, methyl-	3327a, 5811b

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
496.	3442-78-2	Pyrene, 2-methyl-	1139, 1471, 1781, 1800, 2037a, 2479, 2939, 3251, 3262, 3273, 3286, 3292, 3302, 3308, 3437, 3616, 3618–3620, 3756, 3758, 3759, 3787, 3788, 3797, 4019, 4031, 4249, 4355, 4356, 5077, 5811b		
497.	3353-12-6	Pyrene, 4-methyl-	394, 966, 1139, 1289, 1378, 1462, 1471, 1475, 1781, 1788, 1800, 2037a, 2079, 2479, 2557, 2709, 2710, 2939, 2961, 3251, 3262, 3273, 3286, 3292, 3302, 3308, 3437, 3616, 3618–3620, 3756, 3758, 3759, 3797, 4018, 4019, 4031, 4249, 5077, 5811b		1378
498.	71608-00-9	Pyrene, 1-octyl-	3339, 4249		
499.	71607-76-6	Pyrene, pentamethyl- {at least three isomers in MSS}	1652, 2479, 3732, 3757, 4249, 5811b		
500.	56142-09-7	Pyrene, propyl-	2328, 4249		
501.	71630-71-2	Pyrene, 1-tetradecyl-	3339, 4249		
502.	66161-17-9	Pyrene, tetrahydro-	2195, 2203, 2205, 3308, 4249		
503.	57633-59-7	Pyrene, 1,2,6,7-tetrahydro-	5811		
504.	60826-75-7	Pyrene, tetramethyl- {at least four isomers in MSS}	1652, 2479, 3618–3620, 3756–3759, 4249, 5811b		
505.	41637-88-1	Pyrene, trimethyl- {at least three isomers in MSS}	1652, 2328, 2479, 3618–3620, 3756–3759, 4249, 5811b		
506.	197-61-5	Rubicene 	1900, 3262, 3337, 3339, 4249, 5077		
507.	27096-03-3 548-35-6	5*H*-Tribenzo[*a,f,l*]trindene, 10,15-dihydro- {5*H*-diindeno[1,2-*a*:1′,2′-*c*]fluorene; {truxene} 	3262, 3337–3339, 4249		
508.	217-59-4	Triphenylene {9,10-benzophenanthrene} 	104, 143, 151, 726, 1405, 1406, 1408, 1409, 1870, 1871, 1873, 1900, 2037a, 2113, 2557, 2799a, 3003, 3262, 3616, 3618–3620, 3756, 3758, 3759, 3787, 3788, 4249, 4315, 5077, 5811b		
509.	60826-76-8	Triphenylene, dimethyl-	3618–3620, 3756–3759, 4249, 5811b		
510.	41637-89-2	Triphenylene, methyl-	3618–3620, 3756, 3758, 3759, 4249		
511.	60826-79-1	Triphenylene, trimethyl-	3618–3620, 3758, 3759, 4249, 5811b		

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke or vice versa.

in cigarette smoke are the major causes of lung cancer in cigarette smokers [Hecht (1557), Hecht and Hoffmann (1571a), Hoffmann and Hecht (1727), the World Health Organization (4279a)] despite the following:

1. Neither B[*a*]P nor any other PAH in CSC either individually or in combination with the other PAHs in CSC can explain more than a few percent of the biological response observed in skin painting with CSC [Druckrey (1056), Roe (3310, 3311), Wright and Wynder (4283), Wynder (4296), Wynder and Hoffmann (4307, 4312, 4343, 4343a, 4354)].
2. Neither B[*a*]P nor any other PAH in CSC either individually or in combination with the other PAHs and assorted promoters (phenols) in CSC can explain more than a few percent of the biological response observed in skin painting with CSC (4332).
3. In general, the *N*-nitrosamines in CSC are not tumorigenic to mouse skin but are organ-specific tumorigens [Preussmann and Stewart (2991)*], a point stressed in numerous reviews issued between the mid-1960s and the late 1990s on *N*-nitrosamines [Rodgman (3256)] and recognized by Hoffmann and Hecht [see p. 75 in (1727)].
4. NNK has never been shown to induce lung cancer in a laboratory animal by inhalation (1727).

While the minor contribution of B[*a*]P to the tumorigenicity of CSC to mouse skin has been recognized since the mid-1950s (4353, 4354), its presence in CSC has elicited continued interest since that time. Examination of the references to various smoke components reveals an interesting fact about B[*a*]P: When all the cigarette smoke components are tabulated with regard to similar selection of references across the board, very few tobacco smoke components exceed B[*a*]P in the number of pertinent references available. Obviously, the smoke component discussed most in publications and presentations between the mid-1950s and 2005 was nicotine. Next was acetaldehyde, followed by B[*a*]P.

Another interesting fact about B[*a*]P is that, despite its minimal contribution to mouse-skin tumorigenicity from CSC, almost every year since the mid-1950s there has been at least one publication on a new and/or improved method to quantitate the yield of B[*a*]P in MSS [see Table 1.21, a modified version of Table 6 in (3306b)].

In 2004, CORESTA published its recommended method for the determination of B[*a*]P in tobacco smoke (825a). Much emphasis has been placed on the determination of B[*a*]P in the MSS from fewer and fewer cigarettes. Before the advent of all the newly introduced and subsequently improved spectral and chromatographic systems, estimations of individual PAHs required the CSC from many cigarettes. For example, in their studies on the effect of various treatments of tobacco on the PAHs in MSS, Rodgman and Cook (3241, 3246, 3269, 3274, 3275) chemically analyzed the MSS from 3600 cigarettes for each control and treated sample. For the MSS PAH analyses in the 50 treated and control samples described in (3246), more than 183,000 cigarettes were smoked, the condensate collected, and processed. Nowadays, only a few cigarettes are needed for similar analyses. To permit comparison of the chemical data with the biological findings of Rodgman–Cook studies in the 1950s, i.e., the cigarettes on a manifold were machine smoked (35 mL puff volume, 2 s puff duration, 3 puffs/min) with a collection system that duplicated the one described by Wynder et al. (4306a). This smoking regime differed from the usual 35 mL puff volume, 2 s puff duration, and 1 puff/min described by Bradford et al. (423b) in 1936 and used by most investigators in smoke studies after that date.

Table 1.22 summarizes the PAHs identified in CSC that were included in earlier descriptions of proposed structure–tumorigenicity theories.

Examination of Table 1.22 indicates that most of the PAHs considered in the various theoretical systems designed to establish a relationship between molecular structure and tumorigenicity are totally benzenoid. Only a few PAHs with a combined benzenoid–cyclopentanoid structure were included in the early studies. Lacassagne et al. (2247a) in their discourse on structure–tumorigenicity relationship mentioned a few benzenoid PAHs, but their major emphasis was on the structure–tumorigenicity relationship of numerous angular benzacridines. While the number of aza-arenes, including the benzacridines, in CSC is less than the number of PAHs, nearly 200 have been identified, many by the USDA group at Athens, GA (3750). With the knowledge that CSC contains nontumorigenic PAHs that have been shown to substantially reduce the tumorigenicity of several potently tumorigenic PAHs, consideration of the study of Lacassagne et al. raises several interesting questions with regard to tobacco smoke composition. (1) Do any of the benzacridines or other aza-arenes in CSC partially or totally inhibit the tumorigenicity of the tumorigenic benzacridines or other aza-arenes? (2) Do any of the benzacridines inhibit the tumorigenicity of tumorigenic PAHs? (3) Do any of the PAHs reduce the tumorigenicity of the tumorigenic aza-arenes?

The mixture known as CSC is so complex that it is not possible to ascribe its biological activity to any individual component because of the known behavior of that component when administered individually.

The following situation pertinent to PAHs is an interesting one: The numerous studies conducted between the early 1930s and the mid-1950s on the tumorigenic PAHs in various air pollutants and the multitude of new and improved procedures reported periodically to define the levels of PAHs, particularly B[*a*]P, in the air pollutants parallel similar studies conducted after the mid-1950s on the tumorigenic PAHs in cigarette smoke and the multitude of new and/or improved analytically procedures reported periodically to define the levels of PAHs, particularly B[*a*]P, in cigarette smoke.

* Subsequent to the publication of the Preussmann and Stewart review (2991), Deutsch-Wenzel et al. (956a) reported that in a skin-painting study with *N′*-nitrosonornicotine (NNN), tumors were initiated at the site of application. The specific tumorigenic potency of NNN was estimated to be only 0.8% of that of B[*a*]P. However, no dose–response relationship was observed with NNN over a treatment range of 12.5–200 µg.

TABLE 1.21
Chronology of Analytical Methodology Used in the Determination of Benzo[*a*]pyrene in Cigarette Mainstream Smoke

Date	Title of Presentation or Publication	Methodology Described	Reference
1956/1958	Analysis of cigarette smoke condensate	Partitioning, complex formation (PA, TNF), LCC, UV, multiple crystallizations, derivatization, m.p., m.m.p.	3240, 3273
1957	Paper chromatography of carcinogenic hydrocarbons	PC	2960
1959	The role of higher polycyclic hydrocarbons in tobacco carcinogenesis	PC, sublimation, m.p., m.m.p.	4307
	Use of the fine structure of the fluorescence spectrum of 3:4-benzpyrene to increase the certainty of its detection	Fluorescence spectrophotometry	977
	Fluorescence spectral analysis of the products of tobacco smoke		978
1960	Characterization and level of 3,4-benzpyrene by luminescence spectrophotometry at −190°C	Spectrophotometry	2650
1961	A method for the estimation of 3,4-benzpyrene in tobacco smoke condensate	Partitioning, PC, LCC, UV	1396
1962	A new method for the determination of 3,4-benzpyrene in tobacco smoke condensate	Partitioning, LCC, PC, UV fluorescence	183
1963	A rapid analytical technique for routine determination of benzo[*a*]pyrene in cigarette smoke condensate	LCC, UV	3889
	A new method for the determination of 3,4-benzpyrene in tobacco smoke condensate	PC	3440
1964	Demonstration of carcinogenic hydrocarbons, with special reference to paper chromatography	PC	2964
	Improved method for the determination of benzo[*a*]pyrene in cigarette smoke condensate	TLC	3503
	Contribution to the determination of 3,4-benzpyrene in tobacco smoke condensate	LCC, PC	2918
1965	Determination of benzo[*a*]pyrene and related compounds in cigarette smoke	PC, TLC, GC, ^{14}C-B[*a*]P	128
	Improved methods for determination of benzo[*a*]pyrene in cigarette smoke	LCC, GC, TLC, fluorescence	3191
	Thin-layer chromatographic separation of benzo[*a*]pyrene from cigarette tar	TLC	2856
	Contribution to the determination of benzo[*a*]pyrene in tobacco smoke condensate	LCC, TLC, UV absorption and fluorescence	2881
1966	The fluorometric determination of benzo[*a*]pyrene in cigarette smoke condensate	Fluorometry	913
	The fluorometric determination of 3,4-benzpyrene in low-temperature carbonization and smoke condensates	Fluorometry	2199
1968/1970	Gas chromatography of polynuclear aromatic hydrocarbons	GC	2473, 2474
1971	Rapid thin-layer method for fluorometric determination of benzo[*a*]pyrene in cigarette smoke	LCC, TLC, fluorometry	3789
1971/1972	Determination of benzo[*a*]pyrene in smoke condensate by ultraviolet spectroscopy	UV	1593
	Modification of routine thin-layer method for determining benzo[*a*]pyrene in smoke	TLC	1594
1972	A rapid method for the determination of polycyclic hydrocarbons in cigarette smoke	LCC, PC or TLC, fluorescence	2819
1973	Separation analysis of polycyclic aromatic hydrocarbons by high pressure liquid chromatography; elective separation system for the quantitative estimation of isomeric benzpyrenes and coronene	HPLC	2115, 2116
1976	A rapid method for the determination of benzo[*a*]pyrene…in cigarette smoke; Quantitative determination of benzo[*a*]pyrene in cigarette smoke condensates by high pressure liquid chromatography	HPLC	2121 2119
	Analysis of benzo[*a*]pyrene in cigarette smoke	HPLC	3638, 3644
	Gas chromatographic quantitation of polynuclear aromatic hydrocarbons in tobacco smoke	GC	3612

TABLE 1.21 (continued)
Chronology of Analytical Methodology Used in the Determination of Benzo[*a*]pyrene in Cigarette Mainstream Smoke

Date	Title of Presentation or Publication	Methodology Described	Reference
1976/1978	Polynuclear aromatic hydrocarbons in cigarette smoke condensate… …multialkylated polynuclear aromatic hydrocarbons in cigarette smoke condensate…	GelC, GC, HPLC, GC/MS	3756, 3758, 3757
1977	Analysis of polycyclic aromatic hydrocarbons (PAH) in the condensates of natural and synthetic smoking materials	GelC, TLC, ^{14}C-labeled B[*a*]P (and DB[*a,h*]A)	2465
1981	Analysis of benzo[*a*]pyrene in cigarette smoke by high-performance liquid chromatography	HPLC	3638
1986	Determination of benzo[*a*]pyrene… in the total particulate matter of cigarette smoke by high-performance liquid chromatography	HPLC	3158
1988/1990	The determination of benzo[*a*]pyrene in the total particulate matter of cigarette smoke	HPLC	3158, 3176
1989	An alternative isolation procedure for the subsequent determination of benzo[*a*]pyrene in total particulate matter of cigarette smoke	HPLC	1076
1998	The measurement of benzo[*a*]pyrene in mainstream cigarette smoke	HPLC, Sep-Pak® cartridge	1246
1999	Determination of benzo[*a*]pyrene in complex matrix by multidimensional high-performance liquid chromatography	HPLC	934
1999	Quantitation of benzo[*a*]pyrene from mainstream smoke by liquid chromatography tandem mass spectrometry	LCC/MSS	2614
2002	Determination of benzo[*a*]pyrene in cigarette smoke total particulate matter by two-dimensional chromatography	2-DimC	4410
2004	CORESTA issued its description of a GC/MS method for the quantitative determination of B[*a*]P in CSC	GC/MS	825a
2005	Microwave-assisted extraction: An efficient method for the determination of polycyclic hydrocarbons in particulate phase mainstream cigarette smoke		746a
	Precursors to the pyrosynthesis of PAHs in cigarette smoke. I. Experimental design, matrix preparation and analytical methods	GC/MS	1435a, 2931a
2006	Distribution of polycyclic aromatic hydrocarbons between the particulate and vapor phase of mainstream cigarette smoke	LC/FLD	3340a
2007	Development and validation of an improved GC/MS method for the determination of polycyclic aromatic hydrocarbons (PAHs) in mainstream tobacco smoke	GC/MS	4966
2008	Determination of PAHs in exhaled cigarette smoke		5010
2009	Analysis of cigarette smoke condensate	Partitioning, complex formation (PA, TNF), LCC, UV, multiple crystallizations, derivatization, m.p., m.m.p.	5077
	Routine analysis of B[*a*]P in cigarette MSS	Modified MDGC/MS	5080
2010	Determination of PAHs in smokeless tobacco	GC/MS	5533, 5567

TNF, 2,4,7-trinitrofluorenone; PA, picric acid; LCC, liquid column chromatography; PC, paper chromatography; TLC, thin-layer chromatography; GC, gas chromatography; HPLC, high pressure liquid chromatography; GelC, gel chromatography; 2-DimC, 2D chromatography; FLD, fluorescence determination; m.p., melting point; m.m.p., mixture melting point; MS, mass spectrometry.

After many decades of failure by numerous investigators who attempted to induce tumors in laboratory animals by treatment with various air pollutants, industrial tars, and pyrolysates, Yamagiwa and Ichikawa described in 1915–1918 the procedure whereby tumors could be successfully induced in laboratory animals by skin painting with a coal-tar solution (4361).

The 1915–1918 reports of the Yamagiwa–Ichikawa success triggered a significant number of studies on the tumorigenicity of a variety of tars produced by the pyrolysis of individual components, e.g., in the mid-1920s, Kennaway and his colleagues studied the tumorigenicity of the pyrolysates of isoprene, acetylene, cholesterol, and other compounds (2073–2080). In 1930, Kennaway and Hieger (2076, 2078) reported the induction of tumors in mice skin painted with solutions of the pentacyclic PAH DB[*a*,*h*]A, subsequently classified as an extremely potent tumorigen.

Shortly thereafter in the early 1930s, the colleagues of Kennaway—Cook, Hewett, and Hieger—isolated from 2 ton of coal tar a series of PAHs, one of which by synthesis was demonstrated to be what is now named benzo[*a*]pyrene (B[*a*]P) (796a, 797, 1631). It was demonstrated not only that

[a] The positions of the two methyl groups were not specified.

[b] Number in square brackets indicates the number of isomers included in the study.

[c] The nature of the benzopyrene was not specified.

[d] The position of the methyl group was not specified.

B[*a*]P was tumorigenic to laboratory animal skin but also that B[*a*]P was an extremely potent tumorigen [194; see pp. 197–232 in (1544)]. The significant tumorigenic potency of B[*a*]P was the reason it was studied for many years between the 1930s and mid-1950s as the marker component in many tumorigenic pollutants such as tars, oils, soots, etc. The B[*a*]P content of coal tar had already been defined by Cook and his colleagues (796a, 797, 1631). In 1937, Hieger described the level of B[*a*]P in pitch (5938). Between 1937 and 1939, Kling et al. (5946, 5947) described the level of B[*a*]P in tumorigenic asphalt road tars.

Surprisingly, during these same years, 1937 through 1939, A.H. Roffo (3323–3325) and his son A.E. Roffo (3316, 3318) described their identification of three PAHs—anthracene, phenanthrene, and B[*a*]P—in a destructive distillate of tobacco and the tumorigenicity of the destructive distillate. Their discoveries were subsequently either ignored because the three PAHs had not been identified at that time in tobacco smoke or much criticized with the claim that a destructive distillate of tobacco was obviously not equivalent to tobacco smoke. In 1942, Roffo also reported (3327) that the organic solvent extraction of tobacco prior to its destructive distillation yielded a destructive distillate with lower levels of the three PAHs and a much reduced tumorigenicity. The criticisms of the reports by the Roffos are discussed in more detail in Section 1.5.1.

In 1943 and 1944, Berenblum and Schoental (5912, 5913) defined the difference between the tumorigenicities of shale and shale oil and the relationship of the difference to their B[*a*]P contents. Later, the tumorigenicity and B[*a*]P content of coal tar was also studied in detail by Berenblum and Schoental (5911, 5914). In 1949, Goulden and Tipler described the identification and quantitation of B[*a*]P in domestic soot (5935). This was followed by the 1951 report from Falk et al. (5934) on the levels of tumorigenic PAHs, including B[*a*]P, in processed rubber such as that used in automobile tires and the 1952 report by Falk and Steiner (5933) on the PAHs in carbon black. Also in 1952, Hieger and Woodhouse (HIE2) described the tumorigenicity and B[*a*]P content of various petroleum fractions.

In 1955, Falk and Kotin reported the results of several of their studies (5930). One involved the fate of PAHs, including B[*a*]P, in soot emitted into the atmosphere and subsequently deposited in human lungs (5930); another involved the presence of PAHs in diesel exhaust and the tumorigenicity of diesel exhaust extracts (5949). A third study did not involve PAHs per se but involved the study of the tumorigenicity of aliphatic hydrocarbons extracted from atmospheric pollution (5956).

In 1957, Fieser, a U.S. PAH expert, criticized (1181) the inadequacy of the spectral data used by Cooper and Lindsey in the United Kingdom (818–821) and Alvord and Cardon in the United States (55–57, 592–594) to define the presence of B[*a*]P in cigarette smoke. Fieser's colleagues, unable to detect B[*a*]P in cigarette smoke, were successful in their identification of B[*a*]P in roast coffee. Obviously, Fieser was unaware of the 1955 and 1956 reports of B[*a*]P identified in cigarette smoke by Falk and Kotin (1172) or the 1956 isolation of B[*a*]P in crystalline form from a commercial cigarette by Rodgman (3240). After the published 1959 report by Wynder and Hoffmann (4307) on the isolation of crystalline B[*a*]P from cigarette smoke, Fieser accepted it as a cigarette smoke component. Later, Fieser served on the 1964 Advisory Committee that prepared the report on smoking and health for the U.S. Surgeon General (3999). Fieser was the Advisory Committee member responsible for the chapter on cigarette smoke composition and emphasized the tumorigenic components identified in it.

The next year, Kuratsune (2237) studied the B[*a*]P content of various pyrolysates, and Tebbens et al. (3874) reported the generation of PAHs during combustion. Commins et al. (5922) reported on the content of B[*a*]P and other PAHs in the atmosphere of a diesel engine bus garage.

In his 1955 review of the epidemiological and experimental data on exogenous respiratory tumorigen, Hueper (5944) concluded that it was unlikely that cigarette smoke was a major factor in lung cancer but that much of the available evidence implicated occupational and/or industry-related factors such as soot, coal tar and pitch, petroleum oils, and gasoline and diesel engine exhausts. Later in 1957, Hueper (5230) modified his view of cigarette smoke but retained his view on environmental pollutants.

Between the mid-1930s and mid-1960s, there were many studies conducted in many countries around the world in which the PAHs (and B[*a*]P) in the atmosphere above many cities and towns were determined.

The rise in lung-cancer rates began many years before cigarette smoking became widespread, and no consistent relation existed between cigarette consumption and lung-cancer rates in different countries. For example, the lung-cancer death rate in England and Wales was twice that in the United States. The per capita cigarette consumption was 30% higher in the United States and primarily involved a blended cigarette (flue-cured, burley, Oriental, Maryland tobaccos), whereas the U.K. cigarettes were primarily flue-cured. Other data indicated that the U.K. cigarette smokers smoked their cigarettes to a shorter butt length [Hammond (5936)]. Additional data were provided on PAHs in smoke (5958) and the cigarette butt lengths in Canada, the United Kingdom, and the United States (5937).

Between the mid-1930s and mid-1950s, a great number of reports were issued in which successively improved analytical procedures for the PAHs, particularly the highly tumorigenic B[*a*]P, in the significant air pollution over urban areas were published (Table 1.23). The air pollutants, particularly PAHs, were determined in the atmosphere over various cities in the United States and in other countries around the world, e.g., Los Angeles, Pittsburgh, New York, New Haven, Cincinnati, Geneva, Osaka, Tokyo, Sidney, Budapest, Copenhagen, Prague, Kiev, Liverpool, London, Genoa, Bologna, Milan, and Rome.

This series of events was subsequently paralleled between the mid-1950s and the years in the early twenty-first century by the history of the PAHs, and of course B[*a*]P,

TABLE 1.23
Studies Prior to 1966 on Carcinogenic Components in Cigarette Smoke *vs.* in Air Pollution and Other Sources

Investigator	Air Pollution Studies	Cigarette Smoke Studies
Yamagiwa and Ichikawa	For over a century, investigators attempted to induce tumors in laboratory animals by skin painting with various pollutant items. All such studies were unsuccessful until the mid-1910s when Yamagiwa and Ichikawa (4361) by significantly increasing the painting period with a coal-tar solution from just a few weeks	
Kennaway	In the mid-1920s and the early 1940s, Kennaway published numerous articles on the tumorigenicity of various commercial tars (140a, 194) and the generation of tumorigenic tars by pyrolysis of various compounds such as isoprene, acetylene, and cholesterol (2073–2080). He and his colleagues became interested in the tumorigenicity of arsenic in air pollutants (5239, 5240, 5264) and subsequently in tobacco and its smoke (159, 889, 889a, 5160)	Kennaway and his colleagues published several articles on the relationship between arsenic I tobacco and tobacco smoke and its effect on smokers (159, 889, 889a, 5160)
Cook, J.W., Hieger, Kennaway	In the early 1930s, Hieger conducted spectral analysis of tumorigen-producing oils and tars (1630, 1631) and in the early 1952 studied the tumorigenicity of petroleum fractions (5939). The spectral procedure was used in the following study by Cook et al. (796a, 797) who described and discussed the tumorigenic PAHs that they had isolated from coal tar. The most significant PAH isolated and identified was the previously unknown potent tumorigenic PAH benzo[*a*]pyrene (B[*a*]P). In many subsequent studies, B[*a*]P was used as a marker for tumorigenicity	Some 30 years later in the early 1960s, Cook published several articles on the tumorigenic PAHs in tobacco smoke (796. 798)
Waller	In 1952, Waller reported on the B[*a*]P content of town air (25A81). Later, he discussed air pollution as significant factor in lung-cancer incidence (5978)	In 1991, Waller coauthored a publication on the cigarette smoke "tar" and certain toxicants from U.K. cigarettes (2947)
Campbell, J.A.	In the 1930s, Campbell (579–581) demonstrated the tumorigenicity of a variety of air pollutants (tarred road dust, exhaust gases from internal combustion engines, atmospheric pollutants). His subsequent studies involved the tumorigenicity of anthracite coal dust and other city atmospheric pollutants (5915)	
Berenblum and Schoental	During the mid-1940s, Berenblum and Schoental studied the PAH content, particularly the B[*a*]P content, in such pollutants as coal tar, shale tar, and shale oil and the relationship to the tumorigenicity of the pollutant (5911–5913)	
Clemmesen	In the 1950s, Clemmesen and his colleagues published several papers on the relationship between respiratory cancer and air pollution in Denmark (5917–5919)	
Cooper	In the early 1950s, Cooper described the level of PAHs in town air (5923–5926)	In the mid-1950s, Cooper's studies moved from air pollution to cigarette-related research in which he and his colleagues determined the various tumorigenic PAHs in cigarette smoke (785, 817, 818, 820, 821), and the PAHs in the pyrolysis product of cigarette paper (819)
Clemo, G.R. et al.	In 1955, Clemo et al. described the carcinogenic action of the smoke issued into the atmosphere over a city (Newcastle-on-Tyne) (5920, 5921)	Between 1958 and 1960, Clemo published several articles on the toxicants in cigarette some (765–767)
Shubik	In 1955, Shubik and Saffiotti described the tumorigenicity and tumor-promoting activity of catalytically cracked oils (SH1). In the mid-1960s, Lijinsky and Shubik described the tumorigenic components identified in various cooked food (2364a, 2364b). Their findings added to those reported in the early 1940s by Steiner et al. (25A69)	
Dickens, F.	In the early 1940s, Dickens and Weil-Malherbe described the results of their study on the tumorigenicity of wood smoke (5928)	In the mid-1960s, Dickens and Black described the results of their chemical and biological studies on some components of tobacco smoke (961)

TABLE 1.23 (continued)
Studies Prior to 1966 on Carcinogenic Components in Cigarette Smoke *vs.* in Air Pollution and Other Sources

Investigator	Air Pollution Studies	Cigarette Smoke Studies
Badger	Beginning in the 1940s and proceeding to the early 1960s, Badger and his colleagues studied the pyrolysis of a number of compounds and their generation of PAHs during pyrolysis (140, 141, 143, 144, 144a, 145–154). Many of the compounds studied were eventually shown to be tobacco and/or smoke components that were subjected to high temperatures during the tobacco smoking process, e.g., isoprene (143), naphthalene (144), indene (146), acetylene (149), *n*-decane (151), several alkylated benzene (153), and 1,3-butadiene (154). Tumorigenic PAHs such as B[*a*]P were generated in each case	In one particular 1965 study, Badger et al. (142) studied the generation by pyrolysis of PAHs from known tobacco components (142). The tobacco components studied were dotriacontane, typical of the many saturated aliphatic hydrocarbons in tobacco, and stigmasterol. Typical of the phytosterols in tobacco. On pyrolysis, both yielded PAHs subsequently identified in cigarette MSS: B[]A, B[a]P, dibenzo[*def,p*]chrysene, dibenzo[*b,def*]chrysene, naphtho91,2,3,4-*def*]chrysene, benzo[*rst*]pentaphene
Eby et al.	In 1954, Eby et al. described the means of reducing the tumorigenicity of high boiling petroleum products (5929)	Wynder et al. (4306a) did note that Eby (25A21), in his examination of the cigarette tar used in the Wynder et al. 1953 biological study (4306a), did not detect B[*a*]P. They made little comment about Eby's failure to identify B[*a*]P or any other tumorigenic PAH in the Wynder et al. cigarette tar
Kotin, Falk et al.	Between 1951 and 1963, Kotin, Falk, and their colleagues conducted numerous studies on the chemical and biological properties of components contributing to the adverse effect of air pollution (5931–5934, 5948–5957, 5977). Several of their publications dealt with the tumorigenesis of PAHs to humans (1173, 5932, 5952, 5954–5956), the inhibition of the tumorigenesis of some PAHs by other coadministered PAHs (1174), and the ciliastatic activity of air pollutants (5977)	In the mid-1950s, Falk and Kotin studied the generation of tumorigenic PAHs from tobacco during a simulated smoking process (1172). In the early 1960s, Kotin, Falk, and colleagues published their views on the ciliastasis of cigarette smoke (1173a, 1175) and on the biological effects of several of its components (methanol, formaldehyde) (2179, 2180). For some years in the 1950s and 1960s, Kotin served on the Industry Technical Committee, Council for Tobacco Research (United States)[a] but left it because of a controversy over his publication of articles on the ciliary activity of cigarette smoke (1173a, 1175).
Stocks	In 1953, Stocks reported on his study of lung-cancer incidence in England and Wales (5971). Later in 1957 and 1959, he described the results of his study on the comparison of the effect of air pollution and tobacco smoking (5972, 5973). In 1955, Stocks and Campbell compared the effect of tobacco smoking, nonsmoking, and exposure to air pollution by B[*a*]P and other compounds (5974)	In 1955, Stocks and Campbell compared the effect of tobacco smoking, nonsmoking, and exposure to air pollution by B[*a*]P and other compounds (5971). In 1957 and 1959, Stocks reported on his comparison of the effect of tobacco smoking and air pollution on respiratory tract problems (5972, 5973)
Commins	In 1956, Commins et al. (5922) described the composition of the air in a London Diesel bus garage with emphasis on the PAHS, including B[*a*]P	In the mid-1950s, Commins with Lindsey reported not only on the PAHs, including B[*a*]P, in cigarette smoke but also on a procedure to determine the levels of various phenols in cigarette smoke (785–789a)
Fieser	In 1957, Fieser, a U.S. PAH expert, criticized (1181) the inadequacy of the spectral data used by various U.K. (818–821) and U.S. investigators (55–57, 592–594) to define the presence of B[*a*]P in cigarette smoke. Fieser's colleagues, unable to detect B[*a*]P in cigarette smoke, successfully identified B[*a*]P in roast coffee	After the published 1959 report by Wynder and Hoffmann (4307) on the isolation of crystalline B[*a*]P from cigarette smoke, Fieser accepted it as a cigarette smoke component. Later, Fieser served on the 1964 Advisory Committee that prepared the report on smoking and health for the U.S. Surgeon General (3999). He was the Advisory Committee member responsible for the chapter on cigarette smoke composition and emphasized the tumorigenic components identified in it
Lyons	In 1957, Lyons and Johnson described the PAHs they identified in vehicular exhausts (5962). In 1959, Lyons (5961) described the results of his additional study on the PAHs in vehicular exhausts (5961). In 1962, Lyons reported on his comparison of the PAHs in gasoline engine and diesel engine exhausts, general atmospheric dust, and cigarette smoke condensate (2428)	Between 1955 and 1962, Lyons and his colleagues published numerous papers on components in cigarette smoke (2425–2435). Several involved the identification of free radicals in both cigarette smoke (2429, 2432) and air pollution (2435). In 1962, Lyons reported on his comparison of the PAHs in gasoline engine and diesel engine exhausts, general atmospheric dust, and CSC (2428)

TABLE 1.23 (continued)
Studies Prior to 1966 on Carcinogenic Components in Cigarette Smoke *vs.* in Air Pollution and Other Sources

Investigator	Air Pollution Studies	Cigarette Smoke Studies
Johne et al.	In 1957, several studies were reported on the tumorigenicity of and the B[*a*]P content of diesel engine exhaust; cf. Johne et al. (5945) and Marterstock and Reuter (5963)	
Bonnet, Neukomm	In 1962, Bonnet (393) described the level of B[*a*]P in melted "tar"	In the late 1950s, Bonnet and Neukomm published the results of their research on the composition of cigarette (394–398)
Wynder, Hoffmann et al.	For several years during the 1960s, Wynder, Hoffmann, and their colleagues not only studied various aspects of cigarette smoke but also studied the contribution of air pollutants to respiratory tract problems. The possible contribution of gasoline engine exhaust (1790, 4315, 4316, 5942, 5943, 26A59) and other pollutants (1799, 4331, 5980, 5981) were studied. In their comparison of gasoline engine exhaust and cigarette smoke, they reported that the levels of tumorigenic PAHs such as B[*a*]P in the gasoline engine exhaust were much higher than that in cigarette MSS and that the mouse-skin tumorigenicity of the "tar" derived from the gasoline engine exhaust was much great than that of cigarette MSS "tar." However, it should be noted that after the 1960s, Wynder, Hoffmann, and their colleagues did almost no further research on air pollutants [see the 1972 study (5941)] but devoted their subsequent research totally to tobacco and tobacco smoke. From the late 1960s to 2005 or so, they were involved in hundreds of scientific meeting presentations and scientific journal publications in which the results of their tobacco-related research were reported	Data generated by Wynder, Hoffmann, and their colleagues outlined many of the problems of tobacco smoke, and such data were presented at literally hundreds of scientific meeting and/or published in scientific journals. Those issued between the early 1950s and the mid-1960s, the date of issuance of the 1964 report to the U.S. Surgeon General (3999), dealt with epidemiology (4293, 4306b), tumorigenicity studies with laboratory animals (1795, 1797, 1798, 4301, 4306, 4306a, 4306c, 4309, 4311, 4312, 4317, 4330, 4351, 4352, 4355, 4356), ciliastasis studies (4304, 4305, 4350), tobacco and/or tobacco smoke components such as the PAHs (589, 1766, 1786–1788, 1796, 3085, 4284, 4303, 4307, 4308, 4353, 4354), aza-arenes (587, 1778), phenols (1789), acidic compounds (1785, 4280, 4313), nitrohydrocarbons (1755, 3086), pesticides, and agronomic compounds (1756, 1767, 2383). In the mid-1960s, Wynder and Hoffmann published a lengthy review article in 1964 (4319) and their noted 1967 book (4332) on the tumorigenicity of tobacco smoke and the suspected responsible components. Between the mid-1960s and his death, Hoffmann presented at scientific meetings and/or published in scientific journals over 500 articles on some aspect of tobacco and/or tobacco smoke
Pailer	In 1965, Pailer et al. (5965) described the results of their determination of B[*a*]P in the atmosphere over Vienna	For several years starting in 1965, Pailer and his colleagues reported on their studies of various components in tobacco smoke, e.g., B[*a*]P (2881), aromatic amines (2882), aliphatic amines (2883, 2889), NNAs (2884, 2885), nickel (2886), and carbonyl components (2887). They also studied the pyrolysates from tobacco additives (2888)
Strach	Shortly after the committee's smoking and health report to the U.S. Surgeon General, the results of comparison studies, e.g., Strach (3821), were issued in which cigarette smoke components and air pollutants were compared with regard to respiratory tract toxicity and exposure	

[a] From 1956 through 1962, one of us (AR) represented R.J. Reynolds on the Industry Technical Committee of the Council for Tobacco Research (United States).

in MSS. Green and Rodgman (1373) noted the interesting fact about B[*a*]P in MSS: Despite its extremely low level in MSS and its minimal contribution to mouse-skin tumorigenicity from CSC, almost every year since the mid-1950s there has been at least one journal publication or meeting presentation on a new and/or improved method to quantitate the yield of B[*a*]P in MSS [see Table 6 in (3306b)]. In 2004, CORESTA published its recommended method for the determination of B[*a*]P in tobacco smoke (825a). Much emphasis has been placed on the determination of B[*a*]P in the MSS from fewer and fewer cigarettes. Before the advent of all the newly introduced and subsequently improved spectral and chromatographic systems, estimations of individual PAHs required the CSC from many cigarettes. For example, in their studies on the effect of various treatments of tobacco on the PAHs in MSS, Rodgman and Cook (3241, 3246, 3269, 3274, 3275) chemically analyzed the MSS from 3600 cigarettes for each control and treated sample. For the MSS PAH analyses in the more than 50 treated and control samples described in (3246), more than 183,000 cigarettes were smoked, the condensates collected, and processed. Nowadays, only a few cigarettes are needed for similar analyses. To permit comparison of the Rodgman–Cook PAH data with the biological findings reported by Wynder et al.

TABLE 1.24
Distribution of Identified Hydrocarbons between Tobacco and Tobacco Smoke

[a] This number includes the various isomers of alkyl-PAHs reported in which the position of the alkyl group or groups has not been precisely defined.

in the 1950s, Genoa (401), i.e., the cigarettes on a manifold were machine smoked (35 mL puff volume, 2 s puff duration, 3 puffs/min) with a collection system that duplicated the one described by Wynder et al. (4306a). This smoking regime differed from the usual 35 mL puff volume, 2 s puff duration, and 1 puff/min described by Bradford et al. (423b) in 1936 and used by most investigators in smoke studies after that date.

1.6 SUMMARY

Detailed examination of the lists presented in the five subchapters on hydrocarbons indicates that over 1200 hydrocarbons have been identified to date in tobacco and tobacco smoke. The data are summarized in Table 1.24.

It is obvious from the tabulation that the PAHs represent nearly 44% of the hydrocarbons identified to date and a substantial number of them are smoke components. The one category in the PAHs that is found to an appreciable extent in a particular type of tobacco, Latakia tobacco, is the bicyclic aromatic hydrocarbon naphthalene and its homologs (1135, 2784). The few remaining PAHs present in both tobacco and its smoke include several tricyclic, tetracyclic, and pentacyclic PAHs, e.g., anthracene, phenanthrene, pyrene, and B[*a*]P. As a result of the study by Bentley and Burgan (285) in the early days of the concern about B[*a*]P in tobacco smoke and its origin, the presence of B[*a*]P and the other PAHs in tobacco is usually attributed to its contamination by pollutants during transportation, curing, etc.

2 Alcohols and Phytosterols

2.1 ALCOHOLS

Periodically, tobacco researchers have reported the progress on the identification of tobacco and smoke components. Review articles by Johnstone and Plimmer (1971) and Izawa (1900) detailed much of the tobacco and smoke research conducted over the preceding century. Izawa listed 440 identified smoke components by 1961. The next year, Quin (3059) published a review of components found in tobacco and smoke. Herrmann (1625) reviewed phenolic compounds in tobacco smoke. In 1963, Philip Morris (2939) published a monograph on tobacco and smoke composition, a copy of which was provided the Advisory Committee on smoking and health to the U.S. Surgeon General (3999). In 1964, Elmenhorst and Reckzeh (1139) tabulated the aromatic hydrocarbons identified in tobacco smoke. Kuhn (2228, 2229) published articles on alkaloids in tobacco and their pyrolysis products in smoke. In their 1967 book, Wynder and Hoffmann (4332) discussed tobacco and smoke chemistry and the results of animal studies with tobacco smoke. Elmenhorst and Schultz (1140) listed 250 low-boiling components and vapor-phase components identified in tobacco smoke. In his 1968 review, Stedman (3797) listed nearly 1200 identified tobacco and smoke components. The next year, Neurath (2724) reported on the presence of 180 *N*-containing compounds in smoke.

With the meaningful advancements in analytical methodology, the number of tobacco and smoke components increased dramatically (1373). In an in-house catalog assembled at R. J. Reynolds Tobacco Company (RJRT) in 1975, Roberts et al. (3224) listed 2783 identified components of tobacco and tobacco smoke. During the mid-1970s at RJRT, Schumacher et al. (3553), Heckman and Best (1587), and Newell et al. (2769) identified over 1540 compounds in the water-soluble and ether-soluble fractions of tobacco smoke. Of these, over 820 compounds were newly reported as tobacco smoke components. In 1977, Schmeltz and Hoffmann (3491) cataloged nearly 500 *N*-containing compounds identified in tobacco smoke, but their catalog did not include the more than 230 *N*-containing compounds newly identified in tobacco smoke by Heckman and Best (1587). Between 1974 and 1978, Snook et al. (3756–3758) published the results of their massive study of the PAHs and a number of benzofurans identified in tobacco smoke, a study that was followed by an equally definitive one on the identification of aza-arenes and monocyclic *N*-containing compounds in tobacco smoke (3750). In 1980, Ishiguro and Sugawara (1884) listed 1889 identified tobacco smoke components in their monograph. However, a tally of the tobacco smoke components reported at that time exceeded 2500. No additional catalogs of the total number of identified components of cigarette mainstream smoke (MSS) have been published since the 1980 Ishiguro and Sugawara (1884) publication. Smith et al. (3712) recently reported the chemical structures of the 253 identified phenols reported in cigarette MSS.

In the past, different authors had different views on the classification of alcohols in tobacco and tobacco smoke. In our catalog, we employ a system different from those used by our forerunners. In 1954, Kosak (2170) in his smoke component compilation listed seven "alcohols": four alcohols (methanol, glycerol, diethylene glycol, and ethylene glycol) and three phenols (phenol, "phenols," and catechol). He did not list either levoglucosan or a "phytosterol" as an alcohol but listed both as miscellaneous smoke components. In 1959, Johnstone and Plimmer (1971) listed 13 alcohols plus 5 phytosterols identified in tobacco and/or smoke.

In his 1968 review, Stedman (3797) divided the alcohols into three categories, namely, alcohols, sterols, and oxygenated isoprenoid constituents. The latter category contained constituents other than those with an alcoholic hydroxyl group, e.g., farnesyl acetone (a ketone), solanachromene (a phenol), the tocopherols (phenols), and the levantanolides and levantenolide (ether–lactone combinations). In the category usually considered alcohols, Stedman listed a total of 25 alcohols (15 aliphatic, 2 aromatic, 5 polyols, and 3 cyclic).

In our current catalog, compiled periodically since 1955, we have considered three types of components with hydroxyl groups: (1) the components with a carboxyl group and its hydroxyl group (discussed in Chapter 4), (2) the components with a hydroxyl group attached to a monocyclic or polycyclic benzenoid nucleus, i.e., a phenol (discussed in Chapter 9), and (3) a hydroxyl group attached to a saturated or unsaturated aliphatic, alicyclic, or nonbenzenoid nucleus which may or may not include another functional entity. An example of category (3) is the first item in Table 2.1, hydroxyacetaldehyde (glycolaldehyde) which is both an alcohol and aldehyde. The saturated aliphatic alcohols range from methanol to 1-triacontanol with alkyl homologs included in some cases, e.g., 1-butanol and 2-methyl-1-propanol. The unsaturated aliphatic alcohols include 2-propen-1-ol (allyl alcohol) and such terpenoid structures as the C_{10} alcohol 3,7-dimethyl-1,6-octadien-3-ol (linalool), the C_{20} alcohol 3,7,11,15-tetramethyl-2-hexadecen-1-ol (phytol), and the C_{45} alcohol 3,7,11,15,19,23,27,31,35-nonamethyl-2,6,10,14,18,22,26,30,34-hexatriacontanonaen-1-ol (solanesol). Examples of the alicyclic alcohols range from cyclopentanol to various carotenediols and triols to numerous cyclotetradecadienols, diols, and triols. Other alicyclic alcohols include a great variety of carbohydrates such as glucose and fructose plus the cases where such carbohydrates are linked to another component such as a phytosterol to form a glycoside.

TABLE 2.1
Tobacco and Tobacco Smoke Components Identified by Classical Chemical Methods

Year	Investigator (Reference)	Component(s) Identified	Smoke	Tobacco
1953	Sasaki (3413)	2,3-Butanedione	+	−

With our method of defining an alcohol in tobacco and/or smoke, the alcohols number over 1400. We realize that some readers may disagree with our classification of several hydroxypyridines as alcohols but the listed ones appear not only in this chapter, Section 2.1, but also appear in Section 17.2 in which monocyclic *N*-containing six-membered ring compounds are described and cataloged.

Present analytical technology to identify a component in a complex mixture such as tobacco smoke or a tobacco extract involves the generation of a variety of spectra from which the compound may be characterized. The spectra may include separation of the component from the mixture by glass capillary gas chromatography, its retention time, plus those generated by ultraviolet, infrared, nuclear magnetic resonance, and mass spectroscopy studies. Nowadays, seldom is the component in the complex isolated in a tangible amount. In the early days, the study of the composition of tobacco was accomplished by so-called classical chemical procedures. The following example illustrates how an isolated terpenoid alcohol was subsequently characterized: Ozonization of the compound followed by degradation of the ozonide and derivatization of the degradation products with 2,4-dinitrophenylhydrazine yielded the 2,4-dinitrophenylhydrazones of the compounds shown in Figure 2.1: glycolic aldehyde (hydroxyacetaldehyde) {II}, levulinaldehyde (4-oxopentanal) {III}, and acetone (2-propanone) {IV}. These findings led to the assignment in 1956 of the structure {I} in Figure 2.1 by Rowland et al. (3359) to the terpenoid alcohol they named solanesol.

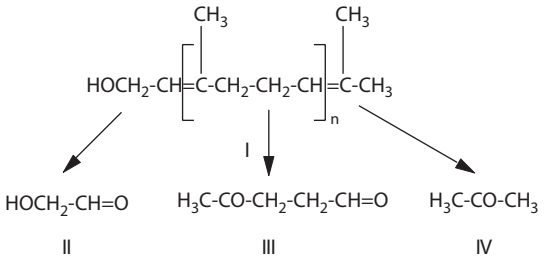

FIGURE 2.1 The degradation products from ozonized solanesol.

In the mid-1950s, the determination of the molecular weight of a compound with a molecular weight above 300–400 was difficult and often inaccurate. As a result, Rowland et al. were unable to precisely define the molecular weight of solanesol and therefore its structure. Originally, they had intended to report that solanesol was either a C_{45} compound (I, $n = 8$ in Figure 2.1) or a C_{50} compound (I, $n = 9$ in Figure 2.1) but were forced to choose one or the other. Because the majority of known isoprenoids at that time were terpenoids, i.e., multiples of C_{10}, and relatively few were sesquiterpenoids, i.e., multiples of C_{15}, Rowland et al. elected to report solanesol as a pentaterpenoid, i.e., a C_{50} compound. In 1957, Mold and Booth (2590) reported the identification of solanesol in cigarette mainstream smoke (MSS).

Subsequently, with more advanced analytical technology, Erickson et al. (2A01) and Shunk et al. (2A03) reported in back-to-back publications in 1959 that a more precise

molecular weight method indicated that solanesol was a C_{45} compound (I, $n = 8$ in Figure 2.1) with the formula $C_{45}H_{74}O$ (molecular weight, 630), 3,7,11,15,19,23,27,31,35-nonamethy l-2,6,10,14,18,22,26,30,34-hexatriacontanonaen-1-ol.

Since its characterization in 1956, solanesol has had an interesting history as a tobacco component. It is present in:

1. The different types of tobacco (flue-cured, burley, Oriental, Maryland) (3295)
2. In the smoke from each when smoked in cigarette form (2559, 3270, 3295)
3. As a variety of esters in tobacco [Rowland and Latimer (3358)] and tobacco smoke [Rodgman and Cook (3270), Rodgman et al. (3286)]

It generates isoprene [Gil-Av and Shabtai (1286); Grossman et al. (1431, 1432)], several solanesenes [Rodgman et al. (3297)], and numerous polycyclic aromatic hydrocarbons [Rodgman and Cook (3269), Severson et al. (3616)] during the smoking process. It was proposed by Wright (4282) as a more significant precursor in tobacco of polycyclic aromatic hydrocarbons (PAHs) in MSS than the aliphatic long-chained hydrocarbons and eventually was found to be such by Rodgman and Cook (3269) and Severson et al. (3616). More recently solanesol was studied as an indicator of environmental tobacco smoke (ETS) in room space [Ogden (2829), Ogden and Maiola (2833, 2834), Robinson et al. (3230), Tang et al. (3868)].

In the early tobacco and tobacco smoke studies, the chemical nature of one or two components was defined by means of classical chemical procedures and described in an appropriate publication, e.g., the identification of the previously discussed terpenoid alcohol solanesol in flue-cured tobacco (3359), the phenols eugenol and isoeugenol identified in the mainstream smoke (MSS) from Oriental tobacco (3280), and maltol identified in the MSS from an ingredient-free German tobacco blend (1131). A random selection of several of these early studies is presented in Table 2.1.

However, as analytical methodology became more sophisticated and precise, many more components—sometimes several hundred newly identified in tobacco or smoke—were reported in a single publication. In his pioneer research on glass capillary gas chromatography in 1965, Grob (1416) in his study of the MSS from cigarettes containing additive-free tobacco identified 63 components, a number of which were polar components. Later, some of the polar components in MSS identified by Grob are also listed in the Doull et al. catalog of cigarette flavor ingredients (1053).

In the 1950s, the organic solvent extraction of tobacco was studied extensively with the purpose of removing PAH precursors from the tobacco. Incorporated into one process was an aqueous alcohol–hexane partition to separate the polar, more flavorful tobacco components from the lipophilic PAH precursors. At that time, almost nothing was known about the nature of the polar tobacco components, although it was apparent they made a considerable positive contribution to the flavor and aroma of cigarette MSS. Despite the lack of knowledge about the precise nature of the polar components, it was demonstrated they were not significant PAH precursors (3262). Our inability at that time to separate highly polar compounds in a complex mixture contributed to our lack of knowledge of the nature of the polar components in tobacco and/or tobacco smoke. This situation continued during years of intensive effort on cigarette MSS composition but was finally resolved and utilized by Schumacher et al. (3553) in the 1970s. Of the total of 1545 MSS components identified by Schumacher et al. (3553), by Newell et al. (2769), and by Heckman and Best (1587), 828 (53.6%) were new to the tobacco smoke literature at the time of the publication and a great number of them were highly polar compounds (see Table 2.2).

[a] Newly reported components to tobacco and/or smoke at the date of the publication.
[b] The first date is that of a scientific conference presentation; the second is that of a publication in a peer-reviewed scientific journal.
[c] NI, not indicated was the number of components not previously identified in tobacco or tobacco smoke.

With regard to tobacco components, Lloyd et al. (2389) identified 275 previously unidentified components of additive-free flue-cured tobacco, 132 new to all additive-free tobacco types. Many of these compounds were highly polar and considered significant contributors to MSS flavor and aroma. Similar detailed studies were conducted on the composition of burley tobacco by Roberts and Rohde (3219), Oriental tobacco by Schumacher and Vestal (3561), and Maryland tobacco by Schumacher (3550). Years later, it became apparent that many of the highly polar components of tobacco and tobacco smoke were identical with or similar to many of the components used in the flavor formulations, i.e., the "top dressing," added to a specific tobacco blend to impart its unique smoking characteristics (1053). Randomly selected publications on the identification of many additive-free tobacco and/or tobacco smoke components are listed in Table 2.2.

The description of the isolation and/or identification of a great number of tobacco and/or smoke components was not always the case even after the development of sophisticated analytical technologies that generated informative spectral data. Between the early 1970s and the late 1980s, the research group at the Swedish Tobacco Company in Stockholm, Sweden, generated a great number of publications on flue-cured and Oriental tobacco composition in many of which only a single component or a few newly identified tobacco components were described. Admittedly, much attention was paid to the definition of the stereoisomerism of some of the components described individually. Selected examples of their extensive study of tobacco composition are presented in Table 2.3.

Periodically between the mid-1970s and the late 1980s, the Swedish Tobacco Company group published excellent reviews of their tobacco component studies and other meaningful related studies in the scientific literature, e.g., Enzell (1149, 1149a), Enzell and Wahlberg (1156), Enzell et al. (1157), Wahlberg and Eklund (4086a), and Wahlberg and Enzell (4089, 4090).

In addition to his isolation of the alcohol solanesol and contribution to its characterization, Rowland was involved in the isolation and characterization of the hydroxylated flue-cured tobacco components solanachromene and α-tocopherol, each of which is a phenol. The solanachromene has not been identified in tobacco smoke, but α-tocopherol, a well-known anticarcinogen, was identified as a cigarette MSS component in 1959 (3271) and many times since in MSS and ETS, e.g., Risner (3170).

In their 1962–1963 study of hydroxylated tobacco components, Rowland and his colleagues next isolated several 1,3- and 1,5-diols from tobacco. Structurally, these diols were shown to be related to the alicyclic diterpenoid hydrocarbon cembrene, previously isolated in 1951 from plant tissue by Haagen-Smit et al. (2A02) and characterized in 1962 as 3,7,11-trimethyl-14-(1-methylethyl)-1,3,6,10-cyclotetradecatetraene (see {V} in Figure 2.2) by Dauben et al. (905a). The 1,3-diol and 1,5-diol isolates were demonstrated to possess the cyclotetradecatriene structures shown as {VI} and {VII}, respectively, in Figure 2.2 [Rowland (3351, 3352), Rowland and Roberts (3360)]. Additional studies indicated the presence in tobacco not only of the diols {VI} and {VII} but also the two oxabicyclo compounds {VIII} and {IX} derived from the 1,5-diol {VII}. A third oxabicyclo type {X} was eventually identified in tobacco (9, 12, 4089–4091). The four compounds {VI}–{IX} were reported by Rowland et al. to be present in cigarette MSS (3361). Cembrene {V} was eventually identified in 1966 in tobacco by Reid (1097a) and in Japanese tobacco in 1980 by Takagi et al. (3853).

The reports of these cyclotetradecatrienediols and their ethers by Rowland, Roberts, and their colleagues led to an intensive study of tobacco by the Swedish Tobacco Company research team. Their study involved the isolation, characterization, and stereochemical definition of nearly 100 compounds containing the 14-carbon ring [Aasen et al. (12), Arndt et al. (94a), Behr et al. (235, 236), Wahlberg et al. (4083–4085, 4091, 4098–4100), Wahlberg and Eklund (4086a, 4088), Wahlberg and Enzell (4091)].

FIGURE 2.2 Tobacco and/or tobacco smoke alcohols related to cembrene.

Much research was conducted after the mid-1950s to identify alcohol components in the particulate phase of cigarette MSS primarily because some were found to contribute consumer acceptable flavor and aroma properties to the MSS. As noted by Rodgman (3266), many components, including alcohols, used by the tobacco industry in its flavor formulations [see listing by Doull et al. (1053)] are known components of additive-free tobacco and/or its smoke. Thus, such additives are not strangers to the tobacco and/or its smoke, but their addition increases the consumer acceptable flavor. Table 2.4 lists some of the tobacco and/or tobacco smoke alcohol components that have been or are used in flavor formulations.

Table 2.5 is a catalog of the alcohols identified in tobacco and/or tobacco smoke. Of the 1722 alcohols identified to date, 675 have been reported in tobacco smoke, 1360 in tobacco, and 313 in both tobacco and tobacco smoke.

2.2 PHYTOSTEROLS

The alcohol category in tobacco and tobacco smoke includes the phytosterols, the plant-derived sterols. The sterols have been examined in considerable detail over the years, an examination that did not actually originate in the study of tobacco and/or its smoke. In 1928, Kennaway and Sampson demonstrated the tumorigenicity of the pyrolysate from the sterol cholesterol (2080). Their study preceded the first reports of induction of skin cancer in laboratory animals with two individual compounds, the PAHs dibenz[*a,h*]anthracene (DB[*a,h*]A) in 1930 by Kennaway and Hieger (2078) and benzo[*a*]pyrene (B[*a*]P) in 1932 by Cook et al. (796a, 797). Both PAHs subsequently were classified as highly potent tumorigens. Based on the results of their detailed study of the tumorigenicity of several PAHs, Barry et al. (194) reported that a third PAH 3-methylcholanthrene was also a highly potent tumorigen. 3-Methylcholanthrene was subsequently named 1,2-dihydro-3-methylbenz[*j*]aceanthrylene. Because of their structural similarity, 1,2-dihydro-3-methylbenz[*j*]aceanthrylene became the object of the search in the pyrolysate from cholesterol (Figure 2.3).

Cholesterol and several similarly structured phytosterols (campesterol, β-sitosterol, stigmasterol) are components of tobacco, and a portion of each is transferred intact to smoke during the smoking process. The phytosterols in tobacco have been reported by numerous investigators, e.g., Traetta-Mosca (3942b), Kobel and Neuberg (2153a), Shmuk (3656a), Khanolkar et al. (2087), and Venkatarao et al. (4042b). All have been reported in tobacco as glycosides by Bolt and Clarke (390), Dymicky and Stedman (1079), Kallianos et al. (2018, 2019), and Khanolkar et al. (2087) and long-chained saturated and unsaturated acid esters (3296). Theoretically, all could yield 1,2-dihydrobenz[*j*]aceanthrylene and/or 1,2-dihydro-3-methylbenz[*j*]aceanthrylene during the smoking process.

To date, the identification of this PAH in tobacco smoke has been reported by only one investigator, Kröller (2191). Dihydrobenz[*j*]aceanthrylene (cholanthrene) was not among the several PAHs isomeric with 1,2-dihydrobenz[*j*]aceanthrylene reported by Snook et al. (3756–3758). In the late 1940s, there was much interest in 1,2-dihydro-3-methylbenz[*j*]aceanthrylene because of its possible generation from cholesterol during the heating of cholesterol-containing foodstuffs. While 1,2-dihydro-3-methylbenz[*j*]aceanthrylene could actually be synthesized from cholesterol by a series of sophisticated chemical

50-70-4	Sorbitol[a]	Glucitol	–	+

[a] Sorbitol (glucitol) is not included in the Doull et al. list (1053) but is included in flavor formulations used by cigarette manufacturers outside of the United States [see Table 7A in (3266)].

reactions (1184a), attempts to generate it by pyrolysis of cholesterol were unsuccessful.

As shown in Figure 2.4, pyrolysis of cholesterol {Ia} yields chrysene {III}, Diels hydrocarbon {IV}—a methylcyclopentaphenanthrene—and numerous other PAHs. Both PAHs noted have also been identified in pyrolysates of the major tobacco phytosterols [Wynder et al. (4356), Van Duuren (4022)]. More recently in the early 1970s, Hecht et al. (1560) discussed the generation of chrysene and alkylchrysenes by pyrolysis of phytosterols.

Although none of the sterols {Ia–Id} have been shown to generate the potent tumorigen 1,2-dihydro-3-methylbenz[*j*] aceanthrylene (3-methylcholanthrene) on pyrolysis, Falk et al. (1171) reported that cholesterol and cholesterol esters on pyrolysis do generate the mouse-skin tumorigens 4-cholesten-3-one {Va} and 3,5-cholestadiene {VIa}. Veldstra (4042a) reported that the pyrolysis of cholesteryl oleate also yielded 3,5-cholestadiene {VIa}. Cholesteryl oleate was probably a component of the mixture of phytosteryl esters described in flue-cured tobacco by Rowland and Latimer (3358). Its analogs stigmasteryl oleate and β-sitosteryl oleate were among the phytosteryl esters in tobacco smoke characterized by Rodgman et al. (3296). The other identified phytosteryl esters included stigmasterol and β-sitosterol esterified with saturated acids (lauric, palmitic, stearic, and myristic) and unsaturated acids (linolenic and linoleic) (3296).

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke.

Relative to the low level of cholesterol {1a}, tobacco usually contains substantial levels of several phytosterols (campesterol {Ib}, β-sitosterol {Ic}, stigmasterol {Id}, and ergosterol {Ie}) structurally similar to cholesterol. Phytosterols {Ib}, {Ic}, and {Id} differ slightly from cholesterol in the structure of the long side chain, whereas ergosterol {Ie} not only differs slightly from cholesterol in the structure of its long side chain but also has an extra double bond at the 7 position (Figure 2.4). They are present in tobacco in both the free and bound form (as glycosides and esters), and they are transferred as such to mainstream smoke (MSS). The sterols constitute about 0.2% of the tobacco weight.

In the late 1950s/early 1960s, Rodgman proposed that the tobacco phytosterols—campesterol, β-sitosterol, stigmasterol, ergosterol—might generate compounds analogous to the tumorigenic 4-cholesten-3-one {Va} and 3,5-cholestadiene

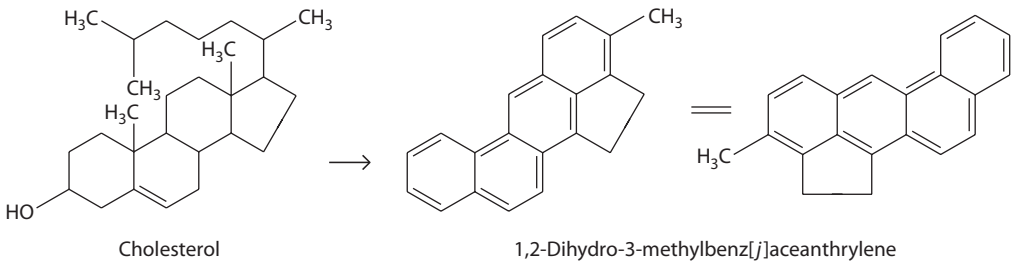

FIGURE 2.3 Theoretical conversion of cholesterol to 1,2-dihydro-3-methylbenz[*j*]aceanthrylene. *Sterol*, R =; Ia, cholesterol -$(CH_2)_3$-$CH(CH_3)_2$; Ib, campesterol -$(CH_2)_2$-$CH(CH_3)$-$CH(CH_3)_2$; Ic, β-sitosterol -$(CH_2)_2$-$CH(C_2H_5)$-$CH(CH_3)_2$; Id, stigmasterol -CH═CH-$CH(C_2H_5)$-$CH(CH_3)_2$; Ie, ergosterol[a] -CH═CH-$CH(CH_3)$-$CH(CH_3)_2$; II, 1,2-dihydro-3-methylbenz[*j*]aceanthrylene (3-methylcholanthrene); III, chrysene; IV, Diels hydrocarbon; Va, 4-cholesten-3-one; Vb, 4-campesten-3-one; Vc, β-4-sitosten-3-one; Vd, stigmasten-3-one; Ve, ergostadien-3-one; VIa, 3,5-cholestadiene; VIb, 3,5-campestadiene; VIc, β-3,5-sitostadiene; VId, 3,5-stigmastadiene; VIe, 3,5,7-ergostatriene; [a]Ergosterol has a double bond at the 7-position.

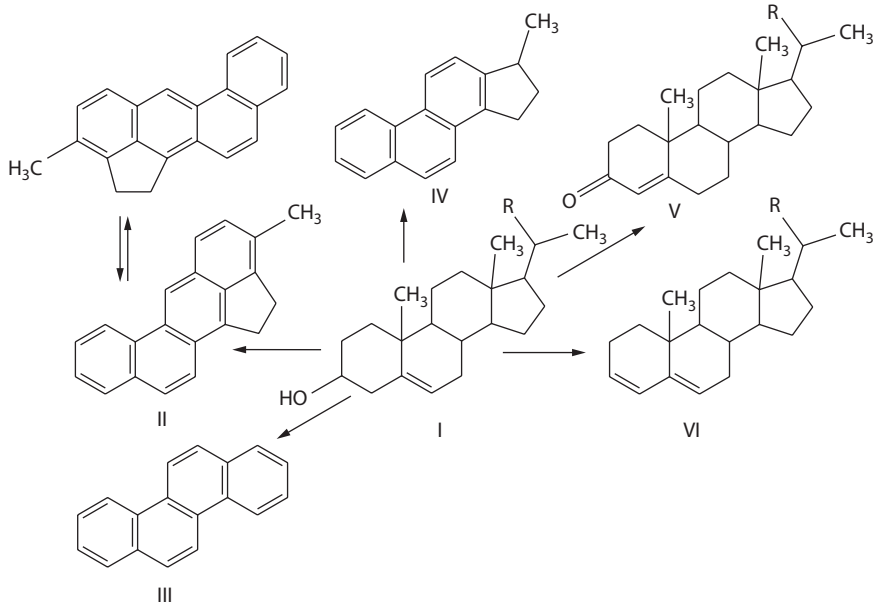

FIGURE 2.4 Possible sterol degradation products.

{VIa} generated from cholesterol, i.e., 4-campesten-3-one {Vb}, 3,5-campestadiene {VIb}, β-4-sitosten-3-one {Vc}, 3,5-sitostadiene {VIc}, 4-stigmasten-3-one {Vd}, 3,5-stigmastadiene {VId}, ergosten-3-one {Ve}, 3,5,7-ergostatriene {VIe} on thermal degradation of these tobacco phytosterols or their esters during the smoking process. These campesterol-, β-sitosterol-, stigmasterol-, and ergosterol-related compounds might also be mouse-skin tumorigens as are their cholesterol counterparts. For nearly a decade, Rodgman and Cook (3286) were unsuccessful in their periodic efforts to isolate any of these phytosteryl ketones or dienes from CSC and identify them. However, Benner et al. (273) did subsequently identify two of these 3,5-dienes, 3,5-campestadiene {VIb} and 3,5-stigmastadiene {VId}, in tobacco smoke, see also Eatough et al. (1099, 1100).

In 1939, the PAHs anthracene, phenanthrene, and B[*a*]P were reported as components of a tobacco-related material by Roffo (3323, 3325, 3326) and his son (3316–3318). In discussions of tobacco smoke, the Roffo findings are generally disregarded because the three PAHs they reported were not detected in tobacco smoke but were identified in a destructive distillate of tobacco. However, Roffo did report another finding that led to much research both within and outside the tobacco industry. Roffo (3327) reported that comparison of the destructive distillate of tobacco with the destructive distillate of an ethanol-extracted tobacco indicated that the PAH content, particularly B[*a*]P, and the specific tumorigenicity of the extracted tobacco destructive distillate were reduced from those of the destructive distillate from the control tobacco. Roffo speculated that the precursors of the tumorigenic PAH components of his distillates were ethanol-soluble phytosterols. Eventually his prediction, as far as it went, was found to be true for cigarette MSS (327, 398). In July 1954, Rodgman—a newly hired scientist at RJRT R&D—described the findings of the Roffos (3316–3318, 3323, 3325, 3327) to two colleagues who were previously

unaware of them. He particularly emphasized the organic-solvent extraction of tobacco to remove PAH precursors. The discussion resulted within a week of one of the colleagues proposing an extraction method for removal of the phytosterols from tobacco (114). A few months later, Rodgman initiated a lengthy study of the effect of organic-solvent extraction on the PAH content of its MSS (3240–3242, 3246, 3251). All of the extractions of different tobacco types and blends with different organic solvents and the fabrication of the cigarettes from the extracted and control tobaccos were conducted by Ashburn (116, 117).

Two major mechanisms were proposed for the pyrogenesis of PAHs in tobacco smoke: (1) PAHs are formed by degradation of organic tobacco components to simpler molecules and/or free radicals during the pyrolysis processes occurring in the burning cigarette, followed by recombination of these simpler fragments to yield PAHs (the degradation–combination mechanism) [cf. Badger et al. (142–144) and earlier papers]. (2) PAHs are formed unimolecularly by cyclization, dehydration, aromatization, ring expansion, etc., of high-molecular-weight tobacco components such as the phytosterols, the tetradecacyclic duvanes, long-chained saturated and unsaturated hydrocarbons, alcohols, and esters (the aromatization reaction) [Rodgman and Cook (3269, 3286)].

Obviously, the mechanism of formation of PAHs is not an either-or situation. Experimental data indicate that both mechanisms are operative in PAH formation in the burning cigarette. Evidence for unimolecular aromatization was provided by pyrolysis data and by MSS PAH data from cigarettes "spiked" with phytosterols (3269, 3286). The relatively large

increase in the levels of chrysene and methylcyclopentaphenanthrene (Diels' hydrocarbon) vs. those for B[*a*]P and other tetra- and pentacyclic PAHs is more readily explained by the unimolecular aromatization of the tetracyclic sterol than by the degradation–recombination mechanism. The formation of several PAHs (chrysene, picene, several cyclopentaphenanthrenes, etc.) from various sterols had been reported by Diels, Ruzicka, and their colleagues in the 1920s and 1930s [see historical summary by Fieser and Fieser (1949)]. Early research on PAHs in roasted and/or grilled meats evolved from the theory that cholesterol when heated would generate the highly potent tumorigen 1,2-dihydro-3-methylbenz[*j*]aceanthrylene (3-methylcholanthrene). As noted previously, sterols in tobacco include cholesterol plus much higher levels of several phytosterols whose structures differ only slightly from that of cholesterol. In 1959, Wynder et al. in an addendum to their publication (4356) reported that the pyrolysis of tobacco phytosterols at 720°C and 850°C gave B[*a*]P and other PAHs plus low levels of alkyl derivatives of phenanthrene, pyrene, and chrysene.

Much of the early research on the isolation and identification of phytosterol and their derivatives from tobacco and tobacco smoke is summarized and referenced in the 1959 review by Johnstone and Plimmer (1971) and the 1968 review by Stedman (3797).

Table 2.6 chronicles many of the reported studies on phytosterols and their derivatives in tobacco and tobacco smoke plus the studies on the pyrolysis of phytosterols. Table 2.7 lists the 134 phytosterols and phytosteryl derivatives identified in tobacco and tobacco smoke. Of these 123 components, 54 have been reported as tobacco smoke components, 123 as tobacco components, and 43 in both tobacco and tobacco smoke.

3 Aldehydes and Ketones

The publication in the early 1950s of the results of several retrospective studies on association between cigarette smoking and respiratory tract cancer, particularly lung cancer, and the study on induction of skin carcinoma in a susceptible strain of mice painted with massive doses of cigarette tar for the better part of their life span [Wynder et al. (4306a)] triggered intensive interest in the composition of cigarette mainstream smoke (MSS). Because the cigarette smoke condensate (CSC) (or total particulate matter [TPM]), the phase of the smoke aerosol reported to be the mouse-skin tumorigen, embodied the particulate phase of the cigarette smoke aerosol, considerable effort was devoted to defining its composition with emphasis on the presence in it of tumorigenic polycyclic aromatic hydrocarbons (PAHs), particularly benzo[*a*]pyrene (B[*a*]P). This effort was conducted by research groups both within and outside of the tobacco industry.

However, because knowledge of the composition of tobacco smoke was so sketchy in the mid-1950s, several research groups initiated the detailed examination of the tobacco smoke aerosol to define not only its physical characteristics but also the composition of its vapor phase. For most of the balance of the 1950s, the results from the composition studies of cigarette smoke vapor phase received little attention compared to that directed at the particulate-phase composition results.

In 1954, Kosak (2170) published a list of components reported to be present in tobacco smoke. His list is shown in Table 3.1. The aldehydes listed included formaldehyde, acetaldehyde, acrolein (2-propenal), butyraldehyde (butanal), benzaldehyde, and 2-furaldehyde. In several instances, Kosak questioned whether the analytical data reported were sufficient to define unequivocally the identity of the smoke component. The ketones listed by Kosak included 3-pentanone (diethyl ketone), 4-heptanone (di-*n*-propyl ketone), 17-tritriacontanone (dipalmityl ketone), 2,3-butanedione (biacetyl), and "higher" ketones.

Because the low-molecular-weight aldehydes such as formaldehyde, acetaldehyde, propionaldehyde (propanal), acrolein (propenal), and butyraldehyde (butanal) and ketones such as acetone, methyl ethyl ketone (2-butanone), and diethyl ketone (3-pentanone) in cigarette MSS occur primarily in the vapor phase, their identification and analysis in the 1950s and 1960s were facilitated by conversion to less volatile compounds. Many of these low-molecular-weight carbonyl compounds form stable compounds with various derivatizing agents, and in many instances, the derivative formation is almost quantitative. The use of Girard T (trimethylamine) or Girard P (pyridine) reagent to derivatize tobacco smoke carbonyl compounds was described by Seligman (3581) and Resnik and Seligman (3108). The derivatives were separated by paper chromatography and identified from their mass spectra. A reagent that proved to be an excellent one to derivatize tobacco MSS aldehydes, ketones, and keto acids was 2,4-dinitrophenylhydrazine. Individual hydrazones were isolated by various chromatographic means (column chromatography, paper chromatography, and eventually HPLC) and their levels estimated spectrophotometrically. Another ingenious use of 2,4-dinitrophenylhydrazine was the following: The less stable Girard T or Girard P derivatives were decomposed and the carbonyl compounds released were converted to the highly stable 2,4-dinitrophenylhydrazones for identification and quantitation. Subsequently, the 2,4-dinitrophenylhydrazine procedure was adapted to the investigation of carbonyl compounds in tobacco, in its headspace vapors, in sidestream smoke (SSS), and in environmental tobacco smoke (ETS).

A third reagent used for the estimation of aliphatic aldehydes in tobacco smoke was 3-methylbenzothiazolone hydrazone hydrochloride [Weaving (4155), Davis and Sneade (915)].

Table 3.2 summarizes some of the studies on low-molecular-weight carbonyl components of tobacco smoke in which various derivatizing reagents were used, the derivatives formed were separated by a variety of techniques (column, paper, TLC, HPLC) and identified and estimated by spectral means (UV, IR, mass, colorimetry).

The results of many of these studies provided quantitative data on the per cigarette MSS yield of several carbonyl compounds of interest.

As the interest in the overall composition of tobacco smoke escalated in the 1950s and 1960s, the potential of the utilization of gas chromatography to examine and define the vapor-phase composition was examined. For example, Seligman et al. (3584) in their gas chromatographic study of the components of a synthetic mixture comprising 17 compounds known to be present in tobacco smoke demonstrated the feasibility that the 17 diverse compounds could be successfully separated by gas chromatography. Among the 17 standard compounds, ranging from methane to water, were acetaldehyde, propionaldehyde, and acetone. Subsequent to the successful separation of the compounds, the identity of each was confirmed by mass spectroscopy.

As a requisite and adjunct to their study of selective filtration of tobacco smoke components and the effect of carbon filters on cigarette MSS composition, Laurene et al. (2305) developed and described a gas chromatographic analysis of acetaldehyde, acrolein, and acetone in cigarette MSS. In addition to the analytical methodology, Laurene et al. also provided data on the MSS yields of acetaldehyde, acetone, and acrolein from 65 mm nonfiltered cigarettes containing individual tobacco types (flue-cured or burley or Oriental tobacco) or a blend of all three (50 mm of the tobacco rod

TABLE 3.1
Tobacco Smoke Components Listed by Kosak (2170)

Class	Component	Class	Component	Class	Component
Hydrocarbons	Hentriacontane (?)	Ketones	3-Pentanone	Acids	Formic acid
	Acetylene		4-Heptanone		Acetic acid
	"Unsaturated hydrocarbons"		17-Tritriacontanone (?)		Butyric acid
			2,3-Butanedione		Valeric acid
	Azulene		"Higher" ketones (?)		Caproic acid
	Phenanthrene (?)				C_7 and C_8 aliphatic acids (?)
	Anthracene (?)				Succinic acid (?)
	Benzopyrene (?)				Fumaric acid (?)
	"Condensed aromatics" (?)				Citric acid (?)
					Benzoic acid (?)
					Phenolic acids (?)
Alcohols and Phenols	Methanol	Alkaloids	Nicotine	Miscellaneous components	Levoglucosan[b]
	Glycerol		Pyridyl ethyl ketone		"Phytosterol" (?)
	Diethylene glycol		Myosmine		$C_{10}H_{14}O$ (a furan ?)
	Ethylene glycol		Nicotyrine		"Resins" (?)
	Phenol (?)		α-Socratine[a]		"Resin acids" (?)
	Catechol (?)		β-Socratine[a]		
			γ-Socratine[a]		
			Obelin[a]		
			Lohitam[a]		
			Anodmin[a]		
			Lathraein[a]		
			Poikiline[a]		
			Gudham[a]		
Aldehydes	Formaldehyde	Other N-containing components	Pyrrole (?)	Inorganic components	Ammonia
	Acetaldehyde		"Pyrroles" (?)		Carbon monoxide
	Butyraldehyde		"*N*-Methyl-pyrrolidines" (?)		Carbon dioxide
	Acrolein (?)		Pyridine		Hydrogen cyanide
	Benzaldehyde		"Picoline" (?)		Hydrogen sulfide
	2-Furaldehyde (?)[c]		"Lutidine" (?)		Thiocyanic acid (?)
			"Collidine" (?)		Oxygen
			"Pyridine bases" (?)		Arsenic[d]
			Methylamine (?)		"Acetates" (?)
			"Chlorophyll degradation products" (?)		"Chlorides" (?)
			"Uric acids" (?)		"Cyanides" (?)
					"Nitrates" (?)

[a] Subsequent study demonstrated this component was not a well-defined compound but an artifact, a mixture, or an ammonium salt [see discussion by Johnstone and Plimmer (1971)].
[b] 1,6-Anhydro-β-*D*-glucopyranose.
[c] The question mark indicates that Kosak did not consider the evidence in the literature to be definitive proof of the identity of the component.
[d] Probably present as As_2O_3.

smoked). The effect of a charcoal filter tip on the MSS levels of these carbonyl compounds was also determined. Their data are summarized in Table 3.3.

Modifications of gas chromatographic methods to determine vapor-phase carbonyl compounds in cigarette MSS continued for more than three decades, e.g., Miyake and Shibamoto (2564).

In Figure 3.1 is shown the approximate composition of MSS from a cigarette that delivers about 22.5 mg of wet total particulate matter (WTPM) and 17.6 mg of FTC "tar." Excluding carbon monoxide and carbon dioxide, acetaldehyde is the vapor-phase component usually found at the highest level in cigarette MSS.

The nonfiltered cigarette MSS yield of acetaldehyde ranged from 18 [Huynh et al. (1853a)] to 2815 µg/cig [Miyake and Shibamoto (2564)]. The acetone yield was slightly less than 50% of the acetaldehyde yield. Acrolein is the next most plentiful aldehyde, followed by formaldehyde, 2-furaldehyde, and crotonaldehyde. Per cigarette formaldehyde MSS yields ranged from 3.4 µg for filtered cigarettes to 283 µg in nonfiltered cigarettes [Schaller et al. (3427), Miyake and Shibamoto (2564)].

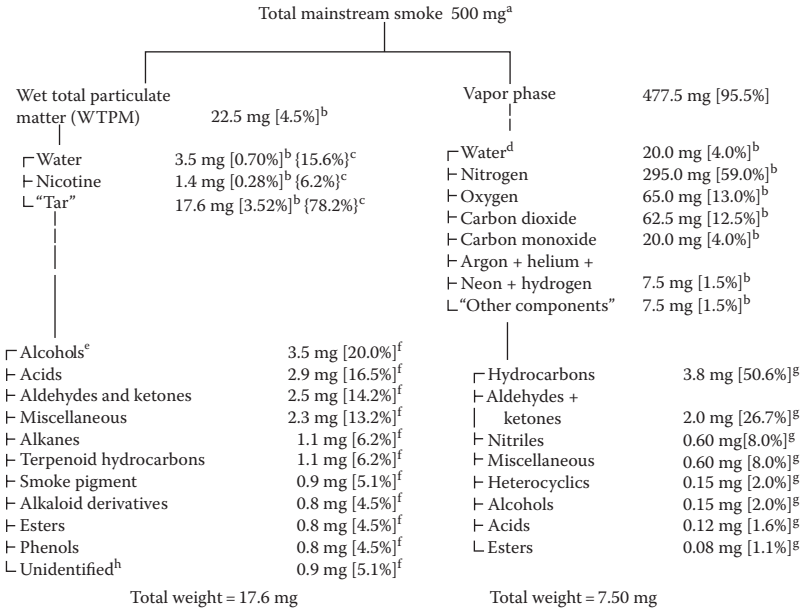
TABLE 3.2
Studies on Low-Molecular-Weight Carbonyls in Tobacco and Tobacco Smoke: Derivatizing Agents

Description	Reference
Girard T or Girard P reagent	
Aldehydes and ketones in cigarette MSS separated by conversion to Girard T or Girard P derivatives; derivatives separated by paper chromatography	Seligman (3581)
Girard T or Girard P derivatives of cigarette MSS aldehydes and ketones were characterized my mass spectroscopy	Resnik and Seligman (3108)
4-Nitrophenylhydrazine (4-NPH)	
To isolate and identify the low boiling aldehydes and ketones in cigarette MSS, they were derivatized with *p*-nitrophenylhydrazine	Sakuma et al. (3396)
2,4-Dinitrophenylhydrazine (2,4-DNPH)	
Classification of the structures of various carbonyl compounds from the UV and IR spectra of their 2,4-DNPH derivatives	Jones et al. (1977a)
Cigarette MSS aldehydes and ketones, regenerated from Girard T or Girard P derivatives, were characterized by conversion to their 2,4-DNPH derivatives	Seligman (3581)
2,4-DNPH derivatives of tobacco smoke carbonyls were separated by paper and column chromatography	Seligman and Edmonds (3582)
Various keto acids in tobacco seeds were identified from their 2,4-DNPH derivatives	Glock and Jensen (1312)
Levels of mono- and dicarbonyl components of cigarette MSS were estimated by spectrophotometry of their 2,4-DNPH derivatives	Harrow et al. (1540)
The levels of low-molecular-weight aldehydes and ketones in cigarette MSS were estimated from their 2,4-DNPH derivatives	McRae and Mold (2525) Mold and McRae (2591)
After removal of other oxidizable material, the glycerol content of tobacco could be estimated by oxidation of the glycerol and conversion of its oxidation product to its 2,4-DNPH derivative	Martin et al. (2581)
Examination of 2,4-DNPH derivatives from tobacco and smoke revealed presence of several keto acids	Glock (1310)
Carbonyl components of cigar MSS were characterized by IR, UV, x-ray diffraction, and paper chromatography of their 2,4-DNPH derivatives	Schepartz and Ogg (3438)
Examination of the 2,4-DNPH derivatives of tobacco smoke carbonyls revealed the presence of several dicarbonyl compounds	Halter et al. (1491)
Identification of dicarbonyl components of tobacco smoke via their 2,4-DNPH derivatives	Martin (2469)
To aid in identification of aldehydes and ketones in tobacco smoke and in cellulose smoke, over 90 2,4-DNPH derivatives were prepared to serve as melting point and spectral standards	Fredrickson et al. (1238)
Carbonyl components in cigar MSS identified after 2,4-DNPH derivative formation, followed by exchange reaction of 2,4-DNPH derivatives with α-ketoglutaric acid	Schepartz and McDowell (3436)
α-Ketoglutaric acid exchange procedure applied to identification of low-molecular-weight carbonyl components of tobacco	Stephens et al. (3817)
2,4-DNPH derivatives of low-molecular-weight carbonyl components of tobacco smoke were separated by TLC	Lindsey et al. (2369)
2,4-DNPH derivatives previously prepared (1238) were used to characterize carbonyl components in cigarette smoke	Frederickson et al. (1239)
Instead of α-ketoglutaric acid, oxalic acid and *p*-dimethylaminobenzaldehyde were used in exchange release of low-molecular-weight smoke carbonyl components from their 2,4-DNPH derivatives	Jones and Monroe (1978a)
2,4-DNPH derivatives of cigarette smoke carbonyls separated by gas chromatography	Donzel (1049)
Formaldehyde level of cigarette MSS estimated by HPLC of its 2,4-DNPH derivative	Hodge and Mansfield (1670) Mansfield et al. (2456)
The levels of C_1 through C_4 aldehydes and ketones in cigarette MSS were estimated by HPLC of their 2,4-DNPH derivatives	Canon and Frank (591)
2,4-DNPH derivatives of acrolein (propenal) and acetone from tobacco smoke were separated by HPLC	Manning et al. (2452)
The level of 5-hydroxymethyl-2-furaldehyde in tobacco and tobacco smoke was estimated via its 2,4-DNPH derivative	Perini and Bell (2930)
Volatile, low-molecular-weight carbonyl components of the headspace from tobacco and from MSS were quantitated through their 2,4-DNPH derivatives	Brunnemann et al. (500)
Development of method to determine formaldehyde in cigarette SSS; method applicable to other low-molecular-weight carbonyl components of SSS	Bell et al. (243)
Low-molecular-weight carbonyl compounds in ETS were collected as their 2,4-DNPH derivatives	DeLuca (929)
3-Methylbenzothiazolone hydrazone hydrochloride	
Aliphatic aldehydes in MSS were estimated by derivative formation, followed by colorimetry	Weaving (4155)
Aliphatic aldehydes in MSS were estimated by derivative formation, followed by colorimetry. Analysis refined to permit estimation of acrolein (propenal)	Davis and Sneade (915)
Aldehyde and ketone derivatization	
Review of compounds used to derivatize aldehydes and ketones in tobacco smoke	Green and Rodgman (1373)

TABLE 3.3
Analysis of Cigarette MSS by Gas Chromatography

Cigarette Sample[a]	Puffs/cig, avge	Acetaldehyde, µg/cig	Acetone, µg/cig	Acrolein, µg/cig
Flue-cured, nonfiltered	9.3	856	372	83
Burley, nonfiltered	7.3	847	533	57
Oriental, nonfiltered	11.0	726	385	54
Tobacco blend, nonfiltered	8.0	832	440	75
Tobacco blend, carbon filtered	8.0	208	42	11

[a] 50 of 65 mm tobacco rod smoked during analysis.



Note: The properties of the cigarette studied were as follows: 85-mm filtered cigarette; 68-mm, tobacco rod; 17-mm triacetin-plasticized cellulose acetate filter tip; cased commercial American blend.

[a] It is now estimated that over 5000 components have been identified in MSS from tobacco cigarettes. Some components such as water, the simple phenols, hydrogen cyanide,and the volatile N-nitrosamines are found in both the vapor and particulate phases of cigarette MSS. Hence the total of the number in the two phases appears to exceed the number in the whole.

[b] Value in brackets represents percent of Total Mainstream Smokweight, 500 mg.

[c] Value in parentheses represents percent of WTPM, 22.5 mg.

[d] Much of this water is contributed by the air drawn through the cigarette during puffing (35-mL puff, 1-s duration, 1 puff/min, total puffs = 10) in a laboratory whose atmosphere is controlled to the specifications proposed by the FTC; namely, temperature = 25°C, relative humidity (RH) = 60%.

[e] This class of compounds includes added humectants (glycerol, propylene glycol) transferred from the tobacco rod to the MSS. The transferred humectants constitute about 10%–12% of the FTC "Tar."

[f] Value in brackets represents percent of FTC "tar" weight, 17.6 mg.

[g] Value in brackets represents percent of "other components" weight, 7.5 mg.

[h] There have been various estimates of the number of unidentified components present in extremely small amounts in the FTC "tar." Several investigators have estimated the number of unidentified components to range from 5 to 20 times the number of identified components, i.e., from about 20,000 to 100,000.

FIGURE 3.1 Approximate composition of cigarette MSS. *Note*: The properties of the cigarette studied were as follows: 85-mm filtered cigarette; 68-mm, tobacco rod; 17-mm triacetin-plasticized cellulose acetate filter tip; cased commercial American blend. [a]It is now estimated that over 5000 components have been identified in MSS from tobacco cigarettes. Some components such as water, the simple phenols, hydrogen cyanide, and the volatile *N*-nitrosamines are found in both the vapor and particulate phases of cigarette MSS. Hence the total of the number in the two phases appears to exceed the number in the whole; [b]Value in brackets represents percent of Total Mainstream Smoke weight, 500 mg; [c]Value in parentheses represents percent of WTPM, 22.5 mg; [d]Much of this water is contributed by the air drawn through the cigarette during puffing (35-mL puff, 1-s duration, 1 puff/min, total puffs = 10) in a laboratory whose atmosphere is controlled to the specifications proposed by the FTC; namely, temperature = 25°C, relative humidity (RH) = 60%; [e]This class of compounds includes added humectants (glycerol, propylene glycol) transferred from the tobacco rod to the MSS. The transferred humectants constitute about 10%–12% of the FTC "*Tar*"; [f]Value in brackets represents percent of FTC "tar" weight, 17.6 mg; [g]Value in brackets represents percent of "Other Components" weight, 7.5 mg; [h]There have been various estimates of the number of unidentified components present in extremely small amounts in the FTC "tar." Several investigators have estimated the number of unidentified components to range from 5 to 20 times the number of identified components, i.e., from about 20,000 to 100,000.

Because of the extreme differences between the levels of various components in cigarette smoke, levels that vary from mg/cig for nitrogen, carbon dioxide, and carbon monoxide to pg/cig for several *N*-heterocyclic amines (Trp-P-1 and Trp-P-2), a logarithmic plot of the levels of specific MSS components was found to be a convenient way to compare their deliveries. In Figure 3.2, a truncated form of the original logarithmic plot presented by Green and Rodgman (1373), are shown the cigarette MSS yields of several of the most plentiful vapor-phase aldehydes and acetone.

Table 3.4, modified and updated from similar tables presented by Chortyk and Schlotzhauer (722) and by Baker (171a), summarizes the major precursor relationships proposed and/or demonstrated to date between tobacco leaf components and tobacco smoke components. These proposals are based in part on the results of a great variety of pyrolysis studies. In some cases, the validation of the proposals is based on the results obtained by addition of leaf components to tobacco and assessing the effect on the levels of specific MSS components when the "spiked" tobacco

	Direct transfer from tobacco; however, lignin is the most likely precursor of many aromatic aldehydes as well as many aromatic acids in tobacco	Wender and Yang (4163) Yang and Wender (4378, 4379)

is actually smoked in a cigarette and its MSS composition is compared to that of the MSS from the control tobacco cigarette.

In their quantitation (via their 4-nitrophenylhydrazone derivatives) of several aldehydes and ketones in the MSS from cigarettes made from flue-cured laminae and from flue-cured midribs, Sakuma et al. (3396) reported no significant differences between the MSS yields of the compounds listed in Table 3.5. However, many were much reduced when the cigarette was tipped with a charcoal filter.

2-Butanone	159	186

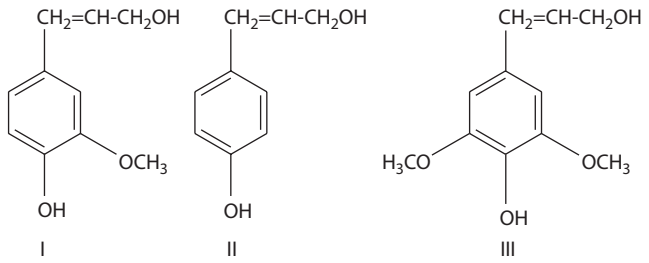

FIGURE 3.3 Phenolic alcohol components of lignin.

From their study of the pyrogenesis of acrolein (propenal) from glycerol, Doihara et al. (1964) and others deduced that a tobacco smoking product that contains glycerol as an humectant has an enhanced potential for the formation and release of acrolein (propenal) during smoking [see Wynder and Hoffmann (4337)].

In their study of the levels of acrolein, acetaldehyde, acetone, hydrogen cyanide, nitrogen oxides, nicotine, and total solids in pipe tobacco MSS, Harbin and Laurene (1497) reported that the acrolein delivery increased as the glycerol level was increased by addition but the acrolein delivery eventually leveled off when the glycerol addition exceeded 6%.

From an examination of the structure of lignin [cf. Ball (176a)], it is obvious why its pyrolysis products include a variety of phenolic aldehydes and acids, many of which have been identified in cigarette MSS. Lignin is composed of coniferyl alcohol {I}, *p*-coumaryl alcohol {II}, and sinapyl alcohol {III} in a variety of ratios that are dependent on the plant species (Figure 3.3).

3.1 ASSERTION OF ALDEHYDES AND KETONES AS CILIASTATIC TOBACCO SMOKE COMPONENTS

The reports by Wynder et al. (4306a, 4306c) in the early 1950s that cigarette smoke tar or CSC was tumorigenic to mouse skin prompted an intense search for the responsible component(s). Initially, the PAHs were selected for investigation because of the wealth of chemical and biological data generated on a great number of them following the synthesis of DB[*a,h*]A in 1929 (760, 1184), the isolation and identification of B[*a*]P from coal tar in 1932 (796a, 797), and the demonstration of the potent tumorigenicity of both of them to mouse skin by the Kennaway group (194, 796a, 797, 2078). Almost immediately after the report by Wynder et al. (4306a) of the mouse-skin-painting results with tobacco tar, the PAHs were proposed by some investigators to be the major tumor initiators in CSC. Because of its level in CSC and its potency in mouse-skin tumorigenesis, B[*a*]P was defined as the most significant of the PAHs in tobacco smoke.

However, it was soon recognized that neither the B[*a*]P content nor its tumorigenicity could explain the biological response observed in the mouse-skin-painting bioassay. Similarly, neither the total content of the PAHs tumorigenic to mouse skin nor their summed tumorigenicities could explain the observed biological response. In fact, it was pointed out many times over the next several decades that the levels of B[*a*]P and other tumorigenic PAHs in tobacco smoke condensate accounted for less than 3% of the observed tumorigenicity [Wynder and Wright (4353, 4354), Wynder and Hoffmann (1959b, 1959c, 1961a, 1963, 1964, 1967, 1968A), Druckrey (1056), Roe (3310, 3311), USPHS (3999, 4005, 4009, 4010), Lazar et al. (2320), Stedman (3767), Selikoff et al. (3584a), Coultson (830)].

As early as the mid-1950s, Wynder and Wright (4353) noted that the concentration of B[*a*]P in CSC was insufficient to account for its observed carcinogenicity to mouse epidermis: "The concentration in which benzo[a]pyrene seems to be in cigarette tar is insufficient to account for the observed carcinogenic activity to mouse epidermis."

At the 1957 Blatnik Committee hearings, Wynder reported Wright's opinion [Wright (4282a)] on the subject as well as his own [Wynder (4296)]. Wynder noted that much attention had been directed at the PAH B[*a*]P. So much in fact that, as Wynder stated, B[*a*]P had become an issue in itself because it was one of the known (tumorigenic) substances and everyone tried to blame everything on it alone. During his testimony, he also noted that his Sloan Kettering group had repeatedly stated that the amount of B[*a*]P in tobacco tar was insufficient to explain the animal results published by his group. He added that cigarette tar contained numerous other B[*a*]P-related compounds much more active than B[*a*]P and they most likely accounted for the majority of the activity, and it was more or less academic whether it was B[*a*]P or a dibenzopyrene or a dibenzanthracene or a substituted B[*a*]P because they were all formed in the same manner during the tobacco smoking process. That same year, Wynder and Wright (4354) wrote that, to that date, no carcinogens had been identified in large enough quantities in tobacco tar or its fractions to account for the observed activity in skin-painting studies:

> We have demonstrated experimentally…that 0.0001 per cent or even 0.0005 per cent benzopyrene in acetone will not produce any tumors in the present experimental mouse or rabbit groups. Thus, there is conclusive proof that the animal results cannot be solely due to the benzopyrene content of tobacco [sic].

> The benzpyrene content of the total tar as well as the active fractions is far too low to account alone for the positive results [in laboratory animal]. So far, no carcinogens have been identified in large enough quantity in tobacco tar or its fractions to account for the observed activity.

These Wynder–Wright 1957 results led to an intensive but unsuccessful 18-month search for a "supercarcinogenic" PAH. The absence of such a PAH was subsequently confirmed by the USDA group at Athens, GA, by their identification of over 500 PAHs in the PAH fraction from cigarette MSS, an identification procedure that completely accounted for the fraction in the cigarette smoke studied (3732, 3736, 3756–3759).

In 1959, unable to explain the bioassay (mouse-skin-painting) results with CSC on the basis of either its B[*a*]P content (less than 2% explainable) or its total PAH content (less than 3% explainable), Wynder and Hoffmann (4307) at the 1959 American Association for Cancer Research (AACR) meeting added the concept of promotion by low-molecular-weight phenols to the concept of tumor initiation by PAHs in an attempt (unsuccessful) to explain the bioassay results. They reiterated their view the following year at the *1960 AACR conference* (4309):

> The phenol fraction could be established as an important promoting portion of the tobacco smoke condensate.

A similar comment that the amount of tumorigenic PAHs found in CSC could not by themselves account for the total biological activity observed was included in a more detailed publication (4307) of their AACR presentation. They also stated (4308) that the higher PAHs played an important role in the carcinogenicity of CSC, but when the various known concentrations of the carcinogenic PAHs as estimated in CSC were summed, it was obvious that they could not account for the established carcinogenicity of the CSC nor of its isolated PAH fraction:

> Several carcinogenic higher aromatic polycyclic hydrocarbons [are] present in tobacco smoke condensate. They include benzo[*a*]pyrene…, benzo[*e*]pyrene…, chrysene…, benz[*a*] anthracene…, dibenz[*a,h*]anthracene…, and dibenzo[*a,i*] pyrene… From the amount in which these materials have been found in tobacco smoke condensate it was evident that these, by themselves, could not account for the total biological activity observed.

In 1960, Van Duuren et al. (4027) reported the identification of several aza-arenes (dibenz[*a,h*]acridine, dibenz[*a,j*] acridine, dibenzo[*c,g*]carbazole) not only structurally similar to some of the known tumorigenic PAHs in CSC but also reported under certain conditions to be tumorigenic to mouse skin. Adding this class of tumorigenic cigarette smoke components to the assessment of the tumorigenicity of CSC failed to account for more than a few percent of the observed response.

However, it should be noted that Candeli et al. (587) could not confirm the findings of Van Duuren et al. on the presence of these three aza-arenes in cigarette MSS. During the next three decades, other research groups in Germany, Japan, and the United States were also unable to confirm the presence in cigarette MSS of dibenz[*a,h*]acridine, dibenz[*a,j*]acridine, and dibenzo[*c,g*]carbazole [3260, 3414, Table 12-7 in (172)].

Wynder and Hoffmann (4311) wrote that the PAHs in CSC accounted for not more than 3% of the total biological activity observed in mouse-skin bioassays:

> The polynuclear aromatic hydrocarbons are mainly formed during the combustion of tobacco. The tobacco of our standard cigarettes contains only very minute quantities of benzo(a)pyrene (0.02 ppm). A bioassay indicates that these polycyclic hydrocarbons of the condensate by themselves, however, can account for not more than 3 per cent of the total biological activity.

Wynder and Hoffmann (4312) also wrote that the established carcinogenicity of CSC to mouse epidermis could to a great extent be accounted for on the basis of initiating carcinogens, largely PAHs, and promoting substances, a major group of which was the phenols. This statement was not true in 1961, nor is it true now.

In their lengthy 1964 review of tobacco carcinogenesis, Wynder and Hoffmann (4319) stated that no one could deny that tobacco products were tumorigenic even though no single component in tobacco smoke could by itself or jointly with other components account for the observed tumorigenic activity of such tobacco products to the skin of laboratory animals:

> It is furthermore true that none of the agents is carcinogenic in the concentrations in which they are present in tobacco products.

Wynder and Hoffmann (4332) expressed similar views on the tumorigenicity of tobacco smoke components in their 1967 book, but they continued to maintain that the PAHs in cigarette smoke were important as tumor initiators:

> While BaP and other carcinogenic PAH can by themselves account for only a small portion of the total tumorigenic activity of cigarette smoke condensate, probably less than 2%, they are, nevertheless, of obligatory importance as tumor initiators.

The next year, Wynder and Hoffmann (4342) wrote:

> Carcinogenic polynuclear hydrocarbons in the concentrations present in tobacco "tar" clearly do not, by themselves, account for the observed carcinogenicity.

On several occasions, the U.S. Surgeon General in his periodic reports on smoking and health discussed the relationship between the levels of PAHs in cigarette smoke, their tumorigenic potency to mouse skin, and the observed biological response with CSC in mouse-skin-painting bioassays:

> The results of a number of such assays [mouse skin-painting] present a puzzling anomaly: the total tar from cigarettes has about 40 times the carcinogenic potency of the benzo(a)pyrene present in the tar. The other carcinogens

known to be present in tobacco smoke are, with the exception of dibenzo(a,i)pyrene, much less potent than benzo(a) pyrene and they are present in smaller amounts. Apparently, therefore, the whole is greater than the sum of the known parts. (3999)

Unable to explain the observed tumorigenicity to mouse skin of CSC in terms of its content of known tumorigenic PAHs and/or tumorigenic aza-arenes, Wynder and Hoffmann (4307, 4309–4313) added the concept of promotion to their arsenal with particular emphasis on this property of the nontumorigenic PAH and low-molecular-weight phenolic components in the CSC. Inclusion of the concepts of initiation, promotion, and cocarcinogenesis by cigarette smoke components could only account for a small percentage of the number of tumor-bearing animals in the mouse skin-painting studies. This inability to explain the results observed in laboratory animals was a major creditability problem in the attempt to relate the laboratory animal data with CSC to human smoking experience.

In an attempt to offset their failure to explain the mouse skin-painting bioassay results with CSC on the basis of its content of tumorigenic PAHs and aza-arenes, promoting and/or cocarcinogenic phenols, and promoting and/or cocarcinogenic nontumorigenic PAHs, Wynder and Hoffmann (4314, 4315) added the concept of ciliastasis in an attempt (unsuccessful) to explain cigarette smoke tumorigenicity in smokers' lungs. It was proposed that impairment of ciliary action would result in prolonged exposure of the ciliated tissue to the inhaled particle and the tumorigens contained therein. Obviously, ciliastasis is not relevant to the initiation of tumors in the mouse skin-painting bioassay with CSC.

Cilia are small, hairlike entities covering the surface of certain portions of the upper respiratory tract,* and these beat rhythmically and synchronously to move a thin layer of mucus upward toward the mouth where it is swallowed or expectorated. Inhaled particle may be entrained in this mucus and thus removed from the respiratory tract by its cilia-induced movement. Impairment of ciliary activity results in a failure to clear particles from the respiratory tract. This impairment of ciliary activity, known as ciliastasis, may be produced by a variety of inhaled materials. [A detailed definition of cilia and description of their action appear in Rivera (3184a).] Many of the early laboratory investigations on ciliastasis produced by cigarette MSS and/or its components were studies involving ciliated tissue from clams, mussels, or extirpated lung tissue from rabbits, etc.

Usually, Hilding (1652a) is credited with initiating the interest in respiratory tract ciliastasis produced by cigarette MSS. In 1956 and 1957, he reported the results of his studies of the effect of cigarette smoke on ciliated tissue in the lungs of cows. However, numerous reports on studies of the ciliastatic action of cigarette MSS had appeared in the literature during the preceding two decades.

* Other anatomical sites in the mammalian body possess ciliated tissue, but these have no relevance to the discussion of tobacco smoke inhalation.

In the late 1930s, Mendenhall and Shreeve (2530a) and Proetz (2991a) described their studies on ciliastasis. Mendenhall and Shreeve (2530a) reported that nicotine in cigarette MSS did not appear to be a contributor to ciliastasis in extirpated bovine tracheal tissue exposed to cigarette MSS, but the difference they observed between the smokes from nonmentholated *vs.* mentholated cigarettes indicated that menthol had a ciliastatic effect. However, in 1952, Rakieten et al. (3072b) reported no difference between the MSSs from nonmentholated *vs.* mentholated cigarettes in the ciliastasis induced in ciliated tissue from humans, rabbits, or rats. Their findings conflicted with those reported by Mendenhall and Shreeve. Rakieten et al. (3072b) also reported that nicotine contributed only slightly to the observed ciliastatic effect of cigarette MSS.

Representative studies on ciliastasis produced by cigarette MSS include those of Dalhamn (891a), Falk et al. (1175), Kotin and Falk (2179), and Ballenger (178). In all these studies, cigarette MSS was reported to be ciliastatic in in vitro systems. Falk et al. reported that nicotine was involved in the ciliastasis induced by cigarette smoke. However, Guillerm et al. (1451a) reported that neither nicotine nor hydrogen cyanide was a contributor to the ciliastasis produced by cigarette MSS when tested individually at the concentrations determined in cigarette MSS. They reported that all the aldehydes and ketones tested at their concentrations in cigarette MSS were ciliastatic and acetaldehyde and acrolein appeared to act synergistically in the ciliastatic action.

In 1962, Wynder and Hoffmann (4314) combined the ciliastasis concept with the three tumorigenesis factors mentioned earlier: it was proposed that impairment of ciliary action would result in prolonged exposure of the ciliated tissue to the inhaled particle and the tumorigens contained therein. For the CSC, they reported low-molecular-weight phenols to be in vitro ciliastats and that cellulose acetate filters plasticized with triacetin substantially reduced the ciliastatic effect of phenols. The same year, Davis and George (911a) reported the effectiveness of triacetin-plasticized cellulose acetate in reducing the phenols level in cigarette MSS with the corresponding reduction of the observed ciliastasis.

Because of the assertion that low-molecular-weight phenols were promoters for tumorigenic PAHs and thus played a role in CSC tumorigenesis and possibly in cancer causation in smokers, research was under way to find methods to reduce their levels in cigarette MSS, e.g., the studies at Lorillard on selective phenols filtration by Spears (2399, 3765), at R.J. Reynolds Tobacco Co. (RJRT) by Laurene (2295) and Laurene et al. (2306), by Hoffmann and Wynder (1791), Mokhnachev et al. (2579), and Morie (2628, 2629, 2636); on phenol precursors by Rodgman et al. (3251, 3277, 3305, 3306); and on the precursors in tobacco of the low-molecular-weight phenols in tobacco smoke by Wynder and Hoffmann (4317). Obviously, the results of these studies were equally applicable to reducing levels of phenols because of their alleged ciliastatic action in the respiratory tract.

Wynder and Hoffmann (4317) and Wynder et al. (4350) reported the results of their study of the ciliastatic components

in CSC: Nicotine was not a factor in the ciliastasis of CSC; the phenolic fraction and the acidic fraction were significant ciliastats.

The same year, Kensler and Battista (2083, 2084) reported their findings on the ciliastatic activity of vapor-phase components of cigarette MSS and its reduction by activated carbon filters. Falk et al. (1173a, 1175) also described the effect of many of the same smoke components on mucus flow. Hydrogen cyanide, acrolein, formaldehyde, acetaldehyde, nitrogen oxides, ammonia, and phenol were considered important vapor-phase ciliastats.*

The Kensler–Battista research on the effectiveness of carbon in reducing vapor-phase ciliastats in cigarette MSS was reported within a few months of the publication of the *Reader's Digest* article on the effectiveness of carbon-containing filters in reducing ciliastats in cigarette MSS and the appearance in the marketplace of Liggett and Myers (L&M) Lark cigarette. Its filter included a chamber filled with a specially treated carbon based on a patent issued to Keith of L&M R&D. The Kensler–Battista study was performed at A.D. Little and was contracted by L&M (2083, 2084).

Because of these reports on vapor-phase components of cigarette MSS, emphasis at RJRT R&D was shifted from attempts to reduce the levels of the phenols reported to be promoters or cocarcinogens to attempts to reduce the levels of vapor-phase components reported to be ciliastatic. These vapor-phase components included the simpler, volatile phenols which equilibrate between MSS vapor phase and particulate phase. From 1963 to 1972, a great variety of filter-tip additives were examined with respect to their ability to remove specific MSS components reported to be ciliastatic in in vitro experiments.

After the Kensler–Battista publications, numerous publications appeared on the reduction of the delivery of ciliastatic components by filter tips (893a), on the ciliastatic action of nicotine (178), and on the ciliastatic activity of phenol (295).

In a preliminary study, Rodgman et al. (3306) examined the removal of water-soluble vapor-phase ciliastatic components from cigarette MSS by saliva and mucous secretions in the upper respiratory tract. They reported that the levels of representative ciliastats such as the aldehydes and ketones were substantially reduced in the oral cavity, resulting in a diminution of the levels reaching the ciliated tissue in the lower respiratory tract. Rodgman et al. also emphasized that such oral cavity absorption of water-soluble ciliastats did not substantially affect the levels of ciliastatic components in the particulate phase. External impetus for this investigation was provided by comments in the Advisory Committee's 1964 Report to the U.S. Surgeon General (3999) on the possible oral cavity removal of water-soluble ciliastats, by comments by Dalhamn and his colleagues (893a, 894b) on the ciliastatic activity of filtered and nonfiltered cigarette MSS, and by Wynder (4301).

In 1965, Wynder et al. (4304) wrote:

> The principle volatile ciliatoxic components appear to be water-soluble… Important considerations are the temperature of the respiratory tract…and the nature of the overlying mucous coat, the layer that all ciliastatic components penetrate to act upon cilia…

In their study, Rodgman et al. (3306) showed that passage of cigarette MSS over moistened filter paper strips substantially reduced the levels of the vapor-phase ciliastats but did not produce much effect on the "tar" delivery. Rodgman and Cook (3289) examined a variety of carbon-containing filter tips and found that the delivery of several vapor-phase ciliastats (the aldehydes and ketones) could be reduced substantially by some of them. In some instances, the ciliastatic components adsorbed on the carbon were eluted from the carbon as the fire cone approached the filter tip and the filter-tip temperature was increased. As a result, the levels of these components were inordinately increased in the last few puffs from the cigarette. RJRT was not the only U.S. tobacco company interested in the removal of water-soluble ciliastats from cigarette MSS.†

Industrial Bio-Test Laboratories (3A12), under contract to RJRT, conducted a series of studies on in vitro ciliastasis of cigarette MSS from 1964 through 1967. Major findings included the following: (1) The theory of reduction of the levels of ciliastats in the smoke stream by moist surfaces was confirmed. (2) The ciliastatic activity of the MSS particulate phase was essentially unchanged by passage over moist surfaces. (3) The ciliastatic activity of cigarette MSS was substantially reduced by passage of the MSS through a carbon-containing filter tip.

In 1966, Dalhamn (891a) and Dalhamn and Rylander (893c) reported on the effect of filtration on the delivery of ciliastatic compounds in MSS. They reported that in vitro ciliastats were present in both the vapor and particulate phases of MSS.

In their 1964 lengthy review and 1967 book, Wynder and Hoffmann (4319, 4332) commented on ciliastasis induced by cigarette MSS as follows:

> All studies reported to date have shown that cigarette smoke affects the metachronic activity of cilia, a motion that is necessary to propel the viscid mucoid mass. During inhalation, in the absence of effectively beating cilia, mucus flow slows down and perhaps stops. At that time, components in cigarette smoke may act upon the underlying cells, as can the entrapped particles.

* Because of its vapor pressure properties, phenol is present in both the particulate phase and the vapor phase of cigarette MSS aerosol. Thus, it is amenable to removal from the vapor phase by selective filtration and to reduction of its level in the particulate phase by all the technologies whereby MSS particulate phase or "tar" delivery is reduced, e.g., filtration efficiency, air dilution (increased paper porosity, filter-tip ventilation), inclusion of expanded tobacco in the blend.

† In 1965, American Tobacco marketed the Waterford cigarette whose filter contained encapsulated water. Prior to smoking the cigarette, the smoker would gently squeeze the filter tip, rupture the capsules to release the encapsulated water which would spread throughout the interstices between the filter-tip fibers. Water-soluble MSS vapor-phase components would be "scrubbed" from the smoke stream. The Waterford had a very short life in the market place.

In their mid-1960s publications, Wynder and Hoffmann commented several times on the fact that most of the known ciliastatic components of MSS demonstrated to be ciliastatic in various in vitro systems were water soluble and this property would markedly influence their fate and behavior during and after inhalation. Wynder and Hoffmann (4330) noted:

> As far as human smoking habits are concerned, it remains also to be estimated to which extent volatile smoke components reach the bronchial tree. Preliminary studies indicate that a significant proportion of the gaseous components is being retained within the oral cavity.

Later, Wynder and Hoffmann [see p. 542 in (4332)] wrote:

> Water-soluble volatile components, which are primarily responsible for the results of the acute in vitro short-term cilia toxicity tests, are, to a large extent, removed when cigarette smoke contacts the saliva in the mouth and the abundant secretions of the trachea and main bronchi.

They added [see p. 646 in (4332)]:

> In man's manner of smoking, however, volatile components are retained to a significant degree in the oral cavity and may, therefore, be far less important than when tested experimentally.

These words, perhaps prophetic, were shown to be true by Dalhamn et al. (892) who reported in 1968 that as much as 60% of the water-soluble (and ciliastatic) components of cigarette MSS were absorbed in the oral cavity of the human smoker, whereas the absorption of water-insoluble (and nonciliastatic) components such as isoprene was low (about 20%). They also reported that about 16% of the MSS particulate matter was retain in the mouth. Mouth absorption of acetaldehyde and acetone averaged about 57%. Earlier, Rodgman et al. (3306) had conducted a study similar to but much less elaborate than that of Dalhamn et al. (892). Rodgman et al. studied the mouth absorption of components of the MSS from five different brands: The total absorption of all vapor-phase aldehydes and ketones averaged 53%; the absorption of isoprene averaged less than 10%.

The more than a dozen cigarette brands tipped with carbon-containing filter tips were already losing market share by the time Dalhamn et al. reported the results of their study of the mouth absorption of water-soluble vapor-phase components (892). Their scientific communication, plus the consumer-unacceptable "carbon-filter" off-taste, not only produced a further reduction of sales but also diminished interest, both within and outside of the tobacco industry, in vapor-phase ciliastats as participants in respiratory problems attributed to cigarette MSS.

From 1968 through 1972, study continued not only at RJRT R&D but also throughout the tobacco industry on ways to reduce the levels of vapor-phase components, many of which were reported to be ciliastatic in in vitro systems. The major effort was aimed at reducing the level of hydrogen cyanide (a potent in vitro ciliastat) because of its level in cigarette MSS (about 200–400 μg from a cigarette delivering 15–25 mg of FTC "tar"), its toxicity (other than ciliastasis) when examined alone, and the fact that consumers would be more familiar with the toxic properties of hydrogen cyanide (also known as hydrocyanic acid or "cyanide") than with the toxic properties of MSS components such as acrolein or phenol. Most of the effort during this period dealt with filter-tip additives other than carbon.

Thus, in the late 1960s, it was known that in vitro ciliastatic components in the vapor phase of MSS were not reaching the ciliated areas of the respiratory tract in the concentrations first considered to be a problem and the levels of the ciliastatic components in the MSS particulate phase could be controlled by the filtration methods used to control "tar" delivery. Another technology to control the *per cigarette* deliveries of both vapor-phase and/or particulate-phase MSS components (whether they be ciliastatic or not) was air dilution via filter-tip ventilation. At RJRT R&D, basic research on this cigarette design technology, subsequently classified as significant in the generation of a "safer" or "less hazardous" cigarette, was pursued into the mid-1970s (3116a, 3119a, 3120).

Dalhamn (891c) stated with regard to a "less hazardous" cigarette:

> If…one were to venture a reply to the question of what a less hazardous cigarette would be like, I cannot for the moment find a better one than that given by Rylander and myself [to the 1968 Consumer Subcommittee of the U.S. Senate Committee on Commerce]:
>
> Our belief, based upon the scientific knowledge available at present, is that the only way to guarantee a reduction in the harmful effects of inhaled smoke is to decrease the overall exposure. This can be done by reducing the number of cigarettes smoked or by using filter cigarettes, provided the reduction brought about by the filter will equal in all respects and for all potentially hazardous compounds the reduction in dose obtained if the number of cigarettes is reduced. Due to the limited amount of data and the difficulty of extrapolating from laboratory findings to man, we believe that a reduction of only selected components of cigarette smoke cannot be accompanied by a statement guaranteeing a reduction in the harmful effects of inhaled smoke.

The topic dealing with ciliastasis and MSS ciliastats (from testing in in vitro systems) is of particular interest with respect to the ETS situation because of the data showing:

1. The major ciliastatic components in tobacco smoke are water soluble. These include formaldehyde, acetaldehyde, crotonaldehyde, ethyl carbamate, and hydrazine:* All are water-soluble tobacco smoke

* Other water-soluble tobacco smoke components categorized as ciliastats on the basis of in vitro test results include ammonia, hydrogen cyanide, acrolein, acetone, nitrogen dioxide, low-molecular-weight phenols. The phenols are distributed between the particulate and vapor phases of tobacco smoke.

components that appear as tumorigens on the various published lists of tumorigens in tobacco smoke (1727, 1740, 1741, 1743, 1744).
2. Dose reduction (effectively, dilution) of MSS or some of its "ciliastatic" components or ciliastatic fractions eventually results in a dose or concentration level at which no ciliastasis is produced in the in vitro systems used.
3. A large proportion of the inhaled MSS components categorized as ciliastats (and in some instances as tumorigens) does not reach the ciliated areas of the respiratory tract because of their removal from the smoke stream during passage over the moist tissues of the mouth and trachea [cf. Rodgman et al. (3306), Dalhamn et al. (892)].
4. Ciliastatic compounds inhaled nasally are removed from the inhaled gas stream by "resorption."

This raises the question as to how much formaldehyde or acetaldehyde or crotonaldehyde in ETS, an already extremely dilute system, will reach the lung whether inhaled orally or nasally! Are the levels of these tobacco smoke components in ETS sufficient for these compounds to be included on the Hoffmann and Hecht list (1727) or the Occupational Safety and Health Administration (OSHA) list (2825) or the Hoffmann and Hoffmann lists (1740, 1741, 1743) or the Hoffmann et al. list (1744)?

3.2 CILIASTASIS STUDIES WITH CIGARETTE SMOKE CONDENSATE FRACTIONS

Wynder and Hoffmann (4314) and Wynder et al. (4350) in their study with mussels of the ciliastatic activity of aqueous extracts of various fractions of CSC demonstrated that reduction of the applied dose of each of the fractions tested eventually changed the ciliastasis from "immediate and complete" to "none." Their findings are summarized in Table 3.6.

Calculation of the ratio Dc/Do, where Dc is the dose producing "immediate and complete" ciliastasis and Do is the dose producing "zero" ciliastasis, gives values ranging from 6 to 24, i.e., a 24-fold dilution of every mainstream CSC fraction tested in this study resulted in or would result in a nonciliastatic situation.

The data in Table 3.6 originally presented at the annual AACR meeting by Wynder and Hoffmann (4314) were subsequently published, but in less detail, by Wynder et al. (4350).

3.3 CILIASTASIS STUDIES WITH INDIVIDUAL CIGARETTE MAINSTREAM SMOKE COMPONENTS

Examination of the in vitro ciliastasis produced by a variety of MSS components reveals that for all components studied, there is a level below which no ciliastasis is observed. Guillerm et al. (1451a) reported the results of their study on the effect of various MSS components in the in vitro system, ciliated rat trachea. Concentrations less than those shown in Table 3.7 produced no ciliastasis in ciliated rat trachea. All of the compounds listed in Table 3.7 are primarily vapor-phase components of MSS.

Wynder et al. (4350) in their study of the phenolic components of cigarette smoke also reported that reduction of the concentrations of solutions of the simple phenols (phenol, *o*-cresol, *m*-cresol, *p*-cresol, *o*-ethylphenol, 2,4-dimethylphenol) from 1.0% to 0.05% (a 20:1 dilution) reduced the ciliary activity of each solution in an in vitro system (ciliated mussel tissue) to zero.

At the highest concentration (1.0%), the phenol derivatives demonstrated greater ciliastatic effects than did phenol itself. At the lowest concentrations tested (0.05%), none of the phenols induced ciliastasis.

TABLE 3.6
In Vitro Ciliary Activity, Cigarette Smoke Fractions, and Dose Level

Smoke Fraction from Which Aqueous Extract Was Obtained	% of Smoke[a]	Immediate and Complete Ciliastasis at Dc[b]	Complete Ciliastasis in 10–40 min at D10	No Apparent Ciliastasis at Do	Dc/Do
Phenolic fraction	9.3 (16.0)[c]	0.03	0.015	0.002	15

3.4 NOSE INHALATION OF ENVIRONMENTAL TOBACCO SMOKE *VS*. MOUTH INHALATION OF MAINSTREAM SMOKE

On several occasions, Rodgman (3255, 3255a, 3257) discussed the effect of water solubility of tobacco smoke components reported to be ciliastatic in in vitro systems on the ultimate exposure of the smoker's lungs to MSS or the nonsmoker's lungs to ETS.

Early in the study of the effect of MSS components on ciliary activity in in vitro systems, it was realized that all of the MSS components (formaldehyde, acetaldehyde, acrolein, hydrogen cyanide, formic acid, acetic acid, etc.) that produced ciliastasis in the in vitro systems were water soluble. This observation led to proposals by Dalhamn and Sjoholm (894b), Dalhamn and Rylander (893a), Rodgman et al. (3306), Wynder (4301), USPHS (3999), Wynder et al. (4304, 4305), and Wynder and Hoffmann (4332, 4342) that this water solubility would result in removal of substantial amounts of the in vitro ciliastatic components from the MSS by their solution in the aqueous fluids coating the surfaces of the oral cavity and trachea during the time that the MSS was held in and/or traversed these portions of the respiratory tract. The levels of ciliastats reaching the ciliated areas in the smoker's lower respiratory tract would produce insignificant ciliastasis, if any at all. This "scrubbing" of ciliastatic components from the inspired MSS stream was demonstrated in smokers by Rodgman et al. (3306) and Dalhamn et al. (892, 893). Nasally inhaled components are removed in the nasal cavity by "resorption," a process similar to the "scrubbing" of water-soluble components from gas streams such as MSS vapor phase.

Dalhamn, in his 1961 study of ciliastatic activity demonstrated that sulfur dioxide was a powerful ciliastat in vitro at or below 100 ppm but did not produce ciliastasis in vivo at or below 100 ppm because much of the sulfur dioxide was removed in the nasal cavity (891a). Sulfur dioxide was subsequently identified as a minor tobacco smoke vapor-phase component (3882). Dalhamn (891a) found that in rabbits exposed to 300, 200, and 100 ppm of sulfur dioxide, the percentage showing cessation of ciliary activity within 45 min was 90, 60, and 0, respectively. Removal of inhaled components in the nasal cavity, termed "resorption," is similar to the "scrubbing" of water-soluble components from gas streams, e.g., MSS vapor phase. This nasal resorption is an important process not only from a ciliastasis–MSS component point of view but also from an ETS point of view since ETS, in contrast to MSS which is primarily inhaled via the mouth, is inhaled primarily through the nose. ETS vapor-phase components that would be removed through resorption in the nasal cavity include formaldehyde, acetaldehyde, crotonaldehyde, hydrazine, and possibly ethyl carbamate, five MSS components listed by Hoffmann and Hecht (1727) as "tumorigens" in MSS. Thus, very little, if any, of these water-soluble components, already highly diluted in ETS, would reach the lungs and the ciliated tissue to be involved in lung cancer causation attributed to ETS by some authors. As noted by Aviado (126a), data from inhalation studies in animals indicate it is unlikely that either formaldehyde or hydrazine contribute to pulmonary carcinogenesis.

In 1965, Dalhamn and Rylander (893b) commented on the possible differences in the effects produced by mouth inhalation *vs*. nose inhalation of tobacco smoke:

> The most important point is probably that the smoke is administered through the mouth. If smoke is administered through the nose quite different absorption conditions are present, and it is likely that the smoke which enters the lungs differs considerably from that inhaled through the mouth. This could also be one of the factors which explains why in animal experiments no tumor-producing effects have been found by tobacco smoke in inhalation studies where the smoke was administered through the nose.

In 1968, Dalhamn et al. published the results of their studies with humans on the mouth absorption (892) and lung retention (893) of various components of cigarette smoke. As noted earlier, the findings that a substantial percentage of the levels of MSS water-soluble components demonstrated to be ciliastatic in vitro is absorbed in the oral cavity lessened the interest in ciliastasis produced by MSS components. The data generated by Dalhamn et al. also served a second useful purpose in that they demonstrated (1) the remarkable difference, albeit with respect to only a few MSS smoke components, between the compositions of inhaled and exhaled MSS and (2) all of the few components measured in the inhaled MSS were found in the exhaled MSS, i.e., none was 100% retained in the lungs, etc., nor 100% absorbed in the oral cavity.

These data are summarized in Tables 3.8 and 3.9. It is obvious that mouth absorptions of such water-soluble ciliastats as acetaldehyde (60%) and acetone (56%) are substantial (Table 3.8); whereas, the mouth absorptions of the relatively water-insoluble components isoprene (20%), toluene (28%), and CO (3%) are much less.

The data in Table 3.9 are derived from those of Dalhamn et al. (892, 893). The change in the composition of the MSS delivered by the cigarette to the composition of the MSS exhaled by the smoker is readily seen from the ratios, e.g., acetaldehyde is inhaled by the smoker at a ratio of 31.3 µg/mg TPM but is

TABLE 3.8
Lung Retention and Mouth Absorption of Several Cigarette MSS Components

		Per Cigarette MSS

CO, mg	1.0[b]	11.5	1.15
TPM, mg	1.0	1.0	1.0

[a] No inhalation.
[b] Per cigarette CO yield assumed to be the same as per cigarette TPM yield.

exhaled at a ratio of 8.3 µg/mg TPM; acetone is inhaled at a ratio of 19.0 µg/mg TPM but exhaled at a ratio of 66.7 µg/mg TPM. Similarly, the MSS composition is altered by holding the smoke in the mouth without inhalation. Since these exhaled smokes—whether originally inhaled, held in the mouth with no or minimal inhalation, or some blend of both (inhalation and mouth retention)—ultimately contribute to ETS, it is obvious that the contribution is not equivalent quantitatively to the MSS originally generated by the cigarette.

The data presented by Dalhamn et al. (892, 893) on lung retention of MSS components were similar to data reported earlier by Laskowski (2267) and to data on lung retention and mouth absorption of ciliastats by Rodgman et al. (3306). The various sets of data are summarized in Table 3.10. Each set of data indicates that exhaled MSS is substantially different quantitatively from the inhaled MSS.

If cigarette MSS is mouth inhaled and held for any length of time (a few seconds) in the mouth prior to being drawn into the lungs, some of the MSS water-soluble vapor-phase components are "scrubbed" from the smoke stream and reach the ciliated areas at much reduced concentrations. This is also true to a lesser degree for water-soluble components of the particulate phase (see Tables 3.8 through 3.10). The exposure of the lungs to "resorbed" entities alleged to be tumorigenic will be much less than some authors claim. Similarly, in nose inhalation of ETS, some of its water-soluble components (formaldehyde, acetaldehyde, crotonaldehyde, ethyl carbamate, hydrazine)—alleged to be tumorigenic at the levels in MSS—will be "resorbed" in the nasal cavity and reach ciliated areas at concentrations reduced not only by the "resorption" mechanism but also by the dilution inherent in ETS generation from exhaled MSS and SSS produced during inter- and intrapuff smoldering. The exposure of the lungs to these "tumorigens" will obviously be substantially less than some writers claim.

Thus, these mechanisms—"scrubbing" and "resorption"—effective in substantially diminishing the amounts of

[a] About 70%–75% of the volatile aldehydes and ketones in MSS is acetaldehyde plus acetone. For cigarettes in the 1950s and 1960s, the acetaldehyde–acetone ratio approximated 2:1.

[b] —, Not determined.

MSS water-soluble in vitro ciliastats that reach the lung during active smoking will be operative during ETS inhalation, whether oral or nasal, and diminish the amounts of the same and similar ETS components that reach the lung. This diminution in amounts will be particularly pertinent in the case of the smoke components formaldehyde, acetaldehyde, crotonaldehyde, ethyl carbamate, and hydrazine on the Hoffmann and Hoffmann "List of 60" (1740).

The following paragraphs include comments about two of the much researched smoke components formaldehyde and acetaldehyde:

Formaldehyde yields in cigarette range from 3.4 μg for filtered cigarettes to 283 μg in unfiltered cigarettes (2564, 3427). This compound is usually found in the vapor phase. The suggested formation mechanism for formaldehyde is destructive distillation and pyrolysis of celluloses, starch, pectins, lignin, and sugars [Burton (535), Chortyk and Schlotzhauer (722), Gager et al. (1264, 1265), Green (1351), Johnson et al. (1960), Stedman (3797)].

In both indoor and outdoor air in the United States, formaldehyde is usually present at the generally nonirritating level of approximately 0.06 ppm (1145a). In May 1992, OSHA ruled the exposure limit to formaldehyde be reduced from 3 to 0.75 ppm (2683a). Although most significant exposure to formaldehyde is generally industrial, it also naturally occurs in food, e.g., fruits and vegetables (2111b). Levels of formaldehyde in fruits and vegetables range from 3.3 μg/g in spinach to 17.3 μg/g in apples (3986a).

Formaldehyde is tumorigenic and mutagenic only at doses many-fold higher than that seen in cigarette MSS. Whether formaldehyde is mutagenic at noncytotoxic doses remains controversial due to the small number of studies and the variability of results (1873a). Formaldehyde has been reportedly found to induce aneuploidy (2363a, 2868a). In addition, results from some studies have suggested that humans routinely exposed to formaldehyde display increases in chromosomal aberrations and sister chromatid exchanges in peripheral lymphocytes. However, rodents treated with formaldehyde in vivo gave negative results for chromosomal aberrations and assays for lethal mutations. Additional rodent studies on DNA damage showed unconvincing results as well (1873a).

The overall tumorigenicity of formaldehyde was tested in two strains of rats and one strain of mice. Significant increases in squamous-cell carcinomas of the nasal cavity were observed in both rat strains after inhaling highly cytotoxic doses of formaldehyde. However, no carcinomas were observed in any of the mice inhaling the same dose (2086a). In other studies to evaluate formaldehyde tumorigenicity, mice and hamsters were exposed via inhalation, rats via subcutaneous injection, and rabbits via exposure in oral tanks. At the time, the results from these studies were considered inadequate to evaluate the tumorigenic risk to humans. Although formaldehyde was tumorigenic in rats when administered at very high dose levels (2610a, 3789b), the evidence of its tumorigenicity in humans was considered by the International Agency for Research on Cancer (IARC) to be inadequate, until 2005 (3A03). Recently, IARC reevaluated the evidence on formaldehyde and reclassified it as a Group 1 human carcinogen (3A16).

As noted previously, the reported MSS yield of acetaldehyde ranged from 18 (1853a) to 2815 μg/cig (2564) for

nonfiltered cigarettes. However, a substantial difference exists between the analytically derived yields of acetaldehyde and other water-soluble vapor-phase components reported to be ciliastatic and the smoker's exposure to them. Dalhamn et al. (892) described how a substantial percentage of water-soluble components such as acetaldehyde are removed from the vapor phase of the smoke stream by solution in the aqueous fluids coating the oral cavity, thus never reaching the upper or lower respiratory tract. The proposed mechanisms of formation for acetaldehyde are destructive distillation and pyrolysis, and its major precursors are reported to be the celluloses, pectins, starch, lignin, and sugars [Burton (535), Chortyk and Schlotzhauer (722), Gager et al. (1264, 1265), Green (1351), Johnson et al. (1960), Stedman (3797)].

Additional complexities exist regarding the predictability of biological activity. For example, a significant amount of vapor-phase water-soluble components such as formaldehyde and acetaldehyde are "scrubbed" from the smoke stream into solution by the fluids coating the oral cavity and upper respiratory tract; thus, they reach the lung at a diminished level (892, 893). Similarly, only a modest percentage of a water-insoluble component such as isoprene is retained by the smoker because a significant portion of it is exhaled. In light of these phenomena and the fragmentary nature of the data on actual exposure and retention, the possible physiological effect of formaldehyde, acetaldehyde, and isoprene at the cited cigarette MSS delivery ranges cannot be extrapolated. Very few studies have been performed in which a smoking machine or system was modified to approximate the effect of oral cavity fluids on the retention of specific MSS components. It has been known since the early 1950s and confirmed in the 1960s that different classes of smoke components are retained to different degrees by the smoker (892, 2267, 3255, 3257, 3306). Thus, the composition of the cigarette MSS retained by the smoker is significantly different from that exhaled by the smoker. Also, both the biologically retained and exhaled smokes are obviously different compositionally from the cigarette MSS retained and analyzed by the smoking machine-collection system.

While much emphasis was placed on the aldehyde and ketone components in the vapor phase of cigarette MSS because of their in vitro ciliastatic activity, much research was also conducted after the mid-1950s to identify aldehyde and ketone components in the particulate phase of cigarette MSS primarily because many were found to contribute consumer-acceptable flavor and aroma properties to the MSS. As noted by Rodgman (3266), many of the aldehydes and ketones used by the tobacco industry in its flavor formulations [see listing by Doull et al. (1053)] are known components of untreated tobacco and/or its smoke. Thus, such additives are not strangers to the tobacco and/or its smoke, but their addition increases the consumer-acceptable flavorants. Table 3.11 lists some of the tobacco and/or tobacco smoke components that have been or are used in flavor formulations.

Tables 3.12 and 3.13 list the aldehydes and ketones, respectively, reported as tobacco and/or tobacco smoke components. The aldehydes number 297 with 187 identified in tobacco smoke, 217 in tobacco, and 107 in both. The ketones number 1253 of which 736 have been identified in tobacco smoke, 799 in tobacco, and 282 in both. Tables 3.12 and 3.13 are followed by Table 3.14 which depicts the chronology of many of the studies on aldehydes and ketones in tobacco and tobacco smoke.

Aldehydes in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
56.	529-20-4	Benzaldehyde, 2-methyl-{*o*-tolualdehyde}	299, 568b, 937, 3266, 3404, 3797, 4249, 5811b	937, 172a, 174b, 568b, 1053, 3266, 3370, 3797, 4249, 5811b	3402, 3404
57.	620-23-5	Benzaldehyde, 3-methyl-{*m*-tolualdehyde}	568b, 1884, 3266, 3302, 3794, 4249, 5811b	120, 172a, 174b, 524, 568b, 1053, 2389, 2544, 2722, 2862, 2939, 3266, 3370, 3547, 3797, 3974a, 4249, 5811b	3402, 3404
58.	104-87-0	Benzaldehyde, 4-methyl-{*p*-tolualdehyde}	299, 568b, 1526, 1427, 3266, 4249, 5811b	172a, 174b, 404, 568b, 1053, 2917a, 3266, 3370, 3547, 3905, 4249	3402, 3404
59.	122-03-2	Benzaldehyde, 4-(1-methylethyl)-{cuminaldehyde}	568b, 1238, 3266, 4249	172a, 174b, 568b, 937, 1053, 1156, 3266, 4090, 4249	
60.	29344-95-4	Benzaldehyde, 2,3,4,5-tetramethyl-		2917a	
61.	487-68-3	Benzaldehyde, 2,4,6-trimethyl-	5811, 5811a, 5811b		
62.	122-78-1	Benzeneacetaldehyde {phenylacetaldehyde} 	299, 568b, 1238, 1949, 2769, 3266, 4159, 4249, 5811b	172a, 174b, 568b, 937, 1053, 1063–1066, 1068–1074, 1590a, 1662, 1949, 2282, 2286, 2337, 2389, 2544, 2917a, 3266, 3370, 3543, 3547, 3549, 3550, 3560, 3561, 4249, 5811b	
63.	4411-89-6	Benzeneacetaldehyde, α-ethylidene-{2-phenyl-2-butenal}	568b, 1587, 3266, 4249, 5811b	174b, 568b, 943, 1053, 2389, 2544, 3266, 3547, 3561, 4249, 5811b	
64.	57568-60-2	Benzeneacetaldehyde, α-(2-furanylmethylene)- 		943, 1587, 3547, 4249	
65.	65545-81-5	Benzeneacetaldehyde,α-(2-furanylmethylene)-,(*E*)-		5811	
66.	5031-83-4	Benzeneacetaldehyde, α-(2-phenylethylidene)-	5811b	3561	
67.	104-09-6	Benzeneacetaldehyde, 4-methyl-		1053, 3266	
68.	104-53-0	Benzenepropanal	5811b	172a, 174b, 1053, 3266	
69.	103-95-7	Benzenepropanal, α-methyl-4-(1-methylethyl)-{cyclamen aldehyde}		172a, 174b, 1053, 3266	
70.	80638-48-8	Benzenepropanal, 4-hydroxy-3-methoxy-	3712	5811b	
71.	120-57-0	1,3-Benzodioxole-5-carboxaldehyde {piperonal; heliotropin} 	1238, 2478, 3266, 3894, 4249	172a, 174b, 1053, 1254, 1256, 1590a, 1662, 2478, 3266, 3370, 3643, 3894, 4249	

TABLE 3.12 (continued)
Aldehydes in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
72.	4265-16-1	2-Benzofurancarboxaldehyde	568b, 4249		
73.	4250-90-2	Benzo[*g*]pteridine-10(2*H*)-acetaldehyde, 3,4-dihydro-7,8-dimethyl-2,4-dioxo-		4249	
74.	61892-65-7	[2,3′-Bipyridine]-1(2*H*)-carboxaldehyde, 3,6-dihydro-, (S)-{*N*′-formylanatabine}	568b, 3739, 3740, 4249, 5811b	64, 568b, 3550, 3973, 4236, 4249, 5811b	
75.	123-72-8	Butanal {butyraldehyde} $H_3C\text{-}(CH_2)_2\text{-}CH{=}O$	174a, 174b, 174c, 174e, 299, 314, 564, 568b, 605, 688, 764a, 1038, 1039, 1140, 1238, 1365, 1374, 1375, 1375b, 1386, 1412–1414, 1416, 1419, 1634, 1853b, 2079, 2089, 2170, 2270, 2310, 2313a, 2337, 2519, 2520, 2545, 2591, 2702, 2767, 2782, 2804, 2822, 2887, 2939, 3007, 3059, 3105, 3135, 3136, 3254, 3300, 3302, 3308, 3396, 3436, 3557, 3794, 3901, 3935, 4078, 4249, 4304, 4319, 4570a, 5034, 5049, 5079, 5135, 5136, 5770, 5811b, 5835, 5836	568b, 1550, 1893b, 2337, 2914, 3350, 3626, 3797, 3973, 3974a, 5811b	2244
76.	4390-05-0	Butanal, 4-amino- $H_2N\text{-}(CH_2)_3\text{-}CH{=}O$		555b, 3973	
77.	34764-22-2	Butanal, 3,4-dihydroxy- $HOCH_2\text{-}CHOH\text{-}CH_2\text{-}CH{=}O$	3553, 4249		
78.	2109-98-0	Butanal, 2,3-dimethyl-	4570a		
79.	97-96-1	Butanal, 2-ethyl-{diethylacetaldehyde} $(C_2H_5)_2{=}CH\text{-}CH{=}O$	568b, 1238, 4249	568b, 3186, 3188, 4249	
80.	107-89-1	Butanal, 3-hydroxy-{aldol} $H_3C\text{-}CHOH\text{-}CH_2\text{-}CH{=}O$	568b, 2170, 2702, 2939, 3302, 3876, 4249, 5079		
81.		Butanal, 3-hydroxy-2-oxo-{methylreductone} $H_3C\text{-}CHOH\text{-}CO\text{-}CH{=}O$		3797, 4249	
82.	25714-71-0	Butanal, 4-hydroxy- $HO\text{-}(CH_2)_3\text{-}CH{=}O$	3553, 4249		
83.		Butanal, 4-(2-hydroxyethoxy)- $HO\text{-}CH_2CH_2\text{-}O\text{-}(CH_2)_3\text{-}CH{=}O$	3553, 4249		
84.	96-17-3	Butanal, 2-methyl-{2-methylbutyraldehyde} $H_3C\text{-}CH_2\text{-}CH(CH_3)\text{-}CH{=}O$	299, 314, 568b, 1221, 1063–1066, 1068–1074, 1221, 1360, 1375a, 1418, 1419, 1999, 2337, 2545, 2767, 3219, 3266, 3308, 3508, 4249, 4570a, 5770, 5811b	172a, 174b, 568b, 1053, 1550, 2337, 2339a, 2917a, 3186, 3188, 3266, 4249, 5811b	1360, 1375a
85.	590-86-3	Butanal, 3-methyl-{3-methylbutyraldehyde; isovaleraldehyde} $(H_3C)_2{=}CH\text{-}CH_2\text{-}CH{=}O$	173a, 299, 314, 405, 407, 408, 568b, 605, 1039, 1063–1066, 1068–1074, 1140, 1238, 1348–1350, 1354, 1360, 1365, 1375, 1375a, 1375b, 1412–1414, 1416, 1418, 1419, 1884, 2003, 2293, 2337, 2573–2375, 2767, 2782, 2804, 2927, 3254, 3266, 3302, 3308, 3413, 3508, 3557, 3794, 3817, 4052, 4056, 4162, 4249, 4319, 4570, 5034, 5770, 5811b	172a, 174b, 568b, 647, 909, 937, 1053, 1157, 1550, 1615, 2337, 2339a, 2914, 2917a, 2939, 3188, 3266, 3350, 3370, 3626, 3797, 3974a, 4223, 4225, 4249, 5811b	1354, 1360, 1375a, 4052, 4056
86.	7729-27-3	Butanal, 4-(methylamino)- $H_3C\text{-}NH\text{-}(CH_2)_3\text{-}CHO$		4249, 4707

TABLE 3.13 (continued)
Ketones in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
242.	529-00-0	Cyclohexanone, 5-methyl-2-(1-methylethenyl)- {isopulegone}		404, 3188, 4249, 4663	
243.	89-80-5 10458-16-7	Cyclohexanone, 5-methyl-2-(1-methylethyl)-, *trans*- {menthone}	309, 568b, 1238, 1361, 1936, 3266, 4247, 4248	172a, 174b, 568b, 1053, 2339a, 2385a, 3266, 3370, 4249	
244.	14073-97-3	Cyclohexanone, 5-methyl-2-(1-methylethyl)-, (L) {*L*-menthone}	5811, 5811a, 5811b		
245.	89-82-7	Cyclohexanone, 5-methyl-2-(1-methylethylidene)-, (R)- {pulegone}		2386, 2917a, 3188, 4249, 4750	
246.	133561-49-6	Cyclohexanone, 3,3,5-trimethyl-4-(3-oxobutyl)-		5811, 5811b	
247.	18378-66-0	1-Cyclohexene-1-carboxaldehyde, 3-oxo-2,6,6-trimethyl-		5811, 5811b	
248.		2-Cyclohexene, 1-(2-oxopropyl) 3,5,5-trimethyl-	2773, 4249	2544, 4249	
249.	35692-98-9	2-Cyclohexene-1,4-dione, 2-hydroxy-3,5,5-trimethyl-		404, 943, 2092, 3219, 3188, 4249	
250.	38770-37-5	2-Cyclohexene-1,4-dione, 2,5,5-trimethyl-	5811, 5811a, 5811b		
251.	1125-21-9	2-Cyclohexene-1,4-dione, 2,6,6-trimethyl- {4-ketoisophorone; 4-oxoisophorone}	568b, 1360, 1375a, 1949, 2543, 2731, 2735, 2761, 2762, 2765, 2766, 2773, 2775, 3266, 4249, 5811b	404, 568b, 937, 1053, 1254, 1590a, 1949, 2338, 2386, 2389, 2544, 2917a, 3188, 3215, 3219, 3266, 3543, 3545, 3560, 3561, 3905, 4249	1360, 1375a
252.	930-68-7	2-Cyclohexen-1-one	299, 568b, 1371, 2506, 2507, 2543, 2545, 2601a, 2731, 2735, 2736, 2773, 2775, 3410, 3553, 3559, 4249, 4570a, 5811b	404, 568b, 3547, 3550, 4249, 5811b	2506, 2507
253.	133304-85-5	2-Cyclohexen-1-one, 3,4-dimethyl-2-hydroxy-	91c, 5811b		
254.	2748-09-6	2-Cyclohexen-1-one, 3,5-dimethyl-2-hydroxy-	91c, 5811b		
255.	2748-08-5	2-Cyclohexen-1-one, 3,6-dimethyl-2-hydroxy-	91c, 5811b		
256.	74051-80-2	2-Cyclohexen-1-one, 2-[1-(ethoximino)butyl]-5-[2-(ethylthio)-propyl]-3-hydroxy- {Sethoxydim®}		3633	
257.	41577-83-7	2-Cyclohexen-1-one, 3-ethyl-2-hydroxy-	91c, 5811b		
258.	10316-66-2	2-Cyclohexen-1-one, 2-hydroxy-	91c, 5811b		
259.	490-03-9 3400-78-0	2-Cyclohexen-1-one, 2-hydroxy-3-methyl- {diosphenol}	91c, 5811, 5811a, 5811b	2917a	
260.	55310-49-1	2-Cyclohexen-1-one, 2-hydroxy-3-propyl-	91c, 5811, 5811a, 5811b		
261.		2-Cyclohexen-1-one, 2-hydroxy-3,5,5-trimethyl-	91c		
262.	1121-18-2	2-Cyclohexen-1-one, 2-methyl-	1360, 1375a, 2543, 2761, 2773, 4249, 4570a		1360, 1375a

TABLE 3.13 (continued)
Ketones in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
263.	99-49-0 6485-40-1	2-Cyclohexen-1-one, 2-methyl-5-(1-methylethenyl)- {*l*-carvone}	568b, 2570, 2769, 3266, 3557, 4249, 5811, 5811a, 5811b	172a, 174b, 568b, 1053, 1156, 1254, 1256, 2339a, 2389, 2544, 3188, 3266, 3370, 4090, 4249, 5811, 5811a, 5811b	
264.	2244-16-8	2-Cyclohexen-1-one, 2-methyl-5-(1-methylethenyl)- {*d*-carvone}	2570, 3557, 4249	174b, 1256, 2544, 3266, 4249	
265.	43205-82-9	2-Cyclohexen-1-one, 2-methyl-5-(1-methylethyl)- {dihydrocarvone}	568b, 4249		
266.		2-Cyclohexen-1-one, 2-propyl-3-methyl- {two isomers}	4570a		
267.		2-Cyclohexen-1-one, 2,4,4-trimethyl-3-(1,3-butadienyl)-	4570a		
268.	27185-77-9	2-Cyclohexen-1-one, 2,4,4-trimethyl-3-(3-oxo-1-butenyl)-	1075, 4249	1256, 2338, 2339b, 3549, 4249, 5811b	
269.	29790-29-2	2-Cyclohexen-1-one, 2,4,4-trimethyl-3-(3-oxo-1-butenyl)-, (1*E*)-		5811b	
270.	20013-73-4	2-Cyclohexen-1-one, 2,6,6-trimethyl-		568b, 2339a, 4249, 4780	
271.	5220-49-5	2-Cyclohexen-1-one, 3-amino-	3553, 4249		
272.	67401-25-6	2-Cyclohexen-1-one, 3-(2-butenyl)-2,4,4-trimethyl-, (*Z*)-		948, 1254, 1256, 4249, 4690, 5811b	
273.	1193-18-6	2-Cyclohexen-1-one, 3-methyl-	2775, 4249, 4570a	404, 937, 2917a, 4249	
274.	89-81-6	2-Cyclohexen-1-one, 3-methyl-6-(1-methylethyl)- {*D*-piperitone}	5811b	404, 568b, 1053, 1156, 2095, 2389, 2544, 3266, 3370, 3547, 4090, 4098a, 4249, 5811b	
275.		2-Cyclohexen-1-one, 3-methyl-2-(1,3-pentadienyl)-	4570a		
276.	17369-60-7	2-Cyclohexen-1-one, 5-ethyl-2,3,4,5-tetramethyl- 		1053, 3266	
277.		2-Cyclohexen-1-one, 5-ethyl-3,4,5,6-tetramethyl- 		1053, 3266	
278.	78-59-1	2-Cyclohexen-1-one, 3,5,5-trimethyl- {isophorone}	568b, 722, 1360, 1371, 1375a, 1949, 2543, 2545, 2570, 2761, 2762, 2765–2767, 2773, 2777, 3410, 3557, 4249, 4570a, 5811b	404, 568b, 937, 943, 1254, 1949, 2338, 2339a, 2386, 2389, 2544, 2917a, 3188, 3205, 3217, 3219, 3543, 3547, 3560, 3561, 4249, 5811b	1360, 1375a

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke or vice versa.

TABLE 3.14
Chronology of Studies on Aldehydes and Ketones in Tobacco Smoke

Year	Event
1843	Acrolein (propenal) was first identified as a component in the destructive distillate from fat by Redtenbacher (3093b)
1859	Formaldehyde (methanal) was discovered by Butlerov (3A02)
1867	Formaldehyde was rediscovered by A.W. Von Hofmann (3A24)
1904	Thomas (3912) reported the presence of formaldehyde in cigarette smoke
1909	From his toxicologic study of cigarette smoke, Lehmann (2343) reported the presence of formaldehyde in cigarette smoke
1926	Neuberg and Kobel in their study of the aldehydes reported the presence of several aldehydes, including formaldehyde (2702a)
1927	Neuberg and Ottenstein (2706) report the presence of formaldehyde in tobacco smoke
1931	Neuberg and Burkard (2701) reported the presence of formaldehyde, acetaldehyde, butyraldehyde (butanal), 3-hydroxybutyraldehyde (3-hydroxybutanal, aldol), benzaldehyde, 3-pentanone, and 4-heptanone in cigarette smoke
1932	McNally (2524) reported the presence of formaldehyde and acrolein (propenal) in tobacco smoke
1933	Pfyl (2937) confirmed the finding of Neuberg and Burkard (2701) on the presence of acetaldehyde in tobacco smoke
1936	In his study of the irritant factors in cigarette smoke, Bogen (1936) classified formaldehyde, acetaldehyde, and acrolein (propenal) as "irritant factors" in cigarette smoke and rated formaldehyde as a major contributor to cigarette smoke irritation
1937	Prentiss (2988a) reported that acrolein (propenal) was a powerful lachrymator; even at 3 ppm (7 mg/m^3) acrolein was reported to be highly irritating to the conjunctiva and to the respiratory tract
1939	Proetz (2991a) attributed ciliastasis on upper respiratory tract mucosa of rabbits exposed to cigarette smoke to the aldehydes in the smoke
1939	Ribeiro (3126) reported the presence of acrolein (propenal) in tobacco smoke
1939	Wenusch (4202) reported 2-furaldehyde and acetone in cigarette smoke
1939	Roffo (3324) reported 2-furaldehyde in cigarette smoke
1939	Schmalfuss (3475) reported biacetyl (2,3-butanedione) in tobacco smoke
1940	Smirnov et al. (3A19) listed 3-pentanone as a tobacco smoke component
1954	In his catalog of the components of tobacco smoke reported to mid-1954, Kosak (2170) provided references to reports in tobacco smoke of the following aldehydes: formaldehyde [Neuberg and Ottenstein (2706), Neuberg and Burkard (2702), McNally (2524)], acetaldehyde [Neuberg and Burkard (2702), Pfyl (2937)], butyraldehyde (butanal) [Neuberg and Burkard (2702)], acrolein (propenal) [McNally (2524)], benzaldehyde [Neuberg and Burkard (2702)], and 2-furaldehyde [Wenusch (1939), Roffo (3324)]. Kosak also cataloged reports on the following ketones in tobacco smoke: 3-pentanone (diethyl ketone) [Neuberg and Burkard (2702)], 4-heptanone (dipropyl ketone) [Neuberg and Burkard (2702)], 17-tritriacontanone (dipalmityl ketone) [Schürch and Winterstein (3562)], and 2,3-butanedione (biacetyl) [Schmalfuss (3475)]
1955	In his study of the vapor phase of cigarette MSS, Laurene (2293) identified acrolein (propenal)
1956	Buyske et al. (564) reported butyraldehyde (butanal) and crotonaldehyde (2-butenal) in cigarette MSS
1959	In their review of the components of tobacco and tobacco smoke, Johnstone and Plimmer (1971) listed 18 aldehydes and ketones in tobacco smoke
1959	In anticipation of their possible utility in the identification of aldehydes and ketones that might be present in the MSS from an all-tobacco and/or an all-cellulose cigarette, Fredrickson et al. (1238) prepared over 90 2,4-dinitrophenylhydrazone derivatives for use as standards and cataloged their infrared spectra. The spectral data were used several years later by Fredrickson et al. to identify numerous aldehydes and ketones in tobacco smoke (1239)
1961	Guillerm et al. (1451a) reported the ciliastatic activity of acetaldehyde and acrolein (propenal) in liquid and in vapor form in an in vitro system. They also reported the synergistic ciliastatic activity of these two aldehydes in cigarette MSS exposure studies
1963	Horton et al. (3A11) reported that exposure of mice via inhalation to formaldehyde induced hyperplasia and metaplasia in the lung and typical hyperplastic changes in the trachea, but the tracheal tissue changes did not progress to invasive carcinoma
1963	Kensler and Battista (2083, 2084) reported significant ciliatoxicity for formaldehyde and acrolein, and their levels in cigarette MSS were reduced by passage of the smoke through a charcoal-containing filter
1963	In a study with human ciliated tonsillar epithelium, George (3A09) reported not only was phenol a strong ciliastat but also that acrolein (propenal) was an even stronger ciliastat
1963	Murphy et al. (3A17) reported that exposure of guinea pigs to low concentrations of acrolein (propenal) resulted in an increase in total respiratory flow resistance plus decreased respiratory rates and increased tidal volume
1964	Even though the Advisory Committee to the U.S. Surgeon General (3999) reported that formaldehyde and acrolein (propenal) were two of the components of cigarette MSS considered to be inhibitors of ciliastatic transport activity, the Committee concluded: No one of these [ciliastatic components] occurs at levels high enough to produce the effect noted for smoke
1964	Laurene et al. (2305) described an analytical method for the quantitative determination of acetaldehyde, acrolein (propenal), and acetone in cigarette MSS. Subsequently, an improvement in the analytical procedure for these three carbonyl components was reported by Laurene and Harbin (2302)
1964	From their study of the pyrogenesis of acrolein (propenal) from glycerol, Doihara et al. (1023) and others deduced that a tobacco smoking product that contains glycerol as a humectant has an enhanced potential for the formation and release of acrolein (propenal) during smoking [see Wynder and Hoffmann (4337)]

TABLE 3.14 (continued)
Chronology of Studies on Aldehydes and Ketones in Tobacco Smoke

Year	Event
1965	In testing the ciliatoxicity of cigarette MSS aldehydes to clam gill cilia, Wynder et al. (4330) reported that formaldehyde, acrolein (propenal), and crotonaldehyde (2-butenal) showed the highest toxicity. They also reported that acrolein was about twice as ciliatoxic as phenol in the clam gill cilia test [see also Wynder and Hoffmann (p. 253 in (4332)]. In addition to their aldehyde ciliatoxicity results, Wynder et al. (4330) also noted the serious error introduced into the results obtained in their study of the ciliatoxicity of low-molecular-weight acids in tobacco smoke
1965	To quantitate the level of formaldehyde in cigarette MSS, Newsome et al. (2782) reported on a colorimetric method involving chromatropic acid
1965/1966	Walker and Kiefer (4109) examined the effect of cigarette MSS vapor phase on clam gill cilia. Removal of the acrolein region from the chromatographed vapor phase resulted in a significant reduction in the ciliastatic activity. Contrary toxicity results were reported for the same MSS in which the levels of acrolein (propenal) and acetaldehyde were reduced by 66% and 82%, respectively, by a "hydrazide" filter. The ciliastatic activity of the vapor phase of the "hydrazide" filtered MSS was, within experimental error, the same as that of the unfiltered smoke. Wynder and Hoffmann (4337) offer a possible explanation for these contradictory results: acrolein administered alone is quite toxic, but in the cigarette smoke vapor phase, its effect is "masked" or "neutralized" by other smoke components (identity not specified)
1966	In their study of the levels of acrolein, acetaldehyde, acetone, hydrogen cyanide, nitrogen oxides, nicotine, and total solids in pipe tobacco MSS, Harbin and Laurene (1497) reported that the acrolein delivery increased as the glycerol level was increased by addition but the acrolein delivery leveled off when the glycerol addition exceeded 6%
1967	Wynder and Hoffmann (4337) discussed the conversion of the glycerol, used as a humectant in tobacco smoking products, to acrolein (propenal) during the smoking process
1968	In their study of the ciliastatic components of cigarette smoke MSS vapor phase, Dalhamn et al. (892, 893) reported that the absorption of the vapor-phase ciliastats by the fluids coating the oral cavity resulted in significant reductions of acetaldehyde (60%) and acetone (56%), i.e., significant levels of these in vitro ciliastats failed to reach the ciliated lung tissue and thus were unable to exert the ciliatoxicity asserted by some investigators
1968	In his review of the components of tobacco and tobacco smoke, Stedman (3797) listed references to some 46 aldehydes and ketones in tobacco smoke
1970	Martin and Thacker (2478) described the quantitation of several aldehydes (piperonal, ethylvanillin, vanillin) used as flavorants in cigarette tobacco
1971	Despite the reported findings of Dalhamn et al. (892, 893), the Royal College of Physicians (3363) noted that acrolein (propenal) was one of the most important ciliastatic components of tobacco smoke, possibly contributing to the causes of pulmonary disease by interfering with the self-cleansing mechanism of the lung and thereby allowing more prolonged contact between the lining of the bronchial tubes and the carcinogenic agents in the smoke
1971/1973	From their study of 85 mm nonfiltered cigarettes made from each of four varieties of flue-cured tobacco, Rathkamp et al. (3087, 3088) reported that the MSS acetaldehyde deliveries ranged from 800 to 1280 μg/cig; the acrolein (propenal) deliveries ranged from 51 to 102 μg/cig
1972	The U.S. Surgeon General (4003) classified formaldehyde as a suspected contributor to the health hazard of smoking and acrolein (propenal) as a probable health hazard in cigarette smoke
1972	Testa and Joigny (3885) reported that the per cigarette delivery of acrolein (propenal) from a cigarette made from black tobacco was 65.7 μg
1975	Tsuchiya et al. (3986a) reported that the levels of formaldehyde in fruits and vegetables ranged from 3.4 μg/g in spinach to 17.3 μg/g in apples
1976	Kitchen et al. (2111b) noted that the most significant exposure to formaldehyde is generally industrial, but formaldehyde occurs naturally in many foodstuffs, e.g., fruits and vegetables
1976	OSHA standards for exposure to air contaminants require an employee's exposure to acrolein (propenal) not exceed an 8 h time-weighted average of 0.25 mg/m^3 (0.1 ppm) in the workplace air, in any 8 h shift, during a 40 h work week
1976	Extensive experimental smoking in an unventilated room provided index levels for acrolein (propenal) that accumulated during the cigarette smoking. The industrially permitted threshold limit value (TLV) for acrolein (0.1 ppm; 0.25 mg/m^3) was only exceeded under experimental conditions where a large number of cigarettes were burned in a closed room [Weber et al. (3A25)]
1977	In his discussion of the vapor phase of cigarette MSS, Norman (2799a) listed per cigarette deliveries of 1200 and 70 μg for acetaldehyde and acrolein (propenal), respectively
1977	Mansfield et al. (2456) described an analytical method to quantitate formaldehyde in cigarette MSS
1977	In their study of the effect of inhaled acrolein (propenal) on the tumorigenicity of benzo[*a*]pyrene or *N*-nitrosodiethylamine, Feron and Kruysse (3A08) conducted inhalation and intratracheal experiments with two groups of 18 male and 18 female 6 week old Syrian hamsters. One group was exposed to 9.2 mg/m^3 (4 ppm) of acrolein in air (7 h/day, 5 day/week, 52 week). The other group was similarly exposed to acrolein via inhalation but received an intratracheal installation of 0.9% saline. All animals alive at 81 week were sacrificed. Only one female had a tracheal papilloma. Tumors at other sites were not increased *vs*. untreated controls
1977	In its assessment of tobacco smoke components reported to be ciliastatic, the Royal College of Physicians (3364) reported that acrolein (propenal) appeared to be the most important

(*continued*)

TABLE 3.14 (continued)
Chronology of Studies on Aldehydes and Ketones in Tobacco Smoke

Year	Event
1979	According to the Chemical Industrial Institute of Toxicology (CIIT) (3A04), data supporting the tumorigenicity of formaldehyde were first reported on October 8, 1979 [see Battelle Institute (3A01)]
1979	U.S. Surgeon General (4005) reported acrolein (propenal) to be one of the major toxic agents in the vapor phase of unaged cigarette MSS
1980	Swenberg et al. (3A21) reported the induction of squamous-cell carcinomas in the nasal cavities of rats exposed to cigarette MSS plus 15 ppm of formaldehyde in chambers, 30 h/week for 18 months. The authors noted that reported per cigarette deliveries for formaldehyde ranged from 20 to 90 µg; for acrolein (propenal), deliveries ranged from 10 to 40 µg. Swenberg et al. listed acrolein as a ciliatoxic agent in cigarette MSS
1981	In its report, the Battelle Institute (3A01) described the induction of tumors in rats and mice exposed via inhalation to formaldehyde
1981	According to NIOSH, workers who smoke cigarettes are exposed to additional levels of formaldehyde since cigarette MSS contains as much as 40 ppm of formaldehyde by volume. It was deduced that an individual who smokes a pack a day (20 cigarettes) would inhaled 0.38 mg of formaldehyde, whereas occupational exposure at 3 ppm could result in a daily intake of 29.0 mg (3A04)
1982	Dalbey (3A06) reported that 88 male Syrian hamsters exposed to 70 ppm of formaldehyde vapor (5 h/day, 5 days/week) for their lifetime showed no detectable respiratory tract tumors. No respiratory tract tumors were observed in a similar inhalation experiment involving male hamsters exposed to 30 ppm of formaldehyde (5 h/day, 1 day/week) for their lifetime
1982	In its assessment of the literature on formaldehyde, the IARC (3A13) reported that it considered the evidence sufficient that formaldehyde was carcinogenic to rats. However, the IARC also stated that the epidemiological data [to that time] did not provide adequate evidence to assess the carcinogenicity of formaldehyde in man
1982	The U.S. Surgeon General (4010) reported that formaldehyde and acrolein (propenal) were "tumorigenic" and each was "a major toxic agent" in the vapor phase of cigarette MSS
1982	In a discussion of low-delivered doses of alleged carcinogenic compounds, Starr (3789b) note: Even though formaldehyde has been demonstrated to be mutagenic/genotoxic in test systems of one kind or another, we do not know that is in the human case. Formaldehyde is a major chemical building block in our society. Its outright ban would cause dramatic changes in society [also see Starr in Clary et al. (3A05)]
1982	At the Chemical Industrial Institute of Toxicology (CIIT) meeting, Fayerweather stated: "When the epidemiological studies are viewed as a whole, the data suggest that formaldehyde has not been responsible for producing cancer in man." [see Fayerweather in Clary et al. (3A05)]
1983	Jenkins et al. (1932) at the Oak Ridge National Laboratory (ORNL) analyzed the MSS from 32 commercial brands of cigarettes marketed in the United States for their deliveries of specific smoke components. Included was acrolein (propenal) whose deliveries ranged from 33 to 141 µg/cig
1983	Kerns et al. (2086b) reported significant increases in squamous-cell carcinomas of the nasal cavity were observed in both strains of rats after inhaling highly cytotoxic doses of formaldehyde. However, no carcinomas were observed in mice after inhaling the same dose. In other studies to evaluate the carcinogenicity of formaldehyde, mice and hamsters were exposed via inhalation, rats via subcutaneous injection, and rabbits via exposure in oral tanks. The results from these studies have been considered inadequate to evaluate the carcinogenic risk to humans (3A06, 3A13)
1984	From its study of formaldehyde, the United States Department of Health and Human Services (USDHHS) (3A23) reported: "The data are sparse and conflicting and do not yet provide persuasive evidence of a causal relation between exposure to formaldehyde and cancer in man. It concluded: Although some epidemiological studies noted that there may be an association between formaldehyde exposure and some forms of cancer, the data from these studies are not sufficient, at this time, for quantitative risk modeling"
1984	The Environmental Protection Agency (EPA) (3A07) noted: "There may be a reasonable basis to conclude that certain exposures to formaldehyde present a significant risk of widespread harm to human beings" This statement contradicts a previous one by the EPA in 1982 that no significant risks to human were expected from formaldehyde
1984	From their assessment of components of indoor air found to be tumorigenic in laboratory animals, Sterling and Arundel (3A20) suggested that formaldehyde was potentially carcinogenic to humans
1984	Theiss et al. (3A22) reported a statistically significant increase in the number of lung adenomas in mice after inhaling air containing 15 ppm of formaldehyde for 18 weeks
1984	Acetaldehyde deliveries ranged from 18 to 2815 µg/cig for nonfiltered cigarettes [Huynh et al. (1853a), Miyake and Shibamoto (2564)]
1985	A proposal to lower the exposure limit of formaldehyde from 5 to 1 ppm was under consideration by OSHA (3A18)
1985	Although formaldehyde was reported by Starr and Gibson (3789b) to be carcinogenic in rats when administered at very high dose levels, IARC found the weight of evidence of its carcinogenicity in humans to be inadequate
1986	The IARC (1870) listed the delivery range for acrolein (propenal) in cigarette MSS vapor phase as 10–110 µg/cig and classified it as a ciliatoxic component
1985/1986	Formaldehyde was reported in two studies to induce aneuploidy [Liang and Brinkley (2363a), Oshimura and Barrett (2868a)]
1986	Brunnemann et al. (500) determined several volatile aldehydes and ketones in tobacco headspace and tobacco smoke by derivatization with 2,4-dinitrophenylhydrazine. Tobacco smoke carbonyl components identified included formaldehyde, acetaldehyde (1000 µg/cig), propionaldehyde (propanal), acrolein (propenal), isobutyraldehyde (2-methylpropanal), crotonaldehyde (2-butenal), methacrolein (2-methylpropenal), benzaldehyde (1 µg/cig), and acetone
1987	Bell et al. (243) used the formation of the 2,4-dinitrophenylhydrazone derivative of formaldehyde in SSS as the means to quantitate the level of formaldehyde in SSS

TABLE 3.14 (continued)
Chronology of Studies on Aldehydes and Ketones in Tobacco Smoke

Year	Event
1987	In its review of formaldehyde, the IARC noted that formaldehyde is carcinogenic and mutagenic only at doses far in excess of that seen in cigarette MSS. Whether formaldehyde is mutagenic at noncytotoxic dose levels remains controversial because of the small number of studies and the variability of the results (3A14). The IARC (3A15) also noted that results from some studies suggest that humans routinely exposed to formaldehyde display increased chromosomal aberrations and sister chromatid exchanges in peripheral lymphocytes. Nevertheless, rodents treated with formaldehyde in vivo gave negative results for chromosomal aberrations and assays for lethal mutations; other rodent studies on DNA damage gave equivocal results
1988	Deluca (929) described a 2,4-dinitrophenylhydrazine procedure for the collection of carbonyl compounds in ETS
1989	Formaldehyde deliveries in MSS vapor phase range from 3.4 µg for filtered cigarettes to 283 µg in unfiltered cigarettes [Schaller et al. (3427), Miyake and Shibamoto (2564)]
1990	Hoffmann and Hecht (1727) included formaldehyde, acetaldehyde, and crotonaldehyde (2-butenal) in their list of 43 tumorigenic components of tobacco and tobacco smoke. Their text accompanying the list plus the authors' disregard of how the tumorigenicity of many of the 43 components was determined experimentally raises serious questions as to why many of the components were listed
1990	The EPA (1148) cited the Hoffmann–Hecht list of 43 tumorigenic components in tobacco and tobacco MSS in their effort to indict ETS as a significant health hazard
1992	In their treatise on ETS, Guerin et al. [(3A10), see p. 197 in (1446)] at ORNL, discussed in detail the levels of formaldehyde in indoor and outdoor air. They noted: "It might be expected that ETS would be an important contributor to indoor air concentrations of formaldehyde because formaldehyde is known to be a constituent of cigarette smoke. Popular commercial cigarettes deliver approximately 20–90 µg of formaldehyde in their MSS and 1–2 mg of formaldehyde in their SSS. While this contribution may at first appear highly significant, it has generally been found to be very minor when compared with other sources"
1992	OSHA ruled that the exposure limit for formaldehyde should be reduced from 3 to 0.75 ppm
1994	OSHA (2825) in its list of 43 tumorigenic components of tobacco smoke included only formaldehyde and acetaldehyde but not crotonaldehyde (2-butenal)
1994	NCI (2683a) reported on the OSHA 1992 ruling that the exposure limit for formaldehyde should be reduced from 3 to 0.75 ppm
1994	Although formaldehyde was reported by Monticello and Morgan (2610a) to be carcinogenic in rats when administered at very high dose levels, IARC found the weight of evidence of its carcinogenicity in humans to be inadequate
1995	Formaldehyde deliveries in MSS vapor phase range from 3.4 µg for filtered cigarettes to 283 µg in unfiltered cigarettes [Schaller et al. (3427), Miyake and Shibamoto (2564)]. Acetaldehyde deliveries ranged from 18 to 2815 µg/cig for nonfiltered cigarettes [Huynh et al. (1853a), Miyake and Shibamoto (2564)]
1996	Green and Rodgman (1373) reviewed presentations during the first half century (1947–1996) of the TCRC on the subject of the identification and quantitation of aldehydes and ketones in cigarette MSS and SSS, as well as in ETS
1997/1998	Hoffmann and Hoffmann (1740, 1741), in their lists of 60 tumorigenic components of tobacco and tobacco smoke, included only two aldehydes—formaldehyde and acetaldehyde. Crotonaldehyde (2-butenal) included in the 1990 Hoffmann–Hecht list (1727) was omitted from the Hoffmann–Hoffmann list (1740), an omission that paralleled the 1994 OSHA list (2825)
1998	According to information from the Environmental Health Center (EHC) (1145a), formaldehyde is usually present at the nonirritating level of about 0.06 ppm
1999	Smith et al. discussed the IARC classification of the tobacco smoke vapor-phase components formaldehyde and acetaldehyde as IARC Group 2A [Smith et al. (3713)] and Group 2B [Smith et al. (3714)] carcinogens, respectively
2003	In a discussion of the various lists of tumorigenic components in tobacco and tobacco smoke issued between 1986 and 2003, Rodgman and Green (3300) and Rodgman (3265) noted that formaldehyde, acetaldehyde, crotonaldehyde (2-butenal), and acrolein (propenal) were included in the majority of them (1217, 1740, 1741, 1743, 1744, 1808, 1870, 2825)
2006	IARC revaluated formaldehyde and classifies it as a Group 1 carcinogen (3A03, 3A16)
	Possibly add statements are the following aldehyde–ketone studies:
2007	Joyeux et al. described a filter-tip procedure for the reduction of formaldehyde and other carbonyl components of cigarette mainstream smoke (4689).
2008	Sharifi et al. described the detection of metabolites of 2-butenal (crotonaldehyde) and 2-propenal (acrolein) in the urine of smokers (5022).
2009	Adam and Mitschke described on analytical method for the determination of vapor-phase components of cigarette smoke by single photon ionization (SPI) and time of flight mass spectrometry (TOFMS): (5034).
2010	In a new listing of cigarette smoke toxicants, Hoffmann and Hoffmann again listed several carbonyl components as hazardous components (5512). Nie et al. described the effect of cigarette paper and filter tips on the delivery of "Hoffmann analytes", among which were included several aldehydes and ketones (5546). Otte and Intorp described a new alternative analytical method for the detemination of several selected volatile "Hoffmann analytes", including carbonyl compounds, in cigarette mainstream smoke (5547). Yip et al. described the analytical determination of the contribution of glycerol added to tobacco to the content of 2-propenal (acrolein) and acetone (2-propanone) in cigarette mainstream smoke (5583).

Note: While many of the following items deal with the identification and quantitation of formaldehyde in cigarette MSS, SSS, and ETS, the evidence for the presence of formaldehyde ($H_2C{=}O$) per se is scant. Data indicate that formaldehyde is present as its hydrate, i.e., as dihydroxymethane [$H_2C(OH)_2$], which in most instances behaves chemically and biologically the same as formaldehyde.

4 Carboxylic Acids

4.1 CARBOXYLIC ACIDS

Numerous organic acids have been identified in tobacco. These volatile, nonvolatile, and amino acids have been discussed in-depth by Tso [see Chapter 24 in (3973)]. The major nonvolatile acids are 2-hydroxy-1,2,3-propanetricarboxylic (citric), hydroxybutanedioic (malic), and ethanedioic (oxalic). The minor nonvolatile acids are hydroxyacetic (glycolic), butanedioic (succinic), propanedioic acid (malonic), butenedioic (*E*) (fumaric acid), and 2-oxopropanoic (pyruvic). The major volatile acids in tobacco are acetic and formic acid, while several minor volatile acids are propanoic, 2-furancarboxylic acid (2-furoic), benzoic, α-methylbutyric, β-methylvaleric, and numerous others. Over 40 amino acids and related compounds have been identified in tobacco [Leffingwell (2337)].

The number of identified carboxylic acids in tobacco and tobacco smoke has escalated greatly since the publication in 1954 by Kosak (2170) of his list of identified components in tobacco smoke. The Kosak list included the following carboxylic acids in tobacco smoke: formic acid, acetic acid, butanoic acid, pentanoic acid (valeric acid), hexanoic acid (caproic acid), 7- and 8-carbon carboxylic acids, butanedioic acid (succinic acid), butenedioic acid (*E*) (fumaric acid), benzoic acid, 2-hydroxy-1,2,3-propanetricarboxylic acid (citric acid), and phenolic acids. Kosak questioned the identification data of many of the acids listed. Johnstone and Plimmer (1971) in their 1959 catalog of tobacco and tobacco smoke components listed 52 specific acids plus a range of saturated aliphatic acids. However, Johnstone and Plimmer listed tobacco and smoke amino acids in a different section of their report and included nicotinic acid and nicotinamide as amino acids [see Table 11 in (1971)]. Also, listed in a third section were such carboxylic acids as 3-[[3-(3,4-dihydroxyphenyl)-1-oxo-2-propenyl]oxy]-1,4,5-trihydroxycyclohexanecarboxylic acid (chlorogenic acid), 1,3,4,5-tetrahydroxycyclohexanecarboxylic acid (quinic acid), and 3,4,5-trihydroxy-1-cyclohexene-1-carboxylic acid (shikimic acid) [see Table 9 in (1971)]. Similar separation problems are encountered on examination of the various assignments of carboxylic acids in the 1968 review by Stedman [see Tables 9, 10, and 14 in (3797)]. In our report, any compound with a carboxyl group is cataloged in this chapter.

Table 4.1 summarizes the numbers of carboxylic acids and amino acids identified to date in tobacco and tobacco smoke. Their listing and references are presented in subsequent tables.

Despite the number of acids identified in tobacco and tobacco smoke, very few of the tobacco smoke acids have been indicted as toxicants. In 1964, Boyland et al. (4A01) described the induction of a bladder carcinoma in 1 of 16 mice (6.5%) implanted with a cholesterol pellet containing 3-(3,4-dihydroxyphenyl)-2-propenoic acid (caffeic acid). However, the carcinogenicity could not be attributed to the acid when it was observed that 5 of the 77 mice (6.5%) implanted with the cholesterol pellet alone developed bladder carcinomas. While caffeic acid was not included in any of the pre-2001 listings by the International Agency for Research on Cancer (IARC) (1871), Hoffmann and Wynder (1808), Hoffmann and Hecht (1727), Hoffmann et al. (1773), and Hoffmann and Hoffmann (1740, 1741, 1743), it was listed in the two 2001 publications by Hoffmann and Hoffmann (1743) and Research on Cancer (IARC) (1871), Hoffmann and Wynder (1808), Hoffmann and Hecht (1727), and Hoffmann et al. (1744), primarily because of its phenolic nature. In the latter two articles, formic, acetic, and propanoic acids are listed as major mainstream smoke (MSS) vapor-phase components [Table 5.1 in (1743), Table 2 in (1744)], and hexadecanoic acid (palmitic acid), octadecanoic acid (stearic acid), 9-octadecenoic acid (oleic acid), 9,12-octadecadienoic acid (linoleic acid), 9,12,15-octadecatrienoic acid (linolenic acid), and 2-hydroxypropanoic acid (lactic acid) are listed as major MSS particulate-phase components [Table 5.2 in (1743), Table 3 in (1744)].* By inclusion of per cigarette yields from the mid-1950s to the date of the publication, these long-chained saturated and unsaturated acids and lactic acid are listed as major particulate-phase components. No comment is made as to whether that statement about the per cigarette yields of the six acids is valid for cigarettes manufactured post-1995.

The formic, acetic, and propanoic acids listed as major MSS vapor-phase components were defined as ciliastats by Wynder et al. (4304, 4350) in the mid-1960s [see summary graph, p. 254, Table 7.31 in (4332)]. However, Wynder and Hoffmann (4332) were among the first to comment on the fact that all vapor-phase ciliastats are water soluble and therefore may be removed from the smoke stream by solution in the fluids coating the oral cavity. In their 1967 book [see p. 646 in (4332)], they stated:

> In man's manner of smoking, however, volatile components are retained to a significant degree in the oral cavity and may, therefore, be far less important than when tested experimentally.

The validity of their 1967 statement had been demonstrated by the results of studies in 1964 by Rodgman et al. (3306,

* From a comparison of the listings in (1743) and (1744), it should be noted that in the particulate-phase acids listed in (1744), stearic acid has been inadvertently omitted and its per cigarette MSS yield assigned to palmitic acid.

TABLE 4.1
Acids Identified in Tobacco and Tobacco Smoke to Date

Acid Category	Total	Smoke	Tobacco	Tobacco and Smoke	Reference
Carboxylic acids	52	37	43	29	Table 8 in (1971)
	787	380	656	249	Table 4.3
Amino acids	28	4	26	2	Table 11 in (1971)
	117	36	117	36	Table 4.10

4A02) and subsequently in 1968 by Dalhamn et al. (892) on the removal of substantial amounts of water-soluble vapor-phase ciliastats from inhaled MSS by the oral cavity fluids.

It is interesting to note that all but two [formic acid, octadecanoic acid (stearic acid)] of the MSS vapor-phase and particulate-phase acids discussed above—whether identified in tobacco, tobacco smoke, or both—are listed by Doull et al. (1053) as compounds included in the flavor formulations added to a tobacco blend by U.S. cigarette manufacturers to enhance consumer acceptability of the product.

Table 4.2 lists the tobacco and/or smoke carboxylic acids that, according to the Doull et al. listing (1073), are or have been used recently as components in flavor formulations for tobacco. It should also be noticed that the flavor ingredient additions in Table 4.2 include 15 amino acids.

Table 4.3 is a catalog of the carboxylic acids identified to date in tobacco, tobacco smoke, and tobacco substitute smoke. Of the 787 components listed, 380 have been identified in smoke, 656 in tobacco, and 249 in both. Because of the recent interest in several amino acid degradation products generated during the tobacco smoking process, a separate section (Section 4.2) is devoted to the amino acids and a discussion of their behavior during pyrolysis and the smoking process.

4.2 AMINO ACIDS AND RELATED COMPOUNDS

Amino acids, both as free acids and as acids bound within protein molecules, are present in all of the tobacco types (flue-cured, burley, Oriental, Maryland) used in the American tobacco blend.

The diversity and levels of amino acids in various tobaccos have been presented by Gori [see Table 2 in (1329), Table 2 in (1330)] and Tso and Chaplin [see Table 8 in (3975)]. Leffingwell (2337) in his report on nitrogen components of leaf and their relationship to smoking quality in 1976 reported that there were 43 amino acids isolated from tobacco. Examples of amino acids occurring free and/or bound in tobaccos include α- and β-alanine, α- and γ-aminobutyric acid, arginine, aspartic acid, cysteic acid, cysteine, cystine, glutamic acid, glycine, histidine, isoleucine, leucine, lysine, methionine, norleucine, ornithine, phenylalanine, proline, serine, threonine, tryptophan, tyrosine, and valine (3983b).

The presence in cigarette MSS of numerous free amino acids and amino acid–derived compounds was demonstrated in the mid-1950s. This occurred soon after the publication of the results of several cigarette smoke–related epidemiological and biological studies led to a massive escalation in tobacco smoke composition studies; e.g., Buyske et al. (562) reported the identification of glutamic acid and its derivative glutamine (glutamic acid 5-amide) in tobacco smoke. Other amino acids identified in tobacco smoke include alanine, aspartic acid (and asparagine), cysteine, glycine, leucine, ornithine, phenylalanine, proline, serine, threonine, and valine [Ishiguro and Sugawara (1884)].

In the early 1960s, pyrocoll (dipyrrolo[*a,d*]pyrazine-5,10-dione) was identified in cigarette MSS by Mold et al. (2592) who proposed that the amino acid proline—either free or bound—was its precursor. During their study of the isolation and identification of *N*-heterocyclic components (the indoles and carbazoles) in cigarette MSS, Rodgman and Cook (3279) confirmed the presence of pyrocoll. Two decades earlier, Van Order and Linwall (4B01) had demonstrated that dry distillation of the amino acid tryptophan yielded indole and 3-methylindole (skatole), both of which were subsequently identified as tobacco smoke components by the isolation and identification of *N*-heterocyclic components (the indoles and carbazoles) in cigarette MSS, Rodgman and Cook (3279). Roberts [see citation in the isolation and identification of *N*-heterocyclic components (the indoles and carbazoles) in cigarette MSS, Rodgman and Cook (3279)] had also identified indole as a component of burley tobacco.

By means of pyrolysis studies (850°C, nitrogen atmosphere) with the amino acids lysine, leucine, and tryptophan, Patterson et al. (2902) demonstrated that each of the three amino acids yielded the *N*-heterocyclic compounds indole, quinoline, isoquinoline, several nitriles, and a series of PAHs ranging in complexity from bicyclic to tetracyclic (their findings are summarized in Table 4.4). In their study, B[*a*]P was found only in the pyrolysate from leucine. From their own findings and from a previous report by Jarboe and Rosene (1923a) that quinoline and isoquinoline were components of a nicotine pyrolysate, Patterson et al. (2902) suggested that the precursors in tobacco of the aza-arenes quinoline and isoquinoline in tobacco smoke might be nicotine and/or the amino acids. They also reported that tryptophan, on a per mole pyrolyzed basis, yielded a phenol fraction whose weight was more than 5 times that generated from lysine and about 30 times that from leucine.

In another series of experiments, Patterson et al. (2903) reported (1) the effect of the pyrolysis temperature on the composition of the pyrolysate from the amino acid phenylalanine with emphasis on the levels of PAHs generated and (2) the effect of other compounds (tryptophan or pyrrole) on the composition of the pyrolysate when mixtures of equimolar

TABLE 4.2
Tobacco and/or Tobacco Smoke Carboxylic Acids Used in Flavor Formulations

CAS No.	Chemical Abstracts Nomenclature	As Listed by Doull et al. (1053)	Identified in

58.	614-75-5	Benzeneacetic acid, 2-hydroxy-	1626, 1884, 2722, 2939, 3302, 3712, 3797, 4163, 4249, 4377, 5811b	2939, 3797, 3973, 3974a, 4163, 4249, 4377, 5811b	
59.	621-37-4	Benzeneacetic acid, 3-hydroxy-	1626, 1884, 2722, 2939, 3302, 3712, 3737, 3741, 3743, 3797, 4113, 4163, 4249, 4377, 5811b	2939, 3797, 3973, 3974a, 4163, 4249, 4377, 5811b	3395
60.	156-38-7	Benzeneacetic acid, 4-hydroxy-	101, 1626, 1884, 1886, 2722, 2939, 3302, 3712, 3797, 4113, 4163, 4249, 4377, 5811b	120, 908, 2722, 2939, 3532, 3560, 3561, 3973, 3974a, 4163, 4249, 4377, 5811b	3393, 3395
61.	306-08-1	Benzeneacetic acid, 4-hydroxy-3-methoxy- {homovanillic acid}	3712, 3737, 3741, 3743, 4113, 4249, 5811b		
62.	343-65-7	Benzenebutanoic acid, α,2-diamino-γ-oxo- {kynurenine} 		4249	
63.	88-99-3	1,2-Benzenedicarboxylic acid {phthalic acid}	1886, 2939, 3053, 3061, 3302, 3308, 3496, 3737, 3741, 3743, 4249, 4319, 5811b	2356, 2386, 4249, 4677, 5811b	
64.	121-91-5	1,3-Benzenedicarboxylic acid {isophthalic acid}	1981, 4249		
65.	100-21-0	1,4-Benzenedicarboxylic acid {terephthalic acid}	2939, 5811b	120, 1221, 2079, 2270, 2283, 3797, 3973, 3974a, 5079, 5439, 5811b	
66.	501-52-0	Benzenepropanoic acid {3-phenylpropionic acid; hydrocinnamic acid}	568b, 1360, 1364, 1371, 1375a, 2543, 2761, 2762, 2765, 2766, 2773, 2775, 3266, 3308, 3410, 3506, 3553, 3555, 4249, 5811b	172a, 174b, 568b, 1053, 2092, 3266, 3555, 3973, 4249, 5811b	1360, 1375a
67.	156-05-8	Benzenepropanoic acid, α-hydroxy- {phenyllactic acid} C_6H_5-CH_2-CH_2OH-COOH		120, 2270, 2722, 3532, 3973, 3974a, 4249

TABLE 4.3 (continued)
Carboxylic Acids in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
68.	7326-19-4	Benzenepropanoic acid, α-hydroxy-, (R)-		3560, 3561	
69.	4593-90-2	Benzenepropanoic acid, β-methyl-	4249, 5811b		
70.	156-06-9	Benzenepropanoic acid, α-oxo- {phenylpyruvic acid}		3797, 3973, 3974a, 4249	
71.	24696-05-7	Benzenepropanoic acid, 2-(β-*D*-glucopyranosyloxy)-		4249, 4915	
72.		Benzenepropanoic acid, dihydroxy-methoxy-	3737, 3741, 3743		
73.		Benzenepropanoic acid, 2-(methylnitrosamino)- 	1013	1008, 1009	
74.	3714-73-6	Benzenepropanoic acid, 2,3-dihydroxy-	3712, 3737, 3741, 3743, 4249, 4897, 5811b		
75.	96937-38-1	Benzenepropanoic acid, 2,3-dihydroxy-ar-methyl-	3737, 3741, 3743, 4249, 4897, 5811b		
76.	5631-68-5	Benzenepropanoic acid, 2,4-dihydroxy-	5811a		
77.	10538-47-3	Benzenepropanoic acid, 2,5-dihydroxy-	101, 3712, 3737, 3741, 3743, 4249, 4897, 5811b	5811b	
78.	96937-34-7	Benzenepropanoic acid, 2,5-dihydroxy-ar-methyl-	3737, 3741, 3743, 4249, 4897, 5811b		
79.	98114-50-2	Benzenepropanoic acid, 2,6-dihydroxy-	5811a		
80.	495-78-3	Benzenepropanoic acid, 2-hydroxy-	3737, 3741, 3743, 4249, 4897, 5811b	1305b, 3973, 3974a, 4249, 5668	
81.	1078-61-1	Benzenepropanoic acid, 3,4-dihydroxy- {dihydrocaffeic acid}	101, 3712, 3737, 3741, 3743, 4113, 5811b	970, 3797, 3973, 3974a, 5811b	
82.	96961-47-6	Benzenepropanoic acid, 3,4-dihydroxy-2,5,6-trimethyl-	3712, 3737, 3741, 3743, 4249, 4897, 5811b		
83.	96937-33-6	Benzenepropanoic acid, 3,4-dihydroxy-ar-methyl-	3737, 3741, 3743, 4249, 4897, 5811b		
84.	621-54-5 33393-93-0	Benzenepropanoic acid, 3-hydroxy-	1884, 2939, 3302, 3712, 3737, 3741, 3743, 3797, 4249, 4377, 5811b	2939, 3973, 3974a, 4249, 4377, 4951	
85.	26539-01-5	Benzenepropanoic acid, 3,5-dihydroxy	5811a		
86.	501-97-3	Benzenepropanoic acid, 4-hydroxy-	1626, 2939, 3302, 3712, 3737, 3797, 3741, 3743, 4163, 4249, 4377, 5811b	2722, 2939, 3532, 3560, 3561, 4163, 4249, 4377, 4951, 5811b	
87.	156-39-8	Benzenepropanoic acid, 4-hydroxy-α-oxo-	1871a, 3712, 4249, 5811b		
88.	1135-23-5	Benzenepropanoic acid, 4-hydroxy-3-methoxy- {hydroferulic acid}	596, 3712, 3737, 3741, 3743, 4249		
89.	96937-36-9	Benzenepropanoic acid, ar,ar-dihydroxy-ar-methoxy-	4249, 4897, 5811b		
90.	96937-35-8	Benzenepropanoic acid, ar,ar-dihydroxy-ar-methyl-	4249, 4897, 5811b

TABLE 4.3 (continued)
Carboxylic Acids in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
269.	7416-57-1	Dodecanoic acid, 10-methyl- H_3C-CH_2 $CH(CH_3)$-$(CH_2)_8$-COOH		4249, 4964	
270.	7548-13-2	2,6,10-Dodecatrienoic acid, 3,7,11-trimethyl-		2917a	
271.	1289-45-8	Dodecenoic acid	809, 3293		
272.	4412-16-2	2-Dodecenoic acid		3547	
273.	3625-52-3	Dotriacontanoic acid H_3C-$(CH_2)_{30}$-COOH	101, 3263, 3327a, 5811b		
274.	25448-01-5	Eicosadienoic acid		4249, 4753	
275.	506-30-9	Eicosanoic acid {arachidic acid} H_3C-$(CH_2)_{18}$-COOH	60, 101, 172, 257, 258, 765, 1348, 1586, 1785, 2570, 2767, 2939, 3302, 3308, 3557, 4030, 4249, 4280, 4719, 5811b	60, 101, 908, 1785, 2389, 2544, 2593, 2939, 3974a, 4249, 4280, 5811b	
276.	36332-93-1	Eicosanoic acid, 18-methyl- H_3C-CH_2-$CH(CH_3)$-$(CH_2)_{16}$-COOH	2570, 4249, 4964	2769, 3974a, 4249	
277.	59708-73-5	Eicosanoic acid, 19-methyl- $(H_3C)_2$═CH-$(CH_2)_{17}$-COOH		3974a, 4249, 4719	
278.	506-32-1	5,8,11,14-Eicosatetraenoic acid, (all-*Z*)- {arachidonic acid}	3797	2939, 3974a, 4249	
279.	26764-41-0	Eicosenoic acid	60, 4249	60, 4249	
280.	144-62-7	Ethanedioic acid {oxalic acid} HOOC-COOH	765, 1375a, 1377, 1886, 2210, 2939, 3053, 3060, 3061, 3302, 3308, 3496, 3555, 4249, 4304, 4319, 5079, 5467, 5811b	120, 256, 385, 555, 634, 677b, 826a, 835, 836, 838, 839, 963, 1063–1066, 1068–1074, 1289, 1330, 1332, 1333, 1548, 1923, 1933a, 1982, 2014, 2079, 2154, 2270, 2283, 2337, 2338, 2356, 2529, 2532, 2543, 2545, 2688, 2761–2763, 2765, 2766, 2891, 2939, 2947c, 3029, 3053, 3060, 3107, 3194, 3555, 3655b, 3701a, 3797, 3974a, 3976, 3984, 3973, 3974b, 4131, 4249, 5079, 5108, 5109, 5126, 5244, 5381, 5389, 5419, 5477, 5745, 5749, 5753, 5764, 5832, 5896	1375a, 1377, 2210
281.	43058-40-8	Ethanedioic acid, labeled with ^{14}C {oxalic acid-^{14}C}	2763, 4249	2763, 4249	
282.	6276-03-5	9*H*-Fluorene-1-carboxylic acid	396, 2939, 3302, 4249	3974a

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke or vice versa.

quantities of tryptophan and phenylalanine or pyrrole and phenylalanine were pyrolyzed. The results from this study are summarized in Table 4.5. The difference between the pyrogenesis of PAHs from phenylalanine and the mixture of equimolar quantities of phenylalanine and the amino acid tryptophan prompted Patterson et al. (2903) to propose the addition of amino acids to tobacco as a possible means to control the PAH content of the CSC:

> These results suggest the possibility that aromatic hydrocarbon content of tobacco "tar" may be affected by the amino acid composition of the tobacco and that it might be possible to affect deliberately the amount of aromatics and bases formed by adding suitable additives, such as amino acids, to the tobacco.

Of course, in 1971 when Patterson et al. offered this suggestion, the presence in amino acid pyrolysates of the so-called cooked food mutagens and the inordinately high mutagenicity of several of them were unknown.

Higman et al. (1647) also reported the generation of PAHs, phenols, pyridines, indole, quinoline, and other aromatic bases during the pyrolysis of amino acids and proteins from tobacco [cf. review on pyrogenesis of smoke components

[a] Pyrolyzed as lysine monohydrochloride.

by Chortyk and Schlotzhauer (722)]. The pyrolysis results reported by Higman et al. are summarized in Table 4.6.

Tryptophan was also found to be the precursor in tobacco of two other *N*-heterocyclic compounds, namely, harman (1-methyl-9*H*-pyrido[3,4-*b*]indole) and norharman (9*H*-pyrido[3,4-*b*]indole), both present in tobacco smoke. These compounds were originally identified in tobacco and tobacco smoke by Philip Morris R&D personnel in 1961 and 1962 [Poindexter and Carpenter (2972)] and in 1963 [Poindexter et al. (2972)]. That tryptophan was indeed a precursor in tobacco of the two harmans in smoke was demonstrated by addition of radiolabeled tryptophan to cigarette tobacco and identification of radiolabeled harman and norharman in the MSS.

In the mid-1970s, pyrolysis studies with several amino acids led to the isolation and identification of several additional polycyclic *N*-heterocyclic compounds, which are reported not only to be tumorigenic to mouse skin but also to show inordinately high mutagenicity when tested in the Ames bioassay with *Salmonella typhimurium*. The impetus for these particular amino acid pyrolysis studies was not the attempt to define the relationship between tobacco leaf precursors and tobacco smoke components but the observation that the extracts of broiled, fried, or roasted foodstuffs (meat, fish, poultry, etc.) were highly mutagenic in the Ames bioassay (*S. typhimurium*). These *N*-heterocyclic compounds, all amines, derived from the amino acids and/or proteins in heated foodstuffs, were often described as "cooked food" mutagens. Eventually they were defined as *N*-heterocyclic amines. In a later chapter, the *N*-heterocyclic amines will be discussed in greater detail than in this chapter.

The studies in the 1970s on the tumorigenicity and mutagenicity of extracts of cooked foodstuffs were reminiscent of the studies in the 1920s by Kennaway (2074–2076, 2080) who reported the tumorigenicity of extracts of heated foodstuffs or pyrolysates from heated organic compounds such as cholesterol and by Roffo (4A03–4A05) who reported the tumorigenicity of pyrolyzed cholesterol. Subsequently it was shown that many of the foodstuff pyrolysates and the cholesterol pyrolysates contained a spectrum of PAHs, including B[*a*]P. Identification of the highly mutagenic *N*-heterocyclic compounds in amino acid pyrolysates was followed by identification of some of them not only in the broiled/roasted meats but also in mainstream CSC.

In 1977, Sugimura et al. (3829) reported the identification of the potent mutagens 3-amino-1-methyl-5*H*-pyrido[4,3-*b*]indole (coded Trp-P-2) and 3-amino-1,4-dimethyl-5*H*-pyrido[4,3-*b*]indole (coded Trp-P-1) in pyrolysates from tryptophan. The next year, Yamamota et al. (4365a) identified two additional highly mutagenic compounds in pyrolysates from glutamic acid: 2-aminodipyrido[1,2-*a*:3′,2′-d]imidazole (coded Glu-P-2) and 2-amino-6-methyldipyrido[1,2-*a*:3′,2′-*d*]imidazole (coded Glu-P-1).

Table 4.7 lists several polynuclear *N*-heterocyclic amines which exhibit extremely high mutagenicity levels in the Ames bioassay, are amino acid pyrolysis products, and have been identified in various broiled, fried, or roasted foodstuffs as well as in CSC [Sugimura (3828c)]. On a per microgram basis, B[*a*]P in the Ames bioassay with *S. typhimurium* (Strain TA 98) shows about 200 revertants/μg. Several of the amino acid-derived compounds in Table 4.7 exceed the B[*a*]P effect with the TA 98 strain by factors ranging from about 10 to over 2100.

Yoshida and Matsumoto (4388) reported the identification of two α-carbolines in CSC: 2-amino-9*H*-pyrido[2,3-*b*]indole (coded AαC) and 2-amino-3-methyl-9*H*-pyrido[2,3-*b*]indole (coded MeAαC). These and several other such compounds were reported in CSC by Yamashita et al. (4367, 4368). The quantitative levels of the possibly amino acid-derived, mutagenic *N*-heterocyclics in CSC are shown in Table 4.7. In their studies, they emphasized in particular the identification and quantitation of 2-amino-3-methylimidazo[4,5-*f*]quinoline (coded IQ) because of its inordinately high mutagenicity (found

[c] Pyrolysis involved equimolar quantities of phenylalanine and pyrrole (total mol. wt. = 232).

to be 433,000 and 490,000 revertant/μg in several determinations) in the Ames bioassay with *S. typhimurium* strain TA98.

Demonstration of the mutagenicity of the compounds listed in Table 4.7 was followed by demonstration of their tumorigenicity in various laboratory animals. Ohgaki et al. (2849b) demonstrated the tumorigenicity of 2-amino-3-methylimidazo[4,5-*f*]quinoline (IQ) in mice. Takayama et al. (3862c) and Tanaka et al. (3865c) reported its tumorigenicity in rats. 3-Amino-1,4-dimethyl-5*H*-pyrido[4,3-*b*]indole (Trp-P-1) and 3-amino-1-methyl-5*H*-pyrido[4,3-*b*]indole (Trp-P-2) were reported to be tumorigenic in mice by Matsukura et al. (2491a) and in rats by Hosaka et al. (1835a) and Takayama et al. (3862d).

Ohgaki et al. (2849b) reported that 2-amino-6-methyldipyrido[1,2-*a*:3′,2′-*d*]imidazole (Glu-P-1), 2-aminodipyrido[1,2-*a*:3′,2′-*d*]-imidazole (Glu-P-2), 2-amino-9*H*-pyrido[2,3-*b*]indole (AαC), and 2-amino-3-methyl-9*H*-pyrido[2,3-*b*]indole (MeAαC) were tumorigenic in mice, and Takayama et al. (3862d) reported Glu-P-1 and Glu-P-2 to be tumorigenic in rats.

In a 1989 manuscript which was subsequently published, Hoffmann and Hecht (1727) discussed amino acid–derived aromatic amines in cigarette MSS as follows:

> Of the known carcinogenic pyrolysis products of the amino acids, so far only 2-amino-3-methylimidazo(4,5-*f*)quinoline has been detected in trace amounts of 0.26 ng in the smoke of a Japanese filter cigarette [Yamashita et al. (4368)].

Apparently, Hoffmann and Hecht had overlooked not only the reports of the identification in CSC of several other known "carcinogenic" pyrolysis products of amino acids, e.g., 2-amino-9*H*-pyrido[2,3-*b*]indole (A*a*C) and 2-amino-3-methyl-9*H*-pyrido[2,3-*b*]-indole (MeA*a*C) (4388) or 3-amino-1,4-dimethyl-5*H*-pyrido[4,3-*b*]indole (Trp-P-1) and 3-amino-1-methyl-5*H*-pyrido[4,3-*b*]indole (Trp-P-2) (4367),

but also the reports on the tumorigenicity of several other *N*-heterocyclic amines in different laboratory animals (1835a, 2491a, 2849, 2849a, 2849b, 3862b, 3862c, 3865c).

Table 4.8 summarizes the reported MSS levels of the *N*-heterocyclic amines considered to be significant tumorigens by Hoffman and Hoffmann (1740, 1741) plus the assessment of the IARC (1870) on their tumorigenicity in laboratory animals and humans.

During tobacco growth, curing, aging, and/or the smoking process, the amino acids in tobacco may react with ammonia and/or amino acids to yield Amadori compounds which, when heated during the smoking process, will generate a variety of pyrazines [Green et al. (1376)]. Many of the pyrazines found in tobacco smoke are highly flavorful and contribute uniquely to the aroma and taste not only of tobacco smoke but also of a variety of consumer food products [Maga and Sizer (1973)] such as coffee, tea, cocoa, roasted peanuts, and roasted, broiled, or fried meats, poultry, and fish.

Table 4.9 lists the tobacco and/or smoke amino acids that, according to the Doull et al. listing (1073), are or have been used recently as components in flavor formulations for tobacco. In their tabulation of possible flavorants for tobacco smoking products, Leffingwell et al. (2341) listed the contributions to tobacco smoke taste and aroma of 23 amino acids added individually to cigarette tobacco filler.

Table 4.10 lists the amino acids and related compounds identified in tobacco, tobacco smoke, and tobacco substitute smoke. In Table 4.10, a total of 117 such components are listed of which 36 have been identified in smoke, 117 in tobacco, and 36 in both smoke and tobacco.

5 Esters

While no esters were reported in tobacco smoke by Kosak (2170) in his 1954 compilation of reported tobacco smoke components, the number of esters in tobacco and/or its smoke has increased dramatically over the years and now exceeds 1000. In 1955, Latimer (2270) collated and reported component data from chemical abstracts and listed only one set of esters reported in tobacco and its smoke, the "glycerides." In 1959, Johnstone and Plimmer (1971) listed 16 identified esters from these two sources. Between the Johnstone and Plimmer review and that of Stedman (3797) in 1968, the number of identified esters in tobacco and/or smoke escalated to over 300.

The research leading to the major part of the increase involved identification of the following classes of esters: (1) esters from long-chained aliphatic alcohols and saturated and unsaturated acids, (2) esters from solanesol and acetic acid and numerous saturated and unsaturated acids, (3) esters from several phytosterols and numerous saturated and unsaturated acids, and (4) β-amyrin and numerous saturated and unsaturated acids.

One other significant finding that stimulated much subsequent research on sugar esters was the isolation, identification, and synthesis of a specific ester in Oriental tobacco by Schumacher (3535) in 1960 and its identification a year later in Oriental tobacco smoke by Rodgman and Cook (3278). The ester was 6-acetyl-2,3,4-*tris*-*d*-3-methylvaleryl-β-*D*-glucopyranoside, i.e., glucose esterified with the two aliphatic acids, acetic and 4-methylpentanoic (β-methylvaleric). The Schumacher research leading to the identification of this ester was described in detail by Green and Rodgman (1373) during the Symposium of the *50th Tobacco Research Chemists' Conference*.

In his 1968 review of tobacco and smoke components, Stedman [see p. 165 and Table VI in (3797)] discussed at some length the procedures used to identify 272 esters of long-chained aliphatic alcohols in tobacco smoke. However, Stedman not only failed to cite the source of his discussion, an article by Rodgman et al. (3294), but also omitted from his text and ester tabulation that an identical series of esters was identified by Rodgman et al. in an aliphatic ester fraction obtained from Rowland and Latimer who had isolated the fraction from flue-cured tobacco (3358) during their 1958 study of the solanesyl esters in tobacco.

The identification of the numerous esters in the aliphatic ester fraction from tobacco and smoke led to the identification of a series of solanesyl and phytosteryl esters of saturated and unsaturated aliphatic acids in tobacco and smoke (3296) and a similar series of β-amyrin esters in tobacco by Fredrickson (1230).

As mentioned previously, the characterization of the glucose ester in tobacco by Schumacher (3535) and the discovery that it generated the flavorful acid, 4-methylpentanoic (β-methylvaleric) during the smoking process, led many years later to a series of studies aimed at determining the structure of the sucrose esters in tobacco. Despite the numerous studies, seldom was the precise structure of a sucrose ester defined. The various studies included those of Rivers (3185) in the early 1980s and of Severson et al. (3606), Schlotzhauer et al. (3473), Wahlberg et al. (4102), and Danehower (896) in the mid- to late 1980s.

Several studies on tobacco and tobacco smoke composition, including studies of the long-chained aliphatic ester fraction, ultimately led to an interesting extrapolation by Green and Rodgman [see endnote 39 in (1373)] on the number of smoke components. Because of the limitations of analytical technology at the time of the Rodgman et al. study (3294) on the long-chained aliphatic ester fraction from tobacco and smoke, the higher-molecular-weight esters could neither be determined nor characterized. However, it was noted that qualitatively the tobacco ester fraction and the smoke ester fraction were similar: Every ester identified by Rodgman et al. in the smoke ester fraction was found in the tobacco ester fraction. Minor quantitative differences between the levels of individual esters in the two fractions were observed. With much improved analytical technology in the late 1980s, Arrendale et al. (103) in their study on the long-chained aliphatic ester fraction in tobacco were able to identify not only many of the esters identified earlier in tobacco and smoke by Rodgman et al. but also many more higher-molecular-weight esters. Logic would dictate that if every ester identified in the Rodgman et al. study was present in both tobacco and smoke, then every tobacco ester identified by Arrendale et al. when included in the smoke list results in a substantial increase in the number of smoke components.

Examination of the esters listed in Table 5.3 indicates that most of the esters identified in tobacco smoke are found in the particulate phase. An ester that exists predominantly in the vapor phase of tobacco smoke and was identified in cigarette MSS vapor phase by Laurene (2310) in 1959 and Grob (1413) in 1962 was the methyl ester of acetic acid. Since then, acetic acid methyl ester has been identified in cigarette MSS vapor phase in over 50 different studies.

Because many esters have an aroma and/or taste acceptable to the consumer, the list of individual compounds used as tobacco ingredients by U.S. tobacco manufacturers contains numerous esters. Such a list was prepared by Doull et al. (1053) from information provided by the U.S. tobacco product manufacturers. A detailed examination of the Doull et al. list by Rodgman (3266) revealed that many of the added ingredients had been identified in additive-free tobacco and/or its smoke.

As Rodgman noted, the compounds added as ingredients to cigarette tobacco may fall into one of the following categories:

- It is a component of one or more of the tobacco types (flue-cured, Oriental, burley, Maryland) commonly used in cigarette blends.
- It is a component of cigarette MSS.
- It is a component of both tobacco and tobacco smoke.
- It is not a component of either the tobaccos or their smoke.

An ingredient compositionally similar to but not identical with a tobacco leaf or smoke component may be categorized in two ways: It is either an isomer or a homolog of a compound identified in natural tobacco leaf and/or its smoke. As noted, there are compounds used as cigarette ingredients that do not fall into any of the first three categories listed.

In the broad spectrum of chemistry, biochemistry, and biology, cases exist where the properties of one homolog vary significantly from those of another or where the properties of one isomer differ significantly from those of another. For example, whether classified as a "Group 2A carcinogen" by the International Agency for Research on Cancer (IARC) (1868a), or a significant carcinogen in cigarette MSS (1727), or overall as a borderline carcinogen by others (983), the specific tumorigenicity of mouse skin painted or subcutaneously injected benz[*a*]anthracene (B[*a*]A) is insignificant compared to that of its homolog, 7,12-dimethylbenz[*a*]anthracene (DMB[*a*]A), one of the four most potent tumorigenic polycyclic aromatic hydrocarbons (PAHs) known (983). The isomeric $C_{20}H_{12}$ PAHs benzo[*e*]pyrene (B[*e*]P) and benzo[*a*]pyrene (B[*a*]P) differ markedly in their specific tumorigenicities in studies involving mouse skin painting or subcutaneous injection (983). B[*e*]P under the usual laboratory test conditions is found to be essentially nontumorigenic on skin painting or subcutaneous injection, whereas the isomeric B[*a*]P under the same conditions is one of the most potent tumorigens known.

Of the 460 individual ingredients listed by Doull et al. [1053, see Table 1 in (3266)], 117 (25%) are esters (Table 5.1) and all have been approved for use by the U.S. Food and Drug Administration or by the Flavor and Extract Manufacturers Association (FEMA). Of the 117 esters listed by Doull et al., 46 (39%) have been identified in untreated cigarette tobacco and/or its smoke (indicated by + in Table 5.1), and 18 are either a homolog (indicated by H in Table 5.1) or an isomer (indicated by I in Table 5.1) of a known tobacco and/or smoke component.

Doull et al. (1053) also listed 146 mixtures reportedly used by U.S. manufacturers as flavoring ingredients in tobacco products [see Table 2 in (3266)]. Many of these mixtures are obviously multicomponent items, and detailed analyses of several of them (cardamom, cocoa, coffee, davana, licorice) indicated the presence of esters [see Table 3 in (3266)] listed by Doull et al. (1053). A similar situation exists with regard to flavorful mixtures used on tobacco products by non-U.S. manufacturers. Some 34 such mixtures are used on tobacco products by non-U.S. manufacturers [172a, 174a, 174b, 174c, see Table 7B in (3266)].

Compounds (48 in number) other than those in the Doull et al. list are used in tobacco products by manufacturers in countries other than the United States [172a, 174a, 174b, 174c, see Table 7A in (3266)]. Among the 48 esters are 19 (21%) that have been identified in untreated cigarette tobacco and/or its smoke (indicated by + in Table 5.2).*

Table 5.3 lists the 1094 esters identified to date in tobacco and/or tobacco smoke; 643 have been identified in tobacco smoke, 987 in tobacco, and 536 in both tobacco and/or tobacco smoke.

* Inadvertently, two esters (methyl anthranilate and methyl 2-octynate) already included in Table 1 in (3266) were included in Table 7A in (3266).

126-64-7	Benzoic acid, 3,7-dimethyl-1,6-octadien-6-yl ester	–	–
87-20-7	Benzoic acid, 2-hydroxy-, 3-methylbutyl ester	–	+
539-90-2	Butanoic acid, 2-methylpropyl ester	–	–
76-50-6	Butanoic acid, 3-methyl-, *endo*-1,7,7-trimethylbicyclo[2,2,1]heptan-2-yl ester	–	+
103-38-8	Butanoic acid, 3-methyl-, phenylmethyl ester	–	+
16409-46-4	Butanoic acid, 3-methyl-, 5-methyl-2-(1-methylethyl)-cyclohexanyl ester	–	–
104-57-4	Formic acid, phenylmethyl ester	–	+
540-07-8	Hexanoic acid, pentyl ester	–	–
591-68-4	Pentanoic acid, butyl ester	–	–
7549-33-9	Propanoic acid, anisyl ester	–	–
105-68-0	Propanoic acid, 3-methylbutyl ester	–	–
103-28-6	Propanoic acid, 2-methyl-, phenylmethyl ester	–	+
78-35-3	Propanoic acid, 2-methyl-, 3,7-dimethyl-1,6-octadien-6-yl ester	–	–
97-62-1	Propanoic acid, 2-methyl-, ethyl ester	–	–
103-59-3	Propanoic acid, 2-methyl-, 3-phenyl-2-propen-1-yl ester	–	–
110-27-0	Tetradecanoic acid, 1-methylethyl ester	–	–

TABLE 5.3
Esters in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
1.	5371-49-3	Acetaldehyde, (acetyloxy)-	568b, 3553, 3653, 4249, 5811b	568b, 2336, 2337a, 4249	
2.	16752-77-5	Acetamidic acid, thio-, *N*-[(methylcarbamoyl)oxy]-, methyl ester {Methomyl®} 		1219, 1219b, 1219c, 2650b, 3633, 3977, 4271a	
3.	13831-30-6	Acetic acid, (acetyloxy)- CH_3-COO-CH_2-COOH	568b, 1375a, 1377, 2387, 3553, 4249, 5811b	568b, 2336, 4249	1375a, 1377, 2387
4.	162188-92-3	Acetic acid, bromo-, 7,9,9-trimethyl-8-oxo-1, 4-dioxaspiro[4.5]dec-7-yl ester, (±)-		4249	
5.	123-86-4	Acetic acid, butyl ester {butyl acetate} CH_3-COO-C_4H_9	222–224, 568b, 1140, 1416, 1422, 1445, 3266, 3302, 3797, 4249	172a, 174b, 568b, 1053, 1063, 1422, 2339a, 3186, 3188, 3266, 3905, 4249	
6.	162188-93-4	Acetic acid, (diethoxyphosphinyl)-, 7,9,9-trimethyl-8-oxo-1,4-dioxaspiro[4.5]dec-7-yl ester, (±)-		4249	
7.	105-87-3	Acetic acid, 3,7-dimethyl-2,6-octadien-1-yl, (*E*)- ester {geranyl acetate}		172a, 174b, 1053, 3266, 3370	
8.	141-12-8	Acetic acid, 3,7-dimethyl-2,6-octadien-1-yl, (*Z*)- ester {neryl acetate}		174b, 3266	
9.	150-84-5	Acetic acid, 3,7-dimethyl-6-octen-1-yl ester {citronellyl acetate}		174b, 3266	
10.	151-05-3	Acetic acid, 1,1-dimethyl-2-phenylethyl ester		1053, 3266, 3370	
11.	112-66-3	Acetic acid, 1-dodecyl ester CH_3-COO-$(CH_2)_{11}$-CH_3		174b, 568b, 3266, 4249	
12.	108-05-4	Acetic acid, ethenyl ester {vinyl acetate} CH_3-COO-CH═CH_2	239, 1140, 1437, 2782, 2799a, 3219, 3300, 3302, 3308, 3797, 4005–4007, 4249, 5811b, 5869a		642
13.	141-78-6	Acetic acid, ethyl ester {ethyl acetate} CH_3-COO-C_2H_5	565, 1140, 1375, 1375a, 1375b, 1377, 1378, 1413, 1414, 1416, 1418, 1445, 1449, 1590, 1903–1905, 1907, 2088, 2782, 2804, 2858, 2939, 3254, 3266, 3308, 3508, 3530, 3553, 3797, 4249, 4319, 5811b	120, 1053, 1063, 1590, 2339a, 2389, 2544, 2861a, 2939, 3266, 3797, 3973, 3974a, 4249, 5811b	1375a, 1377, 1378
14.	112-06-1	Acetic acid, heptyl ester		1053, 3266	
15.	629-70-9	Acetic acid, 1-hexadecyl ester CH_3-COO-$(CH_2)_{15}$-CH_3		404	
16.	142-92-7	Acetic acid, hexyl ester {hexyl acetate} CH_3-COO-$(CH_2)_5$-CH_3	1157, 4249	172a, 174b, 1053, 1063, 1157, 3266, 3370, 4249	
17.	623-50-7	Acetic acid, hydroxy-, ethyl ester $HOCH_2$-COO-C_2H_5	3255, 3553, 4249		
18.	61892-60-2	Acetic acid, hydroxy-, 2-hydroxypropyl ester $HOCH_2$-COO-CH_2-CHOH-CH_3	568b, 3553, 4249, 5811b	568b, 2389, 2544, 4249

Esters in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
19.	96-35-5	Acetic acid, hydroxy-, methyl ester $HOCH_2$-COO-CH_3	3553, 3557, 4249, 5811b		
20.	90357-58-7	Acetic acid, hydroxy-, propyl ester $HOCH_2$-COO-C_3H_7	3553	2389, 2544, 3550	
21.		Acetic acid, hydroxymethyl ester CH_3-COO-CH_2OH	2767, 4249		
22.	79-20-9	Acetic acid, methyl ester CH_3-COO-CH_3	37, 38, 112, 314, 568b, 605, 1140, 1284, 1338, 1348–1350, 1365, 1375, 1375a, 1375b, 1377, 1413, 1414, 1416, 1418, 1419, 1449, 1495, 1586, 1589, 1634, 1637, 1875, 2301, 2310, 2543, 2545, 2765, 2767, 2777, 2782, 2804, 2857, 2939, 3132, 3302, 3308, 3530, 3553, 3557, 3797, 4104, 4249, 4257, 4319, 5770, 5811b	568b, 1157, 1550, 2339a, 4249, 5811b	1375a, 1377
23.	624-41-9	Acetic acid, 2-methylbutyl ester CH_3-COO-CH_2-CH(CH_3)-CH_2-CH_3		2339a	
24.	123-92-2	Acetic acid, 3-methylbutyl ester CH_3-COO-$(CH_2)_2$-CH═$(CH_3)_2$		404, 1053, 2339a, 3266	
25.	1191-16-8	Acetic acid, 3-methyl-2-butenyl ester CH_3-COO-CH_2-CH═C═$(CH_3)_2$		404	
26.	108-21-4	Acetic acid, 1-methylethyl ester CH_3-COO-CH═$(CH_3)_2$	568b, 1378, 4249	568b, 2917a, 4249	1378
27.	35897-16-6	Acetic acid, 2-methyl-3-pentyl ester CH_3-COO-CH(C_2H_5)-CH═$(CH_3)_2$		2917a	
28.	140-39-6	Acetic acid, 4-methylphenyl ester {*p*-tolyl acetate}		172a, 174b, 1053, 3266, 3370	
29.	110-19-0	Acetic acid, 2-methylpropyl ester {isobutyl acetate} CH_3-COO-CH_2-CH═$(CH_3)_2$		172a, 174b, 1053, 2339a, 3266, 3370	
30.	143-13-5	Acetic acid, nonyl ester		1053, 3266, 3370, 5811	
31.	2442-10-6	Acetic acid, 1-octen-3-yl ester		1053, 3266, 3370	
32.	112-14-1	Acetic acid, octyl ester		5811	
33.	628-63-7	Acetic acid, pentyl ester CH_3-COO-$(CH_2)_4$-CH_3		1157, 4249	
34.	24851-98-7	Acetic acid, 2-pentyl-3-oxo-1-cyclopentyl-, methyl ester {methyl dihydrojasmonate}		172a, 174b, 1053, 3266	
35.	103-45-7	Acetic acid, 2-phenylethyl ester {2-phenethyl acetate} CH_3-COO-$(CH_2)_2$-C_6H_5	568b, 937, 3224, 3266, 3302, 3794, 4249, 5811b	120, 172a, 174b, 404, 568b, 937, 1053, 1063, 2339a, 2386, 2389, 2544, 2611, 2861a, 2917a, 2939, 3266, 3354, 3370, 3543, 3547, 3560, 3561, 3905, 3973, 3974a, 4249, 5811b

TABLE 5.3 (continued)
Esters in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
641.	1731-84-6	Nonanoic acid, methyl ester H_3C-$(CH_2)_7$-COO-CH_3	568b, 3402, 4249	568b, 908, 2339a, 2389, 2544, 4098a, 4249, 5811b	
642.	37822-76-7	Nonenoic acid, methyl ester		1248, 4249, 5811b	
643.	111-79-5	2-Nonenoic acid, methyl ester		5811, 5811b	
644.	18444-66-1	19-Norlanosta-1,5,23-triene-3,11,22-trione, 25-(acetyloxy)-2,16,20-trihydroxy-9-methyl-, (9β,10α,16α,23*E*)-		4249	
645.	17278-28-3	19-Norlanosta-5,23-diene-2,11,22-trione, 25-(acetyloxy)-3,16,20-trihydroxy-9-methyl-, (3α,9β,10α,16α,23*E*)-		4249	
646.	89647-62-1	19-Norlanosta-5,23-diene-2,11,22-trione, 25-(acetyloxy)-3,16,20-trihydroxy-9-methyl-, (3β,9β,10α,16α,23*E*)-		4249	
647.	121878-02-2	Octacosanoic acid, docosyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{21}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
648.		Octacosanoic acid, dodecyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{11}$-CH_3	3251, 3294	3251, 3294	
649.	121877-91-6	Octacosanoic acid, eicosyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{19}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
650.		Octacosanoic acid, ester with olean-12-en-3-ol, (3β)- {β-amyrenyl octacosanoate}	1230	1230	
651.	121877-95-0	Octacosanoic acid, heneicosyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{20}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294	
652.		Octacosanoic acid, heptacosyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{26}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
653.		Octacosanoic acid, heptadecyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{16}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
654.		Octacosanoic acid, hexacosyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{25}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
655.	80756-16-7	Octacosanoic acid, hexadecyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{15}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
656.		Octacosanoic acid, nonadecyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{18}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
657.	95415-29-5	Octacosanoic acid, octadecyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{17}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
658.		Octacosanoic acid, pentacosyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{24}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
659.		Octacosanoic acid, pentadecyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{14}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
660.	80252-40-0	Octacosanoic acid, tetracosyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{23}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
661.	28570-28-7	Octacosanoic acid, tetradecyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{13}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
662.		Octacosanoic acid, tricosyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{22}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
663.		Octacosanoic acid, tridecyl ester H_3C-$(CH_2)_{26}$-COO-$(CH_2)_{12}$-CH_3	3251, 3294, 4249	3251, 3294, 4249	
664.	121878-04-4	Octacosanoic acid, 26-methyl-, docosyl ester H_3C-CH_2-$CH(CH_3)$-$(CH_2)_{24}$-COO-$(CH_2)_{21}$-CH_3	103 [see 2809]	103	
665.	97145-16-9	Octadecadienoic acid, 1-[[[(2-aminoethoxy)hydroxyphosphinyl] oxy]methyl]-1,2-ethanediyl ester, (all-*Z*)-		4249

992.	85373-77-9	4*H*-Pyran-3-carboxylic acid, 5,6-dihydro-2,6-dimethyl-, methyl ester	568b, 4249		
993.		4*H*-Pyran-4-one-2-carboxylic acid, 5-hydroxy-, (1-methylethyl) ester 	1375a (0), 1377 (0)		1375a, 1377, 4249
994.	614-18-6	3-Pyridinecarboxylic acid, ethyl ester	5811	5811	
995.	93-60-7	3-Pyridinecarboxylic acid, methyl ester {methyl nicotinate}	278, 1568, 3266, 4249, 5811b	1053, 1254, 1256, 1568, 2338, 2339a, 2611, 3266, 3491, 4249	
996.	55557-02-3	3-Pyridinecarboxylic acid, 1,2,5,6-tetrahydro-1-nitroso-, methyl ester		5811, 5811b	
997.	17747-43-2	3-Pyridinol, acetate (ester)	568b, 3553, 4249, 4407, 5811b		
998.	50609-61-5	4*H*-Pyrido[1,2-*a*]pyrimidine-3-acetic acid, 9-hydroxy-4-oxo-, ethyl ester	2601a		
999.	107-49-3	Pyrophosphoric acid, tetraethyl ester {TEPP} $[(H_3C\text{-}CH_2\text{-}O)_2\text{-}P{=}O]_2{=}O$		5079, 5439	
1000.	72692-79-6	1*H*-Pyrrolecarboxylic acid, ethyl ester	2767, 3553, 4249		
1001.	52115-69-2	1*H*-Pyrrole-2-carboxaldehyde, 5-[(acetyloxy)methyl]-		4249, 4788a	
1002.	3284-51-3	1*H*-Pyrrole-2-carboxylic acid, 5-methyl-, ethyl ester	568b, 3553, 4249, 5811b		
1003.	1194-97-4	1*H*-Pyrrole-2-carboxylic acid, 5-methyl-, methyl ester	568b, 3553, 4249		
1004.	1193-62-0	1*H*-Pyrrole-2-carboxylic acid, methyl ester	1587a, 3650, 4249, 5811b	5811b	
1005.	936-12-9	1*H*-Pyrrole-3-carboxylic acid, 2-methyl-, ethyl ester	568b, 2543, 2773, 4249		
1006.		Pyrrolidine, 2-acetyloxy-methyl-	2767, 4249		
1007.	69730-90-1	1-Pyrrolidinecarboxylic acid, 2-(3-pyridinyl)-, ethyl ester, (S)-		1156, 2497, 2498, 3742, 4090, 4249	
1008.	56078-08-1	1-Pyrrolidinecarboxylic acid, 2-(3-pyridinyl)-, methyl ester, (S)-	1578, 3491, 3742, 4249, 5811b	1578, 2497, 2498, 3742, 4249	
1009.	106777-19-9	*D*-Ribonic acid, 2-C-[(phosphonooxy)methyl]-		429b, 4249	
1010.	27442-42-8	*D*-Ribonic acid, 2-C-[(phosphonooxy)methyl]-, 5-(dihydrogen phosphate)		429b, 4249	
1011.	63231-63-0	Ribonucleic acid		4249, 4442, 5863	
1012.	3615-55-2	Ribose, 5-(dihydrogen phosphate)		429b, 4249, 4670	

TABLE 5.3 (continued)
Esters in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

	CAS No.	Name (per CA Collective Index)	References: Tobacco Smoke	References: Tobacco	References: Tobacco Substitute Smoke
1013.	5147-00-2	*L*-Serine, acetate (ester) CH_3-COO-CH_2-CH(NH_2)-COOH		429b, 4249, 4895	
1014.	71607-87-9	Stigmasta-5,22-dien-3-ol, 9,12,15-octadecatrienoate, [3β(*Z,Z,Z*),22*E*]- {stigmasteryl linolenate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1015.	71278-15-4	Stigmasta-5,22-dien-3-ol, 9,12-octadecadienoate, [3β(9*Z*,12*Z*),22*E*]- {stigmasteryl linoleate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1016.	31615-93-7	Stigmasta-5,22-dien-3-ol, 9-octadecenoate, [3β(*Z*),22*E*]- {stigmasteryl oleate}	3251, 3296, 4249	2939, 3296, 4249	
1017.	20242-97-1	Stigmasta-5,22-dien-3-ol, dodecanoate, (3β,22*E*)- {stigmasteryl laurate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1018.	2308-84-1	Stigmasta-5,22-dien-3-ol, hexadecanoate, (3β,22*E*)- {stigmasteryl palmitate}	3251, 3296, 4249	2939, 3296, 4249	
1019.	23838-16-6	Stigmasta-5,22-dien-3-ol, octadecanoate, (3β,22*E*)- {stigmasteryl stearate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1020.	20242-98-2	Stigmasta-5,22-dien-3-ol, tetradecanoate, (3β,22*E*)- {stigmasteryl myrsitate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1021.	3177-92-2	Stigmast-5-en-3-ol, 9,12,15-octadecatrienoate, [3β(9*Z*,12*Z*,15*Z*)]- {β-sitosteryl linolenate}	3251, 3296, 4249	2939, 3296, 4249	
1022.	3577-13-7	Stigmast-5-en-3-ol, 9,12-octadecadienoate, [3β(*Z,Z*)]- {β-sitosteryl linoleate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1023.	3712-16-1	Stigmast-5-en-3-ol, 9-octadecenoate, [3β(*Z*)]- {β-sitosteryl oleate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1024.	41005-65-6	Stigmast-5-en-3-ol, dodecanoate, (3β)- {β-sitosteryl laurate}	3251, 3296, 4249	2939, 3296, 4249	
1025.	2308-85-2	Stigmast-5-en-3-ol, hexadecanoate, (3β)- {β-sitosteryl palmitate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1026.	34137-25-2	Stigmast-5-en-3-ol, octadecanoate, (3β)- {β-sitosteryl stearate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1027.	10473-40-2	Stigmast-5-en-3-ol, tetradecanoate, (3β)- {β-sitosteryl myristate}	3251, 3296, 4249	2939, 3296, 4249, 5811b	
1028.	1401-55-4	Tannins {tannic acid}		120, 1053, 2270, 2154, 2939, 2947c, 3266, 3708, 3973, 4249, 5079, 5126, 5381	
1029.	42233-59-0	Tetracosanoic acid, docosyl ester H_3C-(CH_2)$_{22}$-COO-(CH_2)$_{21}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1030.	42233-49-8	Tetracosanoic acid, dodecyl ester H_3C-(CH_2)$_{22}$-COO-(CH_2)$_{11}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1031.	42233-57-8	Tetracosanoic acid, eicosyl ester H_3C-(CH_2)$_{22}$-COO-(CH_2)$_{19}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1032.		Tetracosanoic acid, ester with olean-12-en-3-ol, (3β)- {β-amyrenyl tetracosanoate}	1230	1230	
1033.	42233-58-9	Tetracosanoic acid, heneicosyl ester H_3C-(CH_2)$_{22}$-COO-(CH_2)$_{20}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1034.		Tetracosanoic acid, heptacosyl ester H_3C-(CH_2)$_{22}$-COO-(CH_2)$_{26}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1035.	42233-54-5	Tetracosanoic acid, heptadecyl ester H_3C-(CH_2)$_{22}$-COO-(CH_2)$_{16}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1036.	121878-03-3	Tetracosanoic acid, hexacosyl ester H_3C-(CH_2)$_{22}$-COO-(CH_2)$_{25}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1037.	42233-53-4	Tetracosanoic acid, hexadecyl ester H_3C-(CH_2)$_{22}$-COO-(CH_2)$_{15}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	

(*continued*)

TABLE 5.3 (continued)
Esters in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
1038.	42233-56-7	Tetracosanoic acid, nonadecyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{18}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1039.	24897-95-8	Tetracosanoic acid, octacosyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{27}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1040.	42233-55-6	Tetracosanoic acid, octadecyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{17}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1041.		Tetracosanoic acid, pentacosyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{24}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1042.	42233-52-3	Tetracosanoic acid, pentadecyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{14}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1043.	1001-43-0	Tetracosanoic acid, tetracosyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{23}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1044.	42233-51-2	Tetracosanoic acid, tetradecyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{13}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1045.	42233-60-3	Tetracosanoic acid, tricosyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{22}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1046.	42233-50-1	Tetracosanoic acid, tridecyl ester H_3C-$(CH_2)_{22}$-COO-$(CH_2)_{12}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1047.	121877-84-7	Tetracosanoic acid, 22-methyl-, docosyl ester	103 [see 2809]	103	
1048.	121877-77-8	Tetracosanoic acid, 22-methyl-, eicosyl ester	103 [see 2809]	103	
1049.	71608-05-4	Tetracosanoic acid, 3,7,11,15-tetramethyl-2-hexadecenyl ester, [R-[R*,R*- (*E*)]]- H_3C-$(CH_2)_{22}$-COO-CH_2-CH=C(CH_3)-CH_2-[$CH_2CH_2CH(CH_3)CH_2]_3$-H	3287, 3308, 3308, 4249		
1050.	110-36-1	Tetradecanoic acid, butyl ester	5811a		
1051.	42232-05-3	Tetradecanoic acid, docosyl ester H_3C-$(CH_2)_{12}$-COO$(CH_2)_{21}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249, 5811b	
1052.	2040-64-4	Tetradecanoic acid, dodecyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{11}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1053.	22413-00-9	Tetradecanoic acid, eicosyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{19}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249, 5811b	
1054.	124-06-1	Tetradecanoic acid, ethyl ester {ethyl myristate} H_3C-$(CH_2)_{12}$-COO-C_2H_5		172a, 174b, 568b, 908, 1053, 2093, 2389, 2544, 3266, 4249, 5811b	
1055.	42218-21-3	Tetradecanoic acid, heneicosyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{20}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1056.		Tetradecanoic acid, heptacosyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{26}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1057.	18299-78-0	Tetradecanoic acid, heptadecyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{16}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1058.	80252-34-2	Tetradecanoic acid, hexacosyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{25}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1059.	2599-01-1	Tetradecanoic acid, hexadecyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{15}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1060.	124-10-7	Tetradecanoic acid, methyl ester H_3C-$(CH_2)_{12}$-COO-CH_3	568b, 809, 3481, 4249	120, 404, 568b, 908, 937, 2339a, 2389, 2544, 2861a, 2917a, 2939, 4249, 5811b	

TABLE 5.3 (continued)
Esters in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
1061.	110-27-0	Tetradecanoic acid, 1-methylethyl ester H_3C-$(CH_2)_{12}$-COO-CH═$(CH_3)_2$		174b, 2339a, 3266	
1062.	36617-28-4	Tetradecanoic acid, nonadecyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{18}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1063.	3234-81-9	Tetradecanoic acid, octadecyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{17}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1064.	121877-45-0	Tetradecanoic acid, pentacosyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{24}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1065.	18299-74-6	Tetradecanoic acid, pentadecyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{14}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1066.	18653-39-9	Tetradecanoic acid, tetracosyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{23}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1067.	3234-85-3	Tetradecanoic acid, tetradecyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{13}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1068.	42232-06-4	Tetradecanoic acid, tricosyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{22}$-CH_3	103 [see 2809], 3251, 3294, 3302, 4249	103, 3251, 3294, 4249	
1069.	36617-27-3	Tetradecanoic acid, tridecyl ester H_3C-$(CH_2)_{12}$-COO-$(CH_2)_{12}$-CH_3	3251, 3294, 3302, 4249	3251, 3294, 4249	
1070.	121877-30-3	Tetradecanoic acid, 12-methyl-, docosyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COO-$(CH_2)_{21}$-CH_3	103 [see 2809]	103	
1071.	121877-23-4	Tetradecanoic acid, 12-methyl-, eicosyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COO-$(CH_2)_{19}$-CH_3	103 [see 2809]	103	
1072.	121877-28-9	Tetradecanoic acid, 12-methyl-, heneicosyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COO-$(CH_2)_{20}$-CH_3	103 [see 2809]	103	
1073.	121877-56-3	Tetradecanoic acid, 12-methyl-, hexacosyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COO-$(CH_2)_{25}$-CH_3	103 [see 2809]	103	
1074.	121877-08-5	Tetradecanoic acid, 12-methyl-, hexadecyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COO-$(CH_2)_{15}$-CH_3	103 [see 2809]	103	
1075.	121877-17-6	Tetradecanoic acid, 12-methyl-, octadecyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COOH	103 [see 2809]	103	
1076.	121877-48-3	Tetradecanoic acid, 12-methyl-, pentacosyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COO-$(CH_2)_{24}$-CH_3	103 [see 2809]	103	
1077.	121877-40-5	Tetradecanoic acid, 12-methyl-, tetracosyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COO-$(CH_2)_{23}$-CH_3	103 [see 2809]	103	
1078.	121877-34-7	Tetradecanoic acid, 12-methyl-, tricosyl ester H_3C-CH_2-CH(CH_3)-$(CH_2)_{10}$-COO-$(CH_2)_{22}$-CH_3	103 [see 2809]	103	
1079.	121877-29-0	Tetradecanoic acid, 13-methyl-, docosyl ester $(H_3C)_2$═CH-$(CH_2)_{11}$-COO-$(CH_2)_{21}$-CH_3	103 [see 2809]	103	
1080.	121877-21-2	Tetradecanoic acid, 13-methyl-, eicosyl ester $(H_3C)_2$═CH-$(CH_2)_{11}$-COO-$(CH_2)_{19}$-CH_3	103 [see 2809]	103

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke.

6 Lactones

At various periods during the past 50 years, lactones in tobacco and tobacco smoke, particularly those in tobacco smoke, were discussed with regard to their toxicity, tumorigenicity, and genotoxicity. However, examination of the numerous lists of tobacco and tobacco smoke components classified as toxic, tumorigenic, and/or genotoxic reveals that seldom is a lactone included. The first significant list, derived from the 1986 International Agency for Research on Cancer (IARC) monograph on tobacco smoke (1870), was published in 1986 by Hoffmann and Wynder (1808). Over the next two decades, the Hoffmann–Wynder list was followed by successive similar but not identical lists by Hoffmann and Hecht (1727) in 1990, Hoffmann et al. (1773) in 1993, the Occupational Safety and Health Administration (OSHA) (2825) in 1994, Hoffmann and Hoffmann (1740, 1741, 1743) in 1997, 1998, and 2001, and Fowles and Bates (1217) in 2001 [see summary of all these lists in Table 2 in Rodgman (3265)].

Based on its February 1985 meeting on tobacco smoking, the IARC working group wrote in 1986 [see p. 107 in (1870)]:

> About 80 lactones have been identified in tobacco smoke. These compounds, especially the γ-butyrolactones, and others, have alkylating potential and some have been reported to be carcinogenic in laboratory animals [Lawley (6A12)]. [See also Appendix 2, pp. 387–394) in (1870)]. Quantitatively, about half the lactones in the smoke consist of γ-butyrolactone [IARC (6A10)] (about 10 µg/cigarette) and its derivatives; δ-valerolactone and some alkylated and unsaturated δ-valerolactones, as well as coumarin [see pp. 427–430 in Wynder and Hoffmann (4332)], 6-methylcoumarin and 3,4-dihydrocoumarin have also been isolated [Schumacher et al. (3553)]. The occurrence of coumarin derivatives in smoke could be due to pyrolysis of polyphenols with a coumarin structure…or of plant extracts added to tobacco to enhance flavour [see pp. 427–430 in Wynder and Hoffmann (4332)]. Coumarin itself is carcinogenic to rats after oral administration [IARC (6A10)].

In its monograph, IARC made no comment on the 10 lactones, including coumarin that Lawley listed as inactive in oncogenesis tests [see Table XXVII in (6A12)], citing the 1965 study on coumarin by Dickens and Jones (6A06). IARC also failed to mention the 1984 listing by Slaga and DiGiovanni (3685) of the report by Wattenberg et al. (4149d) who described the anticarcinogenicity of coumarin toward the potent tumorigenic polycyclic aromatic hydrocarbons (PAHs) benzo[*a*]pyrene (B[*a*]P) and 7,12-dimethylbenz[*a*]anthracene (DMB[*a*]A).

At the time of the writing of the IARC 1986 monograph on tobacco smoking, over 100 lactones had been identified in tobacco smoke.

The information on pp. 387–394 in Appendix 2 in (1870), particularly the information provided by the IARC working group on lactones on p. 391, is as follows:

Compound	Degree of Evidence in Animals (and Humans)
5. *Lactones*	
Coumarin	Limited evidence
γ-Butyrolactone	No evidence

In Figure 5 [see p. 93 in (1870)], only the following five lactones (substituted coumarins) of the nearly two dozen identified in tobacco and/or tobacco smoke were depicted, namely, scopoletin (7-hydroxy-6-methoxy-2*H*-1-benzopyran-2-one), scopolin [7-(β-*D*-glucopyranosyloxy)-6-methoxy-2*H*-1-benzopyran-2-one],esculetin(6,7-dihydroxy-2*H*-1-benzopyran-2-one),cichoriin [7-(β-D-glucopyranosyloxy)-6-hydroxy-2*H*-1-benzopyran-2-one], and scopoletin-β-gentiobioside.

Two lactones that received some attention with regard to tobacco and smoke were aflatoxins, B_1 and B_2, primarily aflatoxin B_1, the more toxic of the two. In 1970, Kaminski et al. (2024) examined the butts, ashes, and mainstream smoke (MSS) vapor phase and particulate phase from machine-smoked commercial nonfilter cigarettes treated with aflatoxin B_1. In six separate smoking experiments, no trace of aflatoxin B_1 was detected in any of the fractions examined. In their 1967 examination of several samples of leaf tobacco, including three types of good-grade tobaccos and heavily molded flue-cured tobacco, and of cigarette smoke condensate (CSC), Tso and Sorokin (3986) failed to detect aflatoxin B_1. They also reported that no aflatoxin B_1 was found in the CSC from cigarettes enriched with authentic aflatoxin B_1 prior to smoking. They concluded that the added aflatoxin B_1 was changed or decomposed during the smoking process. Later, Tso (3970) again reported the results of this aflatoxin B_1 study at the *1967 World Conference on Smoking and Health*. In his 2000 review of scientific publications on aflatoxin B, tobacco, and tobacco smoke, Massey (2484) concluded that aflatoxin B was not a contamination issue on tobaccos and, even if present, would decompose in the burning cigarette and would not transfer to smoke.

As noted in the quotation from the 1986 IARC monograph, orally administered coumarin (2*H*-1-benzopyran-2-one) had been reported as carcinogenic in rats. The results reported from several studies on the tumorigenicity of coumarin eventually resulted in coumarin being removed from the flavor formulations used throughout the tobacco industry on cigarette and pipe tobacco. Coumarin was considered by the consumer as a significantly acceptable contribution to

tobacco smoke. Coumarin was identified by Schumacher and Vestal as a minor component of untreated Oriental tobacco in the early 1960s (3560).

The initial concern in the early 1960s about the addition of coumarin {I} to tobacco products was whether or not it was converted during the smoking process to dicumarol (3,3′-methylenebis[4-hydroxy-2*H*-1-benzopyran-2-one) {II} (Figure 6.1). Dicumarol is a powerful anticoagulant that had been identified in sweet clover hay (6A21).

In previous metabolic studies, it had been reported that coumarin was not a precursor of dicumarol {II} (6A03, 6A15)) or of *o*-coumaric acid [3-(2-hydroxyphenyl)-2-propenoic acid] {III} (6A21). {III} was known to be a precursor of dicumarol via 4-hydroxycoumarin {IV}. Laboratory animals (rats, rabbits) fed coumarin excreted 4-hydroxycoumarin {IV} (6A04). Between 70% and 90% of coumarin administered to humans resulted in excretion of 7-hydroxycoumarin {V} (6A17), a coumarin derivative never indicted as dangerous to any species or proposed as a dicumarol precursor.

Newell reported in 1963 that (1) inclusion in cigarette tobacco of 3-^{14}C-coumarin {I} gave no dicumarol {II} in either the MSS or the sidestream smoke (SSS) and (2) inclusion in cigarette tobacco of unlabeled dicumarol gave no dicumarol {II} in either the MSS or the SSS (2757). Of the 3-^{14}C-coumarin applied to the tobacco blend, Newell reported that 60% appeared unchanged in the MSS and SSS.

To assess the claims of the possible adverse effect of including coumarin in flavor formulations, several reports and memoranda were written in the late 1970s about the coumarin situation in an obvious attempt to put the issue in perspective. In 1978, Buchner (6A05) listed several of the authorities that incorrectly cited negative tumorigenicity results as positive; e.g., in 1976, the National Institute for Occupational Safety and Health (NIOSH) (6A16) incorrectly cited results published in 1955 by Roe and Salaman (6A20). Much weight was given to the reported findings of Griepentrog (6A02, 6A07), the only findings on the induction of bile duct carcinomas in coumarin-fed rats. Buchner (6A05) summarized many of the results of studies that raised questions about the classification of coumarin as a carcinogen, e.g., the negative tumorigenicity results reported by Hagan et al. (6A08) and Hazleton et al. (6A09). He also cited several genotoxicity studies in which coumarin was found to be inactive against human chromosomes (6A22) and

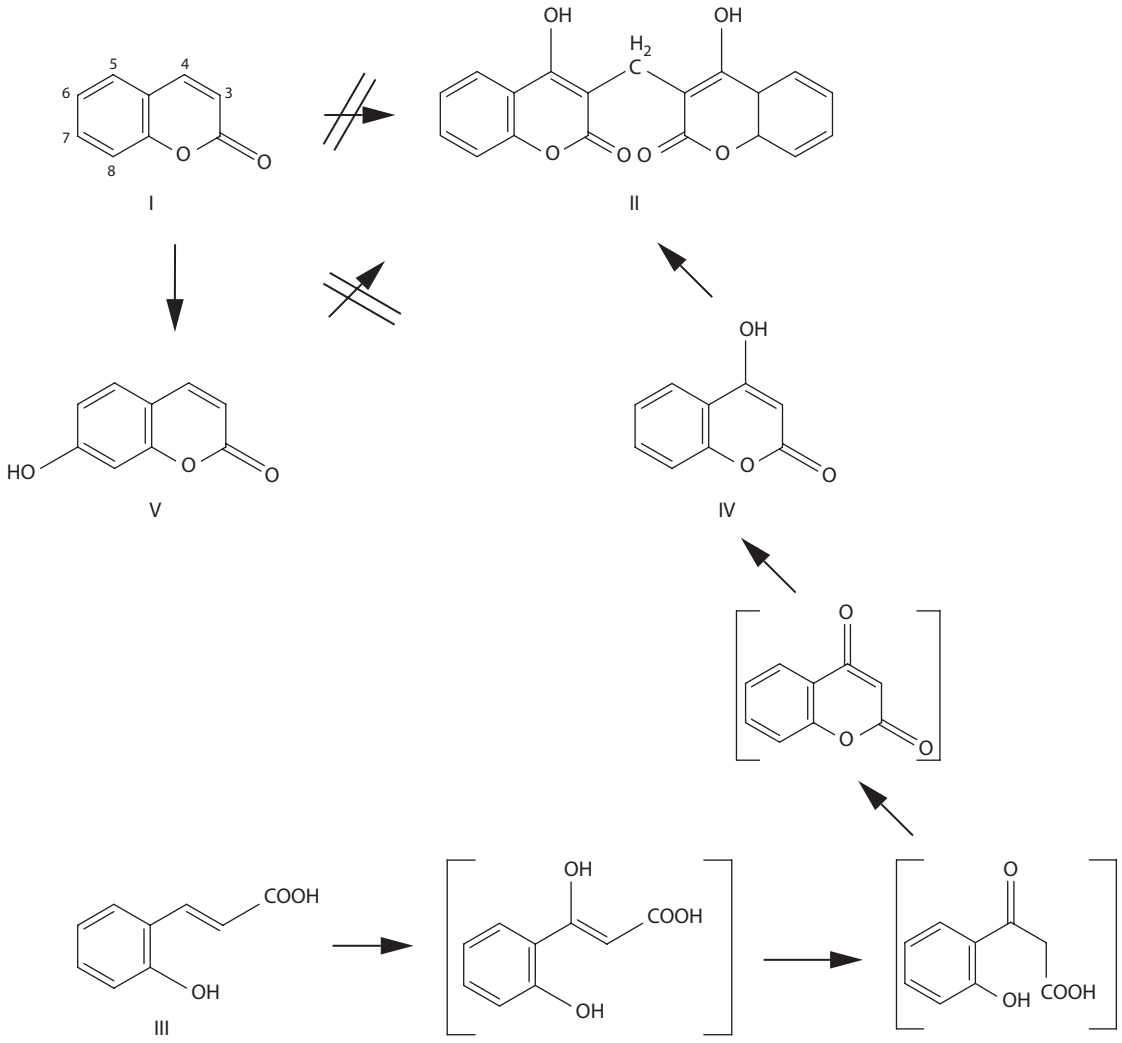

FIGURE 6.1 Relationships between coumarin, its derivatives, and dicumarol.

against *Salmonella typhimurium* strains TA1535, TA1537, TA98, and TA100 in the Ames test [private communication to Buchner, see Reference 26 in (6A22)].

Paralleling the report by Buchner were several memoranda on coumarin by Rodgman in 1978 (6A18) and 1982 (6A19) in which the problems of misinterpretation of data and contrary data pertinent to coumarin were presented. Included in the memoranda were the negative mutagenicity results obtained in Ames tests with five strains (TA1535, TA1537, TA1538, TA898, TA100) of *S. typhimurium* on coumarin conducted in-house by Lee (6A13) at R.J. Reynolds Research and Development. His results were confirmed on a coded coumarin sample among a set of coded samples tested at a contract laboratory (6A14).

Despite the controversies over the tumorigenicity of coumarin, its use in tobacco flavor formulations was subsequently discontinued throughout the tobacco industry worldwide.

In its 2000 evaluation of the tumorigenicity of coumarin (2*H*-1-benzopyran-2-one), IARC (6A11) noted the following as of August 21, 2000:

> Coumarin is a natural product occurring in the essential oils of a large number of plants, such as cinnamon, cassia, lavender and woodruff. It is used for its fragrance in many personal care products (perfumes, deodorants, soaps) and in tobacco, in household and industrial products to mask unpleasant odours and, in some countries, as a flavouring agent in food and beverages. It has also been used to treat several medical conditions. Exposure to coumarin may occur from its production, its natural presence in many plants and essential oils, and its several industrial, medical and consumer uses.

According to IARC, no data were available to its working group on the carcinogenicity of coumarin in humans. After assessment of various studies in which coumarin was administered to laboratory animals, IARC concluded that the evidence was limited in laboratory animals on the carcinogenicity of coumarin. IARC described its overall evaluation of coumarin as a carcinogen as follows: Coumarin is not classifiable as to its carcinogenicity to humans.

In 1998, Abbott (6A01) described the results of the examination of numerous food additives by the World Health Organization. The food additives in this particular study comprised a series of so-called aliphatic lactones. Among the lactones discussed were several that not only are used as foodstuff additives but that also occur in tobacco and/or its smoke and several that are used as tobacco additives. The results of several toxicological studies (acute toxicity, short- and long-term toxicity, carcinogenicity) and genotoxic studies on the lactones were described in detail by Abbott. Table 6.1 presents the results listed by Abbott on those lactones that are used in tobacco products.

Table 6.2 lists the tobacco and/or smoke lactones that, according to the Doull et al. listing (1053), are or have been used recently as components in flavor formulations for tobacco.

The number of lactones identified to date in tobacco and/or tobacco smoke is 336. Of these, 201 have been identified in tobacco smoke, 213 in tobacco, and 78 in both tobacco and tobacco smoke. In Table 6.3 are listed the lactones identified in tobacco and tobacco smoke to date.

TABLE 6.1
Some Biological Properties of Lactones Used as Additives in Foodstuffs as Well as in Tobacco Products (6A01)

	Lactone						
CAS No.	CAS Nomenclature	Common Name	Smoke or Tobacco Component	Flavor Formulation Additive	Genotoxicity[a]	Acute Toxicity, LD_{50}, mg/kg	Short-Term Toxicity, NOEL[b], mg/kg/day

Lactones Identified in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
151.	1679-49-8	2(3*H*)-Furanone, dihydro-4-methyl-	568b, 1378, 3255, 4249, 5811b	404, 568b, 3543, 3546, 3547, 3560, 3561, 4048, 4249, 5811b	1378, 4249
152.	108-29-2	2(3*H*)-Furanone, dihydro-5-methyl- {γ-valerolactone}	1360, 1371, 1375a, 1883, 2731, 2735, 2775, 3266, 4249	172a, 174b, 404, 1053, 2389, 2544, 2917a, 3219, 3266, 3370, 4249, 5811b	1360, 1375a
153.		2(3*H*)-Furanone, dihydro-5-methyl-5-(3-methyl-1-butenyl)-		568b, 3545, 4249	
154.		2(3*H*)-Furanone, dihydro-5-methyl-5-(3-oxobutyl)-		3543	
155.	80797-69-9	2(3*H*)-Furanone, dihydro-5-(3-methyl-1-butenyl)-		3547, 4249	
156.	2429-94-9	2(3*H*)-Furanone, dihydro-5-(3-methylbutyl)-		1980, 3543, 4249	
157.	10547-88-3	2(3*H*)-Furanone, dihydro-4-(1-methylethyl)-	5811b	404, 568b, 3219, 3543, 3547, 3560, 3561, 4249, 5811b	
158.	38624-29-2	2(3*H*)-Furanone, dihydro-5-(1-methylethyl)-		404, 2943a, 3547, 4249	
159.		2(3*H*)-Furanone, dihydro-5-(1-methylethyl)-5-(3-methyl-1,2-butadienyl)-		3547, 4249	
160.	133561-47-4	2(3*H*)-Furanone, dihydro-5-(1-methylethyl)-5-(3-oxo-1-butenyl)-		5811, 5811b	
161.	129742-48-9	2(3*H*)-Furanone, dihydro-5-(1-methylethyl)-5-(3-oxo-1-butenyl)-, (*E*)-(+)-		4249, 5811b	
162.	2305-05-7	2(*3H*)-Furanone, dihydro-5-octyl- {γ-dodecalactone}		172a, 174b, 1053, 3266, 3370	
163.	76710-90-2	2(3*H*)-Furanone, dihydro-5-(2-pentenyl)-, (*Z*)-		404, 2934b, 3547	
164.	104-61-0	2(3*H*)-Furanone, dihydro-5-pentyl- {γ-nonalactone}	5811b	172a, 174b, 404, 568b, 1053, 2337a, 2339a, 2389, 2544, 3215, 3266, 3370, 3543, 3547, 3555, 3560, 3561, 4098a, 4249, 5811b	
165.	105-21-5	2(3*H*)-Furanone, dihydro-5-propyl- {γ-heptalactone}	568b, 2601a, 4249	120, 172a, 174b, 568b, 1053, 2283, 2270, 3266, 4249	
166.	20971-79-3	2(3*H*)-Furanone, dihydro-5-(3-pyridinyl)-	568b, 3553, 4249, 5811b		
167.	72507-34-7	2(3*H*)-Furanone, dihydro-5-[1-methyl-4-(1-methylethyl)-7-oxo-2-octenyl]-		4249	
168.	102734-52-1	2(3*H*)-Furanone, dihydro-5-[4-hydroxy-4-methyl-7-(1-methylethyl)-10-oxo-1,5-undecadienyl]-5-methyl-, [5S-[5R*(1E,4R*,5E,7R*)]]- 		453, 4089, 4249, 5811b	
169.	102734-53-2	2(3*H*)-Furanone, dihydro-5-[4-hydroxy-4-methyl-7-(1-methylethyl)-10-oxo-1,5-undecadienyl]-5-methyl-, [5S-[5R*(1E,4S*,5E,7R*)]]-		4089, 5811b	

TABLE 6.3 (continued)
Lactones Identified in Tobacco, Tobacco Smoke, and Tobacco Substitute Smoke

			References		
	CAS No.	Name (per CA Collective Index)	Tobacco Smoke	Tobacco	Tobacco Substitute Smoke
170.	102734-54-3	2(3*H*)-Furanone, dihydro-5-[4-hydroxy-4-methyl-7-(1-methylethyl)-10-oxo-1,5-undecadienyl]-5-methyl-, [5R-[5R*(1E,4S*,5E,7S*)]]-		4089, 5811b	
171.	102734-55-4	2(3*H*)-Furanone, dihydro-5-[4-hydroxy-4-methyl-7-(1-methylethyl)-10-oxo-1,5-undecadienyl]-5-methyl-, [5R-[5R*(1E,4R*,5E,7S*)]]-		4089, 5811b	
172.	80744-25-8	2(3*H*)-Furanone, dihydro-5-[4-hydroxy-4-methyl-7-(1-methylethyl)-10-oxo-1,5-undecadienyl]-5-methyl-		4249, 4947	
173.		2(3*H*)-Furanone, dihydro-5-[4-hydroxy-4-methyl-7-(1-methylethyl)-10-oxo-1,5-undecadienyl]-5-methyl- {stereoisomer}		4249, 4947	
174.		2(3*H*)-Furanone, dihydro-5-methyl-5-(5-methyl-2-furanyl)-		2934b	
175.	60646-31-3	2(3*H*)-Furanone, dihydro-5-methyl-5-(1-methylethyl)-, (S)-	4249, 4749		
176.	57213-51-1	2(3*H*)-Furanone, dihydro-5-methyl-5-[3-(1-methylethyl)-6-oxo-1-heptenyl]- 		8, 9, 909, 943, 1151, 1156, 4090, 4249	
177.	3284-93-3	2(3*H*)-Furanone, dihydro-5-methyl-5-propyl-		568b, 3547, 4249	
178.	10008-73-8	2(3*H*)-Furanone, dihydro-5-methylene-	2761, 2762, 2777, 4249		
179.	2981-96-6	2(3*H*)-Furanone, dihydro-4,5,5-trimethyl-	568b, 4249		
180.		2(3*H*)-Furanone, dihydro-5-(1,1,3-trimethyl-2-butenyl)-		3547, 4249	
181.	64291-81-2	2(3*H*)-Furanone, dihydrodimethyl-		1157, 4249, 4359a	
182.		2(3*H*)-Furanone, 3,3-dimethyl-		3543	
183.		2(3*H*)-Furanone, 3,4-dimethyl-	1375, 1375b, 2387	3206	2387
184.	61892-58-8	2(3*H*)-Furanone, 3-(hydroxymethyl)-5-methyl-	568b, 1352, 1371, 2543, 2570, 2773, 2775, 3553, 4249, 5811b		
185.	591-12-8	2(3*H*)-Furanone, 5-methyl- {4-hydroxy-3-pentenoic acid lactone; α-angelica lactone}	568b, 2570, 2769, 2775, 3255, 3257, 3265, 3266, 3553, 3557, 4032, 4407, 5811b	172a, 174b, 568b, 1053, 1980, 2336, 2337a, 2389, 2544, 3266, 4249, 5811b	3401
186.	497-23-4	2(5*H*)-Furanone {crotonolactone} 	568b, 1360, 1375, 1375a, 1375b, 1377, 2570, 2761, 2762, 2765–2767, 2773, 2775, 2777, 3255, 3553, 3557, 3559, 4249, 4407, 5811b	568b, 2389, 2544, 2917a, 3555, 4249	1360, 1375a, 1377, 3401, 3405
187.		2(5*H*)-Furanone, acetyl-	3557		
188.	80436-91-5	2(5*H*)-Furanone, 3-acetyl-	4249		
189.	38260-27-4	2(5*H*)-Furanone, 4-acetyl-	4249

Note: The symbol (0) indicates the component identified in tobacco substitute smoke was not detected in tobacco smoke or vice versa.

7 Anhydrides

The number of anhydrides identified in tobacco and tobacco smoke is small. In 1988, Roberts (3215) reported that there were only 10 anhydrides identified in tobacco, 10 identified in tobacco smoke, and 4 in both tobacco and tobacco smoke. The number of anhydrides in tobacco and tobacco smoke has not changed substantially since that time. There are presently 13 anhydrides identified in tobacco, 13 in tobacco smoke, and 6 identified in both tobacco and tobacco smoke.

In his 1984 review of the carcinogenesis induced by alkylating agents, Lawley (Table XXV, p. 434 in 7A04) tabulated the findings of Dickens and Jones on a study of the tumorigenicity (sarcogenicity) of maleic anhydride (7A01) and 2,3-dimethylmaleic anhydride and succinic anhydride (7A02) administered by subcutaneous injection to Wistar rats.

In its 1986 monograph, the International Agency for Research on Cancer (IARC) wrote very little on the few anhydrides in tobacco smoke [see p. 107 in (1870)]. IARC commented as follows:

> At least eight acid anhydrides have been found in cigarette smoke, including maleic anhydride and succinic anhydride and their alkylated derivatives [Schumacher et al. (3553), Newell et al. (2769)]. These smoke constituents are of particular concern because of their alkylating potential. Maleic anhydride, 2,3-dimethylmaleic anhydride and succinic anhydride have produced local tumours in one experiment in rats [Dickens and Jones (7A01, 7A02)], IARC (7A03)].

An inserted comment in the IARC monograph referred the reader to Appendix 2, pp. 389–394 in (1870) which listed the components in tobacco smoke that had been evaluated for carcinogenicity in the IARC monograph series. The tumorigenicity of succinic anhydride was listed as follows:

Compound	Degree of Evidence in Animals (and Humans)
7. *Agricultural chemicals and derivatives*	
Succinic anhydride	Limited evidence

It is obvious from the review by Lawley (7A04) and the data in the Dickens and Jones reports (7A01, 7A02) that the anhydrides are sarcogens, not carcinogens; i.e., they do not fit the definition of a carcinogen, a factor that induces a carcinoma.

At R.J. Reynolds Tobacco Co. (RJRT) R&D, two anhydrides, 3,4-diethyldihydro-2,4-furandione (diethylsuccinic anhydride) and 3,4-dimethyldihydro-2,4-furandione (dimethylsuccinic anhydride), were identified by Jones and Latimer during their research on Oriental tobacco composition. The two anhydrides were listed in their 1943 report on the Oriental tobacco components they identified through the end of 1942 (1980).

In a subsequent RJRT research effort in 1963 and 1964, several anhydrides (see Table 7.1) were isolated from tobacco smoke and identified by Fredrickson (1233, 1235) during his study of the composition of burley tobacco smoke condensate. Two decades later, several additional anhydrides (see Table 7.1) were identified as components of Oriental tobacco by Schumacher (3543).

Table 7.1 lists the 24 anhydrides identified to date in tobacco and/or tobacco smoke: 17 in tobacco smoke, 16 in tobacco, and 9 in both tobacco and tobacco smoke. None of the anhydrides listed in Table 7.1 were included in any of the many publications issued between 1986 and 2001 in which the toxicants in tobacco and/or tobacco smoke were listed (1217, 1727, 1740, 1741, 1743, 1744, 1773, 1808, 2825).

No anhydride was included in the 1994 Doull et al. list (1053) on compounds in flavor formulations used on tobacco products by members of the U.S. tobacco industry.

8 Carbohydrates and Their Derivatives

The four macromolecules that have been called the "building blocks of life" are carbohydrates, proteins, lipids, and nucleic acids. Tso (3873) estimated that as much as 75% of all the carbon from CO_2 that is reduced by plants enters into some form of carbohydrate for at least a brief period of time. Via numerous metabolic pathways, these carbohydrates are converted into hundreds of functional molecules necessary to sustain life.

There are 316 components in tobacco and/or tobacco smoke that may be considered as a complete carbohydrate or one in which a carbohydrate is linked to another structure, such as in a glycoside. This number is greater than the 156 listed by Tso in his 1990 book [see Table 1.38 in (3873)] because of our inclusion of the carbohydrate-combined components. The following indicates the difference in numbers:

	Reference	Total	Smoke	Tobacco	Tobacco and Smoke
Tso	Table 1.38 in (3873)	156	30	138	12
Carbohydrates	Table 8.3	316	44	310	38

A great number of carbohydrate-linked components, mostly in tobacco, involve the linkage of a carbohydrate to a 2*H*-1-benzopyran-2-one or 4*H*-1-benzopyran-4-one which may not only be hydroxylated, e.g., 6-(β-*D*-glucopyranosyloxy)-7-hydroxy-2*H*-1-benzopyran-2-one (esculin), but also may have one or more hydroxyphenyl links, e.g., 3-[(6-deoxy-α-*L*-mannopyranosyl)oxy]-2-(3,4-dihydroxyphenyl)-5,7-dihydroxy-4*H*-1-benzopyran-4-one (quercetrin), 3-[[6-*O*-(6-deoxy-α-*L*-mannopyranosyl)-β-*D*-glucopyranosyl]oxy]-2-(3,4-dihydroxyphenyl)-5,7-dihydroxy-4*H*-1-benzopyran- 4-one (rutin), and 3-(β-*D*-glucopyranosyloxy)-5,7-dihydroxy-2-(4-hydroxyphenyl)-4*H*-1-benzopyran-4-one (kaempferol glycoside). Components such as these were classified as polyphenols. Tobacco components such as the latter three may be the precursors of part of the phenols yield in tobacco smoke. Snook et al. (8A08) determined the levels of rutin and kaempferol glycoside in 62 different species of *Nicotiana*. Their levels ranged from <0.005% to 1.6% for rutin and <0.005% to 0.16% for the kaempferol glycoside. There are, of course, in tobacco several carbohydrate-linked benzopyranones that lack a hydroxyphenyl group, e.g., 6-(β-*D*-glucopyranosyloxy)-7-hydroxy-2*H*-1-benzopyran-2-one (esculin) and 7-(β-*D*-glucopyranosyloxy)-6-methoxy-2*H*-1-benzopyran-2-one (scopolin).

As indicated in Table 8.1, only a few tobacco and/or tobacco smoke carbohydrates are used in the flavor formulations used by cigarette manufacturers in the United States (1053) and in other countries (3266). None of those used in that way are linked to a noncarbohydrate entity.

The use on tobacco containing various carbohydrate additives, such as the various sugars listed in Table 8.1, has been the subject of much discussion recently in attempts to link such additives to medical problems induced by cigarette smoke. The major concern was the generation of carbonyl compounds such as formaldehyde and acetaldehyde.

Although Baker (8A02), in his letter to the editor of Food and Chemical Toxicology, agrees with the statements of Talhout et al. (3865b) that addition of sugars to tobacco results in increased yields of formaldehyde in the mainstream smoke (MSS), he also provided numerous references [Baker (8A01), Baker and Bishop (172a, 172b), Baker et al. (172c, 174a, 174b, 174c, 8A03), Baker and Smith (174e), Gori (1332), Massey (2484a), Rodgman (3264), Rustemeier et al. (3370), Seeman et al. (3579, 8A06), Thornton and Massey (3913), Zilkey et al. (4418)] and much discussion to counter the assertions by Talhout et al. (3865b) that sugar addition had an adverse effect on the biological properties of the MSS. Not included in Baker were the facts that (1) Doull et al. (1053), in their detailed 1994 assessment of 599 additives used by members of the U.S. tobacco industry in cigarette manufacture, reported no significant biological problem from the use of sugars in the flavor formulations and (2) Dalhamn et al. (892) had reported in 1968 that a significant percentage of water-soluble MSS vapor-phase components such as formaldehyde, acetaldehyde, and other carbonyls never reached the respiratory tract cilia of the smoker because of their solution in the fluids coating the oral cavity. The findings of Dalhamn et al. (892) were a confirmation of those by Rodgman et al. (3306), Industrial Bio-Research Laboratories, an independent contract laboratory (8A04), and the repeated assertions by Wynder and Hoffmann that such would be the case with water-soluble ciliastats (4330, 4332).

In their mid-1960 publications, Wynder and Hoffmann commented several times on the fact that most of the known ciliastatic components of MSS demonstrated to be ciliastatic in various in vitro systems were water soluble and this property would markedly influence their fate and behavior during and after inhalation. Wynder and Hoffmann (4330) noted:

> As far as human smoking habits are concerned, it remains also to be estimated to which extent volatile smoke components reach the bronchial tree. Preliminary studies indicate that a significant proportion of the gaseous components is being retained within the oral cavity.

TABLE 8.1
Tobacco and/or Smoke Carbohydrates Used in Flavor Formulations

CAS No.	Chemical Abstracts Nomenclature	As Listed by Doull et al. (1053)	Identified in	
			Smoke	Tobacco
57-48-7	*D*-Fructose	Sugars	+	+
59-23-4	*D*-Galactose	Sugars	+	+
50-99-7	α-*D*-Glucose	Sugars	+	+
57-50-1	α-*D*-Glucopyranoside, β-*D*-fructofuranosyl- {sucrose}	Sugars	+	+
50-99-7	α-*D*-Glucose	Sugars	+	+
31103-86-3	Mannose	Sugars	+	+
50-70-4	Sorbitol[a]	Glucitol	–	+

[a] Sorbitol (glucitol) is not included in the Doull et al. list (1053) but is included in flavor formulations used by cigarette manufacturers outside of the United States [see Table 7A in (3266)].

Later, Wynder and Hoffmann [see p. 542 in (4332)] wrote:

> Water-soluble volatile components, which are primarily responsible for the results of the acute in vitro short-term cilia toxicity tests, are, to a large extent, removed when cigarette smoke contacts the saliva in the mouth and the abundant secretions of the trachea and main bronchi.

They added [see p. 646 in (4332)]:

> In man's manner of smoking, however, volatile components are retained to a significant degree in the oral cavity and may, therefore, be far less important than when tested experimentally.

Baker (8A02), in the letter to the editor of *Food and Chemical Toxicology* in which he responded to the assertions of Talhout et al. (3865b), noted several early studies cited by Talhout et al., those of Thornton and Massey (3913) and Shelar et al. (8A07) in which high levels of a carbohydrate (sugar) were added to the tobacco resulting in a significant increase in the MSS yield of several carbonyl compounds, namely, formaldehyde, acetaldehyde, acrolein. However, the added carbohydrate greatly exceeded the amount usually added in an industrial situation.

As noted by Baker (8A02), Talhout et al. (3865b) commented on the effect on MSS carbonyl component yields produced by additions to tobacco of 12% of three sugars, but they did not describe the effect of the additions of 4% of each sugar, an addition level which more closely resembled that used commercially. Table 8.2 lists the changes reported by Shelar et al. (8A07) in per cigarette MSS yield of formaldehyde, acetaldehyde, acetone, and acrolein by addition of 4% fructose, glucose, or sucrose to two different burley samples.

Not discussed by either Baker (8A02) or Talhout et al. (3865b) was a 1970 study by Best (297) in which a flue-cured tobacco sample was treated with sugar to raise its level from 12.6% to 21.0%. Even though the sugar addition to the flue-cured tobacco represented a 66% increase, the MSS yields of carbonyl components increased as follows: formaldehyde from 35.4 to 48.8 µg/cig, a 37.8% increase; acetaldehyde from 998 to 1020 µg/cig, a 2.2% increase; acrolein from 124 to 131 µg/cig, a 5.6% increase.

In his review of the genotoxicity of tobacco smoke and tobacco smoke condensate, DeMarini (933) described in

TABLE 8.2
Effect of Sugars Added to Burley Tobacco on MSS Aldehyde and Ketone Yields (8A07)

	Per Cigarette MSS Yield			
	Formaldehyde	Acetaldehyde	Acetone	Acrolein

detail the 1979 findings of Mizusaki et al. (2568) on the effect of the cigarette smoke condensate (CSC) from high-sugar tobacco (20%–30%) *vs.* the CSC from low-sugar tobacco (5%) in the Ames test (*Salmonella typhimurium* strain TA1538). The high-sugar tobacco CSC was much less mutagenic than the low-sugar tobacco CSC. DeMarini (933) also summarized the results of a study by Sato et al. (8A05) in which various sugars were added to the tobacco in high-"tar" and low-"tar" cigarettes, the CSCs collected, and tested for mutagenicity in the Ames test with *S. typhimurium* TA98 and TA100, with and without activation. The sugars tested included glucose, fructose, galactose, lactose, sucrose, and sorbitol. The mutagenicity of the CSC from the sugar-treated high-"tar" cigarettes was reduced 35% from the mutagenicity observed for the CSC from the untreated tobacco cigarette. The mutagenicity of the CSC from the low-"tar" cigarettes was reduced 36% from mutagenicity of the CSC from the untreated tobacco cigarette.

In the National Cancer Institute study of the third set of cigarettes, Gori (1332) reported the effect of adding invert sugar at a level approximating that used commercially to the Standard Experimental Blend III (SEB III) [see Table 8, p. 99, cigarette 81 in (1332)] on the per cigarette MSS yields of numerous smoke components, including formaldehyde, acetaldehyde, and acrolein [see Table 8, p. 59 in (1332)]. The multiple samples of SEB III yielded an average of 33.8 µg/cig of formaldehyde, 1212 µg/cig of acetaldehyde, and 110 µg/cig of acrolein. Cigarette 81, fabricated from SEB III with added invert sugar, yielded 32.3 µg/cig of formaldehyde, 1090 µg/cig of acetaldehyde, and 113 µg/cig of acrolein. Dermal assays were initiated with 100 ICR Swiss female mice in each group. Multiple samples of CSC from SEB III at 12.5 and 25.0 mg doses produced 27 and 47 tumor-bearing animals (TBA), respectively [see Table 2, p. 86 in (1332)], whereas the CSC from the invert sugar-treated SEB III at 12.5 and 25.0 mg doses produced 19 and 41 TBA, respectively [see Table 3, p. 87, cigarette 81 in (1332)]. However, the CSCs studied would be devoid of formaldehyde, acetaldehyde, and acrolein because of their vaporization during the collection, solution preparation, and administration of the CSCs.

Table 8.3 lists the carbohydrates and their derivatives identified to date in tobacco, tobacco smoke, and tobacco substitute smoke. Of the 316 identified carbohydrates listed, most of them are tobacco components: 310 have been identified in tobacco *vs.* only 44 in smoke; 38 have been identified in both tobacco and tobacco smoke.

9 Phenols and Quinones

9.1 PHENOLS

Examination of the extensive literature on the composition of tobacco smoke reveals that considerable effort was expended in the early 1960s in defining the nature of the phenolic components of tobacco smoke. Subsequently, even though the identity of many phenols in tobacco smoke is now known, research has indicated their identified number in tobacco smoke is much fewer than the number of identified polycyclic aromatic hydrocarbons (PAHs).

With the tremendous effort expended on the identification of PAHs and some of their nitrogen analogs in tobacco smoke, what series of events triggered the interest in and the emphasis on phenols in tobacco smoke in the early 1960s?

The reports by Wynder et al. (4306a, 4306c) in the early 1950s that cigarette smoke "tar" or cigarette smoke condensate (CSC) was tumorigenic to mouse skin prompted an intense search for the responsible component(s). Initially, the PAHs were selected for investigation because of the wealth of chemical and biological data generated on a great number of them following the synthesis of dibenz[*a,h*]anthracene (DB[*a,h*]A) in 1929 (760, 1184), the isolation of benzo[*a*]pyrene (B[*a*]P) from coal tar in 1932 (796a, 797), and the demonstration of the potent tumorigenicity of both of them to mouse skin (194, 2078). Almost immediately after the report by Wynder et al. (4306a) of the mouse-skin-painting results with tobacco "tar," the PAHs were proposed by some investigators to be the major tumor initiators in CSC. Because of its level in CSC and its potency in mouse-skin tumorigenesis, B[*a*]P was defined as the most significant of the PAHs in tobacco smoke.

However, it was soon recognized that neither the B[*a*]P content nor its tumorigenicity could explain the biological response observed in the mouse-skin-painting bioassay. Similarly, neither the total content of the PAHs tumorigenic to mouse skin nor their summed tumorigenicities could explain the observed biological response. In fact, it was pointed out repeatedly over the next several decades that the levels of B[*a*]P and other tumorigenic PAHs in CSC accounted for less than 3% of the observed tumorigenicity [Wynder and Wright (4353, 4354), Wynder and Hoffmann (4307, 4308, 4312, 4317, 4319, 4332, 4342) Druckrey (1056), Roe (3310, 3311), USPHS (3999, 4005, 4009, 4010) Lazar et al. (2320), Stedman (3797), Selikoff et al. (3584a), Coultson (830)].

As early as the mid-1950s, Wynder and Wright (4353) noted that the concentration of B[*a*]P in cigarette tar was insufficient to account for its observed carcinogenicity to mouse epidermis: "The concentration in which benzo[*a*]pyrene seems to be in cigarette tar is insufficient to account for the observed carcinogenic activity to mouse epidermis."

At the 1957 Blatnik Committee hearings, Wynder reported Wright's opinion (4282a) on the subject as well as his own (4296). Wynder noted that much attention had been directed at the PAH B[*a*]P. So much in fact that, as Wynder stated, B[*a*]P had become an issue in itself because it was one of the known tumorigenic substances and everyone tried to blame everything on it alone. During his testimony, he also noted that his Sloan Kettering group had repeatedly stated that the amount of B[*a*]P in tobacco "tar" was insufficient to explain the animal results published by his group. He added that cigarette "tar" contained numerous other B[*a*]P-related compounds much more active than B[*a*]P and they most likely accounted for the majority of the activity, and it was more or less academic whether it was B[*a*]P or a dibenzopyrene or a dibenzanthracene or a substituted B[*a*]P because they were all formed in the same manner during the tobacco smoking process. That same year, Wynder and Wright (4354) wrote that, to that date, no carcinogens had been identified in large enough quantities in tobacco "tar" or its fractions to account for the observed activity in mouse-skin-painting studies:

> We have demonstrated experimentally … that 0.0001 per cent or even 0.0005 per cent benzopyrene in acetone will not produce any tumors in the present experimental mouse or rabbit groups. Thus, there is conclusive proof that the animal results cannot be solely due to the benzopyrene content of tobacco [sic].
>
> The benzpyrene content of the total tar as well as the active fractions is far too low to account alone for the positive results [in laboratory animal]. So far, no carcinogens have been identified in large enough quantity in tobacco tar or its fractions to account for the observed activity.

These Wynder–Wright results led to an intensive but unsuccessful 18-month search for a "supercarcinogenic" PAH by Wright. The absence of such a PAH was subsequently confirmed by the USDA group at Athens, GA [Snook (3732), Snook et al. (3756–3758)], by their identification of over 500 PAHs in the PAH fraction from cigarette mainstream smoke (MSS), an identification procedure that completely accounted for the fraction in the cigarette smoke studied.

In 1959, unable to explain the bioassay (mouse-skin-painting) results with CSC on the basis of either its B[*a*]P content (less than 2% explainable) or its total tumorigenic PAH content (less than 3% explainable), Wynder and Hoffmann (4307) added the concept of promotion by low-molecular-weight phenols to the concept of tumor initiation by PAHs in an attempt (unsuccessful) to explain the bioassay results:

A similar comment that the amount of tumorigenic PAHs found in CSC could not by themselves account for the total biological activity observed was included in a more detailed publication (4307). They also stated (4308) that the higher PAHs played an important role in the carcinogenicity of CSC but when the various known

concentrations of the carcinogenic PAHs, as estimated in CSC, were summed, it was obvious that they could not account for the established carcinogenicity of the CSC nor of its isolated PAH fraction:

> Several carcinogenic higher aromatic polycyclic hydrocarbons [are] present in tobacco smoke condensate. They include benzo[*a*]pyrene …, benzo[*e*]pyrene …, chrysene …, benz[*a*]anthracene …, dibenz[*a,h*]anthracene …, and dibenzo[*a,i*]pyrene… From the amount in which these materials have been found in tobacco smoke condensate it was evident that these, by themselves, could not account for the total biological activity observed.

In 1960, Van Duuren et al. (4027) reported the identification of several aza-arenes (dibenz[*a,h*]acridine, dibenz[*a,j*]acridine, dibenzo[*c,g*]carbazole) not only structurally similar to some of the known tumorigenic PAHs in CSC but also tumorigenic under certain conditions to mouse skin. Adding this class of tumorigenic cigarette smoke components to the assessment of the tumorigenicity of CSC failed to account for more than a few percent of the observed response.

However, it should be noted that Candeli et al. (587) could not confirm the findings of Van Duuren et al. on the presence of these three aza-arenes in cigarette MSS. During the next three decades, other research groups, as shown in Table 9.1, in Germany, Japan, and the United States were also unable to confirm the presence in cigarette MSS of dibenz[*a,h*]acridine, dibenz[*a,j*]acridine, and dibenzo[*c,g*]carbazole.

Wynder and Hoffmann (4312) wrote that the PAHs in CSC accounted for not more than 3% of the total biological activity observed in mouse-skin bioassays:

> The polynuclear aromatic hydrocarbons are mainly formed during the combustion of tobacco. The tobacco of our standard cigarettes contains only very minute quantities of benzo(a)pyrene (0.02 ppm). A bioassay indicates that these polycyclic hydrocarbons of the condensate by themselves, however, can account for not more than 3 per cent of the total biological activity.

They also wrote (4313) that the established carcinogenicity of CSC to mouse epidermis could to a great extent be accounted for on the basis of initiating carcinogens, largely PAHs, and promoting substances, a major group of which was the phenols. This statement was not true in 1961, nor is it true now.

Wynder and Hoffmann (4314), unable to explain the mouse-skin-painting bioassay results with CSC on the basis of its content of tumorigenic PAHs and aza-arenes, promoting and/or cocarcinogenic phenols, and promoting and/or cocarcinogenic nontumorigenic PAHs, added the concept of ciliastasis in an attempt (unsuccessful) to explain cigarette smoke tumorigenicity in smokers' lungs.

In their lengthy 1964 review of tobacco carcinogenesis, Wynder and Hoffmann (4319) stated that no one could deny that tobacco products were tumorigenic even though no single component in tobacco smoke could by itself or jointly with other components account for the observed tumorigenic activity of such tobacco products to the skin of laboratory animals:

> It is furthermore true that none of the agents is carcinogenic in the concentrations in which they are present in tobacco products.

Wynder and Hoffmann (4332) expressed similar views on the tumorigenicity of tobacco smoke components in their

Sasaki and Moldoveanu (3414)	NE	No	NE	No	NE	NE
Rustemeier et al. (3370)	NE	No	NE	Yes	NE	NE

Yes, compound identified; No, compound not found or identified; NE, substrate not examined for compound in question.

Examination of these results indicates that Van Duuren et al. (4027) reported the identification of the three *N*-heterocyclic compounds (I, II, and III) in MS CSC and two of them (I and II) in a nicotine pyrolysate, whereas Candeli et al. (587) failed to identify I but did identify II in MS CSC. The 1963 Candeli et al. findings on II in MS CSC were not confirmed in 1979 by investigators (3512) from the same laboratory: Hoffmann was a participant in both the 1963 and 1979 studies. Two studies (3499, 3512) confirmed the 1960 report by Van Duuren et al. that 7*H*-dibenzo[c,g]carbazole (III) was not present in a nicotine pyrolysate.

1967 book, but they continued to maintain that the PAHs in cigarette smoke were important as tumor initiators:

> While BaP and other carcinogenic PAH can by themselves account for only a small portion of the total tumorigenic activity of cigarette smoke condensate, probably less than 2%, they are, nevertheless, of obligatory importance as tumor initiators.

The next year, Wynder and Hoffmann (4342) wrote: "Carcinogenic polynuclear hydrocarbons in the concentrations present in tobacco 'tar' clearly do not, by themselves, account for the observed carcinogenicity."

On several occasions, the U.S. Surgeon General in his periodic reports on smoking and health discussed the relationship between the levels of PAHs in cigarette smoke, their tumorigenic potency to mouse skin, and the observed biological response with CSC in mouse-skin-painting bioassays:

> The results of a number of such assays [mouse skin-painting] present a puzzling anomaly: the total tar from cigarettes has about 40 times the carcinogenic potency of the benzo(a)pyrene present in the tar. The other carcinogens known to be present in tobacco smoke are, with the exception of dibenzo(a,i) pyrene, much less potent than benzo(a)pyrene and they are present in smaller amounts. Apparently, therefore, the whole is greater than the sum of the known parts. [see p. 58 in (3999)]
>
> Benzo(a)pyrene is present in much larger concentrations than is any other carcinogenic polycyclic hydrocarbon. The inability to account for the carcinogenicity of the tobacco products, except to a very minor degree, by the amount of benzo(a)pyrene present was unanticipated. Both Druckrey (1056) and Wynder (4300) emphasized that the benzo(a) pyrene concentration of various tobacco and smoke preparations is only sufficient to account for a very small part of the carcinogenicity of these materials. [see pp. 144–145 in (3999)]
>
> PAH alone, however, account for only a small portion of the carcinogenicity of tobacco 'tar'… The levels of carcinogenic PAH in tobacco smoke are well below their practical threshold as complete mouse skin carcinogens… (see 4005)
>
> The contribution of BaP or PAH in general to mouse skin carcinogenesis by cigarette smoke condensate cannot be fully measured at this time. Wynder and Hoffmann [1967] found a correlation between BaP levels and carcinogenicity of smoke condensates from several types of cigarettes. A much larger series of experimental cigarettes was studied in the smoking and health program of the National Cancer Institute. No significant dependence of carcinogenic potency on BaP content was observed [Gori (1329, 1330, 1332, 1333), NCI (2683)]. (see 4009)

The carcinogenic activity of the particulate matter of tobacco smoke in epithelial tissues of laboratory animals is greater than the sum of the effects of the known carcinogens present [(see 4010); cf. the comment in the 1964 Advisory Committee Report to the Surgeon General]. Apparently, therefore, the whole is greater than the sum of the known parts (3999).

In 1980, Coultson (830) commented on the decades of attention on B[*a*]P in cigarette MSS and its supposed relevance in cigarette smoke-induced cancers:

> Whether it's benzo[*a*]pyrene or not, nobody really knows. More work has been done on benzo[*a*]pyrene to prove it to be the causative agent in cigarette smoking than I think on any other chemical for any disease that I know. And yet the point is, you can't prove it.

The failure of PAHs to explain no more than a few percent of the tumorigenicity of CSC led to the inclusion of the concept of promotion in the overall equation. As noted previously, Wynder and Hoffmann (4313) asserted that the established carcinogenicity of CSC on mouse epidermis could to a great extent be accounted for on the basis of initiating carcinogens, largely PAHs, and promoting substances, a major group of which was the phenols. Their assertion was incorrect in 1961, and it is incorrect today.

In his listing of reported identified tobacco smoke components (Table 9.2), Kosak (2170) listed published reports on two simple phenols, the early reports on phenol by Wenusch (4202) and Ikeda (1857) and on catechol (1,2-benzenediol) by Kissling (2107) and Wenusch (4202), but he questioned the identification of phenol. Kosak also cited earlier reports by Thoms (3912) and McNally (2524) who mentioned the presence of "phenols" in tobacco smoke and Roffo (3324) who mentioned the presence of phenolic acids. However, it should be remembered that Roffo's 1939 studies dealt with a destructive distillate from tobacco, not with tobacco smoke generated in a tobacco smoking process simulating that used by human smokers.

Table 9.3 summarizes 1954 listing by Kosak of phenolic components reported in tobacco smoke, the year of the report, the investigators involved.

However, critical examination of the chronology of the pre-1954 investigations of phenolic compounds in tobacco smoke reveals that Kosak's 1954 publication suffers from several deficiencies with regard to reports on this class of tobacco smoke components. The examination indicates that his manuscript was submitted to the journal *Experientia* in September 1953, accepted for publication shortly thereafter, and appeared in a February 1954 issue of the journal. One of the significant omissions was the report by Rayburn and his colleagues at the Research Department of the American Tobacco Company: At the *6th Tobacco Chemists' Research Conference* (TCRC) in December 1952, Rayburn (3089) described the unequivocal identification of four low-molecular-weight phenols in the MSSs from a series of cigarettes, each member of the series fabricated from one of the four major tobacco types (flue-cured, burley, Maryland, Oriental). The phenols identified were phenol, guaiacol (2-methoxyphenol), *o*-cresol (2-methylphenol), and *m*-cresol (3-methylphenol). The next year, these results were published by Rayburn et al. in the journal *Analytical Chemistry* (3090).

In Table 9.4 literature references are listed for phenolic components in tobacco smoke cited by Kosak (2170) plus several pertinent references not included in his publication.

The report of the possible presence of phenol-like compounds in Oriental tobacco by Jones and Latimer (1980) at RJRT R&D eventually prompted a research project to synthesize a series of phenols in an attempt to find one or more which would impart a pleasant leatherlike aroma to cigarette smoke (3235a, 3240a). Some 20 phenols were synthesized. However, none was ever used commercially as a tobacco

TABLE 9.2
Tobacco Smoke Components Listed by Kosak (2170)

Class	Component	Class	Component	Class	Component
Hydrocarbons	Hentriacontane (?)	Ketones	3-Pentanone	Acids	Formic acid

			"Chlorophyll degradation products" (?)		"Cyanides" (?)
					"Nitrates" (?)
			"Uric acids" (?)		

[a] In smoke because of transfer of an humectant added to tobacco.
[b] Subsequent study demonstrated this component was not a well-defined compound but an artifact, a mixture, or an ammonium salt [see discussion by Johnstone and Plimmer (1971)].
[c] 1,6-Anhydro-β-*D*-glucopyranose.
[d] The question mark indicates that Kosak did not consider the evidence in the literature to be definitive proof of the identity of the component.
[e] Probably present as As_2O_3.

flavorant nor in any extensive in-house panel tests for the following reasons:

During the course of his initial research project (3235a, 3240a) at RJRT R&D, Rodgman suggested the possibility of the conversion of several of the phenols to a quinone during the smoking process. This suggestion, coupled with the reports by Takizawa (3865a) that several simple quinones such as *p*-benzoquinone (2,5-cyclohexadiene-4-dione), 1,2-naphthoquinone (1,2-naphthalenedione), and 1,4-naphthoquinone (1,4-naphthalenedione) were tumorigenic to mouse skin, raised serious questions about the addition of phenols to the tobacco blend. The biological findings on *p*-benzoquinone were subsequently confirmed by Tiedemann (3916a). Takizawa (3865a) reported that neither of the higher molecular weight quinones 9,10-anthraquinone (9,10-anthracenedione) or 9,10-phenanthrenequinone (9,10-phenanthrenedione) was tumorigenic to mouse skin.

Rodgman also communicated to management the substance of the early reports by Boutwell et al. (414), subsequently amplified by Boutwell and Bosch (414), that when certain low-molecular-weight phenols were applied to mouse skin in sequence with a level of a tumorigenic PAH such as B[*a*]P either insufficient

to induce tumors or sufficient to induce tumors in only a small percentage of the treated animals, the phenols enhanced (or promoted) the tumorigenic effect of the PAH, i.e., the % tumor-bearing animals (% TBA) was much higher than that anticipated on the basis of the PAH dose administered.

The effectiveness of the promotion of the tumorigenicity of a tumorigenic PAH by a phenol is dependent on the substituents R_2 and R_6 on the C_2 and C_6 carbons, the carbon atoms adjacent to the carbon to which the hydroxyl group is attached (Figure 9.1). If $R_2 = H$ or $R_6 = H$ or if $R_2 = R_6 = H$, then the phenol will exert a promoting effect, the effect being greatest when both substituents $R_2 = R_6 = H$. If neither R_2 nor R_6 is hydrogen, i.e., when $R_2 \neq H$ and $R_6 \neq H$, no promoting effect is observed.

The coupling of the findings reported by Boutwell et al. (414) on the promoting effects of low-molecular-weight phenols on PAHs in the mouse-skin-painting bioassay with the failure to explain the tumorigenicity of CSC on the basis of its PAH content subsequently triggered extensive research both

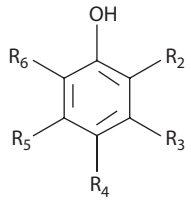

FIGURE 9.1 A substituted phenol.

within and outside of the tobacco industry on several aspects of the phenols in tobacco smoke:

1. Identification and quantitation of phenols in cigarette MSS: To date, the number of phenols identified in tobacco smoke exceeds 400 (see Table 9.22). While the number of phenols identified is significantly fewer than the number of PAHs identified in cigarette MSS, the number of identified tobacco smoke phenols is much greater than that identified in any other consumer product such as tea, coffee, or cocoa, again a reflection of the intense scrutiny directed at tobacco smoke *vs*. that directed at any other consumer product.
2. Bioassays to determine contribution of phenols to CSC tumorigenicity: Determination of the biological relationship, if any, between the phenol fraction from cigarette MSS or its individual components and the PAH fraction from cigarette MSS or its individual components needed to be conducted. Was the biological relationship between phenol and the tumorigenic PAHs one of promotion, cocarcinogenesis, inhibition, or anticarcinogenesis?
3. Determination of the nature of the precursors in tobacco of the phenols in cigarette MSS: The studies in the mid-1960s to identify the major precursors in tobacco of the phenols in tobacco smoke paralleled the studies in the late 1950s and early 1960s on the precursors in tobacco of the PAHs in tobacco smoke.
4. The effect of cigarette design parameters on delivery of MSS phenols: Determinations of which cigarette design parameters enabled significant control of the levels of phenols in MSS needed to be conducted.

In the following paragraphs, each of the previously listed topics is discussed in considerable detail with an attempt to put in perspective the relationships between isolation/identification, precursor definition, bioassay results, and delivery control pertinent to the phenols in cigarette MSS.

9.1.1 Identification and Quantitation of Phenols in Cigarette MSS

In their reviews of phenolic components of tobacco smoke, Wynder and Hoffmann (4319, 4332) concluded their report on the first successful isolation of phenols from tobacco smoke by Vohl and Eulenberg (4065) and Ludwig (2408) with the comment: "Since that time, publications have dealt sporadically with smoke phenols."

From the early 1950s through 1967, over 110 reports dealing with phenols in smoke were presented at scientific

meetings and/or published in peer-reviewed journals. Such a number can hardly be considered as sporadic!

Many of the studies in the 1950s dealt with the identification and quantitation of various low-molecular-weight phenols in cigarette MSS [cf. the studies on phenol, the methylphenols (the cresols), 2-methoxyphenol (guaiacol), the dimethylphenols (the xylenols) by Rayburn (3089), Rayburn et al. (3090), Commins and Lindsey (786–789, 789a), Izawa et al. (1906), and on scopoletin by Yang et al. (4373–4375)].

Not only was a variety of separation techniques employed to obtain the phenols but also a variety of analytical techniques was employed for the quantitation. Examples of these methods follow:

Diazotization with *p*-nitroaniline, paper chromatography, UV absorption spectrophotometry	Rayburn et al. (3090)
Methylation, paper chromatography, UV absorption spectrophotometry	Commins and Lindsey (786)
Formation of 2,4-dinitrobenzoates	Izawa et al. (1906)
Formation of phenylazobenzene sulfonic acid derivatives	Izawa et al. (1906)
Methylation, gas chromatography	Carruthers and Johnstone (615)
Gas chromatography, internal standard addition	Hoffmann and Wynder (1789), Crouse et al. (851), Spears (3764)
Gas chromatography	Oakley et al. (2820)
4-Aminoantipyrine treatment, colorimetry	Lorentzen and Neurath (2397)
Glass capillary gas chromatography	Smith and King (3716)
Diazotization with *p*-nitroaniline, colorimetry	Smith and King (3717, 3718)
Thin-layer chromatography	Smith and Sullivan (3719)
Derivatization, colorimetry	Knoop and Rosene (2142a)

In 1959, Johnstone and Plimmer (1971) cataloged the 16 tobacco smoke phenols listed in Table 9.5.

Examination of the chronology of the published reports on phenols in tobacco smoke reveals the escalation (see Table 9.6) of the scientific publications/presentations between 1952 and 1964, the year of the Advisory Committee's Report on Smoking and Health to the U.S. Surgeon General (3999). This escalation was similar to but not as extensive as the increase from 1953 to 1964 in the number of presentations/publications pertinent to PAH in tobacco smoke.

In January 1964, the Advisory Committee on Smoking and Health submitted its report to the U.S. Surgeon General (3999). Because of the widespread dissemination of the contents of this report, its January 1964 publication provides an appropriate point in time to assess the situation with regard to prior research publications on phenolic compounds in tobacco smoke. Table 9.6 summarizes chronologically some of the various reports issued between 1952 and 1964 on tobacco smoke phenols. Of the 82 reports cited in Table 9.6 from 1952 through 1964, 80 were issued from 1955 through 1964. If, because of the early 1964 issuance of the Advisory Committee's Report, the publications on tobacco smoke phenols in 1964 are omitted from the listing, the number from 1953 through 1963 becomes 65. As noted previously in the discussion of the early studies of PAHs, a similar assessment of publications on PAHs in tobacco smoke indicated that some 213 reports were issued from 1953 through 1964. If the publications on tobacco smoke PAHs in 1964 are omitted, the number from 1953 through 1963 becomes 200.

During the first decade of research on tobacco smoke, effort was divided between the identifications of the various

phenolic compounds and improvements of their quantitation in cigarette MSS.

Less than a decade after the Johnstone and Plimmer 1959 review, Stedman (3797) tabulated the reports in which the identifications of 54 phenols in tobacco smoke were described (Table 9.7).

In their 1980 review, Ishiguro and Sugawara (1884) listed over 150 phenolic compounds that had been identified as tobacco smoke components.

By the mid-1990s, over 270 completely identified phenolic compounds were reported as tobacco smoke components (Table 9.22). It should be noted that, despite repeated criticisms of the publication policy of the R.J. Reynolds Tobacco Company on tobacco smoke composition, 70 of the phenolic compounds listed in Table 9.22 were first reported as tobacco smoke components by R.J. Reynolds Tobacco Company R&D personnel and the identities of an additional 25 phenolic smoke components reported by others were confirmed.

As shown by the citations included in Table 9.8, the TCRC over the years has been a significant forum for the dissemination of new and meaningful information pertinent to phenolic components in tobacco smoke.

While the nature and levels of the low-molecular-weight phenols in tobacco smoke were being defined in the late 1950s and early 1960s, additional research permitted the identification of several more complex phenolic components of tobacco smoke, e.g., the naphthalenols by Commins and Lindsey (789, 789a), hydroxybenzopyranones such as scopoletin by Yang et al. (4373–4375) and Wender et al. (4164), esculetin by Dietermann et al. (969), α-tocopherol by Rodgman and Cook (3271), hydroxycinnamic acids by Yang and Wender (4376), hydroxyphenylacetic acids by Yang and Wender (4377) and Wender and Yang (4163), and several hydroxybenzaldehydes by Yang and Wender (4379). In contrast to the low-molecular-weight phenols, many of these more complex phenols are also present at more than trace amounts in tobacco. A series of low-molecular-weight, volatile phenols were identified in the tobacco type Latakia by Irvine and Saxby (1876, 1877a) at much greater levels than volatile phenols found in other tobacco types such as flue-cured and burley.

Eventually, several hydroxyphenyl alcohols and hydroxybenzyl alcohols were identified in tobacco and tobacco smoke by Hecht et al. (1561). These identifications were soon followed by the identification of a series of phenolic acids from tobacco by Snook et al. (3749, 3751). Table 9.5 had summarized the studies on phenols in tobacco smoke up to 1964. In Table 9.9, studies on phenols in tobacco smoke from 1964 to date are summarized.

9.1.2 Bioassays to Determine the Contribution of Phenols to Cigarette Smoke Condensate Tumorigenicity

At several scientific meetings in the mid-1950s, Boutwell et al. (414) described their preliminary findings on the promoting effect of phenol on the specific tumorigenicity of 7,12-dimethylbenz[*a*]anthracene (DMB[*a*]A) when the application of the PAH to mouse skin was followed by an

TABLE 9.7
Tobacco Smoke Phenols Cataloged by Stedman (3797)

No.	CAS Nomenclature	Common Name
1.	Acetic acid, 2-hydroxyphenyl-	
2.	Acetic acid, 3-hydroxyphenyl-	
3.	Acetic acid, 4-hydroxyphenyl-	
4.	Benzaldehyde, 3,4-dihydroxy-	Protocatechualdehyde
5.	Benzaldehyde, 3,5-dimethoxy-4-hydroxy-	Syringaldehyde
6.	Benzaldehyde, 2-hydroxy-	Salicaldehyde
7.	Benzaldehyde, 3-hydroxy-	
8.	Benzaldehyde, 4-hydroxy-	
9.	Benzaldehyde, 4-hydroxy-3-methoxy-	Vanillin
10.	1,2-Benzenediol	Catechol
11.	1,3-Benzenediol	Resorcinol
12.	1,4-Benzenediol	Hydroquinone
13.	Benzoic acid, 3,4-dihydroxy-	Protocatechuic acid
14.	Benzoic acid, 3,5-dimethoxy-4-hydroxy-	Syringic acid
15.	Benzoic acid, 2-hydroxy-	Salicylic acid
16.	Benzoic acid, 3-hydroxy-	
17	Benzoic acid, 4-hydroxy-	
18.	Benzoic acid, 3-hydroxy-4-methoxy-	Isovanillic acid
19.	Benzoic acid, 4-hydroxy-3-methoxy-	Vanillic acid
20.	2*H*-1-Benzopyran-6-one, 6,7-dihydroxy-	Esculetin
21.	2*H*-1-Benzopyran-6-one, 7-hydroxy-6-methoxy-	Scopoletin
22.	Cinnamic acid, 3,4-dihydroxy-	Caffeic acid
23.	Cinnamic acid, 3,4-dihydroxy-, 3-ester with 1,3,4,5-tetrahydroxycyclohexanecarboxylic acid	Chlorogenic acid
24.	Cinnamic acid, 3,4-dihydroxy-, 5-ester with 1,3,4,5-tetrahydroxycyclohexanecarboxylic acid	Neochlorogenic acid
25.	Cinnamic acid, 3,5-dimethoxy-4-hydroxy-	Sinapic acid
26.	Cinnamic acid, 4-hydroxy-	Coumaric acid
27.	Cinnamic acid, 4-hydroxy-3-methoxy-	Ferulic acid
28.	Ethanone, 1-(2-hydroxyphenyl)-	Acetophenone, 2′-hydroxy-
29.	Ethanone, 1-(3-hydroxyphenyl)-	Acetophenone, 3′-hydroxy-
30.	Ethanone, 1-(4-hydroxyphenyl)-	Acetophenone, 4′-hydroxy-
31.	1-Naphthalenol	1-Naphthol
32.	2-Naphthalenol	2-Naphthol
33.	Phenol	
34.	Phenol, 2,6-dimethoxy-	
35.	Phenol, 2,3-dimethyl-	2,3-Xylenol
36.	Phenol, 2,4-dimethyl-	2,4-Xylenol
37.	Phenol, 2,5-dimethyl-	2,5-Xylenol
38.	Phenol, 2,6-dimethyl-	2,6-Xylenol
39.	Phenol, 3,4-dimethyl-	3,4-Xylenol
40.	Phenol, 3,5-dimethyl-	3,5-Xylenol
41.	Phenol, 2-ethyl-	
42.	Phenol, 3-ethyl-	
43.	Phenol, 4-ethyl-	
44.	Phenol, 2-methoxy-	Guaiacol
45.	Phenol, 2-methoxy-	
46.	Phenol, 4-methoxy-	
47.	Phenol, 2-methoxy-4-(1-propenyl)-	Isoeugenol
48.	Phenol, 2-methoxy-4-(2-propenyl)-	Eugenol
49.	Phenol, 2-methyl-	*o*-Cresol
50.	Phenol, 3-methyl-	*m*-Cresol
51.	Phenol, 4-methyl-	*p*-Cresol
52.	Phenol, 5-methyl-2-(1-methylethyl)-	Thymol
53.	Phenol, 2,4,6-trimethyl-	Mesitol
54.	Propanoic acid, 3-hydroxyphenyl-	
55.	Propanoic acid, 4-hydroxyphenyl-

application of phenol. Subsequently, Boutwell and Bosch (414) reported that phenol and many substituted phenols enhanced or promoted the specific tumorigenicity of PAHs. However, they reported that 1,2-benzenediol (catechol) exhibited no tumor-promoting activity. Later, 1,2-benzenediol (catechol) was found to be the most plentiful low-molecular-weight phenol in cigarette MSS [Kallianos et al. (2016), Schlotzhauer et al. (3462), Schlotzhauer and Chortyk (3453), Morée-Testa (2615), Risner and Cash (3171–3174), Risner (3165)] and was reported [Van Duuren et al. (4029)] to be a cocarcinogen for PAHs, not a promoter.

Coincident with the phenol studies of Boutwell et al. (414) and during the time that much effort was being expended to resolve the question about the presence of PAHs in tobacco smoke, Gwynn and Salaman (1463b) reported the promoting effect of CSC.

Two years later, Gellhorn (1281) reported that whole CSC acted as a promoting agent for several tumorigenic PAHs applied to mouse skin.

The next year, Roe et al. (3314) reported that the phenolic fraction from CSC exerted a significant promoting effect on the specific tumorigenicity of PAHs. They theorized:

> Cigarette smoke condensate may be richer in tumour-promoting substances than in tumour-initiating substances. Phenolic compounds may be responsible for much of its promoting activity.

As noted previously, Wynder and Hoffmann (4307), unable to explain the bioassay (skin painting) results with CSC on the basis of either its B[*a*]P content (less than 2% TBA explainable) or its total tumorigenic PAH content (less than 3% TBA explainable), added the concept of promotion, particularly that attributed to low-molecular-weight phenols, in an attempt (unsuccessful) to explain the bioassay results in laboratory animals. They amplified their theory in a more detailed publication (4307). They also stated (4308) that the higher molecular weight PAHs played an important role in the carcinogenicity to mouse skin of CSC but when the various known concentrations of the carcinogenic PAHs as estimated in CSC were summed, it was obvious that these smoke components acting either individually or in concert could not account for the established carcinogenicity to mouse skin of the CSC nor of its isolated PAH fraction.

Because of the inability to explain the mouse-skin-painting bioassay results with CSC on the basis of its PAH content and because of the presumed biological relationship between the phenol fraction and/or its individual components and the PAH fraction and/or its individual components, the findings reported by Boutwell et al. (414), Gwynn and Salaman (1463b), Gellhorn (1281), and Roe et al. (3314) stimulated extensive research on the nature and levels of the phenols in cigarette MSS in the late 1950s to early 1960s. Over the next few years, the results from different laboratories of the bioassays involving tobacco smoke phenols varied considerably. The variations raised the question as to whether the relationship between the tobacco smoke phenols and PAHs was one of promotion, cocarcinogenesis, inhibition, or anticarcinogenesis.

From the results of their studies on the administration of B[*a*]P plus phenol and the administration of DMB[*a*]A plus phenol, Wynder and Hoffmann (4313) concluded:

> [Our results] show that promoting substances present in tobacco smoke can increase and accelerate the tumor yield of carcinogenic polynuclear hydrocarbons that by themselves are not present in sufficient concentration to yield any tumors or yield them only after a prolonged latent period.

In 1958, Wynder et al. (4355) proposed the use of the level of B[*a*]P in CSC as an "indicator" or "marker" of the specific tumorigenicity (mouse skin) of CSC as well as an "indicator" or "marker" of its levels of tumorigenic PAHs with four or more rings. When the low-molecular-weight phenols in tobacco smoke attracted considerable attention because of their claimed contribution to the specific tumorigenicity of CSC, Hoffmann et al. (1766) and Wynder and Hoffmann (4317) extended the "indicator" concept to phenol, designating it as an "indicator" or "marker" for the promoting

low-molecular-weight, volatile phenols in cigarette MSS. Just as the concept of B[*a*]P as an "indicator" or "marker" of CSC-specific tumorigenicity and tumorigenic higher PAHs content was subsequently shown to be incorrect, so was the concept of phenol as an "indicator" or "marker" of phenol-induced promoting activity of CSC and promoting phenols content shown to be incorrect. The phenol "indicator" situation is discussed in the following.

Table 9.10 summarizes some of the diversity observed in the bioassay results on the properties pertinent to the tumorigenicity of PAHs of several phenol components of tobacco smoke (phenol, catechol, α-tocopherol), the phenolic fraction from CSC, and CSC itself.

Although much attention and effort were devoted to the supposed deleterious effects of various tobacco smoke components such as the PAHs, the aza-arenes, and the low-molecular-weight phenols, very little was reported about the tobacco smoke components with properties that offset the supposed tumorigenicity or promoting effects of the compound classes mentioned. One of the first examples of cigarette MSS components inhibiting the action of a "tumorigen" was described by Wynder and Hoffmann (4311). This finding was an outgrowth of their studies on the effect of organic solvent extraction of tobacco on the PAH content of the extracted tobacco smoke. Lam (2255) and Wynder (4294) in the mid-1950s proposed that the precursors in tobacco of PAHs in cigarette MSS were the saturated aliphatic hydrocarbons; Wright (4282a) and Wynder et al. (4355, 4356) proposed the phytosterols as the PAH precursors, and Wright (4282) also proposed the terpenoid compounds as major PAH precursors. These compounds are removable almost totally or to a substantial degree by extraction of tobacco with organic solvents such as hexane or pentane. Cigarettes fabricated from the extracted tobacco yielded lower quantities in MSS of PAHs such as B[*a*]P that were known under certain laboratory conditions to produce tumors on the shaved backs of susceptible strains of mice. Skin-painting studies with mainstream CSC collected by smoking cigarettes made with the control and extracted tobaccos gave a lower percentage of TBA in the extracted tobacco CSC group. However, the decrease in % TBA was much less than the percent decrease in the level in the CSC of tumorigenic PAHs such as B[*a*]P (4282, 4294, 4307, 4355, 4356).

One explanation for this difference was that the solvent extraction removed nearly all the aliphatic saturated hydrocarbons from the tobacco, and thus, they were either absent from the MSS from the extracted tobacco cigarettes or present at extremely low levels. Wynder and Hoffmann [see pp. 330–331 in (4319) and pp. 370–371 in (4332)] reported that this aliphatic saturated hydrocarbon fraction (constituting about 3% of the mainstream CSC) inhibited the activity of tumorigenic PAHs, including B[*a*]P. The components in the aliphatic hydrocarbon fraction ranged from pentadecane (C_{15}) to pentatriacontane (C_{35}). Each hydrocarbon was present as the *normal*, *iso*, and *anteiso* isomers. The C_{27}–C_{33} hydrocarbons constituted about 80% of the saturated hydrocarbon fraction; with C_{31} (*n*-hentriacontane) and C_{33} (*n*-tritriacontane) hydrocarbons usually being the most plentiful components in the fraction. Subsequent study with improved analytical methodology demonstrated the presence of trace amounts of additional isomeric aliphatic saturated hydrocarbons with as many as 40 carbons.

TABLE 9.10
Variation in Bioassay Results with Phenols or Phenol-Containing Materials

	Effect on Specific Tumorigenicity of PAHs		
Phenol	**Promotion**	**Cocarcinogenicity**	**Inhibition or Anticarcinogenesis**
CSC	Yes: Gwynn and Salaman, (1463b), Gellhorn (1281)		
Phenolic fraction from CSC	Yes: Roe et al. (3314)		
Phenols	Yes: Boutwell et al. (414)		
Phenol	Yes: Wynder and Hoffmann, (4313, 4317), Hoffmann and Wynder (1791), Hoffmann et al. (1736)	No: Van Duuren et al. (4029)	Yes: Van Duuren et al. (4029, 4035)
1,2-Benzenediol {catechol}	No: Van Duuren and Goldschmitt (4028)	Yes: Van Duuren et al. (4029), Van Duuren and Goldschmitt (4028), Hecht et al. (1562), Hoffmann et al. (1736)	
1*H*-1-Benzopyran-6-ol, 3,4-dihydro-2,5,7,8-tetramethyl-2-(4,8,12-trimethyltridecyl)-{α-tocopherol}			Yes: Shamberger (3625), Slaga and Bracken (3684), Viaje et al. (4049a), Shklar (3655a), Weerapradist and Shklar, (4159a), Toth and Patil (3927a), Mirvish (2559b)

CSC, cigarette smoke condensate.

Studies with B[*a*]P and the C_{31} and C_{35} saturated hydrocarbons (SHC), where the SHC to B[*a*]P ratio was 200:1 and 100:1, showed that both saturated hydrocarbons exerted a significant inhibiting effect at both levels on the specific tumorigenicity of B[*a*]P in mouse-skin-painting experiments [4311, 4314, see also pp. 330–331 in (4319) and pp. 370–371 in (4332)].

When the saturated hydrocarbon content (normally about 3% of the particulate phase) of mainstream CSC was increased from 3% to 4% (an overall 33% increase) by addition of the saturated hydrocarbon fraction isolated from CSC, the specific tumorigenicity of the CSC decreased, and the % TBA decreased from 40% to 24%. The MSS of a cigarette delivering 20 mg of CSC contains about 0.6 mg (600,000 ng) of this saturated hydrocarbon fraction and 10 ng of B[*a*]P, a SHC to B[*a*]P ratio of 60,000:1, far in excess of the 200:1 or 100:1 SHC to B[*a*]P ratio that produced the significant inhibition of the specific tumorigenicity of B[*a*]P reported in the mouse-skin-painting bioassay (4314, 4319, 4332).

Other MSS components may have also influenced the PAH and mouse-skin-painting results obtained with control tobacco CSC *vs*. the CSC from organic solvent-extracted tobacco. The extraction of tobacco with a solvent such as hexane not only removed the saturated aliphatic hydrocarbon inhibitors from the tobacco, thus making impossible their transfer to MSS when such tobacco is smoked, but also removed other components such as β-sitosterol (4356), α-tocopherol (vitamin E) (3271, 3347), indole 3279), and α- and β-4,8,13-duvane-1,3-diol (3221, 3361, 3389), thus preventing their transfer to MSS during the smoking process. Subsequently, these tobacco components, now known to transfer from the tobacco rod to MSS during the smoking process and presumably to sidestream smoke (SSS) during cigarette smolder, have been shown to behave as anticarcinogens for several of the reported tobacco smoke "tumorigens" such as the PAHs, the *N*-nitrosamines, and ethyl carbamate. Neither the presence of several of these tobacco and MSS components nor their anticarcinogenic or inhibitory activity *vs*. known tumorigens was known in the late 1950s/early 1960s.

Despite the emphasis on the contribution of CSC components to its specific tumorigenicity when administered to laboratory animals via skin painting, the inhibition of tumorigenesis by CSC and several of its components was not completely ignored during the 1960s. In addition to the role of saturated aliphatic hydrocarbons in the inhibition of the specific tumorigenicity of CSC reported by Wynder and Hoffmann [4311, 4314, see also pp. 330–331 in (4319) and pp. 370–371 in (4332)], other studies pertinent to the antitumorigenicity of tobacco smoke included an earlier one in 1958 by Hoffman and Griffin (1672a) plus later ones in the mid-1960s by Homburger and his colleagues (1823, 1823b, 1824) as well as one reported in the late 1970s by Chamberlain et al. (663) at the USDA.

Comparison of the list of the 6000 or so identified components in tobacco smoke with extensive lists presented by Fay et al. (1177a) and Slaga and DiGiovanni (3685) of compounds and elements reported to possess inhibitory or anticarcinogenic action in carcinogenesis-type experiments in laboratory animals reveals not only that tobacco smoke contains numerous anticarcinogens but also that the levels in tobacco smoke of many of them far exceed those of the levels of the reported tobacco smoke "tumorigens" (3255a). The levels of many of the anticarcinogens in tobacco smoke *vs*. those of the reported smoke "tumorigens" are far in excess of the ratio needed for the anticarcinogenicity to be effective. Table 9.11, adapted from Rodgman (3255a), lists tobacco smoke components reported to be inhibitory or anticarcinogenic to several of the "tumorigens" reported to be present in tobacco smoke.

TABLE 9.11
Inhibitors and Anticarcinogens in Tobacco Smoke

Tobacco Smoke Component Class (Examples)	Tumorigen Suppressed
Hydrocarbons, saturated (e.g., $C_{31}H_{64}$, $C_{35}H_{72}$)	B[*a*]P
Hydrocarbons, unsaturated (*D*-limonene)	NNK, dibenzo[*a,i*]pyrene
Hydrocarbons, monocyclic aromatic (benzene)	B[*a*]P, DB[*a,h*]A
Hydrocarbons, aromatic, polycyclic (naphthalene, anthracene, phenanthrene, fluoranthene, pyrene, benzo[*e*]pyrene, benzo[*b*]triphenylene)	B[*a*]P, DB[*a,h*]A, DMB[*a*]A
Lactones (coumarin, α-angelica lactone)	B[*a*]P, DMB[*a*]A
Alcohols (ethanol, *n*-butanol, *tert*-butanol, cholesterol, β-sitosterol, α- and β-4,8,13-duvane-1,3-diol	NNN, DMB[*a*]A
Purines (caffeine, theobromine)	Ethyl carbamate, *N*-nitrosamines, DMB[*a*]A
Indoles (indole, indole-3-acetonitrile)	B[*a*]P
Miscellaneous components (maleic anhydride, aconitic acid, selenium, carbon disulfide)	B[*a*]P, DMB[*a*]A, 1,2-dimethylhydrazine
Phenols (phenol, caffeic acid, ferulic acid, gallic acid; 2-hydroxycinnamic acid; 4-methoxyphenol; α-tocopherol) (see Table 9.9)	B[*a*]P, *N*-nitrosamines, 1,2-dimethylhydrazine, DMB[*a*]A, 1,2-dihydro-3-methylbenz[*e*]aceanthrylene (3-methylcholanthrene)

NNK, 4-(*N*-methylnitrosamino)-1-(3-pyridinyl)-1-butanone; NNN, *N*′-nitrosonornicotine.

Hoffmann et al. (1766) reported that the results from their study of the levels of several selected components in the MSSs from different tobacco products gave suggestive support to the hypothesis that B[*a*]P and phenol may serve as "indicators" of the specific tumorigenic activities (initiation, promotion) of tobacco "tars." During the next decade, the hypothesis that phenol was an "indicator" of the low-molecular-weight, promoting phenols was reiterated numerous times by Wynder and Hoffmann (4319, 4330, 4332, 4342, 4344, 4346, 4346a). However, as research on the biological effects of phenols in tobacco smoke escalated, it became obvious that the promoting effect of the low-molecular-weight phenols on the specific tumorigenicity of PAHs in tobacco smoke was not as definitive as Wynder and Hoffmann and other investigators asserted. The discovery that a large percentage of the volatile phenols are removed from MSS by the plasticized filter tip led to differences of opinion on the promoting action of the volatile phenols.

Numerous statements in Hoffmann–Wynder presentations and publications described their conclusions with respect to volatile phenols removal *vs*. tumorigenicity of the phenol-depleted CSC. Examples of Wynder–Hoffmann statements follow:

In their 1967 book, Wynder and Hoffmann [(4340), see p. 626 in (4332)] stated:

> It should be noted, however, that a reduction of phenols in tobacco smoke condensate has not led to a concomitant reduction of tumorigenicity in the corresponding "tars."

In 1968, Wynder and Hoffmann (4342) again discussed phenols as promoters:

> Volatile phenols represent one type of tumor promoter in tobacco smoke. In mouse-skin carcinogenesis, however, they evidently do not play an essential role as such, since a significant reduction of phenols in the smoke condensate is not accompanied by a similar reduction in carcinogenic activity of the "tar" [4332].

A year later, Wynder and Hoffmann [see p. 298 in (4344)] wrote:

> The only known group of promoters in tobacco smoke are the volatile phenols. Their reduction of up to 80% by selective filtration, however, did not lead to a reduction of tumor promoting activity.

In the same article, they added [p. 299 in (4344)]:

> A reduction of phenol in tobacco smoke through the use of filters, however, does not alter the complete tumorigenic activity of "tar" obtained from such cigarettes. This infers that a selected reduction of volatile phenols will not reduce the tumor-promoting activity of such "tar."

In the written introduction to their presentation at the 28th TCRC in 1974, Hecht et al. (1582) stated the following and cited Wynder and Hoffmann (4332) as their source:

> Phenol and some substituted phenols are weak promoters, but they alone contribute only a small part of the promoting activity, since selective filtration of phenol does not change significantly the biological activity of the resulting condensate.

In their discussion of tumor promoters and the complexity of CSC, Van Duuren et al. (4035) reported:

> Phenol, which is a weak tumor-promoting agent, is indeed an inhibitor of tumorigenesis when applied simultaneously with benzo[*a*]pyrene.

Van Duuren et al. also noted that rutin, a tobacco component, also inhibited B[*a*]P carcinogenesis in the mouse-skin-painting bioassay. From the results of their biological experiments on cocarcinogenesis [simultaneous and repeated application of an agent, in this case 1,2-benzenediol (catechol)], with B[*a*]P, Van Duuren et al. (4029) deduced that 1,2-benzenediol (catechol) showed remarkable cocarcinogenic activity with B[*a*]P. They reported:

> Phenol has been regarded as an important 'tumor promoter' in cigarette smoke condensate…[but our] work indicates it is inactive in cocarcinogenesis and, indeed, has a slightly inhibitory effect on benzo[*a*]pyrene carcinogenesis.

Later, Van Duuren and Goldschmidt (4028) demonstrated the cocarcinogenicity of 1,2-benzenediol (catechol) when applied as a 2% solution to mouse skin three times weekly with a solution of 0.005% B[*a*]P. They contrasted the remarkable cocarcinogenic activity of 1,2-benzenediol (catechol) with its inactivity as a tumor promoter for B[*a*]P.

Hecht et al. (1562) described the importance of 1,2-benzenediol (catechol) as a tobacco smoke cocarcinogen. They also noted that the levels of 1,2-benzenediol (catechol) in MSS were reduced by prior extraction of the tobacco with hexane–ethanol or by inclusion of reconstituted tobacco sheet (RTS) in the tobacco blend.

While Wynder and Hoffmann wrote at length about the promoting effect of low-molecular-weight phenols and the phenol fraction of CSC on PAH tumorigenicity, it is interesting to note their change in emphasis in 1986. In a 1986 article (1808), the Hoffmann–Wynder discussion dealt primarily with the nature of tumor initiators (PAHs) and cocarcinogens (catechols), with no mention of the phenolic promoters they had discussed repeatedly for more than two decades since the early 1960s! In that same year, the IARC published its monograph on tobacco smoking to which Wynder and Hoffmann had contributed substantial information on tobacco smoke chemistry. In its monograph, IARC defined the phenols as a major group of promoting agents in tobacco smoke (1870), but IARC made no mention of the Wynder–Hoffmann observation of a lack of effect on specific tumorigenicity of the almost complete removal of the phenols from MSS.

Although much was written during the 1950s, 1960s, and 1970s about the supposed adverse effect, i.e., the promoting effect of phenolic compounds in tobacco smoke on its specific tumorigenicity in laboratory animals, significant properties, e.g., their anticarcinogenicity and/or antipromoting

TABLE 9.12
Tobacco Smoke Phenols with AC or AP Properties

Phenolic Smoke Component	Reference to Identification in Tobacco Smoke	Reference to AC or AP
Benzoic acid, 3,4,5-trihydroxy- {gallic acid}	Kröller (2195)	(AC) Mirvish et al. (2559c)
1*H*-1-Benzopyran-6-ol, 3,4-dihydro-2,5,7,8-tetramethyl-2-(4,8,12-trimethyltridecyl)- {α-tocopherol}	Rodgman and Cook (3271, 3286), Rodgman (3251)	(AC) Shamberger (3625), Slaga and Bracken (3684), Viaje et al. (4049a), Shklar (3655a), Weerapradist and Shklar, (4159a), Toth and Patil (3927a), Mirvish (2559b)
Phenol	Vohl and Eulenberg (4065), Ludwig (2408), Ikeda (1857)	(AP) Van Duuren et al. (4035)
Phenol, 4-methoxy-	Spears (3764)	(AC) Wattenberg et al. (4149c)
2-Propenoic acid, 3-(3,4-dihydroxyphenyl)-, *cis*- {*cis*-caffeic acid}	Yang et al. (4376), Yang and Wender (4377), Wender and Yang (4163)	(AC) Wattenberg et al. (4149c); Wattenberg (4149b)
2-Propenoic acid, 3-(3,4-dihydroxyphenyl)-, *trans*- {*trans*-caffeic acid}	Yang et al. (4376), Yang and Wender (4377), Wender and Yang (4163)	(AC) Wattenberg et al. (4149c); Wattenberg (4149b)
2-Propenoic acid, 3-hydroxy-4-methoxyphenyl)-, *trans*- {ferulic acid}	Yang and Wender (4377)	(AC) Wattenberg (4149b)

AC, Anticarcinogenesis; AP, Antipromotion.

effects, of several specific tobacco smoke phenols have generally been overlooked. Phenolic compounds in tobacco smoke known to possess either of these properties are listed in Table 9.12.

In addition to the known antitumorigenic and anti-promoting effects of CSC and several specific components in it, it has also been shown by Lee et al. (2327a, 2327b, 2337c) that cigarette MSS possess antimutagenic properties that offset the mutagenicity in the Ames test (*Salmonella typhimurium*)of several *N*-nitrosamines and several of the *N*-heterocyclic amines defined as "cooked food" mutagens.

9.1.3 Determination of the Nature of the Precursors in Tobacco of the Phenols in Mainstream Smoke

Resolution of the question of the presence of tetracyclic and higher PAHs, particularly B[*a*]P, in tobacco smoke was followed chronologically by studies to determine the source of the PAHs in tobacco smoke. When the PAH-containing environmental pollutants from lighting sources (matches, hydrocarbon-fueled cigarette lighters, etc.) were discarded in the early 1950s as significant contributors to the PAHs in tobacco smoke, particularly cigarette MSS, the contribution of tobacco itself to the PAHs in smoke was questioned: What were the components in tobacco that, during the smoking process, could act as significant precursors of the PAHs in its smoke? The investigation sequence was essentially the same with the reported tumorigenic aza-arenes in tobacco smoke: Initially, the identifications of the aza-arenes were resolved. Subsequently, studies were conducted to define the precursors in tobacco of the aza-arenes identified in tobacco smoke. As noted previously, however (see Table 9.1 and accompanying text), the results reported on numerous studies between 1963 and 1992 have raised other serious questions concerning the presence of the aza-arenes dibenz[*a,h*]acridine, dibenz[*a,j*] acridine, and 7*H*-dibenzo[*c,g*]carbazole in tobacco smoke and their supposed generation from nicotine.

The difference in the levels of simple phenols in tobacco smoke *vs*. their levels in the major tobacco types (flue-cured, burley, Maryland tobaccos), which collectively constitute the major proportion of American cigarette tobacco blends, suggested that the simple phenols in cigarette MSS were present not as a result of their significant direct transfer per se from the tobacco but as a result of their pyrosynthesis from precursors comprising one or more tobacco components. Long before the concern expressed that the simple phenols possessed promoting activity that enhanced the tumorigenicity of tumorigenic PAHs (414) and the concern expressed by Roe et al. (3314) and Wynder and Hoffmann (4307) about the presence of the simple phenols in tobacco smoke, Wenusch (4202) had suggested that the major sources in tobacco of the tobacco smoke phenols were its lignin and complex carbohydrate and polyphenol components.

In contrast to flue-cured, burley, and Maryland tobaccos, highly aromatic tobaccos such as Latakia were reported to contain significant levels of free simple phenols (1876, 1877a). As the complexity of the phenols increased, the likelihood of their presence in tobacco increased and many were found in smoke as a result of direct transfer, e.g., the high-molecular-weight phenol 3,4-dihydro-2,5,7,8-tetramethyl-2-(4,8,12-trimethyltridecyl)-1*H*-1-benzopyran-6-ol (α-tocopherol), first identified as a tobacco component by Rowland (3347) and as a tobacco smoke component by Rodgman and Cook (3271), and 6,7-dihydroxy-2*H*-1-benzopyran-6-one (esculetin), identified in tobacco and its smoke by Dieterman et al. (969). In the early 1960s, Herrmann (1625, 1626) reviewed

various studies on the phenols, phenolic acids, and related compounds identified in tobacco and tobacco smoke.

Examination of the chronology of the investigation of phenolic components of tobacco smoke reveals an interesting situation. In the early 1960s, substantial research was conducted on the phenols in tobacco smoke, their identification, their quantitation, and their major precursors in tobacco. When the promoting effect of the low-molecular-weight monohydric phenols was seriously questioned, the effort on phenols waned for some years but accelerated again when the claims on the cocarcinogenicity of the dihydric phenols, particularly 1,2-benzenediol (catechol), surfaced. This situation triggered examination of the levels of the benzenediols in tobacco smoke and their possible precursors in tobacco. Table 9.13 summarizes some of the studies conducted to define the nature of the major precursors in tobacco of the phenolic components of tobacco smoke.

Zane and Wender (4403) described their pyrolysis (pyrolysis temperature that of a Bunsen burner flame) of the tobacco components rutin, quercetin, and chlorogenic acid. In addition to nonphenolic compounds, each pyrolysate was reported to contain 1,2-benzenediol (catechol) with lesser amounts of 4-methyl-1,2-benzenediol, 1,3-benzenediol (resorcinol).

The amounts of phenol and 4-methylphenol (*p*-cresol) in the pyrolysates obtained under various conditions from several major tobacco components (cellulose, pectin, and lignin), a tobacco additive (invert sugar), several individual tobacco types (flue-cured tobacco, cased burley tobacco, Maryland tobacco), and a tobacco substitute (spinach) were reported by Rodgman and Mims (3305) and Rodgman and Cook (3286). Table 9.14 summarizes the results.

Spears et al. (3767) and Bell et al. (248) determined the generation of phenol when flue-cured and burley tobaccos and various tobacco components (glucose, sucrose, starch, cellulose, and pectin) were pyrolyzed at various temperatures in an air or nitrogen atmosphere. In each instance, phenol was generated.

In their study of tobacco lignin as a phenols precursor, Kato et al. (2043) examined the residue resulting from heating tobacco stalk lignin at 450°C–500°C for 2 h. They identified the following phenols: phenol, 2-methoxyphenol (guaiacol), 2-methylphenol (*o*-cresol), 3-methylphenol (*m*-cresol), and 4-methylphenol (*p*-cresol). Kato et al. (2046) also conducted a comparative thermal analysis of tobacco stalk-derived cellulose, holocellulose, and lignin subjected to similar heating.

In a continuation of the pyrolysis study by Chortyk et al. (725a, 726) on the possible contribution of the tobacco pigment to the PAH content of tobacco smoke composition, Schlotzhauer et al. (3468) examined the pyrogenesis of phenols from high-molecular-weight components of tobacco, specifically the tobacco pigment and the biopolymers lignin, cellulose, and pectin. Schlotzhauer et al. (3468) reported that the phenol amounts [phenol, 3- and 4-methylphenol (*m*- and *p*-cresol)] found in the pyrolysates from Oriental tobacco and the high-molecular-weight tobacco components (pigment, lignin, pectin, cellulose) pyrolyzed at 700°C/nitrogen atmosphere were generated in the following sequence:

Oriental tobacco > pigment > lignin ≥ pectin >> cellulose

In a study of the effect of steady state pyrolysis of tobacco *vs.* pulsed pyrolysis simulating the puffing sequence in a smoked cigarette, Patterson et al. (2904) reported that the pulsed pyrolysis procedure gave much higher levels of the low-molecular-weight phenols [phenol, 2-, 3-, and 4-methylphenol (*o*-, *m*-, and *p*-cresol), 2-, 3- and 4-ethylphenol, 2,4- and 2,5-dimethylphenol (2,4- and 2,5-xylenol), 2-methoxyphenol (guaiacol)] in the pyrolysate than did the steady state pyrolysis.

The report of the significant cocarcinogenicity of 1,2-benzenediol (catechol) by Van Duuren and Goldschmidt (4028) and the subsequent confirmation of its cocarcinogenicity by Hecht et al. (1562) triggered considerable interest in the source in tobacco of 1,2-benzenediol (catechol) in tobacco smoke.

In the early 1980s, Schlotzhauer et al. (3462) and Schlotzhauer and Chortyk (3453) at the USDA in their study of the precursors in tobacco of phenols in tobacco smoke investigated the pyrolysis of various solvent-extracted fractions from tobacco plus the tobacco residue after extraction. The extracted tobacco residue, the ethanol extract, and the methanol extract were the major sources of benzenediols (catechol, resorcinol, hydroquinone). From these results, it was proposed that chlorogenic acid in tobacco was a major precursor of the benzenediols, particularly 1,2-benzenediol (catechol), in tobacco smoke. The extracted tobacco residue was also reported as the major source of the monohydric phenols (phenol, cresols, xylenols, guaiacols).

Figure 9.2 illustrates the possible relationship between 1,2-benzenediol (catechol) and several complex tobacco phenols subsequently studied as its precursor.

In a continuation of their study of the conversion of various tobacco components to catechol, Schlotzhauer et al. (3462) examined the phenols formed during the pyrolysis of a variety of tobacco components, including chlorogenic and caffeic acids, rutin and quercetin, cellulose and lignin, and fructose and sucrose (Table 9.15). They reported that chlorogenic acid, usually the most abundant polyphenol in tobacco, produced the highest levels of 1,2-benzenediol (catechol) and 4-ethyl-1,2-benzenediol (4-ethylcatechol) during pyrolysis. In addition, the tobacco biopolymer lignin was also reported to be a significant source of 1,2-benzenediol (catechol). Their examination of the phenols generation by pyrolysis of several different flue-cured and burley tobaccos indicated that the flue-cured tobaccos produced significantly higher levels of the phenols than did the burley tobaccos. A similar situation is obtained when the MSS phenols from cigarettes fabricated from all flue-cured and all burley tobaccos are compared on a per milligram of phenol per milligram of CSC basis [Wynder and Hoffmann (4317), cf. Wynder and Hoffmann (4332)].

Because they considered 1,2-benzenediol (catechol) a "major constituent of tobacco smoke," a component they considered an important contributor to the biological properties of smoke, Hoffmann and his colleagues at the American Health

TABLE 9.13
Precursors in Tobacco of Phenols in Tobacco Smoke

[a] Quinic acid = 1,3,4,5-tetrahydroxycyclohexanecarboxylic acid.
[b] Chlorogenic acid = 3-(3,4-dihydroxyphenyl)-2-propenoic acid, 3-ester with 1,3,4,5-tetrahydroxycyclohexanecarboxylic acid.

Foundation conducted an extensive study in the early 1980s on the pyrosynthesis of 1,2-benzenediol (catechol) during the tobacco smoking process. The goal of the study was to determine the major precursor(s) in tobacco of the 1,2-benzenediol (catechol) in MSS. Initial experiments by Carmella et al. (600) involved the sequential extraction of tobacco with hexane, chloroform, benzene, and methanol, followed by pyrolysis of the material extracted by each solvent and determination of the 1,2-benzenediol (catechol) in the pyrolysate. Only the pyrolysates from the methanol extract and the residual extracted tobacco indicated the presence of 1,2-benzenediol (catechol) precursors.

[b] Isoeugenol.
[c] Catechol.
[d] Furfural and/or 5-(hydroxymethyl)furfural.

From the results of a study in which Kentucky reference 1R1 cigarettes were "spiked" with increasing levels of chlorogenic acid (the 3-ester of 3,4-dihydroxycinnamic acid with 1,3,4,5-tetrahydroxycyclohexanecarboxylic acid), smoked under standard conditions, and the MSS analyzed for 1,2-benzenediol (catechol), Carmella et al. (598) concluded that, under their experimental conditions, chlorogenic acid was not a major precursor in tobacco of 1,2-benzenediol (catechol) in tobacco smoke. This finding was the opposite of that reported by Schlotzhauer et al. (3453, 3462).

In a subsequent study by Carmella et al. (602), tobacco was extracted sequentially with hexane then aqueous methanol. The major components of the aqueous methanol extract were identified as fructose, glucose, sucrose, and chlorogenic acid. Contributions of each of these tobacco components plus the contributions of the tobacco components cellulose and rutin to the 1,2-benzenediol (catechol) level in cigarette MSS were determined in a "spiking" experiment in which cigarettes were "spiked" with each of the components mentioned, two of which were radiolabeled (fructose and cellulose). The minimum contributions of these components to the 1,2-benzenediol (catechol) level in MSS were as follows: cellulose, 7%–12%; total of the sugars, glucose, fructose, and sucrose, 4%; chlorogenic acid, 13%; and rutin, less than 1%. Carmella et al. considered that a significant portion of the unaccounted for 1,2-benzenediol (catechol) was formed from the other biopolymers, pectin, starch, and hemicellulose. It would appear that these 1984 results on the involvement of chlorogenic acid as a 1,2-benzenediol (catechol) precursor differed from those presented previously by the same investigators [Carmella et al. (602) *vs.* Carmella et al. (598) who earlier stated in 1981:

> The results under these experimental conditions [a "spiking" experiment] suggest that chlorogenic acid is not a major precursor of catechol in cigarette smoke.

Carmella et al. (601) reported that cellulose in tobacco was a major precursor of 1,2-benzenediol (catechol) in tobacco smoke. Comparison of the pyrogenesis of 1,2-benzenediol (catechol) from cellulose and carboxymethylcellulose suggested that the 1,2-benzenediol (catechol) level in tobacco smoke might be reduced by modification of the tobacco cellulose. Subsequently, Carmella et al. (599) reported that carboxymethylation of the cellulose in tobacco reduced the1,2-benzenediol (catechol) in the MSS from 252 to 162 µg/cig, a 36% reduction.

In addition to investigations of the possible precursors in tobacco of phenols in cigarette MSS, the contribution of several tobacco additives to phenols in MSS was studied. Many years before the advent of the use of expanded tobacco and filter-tip perforations in the design of low- to medium-"tar" cigarettes, Kato and Shibayama (2044) reported that vanillin (4-hydroxy-3-methoxybenzaldehyde) incorporated in the tobacco blend as a flavorant by many cigarette was converted to phenol during the smoking process and therefore should not be used as a cigarette tobacco flavorant. Contradictory results were reported in a subsequent study by Eble et al. (1105). They reported that no radiolabeled phenol was detected in the cigarette MSS and concluded that vanillin did not generate phenol during the smoking process. The difference between the Kato and Shibayama 1962 results and the Eble et al. 1985 results was readily explained by the difference in the experimental conditions used in the two studies: Kato and Shibayama (2044) used continuous draw in their smoking regime, i.e., no alternating puff and smoldering period, whereas Eble et al. (1105) used the intermittent-puff regime and smoking procedure defined by in the U.S. FTC "tar" and nicotine procedure (35 mL puff volume, 2 s puff duration, 1 puff/min 25°C, 60% relative humidity, etc.).

Many flavoring materials have been proposed for use as flavoring materials in tobacco smoking products. Leffingwell et al. (2341) reported that these range from

individual chemical compounds to a variety of natural herbs, essential oils, and extracts. Many of the proposed flavoring additives for tobacco smoking products have been included in commercial products, but many have not. Among the naturally occurring mixtures used historically were deer tongue, tonka bean, and vanilla extract (2341). In the early 1970s, Higman et al. (1649) investigated the pyrolysis of these three historically used tobacco additives to determine their possible contributions to the composition of cigarette smoke. In addition to numerous monocyclic and PAHs and their monocyclic and polycyclic nitrogen analogs, all three pyrolysates contained phenol, cresols, and xylenols. The deer tongue and tonka bean pyrolysates also contained naphthols and coumarin. With regard to the use of these three materials as tobacco additives, the authors noted:

> The contribution of such additives [tonka bean, deer tongue, vanilla extract] to the chemical and biological effects of cigarette smoke would be in proportion to the amounts of such additives used and also to the pyrolytic-distillation pattern to which the additive is subjected in the thermal flow environment of the burning cigarette.

The report by Gori (1332) and the NCI (2683) on the results obtained in the NCI Smoking and Health Program on "less hazardous" cigarettes (1329, 1330, 1332, 1333, 2683) led to an initial concern about the contribution of cocoa added to tobacco to the chemical and biological properties of the smoke from cigarettes containing cocoa-treated tobacco. Subsequent examination of the biological data indicated that the initial concern was unfounded. Schlotzhauer (3447) at the USDA Athens, GA, research center reported the results of his analysis of the pyrolysis of cocoa powder and its possible contribution to the phenol content of smoke from cigarettes made with cocoa-treated tobacco. Pyrolysis of cocoa at various temperatures (350°, 450°, 550°, 650°, 750°C) yielded phenol, the three dimethylphenols (*o*-, *m*-, and *p*-cresol), several dimethylphenols (xylenols), and 1,2-benzenediol (catechol). From his results, Schlotzhauer concluded:

> Addition of cocoa powder to tobacco products in the quantities normally utilized for flavoring purposes would not… be expected to significantly enhance the phenolic content of tobacco smoke.
>
> Results of the study indicate that the levels of phenols derived from pyrolysis of cocoa should not significantly enhance the phenol content of tobacco smoke…

As shown in Table 9.16, comparison of the MSS phenol data from the NCI study on cocoa-free (Sample Code 83) *vs.* cocoa-treated (Sample Code 82) (1332, 2683) confirms the view expressed by Schlotzhauer (3447):

Over a decade later in 1990, Roemer and Hackenberg (3314a) reported the results of mouse-skin-painting bioassay in which the CSCs from cigarettes containing various levels of cocoa were tested. The CSCs from cigarettes containing different levels of cocoa (0%, 1%, and 3%) were studied for their specific tumorigenicity. Their results contradicted those reported by Gori (1332) for the NCI less hazardous cigarette study. The 1% and 3% addition levels of cocoa were equivalent to and three times, respectively, the level of cocoa usually added to commercial cigarettes. Roemer and Hackenberg noted:

> We found no evidence for indicating an enhancement of the biological activity of cigarette smoke condensates derived from cigarettes to which 1 and 3% cocoa was added.

Additional details pertinent to cocoa are summarized by Rodgman (3264).

TABLE 9.16
Smoke Chemistry Data: NCI Study of Cocoa Addition (1332)

Code No.	Filler	Relative to "Dry" Condensate, µg/g		
		Phenol	*o*-Cresol	*m*- and *p*-Cresol
83	SEB III	4.33	0.68	1.98
82	SEB III + 1% cocoa	4.46	0.75	2.02

9.1.4 Effect of Cigarette Design Parameters on Yield of MSS Phenols

Despite the controversy over the biological properties of the phenols in tobacco smoke, i.e., were they promoters of the tumorigenicity of the PAHs in the mouse-skin-painting bioassay, or were they cocarcinogens for the PAHs in that bioassay, or were they noncontributors or minor contributors to the bioassay results, the next step after identification, refinement of quantitation procedures, and resolution of the question of precursors was the determination of which cigarette design parameters would permit control of the levels of phenols in MSS.

Of course, the first method discovered to control the MSS levels of phenols was their selective filtration by the plasticized cellulose acetate filter tip.
